INOVANCE

Advancing industrial technology,
for a better world

iFA Information System

Industrial Automation | New Energy Vehicle | Intelligent Elevator | Intelligent Robot | Digital Energy | Rail Transit

Preface

Introduction

This guide describes basic functions, product configuration in programming applications, instruction examples, and fault codes of the iFA software.

Target audience

This guide is intended for:

- Electrical engineers
- Software engineers
- System engineers

Revision history

Date	Document Version	Software Version	Description of Changes
2026-07	A15	V1.5.2.5	For detailed changes, see New Features in V1.5.2.5.
2026-06	A14	V1.4.4.5.Patch.20260610	**Modified content** • Removed view restrictions for online variable tables, supporting viewing all variables by mouse scrolling. For details, see visible element range setting. • CFC language can be used for FBs/FCs. For details, see CFC Language Programming. • SFC language can be used for the full series products. For details, see SFC Language Programming. • The Modbus TCP port number range has been expanded to 1-65535. For details, see Configuring a Modbus TCP Slave/Modbus TCP Slave Configuration and Configuring a Modbus TCP Slave Under the Master/Modbus TCP Slave Configuration. • Added the instructions of accumulation timer and sequencer output. For details, see AccumulationTimer2 and SQO. • The general instruction of delay timer supports modification of the ET pin. For details, see TON2. • Added the applicable EVO510 series PLCs. • Corrected minor errors and website related issues.

2026-05	A13	V1.4.4.5	• Added Fins communication instructions. For details, see FINS Communication. • Added Sftp communication instructions. For details, see SFTP Communication. • Added Melsec communication instructions. For details, see Melsec Communication. • Added program trace function. For details, see Loading Fault/Data Trace Files, SysHC_FaultRecord and SysHC_OperationRecord. • Added SFTP server. For details, see SFTP Server Configuration. • Added EtherCAT master system variables. For details, see EtherCAT master system variables. • Added BASE64 encoding instruction. For details, see AnyBASE64. • Added duplicate name checking for new variables against library variables and POUs. For details, see program check. • Added system information instruction. For details, see SysHC_AppDownInfo. • Added advanced process control instructions. For details, see PFCs_v2, PFCm_v2, PFCs_dv_v2, PFCm_dv, PIDR, PFCm22, and PRBS. • Added the instruction of enabling or disabling axes in an axis group. For details, see MC_GroupPower. • Added "HIC" configuration to the mechanical types for axis groups. For details, see Axis Configuration and HIC Configuration Example. • Added default gateway settings to EVO400 series. For details, see Ethernet Address Settings. • Added the feature of EIP quick connection to EVO700C series. For details, see Network Port Configuration. • Added HMI security authentication policies. For details, see HMI Security Authentication Policies.

Date	Document Version	Software Version	Description of Changes
			Modified content • Updated the number of OPC UA exposed variables for EVO500 series to 100–5000. For details, see Configuring OPC UA Server. • Updated the number of key points in the cam table to 20,000. • In the rotary axis mode, the servo drive can operate in either multi-turn or single-turn mode. For details, see Position Retention upon Power Failure.
2026-04	A12	V1.4.4.5	**New content** • Added the SFC language to programming languages. For details, see CFC Language Programming. • Added Ethernet expansion module property configuration. For details, see Ethernet Expansion Module Property Configuration. • Added PRP monitoring. For details, see PRP Monitoring. • Added EVO400 series related functions. **Modified content** Corrected minor errors and website related issues.
2026-03	A11	V1.4.4.5	**Modified content** Corrected minor errors and website related issues.
2026-02	A10	V1.4.4.5	**Modified content** Corrected minor errors and website related issues.
2026-01	A09	V1.4.4.5	For detailed changes, see New Features in V1.4.4.5.
2026-01	A08	V1.4.3.5	**Modified content** Corrected minor errors and website related issues.
2025-12	A07	V1.4.3.5	**Modified content** Corrected minor errors and website related issues.

Date	Document Version	Software Version	Description of Changes
2025-11	A06	V1.4.3.5	**New content** • Added password complexity setting policies. For details, see Setting Password Policies. • Added screen zoom level setting. For details, see Zooming a Screen. **Modified content** Corrected minor errors and website related issues.
2025-10	A05	V1.4.3.5	For detailed changes, see New Features in V1.4.3.5.
2025-10	A04	V1.4.2.5	**Modified content** Corrected minor errors and website related issues.
2025-09	A03	V1.4.2.5	**Modified content** Corrected minor errors and website related issues.
2025-08	A02	V1.4.2.5	**New content** • Added information related to safety PLC functions. For details, see Safety PLC Programming. • Added functions related to EVO800 and EVO700 series. For details, see the content with model description.
2025-07	A01	V1.4.2.5	For detailed changes, see New Features in V1.4.2.5.
2025-02	A00	V1.3.4.5	First release.

Access to the guide

This guide is not delivered with the product. You can obtain the PDF version in the following ways:

- Visit https://www.inovance.com/global to download the PDF documents.
- Get it directly from the help system of the software.

Contents

1 Legal Information 78

2 Version Information 79

2.1 New Features in V1.5.2.5 79

2.1.1 Introduction 79

2.1.2 Newly Supported Hardware Models 79

2.1.3 New Software Features 80

2.2 New Features in V1.4.4.5 86

2.2.1 Introduction 86

2.2.2 Newly Supported Hardware Models 86

2.2.3 New Software Features 87

2.3 New Features in V1.4.3.5 92

2.3.1 Introduction 92

2.3.2 Newly Supported Hardware Models 92

2.3.3 New Software Features 92

2.4 New Features in V1.4.2.5 96

2.4.1 Introduction 96

2.4.2 Newly Supported Hardware Models 96

2.4.3 New Software Features 97

2.5 Compatibility 101

2.6 Feature Upgrade 101

3 Introduction to iFA Evolution 104

3.1 Software Overview 104

3.2 Features 104

3.3 Help and Support 104

3.3.1 Help System 104

3.3.2 Online Help 106

3.3.3 Issue Feedback 108

3.3.4 Technical Forum 109

3.3.5 About iFA 110

3.4 AI Assistant 111

4 Installation and Uninstallation 115

4.1 Operating Environment Requirements 115

4.2 Installing the Software 115

4.3 Uninstalling the Software 117

4.4 Licensing the Software 118

4.5 Upgrading the Software 119

5 Software Interface Layout 123
5.1 Opening and Exiting the Software 123
5.2 Project View 123
5.3 Toolbar 127
5.4 Project Tree 129
5.5 Workspace 133
5.5.1 Workspace Feature and Layout 133
5.5.2 Splitting the Workspace 134
5.5.3 Moving to Previous/Next Group 136
5.5.4 Floating an Element 136
5.5.5 Maximizing an Element 137
5.5.6 Switching Between Elements 138
5.5.7 Closing an Element 138
5.5.8 Inverting Object Selection 139
5.6 Monitoring Area 139
5.6.1 Monitoring Area Feature and Layout 139
5.6.2 Floating a Tab 140
5.6.3 Maximizing a Tab 141
5.7 Toolbox 142
5.7.1 Toolbox Features and Layout 142
5.7.2 Floating a Tab 144
5.7.3 Maximizing a Tab 145
6 System Settings 146
6.1 General Settings 146
6.2 HMI Visualization 148
6.3 PLC Programming 149
7 Project Deployment 156
7.1 Creating a Project 156
7.2 Configuring a Device 157
7.2.1 Adding a Device 157
7.2.2 Copying a Device 164
7.2.3 Renaming a Device 165
7.2.4 Deleting a Device 166
7.2.5 Replacing a Device 167
7.3 Configuring a Network 169
7.3.1 HMI Ethernet Settings 170
7.3.2 Online Network Settings 171

8 Project Management 174
8.1 Opening a Project 174
8.2 Saving a Project 174
8.3 Saving a Project As 175
8.4 Backing up a Project 175
8.5 Closing a Project 175
8.6 Removing a Project 176
8.7 Finding and Replacing Within a Project 178
8.8 Reuse by Copy and Paste 180
8.9 Packaging a Project 182
8.10 Importing a Project 183
8.11 Upgrading a Project 183
8.12 Importing/Exporting a PLCopenXML File 185
8.13 Migrating a Project 189
8.14 Collapsing Project Child Nodes with One Click 190
8.15 Using the Device Library 191
8.15.1 Installing a Device 191
8.15.2 Exporting a Device 191
8.15.3 Uninstalling a Device 192
8.15.4 Device Details 193
9 Project Security Management 195
9.1 Overview 195
9.2 Feature Permissions in User Management 197
9.3 Enabling Project Protection 200
9.4 Disabling Project Protection 202
9.5 Setting Password Policies 202
9.6 HMI Security Authentication Policies 203
9.7 Managing Users 208
9.8 Managing Roles 209
9.9 Assigning Roles 211
9.10 Opening a Protected Project 213
9.11 Changing the Password 214
9.12 Switching the User 215
9.13 Exiting a Project 215
9.14 PLC Permissions 216
9.15 Library Project Security Management 217

10 PLC Programming 220
10.1 Programming Basics 220
10.1.1 Variables 220
10.1.1.1 Global Variables 220
10.1.1.2 Local Variables 222
10.1.1.3 Temporary Variables 223
10.1.1.4 Instance Variables 224
10.1.1.4.1 Input Variables 225
10.1.1.5 Output Variables 225
10.1.1.6 Static Variables 226
10.1.1.7 Input/Output Variable 228
10.1.1.8 Data Types (EVO400, EVO500, EVO700, EVO800) 229
10.1.1.8.1 Standard Data Types 229
10.1.1.8.2 User-Defined Types 231
10.1.1.8.2.1 STRUCT 231
10.1.1.8.2.2 UNION 238
10.1.1.8.2.3 ENUM 240
10.1.1.8.2.4 ALIAS 242
10.1.1.8.3 Complex Types 244
10.1.1.8.3.1 ARRAY 244
10.1.1.8.3.2 POINTER 246
10.1.1.8.4 BIT 247
10.1.1.8.5 ANY 247
10.1.1.8.6 REFERENCE 250
10.1.1.8.7 Data Type Conversion 251
10.1.1.9 Variable Declaration 252
10.1.1.9.1 Adding a Global Variable Table 252
10.1.1.9.2 Adding a Param Table 253
10.1.1.9.3 Variable Declaration Properties 254
10.1.1.9.4 Variable Address Range 258
10.1.1.9.5 Default Variable Table 258
10.1.1.9.6 System Variable Table 258
10.1.1.9.7 Power Failure Retention Table 264
10.1.1.9.8 Resource Usage Table 267
10.1.1.10 Variable Operations 269
10.1.1.10.1 Adding a Variable 269
10.1.1.10.2 Copying and Pasting a Variable Table 270
10.1.1.10.3 Setting Variable Properties 271

10.1.1.10.4 Changing Variable Category 272
10.1.1.10.5 Cross-Reference 272
10.1.1.10.6 Variable Import 274
10.1.1.10.7 Variable Export 275
10.1.1.10.8 Smart Input 276
10.1.1.10.9 Parameter Update 278
10.1.1.10.10 Input Assistant 280
10.1.1.10.11 Public Variable Export 282
10.1.1.10.12 Going to Definition 283
10.1.1.10.13 Going to Next Level 284
10.1.2 Program Block 285
10.1.2.1 Program 285
10.1.2.1.1 Overview 285
10.1.2.1.2 Adding a User Program 286
10.1.2.1.3 Adding a Method to a Program 288
10.1.2.1.4 Adding an Action to a Program 292
10.1.2.1.5 Calling a User Program 293
10.1.2.2 Functions 294
10.1.2.2.1 Adding a User Function 294
10.1.2.2.2 Modifying a User Function 295
10.1.2.3 Function Block 297
10.1.2.3.1 Adding a User Function Block 297
10.1.2.3.2 Adding a Method to a Function Block 298
10.1.2.3.3 Adding an Action to a Function Block 298
10.1.2.3.4 Adding a Property to a Function Block 298
10.1.2.3.5 Modifying a User Function Block 301
10.1.2.3.6 Using a User Function Block 302
10.1.2.4 Program Block Callee Update 309
10.1.2.5 Program Block Access Permissions 311
10.1.2.6 Program Block Cross-Reference 314
10.1.2.7 Viewing Call Relationships Between Program Blocks 315
10.1.3 LD Language Programming 316
10.1.3.1 LD Language Overview 316
10.1.3.2 LD Creation and Management 317
10.1.3.2.1 Creating an LD Program Block 317
10.1.3.2.2 Managing an LD Program Block 318
10.1.3.2.2.1 Copying an LD Program Block 318
10.1.3.2.2.2 Renaming an LD Program Block 318

10.1.3.2.2.3 Deleting an LD Program Block 319
10.1.3.3 LD Editor 320
10.1.3.3.1 LD Editor Interface 320
10.1.3.3.2 LD Editor Settings 323
10.1.3.3.3 Lines in LD Editor 326
10.1.3.3.4 LD Elements 327
10.1.3.3.5 LD Instructions 330
10.1.3.3.5.1 Up 330
10.1.3.3.5.2 Down 331
10.1.3.3.5.3 = ... 333
10.1.3.3.5.4 >= 334
10.1.3.3.5.5 > 335
10.1.3.3.5.6 <= 337
10.1.3.3.5.7 < 338
10.1.3.3.5.8 <> 339
10.1.3.4 Network Usage 341
10.1.3.4.1 Network Overview 341
10.1.3.4.2 Adding a Network 341
10.1.3.4.3 Inserting a Network 342
10.1.3.4.4 Moving a Network 343
10.1.3.4.5 Inserting a Label 344
10.1.3.4.6 Modifying Network Comment 345
10.1.3.4.7 Switching Network Comment Status 345
10.1.3.4.8 Collapsing/Expanding a Network 346
10.1.3.4.9 Deleting a Network 346
10.1.3.5 Branch Usage 347
10.1.4 ST Language Programming 348
10.1.4.1 Overview 348
10.1.4.2 ST Creation and Management 349
10.1.4.2.1 Creating an ST Program Block 349
10.1.4.2.2 Managing an ST Program Block 349
10.1.4.2.2.1 Copying an ST Program Block 349
10.1.4.2.2.2 Renaming an ST Program Block 350
10.1.4.2.2.3 Deleting an ST Program Block 350
10.1.4.3 ST Editor 351
10.1.4.3.1 ST Editor Interface 351
10.1.4.3.2 ST Editor Settings 353
10.1.4.3.3 Basic Operations of ST Editor 354

10.1.4.4 ST Operators 357
10.1.4.5 ST Keywords 359
10.1.4.6 ST Statements 360
10.1.5 CFC Language Programming 372
10.1.5.1 CFC Language Overview 372
10.1.5.2 CFC Creation and Management 372
10.1.5.2.1 Creating a CFC Program Block 372
10.1.5.2.2 Creating a CFC Partition 373
10.1.5.2.3 Managing a CFC Program Block and Group 375
10.1.5.2.3.1 Adding a Group 375
10.1.5.2.3.2 Copying a CFC Block/Group 375
10.1.5.2.3.3 Renaming a CFC Block/Group 376
10.1.5.2.3.4 Deleting a CFC Program Block 377
10.1.5.2.3.5 Deleting a Group 378
10.1.5.3 CFC Editor 378
10.1.5.3.1 CFC Editor Interface 378
10.1.5.3.2 CFC Editor Settings 380
10.1.5.3.3 CFC Program Configuration Options 380
10.1.5.4 CFC Object Creation and Management 381
10.1.5.4.1 Creating an Operation Block 381
10.1.5.4.2 Creating a Comment 384
10.1.5.4.3 Managing an Operation Block 385
10.1.5.4.3.1 Configuring Operation Block Properties 385
10.1.5.4.3.2 Reordering an Operation Block 387
10.1.5.4.3.3 Resizing an Operation Block 389
10.1.5.4.3.4 Repositioning an Operation Block 389
10.1.5.4.3.5 Deleting an Operation Block 390
10.1.5.4.3.6 Updating an Operation Block 390
10.1.5.4.3.7 Operation Block Operations 392
10.1.5.5 Input/Output Parameter Connection 393
10.1.5.5.1 Setting Input/Output Parameters 393
10.1.5.5.2 Adding an Input Parameter 394
10.1.5.5.3 Connection Routing 394
10.1.5.5.4 Connecting Input and Output Parameters 397
10.1.5.5.5 Modifying a Connection 398
10.1.5.5.6 Changing Connection Line Color 398
10.1.5.5.7 Deleting a Connection 399
10.1.5.5.8 Text Connection 400

10.1.5.6 CFC Configuration and Commissioning 400
10.1.5.6.1 Execution Order Between CFC Blocks 400
10.1.5.6.2 Execution Order of Operation Blocks within a CFC Block 401
10.1.5.6.3 CFC Instance Call 401
10.1.5.6.4 CFC Commissioning 401
10.1.6 SFC Language Programming 402
10.1.6.1 SFC Language Overview 402
10.1.6.2 SFC Creation and Management 402
10.1.6.2.1 Creating an SFC Program Block 402
10.1.6.2.2 Managing an SFC Program Block 403
10.1.6.2.2.1 Copying an SFC Program Block 403
10.1.6.2.2.2 Renaming an SFC Program Block 404
10.1.6.2.2.3 Deleting an SFC Program Block 405
10.1.6.3 SFC Editor 405
10.1.6.3.1 SFC Editor Interface 405
10.1.6.3.2 SFC Editor Settings 407
10.1.6.3.2.1 Setting the SFC Editor in iFA Options 407
10.1.6.3.2.2 Setting SFC Program Block Properties 408
10.1.6.3.2.3 Setting SFC Program Block Power Failure Retention Property 410
10.1.6.3.2.4 Setting SFC Program Block Interface Mode 410
10.1.6.3.3 SFC Programming Window 411
10.1.6.3.4 SFC Elements 412
10.1.6.3.5 Opening/Closing All Program Segments 418
10.1.6.3.6 SFC Program Block Interface Parameters 420
10.1.6.3.6.1 Overview 420
10.1.6.3.6.2 Interface Parameter Mode 420
10.1.6.3.6.3 Input Parameters 421
10.1.6.3.6.4 Output Parameters 422
10.1.6.3.6.5 Static Parameters 423
10.1.6.4 Step and Transition Condition 425
10.1.6.4.1 Step and Transition 425
10.1.6.4.1.1 Step Overview 425
10.1.6.4.1.2 Transition Overview 425
10.1.6.4.2 Step 425
10.1.6.4.2.1 Step Basic Properties 425
10.1.6.4.2.2 Step Status 427
10.1.6.4.2.3 Condition 427
10.1.6.4.2.4 Action 428
10.1.6.4.2.5 Monitoring 431

10.1.6.4.3 Transition 431
10.1.6.4.3.1 Transition Basic Properties 431
10.1.6.4.3.2 Transition Status 432
10.1.6.5 Step and Transition Usage 433
10.1.6.5.1 Adding a Step and Transition 433
10.1.6.5.2 Adding a Step 433
10.1.6.5.3 Adding a Transition 434
10.1.6.5.4 Deleting a Step and Transition 435
10.1.6.6 Branch Usage 435
10.1.6.6.1 Adding a Selective Branch 435
10.1.6.6.2 Adding a Parallel Branch 438
10.1.6.6.3 Closing a Branch 440
10.1.6.6.4 Deleting a Branch 444
10.1.6.7 Jump Usage 445
10.1.6.7.1 Adding a Jump 445
10.1.6.7.2 Changing Jump Target 446
10.1.6.7.3 Deleting a Jump 446
10.1.6.8 SFC Configuration and Commissioning 447
10.1.6.8.1 SFC Instantiation 447
10.1.6.8.2 SFC Commissioning 448
10.2 Oscilloscope 450
10.2.1 Basic Oscilloscope 450
10.2.1.1 Adding a Basic Oscilloscope 450
10.2.1.2 Variable Area 452
10.2.1.3 Plot Area 460
10.2.1.4 Loading Fault/Data Trace Files 464
10.2.2 Task Oscilloscope 465
10.3 Recipe 468
10.3.1 Configuring a Recipe 468
10.3.2 Adding a Recipe 473
10.3.3 Online Recipe 475
10.4 Watch Table 477
10.4.1 Monitoring Variable Table 477
10.4.2 Monitoring Specified Variables 480
10.4.3 Drive Watch Table 481
10.4.4 Derivative Watch Table 484
10.5 Task Configuration 486
10.5.1 Adding a Task 486
10.5.2 Configuring Task Parameters 488

10.5.3 System Event Management 492
10.6 PLC Configuration 494
10.6.1 Hardware Configuration and Device Management 494
10.6.1.1 Device Scanning 494
10.6.1.2 Viewing Device ID 496
10.6.1.3 Exporting I/O Mapping 496
10.6.1.4 Importing I/O Mapping 497
10.6.2 Device and Network Editor 498
10.6.2.1 Overview 498
10.6.2.2 Network View 499
10.6.2.3 Device View 501
10.6.2.4 Device List 503
10.6.3 EtherCAT Communication Configuration (EVO500, EVO700, APC500, EVO700C) 505
10.6.3.1 Adding an EtherCAT Device 505
10.6.3.1.1 Adding a Master 505
10.6.3.1.2 Adding a Slave 506
10.6.3.1.3 Adding a Wireless Management Station 507
10.6.3.1.4 Adding an Online EtherCAT Slave to Project 509
10.6.3.2 Configuring Master Parameters 511
10.6.3.2.1 General Settings 511
10.6.3.2.2 Parameters 517
10.6.3.2.3 Upgrade 517
10.6.3.2.4 Unit Synchronization Assignment 518
10.6.3.2.5 Online 518
10.6.3.2.6 Overview 519
10.6.3.2.7 Machine Parameter Management 520
10.6.3.2.7.1 Machine Recipe Management 520
10.6.3.2.7.2 Machine Parameter Management 523
10.6.3.2.7.3 Batch Firmware Upgrade 527
10.6.3.2.8 I/O Mapping 528
10.6.3.2.9 System Variables 529
10.6.3.2.10 Information 530
10.6.3.3 Configuring Slave Parameters 530
10.6.3.3.1 General Settings 530
10.6.3.3.2 Process Data (PDO Configuration) 533
10.6.3.3.3 Startup Parameters (SDO Configuration) 534
10.6.3.3.4 Online 536
10.6.3.3.5 Online CoE 538

10.6.3.3.6 EoE Settings 538
10.6.3.3.7 Servo Parameters 540
10.6.3.3.8 ESC Register 541
10.6.3.3.9 I/O Mapping 542
10.6.3.3.10 System Variables 545
10.6.3.3.11 Information 546
10.6.3.4 Disabling/Enabling an EtherCAT Device 546
10.6.4 EtherNet Communication Configuration 548
10.6.4.1 Modbus TCP Device Configuration 548
10.6.4.1.1 Adding a Modbus TCP Device 548
10.6.4.1.2 Configuring a Modbus TCP Master 550
10.6.4.1.2.1 Modbus TCP Master Configuration 550
10.6.4.1.2.2 System Variables 551
10.6.4.1.2.3 Information 551
10.6.4.1.3 Configuring a Modbus TCP Slave 551
10.6.4.1.3.1 Modbus TCP Slave Settings 551
10.6.4.1.3.2 System Variables 552
10.6.4.1.3.3 Information 552
10.6.4.1.4 Configuring a Modbus TCP Slave Under the Master 553
10.6.4.1.4.1 Modbus TCP Slave Settings 553
10.6.4.1.4.2 Modbus TCP Slave Communication Settings 553
10.6.4.1.4.3 I/O Mapping 555
10.6.4.1.4.4 System Variables 555
10.6.4.1.4.5 Information 556
10.6.4.1.5 Modbus TCP Variable Addressing 556
10.6.4.1.6 Modbus TCP Communication Frame Format 558
10.6.4.1.7 Common Modbus TCP Faults 564
10.6.4.2 EtherNet/IP Device Configuration 566
10.6.4.2.1 Adding an EtherNet/IP Device 566
10.6.4.2.2 EtherNet_IP_Scanner Configuration 569
10.6.4.2.2.1 Scanner Settings 569
10.6.4.2.2.2 General Settings of Remote Adapters 570
10.6.4.2.2.3 I/O Mapping 572
10.6.4.2.3 EtherNet_IP_Adapter Configuration 572
10.6.4.2.3.1 General Settings of Local Adapters 572
10.6.4.2.3.2 I/O Mapping 573
10.6.4.2.3.3 Connection Status 573
10.6.4.2.3.4 Information 574

10.6.4.2.4 Connection Configuration (Class1) 574
10.6.4.2.5 Communication Between Producer and Consumer Labels 577
10.6.4.2.6 Communication Between PLCs 580
10.6.4.2.7 Communication with HMI 584
10.6.4.2.8 Quick Connect Communication (EVO700, EVO700C, EVO800, APC760C) 590
10.6.4.3 Free Network Port Communication 593
10.6.4.4 Disabling/Enabling an EtherNet Device 595
10.6.5 PROFINET Communication Configuration (EVO400, EVO500, EVO700, APC500, EVO800)\ 596
10.6.5.1 Overview 596
10.6.5.2 PN Slave Configuration(EVO400,EVO500,EVO700,APC500) 597
10.6.5.2.1 PN Slave Configuration 597
10.6.5.2.2 PROFINET I/O Module 601
10.6.5.2.3 TIA Portal and PN Master Configuration 602
10.6.5.2.4 PN Slave Troubleshooting 606
10.6.5.3 PN Master Configuration (EVO800) 607
10.6.5.3.1 PN Master Configuration (SYCON.net) 607
10.6.5.3.2 PN Master Configuration (iFA) 613
10.6.5.3.3 PN Master Configuration 616
10.6.5.3.3.1 General Configuration 616
10.6.5.3.3.2 I/O Mapping 617
10.6.5.3.3.3 Information 617
10.6.6 CANopen Communication Configuration (EVO400, EVO500, EVO700, APC500) 618
10.6.6.1 Usage Workflow 618
10.6.6.2 CANopen Master Configuration 621
10.6.6.2.1 General Settings 621
10.6.6.2.2 I/O Mapping 624
10.6.6.2.3 System Variables 624
10.6.6.2.4 Information 624
10.6.6.3 CANopen Slave Configuration 624
10.6.6.3.1 General Settings 624
10.6.6.3.2 Process Data (PDO) 627
10.6.6.3.3 Startup Parameter (SDO) 630
10.6.6.3.4 Online 631
10.6.6.3.5 I/O Mapping 633
10.6.6.3.6 System Variables 634
10.6.6.3.7 Information 634
10.6.6.4 CANopen Module 634
10.6.6.5 CANopen Parameter Configuration 634

10.6.6.6 Programming Interface 635
10.6.7 CAN Free Communication Configuration (EVO400, EVO500, EVO700, APC500) 635
10.6.7.1 Network Configuration (EVO400, EVO500, APC500) 635
10.6.7.2 Network Configuration (EVO700) 637
10.6.7.3 CAN Free Protocol Configuration 638
10.6.7.4 Usage Example 638
10.6.8 COM Communication Configuration (EVO400, EVO500, EVO700, APC500) 640
10.6.8.1 Modbus RTU Device Configuration 640
10.6.8.1.1 Adding a Modbus RTU Device 640
10.6.8.1.2 Configuring a Modbus RTU Master 642
10.6.8.1.2.1 Modbus RTU Master Configuration 642
10.6.8.1.2.2 Information 643
10.6.8.1.3 Configuring a Modbus RTU Slave 643
10.6.8.1.3.1 Modbus RTU Slave Configuration 643
10.6.8.1.3.2 Modbus RTU Slave Communication Configuration 644
10.6.8.1.3.3 System Variables 645
10.6.8.1.3.4 Information 645
10.6.8.1.4 Modbus RTU Variable Addressing 645
10.6.8.1.5 Modbus RTU Communication Frame Format 648
10.6.8.1.6 Common Modbus RTU Faults 652
10.6.8.2 Free Serial Communication 652
10.6.8.2.1 Adding Serial_Port_Free 652
10.6.8.2.2 Configuring Serial_Port_Free 653
10.6.8.2.3 Transmitting/Receiving Data Through Free Serial Port 654
10.6.8.3 Disabling/Enabling a COM Device 655
10.6.9 FINS TCP&UDP Communication Configuration 656
10.6.9.1 Overview 656
10.6.9.2 FINS Parameters and Addresses 656
10.6.9.3 FINS Protocol Configuration 657
10.6.10 DP Communication Configuration (EVO800) 657
10.6.10.1 DP Master Configuration (SYCON.net) 657
10.6.10.2 DP Master Configuration (iFA) 666
10.6.10.3 DP Master Configuration 668
10.6.10.3.1 General Configuration 668
10.6.10.3.2 I/O Mapping 669
10.6.10.3.3 Information 669
10.6.11 I/O Module Configuration 670
10.6.11.1 Rack Overview 670
10.6.11.2 Adding a Local I/O Module 673

10.6.11.3 Adding a Remote I/O Module 675
10.6.11.4 Deleting a Module 679
10.6.11.5 Inserting a Module 679
10.6.11.6 Replacing a Module 679
10.6.11.7 Moving a Module 680
10.6.11.8 Disabling/Enabling an I/O Module 680
10.6.12 High Speed I/O Module Configuration (EVO400, EVO500, EVO700) 681
10.6.12.1 Opening High-Speed I/O Module Interface 681
10.6.12.2 Configuring a High-Speed I/O Module 682
10.6.12.3 Disabling/Enabling a High-Speed I/O Module 684
10.6.13 EXPA/EXPB (Local Expansion Module) Configuration (EVO400, EVO500, APC500) 685
10.6.13.1 Adding/Deleting a Local Expansion Module 685
10.6.13.2 Disabling/Enabling a Local Expansion Module 686
10.6.14 PLC Property Configuration 687
10.6.14.1 I/O Settings (EVO400, EVO500, EVO700) 687
10.6.14.2 Network Settings (EVO500) 688
10.6.14.3 Network Port Switching 689
10.6.14.4 Ethernet Address Settings 692
10.6.14.5 OPC UA Server Configuration 695
10.6.14.5.1 Overview 695
10.6.14.5.2 Configuring OPC UA Server 696
10.6.14.5.3 OPC UA Diagnostics 702
10.6.14.5.4 Fault Codes 708
10.6.14.6 SFTP Server Configuration 710
10.6.14.7 Web Server Configuration 712
10.6.15 Ethernet Expansion Module Property Configuration 715
10.6.15.1 Setting Ethernet Address 715
10.6.15.2 Setting PRP 717
10.6.15.3 Configuring OPC UA Server 719
10.6.15.4 Configuring Web Server 720
10.7 PLC Compilation 720
10.7.1 Overview 720
10.7.2 Pre-Check 720
10.7.3 Compilation 721
10.7.4 Recompilation 723
10.7.5 Clearing 725
10.7.6 Clearing All 727

10.7.7 Option Configuration 727
10.7.7.1 Compilation Options 727
10.7.7.2 Public Variables 728
10.8 PLC Download 729
10.8.1 PLC Connection 729
10.8.2 Download Permission Check 732
10.8.3 Full Download 732
10.8.4 Online Modification/Monitoring without Modification 736
10.8.5 Redundant System Download (EVO800) 739
10.9 PLC Upload 741
10.9.1 Uploading 741
10.9.2 Uploading with a New Device 743
10.10 PLC Commissioning 745
10.10.1 PLC Start/Stop 745
10.10.2 PLC Online/Offline 747
10.10.3 Value Display and Calculation 749
10.10.3.1 Writing a Value 749
10.10.3.2 Forcing a Value 750
10.10.3.3 Releasing a Value 751
10.10.3.4 Display Modes 752
10.10.4 Breakpoint Commissioning 754
10.10.4.1 Enabling a Breakpoint 754
10.10.4.2 Modifying a Breakpoint 757
10.10.4.3 Deleting a Breakpoint 760
10.10.4.4 Disabling a Breakpoint 762
10.10.5 ST Program Commissioning 764
10.10.5.1 Step Execution 764
10.10.5.2 Running to Cursor 765
10.10.5.3 Displaying Current Statement 766
10.10.5.4 Stepping Out 766
10.10.5.5 Stepping Into 767
10.10.5.6 Executing One Scan Cycle 768
10.10.6 PID Function Block Commissioning Wizard 769
10.10.6.1 Overview 769
10.10.6.2 Adding a PID Function Block 769
10.10.6.3 Configuration and Commissioning 771
10.11 PLC Online Operations 778
10.11.1 Hot Reset 778

10.11.2 Cold Reset 779
10.11.3 Clearing User Program 780
10.11.4 Synchronizing Files to PLC 781
10.11.5 Network Settings 783
10.11.6 PLC Permission Configuration 785
10.11.7 WIFI Settings (EVO820) 789
10.11.8 Backing up Program to External Storage 792
10.11.9 Exporting Device Data 793
10.11.10 Power Failure Data Management 794
10.11.11 Restoring Factory Settings (EVO800, EVO1000) 798
10.11.12 Web Diagnostics and Monitoring 799
10.11.13 Time Settings 803
10.11.14 Task Monitoring 804
10.11.15 Time Synchronization Settings 805
10.11.16 DLR Ring Network Management (EVO800) 807
10.11.17 Ethernet Loop Monitoring 811
10.11.18 Monitoring Main/Backup Device Status (EVO800) 812
10.11.19 Calling a Stack 813
10.11.20 Diagnostic Information 814
10.11.21 Operation Log 815
10.11.22 Network Port Configuration 817
10.11.23 PRP Monitoring 820
10.11.24 Uploading/Downloading Permission Settings (EVO500) 822
10.12 PLC Project Comparison 823
10.12.1 Overview 823
10.12.2 Offline/Offline Comparison 825
10.12.3 Offline/Online Comparison 826
10.12.4 Viewing and Processing Comparison Results 827
10.13 PLC Simulation Mode 830
10.13.1 Simulation Panel Overview 830
10.13.2 Establishing a Simulation Environment 832
10.13.3 Simulation Function Description 835
10.13.4 Simulation Commissioning 838
10.13.4.1 OPCUA Communication Protocol Simulation 838
10.13.4.2 EtherNet/IP Communication Protocol Simulation 839
10.13.4.3 Modbus TCP Communication Protocol Simulation 841
10.13.4.4 EtherCAT Communication Protocol Simulation 841

10.14 Multi-User Collaboration 843
10.14.1 Overview 843
10.14.2 Multi-User Online Editing 844
10.14.3 Multi-User Download Synchronization 846
10.14.4 Multi-User Commissioning 848
10.14.5 Uploading Only Differences 849
11 Safety PLC Programming 851
11.1 Safety PLC Access Protection 851
11.1.1 PLC Configuration Write Protection 851
11.1.2 PLC Permission Configuration 851
11.2 Programming Basics 852
11.2.1 Variables 852
11.2.1.1 Data Types 852
11.2.1.1.1 Standard Data Types 852
11.2.1.1.2 Safety Data Types 852
11.2.1.1.3 User-Defined Types 853
11.2.1.1.4 Data Type Conversion 854
11.2.1.2 Variable Declaration 854
11.2.1.2.1 Variable Declaration Properties 854
11.2.1.2.2 Variable Address Range 856
11.2.1.2.3 Default Variable Table 856
11.2.1.2.4 System Variable Table 856
11.2.1.2.5 Resource Usage Table 857
11.2.1.3 Variable Operations 859
11.2.2 Library Reference 859
11.2.3 Program Block 860
11.2.3.1 Program 860
11.2.3.1.1 Adding a User Program 860
11.2.3.1.2 Calling a User Program 861
11.2.3.2 Function Block 862
11.2.3.2.1 Adding a User Function Block 862
11.2.3.2.2 Using a User Function Block 863
11.2.4 Safety LD Language Programming 864
11.2.4.1 Overview 864
11.2.4.2 Opening the Safety LD Editor 864
11.2.4.3 Setting the Safety LD Editor 865
11.2.4.4 Safety LD Elements 865
11.2.4.5 Safety LD Programming 869

11.2.4.6 Graphic Configuration Modification 873
11.2.4.6.1 Modifying Text Data 873
11.2.4.6.2 Modifying Block Type 874
11.2.4.6.3 Moving an Element 874
11.2.5 Safety FBD Language Programming 875
11.2.5.1 Overview 875
11.2.5.2 Opening the Safety FBD Editor 875
11.2.5.3 Setting the Safety FBD Editor 875
11.2.5.4 Safety FBD Elements 878
11.2.5.5 Safety FBD Programming 881
11.2.5.6 Graphic Configuration Modification 884
11.2.5.6.1 Modifying Text Data 884
11.2.5.6.2 Modifying Block Type 885
11.2.5.6.3 Moving an Element 886
11.3 Data Record Configuration 886
11.4 PLC Configuration 889
11.4.1 Hardware Configuration and Device Management 889
11.4.1.1 Adding a Safety PLC and Communication Unit 889
11.4.1.2 Device Scanning 891
11.4.2 Failsafe I/O Module Configuration 891
11.4.2.1 Rack Overview 891
11.4.2.2 Adding a Module 892
11.4.2.3 Deleting a Module 895
11.4.2.4 Inserting a Module 896
11.4.2.5 Replacing a Module 897
11.4.2.6 Moving a Module 898
11.4.2.7 Failsafe I/O Module Configuration 898
11.4.3 EtherNet/IP Communication Configuration 903
11.4.3.1 Standard EtherNet/IP Communication Configuration 903
11.4.3.1.1 EtherNet/IP Communication Between PLCs 903
11.4.3.1.2 EtherNet/IP Communication with HMI 906
11.4.3.2 Safety CIP Safety Communication Configuration 907
11.4.3.2.1 Overview 907
11.4.3.2.2 CIP Safety Communication Between PLCs 907
11.4.3.2.3 Adding a Remote CIP Safety Device 910
11.4.3.2.4 Configuring a Remote CIP Safety Device 913
11.4.3.3 Modbus TCP Communication Configuration 915

11.4.4 EtherCAT Communication Configuration 917
11.4.4.1 Configuring a Safety PLC as an EtherCAT Slave of a Standard PLC 917
11.4.4.1.1 Configuring an Independent Safety PLC as an EtherCAT Slave 918
11.4.4.1.2 Directly Creating a Safety PLC as an EtherCAT Slave 920
11.4.4.1.3 Configuring Communication Parameters of Safety PLC 920
11.4.4.2 Configuring I/O Modules 922
11.4.4.2.1 Adding a Local Failsafe I/O Module 922
11.4.4.2.2 Adding a Remote Failsafe I/O Module 923
11.4.4.2.3 Assigning FSoE Master to Failsafe I/O Modules 924
11.4.4.2.4 Reading FSoE DIP Switch Addresses of Failsafe I/O Modules 925
11.4.4.2.5 Configuring Failsafe I/O Module Parameters 927
11.4.4.3 Configuring Safety Servo Modules 928
11.4.4.4 FSoE Communication Between Safety PLCs 929
11.4.4.5 EtherCAT Communication Between Safety PLC and Standard PLC 932
11.4.5 PLC Property Settings 933
11.4.5.1 PLC Configuration 933
11.4.5.2 Ethernet Address and Safety Network Settings 934
11.4.5.3 Power-On Confirmation 935
11.4.5.4 Safety Information 936
11.4.6 Task Configuration 938
11.5 PLC Compilation 939
11.6 PLC Download 939
11.6.1 Full Download 939
11.7 PLC Commissioning 943
11.7.1 PLC Start/Stop 943
11.7.2 PLC Online/Offline 943
11.7.3 Value Display and Calculation 943
11.8 PLC Online Operations 944
11.8.1 Operation Modes 944
11.8.2 Safety Confirmation 948
11.8.3 Power-On Manual Confirmation 949
11.8.4 Operation Log 950
11.9 Safety PLC Simulation Mode 950
11.10 Common Safety Instructions 951
11.10.1 Basic Instructions 951

13.4 Template Library Usage 1624
13.4.1 Introduction 1625
13.4.2 Folder Usage 1625
13.4.2.1 Adding a Folder 1625
13.4.2.2 Deleting a Folder 1625

13.4.2.3 Renaming a Folder 1626
13.4.3 Symbol Template Usage 1626
13.4.3.1 Overview of Symbol Template 1626
13.4.3.2 Adding a Symbol Template 1626
13.4.3.3 Modifying a Symbol Template 1627
13.4.3.3.1 Modifying a Symbol Template 1628
13.4.3.3.2 Adding a Variable Interface 1630
13.4.3.3.3 Adding a Property Interface 1632
13.4.3.3.4 Adding an Event Interface 1633
13.4.3.3.5 Adding a Local Variable 1635
13.4.3.3.6 Adding an Animation to Object 1636
13.4.3.3.7 Adding an Event to Object 1636
13.4.3.4 Applying a Symbol Template 1636
13.4.4 User-Defined Types 1639
13.4.4.1 Adding a User-Defined Type 1639
13.4.4.2 Modifying a User-Defined Type 1641
13.4.4.3 Impact of User-Defined Type Version Upgrade 1642
13.4.4.4 Applying a User-defined Type 1644
13.4.5 Template Status Management 1645
13.4.6 Common Operations on Template 1646
13.4.6.1 Opening a Template 1646
13.4.6.2 Modifying a Template 1647
13.4.6.3 Publishing a Template 1648
13.4.6.4 Updating a Template 1649
13.4.6.5 Deleting a Template 1651
13.4.6.6 Renaming a Template 1652
13.4.6.7 Copying a Template 1652
13.4.6.8 Exporting a Template 1653
13.4.6.9 Importing a Template 1654
13.4.6.10 Setting as Default 1654
13.4.6.11 Synchronizing PLC Types 1655
13.4.7 Copying and Pasting a Template Across Projects 1656
13.4.8 Copying and Pasting a Template Instance Across Projects 1658
13.5 Alarm Usage 1659
13.5.1 Discrete Alarm Configuration 1659
13.5.2 Analog Alarm Configuration 1660
13.5.3 System Event Configuration 1662

13.5.4 Alarm Category Configuration 1670
13.5.5 Alarm Group Configuration 1672
13.5.6 Historical Alarm Records 1673
13.5.7 Alarm Import/Export 1675
13.5.8 Alarm Runtime Configuration 1677
13.5.9 Alarm Application Example 1677
13.6 Recipe Usage 1680
13.6.1 Function Overview 1680
13.6.2 Adding a Recipe 1681
13.6.3 Modifying a Recipe 1684
13.6.4 Deleting a Recipe 1685
13.6.5 Copying and Pasting a Recipe 1685
13.6.6 Importing and Exporting a Recipe 1685
13.7 Scheduled Task 1687
13.7.1 Adding a Task 1687
13.7.2 Editing a Task 1688
13.7.3 Task Properties 1689
13.7.4 Event Configuration for Tasks 1690
13.7.5 Copying and Pasting a Task 1691
13.7.6 Deleting a Task 1691
13.8 Operation Record Usage 1691
13.8.1 Operation Record Configuration Process 1692
13.8.2 Operation Records for Stored Projects 1693
13.8.3 Operation Record Runtime Configuration 1694
13.9 Text List Usage 1694
13.9.1 Adding a Text List 1694
13.9.2 Modifying a Text List 1695
13.9.3 Deleting a Text List 1697
13.9.4 Copying/Pasting a Text List 1697
13.9.5 Exporting a Text List 1698
13.9.6 Importing a Text List 1698
13.10 System Function and Script Usage 1699
13.10.1 System Functions 1699
13.10.2 User Script 1700
13.10.2.1 Adding a Script 1700
13.10.2.2 Grouping Scripts 1700
13.10.2.3 Modifying a Script 1701
13.10.2.4 Script Properties 1704

13.10.2.5 Script Toolbox 1706
13.10.2.6 JavaScript Syntax Basics 1707
13.10.2.6.1 Language Overview 1707
13.10.2.6.2 Common Operators 1707
13.10.2.6.3 Operator Precedence 1713
13.11 Installment Payment 1715
13.11.1 Function Overview 1715
13.11.2 Enabling Installment Payment 1716
13.11.3 Selecting an Installment Strategy 1717
13.11.4 Installment Unlocking Modes 1720
13.11.5 Configuring Pre-Due Reminder 1721
13.11.6 Configuring Lock Screen 1723
13.11.7 Impact of Installment Payment on Other Functions 1727
13.12 Monitoring Runtime Configuration 1727
13.12.1 Screen Display Configuration 1728
13.12.2 Preload Screen Configuration 1730
13.12.3 OPC UA Server Configuration 1730
13.12.4 VNC Server Configuration 1731
13.12.5 VNC Client Configuration 1733
13.13 Compilation Configuration 1733
13.13.1 Compiling/Clearing 1733

1 Legal Information

Copyright

This documentation is the exclusive property of Shenzhen Inovance Technology Co., Ltd. No individual or entity may excerpt, reproduce, modify, translate, or distribute any content herein without written consent from Inovance.

Legal action will be taken against infringement.

Trademarks

INOVANCE is a registered trademark of Shenzhen Inovance Technology Co., Ltd. and its affiliates. All other trademarks or registered trademarks mentioned in this documentation are the property of their respective owners. Unauthorized use of these trademarks by third parties for any purpose without written authorization could violate the rights of their owners.

Disclaimer of Liability

Due to continuous updates and improvements of products and technologies, the content of this documentation may not fully match the actual products. In the event of any discrepancies, the actual products shall prevail.

The contents are subject to change without notice due to product upgrade.

Waste Disposal

The storage, use, and disposal of this product (including optional accessories) must comply with local laws and regulations.

Qualifed Personnel

The product/system described in this documentation may be operated only by personnel qualified for the specific task in accordance with the relevant documentation, in particular its warning notices and safety instructions. Qualified personnel can identify the risks of the product/system and prevent possible dangers.

Proper Use of the Product

Proper transportation, storage, assembly, installation, commissioning, operation, and maintenance are required to ensure the safe operation of the product without any problems. The required ambient conditions must be met. All operations must follow the guidelines provided in this documentation.

2 Version Information

2.1 New Features in V1.5.2.5

2.1.1 Introduction

This section summarizes all the important new features compared to software V1.4.4.5. For more details on each topic, see corresponding sections in the product documentation.

2.1.2 Newly Supported Hardware Models

This section summarizes the newly added hardware product series. For more details on each topic, see the product documentation.

PLC

Product Series	Firmware Version
EVO522-0808TN	V1.7
EVO410-A12N16	V1.5
EVO410-A14N16	V1.5
EVO410-A15N16	V1.5
EVO410-A17N16	V1.5
EVO510-A12P16	V1.5
EVO510-A14P16	V1.5
EVO510-A15P16	V1.5
EVO800-CM-DPM	V1.2
EVO800-CM-PNM	V1.2

Safety PLC

Product Series	Firmware Version
EVO1000EF-F50	V1.1
EVO1000EF-F51	V1.1
EVO1000EF-F52	V1.1

Monitor

Product Series	Firmware Version
IT9100E	V1.0
IT9070E	V1.0

Drive

Product Series	Firmware Version
SV630NS	H01-00=1042.0/H00-02=000.00

Product Series	Firmware Version
MD520	F7-10=U60.12/F7-11=U61.12/F7-15=000.00/F7-16=000.00

2.1.3 New Software Features

This section summarizes the important new features of the software. For more details on each topic, see corresponding sections in the documentation.

Feature	Description	Applicable Products
Library project security management (new)	Supports security settings for library projects. For details, see 9.15 Library Project Security Management.	General
HMI security authentication policies (new)	Added HMI security authentication policies. For details, see 9.6 HMI Security Authentication Policies.	General
Collapsing project child nodes with one click (new)	All child nodes under the PLC can be collapsed. For details, see 8.14 Collapsing Project Child Nodes with One Click.	General
Uninstalling the software while keeping user configuration data	Reinstallation does not require reconfiguring user information.	General
Inverting object selection in the view area (new)	The parent node objects in the view area can be inverted. For details, see 5.5.8 Inverting Object Selection.	General

PLC

Feature	Description	Applicable Products
Default gateway configuration (new)	Supports enabling the default gateway. For details, see 10.6.14.4 Ethernet Address Settings.	EVO400, EVO500, EVO700, APC, EVO800
Importing/Exporting a PLCopenXML file (updated)	PLCopenXML files can be imported and exported using LD and CFC languages. For details, see 8.12 Importing/Exporting a PLCopenXML File.	Full product series
Overwriting existing data during the PLC upload	Project upload supports overwriting existing data. For details, see 10.9.1 Uploading.	Full product series

Feature	Description	Applicable Products
Watch table and power failure retention table (optimized)	Removed view restrictions for watch tables, and power failure retention tables, supporting viewing all variables by mouse scrolling. For details, see visible element range setting and power failure retention table.	Full product series
Offline variable table (optimized)	Expansion of up to 100,000 child elements are supported in offline variable tables.	Full product series
Library reference (updated)	System library references are bound to a placeholder library by default. For details, see library referencing and dereferencing.	Full product series
Finding and replacing within a project (updated)	Search in both source code libraries and projects can be performed simultaneously. For details, see 8.7 Finding and Replacing Within a Project.	Full product series
CFC programming language (optimized)	• Pins can be hidden and pin comments can be edited through a right-click pop-up dialog. For details, see 10.1.5.4.3.1 Configuring Operation Block Properties. • Added the feature of quick operation block alignment. For details, see 10.1.5.4.3.4 Repositioning an Operation Block. • Supports quick one-to-many connection. For details, see 10.1.5.5.4 Connecting Input and Output Parameters. • Added the feature of distinguishing connection line colors by data type. For details, see 10.1.5.5.6 Changing Connection Line Color. • Added the feature of text connection. For details, see 10.1.5.5.8 Text Connection.	Full product series

Feature	Description	Applicable Products
SFC programming language (optimized)	• Supports dual-line display. For details, see 10.1.6.3.2.1 Setting the SFC Editor in iFA Options. • Supports enabling or disabling all networks with a single click. For details, see 10.1.6.3.5 Opening/Closing All Program Segments. • Supports the power failure retention property setting. For details, see 10.1.6.3.2.3 Setting SFC Program Block Power Failure Retention Property. • Supports viewing the SFC view by right-clicking and dragging. For details, see 10.1.6.3.3 SFC Programming Window. • Updated some UIs. For details, see the actual display in the software.	Full product series
Program block access permission settings (updated)	For details, see 10.1.2.5 Program Block Access Permissions.	Full product series
Variable comment display method (new).	Instance comments can be edited. For details, see 10.1.3.3.2 LD Editor Settings.	Full product series
Cumulative timer and sequencer output instructions (new)	For details, see 18.1.9.13 AccumulationTimer2and 18.2.20.2 SQO.	Full product series
General instruction of delay timer (updated)	The general instruction of delay timer supports modification of the ET pin. For details, see 18.1.9.5 TON2.	Full product series
Added the feature of task startup initialization.	For details, see 10.5.3 System Event Management.	Full product series
Copying and pasting between the variable table and Excel.	For details, see 10.1.1.10.2 Copying and Pasting a Variable Table.	Full product series
Batch reset/set instructions (new)	For details, see 18.1.4.10 RESET_BFand 18.1.4.11 SET_BF.	Full product series
Instruction of conversion between string and numeric formats (new)	For details, see 18.2.5.21 AnyNumFmt.	Full product series

Feature	Description	Applicable Products
Instruction for calling C function (new)	For details, see 18.2.19.4 IOBlockLibCalland 18.2.19.5 IOBlockLibProcess.	Full product series
Instructions of conversion between GB2312 encoding and STRING/WSTRING (new)	For details, see 18.4.1.29 UTF16ToGB2312, 18.4.1.30 UTF8ToGB2312, 18.4.1.31 GB2312ToUTF16, and 18.4.1.32 GB2312ToUTF8.	Full product series
Instruction of reading axis parameters (new)	For details, see 18.3.3.3.59 MC_GetGearingRatio.	EVO400, EVO500, EVO700, EVO700C, APC520, and APC760C
Instruction of getting all the status flags of SD memory card (new)	For details, see 18.4.1.33 SDCard1StatusGet.	Full product series
In-position check for motion control instructions	For details, see each instruction section.	EVO400, EVO500, EVO700, EVO700C, APC520, and APC760C
I/O mapping variable binding (updated)	I/O mapping supports one-click binding of structures. For details, see 10.6.3.3.9 I/O Mapping.	Full product series
Using one-dimensional Bit array in unions	For details, see 10.1.1.8.2.2 UNION.	Full product series
Renaming EVO760C	Modified the device name for EVO760C series PLCs. For details, see 20.2.4 EVO700C.	EVO760C
Power failure data management (new).	Data import and export can be performed during power failure. For details, see 10.11.10 Power Failure Data Management.	Full product series
Instruction Of Rotary Axis Modulo Positioning (new)	For details, see 18.3.3.3.33 MC_MoveModulo.	EVO400, EVO500, EVO700, EVO700C, APC520, and APC760C
Instruction of clearing UDP stack buffer (new)	For details, see 18.4.13.6 SktUDPClearBuffer.	Full product series
NTP time synchronization instruction (new)	For details, see 18.4.1.34 SysHC_NtpClient.	Full product series
Instructions of getting network information and setting network properties (updated)	The instructions of getting network information and setting network properties support checking the enable status of the default gateway. For details, see 18.4.1.35 SysHC_NetworkInfoV2and 18.4.1.36 SysHC_NetworkConfigV2.	Full product series
Instruction of processing special files (new)	XML file processing is supported. For details, see 18.2.12 Special File Processing.	EVO400, EVO500, EVO700, EVO700C, APC520, and APC760C

Feature	Description	Applicable Products
EtherCAT master configuration parameter "Overview" interface (updated)	The "Overview" interface includes "Associated array" and "Array index" items. For details, see 10.6.3.2.6 Overview.	EVO400, EVO500, EVO700, EVO700C, APC520, and APC760C
Advanced process control instructions (optimized)	For details, see 18.3.2.12 PFC11, 18.3.2.13 PFC22, and 18.3.2.14 PFC_DV.	APC520
Oscilloscope (optimized)	Updated the oscilloscope UI and basic operations on the interface. For details, see 10.2 Oscilloscope.	Full product series
Phase offsetting for task configuration	For details, see 10.5.2 Configuring Task Parameters.	EVO800
PN/DP master expansion module (new)	For details, see 10.6.5.3 PN Master Configuration (EVO800)and 10.6.10 DP Communication Configuration (EVO800).	EVO800
SysPub instruction (new)	For details, see 18.4.18 SysPub.	EVO800
PN/DP master diagnostic codes (new)	For details, see 21.3 Appendix 3: PN/DP Master Diagnostic Codes.	EVO800
VarForce instruction (new)	For details, see 18.4.19.2 CheckPrgForceValueState.	EVO800

Safety PLC

Feature	Description	Applicable Products
Data types (new)	• Added the data types of DWORD and DATE_AND_TIME. For details, see 11.2.1.1.1 Standard Data Types. • Added the data types of SAFEDWORD and SAFE_DATE_AND_TIME. For details, see 11.2.1.1.2 Safety Data Types.	Full product series of safety PLCs
Safety PLC models and communication unit models (new)	For details, see 11.4.1 Hardware Configuration and Device Management.	Full product series of safety PLCs
EtherNet/IP communication with HMI (new)	For details, see 11.4.3.1.2 EtherNet/IP Communication with HMI.	Full product series of safety PLCs
Modbus TCP communication (new)	For details, see 11.4.3.3 Modbus TCP Communication Configuration.	Full product series of safety PLCs
Communication between safety PLCs and standard PLCs via EtherCAT, communication between safety PLCs via FSoE, and compatibility of FSoE-capable servo devices with safety PLCs (new)	Added the EtherCAT communication. For details, see 11.4.4 EtherCAT Communication Configuration.	Full product series of safety PLCs

Feature	Description	Applicable Products
Operation log (new)	For details, see 11.8.4 Operation Log.	Full product series of safety PLCs
Safety PLC simulation (new)	For details, see 11.9 Safety PLC Simulation Mode.	Full product series of safety PLCs
Safety PLC firmware upgrade (EVO1000) introduction (new)	For details, see 14.1.1.6 Upgrading Safety PLC Firmware(EVO1000).	Full product series of safety PLCs
DWORD data conversion operator instructions (new) and data types of all conversion operator instructions (updated)	For details, see 11.10.1.6 Conversion Operators.	Full product series of safety PLCs
Safety function block instructions (new)	For details, see 11.10.2.2.35 SF_GetSafetyConfirmInfo, 11.10.2.2.36 SF_GetCouplerState, 11.10.2.2.37 SF_GetGlBusState, 11.10.2.2.38 SF_GetEtherNetIpStateCode, 11.10.2.2.39 SF_GetFSoeStateCode, and 11.10.2.2.40 SF_GetCIPSafetyStateCode.	Full product series of safety PLCs
Extended function block instructions (new)	For details, see 11.10.2.3 Extended Function Blocks.	Full product series of safety PLCs
Overall resource usage of FSoE (new)	For details, see the "Equipped with an ECT communication unit" section under 11.2.1.2.5 Resource Usage Table.	Full product series of safety PLCs
Safety library project (updated) and risk warnings (new)	For details, see 11.2.2 Library Reference.	Full product series of safety PLCs
FSoE master functionality, enabling local or remote communication with failsafe I/O modules (new)	Added the FSoE configuration. For details, see 11.4.2.7 Configuring a Failsafe I/O Module.	Full product series of safety PLCs
DLR networking on the EIP2 port (new)	For details, see 11.8 PLC Online Operations.	Full product series of safety PLCs
SF_SafetyConnStatus instruction (updated)	For details, see 11.10.2.2.31 SF_SafetyConnStatus.	Full product series of safety PLCs
"Instruction," "Library," and "Applicable Library Version" in instruction lists of all common safety instructions (updated)	For details, see 11.10 Common Safety Instructions.	Full product series of safety PLCs

Monitor

Feature	Description	Applicable Products
Installment payment (new)	For details, see 13.11 Installment Payment.	HMI products
Reusing HMI program across projects	For details, see 13.18 HMI Program Reuse Across Projects.	HMI products

Feature	Description	Applicable Products
Image resource management (optimized)	For details, see 13.3.6 Gallery Usage.	HMI products
Automatic screen scaling across HMI devices	For details, see 13.3.10.4 Changing Screen Resolution.	HMI products

2.2 New Features in V1.4.4.5

2.2.1 Introduction

This section summarizes all the important new features compared with software V1.4.3.5. For more details on each topic, see corresponding sections in the product documentation.

2.2.2 Newly Supported Hardware Models

This section summarizes the newly added hardware product series. For more details on each topic, see the product documentation.

PLC

Product Series	Firmware Version
EVO760C	V1.5
EVO780C	V1.5
APC760C	V1.5
EVO800-CM-EN	V1.1
EVO810-A10	V1.1
EVO810-A30	V1.1
EVO820-A30	V1.1
EVO820-A50	V1.1
EVO410-A12P16	V1.5
EVO410-A14P16	V1.5
EVO410-A15P16	V1.5
EVO410-A17P16	V1.5

Drive

Product Series	Firmware Version
SV660ND	H01-00=2401.9/H00-02=000.00
SV630ND	H01-00=2501.6/H00-02=000.00
IS810N multi-axis	H01-00=5702.5/H00-02=000.00

2.2.3 New Software Features

This section summarizes the important new features of the software. For more details on each topic, see corresponding sections in the documentation.

Feature	Description	Applicable Products
Logging in to technical forum using an account (new)	Supports logging in to the iFA software, Inovance Planet, and course platform with the same account. For details, see 3.3.4 Technical Forum.	General
Separate installation and uninstallation of AI Assistant	Supports separate installation and uninstallation of the AI Assistant. For details, see 3.4 AI Assistant3.4 installation and uninstallation.	General
Diagnostics (new)	Updated the diagnostic methods and improved the related content. For details, see 15 Diagnostics.	General

PLC

Feature	Description	Applicable Products
Export method for source code library (new)	Supports saving library files as source code libraries. For details, see 12.1.4 Source Code Library.	Full product series
Library version upgrade or downgrade (new)	Supports one-click upgrade or downgrade of the library version when a device is changed. For details, see One-click upgrade/downgrade.	Full product series
Library version switching (new)	Supports changing the dependent library version in a project. For details, see Library version switching.	Full product series
Basic LD instructions (new)	For details, see 10.1.3.3.4 LD Elements and 10.1.3.3.5 LD Instructions.	Full product series
Network title navigation in LD editor area	For details, see Network title navigation area.	Full product series
Column operations in ST editor	For details, see Column operations.	Full product series
Array Intellisense in ST editor	For details, see Direct input.	Full product series
Region navigation in ST editor	For details, see Region navigation area.	Full product series
Breakpoint (optimized)	Added the Ctrl+F9 shortcut to disable breakpoints. The "Enable breakpoint" menu item is now renamed "Enable/Delete breakpoint". For details, see 10.10.4 Breakpoint Debugging.	Full product series
Variable category change (new)	Supports changing the categories of POU input/output variables. For details, see 10.1.1.10.4 Changing Variable Category.	Full product series

Feature	Description	Applicable Products
Configuration of external event task (new)	Supports selecting external event task as the task type. For details, see Task types.	EVO500 and APC500
EIP remote adapter status variable (new)	Supports selecting remote adapter status variable as the system variable. For details, see Remote adapter status variable.	Full product series
I/O mapping import/ export (new)	Supports I/O mapping import/export of the hardware configuration. For details, see 10.6.1.4 Importing10.6.1.4 I/O Mappingand 10.6.1.3 Exporting10.6.1.3 I/O Mapping.	Full product series
EIP quick connection (new)	Supports EtherNet/IP quick connection. For details, see 10.6.4.2.8 Quick Connect Communication.	EVO700 and EVO800
Wireless master station (new)	Supports adding the wireless management station under the EtherCAT node. For details, see 10.6.3.1.3 Adding a Wireless Management Station.	EVO500, EVO700, and APC500
Instruction cheat sheet (new)	For details, see each instruction section.	Full product series
Mathematical operation instructions (new)	For details, see 18.1.5.34 RAD, 18.1.5.35 DEG, 18.1.5.36 SCALE_X, and 18.1.5.37 NORM_X.	Full product series
Logic operation instructions (new)	For details, see 18.1.4.6 TestABit, 18.1.4.7 TestABitN, 18.1.4.8 SetBits, and 18.1.4.9 ResetBits.	Full product series
System time instruction (new)	For details, see 18.2.1.8 GetSystemTime.	Full product series
Data processing instructions (new)	For details, see 18.1.2.10 Byte_To_HexString, 18.1.2.11 Word_To_HexString, and 18.1.2.12 Dword_To_HexString.	Full product series
EtherCAT instructions (new)	For details, see 18.4.9.4 ETC_COE_SdoReadand ETC_COE_SdoWrite .	EVO500, EVO700, and APC500
S7 communication instruction (new)	For details, see 18.4.14 S7 Communication.	Full product series
Free serial port instructions (new)	For details, see 18.4.7.6 Serial_Connect, 18.4.7.7 Serial_Recv, 18.4.7.8 Serial_Recv_By_Idle_Time, 18.4.7.9 Serial_Recv_Ch, and18.4.7.10 Serial_Send.	Full product series
Power failure retention instructions (new)	For details, see 18.4.1.10 SysHC_GetPersistentDatainfo, 18.4.1.11 SysHC_WritePersistentData, and 18.4.1.12 SysHC_ReadPersistentData.	Full product series

Feature	Description	Applicable Products
System information instructions (new)	For details, see 18.4.1.13 SysHC_Umount, 18.4.1.14 SysHC_GetSystemDate, 18.4.1.15 SysHC_SetSystemDate, 18.4.1.16 SysHC_GetSystemTimeZone, 18.4.1.17 SysHC_SetSystemTimeZone, 18.4.1.18 SysHC_CPUInfo, 18.4.1.19 SysHC_UDiskPath, 18.4.1.20 GetBootVersion, GetPLCVersion, 18.4.1.22 GetProductName, 18.4.1.23 GetSerialNumber, 18.4.1.24 GetFPGALogicVersion, and 18.4.1.25 SysHC_Appbackup.	Full product series
Instruction for setting remote adapter IP via EIP (new)	For details, see 18.4.3.15 EIP_SetRemAdapterConfIP.	Full product series
Instructions for getting EIP system status and connection status (new)	For details, see 18.4.3.13 GetEIPSystemstatsand 18.4.3.14 GetEIPConnectstats.	Full product series
EIP instructions (new)	For details, see 18.4.3.8 generic_Service, 18.4.3.9 Get_Attributes_All, 18.4.3.10 Get_Attribute_Single, 18.4.3.11 Set_Attributes_All, and 18.4.3.12 Set_Attribute_Single.	Full product series
High-speed I/O instruction (new)	For details, see 18.3.5 High-Speed I/O Instructions.	EVO500, EVO700, and APC500
Recipe library instructions (new)	For details, see 18.2.18.1.31 CreateRecipeV3, 18.2.18.1.32 DeleteALLRecipeV3, 18.2.18.1.33 DeleteRecipeV3, 18.2.18.1.34 GetRecipeDefinitionInfoV3, 18.2.18.1.35 GetRecipeInfoV3, 18.2.18.1.36 LoadRecipeV3, 18.2.18.1.37 ReadRecipeV3, 18.2.18.1.38 RenameRecipeV3, 18.2.18.1.39 SaveRecipeV3, 18.2.18.1.40 SetRecipeValuesV3, 18.2.18.1.41 WriteRecipeV3, and 18.2.18.1.42 SetStoragePathV3.	Full product series
EtherCAT slave reset instruction (new)	For details, see 18.4.9.11 ETC_SlaveReset.	EVO500, EVO700, and APC500
Memory comparison instruction (new)	For details, see 18.2.17.5 AnyMemCmp.	Full product series
Local bus instructions (new)	For details, see 18.4.4.4 LBus_GetModuleInfo, 18.4.4.5 SysHC_GetAllGL20ModuleInfo, and 18.4.4.6 SysHC_GetGL20ModuleInfo.	EVO500, EVO700, and APC500
Axis array variables (new)	The system variables include axis array variables. For details, see Axis array variables.	EVO500, EVO700, and APC500

Feature	Description	Applicable Products
Upper limit of string length (adjusted)	The STRING length is increased from 256 to 4096 bytes, and the WSTRING length is increased from 512 to 16382 bytes. For details, see 10.1.1.8.1 Standard Data Types. The instruction string length is increased from 256 to 1985 bytes.	Full product series
Axis commissioning interface (updated)	Updated the configuration UI for axis commissioning. For details, see 16.1 Axis16.1 Configuration.	EVO500, EVO700, and APC500
PLC simulation mode (updated)	Updated the UI for PLC simulation. For details, see 10.13 PLC Simulation Mode.	Full product series
File operation instruction (updated)	Supports file operations for the user directory on the PLC. For details, see 18.2.11 File Operations.	Full product series
Instruction for disabling ECAT device (updated)	Updated the instruction for disabling ECAT device - slave disable function. For details, see 18.4.9.7 ETC_DisableDevice.	EVO500, EVO700, and APC500
Removing variable download restrictions for oscilloscope	For details, see 10.2 Oscilloscope.	Full product series
ECAT instruction renaming	ETCMaster_Restart is renamed to ETC_MasterRestart. For details, see 18.4.9.12 ETC_MasterRestart. SysHC_ETCMasterDiagnose is renamed to ETC_MasterDiagnose. For details, see 18.4.9.13 ETC_MasterDiagnose.	EVO500, EVO700, and APC500
DHCP configuration method (new)	Added the DHCP configuration method for Ethernet. For details, see 10.6.14.4 Ethernet Address Settings.	EVO500, EVO700, and APC500
EtherCAT scanning (optimized)	For details, see 10.6.3.1.4 Adding an Online EtherCAT Slave to Project.	EVO500, EVO700, and APC500
EtherCAT slave system variables (updated)	Added ConfigProductID, ProductID, and Name to the EtherCAT slave system variable structure members. For details, see EtherCAT slave system variables.	EVO500, EVO700, and APC500
EtherCAT master configuration parameters (updated)	Optimized the Overview interface. For details, see 10.6.3.2.6 Overview.	EVO500, EVO700, and APC500
EtherCAT slave configuration parameters (updated)	Optimized the EoE interface. For details, see 10.6 .3.3.6 EoE Settings.	EVO500, EVO700, and APC500

Feature	Description	Applicable Products
AXIS_REF: New axis structure variables	Added wAxNo to the axis structure variables. For details, see 18.3.3.2.2.1 AXIS_REF: Axis Structure.	EVO500, EVO700, and APC500
New trigger mode for MC_TouchProbe	Adjusted the valid range of the input parameter TriggerMode for MC_TouchProbe to 0-2, and updated the continuous trigger mode. For details, see 18.3.3.3.10 MC_TouchProbe.	EVO500, EVO700, and APC500
ALT instruction format (updated)	Adjusted the variable xOut type of ALT from output variable to in-out variable. The corresponding library version is Util 1.2.0.0 or later. For details, see 18.1.1.8 ALT.	Full product series
Function block (FB) declaration restriction	The FB is not allowed to be declared as a stack variable. For details, see function block instantiation.	Full product series
Ethernet expansion module property configuration (new)	For details, see 10.6.15 Ethernet Expansion Module Property Configuration.	EVO800-CM-EN
PRP monitoring (new)	For details, see 10.11.23 PRP monitoring.	EVO800-CM-EN

Monitor

Feature	Description	Applicable Products
Multiple languages (new)	HMI interface supports multi-language switching. For details, see 13.17 Multilingual Settings.	IT9000 series HMI
Multimedia control (new)	See 13.3.5.5.6 Multimedia.	IT9000 series HMI
Batch editing of alarms	Supports importing or exporting the alarm variables. For details, see 13.5.7 Alarm13.5.7 Import/Export.	IT9000 series HMI
Delayed triggering of button events	Supports delayed triggering for events associated with 13.3.5.2.5 Bit Button and 13.3.5.2.6 Word Button.	IT9000 series HMI
Mitsubishi Q series drive (new)	For parameter configuration, see 13.1.6 Supported Device Drives.	IT9000 series HMI

Drive

Feature	Description	Applicable Products
Servo common function - multi-axis device (new)	Added a servo common function of multi-axis device. For details, see 17.3.3 Multi-Axis Devices.	SV660ND, SV630ND, and IS810N

2.3 New Features in V1.4.3.5

2.3.1 Introduction

This section summarizes all the important new features compared with software V1.4.2.5. For more details on each topic, see corresponding sections in the product documentation.

2.3.2 Newly Supported Hardware Models

This section summarizes the newly added hardware product series. For more details on each topic, see the product documentation.

PLC

Product Series	Firmware Version
APC520-A10P(N)16	V1.4

Drive

Product Series	Firmware Version
SV680N	H01-00=4002.5/H00-02=000.00
SV680N-INT	H01-00=2000.1/H00-02=000.00
SV680L	H01-00=4701.6/H00-02=000.00
SV640N	H01-00=3604.8/H00-02=000.00
SV670N-LK	H01-00=5001.6/H00-02=180.02
SVD60N	H01-00=1600.4/H00-02=000.00
IS810N single axis	H01-00=5701.9/H00-02=000.00
MD630N	A2-22=U63.02/A2-23=U63.04/A2-24=000.00/A2-25=000.00
MD810	F7-10=L02.03/F7-11=L03.04/F7-15=000.01/F7-16=000.00
MD800 rectifier	F0-02=U05.07/F0-03=000.00
MD800 inverter	F7-10=U80.05/F7-11=U84.04/F7-15=000.00/F7-16=000.00

2.3.3 New Software Features

This section summarizes the important new features of the software. For more details on each topic, see corresponding sections in the documentation.

Feature	Description	Applicable Products
Floating window (new)	Added the floating window. For details, see 5.2 Project View.	General
PLCopenXML import and export (new)	Added the feature of PLCopenXML import and export. For details, see 8.12 Importing and Exporting a8.12 PLCopenXML File.	General

Feature	Description	Applicable Products
Batch installation and uninstallation of device files (new)	Supports batch installation and uninstallation of device files. For details, see 8.15.1 Installing a Deviceand 8.15.3 Uninstalling a Device.	General

PLC

Feature	Description	Applicable Products
CFC programming language (new)	Added the CFC language to programming languages. For details, see 10.1.5 CFC Language Programming.	Full product series
Template creation for user-defined types in PLC (new)	Supports template creation for user-defined data types in the PLC. Fore details, see Structure templating.	Full product series
Function block property (new)	Supports adding properties for the function block. For details, see 10.1.2 .3.4 Adding Properties to a Function Block.	Full product series
Whole-structure access to tag structures (new)	Supports whole-structure access to EIP tag communication variable types. For details, see 10.6.4.2.7 Communication with HMI.	Full product series
Web server for EVO500 (new)	EVO500 supports Web server. For details, see 10.6.14.7 Web Serverand 10.11.12 Web Diagnostics and Monitoring.	EVO500
Memory copy instruction (new)	For details, see 18.2.17 Memory Copy.	Full product series
Instruction for converting UNICODE to UTF8 (new)	For details, see 18.1.12.24 UNICODE_TO_UTF8.	Full product series
Instruction for deleting all recipes (new)	For details, see 18.2.18.1.5 DeleteAllRecipe.	Full product series
Instruction for binding cam node (new)	For details, see 18.3.3.4.20 MC_CamNodeBinding.	EVO500, EVO700, and APC500
Instructions for backing up servo parameters and restoring servo parameters (new)	For details, see 18.3.3.7.4 MC_BackupServoParameter2 and 18.3.3.7.5 MC_RestoreServoParameter2.	EVO500, EVO700, and APC500
Instruction for advanced process control (new)	For details, see 18.3.2 Advanced Process Control.	APC500
EtherNet/IP online scan to add device (new)	Supports EtherNet/IP online scan to add a device. For details, see 10.6.4.2.1 Adding an EtherNet/IP Device.	Full product series

Feature	Description	Applicable Products
100 ms timer instruction (updated)	For details, see 18.1.9.15 Timer100ms.	Full product series
Instructions for getting device diagnostic information (new)	For details, see 18.4.1.7 GetDeviceDiag.	Full product series
Instructions for getting device status (new)	For details, see 18.4.1.8 GetDeviceStatus.	Full product series
Timed pulse output instructions (new)	For details, see 18.2.7.5 GetClk_1ms, 18.2.7.6 GetClk_10ms, 18.2.7.7 GetClk_20ms, 18.2.7.8 GetClk_100ms, 18.2.7.9 GetClk_1s, and 18.2.7.10 GetClk_1min.	Full product series
Instruction for calling C function (new)	For details, see 18.2.19 C Function Support.	EVO500, EVO700, and APC500
Free TCP instruction (new)	For details, see 18.4.12 Free TCP.	EVO500, EVO700, and APC500
Free UDP instruction (new)	For details, see 18.4.13 Free UDP.	EVO500, EVO700, and APC500
Homing method filter option in axis parameter configuration (new)	For details, see 16.1.5.5 Homing Parameter Settings.	EVO500, EVO700, and APC500
Adding remote I/O module	For details, see 10.6.11.3 Adding a Remote I/O Module.	Full product series
Delta configuration in axis group (new)	For details, see 16.2.2.1 Mechanical Types, 16.2.2.2 Structural Parameters, and 16.2.2.3 Axis Configuration.	EVO500, EVO700, and APC500
AXIS_REF: New axis structure variables	The new axis structure variables include fSetJerk, fFollowingError, bHomed, uiPhysSlaveAddr, and uiAliasSlaveAddr. For details, see 18.3.3.2.2.1 AXIS_REF: Axis Structure.	EVO500, EVO700, and APC500
Program check (new)	Supports program check. For details, see program check.	Full product series
Parameter update (new)	Supports parameter update. For details, see 10.1.1.10.9 Parameter Update.	Full product series
Program block callee update (new)	Supports program block update callees. For details, see 10.1.2.4 Program Block10.1.2.4 Callee Update.	Full product series
EtherCAT online and overview interfaces (optimized)	For details, see 10.6.3.2.5 Online and 10.6.3.2.6 Overview.	EVO500, EVO700, and APC500
Oscilloscope (optimized)	For details, see 10.2 Oscilloscope.	Full product series
ST language programming (optimized)	For details, see 10.1.4 ST Language Programming.	Full product series

Feature	Description	Applicable Products
LD language programming (optimized)	For details, see 10.1.3 LD Language Programming.	Full product series
Upper limit of public variables (adjusted)	Adjusted the upper limit of public variables. For details, see network public property.	Full product series

Monitor

Feature	Description	Applicable Products
Module channel fault monitoring for system diagnostics control	For details, see 13.3.5.4.7 System Diagnostics.	IT9000 series HMI
New device driver–Rockwell (AB) EtherNet/IP	HMI devices support communication with ControlLogix series PLCs. For configuration information, see 13.1.6.3 Communication with Rockwell (AB) Devices.	IT9000 series HMI
Expansion of user-defined types in module library	User-defined structures in the PLC can be dragged into the template library to achieve templating. For related operations, see 13.4.4 User-defined Types and 13.4.6 Common Operations on Templates.	IT9000 series HMI
Cross-project template copy/paste	When a template instance is copied/pasted, the associated templates are also pasted. For related requirements and operations, see 13.4.7 Copying/ Pasting a Template Across Projects and 13.4.8 Copying/Pasting a Template Instance Across Projects.	IT9000 series HMI
Customizing pop-up window location	The display position of a pop-up screen can be set as a constant. For position settings, see 19.4.4 Showing the Popup Screen.	IT9000 series HMI
Group management of user scripts	Supports group management of user scripts. For related operations, see 13.10.2.2 Grouping13.10.2.2 Scripts.	IT9000 series HMI
Batch editing of the same type of control properties	Supports batch editing of the same type of control properties on the screen. For the applicable scope, see 13.3.7.20 Setting Properties in Batch.	IT9000 series HMI

Feature	Description	Applicable Products
Extended time format for "Date-time field" control	Supports display of system time that consists of date and time. For details, see 13.3.5.2.3 Date-Time Domain.	IT9000 series HMI
Displaying linkage name of external variables	Set whether to automatically display the linkage name through configuration options. For configuration details, see 13.2.5.2.2 Naming an External Variable.	IT9000 series HMI

Drive

Feature	Description	Applicable Products
AC drive common function - parameter list	Added an AC drive common function of parameter list. For details, see 17.2.2.6 Parameter List.	MD800, MD810, and MD630N
AC drive common function - fault management	Added an AC drive common function of fault management. For details, see 17.4.1 Fault Management.	MD800, MD810, and MD630N
AC drive common function - control panel	Added an AC drive common function of control panel. For details, see 17.4.2 Control Panel.	MD800 inverter, MD810 inverter, and MD630N
AC drive common function - function diagram	Added an AC drive common function of function diagram. For details, see Function Diagram.	MD630N
AC drive common function - motor auto-tuning	Added an AC drive common function of motor auto-tuning. For details, see 17.4.4 Motor Auto-Tuning.	MD630N
AC drive common function - black box	Added an AC drive common function of black box. For details, see 17.4.5 Black Box.	MD630N
AC drive common function - I/O monitoring	Added an AC drive common function of I/O monitoring. For details, see 17.4.6 I/O Monitoring.	MD800 rectifier

2.4 New Features in V1.4.2.5

2.4.1 Introduction

This section summarizes all the important new features compared with software V1.3. For more details on each topic, see corresponding sections in the product documentation.

2.4.2 Newly Supported Hardware Models

This section summarizes the newly added hardware product series. For more details on each topic, see the product documentation.

PLC

Product Series	Firmware Version
EVO521-0808TN(TP)	V1.3
EVO522-0808TN(TP)	V1.3
EVO523-0808TN(TP)	V1.3
EVO763-0804TN	V1.1
EVO764-0804TN	V1.1
EVO765-0804TN	V1.1
EVO766-0804TN	V1.1
EVO810	V1.0
EVO820	V1.0
EVO1000EF	V1.0

Drive

Product Series	Firmware Version
SV630N	H01-00=3704.3/H00-02=000.00
SV660N	H01-00=0904.3/H00-02=000.00
SV670N	H01-00=5002.5/H00-02=000.00
SV635N	H01-00=3404.6/H00-02=000.00
STD60N	H01-00=6000.4/H00-02=000.00
IS650N-PLUS	H01-00=1110.2/H00-02=000.00
SV660NC	H01-00=5201.9/H00-02=000.00
SV660NS	H01-00=1022.0/H00-02=000.00

2.4.3 New Software Features

This section summarizes the important new features of the software. For more details on each topic, see corresponding sections in the documentation.

Feature	Description	Applicable Products
Project comparison (new)	Project comparison can be performed before downloading. For more details, see 10.8.4 Online Modification/Monitoring without Modification.	General
Update check (optimized)	Supports software version upgrade. For details, see 4.5 Upgrading the4.5 Software.	General
Enabling project protection (new)	Supports enabling project protection during project permission setting. For details, see 9.3 Enabling Project Protection.	General

Feature	Description	Applicable Products
AI Assistant (new)	Added the feature of AI assistant. For details, see 3.4 AI Assistant.	General
Project upgrade (new)	Project upgrade is required to open a project created in the historical software version in a new software version. For more details, see 8.11 Upgrading a8.11 Project.	General
Batch setting of axis parameters (new)	Supports batch setting of axis parameters when a device has multiple axes. For details, see 16.1.4 Batch Servo Assignment and Axis Parameter Settings.	General
CFC programming language (new)	Added the CFC language to programming languages. For details, see Programming with CFC Language.	General
Template library (optimized)	Supports expanding the template configuration and version management. For details, see 13.4 Template Library Usage.	General

PLC

Feature	Description	Applicable Products
CANopen communication protocol (new)	Added the CANopen communication protocol in hardware configuration. For details, see 10.6.6 CANopen Communication Configuration.	EVO500 and EVO700
CAN free protocol (new)	Added the CAN free protocol in hardware configuration. For details, see 10.6.7 CAN Free Communication Configuration.	EVO500 and EVO700
PROFINET communication protocol (new)	Added the PROFINET communication protocol in hardware configuration. For details, see 10.6.5 PROFINET Communication Configuration.	EVO500 and EVO700
Network settings (new), supporting independent IP settings for dual network ports	Added the network settings in the property configuration of the network configuration view. For details, see 10.6.14.2 Network settings.	EVO500

Feature	Description	Applicable Products
Ethernet settings (new)	Added the Ethernet settings in the property configuration of the network configuration view. For details, see 10.6.14.4 Ethernet Address Settings.	EVO500 and EVO700
PLC permission configuration	Added the PLC permission configuration in online operations. For details, see 10.11.6 PLC Permission Configuration.	Full product series
Firmware upgrade (new)	Added the firmware upgrade method. For details, see 14.1.1.3 Upgrading14.1.1.3 Firmware via TypeC.	EVO500 and EVO700
User program upgrade method (new)	Added the user program upgrade via TypeC and Ethernet. For details, see 14.1.2.3 Upgrading a User Program via Type-C/Ethernet.	EVO500 and EVO700
Ethernet loop monitoring (new)	Supports monitoring the Ethernet loop status when the device is online. For details, see 10.11.17 Ethernet Loop10.11.17 Monitoring.	EVO500, EVO700, and EVO800
OPC UA diagnostics (new)	Supports displaying the status through OPC UA diagnostics when the device is online. For details, see 10.6.14.5.3 OPC UA Diagnostics.	EVO500, EVO700, and EVO800
PID instruction auto-tuning (new)	Added the auto-tuning algorithms for PID_AT and PID_ATC instructions. For details, see 18.3.1.5 PID_ATand 18.3.1.6 PID_ATC.	EVO500, EVO700, and EVO800
EtherNetIP communication instruction (new)	For details, see 18.4.3 EtherNetIP.	EVO500 and EVO700
ModbusRTU communication instruction (new)	For details, see 18.4.5 ModbusRTU.	EVO500 and EVO700
ModbusTCP communication instruction (new)	For details, see 18.4.6 ModbusTCP.	EVO500 and EVO700
CAN free communication instruction (new)	For details, see 18.4.10 CANBus.	EVO500 and EVO700
CANopen communication instruction (new)	For details, see 18.4.11 CIA405.	EVO500 and EVO700

Monitor

Feature	Description	Applicable Products
Operation record control (new)	For details, see 13.3.5.4.8 Operation Logs.	IT9000 series HMI
HMI project upload	Supports uploading the HMI device projects to the project. For details, see 13.14.3 Project13.14.3 Upload.	IT9000 series HMI
HMI project screen capture	Supports screen capture and storage of the monitoring interface during the HMI project operation. For details, see 19.11.1 Screenshot.	IT9000 series HMI
Communication with S7-300 PLC	Supports the communication between the HMI device and S7-300 PLC. For configuration information, see 13.1.6.2.1 S7-300 PLC.	IT9000 series HMI

Drive

Feature	Description	Applicable Products
Fully closed-loop function debugging (new)	Added the feature of fully closed-loop function debugging. For details, see 17.3.19 Fully Closed-Loop Function.	IS650N-PLUS
Current loop tuning (new)	Added the feature of current loop tuning. For details, see 17.3.18 Current Loop Tuning.	IS650N-PLUS
Single triggering of oscilloscope	Supports single triggering of the oscilloscope. For details, see 17.2.1.5 Triggering the Oscilloscope.	SV630N, SV630NS, SV660N, SV670N, SV680N, SV635N, IS650N-PLUS
Process segment (new)	Added the feature of process segment. For details, see 17.3.21 Process Segment.	STD60N
Overload protection (new)	Added the feature of overload protection. For details, see 17.3.22 Overload Protection.	SV680N-INT, SV670N-INT, and SV680LN
Motor management library (new)	Added a servo commissioning function of motor management library. For details, see 17.3.23 Motor Management Library.	SV680N-INT, SV670N-INT, and SV680LN
Accuracy compensation (new)	Added a servo commissioning function of accuracy compensation. For details, see 17.3.24 Accuracy Compensation.	SV680N-INT, SV670N-INT, and SV680LN

Feature	Description	Applicable Products
Cogging compensation (new)	Added a servo commissioning function of cogging compensation. For details, see 17.3.25 Cogging Compensation.	SV680N-INT, SV670N-INT, and SV680LN
Gantry synchronization (new)	Added a servo commissioning function of gantry synchronization. For details, see 17.3.26 Gantry Synchronization.	SV680N-INT and SV680LN
Motion unit configuration (new)	Add a servo commissioning function of motion unit configuration. For details, see 17.3.27 Motion Unit Configuration.	SV680N-INT, SV670N-INT, and SV680LN
Motion trajectory and simulation (new)	Add a servo commissioning function of motion trajectory and simulation. For details, see 17.3.28 Motion Trajectory and Simulation.	SV660NS, SV660NC, SV660N, SV635N, SV630N, SV630NS, IS650N-PLUS, SV680N, SV680N-INT, SV670N-INT, and SV680LN

2.5 Compatibility

Software V1.4.2.5 and later support firmware updates for different PLCs. For details, see 14.1.1 Firmware Update.

When the updated PLC firmware is incompatible with the PLC program, the user program and related configurations can be cleared.

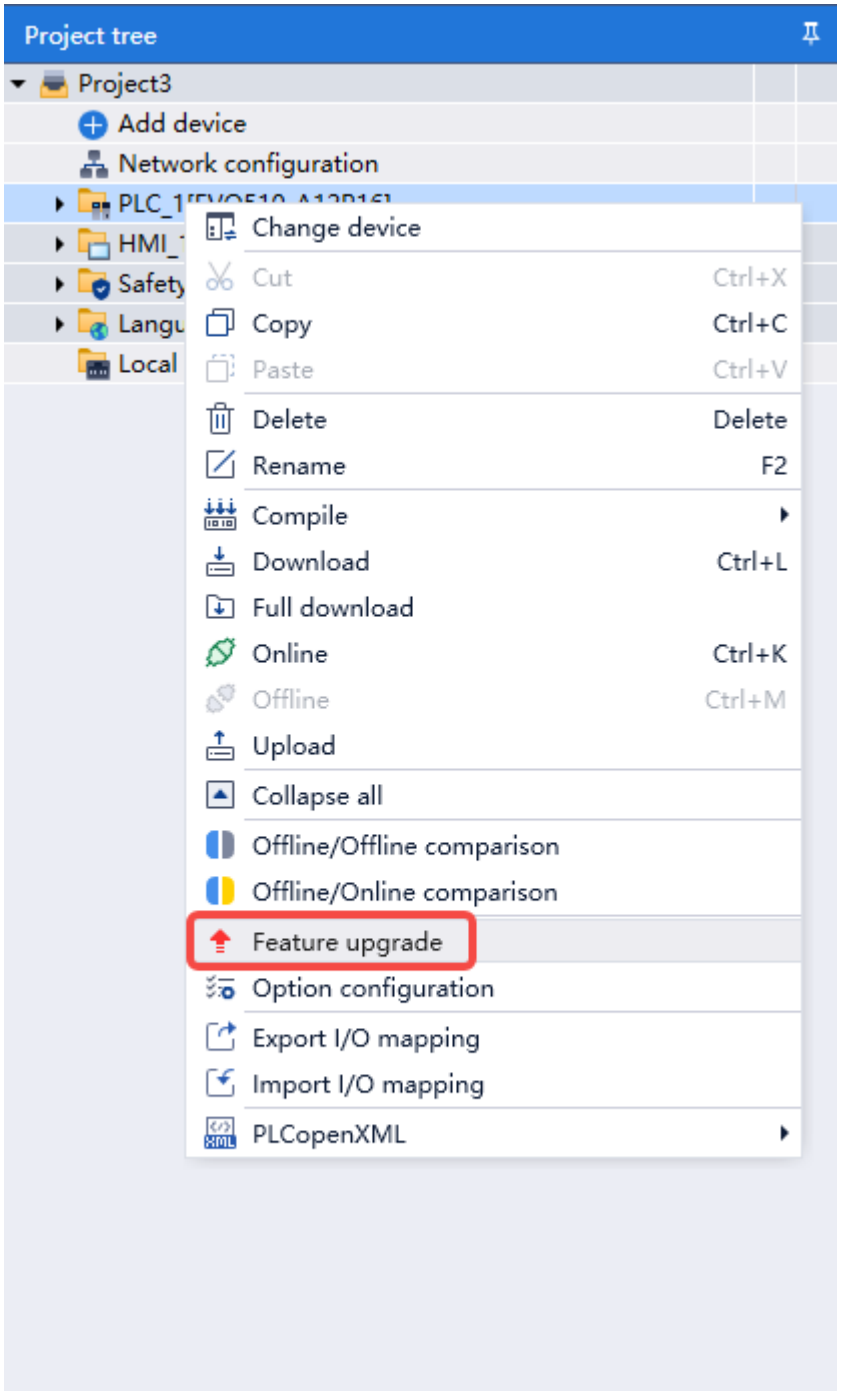
The firmware version of the actual PLC can be greater than or equal to that of the configured PLC in the iFA.

Projects are backward compatible, which means that later version software can open projects configured in earlier version software, but earlier version software cannot open projects configured in later version software.

When some feature permissions are incompatible, upgrading or downgrading the firmware automatically deletes the old permissions in the PLC.

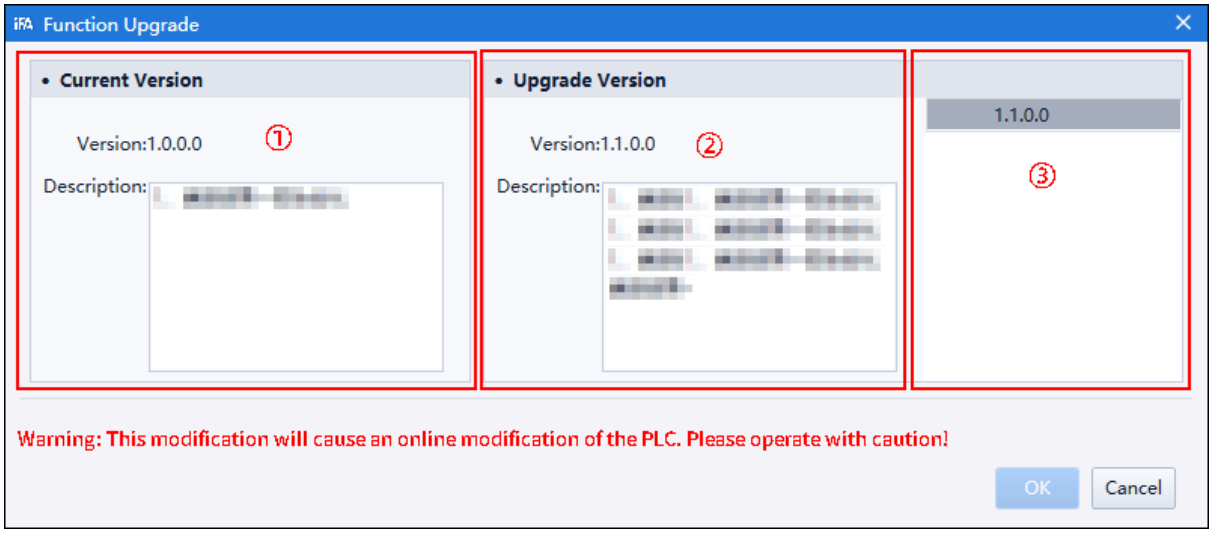
2.6 Feature Upgrade

Provided that the device firmware version remains unchanged, the feature upgrade supports online modification of the device or a full download to the device.



Device feature upgrade

Prerequisites



- A project has been created.
- A device has been added.

Procedure

1. Right-click the device node in the left project tree, and select "Feature upgrade" to access the "Feature upgrade" tab.

2. Select the upgrade version number and confirm the relevant feature information.

①: The feature version at the time of creating the current PLC node or the version after the last feature upgrade and the description of the current feature version.

②: The upgrade version number and related description.

③: Supported upgrade versions of the feature.

3. Click "OK" to perform feature upgrade.

> **NOTE**
>
> Before feature upgrade, the original project is backed up by default to the backup folder, with the file named in the format "Projectname_BackUp_YYYYMMDDHHMMSS". You can also choose a directory for backup.

Library project feature upgrade

The feature upgrade procedure for a library project is similar to the that for a device.

3 Introduction to iFA Evolution

3.1 Software Overview

iFA Evolution is an intelligent industrial control software platform developed by Inovance to support diverse industrial scenarios. It enables the development and maintenance of fully integrated automation systems for the entire factory, production lines, and individual machines of modern digital factories. Currently, it can be used for PLC configuration and development, HMI configuration and development, servo commissioning, as well as PLC and HMI simulation. As its functions continue to improve, it will support more scenarios and products in the future.

3.2 Features

The iFA Evolution software development environment includes the following software components:

Logic: PLC configuration and programming commissioning software, including single PLC and redundant PLC systems;

View: HMI system configuration and programming commissioning software;

Drive: Drive commissioning software.

You can selectively install the above components during installation based on actual usage.

All of the above software supports online updates, ensuring that users can promptly receive the latest software to experience new products and features. Moreover, the software provides unified permission management, allowing centralized control and flexible allocation of PLC and HMI development and operation permissions.

With a fully integrated development environment, iFA Evolution improves project development efficiency by functions such as variable referencing and variable dragging.

3.3 Help and Support

3.3.1 Help System

The iFA help system integrates the software help guide and can provide detailed guidance on basic functions and complex operation steps for users who are new to the iFA software. It helps users quickly find resolutions to problems encountered while using the software, such as function details and error message meanings. The system covers both basic operation instructions and advanced features and application cases, helping users have a deeper understanding of the software applications and expand their knowledge.

The help guide can only be accessed with network connectivity; otherwise, issues such as lagging or errors may occur.

Procedure

1. Choose “Help -> Help System” from the menu bar, or press the shortcut <F1>.
2. Access the help system interface that consists of search area, navigation area, and content area, as shown in the following figure.
   ①: Search area

   Enter a keyword in the search box, click the "Search" button or press Enter to perform a full-text search in the help guide. The search results are displayed below the search box. The search history can be found in the drop-down list of the search box.

   ②: Navigation area

   Includes the Contents and Favorites tabs, which display the guide's contents and the favorites, respectively.

   ③: Content area

   Displays the specific page of the guide.

3. Click the page you want to view in the Contents of the navigation area, or double-click a page in the search results list. The page is displayed in the content area.
4. The functions of the icons are described in the following table.

Icon	Function	Note
	Indent	Adjust the width of the search area.
	Previous/Next	Go to previous/next page among the opened pages.
	Print	Print the page of the help guide.

Icon	Function	Note
☆	Favorite	Add the current page to the Favorites. Favorited pages are displayed in the Favorites of the navigation area. Even if the help system is closed, the content of the Favorites will not be lost, saving time for subsequent searches of such pages.

3.3.2 Online Help

The iFA online help integrates the software help guide and can provide detailed guidance on basic functions and complex operation steps for users who are new to the iFA software. It helps users quickly find resolutions to problems encountered while using the software, such as function details and error message meanings. The online help covers both basic operation instructions and advanced features and application cases, helping users have a deeper understanding of the software applications and expand their knowledge.

Users can access the online help via a browser on any devices connected to the Internet. There are two ways to access the online help.

- Choose "Help > Online help" from the menu bar in the iFA software.
- Use the shared web page link.

Homepage

The online help homepage includes the following contents.

No.	Name	Description
①	Management tab	Includes the Homepage and Contents. • Homepage: Displays the home interface of the online help. • Contents: Switches to the contents interface of the online help.
②	-	ⓘ Click the icon to access the online help license agreement on the web page. ⊙ Click the icon to enter access the contents interface of the online help. Click the icon to collapse the left management tabs; click to unfold the management tabs.

No.	Name	Description
③	Filter and search	• Filter: Filter products by type. When a type is selected, the search is performed within the help information related to the selected product type. The product types available for filtering include PLC (all, EVO500, EVO700, EVO800, EVO1000EF), HMI, Drive, I/O (Hi50, Hi80). • Search: Enter a keyword in the search box, and then click or press Enter to perform a full-text search in the help guide. Click the title of a search result to redirect to the target page, or click in the search results area to open the guide in a new browser tab.
④	Function navigation	Provides quick access to four sections: Getting Started, PLC Programming, Motion Control, and Visual Configuration. Clicking any section navigates to the default page of that section.
⑤	Additional features	Not available yet.

Contents

The online help contents include the following:

No.	Name	Description
①	Contents bar	Contents navigation for the help guide. Enter a keyword in the search box and press Enter to search the contents of the help guide. The matched entries will be highlighted.
②	My favorites	Displays the favorited pages.
③	Advanced features area	Provides access to favorite, copy link, and print current page functions.
④	Content	Displays the content of the current page.

My favorites

1. Select the target section, and then click in the "Advanced features area".
2. In the opened "Add to my favorites" dialog box, edit the name as needed, and then click "OK".
3. View the favorites in the "My Favorites" area. Proceed as follows to unfavorite a page:
   - In the "My favorites" area, click to remove all favorites.
   - Open a page you have favorited, and then click the Favorite icon in the "Advanced features area" to unfavorite the current page.

Sharing

1. Select the target section, and then click in the "Advanced features area" to copy the current page link.
2. Share the link by social media.

Printing current page

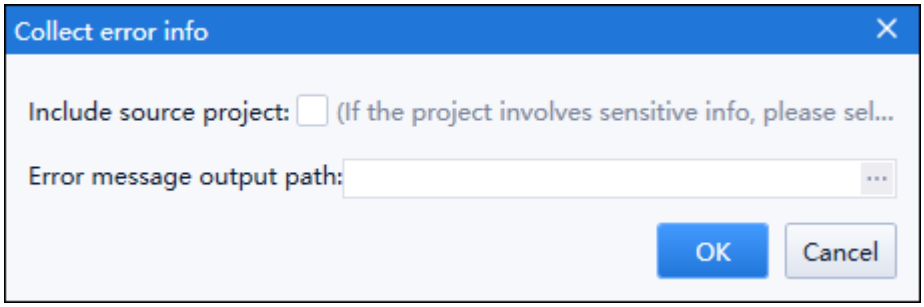
1. Select the target section, and then click in the "Advanced features area" to go to the print page.
2. Configure print parameters on the print page, and then click "Print".

3.3.3 Issue Feedback

In the iFA software, the Issue Feedback feature provides you with a direct channel to communicate with the technical support team, facilitating the continuous optimization and upgrade of the software. This feature includes submitting issue reports and feature suggestions, and collecting error information.

> NOTE
>
> Network connectivity is required to open and use the feedback related functions.

Issue report/Feature suggestion



1. Choose “Help -> Issue Feedback -> Issue Report/Feature Suggestion” from the menu bar.
2. The system opens the relevant feedback page in the browser. On the opened page, fill in related information about issue report or feature suggestion, and upload attachments as needed.
   - Issue report: Provide feedback on the issue report page in case of any abnormalities while using the iFA software, such as software crashes, performance degradation, or feature malfunction. Describe the issue in detail, including the scenario where the issue occurred, the steps taken, the frequency/time of occurrence, any possible triggering conditions, and the software version number and operating system information at the time. Upload proper attachments. This information helps the technical support team quickly identify, analyze, and resolve the issue.
   - Feature suggestion: Provide feedback on the feature suggestion page if you wish to add a new feature or optimize an existing feature based on your experience and business needs. Describe in detail the feature you wish to improve or add, and upload proper attachments. This information helps the technical support team understand the value and priority of the requirement implementation, and provides reference and direction for future feature development of the software.

3. Click "Submit". The technical support personnel analyzes the feedback upon receipt, and then takes appropriate actions.

Collecting error information

With the "Collect error info" function, you can package the current project files, including user project, operation logs, software version number, etc. Upload the packaged file when providing feedback on issues or suggestions. This feature helps technical support personnel efficiently analyze and resolve issues, and avoids missing details during manual information sorting, making the issue or suggestion feedback simpler.

1. Choose "Help -> Issue feedback -> Collect error info" from the menu bar.
2. In the opened "Collect error info" window, select whether to include the source project and error message output path.
   - Include source project: Check the box to include the project files in the package. If the project involves sensitive information, check this box with caution.
   - Error message output path: Select the path where the error message is saved.

3. Click "OK", and then the collected error information is packaged into a zip file and saved to the selected path, as shown in the following picture.

3.3.4 Technical Forum

"Inovance Planet" is a technical sharing and exchange platform provided by Inovance, aiming to offer users a space for learning and interactions. Here you can find diverse tutorials, case analyses, and technologies about Inovance's products, covering everything from beginner basics to advanced topics. You can also join discussions or create new posts to communicate with other users and experts, improving your technical skills.

The main functions of the platform are as follows:

- Knowledge sharing and learning

The platform offers a comprehensive resource library with diverse tutorials, case analyses, and technologies about Inovance's products, covering everything from beginner basics to advanced topics, all available for users to explore and download. It also offers comprehensive online training courses to help users better understand and use Inovance's products.

- Technical exchange and experience sharing

The platform has a discussion section where users can post questions or answers, engage in real-time communication and discussion on technical challenges, and share successful cases and technical research findings. For example, you can help other users find solutions more quickly by sharing practical experience in solving real-world problems; you can propose innovative ideas and perspectives during in-depth discussion on underlying product technology principles, cutting-edge technology applications, and other aspects, enhancing technical understanding and promoting innovation.

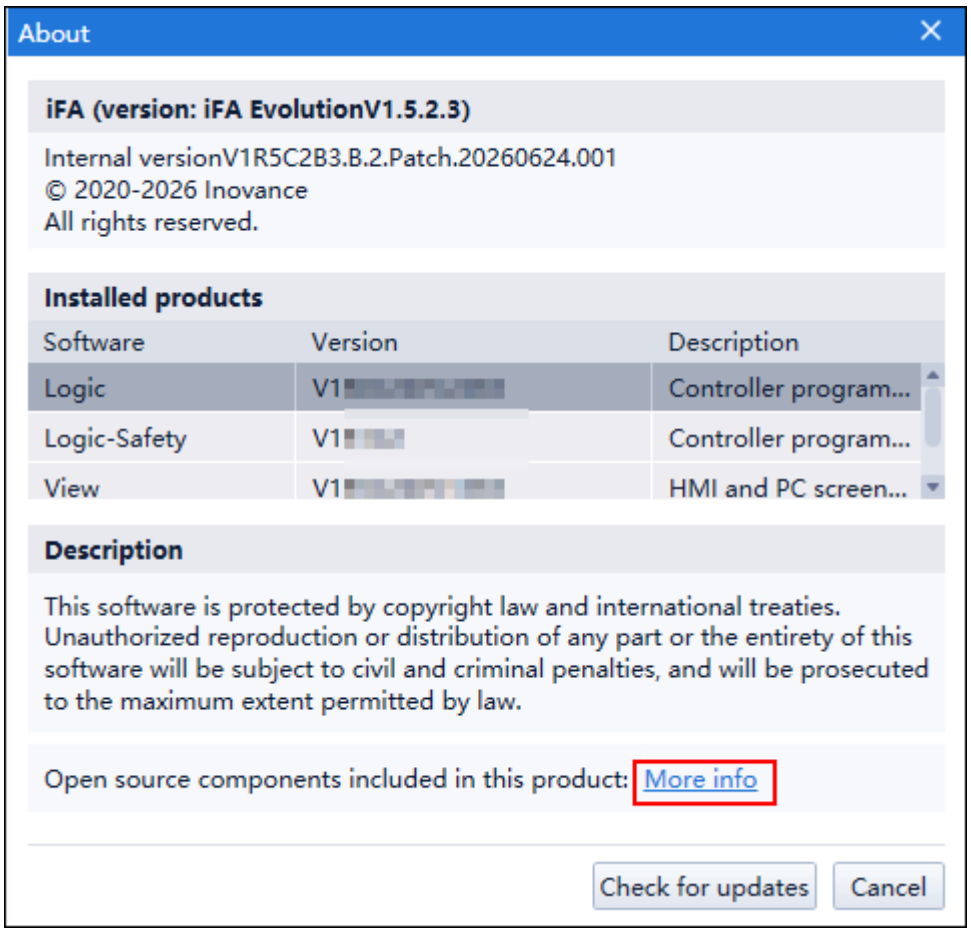
NOTE

Inovance Planet page can only be accessed with network connectivity.

Procedure

1. Choose "Help > Inovance Planet iFA Zone" from the menu bar, or click  in the upper right corner of the interface.
2. The browser opens the iFA page of "Inovance Planet", where you can view related introductions, guides, and courses for the iFA software. You can also access other sections of the forum as needed. See the actual interfaces for details.

You can log in to Inovance Planet in the following ways:



- Log in with the mobile number registered through the iFA software, which enables registration-free access to the Inovance Planet and course platform;
- Register and log in through the Inovance Planet website, which enables registration-free access to the course platform.

3.3.5 About iFA

On the "About iFA" page, you can view information such as the current software version, installed products, and open-source components. This feature makes it easy to compare with the latest official version, and supports online version updates, ensuring that users can continuously obtain the latest version.

Procedure

1. Choose "Help -> About iFA" from the menu bar.
2. In the opened interface, you can view the software version, installed products and their versions and descriptions, as well as open-source components.
3. Click the "More info" button in the opened interface, and the browser pops up the window displaying the open-source components included in the product, including component name and open-source licenses.

4. Click the "Check for updates" button to perform online update of the software version. For details, see 4.5 Upgrading the4.5 Software.

3.4 AI Assistant

iFA software is developed based on mature AI technology and introduces the AI Assistant to improve development efficiency and answer user questions. AI Assistant plays a significant role in multiple aspects, mainly reflected in helping improve programming efficiency and code quality, accelerating knowledge acquisition, lowering technical barriers, and optimizing production process.

AI Assistant installation and uninstallation

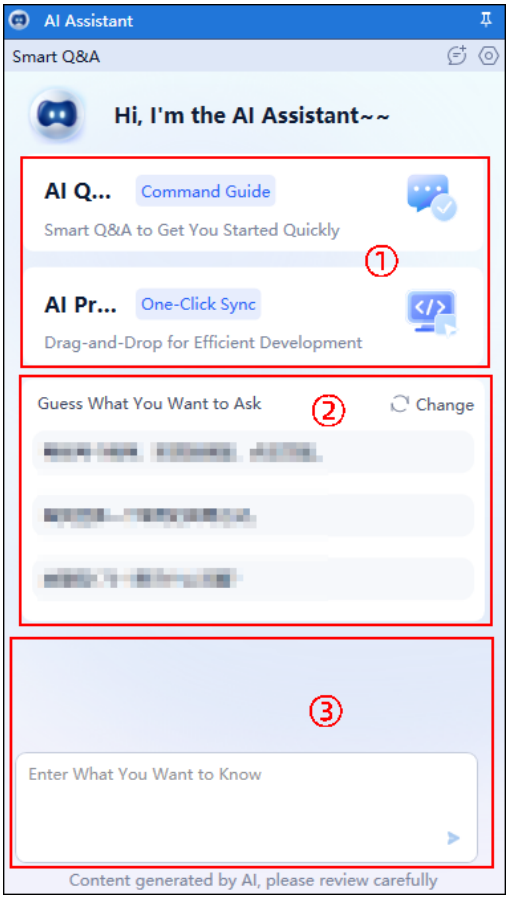
AI Assistant exists as a component and can be installed or uninstalled separately.

Install the AI Assistant

- Check the AI Assistant component during software installation and follow the installation procedure.
- If the AI Assistant is not checked during software installation, you can install it later as follows:
  1. Double-click the software installer (.exe file).
  2. Select "Add or remove components" and click "Next". The component selection tab pops up.
  3. Check the AI Assistant component and click "Install" to complete the installation.

Uninstall the AI Assistant

Proceed as follows to uninstall the AI Assistant:



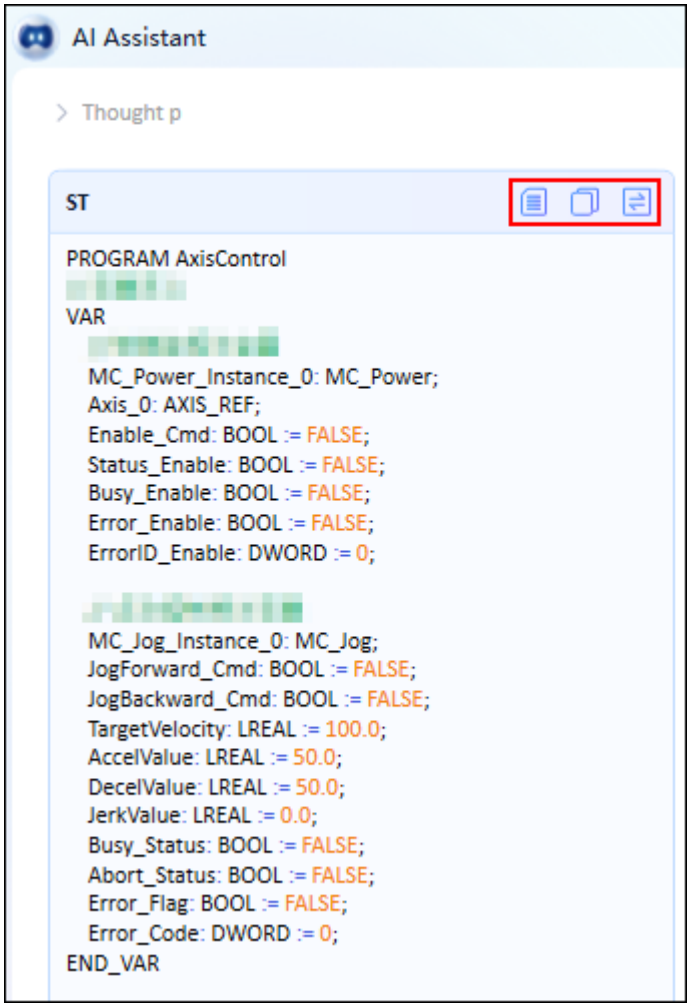
1. Double-click the software installer (.exe file).
2. Select "Add or remove components" and click "Next". The component selection tab pops up.
3. Uncheck the AI Assistant component and click "Install" to complete the uninstallation.

Use the AI Assistant

Procedure

1. Launch the iFA Evolution and open a project, and then click the "AI assistant" from the toolbar on the right side of the interface.
2. The AI Assistant interface mainly consists of three parts, as detailed below.
   - ① Function introduction area: Introduces the main functions of the AI Assistant, including AI Q&A and AI programming.
   - ② Quick input area: A series of commonly used input entries are provided. The AI Assistant quickly generates the proper answer when you click an entry, providing you with relevant information quickly.

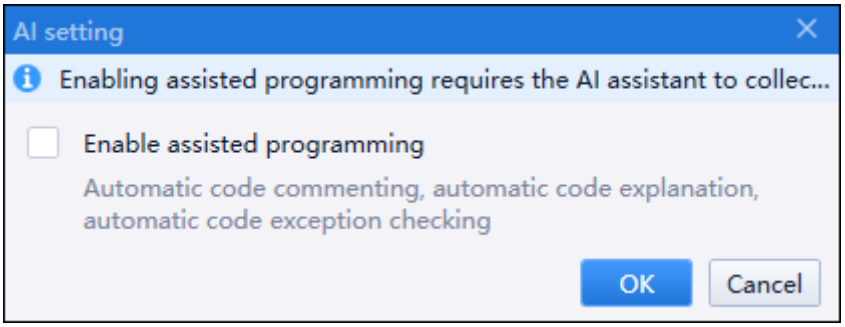
     By default, three entries are displayed. You can switch entries by clicking Change.
   - ③ Q&A area: You can interact with the AI Assistant in natural language by asking questions in the input box of this area. The AI Assistant quickly and accurately parses your needs and output detailed and comprehensive answers. The AI Assistant provides Q&A interaction with extensive coverage, including but not limited to answering questions about Inovance's products and solutions; providing support for PLC programming, including code generation, code commenting, code explanation, code error detection, and instruction search; and offering technical consultations about IEC 61131-3 standards, Structured Text programming, and functional interface design.



3. Multi-round interactions are supported. When you are dissatisfied with an answer, you can continue to ask follow-up questions.

> NOTE
>
> The input box supports up to 500 characters.

4. During the process of generating answers, you can click the Stop icon in the input box at any time to terminate the response.



5. The generated answers can be selected as a whole or in part and then copied by right-clicking Copy icon or using the shortcut "Ctrl+C." The generated codes can be dragged, copied, and synchronized to relevant programming modules.

6. Click  in the top right corner of the interface to clear the conversation history and start a new conversation.

7. Click  in the top right corner of the interface. In the pop-up window, set whether to enable assistive programming, which is enabled by default.

   The AI-based assistive programming helps users write codes. Its main functions include automatic code commenting, automatic code explanation, and automatic code error detection, greatly improving coding efficiency and quality, making the coding process smoother and more efficient, and enhancing code stability and reliability.

Disclaimer of liability

The contents generated by the AI Assistant, including but not limited to generated codes, comments, and answers, are provided for reference only and do not constitute professional advice in any field. Information is generated based on training data and algorithms and may be inaccurate, incomplete, or outdated. For:

- High-risk business activities

- Scenarios that may affect personal safety

4 Installation and Uninstallation

4.1 Operating Environment Requirements

Basic hardware requirements

Item	Requirements
CPU	Intel Core i5 standard version 4xxx or later
RAM	More than 8 GB; 16 GB is recommended.
Hard disk	Available space > 100 GB
Resolution	Laptop: 1920*1080 or 22-inch monitor
Language	English

NOTE

When the screen resolution exceeds 1920*1080, it may result in text and interface elements appearing too small. You would better follow the system recommended default zoom ratio to ensure the best display effect. To adjust the display ratio, you can modify your computer system resolution through the "Scale and Layout". The change takes effect upon modification.

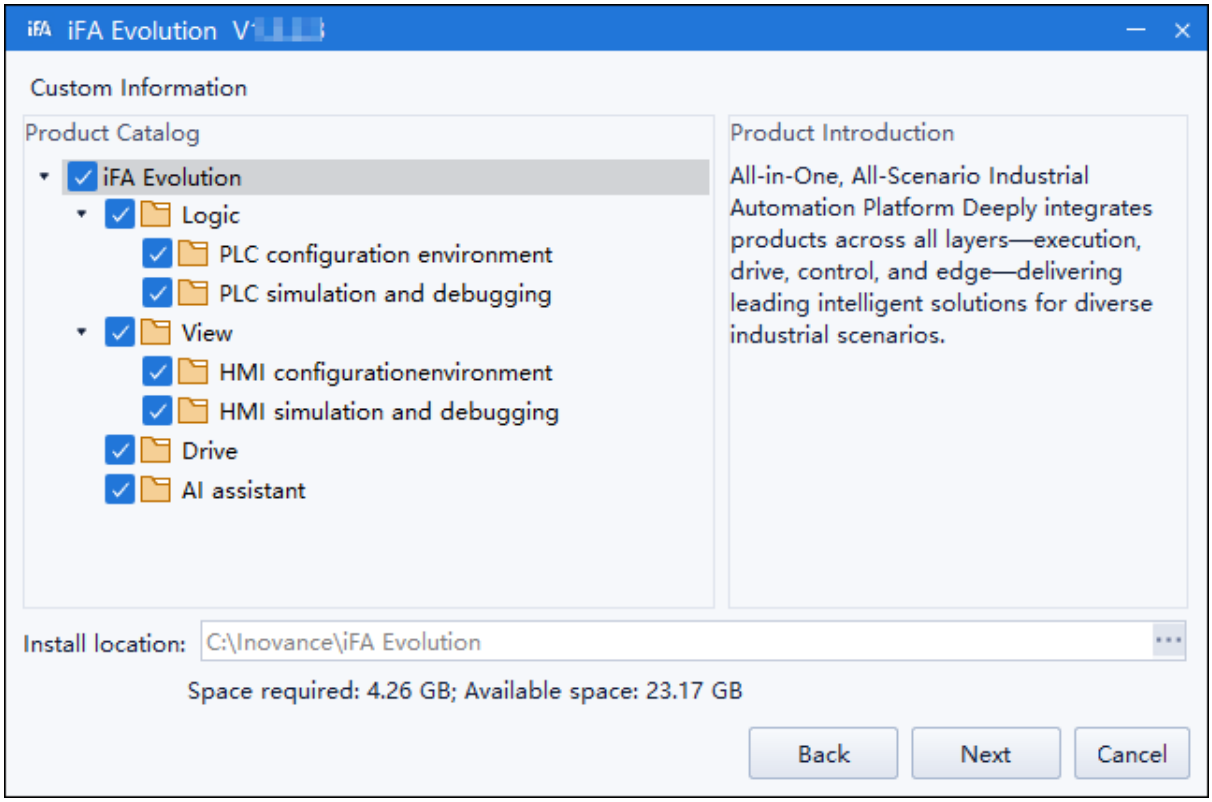
Basic software requirements

Operating System	Version
Windows 10	Enterprise edition (64-bit)
Windows 10	Professional edition (64-bit)
Windows 11	Enterprise edition (64-bit)
Windows 11	Professional edition (64-bit)

4.2 Installing the Software

The software package is automatically installed through the installer, which is started immediately after the installation medium is inserted into the drive.

Requirements



- The hardware and software meet the system requirements.
- The administrator privileges on the computer are obtained.
- All running programs have been closed.

Procedure

> **NOTE**
>
> When installing the software package for the first time, you will see a prompt on the interface indicating that licensing is required. For specific steps and instructions, see 4.4 Licensing the Software.

Proceed as follows to install the software package:

1. Double-click the installer to access the installation interface.
   You can select the language version for installation as appropriate, or modify the language in "Options -> General". For details, see language setting in 6.1 General Settings.
2. Click "Install" after selecting the language.
3. (Optional) If the iFA software already exists in your computer, running the installer will display the following options. Select the appropriate option and click "Next".
   - Add or remove components: Add or remove components based on the currently installed software, which means incremental installation.
   - Repair: Reinstall the software by directly overwriting it.
   - Uninstall: Uninstall all installed products.
4. (Optional) This step is required for a fresh installation. Carefully read the Software License Agreement, and then select "I accept the licenses" and click "Next".
5. Select the installation options and installation location.

   - Select proper components based on the project planning.
     - Logic: Integrated development software for controllers, including development and simulation components.
       - PLC configuration environment: Controller programming software, used for controller hardware configuration and software development, supporting languages such as LD, ST, CFC, and SFC.

        - PLC simulation commissioning: Supports code simulation for controllers (excluding safety controllers and redundant controllers).
    - View: Integrated development software for monitoring, supporting the development and simulation of operation screens and PC monitoring. Currently, the following two components are supported and cannot be installed separately.
        - HMI configuration environment: Monitoring development software, currently supporting HMI devices.
        - HMI simulation commissioning: Monitoring simulation software, which can be used to simulate HMI projects.
    - Drive: Drive commissioning software, supporting online commissioning of drive devices.
    - AI Assistant: The AI Assistant component can be installed separately. For details, see 3.4 AI Assistant.
  - Specify the installation location.

    The installation path cannot be changed in subsequent steps. Therefore, it is recommended to choose a hard disk with sufficient space.

6. Click "Install" to start the program installation.

7. After the program installation is complete, click "Run now" to open iFA. The iFA shortcut icon 

will appear on the desktop.

4.3 Uninstalling the Software

The software can be installed by:

- Using the control panel.
- Using the uninstall.exe.
- Using the software package.

Prerequisite: The software has been closed and is not running in the background.

- **Procedure (using the control panel)**

1. Open "Control panel" and select "Programs and Features".
2. Right-click 

and select "Uninstall".
3. Click "Start", and then click "Yes" in the pop-up dialog box.
4. The uninstallation is complete.

   Confirm that the uninstallation is complete in the pop-up window. At this point, the Inovance folder in the installation path is cleared.

- **Procedure (using the uninstall.exe)**

Double-click 

in the installation path to start the uninstallation; the default path is C:\Inovance\iFA Evolution.

For subsequent steps, see the uninstallation procedure using the control panel.

- **Procedure (using the software package)**

  1. Double-click the installer (.exe file).
  2. Click "Run" to access the "Installation type" tab.
  3. Select "Uninstall" and click "Next". A confirmation tab for uninstallation appears.
  4. Click "OK" to complete the uninstallation.

Keep local settings

During software uninstallation, the system enables the "Keep local settings" option by default. When the current version is installed, the user data such as third-party reference libraries and device files will be retained. When the software is reinstalled, these retained data can be directly loaded and used without reconfiguration.

4.4 Licensing the Software

When installing the software package for the first time, you will see a prompt on the interface indicating that licensing is required. You can proceed with the installation only after licensing is complete.

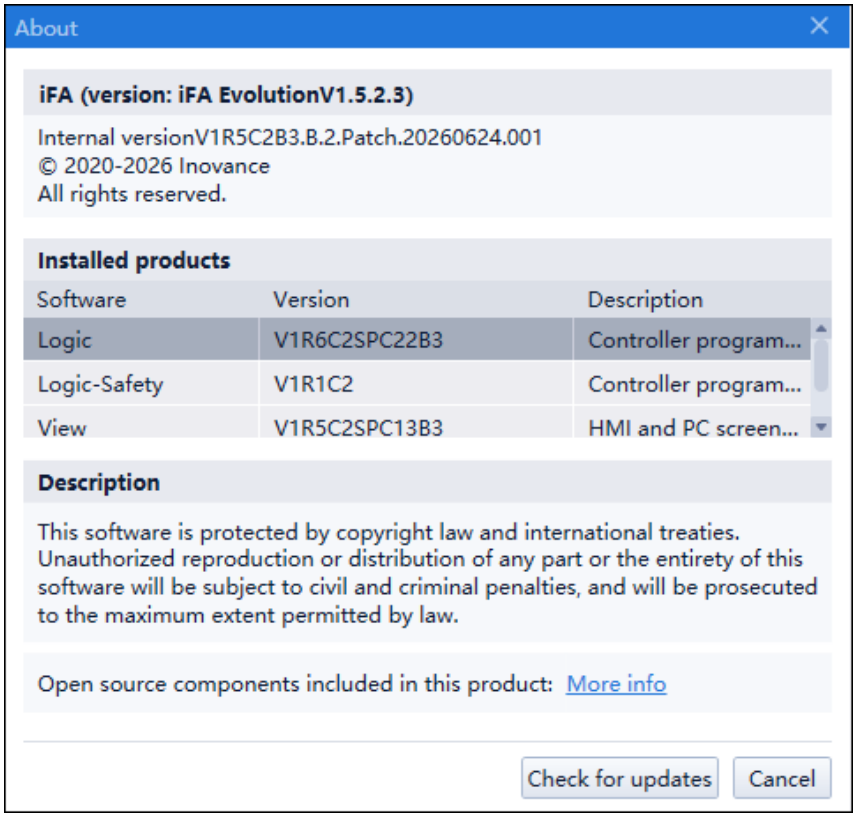
Procedure

1. Double-click the installer to access the "iFA Software Licensing" interface.
2. "Apply for licensing" is selected by default. Take appropriate steps for the licensing application based on the actual conditions.
   - If your PC can access the Internet, directly click the "Apply for licensing" button in the lower right corner.
   - If your PC cannot access the Internet, click the "Copy link" button, copy the link to a PC that can access the Internet, and paste the link in the browser.
3. On the left side of the licensing application interface, carefully read the Software License Agreement and check "I accept the licenses"; on the right side, fill in the "Licensing Application Information" and then click "Submit."

> **NOTE**
>
> In the Licensing Application Information section, items marked with an asterisk are mandatory. The specific items are described as follows:
>
> - PC ID: Automatically identifies and populates the ID of the PC on which the licensing application is sent. It is not editable. When the link is sent to another PC for licensing application, the PC ID remains unchanged.
> - iFA Evolution version: Automatically identifies and populates the version of the software being installed. It is not editable.
> - Recipient email: Enter an email address to receive the license.
> - User information: Enter relevant information of the user, so that the approver can identify the applicant's identity based on this information.
> - Company information: Enter the user's company information. It is optional.

4. Inovance will process the application within 2 working days upon receipt. Once the application is approved, the license code will be sent to the provided email address.
5. After receiving the license code email, select "Install license" in the "iFA Software Licensing" interface, copy and paste the license code from the email into the input box, and click the "Install license" button in the lower right corner.
6. At this point, the interface redirects to the installation interface. See 4.2 Installing the Software to complete the installation.

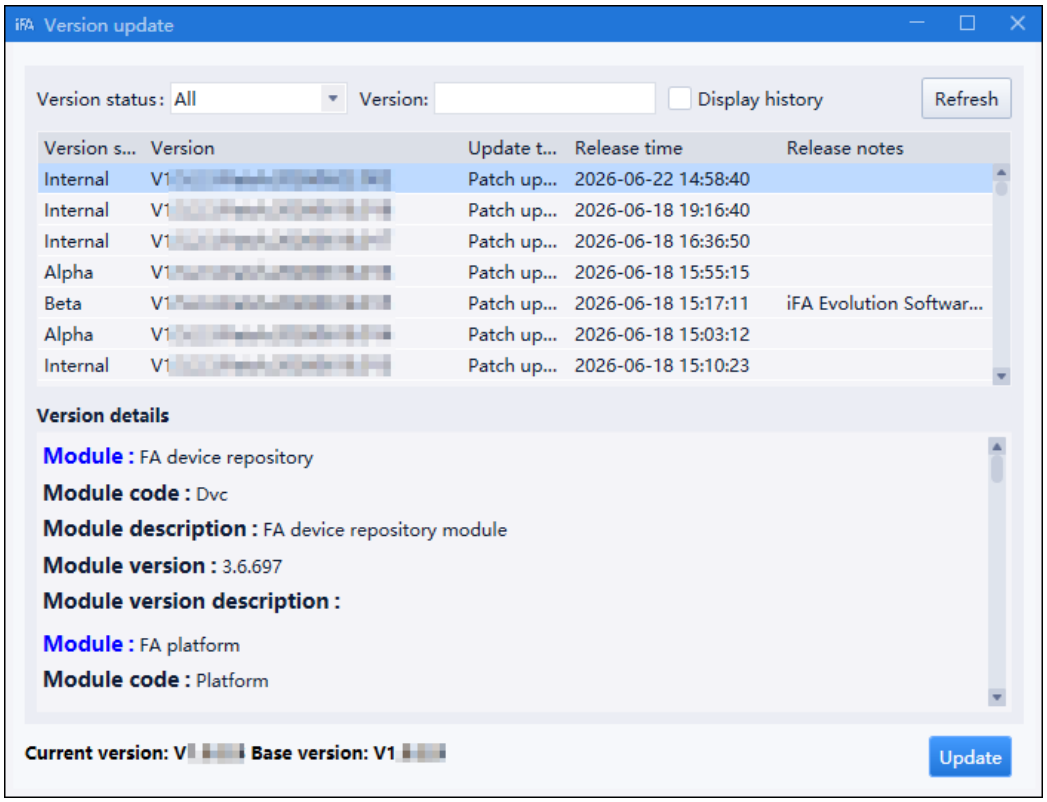
> **NOTE**
>
> - The license code is valid for 14 days. You must complete the licensing within this period; otherwise, reapply for a new license code.
> - If the software is uninstalled and reinstalled within 30 days after the licensing and installation are complete, no additional licensing is required; if uninstalled and reinstalled after 30 days, a new license code must be requested; if not uninstalled or reinstalled, this restriction does not apply.



4.5 Upgrading the Software

iFA software supports both online and offline version updates.

Online update



iFA software supports online version detection and upgrade. Follow the steps below:

1. Check that the device on which iFA software is installed has a stable Internet connection.
2. Open a project.
3. Open the "About iFA" window.
   Choose "Help -> About iFA" from the menu bar to open the window.

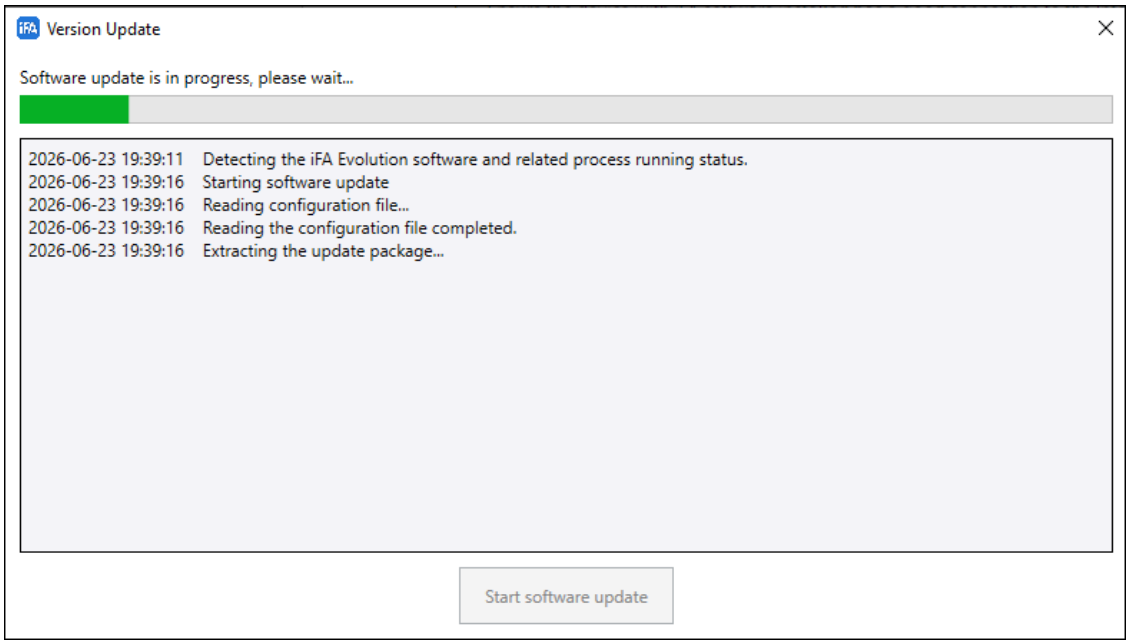
4. Select the upgrade package or the version to be updated.

   Click "Check for updates" to access the version update window.

   When retrieving update packages from the server, you will see the latest software version or patches based on the current software version. You can select the target version from the result list for upgrade installation.

   Check Historical Versions to view details. This feature is supported from V1.4.3.5 and later.

   Version details display the patch package or version description.



> **NOTE**
>
> If the current version is low, you must complete the update in the following order: Upgrade the software to the latest version, and then install the latest patches. To ensure system compatibility, it is essential to strictly follow the order of upgrading the software version and then installing the patches; otherwise, it may result in component dependency error.

5. Download and install the patch package.
   a. Click the "Update" button, and then click "OK" in the pop-up window to download the patch package.
   b. After the patch package is downloaded, click "Yes" in the pop-up window.

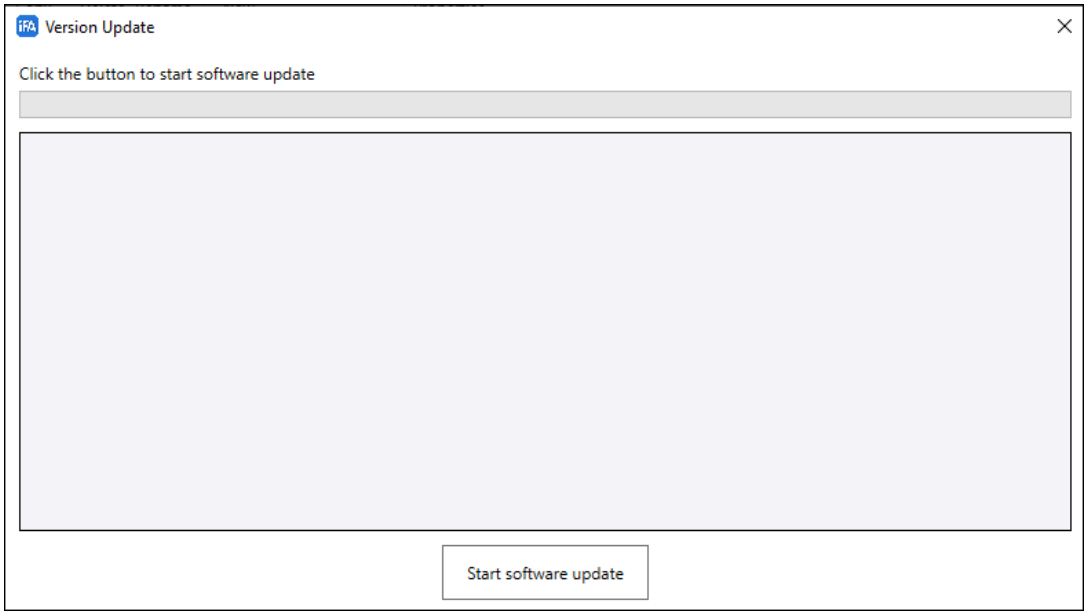
   c. Click "Start software update" in the pop-up dialog box.

      After the update is complete, the iFA software is started automatically.

The procedure for software version upgrade is similar to that for patch installation.

Offline update

iFA software also supports offline version update.



Prerequisites

- A PLC with Internet access is available.
- A USB flash disk is available for file copying.
- Check that the iFA software version matches the patch package version for offline update.

- The iFA software has been started or opened once.

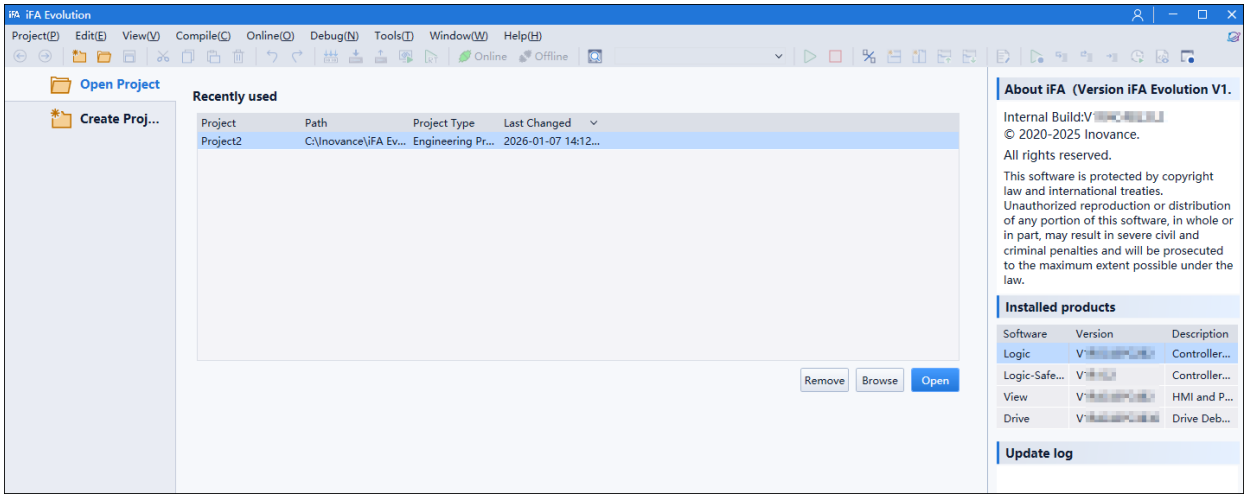
Procedure

1. Perform an "Online Patch Upgrade" on a device with Internet access. After the upgrade is complete, a "Package_Update" folder is generated in the installation directory xx\iFA Evolution.
2. Compress the generated folder using a compression tool to create a .zip file as the offline patch package.
3. Copy the .zip file with USB flash disk, place it in the iFA software installation directory xx\iFA Evolution on the device without Internet access, and then decompress it.
4. Open the decompressed "Package_Update" folder and verify the file information (with the .fapack extension) and version information.
5. Double-click to open the xx.fapack file or right-click to open it using the xx\Bin\FA_Update.exe in the installation directory.
6. Click "Start software update" to perform the patch upgrade.

CAUTION

To apply offline software patches, ensure that the base versions are identical; otherwise, the upgrade will fail. For example, software with a base version of V1.4.4.5 cannot be upgraded using a patch package intended for V1.5.2.1.

5 Software Interface Layout



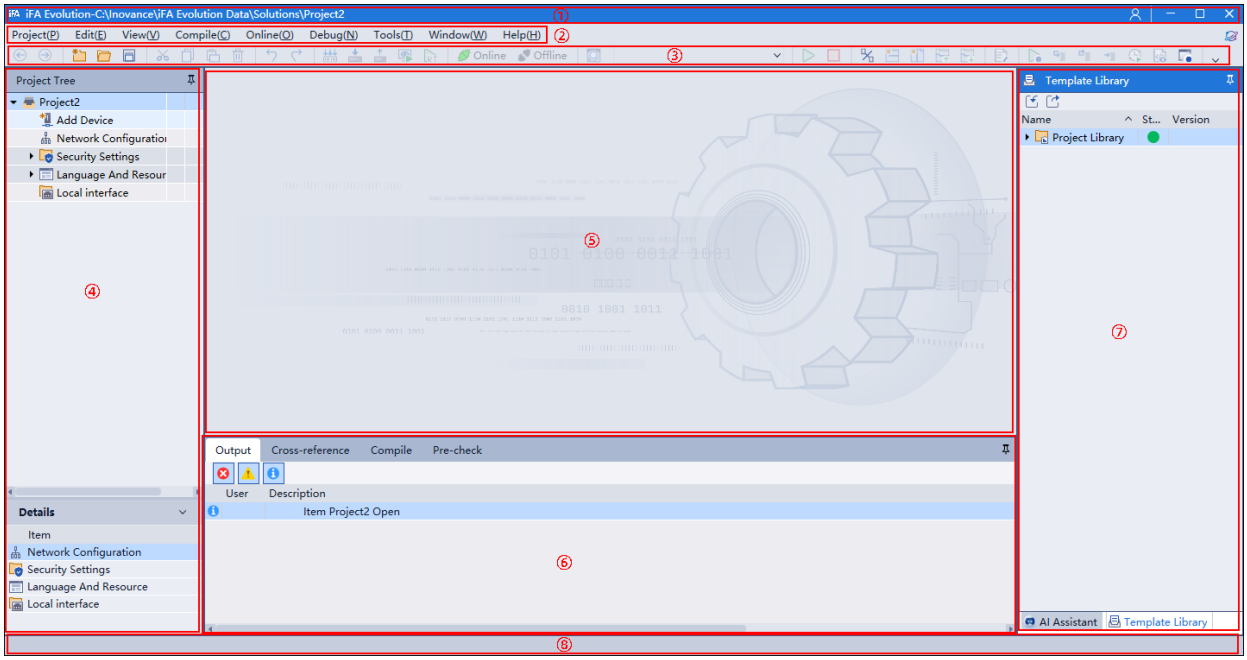
5.1 Opening and Exiting the Software

Open the iFA

The iFA can be opened by:

- Choosing "Inovance > iFA Evolution" from the Windows Start menu;
- Double-clicking the "iFA Evolution" icon on the desktop;
- Double-clicking the FASLN file in the project storage path (Default path: C:\Users\Administrator\Documents\Inovance\iFA\Projects\Project Name).

After opening the software, you can access the project interface, which provides an entrance for creating or opening projects and displays recent projects in a list.



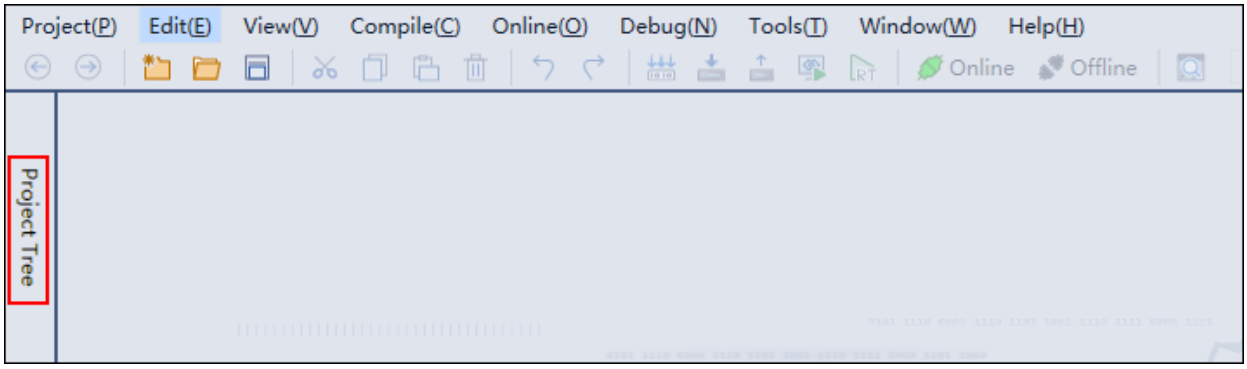
Exit the iFA

Click "Exit" in the "Project" menu. If the project contains unsaved changes, the system will prompt you to save them:

- Select "Yes" to save the changes in the current project and then close the iFA.
- Select "No" to close the iFA without saving the recent changes in the project.
- Select "Cancel" to cancel the closing process (the software will remain open).

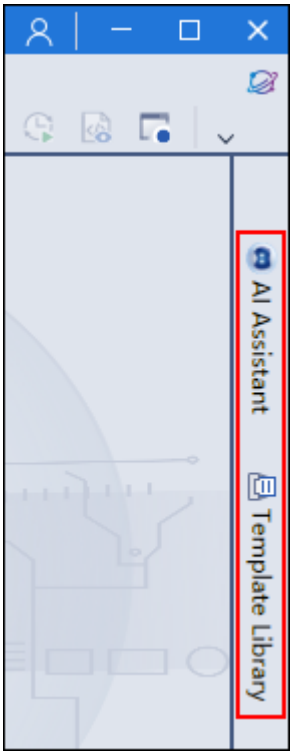
5.2 Project View

The project view of the iFA Evolution consists of title bar, menu bar, toolbar, project tree, workspace, monitoring area, toolbox, and status bar, as shown in the following figure.



No.	Name	Description
①	Title bar	Located at the top of the main interface, and includes the following functions: • Displays the main project path. • Controls the main window maximizing/minimizing and closing, as well as account login/logout.
②	Menu bar	Collection of buttons grouped by program function; located in a horizontal bar just below the title bar. Provides an entrance to commonly used functions, including primary menus such as Project, Edit, View, Compile, Online, Debug, Tools, Window, and Help, each containing multiple submenus.
③	5.3 Toolbar	When the main interface opens, the toolbar is pinned below the menu bar, offering commonly used editing tools.
④	5.4 Project Tree	Provides an entrance for displaying and operating all project data, and displays projects in tree and table formats. The following tasks can be performed in the project tree. • Add a new node. • Edit an existing node. • Scan and modify the properties of an existing node.
⑤	5.5 Workspace	Displays the opened objects, such as tables, editors, and views.
⑥	5.6 Monitoring Area	Located at the bottom of the interface, and displays information about Output, Cross-reference, Compile, and Pre-check.
⑦	5.7 Toolbox	Provides related tool tabs for performing additional operations based on the edited or selected object. The tool tabs can be collapsed or reopened at any time.

No.	Name	Description
⑧	Status bar	Located at the bottom of the main interface, and includes the following functions: • Left: Displays the path. The path consists of an icon and path text and is displayed when the edit window is activated. • Right: Displays the prompt. The prompt consists of status prompt text and an indicator. For example: When a PLC is online, it displays the current number of logged-in users, CPU utilization, and memory utilization.

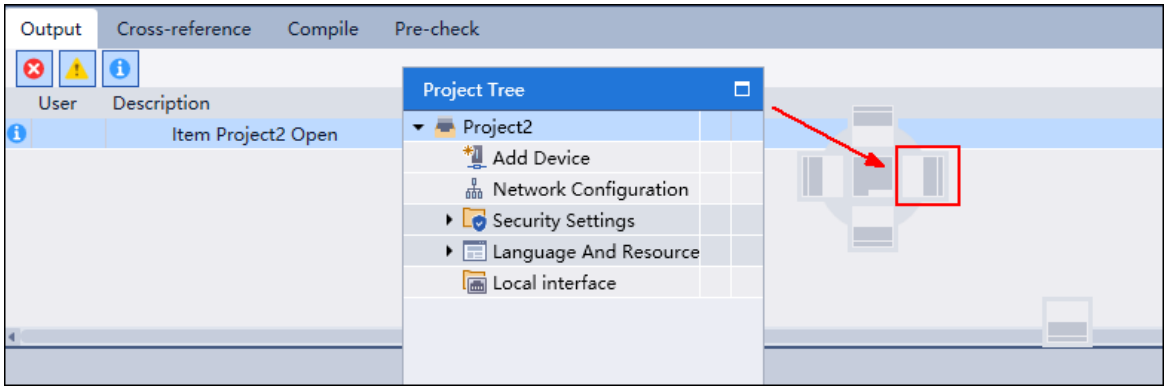


Hide an area

You can hide the project tree, toolbox, and monitoring area.

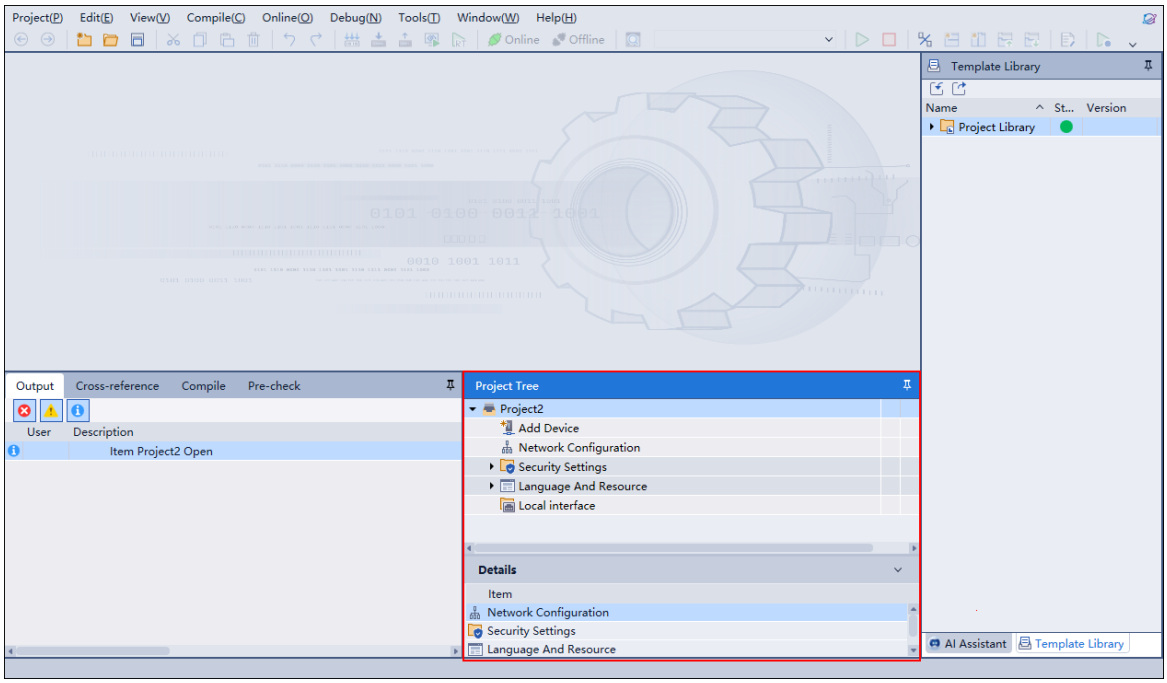
- Hide: Click in the title bar of an area.
- Unhide
  - Project tree: When the project tree is hidden, "Project Tree" is displayed on the sidebar, as shown in the following figure. Click "Project Tree" to display it, and click again to pin the area.

  - Monitoring area: When the monitoring area is hidden, the pushpin icon in the title bar changes to . Click the icon to unhide the area.
  - Toolbox: When the toolbox is hidden, the tool tabs are displayed on the sidebar, as shown in the following figure. Click any tab to display the content, and click again to pin the area.



Float an area

You can float the project tree or toolbox window and dock it back.



- Float
  Hover over the title bar of the project tree or toolbox, and then drag the window to any desired position.
- Dock
  - Method 1: Hover over the title bar of the floating window, and then drag the window until the docking buttons appear on the interface, as shown in the following figure. Drag the floating box to the target position indicated by the docking button.
    ① indicates docking into a specific direction within the area.
    ②③④⑤ indicate docking into the top, left, right, and bottom sides of the project view, respectively.

Taking the floating project tree window as an example, drag the window to the monitoring area; after the docking buttons appear, drag the window to the right side of the monitoring area, as shown in the following figure.

The docking effect is as follows:

- Method 2: In the "Window" menu, select "Reset window layout" to dock the floating window back to its previous position.

> **NOTE**
>
> The Reset Window Layout function does not apply to docked windows, which means once a floating window is docked, Clicking "Reset window layout" cannot restore the window to its previous position.

Maximize an area

You can maximize a floating window.

- Maximize: Click in the upper-right corner of the floating window to maximize the window.
- Restore: Click in the upper right corner of the maximized window to restore the window.

5.3 Toolbar

When the main interface opens, the toolbar is pinned below the menu bar, offering commonly used editing tools.

The toolbar categories and icons are described in the following table.

Category	Icon	Name	Note
Navigate		Navigate backward	Move the mouse focus back to the previous position in the workspace.
		Navigate forward	Move the mouse focus to the next position in the workspace.
Project		New	Create and open a new project by entering the required information.
		Open	Select and open the target project from existing local projects.
		Save	Save the active project data to its original path.
Edit		Cut	Cut the selected object in the project.
		Copy	Copy the selected object in the project.
		Paste	Paste the copied object to the selected position.
		Delete	Delete the selected object in the project.
Undo/ Redo		Undo	Revert the project configuration data to the previous step.
		Redo	Advance the project configuration data to the next step.
Compile		Compile	Compile the project to generate compiled data or executable code.
Upload/ Download		Download to device	Download the project, hardware configuration, or program to a device in the network.
		Upload from device	Upload the entire project, including control-level devices, slaves, and network topology relationships.
		Start/Stop simulation	See 10.13 PLC Simulation Mode.
		Start runtime system on PLC	See 10.13 PLC Simulation Mode.
Online/ Offline		Online	Log in to a control-level device to directly control and debug the device.
		Offline	Log out to end the device control and debugging.
Device		Device connection	Display the device connection history.
		Device scanning	Scan for all compatible devices in the same network. You can select the target device for connection as desired.
Start/Stop		Start	See 10.10.1 PLC Start/Stop.
		Stop	See 10.10.1 PLC Start/Stop.
Window		New horizontal group	Create a horizontal group for the active tab and other tabs.

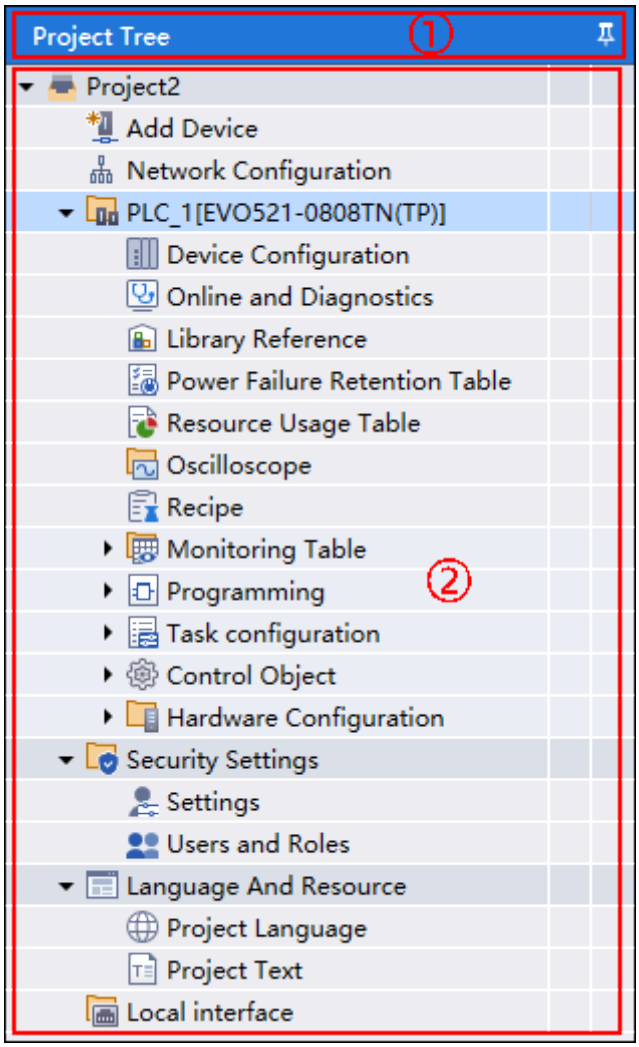
Category	Icon	Name	Note
		New vertical group	Create a vertical group for the active tab and other tabs.
		Move to previous group	Move the active tab to the previous group.
		Move to next group	Move the active tab to the next group.
		Cross-reference	Open the cross-reference view in the monitoring area.
Debug		Write value	Write a variable value while running.
		Step over	Step over the next statement.
		Step into	Step into the next statement.
		Step out of	Step out of a stored procedure/function. If there is a breakpoint between the stop statement and the end of the procedure/function, execution will stop at the breakpoint; if there is no breakpoint, execution will step out of the call hierarchy.
		Run to cursor	The program runs to the location of the cursor. If there is a breakpoint between the stop statement and the cursor, the program will stop at the breakpoint.
		Execute one scan cycle	The program runs for one cycle. If the pointer does not stop at the beginning of the program, the program will run from the current position to the end. If a breakpoint exists between the stop pointer and the end position, it will be triggered.
		Set next statement	Move the cursor to the next statement.
		Show current statement	Move to the statement where the pointer stops.
		Breakpoint window	See 10.10.4 Breakpoint Debugging.

5.4 Project Tree

Feature

The project tree serves as the entrance for displaying and operating all project data, and displays projects in tree and table formats. The following tasks can be performed in the project tree.

- Add a new node.
- Edit an existing node.
- Scan and modify the properties of an existing node.



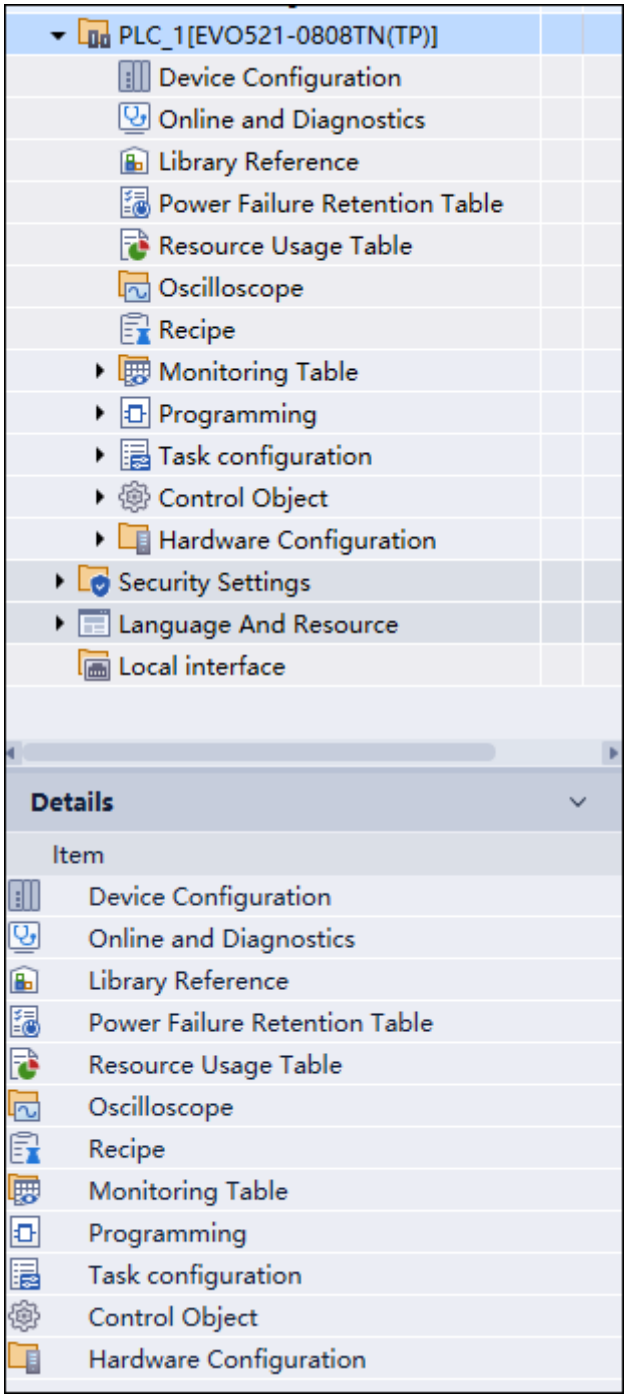
Layout

The project tree consists of a main project and a details view, which are arranged sequentially from top to bottom.

- Main project: Entrance for adding, editing, and previewing a node.
- Details view: Displays detailed information of the currently selected node in the main project and reference project in a list.

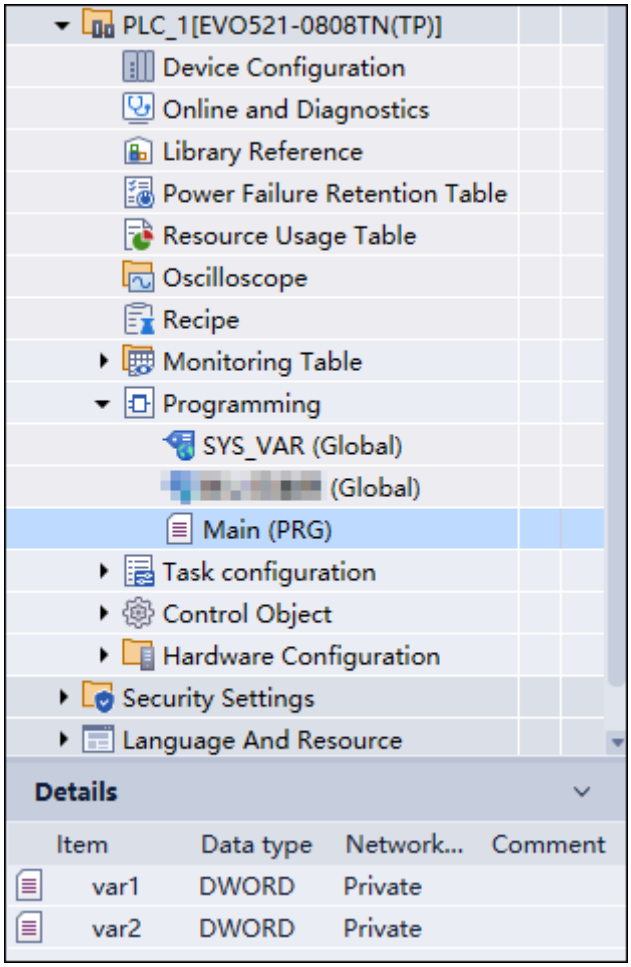
Main project

The main project consists of the window title bar and project elements (including Add Device, Device and Network Configuration, Devices/Folders, Safety Setting nodes), as shown in the figure below.



No.	Name	Description
①	Title bar	Title bar of the project tree, which can be hidden using the pushpin button.

No.	Name	Description
②	Project	A project consists of a three-column tree table. • First column: ◦ Project root node: expanded by default, and displays project nodes in a tree structure, which can be manually expanded or collapsed. ◦ Devices/Folders: child nodes of the project; displays devices/folders and their child nodes in a tree structure. ◦ Safety setting: Allows viewing and setting project permissions and user roles. • Second column: Node (online) status indicator ◦  Appears next to the project tree root node when any node in the project tree has an abnormal status. ◦  Applies to child nodes for programming; indicates that a program is not configured in the task. ◦  Applies to hardware device nodes; indicates that a device is operating properly. ◦  Applies to hardware device nodes; indicates that a device is disabled. ◦  Applies to hardware device sub-nodes; indicates that a device malfunctions. Double-click the icon to access the "Online and diagnostics" page for fault information. ◦  Applies to hardware device parent nodes; appears next to the parent node when any of devices on its child node malfunctions. • Column 3: Project comparison status indicator Applies to the project comparison results in the online/offline state. See 10.12 PLC Project Comparison.



Details view

- Displays detailed information of the currently selected node in the main project and reference project in a list;
- Supports the same double-click behavior for both main and reference projects;
- Only supports the copy operation for dynamically created type nodes.

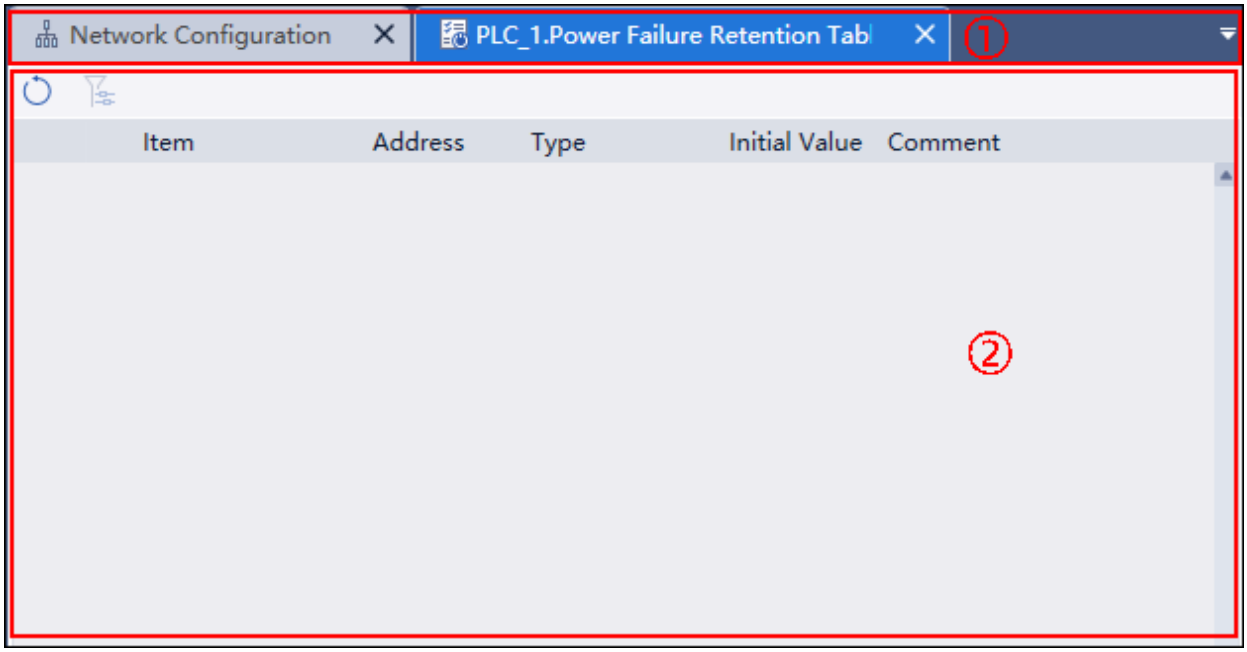
When a parent node is selected, all child nodes at the next level are displayed. For example, the details view is shown as follows when a PLC device node is selected:

When a child node is selected, the detailed information is displayed based on the added product. For example, the following details view displays the variable table for the selected Main node:

When you edit the details of a node in the workspace, the details view will be refreshed simultaneously.

5.5 Workspace

5.5.1 Workspace Feature and Layout



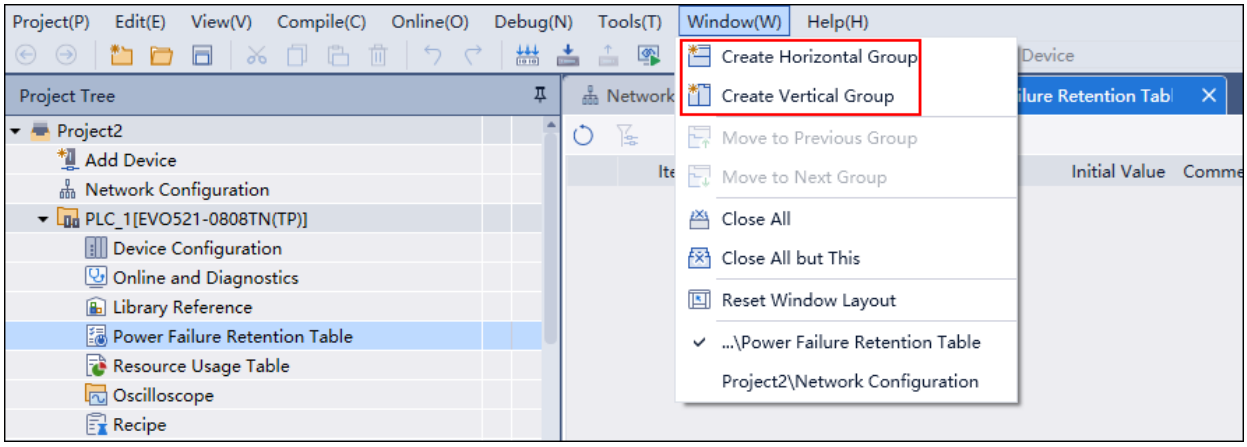
Feature

The workspace is the primary area for users to perform core editing operations. All opened editable objects (such as editors and tables) are loaded into the workspace as separate windows for visual editing.

> NOTE
>
> Up to 64 tabs can be created.

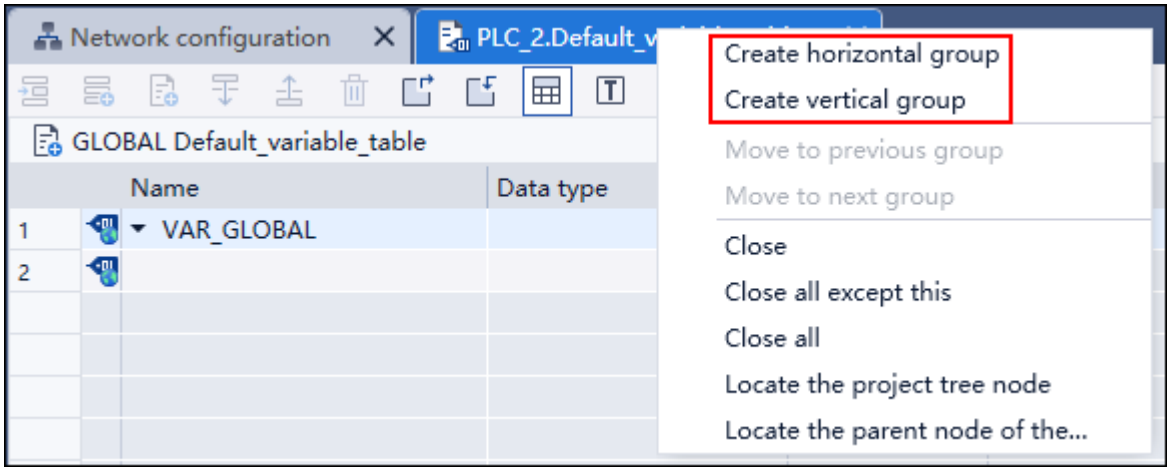
Layout

The workspace is located in the center of the main interface and its size can be adjusted by dragging the splitter to the left, right, or bottom. The default background image is displayed when no editing window is added. The workspace consists of a tab bar at the top and an edit view below. The edit view is filled by the operator. See the following interface screenshot for reference.



Area	Name	Description
①	Tab bar	Each tab bar contains a tab name and a close icon. Tabs can be moved by dragging with the mouse. The shortcut menu for a single tab includes Create Horizontal Group, Create Vertical Group, Move to Previous Group, Move to Next Group, Close, Close All Except This, Close All, Invert Object Selection, and Invert Parent Object Selection.
②	Edit view	The edit view is filled by the operator.

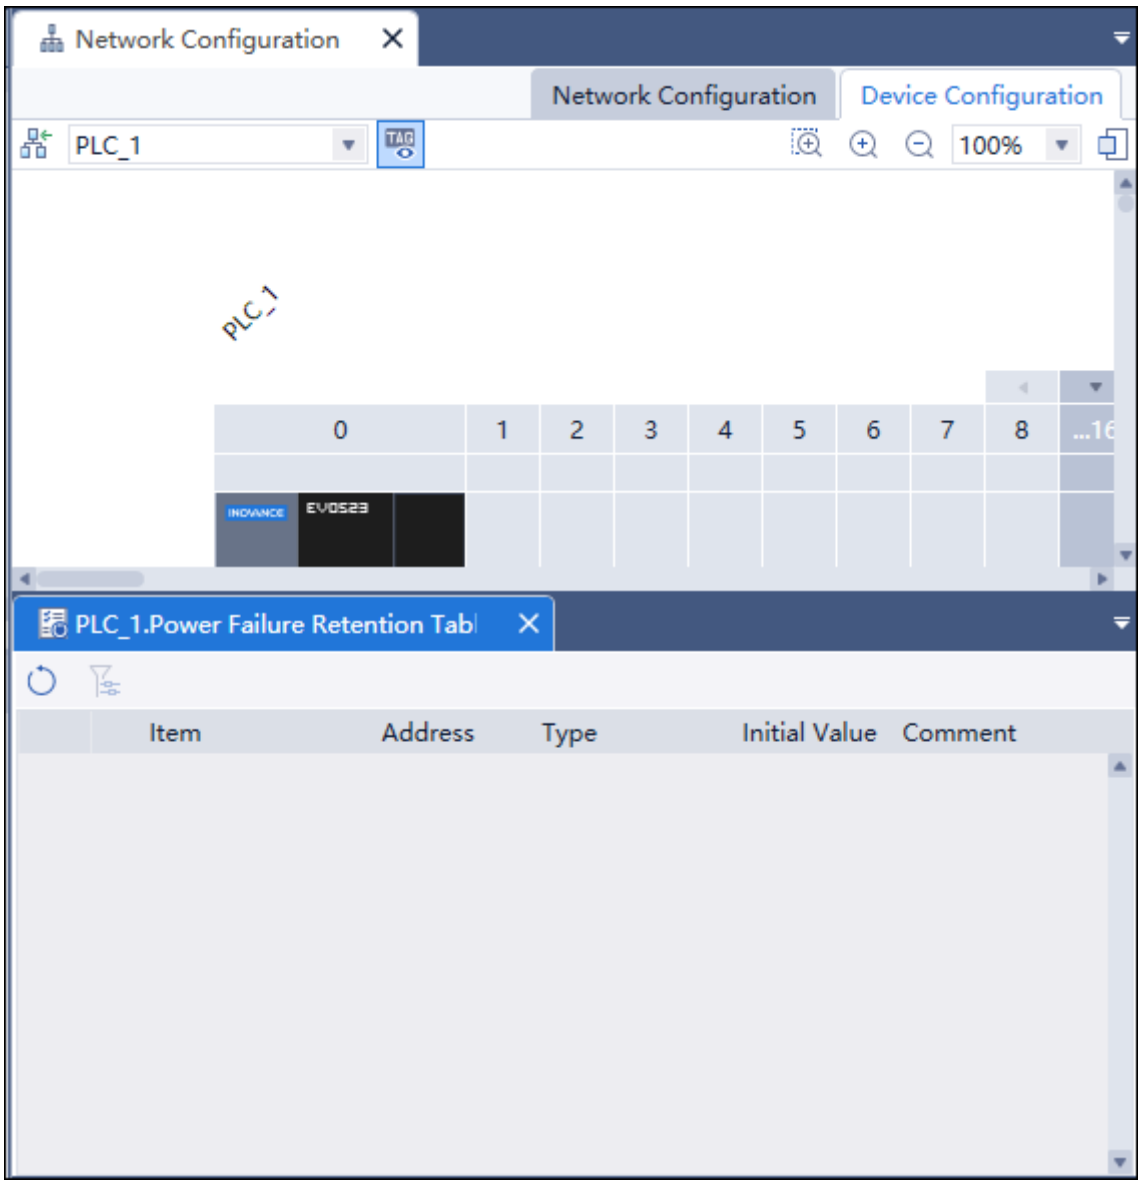
5.5.2 Splitting the Workspace



You can split the workspace vertically or horizontally to display the selected elements side-by-side or stacked with other elements in the editor bar.

Perform one of the following steps to split the workspace vertically or horizontally:

- In the Window menu, select "Create Horizontal Group" or "Create Vertical Group".



- Select the title bar of the workspace, and then select "Create Horizontal Group" or "Create Vertical Group" from the shortcut menu.

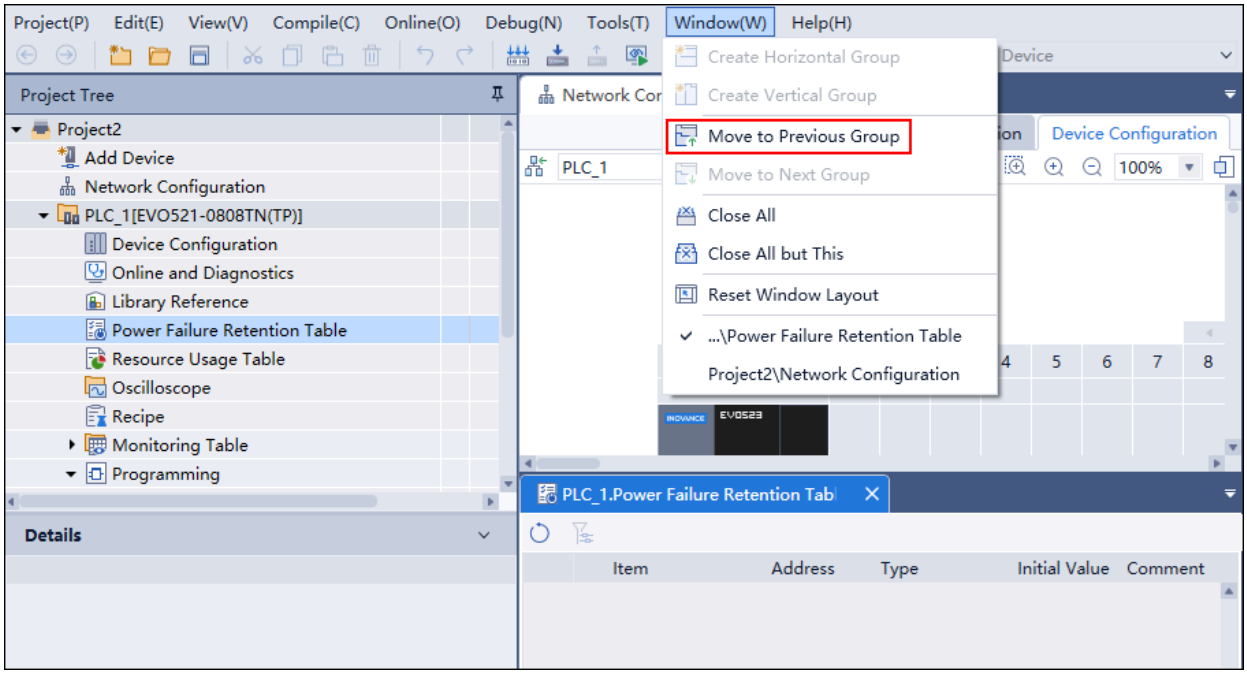
NOTE

When less than two elements are included in the workspace, the "Create Horizontal Group" and "Create Vertical Group" options cannot be selected.

Example: Splitting the workspace horizontally.

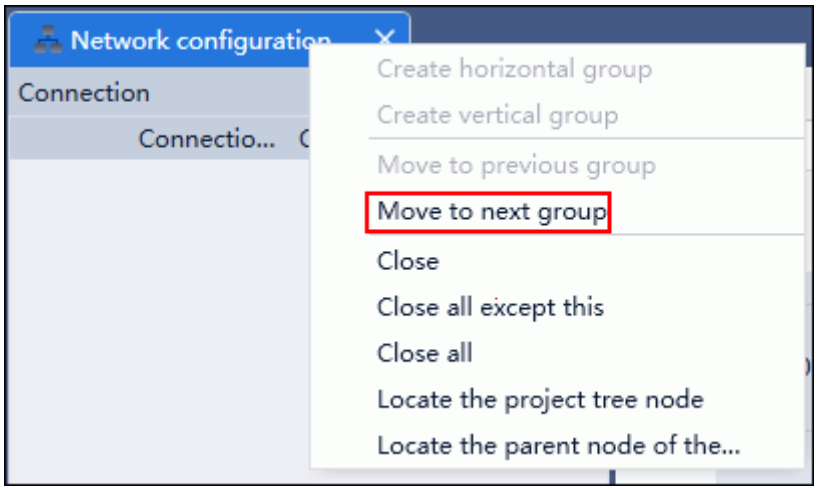
5.5.3 Moving to Previous/Next Group

You can flexibly move elements in the workspace to the previous or next split window by using Move to Previous/Next Group, so as to display similar or related elements as a group in the same split window.



Prerequisites

- The workspace has been split vertically or horizontally.



Procedure

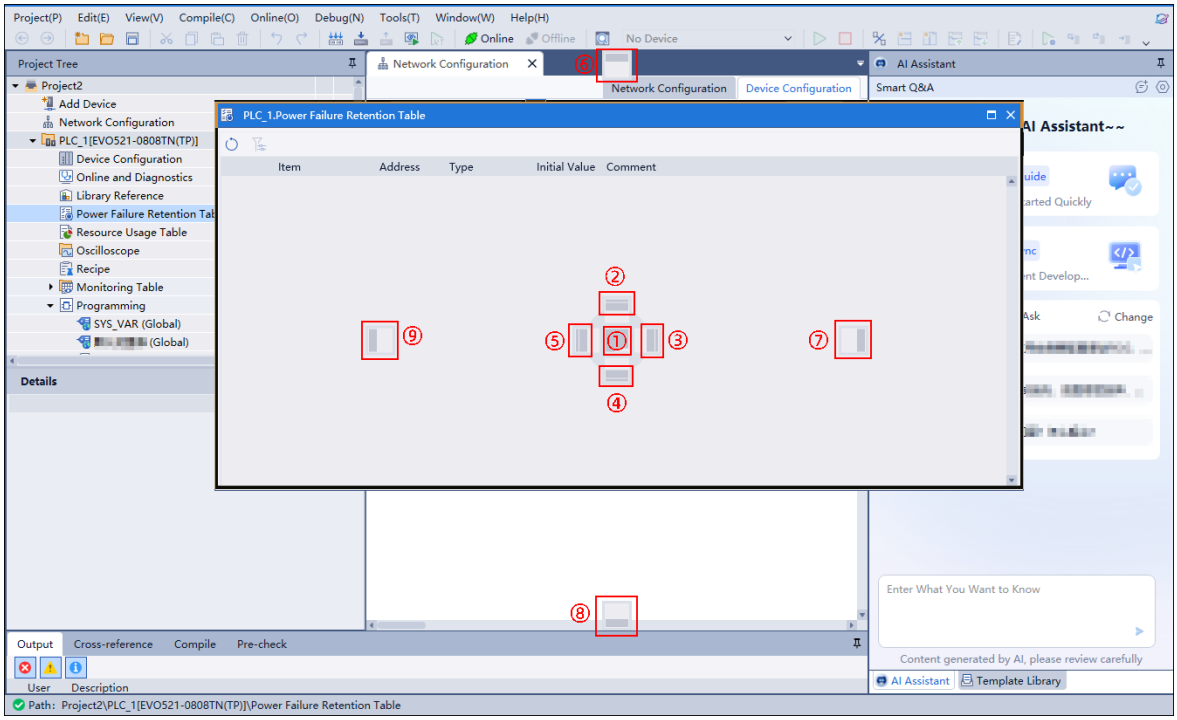
Follow one of the following steps to move to the previous or next group:

- In the "Window" menu, select "Move to Previous Group" or "Move to Next Group".

- Select the title bar of the workspace, and then select "Move to Previous Group" or "Move to Next Group" from the shortcut menu.

5.5.4 Floating an Element

You can float elements in the workspace into separate windows and then dock them back at any time.



Float an element

Hover over the title of a workspace element and drag the element.

The element will move out of the workspace and appear in a separate window. At this point, you can put the window at any desired position.

Dock a floating element

- Method 1:
  1. Hover over the title bar of a floating element and drag the element until the docking buttons appear on the interface, as shown in the following figure.
     ① indicates docking into the current window in the workspace.
     ②③④⑤ indicate docking into the top, right, bottom, and left sides of the current window in the workspace, respectively.
     Floating elements in the workspace can be docked back to the workspace only. Therefore, the outer docking buttons ⑥⑦⑧⑨ have the same functions as ②③④⑤, indicating docking into the top, right, bottom, and left sides of the current window in the workspace, respectively.

  2. Drag the floating box to the target position indicated by the docking button.

- Method 2:

  In the "Window" menu, select "Reset window layout" to dock the floating window back to its previous position.

> **NOTE**
>
> The Reset Window Layout function does not apply to docked windows, which means once a floating window is docked, Clicking "Reset window layout" cannot restore the window to its previous position.

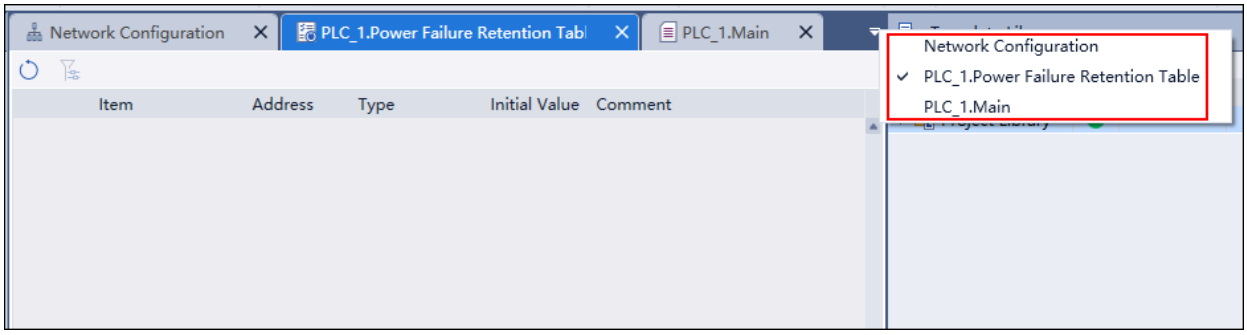
5.5.5 Maximizing an Element

You can maximize an element in the workspace.

Maximize an element

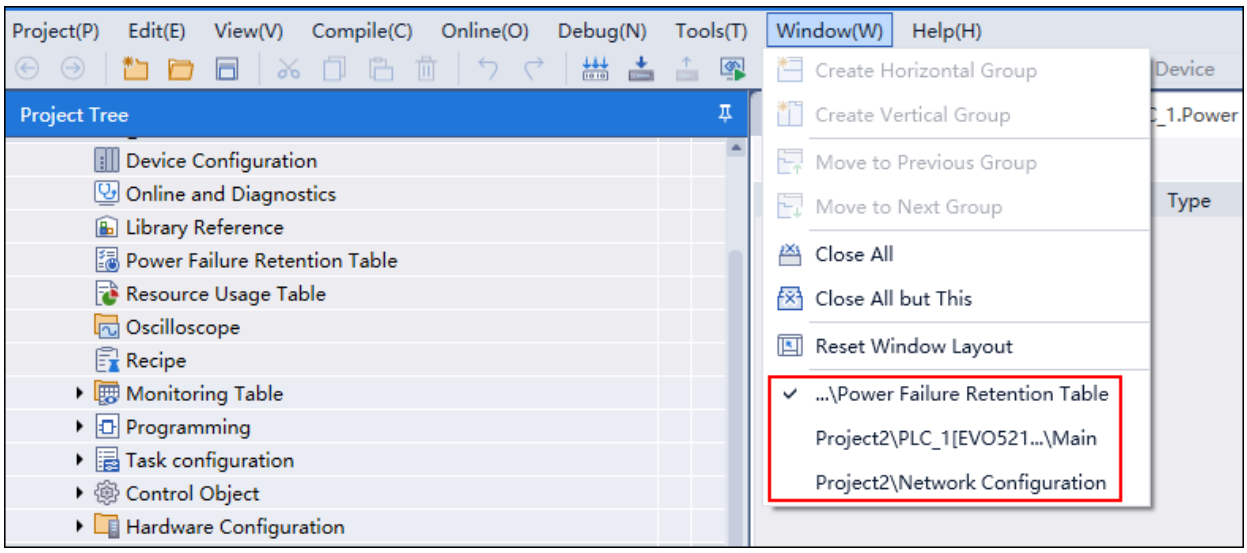
1. Hover over the title of a workspace element, and then drag the element to float it.
2. Click in the upper right corner of the floating window.

Restore the maximized element



Click in the upper right corner of the maximized window to restore the window.

5.5.6 Switching Between Elements



You can switch between elements in the workspace at any time.

Perform either of the following steps to switch between elements in the workspace:

- Click on the right side of the title bar in the workspace, and then select the element name from the drop-down list.

- In the "Window" menu, select the element name.

5.5.7 Closing an Element

Close the current element

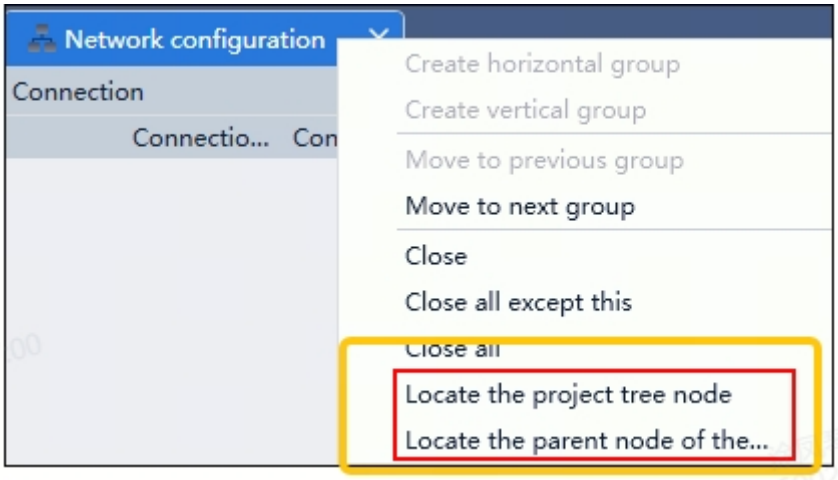
Perform either of the following steps to close the current element in the workspace:

- Click in the title bar of the target element in the workspace.
- Select the title bar and then select "Close" from the shortcut menu.

Close all except this

Perform either of the following steps to close all elements in the workspace except the selected one:

- In the "Window" menu, select "Close All Except This".
- Select the title bar of the workspace, and then select "Close all except this" from the shortcut menu.



Close all

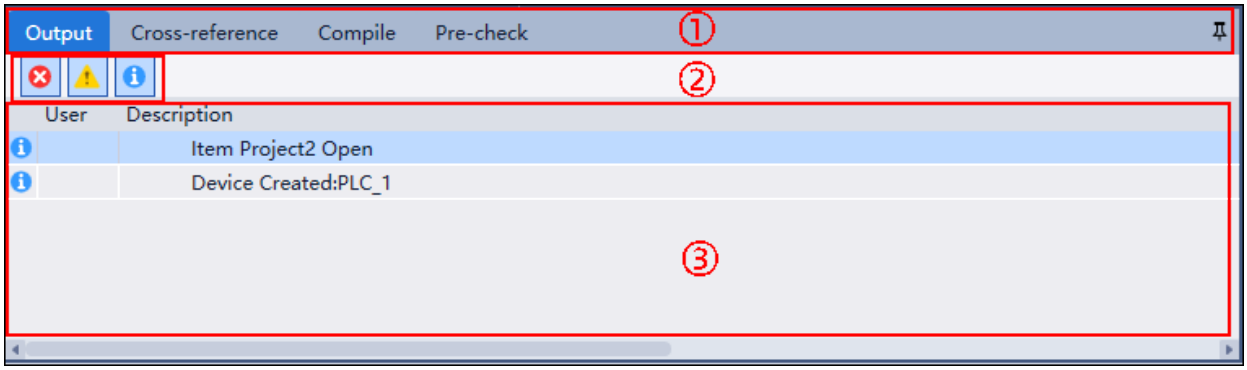
Perform either of the following steps to close all elements in the workspace:

- In the "Window" menu, select "Close all".
- Select the title bar of the workspace, and then select "Close all" from the shortcut menu.

5.5.8 Inverting Object Selection

Select the target window in the workspace, right-click the title bar to open the context menu, and click "Locate the project tree node" or "Locate the parent node of the project tree" to locate the node or parent node to which the current window belongs in the project tree.

5.6 Monitoring Area



5.6.1 Monitoring Area Feature and Layout

Feature

Additional information about the selected object or the executed operation is displayed in the monitoring area.

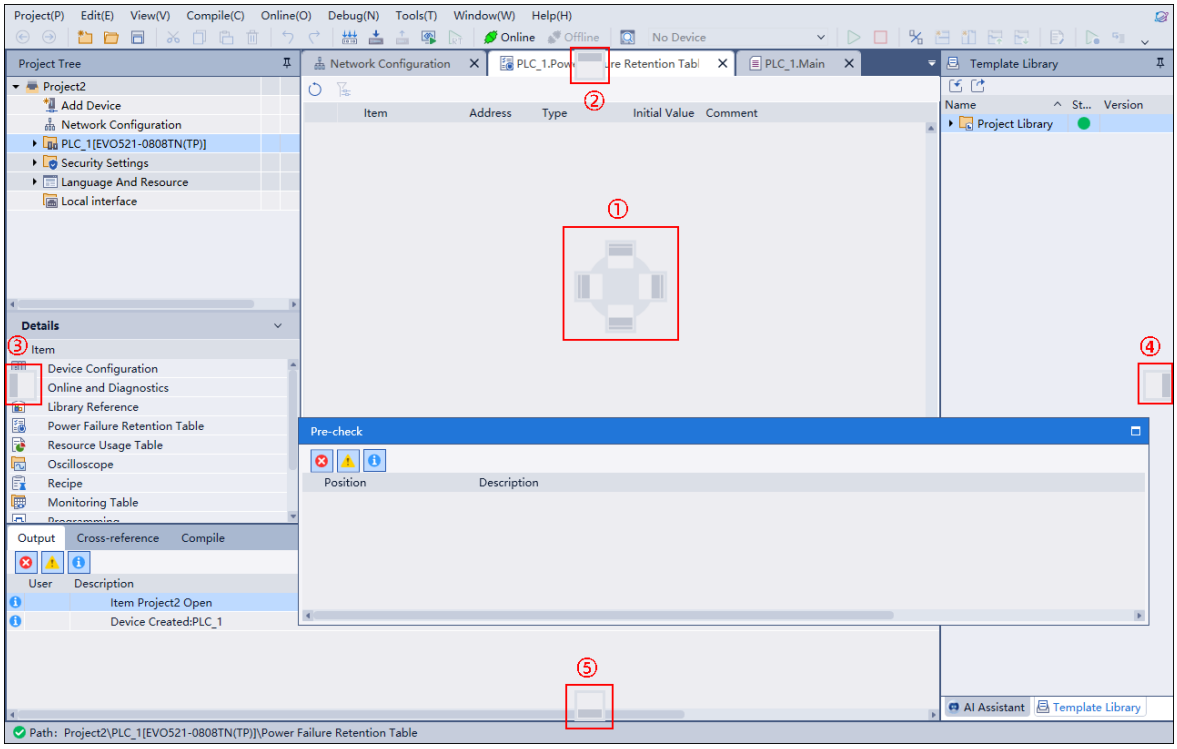
Layout

The monitoring area is located at the bottom of the interface and displays information including Output, Cross-reference, Compile, and Pre-Check, as shown in the following figure.

No.	Name	Description
①	Tab bar	Displays information about Output, Cross-reference, Compile, and Pre-Check. Click the pushpin button to hide the monitoring area. • Output: Used to display and edit properties of the project tree, workspace, or selected object in the workspace. When different objects in the workspace are selected, the Output area displays different information. • Cross-reference: Displays cross-reference relationships for the selected project tree node on the left or the selected object in the workspace, in a tree list format. • Compile: Displays information related to device compilation. • Pre-check: Checks for syntax errors in the configuration project in a real-time manner and displays corresponding prompts. Pre-check performs only basic syntax checks and does not include analysis or checks for user-defined types.
②	Toolbar	Used in the "Output," "Compile," and "Pre-check" tabs to filter the prompt types to be displayed. The following prompt types can be displayed or hidden: • Error • Alarm • Information
③	Display content	Displays additional information about the selected object or the executed operation.

5.6.2 Floating a Tab

You can float tabs in the monitoring area into separate windows and then dock them back at any time.



Float a tab

Hover over a tab in the tab bar of the monitoring area, and then drag the tab.

The tab will move out of the monitoring area and appear in a separate window. At this point, you can put the window at any desired position.

Dock a floating tab

- Method 1:
  1. Hover over the title bar of a floating tab and drag the window until the docking buttons appear on the interface, as shown in the following figure.
     ① indicates docking into a specific direction within the area.
     ②③④⑤ indicate docking into the top, left, right, and bottom sides of the project view, respectively.

  2. Drag the floating box to the target position indicated by the docking button.

- Method 2: In the "Window" menu, select "Reset window layout" to dock the floating window back to its previous position.

> **NOTE**
>
> The Reset Window Layout function does not apply to docked windows, which means once a floating window is docked, Clicking "Reset window layout" cannot restore the window to its previous position.

5.6.3 Maximizing a Tab

You can maximize a tab in the monitoring area.

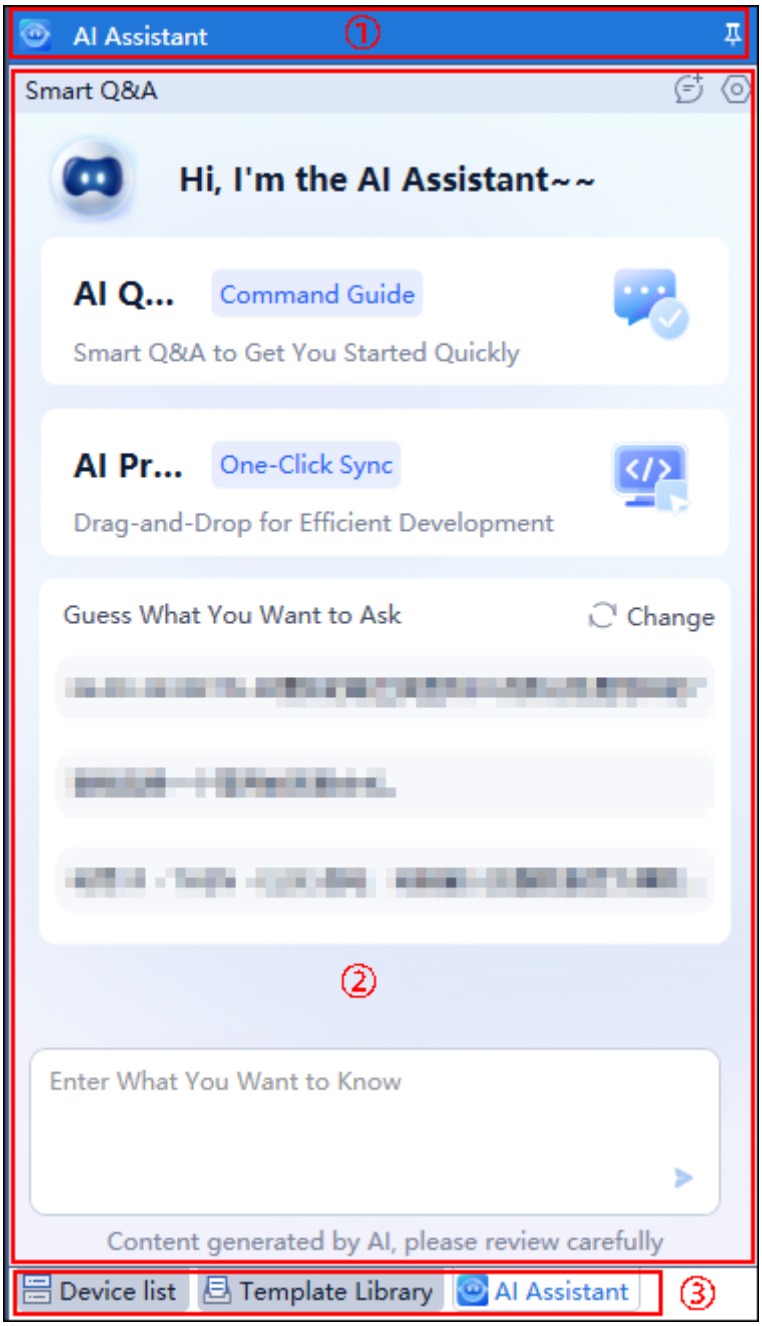
Maximize a tab

1. Hover over a tab in the tab bar of the monitoring area, and then drag the tab to float it.
2. Click in the upper right corner of the floating window.

Restore the maximized tab

Click  in the upper right corner of the maximized window to restore the window.

5.7 Toolbox



5.7.1 Toolbox Features and Layout

Features

The toolbox provides the following features:

- Appropriate tool tabs for performing additional operations based on the active object or view type in the workspace. For example, when the device configuration and network configuration views are present in the workspace, the "Device list" tab is displayed.
- AI Assistant: a smart Q&A tool that provides answers to questions regarding industrial automation, PLC, servo, ST programming, or other related fields.

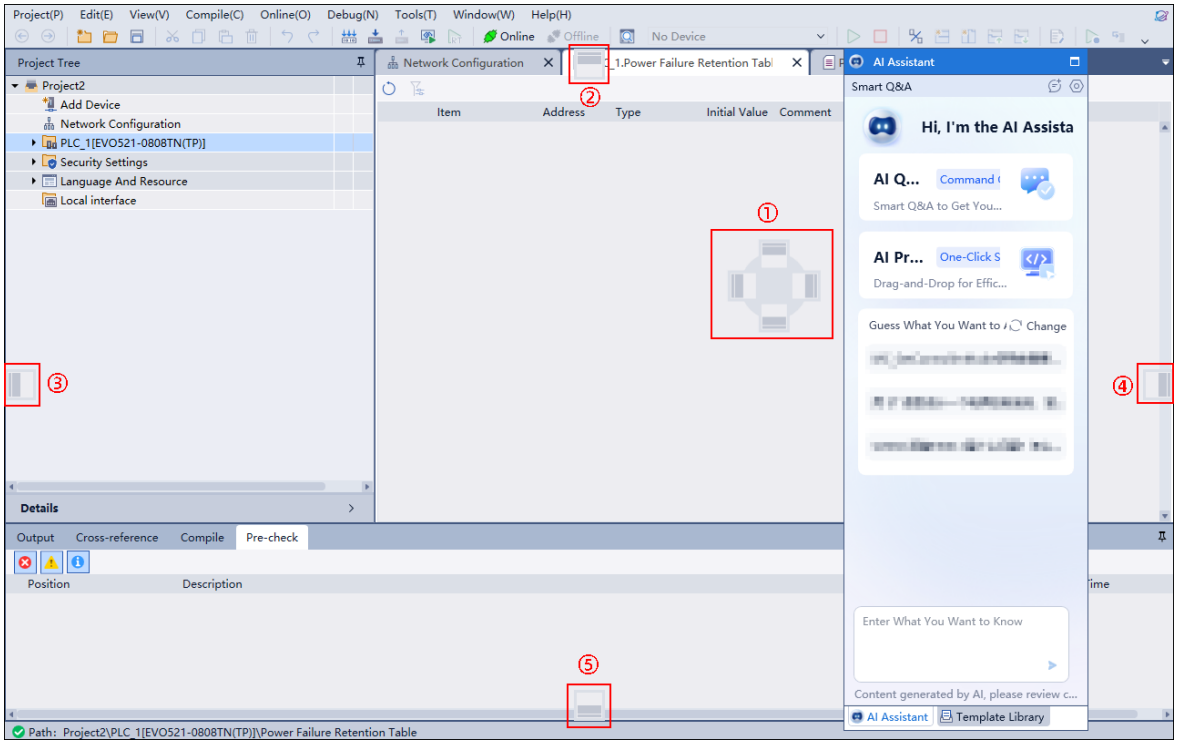
Layout

No.	Name	Description
①	Title bar	Title bar of the Toolbox, which can be hidden using the pushpin button.
②	Function area	• Provides related functions based on the tool tabs. • AI Assistant Q&A workspace.

No.	Name	Description
③	Tab bar	Provides tool tabs, including Device List, Template Library, AI Assistant, etc. The Template Library and AI Assistant tabs are pinned, while other tabs automatically appear based on the active object or view type in the workspace. • Library: Displays elements from the project library and opened global library. • Device List: Displays hardware components by type to facilitate component selection. • Toolbox: When the workspace is in POU view, the toolbox includes operation methods, library files, and operators for configuration programs. • General Properties: When the workspace is in the monitoring variable table view, the toolbox adds a General Properties tab, allowing reconfiguration of variable-related parameters. • Monitoring Toolbox: When the workspace is in the monitoring view, the toolbox adds a Toolbox tab, displaying specific graphics and controls for configuring a monitoring screen. • AI Assistant: a smart Q&A tool that provides answers to questions regarding industrial automation, PLC, servo, ST programming, or other related fields.

5.7.2 Floating a Tab

You can float tabs in the tab bar of the toolbox into separate windows and then dock them back as desired.



Float a tab

Hover over a tab in the tab bar of the toolbox and drag the tab.

The tab will move out of the toolbox and appear in a separate window. At this point, you can put the window at any desired position.

Dock a floating tab

- Method 1:
  1. Hover over the title bar of a floating tab and drag the window until the docking buttons appear on the interface, as shown in the following figure.
     ① indicates docking into a specific direction within the area.
     ②③④⑤ indicate docking into the top, left, right, and bottom sides of the project view, respectively.

2. Drag the floating box to the target position indicated by the docking button.

- Method 2: In the "Window" menu, select "Reset window layout" to dock the floating window back to its previous position.

> **NOTE**
>
> The Reset Window Layout function does not apply to docked windows, which means once a floating window is docked, Clicking "Reset window layout" cannot restore the window to its previous position.

5.7.3 Maximizing a Tab

You can maximize a tab in the toolbox.

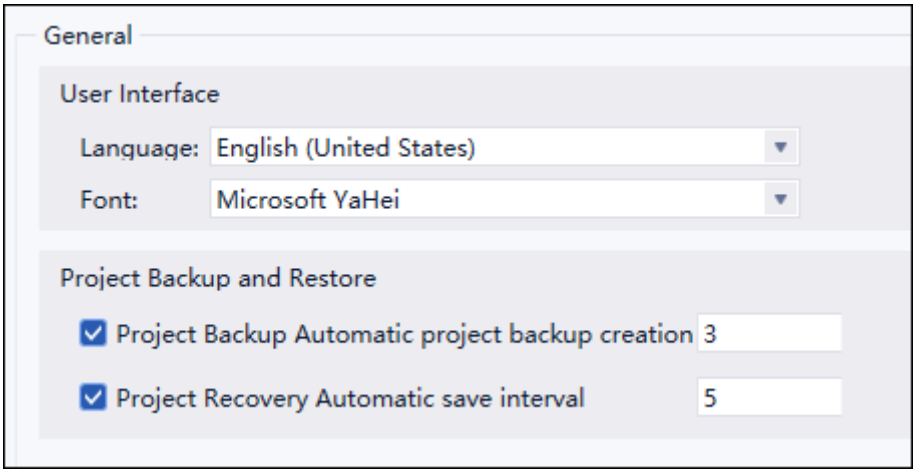
Maximize a tab

1. Hover over a tab in the tab bar of the toolbox, and then drag the tab to float it.
2. Click in the upper right corner of the floating window.

Restore the maximized tab

Click in the upper right corner of the maximized window to restore the window.

6 System Settings



6.1 General Settings

Choose "Tools -> Options" from the menu bar, and open the "General" tab, where the following settings can be made.

General settings

- Language: Switch between Chinese and English.
- Font: Select the system font. Changing the font may affect all comments on the interface, including but not limited to menu names, tab names, and node names.
- Project backup: For details about automatic project backup, see 8.4 Backing up a Project.
- Project restore: Set the automatic save interval (in minutes). You can use the default 5 min or set another value [1-1440].
  When a project is not manually saved, it will be automatically backed up at the set interval for project recovery. The default file path is the same as the project creation path, with the default name being projectname.recovery.

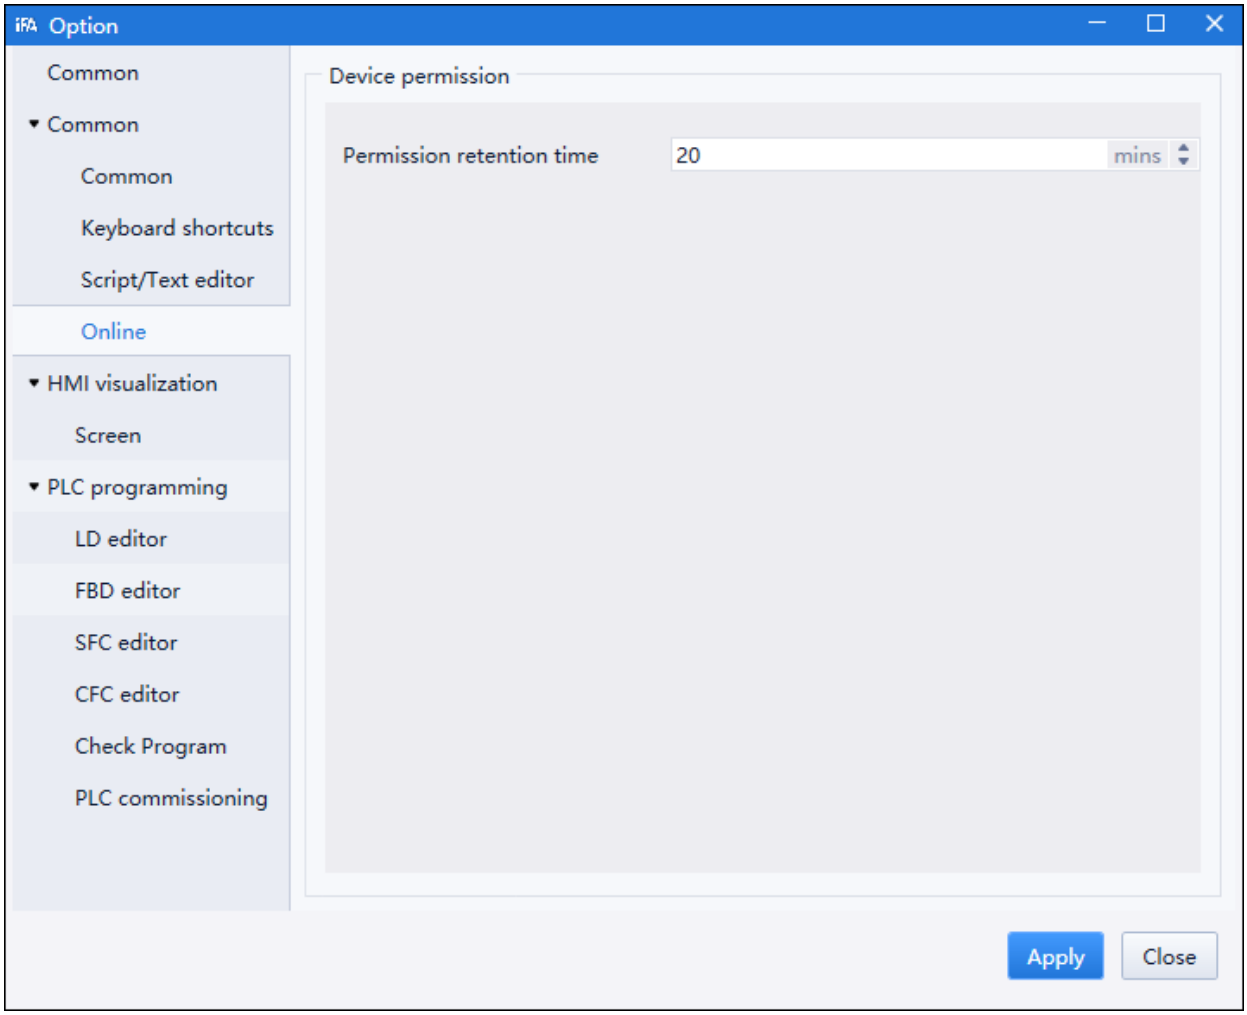
  Any of the above settings will take effect only after "OK" is clicked.
  When reopening the software, you will see a prompt asking whether to open the original project or the automatically backed-up project. Choose the appropriate option as needed.

Keyboard shortcuts

This tab is used to view, modify, and delete shortcuts for editor-related operations.

- System-defined Shortcuts: default shortcuts for editor-related operations.
- User-defined Shortcuts: shortcuts defined by the user. Select a row, and click "..." to open the editing window to modify or delete the system-defined shortcut.
- Reset to Default Values: After modifying any default shortcuts, you can use this button to reset all shortcuts to their default values. This operation will take effect after "Apply" is clicked.

Script/text editor

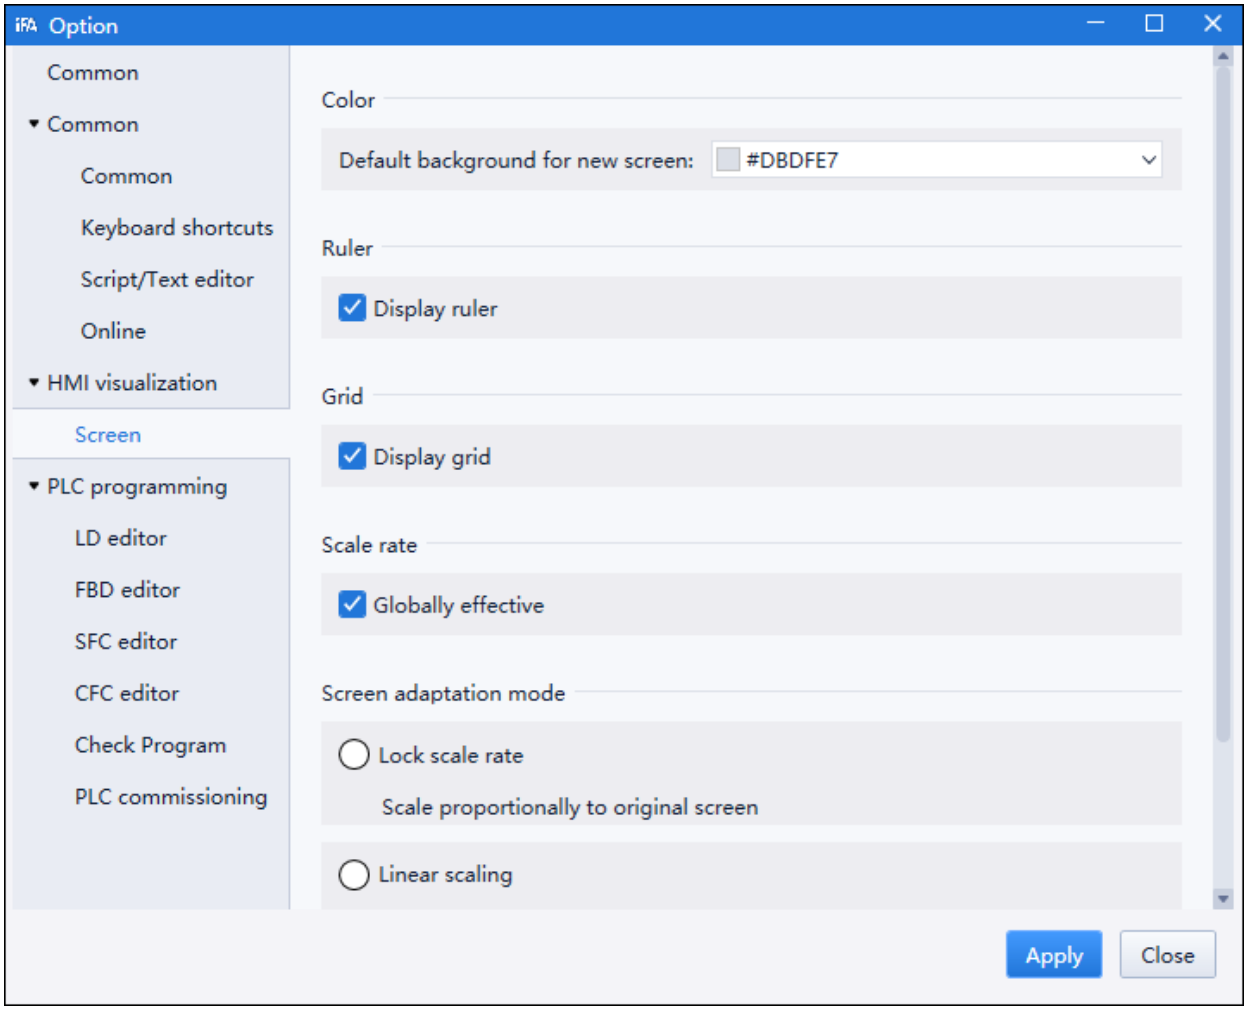


You can use the script/text editor to set the editor font and color.

For details, see 10.1.4.3.2 ST Editor10.1.4.3.2 Settings.

Online

Set the online duration (in minutes) for the PLC. The default value is 20, and the value range is [1-1440]. This setting will take effect after "Apply" is clicked.



When a device comes online, you can bypass account verification within the valid time range. The permission validity is reset when the current project or software is closed.

6.2 HMI Visualization

Choose "Tools -> Options" from the menu bar, and open the "Screen" tab under Visualization to perform the following settings:

- Default Background for New Screen: Set the background color of the screen. After modifying the color, you can choose to automatically restore the default background color.
- Ruler: Set whether to display the ruler in the screen.
- Grid: Set whether to display the grid in the screen background.
- Zoom level: Set whether the screen zoom factor applies globally. This option is checked by default. Adjusting the zoom level of any screen will synchronously update the zoom level of all screens in the project. For details, see 13.3.10.2 Zooming a Screen.

Any of the above settings will take effect immediately after "Apply" is clicked.

6.3 PLC Programming

LD editor

For details, see 10.1.3.3.2 LD Editor Settings.

FBD editor

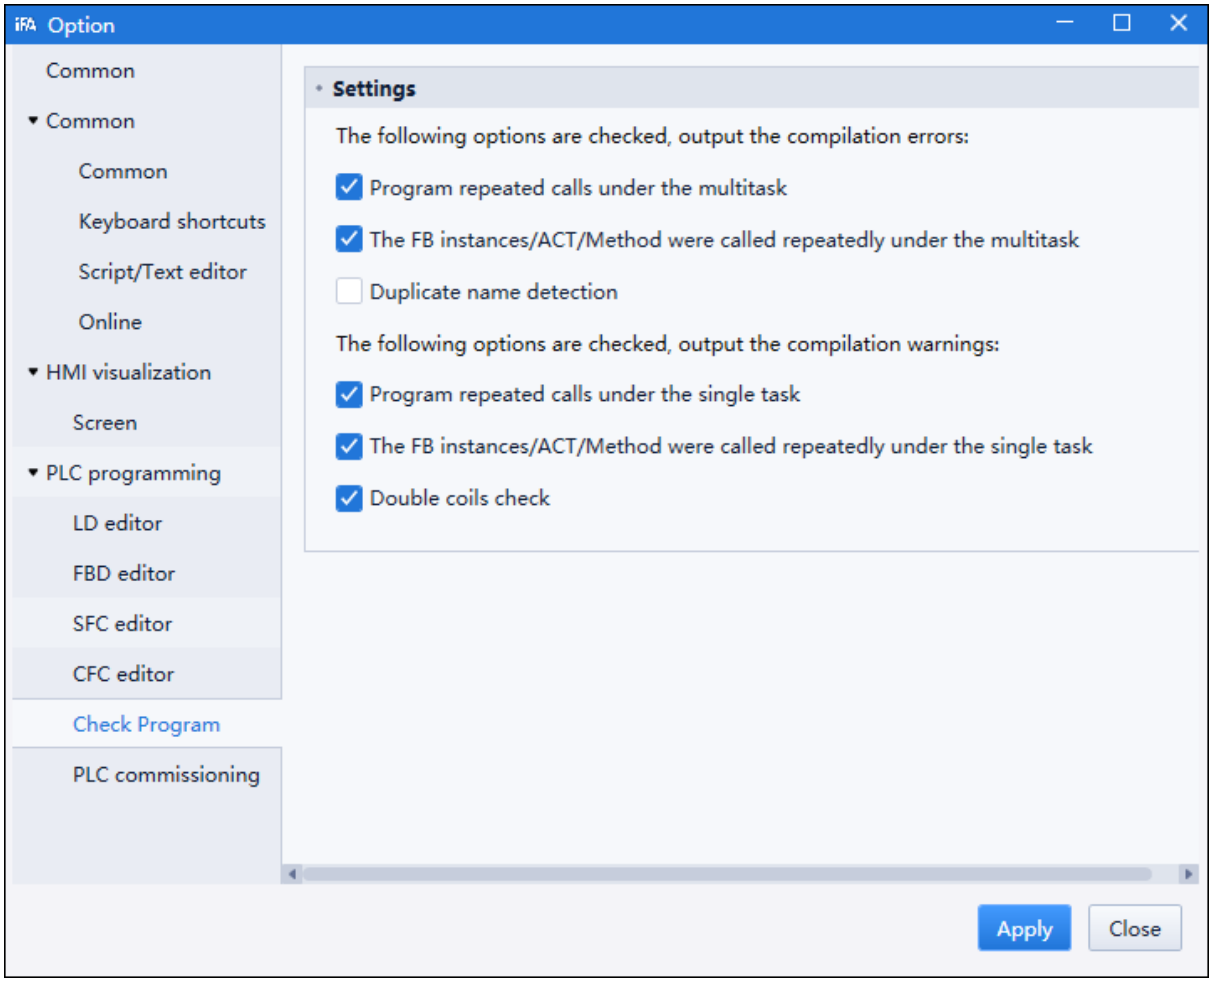
For details, see 11.2.5.3 Setting the Safety FBD Editor.

SFC editor

For details, see 10.1.6.3.2 SFC Editor Settings.

CFC editor

For details, see 10.1.5.3.2 CFC Editor Settings.

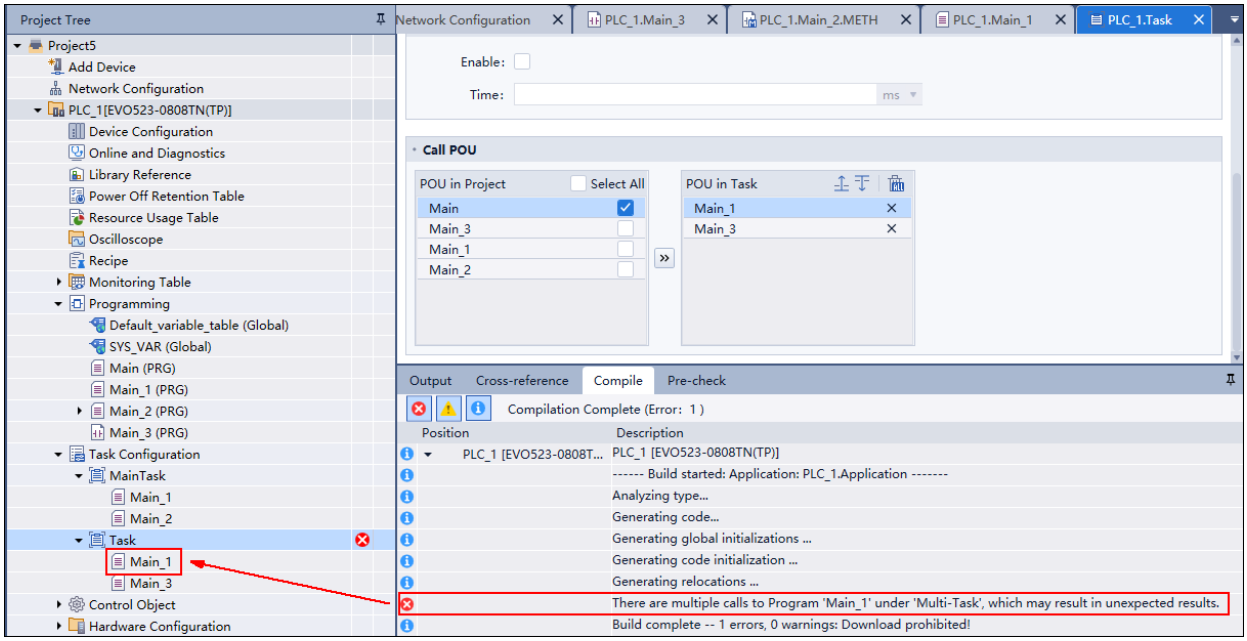


Program check

Program check is used for comparing or verifying whether all programs under the task scheduling list are repeatedly called within the programming environment to ensure logical consistency and accuracy.

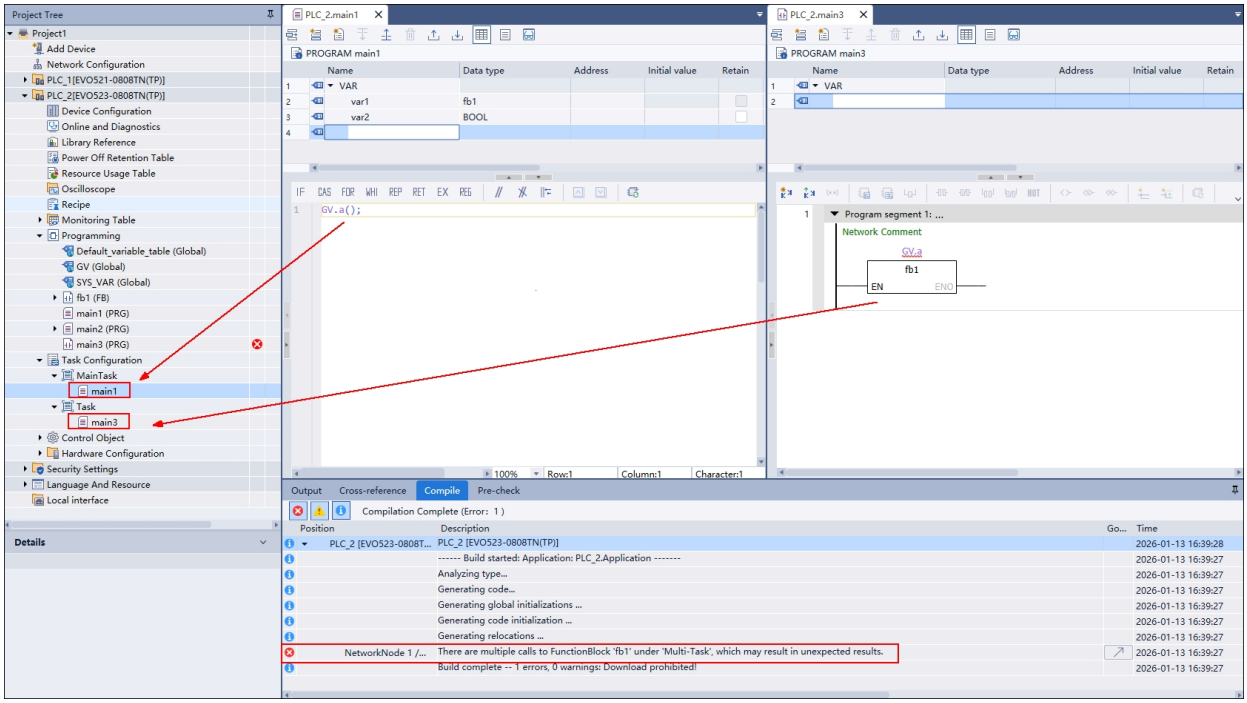
Configuring program check

1. Choose "Tools -> Options" from the menu bar.



2. Choose "PLC programming -> Check program" in the displayed "iFA Options" window.
3. Select the appropriate check items. During compilation or pre-check, the system checks the selected items and outputs any errors or warnings. For details on the check items, see description of check items.

4. Click "Apply" to apply the configuration.



Description of check items

- Once the following options are applied, the system will output any compilation error:
  - Program called repeatedly in multiple tasks
    In this case, an error will be displayed, indicating that the program XXX is called in multiple tasks, which may lead to unexpected results.

- FB instance/ACT/Method called repeatedly in multiple tasks

  In this case, an error will be displayed, indicating that the function block/action/method XXX is called repeatedly in multiple tasks, which may lead to unexpected results.

Duplicate name check

Check whether any symbols in the project have duplicate names. The scope of the check includes referenced libraries, POUs, global variable tables, default variable tables, system variable tables, custom types, and device system variables. If there is a duplicate name among the aforementioned objects (all involved variables are global variables), an error "duplicate names for XXX and XXX" will be displayed.

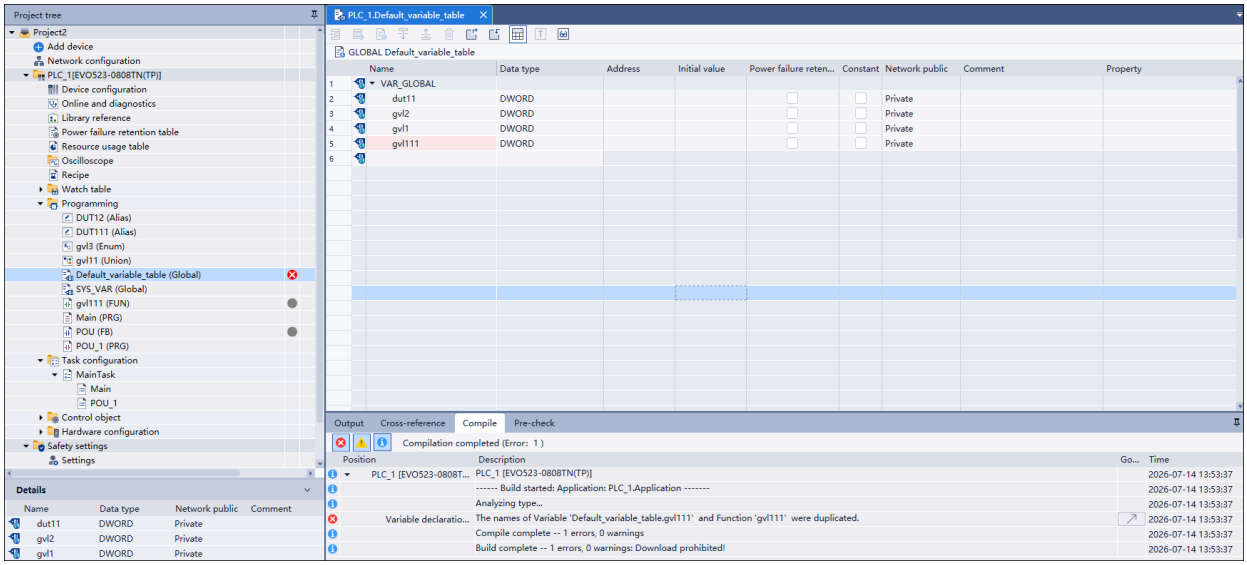


Figure 6-3-1 Compilation error

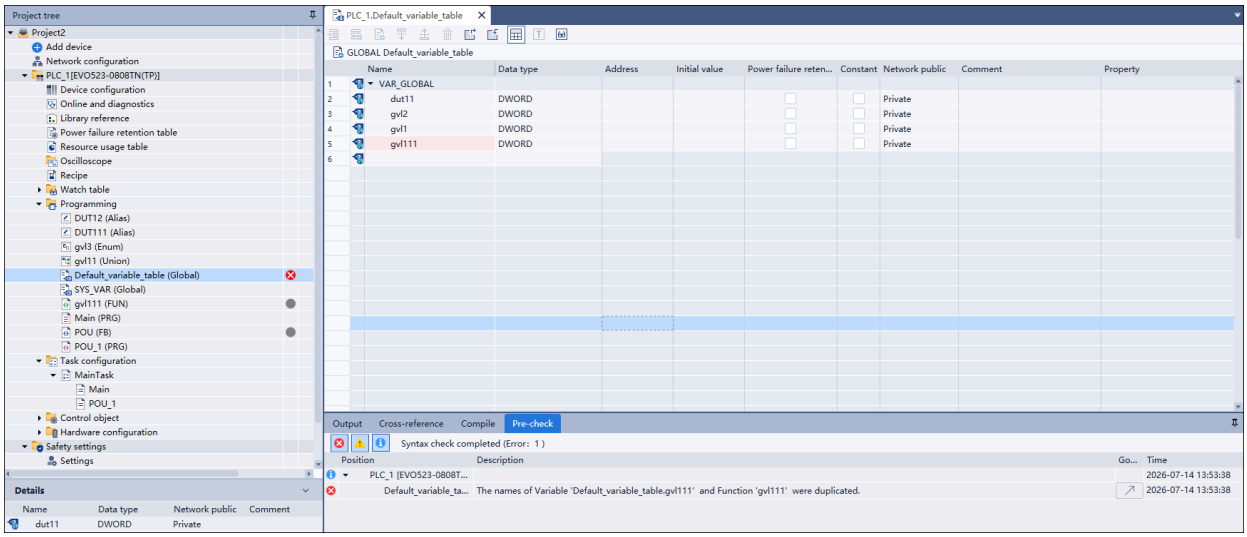

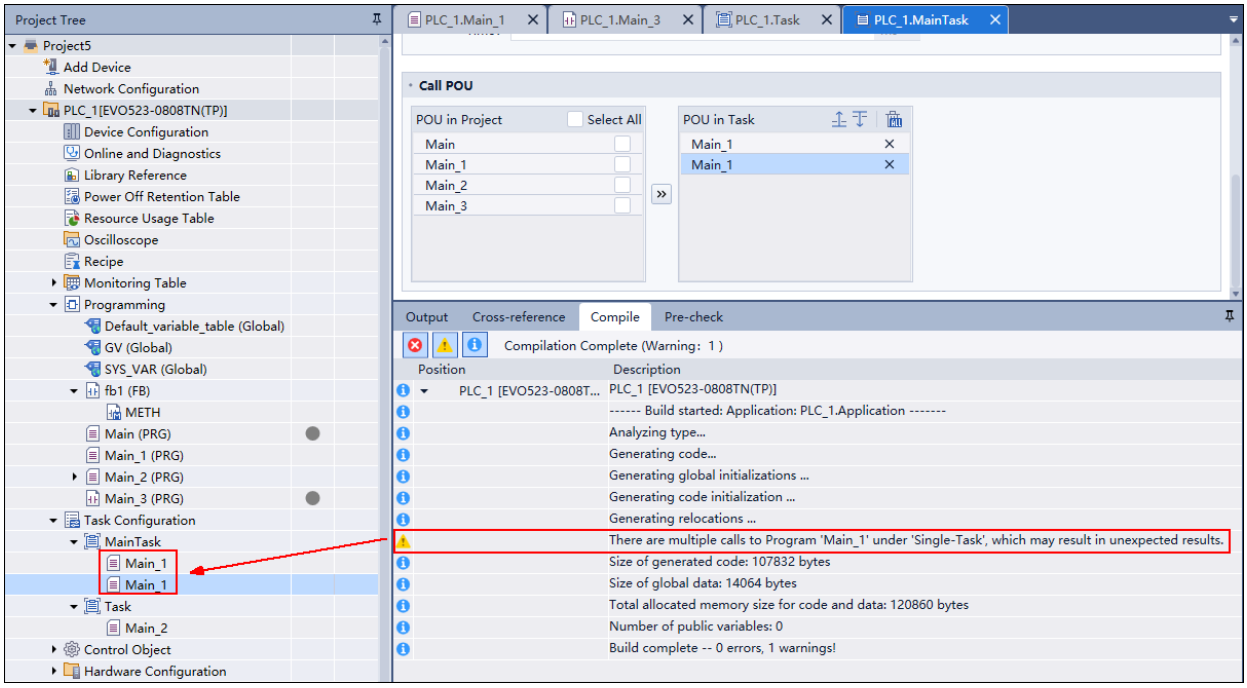

Figure 6-3-2 Pre-check error

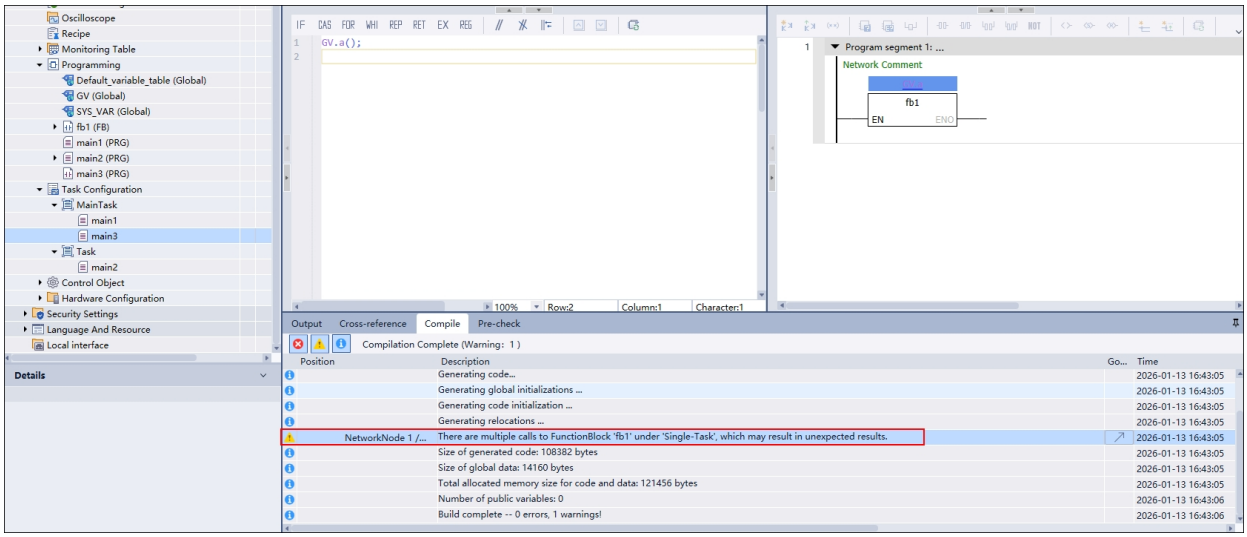
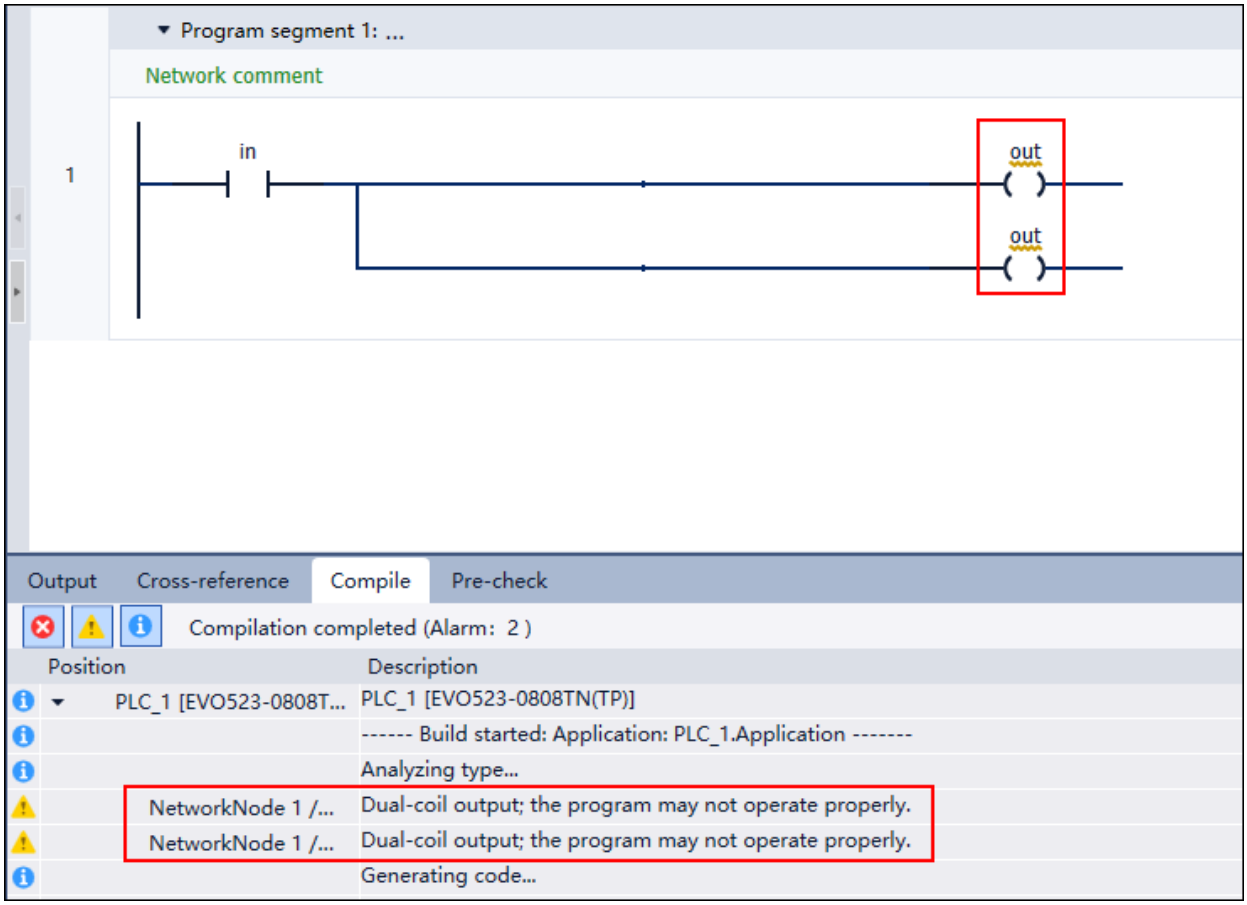


- Once the following options are applied, the system will output any compilation alarm:
  - Program called repeatedly in the same task

    In this case, an alarm will be displayed, indicating that the program XXX is called repeatedly in the same task, which may lead to unexpected results.



- FB instance/ACT/Method called repeatedly in the same task

  An alarm will be reported, indicating that the function block/action/method XXX is called in the same task, which may produce unexpected results

- Double coil check

  Check whether the same variable is assigned to multiple coils. Once this option is checked, the system will scan all ladder diagram (LD) POUs called by the task during the program check or compilation, and will issue an alarm when any variable assigned to multiple double coils is found (reset/ set coils are excluded from the check).

PLC commissioning

PLC commissioning is used for configuring the method of writing values to the program editing area in online mode. You can configure whether pressing Enter applies the value immediately or stores it as a pending value.

Choose "Tools > Options > PLC programming > PLC commissioning" from the menu bar.

7 Project Deployment

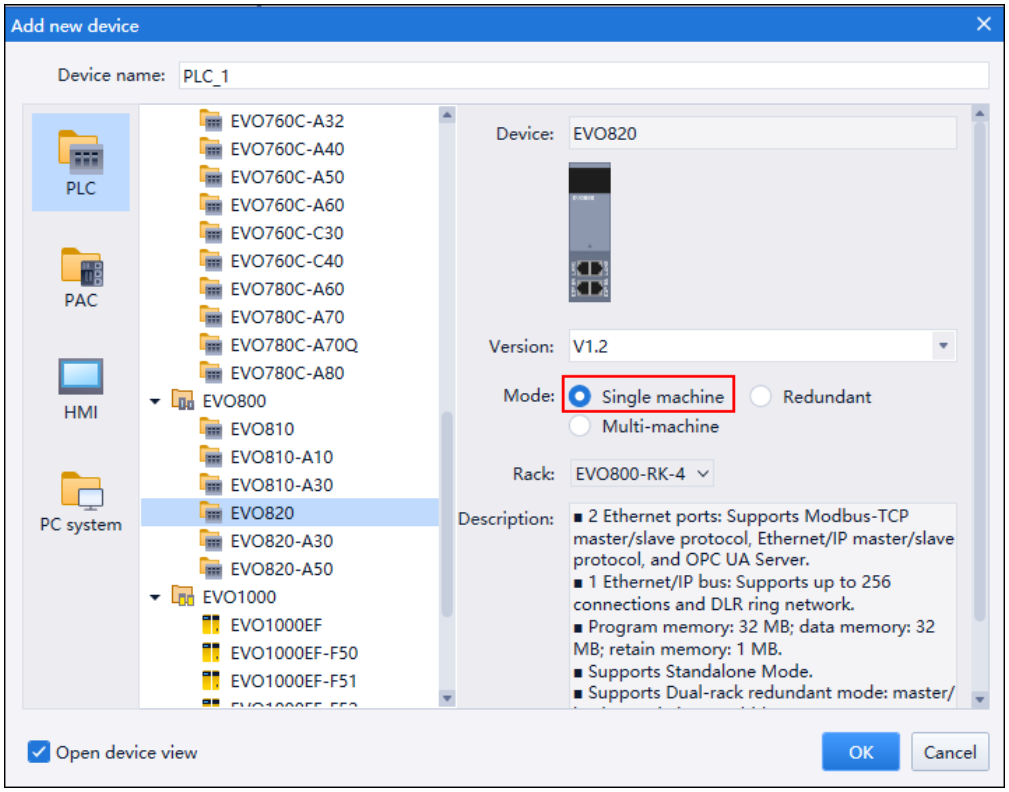
7.1 Creating a Project

Proceed as follows to create a new project:

1. Open the "Create new project" window in one of the following ways:
   - Method 1: On the startup interface, select "Create project".
   - Method 2: On the system interface, choose "Project -> New" from the menu bar.
   - Method 3: On the system interface, click the New icon on the toolbar.
   - Method 4: On the system interface, use the shortcut key Ctrl+N.
2. Taking Method 1 as an example: After the "Create new project" window appears, configure the project information, and then click "Create". At this time, a new project is created and opened automatically.

Item	Description
Name	Enter the project name. The name can contain Chinese characters, English letters, numbers, and underlines, but cannot start with a number.
Type	Select a project type: • Engineering project • Library project
Path	Select the path where the project will be saved.
Author	Enter the author's name.
Description	(Optional) Enter the project description.

7.2 Configuring a Device



7.2.1 Adding a Device

You can add a device in the project tree after creating a project.

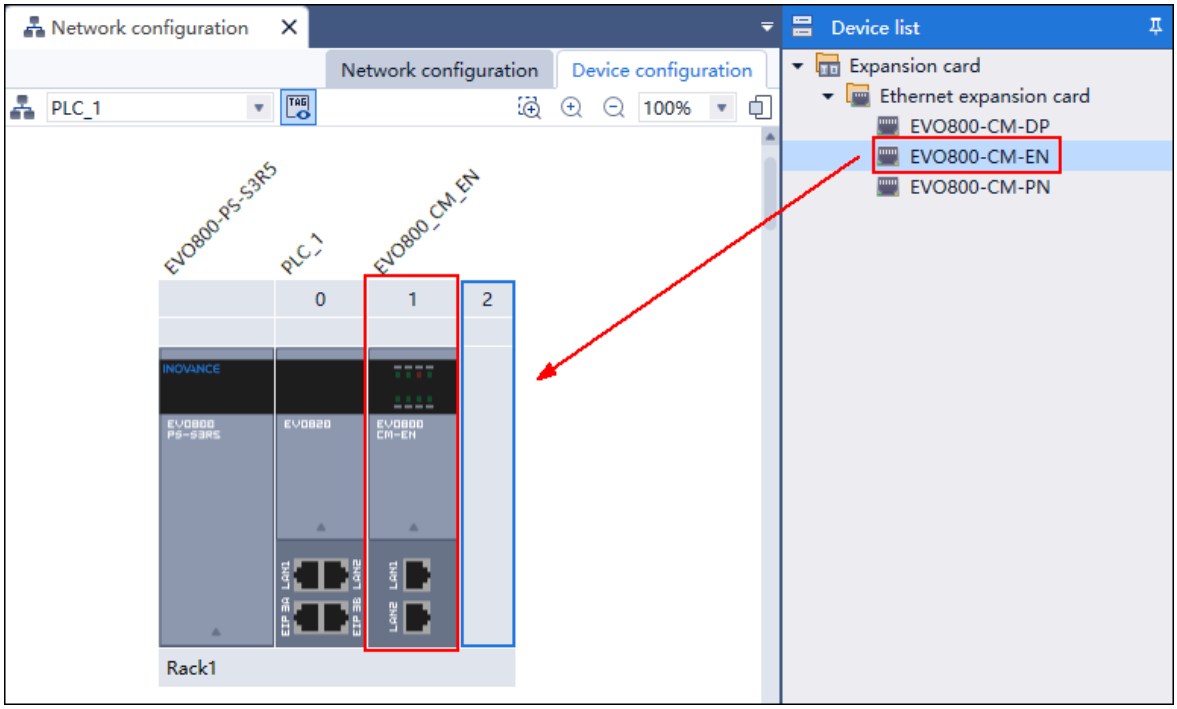
Taking the EVO800 series as an example, the procedure for adding the EVO800 series single PLC is similar to that for adding other series PLC.

Add a single PLC

1. Double-click the "Add device" node in the project tree to access the "Add new device" dialog box, in which the PLC is selected by default.
2. Click the required PLC, and the product information will be displayed on the right side, as shown in the following figure:

The product information related parameters are described in the table below.

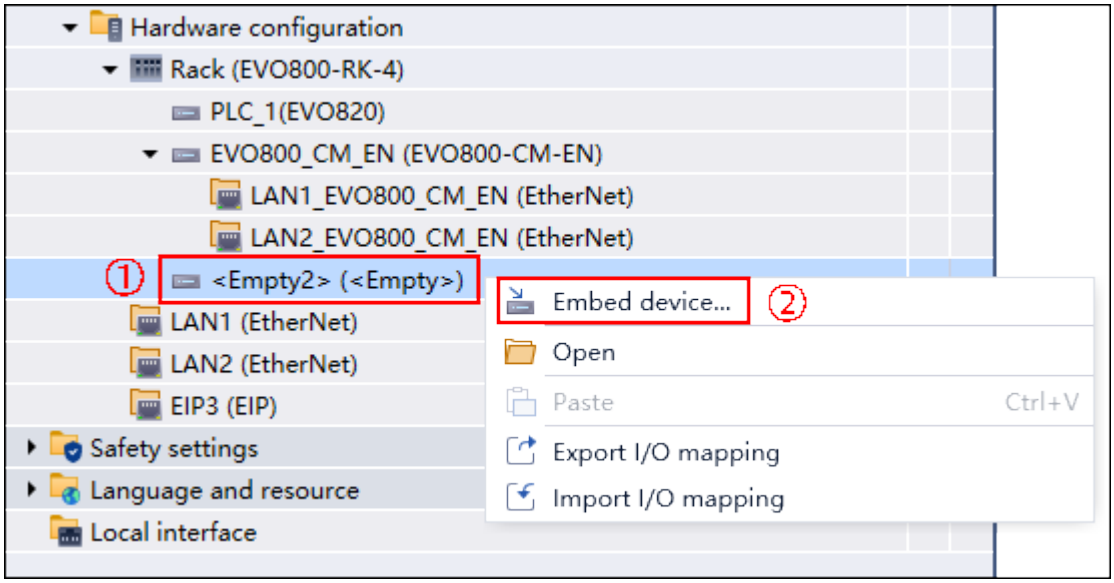
Parameter	Description
Device	Displays the device model.
Version	Displays the current available versions of the device. When multiple versions are available, select the desired one from the drop-down list.
Mode (optional for EVO800 series)	Displays different modes. Select "Single machine" here.
Description	Displays related product information.



3. (optional for EVO800 series) Select an appropriate rack from the "Rack" drop-down list.
   The default rack is EVO800-RK-4; options include EVO800-RK-4, EVO800-RK-6, EVO800-RK-5R, and

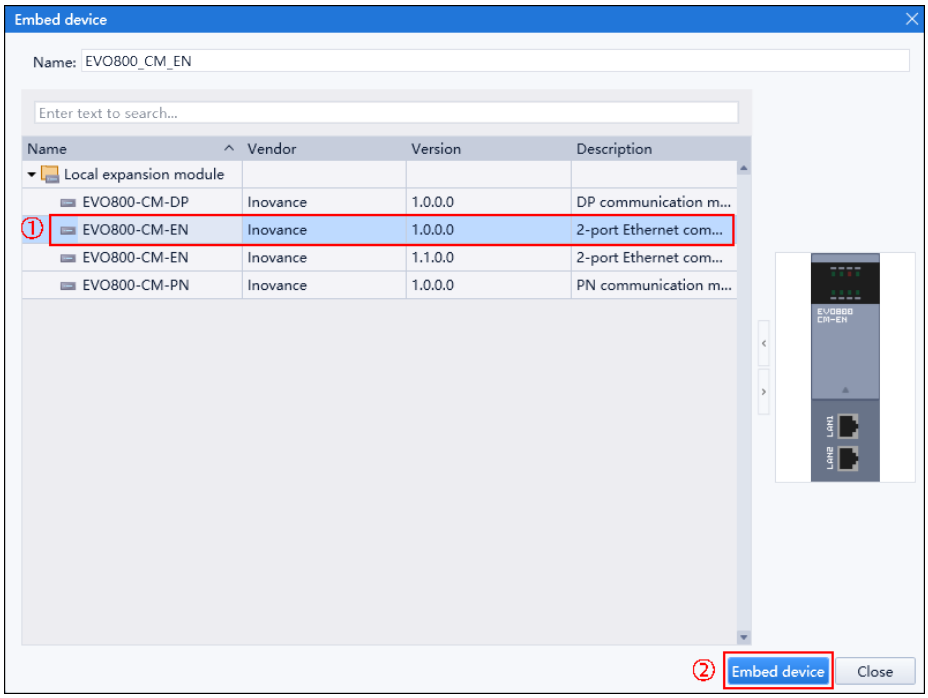
EVO800-RK-7R. Among them, EVO800-RK-4 and EVO800-RK-6 are single-power racks, while EVO800-RK-5R and EVO800-RK-7R are dual-power racks. In the Device Configuration view, one power supply module can be seen in the single-power racks, and two power supply modules can be seen in the dual-power racks.

4. Click "OK" to add the PLC.



5. (Optional for EVO800 series) Add an Ethernet/DP master/PN master expansion module. The following uses the Ethernet expansion module as an example.
   In the project engineering, the slot positions of the configured modules must match the corresponding slot positions in the actual physical topology.

➢Method 1: In the "Device configuration" interface, select an empty slot, drag an Ethernet module from the "Device list" to this empty slot.

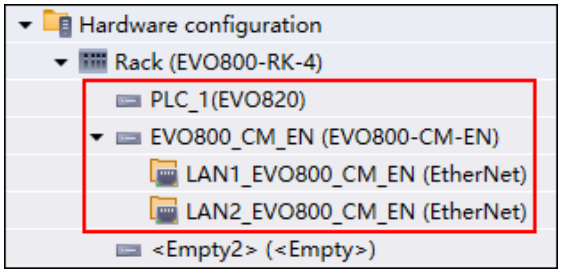


➢Method 2:

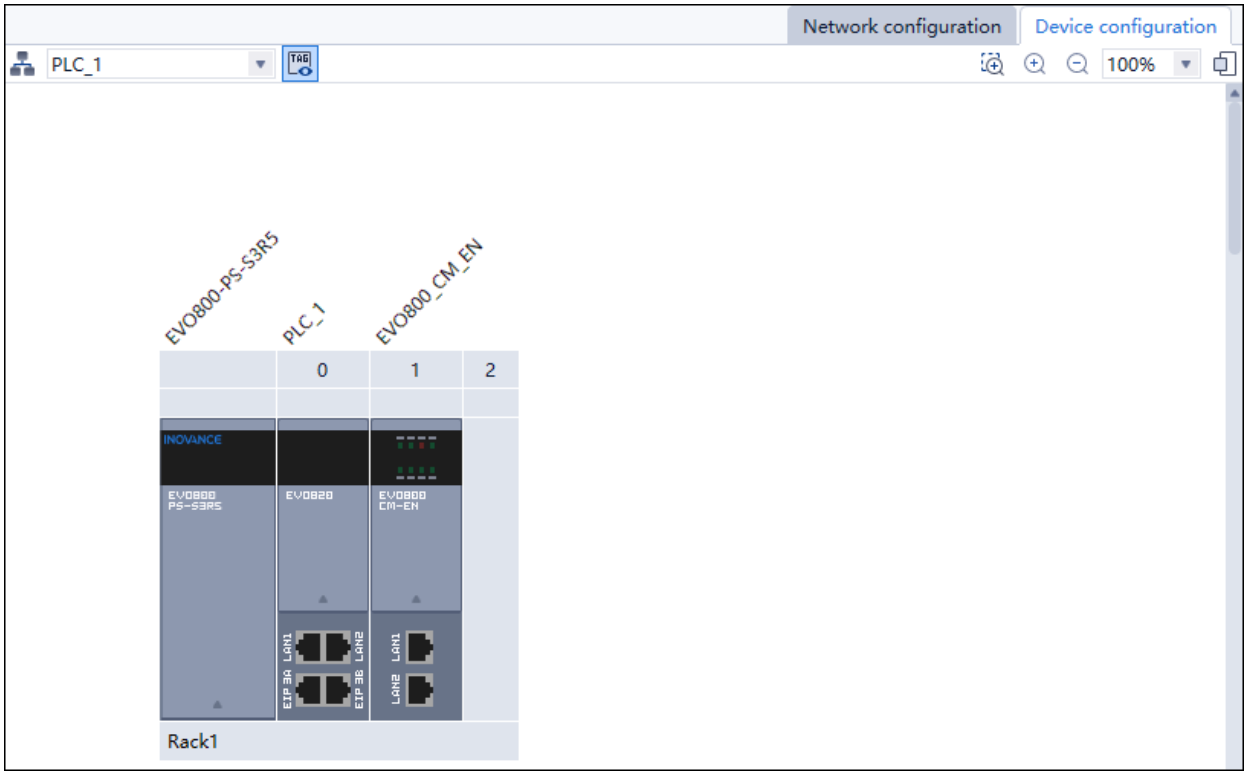
a. Right-click an empty slot in the "Project Tree" and select "Embed device" from the shortcut menu.

b. In the opened dialog box, select "EVO800-CM-EN", and click "Embed device" to add the Ethernet

expansion module.



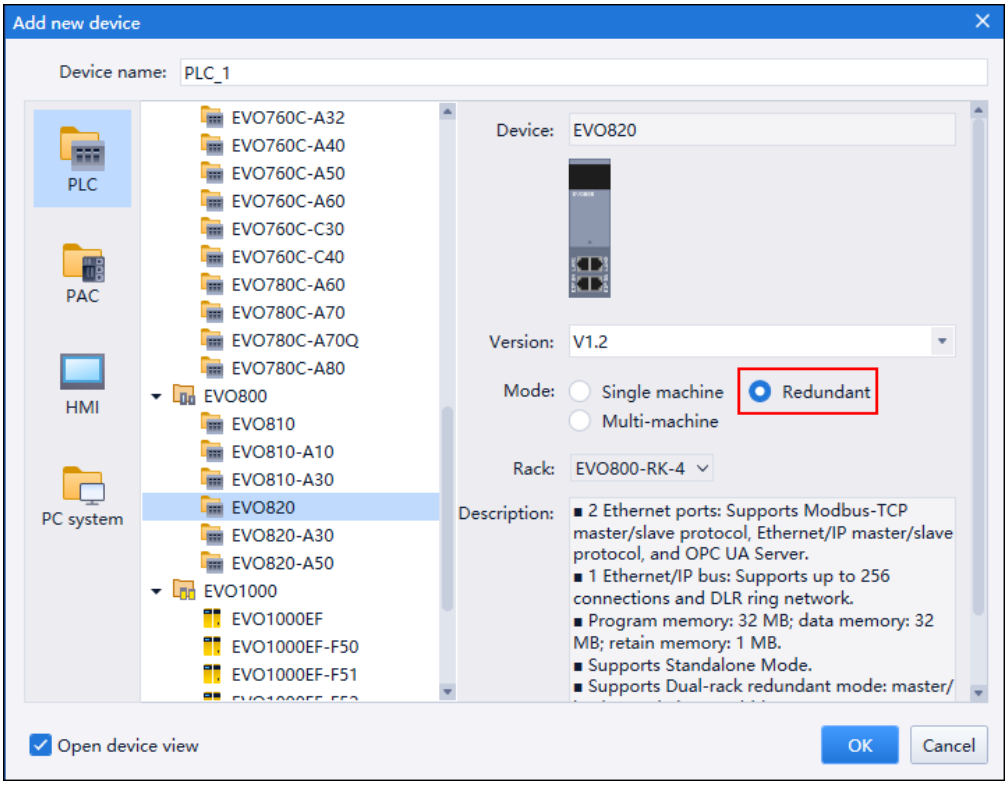
NOTE



The added Ethernet expansion module is part of the EVO800 PLC.

Result

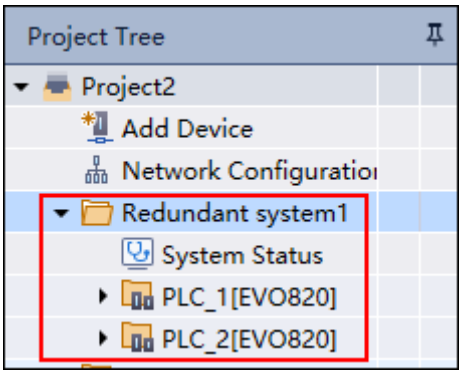
After the device is added, the device node appears in the project tree.



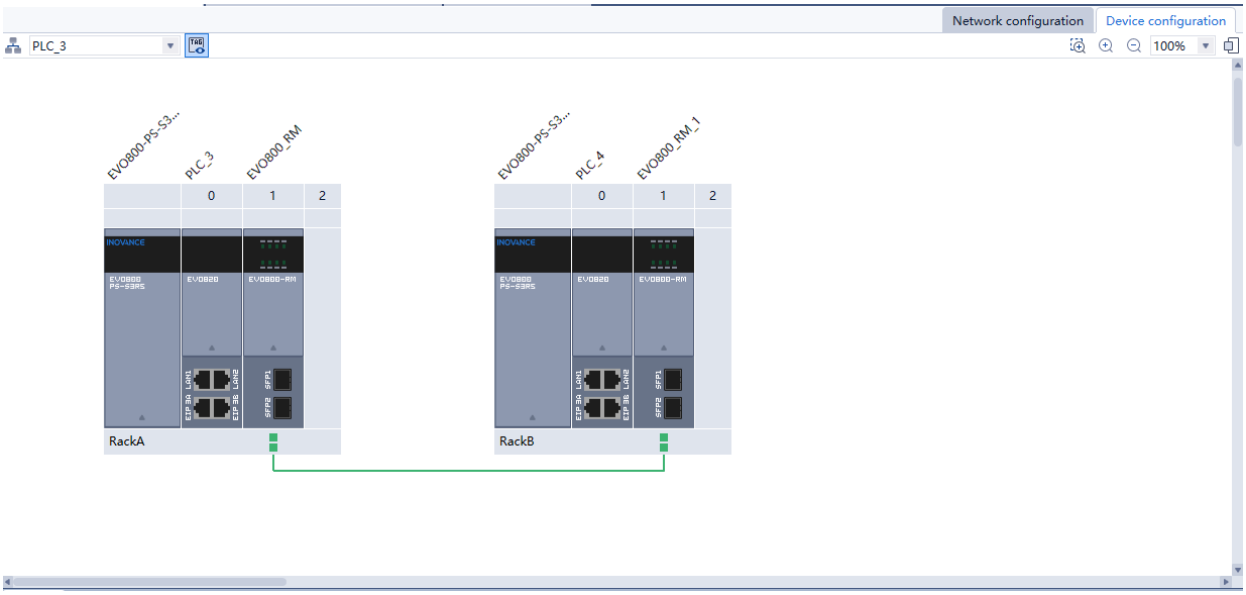
The Device Configuration view is shown as follows:

Add a redundant PLC

The procedure for adding a redundant PLC is basically similar to that for adding a single PLC, with the only difference being that the mode on the right side must be changed to "Redundant" after selecting the EVO820 product. Click "OK" to complete the addition of the redundant PLC.



NOTE

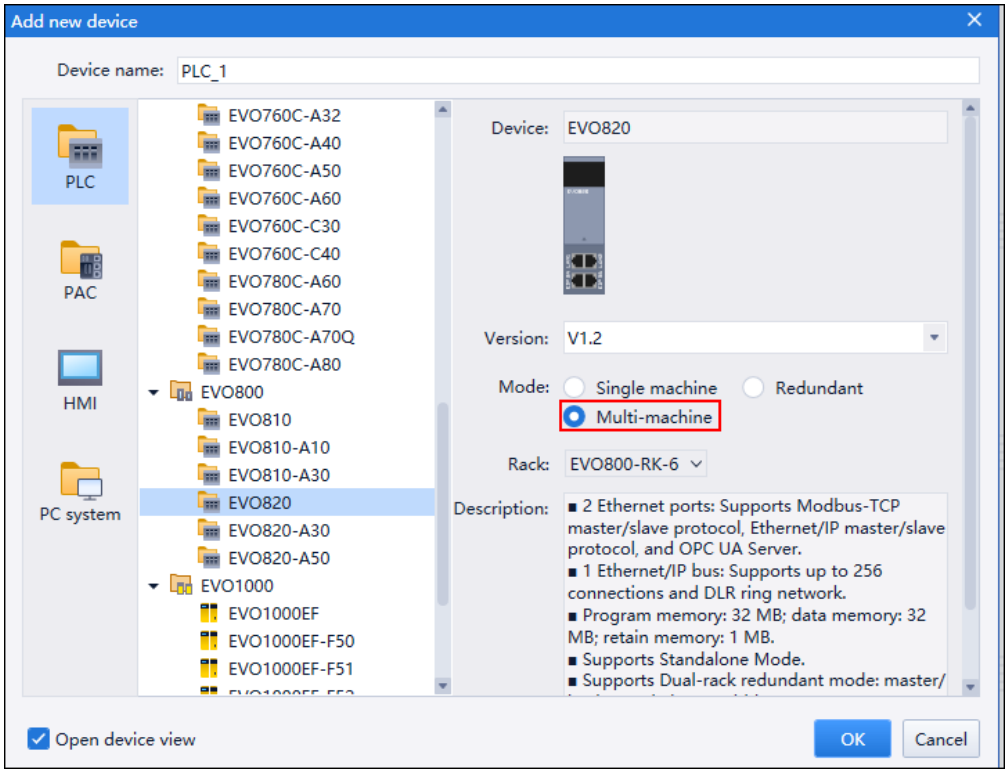


- Any of the EVO800-RK-4, EVO800-RK-6, EVO800-RK-5R, and EVO800-RK-7R racks also applies to the redundant PLC.
- The redundant mode is not applicable to EVO810 series devices.

Result

After adding the redundant PLC, the device node appears in the project tree.

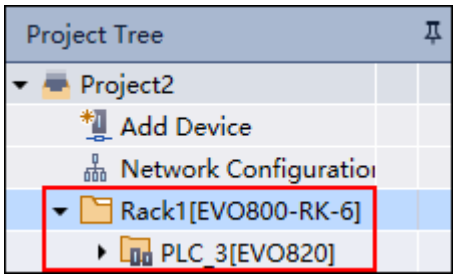
The Device Configuration view for the redundant PLC is shown as follows:



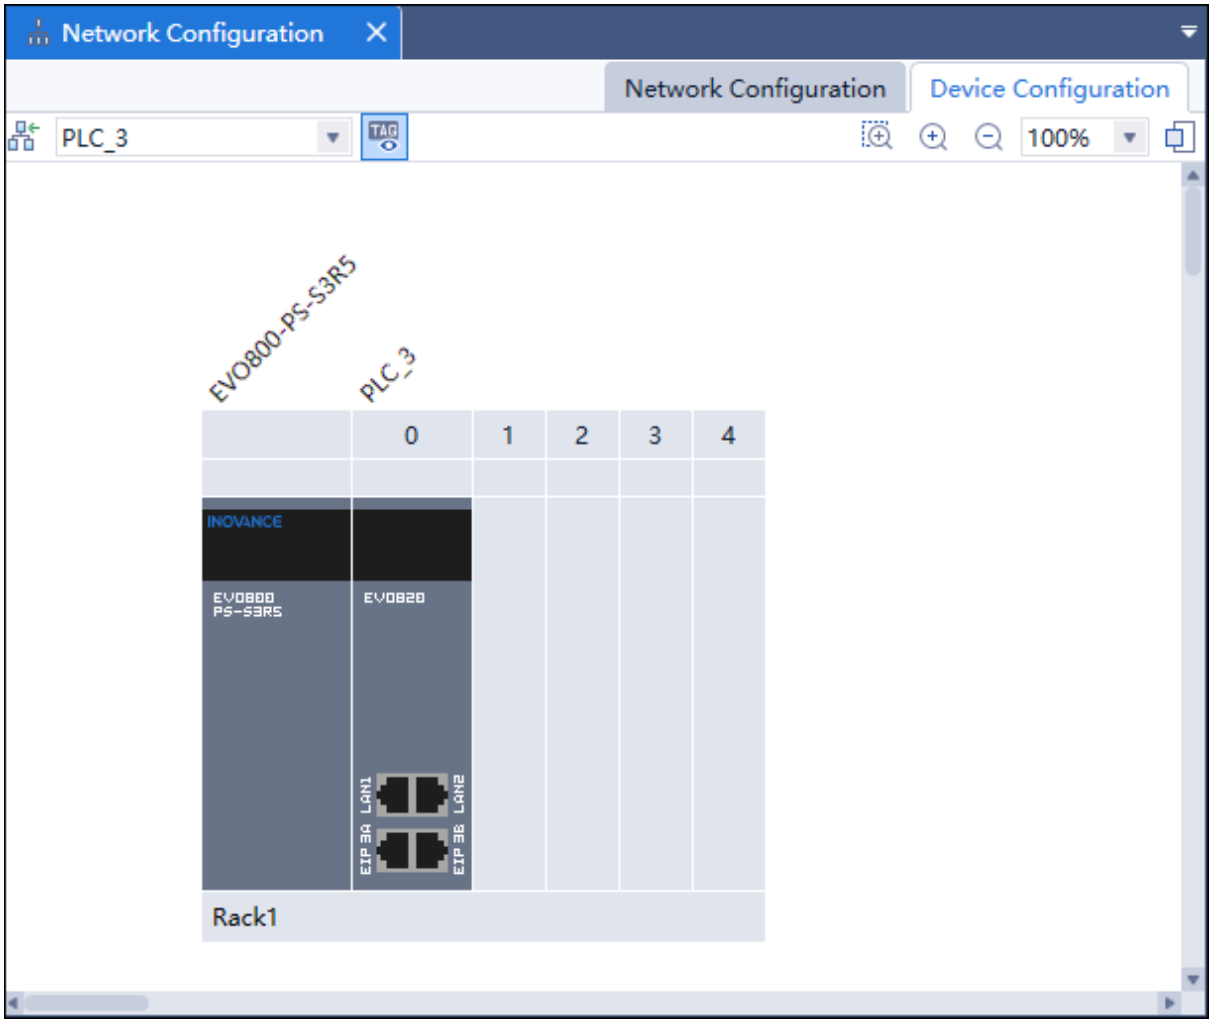
Add multiple PLCs

CAUTION

The firmware versions of all CPUs must be consistent. For specific firmware upgrade operations, see "14.1.1 Firmware Update."



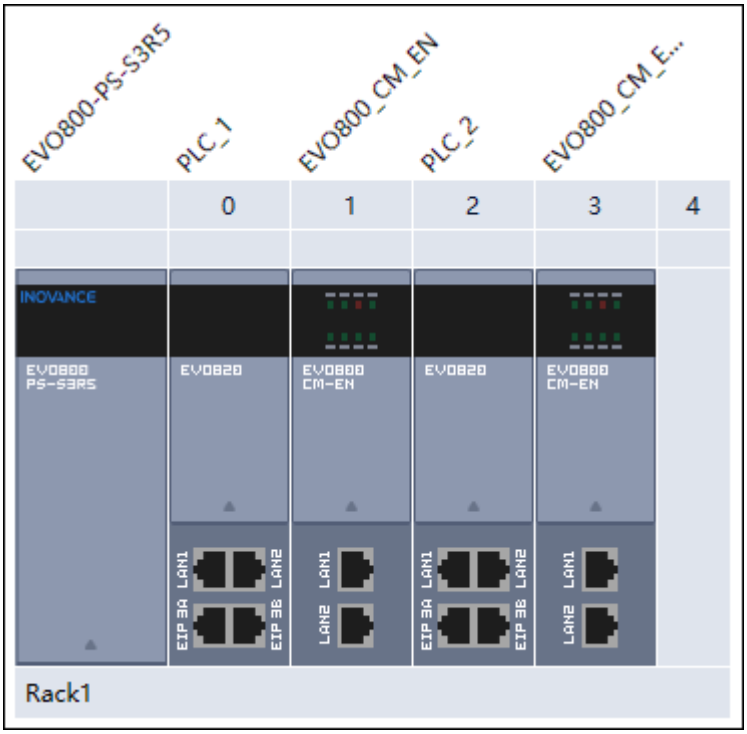
1. The procedure for adding multiple PLCs is basically similar to that for adding a single PLC, with the only difference being that the mode on the right side must be changed to "Multi-machine" after selecting the EVO820 product. Click "OK" to complete the addition of multiple PLCs.



NOTE

- The default rack for multiple PLCs is EVO800-RK-6, but any of EVO800-RK-4, EVO800-RK-6, EVO800-RK-5R, and EVO800-RK-7R racks can be freely selected.
- Ethernet expansion modules can be also added for multiple PLCs.

After adding multiple PLCs, the device node appears in the project tree.



Generate a single PLC node. The Device Configuration view is shown as follows:

2. Add a PLC module or an Ethernet expansion module. For the addition procedure, see "Step 5" in the "Add a single PLC" section.

NOTE

- PLC modules can only be added via drag-and-drop from the "Device list" in the toolbox. A six-slot rack supports adding up to four PLC devices.
- The added Ethernet modules belong to the nearest PLC on their left. For example, in the figure below, the Ethernet expansion modules in slots 1 and 2 belong to PLC_1 in slot 0, and the Ethernet expansion module in slot 4 belongs to PLC_2 in slot 3.

7.2.2 Copying a Device

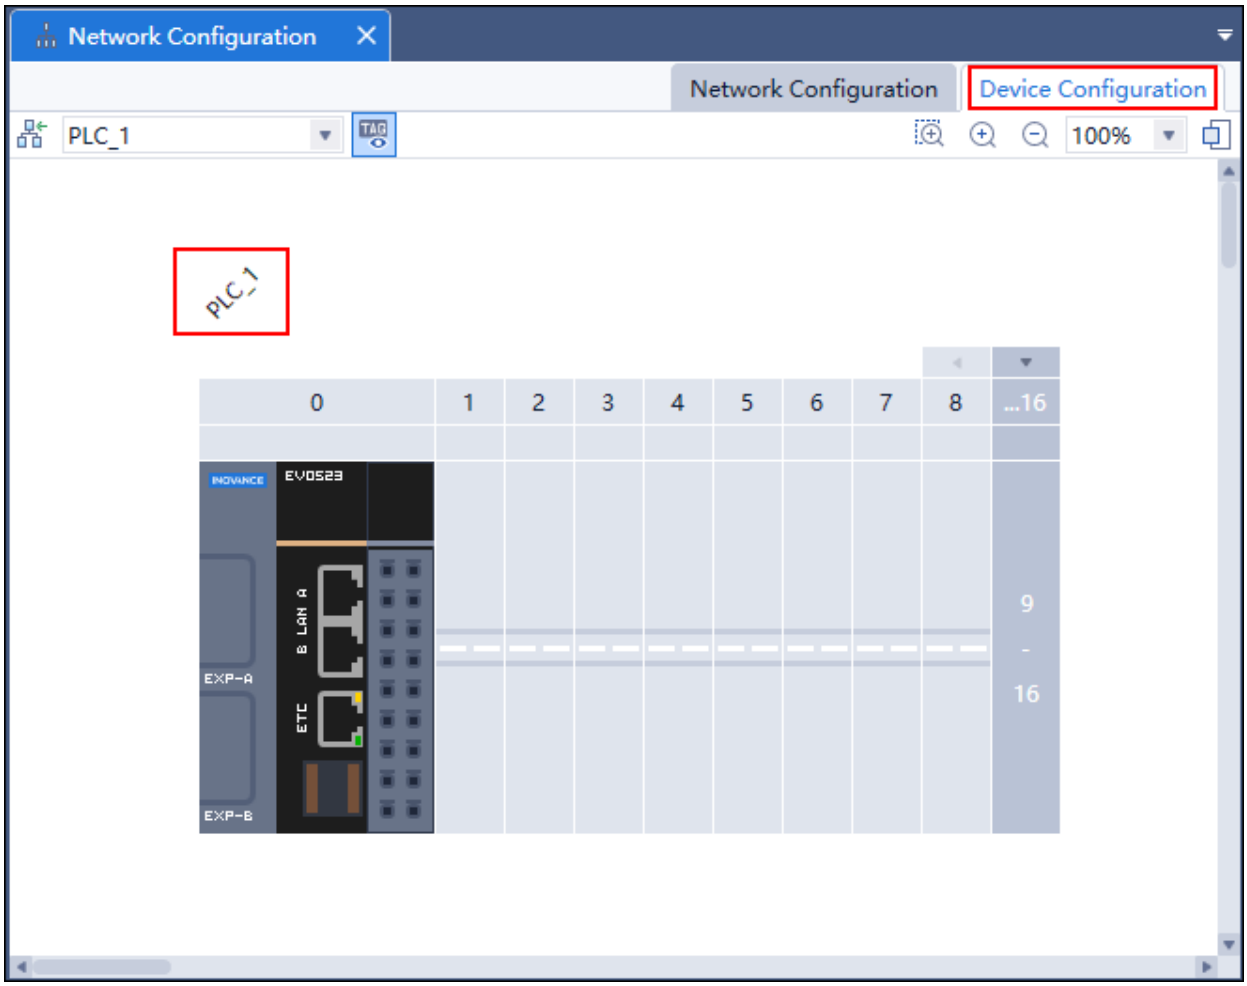
You can copy the relevant hardware devices in the Device Configuration or Network Configuration view. The copied hardware devices are stored in the clipboard and can be pasted to a valid location from the clipboard.

Usage

- Either a single device or multiple devices can be copied at a time.
- Copied devices and modules can be pasted to the rack in the Network Configuration or Device Configuration view.
- Modules installed in a rack can be copied.
- Copied devices and modules can be pasted to available slots provided that the slot usage is followed.

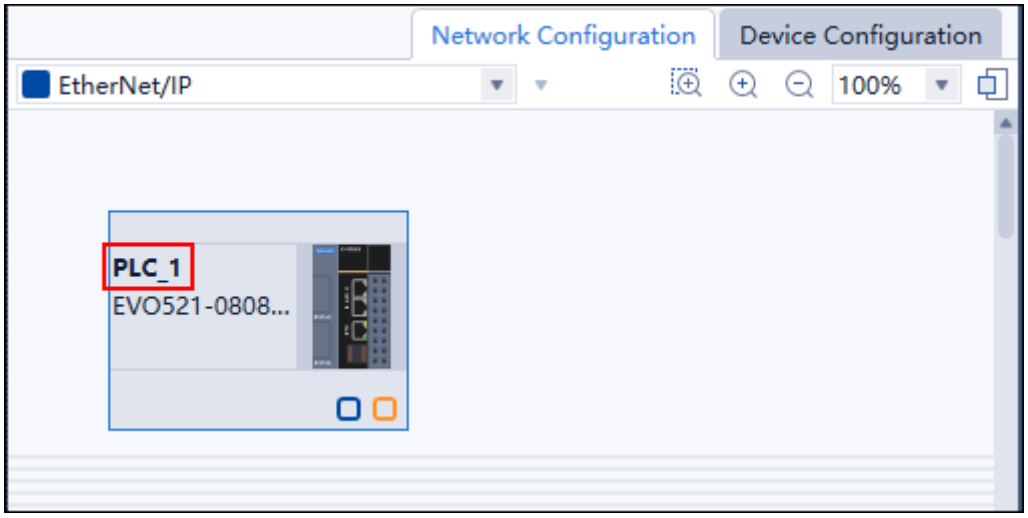
Procedure

1. Select a device you want copy.
   - Device Configuration: Select a module on the rack.
   - Network Configuration: Select a device.
   - Project tree: Select a device.
2. Select "Copy" from the shortcut menu or press <Ctrl+C>.



When the "Copy" item cannot be selected, it indicates that the selected content includes at least one device that cannot be copied.

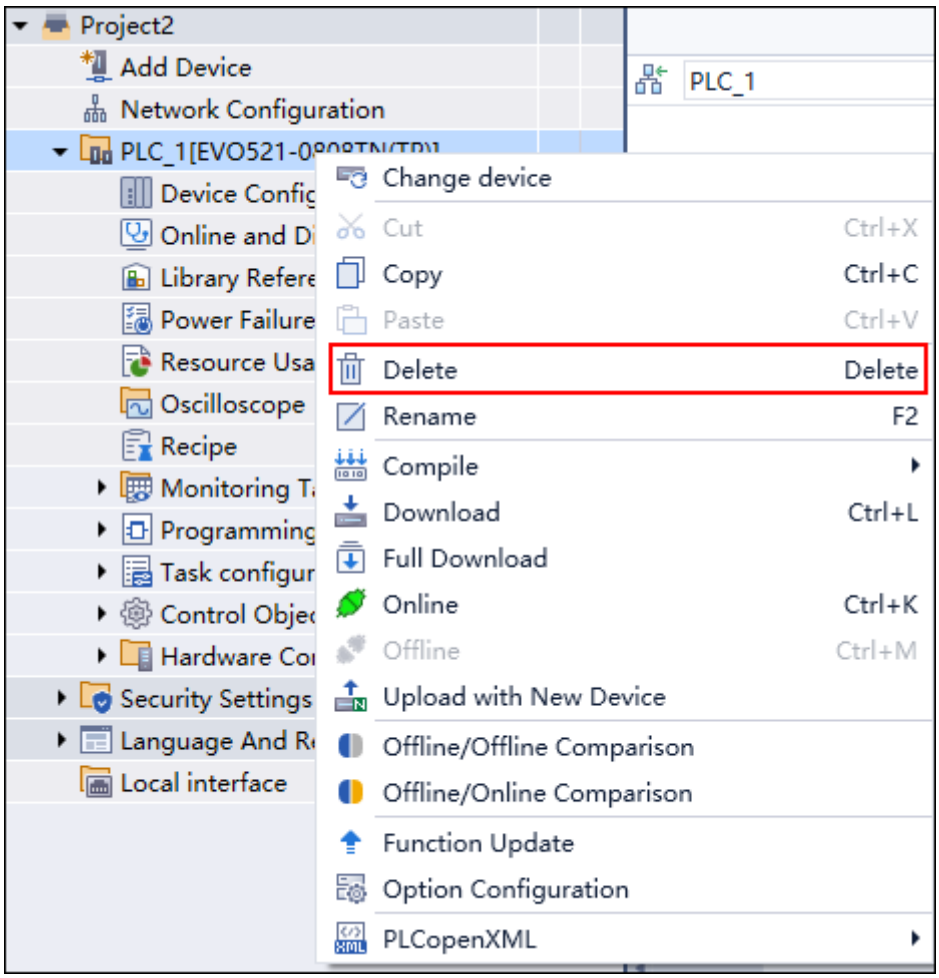
3. Select the position where you want to paste the clipboard content.
   - Device Configuration: Select a free slot in the rack or an area without a module installed.
   - Network Configuration: Select a device to insert.
4. Select "Paste" from the shortcut menu or press <Ctrl+V>.
   - If you paste the copied object using the shortcut menu without making a selection in the Network Configuration view, the object will be pasted at the pointer position.
   - If you paste the copied object using <Ctrl+V> without making a selection in the Network Configuration view, the copied object will be pasted to the right of the original object.



7.2.3 Renaming a Device

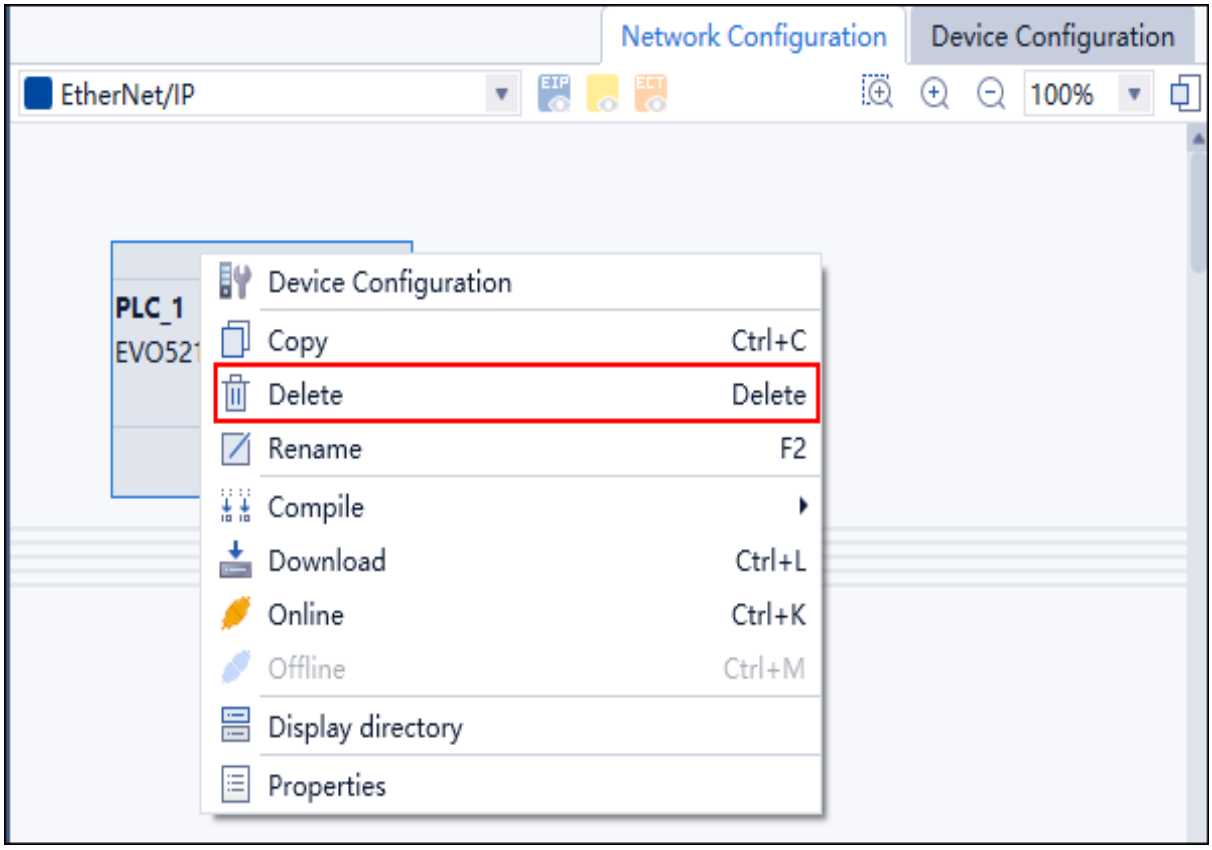
You can edit the device name in the "Network Configuration" and "Device Configuration" tabs for a device.

- Proceed as follows to rename a device in the graphics field of the "Device Configuration" tab:
  1. Selects a device.
  2. Double-click the name above the device to modify it.



- Proceed as follows to rename a device in the "Network Configuration" tab:
  1. Selects a device.
  2. Double-click the name above the device to modify it.

7.2.4 Deleting a Device



Perform one of the following steps to delete an added device.

- Right-click the device node in the left project tree and select "Delete".

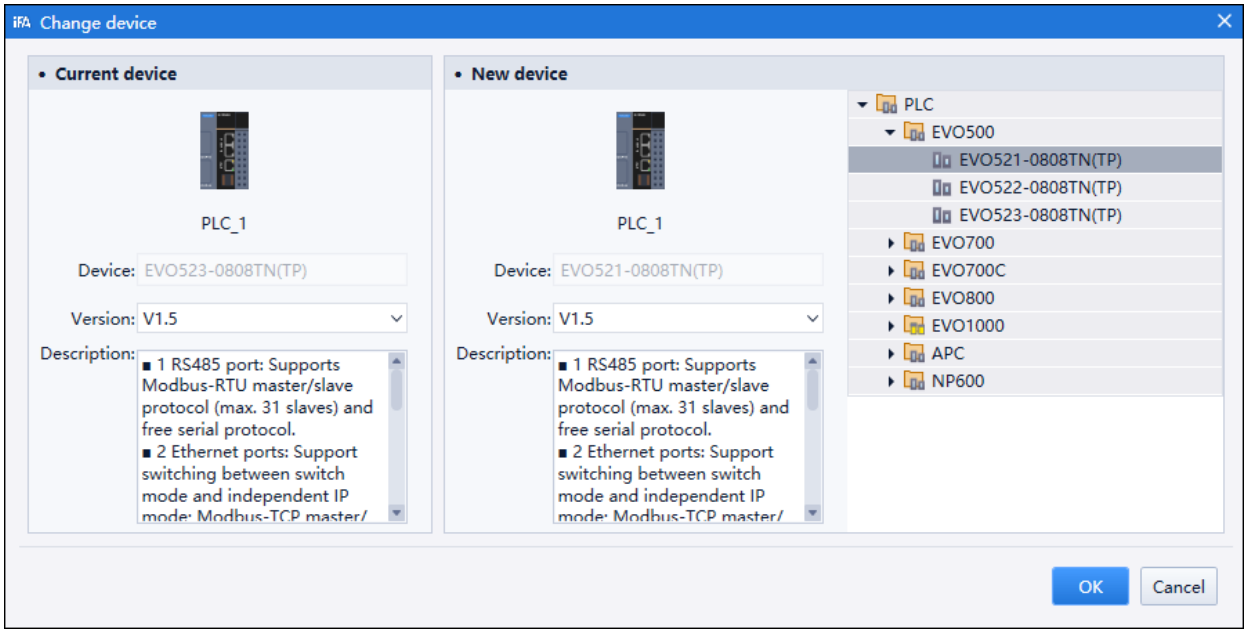
- In the Network Configuration or Device Configuration view, select the device, right-click, and choose "Delete".

  Note: The PLC cannot be deleted in the Device Configuration view.

CAUTION

Deleting a PLC device takes effect immediately and cannot be undone!

7.2.5 Replacing a Device



Replacing a device applies to replacing a created device to another one. This operation is allowed only when the device node is in offline mode.

Prerequisites

- A project has been created and opened.
- A device has been added to the project.

Procedure

1. Open the Change Device tab.
   Right-click the device in the project tree and select "Change device".
2. Select the target device from the list on the right.
3. Select the firmware version of the new device following the "Version" field.
4. Click "OK" to replace the device.

Compatibility rules for replacing different devices

- Rule 1: When the new device does not support certain configuration data from the old device, it will discard such data after the replacement.

  Example 1: The EtherCAT communication and slave have been configured for PLC 1. If PLC 2 does not support EtherCAT communication, it will discard all EtherCAT configuration data from PLC 1 after the replacement.

  Example 2: Some basic elements and special controls have been configured on the HMI 1 screen. If HMI 2 does not support certain special controls, it will discard such controls from HMI 1.

- Rule 2: When the new device supports only part of the configuration data from the old device, it will retain such configuration data after the replacement.

  Example 1: All parameters and I/O variable mappings for 8 channels have been configured for GL20-0800END. When GL20-0800END is replaced by GL20-1600END, GL20-1600END will retain all 8 channels of data from GL20-0800END and map them channel by channel. The additional 8 channels will be set to default values.

- Rule 3: When the new device fully supports the configuration data from the old device, it will retain all configuration data after the replacement.

  Example 1: When PLC 1 is replaced by PLC 2 within the same series, PLC 2 will retain all variables and programs from PLC 1.

  Note: This requires that PLC 2 and PLC 1 support the same variable data types, POU types, and POU programming languages.

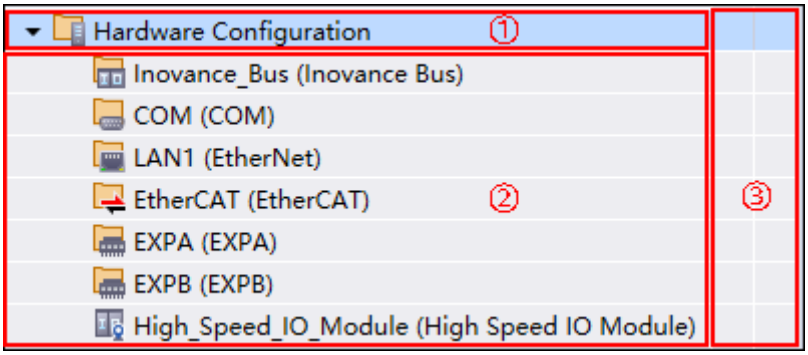
- Rule 4: When the firmware version is switched from a lower version to a higher version for the same device, Rule 3 applies. When the firmware version is switched from a higher version to a lower version, Rule 1 or Rule 2 applies.

The following table shows the PLC model replacement relationships:

Product Series	EVO52X	EVO76X	EVO8XX	EVO1000EF
EVO52X	√	√	√	×
EVO76X	√	√	√	×

Product Series	EVO52X	EVO76X	EVO8XX	EVO1000EF
EVO8XX	√	√	√	×
EVO1000EF	×	×	×	√

Note: √ indicates that product replacement is supported; x indicates that product replacement is not supported.



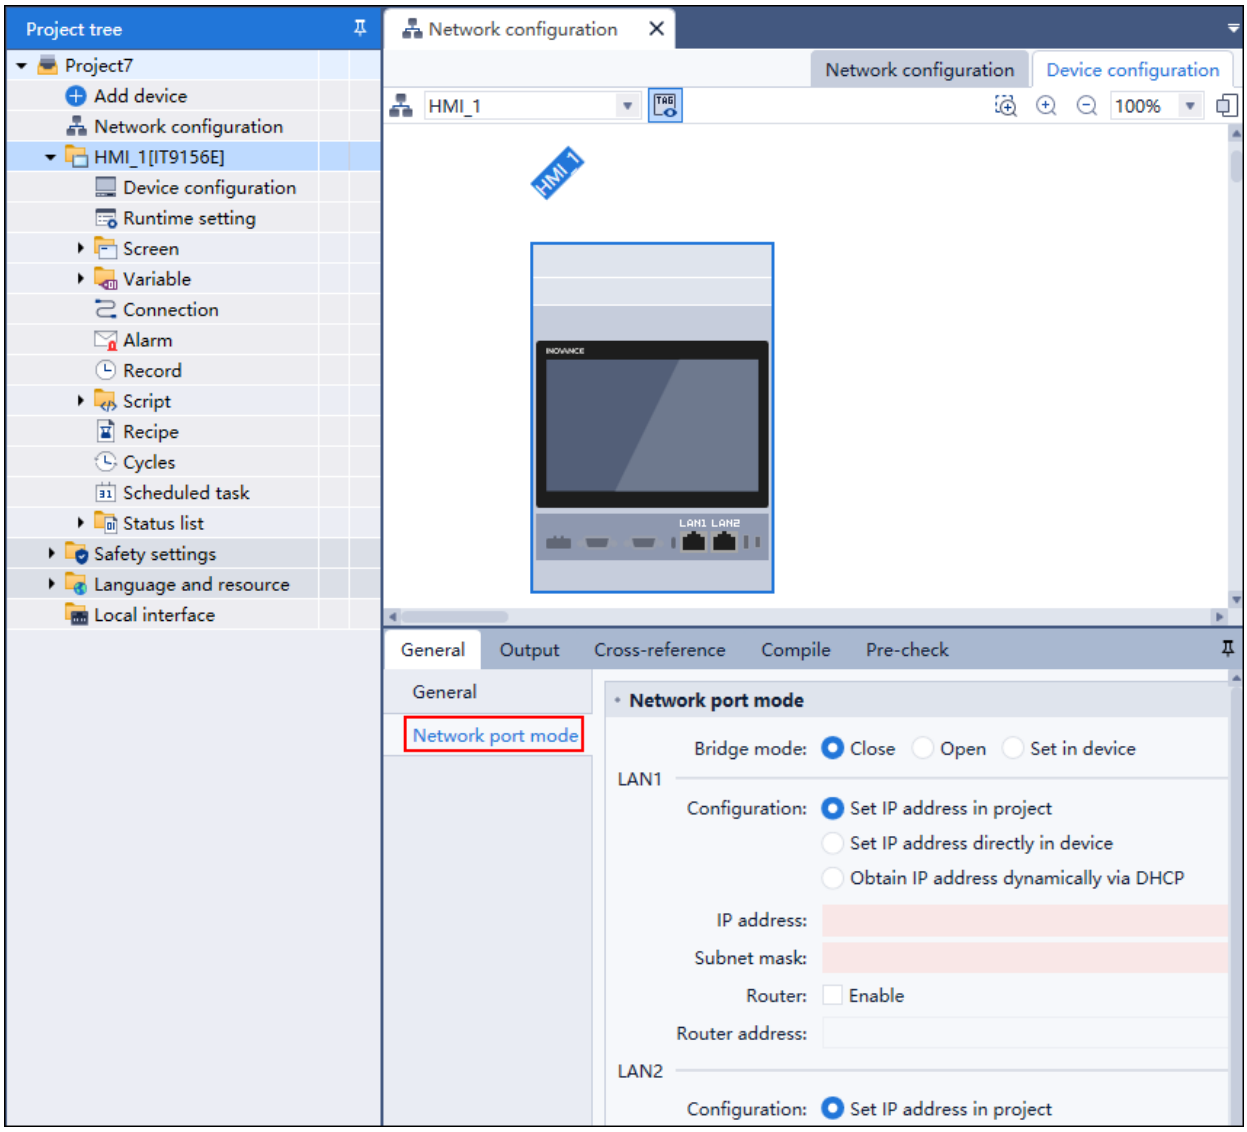
The following table shows the HMI/PC product replacement relationships:

Product Series	IT9000	PC Station (HMI)
IT9000	√	×
PC Station (HMI)	×	√

7.3 Configuring a Network

The communication protocols supported by the PLC model are displayed under "Hardware Configuration". These protocols can be used to meet different functional requirements by expanding the PLC. To communicate with or use different external devices, you can use the hardware configuration function in the project tree to perform hardware configuration and communication protocol configuration.

Taking the EVO500 series as an example, commonly used protocols include Inovance_Bus, Modbus protocol via COM port, EtherCAT protocol, EtherNet protocol based on TCP/IP, Modbus TCP protocol based on TCP/IP, EXPA and EXPB peripheral expansion ports, and high-speed counter modules. The configurable protocols depend on the actual PLC model. The hardware configuration interface and supported protocols are shown in the following figure:



No.	Function	Description
①	Title bar	Using the button on the left side of the hardware configuration title bar, you can manually collapse or expand the hardware configuration project tree.
②	Supported protocols	Under the hardware configuration list of the selected device, the protocols supported by the device are displayed by default.

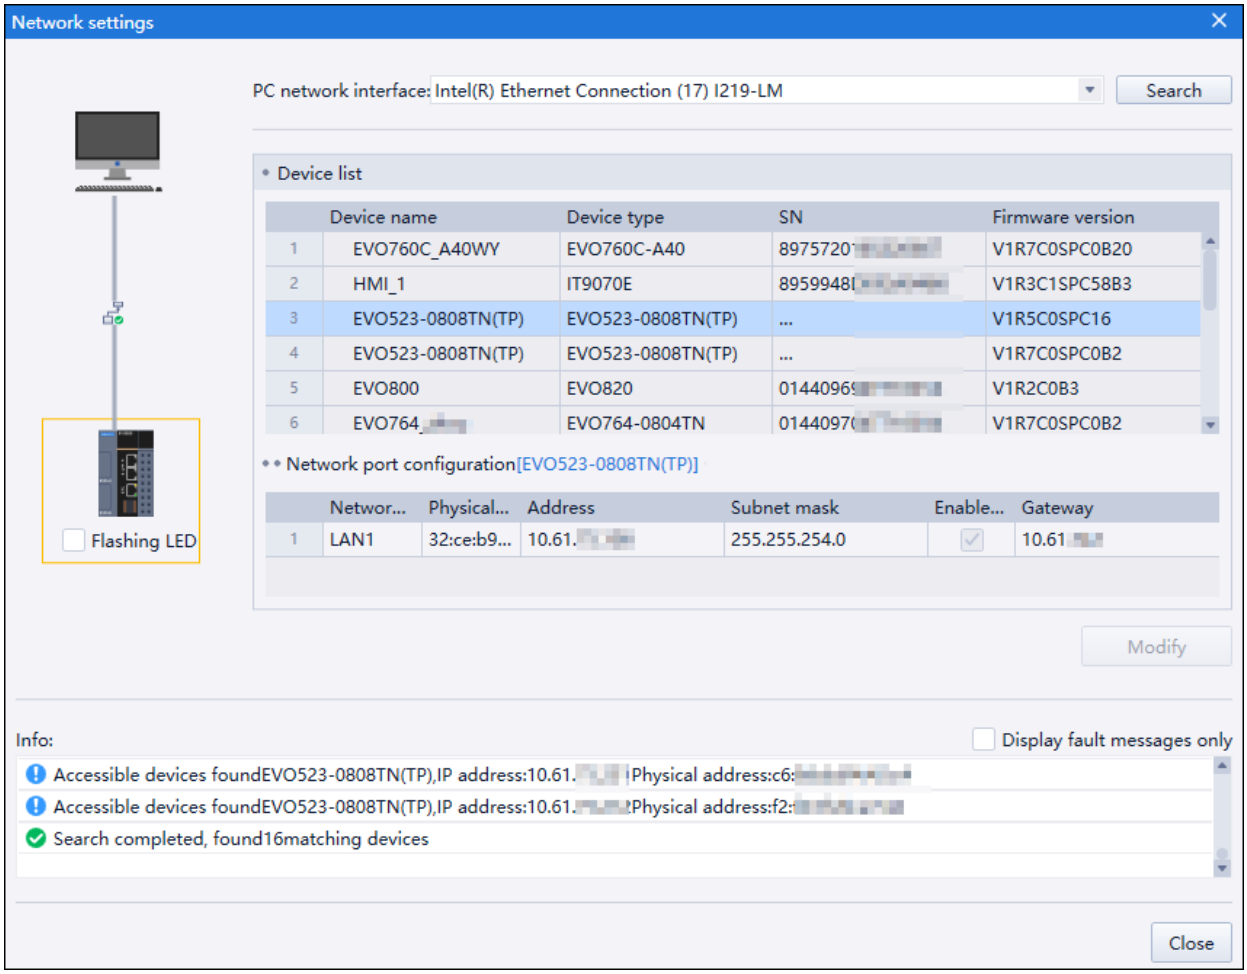
No.	Function	Description
③	Status bar	Hardware status display bar.

7.3.1 HMI Ethernet Settings

Before downloading a project, set the network port mode of the HMI device according to the network deployment.

Double-click the "Device configuration" node under the HMI device, and in the opened window, click the device image:

Category	Property	Description
Bridge mode	Close	In non-bridge mode, each network port operates independently and is connected to a separate network. This mode is suitable for scenarios requiring simultaneous connection to multiple networks.



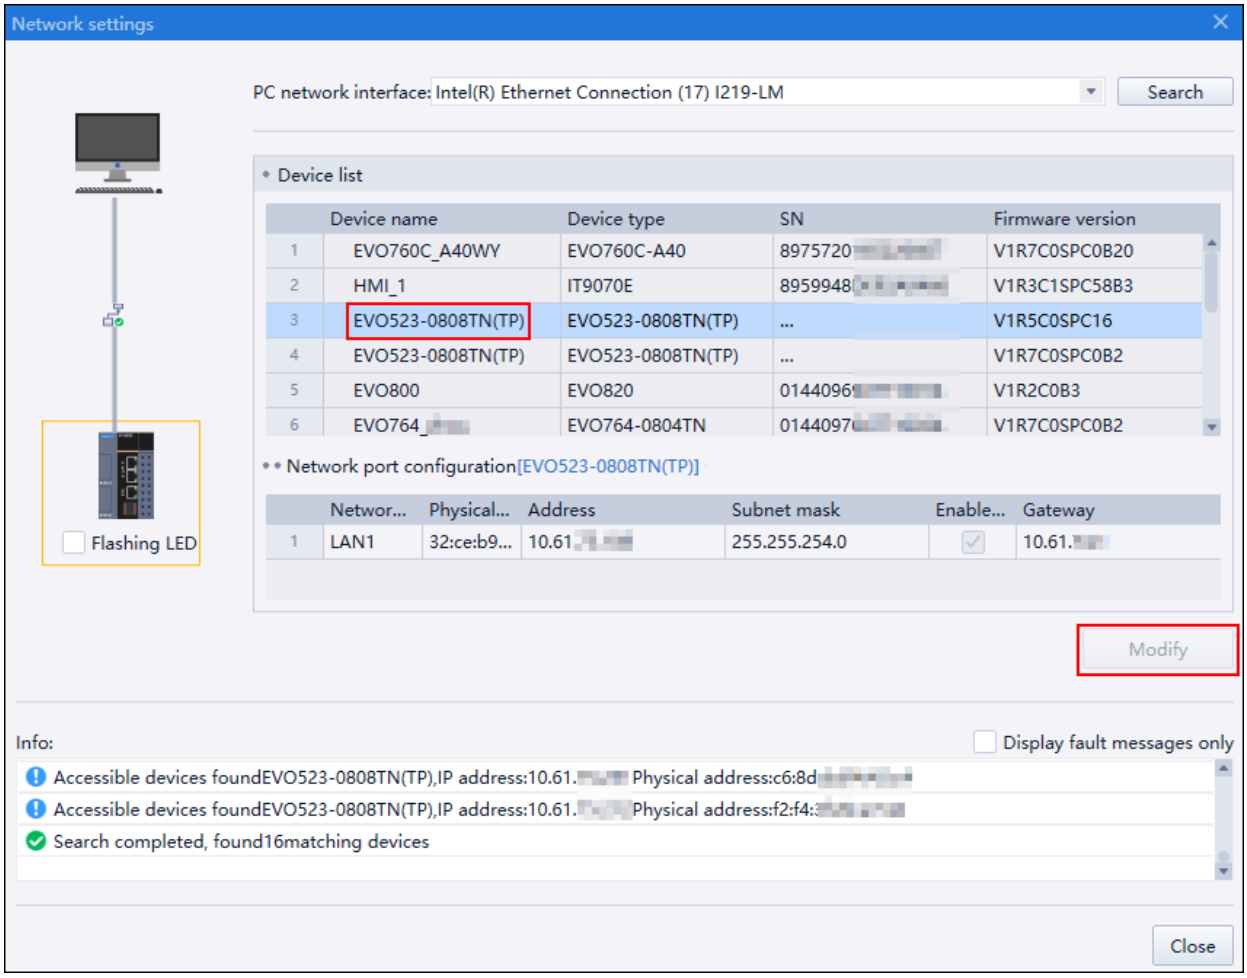
Category	Property	Description
	Open	In bridge mode, the HMI device combines two network ports into a single logical interface, and the IP address can be set by configuring LAN1. In this way, the devices connected to LAN1 and LAN2 can communicate within the same local area network. For example, when two network ports of the HMI device are connected to Device A and Device B respectively, Device A and Device B can exchange data.
	Set in device	Set whether to enable the bridge mode in the control panel of the HMI device.
LAN1/LAN2	Configuration	Methods for configuring the HMI device IP address: • Set IP address in project: Configure the IP address in the current window, and then download the project to the device to make the address effective. • Set IP address directly on device: Configure the IP address on the control panel of the HMI device and apply it. • Obtain IP address dynamically via DHCP: The device acquires an IP address dynamically from a DHCP server. Ensure that a properly configured DHCP server is running in the network to assign IP addresses.
	IP address	Access information for LAN1/LAN2 network card. For example, the LAN1 IP address is 192.168.0.100, and the subnet mask is 255.255.255.0.
	Subnet mask	
	Router	Enter gateway access information, and select or fill in the fields as required based on the network deployment.
	Router address	

7.3.2 Online Network Settings

This section use the EVO500 series PLC as an example.

1. Choose "Online -> Network Settings" from the menu bar to open the Network Settings page.

2. Click "Search" to view all devices on the same or different network segments.



3. Confirm the devices

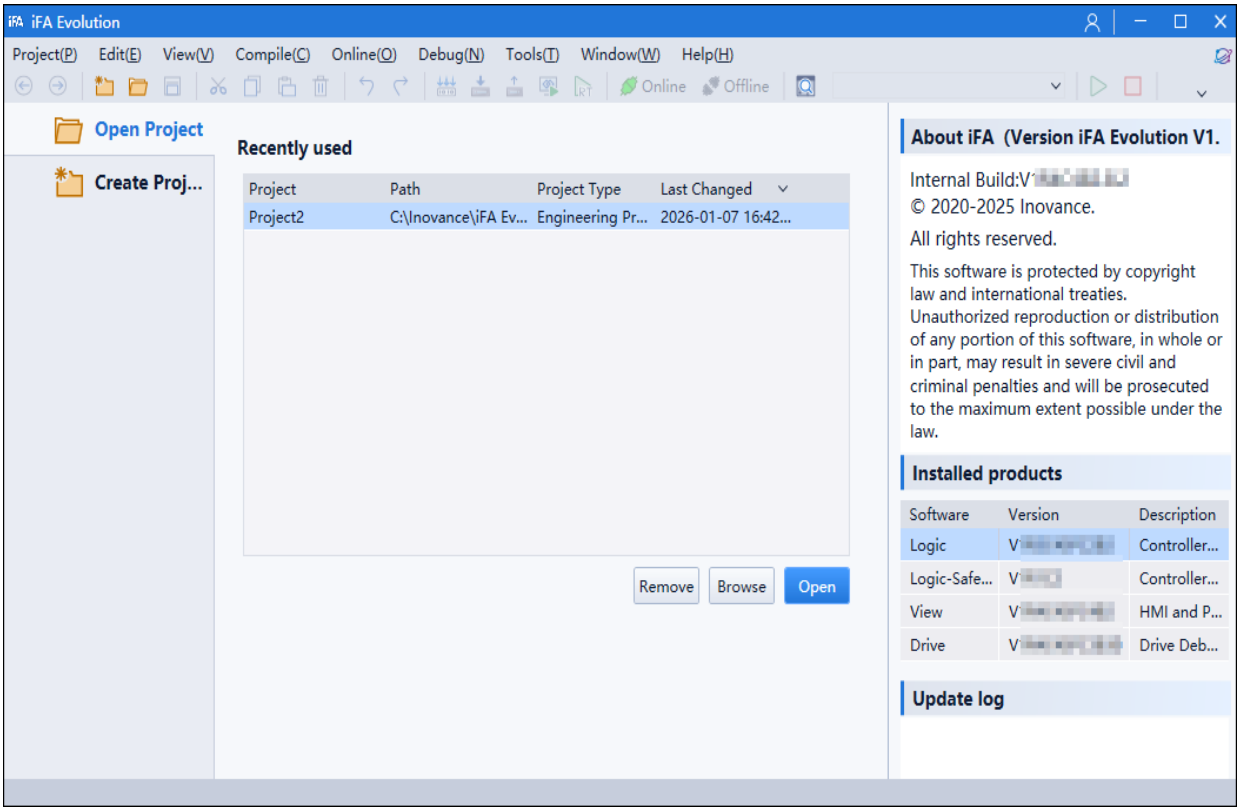
   Confirm that the device selected online matches the target device in the physical environment to avoid connection errors. Two confirmation methods are provided below:

   - SN consistency check: Check for consistency between the SN in the window and the SN on the physical device.
   - LED flashing check: While the "Flashing LED" option is checked in the window, the **RUN** indication on the physical device will flash in response.

4. Edit the device information

   In the device list of the current window, double-click a row to modify the device name, address, and gateway, and then click the "Modify" button to apply the changes.

The information bar displays the changes and operation result.



8 Project Management

8.1 Opening a Project

With this feature, you can directly open a target project from existing local projects.

You can open a project in the following ways:

- On the startup interface, select the "Open project" tab, select a project, and then click "Open". The effect is shown below:

- On the system interface, choose "Project -> Open" from the menu bar.
- On the system interface, click the Open icon on the toolbar.
- On the system interface, use the shortcut Ctrl+O.
- Double-click or right-click the project file.

CAUTION

- The same project cannot be opened repeatedly.
- Projects that do not exist or are corrupted cannot be opened.
- Opening a project from the system interface closes the current project and opens the new one.

8.2 Saving a Project

With this feature, you can save the active project data in the original project path and update the last saved time of the project. The current workspace keeps unchanged after the saving is complete.

A project can be saved in the following ways:

- Choose "Project -> Save" from the menu bar.
- Click the Save Project icon on the toolbar.
- Use the shortcut Ctrl+S.

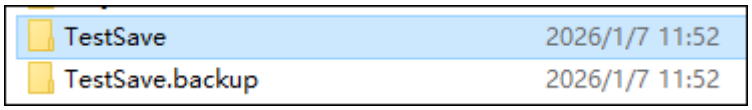
> CAUTION
>
> A project cannot be saved without any changes.

8.3 Saving a Project As

With this feature, you can save the active project as a new project by specifying a new name and save path. After the saving is complete, the active project is switched to the newly saved project.

1. You can open the "Save as" dialog in the following two ways:
   - On the system interface, choose "Project -> Save as" from the menu bar.
   - Use the shortcut Ctrl+Shift+S.
2. In the "Save as" dialog, select the save path, enter the project name, and then click "Save".
3. After successful saving, the active project is switched to the newly saved project.

> CAUTION
>
> If any functions in the project cannot be closed, attempting "Save as" will trigger an error message and prevent the save operation.



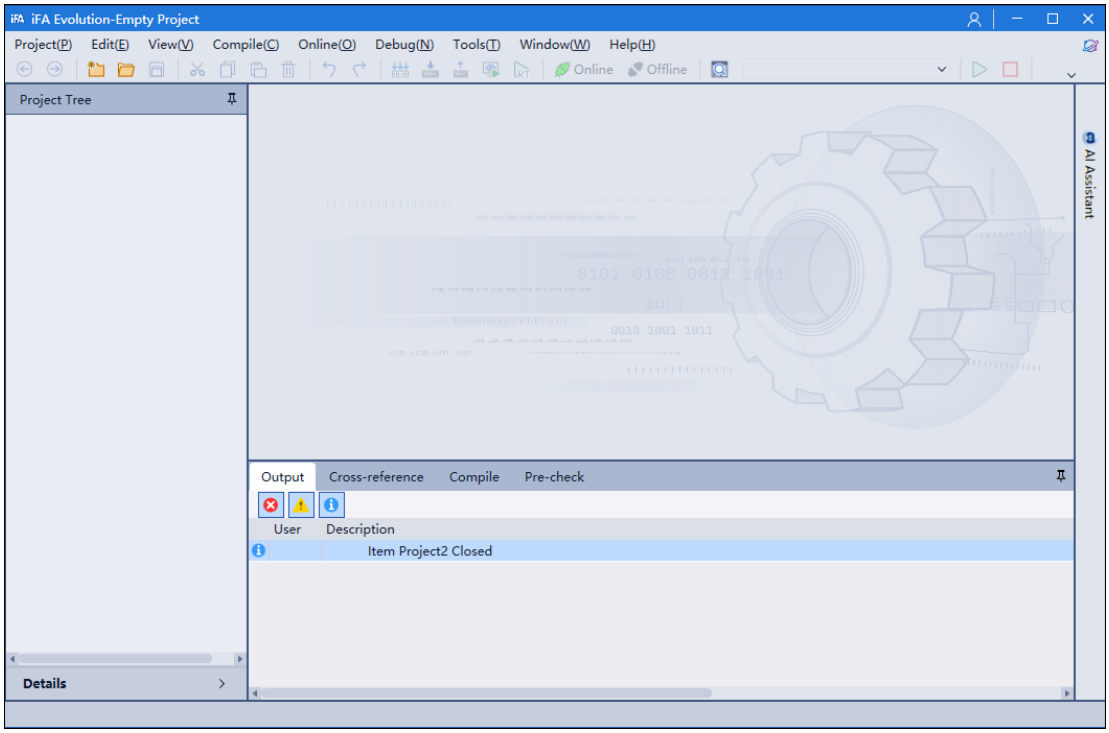
8.4 Backing up a Project

iFA supports automatic backup of project data. You can restore a project to the "historical" version by opening the automatically backed-up project file.

Project backup is triggered automatically when the "Save" option is selected.

The backed-up project is named as xxx.backup and stored in a separate project folder (xxx is the original project name).

For example: If the original project is TestSave, the backed-up project is TestSave.backup. The original and backed-up project are stored in the same directory.



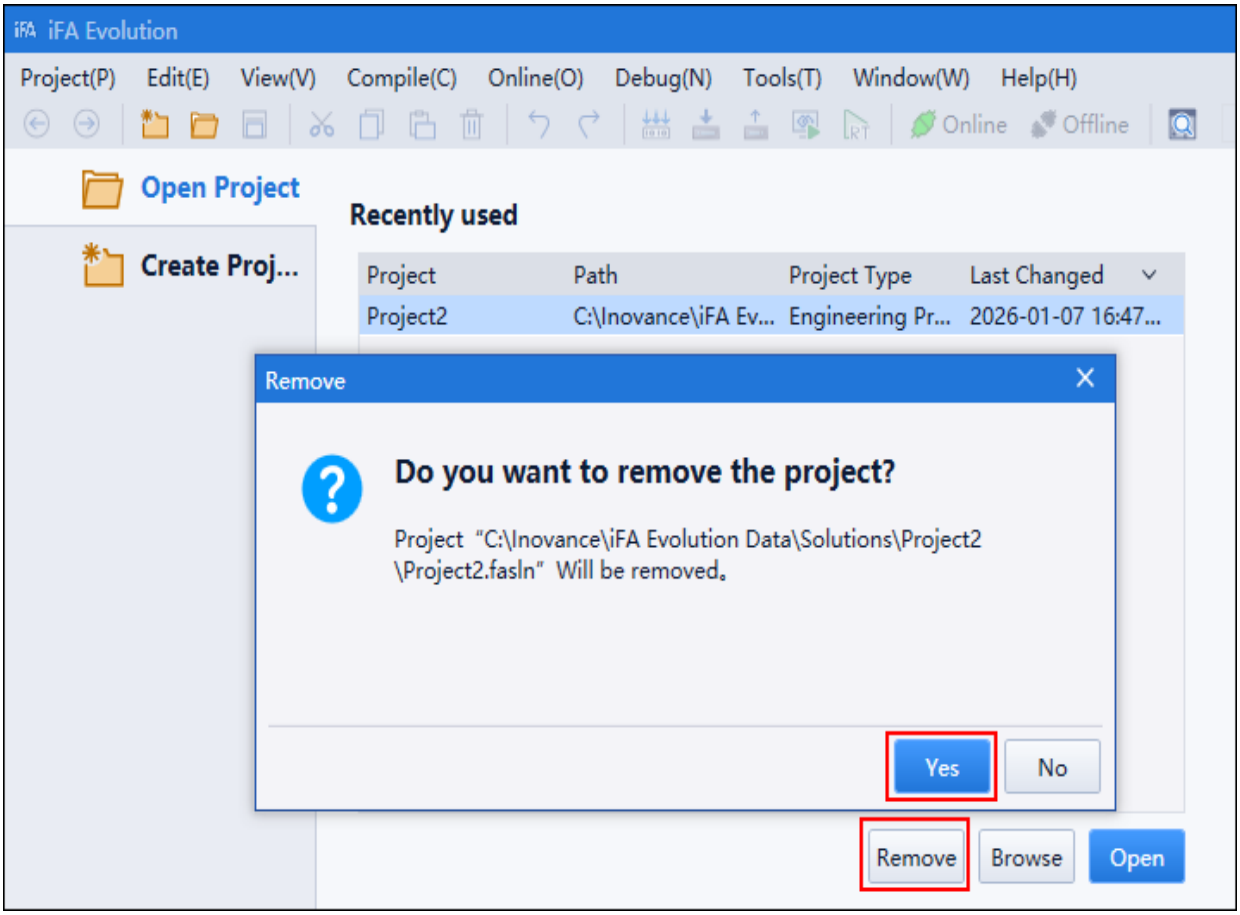
8.5 Closing a Project

With this feature, you can save and close the active project, and restore the system to an empty project state.

Choose "Project -> Close" from the system menu bar to close a project.

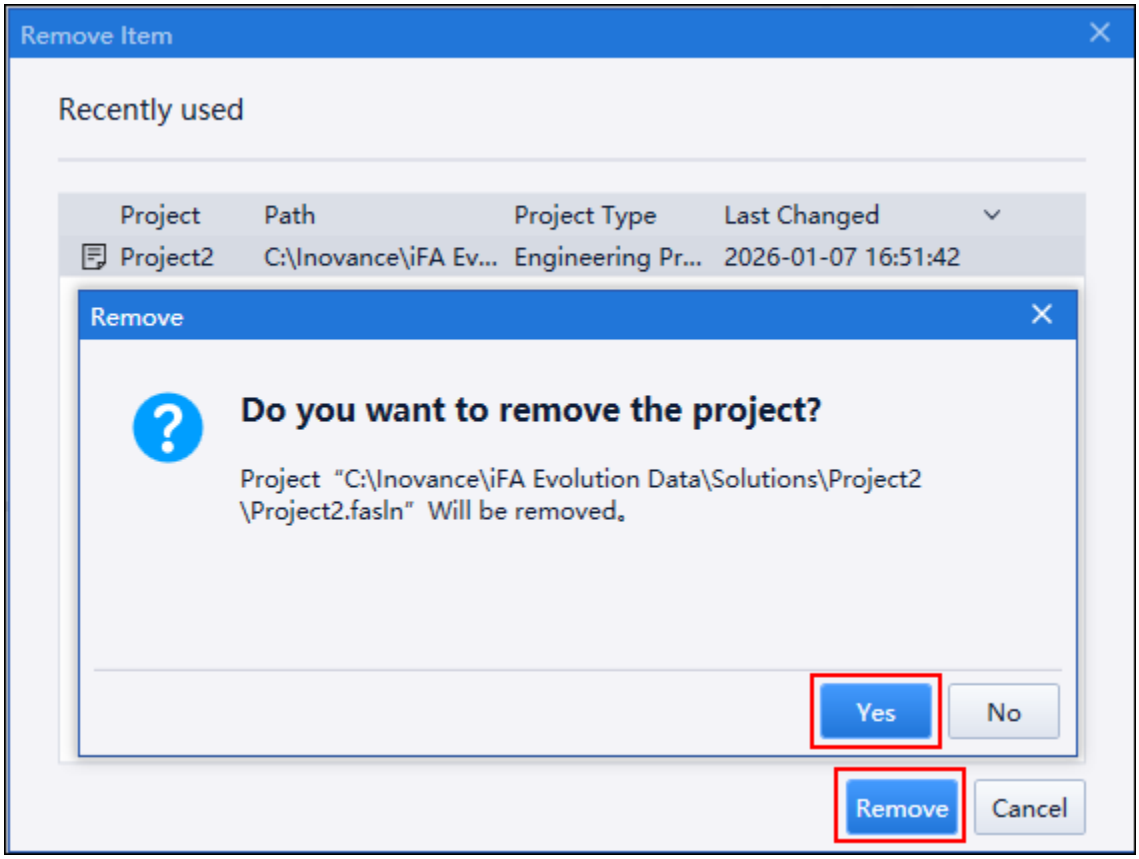
After the project is closed, the iFA interface appears as follows:

CAUTION



- If a project has not been saved, closing the project will prompt whether to save the current project.
- If any functions in the project cannot be closed, closing the project will trigger an error message and prevent the close operation.

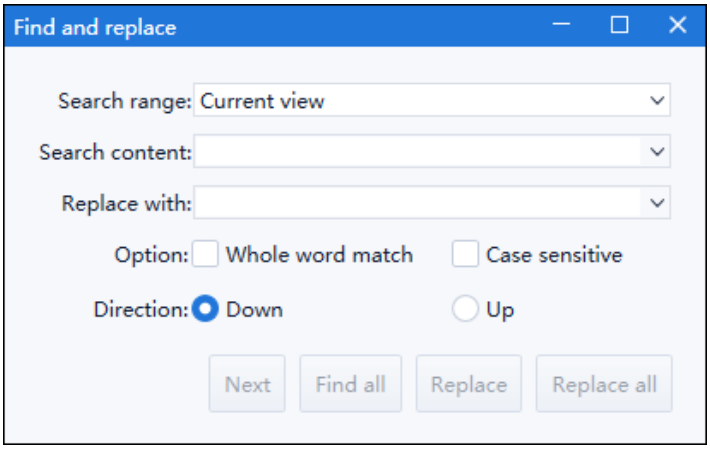
8.6 Removing a Project



With this feature, you can remove a project from the list of recently used projects, which will not delete the project data file.

Use one of the following methods to remove a project:

- On the startup interface, select the "Open project" tab, choose the desired project, click "Remove," and then click "Yes" in the pop-up window. The effect is shown below:



- Click "Remove" from the "Project" menu bar, access the Remove Project interface, select the desired project, click "Remove," and then click "Yes" in the pop-up window. The effect is shown below:

8.7 Finding and Replacing Within a Project

With this feature, you can search for and replace editable information in a project. Proceed as follows to meet specific requirements:

- Optimize the search by adding options.
- Specify the search area.
- Specify the search direction.

Function		Description
Scope	Current view	The page currently displayed in the workspace.
	Current device	Applies to PLCs only. • If a node in the project tree is selected, it refers to the device associated with the selected node. • If a view in the workspace is opened, it refers to the device associated with the opened view.
	Current device and source code library	If the source code libraries are already installed, search can be performed in the source code libraries and the current device simultaneously.
	Opened views	All views opened in the workspace.
	Selection	Applies to HMI devices only. This option is valid when the HMI screen is the current page. The Find and Replace operations are limited to the selected area.
Find		Enter up to 32 keyword characters for search.
Replace with		Enter up to 32 keyword characters for replacement.
Options	Case sensitive	• When this option is selected, the search mode becomes case-sensitive; • When not selected, the search mode ignores case differences, and this is the default state.

Function		Description
	Match whole word	• When this option is selected, the search mode is whole word matching; • When not selected, the search mode is fuzzy matching, and this is the default state.
	Forward	When this option is selected, the search starts from the current cursor position or selected location and proceeds forward.
	Backward	When this option is selected, the search starts from the current cursor position or selected location and proceeds backward. By default, the search starts backward.
Next		Click the "Next" button to perform the search and highlight the result. Click this button again to continue searching according to the specified conditions.
Find all		Click the "Find all" button to display all matching results in the "Find and replace" panel in the monitoring area; double-click a result to directly locate the specific object.
Replace		Click the "Replace" button to perform a single target replacement.
Replace all		Click the "Replace all" button to replace all matching items within the selected scope.

Start search

Follow the following steps to start the "Find and replace" function:

1. Open the "Find and replace" tab in one of the following ways:
   Menu bar: Choose "Edit -> Find and replace" from the menu bar.

   Shortcut: Press Ctrl+F on the keyboard.
2. Enter the search word in the "Find" input box.
3. Select the required option.
4. Select the search direction.
5. Click "Next". At this point, the first result is highlighted in the editor.
6. Click "Next" again to display the next result. Repeat this step as needed until the last result is displayed.
7. Click "Find all" to immediately locate all results.

Replace keywords

You can replace the search results one by one or all found results at once. Proceed as follows to perform replacement:

1. Open the "Find and replace" tab in one of the following ways:
   Menu bar: Choose "Edit -> Find and replace" from the menu bar.

   Shortcut: Press Ctrl+F on the keyboard.
2. Enter the search word in the "Find" input box.

3. Select the required option.
4. Click "Next" to start searching for a specified keyword. At this point, the first result is highlighted in the editor.
5. Enter the text you want to replace with in the "Replace with" input box.
6. Click the "Replace" button to replace a selected result with the specified text. Repeat this step until all desired results have been replaced.
7. Click "Replace all" to automatically replace all results immediately.

8.8 Reuse by Copy and Paste

Device scope

- Master devices: PLC, HMI, PC.
- Slave devices: servo, distributed I/O, I/O coupler.

Naming rules for objects created by copy and paste

- The new object name is the original name with "_x" appended, where x is a number. For details, see the following:

If the original object name does not end with "_x", the pasted new node name will be formed by appending "_x". The value of "x" is determined by searching from 1 until a unique value is found.

Example 1: If only one node is named "nodename", the first new object created by copy and paste will be named "nodename_1".

Example 2: Based on Example 1, the second new object created by copy and paste will be named "nodename_2"; other new objects follow the same pattern.

- If the original object name ends with "_x", the pasted new node name will be also formed by appending "_x". The value of "x" is determined by searching from 1 until a unique value is found.

Example 3: If three nodes of nodename, nodename_1, nodename_2 are present, and copy and paste operations are performed on nodename_1, the pasted new object name will be nodename_3.

Example 4: If two nodes of nodename_2 and nodename_3 are present, and copy andpaste operations are performed on nodename_3, the pasted new object name will be nodename_1; the second new object name will be nodename_4.

Copyable content

- Operation nodes in the project tree cannot be copied.

Example 1: iFA projects: "Add device" and "Device and network".

Example 2: PLC: "Device configuration" and "Online and diagnostics".

- All user-added resource nodes in the project tree can be copied.

Example 3: User-added devices in the project tree, such as PLC and HMI.

Example 4: Resources within devices in the project tree, such as POU and variable tables in the PLC; screens and recipes in the HMI.

Within-project copy and paste

Copy a device

- Copying and pasting a device is supported within a project. The pasted new device has the same configuration data as the original one.
- A device can be copied once and then pasted multiple times.
- Multiple devices can be copied and pasted at a time.
- Paste position.
  - Project tree root node (project name node). New devices will be added at the end of the device list.
  - Any device in the project tree. New devices will be added at the end of the device list.
- Operation areas and methods.
  - Operation areas: project tree, network view.
  - Operation methods: top menu, shortcut menu, shortcuts, toolbar buttons.

Copy resources under a device

- Copy and paste within a device

In the project tree, the sub-resources of a device can be copied and pasted into the same resource area of the current device.

- Copy and paste across devices

In the project tree, the sub-resources of a device can be copied and pasted into the same type of resource area of another device.

  - In case of no name conflict, the same name will be used for the new resource in the target area.
  - In case of a name conflict, a new name will be created for the new resource according to the above naming rules.

- Any copyable object can be copied once and consecutively pasted multiple times.
- Multiple child nodes under the same node can be selected using the Ctrl key for copy and paste operations.
- Exception handling: If multiple objects are copied and then some resources are deleted, a prompt box will appear stating that "Some objects have been deleted. Do you want to continue pasting the remaining objects?"

Options: Yes or No. Yes: Paste the remaining objects; No: Cancel the paste. The prompt appears only once, irrespective of the number of deleted objects.

- Folders under a device can be copied and pasted. All resources under the folders can be also copied and pasted. The position restriction rules for resources under folders also apply to the pastable positions.
- If the read-only access is granted for a resource in the project, the resource cannot be copied.
- Paste positions.
  - Select a parent node of the target device for pasting. The new resource can be pasted under the parent node or under a folder within the parent node.
  - If a resource with the same name already exists under the parent node of the target device, the newly pasted object will be renamed.
  - After the pasting is complete, the resource under the parent node is expanded automatically.

- Operation area and methods
  - Operation area: project tree.
  - Operation methods: top menu, shortcut menu, shortcuts, toolbar buttons.

Copy and paste permissions

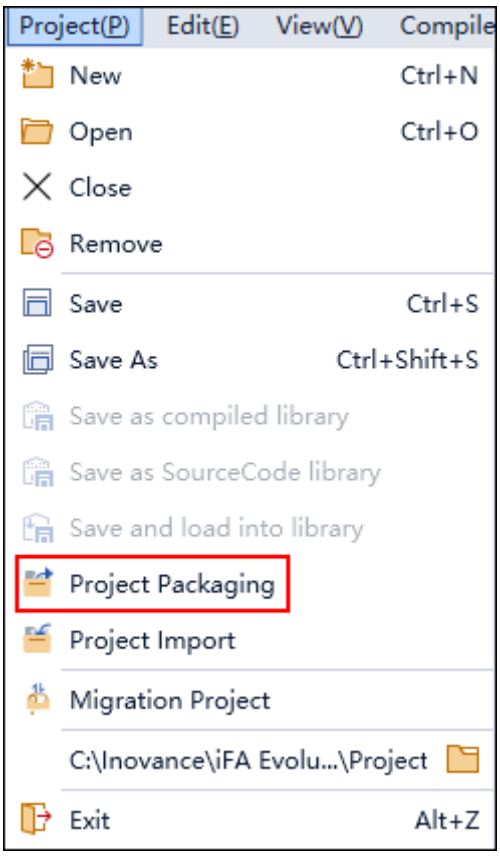
If the project-specific permissions have been configured for the current project, only users with write permissions can perform paste operations.

Across-project copy and paste

Open different projects in two iFA software in the same PC, and then perform copy and paste operations between the projects.

Copy an entire device

A device within a project can be copied and pasted into another project.



Copy resources within a project

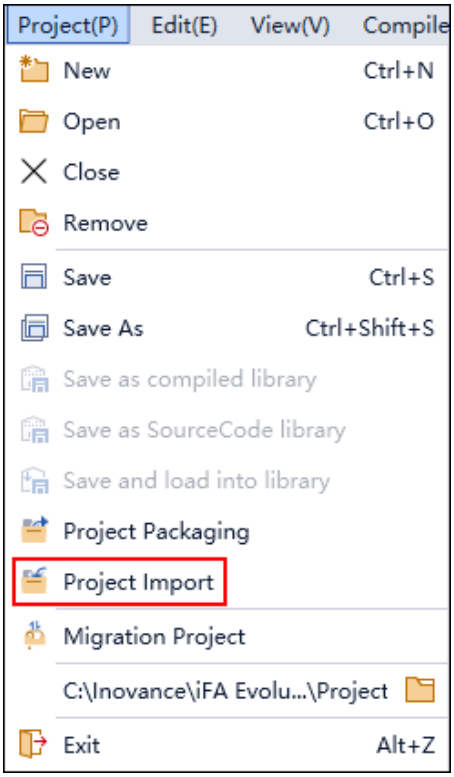
Child node resources under a device of a project can be copied and pasted into a resource node of the same type under a device in another project.

8.9 Packaging a Project

With this feature, you can save the active project in the current software to the local disk in a file (.slnpkg format) by specifying a new save path. The file name is the project name plus a timestamp.

When selecting "Project packaging" for a modified but not saved project, a prompt will appear asking whether to save the current project changes. You can select an option as needed.

Select the save path for a packaged project, and handle it follows when saving the project:



- If no file with the same name exists in the project path, the corresponding directory will be automatically created;
- If a file with the same name exists in the project path, you can choose to overwrite it or create a new file name.

> NOTE
>
> Project packaging does not affect the currently opened projects.

8.10 Importing a Project

With this feature, you can import the packaged project file into a project in the software.

Select "Project import" from the "Project" menu bar, double-click to select the .slnpkg file, and then import the file into the software.

8.11 Upgrading a Project

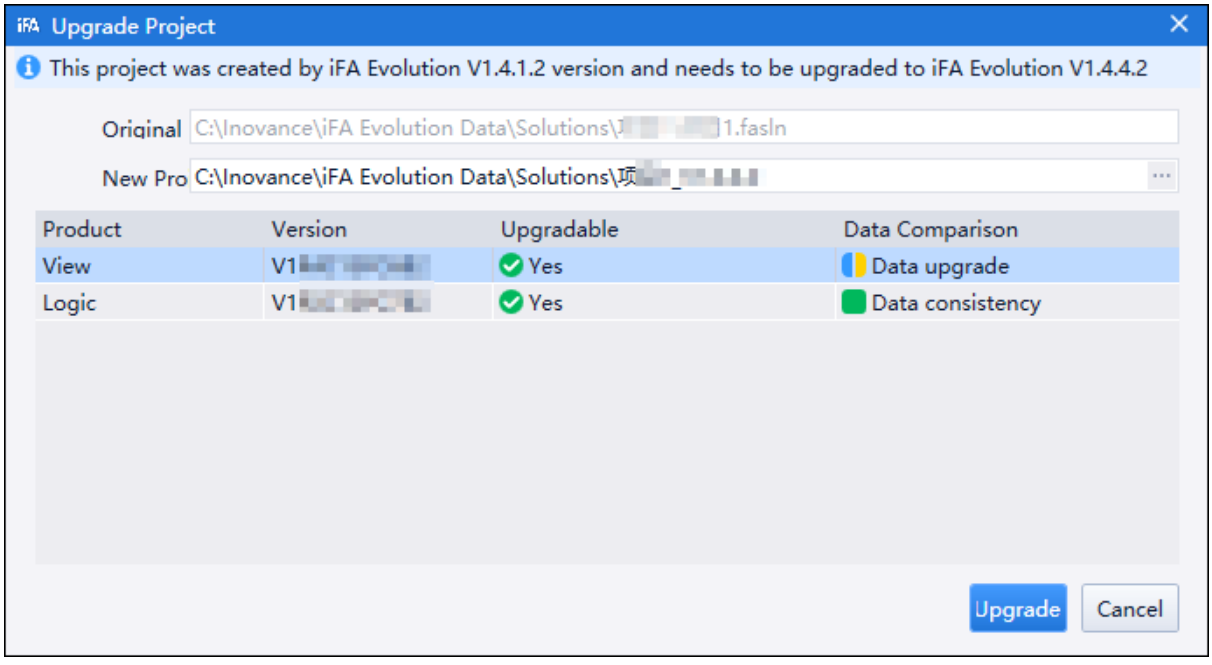
Projects created in the old versions (V1.3 and earlier) of the iFA Evolution cannot be opened before the software is upgraded to a later version.

You can see the system prompt for project upgrade when opening a project containing HMI products. You can directly open a project not containing HMI products.

Projects requiring upgrade will be upgraded under a new path, without any impact on the original project.

Upgrading a protected project

If you need to upgrade a project created in an earlier product version and protected by administrator permissions, the upgrade can be performed directly without permission restrictions, and the original project permissions are retained after the upgrade.
Operations on an upgraded protected project are still subject to permissions configured for the original project.



Upgrade method

Prerequisites

- All components in the original project have been installed;
- The new version software can be opened normally.

Procedure

1. Click the "Open" option from the "Project" menu.
   The "Open project" dialog box appears immediately, displaying a list of recently used projects.
2. Select a project from the list, and then click "Open".
3. If the target project is not in the list, click "Browse". Navigate to the specified project folder, and open the project file.
   The "Open project" dialog box appears immediately.
4. In the project folder, double-click to open the project file.
5. Click "Upgrade" to access the "Upgrade project" dialog box.
   Original Project: Displays the storage path of the original project, which is not editable.
   New Project: Displays the default storage path and new name of the new project, which are editable. The name must comply with the project naming rules.
   Upgrade Information: Displays the information about Product, Version, Upgradable, and Data Comparison.

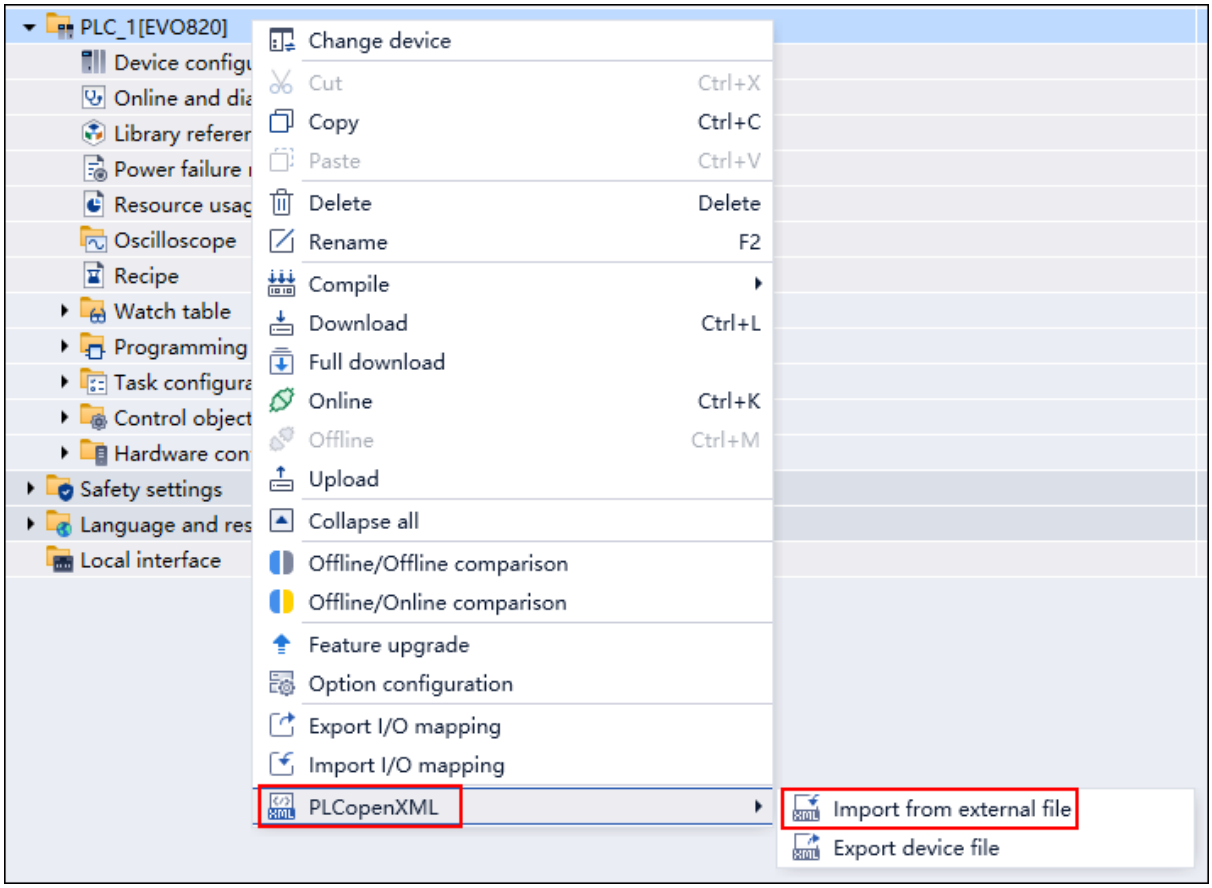
6. Click "OK".
   The project is upgraded and then the upgraded new project is opened.

8.12 Importing/Exporting a PLCopenXML File

PLCopenXML is used for programming standardization. It supports exporting XML files for editing with third-party tools and re-importing them into the software.

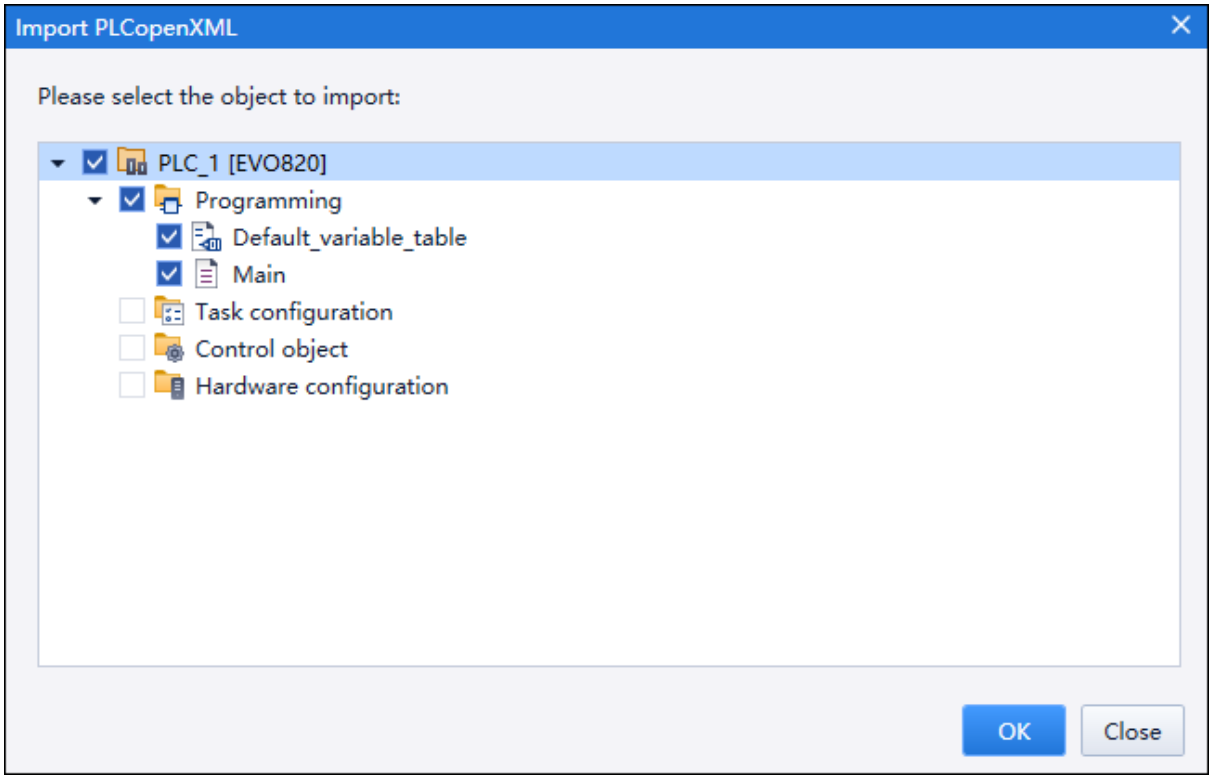
NOTE

- This feature requires software V1.4.2.5 or later and is not currently supported by the Safety PLCs.
- Currently, import or export is not supported in the following scenarios:
  - If there are duplicate names among the GV (global variable table), DUT (user-defined data types), and POU (program organization units), import with overwrite will fail. For example, if the global variable table has the same name as the PRG, the import will fail and the monitoring area will display a warning.
  - The POUs are encrypted.
  - If the PLC type or version is inconsistent, the import of hardware configuration nodes will fail.
  - Only ST (structured text), LD (ladder diagram), and CFC (continuous function chart) languages can be imported and exported, while other languages are not supported yet.



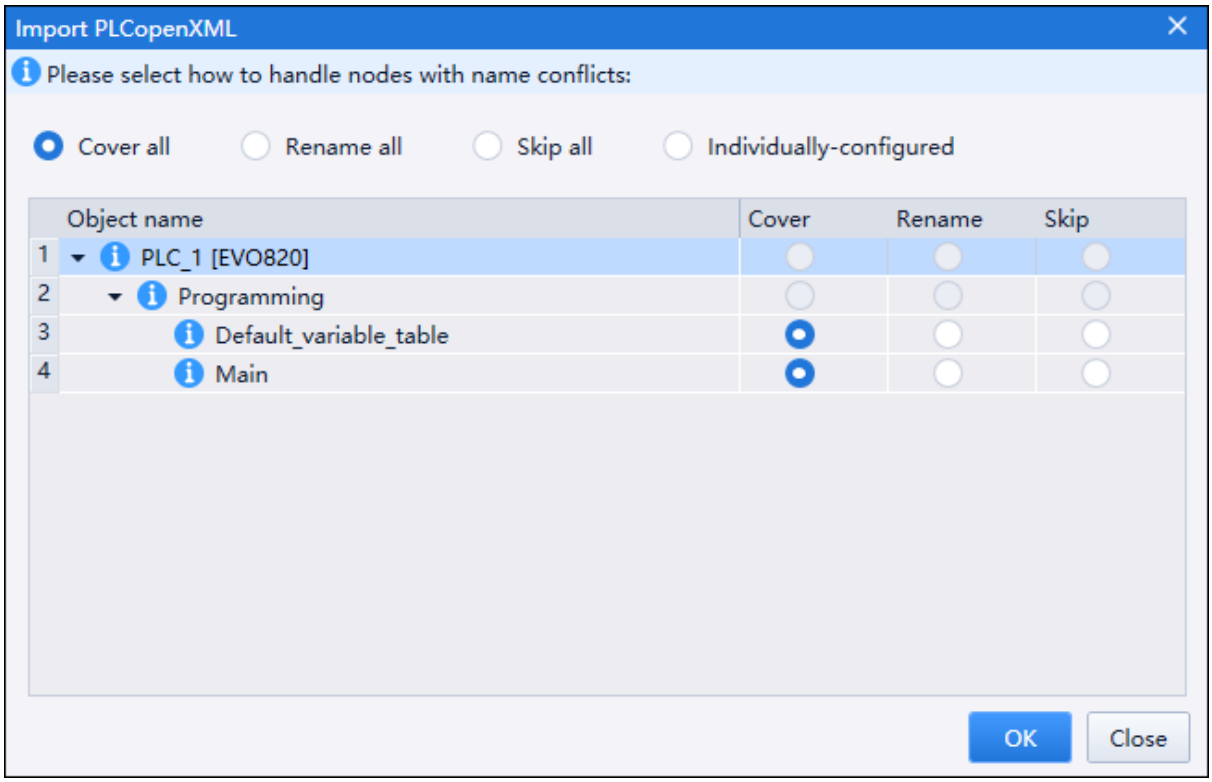
Import a PLCopenXML file

Prerequisites



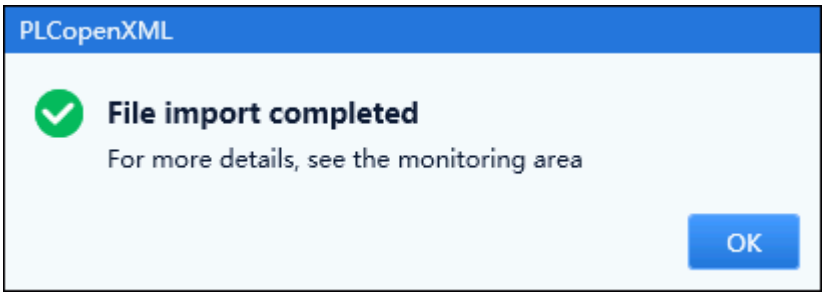
- A PLC has been created.
- The XML file conforms to the PLCopenXML standards.

Procedure



1. Right-click the added PLC in the left project tree and select "PLCopenXML -> Import from external file".

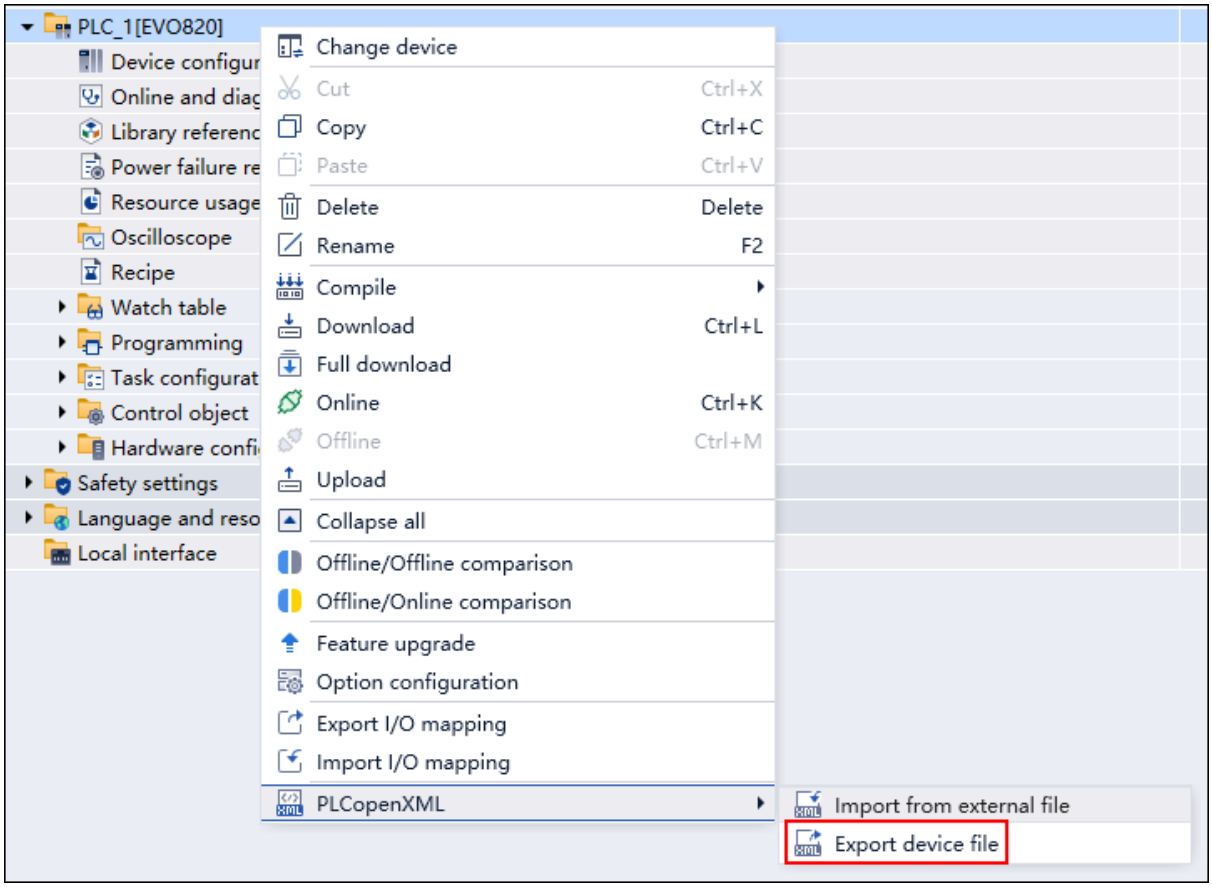
2. In the opened dialog box, select an appropriate XML file, click "Open", and the "Import PLCopenXML" dialog box will appear. Select the target object and click "OK".



3. After clicking "OK", select how to handle node name conflicts.

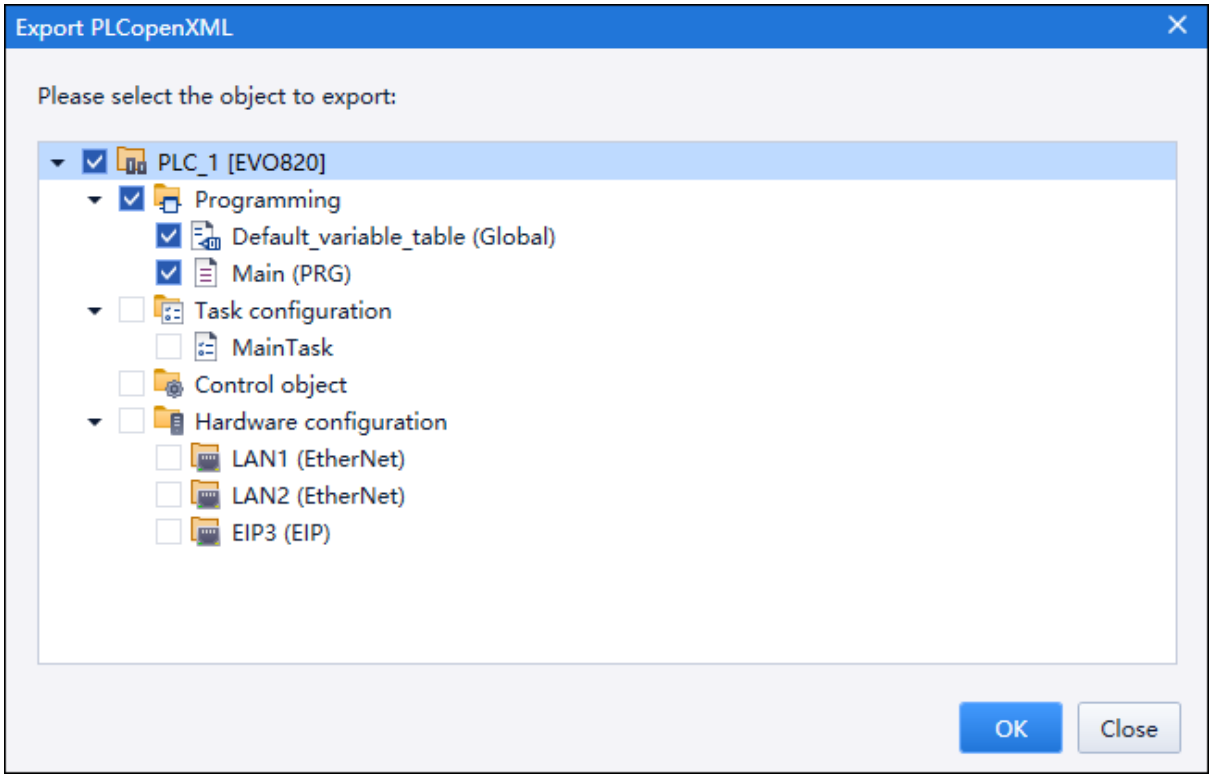
- Overwrite all: Overwrite nodes in the current project.
- Rename all: Rename all according to the current renaming rules.
- Skip all: Do not perform import.
- Individually configure: Process the imported list individually.

4. After clicking "OK", the file import is complete, and relevant information is displayed in the monitoring area.



Export a PLCopenXML file

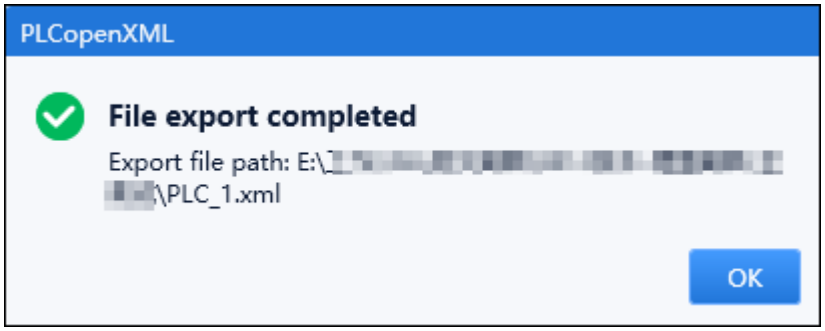
Prerequisites



A PLC has been created.

Procedure

1. Right-click the added PLC device in the left project tree and select "PLCopenXML -> Export device file".

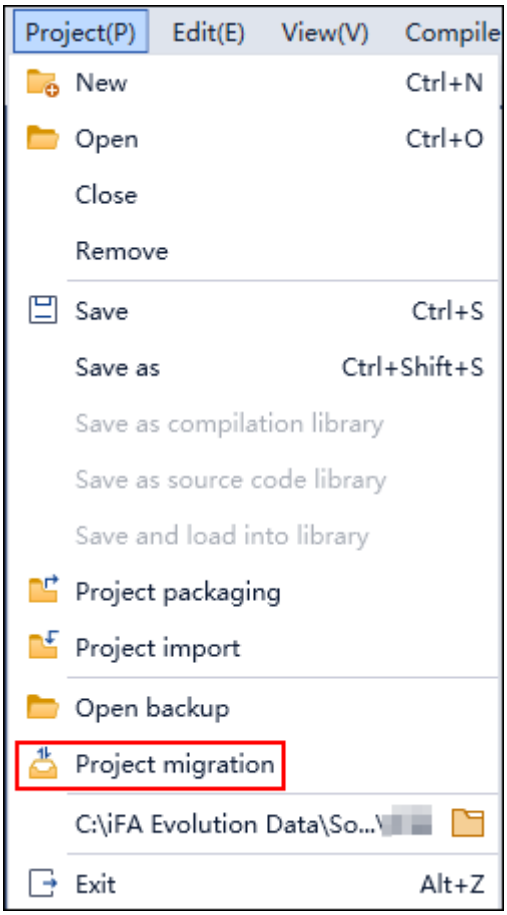


2. In the opened "Export PLCopenXML" dialog box, select the target object and click "OK".

3. In the opened dialog box, select the export path. You can define the file name according to naming conventions. The default file name is "Device Name.xml".

4. Click "OK" to complete the file export. After successful export, the system will display a dialog box showing the path of the exported file.

8.13 Migrating a Project



With this feature, you can migrate projects created in the original InoProShop or InoTouchPad software to the iFA.

Prerequisites

- A project has been created in the iFA.
- The project file with an extension of .ino/.itp/.transform is ready.

Procedure

1. Choose "Project > Project migration" without adding any devices.

2. Select the target project file and then click "Open".

   After successful import, the import result is displayed in the monitoring area.

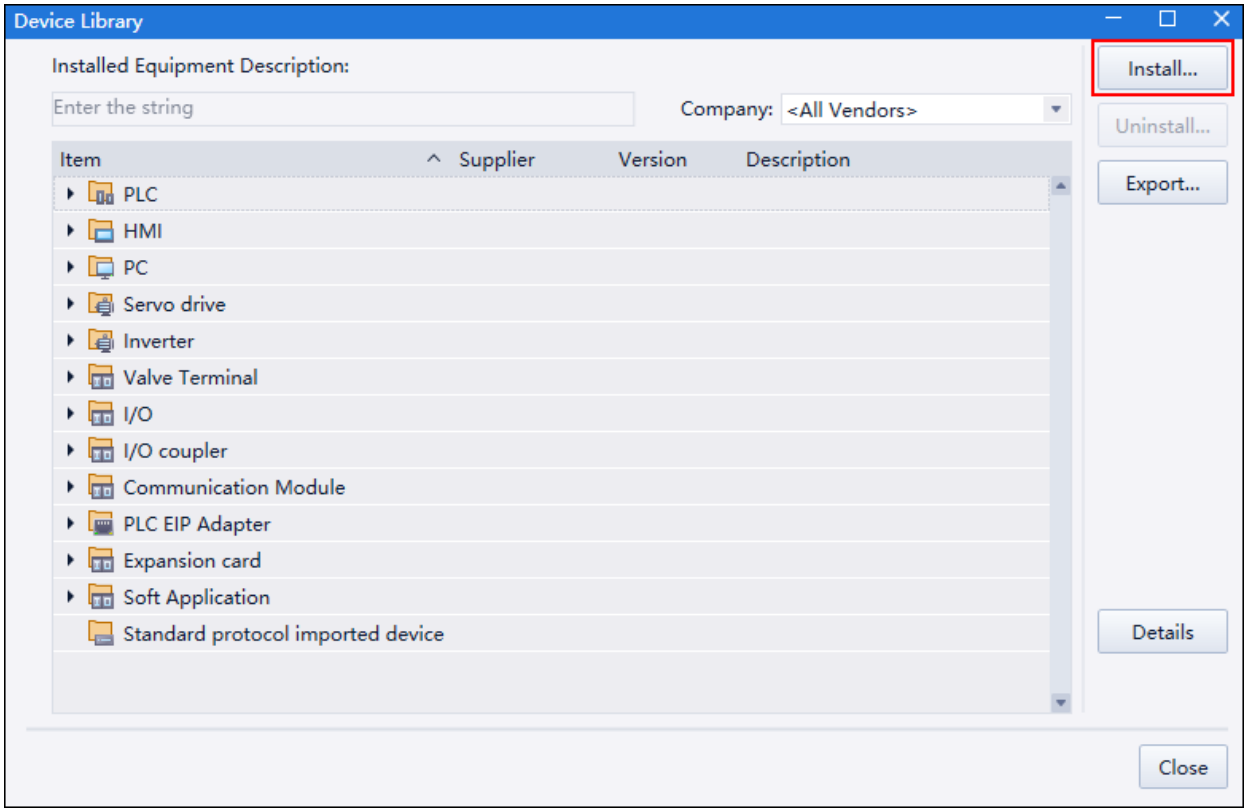
NOTE

- A project can be imported when multiple PLCs or HMIs are used.
- Repeated import is supported.
- The imported projects are named according to the device names. If the new name duplicates an existing name, it will be sequentially named as Device_1, Device_2, and so on.

8.14 Collapsing Project Child Nodes with One Click

When multiple levels of expanded child nodes exist under a device or folder node, making the list too long to locate items easily, right-click the device/folder node and select "Collapse all" to instantly collapse that node and all its child nodes, restoring the initial state.

8.15 Using the Device Library



8.15.1 Installing a Device

You can select ZIP, XML, EDS, and DVC files for offline device installation to add devices to the device library.

Procedure

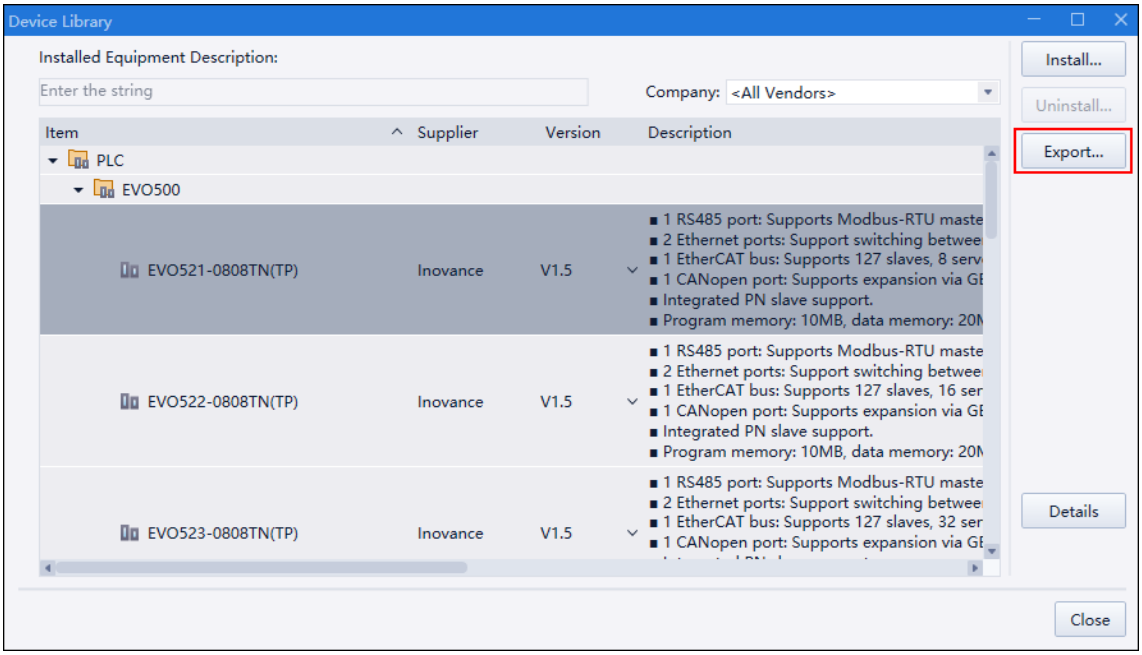
1. Click the "Tools" option in the menu bar, and then select "Device Library" to access the Device Library dialog box.

2. Click "Install Device" in the right-side menu bar.

3. Select a supported file type in the appropriate path, and then click "Open" to import the file. You can also select multiple device description files at a time.

4. After successful import, click "OK."

After the device installation is complete, the newly installed device appears under the "Add Device" node in the project tree and in the "Device List" on the right-side menu bar.



8.15.2 Exporting a Device

You can export the selected devices in the device library to generate a DVC file.

Procedure

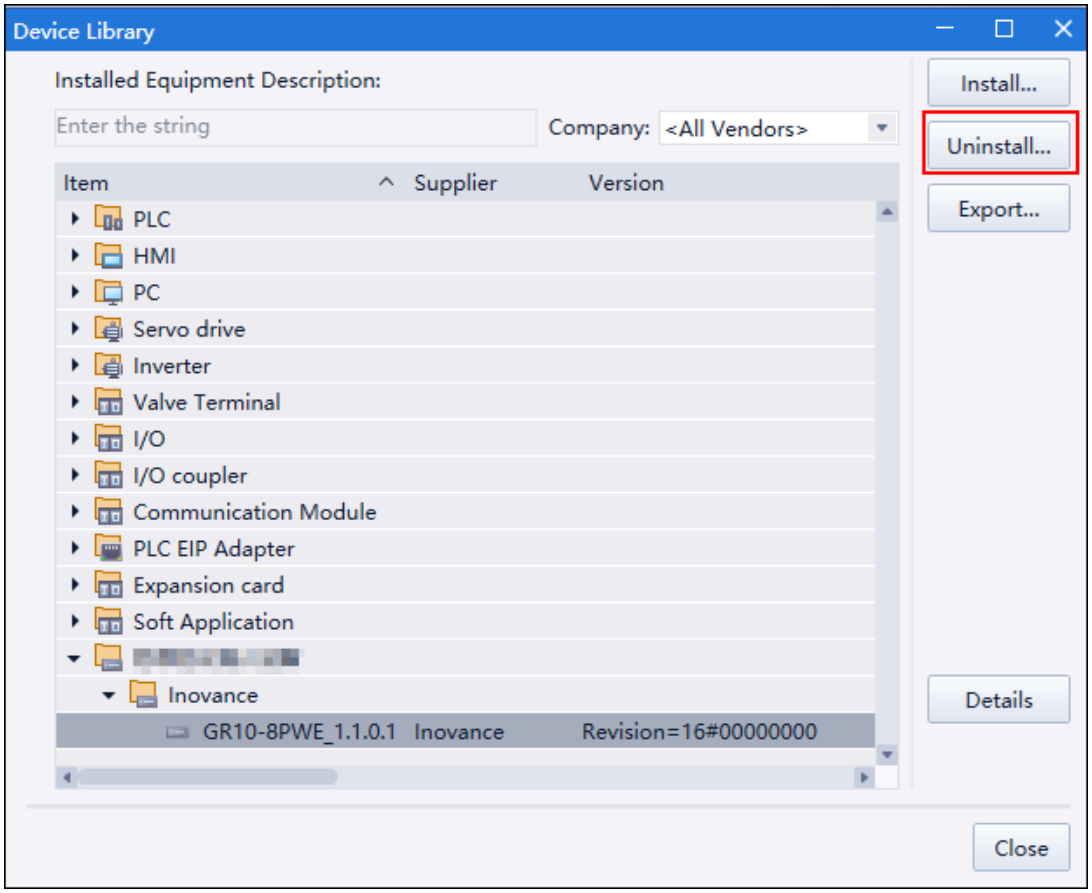
1. Click the "Tools" option in the menu bar, and then select "Device Library" to access the Device Library dialog box.

2. Search for and select devices using the device description, company, or device information fields.

3. Click "Export Device" on the right-side menu bar.

4. Select a path, and then click "OK" to complete the device export.

After the device is exported, a DVC file is generated in the specified path.



8.15.3 Uninstalling a Device

With this feature, you can uninstall third-party devices imported into the device library to prevent their use in projects. Devices pre-installed in the software cannot be uninstalled.

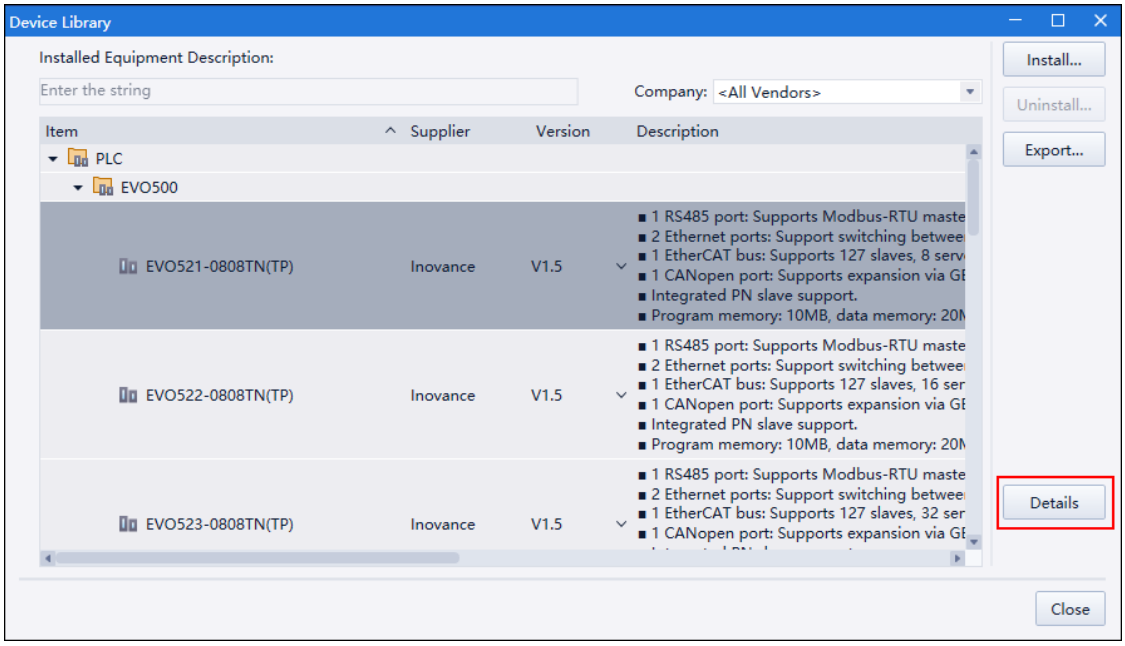
Procedure

1. Click the "Tools" option in the menu bar, and then select "Device Library" to access the Device Library dialog box.

2. Search for and select third-party devices using the device description, company, or device information fields.

3. After selecting one or more third-party devices, click "Uninstall Device" in the right-side menu bar, and then click "OK".

The uninstalled devices cannot be found under the "Add Device" node or in the "Device List".



8.15.4 Device Details

You can view the detailed information about the selected device.

Procedure

1. Click the "Tools" option in the menu bar, and then select "Device Library" to access the Device Library dialog box.

2. Search for and select devices using the device description, company, or device information fields.

3. Click "Details" in the right-side menu bar to view the device details.

9 Project Security Management

9.1 Overview

In the fully integrated iFA Evolution, permissions are divided into project permissions, feature permissions, and device permissions.

- Project permissions: permissions for encrypting projects, managing members and roles, etc.
- Feature permissions: permissions for editing, using, and viewing functions.
- Device permissions: built into the devices; controlling internal parameters or operating permissions on the devices; unrelated to the iFA Evolution.

Relationships among permissions

- Relationships between project permissions/roles and user-defined permissions/roles
  - The relationships between project permissions and roles are fixed and cannot be changed;
  - The user-defined permissions are limited to be used during the operation of the monitoring system;
  - User-defined roles can be linked to both built-in system permissions and user-defined permissions, enabling more flexible permission management.
- Relationships between project permissions and device permissions
  Project permissions and device permissions are independent of each other. If a user has permissions for editing and downloading projects in the development environment, it does not guarantee that the user can download a project successfully. If device permissions are activated, the device will perform permission verification in the download process.
- Relationships between PLC upload password and other permissions
  The PLC project upload password (for project encryption) is independent of project permissions. Activating PLC device permissions represents activating the PLC upload password; projects can be uploaded only when the administrator password is entered. Each PLC is activated and configured separately, and the settings are saved within the PLC. If the device permissions are not activated on the PLC, projects can be uploaded without password input.
- Relationships between POU permissions and other permissions
  POU permissions are configured separately and are independent of project permissions. The POU can be opened with the POU password, irrespective of offline or uploaded projects.
- Relationships between PLC hardware parameter settings and other permissions
  PLC hardware parameters, including IP address, Wi-Fi function enable (only for large-scale PLCs), and Wi-Fi parameters, can be configured for both offline and online projects. These parameters can be also configured in the iFA software without any project.

  NTP settings are synchronized with project settings and can also be performed online on the device diagnosis page.

  If the PLC permission protection is enabled, the user logging into the PLC will be subject to permission verification before setting parameters. Only after successful permission verification, the user can modify the parameters.
- Relationships between PLC Web user permissions and other permissions
  PLC Web is activated on the CPU Properties page of the iFA Evolution, and its login username and password must be configured. These settings are saved with the project and downloaded to the PLC. The

Web username and password must be configured and downloaded separately for each PLC, independent of the iFA Evolution.

- Relationships between CPU properties and feature entry points
  √ indicates the feature entry point supports setting the CPU properties; × indicates it does not support.

Feature	iFA Evolution			Web Client
	Project CPU Properties	Project CPU Online Diagnostics Page	Interface Independent of Projects	Web Page
Activating PLC Web	√	×	×	×
PLC Web user	√	×	×	×
Adding variables to be monitored via Web	√	×	×	×
Setting PLC Wi-Fi parameters	×	×	√	√
IP	√	×	√	×
NTP	×	√	×	×
Activating OPC UA	√	×	×	×
Setting OPC UA parameters	√	×	×	×
Updating firmware	×	×	√	×
Exporting device data	×	×	√	×
Restoring factory settings	×	×	√	×

- Relationships between development permissions and operation permissions
  Due to the special nature, the monitoring system is generally developed and operated by different roles. Development engineers are responsible for project development, while on-site operation engineers are responsible for operating devices in running mode. Development and operation permissions are both configured in the iFA Evolution. Development permissions take effect immediately upon configuration, while operation permissions take effect after the project is downloaded to the runtime environment and started.
- Relationships between drive permissions and other permissions
  The built-in drive permissions are independent of project permissions. Each drive has its own password set and downloaded separately. If the user using the iFA Evolution has the permission for debugging a drive (or the PLC code debugging permission for drives connected to the PLC), the user can perform the drive debugging. For independent drive debugging software (IDE) without PLC, the debugging software permissions are controlled by the iFA Evolution, but the drive's internal permissions undergo a secondary verification.

Permission categories

Category		Permissions
Project permissions	Project permissions	Encrypting projects, managing members, managing roles
Feature permissions	PLC feature permissions	Editing PLC hardware, editing PLC programs, downloading PLC projects, editing PLC libraries
	Drive feature permissions	Editing drive hardware, editing drive programs, downloading drive projects, editing drive libraries
	Monitoring system feature permissions	Editing the monitoring system, downloading the monitoring system, editing monitoring system libraries, managing the monitoring system, operating the monitoring system, viewing the monitoring system
	User-defined permissions	A supplement to built-in system permissions. The permission name can be self-defined, with a default name of "Right_x". Up to 32 user-defined permissions can be created, mainly including detailed operation permissions related to monitoring system, such as assigning permissions for buttons A and button B separately to a role (enabling precise control over operation permissions).

9.2 Feature Permissions in User Management

Permission management in the iFA Evolution include two categories:

- Permissions bound to user accounts (username and password must be set and are managed in the iFA Evolution).
  The permission categories and descriptions are as follows:

Category			Description
Role category	Project configuration	Project configuration administrator	Has all permissions in the project, including global development, device development, and device operation permissions.
		Project configuration member	Assigning roles
	PLC development	PLC engineer	Editing PLC hardware, editing PLC programs, editing PLC libraries, downloading PLC projects (For PLC runtime password authentication, see 10.11.6 PLC Permission Configuration) Note: For the relationships between the PLC-related operation scopes and built-in system permissions, see 9.14 PLC Permissions.

Category				Description
	Drive	Drive engineer		Editing drive hardware, editing drive parameters and programs (password authentication performed by the drive when parameters are modified), editing drive libraries, downloading drive projects
	Monitoring	Development permissions	Monitoring engineer	Editing monitoring parameters and screens, downloading monitoring projects to target devices, editing monitoring libraries and templates, managing users in running mode, operating and viewing the monitoring system in running mode
		Operation permissions	Monitoring administrator	Managing users in running mode, operating and viewing the monitoring system in running mode
			Monitoring operator	Operating and viewing the monitoring system in running mode
			Monitoring observer	Viewing the monitoring system in running mode
	User-defined roles			A supplement to built-in system roles; allows binding permissions (all permissions except project encryption /decryption and user creation/deletion) to meet on-site needs
Category	Development	PLC		Configuration, modifying PLC settings
		Monitoring		Configuration, modifying monitoring settings, editing monitoring templates
		Drive		Independent drive commissioning software, drive commissioning, parameter modification
		User-defined permissions		A supplement to built-in system permissions. The permission name can be self-defined, with a default name of "Right_x". Up to 32 user-defined permissions can be created, mainly including detailed operation permissions related to monitoring system, such as assigning permissions for buttons A and button B separately to a role (enabling precise control over operation permissions).

- Permissions not bound to user accounts (permission granted upon password match). The permission categories and descriptions are as follows:

Category			Description
Permissions set independently but managed by username and password	Web server access	Web user	Username and password are set independently. For details, see 10.6.14.7 Web Server Configuration.

Category			Description
	OPC UA access	Username and password	Set independently for each device. For details, see 10.6.14.5.2 Configuring10.6.14.5.2 OPC UA server.
		Credential	Credentials are managed independently for each device.
Permissions managed solely by password	PLC program protection		Read-only permission
			Comparison permission (write protection)
	PLC built-in access permission	Administrator	Full access to all device functions
		Operator	Modifying parameters unrelated to program operation
		Observer	View-only permission without any operation permission
		Anonymous	Viewing diagnostic information without password
	Online setting of PLC hardware parameters		IP address
			NTP server
			Wi-Fi
	Drive access permission		Modifying parameters with the drive password
	Drive	Modifying parameters	Password verification by the drive
		Viewing parameters	Password verification by the drive
	Uploading	Uploading PLC projects	Projects can be uploaded with the upload password.
		Uploading monitoring projects	Projects can be uploaded with the upload password.

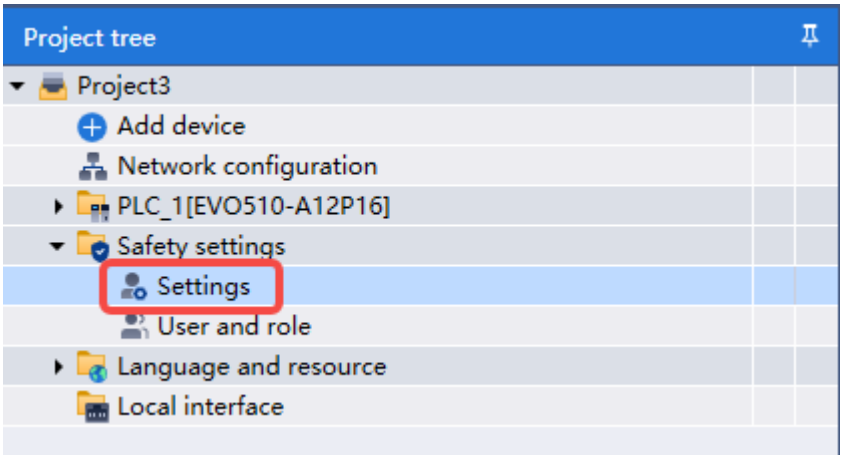
Permission setting

In the iFA Evolution, the permissions include built-in system permissions and user-defined permissions. Among the built-in system permissions, all permissions are project configuration permissions except "Monitoring operation" and "Monitoring view," which are operation permissions.

In the "User and role" configuration item, select the "Permissions" tab. You can add permissions by double-clicking "Add permission" in the permission list. Comments can be added for newly added permissions, but the comments for other system permissions cannot be modified.

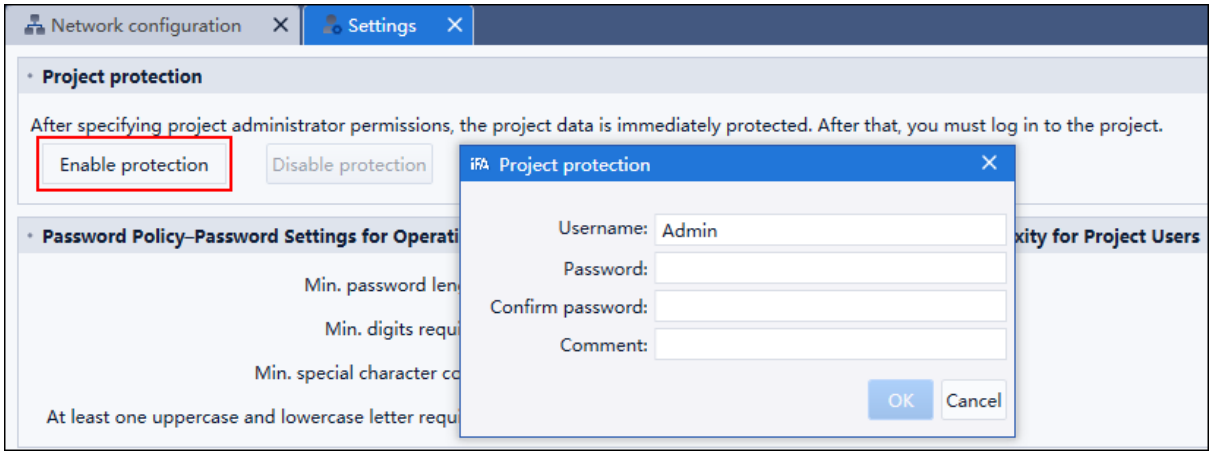
NOTE

If the logged-in user does not have the required permission, the following will occur:



- In editing mode, the user will be unable to perform modification. Any modification attempts will trigger a pop-up window indicating that the current user lacks modification permission and is allowed to view information only.
- Clicking the Download button will trigger a pop-up window indicating that the current user lacks download permission; this also applies for operation permissions of the monitoring system.
- If a module is not installed in the user's software, the roles and permissions for that module will not be displayed on the page.

9.3 Enabling Project Protection



You can protect the project data in a project by managing users to prevent unauthorized access. To enable project protection, create a project configuration administrator, who can subsequently create other users and assign them appropriate roles and permissions. Only users with sufficient permissions can open and modify the project.

Procedure

1. In the project tree, select "Safety settings" and then double-click the "Settings" tab.

2. Click "Enable protection", and then "Project protection" dialog box appears.

3. Enter a username.
4. Enter the password.
   When activating user management for the first time, follow these password policies:

   “Min. password length” : The minimum number of characters in the user password must be between 3 and 32, with a default value of 8.

   “Min. digit count” : The minimum number of digits in the user password must be between 0 and the minimum password length, with a default value of 1.

   “Min. special character count” : The minimum number of special characters in the user password must be between 0 to the minimum password length, with a default value of 0.

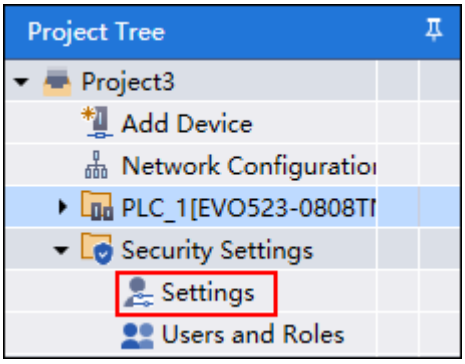
   “At least one uppercase and lowercase letter required,” which is optional. When this option is selected, the password must meet this requirement. This option is selected by default.

   The project administrator can adjust these password policies as needed. For details, see 9.5 Setting Password Policies.
5. Re-enter the password for confirmation.
6. When necessary, enter the comments.
7. Click "OK" to enable project protection and encrypt the project data.

> NOTE
>
> The first user created in the system is the project administrator, who can create other roles.

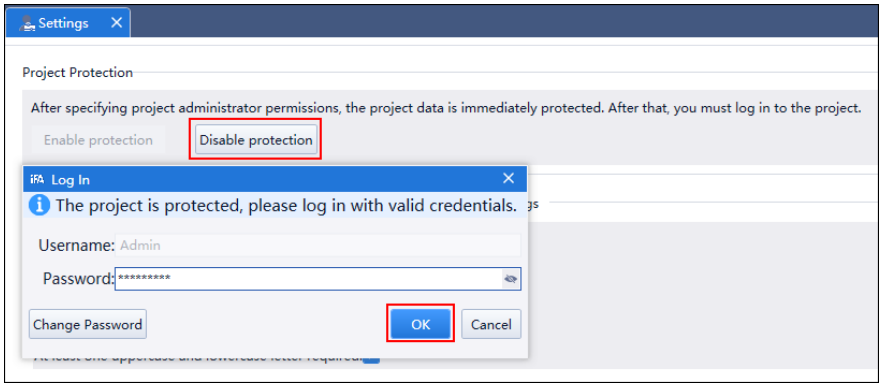
Subsequent operations

When project protection is enabled, a pop-up window will appear during project login, which states that "This project is protected. Log in with valid credentials." Enter the appropriate username and password in the login field, and then click "OK" to access the project. You can only perform operations allowed by your permissions after logging in.



After logging in as the project configuration administrator, you can create new users, assign them appropriate roles, and add user-defined roles and permissions. For details, see 9.7 Managing Users, 9.8 Managing Roles, and 9.9 Assigning Roles.

9.4 Disabling Project Protection



When project protection is enabled, the project configuration administrator can cancel the project protection at any time, and then the project data will no longer be encrypted.

Procedure

1. In the project tree, select "Safety settings" and then double-click the "Settings" tab.

2. Click "Disable protection," and enter the project configuration administrator's password in the pop-up window.

3. Click "OK" to disable the project protection; no login is required for subsequent access to the project.

9.5 Setting Password Policies

The following are the restrictions regarding the project configuration administrator and users, including usernames, passwords, and comments.

Username

The rules for entering a username are as follows:

- The number of input characters cannot exceed 128.
- The username can consist of letters, numbers, and special characters. Supported special characters include (~`!@#$%^&*()-_=+[]{}|\;:,.<>/? “”).

Password

You can flexibly set your own password rules to meet different requirements on password complexity.

“Min. password length” : The minimum number of characters in the user password must be between 3 and 32, with a default value of 8.

“Min. digit count” : The minimum number of numeric characters in the user password must be between 0 and the minimum password length, with a default value of 1.

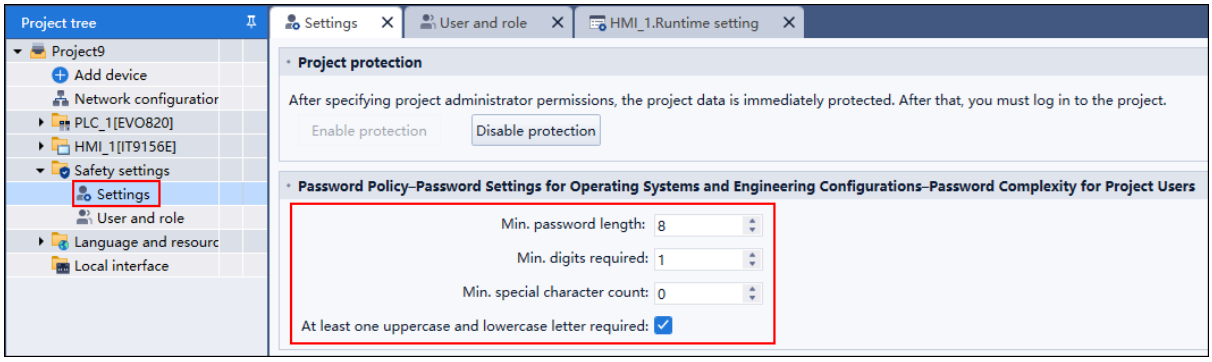
"Min. special character count" : The minimum number of special characters in the user password must be between 0 to the minimum password length, with a default value of 0.

"At least one uppercase letter and lowercase letter required," which is optional. When this option is selected, the password must meet this requirement. This option is selected by default.

Supported characters for usernames and passwords:

- ~`!@#$%^&*()-_=+[]{}|\;:,.<>/?
- 0123456789
- A...Z a...z

Comment



The rules for entering comments are as follows:

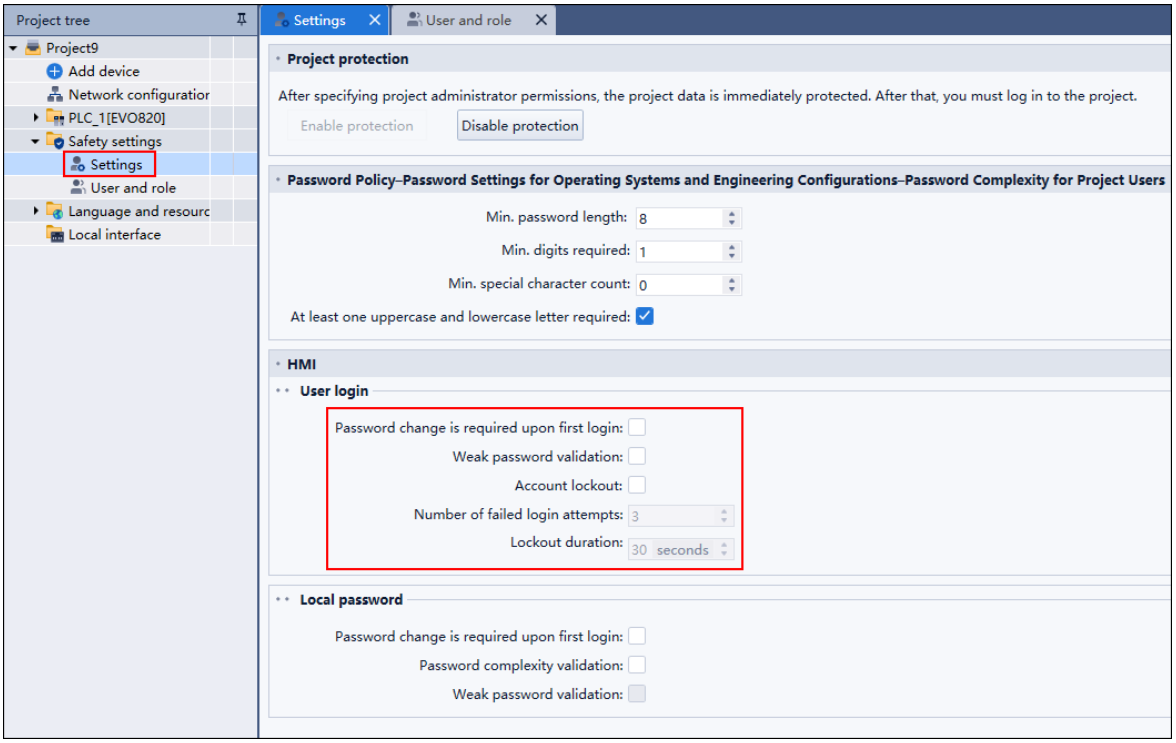
- The number of input characters cannot exceed 128.
- The input content is unrestricted and may be left empty.

Procedure

Proceed as follows to set the password policies:

1. Open a project for which you want to set the password policies.
2. In the project tree, select "Safety settings" and then double-click the "Settings" tab.
3. Perform the required settings.

4. Save the project, and then the password policies take effect.



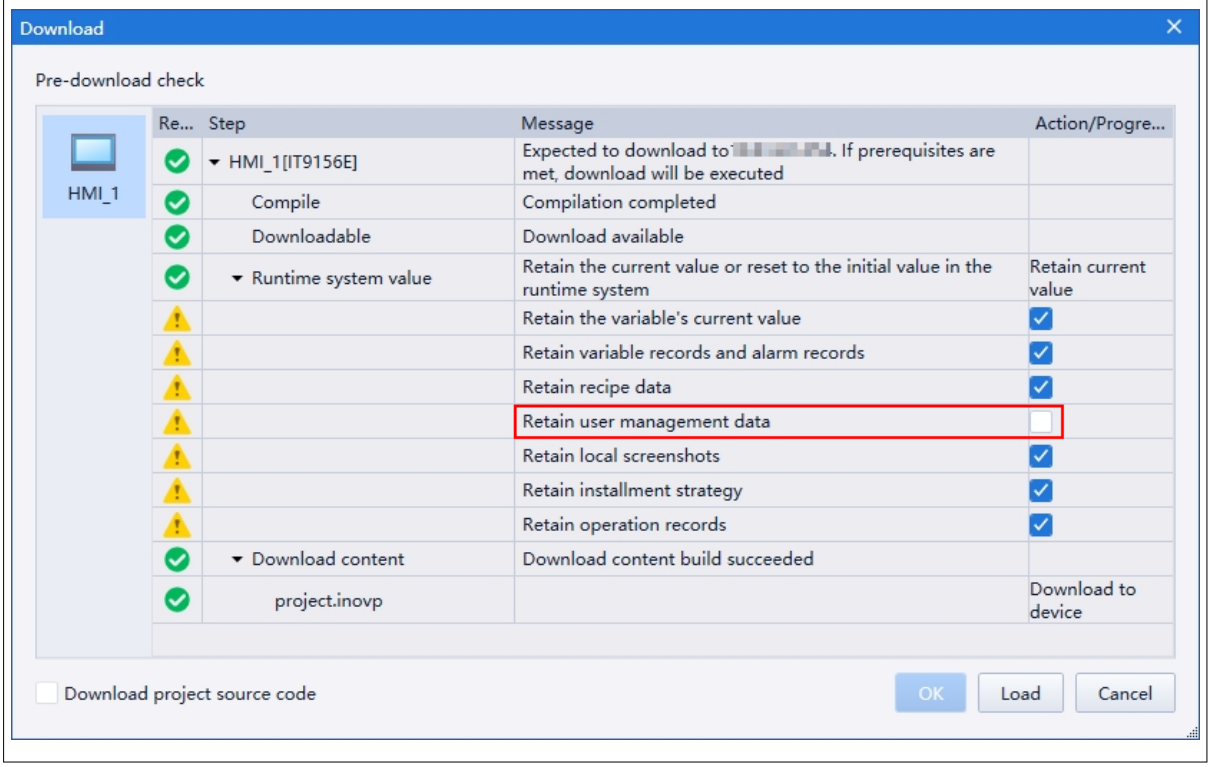
> **NOTE**
>
> Password storage uses AES-128 encryption, ensuring secure, reliable, and efficient protection of stored passwords.

9.6 HMI Security Authentication Policies

Set the security authentication policies for HMI user login and local password.

User login

1. In the project tree, select "Safety settings" and then double-click the "Settings" tab.
2. Set the security authentication policies for HMI user login.

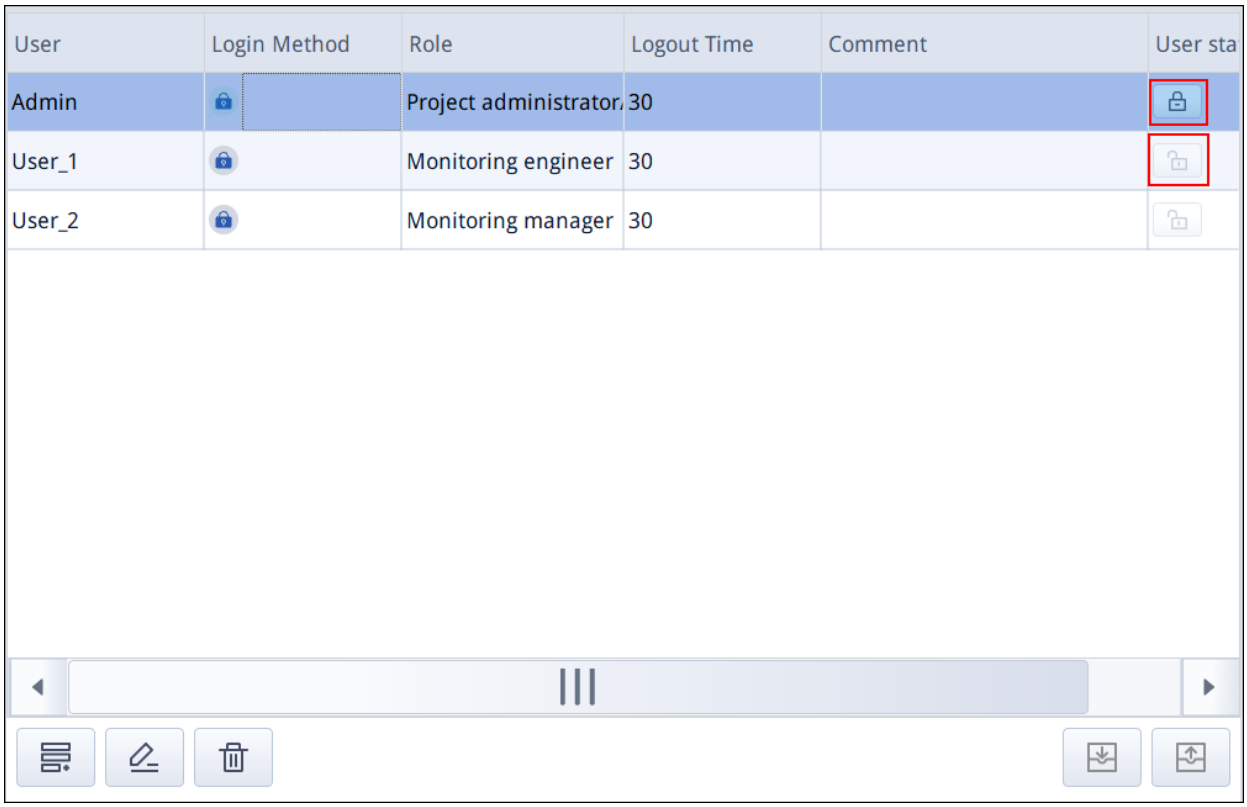


Item	Description
Password change is required upon first login	Unchecked by default. Once this option is checked, users must change their passwords upon first login. The new password must comply with the password complexity requirements. For details, see 9.5 Setting Password Policies.
Weak password validation	Unchecked by default. Once this option is checked, the password strength will be validated; if a weak password is identified, set a new password. Weak passwords: 1QAZ@wsx, Aa1!aaaa, Passw0rd!, Qwerty1@, Hello123#, Abc123!@
Account lockout	Unchecked by default. Once this option is checked, the system will keep track of the number of failed login attempts. When the number of failed login attempts reaches the setpoint, the account will be locked and cannot be used to log in during the configured lockout duration. NOTE ◦ During account lockout, the lockout duration remains active even after the device is restarted. ◦ After the lockout duration expires, you can attempt to log in again. If the password is still incorrect, the failed login attempts will not be counted, and the account will be immediately locked until the lockout duration expires again.

Item	Description
Number of failed login attempts	When the "Account lockout" option is checked, you can define the number of failed login attempts. Once exceeded, the account will be locked. The default value is 3 attempts, with a configurable range of 1 to 9. Note: Login attempts without a password are considered invalid and not counted toward the failed login attempt limit.
Lockout duration	When the "Account lockout" option is checked, you can define the lockout duration, during which the account will be prevented from logging in. The default value is 30s, with a configurable range of 1s to 3600s.

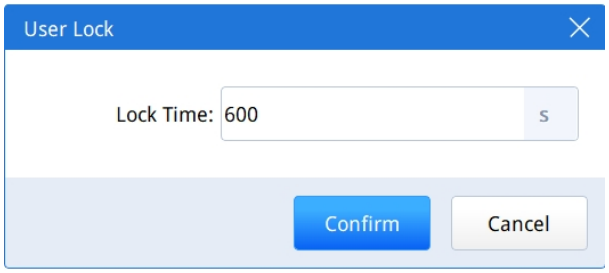
3. After the previous step is done, all subsequent HMI login attempts will be authenticated according to the configured security policies.

NOTE



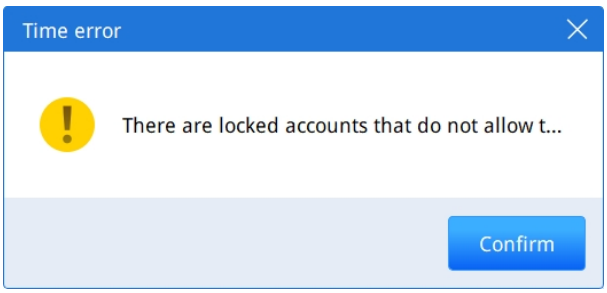
If the "Retain user management data" option is checked before the project download, the account status, lockout duration, and current number of failed login attempts remain active; if unchecked, all data will be cleared.

Manual account lock/unlock



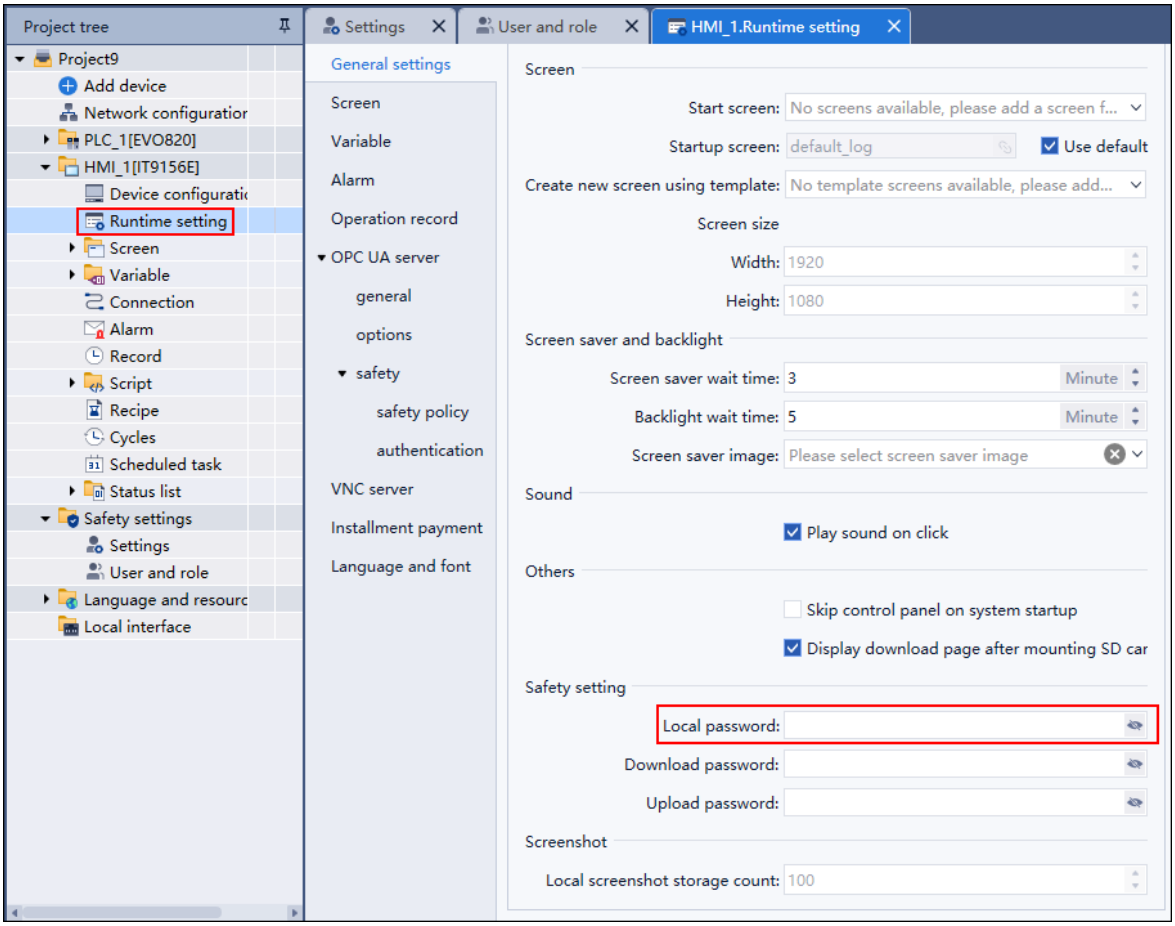
The 13.3.5.4.5 User View control is used to display and manage user information for the current device. You

can view the user status and manually lock/unlock accounts through this control.



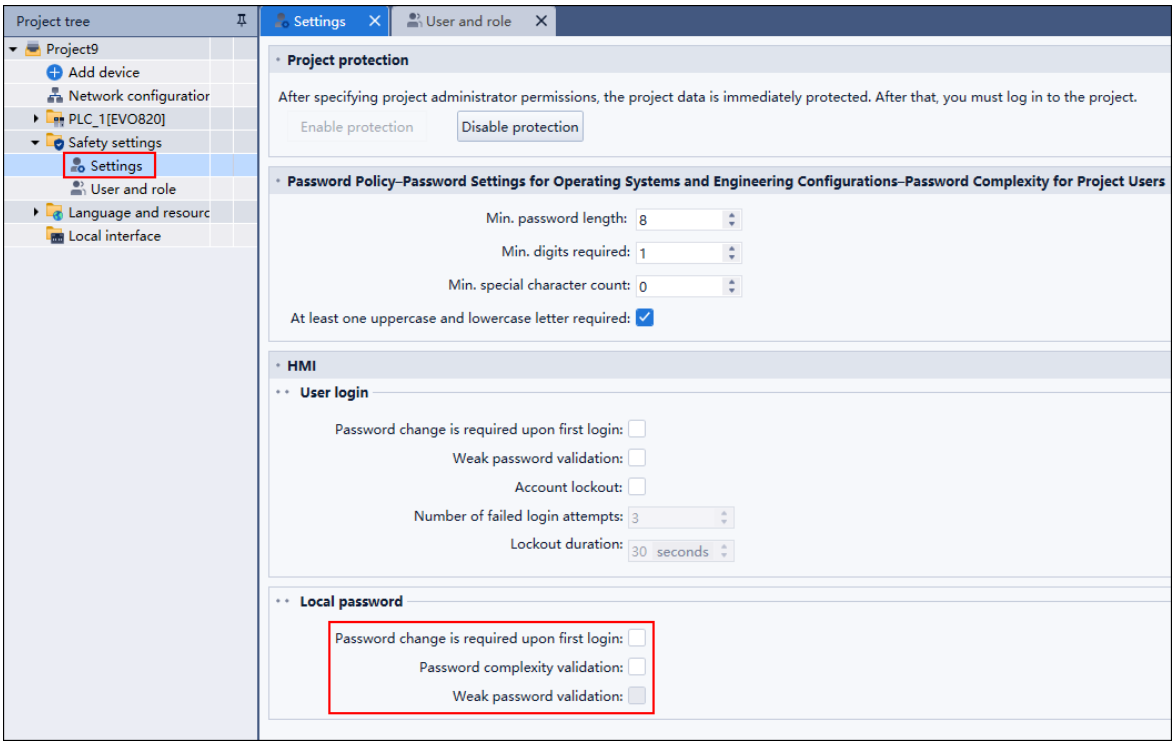
1. When the "User view" control is operating, clicking in the User Status column will immediately unlock the account.

2. Click in the User Status column, set the lockout duration in the pop-up window, and then click "Confirm" to lock the account.
   The default lockout duration is 0s, with a configurable range of 0 to 3600s. Setting it to 0s means permanently locking the account.



NOTE

- Users with the monitoring administrator permissions are authorized to unlock and lock accounts.
- Users with the monitoring administrator permissions can unlock one another, but cannot lock one another.
- Users with the monitoring administrator permissions cannot lock themselves. The field under the User Status column for the currently logged-in user with the monitoring administrator permissions is disabled.
- When an account is temporarily locked and its lockout timer is counting down, the following operations will not take effect: setting the time zone, date, time, or date and time through system functions; modifying the time zone, time, or date through the touchscreen. If an attempt is made to perform any of the preceding operations, a prompt box will pop up on the interface, as shown in the following figure.



Local password

1. The local password is the password for accessing the HMI control panel. It can be set by clicking the "General settings" tab of the "Runtime setting" node on an HMI device.

2. In the project tree, select "Safety settings" and then double-click the "Settings" tab.

3. Set the security authentication policies for HMI local password.

Item	Description
Password change is required upon first login	Unchecked by default. Once this option is checked, change the local password when accessing the HMI control panel for the first time with this password.
Password complexity validation	Unchecked by default. Once this option is checked, the local password complexity will be validated. If any password does not meet the requirements, set a new password. For password complexity settings, see 9.5 Setting Password Policies.
Weak password validation	Unchecked by default. Once this option is checked, the local password strength will be validated; if a weak password is identified, set a new password. Weak passwords: 1QAZ@wsx, Aa1!aaaa, Passw0rd!, Qwerty1@, Hello123#, Abc123!@

4. After the previous step is done, subsequent HMI control panel login attempts with a local password will be authenticated according to the configured security policies.

9.7 Managing Users

After enabling project protection, the project configuration administrator can add users to a project and assign them appropriate roles. Users can be assigned one or more roles. For example, if role A and role B each include five different permissions, a user being assigned both roles A and B can perform operations defined by ten permissions.

Add a user

1. In the project tree, select "Safety settings" and then double-click "User and role" tab.
2. Double-click "<Add user>" in the user list.
3. Enter the user password twice in the pop-up window, and then click "OK".
4. In the user list, select the desired user, and then check the appropriate roles on the "Developer role" or "Monitoring runtime role" tab below.

NOTE

- The default name for a new user is User_x; the initial password is null; the default logout time is 30 min.
- If a new user does not set a password, role association and related operations are not supported.
- Up to 100 users can be created, including the project configuration administrator.
- In the password field of the user interface, the project configuration administrator can set passwords for any user.
- Each user can modify their own information; the users without user management permission cannot modify other users' information.
- The logout timeout is enabled by default and can be configured from 1 to 600 min. You can also choose to disable it.
- When the logout timeout is enabled and a user logs in during runtime, the user will be automatically logged out after the specified period of inactivity and must log in again to perform further operations.
- The "HMI enable" option is checked by default for new users, indicating that the users are allowed to log in to the HMI runtime and perform related operations. Users that are not enabled will not be displayed in the HMI runtime login interface and User View control, and a pop-up prompt "Your account is not enabled" will appear when the login, password change, or user switching function is used.

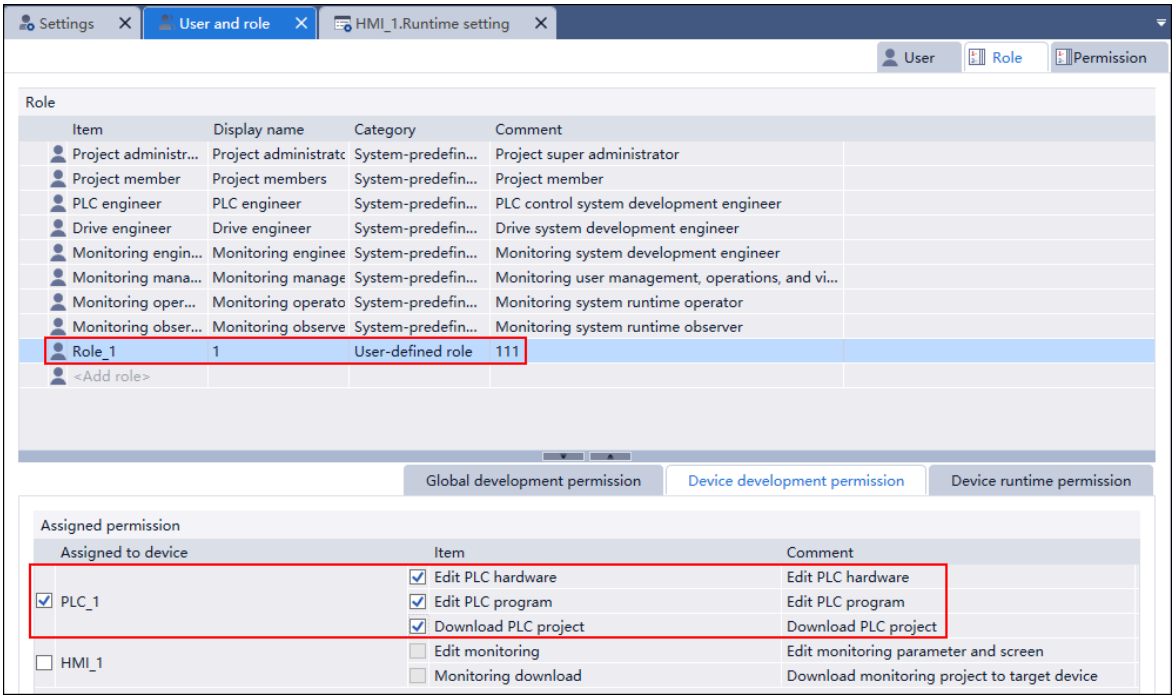
Copy/Paste/Delete a user

Right-click an existing user in the user list to copy, paste, delete, or rename the user.

- Pasted roles are automatically renamed and arranged at the end of the list.
- The current user's password cannot be copied.
- The project configuration administrator cannot be deleted.
- Multiple rows can be selected for batch copying, pasting, and deletion.

9.8 Managing Roles

A role represents a group of permissions. One or more permissions can be assigned to a role, and then the role can be assigned to a specific device. Once a user is bound to a role, the user can perform the relevant operations defined by the permissions contained in that role on the corresponding device.



Roles include built-in system roles and user-defined roles. Built-in system roles are associated with appropriate permissions by default, while user-defined roles require manual permission assignment to allow more granular and flexible permission control.

Role categories

Role	Description
Project configuration administrator	By default, the first administrator who enables project protection is the project configuration administrator, possessing all permissions in the project.
Project configuration member	More than one member can be designated by the project configuration administrator, and each of them can be granted additional permissions beyond the default ones.
PLC engineer	Primarily responsible for development and commissioning of PLCs.
Drive engineer	Primarily responsible for development and commissioning of drives.
Monitoring engineer	Primarily responsible for development and commissioning of monitoring systems.
Monitoring administrator	Monitoring runtime administrator, mainly responsible for managing users in the monitoring runtime mode, and operating and viewing the runtime monitoring system.
Monitoring operator	Monitoring runtime operator, having monitoring system operation permissions matched with the control permissions configured in the configuration environment.
Monitoring observer	Monitoring runtime observer, having the permissions to switch screens and view equipment operation status but no control permissions over the monitoring system.
User-defined role	A supplement to built-in system roles, for which appropriate permissions can be defined by the user to meet on-site practical needs; more than one role can be added.

Add a role

1. In the project tree, choose "Safety settings -> Settings", enable project protection, and set the username and password.
2. In the project tree, select "Safety settings" and then double-click "User and role" tab.
3. Select the "Role" tab, and then double-click "Add role" in the role list.
4. After selecting a role, check the boxes in the "Global development permission," "Device development permission," or "Device runtime permission" tab below to assign permissions.
   Among these, "Device development permission" and "Device runtime permission" only take effect after being assigned to specific devices. For details, see 9.9 Assigning Roles.

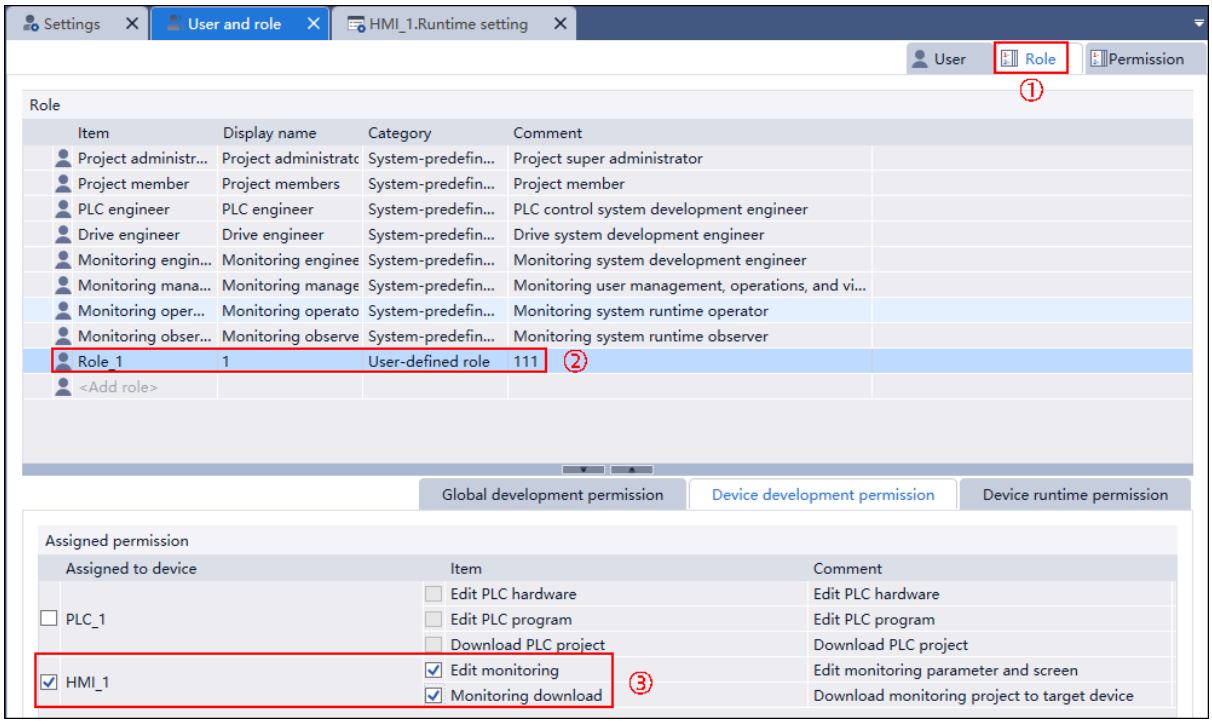
NOTE

- Only when project protection is enabled, the device development and runtime permissions can be configured.
- Up to 100 roles can be created, including the built-in system roles, and only one project configuration administrator is allowed.
- For user-defined roles, the name, display name, and description can be modified; for built-in system roles, only the display name can be modified.
- The default name for a new role is Role_x.

Copy/Paste/Delete a role

Right-click an existing role in the role list to copy, paste, delete, or rename the role. The built-in system roles cannot be deleted or renamed.

- Pasted roles are automatically renamed and arranged at the end of the list.
- Multiple roles can be selected for batch copying, pasting, and deletion.
- For pasted "built-in system roles", their role category is automatically changed to "user-defined role."



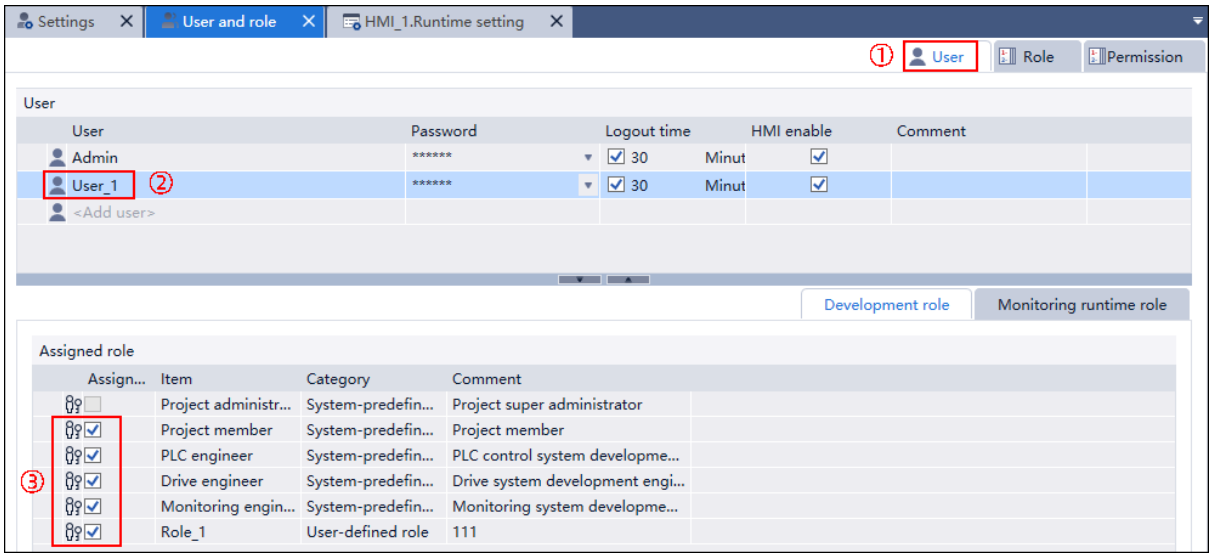
9.9 Assigning Roles

When project protection is enabled, the project configuration administrator can assign different permissions and devices to appropriate roles, and then assign these roles to different users, enabling role-based and domain-based access control.

> **NOTE**
>
> When a project contains online devices, operations such as assigning roles to users and assigning permissions and devices to roles are not supported; these operations can be performed only when the devices are offline.

Procedure

1. In the project tree, select "Safety settings" and then double-click "User and role" tab.
2. Select the "Role" tab and select the desired role from the role list.
3. Assign appropriate permissions and devices in the "Global development permission," "Device development permission," and "Device runtime permission" tabs below.



Category	Note
Global development permission	Project configuration permissions, including project encryption, member management, and role permission management; not bound to devices. The permissions for built-in system roles cannot be modified; user-defined roles can be assigned "management" permissions.
Device development permission	Includes development permissions for PLCs, drives, and monitoring devices. Permissions only take effect after being bound to a device. The permissions for built-in system roles cannot be modified, and they can be assigned to devices; user-defined roles allow flexible assignment of permissions and devices.

Category	Note
Device runtime permission	Includes monitoring device operation permission and user-defined permissions. Permissions only take effect after being bound to a device. The permissions for built-in system roles cannot be modified, and users can define permissions and link them to specific devices; user-defined roles allow flexible assignment of permissions and devices.

4. Select the "User" tab and select the desired user from the user list.

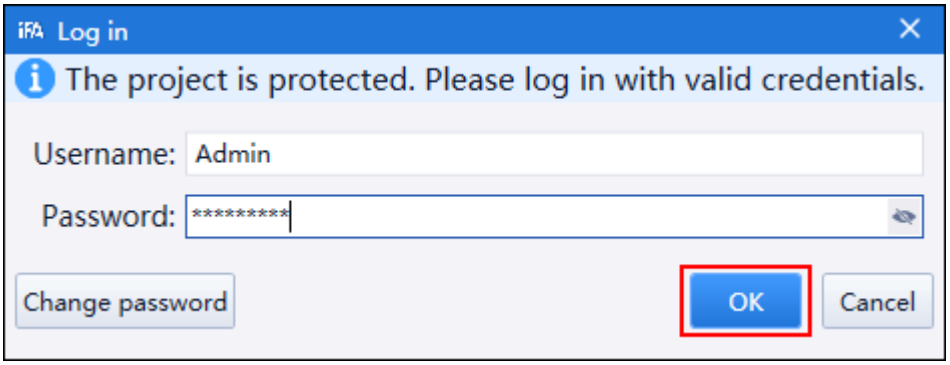
5. Assign appropriate roles in the "Development role" and "Monitoring runtime role" tabs below.

Role category	Note
Development roles	Includes built-in system roles such as project configuration administrator, project configuration member, PLC engineer, drive engineer, and monitoring engineer.
Monitoring runtime roles	Includes built-in system roles such as monitoring administrator, monitoring operator, and monitoring observer, as well as user-defined roles.

NOTE

User-defined roles are widely used in monitoring devices and can be used to accurately control the operation permissions of a specific widget on the HMI runtime screen. For example, if a permission is configured for a specific button and only user-defined role A is allowed to operate it, only users assigned user-defined role A can operate the button after logging in.

9.10 Opening a Protected Project



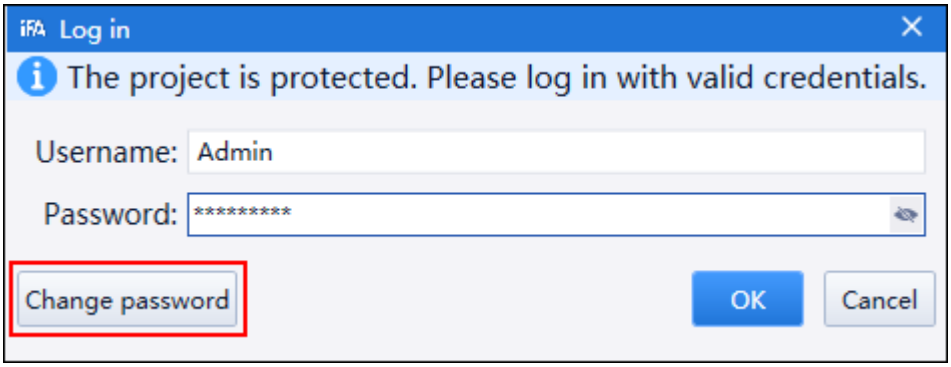
When project protection is enabled, enter the appropriate username and password to open the project. Logged-in users can perform operations defined by their permissions.

Procedure

1. Choose "Project -> Open" from the menu bar to access the "Open project" page.

2. Select the required protected project from the project list and click "Open".
   For other ways to open a project, see 8.1 Opening a Project.

3. In the "Log in" dialog box, enter the username and password, and then click "OK".

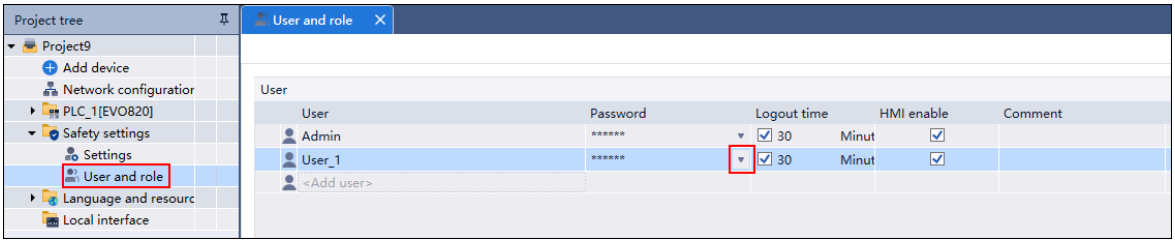


4. In the "Log in" dialog box, click the "Change password" button to change the password. For details, see 9.11 Changing the Password.

9.11 Changing the Password

After enabling project protection, you can change the user password in either of the following ways. If you log into a protected project as the project configuration administrator, you can change the password for any user; if you log in as any other user, you can change your password only.

Change the password when opening a protected project

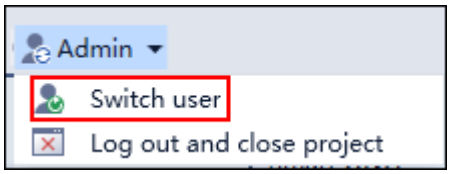


1. Choose "Project -> Open" from the menu bar to access the "Open project" page.
2. Select the required protected project from the project list and click "Open".
   For other ways to open a project, see 8.1 Opening a Project.
3. Click the "Change password" button in the "Log in" dialog box.

4. In the "Change password" dialog box, enter the username, old password, new password, and then confirm the new password.
5. Click "OK". Afterward, use the new password to log into the protected project.

Change the password when operating a protected project

1. In the project tree, select "Safety settings" and then double-click "User and role" tab.
2. In the user list, click the dropdown button in the field under the Password column corresponding to the target user.



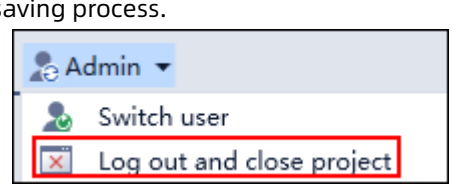
3. In the "Change password" dialog box, enter a new password and re-enter it to confirm.
4. Click "OK". Afterward, use the new password to log into the protected project.

9.12 Switching the User

After logging into a protected project, you can directly switch the logged-in user without closing the project.

Procedure

1. Log into a protected project.
2. Choose "Admin -> Switch user" from the toolbar.



3. If you have made changes to the project but not saved them, a dialog box will appear asking "Save project?". At this point, click "OK".
4. In the "Log in" dialog box, enter the username and password of the new user.
5. Click "OK".

9.13 Exiting a Project

After logging into a protected project, you can log the user out and close the project in one of the following ways:

- Directly close the iFA Evolution. The system logs out and closes the project according to the project saving process.
- Directly close the project. The system logs out and closes the project according to the project saving process.
- Choose"Admin -> Log out and close project" from the menu bar. The system logs out and closes the project according to the project saving process.

9.14 PLC Permissions

Permission matrix

For the most complex PLC permissions in access control scenarios, the following table lists the relationships between PLC-related operation scopes and built-in system permissions.

Operation Scope\System Permission	Edit PLC hardware	Edit PLC Program	Download PLC Project
Adding deleting, or modifying a device in the network view	√	×	×
Adding or deleting all nodes under hardware configuration	√	×	×
Configuring I/O mapping	×	×	×
Establishing communication between PLCs	√	×	×
Modifying properties of the monitoring area in the network view	√	×	×
Adding deleting, or modifying a sub-module in Device Configuration view	√	×	×
Adding a new PLC, module, or I/O slave	√	×	×
Library reference (installation and reference)	×	√	×
Configuring the oscilloscope (viewing and downloading are not restricted)	×	√	×
Recipe manager operations	×	√	×
Operations under programming nodes	×	√	×
Task configuration operations	×	√	×
POU encryption	×	√	×
Adding, deleting, or renaming under motion control nodes	×	√	×
PID\PFC	×	√	×
Project comparison (online)	×	×	√
Project comparison (Copying to the left and right - software)	×	√	×

Operation Scope\System Permission	Edit PLC hardware	Edit PLC Program	Download PLC Project
Project comparison (Copying to the left and right - hardware)	√	×	×
Downloading to device	×	×	√
Uploading a project	×	×	√
Switching to online/Switching to offline	×	×	√
Replace	√	√	×
Controlling objects (including cams/axes/ axis groups)	×	√	×
Controlling objects (PID/PFC)	×	√	×
Adding and deleting watch tables and variables	×	√	×
Copying and pasting the entire PLC nodes	√	√	×
Replacing a device	√	√	×
Overwrite upload	√	√	√

NOTE

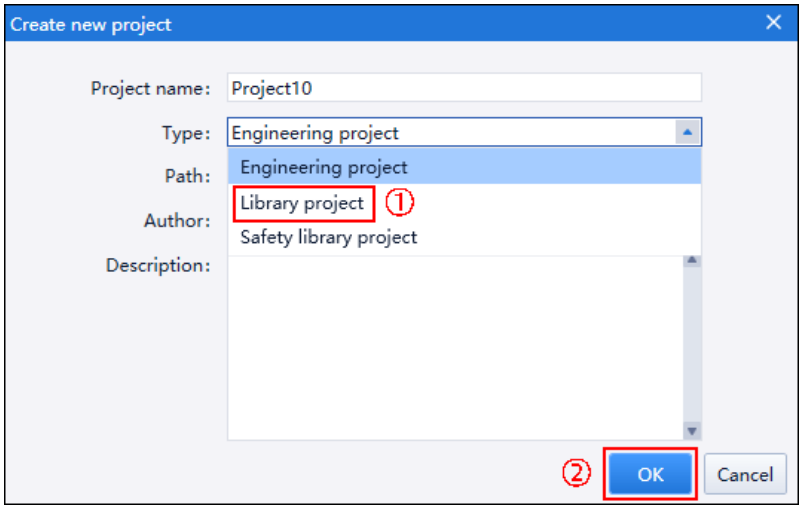
- √ indicates that the permission allows the operation. All conditions required for the operations covered by this permission must be satisfied; otherwise, the permission will not take effect.
- × indicates that no permissions are required to perform the operation.

Restrictions

- Without PLC hardware editing permission, hardware cannot be added or deleted, and hardware parameters cannot be modified.
- Without PLC program editing permission, POUs cannot be opened for viewing, and software parameters cannot be modified.
- Without PLC project downloading permission, the Download button will be grayed out, and all online permissions associated with the project will also be grayed out.

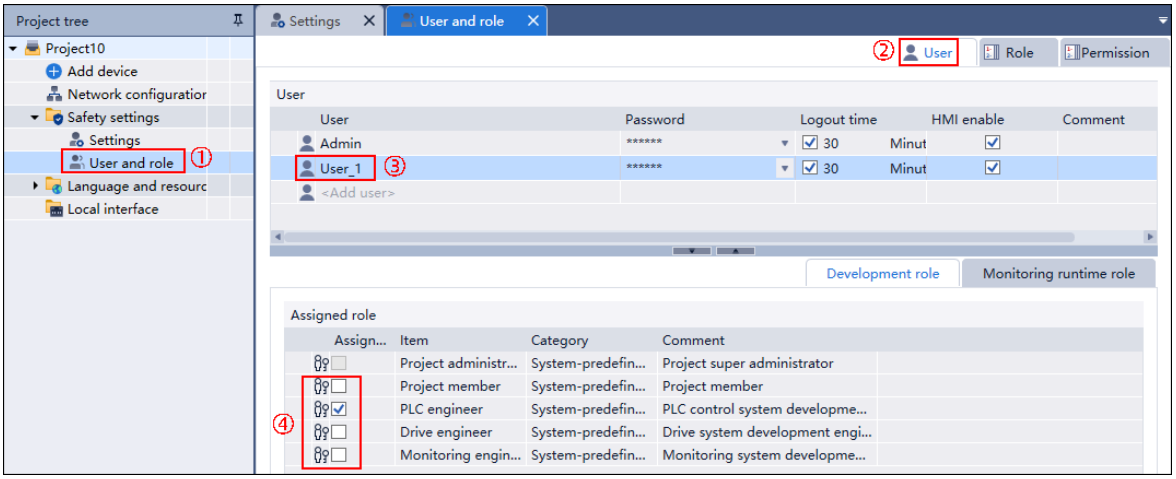
9.15 Library Project Security Management

Overview



You can protect the project data in a library project by managing users to prevent unauthorized access. To enable project protection, create a project administrator, who can subsequently create other users and

assign them appropriate roles and permissions. Only users with sufficient permissions can open, edit, and view the library project.



After creating or opening a library project, the operations for 9.3 Enabling Project Protection, 9.4 Disabling Project Protection9.4 ,9.5 Setting Password Policies, 9.10 Opening a Protected Project, 9.11 Changing the Password, 9.12 Switching the User, and 9.13 Exiting a Project are the same as those for regular projects.

Manage users

1. Create or open a library project.

2. After 9.3 enabling project protection, the project administrator can add users to a project and assign them appropriate roles.
3. In the project tree, select "Safety settings" and then double-click "User and role" tab.
4. Select the "User" tab, and double-click "<Add user>" in the user list.
5. Enter the user password twice in the pop-up window, and then click "OK".
6. In the user list, select the desired user, and then check the appropriate roles on the "Developer role" or "Monitoring runtime role" tab below.

NOTE

- The default name for a new user is User_x; the initial password is null; the default logout time is 30 min.
- If a new user does not set a password, role association and related operations are not supported.
- Up to 100 users can be created, including the project configuration administrator.
- In the password field of the user interface, the project configuration administrator can set passwords for any user.
- Each user can modify their own information; the users without user management permission cannot modify other users' information.
- The logout timeout is enabled by default and can be configured from 1 to 600 min. You can also choose to disable it.
- When the logout timeout is enabled and a user logs in during runtime, the user will be automatically logged out after the specified period of inactivity and must log in again to perform further operations.

7. Select the "Role" tab. In the role list, select the desired role. In the "Global development permissions" list below, check the permissions of the selected role.
   The built-in system roles and permissions are shown in the table below:

Role	Permissions	Description
Project administrator	◦ Project encryption ◦ Member management ◦ Role management ◦ PLC library editing ◦ PLC library viewing	By default, the first user who enables project protection is the project administrator, possessing all permissions, including project encryption/decryption, user management, role assignment, PLC library editing, and PLC library viewing.
Library development engineer	◦ PLC library editing ◦ PLC library viewing	This role can view and edit PLC library codes.
Library observer	PLC library viewing	This role can view PLC library code logic, but cannot perform operations such as editing, copying, pasting, cutting, and deleting.

NOTE

- Only built-in system roles and permissions can be used in library projects, while user-defined roles and permissions cannot be used. The built-in system roles are fixed to their permissions and cannot be reassigned.
- It is possible to view the built-in system roles and permissions and assign permissions to users only after the project protection is enabled.

10 PLC Programming

10.1 Programming Basics

10.1.1 Variables

10.1.1.1 Global Variables

Global variables refer to variables between VAR_GLOBAL and END_VAR that are used within the corresponding configuration and resource.

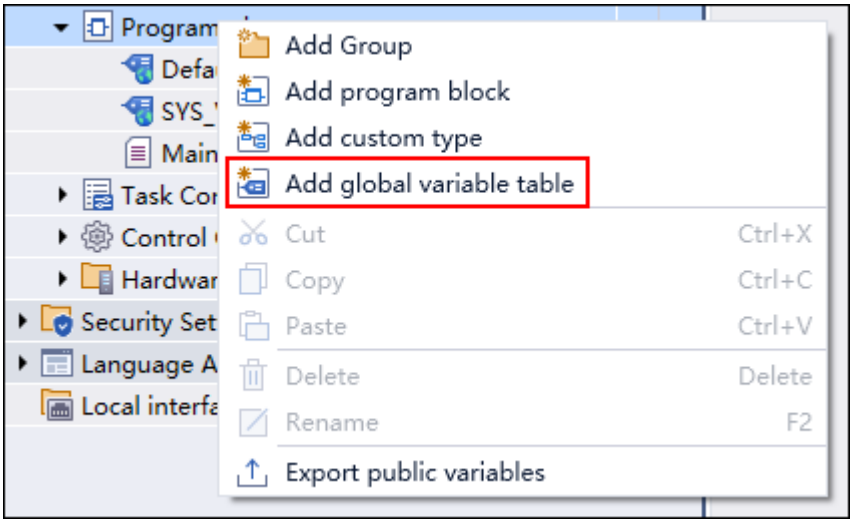
This includes system-generated SYS_VAR variables and user-defined variables in the program, as described below:

SYS_VAR

The system variable table is automatically deployed under the programming node upon project creation, named "SYS_VAR". It cannot be modified or deleted.

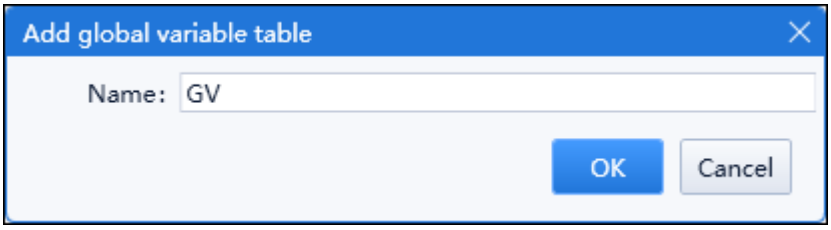
- When users add slave devices (devices configured under the hardware configuration node, such as I/O modules and branch modules), corresponding variables are generated. Each slave device corresponds to a unique system variable (including the disabled variable bDisableEnable); when a slave device is modified or deleted, the system variable will be updated synchronously.
- System variables support export, but do not support paste, copy, cut, and delete operations.
- The names and data types of system variables cannot be modified by users.
- When the disabled variable bDisableEnable is called in the program, the variable value of True/False is used to enable or disable the slave.

User-defined variable



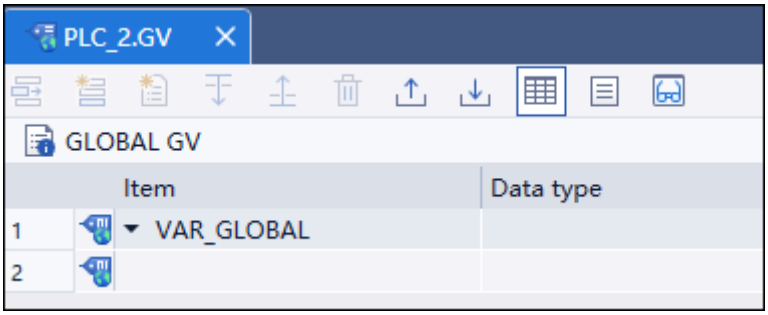
All POUs under "Programming" can use the global variables declared in the global variable table.

Prerequisites

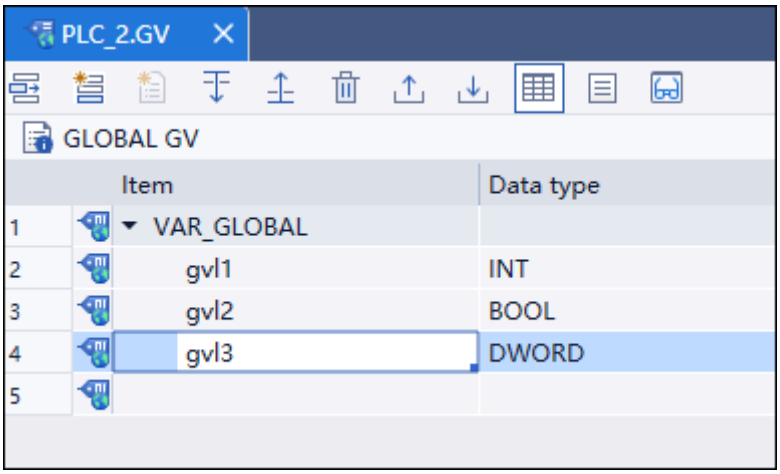


A global variable table has been created.

Procedure



1. Right-click "Programming > Add global variable table" and the "Add global variable table" dialog box pops up.



2. Set the name of the global variable table and click "OK".

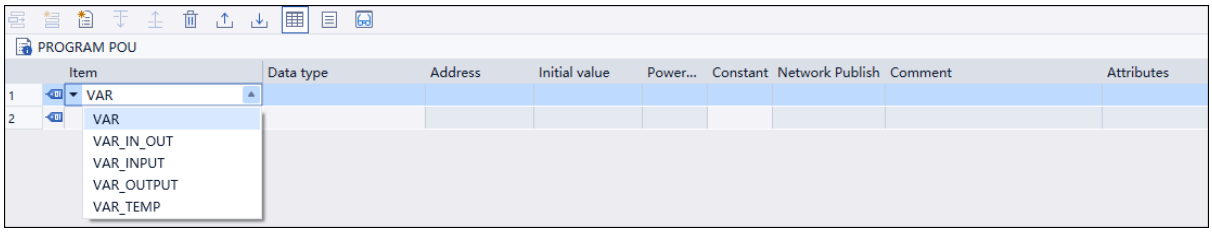
3. Set the variable category to "VAR_GLOBAL" in the global variable table and add variables.

Operation result

NOTE

- When operating through variable names, if the name of a local variable and a global variable are the same, the local variable is operated on. Global variables can be accessed by prefixing the variable name with the "global variable list name" followed by a ".", such as "GV.gvl1".
- The global variable list is initialized before POU local variables are defined.

10.1.1.2 Local Variables

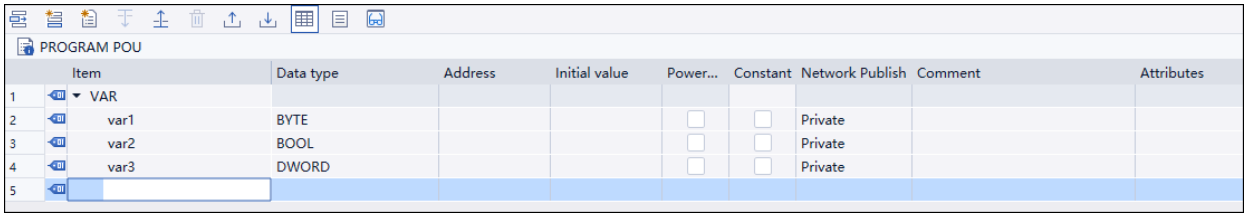


Local variables refer to variables between VAR and END_VAR in a program organization unit (POU). They can be used within this POU and other POUs.

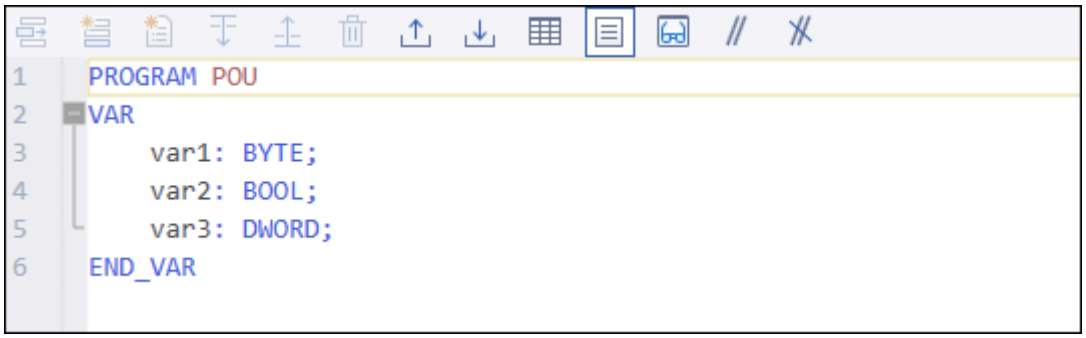
Prerequisites

A POU has been created.

Procedure



1. Open a POU (PRG, FB, or FUN) under "Programming". In the variable declaration editor in the table view, set the variable category to "VAR".



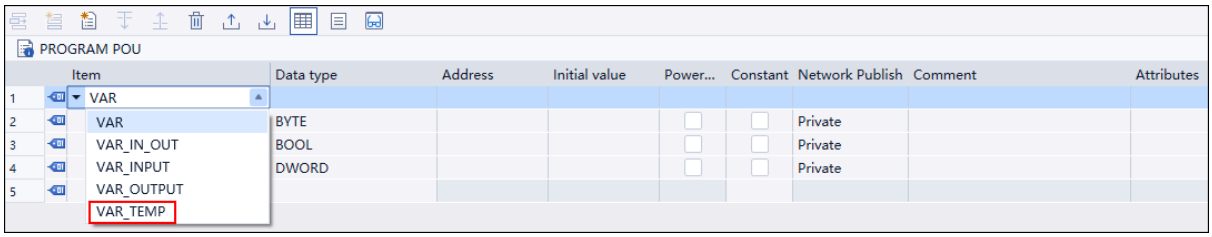
2. Add variables, and set their properties such as names and data types.

Operation result

The variable declaration editor in table view is shown in the figure below:

The variable declaration editor in text view is shown in the figure below:

10.1.1.3 Temporary Variables

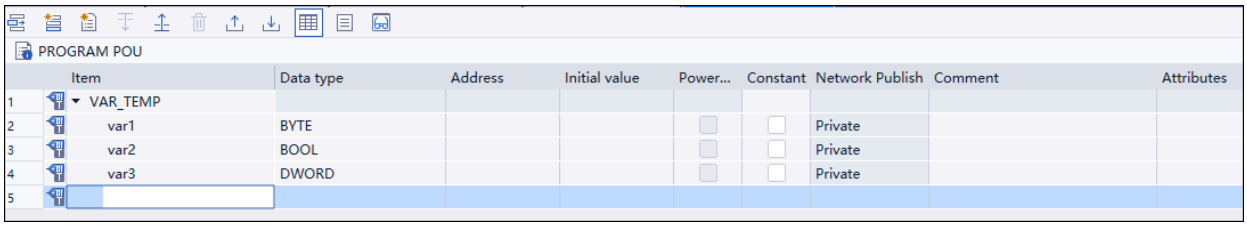


Temporary variables refer to variables defined between VAR_TEMP and END_VAR. They are stored temporarily in a program (PRG) or function block (FB). Temporary variables are initialized each time they are called.

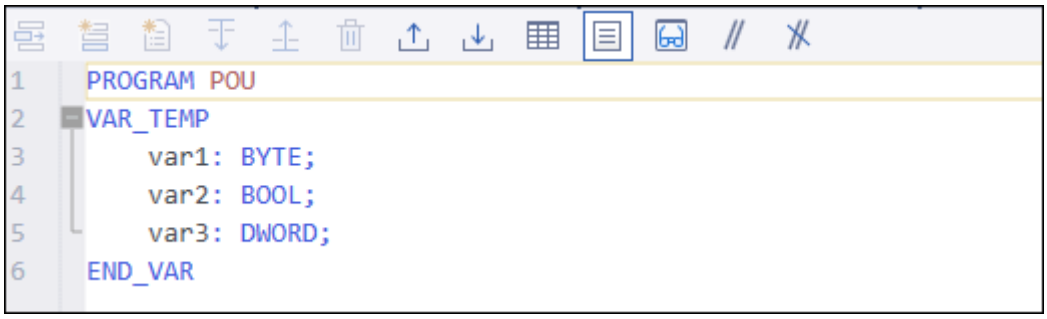
Prerequisites

A POU (only PRG and FB) has been created.

Procedure



1. Open a POU (PRG or FB) under "Programming". In the declaration editor in table view, set the variable category to "VAR_TEMP".



2. Add variables, and set their properties such as names and data types.

Operation result

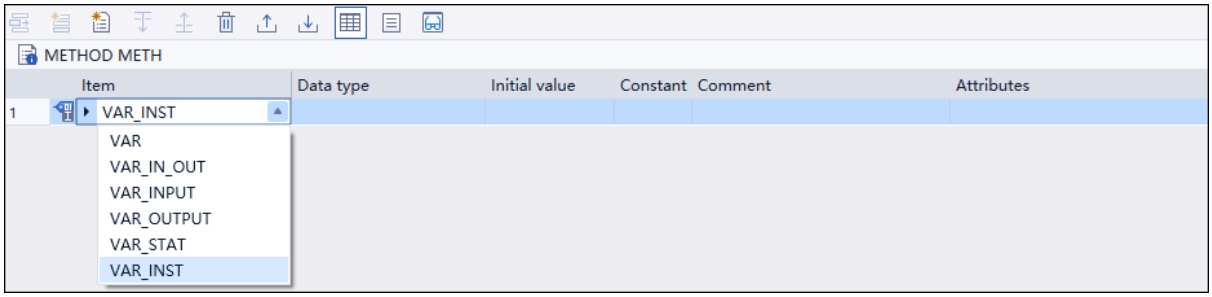
The variable declaration editor in table view is shown in the figure below:

The variable declaration editor in text view is shown in the figure below:

NOTE

- Temporary variables can only be declared in programs (PRG) and function blocks (FB), and not in functions (FUN).
- Temporary variables are non-public variables.

10.1.1.4 Instance Variables

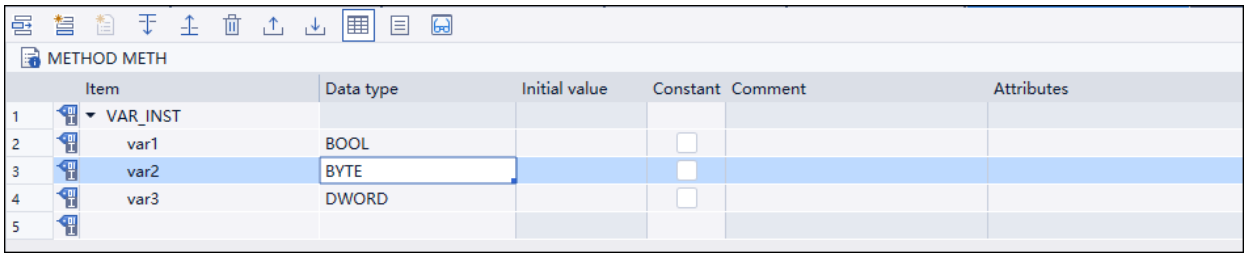


Instance variables refer to variables declared between VAR_INST and END_VAR. They are stored on the function block instance stack.

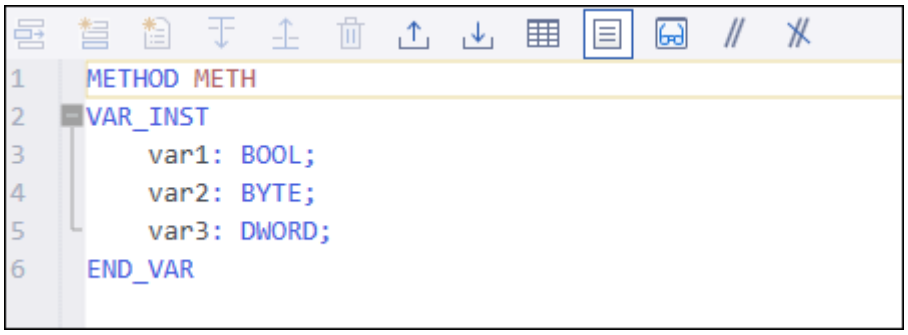
Prerequisites

A POU (only for methods under FB) has been created.

Procedure



1. Open a METH under an FB under "Programming". In the declaration editor in table view, set the variable category to "VAR_INST".



2. Add variables, and set their properties such as names and data types.

Operation result

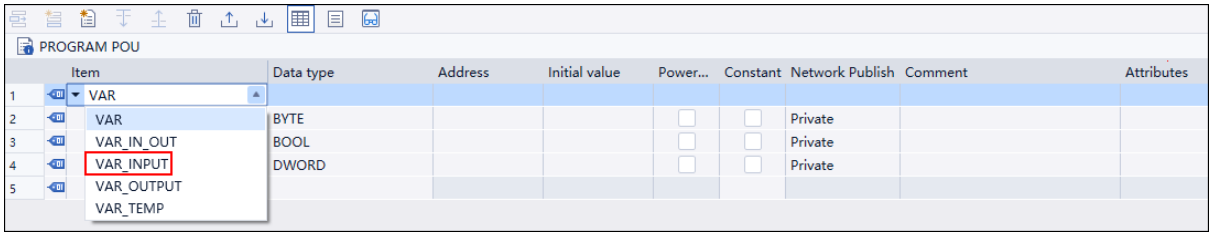
The variable declaration editor in table view is shown in the figure below:

The variable declaration editor in text view is shown in the figure below:

NOTE

- Instance variables can only be added and used within methods under a custom function block.
- When a function block calls a method, the values of instance variables are not initialized.

10.1.1.4.1 Input Variables

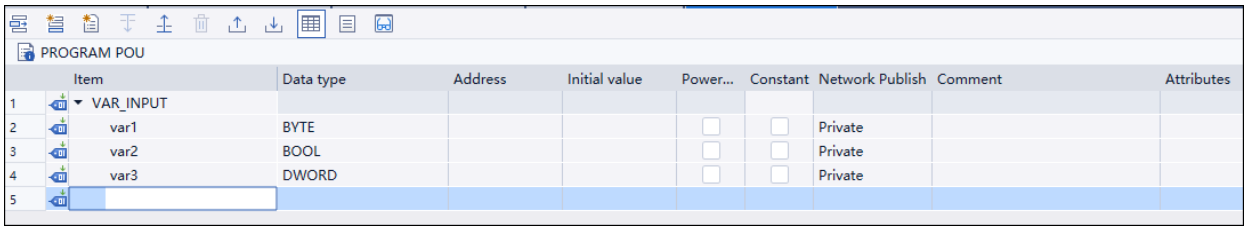


Input variables refer to variables provided externally and defined between VAR_INPUT and END_VAR. They are assigned values at the call location.

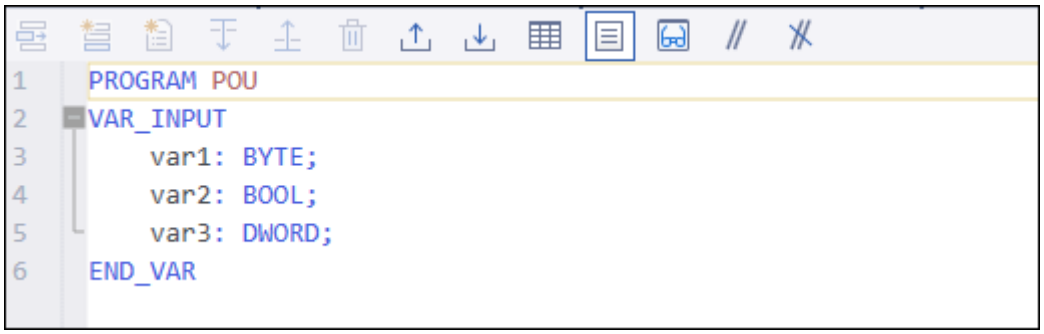
Prerequisites

A POU has been created.

Procedure



1. Open a POU (PRG, FB, or FUN) under "Programming". In the variable declaration editor in the table view, set the variable category to "VAR_INPUT".



2. Add variables, and set their properties such as names and data types.

Operation result

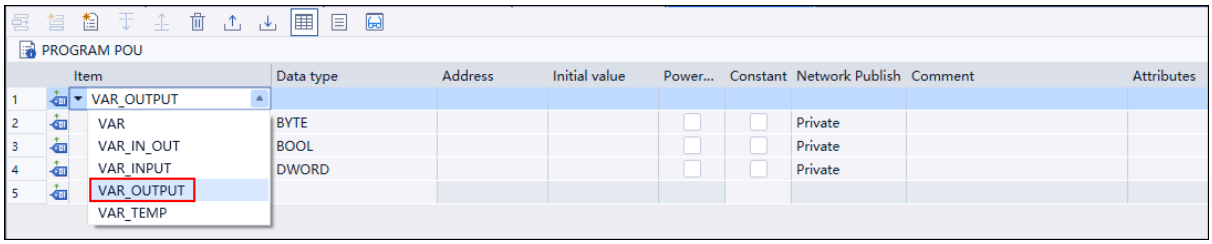
The variable declaration editor in table view is shown in the figure below:

The variable declaration editor in text view is shown in the figure below:

NOTE

- Input variables can also be modified within the POU, even if the CONSTANT property has been added.
- Supports data types ANY or ANY_<Type>.

10.1.1.5 Output Variables

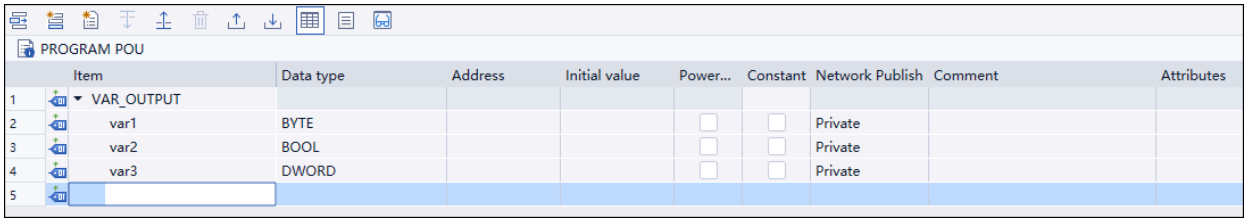


Output variables refer to variables provided internally and defined between VAR_OUTPUT and END_VAR. They are only accessible by external entities. They return values to the caller upon call for further processing.

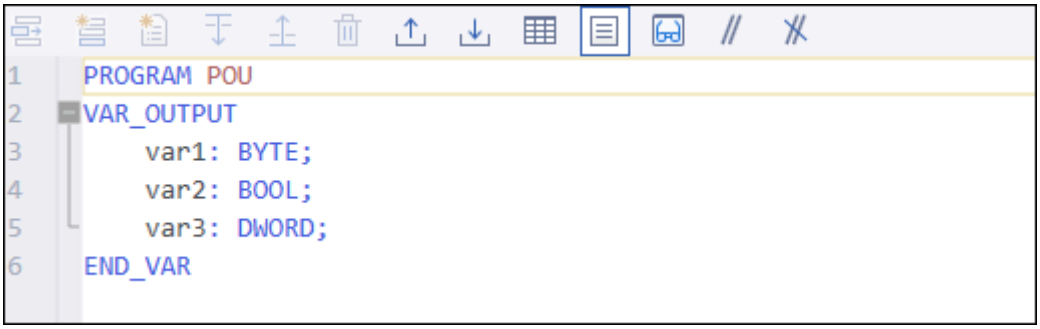
Prerequisites

A POU has been created.

Procedure



1. Open a POU (PRG, FB, or FUN) under "Programming". In the variable declaration editor in the table view, set the variable category to "VAR_OUTPUT".



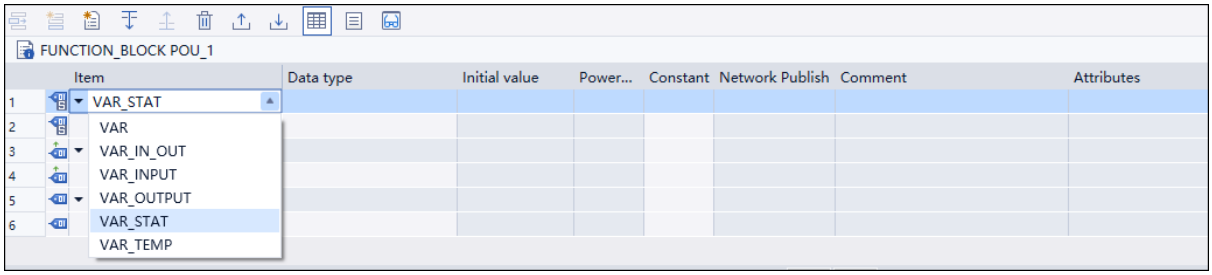
2. Add variables, and set their properties such as names and data types.

Operation result

The variable declaration editor in table view is shown in the figure below:

The variable declaration editor in text view is shown in the figure below:

10.1.1.6 Static Variables

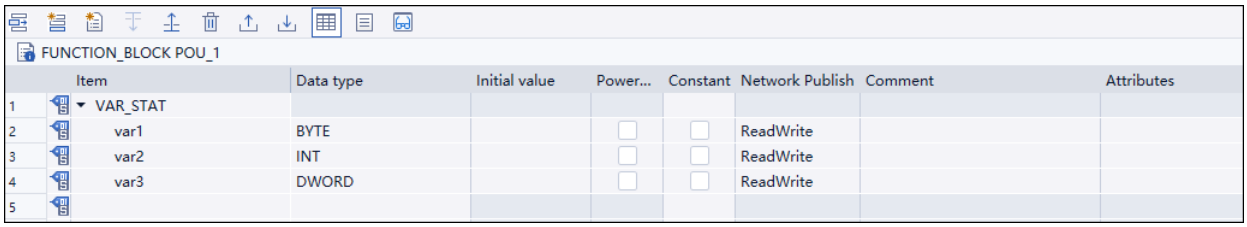


Static variables refer to variables defined between VAR_STAT and END_VAR. Stored in the global data area, they are initialized only upon the first call and retain their values after every POU call.

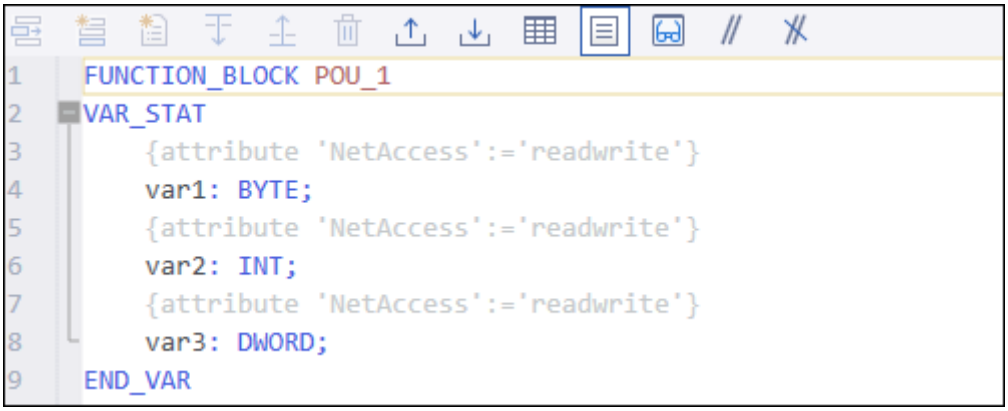
Prerequisites

A POU has been created.

Procedure



1. Open a POU (FB, FUN, or METH) under "Programming". In the variable declaration editor in the table view, set the variable category to "VAR_STAT".

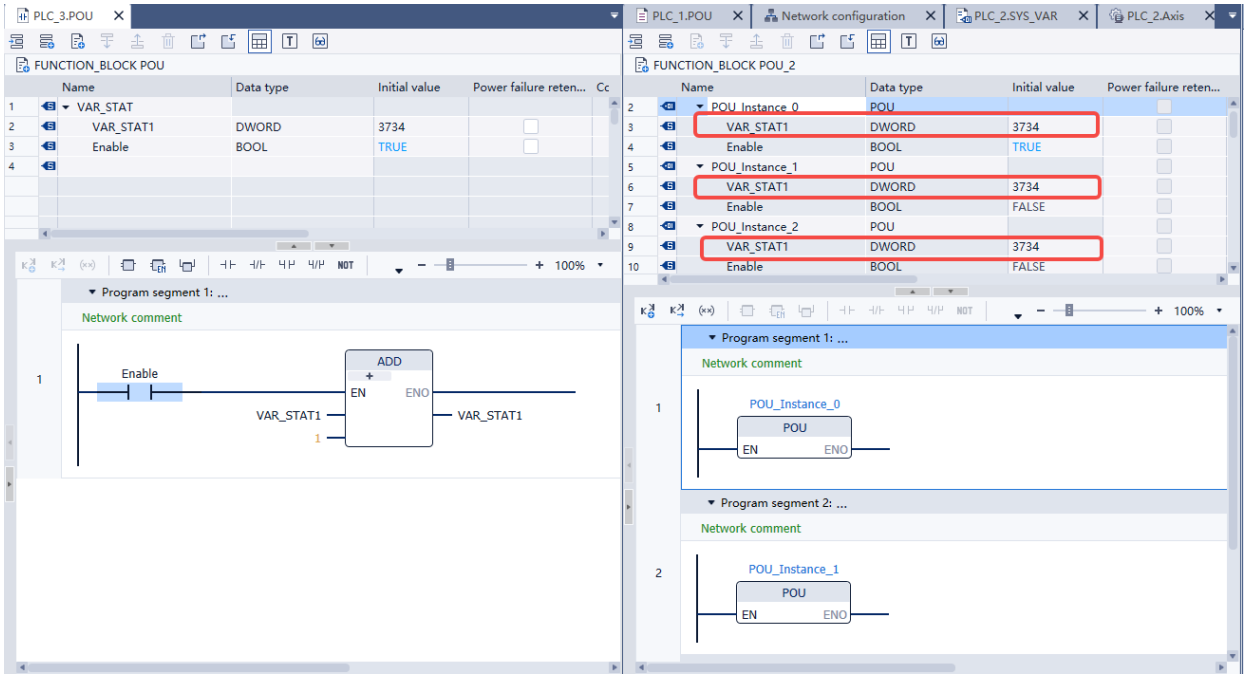


2. Add variables, and set their properties such as names and data types.

Operation result

The variable declaration editor in table view is shown in the figure below:

The variable declaration editor in text view is shown in the figure below:



NOTE

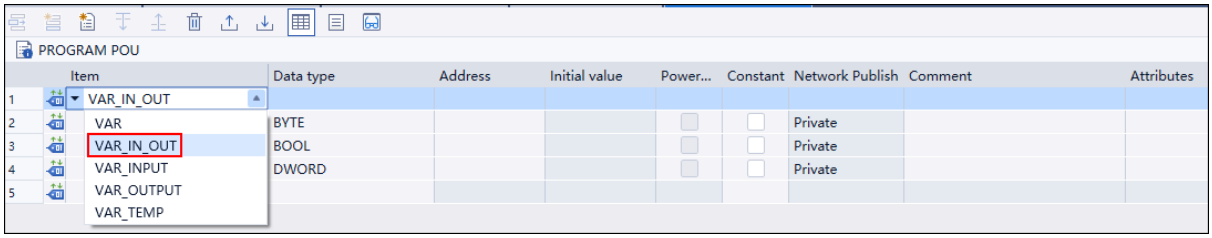
- Static variables can only be declared in function blocks, functions, and methods, but cannot be declared in programs.
- Static variables can only be used in the declared POU.

Application Scenarios

- Static variables in FB
  Static variables declared in FB are shared across all instances of the FB.
- Static variables in FUN
  Static variables defined in FUN are unrelated to the return value of FUN. As they are in the global data area, their values can be viewed online even without setting breakpoints.

  Take self-increment operation using a static variable defined in FB as an example. Although each FB instance is independent, the static variable is stored in the global data area and is shared across all instances. Updating it in one instance affects all others.

10.1.1.7 Input/Output Variable

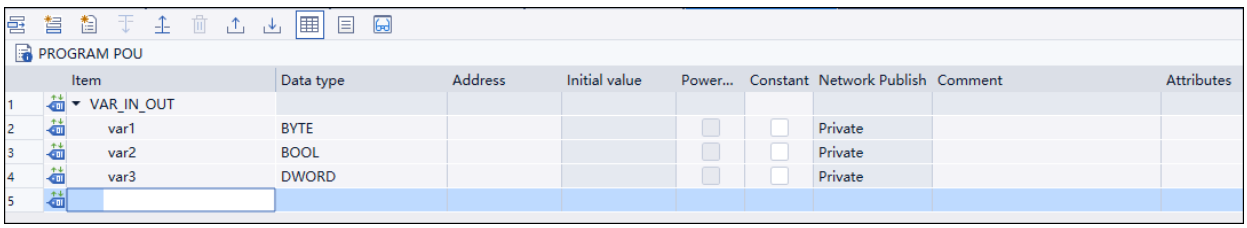


Input/output variables refer to variables defined between VAR_IN_OUT and END_VAR. They can be transferred to the called POU and modified within the called POU. The variables transferred to the called POU are referenced by the caller.

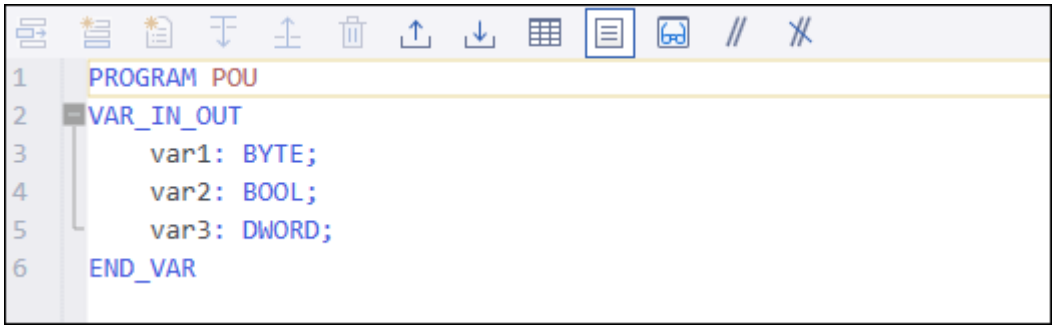
Prerequisites

A POU has been created.

Procedure



1. Open a POU (PRG, FB, or FUN) under "Programming". In the variable declaration editor in the table view, set the variable category to "VAR_IN_OUT".



2. Add variables, and set their properties such as names and data types.

Operation result

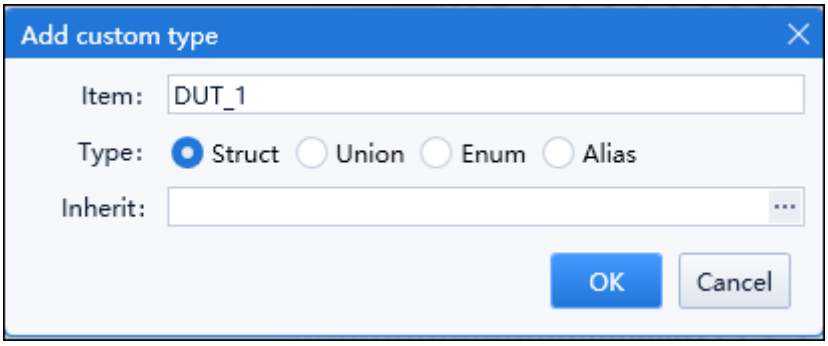
The variable declaration editor in table view is shown in the figure below:

The variable declaration editor in text view is shown in the figure below:

NOTE

The input and output variables are non-public variables.

10.1.1.8 Data Types (EVO400, EVO500, EVO700, EVO800)



10.1.1.8.1 Standard Data Types

Data Type	Value Range	Memory Usage (Byte)	Input Example
BOOL	TRUE, FALSE	1	TRUE FALSE
BYTE	0 to 255	1	BYTE#2#0000_1111
WORD	0~65535	2	WORD#61_680
DWORD	0 to 4294967295	4	DWORD#2#0000_0000_1111_0000_1111_1111_0000_1111
LWORD	0 to 18446744073709551615	8	8#13_724_557_213
SINT	-128 to 127	1	100 INT#2#00000000_01100100 INT#8#144 INT#10#100 INT#16#64 -100
USINT	0 to 255	1	
INT	-32768~32767	2	
UINT	0~65535	2	
DINT	-2147483648 to 2147483647	4	
UDINT	0 to 4294967295	4	
LINT	-9223372036854775808 to 9223372036854775807	8	
ULINT	0 to 18446744073709551615	8	
REAL	-3.402823e+38 to -1.175495e-38 ±0.0 +1.175495e-38 to +3.402823e+38 +Inf/-Inf	4	-3.14 1.0e-5 LREAL#1.0e-5

Data Type	Value Range	Memory Usage (Byte)	Input Example
LREAL	-1.7976931348623157e+308 to -2.2250738585072014e-308 ±0.0 +2.2250738585072014e-308 to +1.7976931348623157e+308 +Inf/-Inf	8	
STRING	UTF-8 encoding 0 to 4096 bytes (default is 80 bytes)	1	'This is a String' Use single quotes with the English input method.
WSTRING	UNICODE encoding 0 to 16382 bytes (default is 160 bytes)	2	"This is a WString" Use double quotes with the English input method.
TIME	T#0d0h0m0s0ms to T#49d17h2m47s295ms	4	T#10d_20h_30m_20s_630ms T#61m5s T#3s20ms TIME#10d_20h_30m_20s_630ms TIME#6d_10m
TIME_OF_DAY (TOD)	TOD#00:00:00.000 to TOD#23:59:59.999	4	Start with TIME_OF_DAY#, time_of_day#, TOD#, or tod# and followed by a time in hh:mm:ss format. tod#12:50:30.14
DATE	D#1970-01-01 to D#2106-02-07	4	Start with DATE#, date#, D#, or d#, and followed by a date in yyyy-mm-dd format. D#2009-12-31, DATE#2009-12-31
DATE_AND_TIME (DT)	DT#1970-01-01-00:00:00 to DT#2106-02-07-06:28:15	4	Start with DT# or dt#, and followed by a date and time in yyyy-mm-dd-hh:mm:ss format. dt#2007-07-01-05:40:25
LTIME	LTIME#0NS to LTIME#213503D23H34M33S709MS551US615NS	8	LTIME#0NS LT#0NS

10.1.1.8.2 User-Defined Types

Right-click "Programming" in the project tree and select "Add user-defined type" to add four types of custom data types: structure, enumeration, union, and alias.

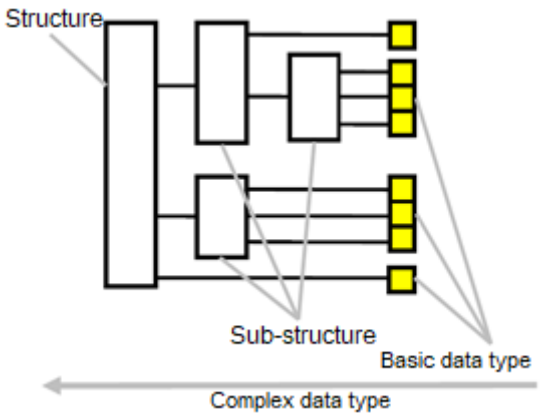
10.1.1.8.2.1 STRUCT

Concepts

A structure is a collection composed of data items of the same type or different types.

It is similar to basic data types, except that it allows custom encapsulation of data types.

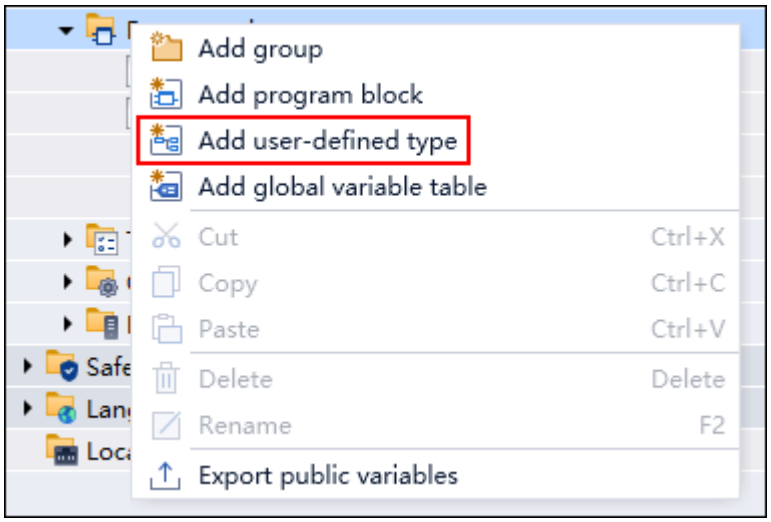
By operating on the internal variables of a structure, a large amount of data can be stored in memory.



For example, a motor has information such as "Product_ID", "Vendor", "Nominal Voltage", "Nominal Current", and "Poles". Combine them through a structure to reflect the relationship among the variables.

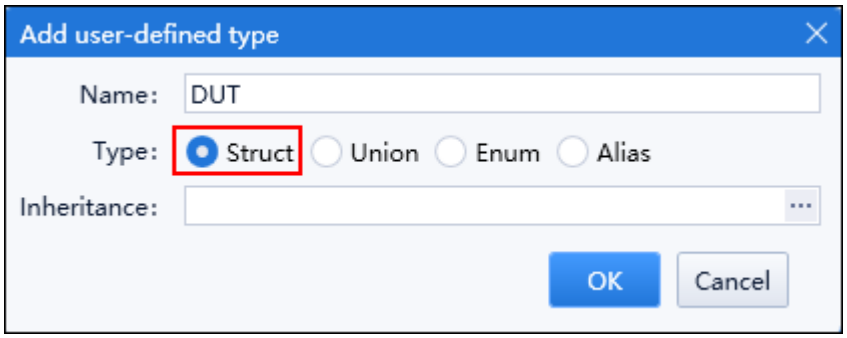
The syntax for the struct declaration is as follows:

```
TYPE <structurename> | EXTENDS DUTTYPE:
STRUCT
   <declaration of variables 1>
   ...
   <declaration of variables n>
END_STRUCTEND_TYPE
```

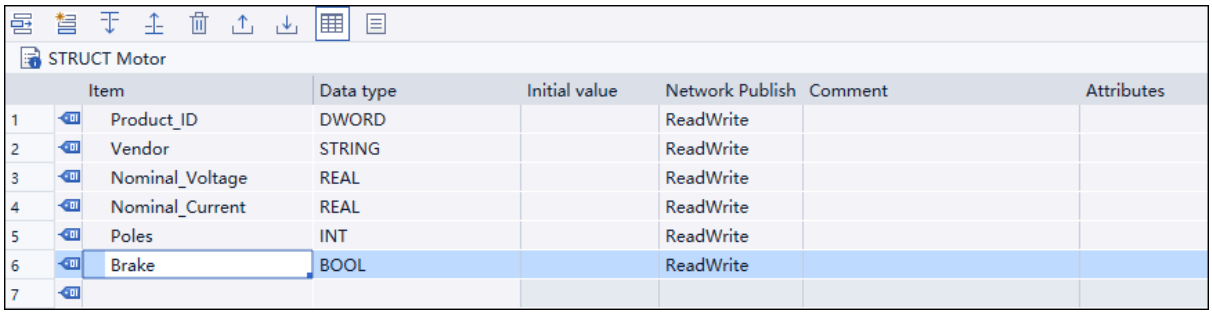


<structurename> is a type and can be used as a data type. EXTENDS DUTTYPE is optional and indicates inheritance from the members of DUTTYPE. Variables of the structure name type can be used to access the members of DUTTYPE. DUTTYPE is of the structure, union, or alias type.

A structure is extensible and supports inheritance. It can inherit from another structure, where the inherited one is the parent and the inheriting one is the child. This process is also called structure nesting. Once nested, the structure is considered a complex data type.



Structure definition



1. Right-click "Programming" in the project tree and select "Add user-defined type".

2. In the "Add user-defined type" window, set the name of the structure, select the type as "Struct", and select Inheritance as needed. Click "OK", and the system automatically enters the DUT editor.

3. Create a structure named "Motor" in the DUT editor, as shown below.

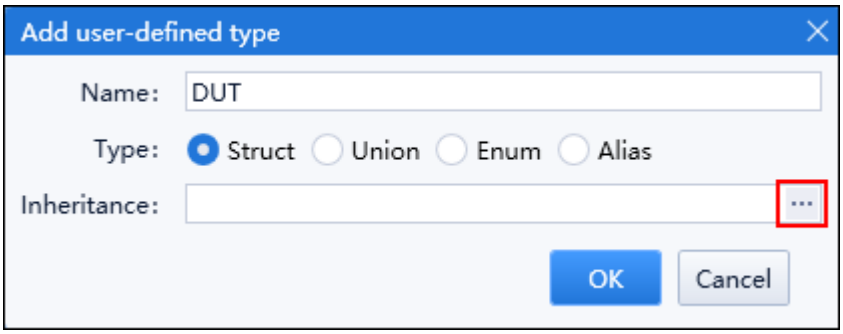
	Item	Data type	Initial value	Network Publish	Comment	Attributes
1	Product_ID	DWORD		ReadWrite		
2	Vendor	STRING		ReadWrite		
3	Nominal_Voltage	REAL		ReadWrite		
4	Nominal_Current	REAL		ReadWrite		
5	Poles	INT		ReadWrite		
6	Brake	BOOL		ReadWrite		
7						

> **NOTE**
>
> The EVO500 series PLC V1.2 version does not support setting the "Network public" property of a structure.

Struct inheritance

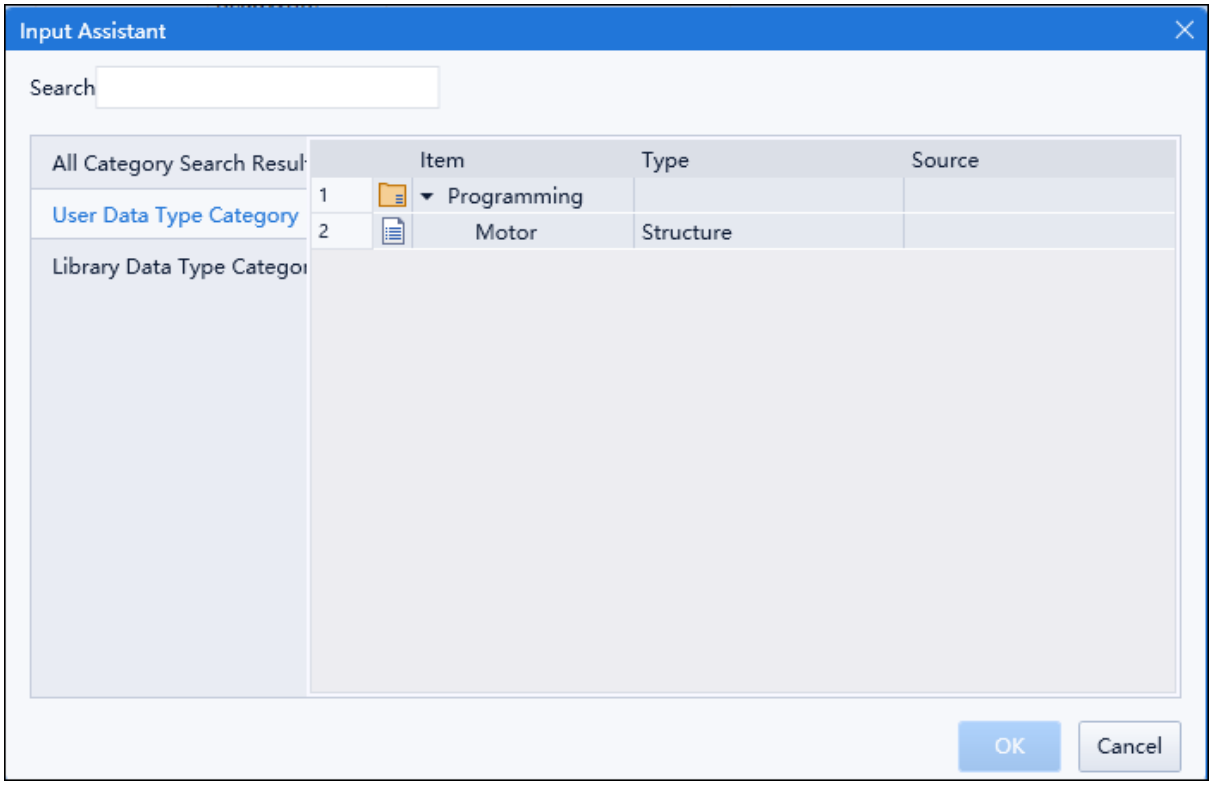
Structures can inherit structure types or alias structures. There are two methods to add "Inheritance" to a structure:

- Method 1: Set in the "Add user-defined type" window.
- Method 2: Set in the variable declaration editor.



Method 2 adds inheritance to a structure that already exists.

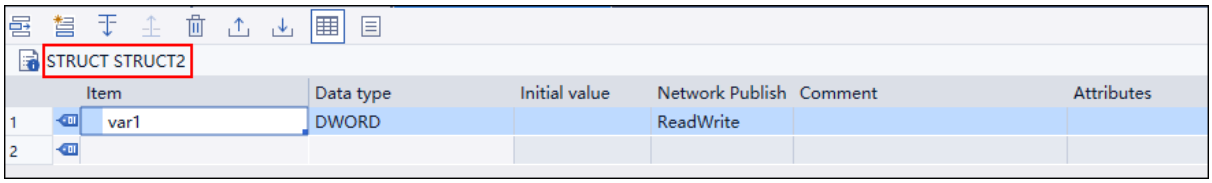
Prerequisites



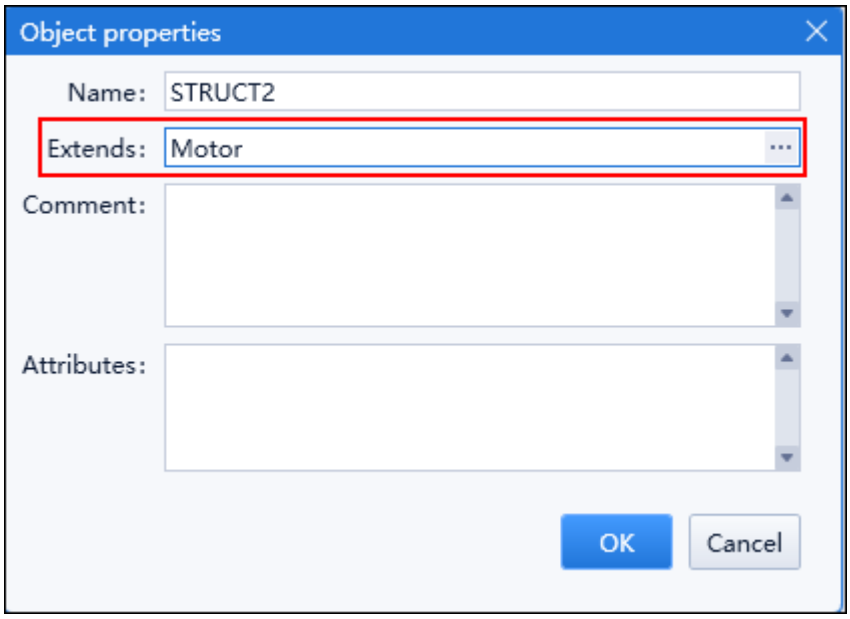
- Method 1: A structure to serve as the base must already exist.
- Method 2: Both a base structure and a child structure must already exist.

Procedure to add inheritance in the "Add user-defined type" window

1. Right-click "Programming" in the project tree and select "Add user-defined type".
2. In the pop-up window, select "Struct" as the type.
3. Click the "..." button after "Inheritance" to open the "Input assistant" window.



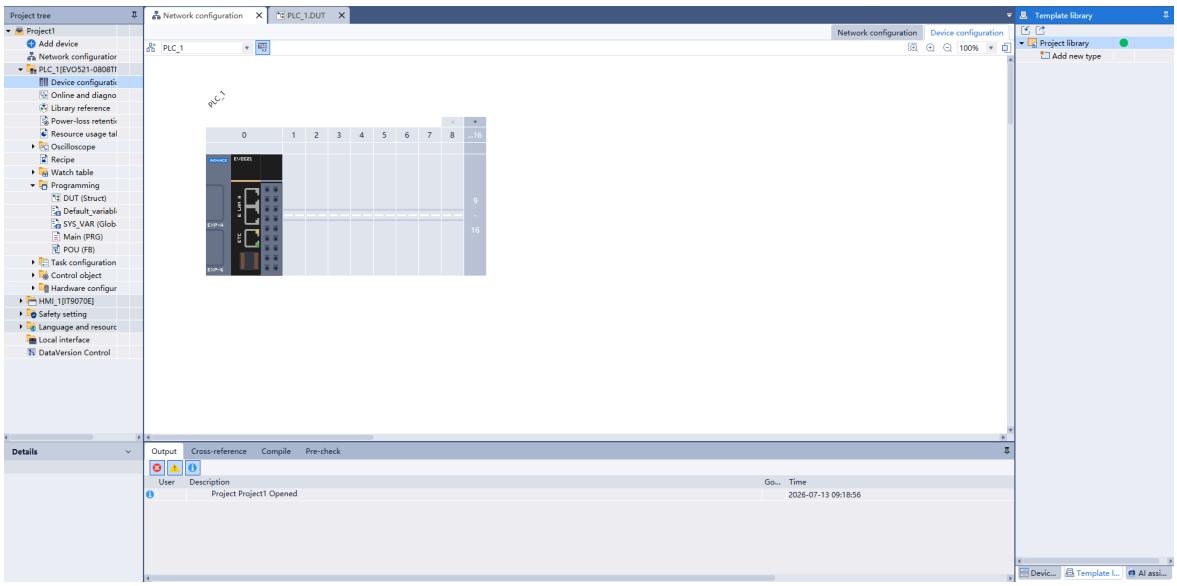
4. Select the inherited structure in the "Input assistant", as shown in the following figure.



Procedure to add inheritance in the variable declaration editor

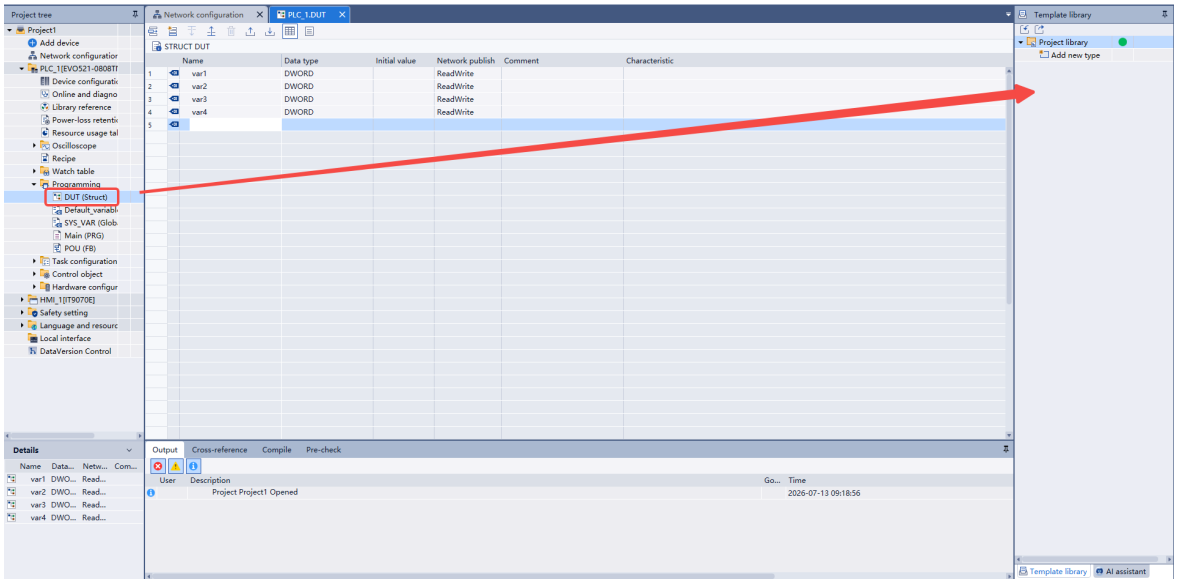
1. In the table view of the variable declaration editor, click the name of the structure and the "Object property" window pops up.

2. Add the structure being inherited, as shown below.



Structural templating

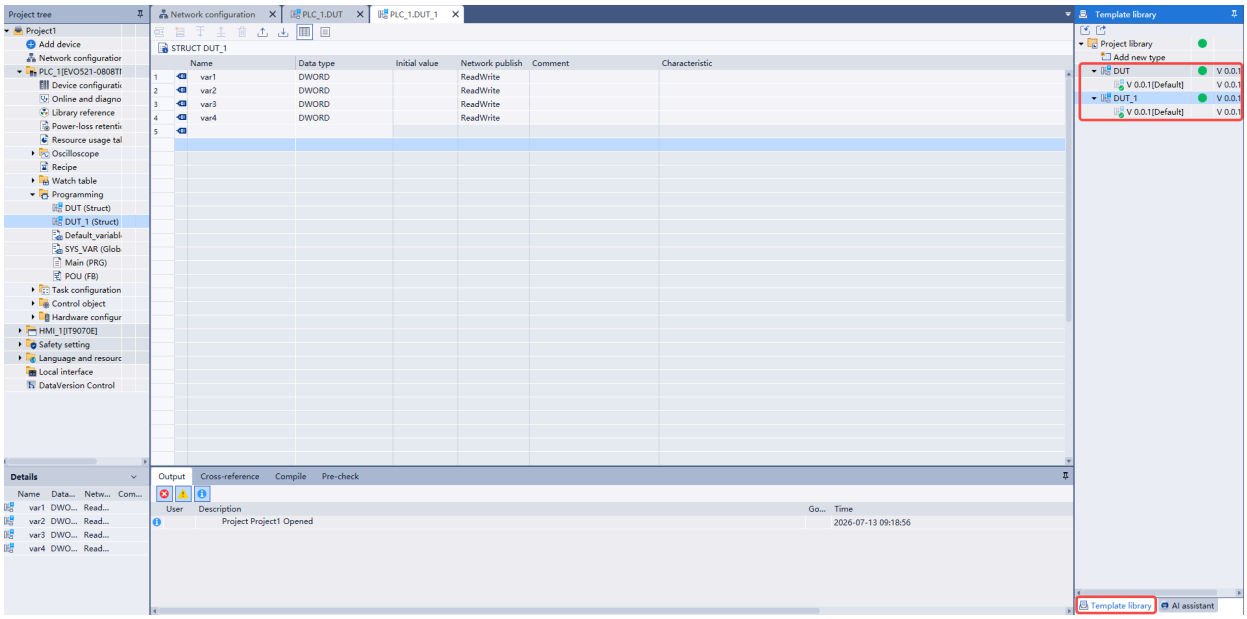
User-defined data types in PLC support templating, allowing common resources to be reused across multiple projects during configuration.



Creating a template

- **Prerequisites**
  - User-defined data types have been created or imported in the current project.
  - Only user-defined 10.1.1.8.1 standard data types and array-type structures in PLC devices can be templated. Arrays support multi-dimensional and nested arrays, with a maximum of 2000 elements. Standard data types with specified upper/lower limits and arrays with non-numeric boundaries are not supported.
  - Enumerations, unions, aliases, FBs, FCs, PRGs, and library types are not supported.
  - Structure inheritance is not supported.
- **Procedure**

1. Open the project view and select the "Template library" tab on the right.



2. Select the user-defined data type for templating under the "Programming" node in the left project tree, and drag it to the "Template library".

- **Result**
  - Create the corresponding user-defined type under "Template library > Project library", with version V0.0.1. The user-defined type nodes in both the project tree and the template library are marked with .

- When editing a templated PLC type, a prompt appears indicating that the content is associated with a type in the template library, and that any changes made must be manually synchronized.

NOTE

- During templating, if the referenced object contains nested user-defined sub-structures, all nested sub-structures will be automatically templated.
- A templated user-defined data type cannot be re-templated, ensuring that each structure type in the project tree maps to a unique type in the template library.

Positioning a template

When multiple user-defined types exist in the project tree, you can quickly view the corresponding type in the template library. Right-click a type and select "Go to type" to jump to the corresponding node in the template library.

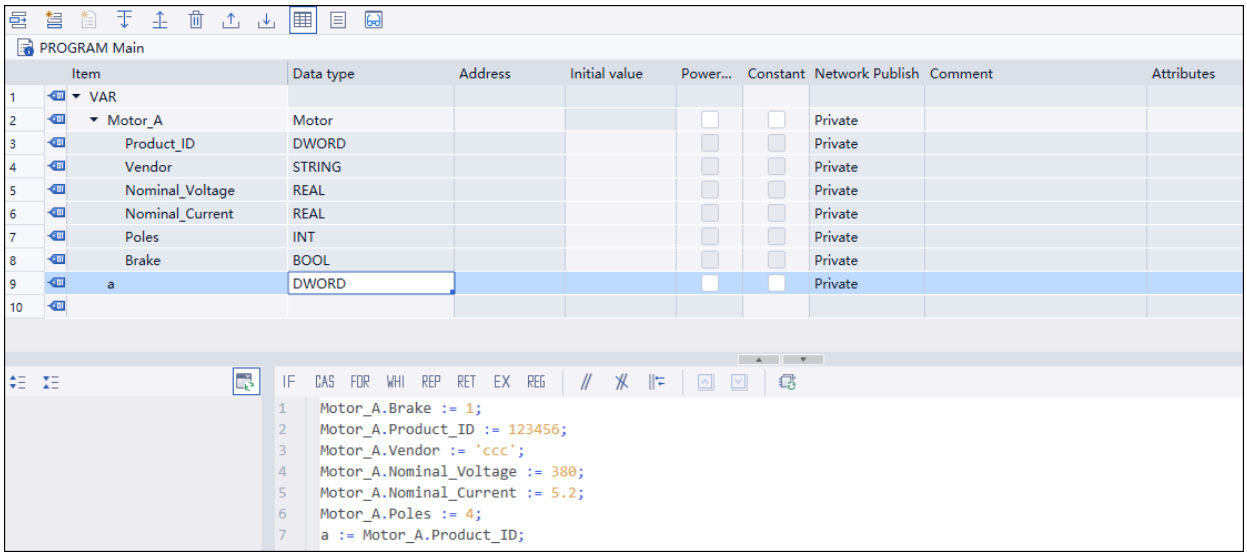
Disconnecting from a template

Right-click the user-defined type to disconnect in the project tree and select "Disconnect from the type" to disconnect this type and the corresponding type in the template library. After disconnection, this type can no longer be used to update instances, and the node identifier of this type becomes .

Deleting a template

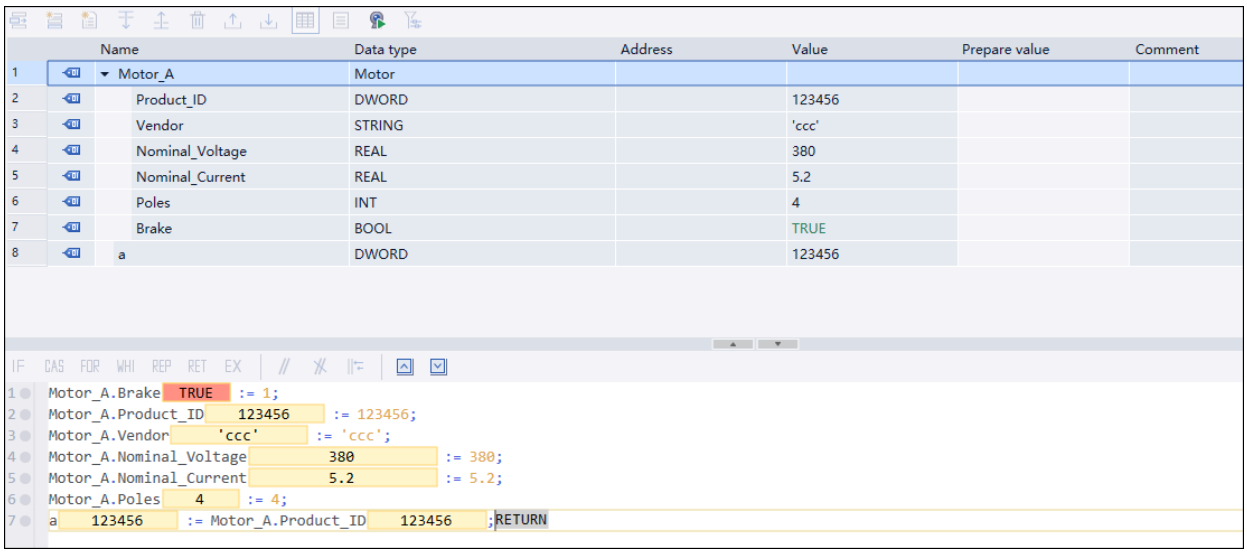
Right-click the user-defined type in the template library and select "Delete" to remove the template.

NOTE



- Deleting a user-defined type from the template library will not delete the corresponding type or its instances from the project tree.
- Deleting a user-defined type from the project tree will not delete the corresponding type from the template library.

Using a template



After the template is created, it can be instantiated and used in other PLC devices. For specific usage, see 13.4.4.4 Applying a User-defined Type.

Structure instantiation

After a structure is defined, create a variable in the program with the type set to the newly created structure name, that is "Motor". In the "PROGRAM Main" window, enter "VariableName." (the variable name followed by a dot). The system will automatically display a dropdown list of the structure's members. Select the target variable and use assignment statements to perform read or write operations on the structure, as shown below.

Go online and run the program to monitor the operation data. As shown in the figure below, the member assignment of the variable Motor_A of type Motor succeeded.

NOTE

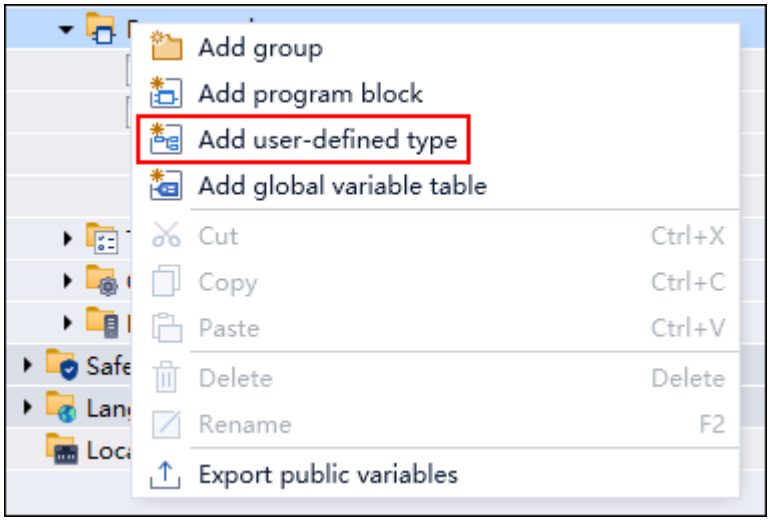
- During structure instantiation, the "Network public" property (options include "Public" and "Private") is set to "Private" by default. If the parent node is set to "Private", all child nodes will also be "Private"; if the parent node is set to "Public", the child nodes will inherit the public property configured for the structure itself.
- During structure instantiation for the EVO500 series PLC V1.2 version, the "Network public" property (options include "Private", "Read/Write", "Read-Only", and "Write-Only") is set to "Private" by default. The child node properties inherit from the parent node and cannot be set separately. If the device version is downgraded from V1.3 to V1.2, a fault of public variable property compilation will be reported.

10.1.1.8.2.2 UNION

Concepts

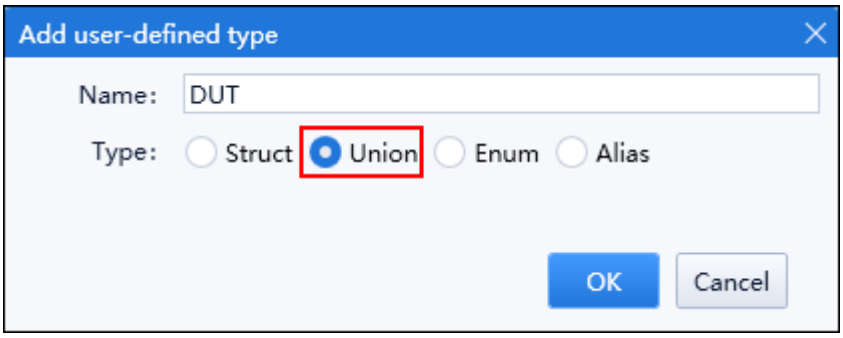
Unions are used to store different types of variables in the same memory unit. The following table shows an example where a BYTE variable, an INT variable, and a DWORD variable are stored in the memory unit starting at address 16#100. The merged part in the table represents the coverage domain region. Such a structure where different variables share the same memory region is called a union.

	16#100	16#101	16#102	16#103
BYTE (8 bits)				
INT (16 bits)				
DWORD (32 bits)				



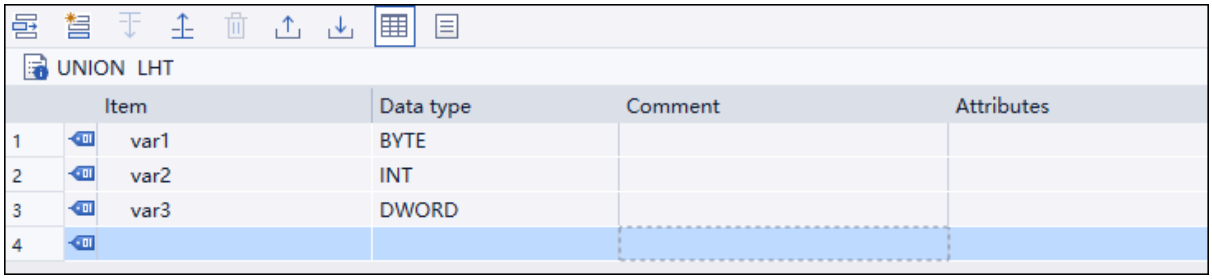
The syntax for the union declaration is as follows:

```
TYPE <unionname>:UNION
   <declaration of variables 1>
   ...
   <declaration of variables n>
END_UNIONEND_TYPE
```



<unionname> is a type and can be used as a data type. All variables of the union type share the same storage location and are allocated with space same as that of the variable that occupies the largest space. The size of the union in the above table is based on DWORD, which is 32 bits.

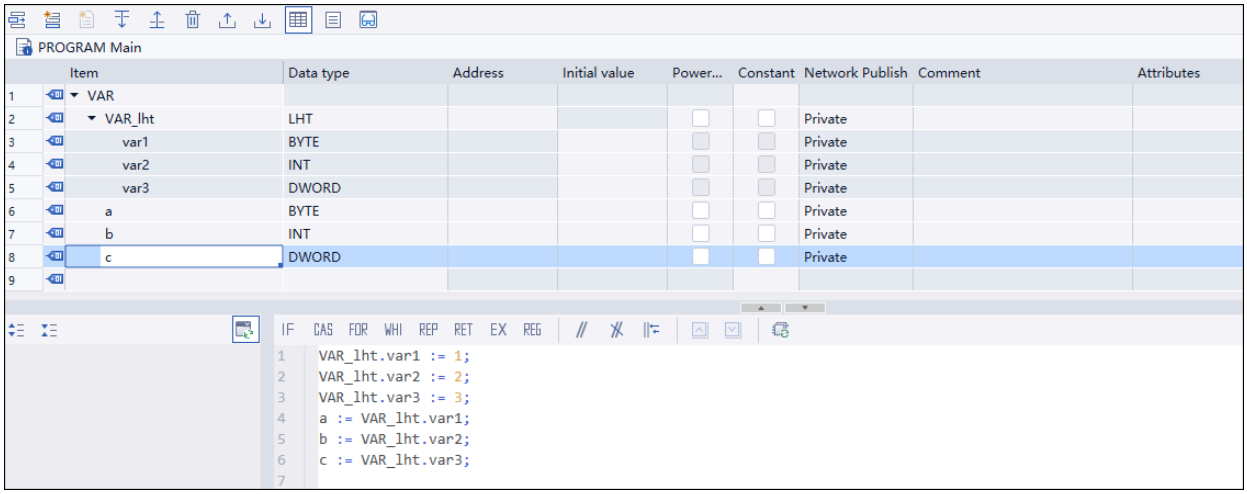
Union definition



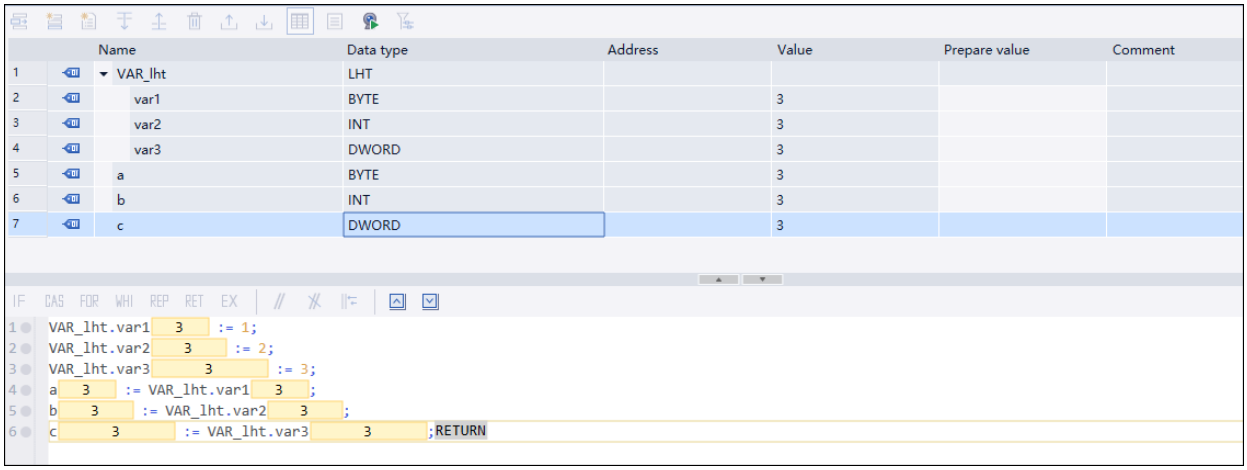
1. Right-click "Programming" in the project tree and select "Add user-defined type".

2. In the "Add user-defined type" window, set the name of the union and select "Union" as the type. Click "OK", and the system automatically enters the DUT editor.

3. Create a union named LHT in the DUT editor, as shown below.



NOTE



Unions support defining one-dimensional BIT arrays, which can be used for bit-level data access.

Union usage

After a union is created, create a variable in the program with the type set to the newly created union name, that is LHT. In the "PROGRAM Main" window, enter "VariableName." (the variable name followed by a dot). The system will automatically display a dropdown list of the union's members. Select the target variable and use assignment statements to perform read or write operations on the union, as shown below.

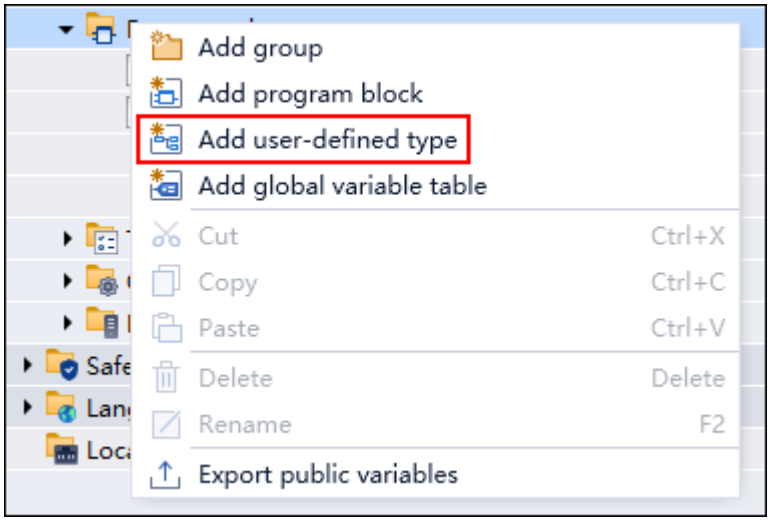
Go online, click the "Run" icon, and monitor the running data, as shown in the following figure.

10.1.1.8.2.3 ENUM

Concepts

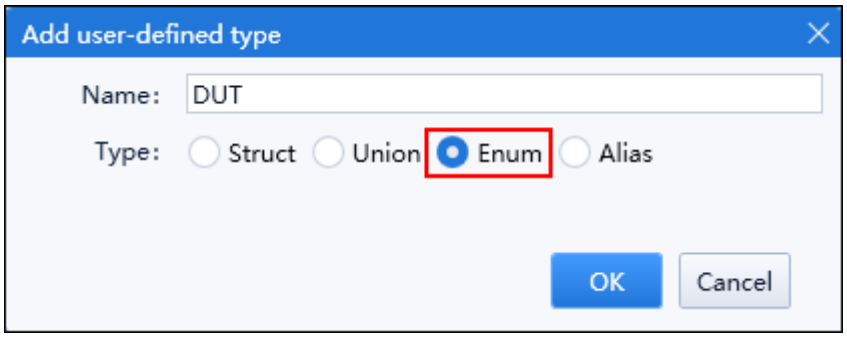
If a variable has several possible values, it can be defined as an enumeration type. Enumeration lists the possible values of a variable one by one. The variable's value is limited to the listed range. For example, define a variable whose value represents the four seasons of a year. This variable can only store four meaningful values. To define these values, you can use an enumeration type. The set of possible values for the four seasons is: {Spring, Summer, Autumn, Winter}

This set can be defined as an enumeration type describing the seasons, which contains four elements. A variable declared with this type is restricted to a single value from the set.



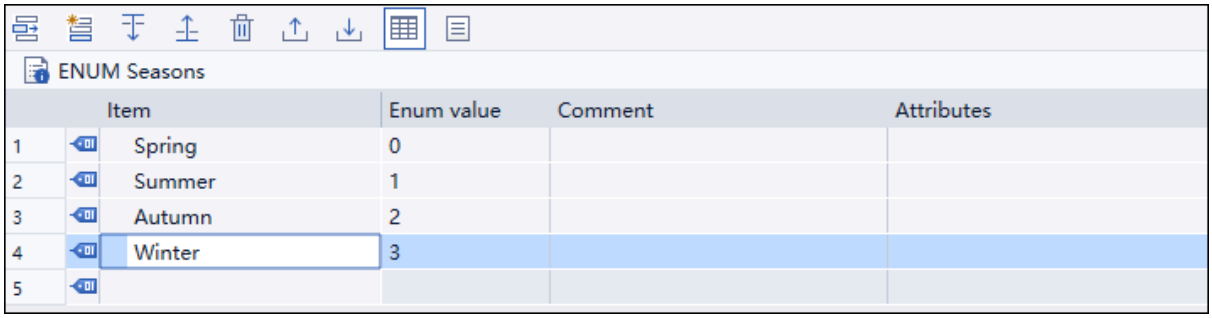
The syntax for an enumeration declaration is as follows:

```
TYPE <identifier>:(<enum_0> ,<enum_1>, ...,<enum_n>) |<base
data type>;END_TYPE
```



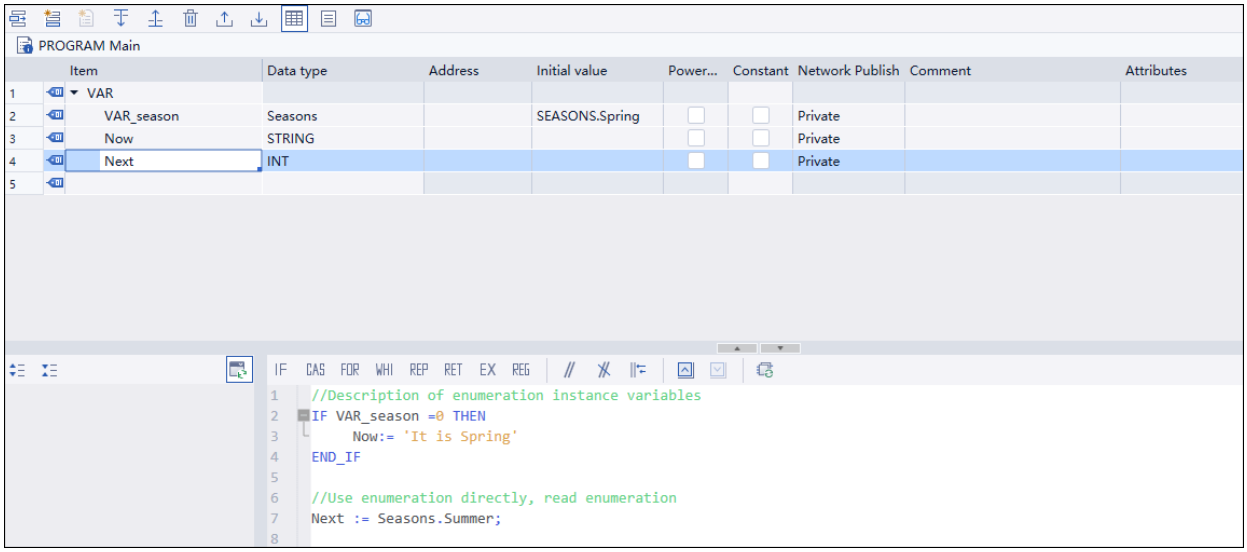
identifier: user-defined enumeration type; enum_n: constant value of the enumeration type. Each constant can declare its value. If no value is declared, the default value is used. The data type of enumerated constants is base data type. The value may not be declared and is an integer by default.

Enumeration definition

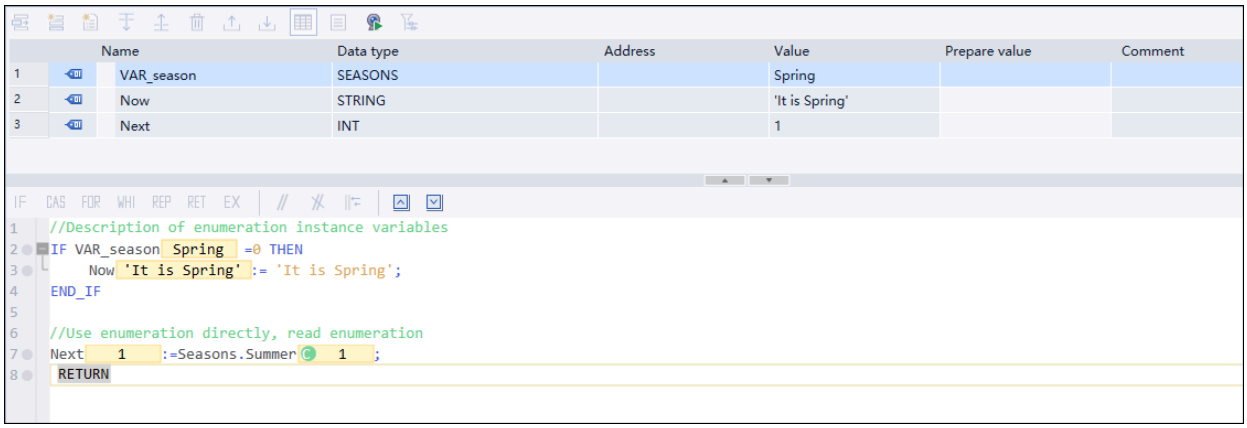


1. Right-click "Programming" in the project tree and select "Add user-defined type".

2. In the "Add user-defined type" window, set the name of the enumeration and select "Enum" as the type. Click "OK", and the system automatically enters the DUT editor.



3. Create an enumeration named Seasons in the DUT editor, as shown below.



Enumeration usage

After an enumeration is created, create a variable in the program with the type set to the newly created enumeration name, that is "Seasons". Select the "Initial value" in the variable table. In the editor, a judgment statement uses an instance of the enumeration variable "Seasons".

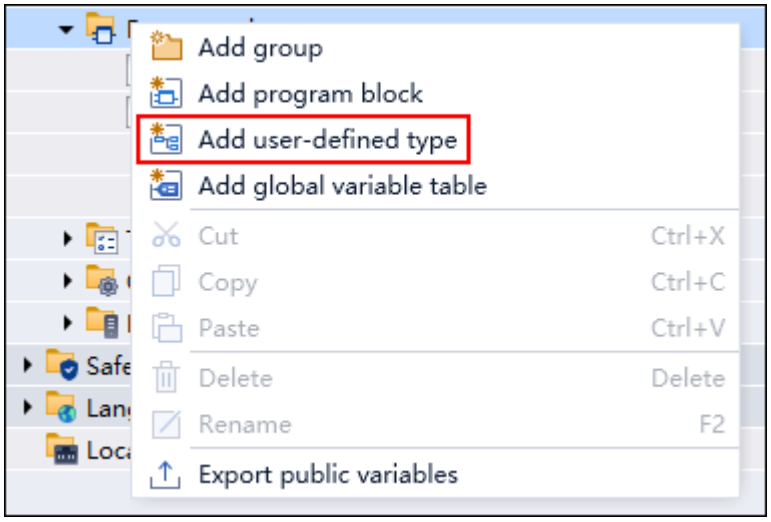
You can also directly use the enumeration for read operations, as shown on line 7 in the figure.

Go online, click the "Run" icon, and monitor the running data, as shown in the following figure.

10.1.1.8.2.4 ALIAS

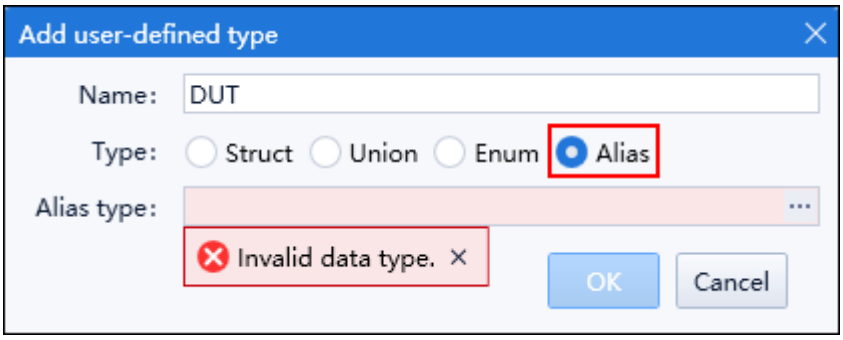
Concepts

An alias represents a data type by another name.



The syntax for the alias declaration is as follows:

```
TYPE <aliasname>:basetype END_TYPE
```

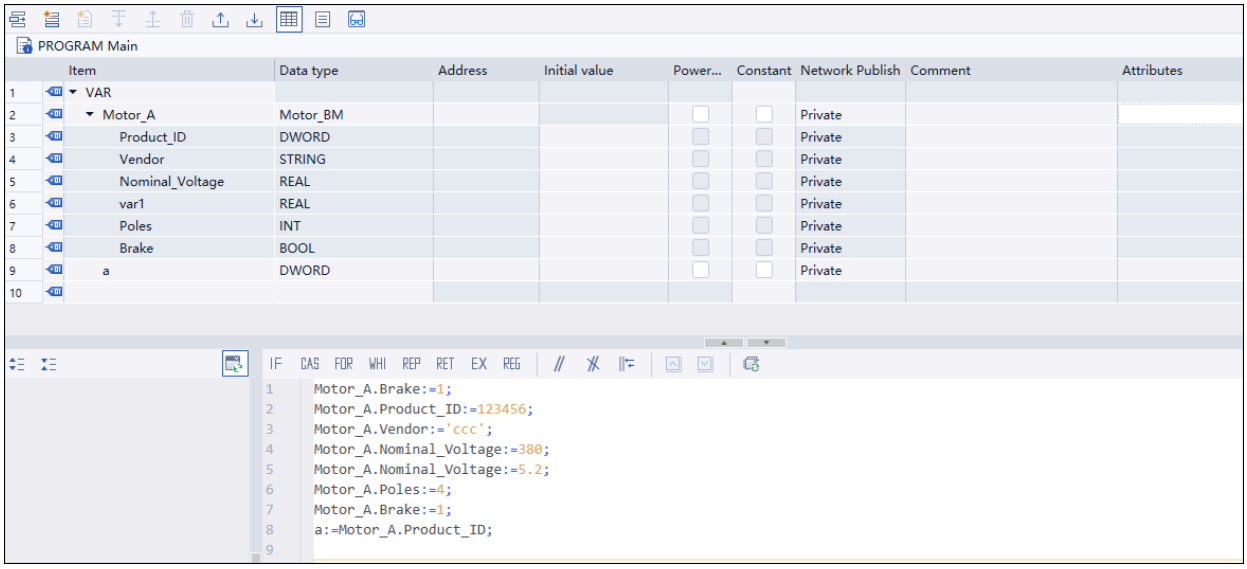


"aliasname" indicates the alias type and is used as a data type. "basetype" is a standard, user-defined data type, or FB.

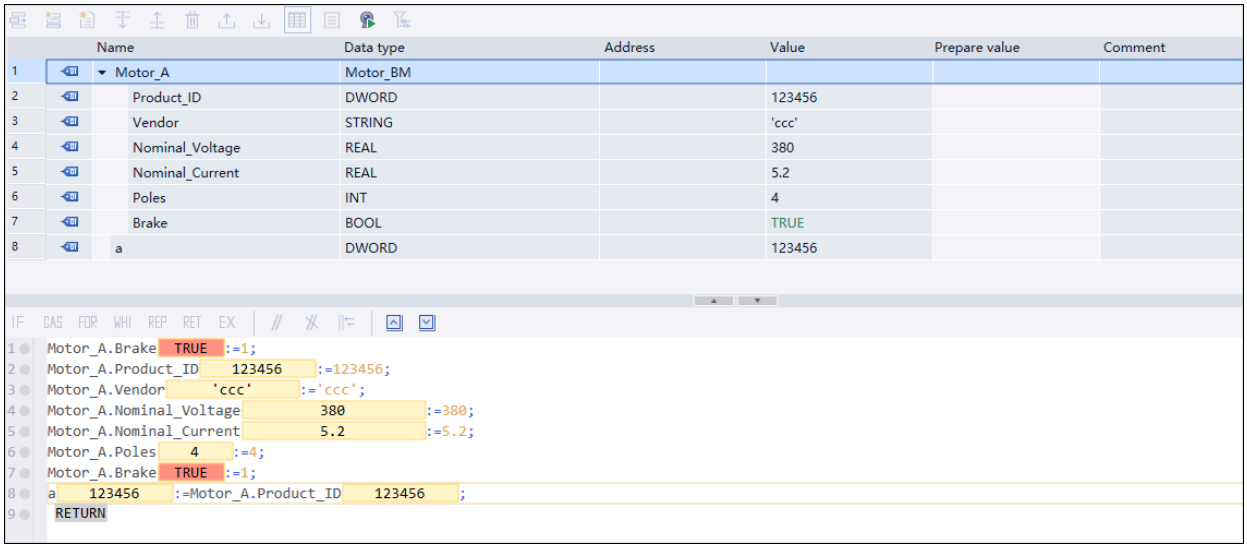
Alias definition

1. Right-click "Programming" in the project tree and select "Add user-defined type".

2. In the "Add user-defined type" window, set the name of the alias, select the type as "Alias", and select "Alias type" as needed. Click "OK", and the system automatically enters the DUT editor.



3. In the DUT editor, configure an alias for the structure Motor as follows.



Alias usage

After an alias is created, create a variable in the program with the type set to the newly created alias name, that is "Motor_BM". In the "PROGRAM Main" window, enter "VariableName." (the variable name followed by a dot). The system will automatically display a dropdown list of the union's members. Select the target variable and use assignment statements to perform read or write operations on the union, as shown below. The interface is shown in the following figure.

Go online, click the "Run" icon, and monitor the running data, as shown in the following figure.

10.1.1.8.3 Complex Types

10.1.1.8.3.1 ARRAY

ARRAY refers to the data structure consisting of a fixed number of elements with the same data type. These elements can be of all data types except ARRAY.

Array variable definition

The syntax for declaring an array-type variable is as follows:

<Array_Name>:ARRAY [<ll1>..<ul1>,<ll2>..<ul2>,<ll3>..<ul3>] OF <elem. Type>

ll1, ll2, and ll3 define the lower limits of the array dimensions, while ul1, ul2, and ul3 define the upper limits. They must be integers. Type defines the data type of each array element.

Array variable usage

- Array initialization example
  Card_game: ARRAY [1..13, 1..4] OF INT;
  arr1 : ARRAY [1..5] OF INT := [1,2,3,4,5];
  arr2 : ARRAY [1..2,3..4] OF INT := [1,3(7)]; (* Array value 1,7,7,7*)

arr3 : ARRAY [1..2,2..3,3..4] OF INT := [2(0),4(4),2,3]; (* Array value 0,0,4,4,4,4,2,3*)

arr4 : ARRAY [1..10] OF INT := [1,2]; (* Partially initialized; uninitialized elements default to 0 *)

- Array structure initialization example

  Structure definition:

PROGRAM Main

	Item	Data type	Address	Initial value	Power...	Constant	Network Publish	Comment	Attributes
1	VAR								
2	arr1	ARRAY[1..3] OF STRUCT1					Private		
3	arr1[1]	STRUCT1					Private		
4	p1	INT		1			Private		
5	p2	INT		10			Private		
6	p3	DWORD		4723			Private		
7	arr1[2]	STRUCT1					Private		
8	p1	INT		2			Private		
9	p2	INT		0			Private		
10	p3	DWORD		299			Private		
11	arr1[3]	STRUCT1					Private		
12	p1	INT		14			Private		
13	p2	INT		5			Private		
14	p3	DWORD		112			Private		

  Syntax of array structure initialization:

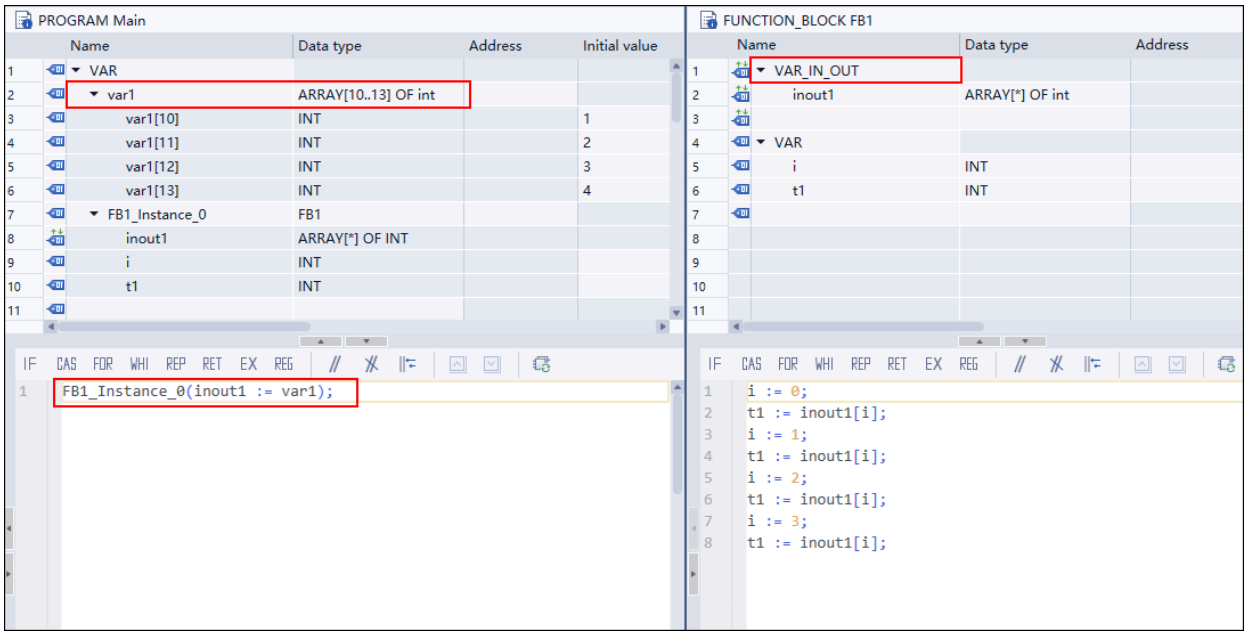
  arr1:ARRAY[1..3] OF STRUCT1:= [(p1:=1,p2:=10,p3:=4723),(p1:=2,p2:=0,p3:=299),(p1:=14,p2:=5,p3:=112)];

- Syntax of accessing union elements

  <Array-Name>[Index1,Index2].

  Example: Card_game [9,2].

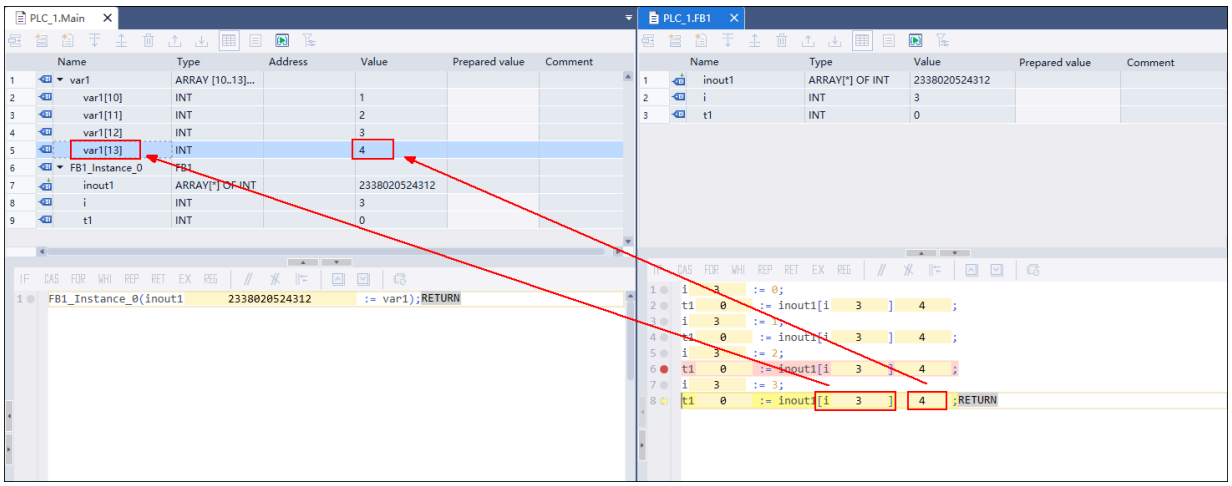
Variable-length fixed-type array definition



A variable-length fixed-type array is an array with variable length, whose elements are of a fixed type. It can only be used for input/output variables (VAR_IN_OUT) in FB or FUN.

The syntax for declaring a variable-length fixed-type array is as follows:

```
VAR_IN_OUT
var1: ARRAY[*] OF specific type;
END_VAR
```



Variable-length fixed-type array usage

As shown in the following figure, define an INT-type variable-length array for the VAR_IN_OUT pin in FB, then instantiate it in "PROGRAM Main". Note that the ARRAY[*] OF INT type is used as a formal parameter in the called POU, and the caller can pass an INT array of any length as an actual parameter.

NOTE

During the call, the online value of the formal parameter expression uses a relative index, while the actual parameter at the call location displays an absolute index. The conversion is: Absolute index = Lower bound of the actual array + Relative index of the formal parameter. As shown in the figure below, the absolute index 13 is calculated as lower bound 10 + relative index 3.

10.1.1.8.3.2 POINTER

Concepts

A pointer represents an address. If a variable is defined in the software, the system allocates corresponding memory space based on the variable's data type after compilation. For example, the system allocates 1 byte of memory space for a BYTE-type variable and 4 bytes for a REAL-type variable.

Generally, programs perform storage operations through variable names. This is because after the program is compiled, variable names are converted into the memory addresses of the variables, and the storage operations on variables are carried out via memory addresses.

For example, define three WORD-type variables var1, var2, and var3 in the program. After compilation, the system allocates 2 bytes of memory to var1 at addresses 1000 and 1001, and var2 at 1002 and 1003. var3 is 1004 and 1005. The specific data stored in addresses 1000 and 1001 corresponds to the data of var1, and the same logic applies to var2 and var3, as shown below. This method of storing data by variable address is also known as "direct access" in high-level languages.

Variable	Data Content
var1	Byte_Low
	Byte_High
var2	Byte_Low
	Byte_High
var3	Byte_Low
	Byte_High

Address	Data Content
1000	Byte_Low
1001	Byte_High
1002	Byte_Low
1003	Byte_High
1004	Byte_Low
1005	Byte_High

Pointer variable

The address of a variable is called the "pointer" of that variable. For example, variables with addresses 1000 and 1001 are pointers to var1. If a variable is specifically used to store the address (pointer) of another

variable, it is called a "pointer variable". A pointer variable is declared in the software using the keyword "POINTER TO+ <type>". The <type> can refer to the memory address of variables, programs, function blocks, methods, and functions. A pointer variable can point to any of the aforementioned objects and any data type, including user-defined data types.

Pointer variable definition

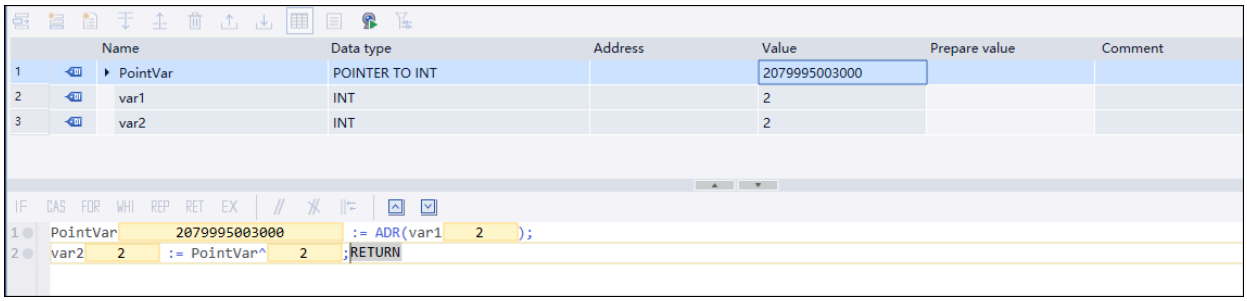
The syntax for declaring a pointer is as follows:

```
<identifier>: POINTER TO <data type>;
```

identifier: The pointer identifier.

data type: The data type that the pointer points to. It can be any data type (except BIT type), function block, program, method, and function.

Pointer operations are performed using address operators. Address operators include ADR (to access variable address) and ^ (value corresponding to variable address).



Pointer variable usage

Reading the content of a pointer address means reading the data stored in the address that the pointer currently refers to. The content can be obtained by adding the content operator "^" after the pointer identifier. The following example illustrates the usage of pointer variables.

Define PointVar as a pointer variable, which will be used to store address data.

In the program, use the ADR instruction in line 1, which is the operator used to obtain the memory address of a variable. After executing line 1, PointVar will have obtained the memory address of var1 (2079995003000 in decimal).

PointVar^ refers to the specific data (data at the address 2079995003000 in decimal) corresponding to this memory address, which is the value 2 stored in var1. After line 2 is executed, the value of PointVar^ is assigned to var2, so var2 will equal 2.

10.1.1.8.4 BIT

The BIT data type is used only for a single variable in a structure or function block, with values of TRUE (1) and FALSE (0).

The keyword "BITADR" can be used to obtain the bit address of a variable. A BIT occupies 1 bit of memory and bit access is relatively time-consuming. Therefore, the BIT data type should only be used when data needs to be defined in a predefined format.

10.1.1.8.5 ANY

ANY refers to runtime assignment of values of any data type.

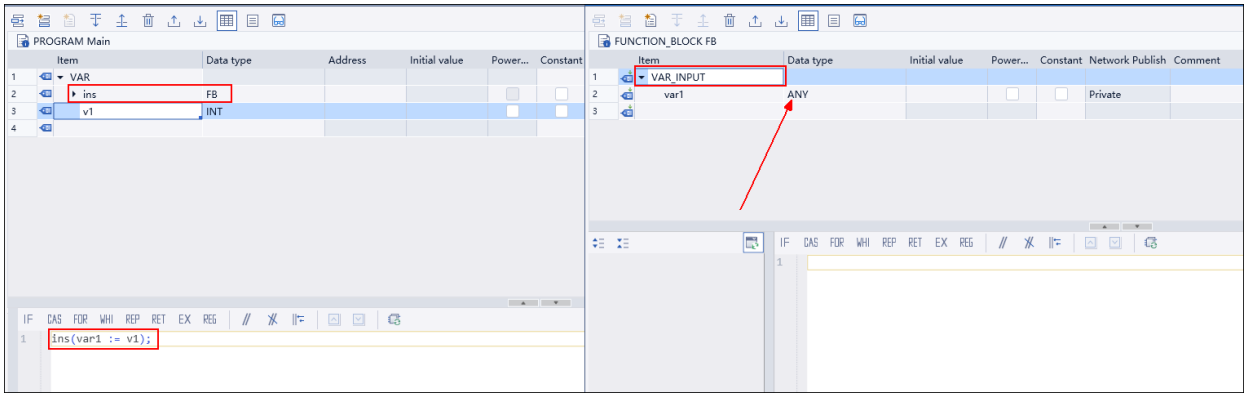
When implementing function blocks, functions, or methods, it is supported to declare the input (<VAR_INPUT) as a variable of data type ANY or ANY_ <type>. ANY is a type used for variables with an undetermined type during programming.

The correspondence between general data types and basic data types is shown in the following table.

Hierarchy of General Data Types			Basic Data Types
ANY	ANY_BIT		BYTE, WORD, DWORD, LWORD
	ANY_DATE		DATE_AND_TIME, DT, DATE, TIME_OF_DAY, TOD
	ANY_NUM	ANY_REAL	REAL, LREAL
		ANY_INT	USINT, UINT, UDINT, ULINT, SINT, INT, DINT, LINT
	ANY_STRING		STRING, WSTRING

ANY-type variable definition

The syntax for declaring an ANY-type variable is as follows:



```
VAR_INPUT
   var1: ANY;
END_VAR
```

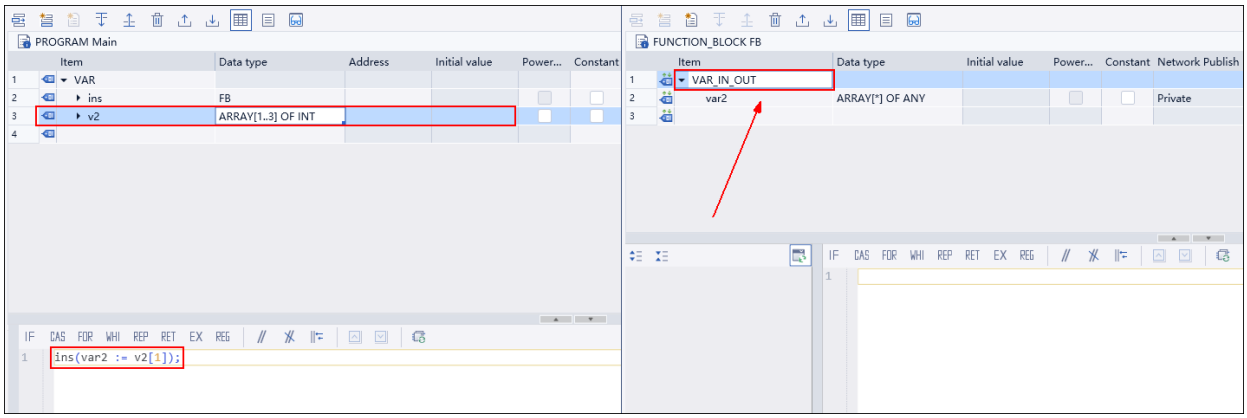
During program compilation, the compiler automatically converts the ANY type into the following structure:

```
TYPE __AnyType:
STRUCT
pValue: POINTER TO BYTE;    // A pointer to array elements
diSize: DINT;                    // Size of array elements
typeClass : __SYSTEM.TYPE_CLASS; // Type of the formal parameter (expressed by semantics)
typeId: INT; // When typeClass is of USEDEF type, typeId points to a unique random number, ensuring that each type has a distinct ID. typeId is used to determine if USERDEF types are identical.
elementTypeClass : _SYSTEM. ELEMENT _TYPE_CLASS; // When typeClass is of USERDEF type, elementTypeClass specifies the type (Struct, Union, FB)
arrayInfo: pointer of __SYSTEM.__ARRAY__DIM__INFO; // A pointer to the array dimension structure on the stack
dimCount: DINT; // Number of array dimensions
END_STRUCT
END_TYPE
```

ANY-type variable usage

As shown in the following figure, define an ANY-type variable for the VAR_INPUT pin in FB, then instantiate it in "PROGRAM Main".

Variable-length ANY-type array definition



A variable-length ANY-type array is an array with variable length, whose elements are of ANY type. It can only be used for input/output variables (VAR_IN_OUT) in FB or FUN.

The syntax for declaring a variable-length ANY-type array is as follows:

```
VAR_IN_OUT
   var2: ARRAY[*] OF ANY;
END_VAR
```

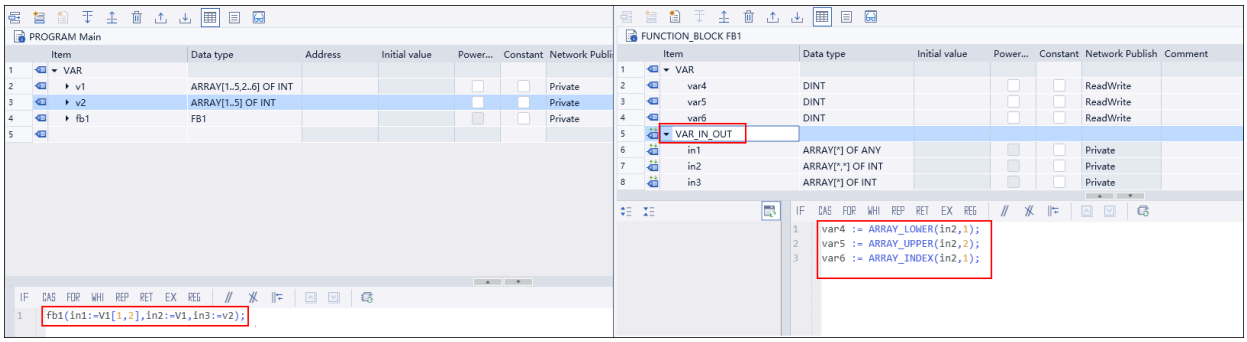
Variable-length ANY-type array usage

As shown in the following figure, define a variable-length ANY-type array for the VAR_IN_OUT pin in FB, then instantiate it in "PROGRAM Main" and pass parameters (subscripts required).

ARRAY_xxx keyword usage

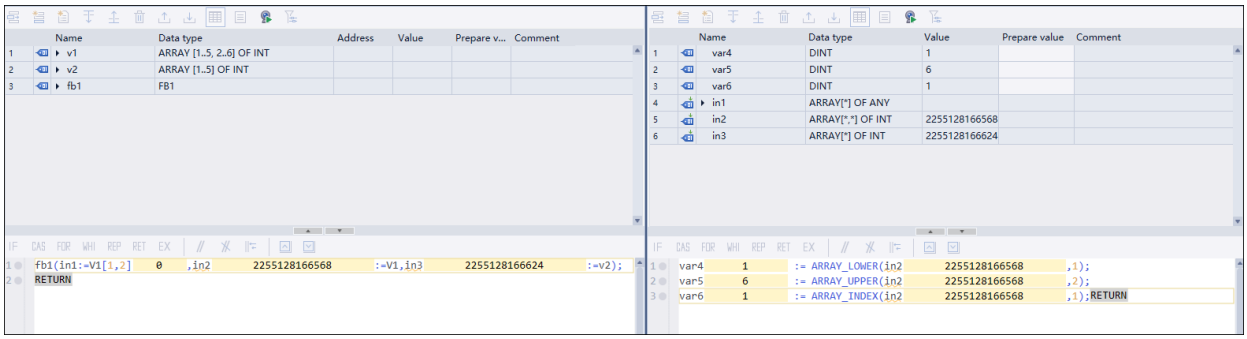
After defining a variable-length array for VAR_IN_OUT in FB or FUN, the ARRAY_LOWER/UPPER/INDEX keywords can be used to obtain the lower limit/upper limit/subscript of the variable-length array.

ARRAY_LOWER: Obtains the lower limit of the variable-length array.
ARRAY_UPPER: Obtains the upper limit of the variable-length array.
ARRAY_INDEX: Obtains the subscript for the current element of the variable-length array.



- Related variables

Input/Output	Variable	Name	Data type	Initial Value	Description
Input	In1	Variable-length array	ARRAY[*]	-	Determined by the array passed in by the formal parameter.



Input/Output	Variable	Name	Data type	Initial Value	Description
	In2	Dimension	BIT, BYTE, WORD, DWORD, LWORD, SINT, USINT, INT, UINT, DINT, UDINT, LINT, ULINT	-	Indicates the dimension of the array, which cannot exceed the maximum dimension limit.
Output	Out	Return value	DINT	-	Indicates the result.

- Program example

Take the ST language as an example. Define a variable-length array for the VAR_IN_OUT pin in FB and use ARRAY_LOWER/UPPER/INDEX keywords to obtain the corresponding values. Then, instantiate the array in "PROGRAM Main" and pass parameters (subscripts required).

The operation result is shown in the figure below.

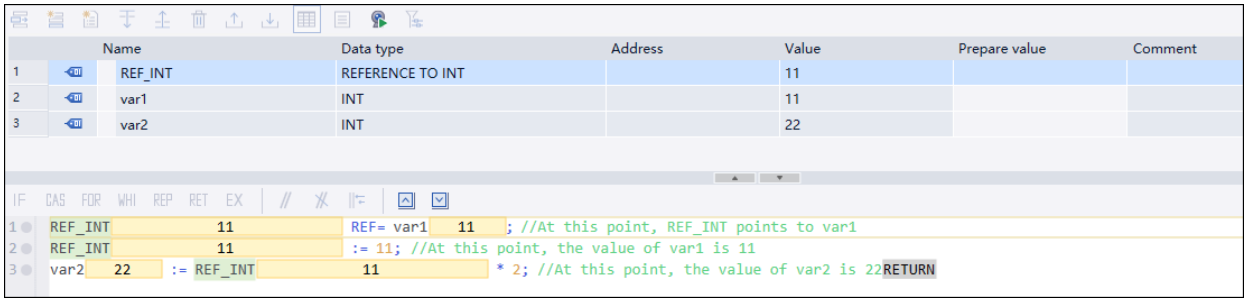
10.1.1.8.6 REFERENCE

A reference is an alias of an object. This alias can be read and written by the variable name. Unlike a pointer, the data that the reference refers to is changed directly, so the assignment of the reference is identical to the data it refers to. A specific assignment is required to set the address of the reference. A dedicated operator can be used to check whether the reference refers to valid data (not equal to 0).

Reference-type variable definition

The syntax for declaring a reference is as follows:

```
<identifier> : REFERENCE TO <data type>
```



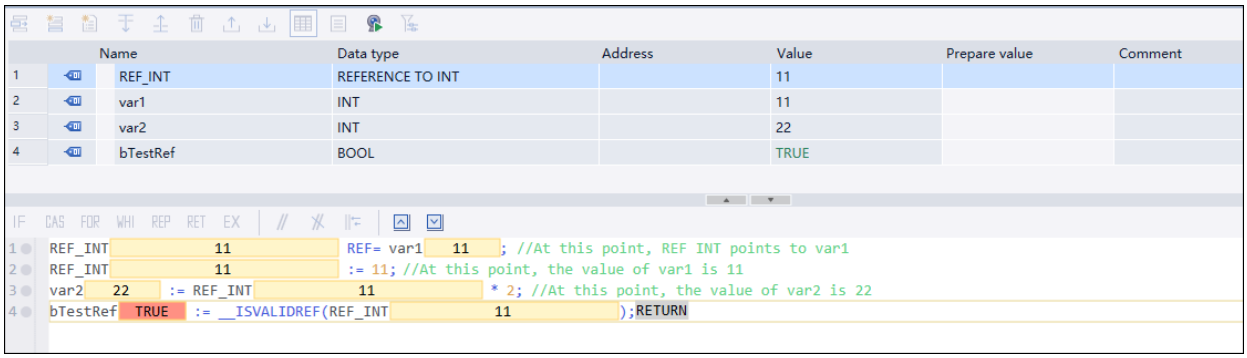
identifier: Reference identifier.

data type: The data type of the referenced object.

> **CAUTION**
>
> The BIT type cannot be referenced. Specifically, the declaration of ref1: REFERENCE TO BIT is invalid.

Reference-type variable usage

The following example illustrates how to use a reference-type variable.



The dedicated instruction "__ISVALIDREF" can be used to check whether a variable has been properly referenced.

Its specific syntax is as follows:

```
<Boolean variable> := __ISVALIDREF(<data type> declared as reference type);
```

The return value <Boolean variable> is TRUE if the reference points to a valid value, otherwise it is FALSE.

<data type> must be declared as reference type, otherwise the instruction is invalid.

10.1.1.8.7 Data Type Conversion

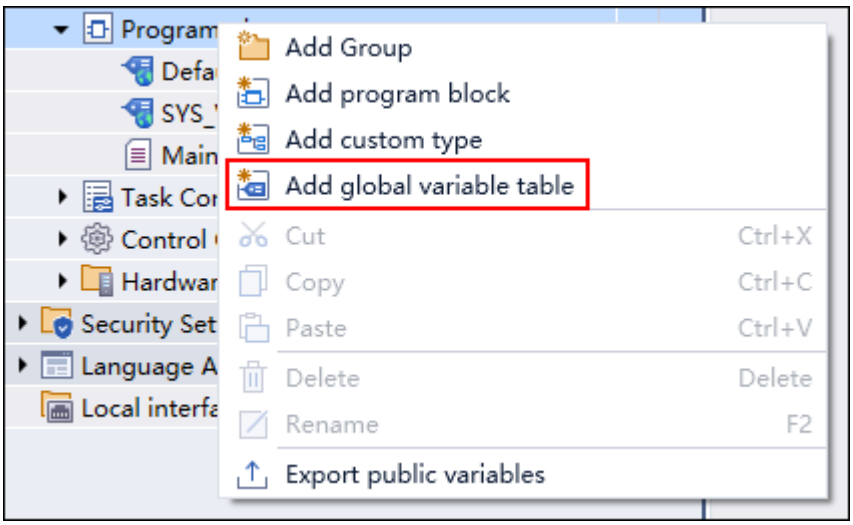
Data type conversion refers to the process of converting data from one type (e.g., integer, floating-point number, string) to another. This is very common in programming and data processing to make different types of data compatible for operation, storage, or transmission.

There are two main methods of data type conversion:

- Explicit type conversion
  Explicit conversion is performed by specifying the target data type. It is usually used to convert a data type with a large range to one with a small range, or to convert between different types. The iFA software provides explicit conversion instructions for users. For details, see 18.1.12 "Conversion Operators".
- Implicit type conversion

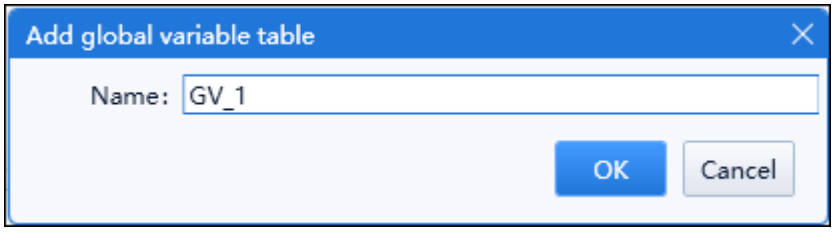
Implicit conversion is performed automatic by the compiler. It ensures security and will not result in significant data or symbol loss during calculation. Implicit type conversion follows the following rules:

- The BOOL type and BIT type can be implicitly converted to each other, but neither can be implicitly converted to other data types.
- Only the following data types support implicit conversion: BYTE, WORD, DWORD, LWORD, INT, SINT, DINT, LINT, UINT, USINT, UDINT, ULINT, REAL, LREAL, STRING, WSTRING, CHAR, and WCHAR.
- The bit length of the source data type shall not exceed that of the target data type. For example, an operand of the WORD type cannot be assigned to a parameter of the BYTE type.



> NOTE
>
> Integer data of any length can be implicitly converted to a floating-point type, while the floating-point type cannot be implicitly converted to an integer. If the word length of the integer data is less than or equal to that of the floating-point data, the conversion will be performed normally without warnings; otherwise, a warning will be reported.

10.1.1.9 Variable Declaration



10.1.1.9.1 Adding a Global Variable Table

Procedure

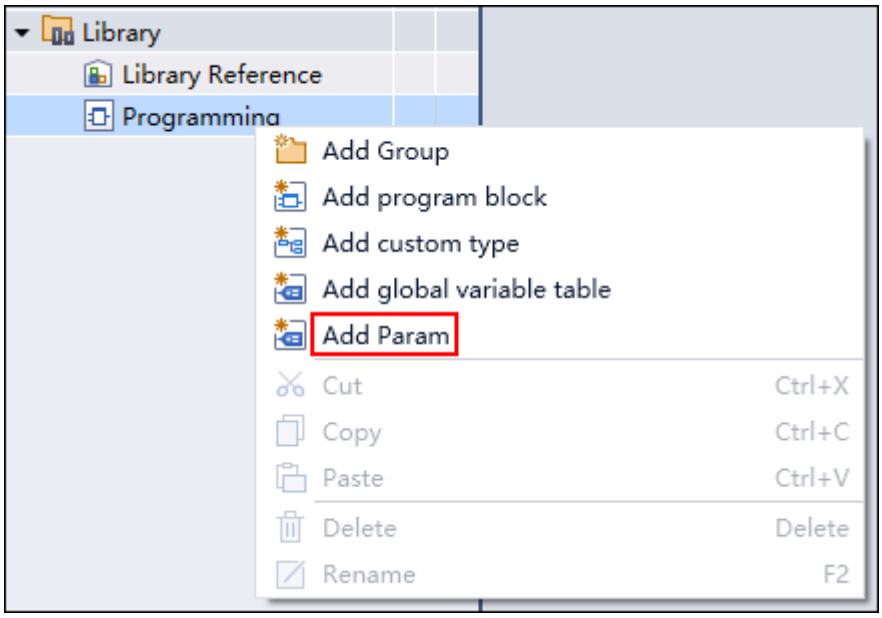
1. Right-click "Programming" and select "Add global variable table".

2. Set the name of the global variable table and click "OK" .

3. The added global variable table is displayed in the project tree under "Programming".

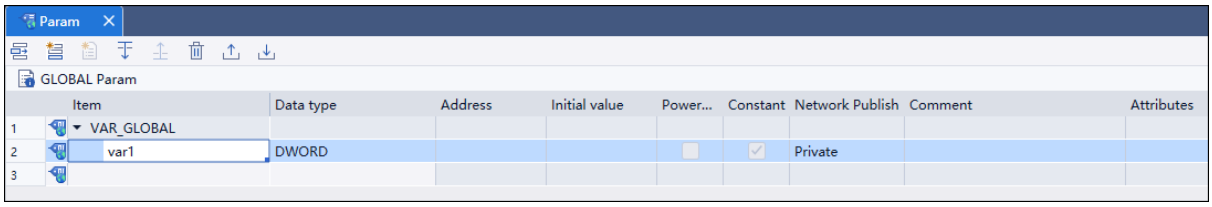
NOTE

The name of the global variable table shall conform to IEC standards and must not exceed 128 in length.



10.1.1.9.2 Adding a Param Table

Prerequisites



A library project has been created or opened.

Procedure

1. Right-click "Programming" and select "Add Param".

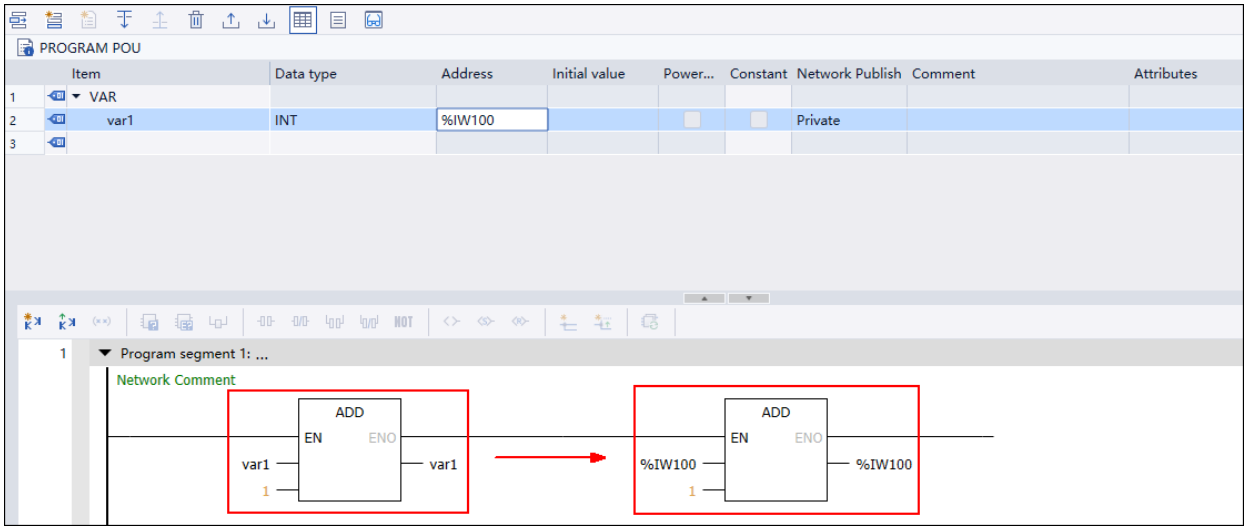
2. Add a constant to the "Param" table.

NOTE

The "Param" table can only be used in library projects and only one table can be added.

10.1.1.9.3 Variable Declaration Properties

A variable has nine properties: ID (name), data type, address, initial value, power-failure retention, constant, network public property, comment, and property.



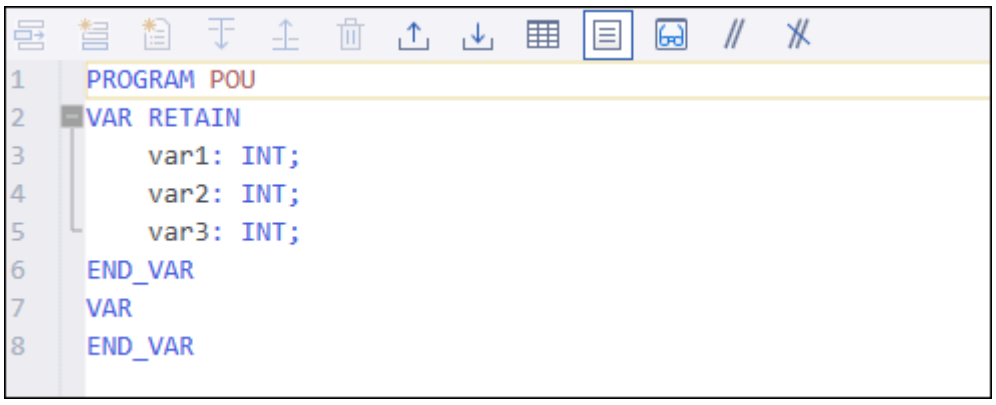
- **ID**
  ID is the variable's name. When naming variables, keep the following in mind:
  - It cannot include spaces or special characters.
  - It cannot be a predefined keyword.
  - Names are not case-sensitive.
  - The maximum length is 128 characters.
  - Names cannot be defined repeatedly.
- **Data type**
  For the supported data types in the iFA platform, see 10.1.1.8 Data Types.
- **Address**
  Address can be used to define the memory location where the variable is stored, known as the direct address (AT). The syntax for defining a direct address is as follows:

```
Plain Text
%<memory area prefix><size prefix><number>|.<number>
```

  The programming system supports the following three storage area prefixes:
  - I: Input, physical input, "sensor".
  - Q: Output, physical output, "activator".
  - M: Storage position.

  The programming system supports the following size prefixes:
  - X: Bit, one bit.
  - B: Byte, one byte.
  - W: Word, two bytes.
  - D: Double Word, four bytes.

  Program editing supports using addresses to manipulate objects.



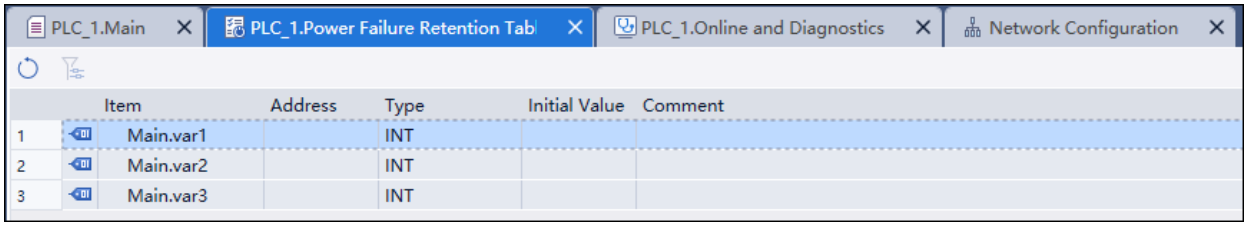
- **Initial value**

  The initial value of a variable defaults to 0 but can be customized during variable declaration.

- **Power failure retention**

  Power failure retention ensures that variables retain their original values after PLC power failures or program downloads. This is commonly used to define critical parameters in projects, preventing the data loss due to unexpected PLC power failures or program downloads.

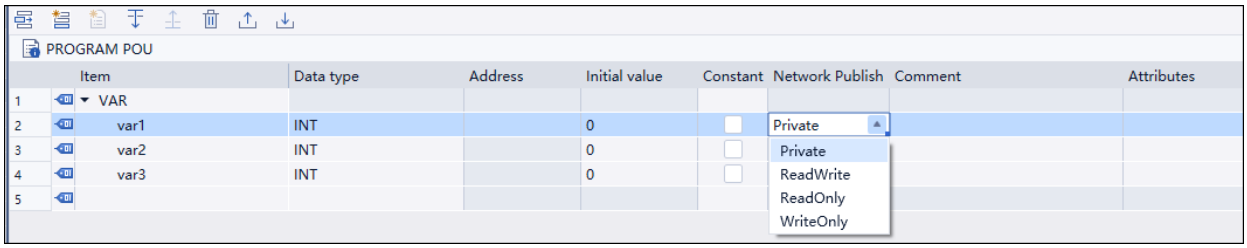
  The power failure retention characteristic is primarily declared using the property key RETAIN.

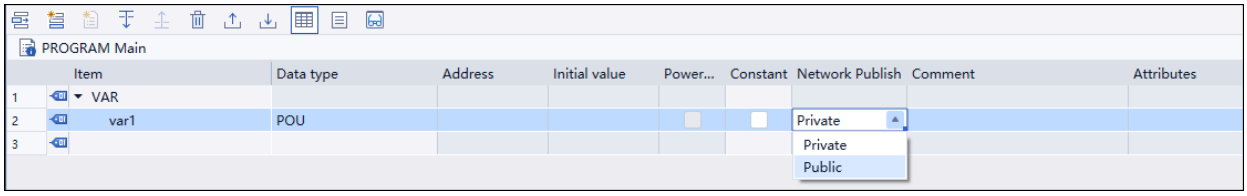


Action	VAR	VAR RETAIN
Power failure	Initialization	Retain the original value.
Hot Reset	Initialization	Retain the original value.
Cold Reset	Initialization	Retain the original value.
Program download	Initialization	Retain the original value.
Online modification	Retain the original value.	Retain the original value.

Power failure retention table

Check the "Power failure retention" options for variables in "PROGRAM Main". After compilation, these variables will be displayed collectively in the power failure retention table.





- **Constants**

  Constants are numerical values that do not change. Constants do not support the power-failure retention property.

- **Network public property**

  The network public property can be used to display the network public status of a variable.

  - When the "Private" option is selected, the variable does not support access by third-party equipment or software.
  - When the "Read/Write", "Read-Only", or "Write-Only" option is selected, the variable supports access by third-party equipment or software.
    - Read/Write: The data of the variable can be modified or viewed.
    - WriteOnly: The data of the variable can only be modified, but cannot be viewed or read.
    - Read-Only: The data of the variable can only be viewed or accessed, but cannot be modified.
  - When the "Public" option is selected, the public property of the child node is applied.

    Network public property restrictions:

  - Restriction rules
    - The number of variables is determined by the number of nodes in the variable or variable group. For complex data types, the number of variables is determined by the number of child elements. For example, the array ARRAY[1...5000] OF INT represents 5000 public variables.
    - Only variables within the compilation call chain are counted, encompassing all global variables and those in referenced PRGs (including various instantiated complex types). When calculating the number of child elements in complex types, elements containing pointers, references, ANY-type variables, input/output variables, temporary variables, constants, and variables within methods are excluded. All private child elements are excluded from the public variable calculation results.
  - Restriction limit

    The upper limits of public variables differs for various products, as follows.

Product Series	Number of network public variables
EVO400/EVO500 series	≤ 50,000
EVO700	≤ 200,000

Product Series	Number of network public variables
EVO800 series	≤ 500,000

◦ Principles

After the upper limit is exceeded, the compilation reports a fault.

Different network public properties:

Type	Public Attribute
Standard type instances	Read-only / Write-only / Read-write / Private
Structure instances	Public / Private
Union instances	Read-only / Write-only / Read-write / Private
Enumeration instances	Read-only / Write-only / Read-write / Private
FB instances	Public / Private
Alias instances	Depends on the original type (following the rules in this table)
Structure / FB array instances	Public / Private
Other array instances	Read-only / Write-only / Read-write / Private

- **Comments**

  Comments are used to add annotations to variables, making them easier to understand.

- **Property**

  Properties are used for differentiated handling of individual variables. For example, when a user needs to permanently display a certain variable in decimal format, this can be achieved by setting the variable's attribute 'displaymode' := 'dec'. The following are commonly used properties:

No.	Keyword	Value	Note
1	displaymode	'bin', 'dec', 'hex'	Specifies the base for displaying the online value of a variable, supporting binary, decimal, and hexadecimal formats.
2	visibility	none	Visibility check for variables/notations; if it includes "none," it is hidden.
3	qualified_only	/	When this marking is added to a global variable, it must be accessed using the global variable group name followed by a dot.
4	strict	/	Specifies a strict enumeration type. After setting this property, the value of an enumeration variable must be a valid enumeration value, otherwise a compilation fault will be reported.
5	to_string	/	Converts an INT-type enumeration value to the corresponding character string using the tostring function.

10.1.1.9.4 Variable Address Range

The following table shows the address ranges of PLC variables. The variable address ranges differ among different products, as shown below.

Storage Area	Address Range				
	EVO400 (Byte)	EVO500 (Byte)	EVO700 (Byte)	EVO800 (Byte)	APC500 (Byte)
I area	0 to 131071	0 to 131071	0 to 131071	0 to 1048575	0 to 131071
Q area	0 to 131071	0 to 131071	0 to 131071	0 to 1048575	0 to 131071
M area	0 to 524287	0 to 524287	0 to 5242879	0 to 2097151	0 to 524287

10.1.1.9.5 Default Variable Table

When adding a PLC device to the project, a "Default variable table (Global)" node is automatically created under the device. Double-click this node to open the corresponding window.

The default variable table does not support copying or deletion, and the node name cannot be modified.

The default variable table supports import and export operations. For details, see sections 10.1.1.10.6 Variable Input and 10.1.1.10.7 Variable Output.

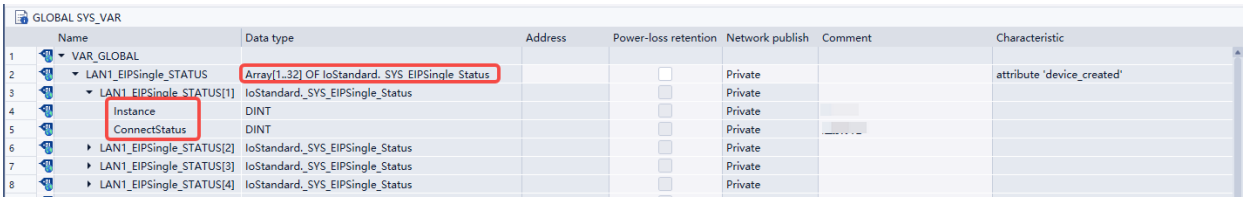
When creating new variables in I/O mapping, they are automatically added to this table.

10.1.1.9.6 System Variable Table

When adding a PLC device to the project, a "SYS_VAR(Global)" node is automatically created under the device. Double-click this node to open the corresponding window.

The system variable table is the variable table created by default, which does not support copying or deletion, and the node name cannot be modified.

The system variable table supports export. For details, see section 10.1.1.10.7 Variable Export. Variable import is not supported.



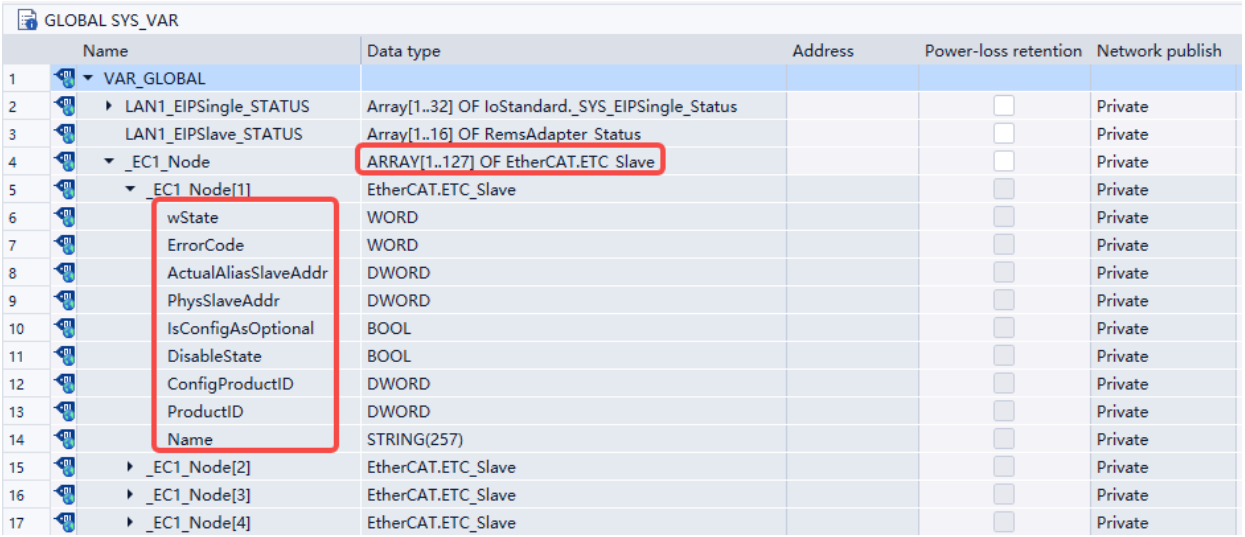
System variables include the following parts:

- **Disabled variables**
  Disabled variables are related to PLC hardware configuration. Each time a new device is added, corresponding variables are automatically created in the system variable table, with the naming rule: J_device name. Variables can only be added or deleted by adding or deleting devices, and the names and data types of variables cannot be modified. Users can modify the address, power failure retention property, and network public property of variables according to requirements. For details, see 10.1.1.9.3 Variable Declaration Property. The structure variable bDisableEnable can be operated to disable or enable the device.

GLOBAL SYS_VAR

	Name	Data type	Address	Power-loss retention	Network publish	Comment	Characteristic
1	VAR_GLOBAL						
2	LAN1_EIPSingle_STATUS	Array[1..32] OF IoStand...			Private		attribute 'device_created'
3	LAN1_EIPSlave_STATUS	Array[1..16] OF RemsA...			Private		attribute 'device_created'
4	J_GL20_4AD	IoStandard._SYS_SlaveS...		☑	Private		attribute 'device_created'
5	bDisableEnable	BOOL			Private		
6	J_GL20_8ADV	IoStandard._SYS_SlaveS...		☑	Private		attribute 'device_created'
7	bDisableEnable	BOOL			Private		
8	J_GL20_8ADI	IoStandard._SYS_SlaveS...		☑	Private		attribute 'device_created'
9	bDisableEnable	BOOL			Private		

- **Device diagnostic status variables**
  Device diagnostic status variables are related to EtherNet/IP device configuration. When adding a PLC device, corresponding variables are automatically created in the system variable table. Variable name: Device network port number_EIPSingle_STATUS. Variables are automatically generated and do not support addition or deletion. The names and data types of variables cannot be modified. Users can modify the address, power failure retention property, and network public property of variables according to requirements. For details, see 10.1.1.9.3 Variable Declaration Property. These variables are used to display connection information of the master. The specific structure details are shown in the table below.



Variable	Definition	Function description
Instance	Instance number	-
ConnectStatus	Connection Status	0: Connection closed 1: Connection is abnormal 3: Connection is abnormal

NOTE

The number of Ethernet ports and the number of connections supported by each port vary by product. For details, see the relevant product manuals.

- **EtherCAT slave system variables**
  EtherCAT slave system variables are related to EtherCAT device configuration and are automatically created in the system variable table when adding an EtherCAT device, with the variable name: _EC1_Node. Variables are automatically generated and do not support addition or deletion. The names and data types of variables cannot be modified. Users can modify the address, power failure retention property, and network public property of variables according to requirements. For details, see 10.1.1.9.3 Variable Declaration Property. These variables are used to display EtherCAT slave information. Take the EVO500 series PLC V1.5 version as an example, the specific structure details are shown in the table below.

GLOBAL SYS_VAR

	Name	Data type	Address	Power-loss retention	Network publish
1	VAR_GLOBAL				
2	LAN1_EIPSingle_STATUS	Array[1..32] OF IoStandard._SYS_EIPSingle_Status			Private
3	LAN1_EIPSlave_STATUS	Array[1..16] OF RemsAdapter_Status			Private
4	_EC1_Node	ARRAY[1..127] OF EtherCAT.ETC_Slave			Private
5	_EC1_Node[1]	EtherCAT.ETC_Slave			Private
6	wState	WORD			Private
7	ErrorCode	WORD			Private
8	ActualAliasSlaveAddr	DWORD			Private
9	PhysSlaveAddr	DWORD			Private
10	IsConfigAsOptional	BOOL			Private
11	DisableState	BOOL			Private
12	ConfigProductID	DWORD			Private
13	ProductID	DWORD			Private
14	Name	STRING(257)			Private
15	_EC1_Node[2]	EtherCAT.ETC_Slave			Private
16	_EC1_Node[3]	EtherCAT.ETC_Slave			Private
17	_EC1_Node[4]	EtherCAT.ETC_Slave			Private

Variable	Definition	Function description
wState	Slave connection status	1: Initialization 2: Pre-operational 3: Boot-operational 4: Safe-operational 8: Operational 17: Initialization fault 18: Pre-operation fault 19: Boot fault 20: Safe-operational fault 24: Operational fault
ErrorCode	Slave fault code	0x0001: Slave device offline 0x0002: Slave device vendor ID mismatch 0x0004: Slave device product code mismatch 0x0008: Slave device version number mismatch 0x0010: Slave device fault flag 0x0020: Slave device reverse connection 0x0040: Slave device port closed 0x0080: Slave device status fault 0x0100: Slave device SDO configuration failed 0x0200: Slave device status transition timeout 0x0400: Slave device SDO download timeout 0x0800: Slave device EEPROM fault Note: When multiple faults exist simultaneously, the slave fault codes will be displayed in an accumulated manner.
ActualAliasSlaveAddr	Slave alias address	-

Variable	Definition	Function description
PhysSlaveAddr	Slave physical address	Slave address 1001
IsConfigAsOptional	Whether the slave is configured with an alias	TRUE: The slave is configured with an alias. FALSE: The slave is not configured with an alias.
DisableState	Whether the slave is disabled	TRUE: The slave is disabled. FALSE: The slave is enabled.
ConfigProductID	Configured product ID	-
ProductID	Actual slave product ID	-
Name	Slave name	-

NOTE

The EVO500 series PLC V1.2 version does not support automatically creating EtherCAT slave system variables when adding EtherCAT devices.

- **Remote adapter status variables**
  Remote adapter status variables are related to EtherNet/IP device configuration. When adding an EtherNet/IP device, corresponding variables are automatically created in the system variable table. Variable name: Device network port number_EIPSlave_STATUS. Variables are automatically generated and do not support addition or deletion. The names and data types of variables cannot be modified. Users can modify the address, power failure retention property, and network public property of variables according to requirements. For details, see 10.1.1.9.3 Variable Declaration Property. These variables are used to display the operation status of the remote adapter. The specific structure details are shown in the table below.

GLOBAL SYS_VAR

	Name	Data type	Address	Power f...	Network ...	Comment	Property
1	VAR_GLOBAL						
2	LAN1_EIPSingle_STATUS	Array[1..32] OF IoStandard._SYS_EIPSingle_Status			不公开		attribute 'device_created'
3	LAN1_EIPSlave_STATUS	Array[1..16] OF EtherNetIP.RemAdapter_Status			不公开		attribute 'device_created'
4	LAN1_EIPSlave_STATUS[1]	EtherNetIP.RemAdapter_Status			不公开		
5	DevName	STRING			不公开		
6	wState	USINT			不公开		
7	ErrorCode	DWORD			不公开		
8	CfgIP	STRING			不公开		
9	ActualIP	STRING			不公开		
10	DisableStatus	BOOL			不公开		
11	DevAliasID	WORD			不公开		
12	LAN1_EIPSlave_STATUS[2]	EtherNetIP.RemAdapter_Status			不公开		
13	LAN1_EIPSlave_STATUS[3]	EtherNetIP.RemAdapter_Status			不公开		
14	LAN1_EIPSlave_STATUS[4]	EtherNetIP.RemAdapter_Status			不公开		
15	LAN1_EIPSlave_STATUS[5]	EtherNetIP.RemAdapter_Status			不公开		

Variable	Definition	Function description
DevName	Remote adapter name	-
wState	Remote adapter connection status	0: Connection closed 1: Remote adapter is disabled 2: Connection is abnormal 3: Connection is abnormal

Variable	Definition	Function description
ErrorCode	Remote adapter fault code	Refer to 21.1 Appendix 1: Fault Code
CfgIP	Remote adapter configured IP	-
ActualIP	Remote adapter actual IP	-
DisableStatus	Remote adapter disabled status	TRUE: The slave is disabled. FALSE: The slave is enabled.
DevAliasID	Remote adapter alias ID	-

NOTE

- The number of Ethernet ports and the number of connections supported by each port vary by product. For details, see the relevant product manuals.
- EVO series PLCs with version below V1.5 do not support automatically creating EtherNet/IP remote adapter status system variables when EtherNet/IP devices are added.

- **Axis array variables**

  Axis array variables are related to axis device configuration. When an axis device is added, the corresponding variables are automatically created in the system variable table. Variable name: _MC_Axis. Variables are automatically generated and do not support addition or deletion. The names and data types of variables cannot be modified. Users can modify the address, power failure retention property, and network public property of variables according to requirements. For details, see 10.1.1.9.3 Variable Declaration Property. These variables are used to manage all real axes and virtual axes under all EtherCAT masters in a centralized way, and store system variable information for these axes. For detailed structure description, refer to 18.3.3.2.2.1 AXIS_REF: Axis Structure.

	Name	Data type	Address	Power f...	Network ...	Comment	Property
1	VAR_GLOBAL						
2	LAN1_EIPSingle_STATUS	Array[1..32] OF IoStandard._SYS_EIPSingle_Status			Private		attribute 'device_created'
3	LAN1_EIPSlave_STATUS	Array[1..16] OF RemsAdapter_Status			Private		attribute 'device_created'
4	MC_Axis	ARRAY[1..64] OF MotionControl.AXIS_REF			Private		attribute 'device_created'
5	_MC_Axis[1]	MotionControl.AXIS_REF			Private		
6	_MC_Axis[2]	MotionControl.AXIS_REF			Private		
7	_MC_Axis[3]	MotionControl.AXIS_REF			Private		
8	_MC_Axis[4]	MotionControl.AXIS_REF			Private		
9	_MC_Axis[5]	MotionControl.AXIS_REF			Private		
10	_MC_Axis[6]	MotionControl.AXIS_REF			Private		

Axis array variables	Description
Array name	_MC_Axis
Array length	Total number of EtherCAT axes supported by this PLC
Array mapping	Axis array subscript represents the axis number. For example, the array element corresponding to "Axis" is _MC_Axis[1].
Variables accessible in the array	Refer to 18.3.3.2.2.1 AXIS_REF: Axis Structure.

Axis array variables	Description
Axis array subscript corresponding to the axis	The subscript of the axis in the axis array is displayed under the project tree "PLC_X node > Control object > Axis". The subscript can be manually adjusted in the 16.1.3 Axis basic settings interface. Note: Axis numbers must not be duplicated and must not exceed the maximum number of axes supported by the PLC.

NOTE

EVO series PLCs with version below V1.5 do not support automatically creating axis array variables when axis devices are added.

- **EtherCAT master system variables**
  EtherCAT master system variables are related to EtherCAT device configuration and are automatically created in the system variable table when adding an EtherCAT device, with the variable name: _EC_Master. Variables are automatically generated and do not support addition or deletion. The names and data types of variables cannot be modified. Users can modify the address, power failure retention property, and network public property of variables according to requirements. For details, see 10.1.1.9.3 Variable Declaration Property. EtherCAT master system variables are used to display information about the EtherCAT master. The specific structure is described in the table below.

GLOBAL SYS_VAR

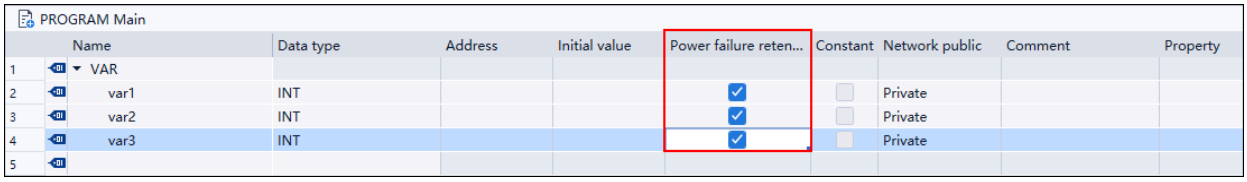
	Name	Data type	Address	Power-loss retention	Network publish
1	VAR_GLOBAL				
2	LAN1_EIPSingle_STATUS	Array[1..32] OF IoStandard._SYS_EIPSingle_Status			Private
3	LAN1_EIPSlave_STATUS	Array[1..16] OF RemsAdapter_Status			Private
4	_EC1_Node	ARRAY[1..127] OF EtherCAT.ETC_Slave			Private
5	_EC_Master	ARRAY[1..1] OF EtherCAT.ETC_Master			Private
6	_EC_Master[1]	EtherCAT.ETC_Master			Private
7	bSyncWindowOver	BOOL			Private
8	ErrorCode	WORD			Private
9	DCClockReferenceTime	ULINT			Private
10	Instance	UINT			Private
11	SyncFinished	BOOL			Private
12	LostFrameCount	UDINT			Private

Variable	Definition	Function description
bSyncWindowOver	Synchronization window deviation	The default value is FALSE. bSyncWindowOver is set to TRUE when the "Sync window" value (μs) is greater than 0 and is no less than the current bus's "Max. sync window deviation".
ErrorCode	Master fault code	0x0001: Configured slave count < scanned slave count 0x0002: Slave alias conflict 0x0004: Slave fault detected 0x0008: Continuous frame loss 0x0010: Slave CRC fault 0x0020: Main network card not connected 0x0040: Redundant network card not connected 0x0080: Slave alias is 0 0x0100: Network card not connected

Variable	Definition	Function description
DCClockReferenceTime	DC reference clock	DC reference clock real-time value (read-only).
Instance	Master instance address	-
SyncFinished	Master synchronization status	SyncFinished is set to TRUE after master startup completes, regardless of whether slaves are in OP (Operational) status.
LostFrameCount	Lost frame count	Consistent with the "Lost frames" displayed on the "Online" configuration page of the EtherCAT master.

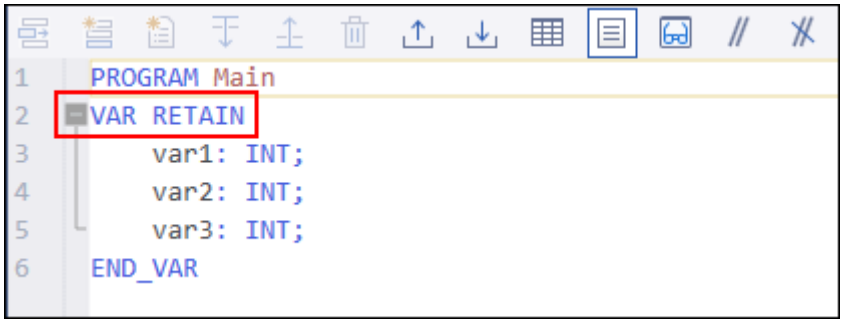
NOTE

The EVO series PLC V1.6 version and below does not support automatically creating EtherCAT master system variables when adding EtherCAT devices.



10.1.1.9.7 Power Failure Retention Table

Power failure retention ensures that variables retain their original values after PLC power failures or program downloads. This is commonly used to define critical parameters in projects, preventing the data loss due to unexpected PLC power failures or program downloads.



Variable definition

Power failure retention variables can be defined in the global variable tables, programs, function blocks, and functions (limited to static variables). They cannot be defined in methods, properties, structures, unions, enumerations, or aliases. The power failure retention property is mainly declared using the keyword RETAIN and can be defined through a table view and a text view. Take definition in a program (PRG) as an example.

- In the table view of the variable declaration editor, check "Power failure retention" options to define the corresponding variables as power failure retention variables, as shown in the figure below.

- In the text view of the variable declaration editor, add the "RETAIN" keyword to the variable to define it as a power failure retention variable, as shown in the figure below.

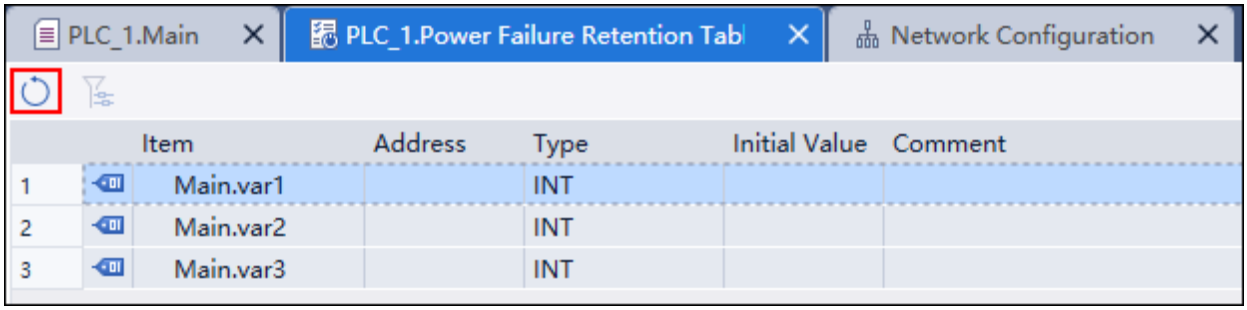
Variable category

Power failure retention variables can be set as local variables, input variables, output variables, static variables, and so on. They cannot be set as input/output variables, temporary variables, constants, etc.

Variable types

- The power failure retention property of variables in an FB can only be configured during the FB's declaration phase, but cannot be configured after the FB is instantiated. If an FB member variable is of FB type, this variable cannot be selected for power failure retention.
- The power failure retention property of variables in structures, unions, and aliases can only be configured through the corresponding instances, but cannot be configured during the declaration phase.
- For sub-members or nested sub-members of a type that contain variables of the FB type, the power failure retention is not supported.
- The power failure retention is not supported for variables of pointer and reference type.
- The power failure retention is not supported for ANY-type variables and ANY arrays, which contain pointers.
- "Constant" and "Power failure retention" can not be checked simultaneously.

Variable address

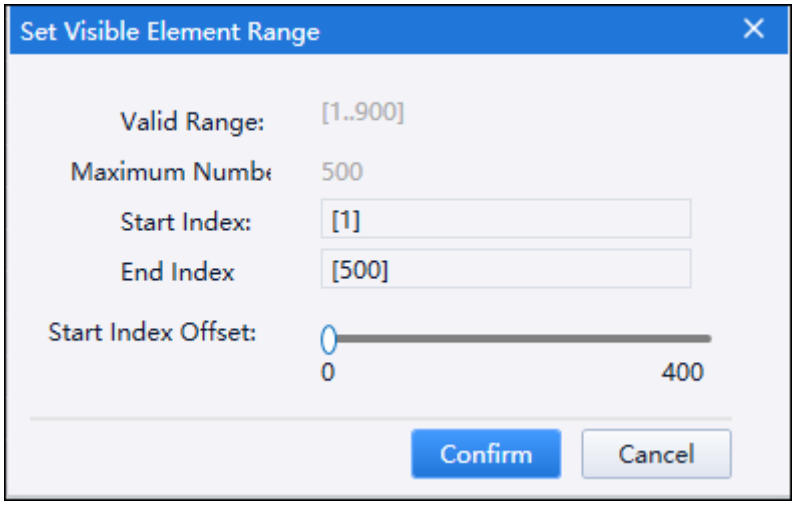


Only variables that are unbound or bound to M area addresses can be marked as power failure retention variables.

Variable response action

Action	VAR	VAR RETAIN
Power failure	Initialization	Retain the original value.
Hot Reset	Initialization	Retain the original value.
Cold Reset	Initialization	Retain the original value.
Program download	Initialization	Retain the original value.
Online modification	Retain the original value.	Retain the original value.

Power Failure Retention Table



- All variables with power failure retention enabled in the project can be displayed in the power failure retention table after compiling and refreshing with the " " button, as shown in the following figure.

NOTE

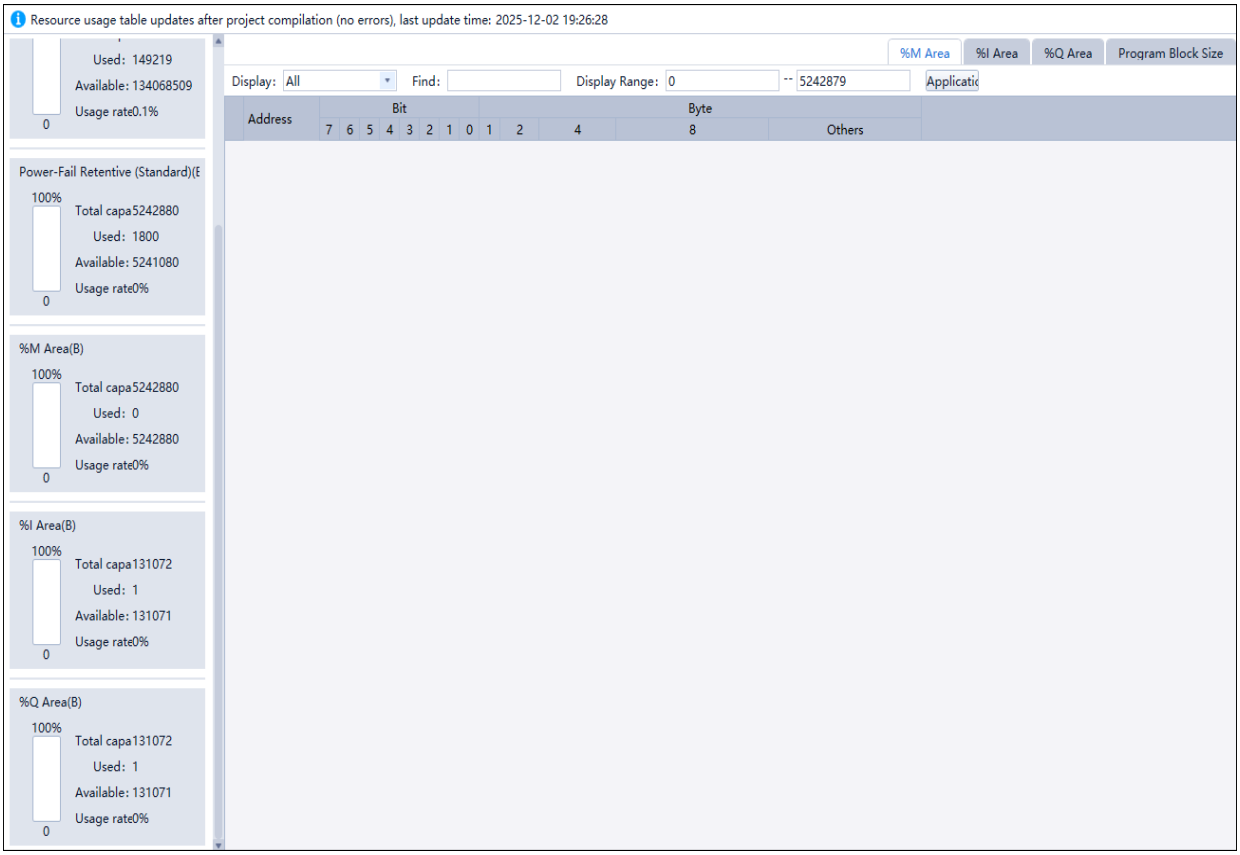
Right-click items in the power failure retention table. For offline mode, "Go to definition" and "Cross-reference" are supported; for online mode, "Go to definition", "Cross-reference", and base switching (binary, decimal, and hexadecimal) are supported.

- The maximum number of variables displayed in the power failure retention table is 500. When this number is exceeded, the " " button will be enabled to set the visible element range. Users can set the variable display range through this button, as shown in the following figure.

NOTE

Since iFA Evolution V1.5.2.5, the viewing function of the power failure retention table has changed:

- For versions prior to V1.5.2.5: The maximum number of viewable variables is limited to 500.
- For versions V1.5.2.5 and later: Users can view all variables with no limit.

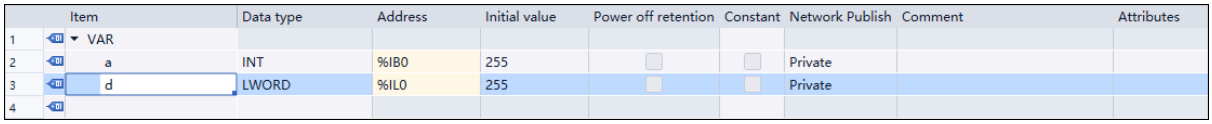


Power failure retention property

1. Power failure retention variables are uniquely identified by their full path variable names. Variables with the same name under different POUs are considered different variables, such as Main.Var1 and PRG_1.Var1. Variables with the same path in different projects are considered the same variable. When the variable path changes, the power failure retention variable is reinitialized.
2. When the binding address, initial value, comment, declaration category, or property of a variable change, the power loss retention variable retains its original value.
3. For non-FB types: When the declaration name changes, all instance variables of this type are reinitialized.
4. For FB types: When the declaration name changes, the direct instance variables of the FB are retained, while the FB instance variables in other higher-level structures that include this FB instance are reinitialized.

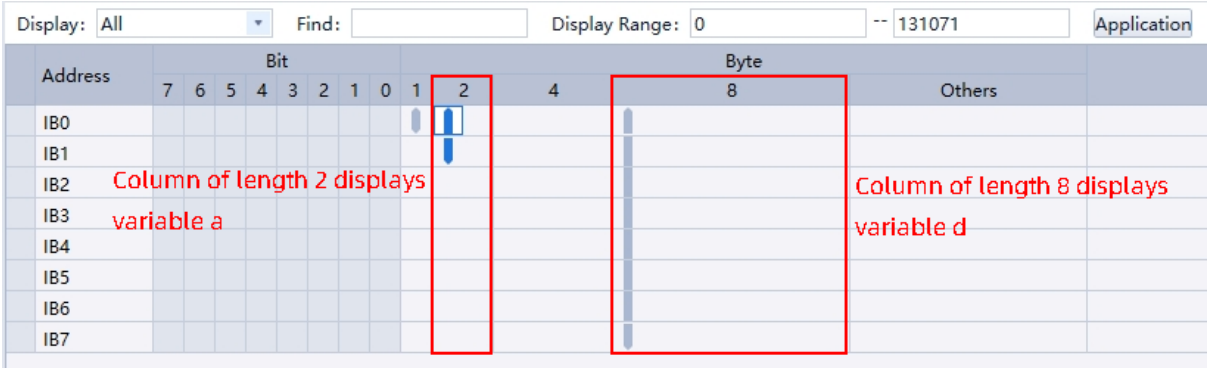
5. For complex types, when their sub-members change:
    - Structures: Members that do not change retain their original values, while members that change are initialized.
    - Function blocks: Members that do not change retain their original values, while members that change are initialized.
    - Unions: Unions are initialized when their total size changes.
    - Enumeration: Enumerations are initialized when their total size changes.
6. For array types:
    - When the element type changes, all elements of the array will be reinitialized.
    - When the number of array dimensions changes, all elements of the array will be reinitialized.
    - When the number of array dimensions does not change, but the upper or lower bounds of some dimensions change, the elements in the overlapping positions retain their original values, while the other elements are initialized.
7. Performance constraints
    - The memory size of power failure retention variables is determined by the configuration files of the device. If it exceeds the limit, a compilation fault will be reported and the generation fails.
    - The memory size of power failure backup code is determined by the configuration files of the device. If it exceeds the limit, all power failure retention variables will be initialized.

10.1.1.9.8 Resource Usage Table



The resource usage table is mainly used to display the status of the program, including the overall resource usage of the program, data, power failure retention, M area, I area, Q area, and program block size, as well as specific displays of the M area, I area, Q area, and program block size.

1. The resource usage table is not generated in real-time but is updated after the project is compiled (without faults). The updated results after compilation need to be saved so that they can be viewed the next time the project is opened. Variables that have not been assigned absolute addresses will not be counted or displayed in the resource usage table. The resource usage table only shows the usage of defined variables in the program. Undefined and unused variables are not displayed in the address conflict table on the right side, but only in the statistical information on the left side. Variables declared with address information AT are also included in the display and statistics.

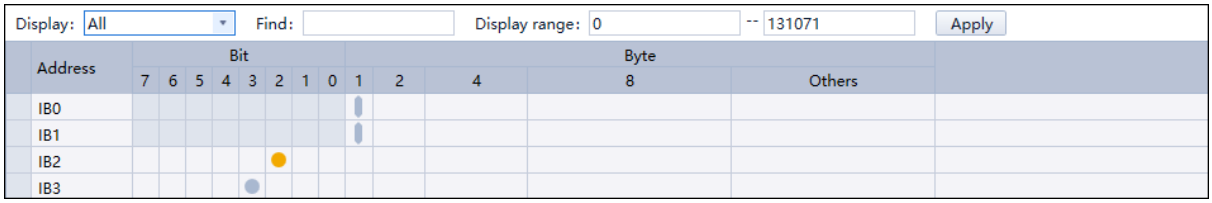


2. The overall resource usage is displayed using six cards on the left side, including program, data, power failure retention, M area, I area, and Q area. The "Display" filter in the tabs of the M area, I area, and Q area can be divided into four categories:
   - All: Lists all defined (configured, used, or coupled) variables.
   - Used: Lists all used variables and addresses (including direct addresses).
   - Idle: Lists all defined but unused variables.
   - Conflict: Lists all variables detected to have address conflicts or overlaps.

3. The width corresponding to the byte length in theh table indicates scenarios where there is byte address overlap among variables. For example, an 8-byte variable of LWORD type can be overlapped with other variables in eight possible ways, so the width is 8. For complex data types such as arrays or structures, the display is based on the unit length of the variable type of their smallest sub-member.
   - As shown in the figure below, two overlapping variables in the I area are defined in the main function. Variable a is of INT type, with a length of two bytes; variable d is of LWORD type, with a length of 8 bytes.

	Item	Data type	Address	Initial value	Power off retention	Constant	Network Publish	Comment	Attributes
1	VAR								
2	a	INT	%IB0	255			Private		
3	d	LWORD	%IL0	255			Private		
4									

   - View the usage of the I area in the resource usage table.



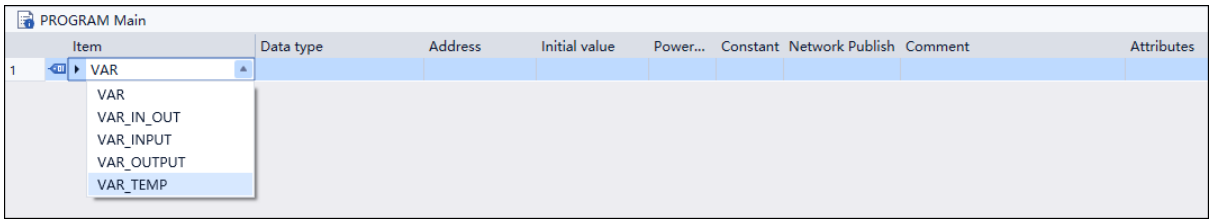
4. The background color is used to distinguish different usage scenarios of addresses. A light background indicates that only a single bit of the address is accessed in the program, not the entire byte. For example, variable a uses only the IX3.3 address. A dark background indicates that the address is accessed as an entire byte. For example, variable b uses the IB1 address. Additionally, if an address is assigned to multiple (≥ 2) variables, the address uses an orange-yellow icon to indicate that this address is shared by multiple variables. For example, variables d and e both use the %IX2.2 address.
   - As shown in the figure below, four variables: a, b, d, and e, are defined in the main function.

	Name	Data type	Address	Initial value	Power failure reten...	Constant	Network public	Comment	Property
1	VAR								
2	a	BOOL	%IX3.3				Private		
3	b	BOOL	%IB1				Private		
4	d	BOOL	%IX2.2				Private		
5	e	BOOL	%IX2.2				Private		

   - The colors of the addresses corresponding to a, b, d, and e can be viewed in the resource usage table.

5. Hover the mouse over a variable to view the variable name. Right-click a variable and select "Go to definition" to jump to the declaration location of this variable; select "Cross-reference table" to view the usage information of this variable.

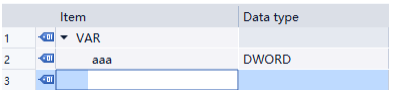
10.1.1.10 Variable Operations

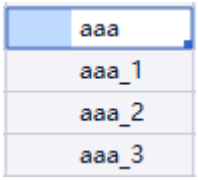


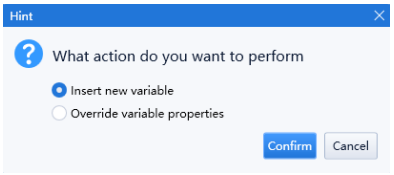
10.1.1.10.1 Adding a Variable

Prerequisites

A POU has been created.





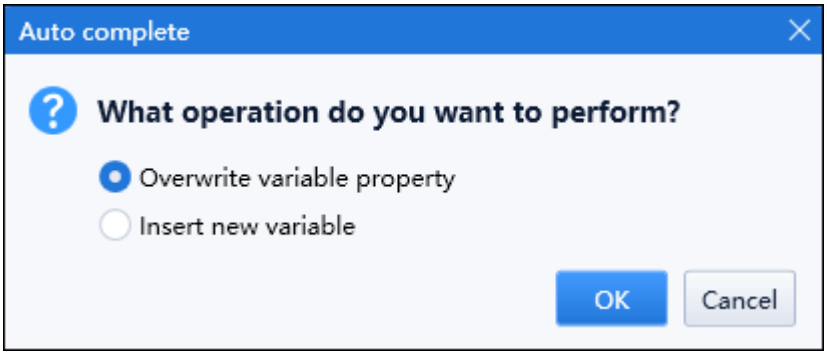


Procedure

1. Open a POU under "Programming" and set the variable category in the variable declaration editor in the table view.

2. Add tags.
   Variables in the table view are managed in a list format, with one row representing one variable

(identifier).



Number	Procedure	Example
One	Double-click the text box , enter a valid variable name, and press Enter to add the variable. The software will automatically fill in the data type with the default value.	
Multiple	Click the name of an existing variable, and hold and pull down the square in the lower right corner of the cell of each column . In the pop-up window, select "Insert new variable" and the new variable will copy the target variable's name and data type by default. The other properties of the new variable depend on whether the corresponding cells are held and pulled down. When adding, the software will automatically check whether the new variable name duplicates with the existing names.  Add or insert new variables in the drop-down area. Existing variables will shift down automatically.	
Multiple	Variables can also be added by batch import. For details, see 10.1.1.10.6 Variable Import.	-

10.1.1.10.2 Copying and Pasting a Variable Table

Users can select partial cells in the variable table for copy-and-paste operations with Excel, improving variable editing efficiency.

Copying Excel content to variable table

1. Copy Excel content.
2. In the variable table, right-click the target location and select "Paste".
3. In the pop-up window, select the operation to execute, and click "OK".
   - Overwrite variable property: Based on the top-left cell of the selected area, paste and overwrite the existing content.
   - Add variable: Insert the data to be pasted below the selected area without overwriting the existing content.

NOTE

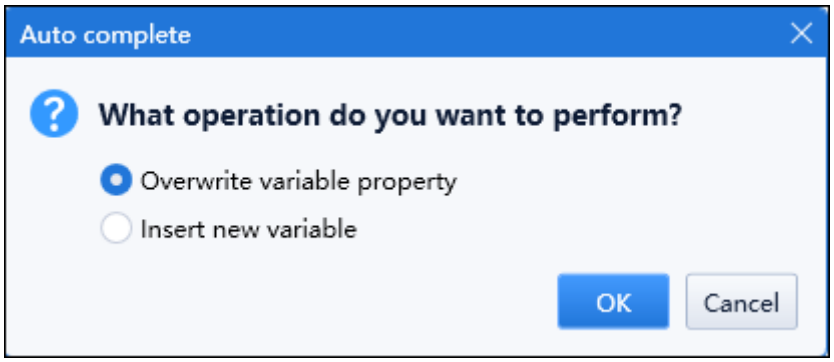
- The property column does not support paste operations.
- Members of array variables, structure variables, and FB instances do not support paste operations. During batch pasting, the content in these cells is automatically ignored.
- When the data type column has no data, the system defaults to "DWORD". When the network public column has no data, the system defaults to "Private".
- If the pasted data in the data type column does not match the system type, an error prompt is displayed in that cell.
- If the pasted data in the address column does not match the address format, an error prompt is displayed in that cell.
- If the pasted data in the initial value column does not match the data type, an error prompt is displayed in that cell.
- When pasting data to the power failure retention column and constant column, if the data is TRUE or FALSE, the system converts it to a checkbox; non-BOOL values are unchecked by default.
- When pasting data to the network public column, if the pasted content matches an item in the cell's dropdown list, it is pasted; otherwise, the original state is retained.

Copying variable table content to Excel

1. Use the Shift key to select data in the variable table.
2. Paste in Excel.

NOTE

When pasting data from the power failure retention column and constant column to Excel, it is automatically converted to TRUE or FALSE.



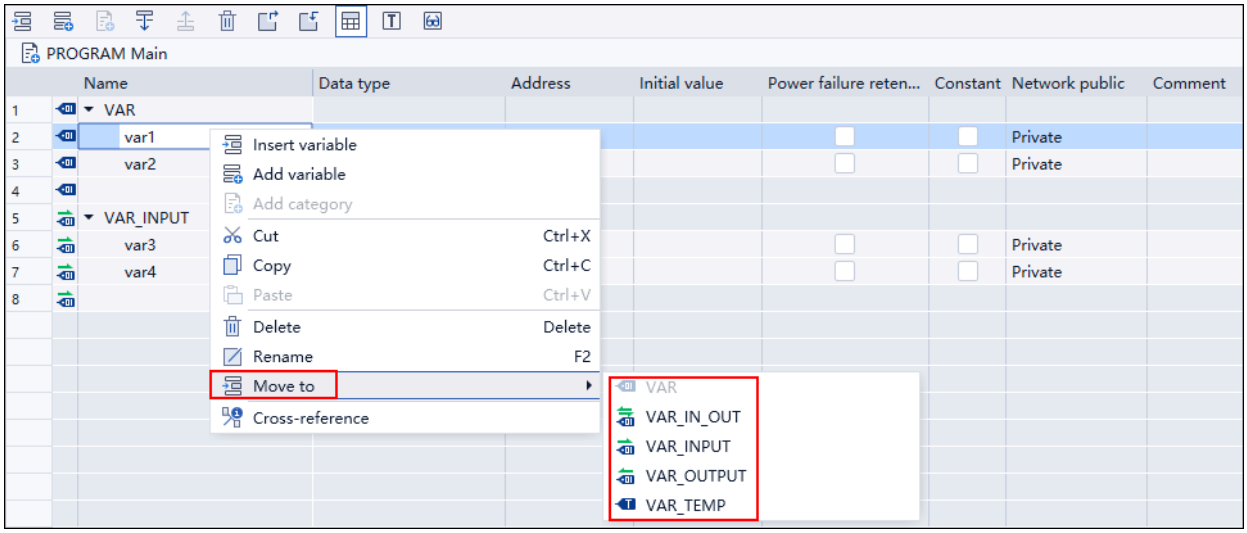
10.1.1.10.3 Setting Variable Properties

After adding variables in the corresponding POU, users can set variable properties as needed. For detailed property descriptions, see 10.1.1.9.3 Variable Declaration Property.

Variable properties support batch processing. Users can hold and pull down the square in the lower right corner of the cell (

) to select the range for batch processing.

In the pop-up "Reminder" window, select "Overwrite variable property" to complete batch modifications of multiple rows of properties.



10.1.1.10.4 Changing Variable Category

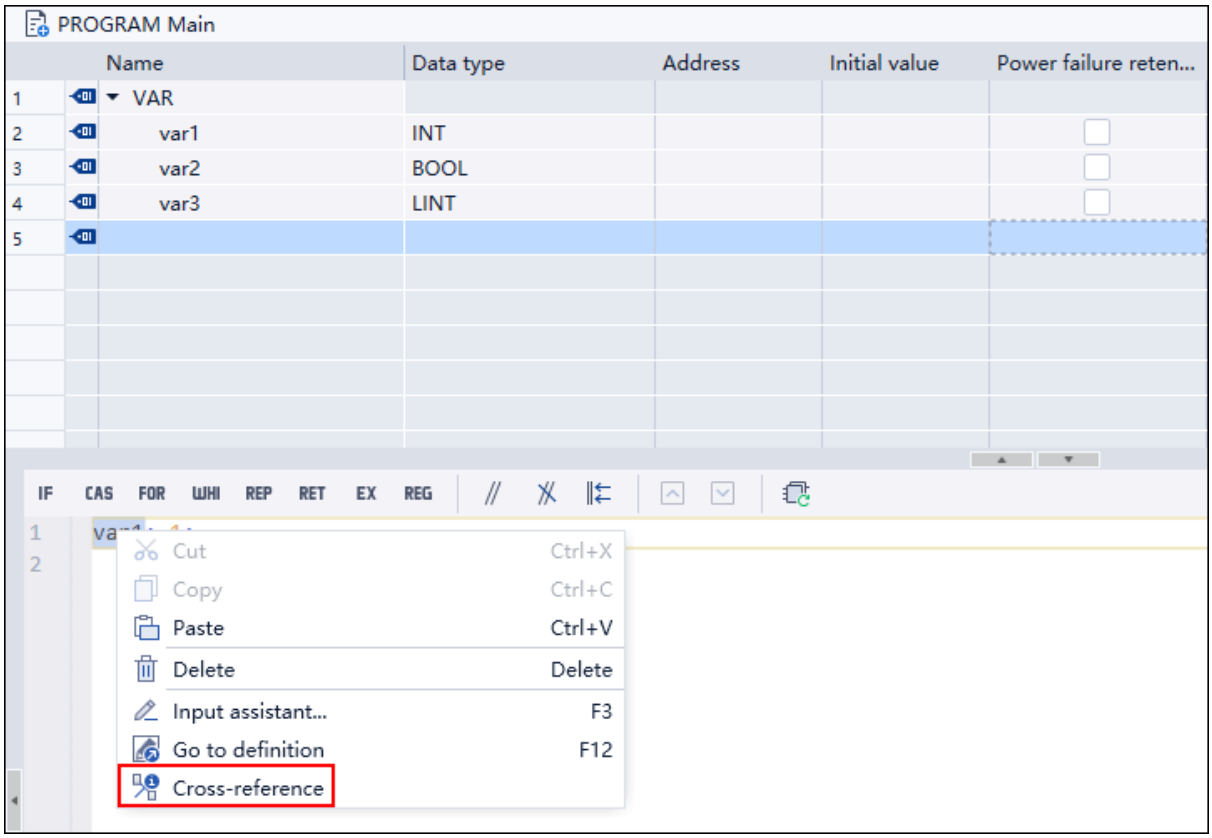
After adding variables in the corresponding POU, users can change the category of the added variables as needed.

Procedure

Right-click a variable and select "Move to" to move this variable to another category.

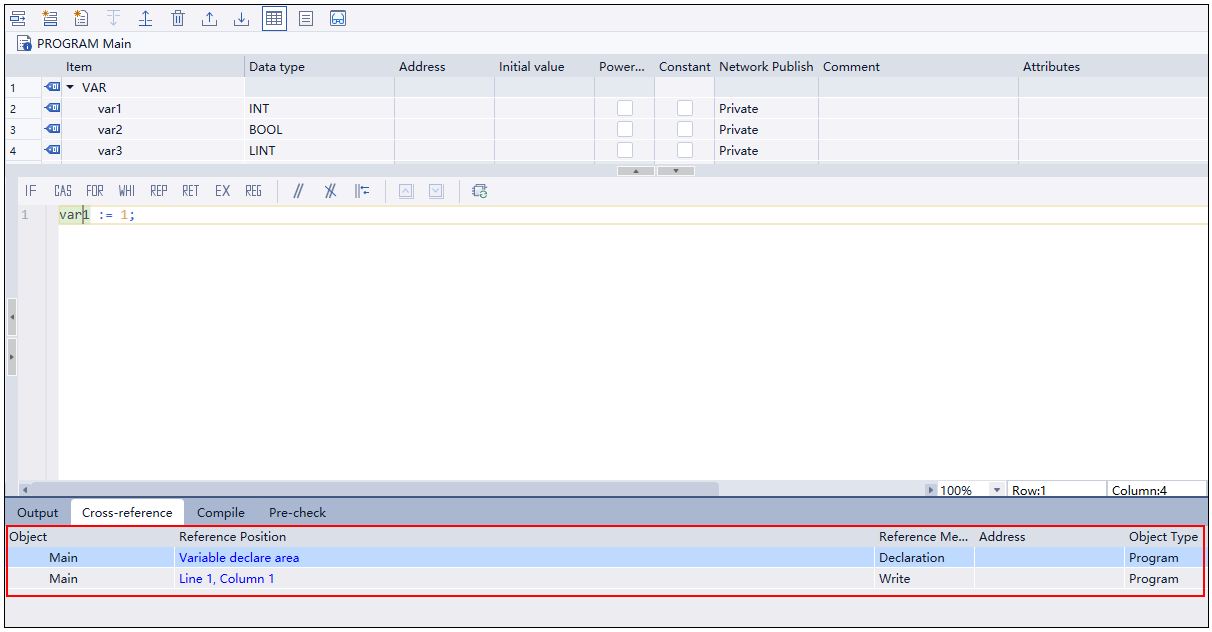
NOTE

After changing the category, the variable will be removed from the original category; this operation does not affect any properties of the variable.



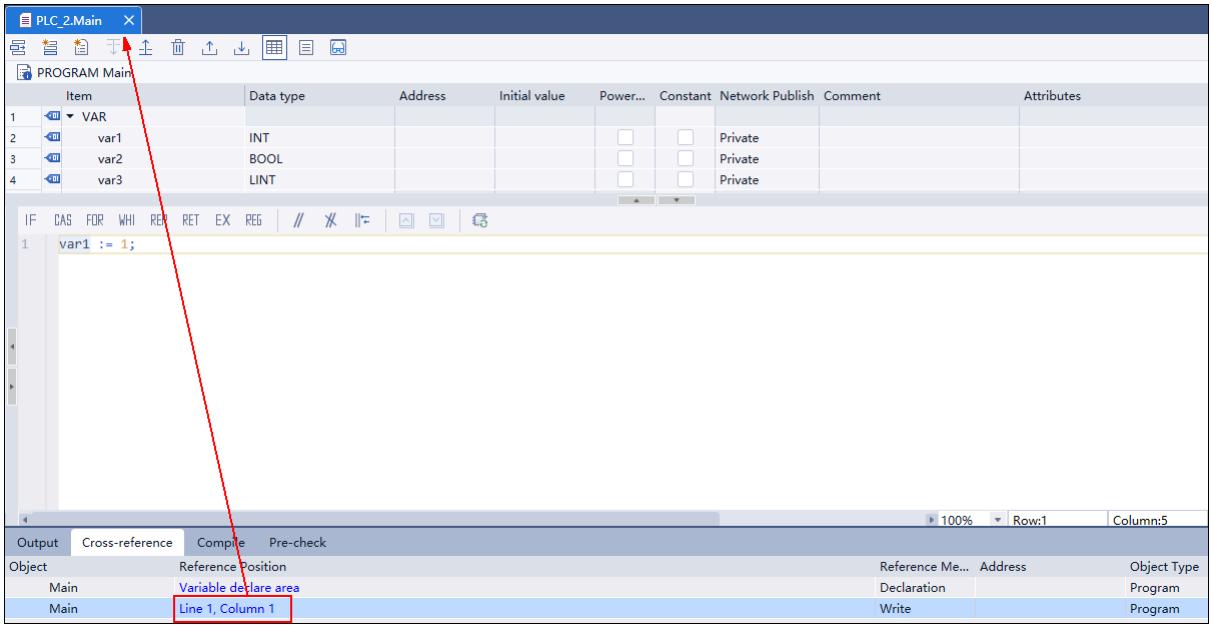
10.1.1.10.5 Cross-Reference

Prerequisites



- The editing area contains variables.
- Variables are used by the POU.

Procedure



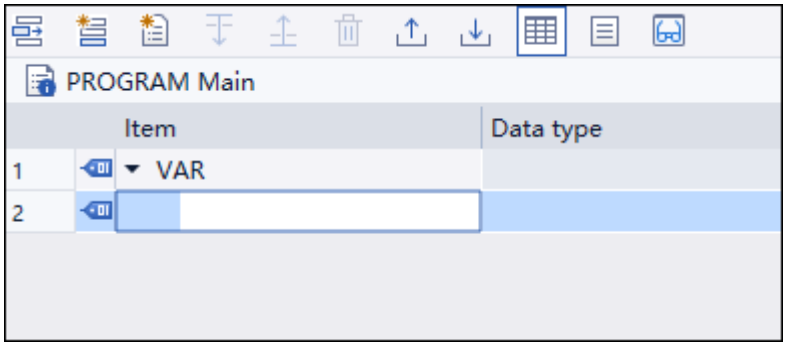
1. Right-click the variable in the editing area and select "Cross-reference", as shown in the following figure.

2. The "Cross-reference" tab will be displayed at the bottom of the interface, showing the usage information of the current variable, as shown in the following figure.

3. Click the link in the "Reference position" column to navigate to the corresponding interface.

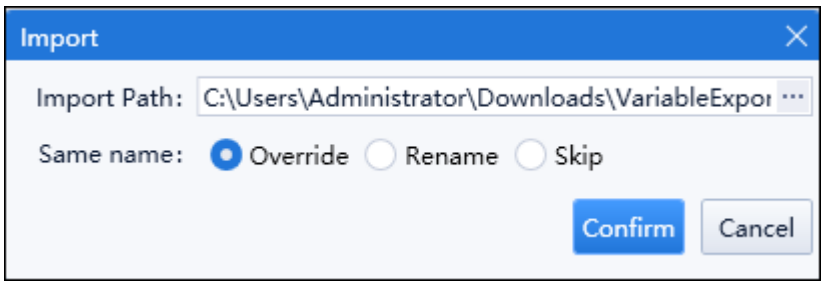
10.1.1.10.6 Variable Import

Prerequisites



A file that meets the import conditions already exists.

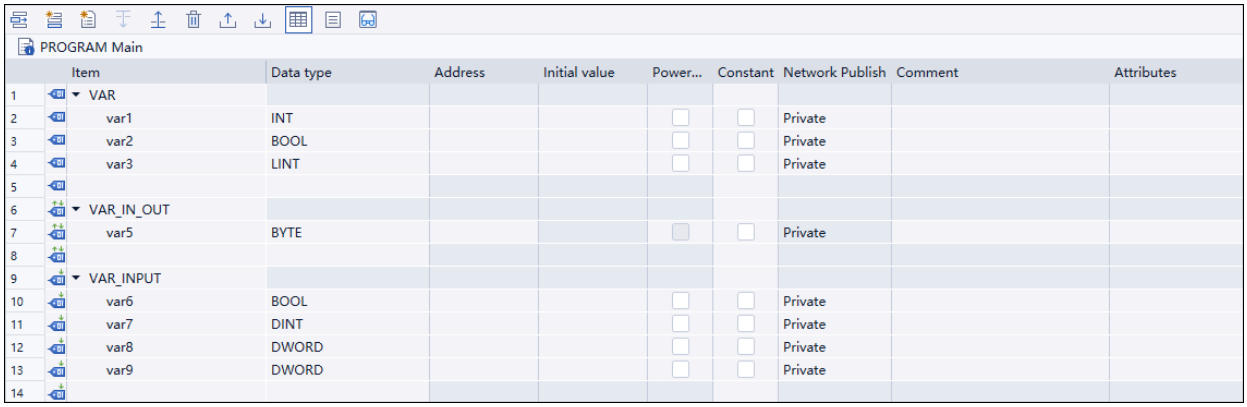
Procedure



1. Open the variable export file "VariableExport.xlsx". Add variable var9, and delete variable var4, as shown in the figure below.

Data type	Address	Initial value	Power off retentior	Constant	Network Publish	Comment	Attributes
INT			False	False	Private		
BOOL			False	False	Private		
LINT			False	False	Private		
BYTE			False	False	Private		
BOOL			False	False	Private		
DINT			False	False	Private		
DWORD			False	False	Private		
DWORD			False	False	Private		

2. In the variable declaration editor, click the "Import" button in the toolbar, and the "Import" dialog box will pop up.



3. Select the file to import. For variables with the same name, the system supports covering, renaming, and skipping them. Click "OK" to import the variables.

4. If the import succeeds, an "Import successful" prompt will pop up. If the import fails, an "Import failed" prompt will pop up. Check the failure reason and resolve the fault before attempting to import again.

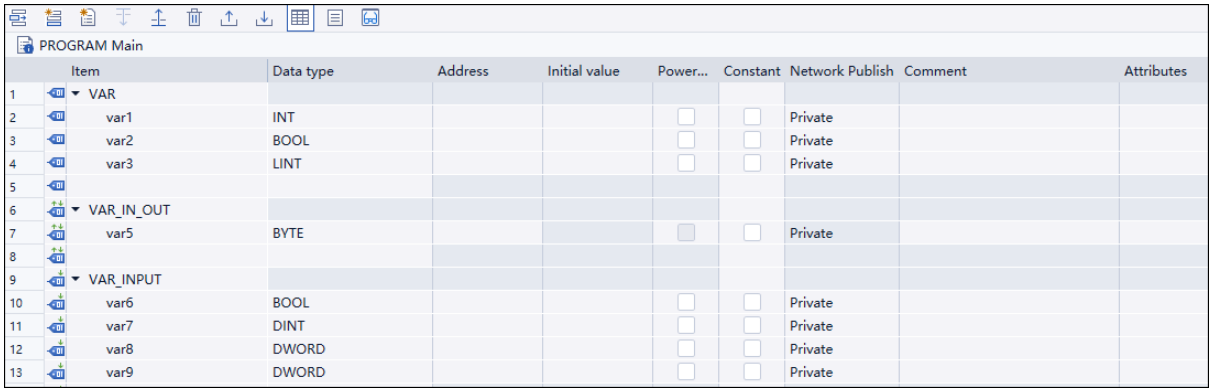
Result

The variables imported into the variable declaration editor are shown in the figure below.

PROGRAM Main

	Item	Data type	Address	Initial value	Power...	Constant	Network Publish	Comment	Attributes
1	VAR								
2	var1	INT					Private		
3	var2	BOOL					Private		
4	var3	LINT					Private		
5									
6	VAR_IN_OUT								
7	var5	BYTE					Private		
8									
9	VAR_INPUT								
10	var6	BOOL					Private		
11	var7	DINT					Private		
12	var8	DWORD					Private		
13	var9	DWORD					Private		
14									

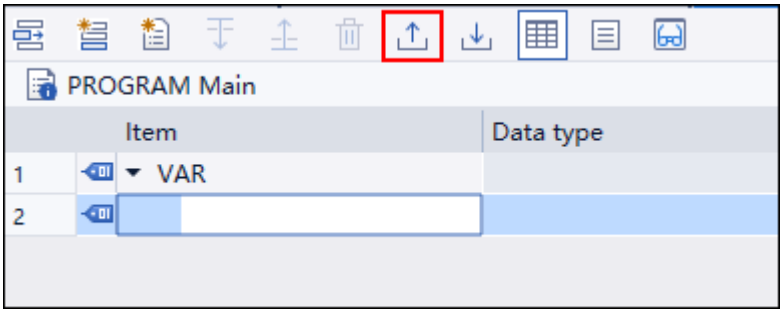
10.1.1.10.7 Variable Export



The variable tables in POU support importing and exporting variables (in XLSX format). Users can also add, delete variables, and modify variable properties in Excel according to the format. The Excel can then be imported back into the iFA variable table.

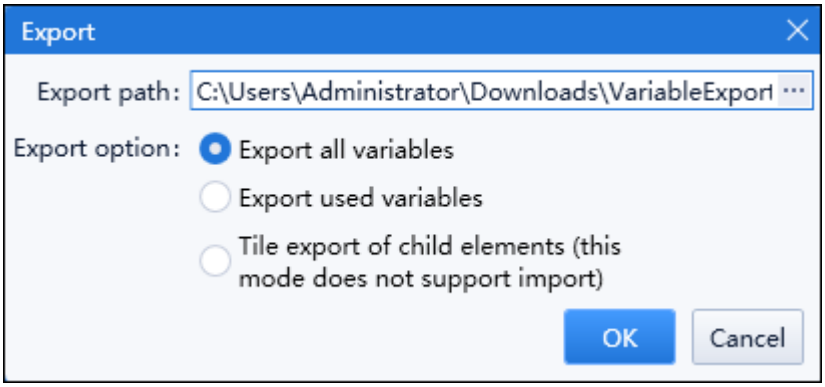
Prerequisites

A POU has been created.



Procedure

1. Add some variables in the variable table.



PROGRAM Main

	Item	Data type	Address	Initial value	Power...	Constant	Network Publish	Comment	Attributes
1	VAR								
2	var1	INT					Private		
3	var2	BOOL					Private		
4	var3	LINT					Private		
5									
6	VAR_IN_OUT								
7	var5	BYTE					Private		
8									
9	VAR_INPUT								
10	var6	BOOL					Private		
11	var7	DINT					Private		
12	var8	DWORD					Private		
13	var9	DWORD					Private		

2. In the variable declaration editor, click the "Export" button in the toolbar, and the "Export" dialog box will pop up.

3. Select the path for export and select the export range in "Export option". Click "OK" to export the variables.

4. If the export succeeds, a prompt window will pop up, asking users whether to open the exported file. If the export fails, an "Export failed" prompt will pop up. Check the failure reason and resolve the fault before attempting to export again.

> NOTE
>
> When "Tile export of child elements" is checked, the variables will be exported in full name mode as "namespace.variable name", displaying all child elements.

Result

Take the configuration of "Tile export of child elements" as an example. The variable export file "VariableExport.xlsx" is shown below.

VariableType	Item	Data type	Address	Initial value	Power off retentior	Constant	Network Publish	Comment	Attributes
VAR	AAA.var1	DWORD			False	False	Private		
VAR	AAA.var2	DWORD			False	False	Private		
VAR	AAA.var3	DWORD			False	False	Private		
VAR_OUTPUT	BBB.var1	DWORD			False	False	ReadWrite		
VAR_OUTPUT	BBB.var2	DWORD			False	False	ReadWrite		
VAR_OUTPUT	BBB.var3	DWORD			False	False	ReadWrite		

10.1.1.10.8 Smart Input

When entering or deleting any character in the offline editing area, the system matches data based on the word currently selected by the cursor. If there is matching data, a smart input page will pop up for user selection, providing convenience for operations.

Applicable position:

- Global variable table
- Variable declaration area of program blocks
- Program editing area
- I/O mapping

Editing data types in the variable list

- Letter search
  Double-click the data type cell of the target variable, and the software will search for relevant data types based on the entered letters.

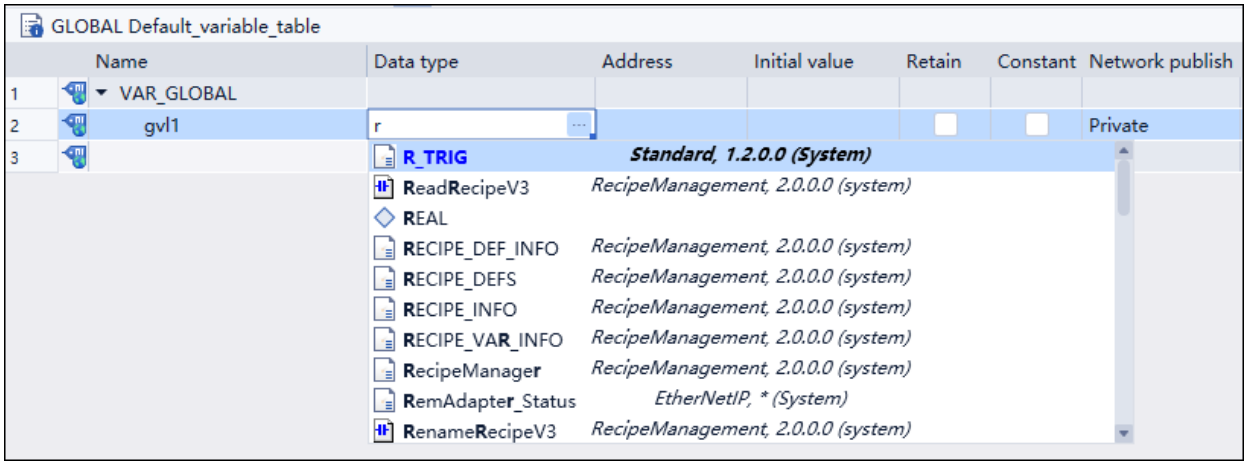


Figure 10-1-1-10-8-1 Operations in the global variable table

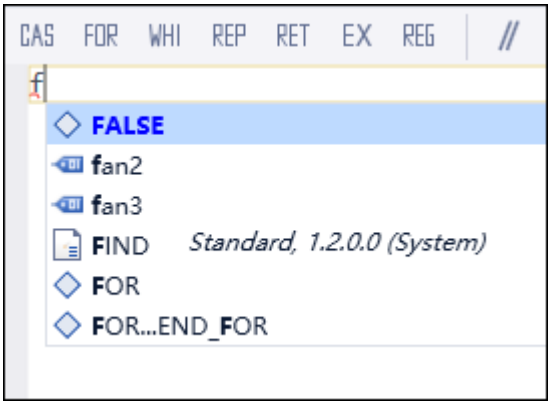
Search results are displayed in alphabetical order based on the position of the input content within the data type. Data types are also categorized as follows.

: Standard data types, such as BOOL and REAL.

: Function block types, such as RTC and TOF. Built-in function blocks will display information about the library they belong to.

: Function block types suitable for application libraries, such as MotionControl library and RecipeManagement library.



: Complex data types, such as structures and enums.

Users can complete input by double-clicking the target object.

Editing programs in the ST editor

- Program input
  1. Text input

     When entering letters in the ST program editing area, the software will automatically search for relevant keywords (in ST language), data types, variable names, and function block instance names.

     Results are displayed in alphabetical order based on the position of the input content within each item, and the results are categorized as follows.

     - : Standard data types and keywords (in ST language), such as BOOL and IF.
     - : Function block types, such as RTC and TOF.
     - : Function block types suitable for application libraries, such as MotionControl library and RecipeManagement library.
     - : Algorithm library names.

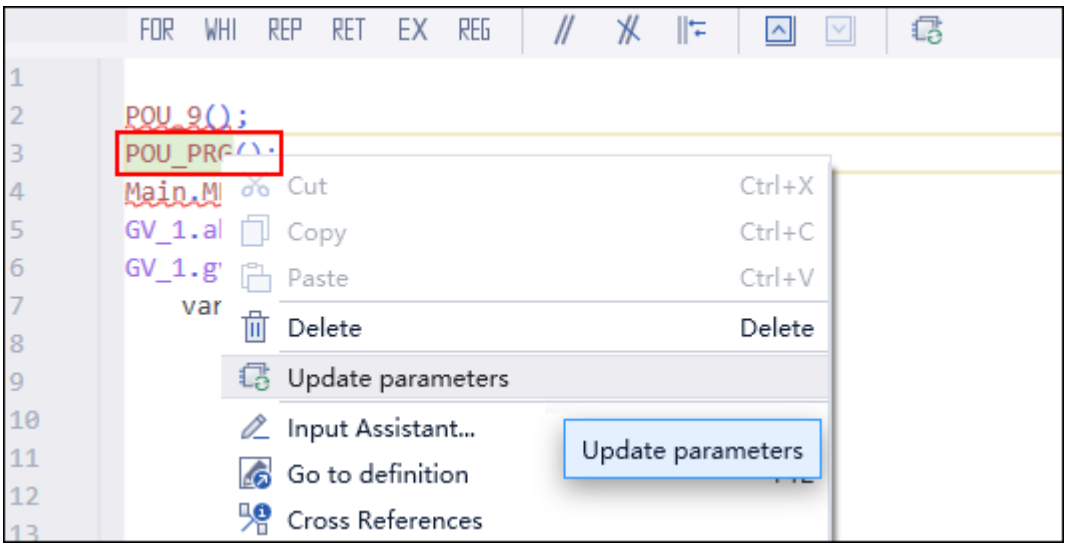
- : Global variables.
- : Local variables.

2. Target object selection

   Double-click the target object to complete the input.

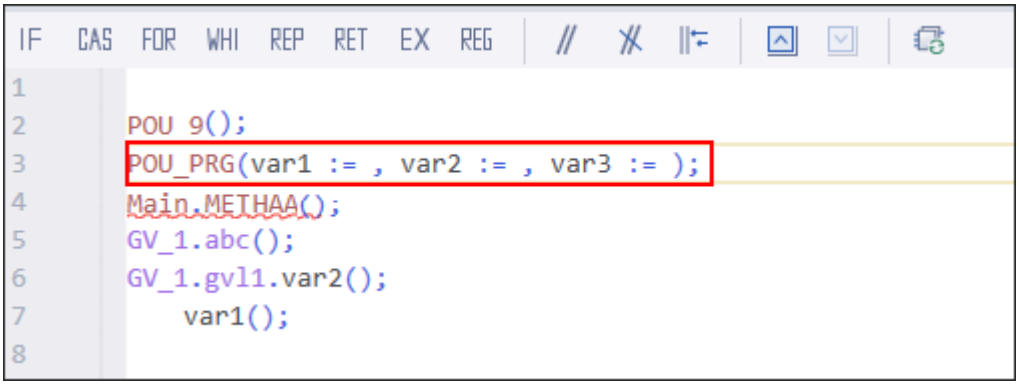
10.1.1.10.9 Parameter Update

When an FB instance, FC, PRG, or Meth is called by the program, if the parameters of the called object change, the parameter update function can be used to update the parameters in the program editing area with one click.



Prerequisites

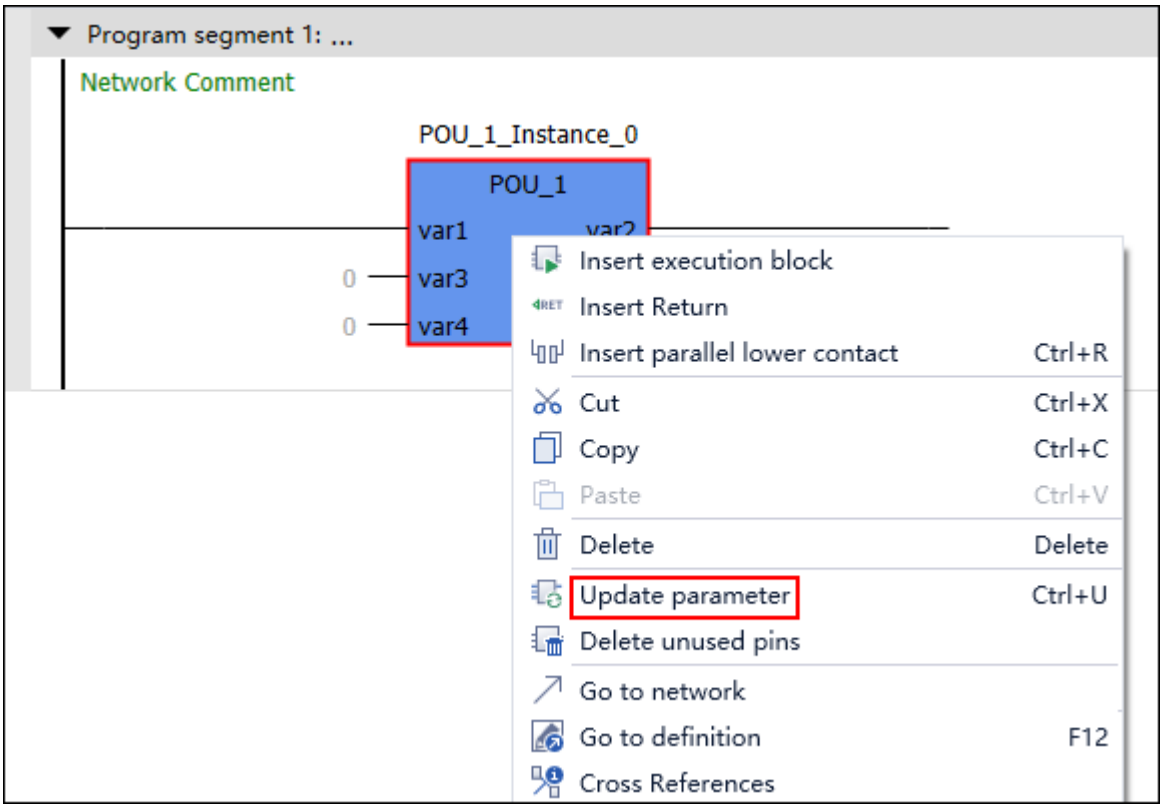
- The FB instance is called in the editing area.
- The FC, PRG, or Meth is called within the editing area.



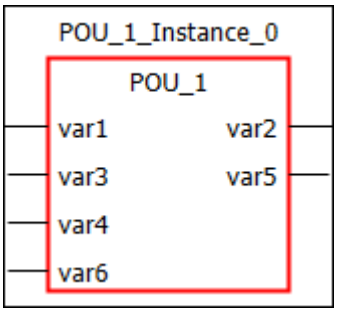
Updating parameters in the ST editor

For the ST editor, the parameter update function is mainly used to complete missing parameters. If the parameters of the called object are deleted, the parameter update operation will not synchronously delete the parameters at the call site; if the parameter name of the called object is refactored, the parameters at the call site will automatically synchronize without manual updates.

1. Right-click the FB instance, FC, PRG, or Meth called in the editing area and a menu will pop up. Click "Update parameter", as shown in the following figure.

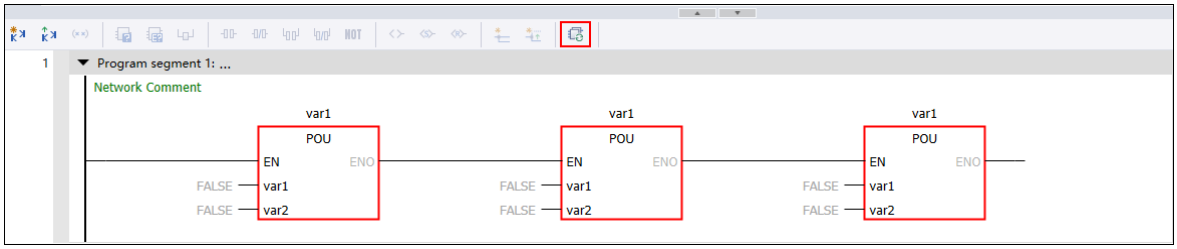


2. Update the parameter list of the target instruction, as shown in the following figure.



Updating parameters in the LD editor

When the parameters of the called object change (including addition, deletion, and parameter name refactoring), a red border appears around the block in the program editing area, indicating that you can update parameters of an individual block or update all parameters.



- Updating parameters of an individual block
  1. Right-click an individual block in the editing area. In the pop-up menu, click "Update parameter", as shown in the following figure.

  2. Update the target instruction parameters to align the parameters in the current block with the parameters of the called object.

- Updating all parameters
  1. Click the "Update all parameter" button in the menu bar of the editing area, as shown in the following figure.

2. Perform a batch update of all blocks with parameter changes in the editing area.

10.1.1.10.10 Input Assistant

The input assistant helps users quickly search for and input target data types or variables while editing variables, reducing programming time.

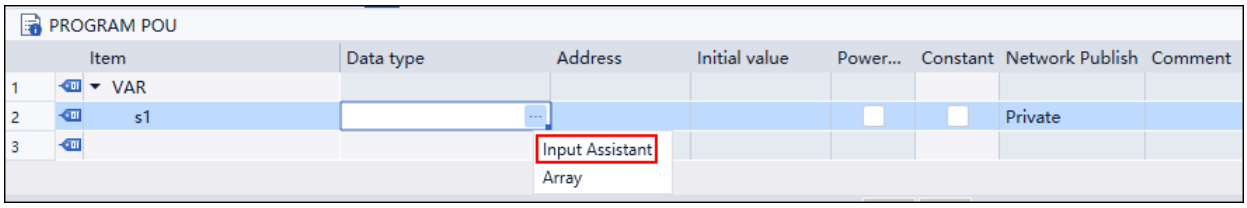
Applicable locations:

- Global variable table
- Variable declaration area of program blocks
- Program editing area
- I/O mapping

Editing data types in the variable list

- In the input assistant window, select the target variable.

  Double-click the data type cell of the target variable and click ... to select "Input assistant".



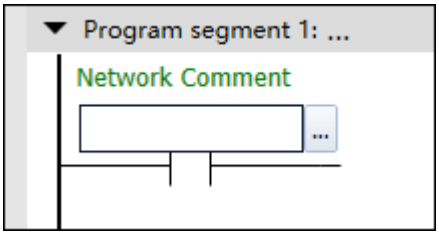


Figure 10-1-1-10-10-1 Operations in the variable declaration area of program blocks

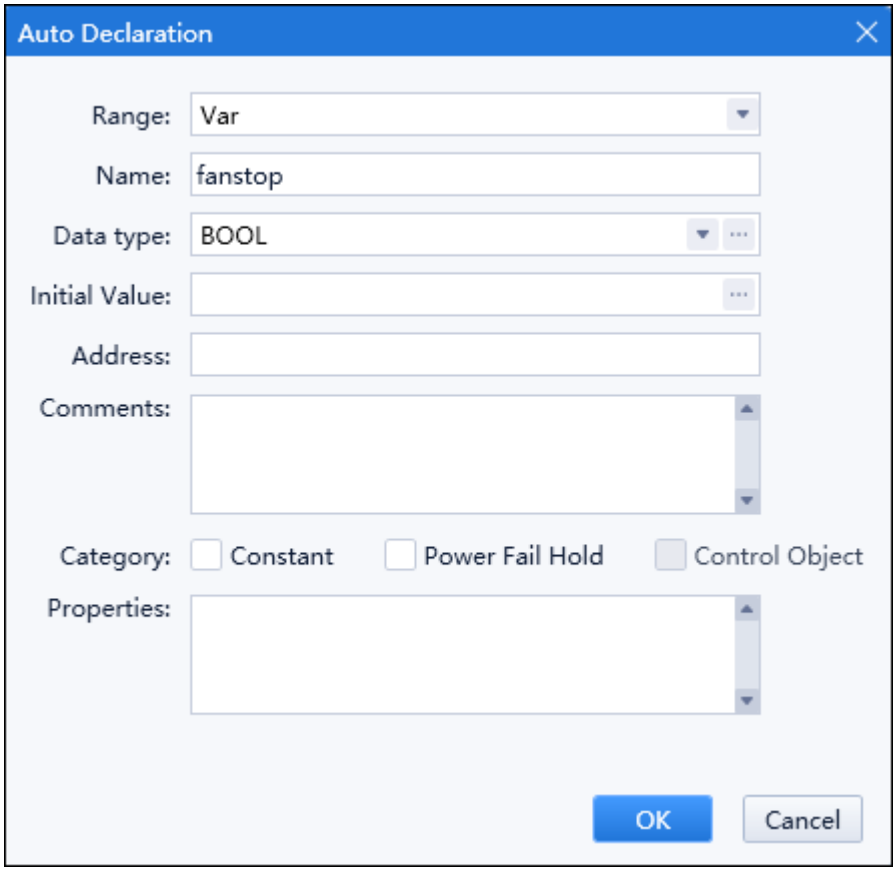
Open the input assistant window, double-click the target object to complete the input of the data type.



Editing programs in the LD editor

- Declaring variables

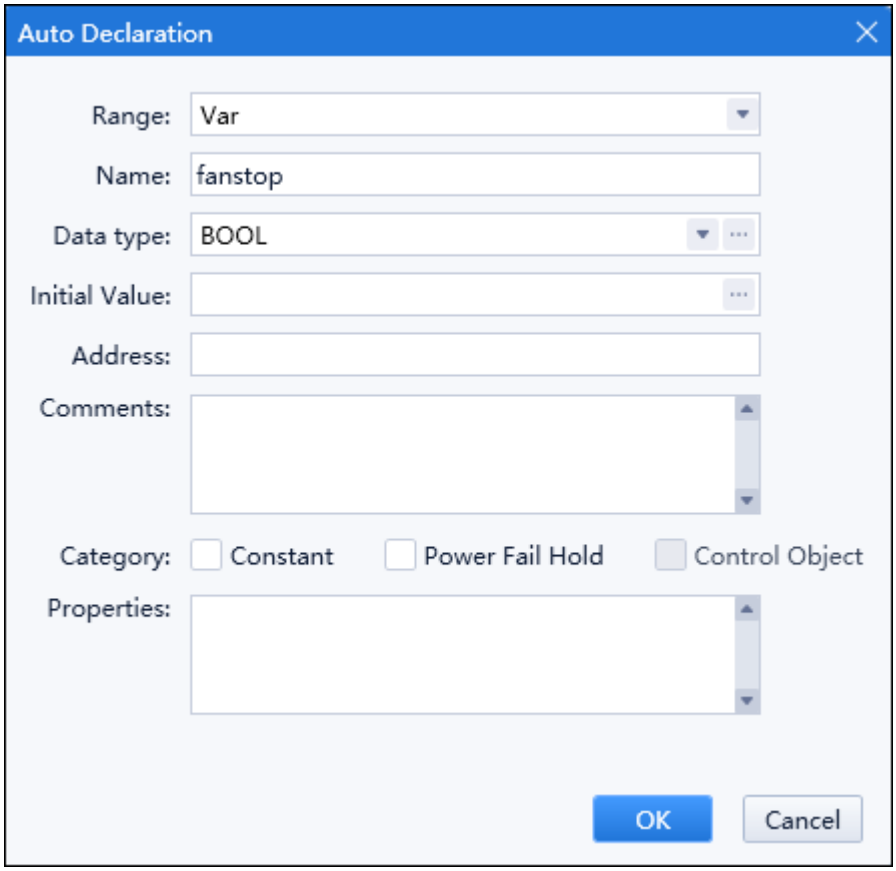
  1. Double-click the variable name of the component. The default is ???.

  2. Enter the desired variable name in the text box and press the Enter key.

3. Select > and open the input assistant window.
4. Double-click the target data type to complete the data type setting.

- Associating variable name or instance name with components

1. Double-click the variable name of the component. The default is ???.



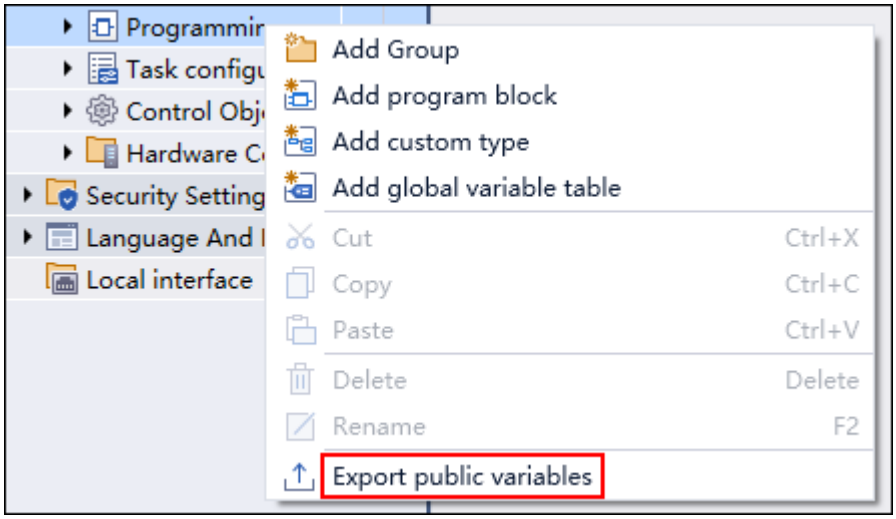
2. Select ... and open the input assistant window.
3. Select the target variable name or instance name to complete the association operation.

Editing programs in the ST editor

- Declaring variables

1. Enter the desired variable name.
   In the ST program editing area, enter the desired variable name, and press the Enter key.

2. Select > and open the input assistant window.
3. Double-click the target data type to complete the data type setting.



10.1.1.10.11 Public Variable Export

Prerequisites

The network public property of the variable is set to public, which can be "Read/Write", "Read-Only", or "Write-Only".

Procedure

1. After the project has been compiled, right-click "Programming" > "Export public variables", and an "Inquiry" dialog box will pop up.

2. Click "Confirm" and select the export path to export public variables in XML format. After successful export, a prompt will appear, saying "Public variables exported successfully".

Result

The exported XML file for public variables is as shown in the following figure.

```
<?xml version="1.0" encoding="utf-8"?>
<Symbolconfiguration>
  <Header>
    <ProjectInfo name="plc" devicename="PLC_1" appname="Application" codeId="341b70a9-0000-0000-0000-0000000(
  </Header>
  <TypeList>
    <TypeSimple name="T_BOOL" size="1" iecname="BOOL" typeclass="Bool" />
    <TypeSimple name="T_INT" size="2" iecname="INT" typeclass="Int" />
    <TypeSimple name="T_LINT" size="8" iecname="LINT" typeclass="LInt" />
    <TypeSimple name="T_DWORD" size="4" iecname="DWORD" typeclass="DWord" />
  </TypeList>
  <NodeList>
    <Node name="Application">
      <Node name="Main">
        <Node name="var1" type="T_BOOL" access="readwrite" offset="292" />
        <Node name="var2" type="T_BOOL" access="readwrite" offset="293" />
        <Node name="var3" type="T_INT" access="readonly" offset="294" />
        <Node name="var4" type="T_LINT" access="writeonly" offset="296" />
        <Node name="var5" type="T_DWORD" access="readonly" offset="304" />
        <Node name="var6" type="T_DWORD" access="writeonly" offset="308" />
        <Node name="var7" type="T_DWORD" access="readwrite" offset="312" />
        <Node name="var8" type="T_DWORD" access="readwrite" offset="316" />
        <Node name="var9" type="T_DWORD" access="readonly" offset="320" />
      </Node>
    </Node>
  </NodeList>
</Symbolconfiguration>
```

NOTE

The structure of the exported XML file depends on the configuration method of the public variables. For details, see 10.7.7.2 Public Variable.

10.1.1.10.12 Going to Definition

The "Go to definition" feature is used to help users quickly jump to the declaration location of a variable during program development, supporting both online and offline operations.

Applicable locations:

- Program editing area
- Recipe manager
- Resource Usage Table
- I/O mapping

Procedure

1. In the program editing area or recipe variable area, right-click the selected variable name, and select "Go to definition" in the pop-up menu or use the shortcut key "F12".

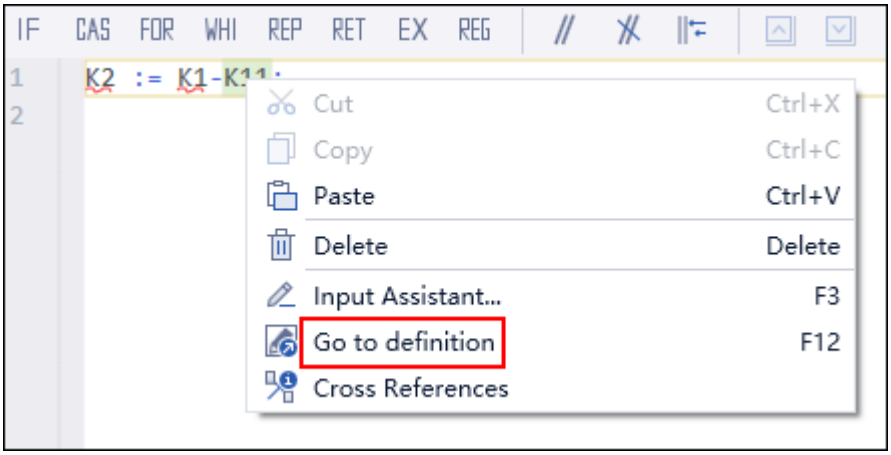


Figure 10-1-1-10-12-1 Operation in the program editing area

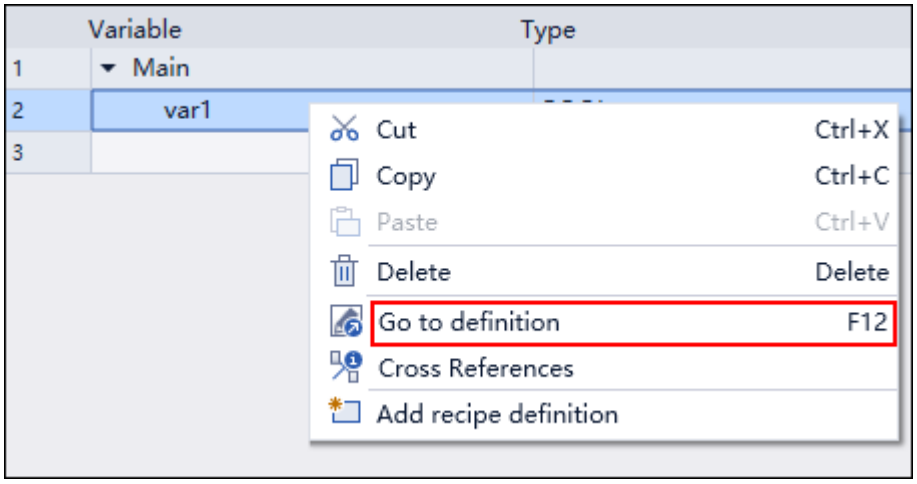

Figure 10-1-1-10-12-2 Operation in the recipe variable area

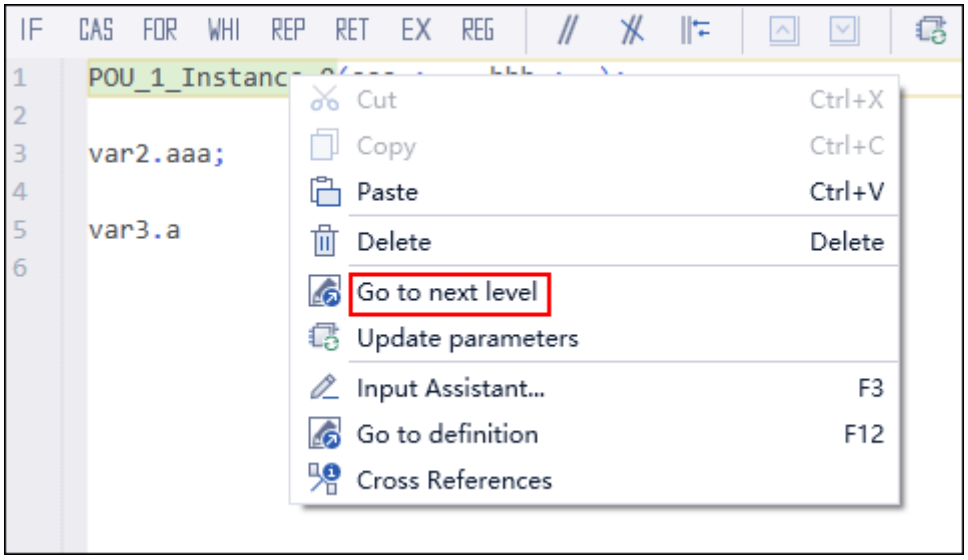
Result

The software will jump to the target variable's declaration location. For user-defined function blocks or functions, it will also open their internal programs simultaneously.

NOTE



- When a variable in the program editing area is in a comment state, the "Go to definition" operation is not supported.
- For variables and types in the compilation library, the "Go to definition" operation is not supported.

10.1.1.10.13 Going to Next Level

The "Go to next level" feature is used to help users quickly jump to the declaration location of a statement during program development, supporting both online and offline operations.

Procedure

1. Right-click the selected instance or function in the program editing area, and select "Go to next level" from the pop-up menu.

Result

The software will jump to the target statement's declaration location. For user-defined function blocks or functions, it will also open their internal programs simultaneously.

> NOTE
>
> When statements in the program editing area are in comment status, the "Go to next level" operation is not supported.

10.1.2 Program Block

10.1.2.1 Program

10.1.2.1.1 Overview

A program is the core of task planning and has the highest calling authority, allowing it to call function blocks and functions.

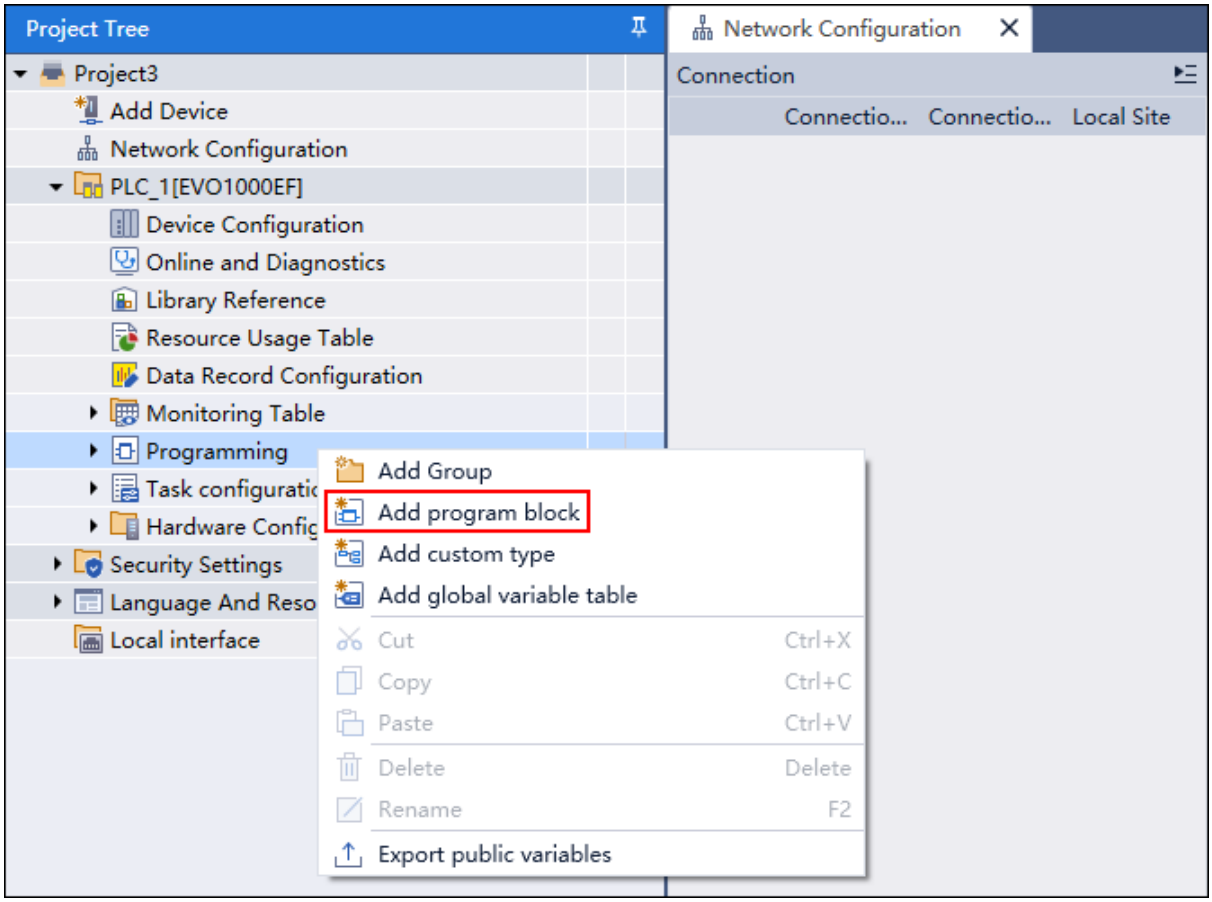
Generally, three types of variables are defined in the program: Regular global variables, global variables mapped to hardware addresses, and local variables. The application logic is implemented through inter-program calls.

- **Custom program representation**
  Custom programs are represented using the following syntax expression.

```
Plain Text
PROGRAM <program name>
VAR_INPUT
… (*input interface variable declaration of the program*)
END_VAR
VAR_OUTPUT
… (*export interface variable declaration of the program*)
END_VAR
VAR
… (*local variable declaration of the program*)
END_VAR
```

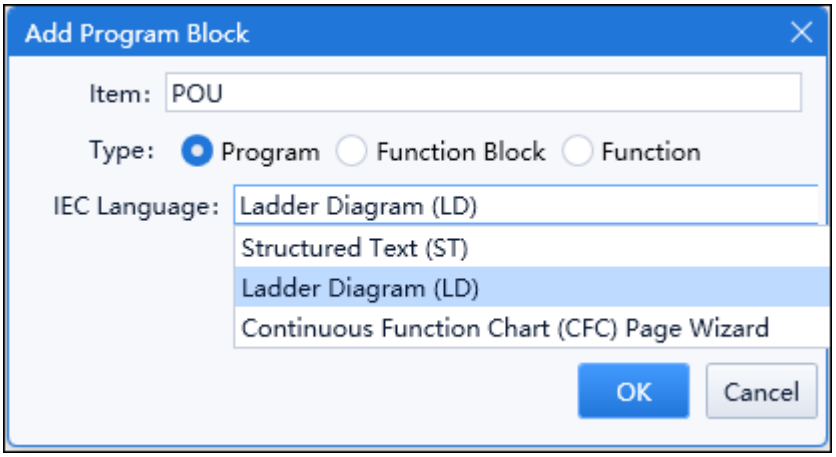
```
Plain Text
...; // program logic
```

- **Variable declaration in a program**
  The syntax for declaring variables in PRG is as shown above. The types of variables that can be declared in PRG include local variables (VAR), input variables (VAR_INPUT), output variables (VAR_OUTPUT), input/output variables (VAR_IN_OUT), and temporary variables (VAR_TEMP). All properties of the variables are configurable.



10.1.2.1.2 Adding a User Program

Prerequisites



- A project has been created.
- A device has been added.

Procedure

1. Right-click "Programming > Add program block".

2. In the "Add program block" window, set the program name, select "Program" as the type, and select the corresponding IEC language, as shown in the figure below.

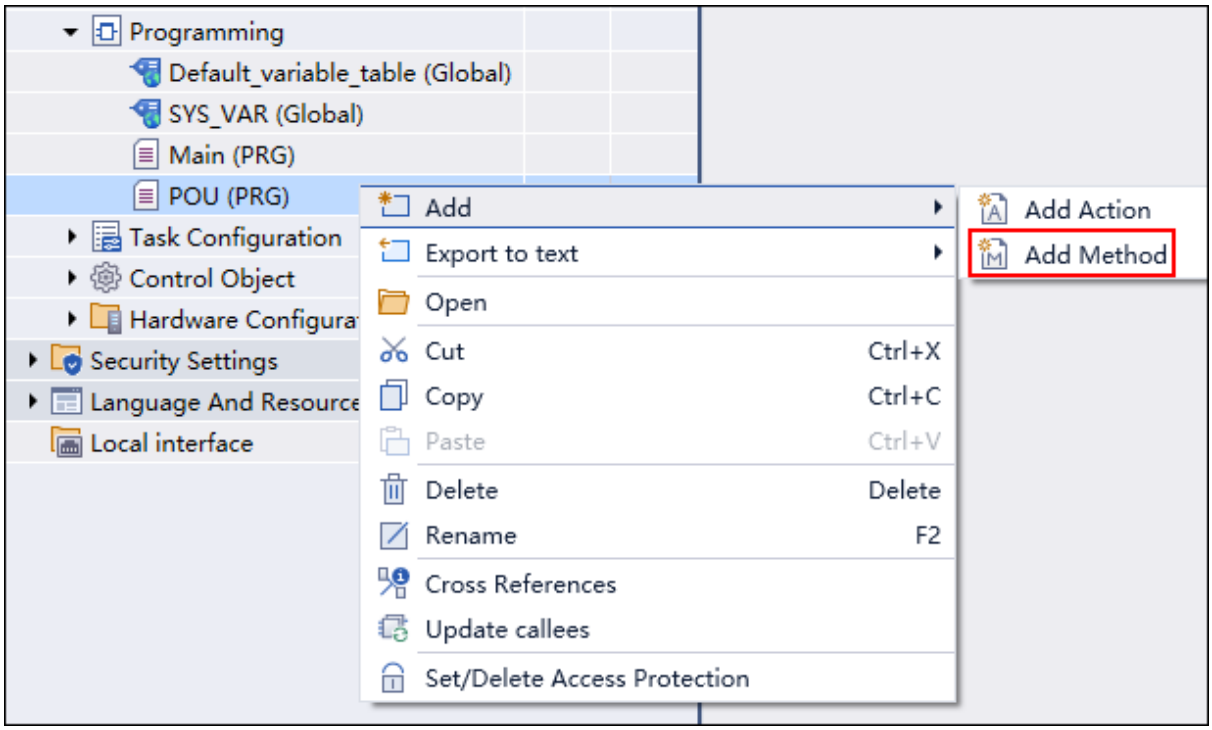
No.	Item	Description
①	Name	Indicates the program name. It supports letters, numbers, and underscores (_), and must start with a letter or underscore. Underscores cannot be used consecutively. The program name is case-insensitive, with a maximum length of 128 bytes. For example, __POU and PO__U are invalid names, while P_O_U is considered valid.
②	Type	Indicates the program block type. To add a user program, select "Program" here.
③	IEC Language	Supports LD, ST, and CFC programming languages.

3. Click "OK" to add the user program POU. The user program has a "(PRG)" suffix. When a user program is added, iFA will automatically open its editor. The editor is divided into the variable declaration area and the program editing area, which can be collapsed and expanded using and .

> NOTE
>
> When a POU is being compiled, the system will check the upper limit based on device requirements. For specific limitations, see the device specifications.

10.1.2.1.3 Adding a Method to a Program

Similar to function (FUN), a method (METH) has at least one input variable, and only returns one value. The difference is that methods must be created under a program (PRG) or function block (FB), and have access modifiers (PUBLIC, PROTECTED, PRIVATE, and INTERNAL). Methods can be used by functions, function blocks, and programs. When a method is called with the same input parameters, it always generates the same result as the return value.



Method Creation

Prerequisites

A program (PRG) or function block (FB) has been created.

Procedure

1. Right-click an FB or PRG under "Programming" in the project tree, and select "Add > Add method", as shown in the figure below.

2. In the "Create method" window, set the name, return value type, IEC language, and access modifier of the method.

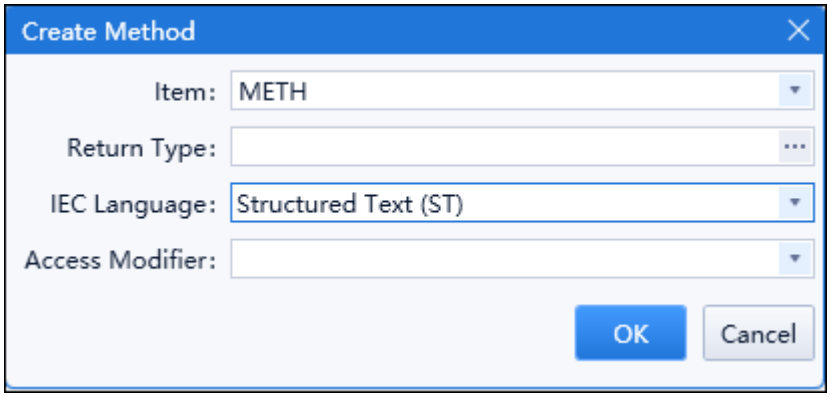


Table10-1-2-1-3-1 Method creation properties

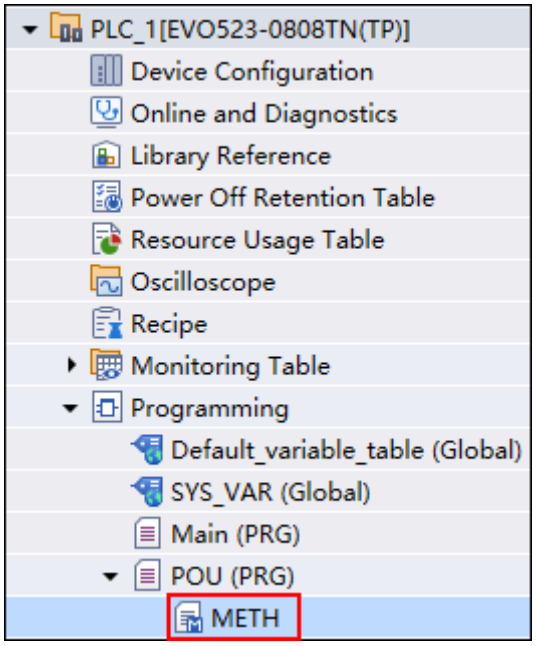


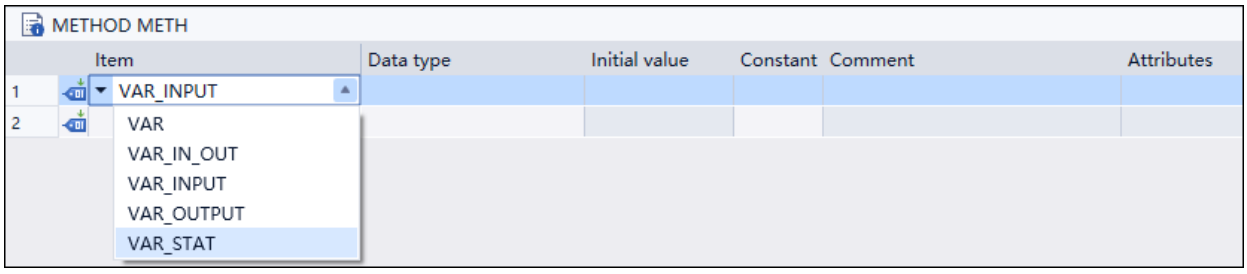
No.	Item	Description
①	Name	Indicates the method name. It must comply with the IEC61131-3 standard and is case-insensitive, with a length ≤ 128 bytes.
②	Return type	• The return value type must be specified and the length of the return value must be less than or equal to 128 bytes. • The return value type can be filled from the input assistant, which provides basic data types, custom types for the current project, and types from custom libraries. • The return value type is case-insensitive.
③	IEC Language	Supports LD and ST programming languages.
④	Access Qualifier	PUBLIC, PROTECTED, PRIVATE, and INTERNAL

Table10-1-2-1-3-2 Descriptions of access modifiers

Access Qualifier	Description
PUBLIC	Public access: Methods added under FB can be used across POU and across libraries.
PROTECTED	Protected access: Used for sub-function block to access the methods of base function block.
PRIVATE	Private access: Methods are only used within the PRG or FB itself and cannot be overridden by sub-function blocks.
INTERNAL	Access permissions within the namespace: Methods added under FB can be used in this project or this library project.

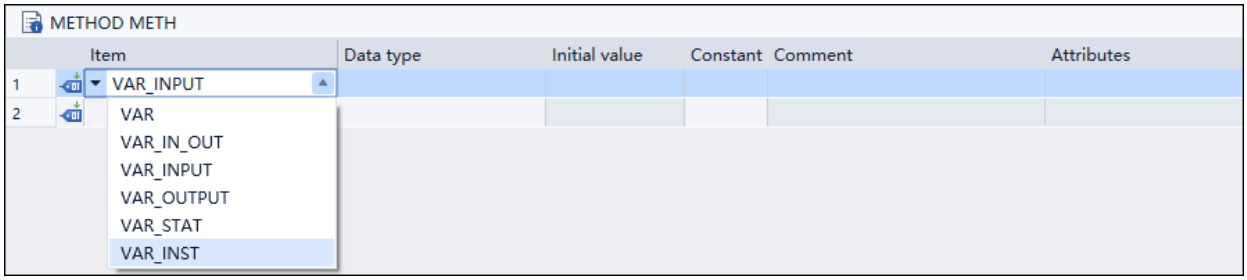
Result

A method (METH) is added under the program (PRG).



Method usage

Syntax for method representation and declaration



```
Go
METHOD  <access modifier>  <method name> : <return value type>
VAR_IN_OUT
// Input/output variable declaration
END_VAR
VAR
// Local variable declaration
END_VAR
VAR_OUTPUT
// Output variable declaration
END_VAR
```

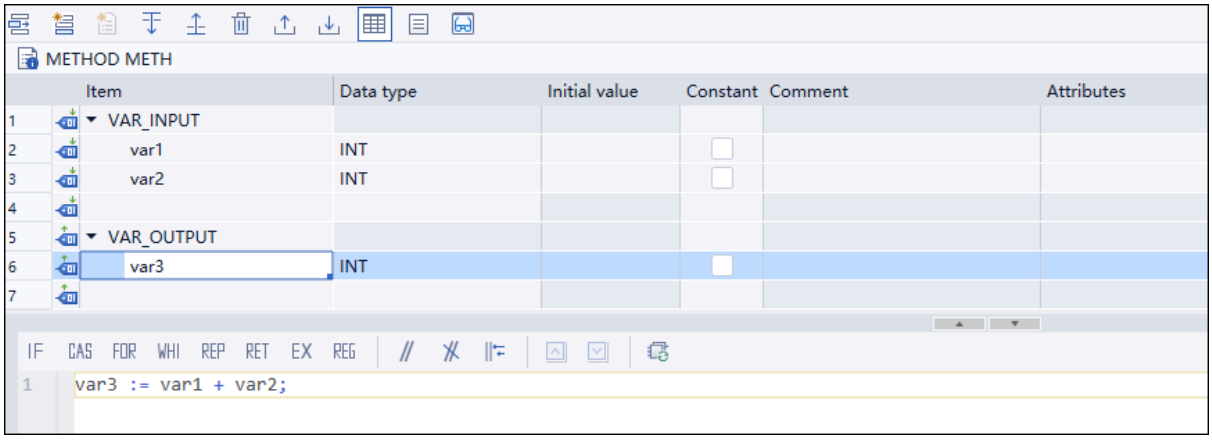
Variable declaration in methods

- The variable types supported by methods under a program include local variables (VAR), input variables (VAR_INPUT), output variables (VAR_OUTPUT), input/output variables (VAR_IN_OUT), and static variables (VAR_STAT). All properties of the variables are configurable.

- The variable types supported by methods under a function block include local variables (VAR), input/output variables (VAR_IN_OUT), input variables (VAR_INPUT), output variables (VAR_OUTPUT), static variables (VAR_STAT), and instance variables (VAR_INST). All properties of the variables are configurable.

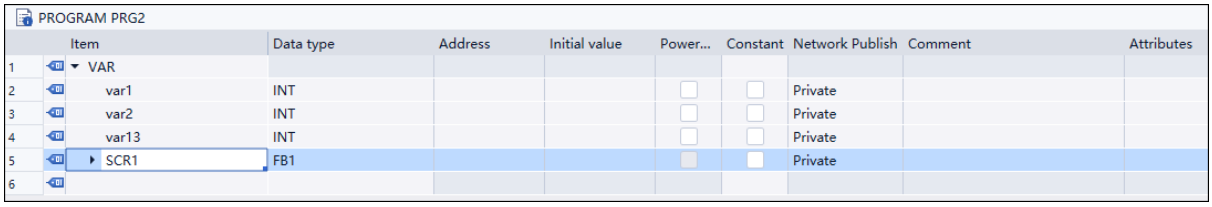
Precautions for variable declaration in methods:

- Supports multiple input variables and output variables. The caller must allocate variables to receive the output variables of the method.
- Supports only one return value (of output variable type).
- Storing values in internal variables is not supported, which is distinctly different from function blocks.
- Functions do not have specified memory allocation and do not need to be instantiated like function blocks.
- The actual arguments configured to VAR_INPUT by the caller can be empty, constants, variables, or function calls. In the case of a function call, The function is executed first, and its return value is passed as the actual argument.



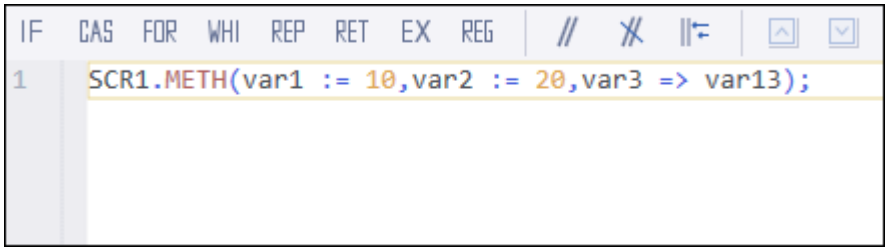
Method usage

- **Prerequisites**



Methods have been added under the program (PRG) or function block (FB).

- **Procedure**



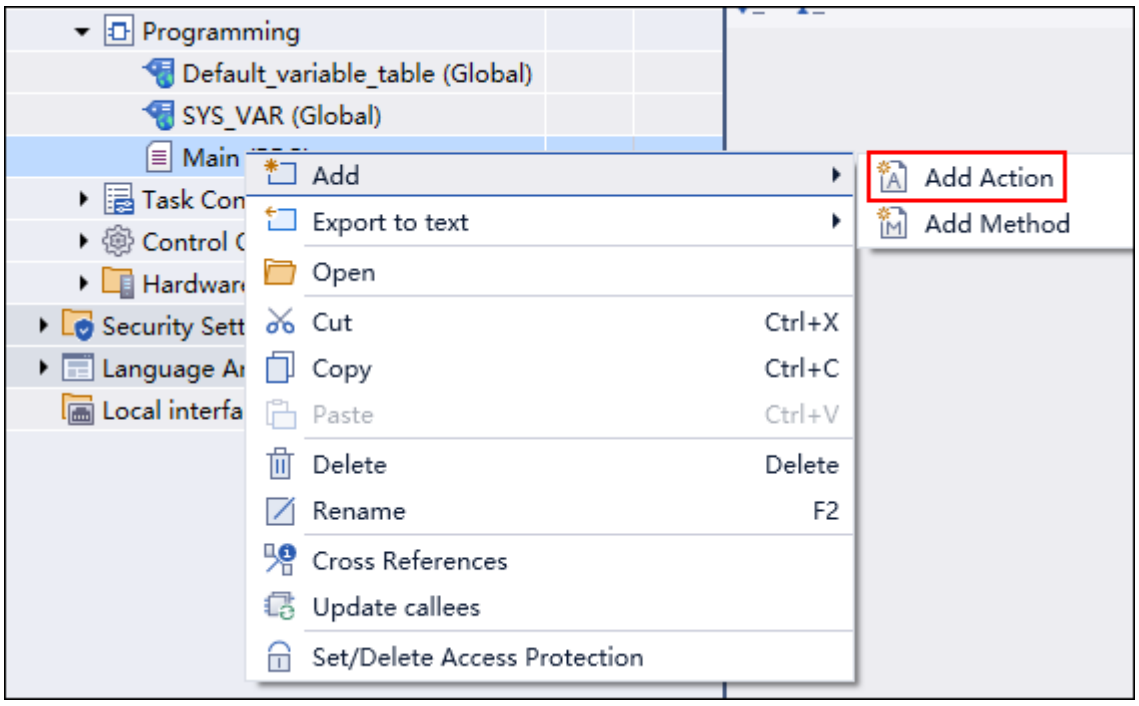
1. Add the method METH under function block FB1, with the variable table and programming logic as shown in the figure below.

2. Instantiate an object SCR1 of FB1 in PRG2 (PRG), and create variable var3.

3. Call METH under FB1, as shown in the figure below.

10.1.2.1.4 Adding an Action to a Program

Actions are added and used under programs and function blocks. They are generally used for operations such as assigning values to variables or performing calculations in PRG or FB, and are called where needed in the program. Actions require no inputs or outputs, do not have their own variable table, and cannot create variables that belong to themselves. They must use variables from PRG or FB.



Action Creation

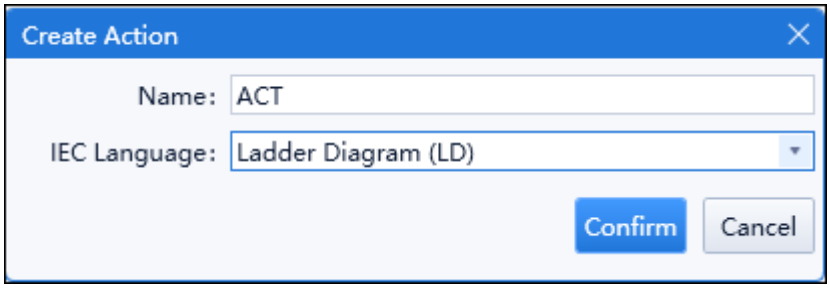
Prerequisites

A program (PRG) or function block (FB) has been created.

Procedure

1. Right-click an FB or PRG under "Programming" in the project tree, and select "Add > Add action", as shown in the figure below.

2. In the "Create action" window, set the name and IEC language of the action.



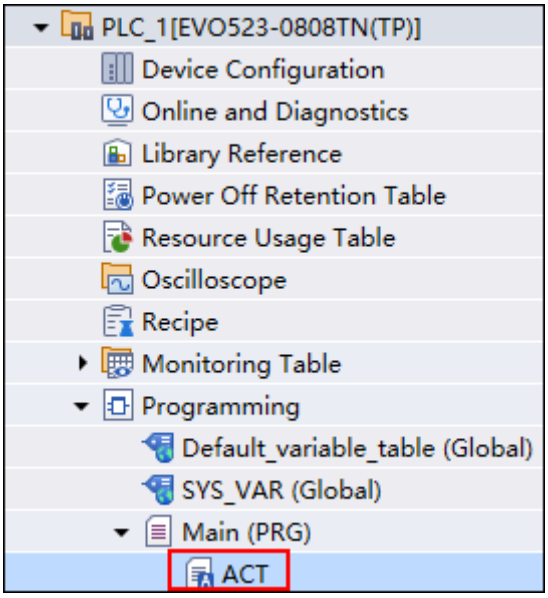


Table10-1-2-1-4-1 Action creation properties

No.	Item	Description
①	Name	Indicates the action name. It must comply with the IEC61131-3 standard and is case-insensitive, with a length ≤ 128 bytes.
②	IEC Language	Supports LD and ST programming languages.

Result

An action is added under a program.

Action Usage

- When the parent object is a program, the call format is "PRG name.ACT name()".
- When the parent object is a function block, the call format is "FB instance name.ACT name()".

```
// Call the action ACT in PRG

Main.ACT( );

// Call the action ACT in FB1

// fb1_1 is an instance of FB1

fb1_1.ACT( );
```

10.1.2.1.5 Calling a User Program

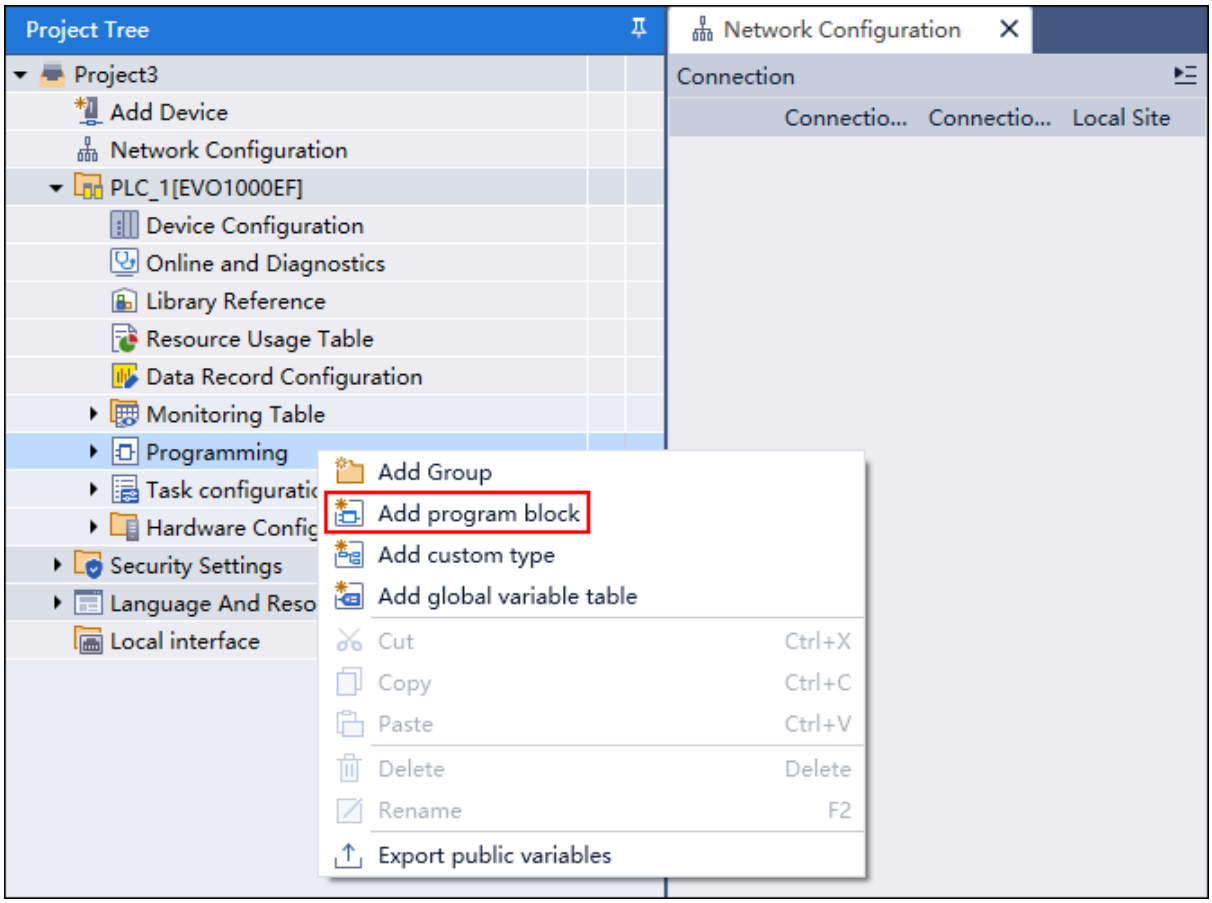
Before a user program is downloaded to the controller, it needs to be called first; otherwise, the program will not be executed.

User program calls are mainly managed in "Task configuration". For details, see 10.5 Task Configuration.

NOTE

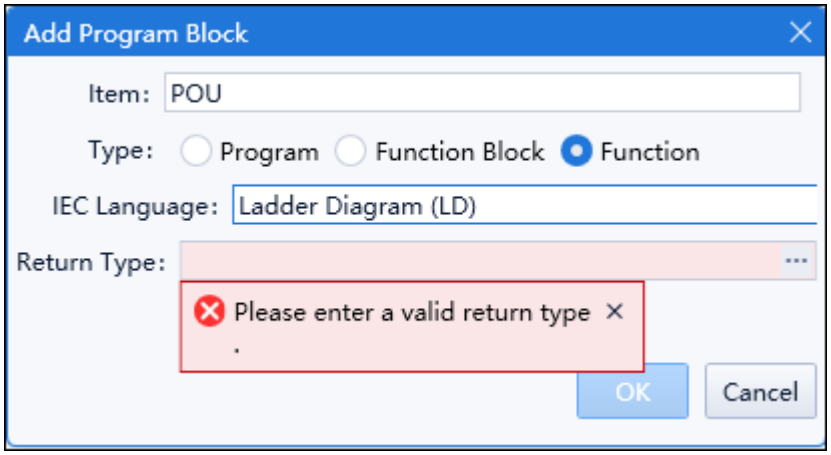
If a user program is added without being called, the program will not be checked during compilation. If the program has not changed, it will not trigger a download.

10.1.2.2 Functions



10.1.2.2.1 Adding a User Function

Prerequisites



- A project has been created.
- A device has been added.

Procedure

1. Right-click "Programming > Add program block".

2. In the "Add program block" window, set the name of the function, select "Function" as the type, select the corresponding IEC language, and select the return value type as needed, as shown in the figure below.

No.	Item	Description
①	Name	Indicates the function name. It supports letters, numbers, and underscores (_), and must start with a letter or underscore. Underscores cannot be used consecutively. The program name is case-insensitive, with a maximum length of 128 bytes. For example, __POU and PO__U are invalid names, while P_O_U is considered valid.
②	Type	Indicates the program block type. To add a user function, select "Function" here.
③	IEC Language	Supports LD and ST programming languages.
④	Return type	◦ The return value type must be specified and the length of the return value must be less than or equal to 128 bytes. ◦ The return value type can be filled from the input assistant, which provides basic data types, custom types for the current project, and types from custom libraries. ◦ The return value type is case-insensitive.

3. Click "OK" to add the user function POU. The user function has a "(FUN)" suffix. When a user function is added, iFA will automatically open its editor. The editor is divided into the variable declaration area and the program editing area, which can be collapsed and expanded using and .

NOTE

When a POU is being compiled, the system will check the upper limit based on device requirements. For specific limitations, see the device specifications.

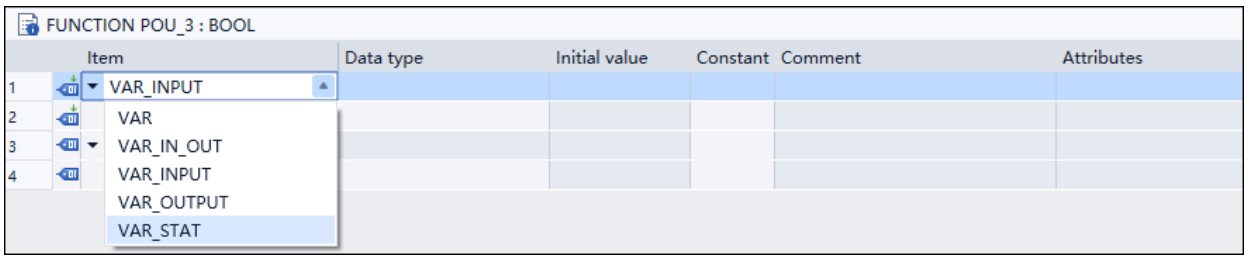
10.1.2.2.2 Modifying a User Function

A function (FUN) is defined as a program organization unit (POU). It can be assigned parameters but has no static variables. That is, when a function is called with the same input parameters, it always generates the same result as the return value. An important characteristic of functions is that they cannot use internal variables to store values, which is completely different from function blocks.

A function is a basic algorithm unit without an internal state (no runtime memory allocation). That is, given the same input parameters, calling the function will definitely produce the same result with no ambiguity. Mathematical operation functions commonly used, such as sin(x) and sqrt(x), are typical examples of functions.

A function has at least one input variable, no private data, and only one return value. Functions can be used by functions, function blocks, and programs.

Representation and declaration of functions



Functions are represented using the following syntax expression. The logic part can be written in either ST or LD programming languages.

```
SQL
FUNCTION <function name/return value>: <return type>
VAR_INPUT
… // Input interface variable declaration of the function*
END_VAR
VAR
… // Local variable declaration of the function
END_VAR
```

```
Plain Text
…; // Internal logic of the function
```

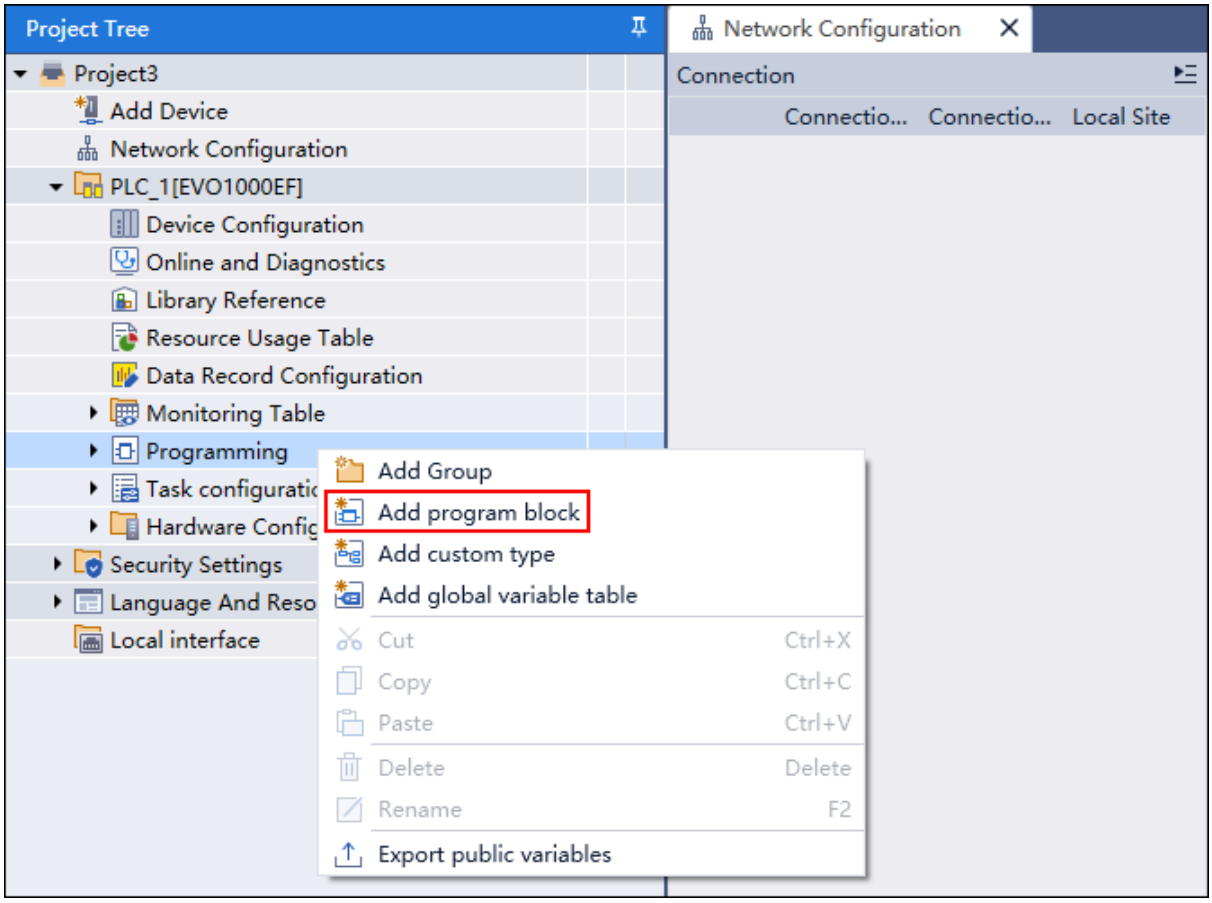
Variable declaration in functions

The syntax for declaring variables in FUN is shown above. The variable types that can be declared in FUN include local variables (VAR), input/output variables (VAR_IN_OUT), input variables (VAR_INPUT), output variables (VAR_OUTPUT), and static variables (VAR_STAT). All properties of the variables are configurable.

When defining a custom function, the following should be noted:

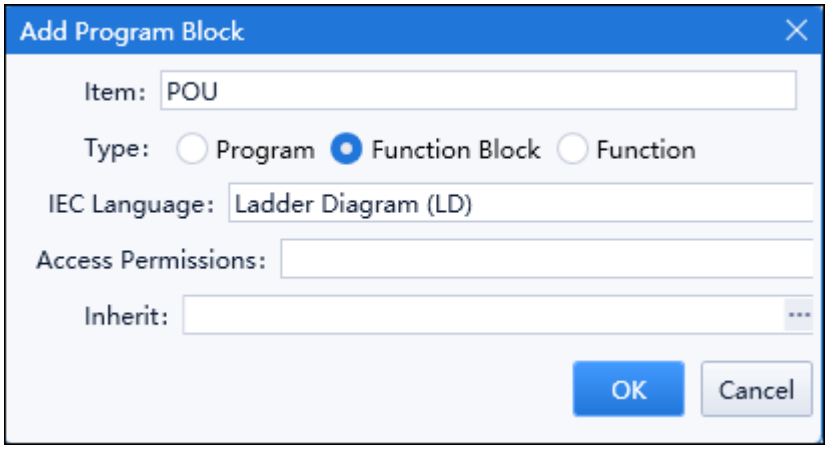
- A function can have many input variables, but it can only have one return value (output variable). There is no restriction on the data type of the return value, which can be a structure.
- An important feature of functions is that they cannot store values in internal variables, which is distinctly different from function blocks.
- Functions do not have specified memory allocation and do not need to be instantiated like function blocks.
- The actual arguments configured to VAR_INPUT by the caller can be empty, constants, variables, or function calls. In the case of a function call, The function is executed first, and its return value is passed as the actual argument.

10.1.2.3 Function Block



10.1.2.3.1 Adding a User Function Block

Prerequisites



- A project has been created.
- A device has been added.

Procedure

1. Right-click "Programming > Add program block".

2. In the "Add program block" window, set the name of the function block and select "Function block" as the type. Select the corresponding IEC language, access permissions, and inheritance relationship, as shown in the figure below.

No.	Item	Description
①	Name	Indicates the name of the function block. It supports letters, numbers, and underscores (_), and must start with a letter or underscore. Underscores cannot be used consecutively. The program name is case-insensitive, with a maximum length of 128 bytes. For example, __POU and PO__U are invalid names, while P_O_U is considered valid.
②	Type	Indicates the program block type. To add a user function, select "Function block" here.
③	IEC Language	Supports LD and ST programming languages.
④	Access Permissions	Options include PUBLIC, INTERNAL, and FINAL.
⑤	Inheritance	You can select the function block being inherited using the input assistant.

3. Click "OK" to add the user function block POU. The user function block has a "(FB)" suffix. When a user function block is added, iFA will automatically open its editor. The editor is divided into the variable declaration area and the program editing area, which can be collapsed and expanded using and .

NOTE

When a POU is being compiled, the system will check the upper limit based on device requirements. For specific limitations, see the device specifications.

10.1.2.3.2 Adding a Method to a Function Block

For details about how to add a method to a function block, see "10.1.2.1.3 Adding a Method to a User Program".

10.1.2.3.3 Adding an Action to a Function Block

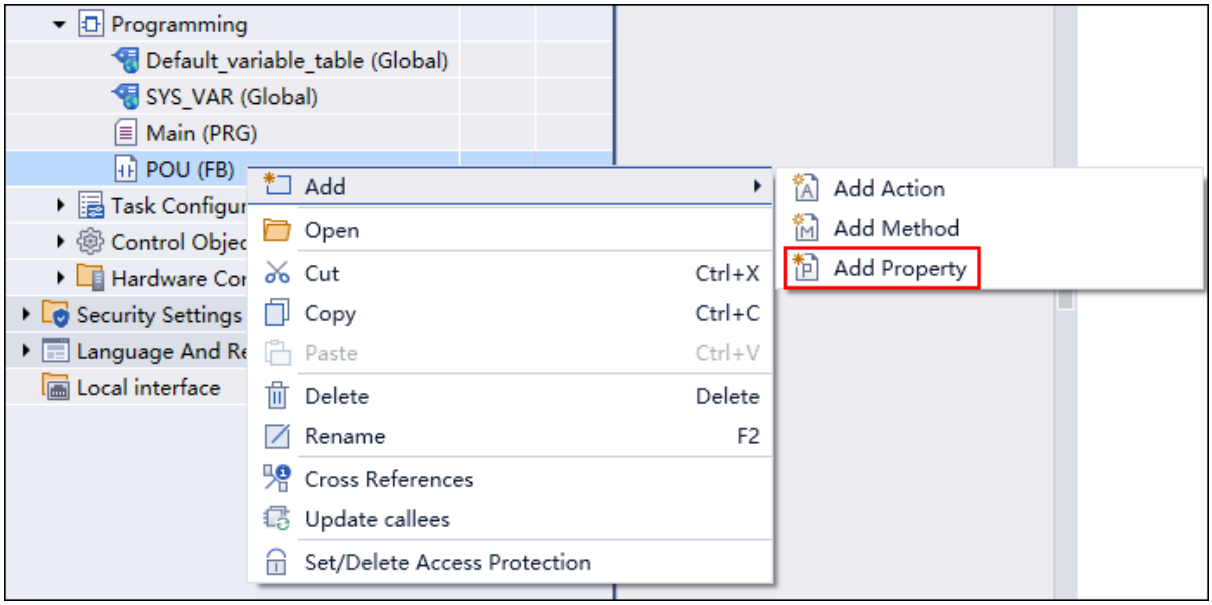
For details about how to add an action to a function block, see 10.1.2.1.4 Adding an Action to a User Program.

10.1.2.3.4 Adding a Property to a Function Block

Properties are added and used under function blocks. They provide two accessor methods: Get and Set, and allow read/write access to the instance data associated with the property.

Get: Read access, used to read properties in FB.

Set: Write access, used to write properties in FB.



Property creation

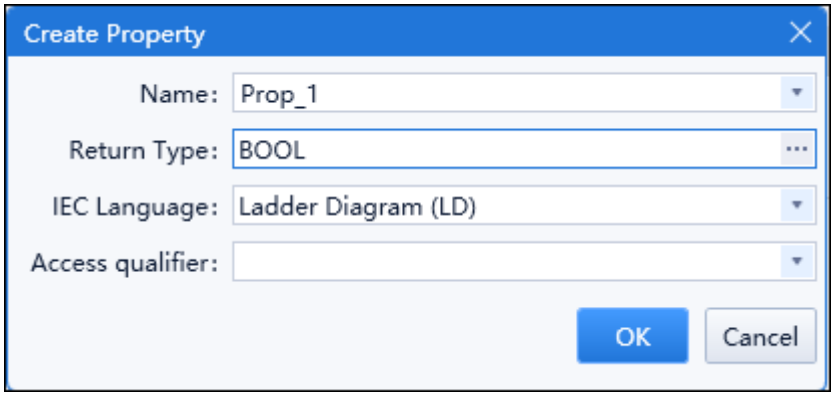
Prerequisites

A function block has been created.

Procedure

1. Right-click an FB under "Programming" in the project tree, and select "Add > Add property", as shown in the figure below.

2. In the "Create property" window, set the property name, return value type, IEC language, and access qualifier.



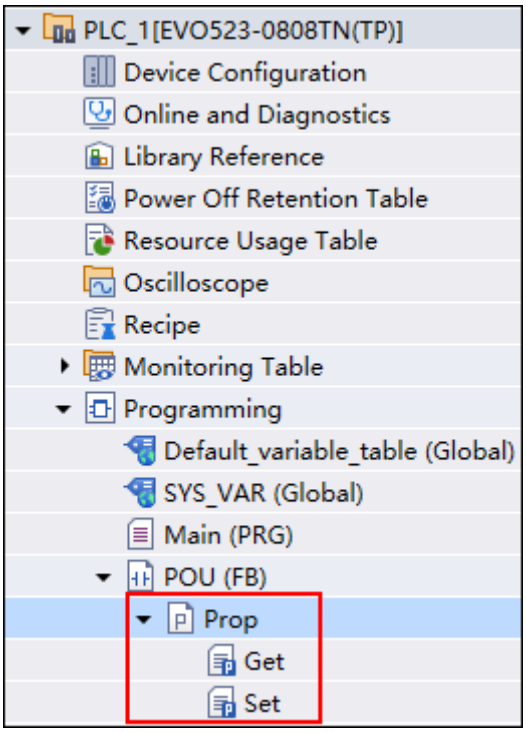


Table10-1-2-3-4-1 Property creation items

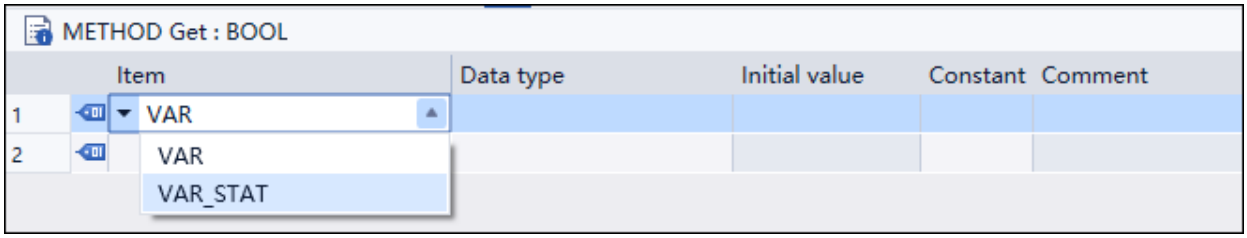
No.	Item	Description
①	Name	Indicates the property name. It must comply with the IEC61131-3 standard and is case-insensitive, with a length ≤ 128 bytes.
②	Return type	• The return value type must be specified and the length of the return value must be less than or equal to 128 bytes. • The return value type can be filled from the input assistant, which provides basic data types, custom types for the current project, and types from custom libraries. • The return value type is case-insensitive.
③	IEC Language	Supports LD and ST programming languages.

No.	Item	Description
④	Access Qualifier	Options include PUBLIC, PROTECTED, PRIVATE, and INTERNAL.

Result

A property is added under a function block. Accessors Get and Set are automatically generated.



NOTE

- Accessors Get and Set can be manually deleted by users.
- After deleting an existing Get or Set accessor, it can be recreated under the "Prop" node, as follows:
  1. Select the "Prop" node.
  2. Select "Add object" > "Get accessor"/"Set accessor".
  3. In the pop-up "Create property" window, set the IEC language and access qualifier for the property.
- Each property supports only one Get accessor and one Set accessor.
- Modifying the return value type of a Get or Set accessor in the variable declaration editor (in text view) is invalid; the system still uses the initial declaration type of the property.

Property usage

Variable declaration in properties

The variable types supported by properties under a function block include local variables (VAR) and static variables (VAR_STAT). The data type, address, initial value, constant, and comment of the variables can be configured.

Property call

When the parent object is a function block (FB), the call format is "FB instance name.Prop name".

```
// Call the property Prop in FB
// FB_1 is an instance of FB
FB_1.Prop;
```

NOTE

The Get accessor is used to read properties in FB, and the Set accessor is used to write properties in FB.

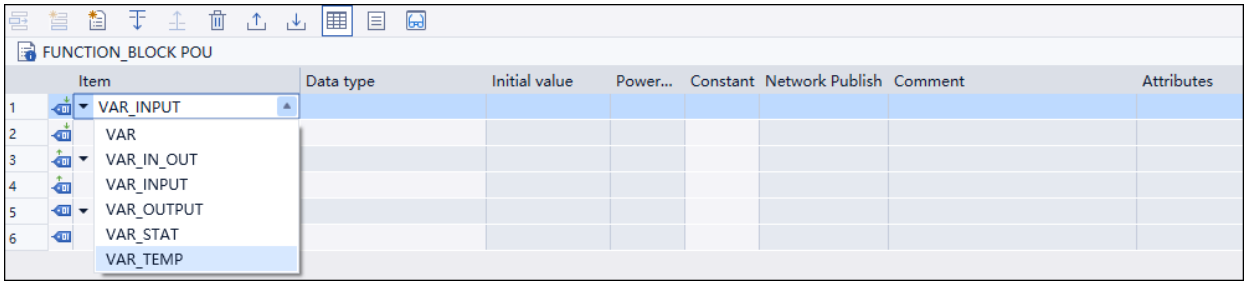
10.1.2.3.5 Modifying a User Function Block

A function block converts frequently used program segments into a reusable component. It can be called by any programming language in the program and reused repeatedly, improving development efficiency and reducing errors, thereby enhancing program quality.

A function block is a program organization unit that can produce one or more values during execution. It retains its own special internal variables, and the controller's target execution system must allocate memory for the internal state variables of the function block. These internal variables form its own state characteristics.

The execution logic of a function block forms its own object behavior characteristics. Therefore, for the same input variable values, calculation results may vary due to different internal state variables.

Representation and declaration of function blocks



Function blocks are represented using the following syntax expression. The logic part can be written in either ST or LD programming languages.

```
FUNCTION_BLOCK <function block name>
VAR_INPUT
… // Input interface variable declaration of the function block
END_VAR
VAR_OUTPUT
… // Output interface variable declaration of the function block
END_VAR
VAR
… // Local variable declaration of the function block
END_VAR
```

```
...; // Internal logic of the function block
```

Variable declaration in function blocks

The syntax for declaring variables in FB is as shown above. The variable types that can be declared in FB include local variables (VAR), input/output variables (VAR_IN_OUT), input variables (VAR_INPUT), output variables (VAR_OUTPUT), static variables (VAR_STAT), and temporary variables (VAR_TEMP). All properties of the variables are configurable.

NOTE

The EVO500 series PLC V1.2 version does not support setting the "Network public" property of a function block.

10.1.2.3.6 Using a User Function Block

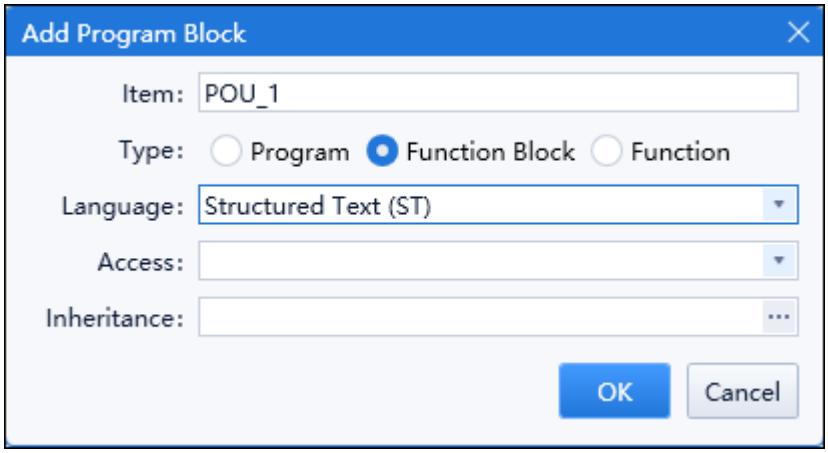
Instantiation of function blocks

According to the IEC61131-3 standard, the type of function block is an abstract definition of a structure, not a real data entity. If it is not defined and instantiated, it cannot be called and executed by the program. Therefore, function blocks need to be instantiated before they can be used. After instantiation, a function block is a completely encapsulated and independent structured variable that owns private data and can perform specific functions according to predefined logic.

The instantiation of a function block is like defining a variable. When the program needs to call this function block, it only needs to declare a variable of the FB type. The program reads and writes to the function block through this variable during execution. Instance types can have the same name, but instance names must not be the same within the same POU.

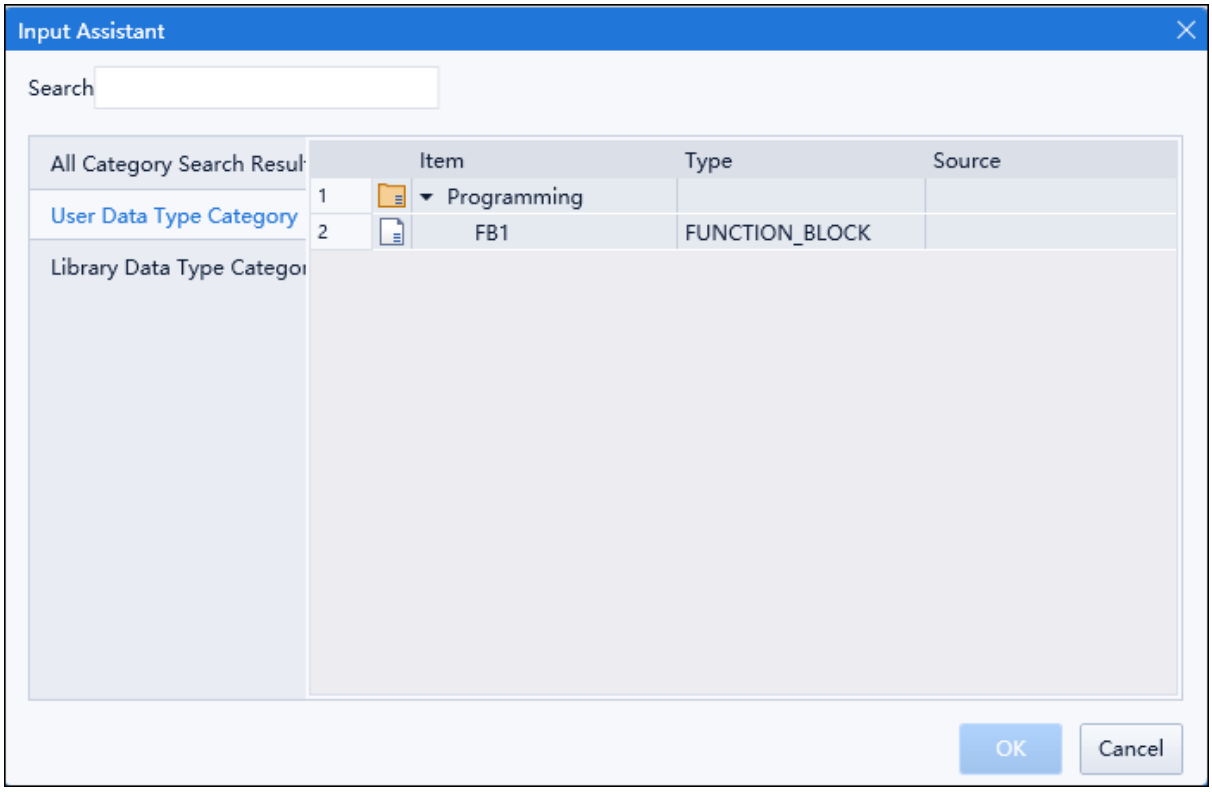
NOTE

- FBs cannot be declared as temporary variables, or local variables of FUN/Meth; otherwise, a compilation fault will be reported.
- FB pointers and FB references can be declared as temporary variables, or local variables of FUN/Meth.
- Regarding FB nesting, a compilation fault will only be reported if the nested FB object is declared as a temporary variable, or a local variable of FUN/Meth. The parent object will not trigger a fault.
- During function block instantiation, the "Network public" property (options include "Public" and "Private") is set to "Private" by default. If the parent node is set to "Private", all child nodes will also be "Private"; if the parent node is set to "Public", the child nodes will inherit the public property configured for the function block itself.
- During function block instantiation for the EVO500 series PLC V1.2 version, the "Network public" property (options include "Private", "Read/Write", "Read-Only", and "Write-Only") is set to "Private" by default. The child node properties inherit from the parent node and cannot be set separately. If the device version is downgraded from V1.3 to V1.2, a fault of public variable property compilation will be reported.



Extension of function blocks

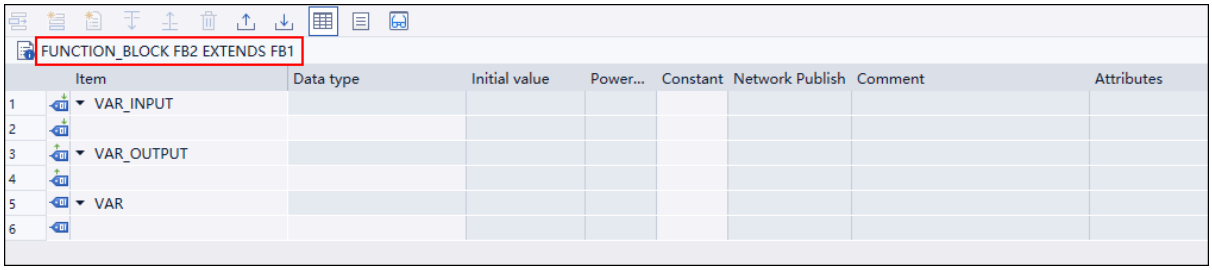
iFA supports object-oriented programming. Function blocks can derive child function blocks. Child function blocks inherit the properties of parent function blocks and can have their own additional characteristics. They can be considered an extension of the parent function block.



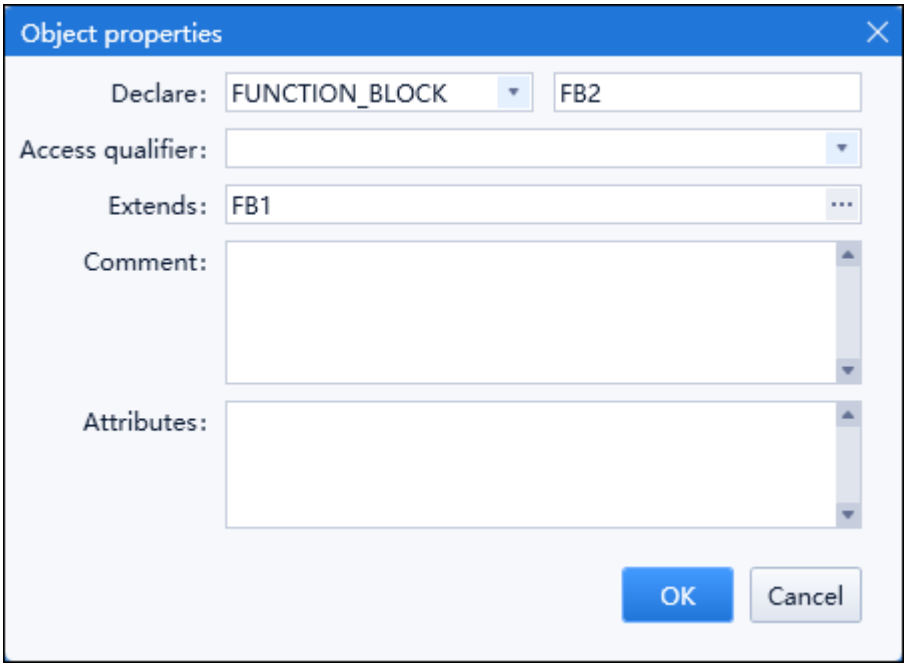
When creating a function block, add the keyword "EXTENDS" to enable the extension feature. This feature can also be enabled through the "Inheritance" configuration when adding a function block.

Enabling extension through inheritance

1. Right-click "Programming > Add program block".
2. In the "Add program block" window, set the name of the function block and check the type as "Function block", as shown in the figure below.



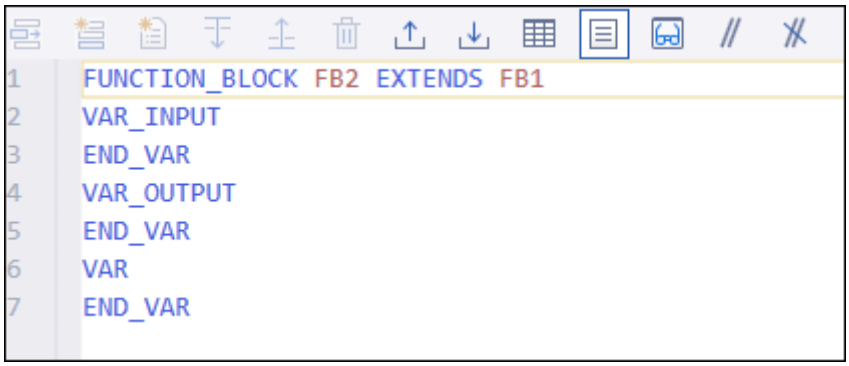
3. Click the "..." button after "Inheritance" to enter the "Input assistant" window and select the function block to be inherited, as shown in the figure below.



Enabling extension through variable declaration editor (in table view)

1. In the table view of the variable declaration editor, click the name of the function block and the "Object property" window pops up.

2. Add the function block being inherited, as shown below.



Enabling extension through variable declaration editor (in text view)

Switch the variable declaration editor to text view, and add the inheritance property for the function block. The format for declaring an extended function block is as follows.

```
FUNCTION_BLOCK <child function block name> EXTENDS <parent function block name>
```

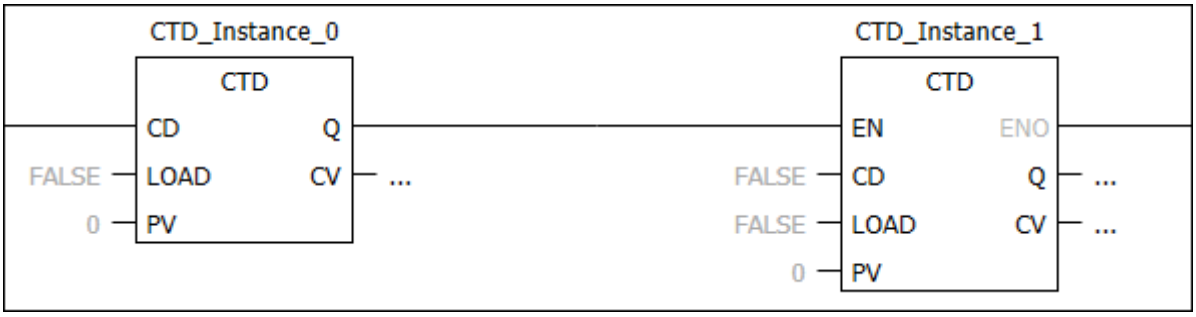
Result

In the above example, function block FB2 is extended from FB1. FB2 includes all variables and methods of FB1 and can replace FB1 wherever FB1 is used.

Methods in FB1 can be overwritten in FB2. That is, users can redeclare a method within FB2 that already exists in FB1, with the same name, inputs, and outputs.

Variables in FB2 and FB1 must not have the same name to avoid compilation faults.

The internal algorithms of FB2 support using variables and methods from FB1 with the keyword "SUPER" ("SUPER^." + "variable name or method name in the parent function block"). The "SUPER" keyword is case-insensitive.



EN and ENO

EN and ENO are the auxiliary properties of function blocks. They are only valid in ladder diagram and function block diagram programming languages. EN and ENO respectively control whether to enable the input and output of function blocks. They can be enabled or disabled by all functions.

The application principles for enabling inputs and outputs are as follows:

- When a function is called and the EN value is set to False, the operations defined by the function block will not be executed by the program, and the ENO value will also be False.
- When a function is called and the EN value is set to True, the operations defined by the function block will be executed and the ENO value will also be True.
- EN and ENO can be enabled or disabled as needed.

The following figure shows a regular function block and a function block with EN/ENO.

> **NOTE**
>
> EN/ENO is specific to the LD programming language. User variables cannot be declared with EN/ENO, otherwise a fault will occur.

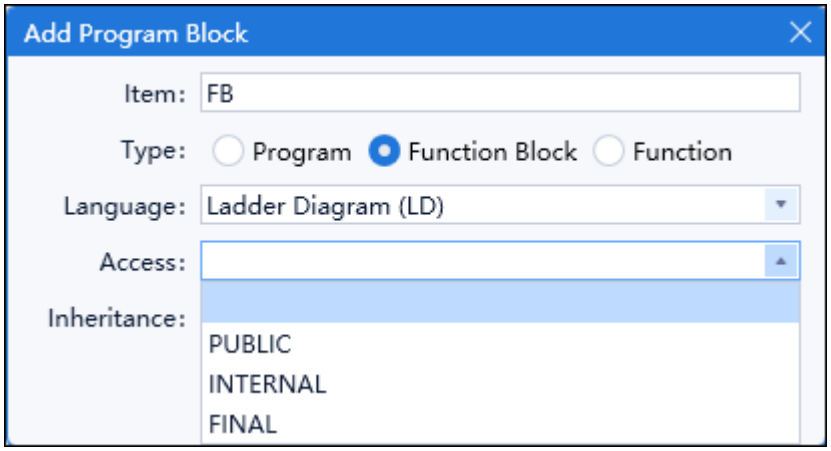
Access partitioning

Function blocks achieve their access partitioning through access qualifiers, which include PUBLIC, INTERNAL, and FINAL. If no access qualifier is set, it defaults to PUBLIC.

There are two methods to set the access qualifier for function blocks:

- Method 1: Set in the "Add program block" window.
- Method 2: Set in the variable declaration editor (in table view).

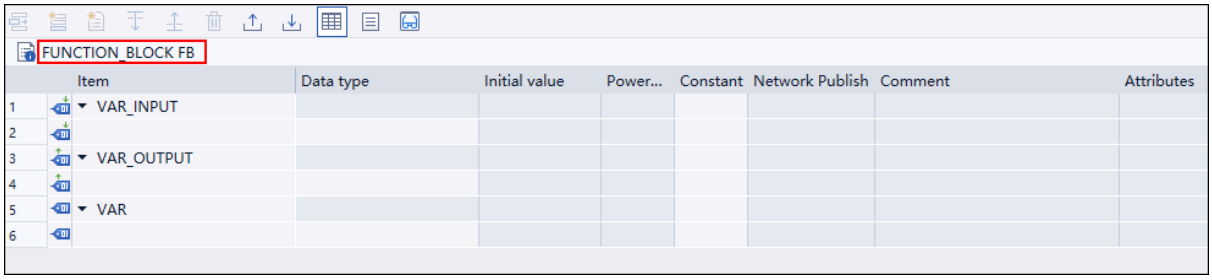
Descriptions of access modifiers



Access Qualifier	Description
PUBLIC	Public access: Variables and methods added under FB can be used across POU and across libraries.
INTERNAL	Access permissions within the namespace: Variables and methods added under FB can be used in this project or this library project.
FINAL	The FB cannot be inherited.

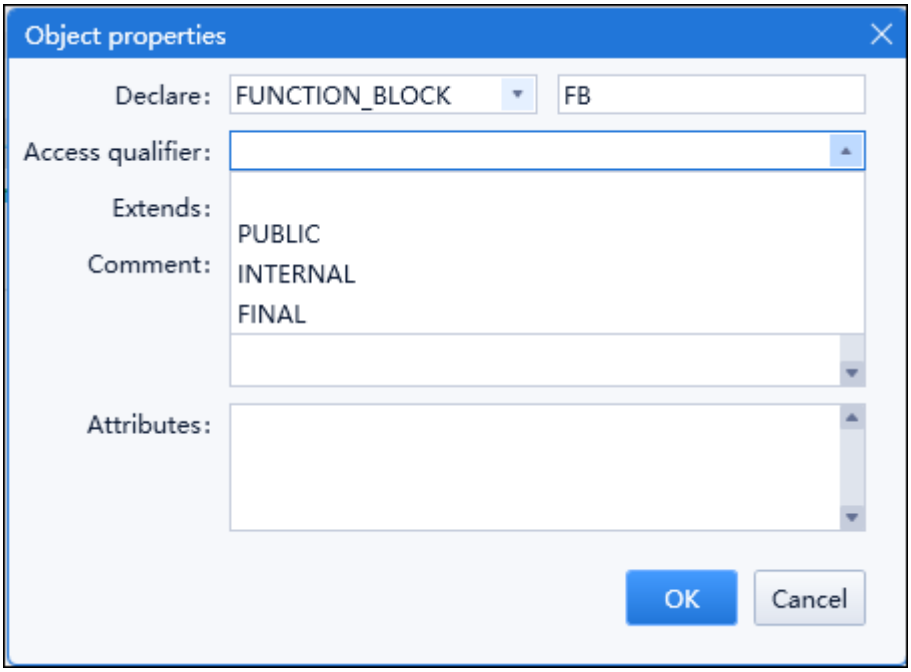
Prerequisites

- Prerequisite for Method 1: Set access modifiers when creating the function block.
- Prerequisite for Method 2: The function block has already been created.



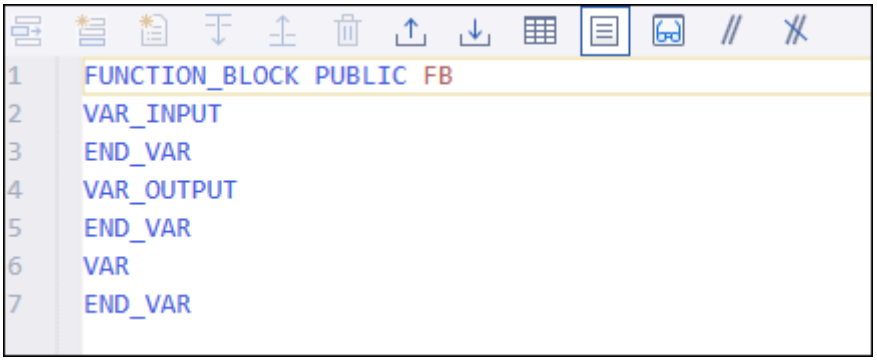
Setting access qualifiers in the "Add program block" window

1. Right-click "Programming" in the project tree and select "Add program block".
2. Select "Function block" as the type.
3. In the "Access" drop-down menu, set the access qualifier as shown in the figure below.

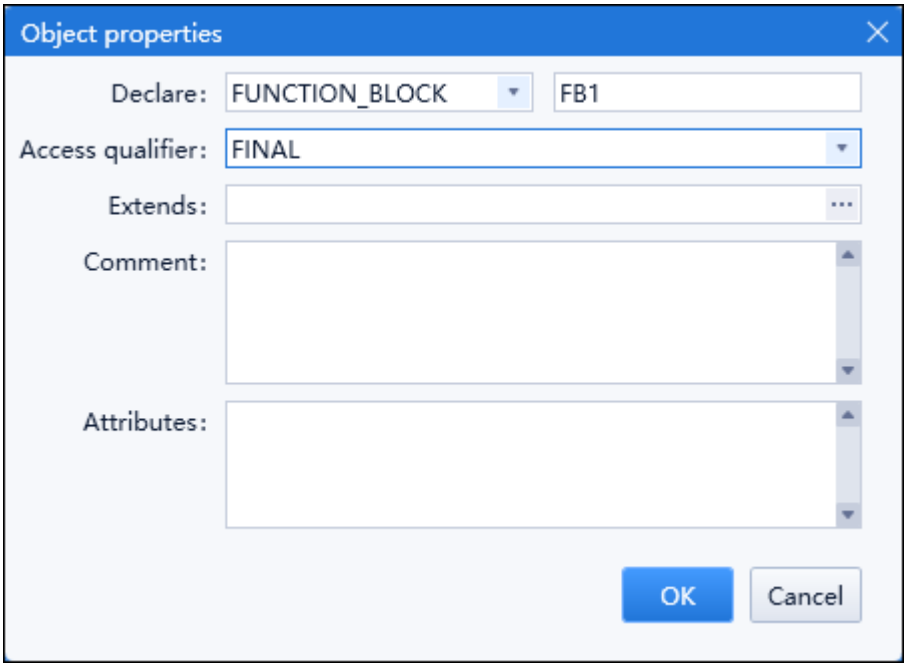


Setting access qualifiers in the variable declaration editor (in table view)

1. Click the name of the function block.

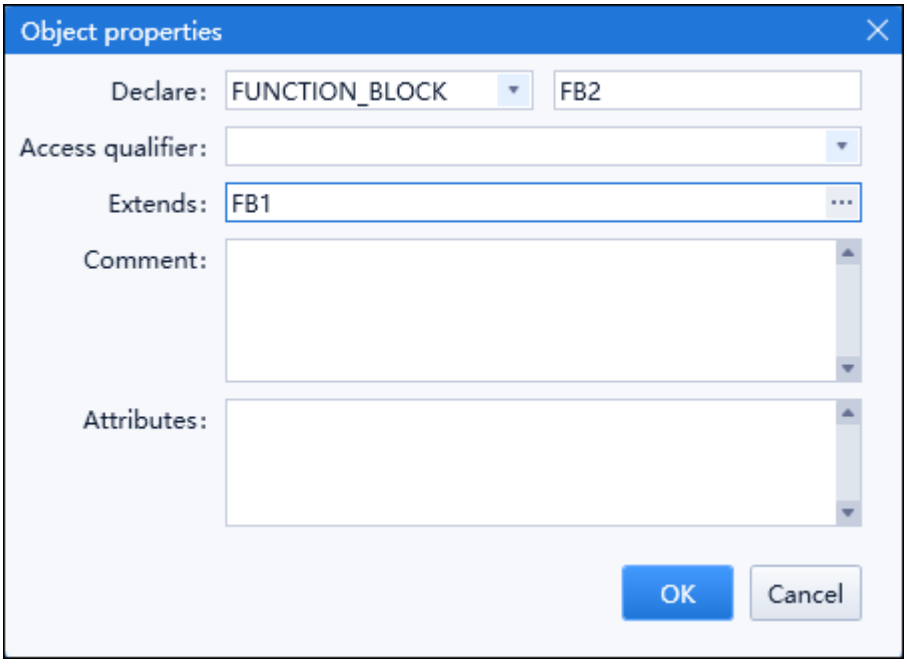


2. Set or modify the access qualifier in the "Object property" window, as shown in the figure below.



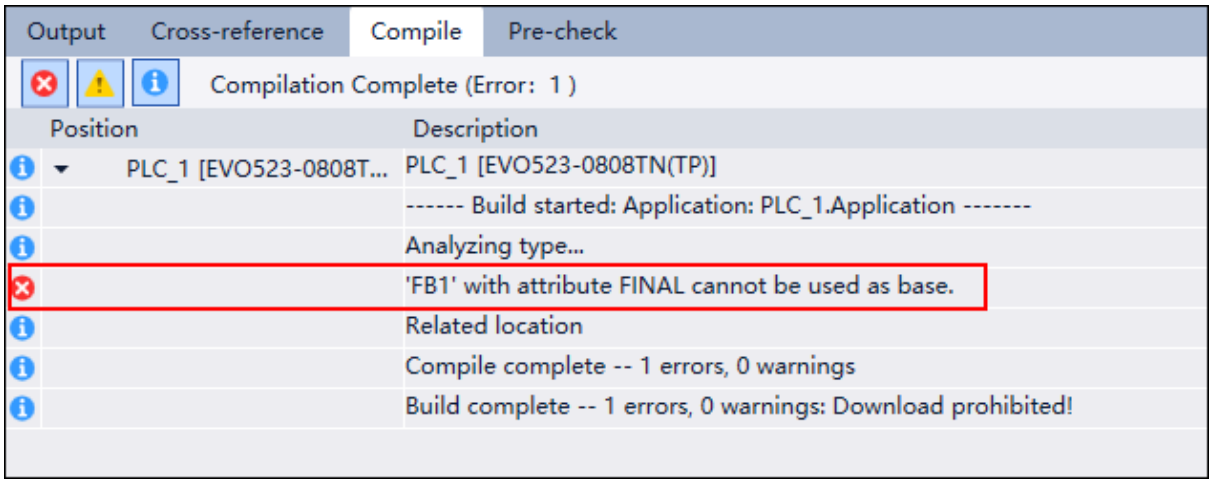
Setting access qualifiers in the variable declaration editor (in text view)

Directly add the access qualifier "PUBLIC", "INTERNAL", or "FINAL" between "FUNCTION_BLOCK" and the name "FB", as shown in the figure below.



Example of adding the "FINAL" access qualifier

1. Add a function block named FB1 and set the access qualifier to "FINAL".



2. Add a function block named FB2 and set it to inherit from FB1.

3. Instantiate FB2.

4. Click the "Compile" tab at the bottom of the interface. A compilation fault is reported, indicating that FB1 with property FINAL cannot be used as a parent function block, as shown in the figure below.

Referencing methods and variables of the current function block

Keyword THIS is used to reference methods and variables of the current function block. It can be used inside functions and function blocks.

Syntax for using keyword THIS

"THIS^." + "variable name or method name" (Keyword THIS is case-insensitive)

In most cases, "THIS^." can be omitted. However, when a local variable has the same name as a member variable of an instance variable, the local variable must be prefixed with **"THIS^."**.

Prerequisites

Functions (FUN) and function blocks (FB) have been created.

Example of using keyword THIS

1. An INT-type variable "age" is added to the function block FB2.
2. An INT-type variable "age" and an instance of FB2 type (named "fb2_Instance_0") are added to the function block FB1.
3. To assign the value of the "age" variable of instance fb2_Instance_0 to the "age" variable of FB1, use the following code: "THIS^.age:=fb2_Instance_0.age;".

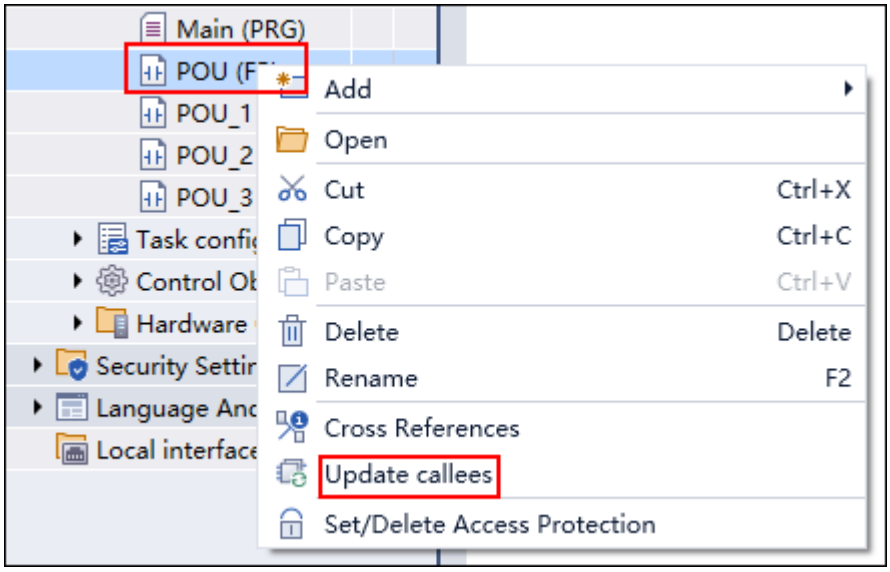
Browsing instance objects

When a user-defined function block contains at least two instances within the current project, double-clicking the function block node during online operation will pop up a window containing all instance objects.

The function block instance box lists the instantiation information of POU_fb2 in the current project. POUld_1.fb2_Instance0 indicates that the instance name of function block POU_fb2 in program POUld_1 is fb2_Instance0. Select any instance, and the real-time internal calculation results of the corresponding instance will be displayed.

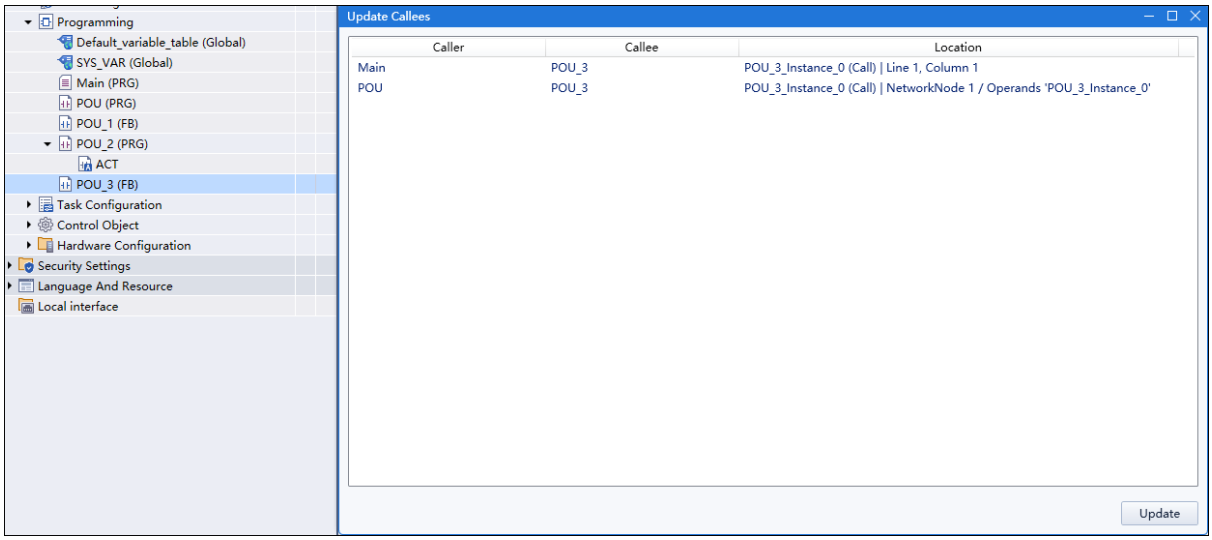
10.1.2.4 Program Block Callee Update

Overview



The "Update callee" function is used to update the parameter list at the call positions of specified FB instances, FCs, PRGs, and Meths in the current project.

Prerequisites



- An FB has been created, and its instance has been called.
- FB instances, FCs, PRGs, and Meths are called in other POUs using the ST and LD programming languages.

Procedure

1. Right-click the FB, FC, PRG, or Meth object in the device tree.
2. In the pop-up menu, select "Update callee"

3. In the pop-up window, the information about the caller, callee, and calling location is displayed.

Parameter	Description
Caller	Indicates which objects have called the specified FB, PRG, FC, or Meth.
Callee	Indicates the name of the called object, including the target object right-clicked, as well as its child objects and grandchild objects (the parent and child objects are separated by a colon).
Position	Indicates where the object is called.

4. Click "Update" to update the parameter list at the call positions of the instruction.

Result

The pins of the POU (FB) call positions are updated, as shown in the following figures.

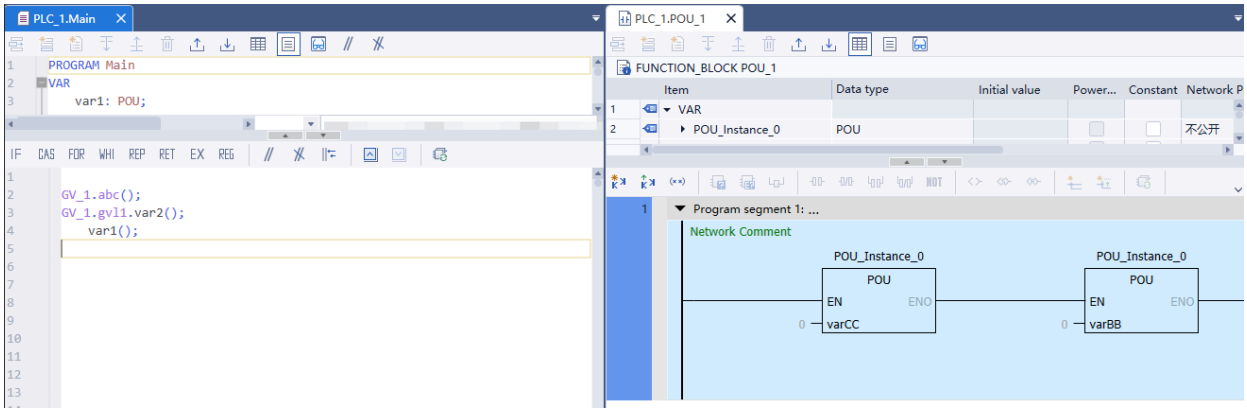


Figure 10-1-2-4-1 Before update

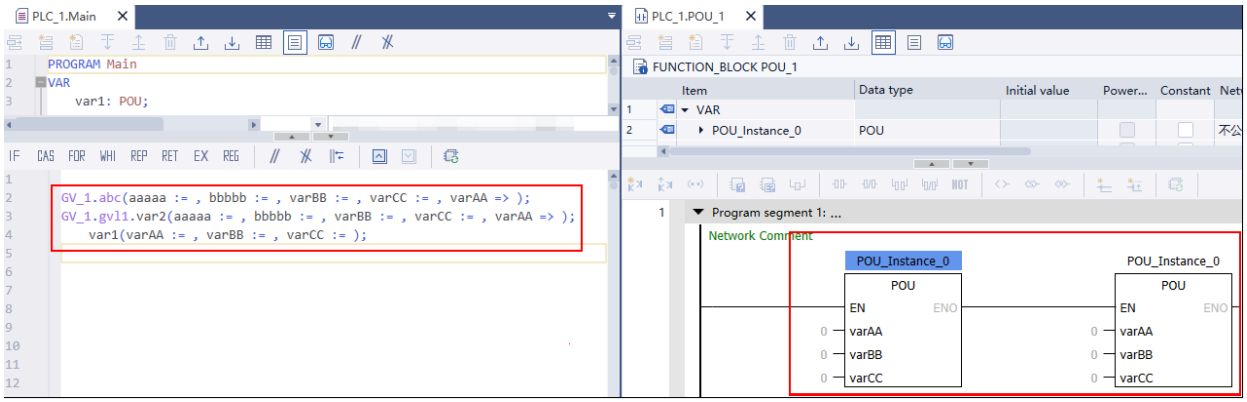

Figure 10-1-2-4-2 After update

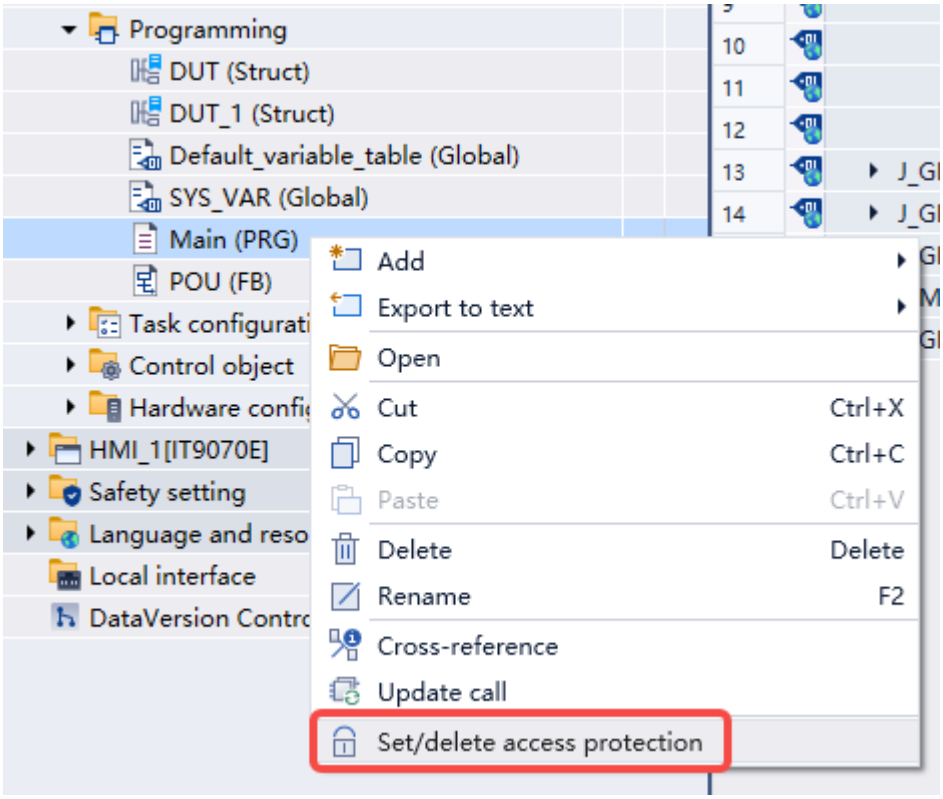
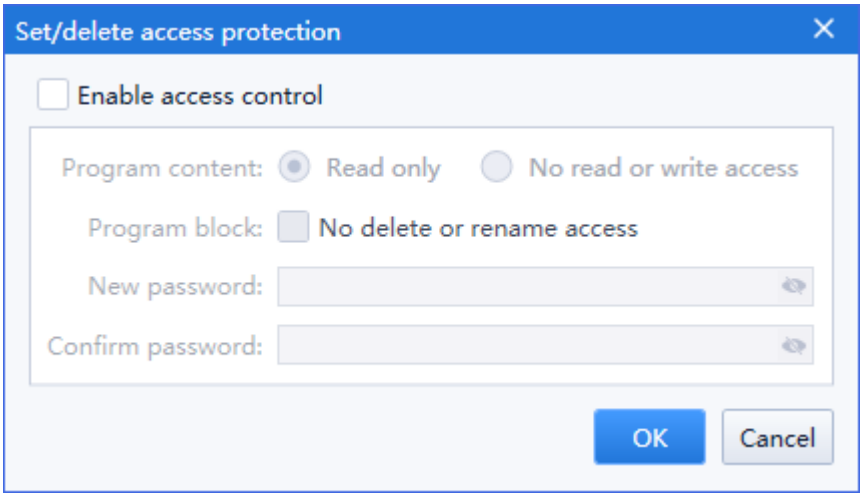
10.1.2.5 Program Block Access Permissions

Overview



The iFA platform defaults to no operation restrictions on program blocks (PRG/FB/FC), allowing direct viewing and modification of content.

Configurable permissions for program blocks include: write protection and read/write protection. Only one of the write protection and read/write protection can be enabled at the same time.

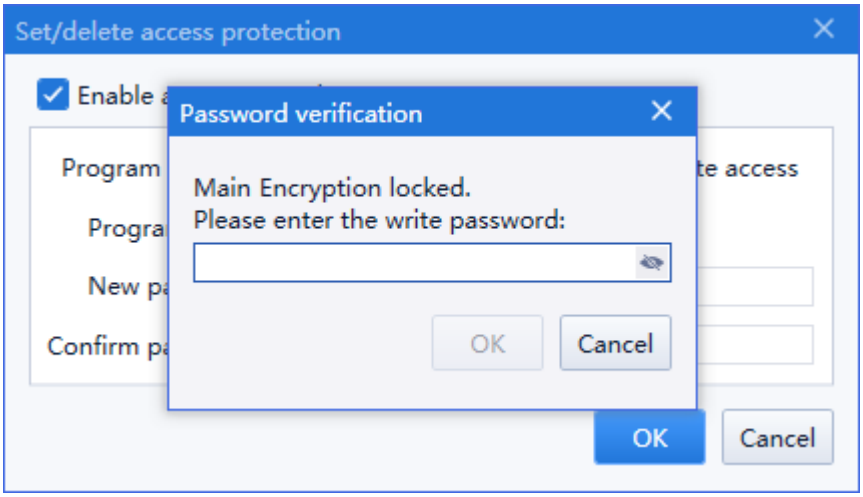


- Write protection: Without a password, the block is view-only. Editing is allowed only after entering the correct password.
- Read/write protection: Without a password, the block cannot be accessed at all. Editing is allowed only after entering the correct password.

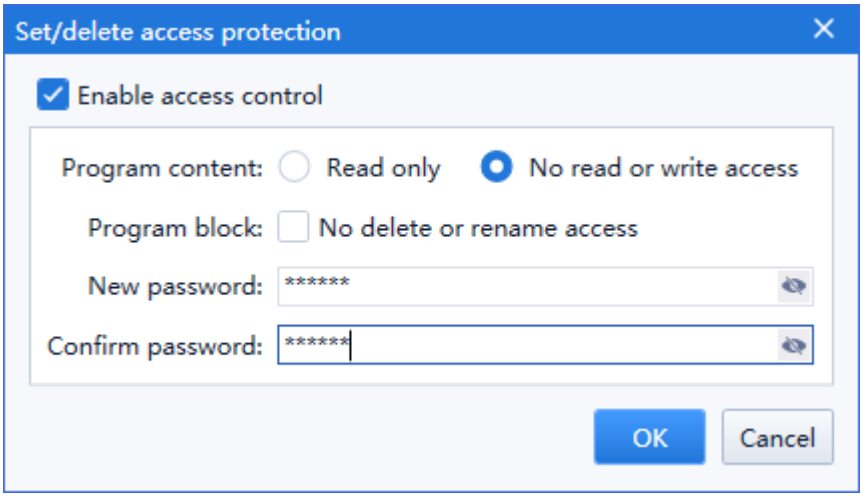
Permission configuration

1. Right-click the PRG/FB/FC node under "Programming" in the project tree and select "Set/delete access protection".

2. In the opened window, set the access permissions for the program block and click "OK" to apply.



Parameter	Description
Enable access control	By default, it is unchecked, and all configuration items are grayed out. When checked, users can configure program content, block access permissions, and password.
Program content	Controls read/write operations for the program in the program editor: ◦ Read-only: Viewable but not editable. ◦ No read or write access: Cannot be viewed or edited.
Program block	Controls renaming and deletion for program blocks (PRG/FB/FC) under the "Programming" node in the project tree. Unchecked by default. When checked, deleting or renaming a program block requires a password.
Password field	Password length should be 6-8 characters, containing at least one digit, one uppercase letter, and one lowercase letter.

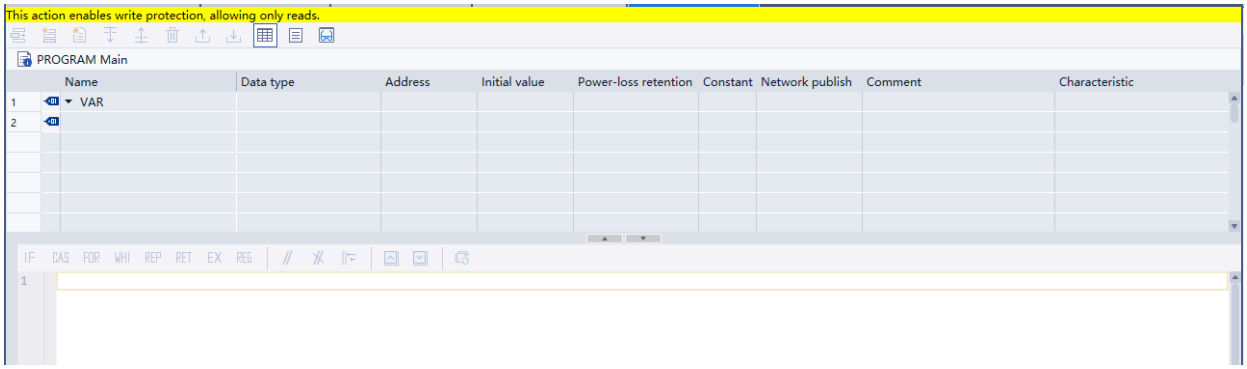


Switching permissions

- Switching from write protection to read/write protection

1. Right-click the PRG/FB/FC node under "Programming" in the project tree and select "Set/delete access protection". In the opened window, check "No read or write access". A dialog box will prompt for the write password.

2. After entering the correct password, check "No read or write access". Enter a valid "New password" and "Confirm password", and click "OK" to switch the permission.



- Switching from read/write protection to write protection
  The switching method is the same as the above operation.

Canceling permissions

- Method 1: Right-click the PRG/FB/FC node under "Programming" in the project tree and select "Set/delete access protection". Uncheck "Enable", the password verification interface will pop up. Enter the correct password and click "OK" to apply.
- Method 2: Right-click the PRG/FB/FC node under "Programming" in the project tree and select "Disable/enable access protection". Enter the correct password on the password verification dialog box, and click "OK" to apply.

Opening a POU with write protection

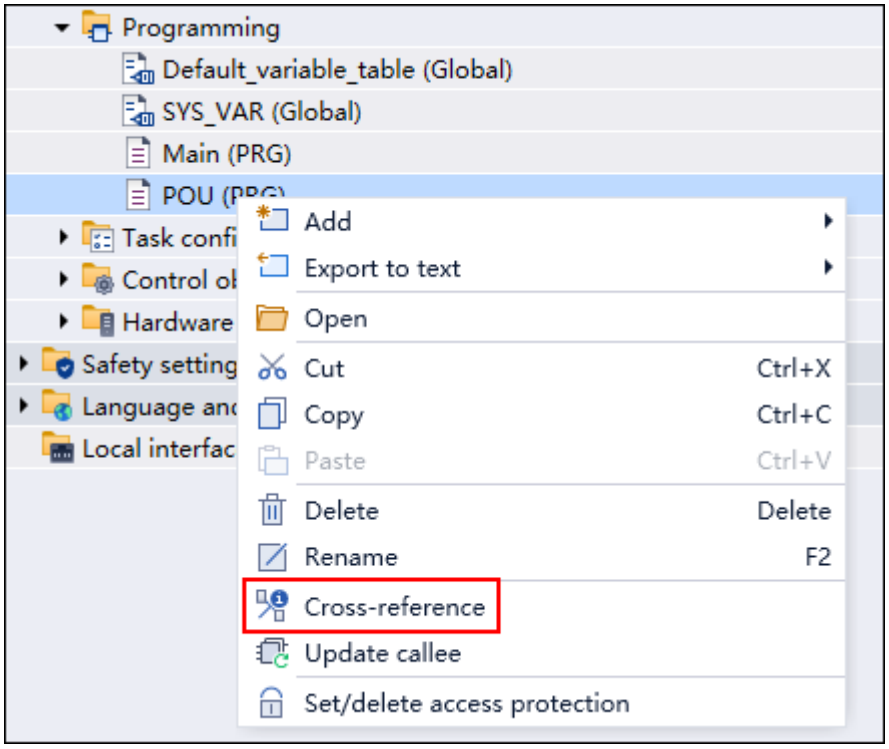
For a POU with write protection, if no password is entered, it can only be opened in read-only mode, and the following prompt message appears.

After entering the correct password, the POU is opened in edit mode without any prompt messages.

Opening a POU with read/write protection

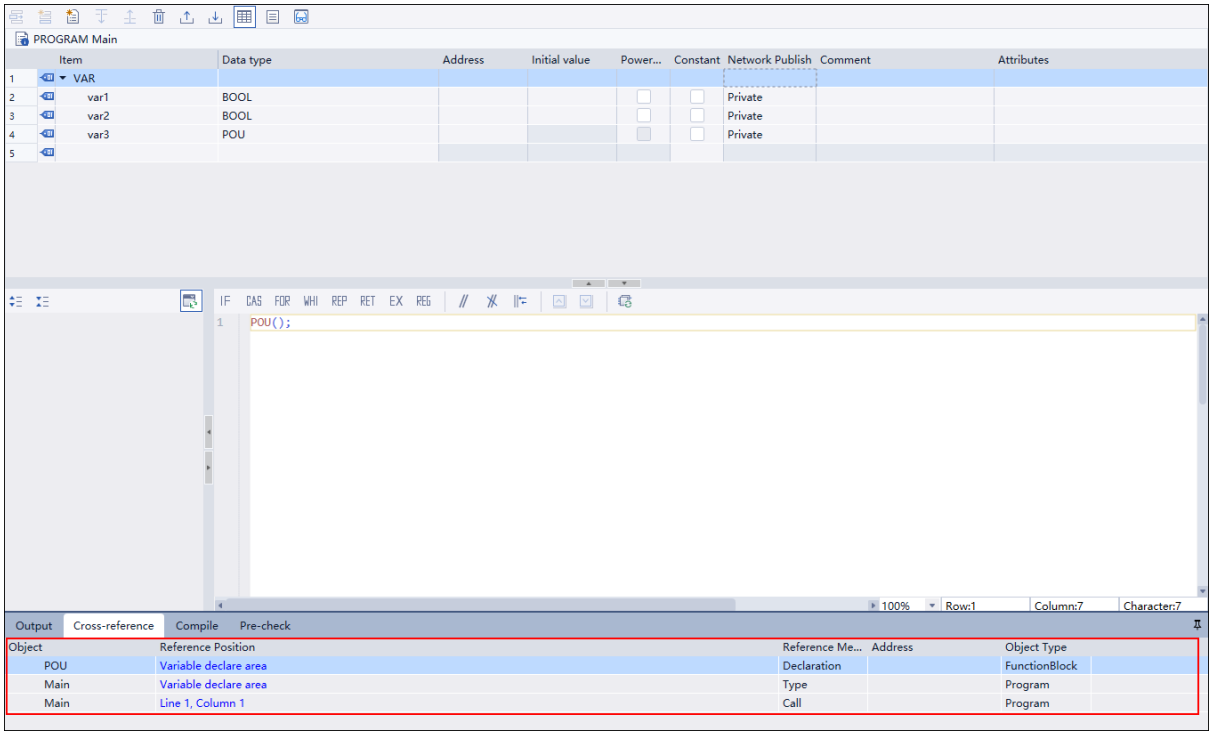
A POU with read/write protection must be successfully verified with a password before it can be opened. After successful verification, the user can normally edit the POU.

10.1.2.6 Program Block Cross-Reference



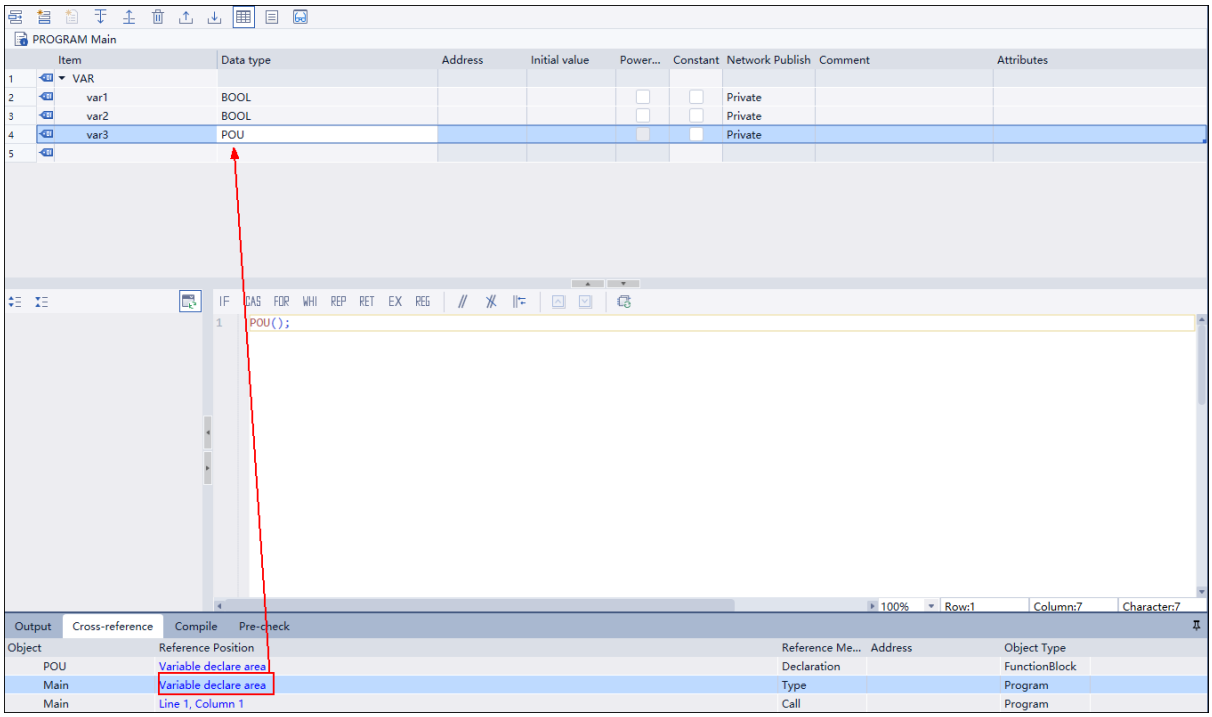
The cross-reference function of program blocks is used to view where a program block is referenced in the program. This helps users quickly locate the usage and position of the specified program block, improving commissioning and maintenance efficiency.

Prerequisites



POUs have been created with cross-reference relationships in between.

Procedure



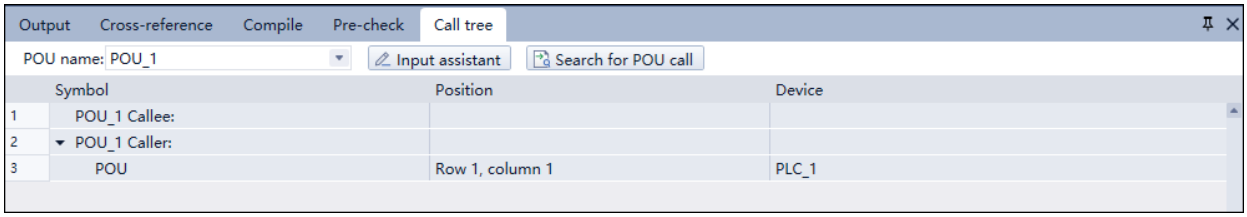
1. Right-click a POU under "Programming" in the project tree, and select "Cross-reference", as shown in the figure below.

2. The "Cross-reference" tab will be displayed at the bottom of the interface, showing the usage information of the current POU, as shown in the following figure.

3. Click "Reference position" to automatically jump to the corresponding position.

10.1.2.7 Viewing Call Relationships Between Program Blocks

The call tree is used to view the call information of a POU, expanding with two root nodes: POU caller and POU callee. The call tree includes the symbol, call position, and device information of the POU.



Prerequisites

POUs have been created with call relationships in between.

Procedure

1. In the software menu, select "View > Call tree" to display the call tree tab at the bottom of the interface.
2. In the "POU name" edit box, enter the name of the POU.
3. Click the "Search for POU call" button.

Result

Introduction to the call tree

Description	Description
POU name	Enter the name of the POU to view the call relationships of it.
Input assistant	Used to select a specified POU.
Search for POU call	Search for the call relationships of the specified POU.
Operator	Displays two root nodes, POU callers and POU callees. Each root node displays the contained POUs.
Position	• For the root node, the "Position" value indicates the line number where the POU is declared. • For POU callers and callees under the root node, the "Position" value indicates the line number, column number, and network number, depending on the programming language.
Device	Displays the device to which the POU belongs.
Double-click to locate	Double-click the selected POU to jump to the declaration position of the POU.

Input methods for POU call querying

- Method 1: Directly enter the name of the POU to be queried in the "POU name" edit box.
- Method 2: Select the POU to be queried from the "POU name" drop-down menu. The drop-down menu contains all records of POUs that have been selected.
- Method 3: Select the POU to be queried in the "Input assistant".

NOTE

The call tree only displays the call relationship information of the POU, and does not include variables.

10.1.3 LD Language Programming

10.1.3.1 LD Language Overview

A ladder diagram is a graphical programming language.

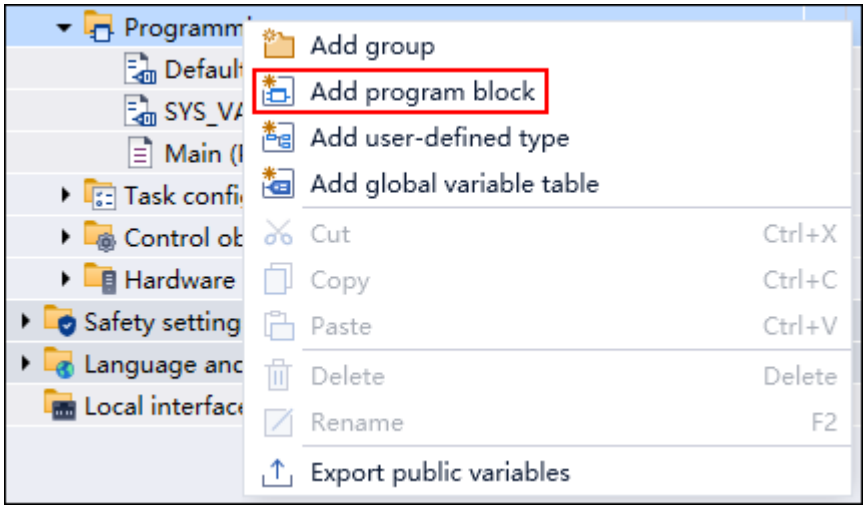
It features two vertical power rails on its left and right sides. The left power rail provides a power flow that passes through various contacts, functions, function blocks, coils, and other components along horizontal rungs from left to right. The right power rail serves as the endpoint of the power flow.

Each contact represents the status of a Boolean variable, each coil represents the status of an actual device, and functions or function blocks correspond to the standard libraries in IEC 61131-3 or user-created functions or function blocks.

In ladder diagram programming, although relay components such as coils and contacts are used, they are not actual physical relays but rather storage units (soft relays) within the PLC. Each soft relay corresponds to a storage unit in the PLC's memory mapped register, and its status (TRUE/FALSE) determines the logical behavior of the soft relay:

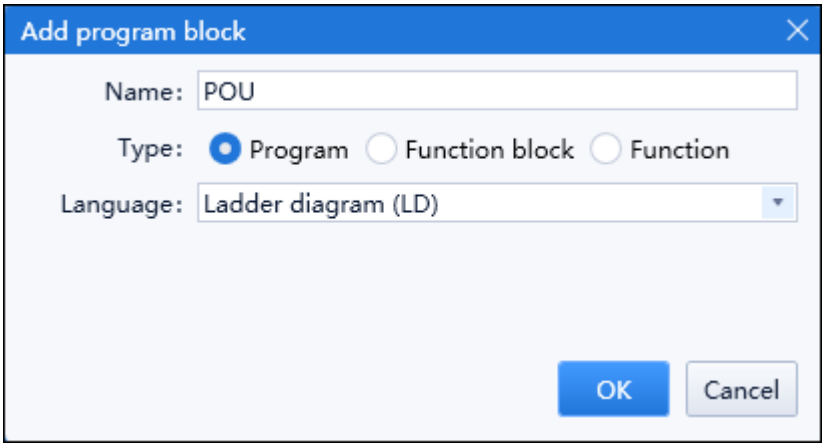
- TRUE (ON) status: When the storage unit is in TRUE status, the corresponding soft relay coil is "energized", with its normally open contacts closed and its normally closed contacts opened.
- FALSE (OFF) status: When the storage unit is in FALSE status, the soft relay coil is "de-energized", with its normally open contacts remain opened, and its normally closed contacts remain closed.

10.1.3.2 LD Creation and Management



10.1.3.2.1 Creating an LD Program Block

Prerequisites

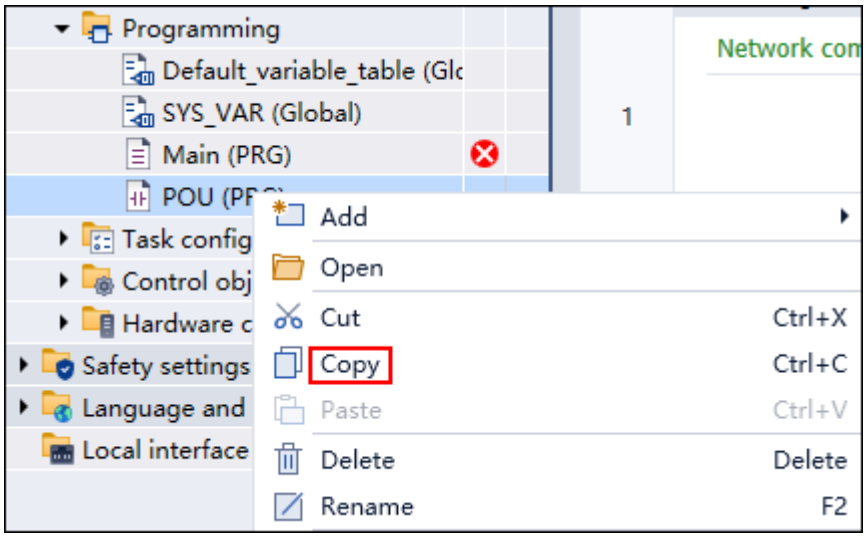


- A project has been created.
- A device has been added.

Procedure

1. Right-click "Programming" in the project tree and select "Add program block".

2. In the pop-up window, set the name of the program block, select "Program", "Function block", or "Function" for the type, and select "Ladder diagram (LD)" for the IEC language, as shown in the figure below.

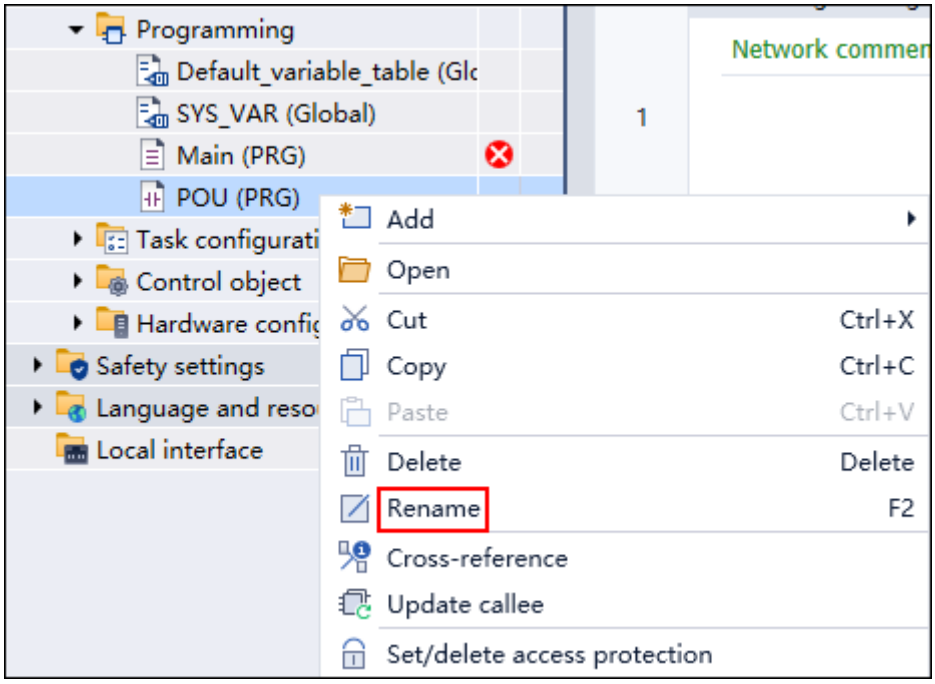


3. Click "OK" and the LD editor will be automatically opened.

10.1.3.2.2 Managing an LD Program Block

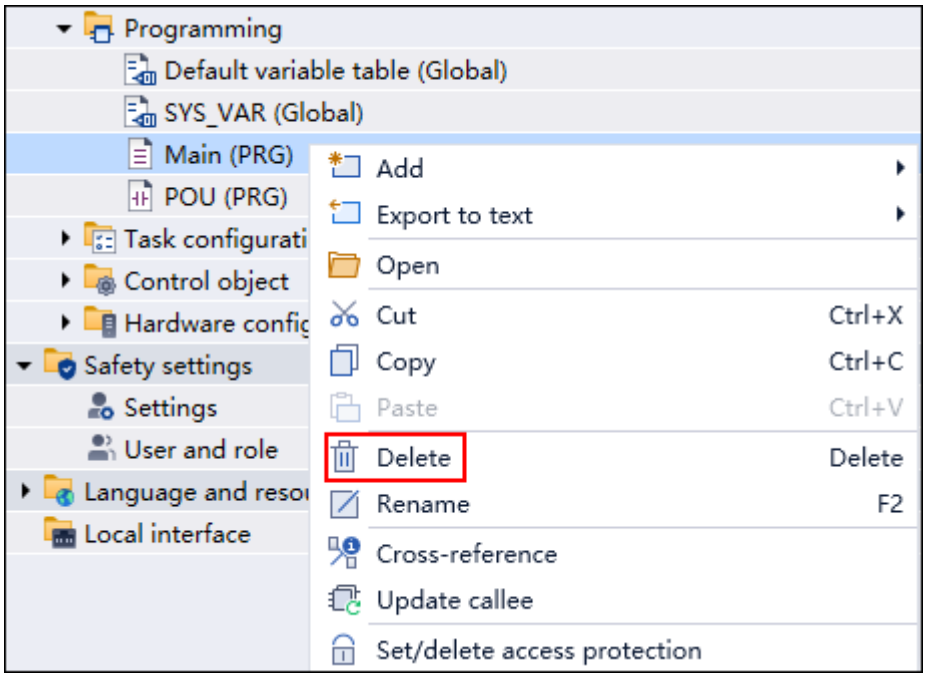
10.1.3.2.2.1 Copying an LD Program Block

LD program blocks can be copied and pasted within a PLC device, between PLC devices in the same project, or between different projects. The internal program logic of the LD program block remains unchanged after pasting.



1. Right-click an LD program block name under the "Programming" node, and select "Copy".

2. Right-click the "Programming" node or its subordinate node, and select "Paste" to paste the copied LD program block at the corresponding location.

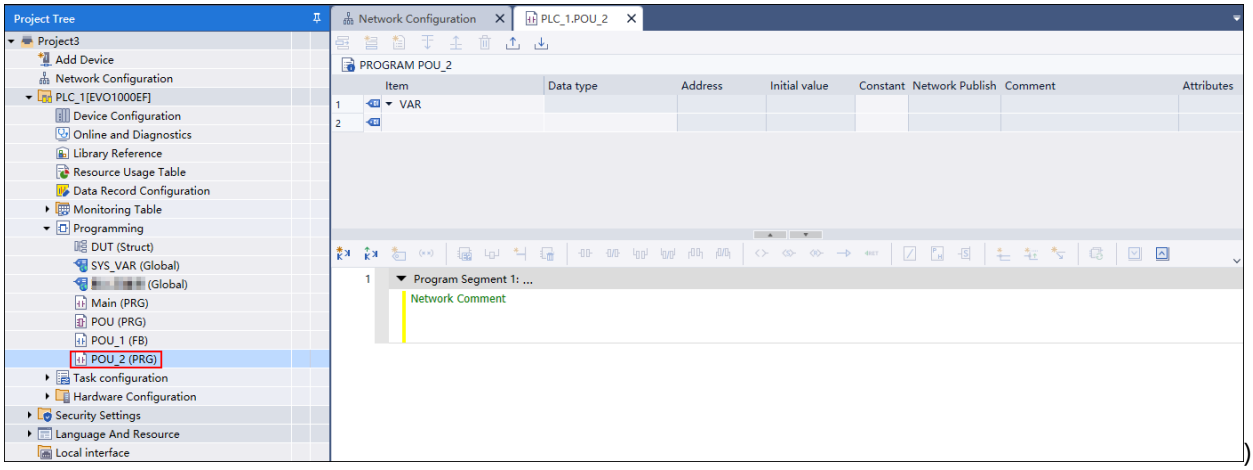


10.1.3.2.2.2 Renaming an LD Program Block

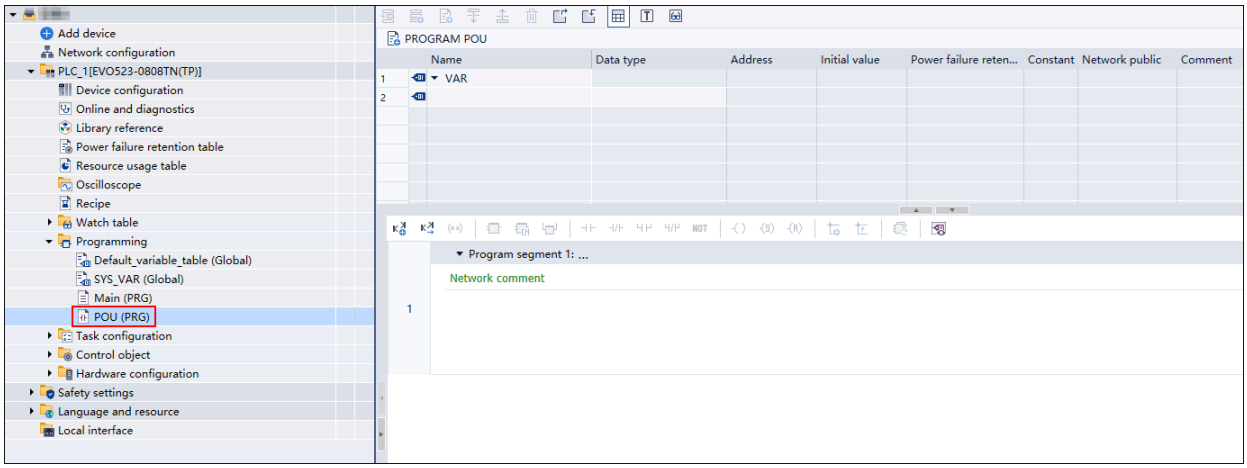
Right-click an LD program block name under the "Programming" node, select "Rename", and modify the group name.

10.1.3.2.2.3 Deleting an LD Program Block

1. Right-click an LD program block name under the "Programming" node, and select "Delete".



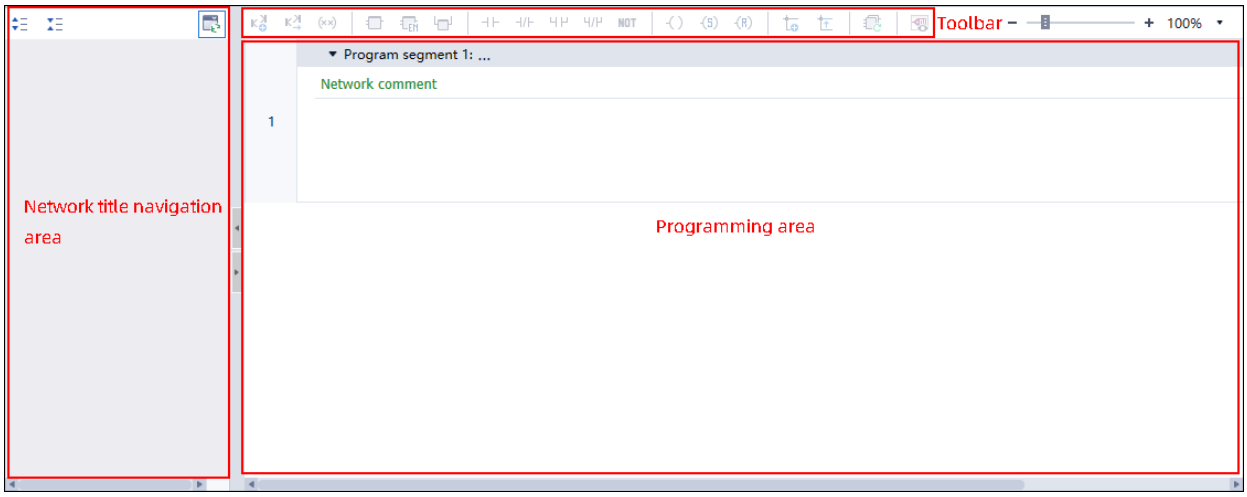
2. Click "OK" in the pop-up window.



10.1.3.3 LD Editor

10.1.3.3.1 LD Editor Interface

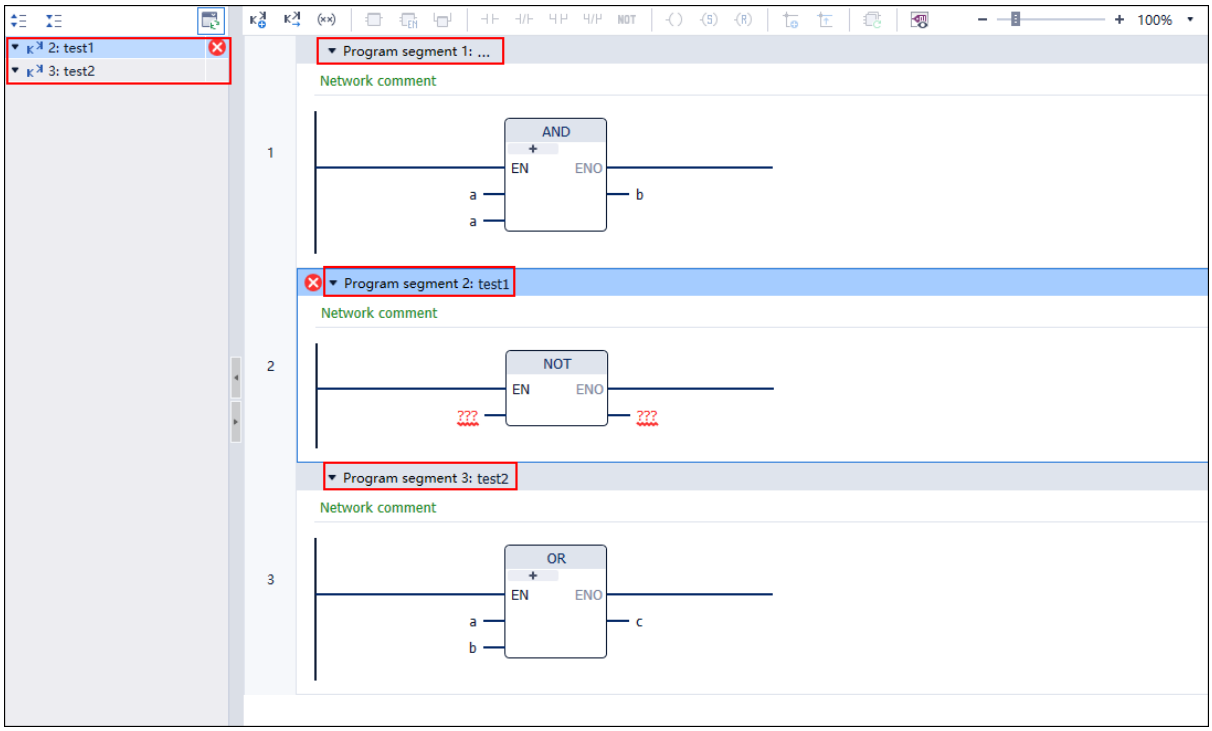
Double-click the LD language program block under the "Programming" node (node identifier:



) to open the LD editor.

The LD editor is divided into the variable declaration area and the program editing area, which can be collapsed and expanded using and .

The program editing area consists of three parts: the toolbar, the programming area, and the network title navigation area, as shown in the figure below:



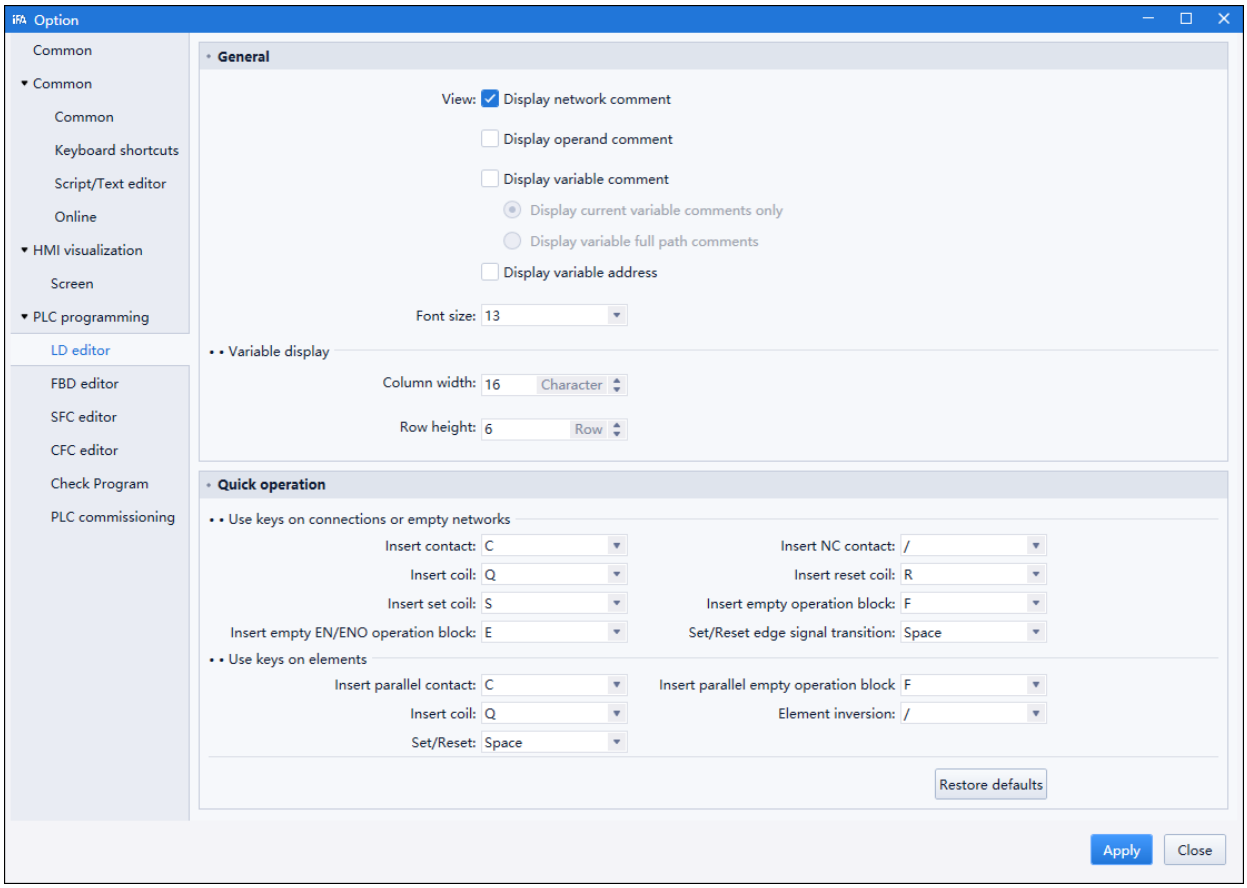
- Toolbar

Description	Icon	Description
Add network		Add a network in the program editing area.
Inserting a Network		Insert a network in the program editing area.
Switching Network Comment Status		During program commissioning, after the network is switched to annotation status, it no longer participates in compilation and computation.
Insert an empty operation block		Used to insert a rectangular block. Enter the name of the function or function block at "???". It is suitable for users who are familiar with functions and function blocks.
Insert an empty operation block with EN/ENO		Directly insert an empty operation block with EN/ENO, suitable for users who are not familiar with functions and function blocks.
Insert parallel operation block below		Insert a parallel operation block below the current operation block.
Insert an NO contact		Insert an NO contact.
Insert an NC contact		Insert an NC contact.
Insert a parallel NO contact		Multiple contacts can be connected in parallel; insert an NO contact in parallel below the current contact.
Insert a parallel NC contact		Multiple contacts can be connected in parallel; insert an NC contact in parallel below the current contact.
Energy flow inversion		Inverts the status of the input signal or the result of a logical operation.
Insert a coil		Insert a coil to pass the status of the left-connected element to the relevant Boolean variable and the right-connected element.
Insert a set coil		Insert a set coil; when the status of the left-connected element is TRUE, the Boolean variable of this coil is set and remains set until it is reset by a reset coil.
Insert a reset coil		Insert a reset coil; when the status of the left-connected element is TRUE, the Boolean variable of this coil is reset and remains reset until it is set by a set coil.
Insert a branch		Insert a branch.
Insert a branch above		Insert a branch above the current position.
Update all parameters		Update all parameters in the program editing area if the parameters of the called object are changed.

Description	Icon	Description
Hide/Show variable comment		Set the visibility of variable comments, which only applies to the current POU.

- Programming area
  Used for LD programming.
- Network title navigation area
  This area visually displays network title information in the LD program, enabling quick location and jump to target positions within the network. The network title navigation area contains two columns: the first column includes the collapse/expand icons and network titles; if the network title is empty, it will not be displayed here; the second column displays the network status, where an error flag is shown if there are pre-check or compilation faults in the network.

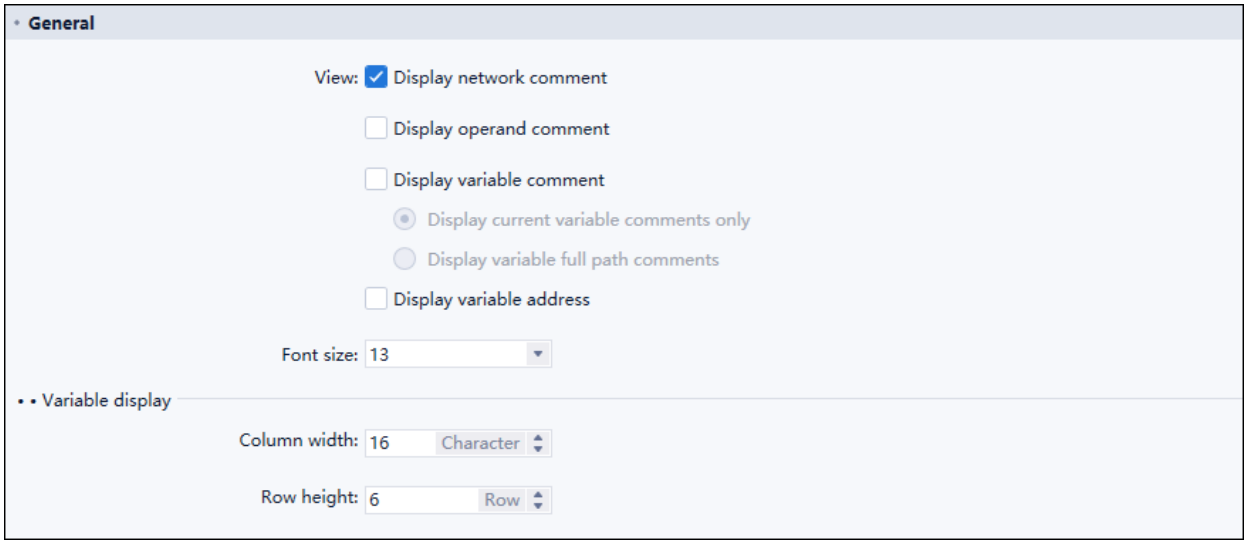
  Use  and  to collapse or expand the network title navigation area.



In this area, network titles can be copied, renamed, expanded/collapsed, and synchronized through the right-click menu or toolbar.

Function	Description
Copy	Copy the network corresponding to the network title node within the LD program editing area. The copied Regions can be pasted in the program editing area.
Rename	Rename the network title node and the name of the corresponding network in the LD program editing area will be synchronized, and vice versa. The network title in the navigation area cannot be empty.
Expand/Collapse	Expand or collapse the selected network title node.
Expand all/ Collapse all	Expand or collapse all network title nodes.

Function	Description
Sync on/off	◦ When synchronization is enabled: click a network title node on the left and the corresponding network will be displayed in the LD program editing area; the collapse, select, and highlight operations performed on the navigation area will be mirrored in the LD program editing area, and vice versa. ◦ When synchronization is disabled: the collapse, select, and highlight operations will not be synchronized between the network title navigation area and the LD program editing area.

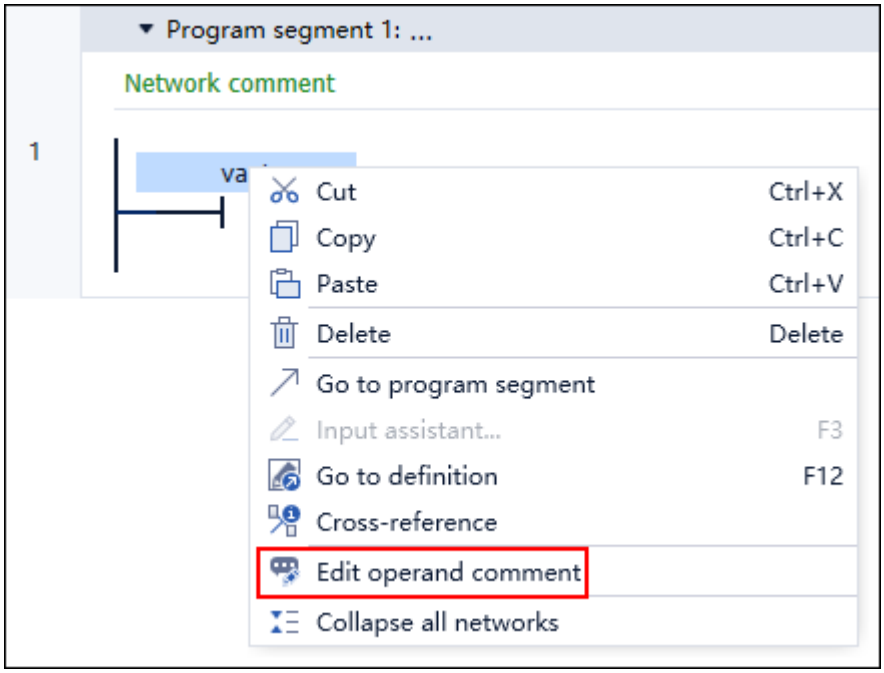


10.1.3.3.2 LD Editor Settings

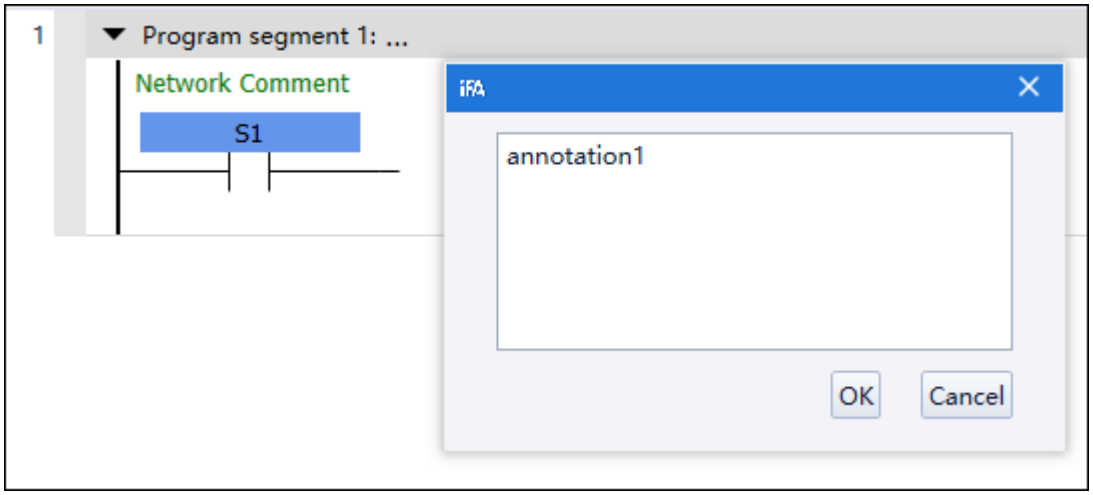
In the software menu, select "Tools > Options > LD editor".

General items

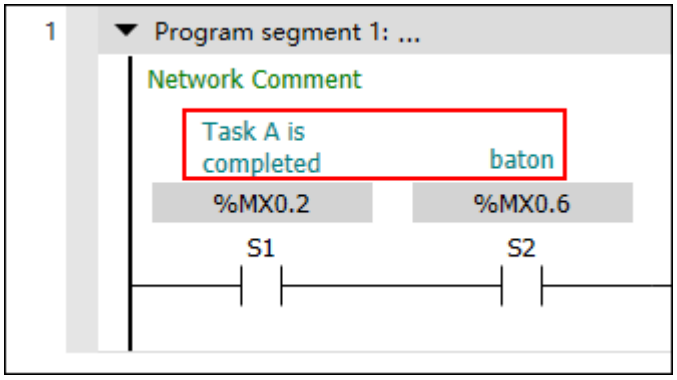
The general items set the information visibility, font size, and variable display range in the LD editing area.



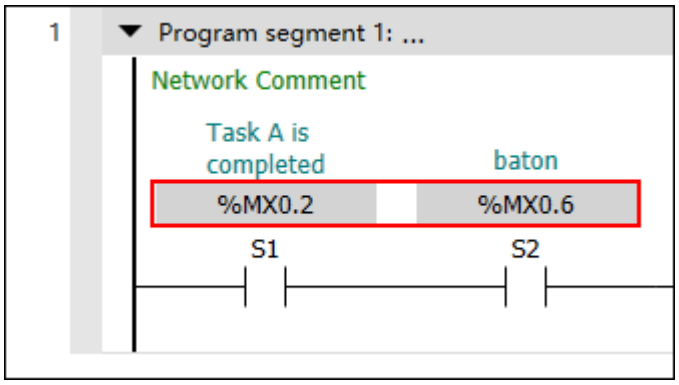
- Show network comment: Sets the visibility of network comment.



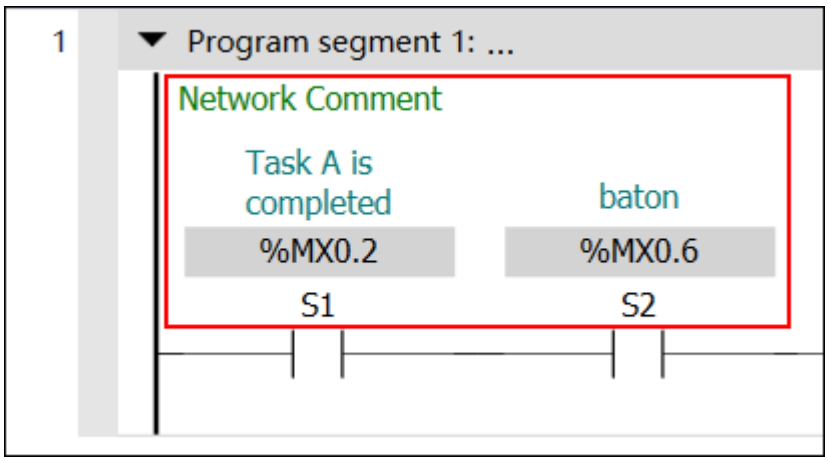
- Show operand comment: Sets the visibility of operand comment.



1. After checking "Display operand comment", right-click an operand in the program editing area and select "Edit operand comment".

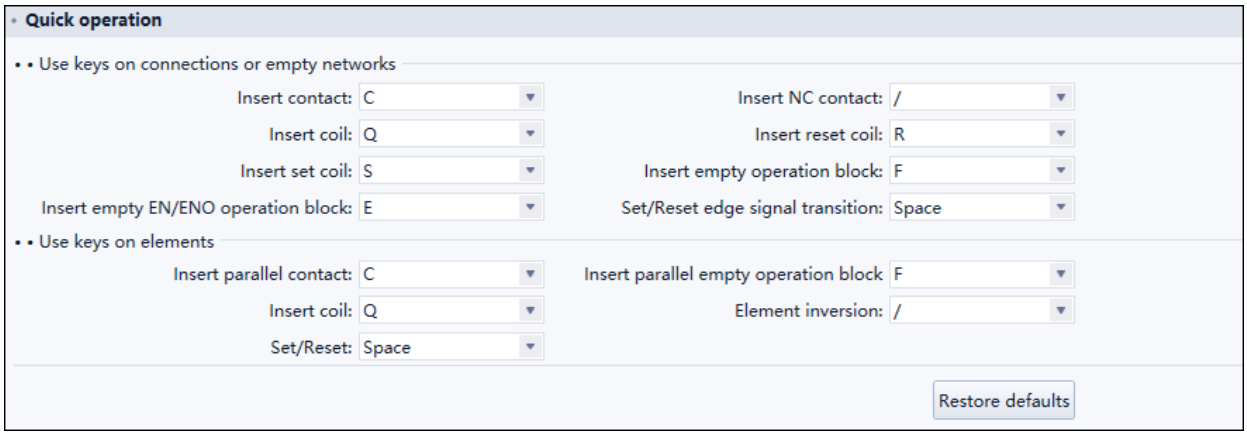


2. The entered comment will be displayed above the operand. If "Display operand comment" is unchecked, the comment will not be displayed.



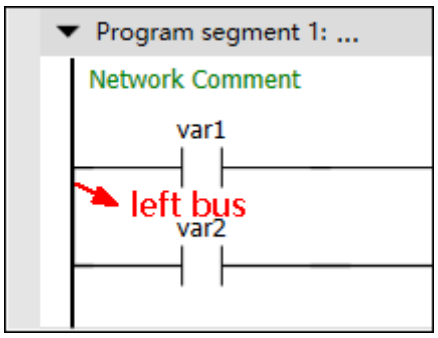
- Show variable comment: Sets the visibility of variable comments. Supports two modes:
  - Display current variable comments only: Displays the comment for only the currently selected variable.
  - Display variable full path comments: Displays the comment for the variable along with its full path.

- Display variable addresses: Sets the visibility of variable addresses.



- Font size: Sets the font size of the text in the editing area.
  Applicable objects include network annotations, operand annotations, label names, variable names, variable annotations, variable addresses, jump positions.

- Variable display: Sets the length and width of variables displayed in the LD editing area. By default, the column width is 16 characters, with a range of 8 to 32 characters, and the row height is 6 lines, with a range of 3 to 99 lines.



LD tab

The items in the "LD" tab sets commonly used shortcut keys for LD program editing, selected from drop-down lists. Click "Restore defaults" to reset all shortcut keys to their default values.

10.1.3.3.3 Lines in LD Editor

- **Power rail**
  The power rails in a ladder diagram are referred to as buses. It is on the left side of the ladder diagram and can also be called the left power bus. The figure below shows the graphical representation of the left bus.

- **Connection**
  A connection line refers to a line connecting one position to another. Connection lines mainly include contact connections, input/output connections of operation blocks, connections between coils, terminal connections, branch terminal connections, and vertical connections.

  Connection line modification include three cases: forming horizontal parallel connections, splitting parallel connections into left and right parts, and closing disconnected connections.

Figure 10-1-3-3-3-1 Horizontal connection elements

Figure 10-1-3-3-3-2 Vertical connection elements

10.1.3.3.4 LD Elements

- **Add network**

  Used to add a network in the program editing area.

  Table10-1-3-3-4-1 Icon and description for adding a network

Function	Icon	Description
Add network		Add a network in the program editing area.

- **Label**

  Label is an optional identifier and its address can be determined when it is jump-referenced.

  Table10-1-3-3-4-2 Icon and description for labels

Function	Icon	Description
Insert label		Enabled when the entire network is selected. A label is at the head of the network and marks the jump position. Users can jump to the label position through a jump element. A jump label is a string in comply with the identifier naming rules.

- **Function block**

  Used to insert an operation block (containing contacts and coils). In the network, a function/function block must be equipped with an input and an output with Boolean values. They can be used like contacts at the same position, that is, on the left side of the LD network.

  Table10-1-3-3-4-3 Icon and description for operation blocks

Function	Icon	Description
Empty operation block		Used to insert a rectangular block. Enter the name of the function or function block at "???". It is suitable for users who are familiar with functions and function blocks.
Empty operation block with EN/ENO		The function or function block is executed only when EN is TRUE. The status can be passed downstream. It is suitable for users who are less familiar with functions and function blocks.

  Ladder diagram programming language supports calling functions and function blocks. When calling, note the following:

  - In ladder diagrams, a function/function block is represented by a rectangular box. Functions can have multiple input parameters but only one return parameter. Function blocks can have multiple input parameters and multiple output parameters.
  - To ensure that energy flow can pass through the functions or function blocks, each called function/function block must have at least one input and one output parameter. To execute the connected function blocks, at least one Boolean input should be connected horizontally to the vertical left power rail.
  - When calling a function block, the actual parameter values can be directly entered at the external connection line of the formal parameter variables within the function block.

- **Execution block**

  Execution blocks can be inserted with embedded ST, where ST statements can be modified within the block. They can be zoomed in and out.

Table10-1-3-3-4-4 Icons and descriptions for execution blocks

Type	Icon	Description
Execution block		Directly inserts an execution block.

- **Contact**

  Contacts are graphical elements of the ladder diagram. They are the same as the contacts in electrical logic diagrams and are used to represent changes in the status of Boolean variables. They pass a status to the horizontally connected elements on their right side.

  Contacts can be divided into normally open contacts (NO) and normally closed contacts (NC). A normally open contact is disconnected under normal operating conditions, with its status being FALSE. A normally closed contact is connected under normal operating conditions, with its status being TRUE. The following table summarizes the commonly used contact icons and descriptions.

Table10-1-3-3-4-5 Icons and descriptions of contacts

Contact	Icon	Description
Normally open contact		If the current Boolean variable value corresponding to the contact is TRUE, the contact closes. If the status of the element connected to the left side of the contact is TRUE, the TRUE status is passed to the right side of the contact, making the status of the element connected to the right side TRUE. Conversely, when the Boolean variable value is FALSE, the status of the element connected to the right side is FALSE.
Normally closed contact		Multiple contacts can be connected in series by inserting contacts on the right side. When all the contacts connected in series are closed, the last contact can transmit TRUE.
Parallel NO contact		Multiple contacts can be connected in parallel by inserting NO contacts below the contact. If one of the two parallel contacts is TRUE, then the parallel line transmits TRUE.
Parallel NC contact		Multiple contacts can be connected in parallel by inserting NC contacts below the contact. NC contacts are closed by default. If the current Boolean variable value corresponding to the contact is FALSE, and the status of the element connected to the left side is TRUE, then the element connected to the right side of the parallel contact transmits TRUE.

- **Energy flow inversion**

  Energy flow inversion is used to invert signal flow or control logic for reverse control.

Table10-1-3-3-4-6 Icons and descriptions for energy flow inversion

Type	Icon	Description
Energy flow inversion		Inverts the status of the input signal or the result of a logical operation.

- **Coil**

  Coils are graphical elements of the ladder diagram. They are the same as the coils in electrical logic diagrams and are used to represent changes in the status of Boolean variables.

Coils can be divided into instantaneous coils and latching coils. The latter can be further divided into set coils and reset coils. The table below lists the commonly used icons and descriptions of coils in ladder diagrams.

Table10-1-3-3-4-7 Icons and descriptions of coils

Type	Icon	Description
Coil		Used to pass the status of the left-connected element to the relevant Boolean variable and the right-connected element. If the status of the left-connected element is TRUE, the Boolean variable of the coil is TRUE; otherwise, the variable is FALSE.
Set coil		There is an S in the coil. When the status of the left-connected element is TRUE, the Boolean variable of this coil is set and remains set until it is reset by a reset coil.
Reset coil		There is an R in the coil. When the status of the left-connected element is TRUE, the Boolean variable of this coil is reset and remains reset until it is set by a set coil.

- **Return**

Table10-1-3-3-4-8 Icon and description for return elements

Function	Icon	Description
Insert return		Insert a return element. When the input on the left side of the return element is TRUE, the program will immediately exits. The return element is located at the far right of the network.

- **Jump**

Table10-1-3-3-4-9 Icon and description for jump elements

Function	Icon	Description
Insert jump		Insert a jump element and specify a label. When the input on the left side of the jump element is TRUE, the program will jump to the specified label position. The jump element is located at the far right of the network.

- **FOR**

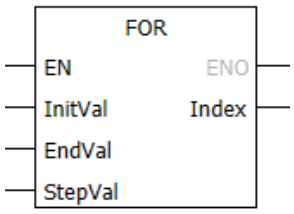


Table10-1-3-3-4-10 Icon and description for operation block FOR

Function	Icon	Description
FOR		The FOR function block is used to mark the starting position of a loop, and set the loop condition and loop count. It occupies an entire network segment.

NOTE

FOR and END_FOR function blocks must appear in pairs, and no other elements are allowed to exist to the right of the EXIT function block, otherwise a compilation fault will occur.

Table10-1-3-3-4-11 FOR function block parameters

Operation block	Parameter		Description
	Input Parameters	Initial value	Loop index start value (INT type)
		EndVal	Loop index end value (INT type)
		StepVal	Loop index increment (INT type)
	Output Parameters	Index	Current loop index value (INT type)

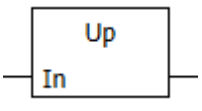
- **END_FOR**

Table10-1-3-3-4-12 Icon and description for operation block ENO_FOR

Function	Icon	Description
ENO_FOR		The END_FOR function block is used to mark the end position of a loop and occupies an entire network segment.

- **EXIT**

Table10-1-3-3-4-13 Icon and description for operation block EXIT



Function	Icon	Description
EXIT		The EXIT function block is used in the network between FOR and END_FOR blocks and occupies an entire network segment. It is used to immediately terminate and exit the current innermost FOR loop iteration when a specific condition is met. When the EXIT statement is executed, it directly jumps out of the FOR loop structure, no longer executing subsequent instructions within the loop, and proceeds to execute the next instruction following the corresponding END_FOR.

10.1.3.3.5 LD Instructions

10.1.3.3.5.1 Up

This instruction outputs a TRUE signal for only one task period when an input signal transitions from FALSE to TRUE (rising edge).

- **Instruction format**

Instruction	Name	FB/FC	LD Representation
Up	Up trigger	FB	

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Input signal	Follows data type.	FALSE	Valid when FALSE changes to TRUE.

Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	Out	Output signal	Follows data type.	FALSE	Rising edge detected.

Variable type

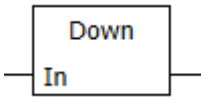
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Out	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

- **Function**

  When the value of the input signal "In" is changed from FALSE to TRUE, the output pin signal is set to TRUE in only one task period and set to FALSE in other conditions.

- **Program example**

  LD:



- **Precautions**

  The Up function block for rising edge detection does not support being called within a function; if called, a compilation fault will occur.

10.1.3.3.5.2 Down

This instruction outputs a TRUE signal for only one task cycle when an input signal transitions from TRUE to FALSE (falling edge).

- **Instruction format**

Instruction	Name	FB/FC	LD Representation
Down	Down trigger	FB	

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Input signal	Follows data type.	FALSE	Valid when TRUE changes to FALSE.
Output	Out	Output signal	Follows data type.	FALSE	Falling edge detected.

  Variable type

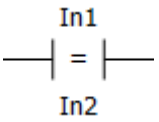
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Out	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

- **Function**

  When the value of the input signal "In" is changed from TRUE to FALSE, the output pin signal is set to TRUE in only one task period and set to FALSE in other conditions.

- **Program example**

  LD:



- **Precautions**

  The Down function block for falling edge detection does not support being called within a function; if called, a compilation fault will occur.

10.1.3.3.5.3 =

EQ determines whether the two input values are equal. If the first input value equals the second, the output is TRUE; otherwise, the output is FALSE.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation
=	Equal instruction	FC	

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Input 1	Follows data type	0	Data 1
	In2	Input 2	Follows data type	0	Data 2
Output	Out	Return value	Follows data type	FALSE	Comparison result

Data type

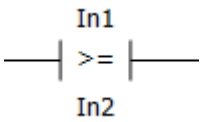
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
In2	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
Out	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

- **Function**

Outputs TRUE when In1 equals In2, otherwise outputs FALSE.

- **Program example**

LD:



- **Precautions**

  When the data types of two input variables are inconsistent, a compilation fault occurs.

10.1.3.3.5.4 >=

GE compares the two input values. If the first input value is greater than or equal to the second, the output is TRUE; otherwise, the output is FALSE.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation
>=	Greater than or equal instruction	FC	

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Input 1	Follows data type	0	Data 1
	In2	Input 2	Follows data type	0	Data 2
Output	Out	Return value	Follows data type	FALSE	Comparison result

  Data type

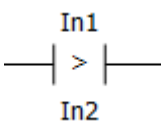
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
In2	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
Out	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

- **Function**

  Outputs TRUE when In1 is greater than or equal to In2, otherwise outputs FALSE.

- **Program example**

  LD:



- **Precautions**

  When the data types of two input variables are inconsistent, a compilation fault occurs.

10.1.3.3.5.5 >

GE compares the two input values. If the first input value is greater than the second, the output is TRUE; otherwise, the output is FALSE.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation
>	Greater than instruction	FC	

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Input 1	Follows data type	0	Data 1
	In2	Input 2	Follows data type	0	Data 2
Output	Out	Return value	Follows data type	FALSE	Comparison result

Data type

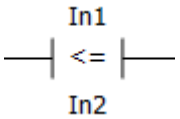
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
In2	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
Out	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

- **Function**

  Outputs TRUE when In1 is greater than In2, otherwise outputs FALSE.

- **Program example**

  LD:



- **Precautions**

  When the data types of two input variables are inconsistent, a compilation fault occurs.

10.1.3.3.5.6 <=

GE compares the two input values. If the first input value is smaller than or equal to the second, the output is TRUE; otherwise, the output is FALSE.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation
<=	Less than or equal instruction	FC	

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Input 1	Follows data type	0	Data 1
	In2	Input 2	Follows data type	0	Data 2
Output	Out	Return value	Follows data type	FALSE	Comparison result

Data type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
In2	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
Out	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

- **Function**

Outputs TRUE when In1 is less than or equal to In2, otherwise outputs FALSE.

- **Program example**

LD:

- **Precautions**

  When the data types of two input variables are inconsistent, a compilation fault occurs.

10.1.3.3.5.7 <

GE compares the two input values. If the first input value is smaller than the second, the output is TRUE; otherwise, the output is FALSE.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation
<	Less than instruction	FC	In1 < In2

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Input 1	Follows data type	0	Data 1
	In2	Input 2	Follows data type	0	Data 2
Output	Out	Return value	Follows data type	FALSE	Comparison result

  Data type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING

  LD:

- **Precautions**

  When the data types of two input variables are inconsistent, a compilation fault occurs.

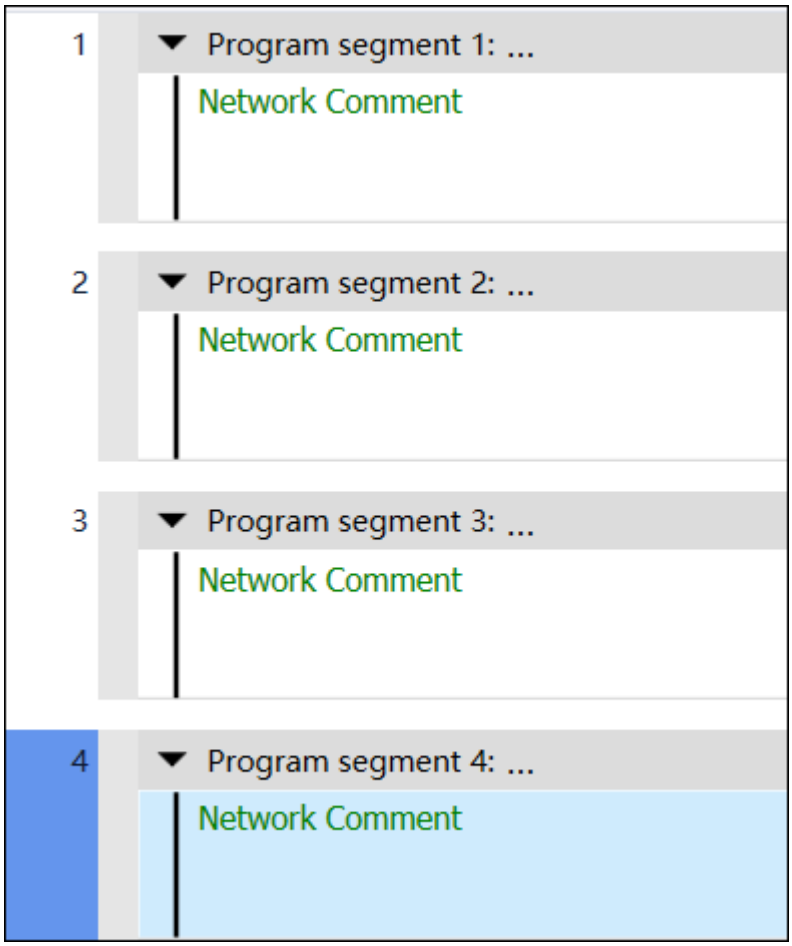
10.1.3.4 Network Usage

10.1.3.4.1 Network Overview

Network is the basic unit of the LD program.

In the LD editor, networks are arranged in a list. Each network has an incremental number on the left, and can include the following: logical and arithmetic expressions, program/function/function block calls, jump and return statements.

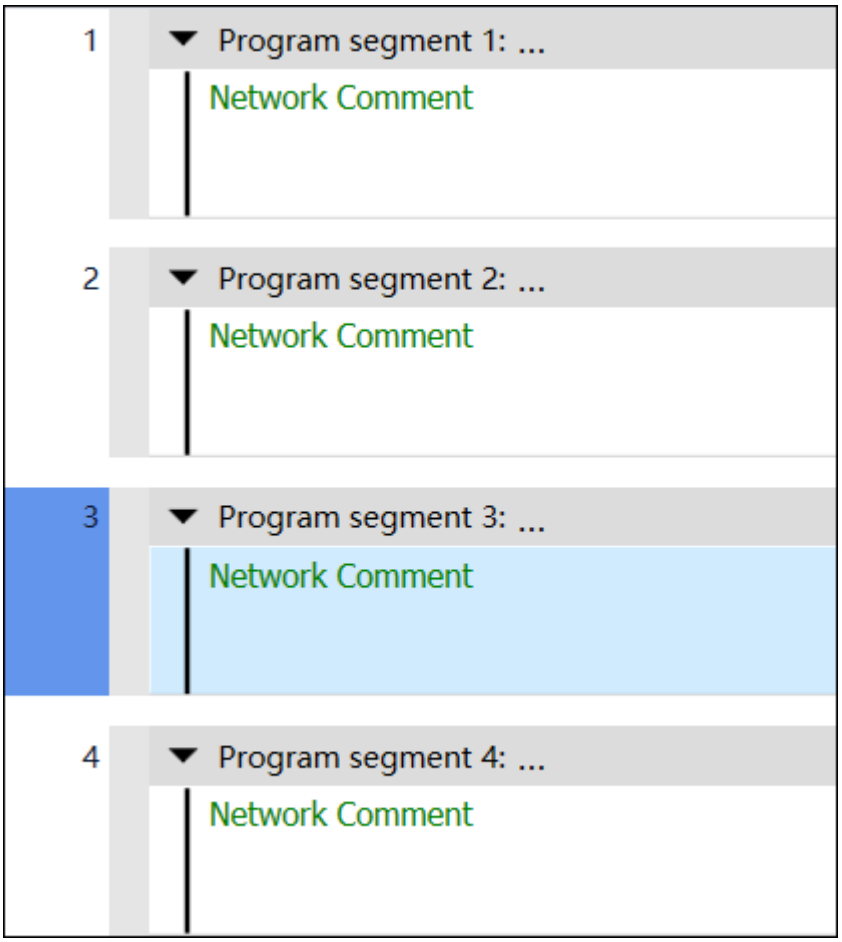
In 10.1.3.3.2 LD editor settings, you can define whether to display network comments, operand comments, variable comments, variable addresses, and so on in the editor.



10.1.3.4.2 Adding a Network

Add a network in the program editing area.

Use the icon  or shortcut key Ctrl + T to add a network.

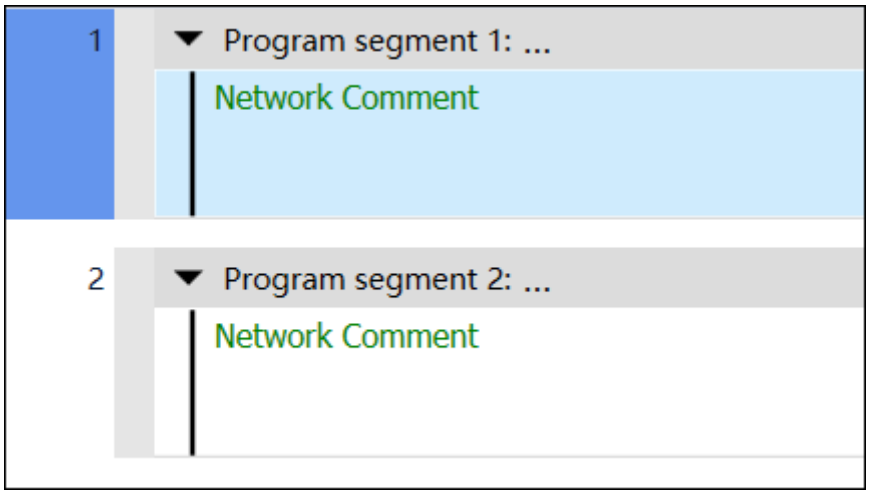


The mouse position affects where the network will be added.

- Selecting an empty space in the editing area
  The new network will be added to the end of the existing networks.

- Selecting a network
  The new network will be added below the selected network. The network number and network title number (program segment n:) of the new network will be automatically re-sorted.
  As shown in the figure below, selecting network 2 will result in the addition of network 3, whose network

number and title number will automatically increment by 1.

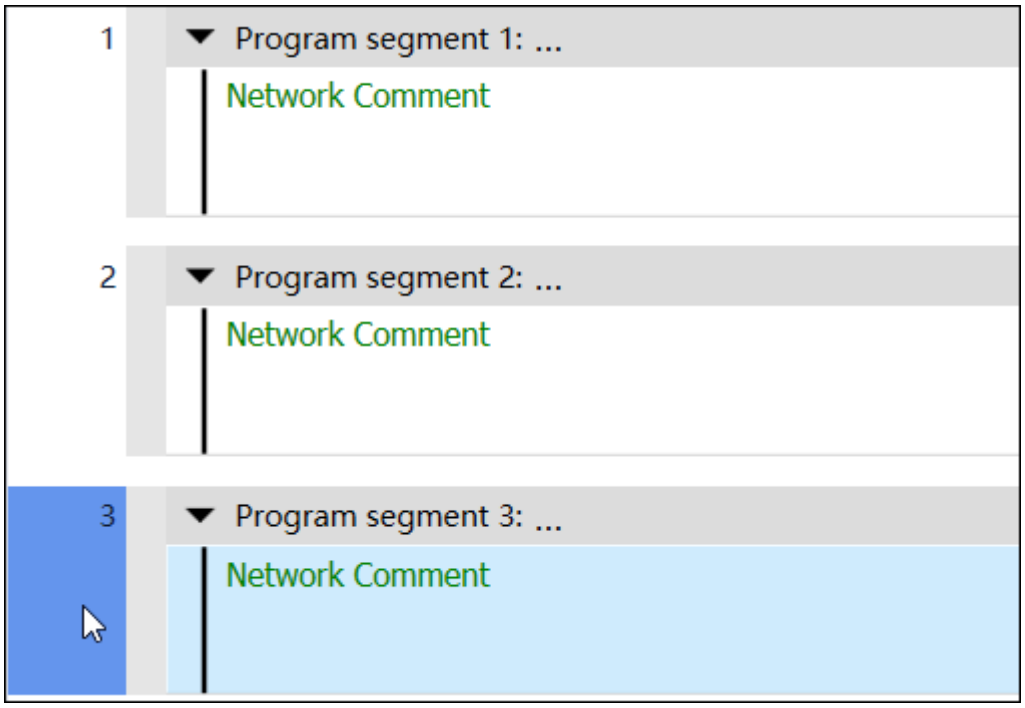


10.1.3.4.3 Inserting a Network

Insert a network in the program editing area.

Use the icon  or shortcut key Ctrl + J to insert a network.

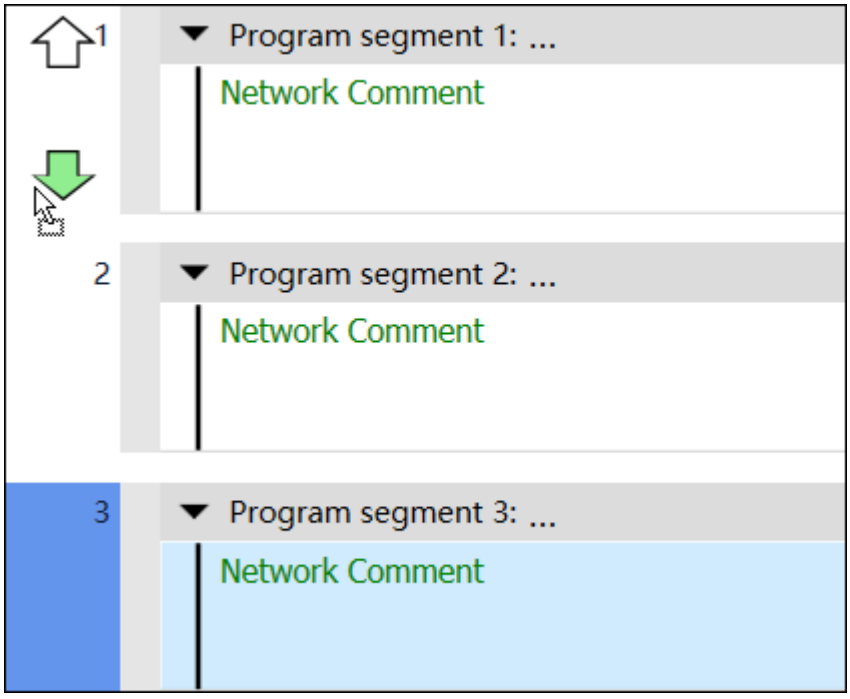
Select a network in the editing area, and the new network will be inserted above the selected network.



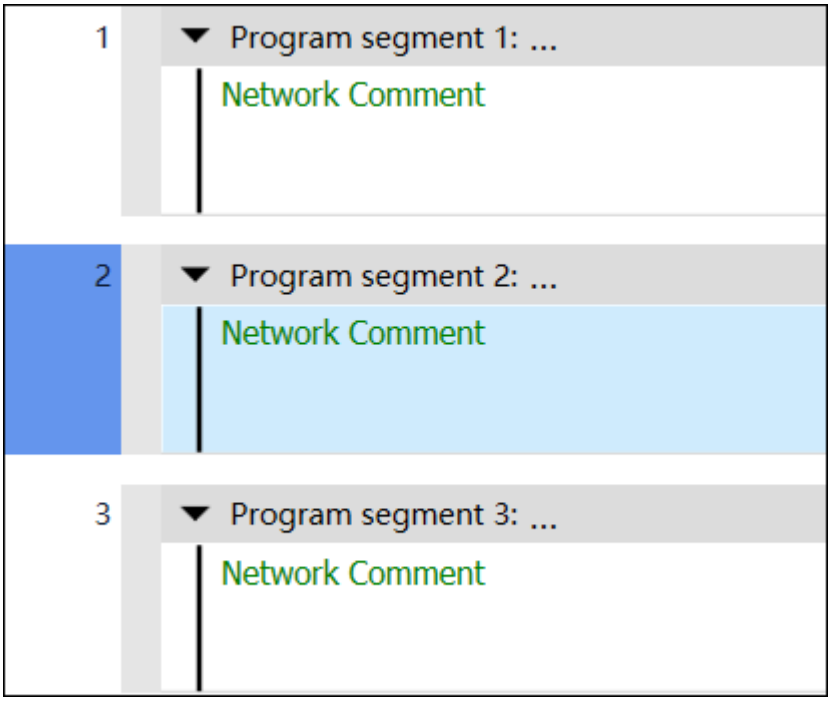
Network numbers and network title numbers (program segment n:) will be automatically re-sorted. In the following figure, network 1 before insertion becomes network 2.

10.1.3.4.4 Moving a Network

The program executes the networks in the editing area from top to bottom. To change the execution order, you must change the order of the network.



1. Select the network whose order you want to change.



2. Drag it to the target position.

   When dragging a network, up/down arrows will appear on the left side of the network at the cursor position, indicating moving the selected network above/below that network. The arrow in green indicates the position where it will be inserted.

   The following figure indicates that Network 3 will be inserted below Network 1.

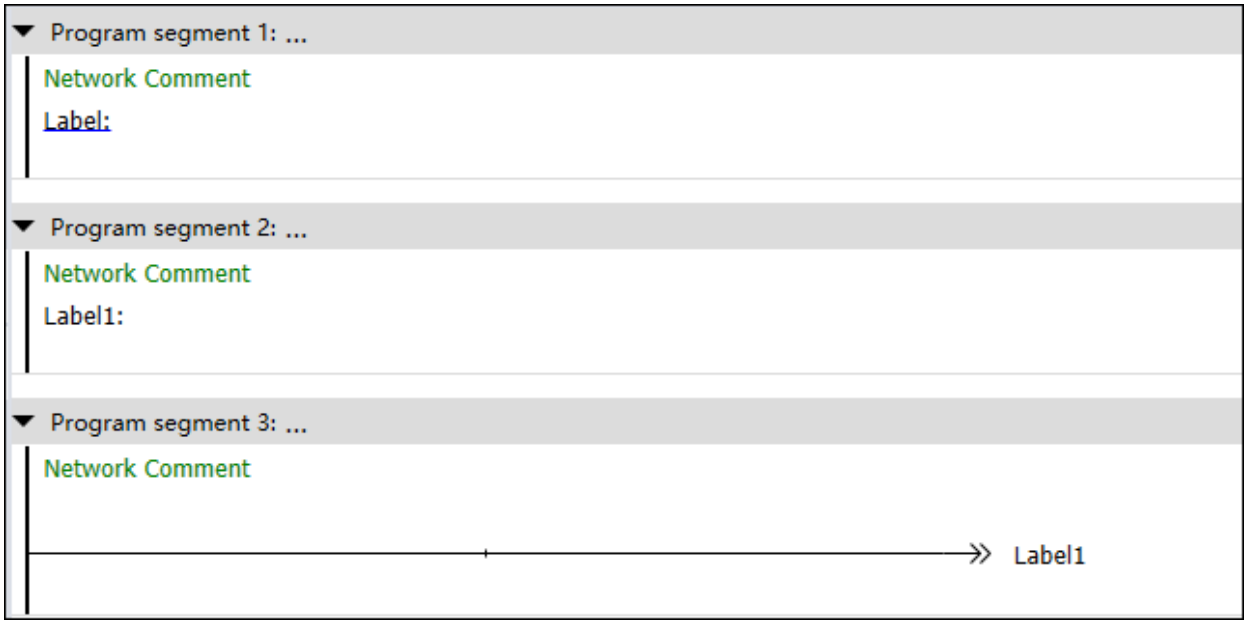
   Release the mouse to complete the moving, and the network number and network title number (program segment n:) will automatically refresh.

10.1.3.4.5 Inserting a Label

Jump labels can be added to a network to facilitate control logic jumps.

Right-click a network and select "Insert tag".

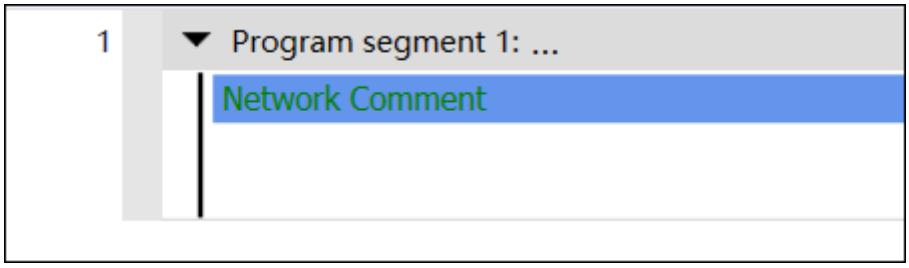
Select a network in the editing area, and the label will be displayed below the network annotation. The label ends a colon (:) and the default label is **Label:**.



Double-click the label to modify its content. Duplicate names are not allowed within an editing area.

The font size of the label can be modified. For details, see 10.1.3.3.2 LD Editor Settings for configuration.

The status of the label is indicated by different symbols:



- Labels referenced: No symbol, such as the label in Network 1.
- Labels not referenced: Blue underline, such as the label in Network 2.
- Duplicate label: Red wavy line, such as the label in Network 3.

For the last two statuses, a prompt will appear when the mouse hovers over the label.

10.1.3.4.6 Modifying Network Comment

Annotations can be added to the program of a network. For example, users can add annotations to describe the control significance of the current network implementation.

Procedure of modifying annotations:

- Double-click the annotation line and type in the new description.
- Right-click a network, select "Edit network comment" and type in the new description.

If the comment line is invisible, see 10.1.3.3.2 LD Editor Settings to make it visible.

The font size of comments is adjustable; see 10.1.3.3.2 LD Editor Settings to complete the operation.

10.1.3.4.7 Switching Network Comment Status

During program commissioning, after the network is switched to annotation status, it no longer participates in compilation and computation.

When the network is in annotation status, operations such as "Go to definition" and "Cross-reference" are not supported.

Use the icon  to switch the network annotation status.

Select the target network. After executing the command, all elements within the network lose their control functions, and labels are converted to plain text, losing their jump positioning functions. Take the following two figures as an example. In the first figure, Label 1 is valid because the network is in normal status. In the second figure, Network 1 is in annotation status, it causes the Label 1 in Network 2 to become invalid.

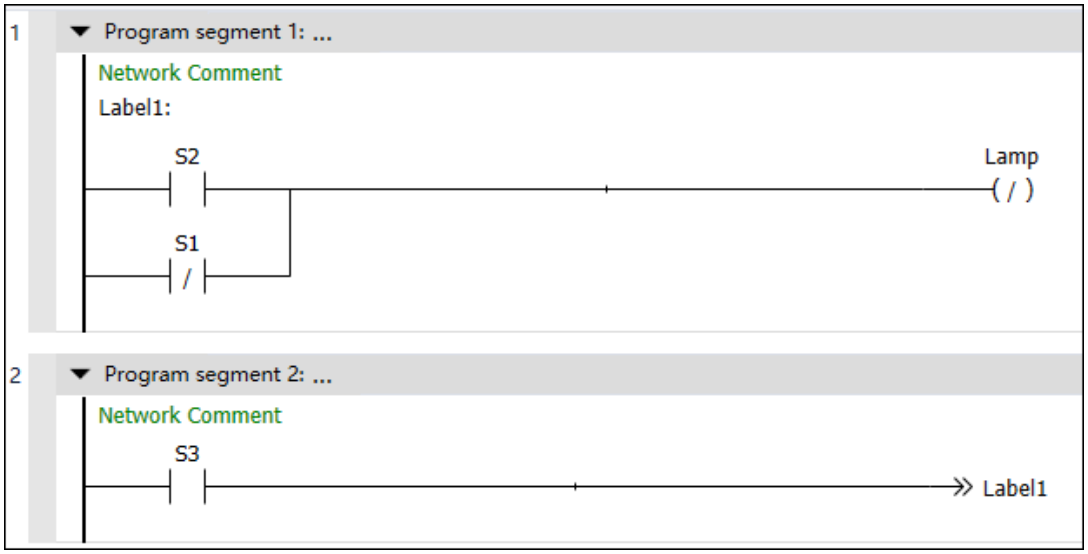


Figure 10-1-3-4-7-1 Network in normal status

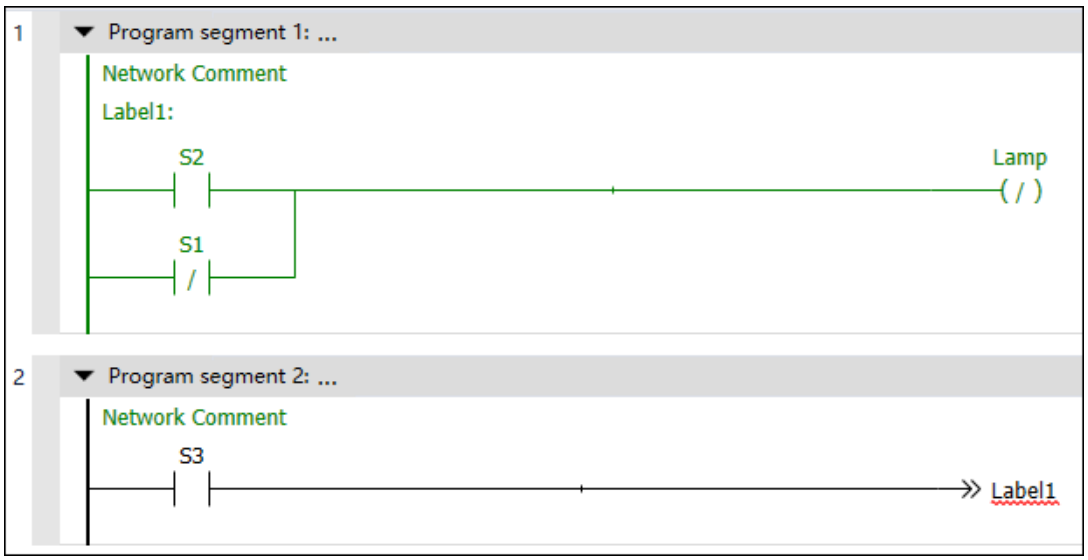

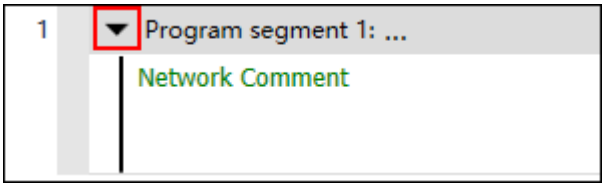

Figure 10-1-3-4-7-2 Network in annotation status

10.1.3.4.8 Collapsing/Expanding a Network

Networks can be collapsed or expanded in the following two ways:

1. Click the triangle icon on the left of the network name to collapse or expand the network.

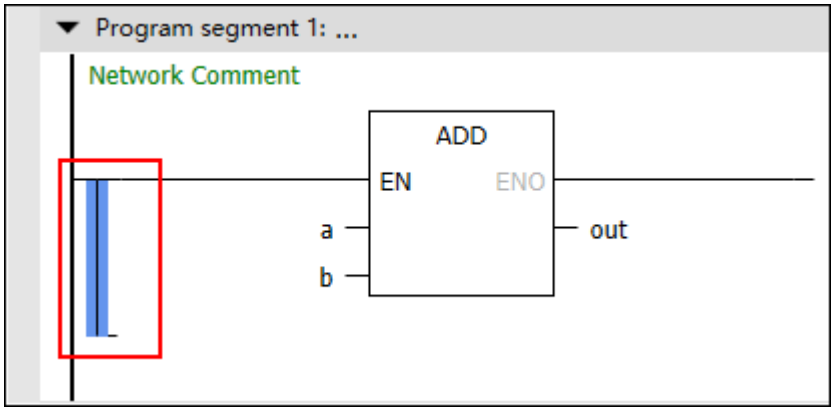
2. Right-click a network and select "Collapse"/"Expand".

10.1.3.4.9 Deleting a Network

Users can delete a single or multiple networks.

1. Select the network(s) to be deleted.
   For batch operations, use the Ctrl key or Shift key.
2. Right-click the network(s) to be deleted and select "Delete", or use the Delete key.

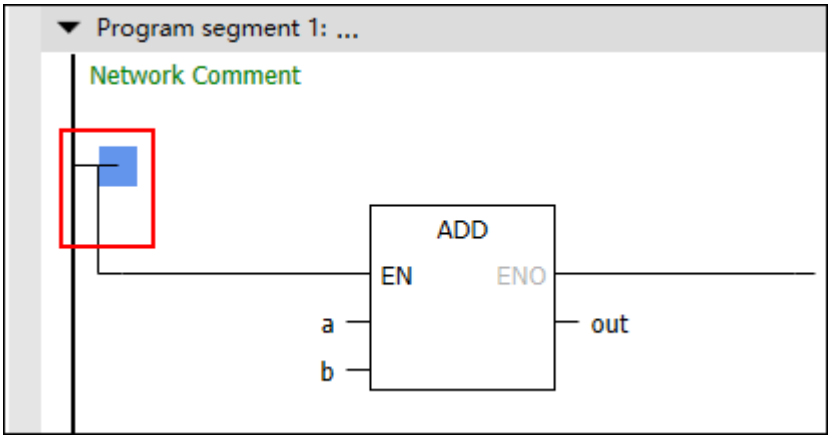
10.1.3.5 Branch Usage



The branch forms a non-closed parallel logic.

Table10-1-3-5-1 Icon and description for branches

Function	Icon	Description
Insert a branch		Insert a branch.
Insert a branch above		Insert a branch above the current position.
Setting branch start/end point		Set the start/end point of the selected branch.



- **Inserting a branch**

  Select a connection line and click the icon to insert a branch below the selected connection line. The inserted branch is an open line.

- **Inserting a branch above**

  Select a connection line and click the icon to insert a branch above the selected connection line.

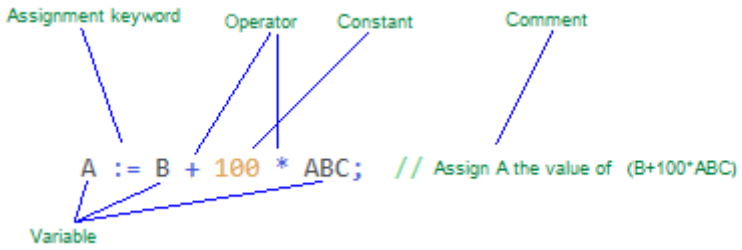
- **Setting branch start/end point**

  This operation is used to connect the start and end points of a branch. To connect the two points, right-click the branch start point and select "Set branch start point". will be displayed at the start point position. Right-click the branch end point and select "Set branch end point". will be displayed at the end point position and the two points are connected.

10.1.4 ST Language Programming

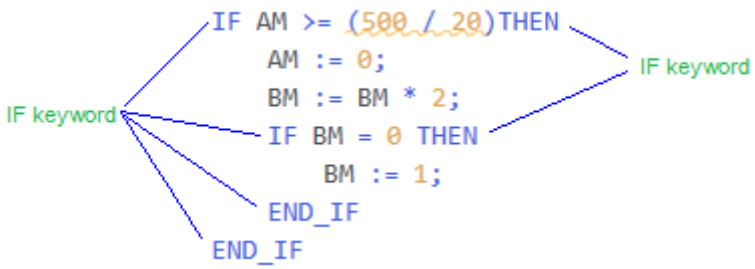
10.1.4.1 Overview

Structured text (ST) is an advanced text programming language that can be used to describe the behavior of functions, function blocks, and programs. It can also describe the behavior of steps, actions, and transitions in sequential function charts. For those familiar with high-level computer language development, ST is easier to learn and use, as it can implement features such as selection, iteration, and jump statements. Moreover, ST is highly readable, helping users quickly understand program logic through semantic identifiers and detailed comments.



ST language structure

ST language allows for various operations, such as calling function blocks, assigning values, and conditionally executing instructions and repeating tasks. The scope of ST language can be extended by calling conditional statements and loop statements with corresponding keywords. The execution order can be determined by the sequence of statements arranged in the ST editor, from top to bottom and from left to right. This order can only be changed by inserting loop statements.



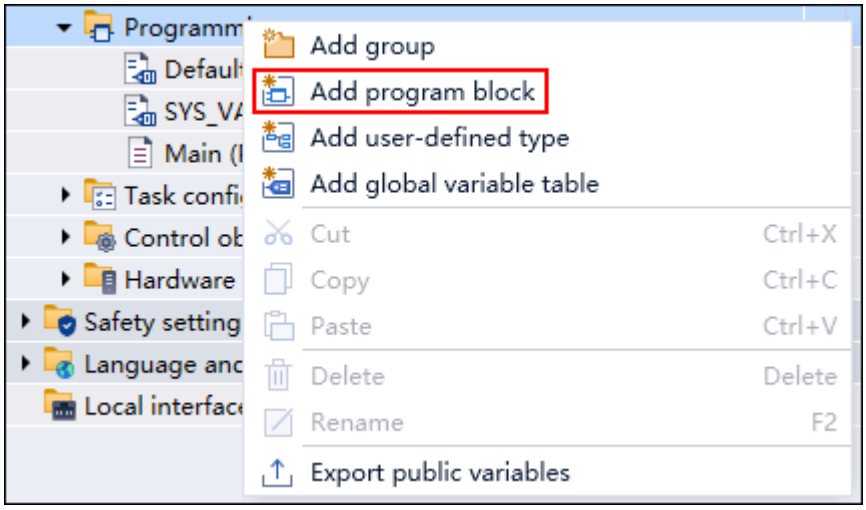
ST language consists of various elements, including the following:

- Expression: A structure composed of operands and operators, which returns a value when executed.
- Operand: Represents variables, numbers, addresses, function blocks, and so on.
- Operator: Symbols used in the execution of operations.
- Statement: Used to assign the value returned by an expression to an actual parameter, and construct and control expressions.

Example of an assignment statement:

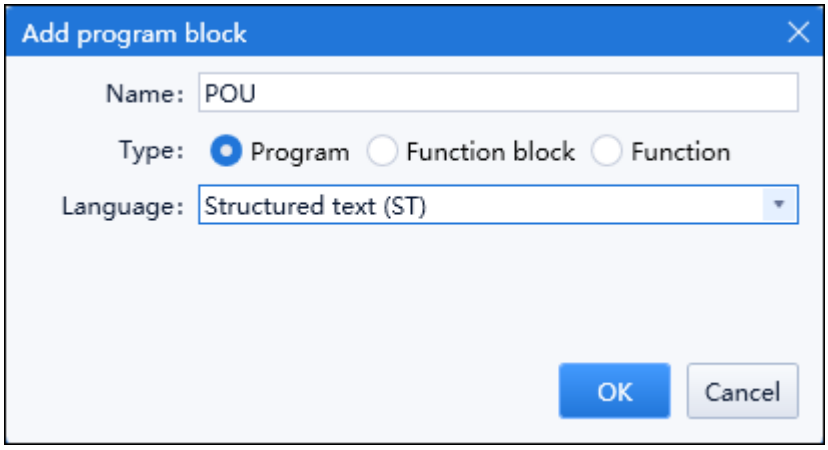
Example of an IF statement:

10.1.4.2 ST Creation and Management



10.1.4.2.1 Creating an ST Program Block

Prerequisites

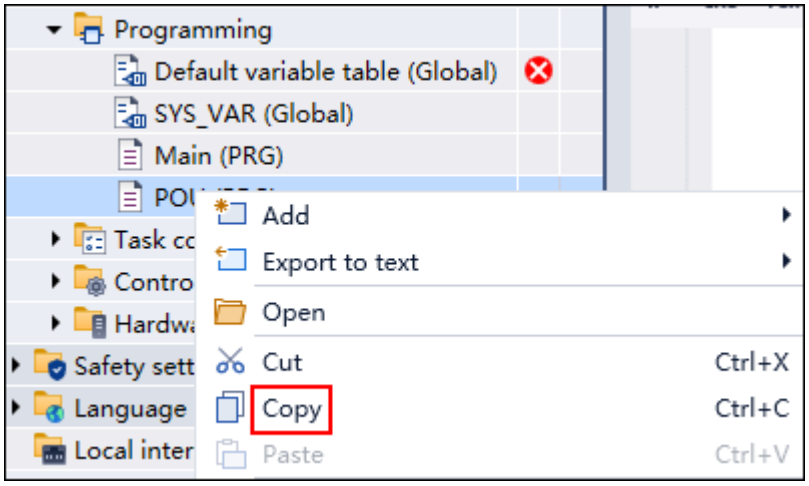


- A project has been created.
- A device has been added.

Procedure

1. Right-click "Programming" in the project tree and select "Add program block".

2. In the pop-up window, set the name of the program block, select "Program", "Function block", or "Function" for the type, and select "Structured text (ST)" for the language, as shown in the figure below.

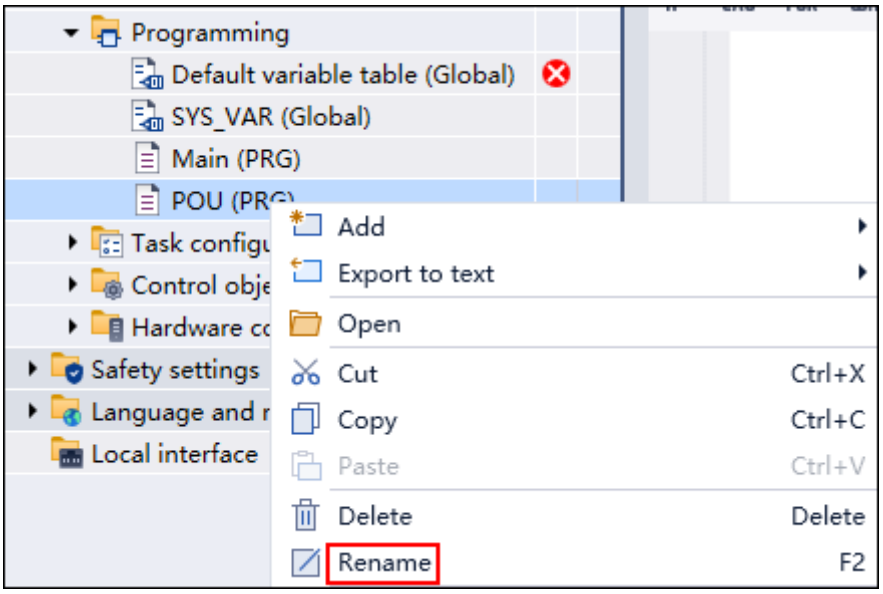


3. Click "OK" and the ST editor will be automatically opened.

10.1.4.2.2 Managing an ST Program Block

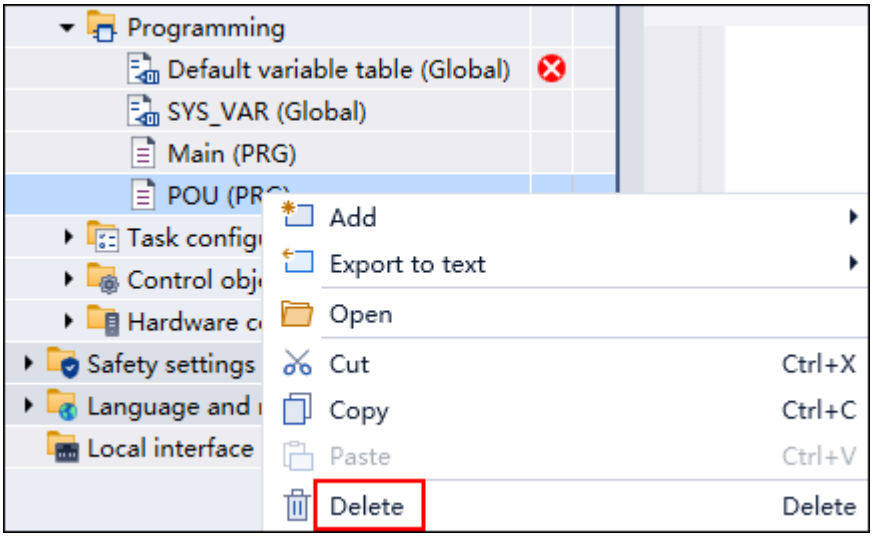
10.1.4.2.2.1 Copying an ST Program Block

ST program blocks can be copied and pasted within a PLC device, between PLC devices in the same project, or between different projects. The internal program logic of the ST program block remains unchanged after pasting.



1. Right-click an ST program block name under the "Programming" node, and select "Copy".

2. Right-click the "Programming" node or its subordinate node, and select "Paste" to paste the copied LD program block at the corresponding location.

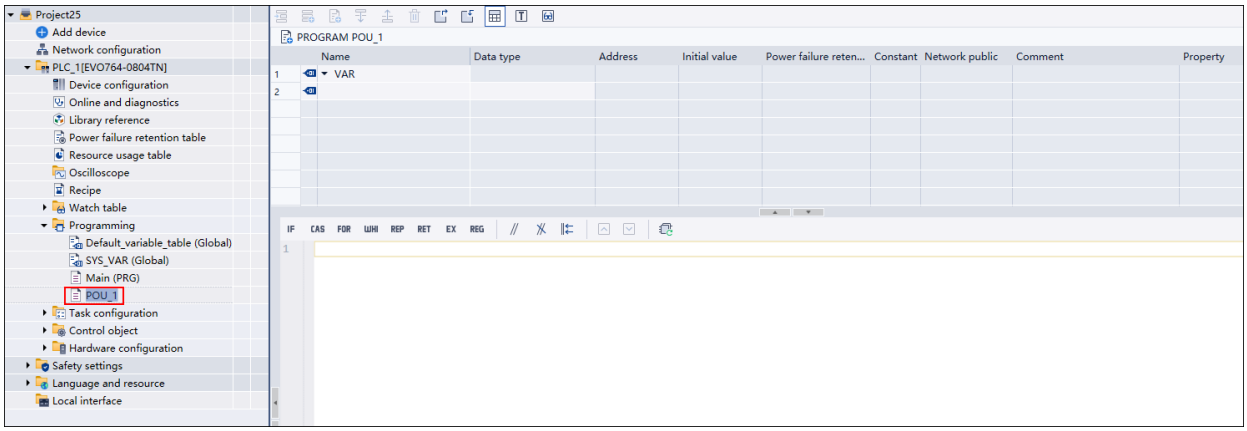


10.1.4.2.2.2 Renaming an ST Program Block

Right-click an ST program block name under the "Programming" node, select "Rename", and modify the name.

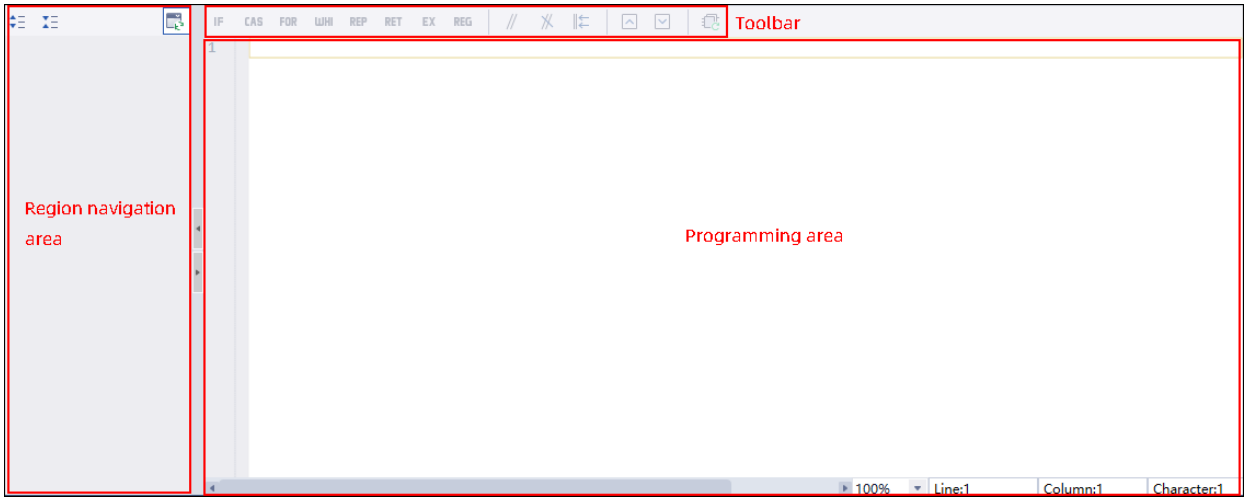
10.1.4.2.2.3 Deleting an ST Program Block

1. Right-click an ST program block name under the "Programming" node, and select "Delete".



2. Click "OK" in the pop-up window.

10.1.4.3 ST Editor



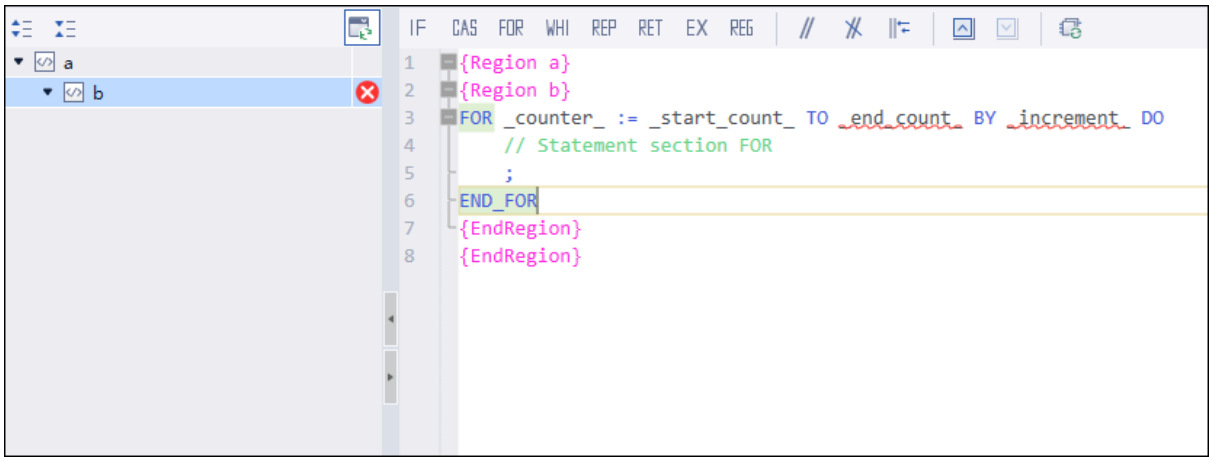
10.1.4.3.1 ST Editor Interface

Double-click the ST language program block under the "Programming" node (node identifier:) to open the ST editor.

The ST editor is divided into the variable declaration area and the program editing area, which can be collapsed and expanded using and .

The program editing area consists of three parts: the toolbar, the programming area, and the Region navigation area, as shown in the figure below:

- Toolbar



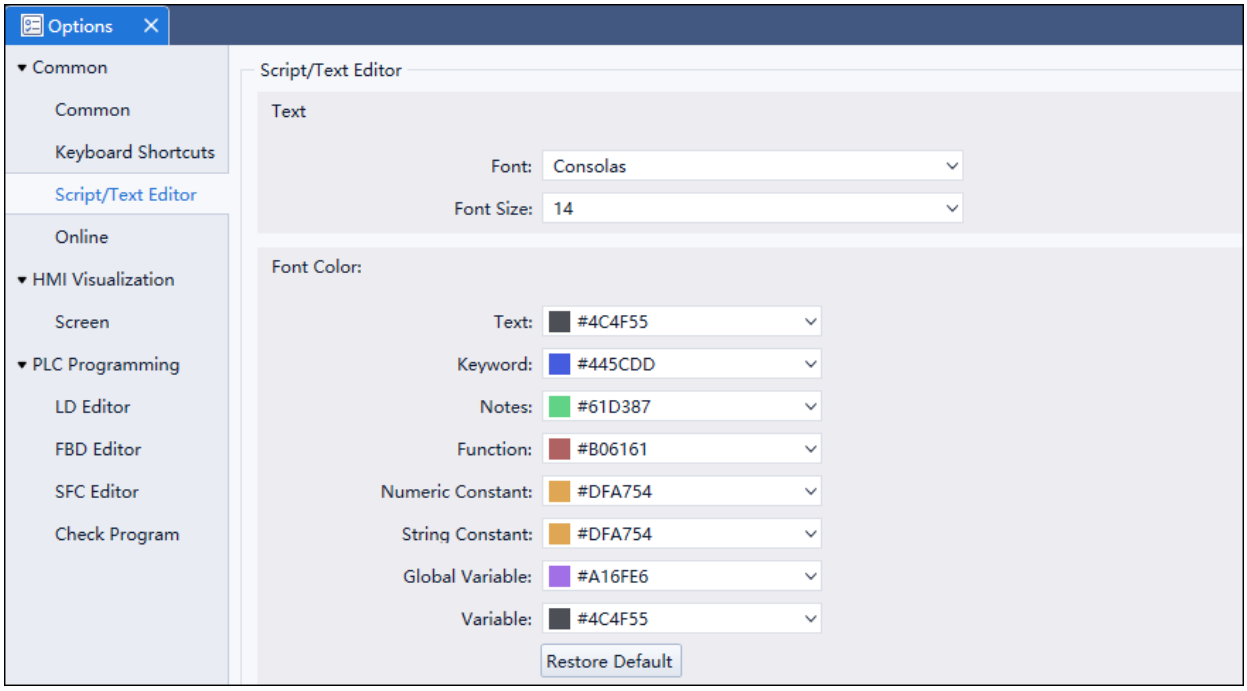
Description	Icon	Description
If	IF	Insert an IF statement.
Case	CAS	Insert a CASE statement.
For	FOR	Insert a FOR loop statement.
While	WHI	Insert a WHILE loop statement.
Repeat	REP	Insert a REPEAT loop statement.
Return	RET	Insert a RETURN instruction.
Exit	EX	Insert an EXIT statement.
Region	REG	Insert a Region instruction.
Comment	//	Insert a single-line comment.
Uncomment	//	Remove a single-line comment.
One-click formatting		Quickly reformat and optimize code layout.
Collapse all		Collapse logical structures that can be folded (such as functions, loops, conditional statements, etc.).
Expand all		Expand all collapsed content.
Update all parameters		Update all parameters in the program editing area if the parameters of the called object are changed.

- Programming area
  Used for ST programming. The bottom of the programming area displays the exact position of the mouse cursor, allowing users to quickly jump to any line in the program.

- Region navigation area
  Used to visually display structurally complete Region blocks in the ST program, helping users efficiently manage program structure and achieve rapid program positioning and navigation to target locations. Region navigation area consists of two columns: the first column contains the collapse/expand buttons and node names; the second column indicates whether the text associated with the node contains pre-compilation faults. Double-click the error flag to navigate to the corresponding code highlighted in the ST

program editing area.

Use and to collapse or expand the Region navigation area.



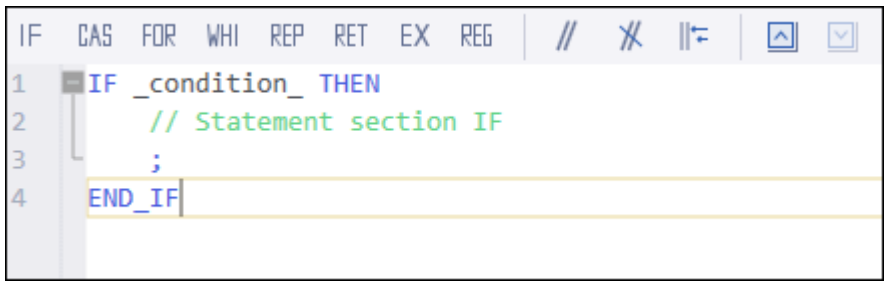
In this area, Regions can be copied, renamed, expanded/collapsed, and synchronized through the right-click menu or toolbar.

Function	Description
Copy	Copy all code within the selected Region block in the ST program editing area. The copied Regions can be pasted in the program editing area.
Rename	Rename the Region node and synchronously update the name of the corresponding Region node in the ST program editing area, and vice versa.
Expand/Collapse	Expand or collapse the selected Region node and its child nodes.
Expand all/ Collapse all	Expand or collapse all Region nodes and their child nodes, including all ST code block keywords.
Sync	◦ When synchronization is enabled, click a Region node on the left to navigate to the corresponding location in the ST program editing area; simultaneously, any changes to the Region structure, name, collapse state, or highlighted display in the editing area are synchronized to the Region nodes on the left, and vice versa. ◦ When synchronization is disabled, the collapse and select operations will not be synchronized between the ST program editing area and the Region navigation area. However, any changes to Region structure or name still sync between the two.

10.1.4.3.2 ST Editor Settings

In the software menu, select "Tools > Options". In the "Script/Text editor" tab, users can set the font, size, and color of the text.

- The settings in the text area will affect the character font and size in the ST program.
- The settings of font color will affect the color display of characters in the ST program. Click "Restore defaults" to reset all font colors to their default values.

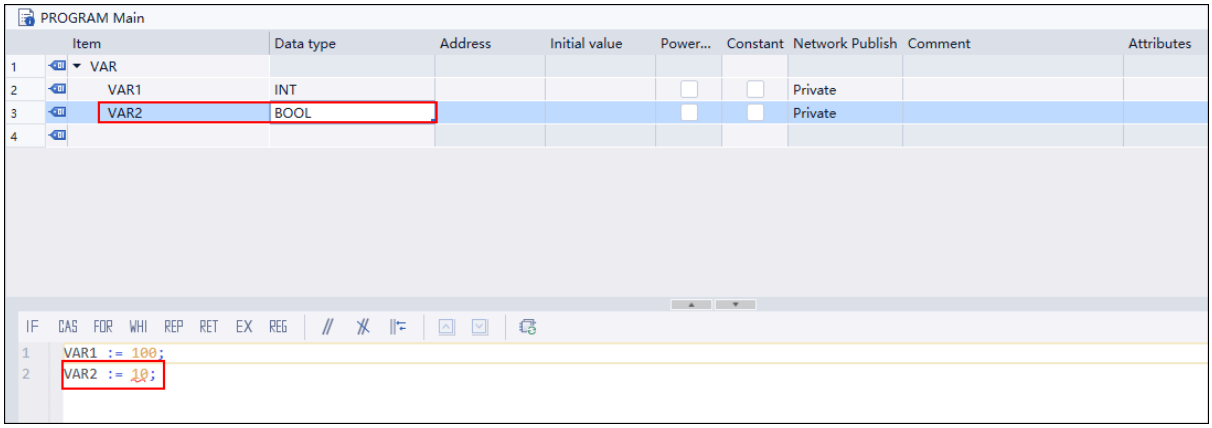


10.1.4.3.3 Basic Operations of ST Editor

Variables, operators, and statements in the program can be input in the following ways:

1. Input assistant
   At the insertion point in the editing area, press F3 to open the "Input assistant" dialog box, select the target object to insert it.
2. Direct input
   At the insertion point in the editing area, directly type the object. When characters are typed, the software automatically searches and matches them in the current project. Users can select the target variable from the result list. When operators are typed, the input method must be switched to English.
   When typing an array variable, enter "0" to trigger intelligent prompts for all sub-items of the current array dimension (cursor position). When array indices contain non-numeric values, non-static variables, or complex constant expressions (e.g., abc.d, ab[8]), the intelligent prompts for array sub-items cannot be accurately listed.
3. Drag-and-drop
   At the insertion point in the editing area, drag and drop the target object from the variable table or toolbox to insert it.
   When dragging a target variable from the variable table to the insertion point in the editor:
   - After dragging the target variable, if the mouse hovers over the insertion point for less than 1.5 seconds, the target variable will be directly inserted at the current position.
   - If the mouse hovers over the insertion point for 1.5 to 3 seconds, the system will draw a border around the variable at the insertion point. Releasing the mouse will perform an overwrite operation, replacing the hovered variable.
   - If the mouse hovers over the insertion point for more than 3 seconds, the system will draw a border around the full path of the hovered variable. Releasing the mouse will also perform an overwrite operation of the full path of the hovered variable.
4. Adding a statement

At the insertion point in the editing area, select the statement icon from the toolbar to insert the corresponding keyword.

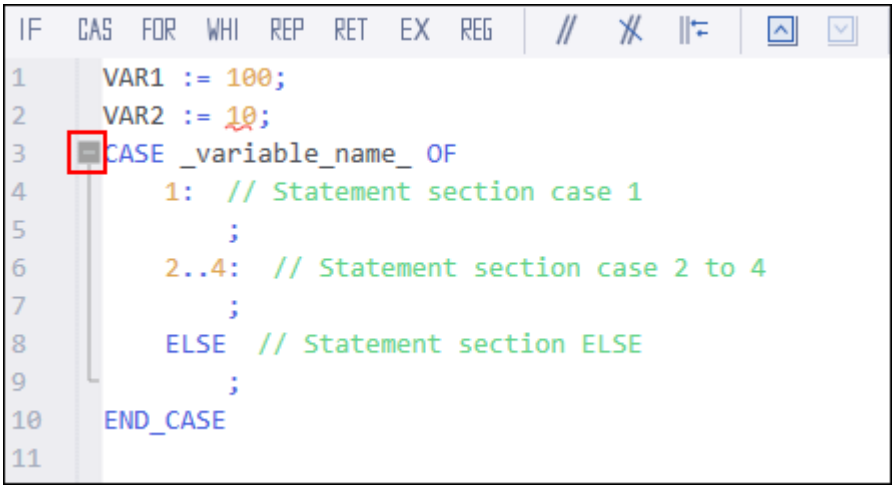


The ST Editor supports the following functions:

① Copy, paste, cut, delete, undo, and redo

These functions are similar to ordinary text. The undo function in the ST editor undoes one action at a time based on user input.

② Indentation with Shift+Tab

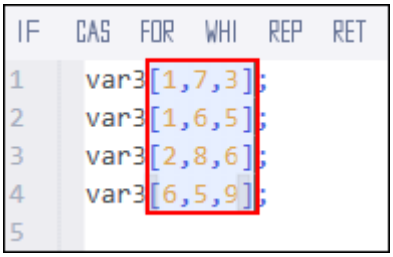


③ The editing area supports syntax highlighting, with red wavy lines for wrong syntax and yellow highlighting for warning syntax.

④ Supports automatic completion of block statements. Parameters for FB instances, FC, PRG, or Meth called within the editing area can be auto-completed using the Tab key.

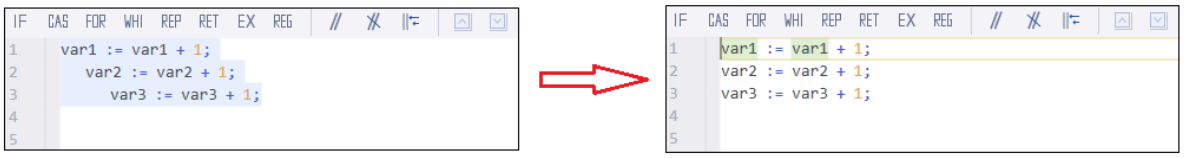
5. Collapsing/Expanding

ST supports code collapsing and expanding code segments. The icon is shown in the following figure.



- Collapsing and expanding are supported in both online and offline statuses.
- Click the icon to collapse or expand the block.

- Click the "Collapse all" icon in the ST toolbar or use the shortcut key "Alt + F" to collapse all code segments. Click the "Expand all" icon in the ST toolbar or use the shortcut key "Alt + U" to expand all code segments.
- The collapsed area include block statements, annotations, and Regions.
- There are collapsing symbols and range lines in the collapsed area.



6. Column operations

   In the ST editor, hold down the Alt key and drag the left mouse button to select specific columns across multiple lines. Users can edit, batch delete, copy, and paste the selected columns.

7. One-click formatting

   Users can select the area to be formatted and click the "One-click formatting" icon in the ST toolbar or use the shortcut key "Ctrl + Shift + W" to quickly optimize the code format.

> **NOTE**
>
> The ST editor also supports automatic text formatting. When users enter a semicolon (;), the editor will automatically format the code according to predefined rules, ensuring orderly and standardized code.

8. Updating all parameters

   The ST editor supports one-click updating of called instruction parameters. Users can click the "Update all parameters" icon in the ST toolbar to quickly update all parameters of the instructions within the current editor program.

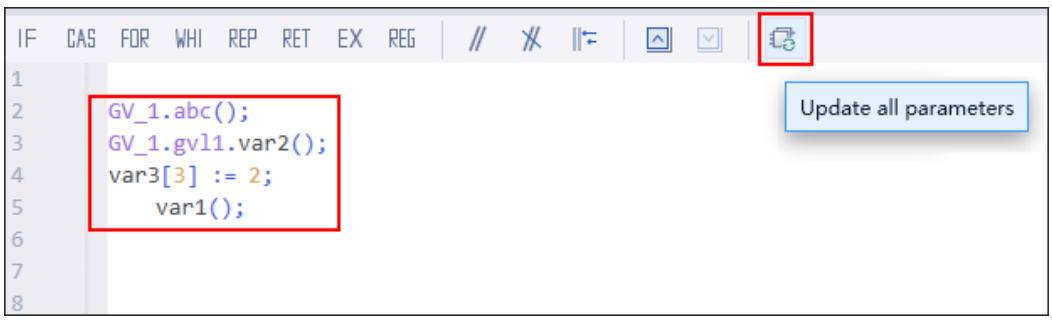


Figure 10-1-4-3-3-1 Updating all parameters

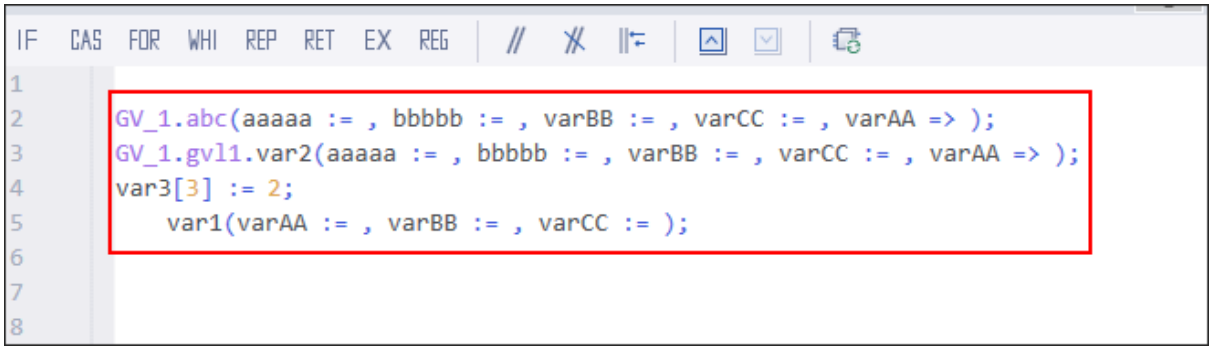

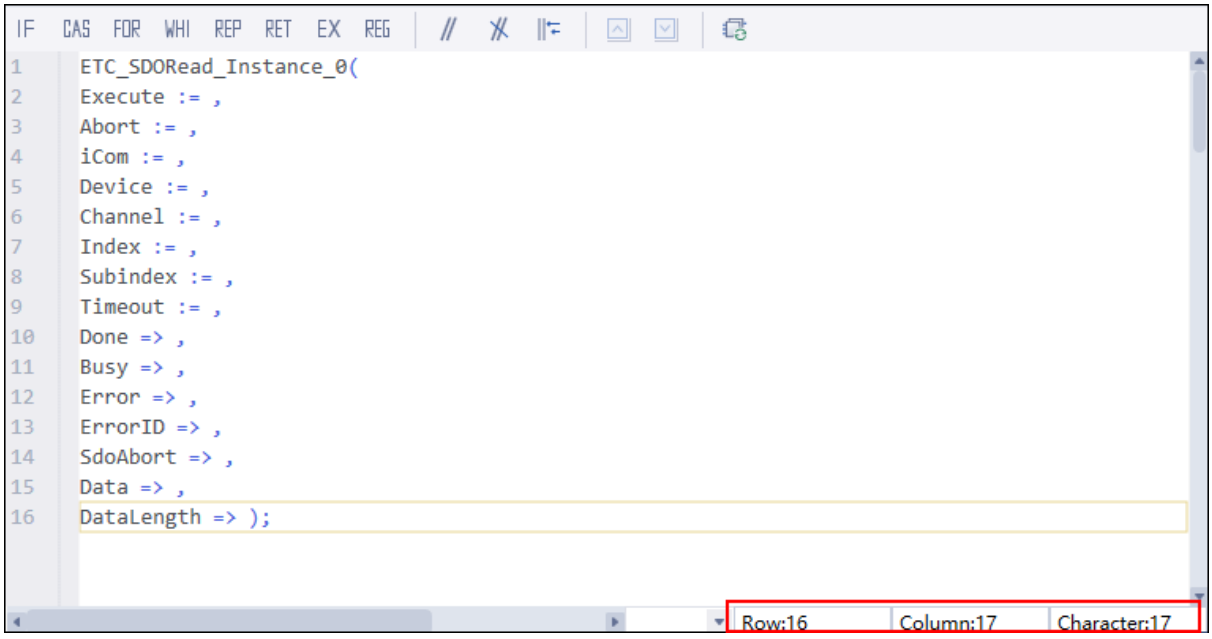

Figure 10-1-4-3-3-2 Update results

9. Line jumping

Line jumping allows users to quickly jump to any line in the program.

The bottom of the editing area displays the exact position of the current mouse. Users can double-click the line number or use the shortcut key Ctrl+G to open a pop-up window. Enter the target line number and click "OK" to jump to the specified line.

10.1.4.4 ST Operators

If there are several operators in an expression, the operators will be executed according to the predefined precedence: operators with higher precedence are executed first, followed by those with lower precedence. If there are operators with the same precedence in an expression, they are executed from left to right in the order they are written. The precedence of operators is shown in the table:

Operation	Operator	Example	Priority
Parentheses	()	(2 + 3) * (5 - 4) The result is 5.	1
Function call	Function name (Parameter list)	FUN2 (FUN1 (Var1A, Var1B) , Var2B) FUN1 is executed first, then FUN2.	2

Operation	Operator	Example	Priority

Truncation	TRUNC
	TRUNC_INT
		OUT := TRUNC (1.234); // Returns the result 1 of the data type DINT.
		OUT := TRUNC_INT (2.456); // Returns the result 2 of the data type INT.
			2

Inversion	NOT	NOT TRUE The result is FALSE.	3
Exponentiation	EXPT	OUT:= EXPT (R1 , R2); If R1 = 5 and R2 = 4, OUT is 625.	4
Multiplication	*	OUT:= R1 * R2; If R1 = 5 and R2 = 4, OUT is 20.	5
Division	/	OUT := R1 / R2; If R1 = 5 and R2 = 4, OUT is 1. // When the data type of OUT is DWORD, the result is 1.	5
Modulus	MOD	OUT := R1 MOD R2; If R1 = 9 and R2 = 4, OUT is 1.	5
Addition	+	OUT := R1 + R2; If R1 = 5 and R2 = 4, OUT is 9.	6
Subtraction	-	OUT := R1 - R2; If R1 = 5 and R2 = 4, OUT is 1.	6
Compare	<, >, <=, >=	OUT := R1 < 9; If R1 = 8, OUT is TRUE.	7
Equal to	=	OUT := R1 := 8; OUT is 8.	8
Not equal	<>	OUT := R1 <> 7; If R1 = 8, OUT is TRUE.	8
Logic AND	AND, &	OUT := B1 & B2; If B1 = TRUE and B2=TRUE, OUT is TRUE.	9
Logical XOR	XOR	OUT := B1 XOR B2; If B1 = FALSE and B2=TRUE, OUT is FALSE.	10
Logic OR	OR	OUT := B1 OR B2; If B1 = TRUE and B2=TRUE, OUT is TRUE.	11

10.1.4.5 ST Keywords

Keyword	Meaning	Example
:=	Assignment	d:=10;
S=	Set a bit	Var1: BOOL; Var2: BOOL; Var1 S= Var2;
R=	Reset a bit	Var1: BOOL; Var2: BOOL; Var1 R= Var2;
RETURN	Return	-

IF	Select	D:=B*B;
		IF D<0.0 THEN
		C:=A;
		ELSIF D=0.0 THEN
		C:=B;
		ELSE
		C:=D;
		END_IF;

CASE	Multiple selection	CASE INT1 OF
		1: g:= 11;
		2: g:= 22;
		ELSE
		g:= 5;
		END_CASE;

FOR	FOR loop	FOR I:=1 TO 100 BY 2 DO J:=J*2; END_FOR;
WHILE	WHILE loop	WHILE J<= 100 DO J:=J+2; END_WHILE;

Keyword	Meaning	Example
AND_THEN	AND operation	Var1: BOOL; Var2: BOOL; Var3: BOOL; Var3 := Var1 AND_THEN Var2;
OR_ELSE	OR operation	Var1: BOOL; Var2: BOOL; Var3: BOOL; Var3 := Var1 OR_ELSE Var2;
REPEAT	REPEAT loop	REPEAT Var1:=Var1*2; Counter:=Counter-1; UNTIL Counter=0; END_REPEAT;

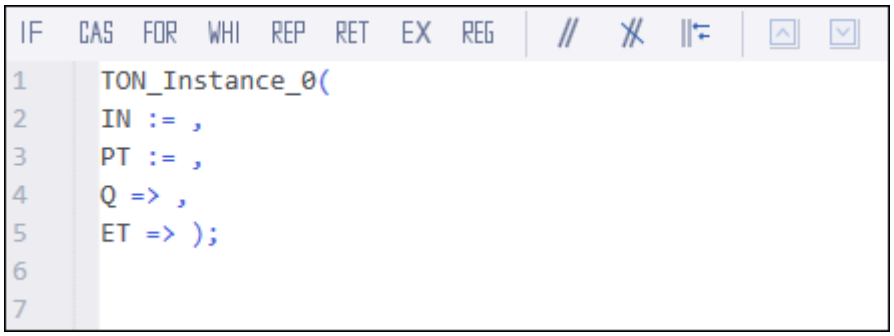
EXIT	Exit loop	FOR I:=1 TO 100 DO
		FOR J:=1 TO 10 DO
		IF Val[I,J]>100 THEN EXIT;
		END_IF;
		END_FOR;
		END_FOR;

;	Empty statement	WHILE Var<0 DO ;(*Empty statement*) END_WHILE;
(* Text *)	Annotation	Motor_A.Nominal_Voltage:=380; (*Voltage 380V*)
// Text	Annotation	Execute:=RUNF1, // Triggers execution flag

10.1.4.6 ST Statements

- Assignment statement
  Assignment statement (represented by ":=") is one of the most commonly used statements in structured text. It is used to assign the value produced by the expression on its right side to the operand (variable or address) on its left side. The specific format is as follows.

```
<variable>:=<expression>;
```

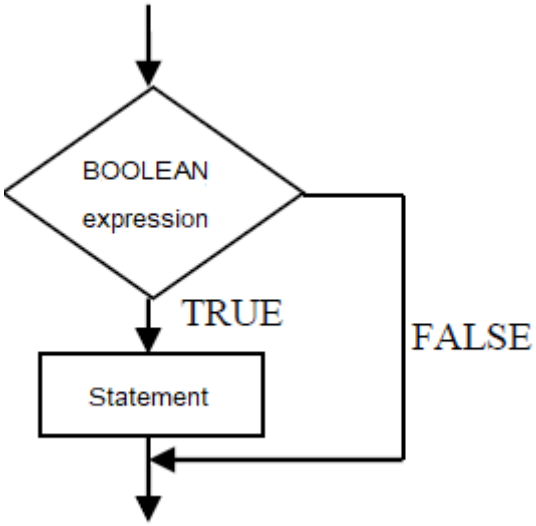


The following example assigns a value to an INT type variable var1.

```
var1:=100;
```

- Function and function block calls
  Function blocks can be called by instantiating their names, with the specific format as follows.

```
Function block instance name: (function block parameters);
```



To call a function block in ST, directly enter the instance name of the function block and assign values or variables to each parameter of the function block in the subsequent parentheses, separated by commas. The function block call ends with a semicolon. The following example calls the TON timer function block (instance name: TON_Instance_0) in ST.

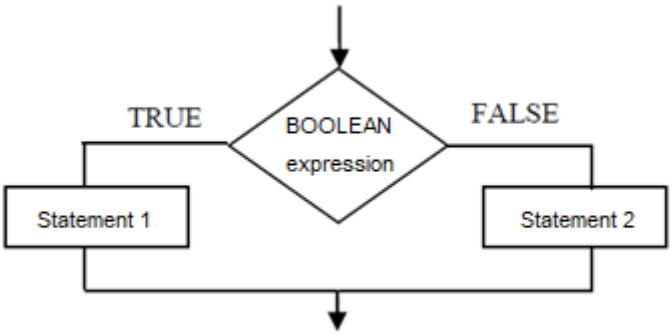
- Selection statements
  - IF statement
    The IF statement is used to implement a single-branch selection structure, with the basic format as follows.

```
IF <Boolean expression> THEN
<statement content>;
END_IF
```

If the above format is used, the statement content is only executed when the <Boolean expression> is TRUE; otherwise, the statement content is not executed. The statement content can be a single statement, an empty statement, or multiple parallel statements. The execution flowchart of the statement expression is shown in the figure below.

The following example shows how to use a PLC to determine whether the current temperature exceeds 65°C. If it does, the program will turn on the fan for cooling. The specific code is as follows.

```
VAR
nowTemp:BYTE; (*current temperature status signal*)
bFan:BOOL; (*fan control signal*)
END_VAR
```



```
nowTemp:=75;
IF nowTemp>60 THEN
bFan:=TRUE;
END_IF
```

- IF...ELSE statement

  The IF...ELSE statement is used to implement a dual-branch selection structure, with the basic format as follows.

```
IF <Boolean expression> THEN
<statement content 1>;
ELSE
<statement content 2>;
END_IF
```

The above expression first evaluates the value within the <Boolean expression>. If it is TRUE, <statement content 1> is executed; if it is FALSE, <statement content 2> is executed. The program execution flowchart is shown in the figure below.

The following example shows how to use a PLC to determine whether the current temperature exceeds 65°C. If it does, the program will turn on the fan for cooling; otherwise, the fan is turned off.

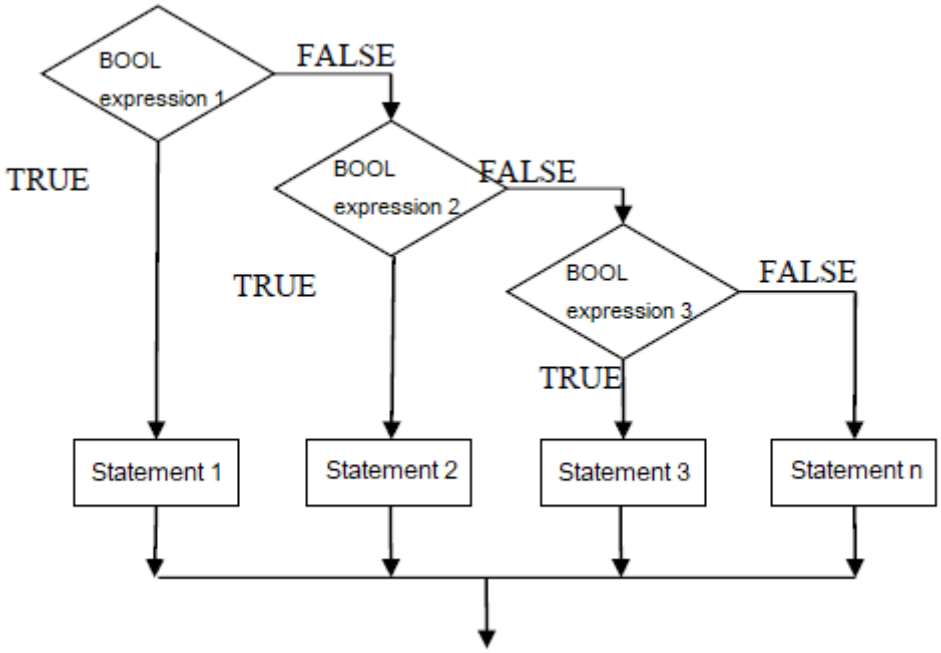
```
VAR
nowTemp:BYTE; (*current temperature status signal*)
bFan:BOOL; (*fan control signal*)
END_VAR
```

```
IF nowTemp>65 THEN
bFan:=TRUE;
ELSE
bFan:=FALSE;
END_IF
```

When there is more than one conditional statement, a nested IF...ELSE statement is needed. It is a multi-branch selection structure and the basic format is as follows.

```
IF <Boolean expression 1> THEN
  IF <Boolean expression 2> THEN
    <statement content 1>;
  ELSE
    <statement content 2>;
  END_IF
ELSE
 <statement content 3>;
END_IF
```

With the following code, For equipment in automatic mode, the fan is turned on and the heater is turned off when the actual temperature is greater than 50°C. If it is less than or equal to 50°Cs, the fan is turned off and the heater is turned on. For equipment in manual mode, neither the heater nor the fan is turned on.



```
VAR
bAutoMode: BOOL; (*manual/auto mode signal*)
nTemp:BYTE; (*current temperature status signal*)
bFan:BOOL; (*fan control signal*)
bHeating:BOOL; (*heater control signal*)
END_VAR
```

```
IF bAutoMode=TRUE THEN
  IF nTemp>50 THEN
    bFan:=TRUE;
    bHeating:=FALSE;
  ELSE
    bFan:= FALSE;
    bHeating:= TRUE;
  END_IF
ELSE
 bFan:= FALSE;
 bHeating:=FALSE;
END_IF
```

- The multi-branch selection structure can also be implemented wit the IF..ELSIF..ELSE statement. The specific format is as follows.

```
IF <Boolean expression 1> THEN
  <statement content 1>;
ELSIF <Boolean expression 2> THEN
  <statement content 2>;
ELSIF <Boolean expression 3> THEN
  <statement content 3>;
. . .
. . .
ELSE
  <statement content n>;
END_IF
```

If the <Boolean expression1> is TRUE, only <statement content1> is executed. Otherwise, judgments are made from the <Boolean expression2> until one of the Boolean expressions is TRUE, and then the corresponding statement content for that Boolean expression is executed. If none of the Boolean expressions are TRUE, only the <statement content n> is executed. The program execution flowchart is shown in the figure below.

◦ CASE statement

The CASE statement is a multi-branch selection statement that selects one branch to execute from multiple branches based on the value of an expression, and the basic format is as follows.

```
CASE <condition variable> OF
  <value 1>: <statement content 1>;
  <value 2>: <statement content 2>;
  <value 3, value 4, value 5>: <statement content 3>;
  <value 6 .. value 10>: <statement content 4>;
  ...
  <value n>: <statement content n>;
ELSE
  <ELSE statement>;
END_CASE;
```

Execution method of CASE statement:

- If the value of <condition variable> is <value i>, the <statement content i> is executed.
- If <condition variable> has no specified value, the < ELSE statement> is executed.
- If the same instruction needs to be executed for several values of <condition variable>, these values can be written consecutively and separated by commas. This ensures the common instruction is executed, as shown in line 4 of the program above.
- If the same instruction needs to be executed for the values of <condition variable> within a certain range, the initial and final values of the range can be entered and separated by two dots. This ensures the common instruction is executed, as shown in line 5 of the program above.

- Iteration statement

  The iteration statement is mainly used for programs that need to be repeated. Common iteration statements include FOR, REPEAT, and WHILE.

  ◦ FOR loop

The FOR loop statement first evaluates an initialization sequence. If the loop condition is TRUE, it repeatedly executes the nested statements and calculates the iteration expression sequence. If the loop condition is FALSE, the loop terminates. The specific format is as follows.

```
FOR <variable> := <initial value> TO <target value> {BY <step>} DO
  <statement content>
END_FOR;
```

The execution order of the FOR loop is as follows:

- Calculate whether <variable> is within the range of <initial value> and <target value>.
- When <variable> is less than <target value>, execute <statement content>.
- When <variable> is greater than <target value>, <statement content> will not be executed.
- Each time <statement content> is executed, <variable> is incremented by the specified step size. The step size can be any integer value. If the step size is not specified, its default value is 1. When <variable> is greater than <target value>, exit the loop.

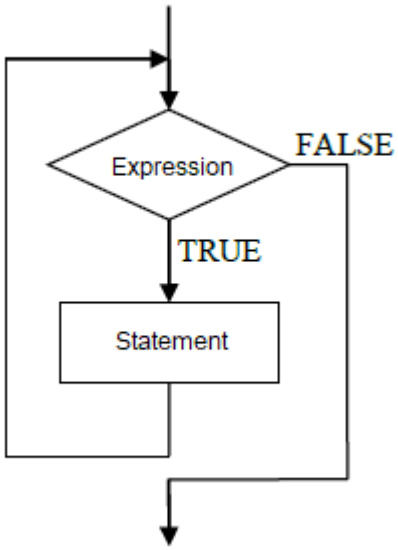
The following example uses the FOR loop to implement increment-by-1 calculation.

```
VAR
Counter: BYTE; (*loop counter*)
Var1:WORD; (*output result*)
END_VAR
```

```
FOR Counter:=1 TO 5 BY 1 DO
  Var1:=Var1+1;
END_FOR;
```

If <target value> equals the limit of <variable>, it will enter an infinite loop. Assuming the variable Counter in the above example is of type BYTE (0 to 255), setting <target value> to 255 will cause the controller to enter an infinite loop. Therefore, the <target value> should not be set to the limit of <variable>.

◦ WHILE loop



The WHILE loop is similar to the FOR loop in usage. The difference is that the termination condition of the WHILE loop can be any logical expression. It can be a condition. When the condition is met, the loop is executed. The specific format is as follows.

```
WHILE <Boolean expression>
  <statement content> ;
END_WHILE;
```

The execution order of the WHILE loop is as follows:

- Calculate the return value of <Boolean expression>.
- When the value of <Boolean expression> is TRUE, repeatedly execute <statement content>.

- If the initial value of <Boolean expression> is FALSE, the <statement content> will not be executed, and the program will jump to the end of the WHILE statement. The flowchart is shown in the following figure.

CAUTION

If the value of <Boolean expression> is always TRUE, an infinite loop will occur. It can be avoided by changing the condition of the loop statement. For example, an incrementing or decrementing counter can be used to avoid an infinite loop.

The following example shows that as long as Counter is not zero, the program within the loop body will be executed continuously.

```
VAR
Counter: BYTE; (*counter*)
Var1:WORD;
END_VAR
```

```
WHILE Counter<>0 DO
  Var1 := Var1+2;
  Counter := Counter-1;
END_WHILE
```

- The difference between a REPEAT loop and a WHILE loop is that the REPEAT loop checks the termination condition only after the statement content has been executed. This means that the loop will be executed at least once regardless of the termination condition.

```
REPEAT
  <statement content>
UNTIL
  <Boolean expression>
END_REPEAT;
```

The execution order of the REPEAT loop is as follows:

- When the value of <Boolean expression> is FALSE, execute <statement content>.
- When the value of <Boolean expression> is TRUE, stop executing <statement content>.
- After the first execution of <statement content>, if the value of <Boolean expression> is TRUE, then <statement content> is only executed once.

If the value of <Boolean expression> is always TRUE, an infinite loop will occur. It can be avoided by changing the condition of the loop statement. For example, an incrementing or decrementing counter can be used to avoid an infinite loop.

When the counter value is 0, the loop stops.

```
VAR
Counter: BYTE;
END_VAR
```

```
REPEAT
  Counter := Counter+1;
UNTIL
  Counter=0
END_REPEAT;
```

The result is that the REPEAT loop is entered in each program cycle. With Counter being a BYTE (0 to 255), 256 calculations are performed in each cycle.

Each time the REPEAT statement is entered, Counter is initially set to 1, and the statement content Counter := Counter + 1 is executed 256 times in each cycle until the Counter variable overflows to 0, at which point the loop exits. The variable then overflows again after being incremented repeatedly, repeating this process.

- Jump statement
  - EXIT statement

    The EXIT statement can be used in FOR, WHILE, and REPEAT loops. The inner loop will immediately stop regardless of the termination condition. The specific format is as follows.

    ```
    EXIT;
    ```

    The following example uses the EXIT statement to avoid division by zero in iterative statements.

    ```
    FOR Counter:=1 TO 5 BY 1 DO
    INT1:= INT1/2;
    IF INT1=0 THEN
    EXIT; (*To avoid division by zero*)
    END_IF
    Var1:=Var1/INT1;
    END_FOR
    ```

When INT1 equals 0, the FOR loop ends.

- CONTINUE statement

  This instruction is an extension of the IEC 61131-3 standard. The CONTINUE statement can be used in FOR, WHILE, and REPEAT loops.

  It interrupts the current loop, ignoring the code after it and starting a new iteration immediately. The specific format is as follows.

```
CONTINUE;
```

  The following example uses the CONTINUE statement to avoid division by zero in iterative statements.

```
VAR
Counter: BYTE; (*loop counter*)
INT1,Var1: INT; (*intermediate variable*)
Erg: INT; (*output result*)
END_VAR
```

```
FOR Counter:=1 TO 5 BY 1 DO
   INT1:= INT1/2;
 IF INT1=0 THEN
      CONTINUE; (*To avoid division by zero*)
  END_IF
   Var1:=Var1/INT1; (*Executed only when INT1 is not 0*)
END_FOR;
Erg:=Var1;
```

- JMP statement

  The JMP statement can be used for unconditional jumps to lines of code marked with a label. The specific format is as follows.

```
<label>:
.
JMP <label>;
```

  <label> can be any identifier, placed at the beginning of a line of code. The JMP statement is followed by a pre-defined label, indicating the target jump position. When the JMP statement is executed, the program jumps to the line corresponding to the label.

Infinite loops can be avoided by using the JMP statement with IF conditions to control jumps.

The following example uses the JMP statement to implement a counter looping within the range of 0 to 10.

```
VAR
nCounter: BYTE;
END_VAR
```

```
Label1:nCounter:=0;
Label2:nCounter:=nCounter+1;
IF nCounter<10 THEN
  JMP Label2;
ELSE
  JMP Label1;
END_IF
```

In the above example, Label1 and Label2 are labels, not variables, so they do not need to be declared as variables in the program.

The IF statement is used to determine if the counter is within the range of 0 to 10. If it is, the JMP Label2 statement is executed, and the program jumps to the Label2 position in the next cycle to execute the program nCounter:=nCounter+1, incrementing the counter by 1. Otherwise, the program jumps to the Label1 position and execute nCounter:=0, resetting the counter to zero.

- RETURN statement
  The RETURN statement is used to exit a program organization unit (POU). The specific format is as follows.

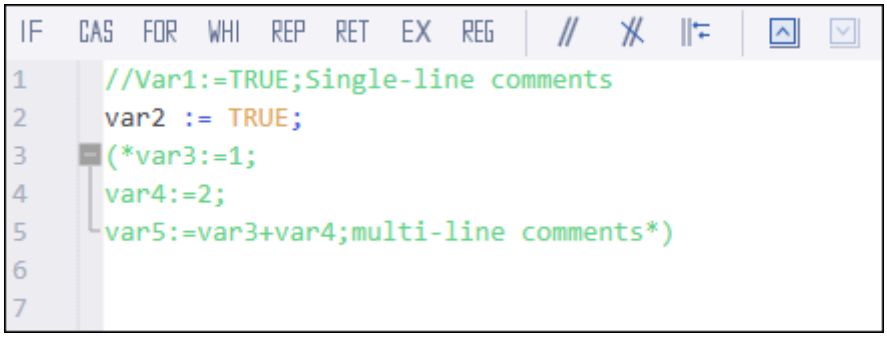
```
RETURN;
```

The following example uses an IF statement for condition check. When the condition is met, the program is immediately terminated.

```
VAR
nCounter: BYTE;
bSwitch: BOOL; (*switch signal*)
END_VAR
```

```
IF bSwitch=TRUE THEN
  RETURN;
END_IF;
nCounter:= nCounter +1;
```

If bSwitch is FALSE, nCounter always increments by 1. If bSwitch is TRUE, nCounter retains its value from the previous cycle and immediately exits the POU.



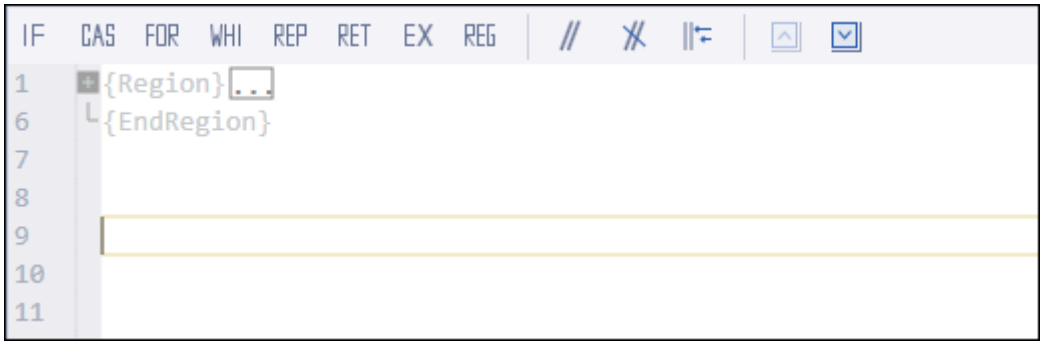
- Empty statement
  An empty statement does not execute any content. The specific format is as follows.

```
;
```

- Comment
  Annotations are an important part of the program, making it more readable without affecting its execution. They can be added anywhere in the declaration or execution sections of the ST editor.

  Annotations can be added with the following two methods in ST programming:

  - Single-line annotations start with "//" and continue until the end of the current line, as shown in the following figure. The ST editor also supports the shortcut "Ctrl + /" to add a single-line annotation, and "Ctrl + ." to remove a single-line annotation.
  - Multi-line annotations start with (* and end with *), as shown in the figure.



- Region statement

  The Region compilation statement is used to group multiple lines into a block in the text editor. The block can be named. The Region statement supports nesting, and can be used in the ST editor and all declaration editors.

  The expanded and collapsed views of code with the Region statement are shown in the figure below.

The syntax format of the Region statement is as follows:

```
{Region} or {Region "name"}
//Code
//Code
{EndRegion}
```

> **NOTE**
>
> When naming a Region block, the name must be separated from the Region start marker by at least one space, no consecutive characters are allowed. The name is case-insensitive and can be "Region".

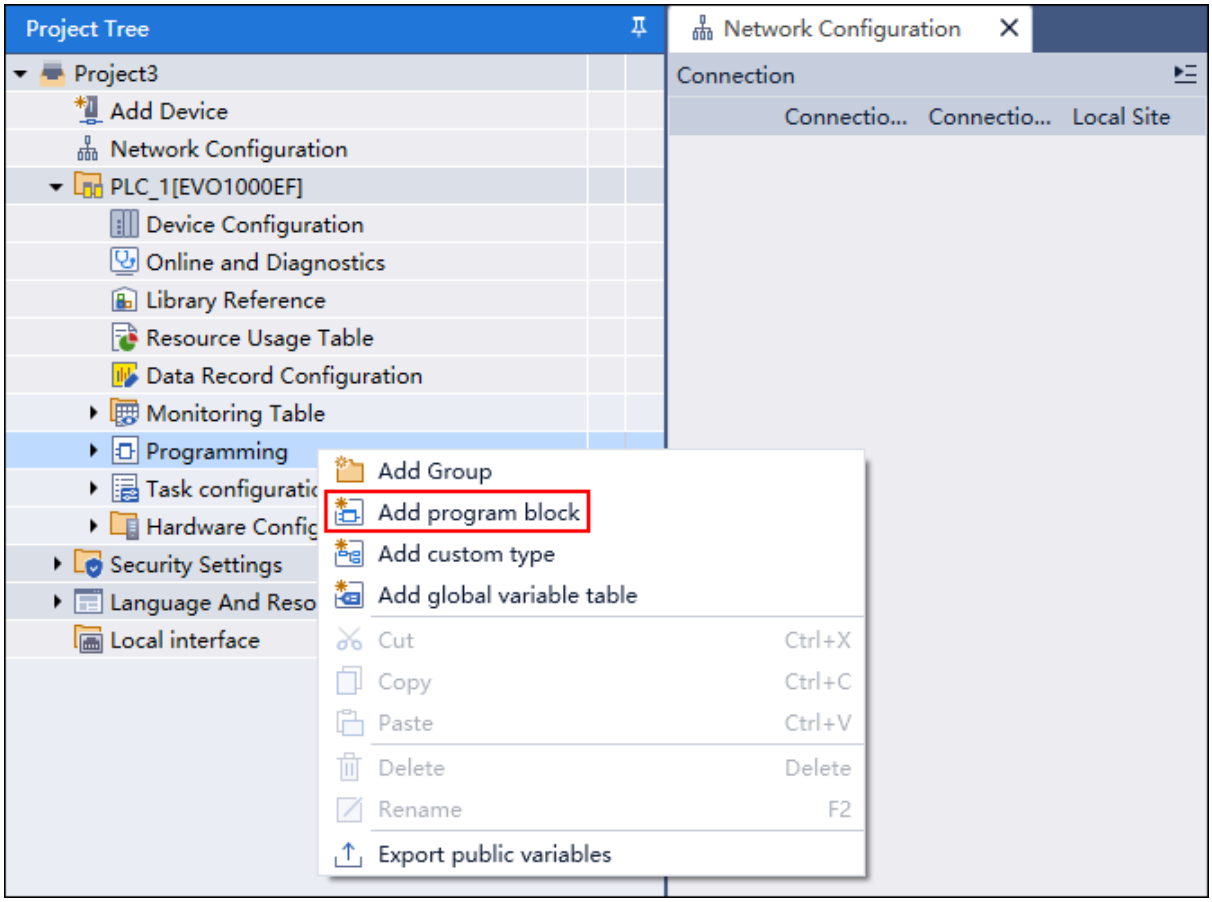
10.1.5 CFC Language Programming

10.1.5.1 CFC Language Overview

Continuous function chart (CFC) is a graphical programming language, an extension of the IEC 61131-3 standard. It describes control logic graphically. By customizing the names and execution order of each block, it facilitates the implementation of process calculations as well as the assignment of tasks to programs and function blocks, enabling intuitive design and implementation of complex control systems.

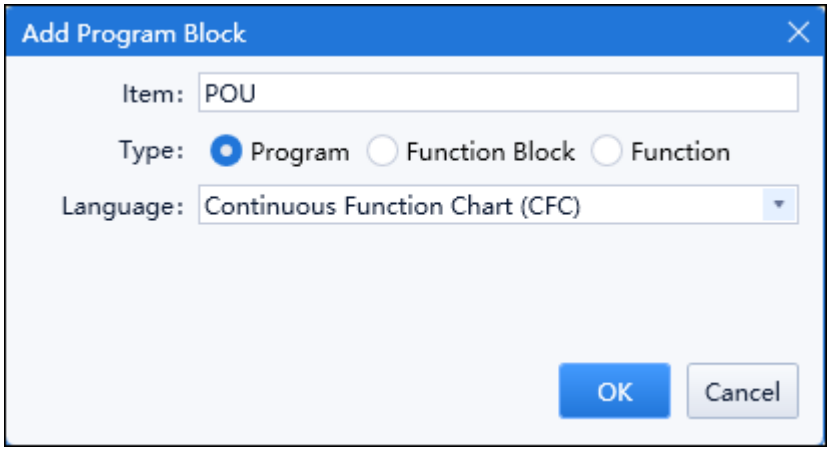
The design and implementation of the CFC language involve the design of signal acquisition circuits, signal conversion, and data processing software workflows, playing a crucial role in industrial automation systems.

10.1.5.2 CFC Creation and Management



10.1.5.2.1 Creating a CFC Program Block

Prerequisites

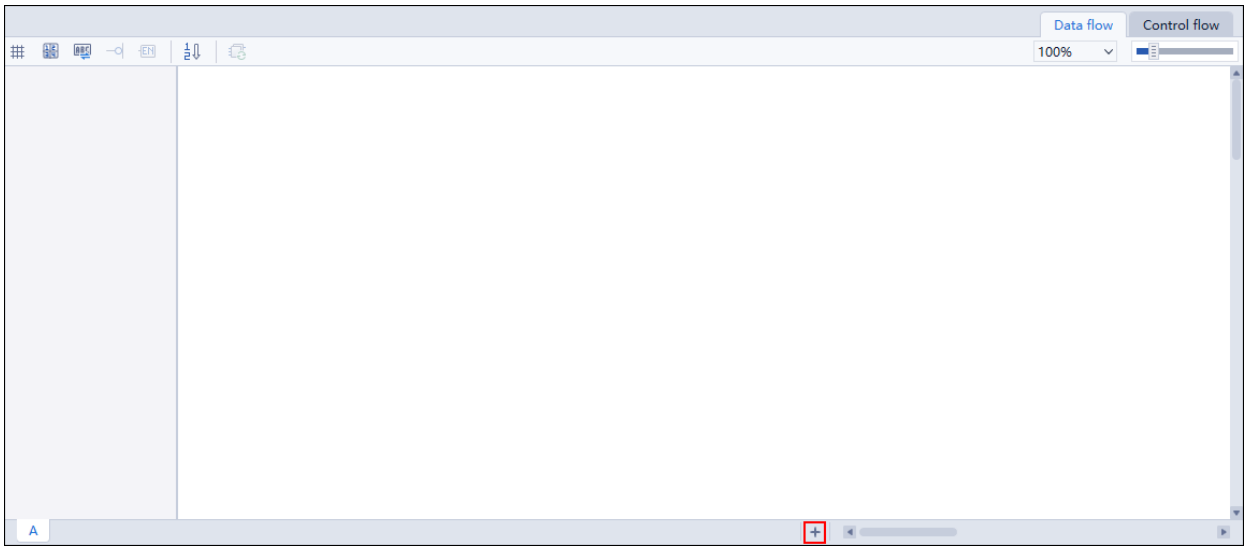


- A project has been created.
- A device has been added.

Procedure

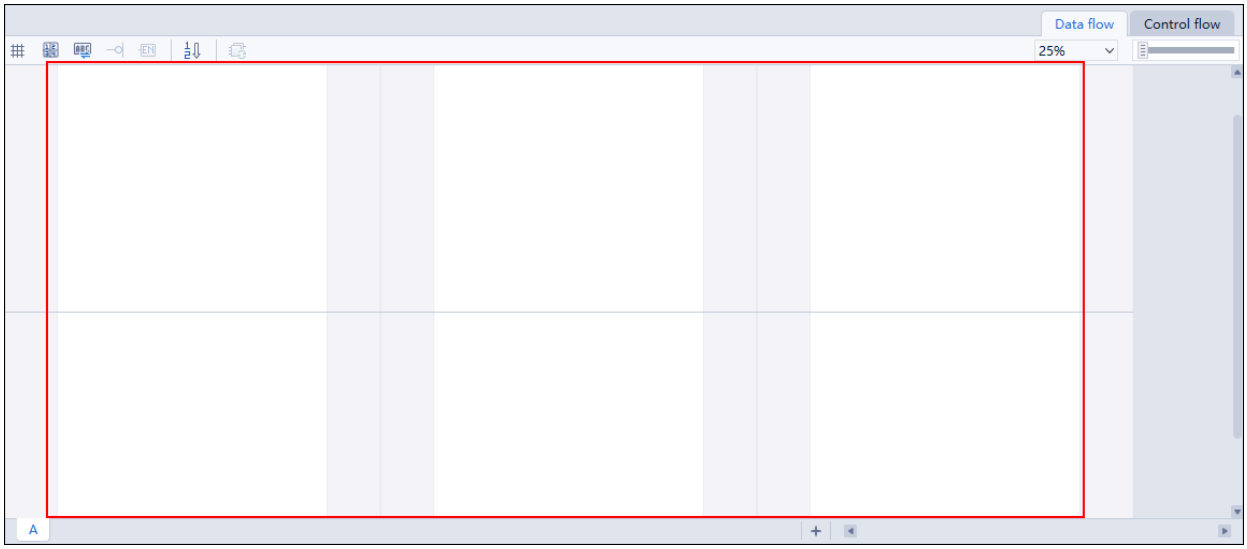
1. Right-click "Programming" in the project tree and select "Add program block".

2. In the pop-up window, set the name of the program block, select "Program" for the type, and select "Continuous function chart (CFC)" for the IEC language, as shown in the figure below.



3. Click "OK" and the CFC editor will be automatically opened.

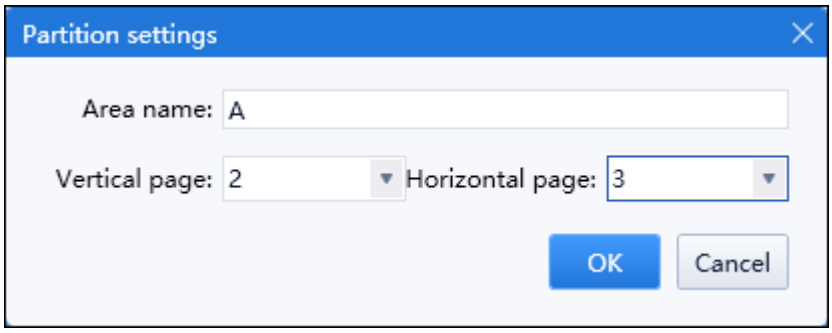
10.1.5.2.2 Creating a CFC Partition



A CFC program block has a partition (with the default name A) by default. Partitions can be added as needed, with a maximum of 26 partitions.

Adding a partition

In the CFC editor, click + in the partition operation bar to add a partition. New partitions are named sequentially as A, B, C, D, etc.



A partition has 6 sub-pages by default, as shown in the figure below. Each sub-page is an independent editing area and does not support adding or deleting.

Partition operations

- Partition settings

  1. Right-click the partition name and select "Partition setting".
  2. In the pop-up window, set the partition name and vertical/horizontal page, as shown in the figure below.

Parameter	Description
Partition name	Customizes the partition name.
Vertical/Horizontal page	Adjusts the sub-page layout. The default sub-page layout is 2*3 (2 rows and 3 columns), meaning the vertical page count is 2 and the horizontal page count is 3. Supported configurations include: 2*3, 3*2, 1*6, 6*1.

- Deleting a partition

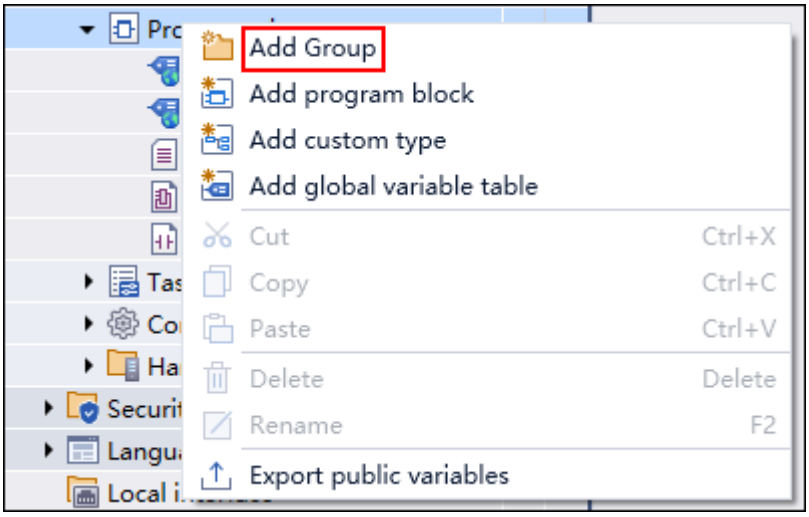
  1. Right-click the partition name and select "Delete partition."
  2. In the pop-up window, click "Yes" to delete the partition.

- Switching view

  Double-click the blank space to the left or right of each sub-page to switch between the sub-page and the overview page.

- Displaying sub-page number

  Click  in the toolbar of the CFC editing area to display the page numbers sub-pages.

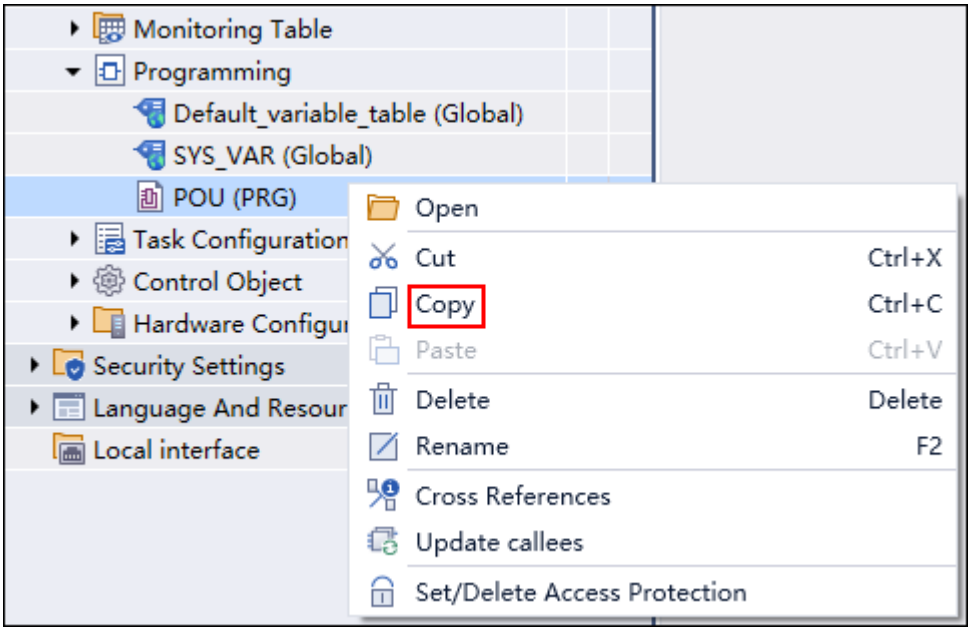


10.1.5.2.3 Managing a CFC Program Block and Group

10.1.5.2.3.1 Adding a Group

A first-level group can be created under the "Programming" node, which supports expanding multiple levels of subgroups.

1. Right-click "Programming" in the project tree and select "Add group".



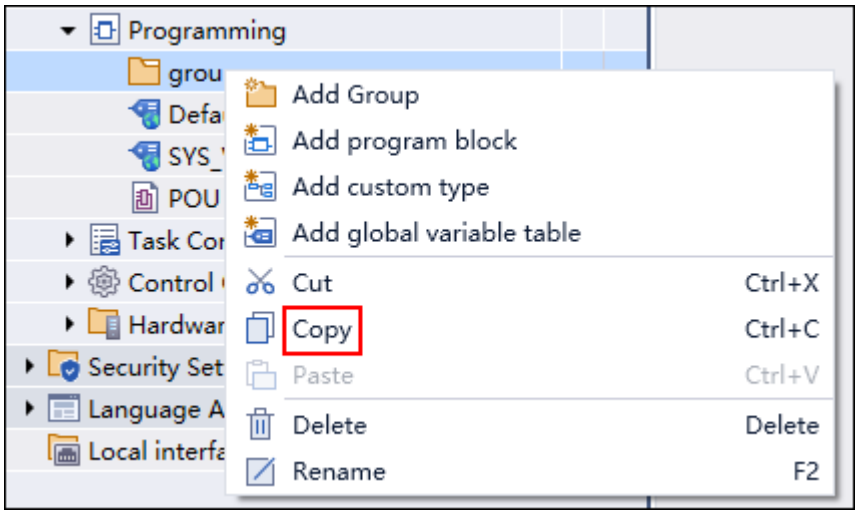
2. In the pop-up window, customize the group name and click "OK".

10.1.5.2.3.2 Copying a CFC Block/Group

Copying/Pasting CFC program blocks

CFC program blocks can be copied and pasted within a PLC device, between PLC devices in the same project, or between different projects. The internal program logic of the CFC program block remains unchanged after pasting.

1. Right-click a CFC program block name under the "Programming" node, and select "Copy".

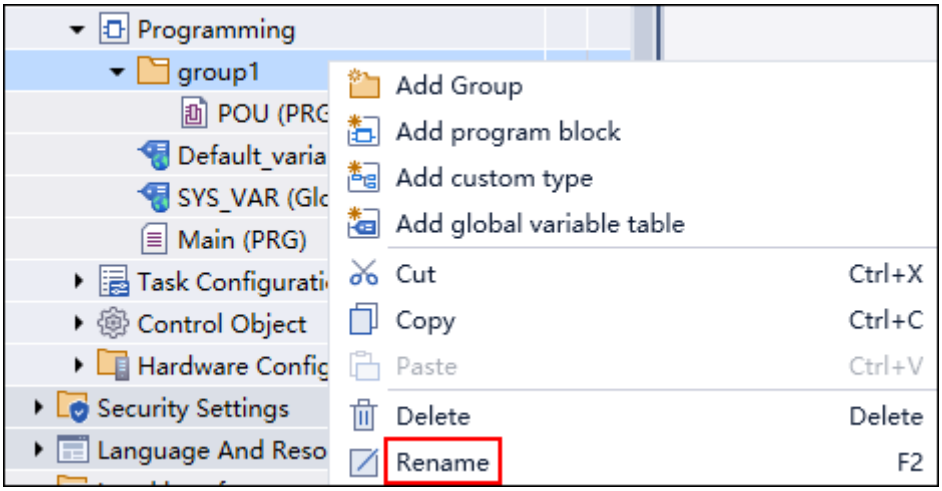


2. Right-click the "Programming" node or its subordinate node, and select "Paste" to paste the copied LD program block at the corresponding location.

Copying/Pasting groups

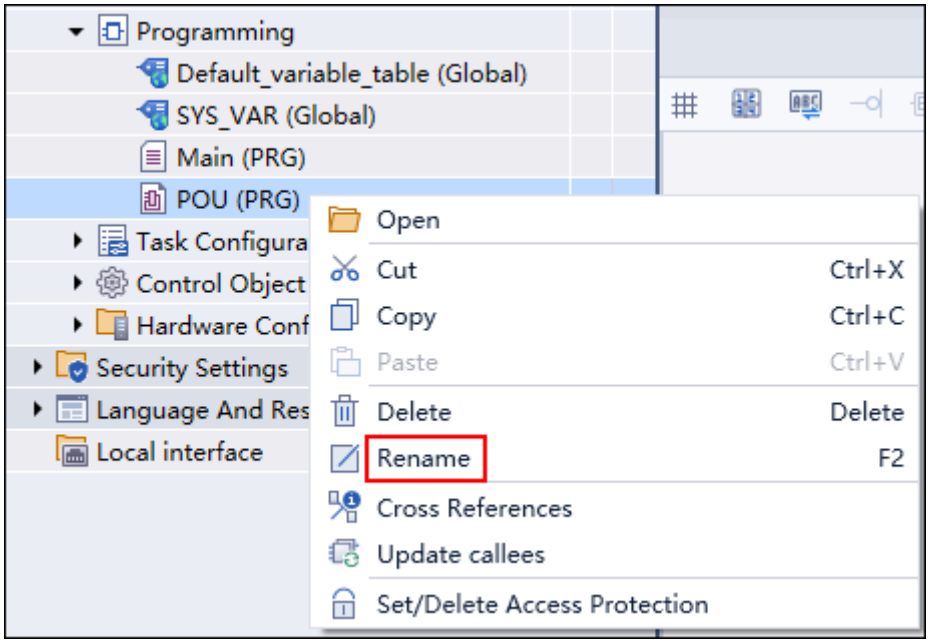
Groups can be copied and pasted within a PLC device, between PLC devices in the same project, or between different projects. When copying a group, the system also copies the resources added to the group, including subgroups, program blocks, global variable tables, and so on.

1. Right-click a group name under the "Programming" node, and select "Copy".



2. Right-click the target location under the "Programming" node, and select "Paste".

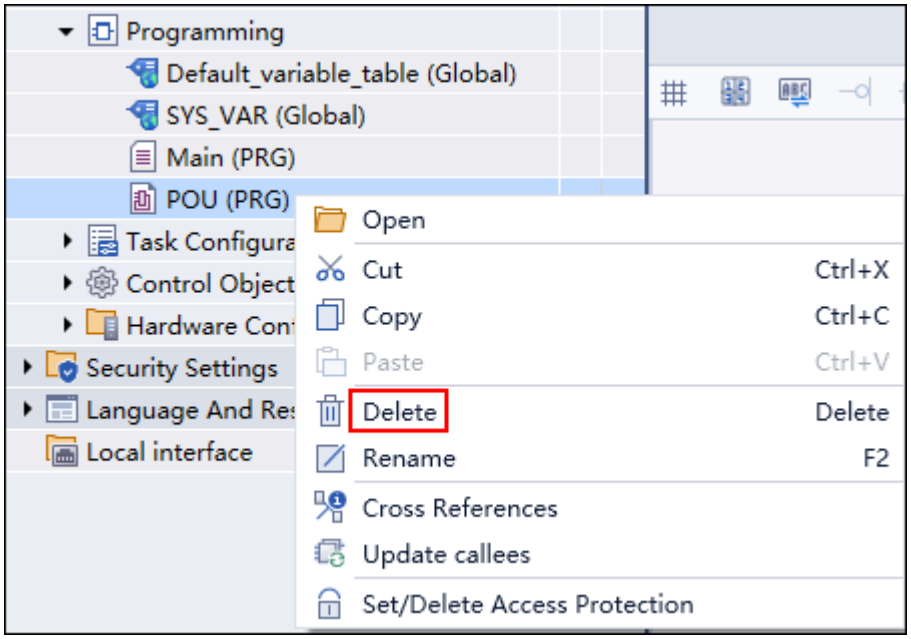
10.1.5.2.3.3 Renaming a CFC Block/Group



Renaming groups

Right-click a group name under the "Programming" node, select "Rename", and modify the group name.

Renaming CFC program block

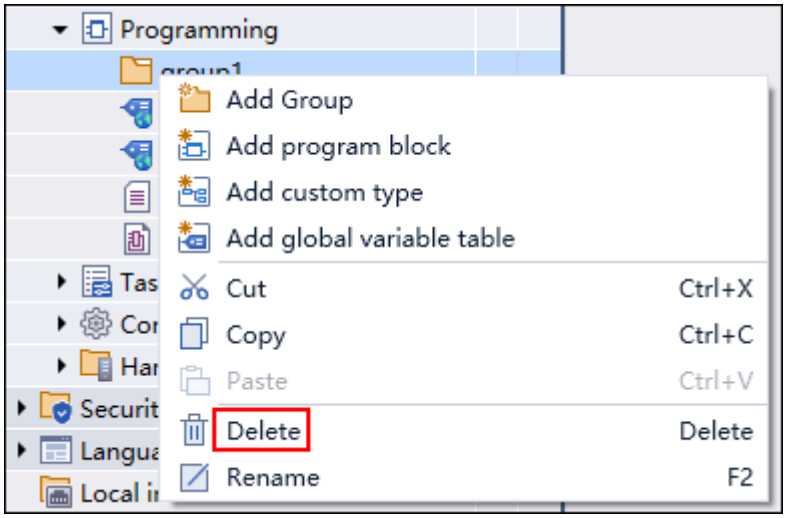


Right-click a CFC program block name under the "Programming" node, select "Rename", and modify the group name.

10.1.5.2.3.4 Deleting a CFC Program Block

After the CFC program block is deleted, its record in the task is also deleted.

1. Right-click a CFC program block name under the "Programming" node, and select "Delete".

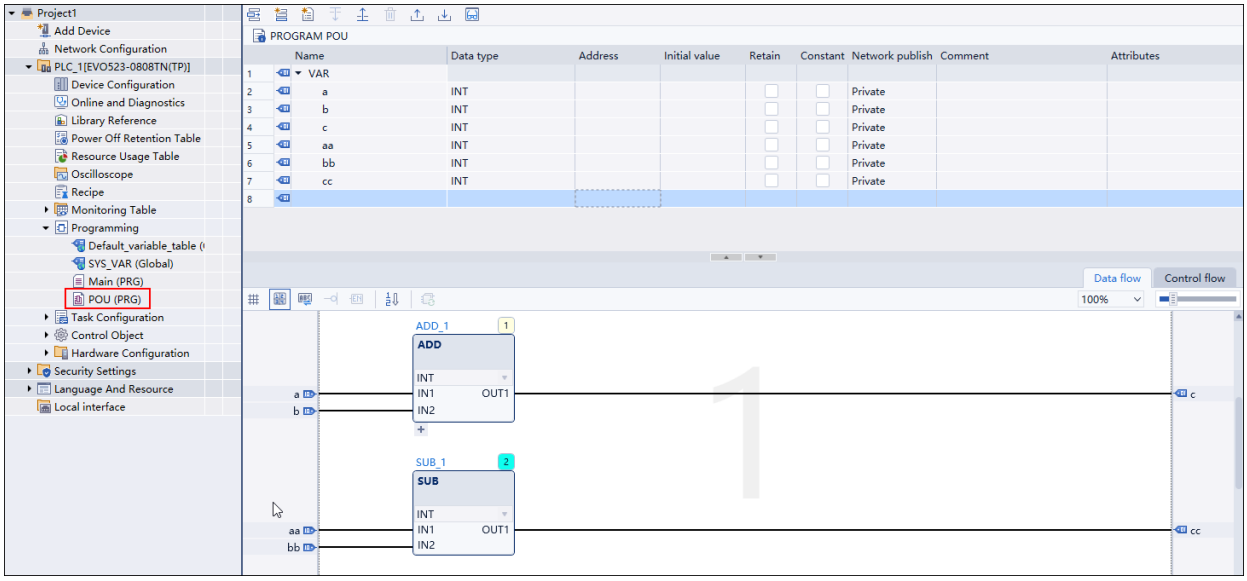


2. Click "OK" in the pop-up window.

10.1.5.2.3.5 Deleting a Group

When deleting a group, the system will also delete the resources added within the group, including subgroups, program blocks, global variable tables, and so on.

1. Right-click a group name under the "Programming" node, and select "Delete".



2. Click "OK" in the pop-up window.

10.1.5.3 CFC Editor

10.1.5.3.1 CFC Editor Interface

Double-click the CFC language program block (identifier: ) under the "Programming" node.

The CFC editor is divided into the variable declaration area and the program editing area, which can be collapsed and expanded using and .

The program editing area is divided into data flow and control flow display modes as follows.

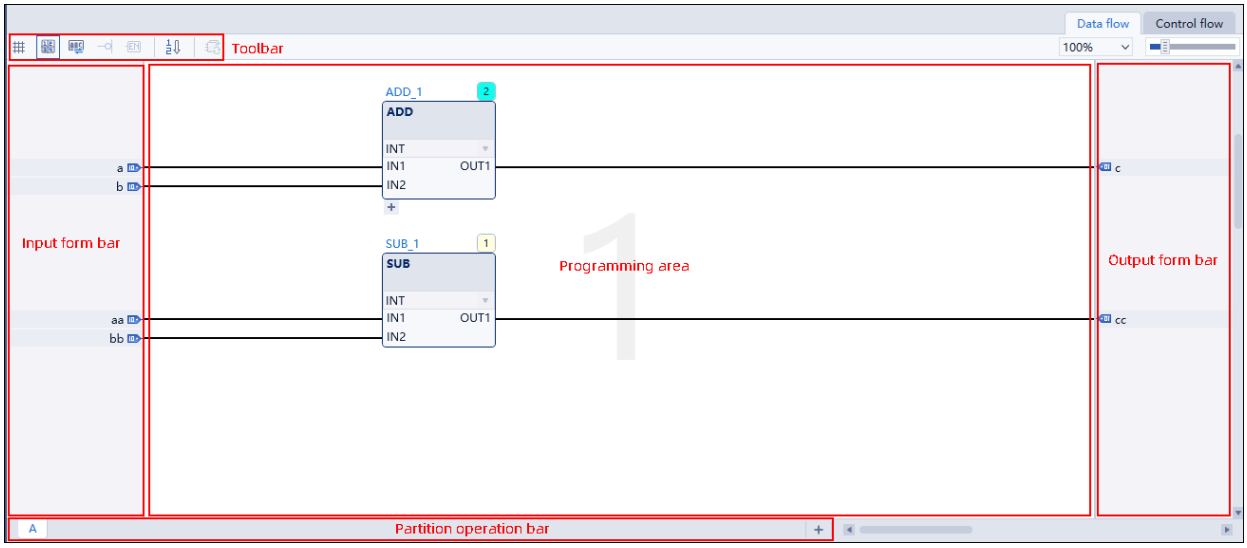


Figure 10-1-5-3-1-1 Data flow mode

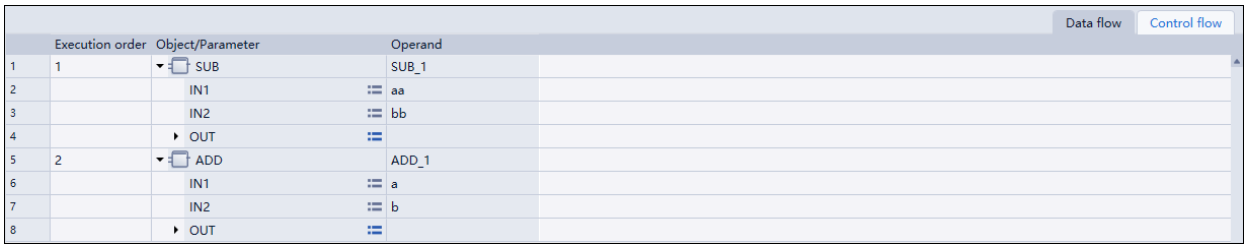

Figure 10-1-5-3-1-2 Control flow mode

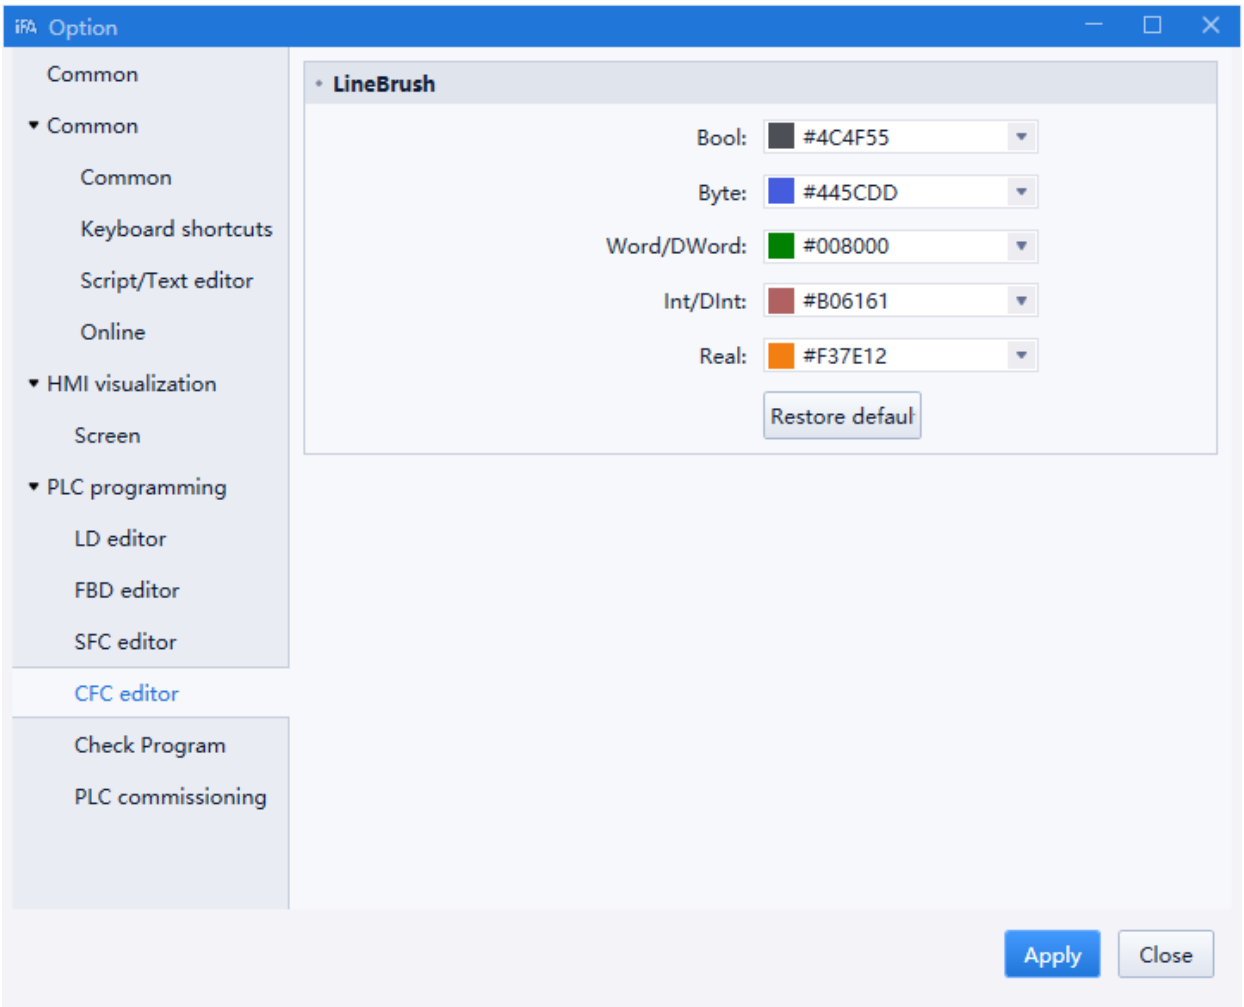

Table10-1-5-3-1-1 Introduction to the toolbar in data flow mode

Description	Icon	Description
Grid		Grid reference lines are displayed in the programming area.
Page number		Sub-page numbers are displayed.
Switch between parameter names and annotations		When input/output pins are set with aliases, the display mode of the pins can be switched between pin names and aliases.

Description	Icon	Description
Inversion		Inverts BOOL pins.
Add/Delete EN/ENO		Add or delete EN/ENO for function blocks.
Sort by data flow		Reorders operation blocks via algorithms according to the logic of "input first, then output". If there are multiple networks, sort them from top-left to bottom-right.
Update all parameters		Updates the parameters of the FC, FB instances called by the CFC program in the program editing area with one click.

10.1.5.3.2 CFC Editor Settings

Select "Tools > Option" from the menu bar. On the "PLC programming > CFC editor" tab, set the color of variable connections in the CFC editor. Click "Restore defaults" to reset all connection colors to their default values.

10.1.5.3.3 CFC Program Configuration Options

Configuring CFC programs

In the CFC editor, it is easy to use graphical tools to configure CFC programs graphically in data flow mode through simple drag-and-drop operations. Users can also switch to control flow mode and view and

manage the relevant textual information in the data flow through a list. Users can switch between the two configuration methods at any time without any restrictions.

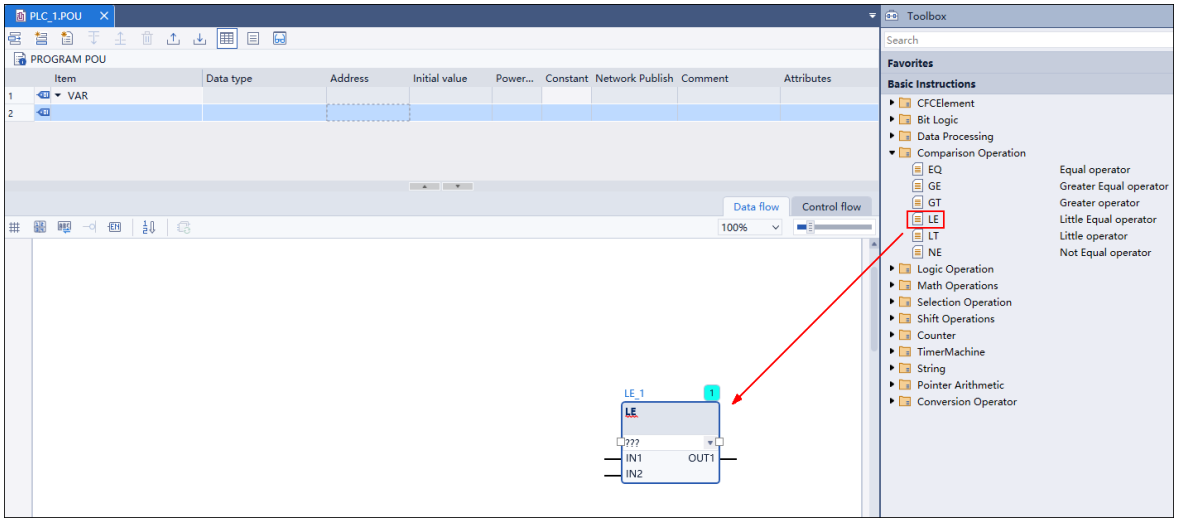
Configuring CFC programs in data flow mode

Data flow is a graphical representation of configured CFC programs, where users can insert, connect, rename, and resort statements and blocks with drag-and-drop operations and shortcuts.

Configuring CFC programs in control flow mode

Control flow displays the relevant information of elements with execution order in the data flow in a tabular form. Users can view the associations between statements and blocks, their execution order, and pin connections.

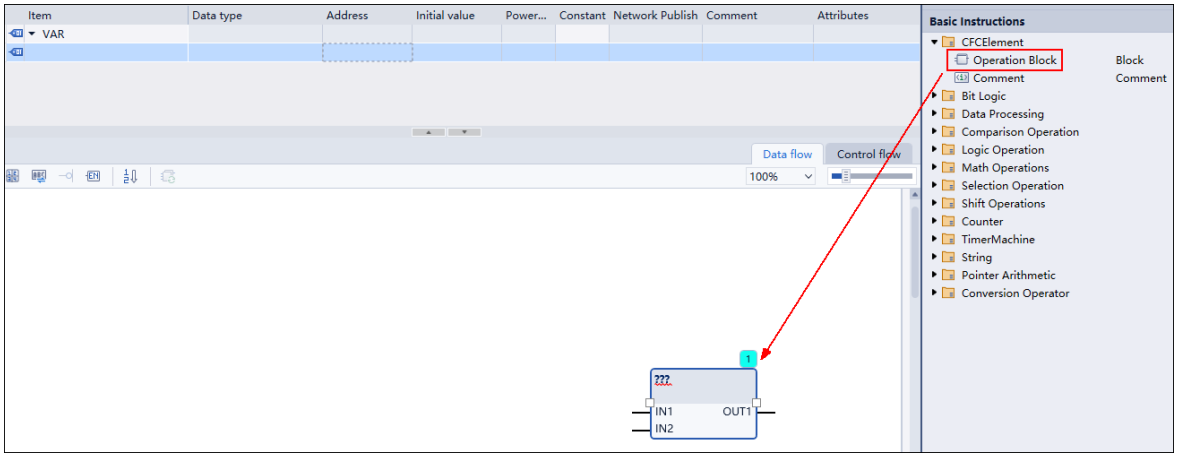
Currently, control flow only supports reordering statements and blocks. After reordering, execution order of the data flow will also be adjusted accordingly.



10.1.5.4 CFC Object Creation and Management

10.1.5.4.1 Creating an Operation Block

Adding an operation block



- Dragging elements from the toolbox
  - Adding an instruction

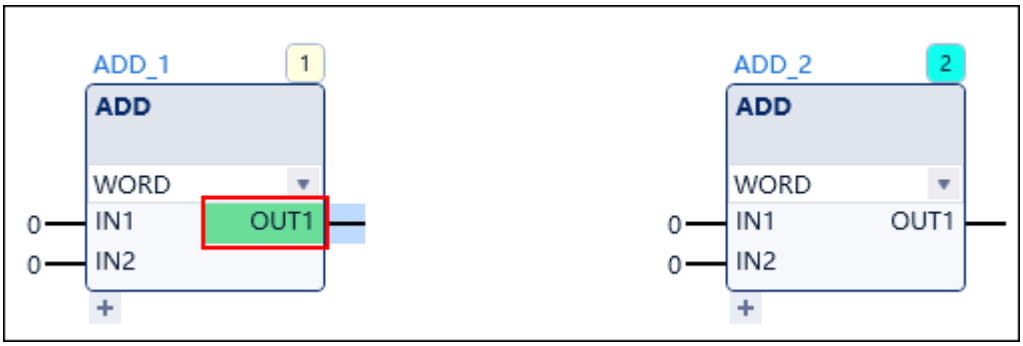
    Drag and drop instructions from the toolbox on the right to the programming area.

  - Adding an empty operation block

    In the toolbox, drag an "Operation block" element under "Basic instructions > CFC elements" to the programming area. It is suitable for users who are familiar with functions and function blocks.

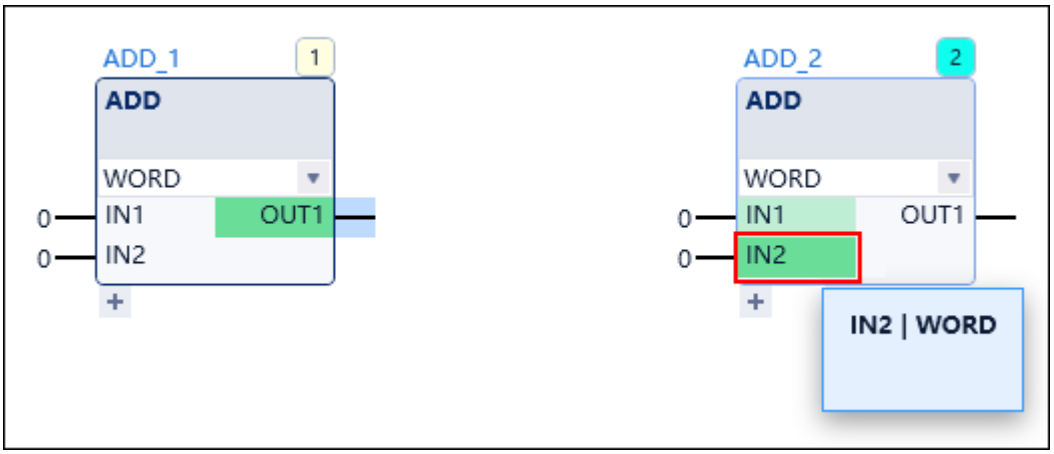
- Dragging from the project tree

  Drag and drop an FB or FC instance from the project tree to the programming area.



Connecting operation block pins

Operation block pins can be connected within the same subpage, across subpages, across partitions, and across program blocks.

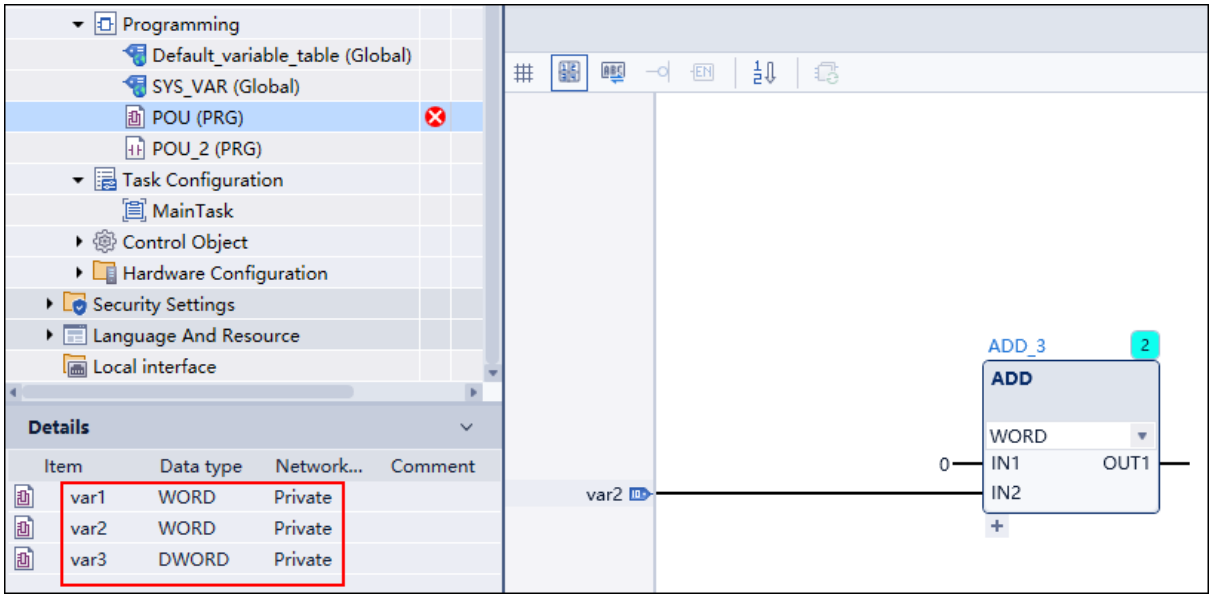


> **NOTE**
>
> All the following methods for connecting two pins support connecting from an Out pin to an In pin, as well as from an In pin to an Out pin, meaning the order of operation is not restricted.

- Connection by dragging
  - Click and hold the pin of the source operation block. All connectable pins are highlighted. Move the mouse to the target pin to complete the connection.
  - If the target pin is already in the form bar (in the blank space to the left/right of each sub-page), you can directly drag the source pin to the form bar object.

- Connection by clicking
  1. Double-click the pin of the operation block to activate the starting pin, which will be highlighted, as shown in the figure below.

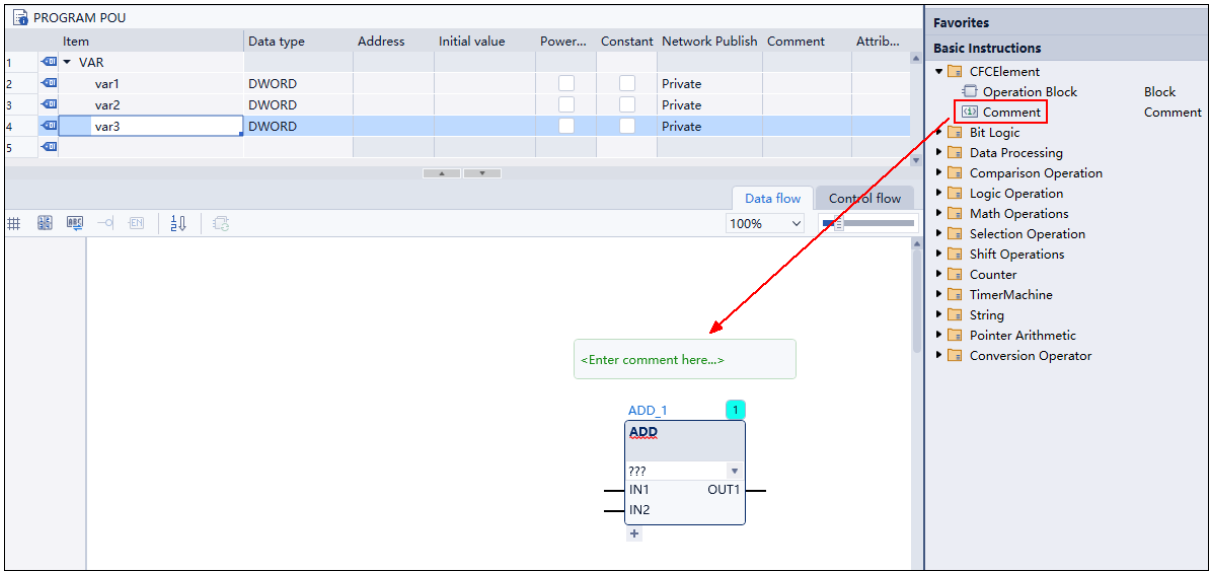
  2. When hovering the mouse over the highlighted starting pin, connectable pins will be highlighted (as shown in the IN1 and IN2 pins of ADD_2 in the figure below). Click the target pin to complete the connection.



Connecting operation block pins and variables

The pins of the operation block can be connected to variables in the variable table. After connection, a connection line is automatically generated in the form bar. There are two methods:

- Drag and drop variables from the variable table to the In or Out pin of the CFC operation block.

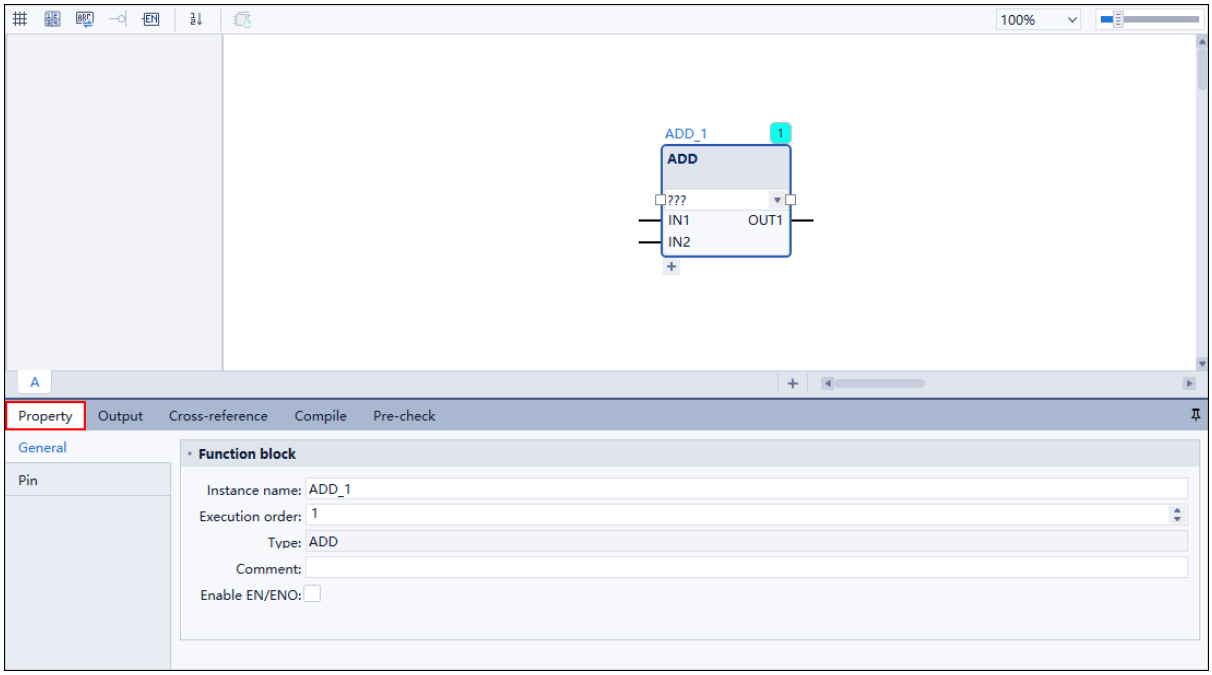


- Drag and drop variables from the "Details" window (in the lower left corner of the interface) to the In or Out pin of the CFC operation block.

10.1.5.4.2 Creating a Comment

Annotate the program content.

1. In the toolbox, drag a "Comment" element under "Basic instructions > CFC elements" to the programming area.



2. Double-click the annotation block and enter the content directly.

10.1.5.4.3 Managing an Operation Block

10.1.5.4.3.1 Configuring Operation Block Properties

1. When selecting an operation block in the programming area, the "Property" tab in the monitoring area displays the properties of this operation block.

2. Configure the operation block and pin properties in the "Property" tab. The parameter descriptions are as follows:
   - General Settings

Name	Editable	Note
Instance name	Yes	Indicates the operation block name, which must be unique within the current program block. The default is type_number. It is user-defined, and supports Chinese, letters, numbers, and underscores (_), with a maximum length of 128 characters.

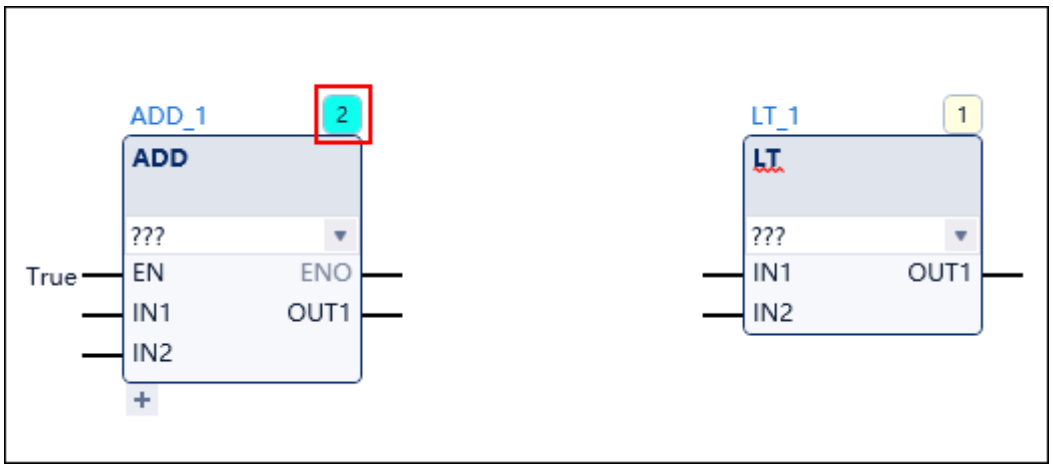
Name	Editable	Note
Execution order	Yes	Indicates the execution order of the selected operation block within the program block, starting from 1 and incrementing according to creation order. It must be unique and continuous within the current CFC program block. It can be modified in both data flow mode and control flow mode.
Type	No	Indicates the function of the selected operation block, such as ADD, MIN, and DIV.
Comment	Yes	Used to explain the function of the operation block in the program or process. It is user-defined and is empty by default.
Enable EN/ENO	Yes	Indicates whether to enable EN/ENO pins for the selected operation block. It is user-defined and is disabled by default.
Network Public Property	No	Indicates whether the pins of the selected operation block are public, which is consistent with the instance definition of variables.

◦ Pin

Name	Editable	Description
Expression	No	Indicates the function of the pin.
Alias	Yes	Indicates the alias of the pin. The maximum length is eight characters.
Value	Yes	Indicates the value corresponding to the pin. When there is no connected object, the default value is displayed and users can manually enter a value.
Unit	Yes	Indicates the process unit represented by the pin data, such as °C, kg/L, and m/s. It is user-defined and is empty by default.
Data Type	No	Indicates the data type of the pin.
Pin Type	No	Indicates whether the pin is input or output.
Monitorable	Yes	Indicates whether the pin displays online values during online commissioning. It is user-defined and is non-onitorable by default.
Invisible	Yes	Indicates whether the operation block displays the pin. It is user-defined and is unchecked by default, indicating that the operation block displays the pin.

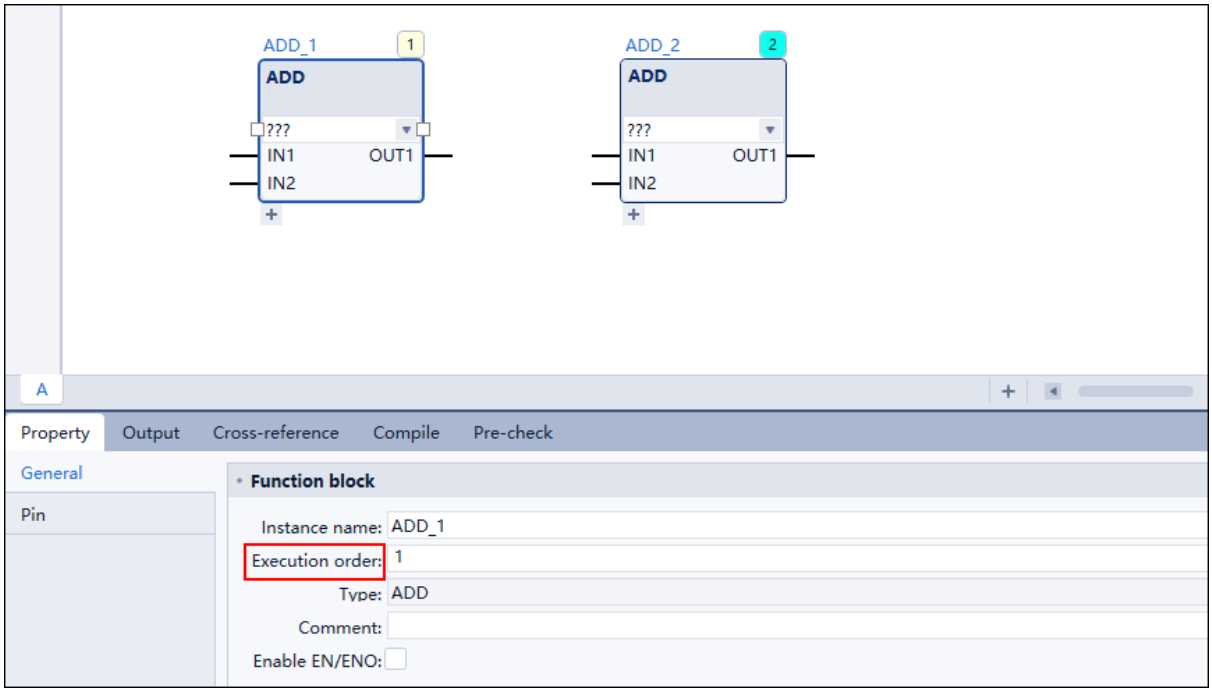
Name	Editable	Description
Network public property	No	Indicates whether HMI and other devices can access the value of the pin. It is consistent with the configuration in the variable type definition.
Comment	Yes	Indicates the additional explanation of the function and meaning of the pin. It is user-defined and is empty by default, with a maximum length of 64 characters.

NOTE



In addition to configuring pin comments in the "Property" tab, you can also directly right-click the target pin and select "Pin comment" for quick editing.

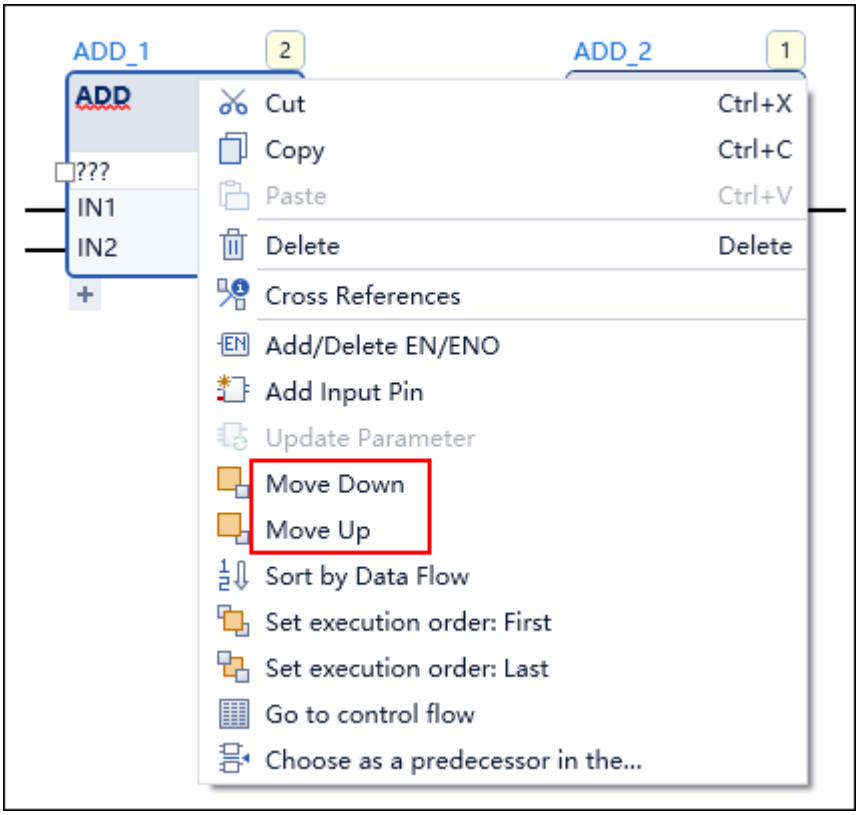
10.1.5.4.3.2 Reordering an Operation Block



The numbers on the operation blocks represent their execution order, which can be adjusted in several ways:

Adjusting execution order in data flow mode

- Modifying numbers
  Double-click the number of an operation block in the programming area, and input a new value. For example, there are three operation blocks, A1, B2, and C3. If the sequence number of C is changed to 1, the execution order will automatically be resorted to C1, A2, and B3.



- Modifying order parameters
  Select an operation block in the programming area, and modify the "Execution order" parameter in the "Property" tab of the monitoring area.

- Moving down/up

  Right-click an operation block in the programming area and select "Move down" or "Move up" to move the block backward or forward by one sequence number.

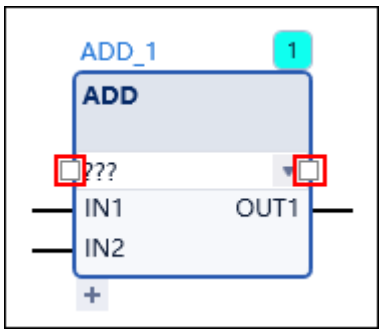
- Set head/tail

  Right-click an operation block in the programming area and select "Set head" or "Set tail" to set the block as the first or last to execute.

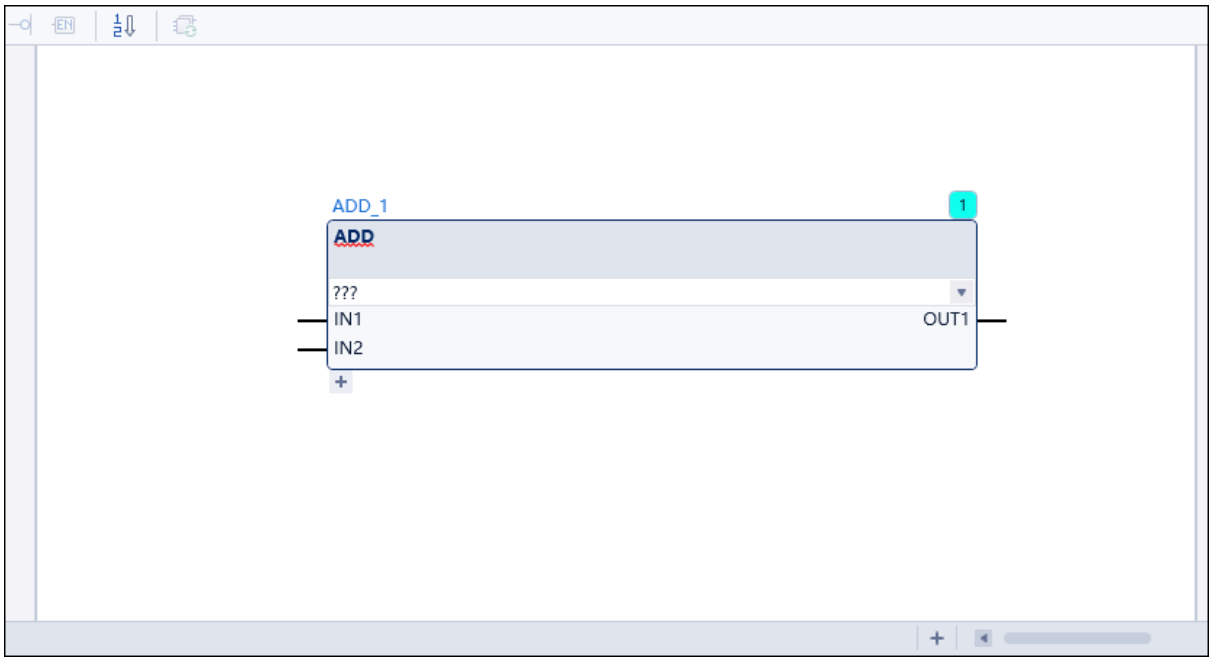
- Sorting by data flow

  Click in the programming area toolbar or right-click an operation block and select "Sort by data flow" to automatically adjust the execution order.

Adjusting execution order in control flow mode



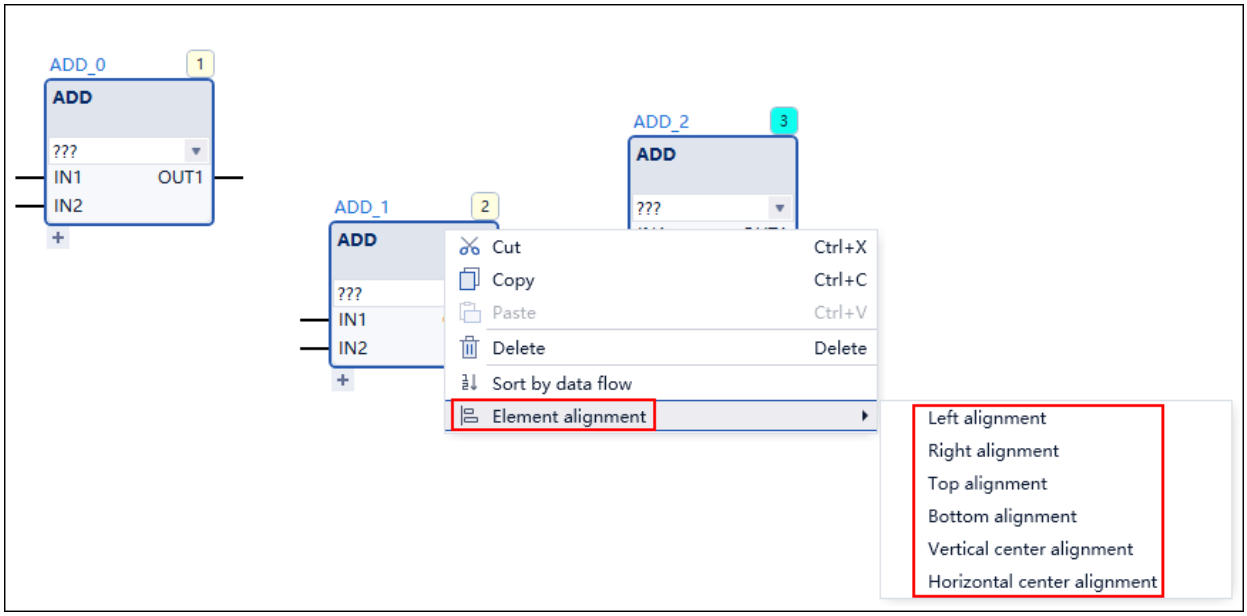
Click the "Control flow" tab in the upper right corner of the programming area to switch to the control flow mode. Double-click the cells in the "Execution order" column to modify the order.



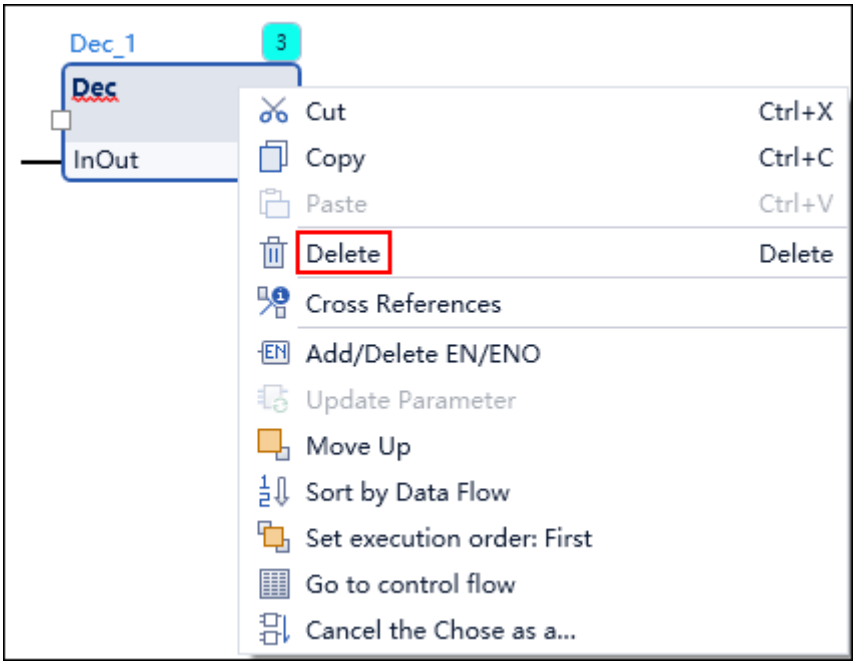
10.1.5.4.3.3 Resizing an Operation Block

The width of an operation block can be adjusted by dragging with the mouse.

1. Click the left/right border of an operation block, and a drag box as shown in the figure below will appear.



2. Move the mouse to the drag box, and drag left/right. The effect is shown in the figure.
   During the dragging process, the system automatically constrains the left and right boundaries. The maximum width of the operation block is 80% of the subpage width.



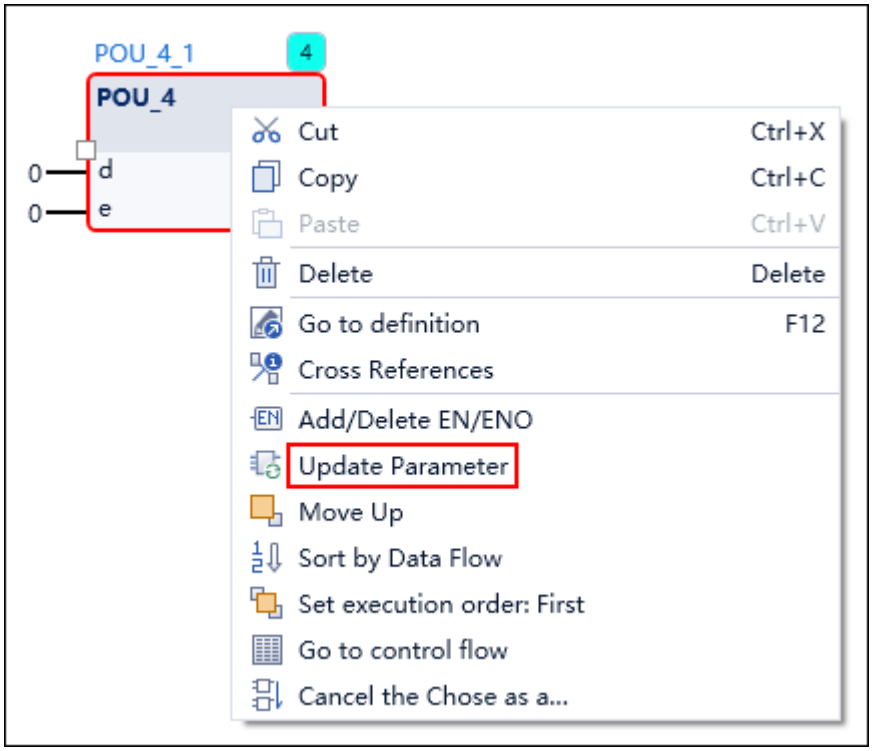
10.1.5.4.3.4 Repositioning an Operation Block

Right-click the operation block to move in the programming area and select "Element alignment" to adjust the alignment position of the operation block.

10.1.5.4.3.5 Deleting an Operation Block

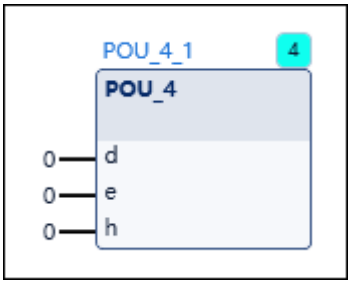
Right-click an operation block in the programming area and select "Delete" to delete the block. After deleting a CFC operation block, all connections to its pins are also deleted.

10.1.5.4.3.6 Updating an Operation Block



When an FB or FC instance is called by a CFC program, the parameters of the called object can be updated with one click in the programming area. Parameter updates are mainly used when parameters are added, deleted, or when their data types are modified. If the parameter names of the called object change, they will be automatically renamed, without the need for manual updates.

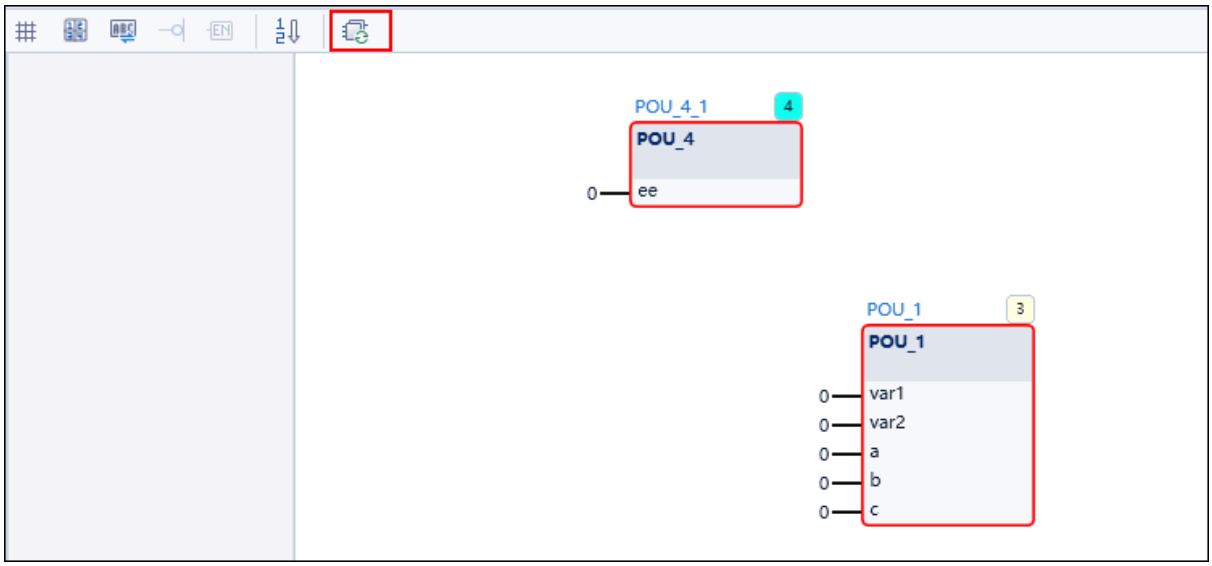
Prerequisites



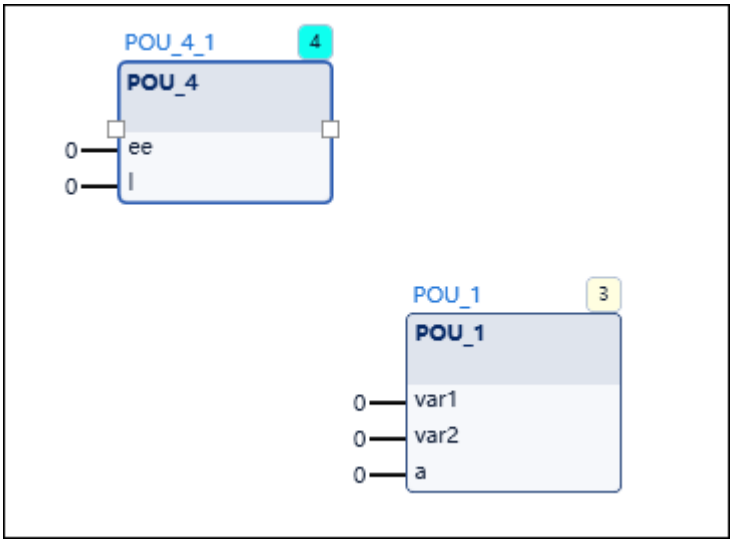
- An FB or FC instance has been called by a CFC program.
- Parameters in the called FB or FC instance are added, deleted, or their data types are modified.

Updating parameters of an individual block

1. In the editing area, right-click a CFC program block and select "Update parameters", as shown in the following figure.



2. Update the parameters of the target instruction to align the parameters in the current program block with the latest parameter configuration of the called object.



Updating all parameters

1. In the toolbar of the program editing area, click the "Update all parameters" icon, as shown in the following figure.

2. All program blocks in the editing area that have parameter changes will be updated in batches.

10.1.5.4.3.7 Operation Block Operations

Introduction to the operation block menu

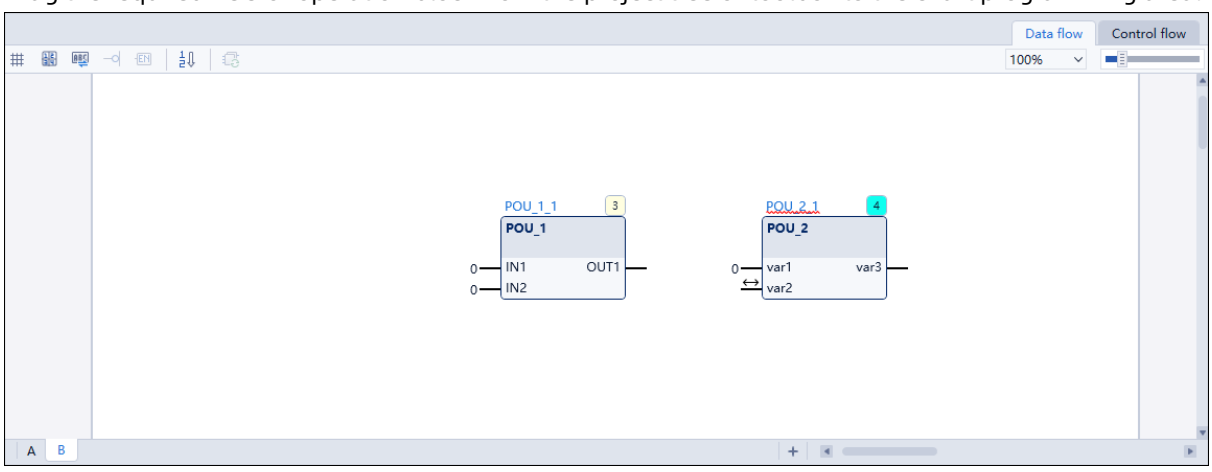
Function	Description
Cut	Cuts the operation block.
Copy	Copies the operation block.
Paste	Pastes the operation block.
Delete	Deletes the operation block.
Cross-reference	Used to view where an operation block is referenced in the program. This helps users quickly locate the usage and position of the specified operation block, improving commissioning and maintenance efficiency.
Add/Delete EN/ENO	Adds or deletes EN/ENO for operation blocks.
Update parameters	Updates the parameters of the FC/FB instances called by the CFC program with one click.
Move down	Moves the execution order of the operation block back by one position.
Move up	Moves the execution order of the operation block forward by one position.
Sort by data flow	Reorders operation blocks via algorithms according to the logic of "input first, then output". If there are multiple networks, sort them from top-left to bottom-right.
Set head	Sets the operation block as the first to execute.
Set tail	Sets the operation block as the last to execute.
Go to control flow	Locates the position of the selected operation block in the control flow.
Switch pin monitoring status	Switches the pin monitoring status between monitorable and non-monitorable modes.
Leading block of execution order	Newly inserted operation blocks will follow the leading block. For example, there are three operation blocks, A1, B2, and C3. If B is set as the leading block, the newly inserted operation block D will follow B, resulting in A1, B2, D3, and C4.

10.1.5.5 Input/Output Parameter Connection

10.1.5.5.1 Setting Input/Output Parameters

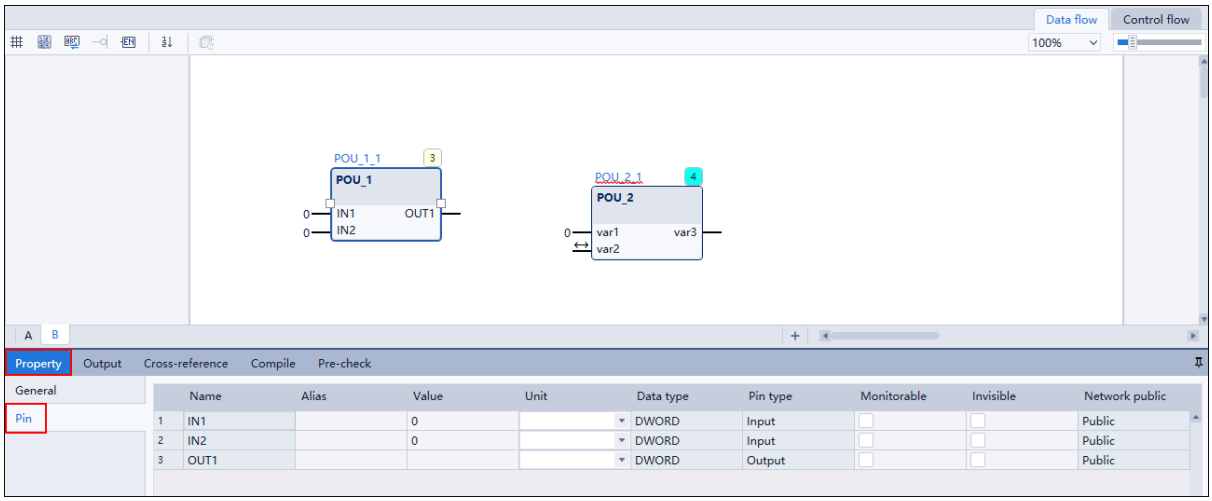
In CFC programming, operation blocks contain two types of predefined pins: input pins and output pins. For pins of basic data types, the system automatically assigns initial default values. When pins are connected to external objects, the connection signals will override the default values of the pins.

Users can define variables of various types in the variable declaration area and connect them to the operation block pins with matched data types, as follows.



Variable Source	Operation Block Pin	Variable type
Current POU	Input pins	VAR
		VAR_IN_OUT
		VAR_INPUT
		VAR_OUTPUT
	Output pins	VAR
		VAR_IN_OUT
		VAR_OUTPUT
External POU	Input pins	VAR
		VAR_INPUT
		VAR_OUTPUT
	Output pins	VAR_INPUT
Default Variable Table	Input pins and output pins	VAR_GLOBAL
Global variable table	Input pins and output pins	VAR_GLOBAL

Prerequisites



- The CFC editor has been opened.
- The CFC editor is in data flow mode.
- The required operation blocks or instructions have been added to the chart.

Procedure

1. Drag the required POU or operation block from the project tree or toolbox to the chart programming area.

2. Select an operation block. Its pin parameters can be viewed and configured in the "Property > Pin" tab in the monitoring area. For detailed parameter descriptions, see Configuring Operation Block Properties > Pin.

Result

The input and output parameters are configured for the operation block. When the CFC chart is downloaded to the device, these parameters will default to all the attributes that have been set.

10.1.5.5.2 Adding an Input Parameter

When inserting an instruction into the CFC chart programming area, the instruction will default to include relevant input and output parameters. For expandable instructions, the system allows the addition of extra input parameters individually. These instructions will be marked with + at the bottom.

Prerequisites

- The CFC editor has been opened.
- The CFC editor is in data flow mode.
- An expandable instruction has been added to the chart.

Procedure

1. Select the required instruction in the CFC chart programming area.
2. Perform one of the following actions:
   Click + to add an input pin.
   Right-click the instruction and select "Add input pin".

Result

The selected instruction is added with one or more input parameters. Select the instruction. Its pin parameters can be viewed and configured in the "Property > Pin" tab in the monitoring area.

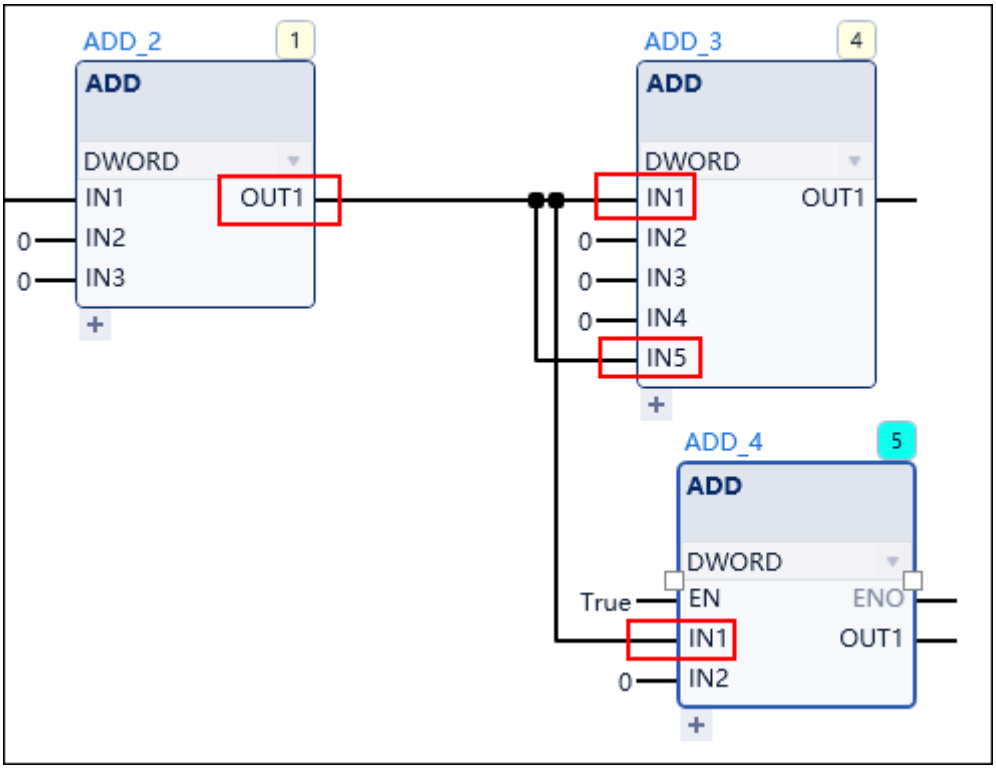
- Click + to add an input pin.
- Right-click the instruction and select "Add input pin".

10.1.5.5.3 Connection Routing

In CFC programming, connection refers to connecting the input and output parameters of operation blocks. The connection routing refers to the path through which data flows from a source object (such as an output

pin of an operation block or a variable) to the input pin of a target operation block. This path is automatically generated by the editor and cannot be manually adjusted by users.

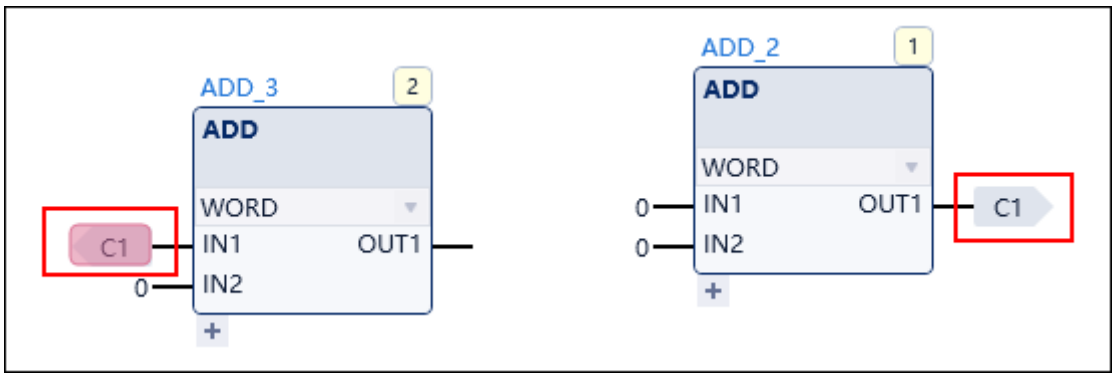
Connection requirements



- Pins of operation blocks within the same chart can be directly connected.
- The same output pin can be connected to multiple different input pins.
- The output pin of an operation block can be connected to its own input pin.
- Pins of operation blocks support connections across partitions, sub-pages, and program blocks.
- Pins of operation blocks can be connected to the variables in the variable declaration area, "Details" window, or the global variable table.
- It is prohibited to connect multiple different output pins to the same input pin.
- It is prohibited to connect the input pins of the same or different operation blocks to each other.
- It is prohibited to connect the output pins of the same or different operation blocks to each other.

NOTE

- Connections are only allowed between pins with matching data types.
- If the data type of either end of a connection is modified after the connection is established:
  - The compiler issues an alarm but the connection is allowed when there is an available implicit conversion.
  - A compilation fault is reported when there is no valid conversion.

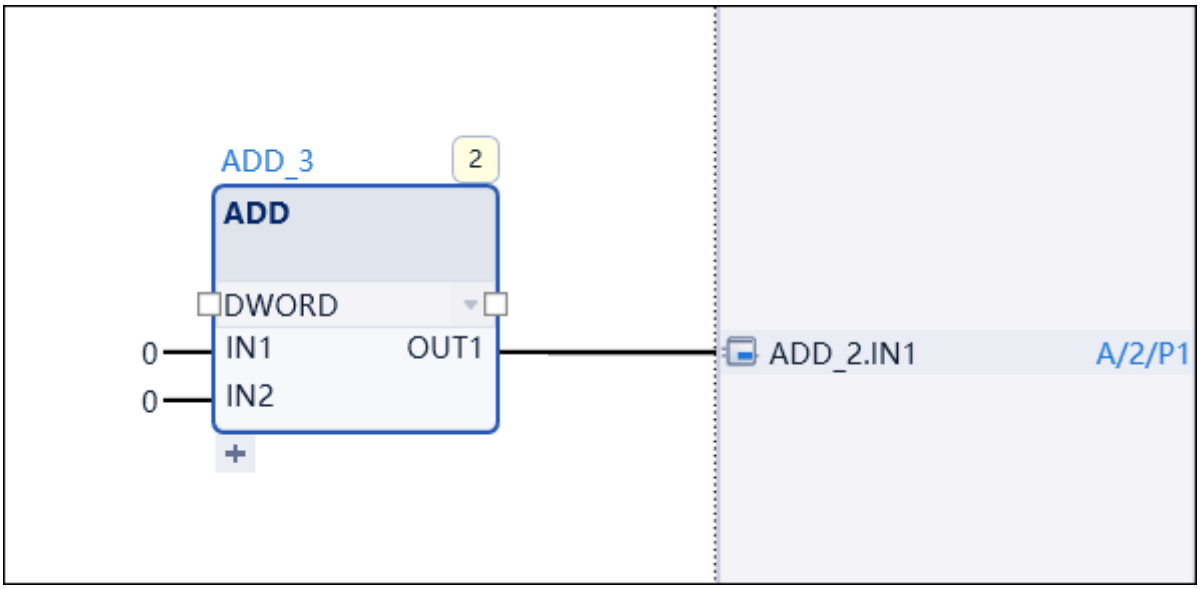


One-output-to-many-inputs connection

One-output-to-many-inputs connection refers to connecting one output parameter to several input parameters. The following figure shows a case where the same output pin is connected to three different input pins.

Incompletely displayed connection

Due to layout limitations, connection lines that cannot be fully displayed will be replaced by connection markers automatically inserted by the editor.



NOTE

- Markers with the same number indicate the same connection.
- If there are multiple connection markers in the chart, their numbers increase sequentially.
- Double-click any marker to quickly locate the matching marker.

Connection across pages and partitions

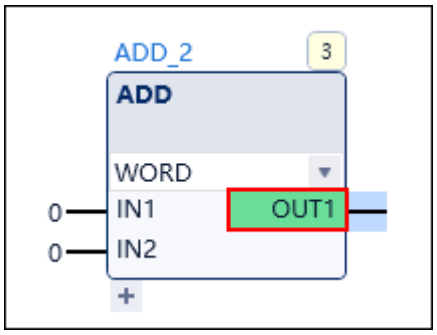
If the connection line extends beyond the current form boundary, the connection information will be displayed in the form bar (the blank space to the left or right of each sub-page).

NOTE

- A connector will be automatically inserted in the form bar, displaying the name of the target object and parameters.
- If the connection target is located in another CFC chart, the name of the target chart will also be displayed.
- If the CFC chart contains multiple sub-pages, the sub-sub-page name and form number will also be displayed.

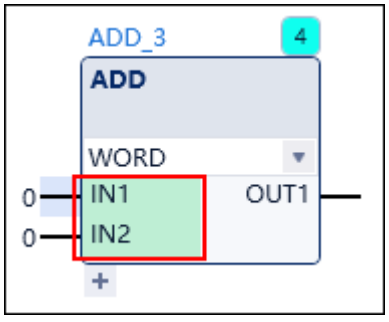
10.1.5.5.4 Connecting Input and Output Parameters

There are three ways to connect input parameters and output parameters.



- Double-click > click
- Copy > click
- Drag and drop

Prerequisites



- The CFC editor has been opened.
- The CFC editor is in data flow mode.
- The required operation blocks or instructions have been added to the chart.

Procedure of double-clicking > clicking

1. Double-click the source pin; the pin will be highlighted and the connection function is activated.

2. Move the mouse to the target pin. If connection is allowed, the target pin will be displayed in a light color. Click any target pin to create a connection.

3. With the source pin being active, move the mouse and click other target pins to quickly establish connections from a single source pin to multiple target pins.

Procedure of copying > clicking

1. Copy the source pin; the pin will be highlighted and the connection function is activated.
2. Move the mouse to the target pin. If connection is allowed, the target pin will be displayed in a light color. Click any target pin to create a connection.
3. With the source pin being active, move the mouse and click other target pins to quickly establish connections from a single source pin to multiple target pins.

Procedure of dragging and dropping

1. Click and hold the source pin. All connectable pins will be displayed in a light color.
2. Drag the source pin to the target pin and drop it to complete connection.

10.1.5.5.5 Modifying a Connection

During the development of CFC charts, users can adjust the connections between parameters by dragging the input and output pins of operation blocks to dynamically update control logic.

Prerequisites

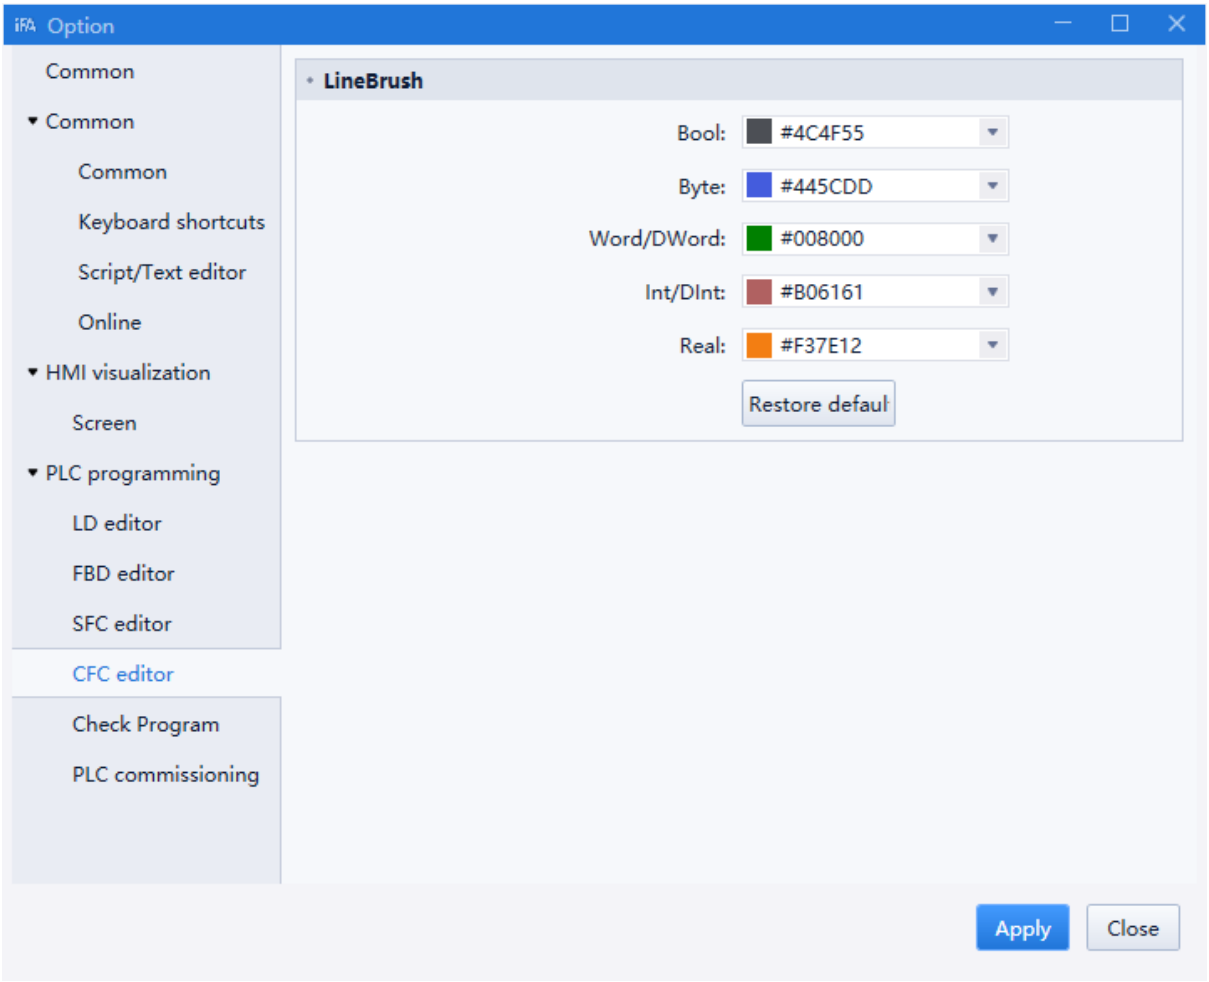
- The CFC editor has been opened.
- The CFC editor is in data flow mode.
- Connections have been established between operation blocks.

Procedure

1. Select the connection line to be modified.
2. Perform one of the following actions:
   Connect the input pin to another output pin.
   Connect the output pin to another input pin.
3. Release the mouse to complete the reconnection.

Result

The connection is successfully updated. The system will automatically adjust the layout of the connection lines to ensure a clear chart. Data flow will be transmitted according to the new connection path.



10.1.5.5.6 Changing Connection Line Color

In the CFC "Data flow" view, connection lines are displayed in different colors based on data type. The data type of the data source automatically determines the color of its connection lines; users can customize the mapping between data types and colors.

Procedure

1. In the software menu, select "Tools > Options > CFC editor".

2. Set the connection line colors for different data types. Click "Restore defaults" to reset all connection line colors to their default values.

Result

Connection line colors are changed successfully.

NOTE

- For operands with undefined data types, their connection lines are black by default.
- The new color setting will apply to connection lines in all open CFC views.

10.1.5.5.7 Deleting a Connection

To interrupt the data flow connection between operation blocks, users can delete the established connections.

Prerequisites

- The CFC editor has been opened.
- The CFC editor is in data flow mode.
- Connections have been established between operation blocks.

Procedure

1. Right-click the connection line to be deleted.

2. Select "Delete" or directly press the Delete key.

> NOTE
>
> If an operation block is deleted, the associated connections will also be deleted.

Result

The selected connection is successfully deleted, and the data flow connection between operation blocks is interrupted. The associated pins revert to an unconnected status, allowing users to reconfigure parameters or establish new connections.

10.1.5.5.8 Text Connection

In CFC, text connection is used to preserve the connection relationships of the original calculation blocks when copying and pasting them within the same POU, between different POUs, or between different PLCs. Text connection marks are automatically generated upon pasting and cannot be manually modified by the user.

CFC calculation block operations and text connection

- **Copy and paste**
  When copying and pasting CFC calculation blocks, the connection relationships of their input pins are also pasted accordingly, as detailed below:
  1. During copy, only the established connections on the input pins are copied.
  2. After pasting, the system searches the current scope for the pins or variables corresponding to the copied connections.
  3. If the target pin or variable is found, a connection is automatically established; if not found, a text connection mark is generated and a fault is reported. Once the target pin or variable becomes available, right-click the text connection mark and select "Text connection" to complete the connection.
- **Move**
  When moving a calculation block, its existing text connection marks move with it. Currently, connection relationships are preserved only when moving within the same POU.
- **Delete**
  When deleting a calculation block, its text connection marks are also deleted.

10.1.5.6 CFC Configuration and Commissioning

10.1.5.6.1 Execution Order Between CFC Blocks

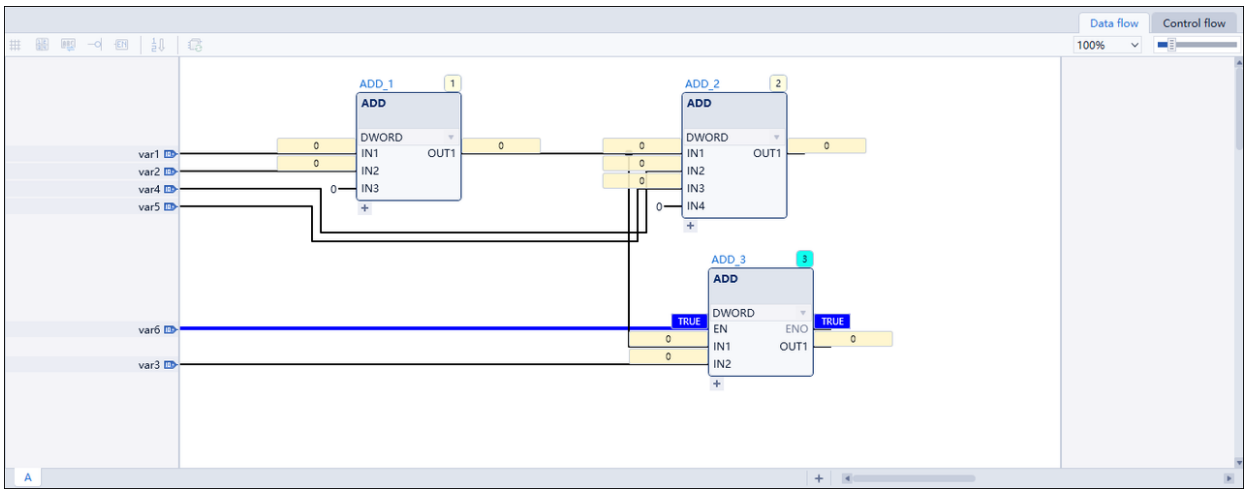
The CFC program blocks are executed in the order of the POU calls as configured in the task configuration window. Users can adjust the execution order of the program blocks. For details, see Call POU.

10.1.5.6.2 Execution Order of Operation Blocks within a CFC Block

The operation blocks in a CFC program block are executed in numerical order. Users can adjust the execution order of the operation blocks. For details, see 10.1.5.4.3.2 Adjusting Operation Block Execution Order.

10.1.5.6.3 CFC Instance Call

A CFC instance call allows dragging one program block into the programming area of another program block. The call relationships are as follows:



- A CFC program block can call FB and FC program blocks written in LD or ST language under the "Programming" node, but cannot call PRG program blocks.
- A CFC program block cannot call methods, actions, or properties under FB.
- A CFC program block cannot call other PRG program blocks written in non-CFC languages.
- A CFC program block cannot call SFC programs.
- Program blocks written in other languages under the "Programming" node cannot call CFC program blocks.

10.1.5.6.4 CFC Commissioning

Continuous function charts support monitoring, operand writing, and forced value writing in online mode.

Monitor

When monitoring programs in online mode, the online values of operation block pins can only be displayed in real-time with the "Monitorable" property set to "Yes".

NOTE

For the configuration of operation block properties, see 10.1.5.4.3.1 Configuring Operation Block Properties.

Writing and forcing values

In online mode, writing and forcing values to variables are supported. The procedure is as follows:

1. Before writing or forcing values, modify the prepared values. There are two methods:
   - Method 1: Modifying in the program editing area
     For BOOL type variables, double-click the variable value position to switch between TRUE and FALSE.
     For non-BOOL type variables, double-click the variable value position to open the "Prepared value" window and enter the prepared value.
   - Method 2: Modifying in the variable declaration area
     For BOOL type variables, double-click the variable prepared value position to switch between TRUE and FALSE.
     For non-BOOL type variables, double-click the variable prepared value position and enter the prepared value.
2. After modifying the prepared value, you can perform write or force operations. For details, see 10.10.3 Numerical Display and Calculation. After forcing a value, you can cancel the forced state by releasing the value.

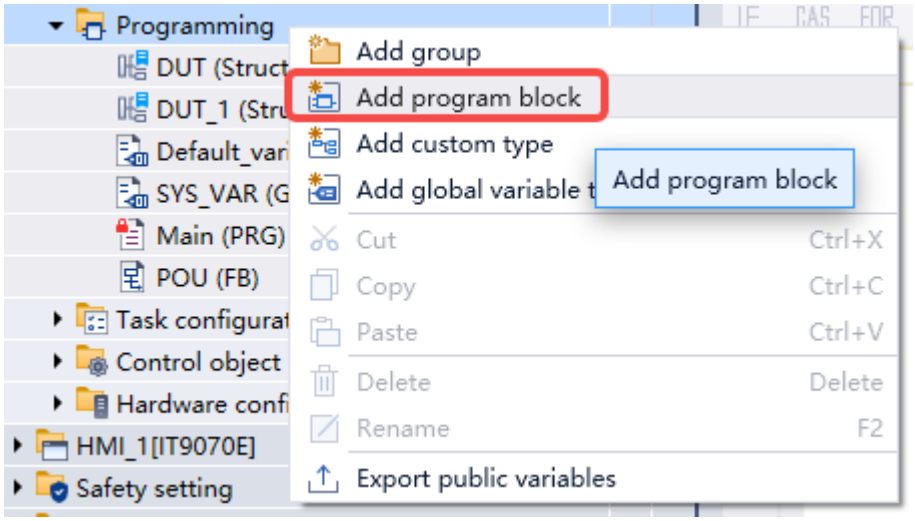
10.1.6 SFC Language Programming

10.1.6.1 SFC Language Overview

Sequential function chart (SFC) is a graphical programming language that follows the IEC 61131-3 standard. It uses graphical elements (steps and transitions) to intuitively describe control logic, reducing programming complexity and making it easier for engineers to locate issues. It is primarily used in industrial automation and process control.

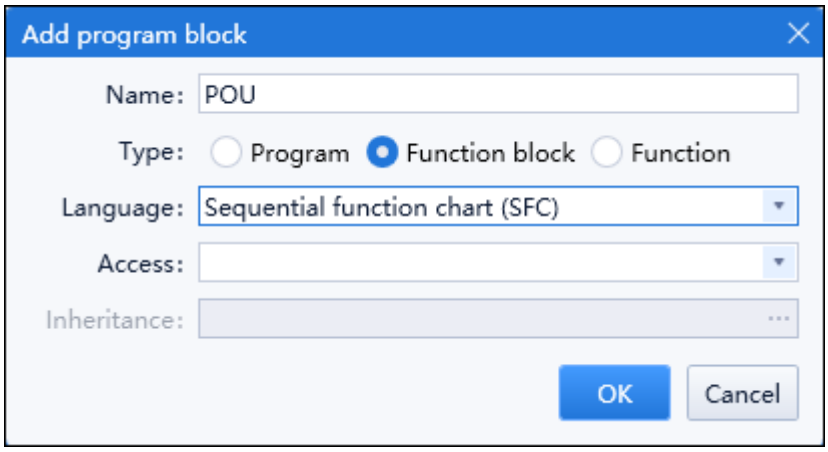
In SFC, the control flow is divided into multiple independent steps, each representing a specific operational state. Steps are connected by transition conditions, which define when the flow moves from one step to the next. This modular and structured design simplifies the management of complex systems, helping developers build stable, flexible, and easily maintainable automated control systems.

10.1.6.2 SFC Creation and Management



10.1.6.2.1 Creating an SFC Program Block

Prerequisites



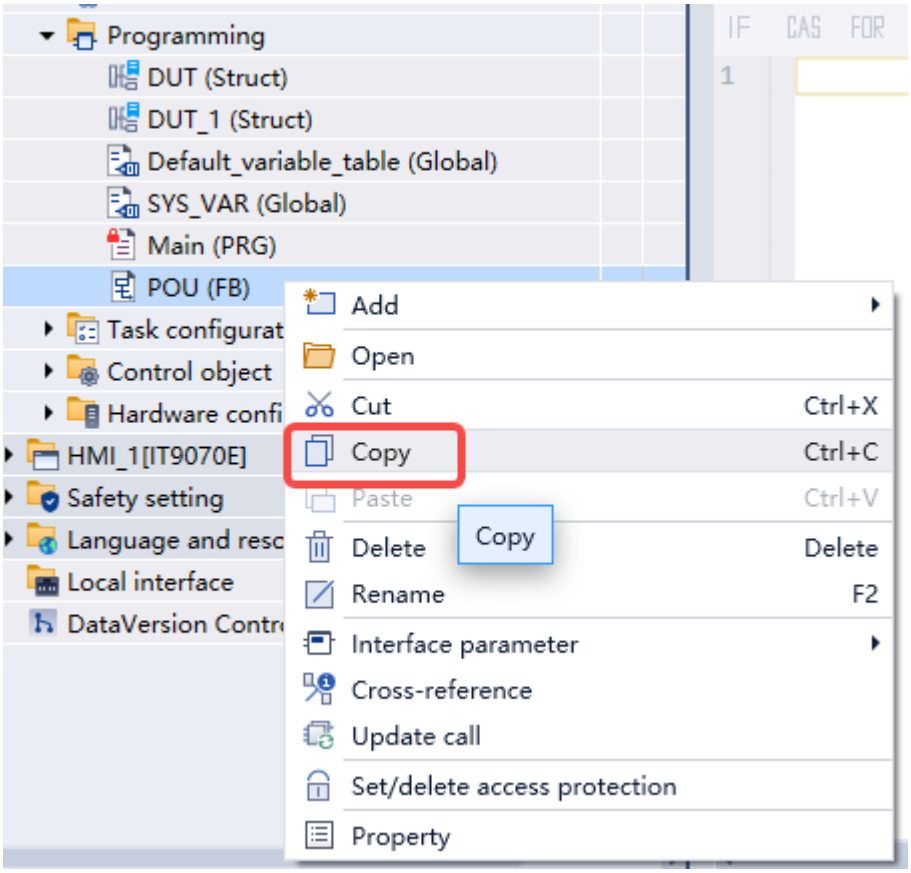
- A project has been created.
- A device has been added.

Procedure

1. Right-click "Programming" in the project tree and select "Add program block".

2. In the pop-up window, set the name of the program block, select "Function block" for the type, and select "Sequential function chart (SFC)" for the IEC language, as shown in the figure below.

3. Click "OK" and the SFC editor will be automatically opened.

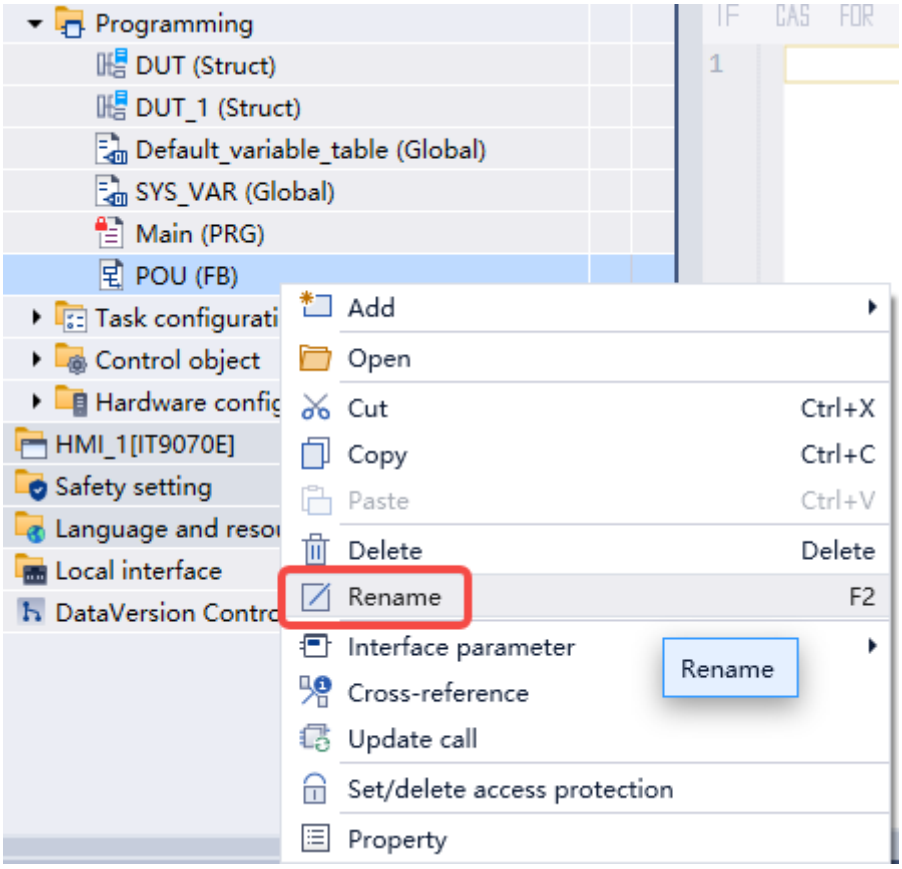


> NOTE
>
> When creating a program block, the SFC programming language is only supported when the program block type is set to "Function block".

10.1.6.2.2 Managing an SFC Program Block

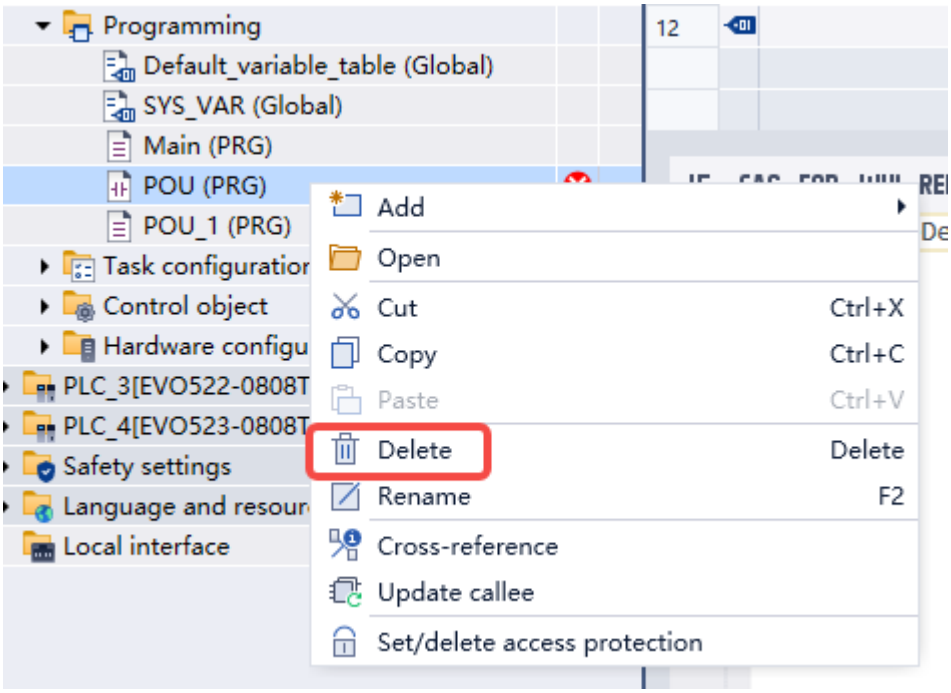
10.1.6.2.2.1 Copying an SFC Program Block

SFC program blocks can be copied and pasted within a PLC device, between PLC devices in the same project, or between different projects. The internal program logic of the SFC program block remains unchanged after pasting.



1. Right-click an SFC program block name under the "Programming" node, and select "Copy".

2. Right-click the "Programming" node or its subordinate node, and select "Paste" to paste the copied LD program block at the corresponding location.

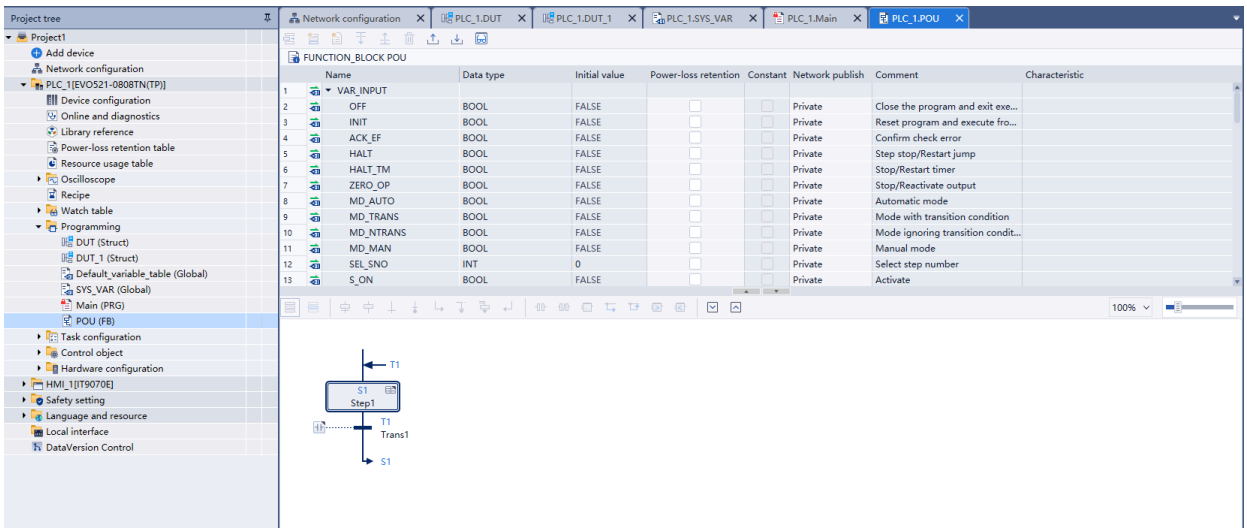


10.1.6.2.2.2 Renaming an SFC Program Block

Right-click an SFC program block name under the "Programming" node, select "Rename", and modify the group name.

10.1.6.2.2.3 Deleting an SFC Program Block

1. Right-click an SFC program block name under the "Programming" node, and select "Delete".



2. Click "OK" in the pop-up window.

10.1.6.3 SFC Editor

10.1.6.3.1 SFC Editor Interface

Double-click the SFC language program block (identifier:) under the "Programming" node.

The SFC editor is divided into the variable declaration area and the program editing area, which can be collapsed and expanded using and .

The program editing area consists of the toolbar and the programming area, as shown in the following figure:

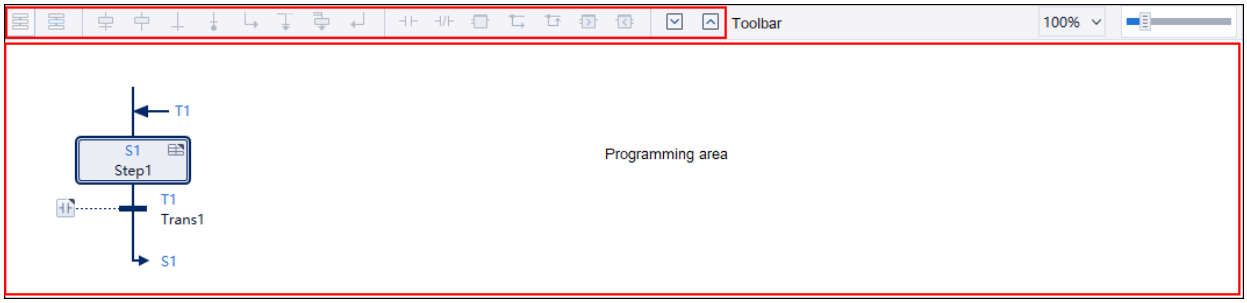


Table10-1-6-3-1-1 Introduction to toolbar

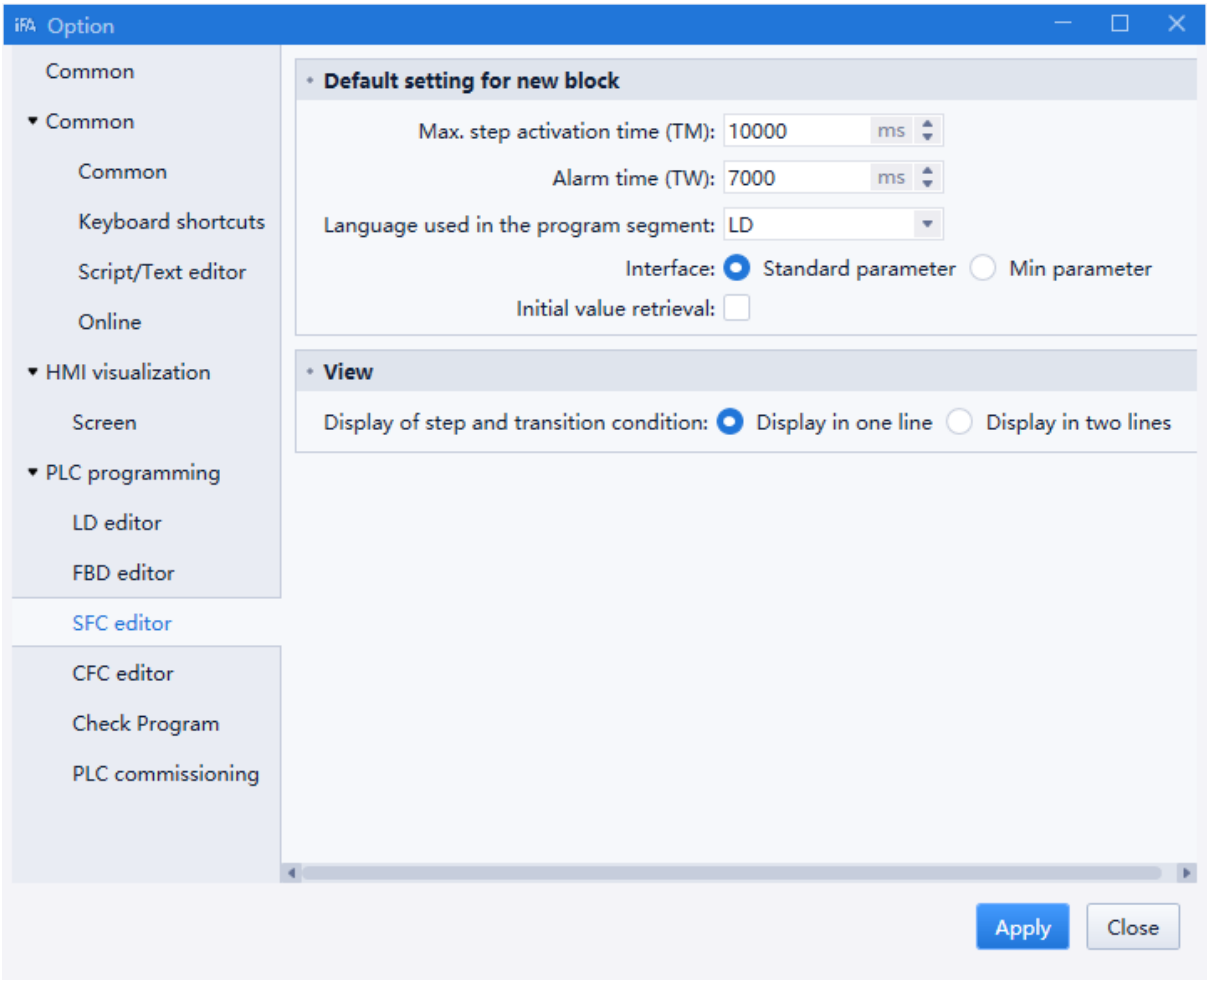
Description	Icon	Description	Application Scope
Program view		Switch to program view	Program view and step view
Step view		Switch to step view	
Step and transition		Add a step and transition below	SFC program view
Step		Add a step below	
Transition		Add a transition below	
Insert an end		Add an end	
Insert a jump		Add a jump	
Selective branch		Add a selective branch	
Parallel branch		Adding a parallel branch	
Branch closing		Add a closed branch	
Insert NO contact		Add a normally open contact	Switch edit mode, inter-lock edit mode, monitoring edit mode
Insert an NC contact		Add a normally closed contact	
Insert an empty operation block		Add an empty operation block	
Branch disconnected		Branch disconnected	
Branch closing		Branch closing	
Insert a greater-than block		Insert a greater-than block	
Insert a less-than block		Insert a less-than block	
Opening all program segments		Expand all program segments in the "Program view"; expand all editing areas in the "Step view"	Program view and step view



Description	Icon	Description	Application Scope
Close all program segments		Collapse all program segments in the "Program view"; collapse all editing areas in the "Step view"	

10.1.6.3.2 SFC Editor Settings

10.1.6.3.2.1 Setting the SFC Editor in iFA Options

The SFC editor parameters in iFA options are global. They affect all SFC blocks in every project.

1. Select "Tools > Option" from the iFA menu bar.
2. In the "Option" window, configure the related parameters for the SFC editor in the "SFC editor" tab under "PLC programming".

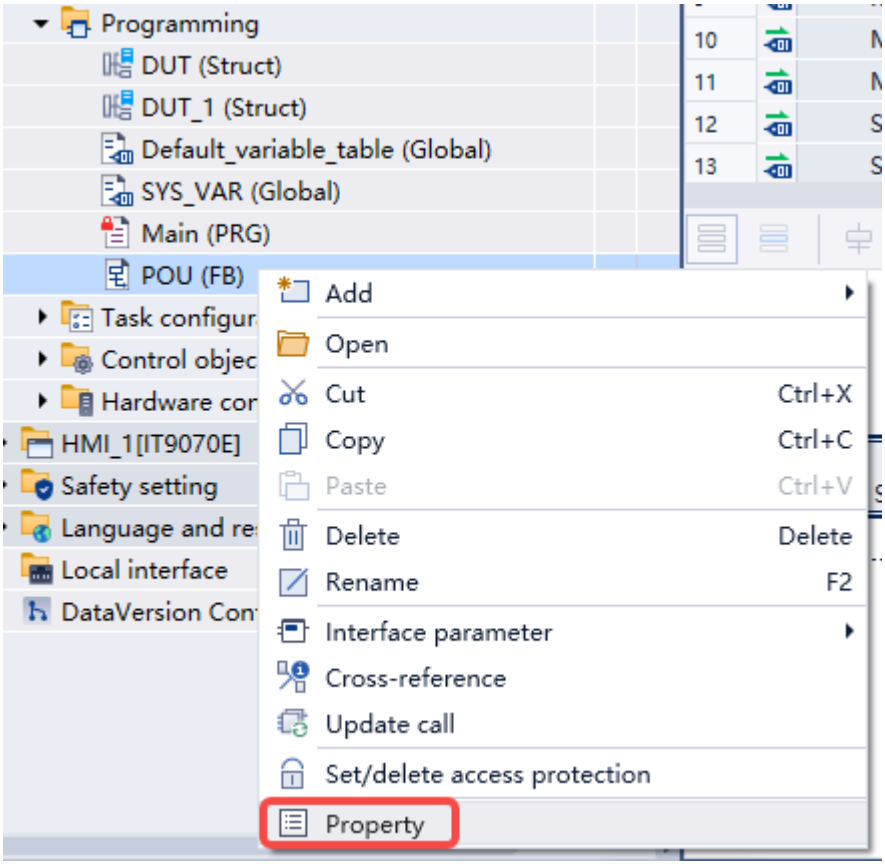
- **Default setting for new block**

Parameter	Description
Maximum step activation time	The maximum time a step is allowed to remain active. It ranges from 0 to 3600000 ms with a default of 10000 ms, and is editable by users.

Parameter	Description
Alarm time	When a step is activated, if its execution time exceeds the set alarm time but does not reach the maximum step activation time, the system issues an alarm but does not interrupt program execution. It ranges from 0 to 3600000 ms with a default of 7000 ms, and is editable by users.
Language used in the program segment	Supports only LD language.
Default interface parameters	• Standard parameters: The user program calling the SFC program block needs to control or externally influence the execution mode and flow of the SFC program. • Minimum parameters: The user program calling the SFC function block does not need to control or externally influence the execution mode and flow of the SFC program.
Initial value retrieval	Records the 32 boolean values of the step's condition, stored in the step's static parameter CD_STAT. Records the 32 boolean values of a transition (e.g., Trans1), stored in the transition's static parameter TRANS.

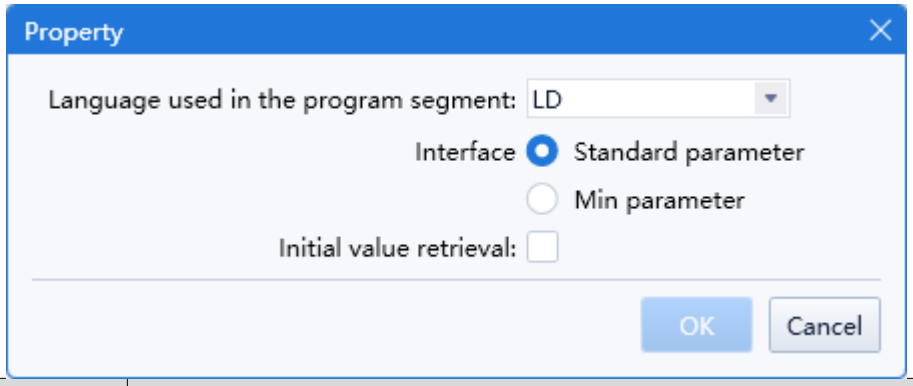
NOTE

In the default settings for new blocks, parameter modifications apply only to newly created SFC programs, while existing programs keep their original configuration.



- **View**

Parameter	Description
Step and transition name length	Sets whether step and transition names are displayed in one line or two lines. Select "Display in two lines" to view longer names.

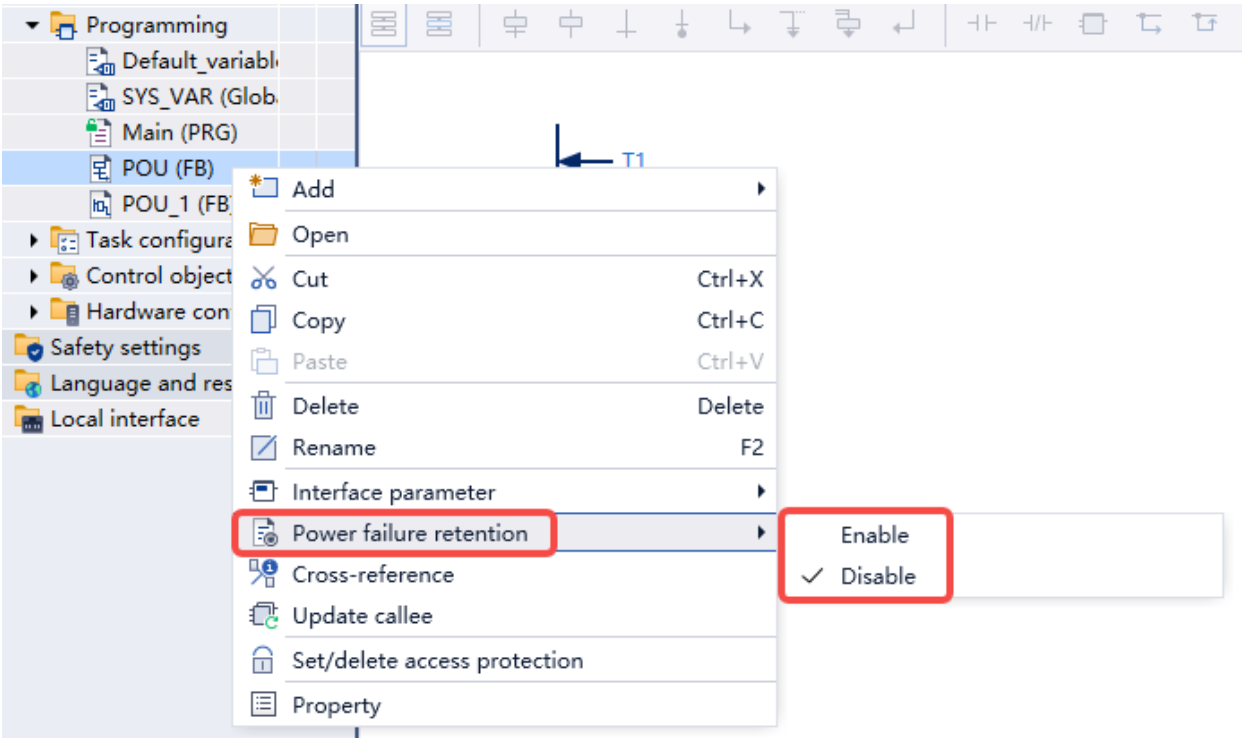


10.1.6.3.2.2 Setting SFC Program Block Properties

After setting the properties of the SFC program block, the settings only apply to the current SFC program block.

1. Right-click the SFC language program block under the "Programming" node in the project tree, and select "Property".

2. In the "Property" dialog box, configure the parameters related to the current SFC program block, and click "OK".



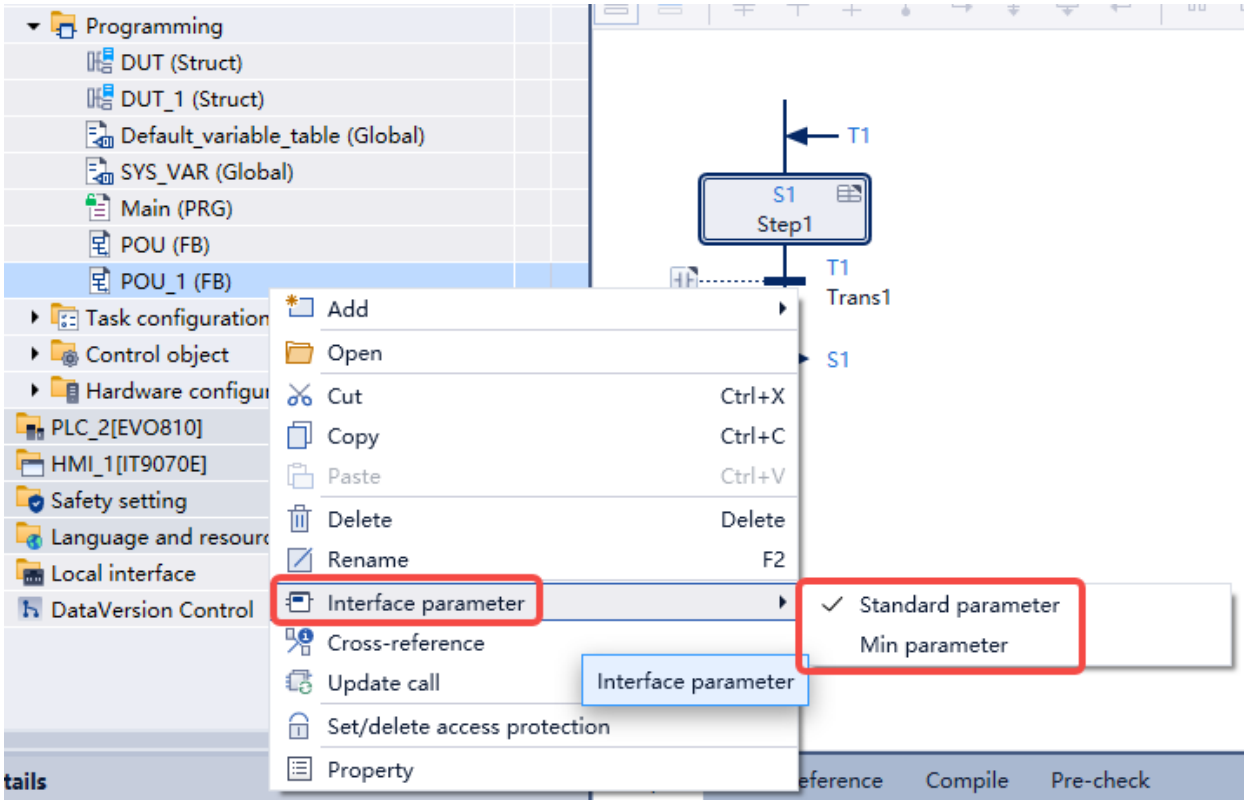
Parameter	Description
Language used in the program segment	Supports only LD language.
Interface	◦ Standard parameter: The user program calling the SFC program block needs to control or externally influence the execution mode and flow of the SFC program. ◦ Minimum parameters: The user program calling the SFC function block does not need to control or externally influence the execution mode and flow of the SFC program.
Initial value retrieval	Records the 32 boolean values of the step's condition, stored in the step's static parameter CD_STAT. Records the 32 boolean values of a transition (e.g., Trans1), stored in the transition's static parameter TRANS.

10.1.6.3.2.3 Setting SFC Program Block Power Failure Retention Property

In an SFC program block, the power failure retention property of automatically generated system parameters is not checked by default and cannot be directly modified in the variable table. To modify this property, follow the steps below:

Right-click the SFC language program block under the "Programming" node in the project tree, select "Power failure retention", and select "Enable" or "Disable" as needed.

NOTE

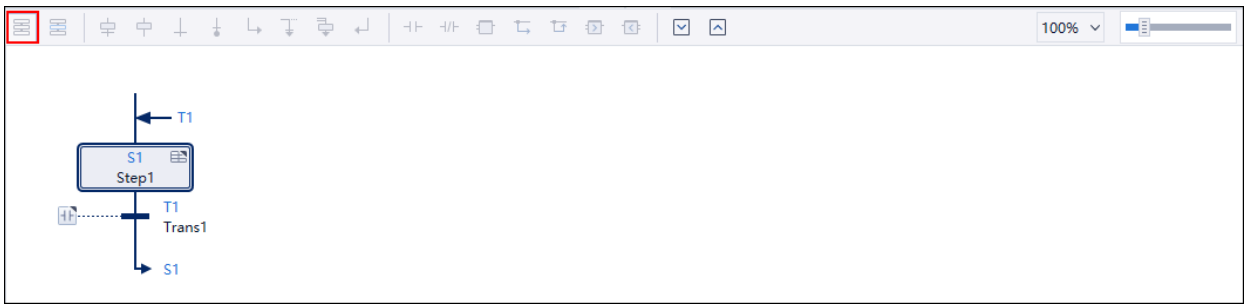


This operation applies only to the system-generated default parameters. For user-defined parameters, this property can be modified directly in the variable table.

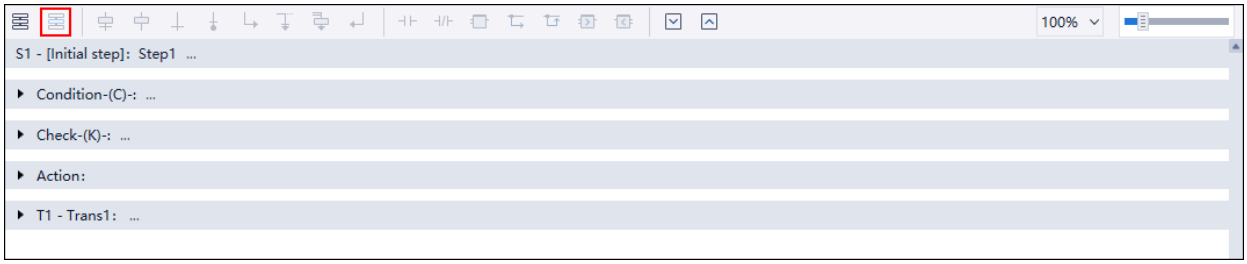
10.1.6.3.2.4 Setting SFC Program Block Interface Mode

The SFC program block supports two interface modes: "Standard parameter" and "Min. parameter". The mode can be set as follows:

Right-click the SFC language program block under the "Programming" node in the project tree, select "Interface parameter", and then select "Standard parameter" or "Min. parameter" as needed.



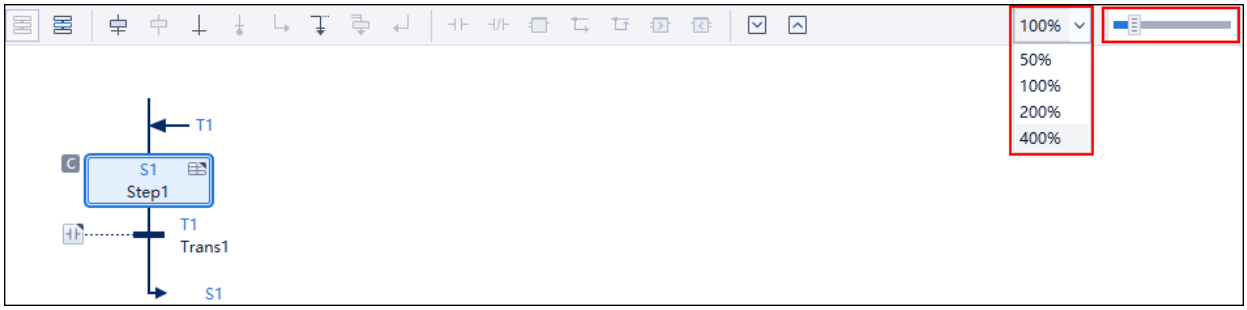
- Standard parameter: The user program calling the SFC program block needs to control or externally influence the execution mode and flow of the SFC program.
- Min. parameter: The user program calling the SFC function block does not need to control or externally influence the execution mode and flow of the SFC program.



10.1.6.3.3 SFC Programming Window

Window introduction

- Program view
  After an SFC program is created, iFA automatically opens the program view of the SFC editor. Core elements such as steps, transitions, branches, jumps, and ends can be added in the program view to complete the SFC main program. In step view, you can switch to program view by clicking the "Program view" icon on the toolbar.

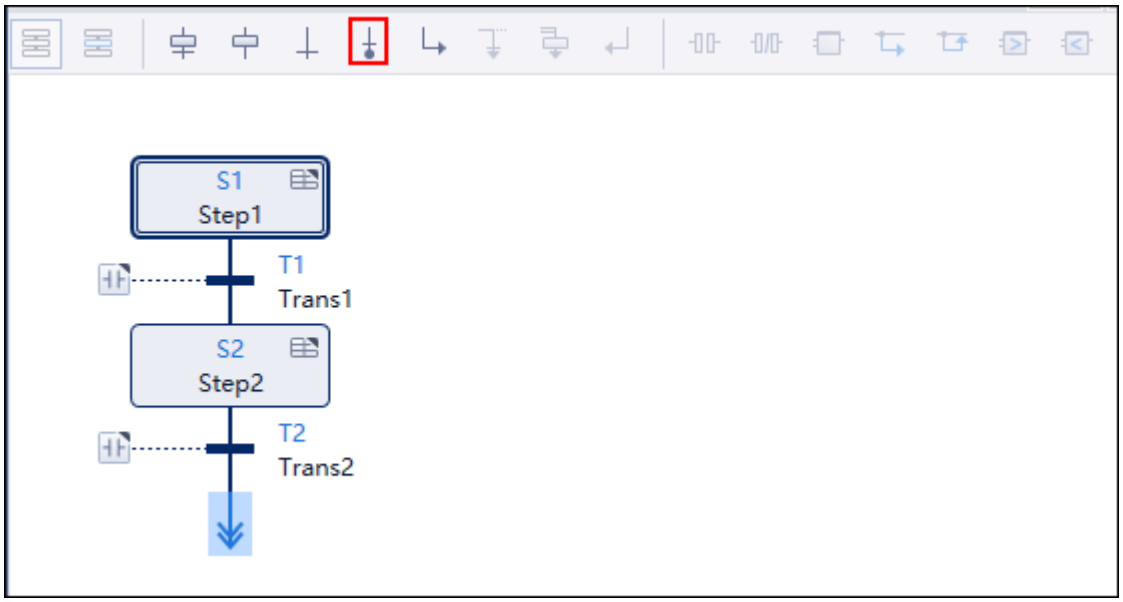


- Step view
  In the program view, select the target step in the SFC program, click the "Step view" icon on the toolbar to enter the editor for the current step. The interface is divided into: condition editing area, monitoring editing area, action editing area, and transition editing area.
  - Condition/Monitoring/Transition editing area: Users can write logic conditions using LD language elements and comparison instructions.
  - Action editing area: Users can define the operations to be completed in the current step.

Window operations

- Scaling
  In the upper-right corner of the program editing area, adjust the display size of the content using the drop-down menu or the slider.

- Offset
  - When the content exceeds the programming area, scrollbars appear in the window; drag the scrollbar to pan the view.
  - When the content exceeds the programming area, hold down the right mouse button and drag within the programming area to pan the view.



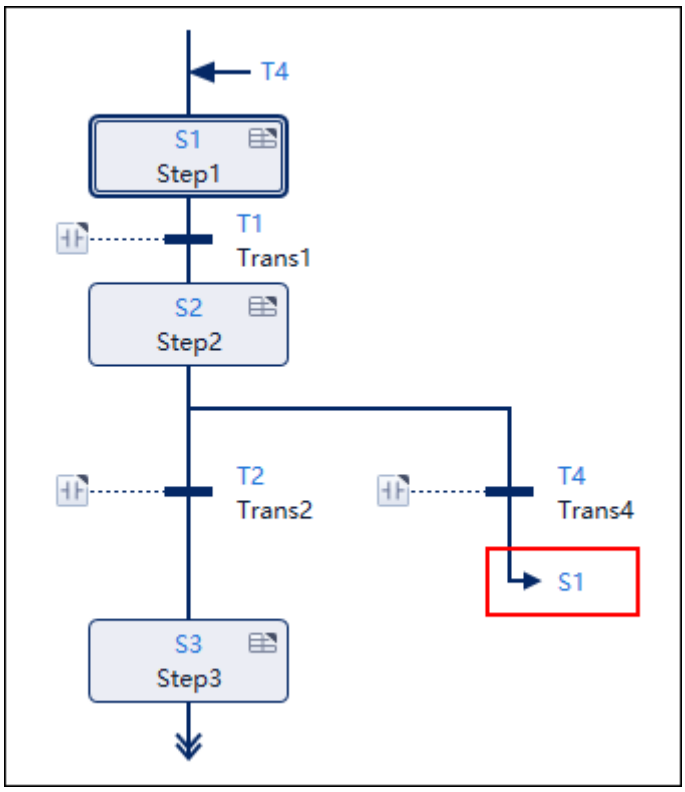
10.1.6.3.4 SFC Elements

Users can select SFC and LD elements through various methods such as the right-click menu, SFC editor toolbar, or the toolbox on the right. For illustration, this section uses toolbar operations as an example. In actual programming, users can flexibly choose the addition method. Other methods will not be elaborated.

SFC elements

- **Step and transition**
  For details, see 10.1.6.5.1 Adding a Step and Transition.
- **Step**
  For details, see 10.1.6.5.2 Adding a Step.
- **Transition**
  For details, see 10.1.6.5.3 Adding a Transition.
- **Insert an end**
  Indicates the end of the SFC POU, where execution stops.
  Select one of the  in the program, click  from the toolbar to insert an end, as shown in the figure

below.

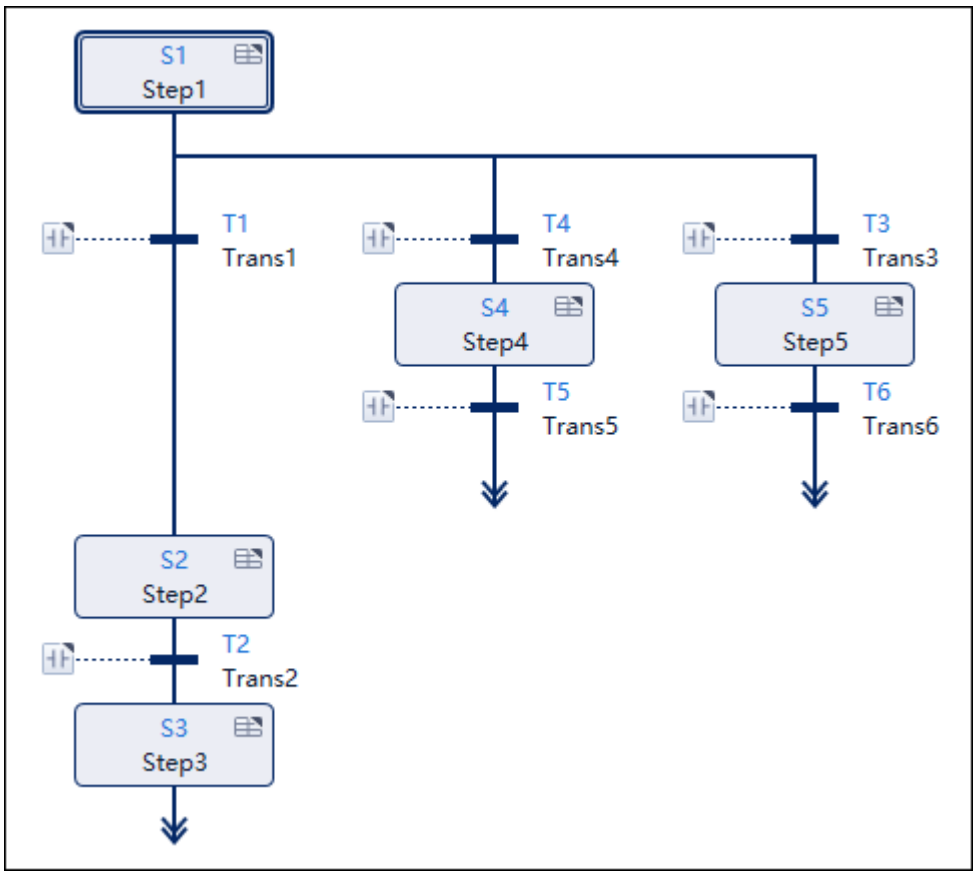


- **Insert a jump**

  By using the jump function, you can jump from any step to a specified step for program loop processing.

> NOTE
>
> A transition must exist before a jump; if missing, please insert a transition first.

1. Select one of the in the program, and click on the toolbar.
2. Select the target step. The target step is a step within this program block (POU).

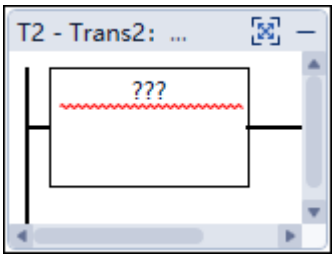


As shown in the figure below, if the Trans4 condition is met and Step2 is completed, the program jumps to Step1.

- **Selective branch**

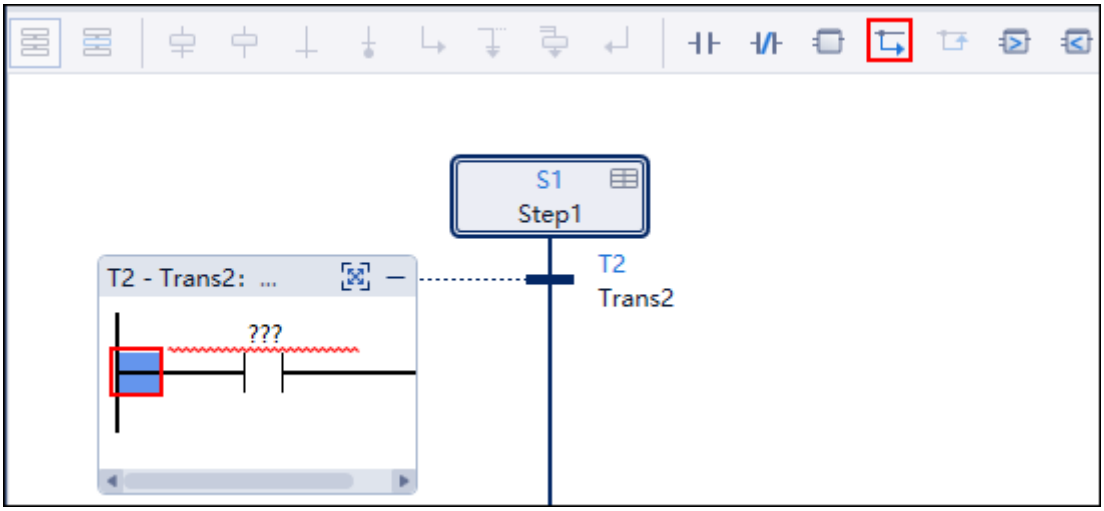
  The logical relationship between multiple selective branches is OR, meaning the program executes only one of them. If multiple conditions are met simultaneously, execute the leftmost branch.

  As shown in the figure below, if both Trans1 and Trans4 conditions are met, Step1 is executed, followed by Step2. See 10.1.6.6.1 Adding a Selective Branch for details.



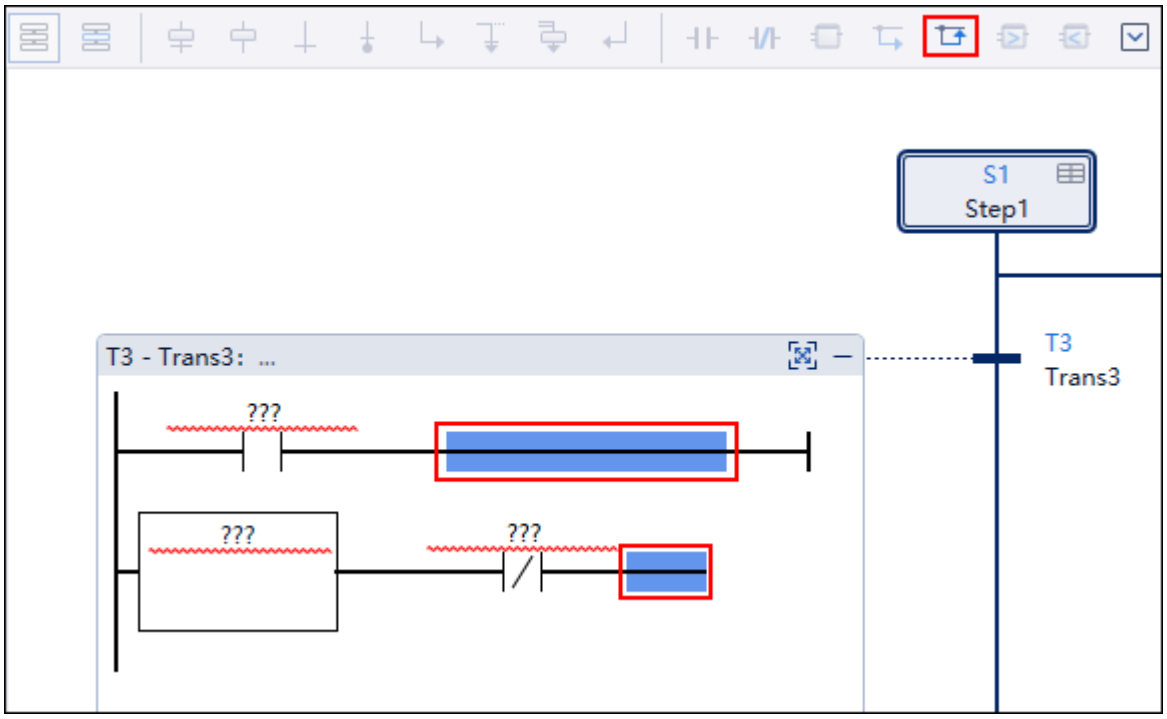
- **Parallel branch**
  The logical relationship between multiple parallel branches is AND, meaning the program executes all branches simultaneously. See 10.1.6.6.2 Adding a Parallel Branch for details.
- **Closed branch**
  Mainly used to end branch tasks and return to the main process. See Returning to Parent Branch for details.

LD elements



- **Insert NO contact**
  A normally open contact is open under normal conditions, and its state is FALSE.
  In the LD programming area, select the connection line, and click from the toolbar, as shown in the following figure.

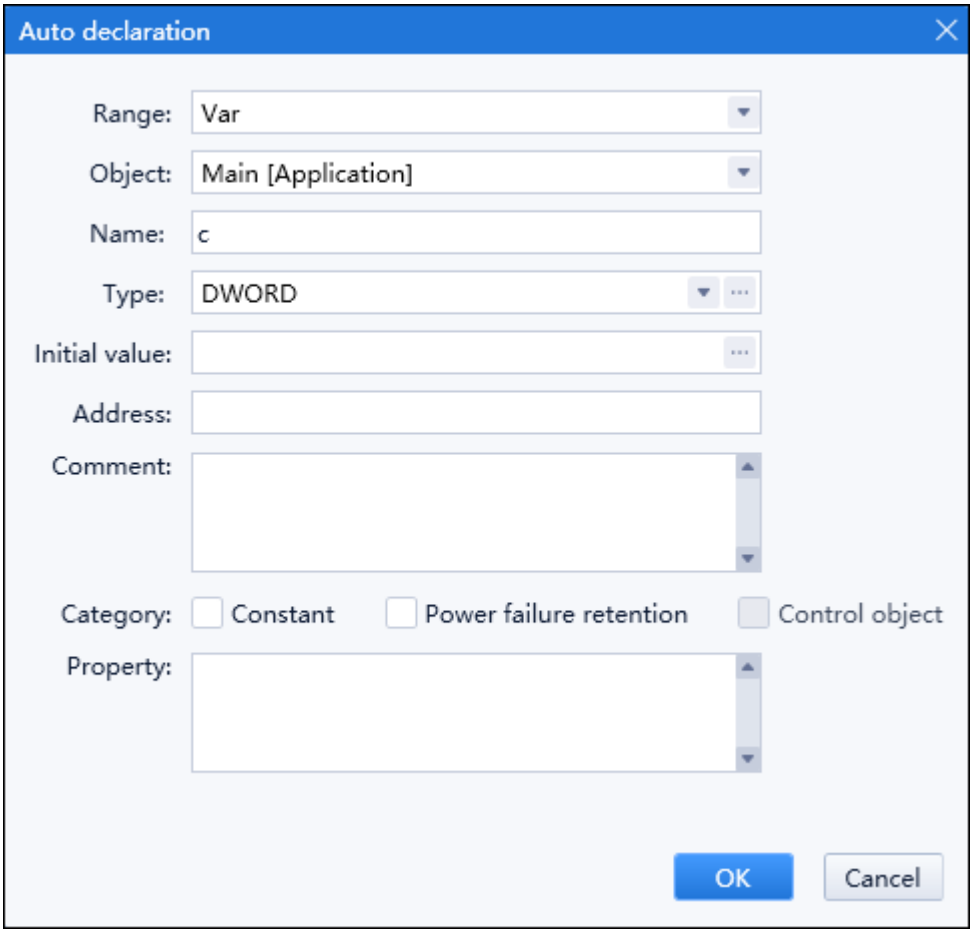
- **Insert NC contact**
  A normally closed contact is closed under normal conditions, and its state is TRUE.
  In the LD programming area, select the connection line, and click from the toolbar, as shown in the following figure.
- **Insert empty operation block**
  Used to insert an empty operation block. It is suitable for users who are familiar with functions and function blocks.
  1. In the LD programming area, select the connection line, and click from the toolbar.
  2. In the operation block, directly enter the function or function block name in the "???" field.



- **Open branch**
  Select a connection line in the LD programming area and click from the toolbar to insert a branch below the selected line. The inserted branch is an open line.

- **Close branch**

  Select a branch start point in the LD programming area, then hold down the Ctrl key to select the branch end point, and click from the toolbar to connect the branch start and end points.

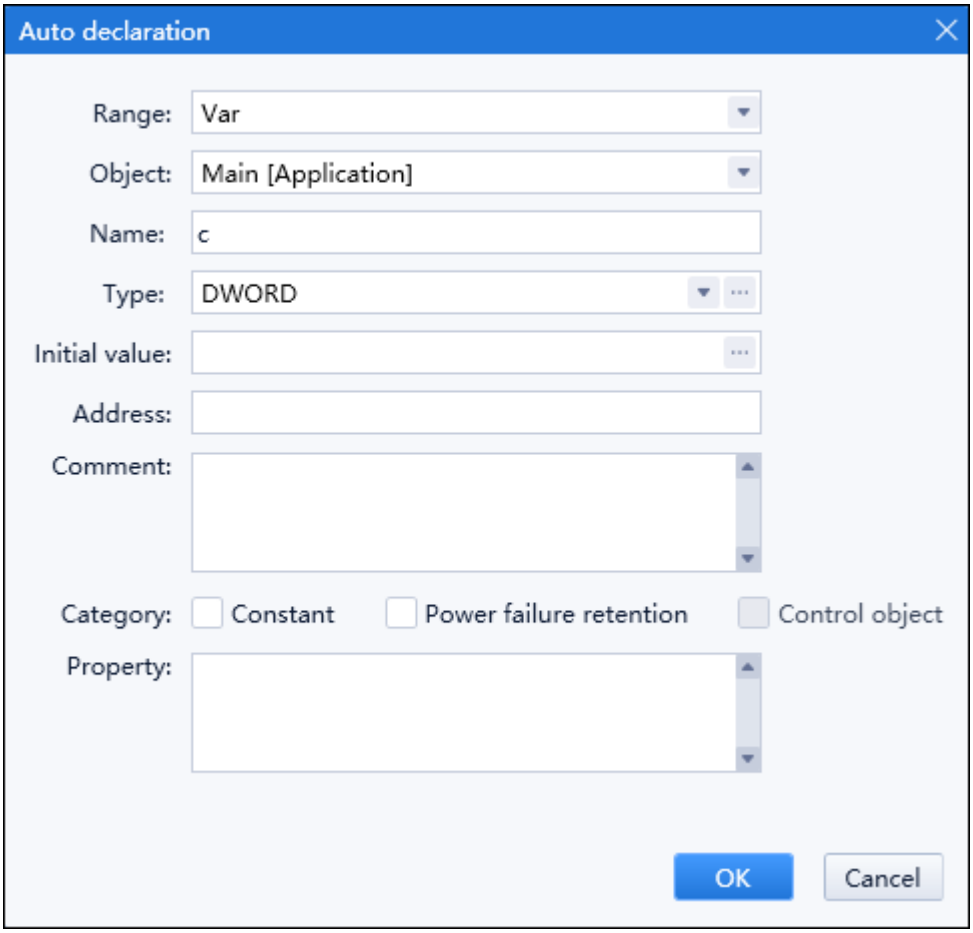


- **Insert a greater-than block**

  1. In the LD programming area, select the connection line, and click from the toolbar.

  2. Enter or select an expression at the input pin of the greater-than operation block.

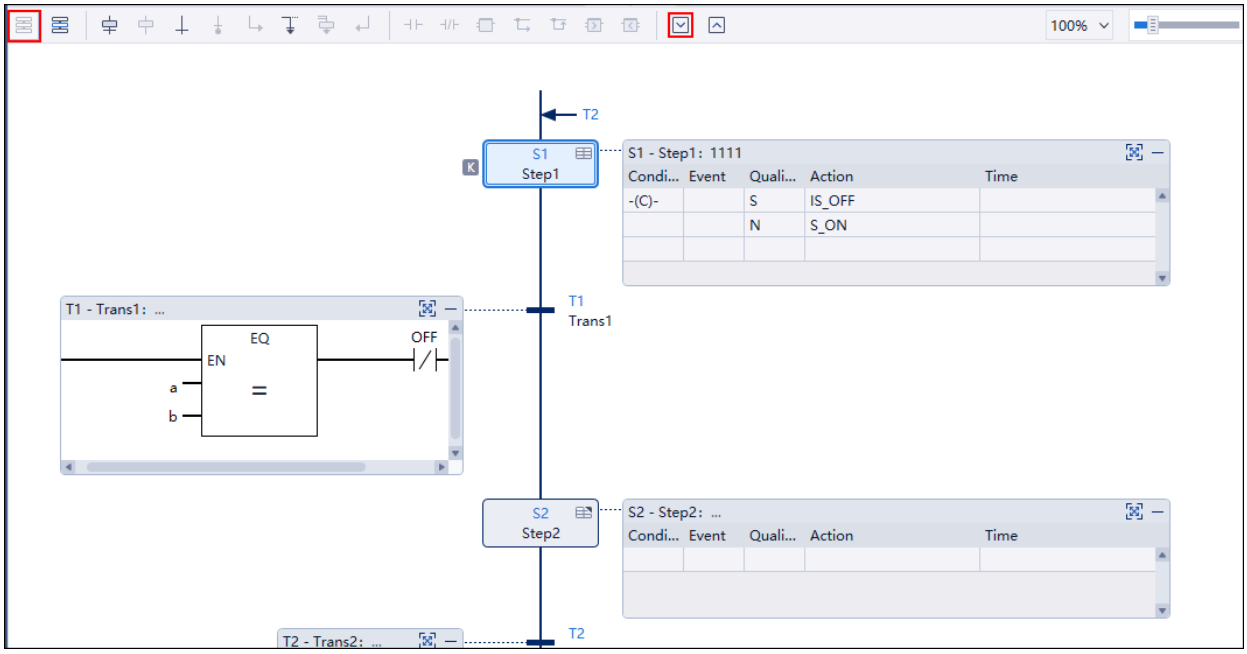
  3. (Optional) User-defined variables require configuration of scope, type, initial value, category, and so on.



- **Insert a less-than block**

  1. In the LD programming area, select the connection line, and click from the toolbar.
  2. Enter or select an expression at the input pin of the less-than operation block.

  3. (Optional) User-defined variables require configuration of scope, type, initial value, category, and so on.



10.1.6.3.5 Opening/Closing All Program Segments

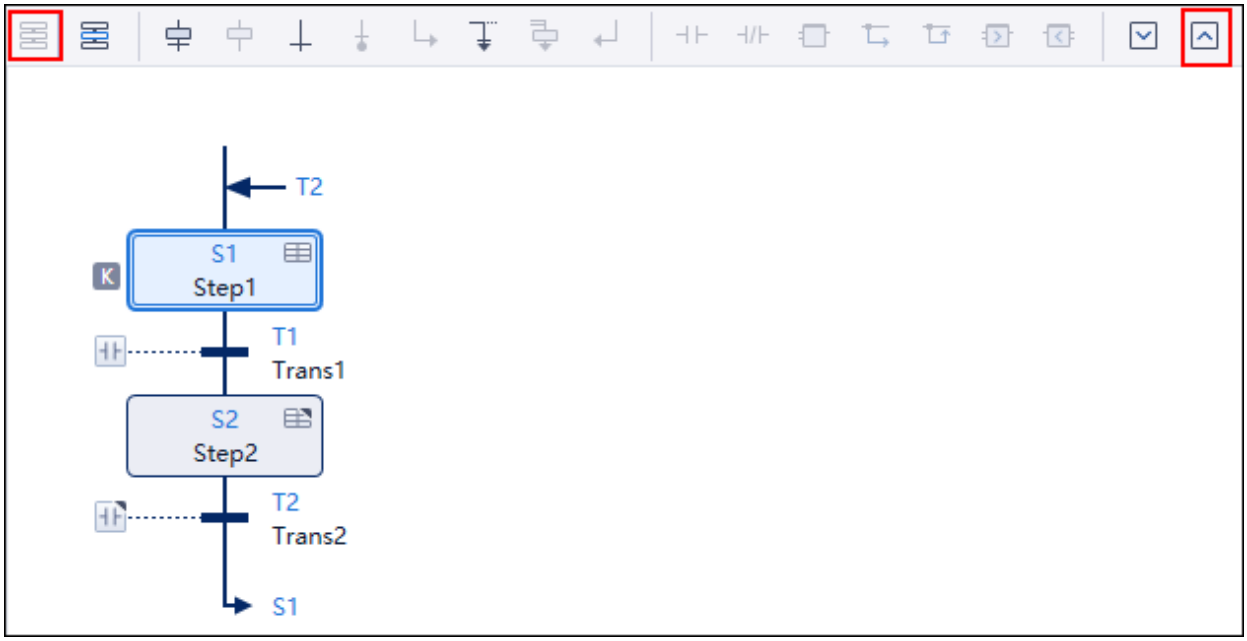
Opening all program segments

- Program view

  In the program view, click the "Open all program segments" icon on the toolbar to expand the actions and transition logic for all steps in the program editing area.

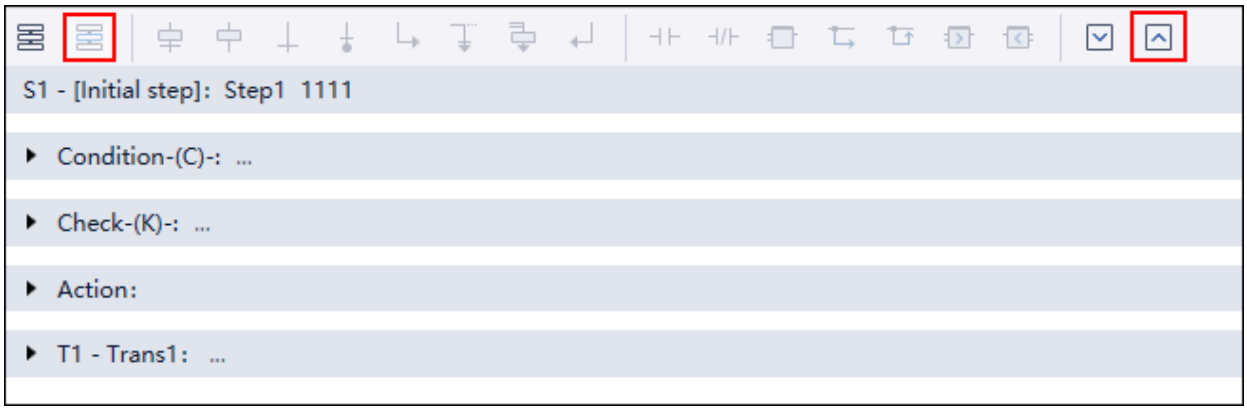
- Step view

  In the step view, click the "Open all program segments" icon on the toolbar to expand all content in



the condition editing area, monitoring editing area, action editing area, and transition editing area for the current step.

Close all program segments



- Program view

  In the program view, click the "Close all program segments" icon on the toolbar to collapse the actions and transition logic for all steps in the program editing area, restoring it to the initial state.

- Step view

  In the step view, click the "Close all program segments" icon on the toolbar to collapse the condition editing area, monitoring editing area, action editing area, and transition editing area for the current step.

10.1.6.3.6 SFC Program Block Interface Parameters

10.1.6.3.6.1 Overview

External programs can dynamically adjust the execution mode and logic of the SFC program through the program block interface parameters.

10.1.6.3.6.2 Interface Parameter Mode

The SFC program interface supports two modes (minimum mode and standard mode), corresponding to different scenarios. System-generated Input-type interface parameters take effect through a rising edge (FALSE > TRUE).

You can set the interface mode of the SFC program in various ways. For details, see 10.1.6.3.2 SFC Editor Settings.

- Minimum mode
  The user program calling the SFC function block does not need to control or externally influence the execution mode and flow of the SFC program.
- Standard mode
  The user program calling the SFC program block needs to control or externally influence the execution mode and flow of the SFC program.

10.1.6.3.6.3 Input Parameters

Input parameters are parameters generated by default when creating an SFC program block. Users cannot manually modify or delete them.

Para. Type	Parameter	Data Type	Initial Value	Note	Minimum Mode	Standard Mode
VAR_INPUT	OFF	BOOL	FALSE	Close the program and exit execution Rising edge triggered.	×	√
	INIT	BOOL	FALSE	Reset program and execute from the initial step Rising edge triggered.	√	√
	ACK_EF	BOOL	FALSE	Confirm monitor error Rising edge triggered.	×	√
	HALT	BOOL	FALSE	Stop/resume step switching Rising edge triggered.	×	√
	HALT_TM	BOOL	FALSE	Stop/resume timer Rising edge triggered.	×	√
	ZERO_OP	BOOL	FALSE	Stop/resume action output Rising edge triggered.	×	√
	MD_AUTO	BOOL	FALSE	Automatic mode Rising edge triggered.	×	√
	MD_TRANS	BOOL	FALSE	Mode with transition condition Rising edge triggered.	×	√
	MD_NTRANS	BOOL	FALSE	Mode ignoring transition condition Rising edge triggered.	×	√

Para. Type	Parameter	Data Type	Initial Value	Note	Minimum Mode	Standard Mode
	MD_MAN	BOOL	FALSE	Manual mode Rising edge triggered.	×	√
	SEL_SNO	INT	0	Select step number Effective immediately.	×	√
	S_ON	BOOL	FALSE	Activate Effective immediately.	×	√
	S_OFF	BOOL	FALSE	Deactivate Effective immediately.	×	√
	T_PUSH	BOOL	FALSE	Execute once Rising edge triggered.	×	√

10.1.6.3.6.4 Output Parameters

Output parameters are parameters generated by default when creating an SFC program block. Users cannot manually modify or delete them.

Para. Type	Parameter	Data Type	Initial Value	Note	Minimum Mode	Standard Mode
VAR_OUTPUT	SNO	INT	0	Step number of the currently executing step	×	√
	ACTIVE	BOOL	FALSE	Step indicated by SNO activated or not	×	√
	ERROR	BOOL	FALSE	Condition error	×	√
	FAULT	BOOL	FALSE	Monitor error	×	√
	ERR_FLT	BOOL	FALSE	Condition or monitor error	×	√
	HALTED	BOOL	FALSE	Stop step switching	×	√
	TM_HALTED	BOOL	FALSE	Stop timer	×	√
	OP_ZEROED	BOOL	FALSE	Stop action output	×	√
	AUTO_ON	BOOL	FALSE	Automatic mode	×	√
	TRANS_ON	BOOL	FALSE	Mode with transition condition	×	√
	NTRANS_ON	BOOL	FALSE	Mode ignoring transition condition	×	√
	MAN_ON	BOOL	FALSE	Manual mode	×	√
	IS_OFF	BOOL	FALSE	Program closed	×	√

10.1.6.3.6.5 Static Parameters

Static parameters of a step

The static parameters of a step are intrinsic read-only properties of each step in the SFC program. They are used to monitor the real-time status of the step, and are independent of the interface parameter mode.

Parameter	Data Type	Initial Value	Description	Function description
SNO	INT	1	Step number	Step number
S1	BOOL	FALSE	Step activation event	Rising edge: TRUE at the moment the step transitions from not inactive to active, then becomes FALSE (remains FALSE even when the step remains active).
S0	BOOL	FALSE	Step deactivation event	Falling edge: TRUE at the moment the step transitions from active to inactive, then becomes FALSE.
SX	BOOL	FALSE	Step activation status	TRUE when the step is active (displayed in green).
C1	BOOL	FALSE	Condition unsatisfied event	Condition (C) leaves: Condition result changes from TRUE to FALSE.
C0	BOOL	FALSE	Condition satisfied event	Condition (C) enters: Condition result changes from FALSE to TRUE.
CA	BOOL	FALSE	Condition unsatisfied status	TRUE when the condition is not satisfied; FALSE when satisfied.
CS	BOOL	FALSE	Condition result	The logical execution result of condition (C).
K1	BOOL	FALSE	Monitor error occurrence event	Transitions from FALSE to TRUE when a monitor (K) error occurs.
K0	BOOL	FALSE	Monitor error confirmed event	Monitoring (K) error is confirmed after occurrence.
KA	BOOL	FALSE	Monitoring active status	TRUE when monitor is active, which is the same as SX.
KS	BOOL	FALSE	Direct monitoring result	The logical execution result of monitor (K).
A1	BOOL	FALSE	Monitor error confirmed	After an error occurs, the step stays at current position (displayed in red). After the error is confirmed, the step continues.
TT	TIME	TIME#0ms	Total active time of step	• Accumulates while the step is active. • When the step becomes inactive, accumulation stops but does not reset to 0.

Parameter	Data Type	Initial Value	Description	Function description
UT	TIME	TIME#0ms	Active time without condition /monitor error	• Accumulates while the step is active and no condition/monitor error is present. If either a condition/monitor error occurs, accumulation stops. • For a condition error, accumulation resumes when the error clears. • For a monitor error, UT resets to 0 when the error is confirmed. • When the step becomes inactive, UT does not reset to 0.
TM	TIME	TIME#10s0ms	Maximum step active time	User configurable. Default value can be set.
TW	TIME	TIME#7s0ms	Step alarm active time	User configurable. Default value can be set.
CD_STAT	DWORD	0	Status of 32 LD elements in the condition	Stores the status of the 32 elements in condition (C).
CD_STAT_ERR	DWORD	0	Copies CD_STAT if the condition leaves	Stores the previous status of the 32 elements in condition (C).

Static parameters of a transition

The static parameters of a transition are intrinsic read-only properties of each step in the SFC program. They are used to determine whether the transition condition is met, and are independent of the interface parameter mode.

Parameter	Data Type	Initial Value	Description	Function description
TNO	INT	1	Transition number	Transition number
TA	BOOL	FALSE	Transition active status	Indicates whether the transition is active.
TT	BOOL	FALSE	Transition result	The logic result of the transition.
TS	BOOL	FALSE	Transition occurrence	Indicates the transition has occurred.
TRANS	DWORD	0	Status of 32 LD elements in the current transition	Stores the status of the 32 elements in the transition.
TRANS_OLD	DWORD	0	Status of 32 LD elements in the previous transition	Stores the status of the 32 elements in the previous transition (copies the value of TRANS).

Parameter	Data Type	Initial Value	Description	Function description
TRANS_ERR	DWORD	0	Copies TRANS if an error occurs	Stores the value of TRANS when an error occurs.

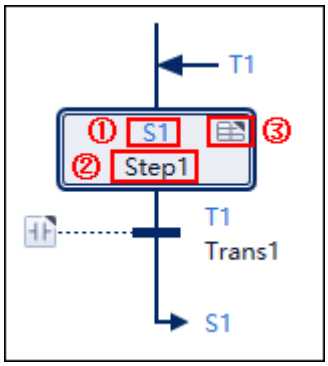
10.1.6.4 Step and Transition Condition

10.1.6.4.1 Step and Transition

10.1.6.4.1.1 Step Overview

In SFC, the control process is divided into clear, sequential stages called steps. Steps are connected by transitions. When the transition condition between two adjacent steps is met, the transition occurs: the previous step is deactivated and the next step is activated, ensuring no overlap between steps. Each step represents the start, continuation, or end of an action. The more steps a process cycle is broken into, the more precisely the entire process is described.

10.1.6.4.1.2 Transition Overview

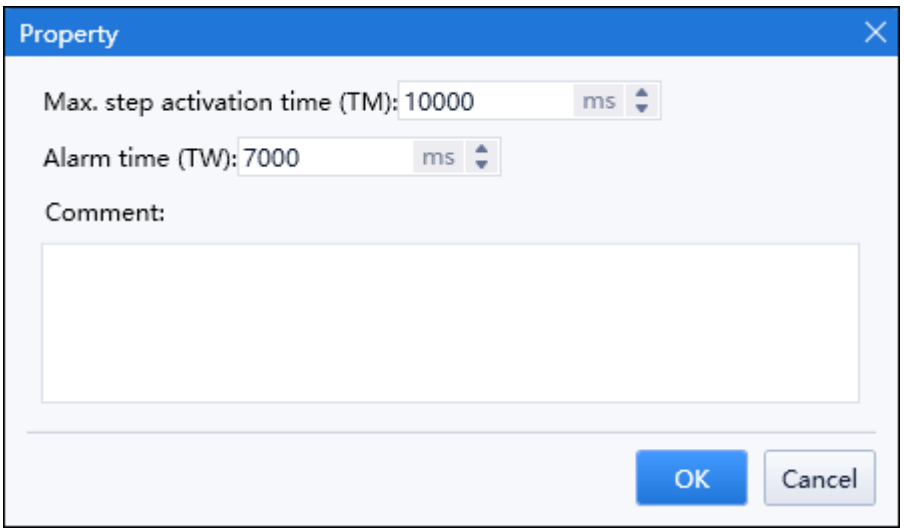


In SFC, transition is the core logical condition that controls the flow of process from one step to the next step. Each transition corresponds to a unique condition. The transition can only be realized when the condition is met, allowing the process to proceed to the next step.

10.1.6.4.2 Step

10.1.6.4.2.1 Step Basic Properties

Each step includes step number, name, action, maximum step activation time, alarm time, and comment.



- Basic properties

No.	Item	Description
①	Step number	Steps are numbered numerically. Each step number is unique within the same program block. The step number is automatically generated when a step is created. Double-click to edit. Valid range: 1 to 32767.

No.	Item	Description
②	Step name	The name of the step, which must be unique within the same program block. The step name is automatically generated when a step is created. Double-click to edit. Allowed characters: letters, Chinese characters, numbers, and underscores. Max length: 64 characters.
③	Action	A step can contain zero or multiple actions. An action includes condition, event, qualifier, and action body. • Condition: If a condition is set, the action is executed only if the step is activated and the condition is met. By default, no condition logic is created; users can program the logic. • Event: If an event is set, the action is executed only when the event occurs and the step is activated. By default, no event is created; users can program the event. • Qualifier: Defines how the action is executed. For example: S is set (sets the operand to 1), and R is reset (sets the operand to 0). • Action: Combined with a qualifier to determine the operand or program call to be executed. It can be a variable, an expression, or a program block call.

- More properties
  1. Right-click the target step and select "Property".
  2. Set the maximum step activation time, alarm time, and comment in the "Property" window, then click "OK".

Item	Description
Max. step activation time (TM)	The maximum time a step is allowed to remain active. It ranges from 0 to 3600000 ms with a default of 10000 ms, and is editable by users.
Alarm time (TW)	When a step is activated, if its execution time exceeds the set alarm time but does not reach the maximum step activation time, the system issues an alarm but does not interrupt program execution. It ranges from 0 to 3600000 ms with a default of 7000 ms, and is editable by users.

Item	Description
Comment	Each step can have a comment, which is an empty string by default and can be modified by users. It can contain letters, Chinese characters, numbers, and underscores, with a length limit of 128 characters.

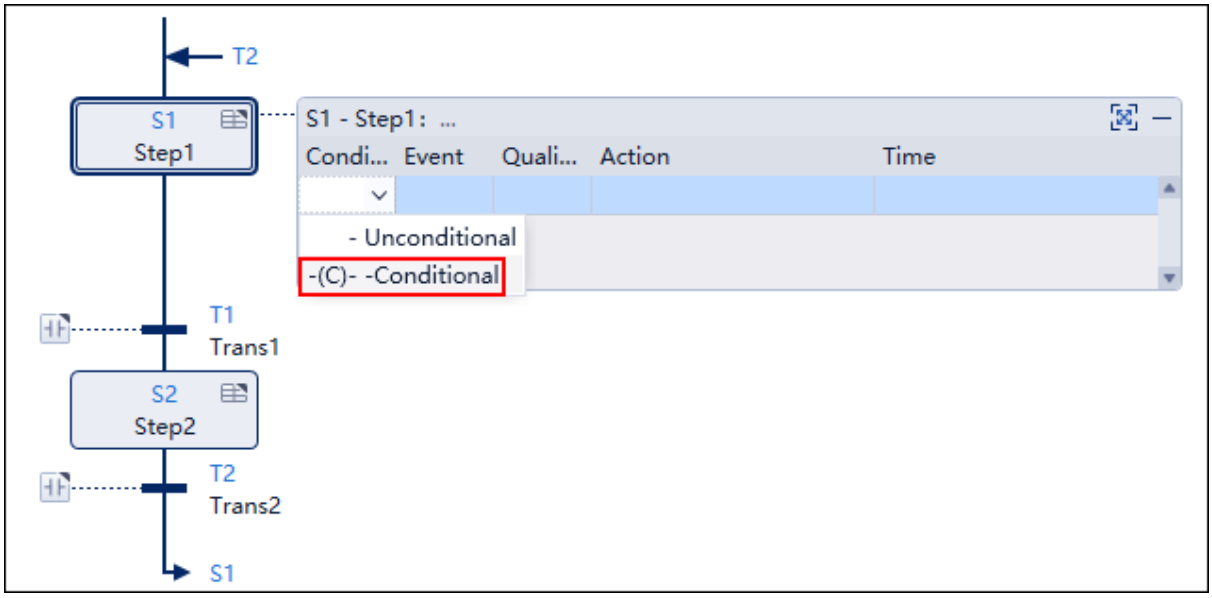
10.1.6.4.2.2 Step Status

Steps have active and inactive states.

- Active state
  When a step is active, the program logic within the step (e.g., conditions, monitors, actions) is executed, and the internal state of the step is updated.
  - Step condition error state
    When the step is active but its condition is not met, the step is in a condition error state.
  - Step monitor error state
    When the step is active and a monitor condition is met, the step is in a monitor error state.
- Inactive state
  When a step is inactive, no logic inside the step is executed.

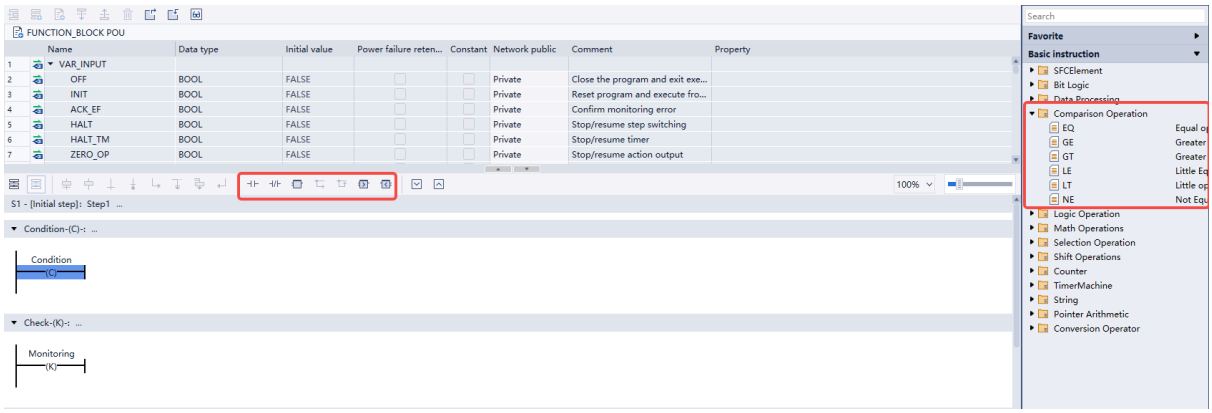
10.1.6.4.2.3 Condition

Conditions are optional in steps. If a condition is set, the action is executed only if the step is activated and the condition is met.



By default, no condition logic is created. Users can program the logic through LD language, but it only supports one LD network segment and only supports comparison operations.

In an SFC program, a maximum of 32 conditions can be added.

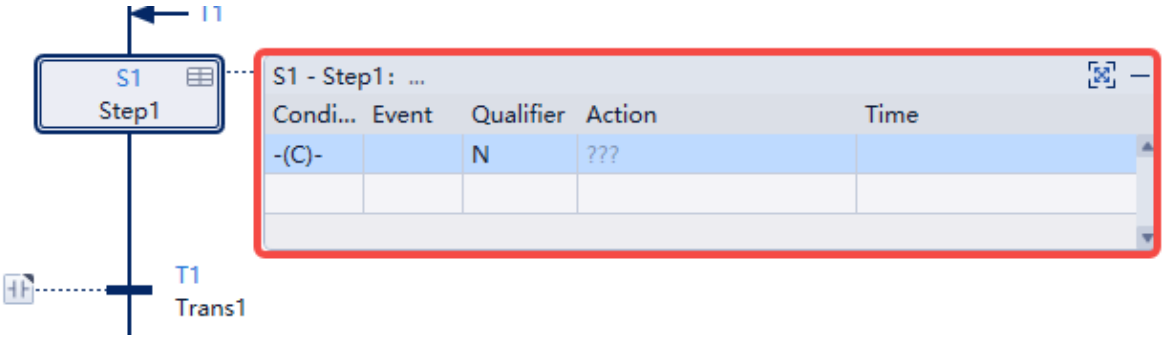


Procedure

1. In the SFC program, click  in the upper right corner.
2. In the "Condition" column of the action list, select "-(C)- -Condition", to add the condition.

3. Select the current step and click in the toolbar to enter the step view.

4. Write the LD program for a condition in the step view. You can use LD elements from the toolbar or the right-side toolbox, as well as comparison operation instructions from the toolbox.



10.1.6.4.2.4 Action

Actions define the operations to be completed in a specific step. An action includes conditions, events, qualifiers, action bodies, and time. Multiple actions are executed in the same step based on their order in the action list, from top to bottom.

> **NOTE**
>
> In an SFC program, a maximum of 100 action blocks can be added.

Click at the upper right corner of the step to open the action list. If there are many actions in the current step, the list may exceed the display area. Click the "Fit size" icon to fully display all action content within the visible area; click the "Minimize" icon to collapse the action list and simplify the interface.

Property	Optional/ Required	Note
Condition	Optional	If a condition is set, the action is executed only if the step is activated and the condition is met. By default, no condition logic is created; users can program the logic.
Event	Optional	If an event is set, the action is executed only when the event occurs and the step is activated. For details, see Event description.
Qualifier	Required	Defines how the action is executed. For example: S is set (sets the operand to 1), and R is reset (sets the operand to 0). For details, see Qualifier description.
Action	Required	Combined with a qualifier to determine the operand or program call to be executed. It can be a variable, an expression, or a program block call.
Time	Optional	When using the qualifiers D and L, a variable of time type must be passed as an input parameter.

Table10-1-6-4-2-4-1 Qualifier description

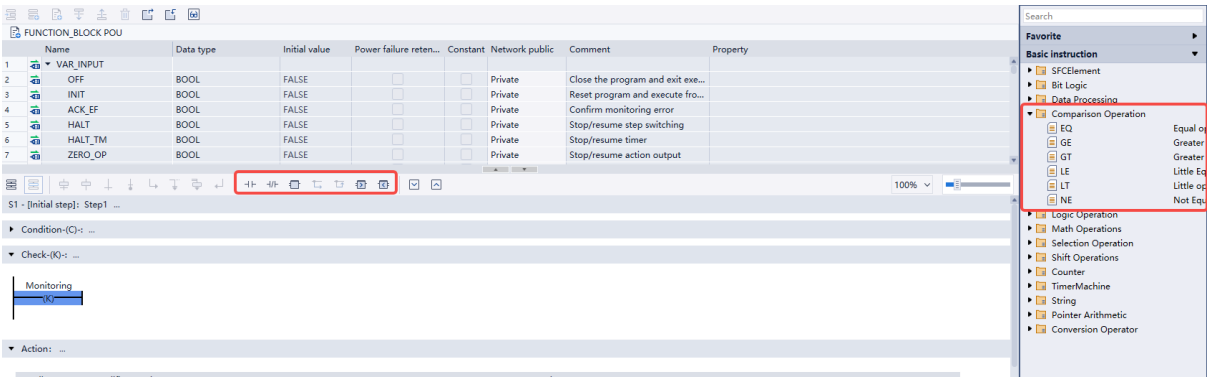
Qualifier	Description	Supported Action Type	Remarks
N	Set whenever the step is active	BOOL variable, expression	When the step is active, the action is executed each cycle.
R	Set to 0	BOOL variable, expression	• Performs a reset operation for a BOOL variable. • Stops executing the action for an ACT call.
S	Set to 1	BOOL variable, expression	• Performs a set operation for a BOOL variable. • Starts executing the action for an ACT call. The action continues even after the step becomes inactive.

Qualifier	Description	Supported Action Type	Remarks
L	Set within the specified time	BOOL variable, expression	When the step becomes active, the action is executed repeatedly for a user-specified duration, until the step deactivates or the time expires. For example, when the time parameter is 3s: • If the step is active for 2s, the action is executed for 2s. • If the step is active for 5s, the action stops after 3s.
D	Switch-on delay	BOOL variable, expression	After the step is activated, the action starts executing only if the step remains active for the user-specified delay. It continues until the step deactivates. For example, when the time parameter is 3s: • If the step becomes inactive within 3s, the action is not executed. • If the step is still active after 3s, the action is executed. • If the step becomes inactive at 5s, the action stops.

Table10-1-6-4-2-4-2 Event description

Event	Description	Triggered Signal	Note
None	No event	-	/
A1	Alarm confirmation	Commissioning panel button clicked or a rising edge triggered on ACK_EF	The monitoring condition has been triggered, i.e., Step.KS = FALSE and Step.KA = TRUE.
C0	Conditions for arrival	Rising edge	The condition is met, i.e., the error is cleared (signal state is 1).
C1	Conditions for departure	Falling edge	The condition is met, i.e., an error occurs (signal state is 0).
S0	Step deactivated	Falling edge	Step has become inactive (signal state is 0).
S1	Step activated	Rising edge	Step has become active (signal state is 1).
K0	Monitor error cleared	Falling edge	The monitoring condition is no longer met, i.e., the error is cleared (signal state is 0).
K1	Monitor error triggered	Rising edge	The monitoring condition is met, i.e., an error occurs (signal state is 1).

10.1.6.4.2.5 Monitoring

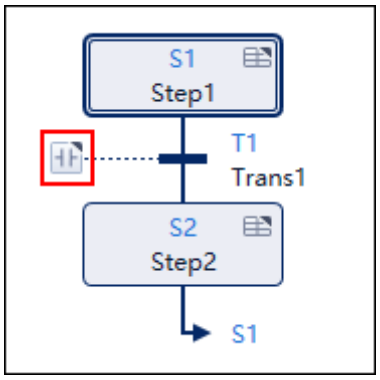


Monitoring is optional element in a step. If the user writes monitor logic, when the step is active and the monitor condition is met, the step reports an error and remains in the current step (even if the following transition condition is met, the step will not switch automatically).

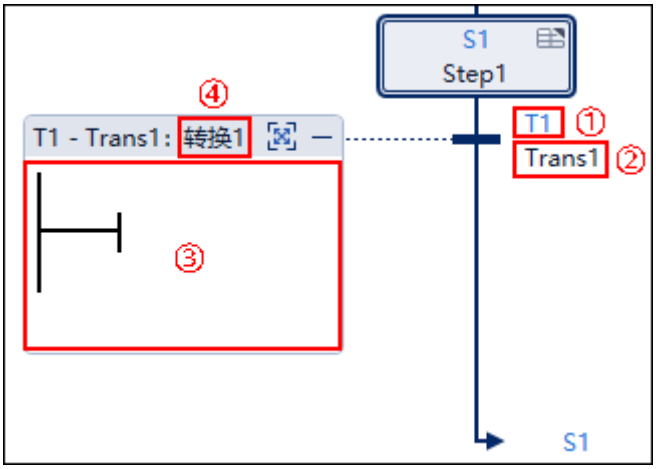
By default, no monitor is created when a step is created. Users can program the logic through LD language, but it only supports one LD network segment and only supports comparison operations.

> NOTE
>
> In an LD program, up to 32 monitors can be added.

Procedure



1. Select the target step and click in the toolbar to enter the step view.
2. Write the LD program for monitor in the step view. You can use LD elements from the toolbar or the right-side toolbox, as well as comparison operation instructions from the toolbox.



10.1.6.4.3 Transition

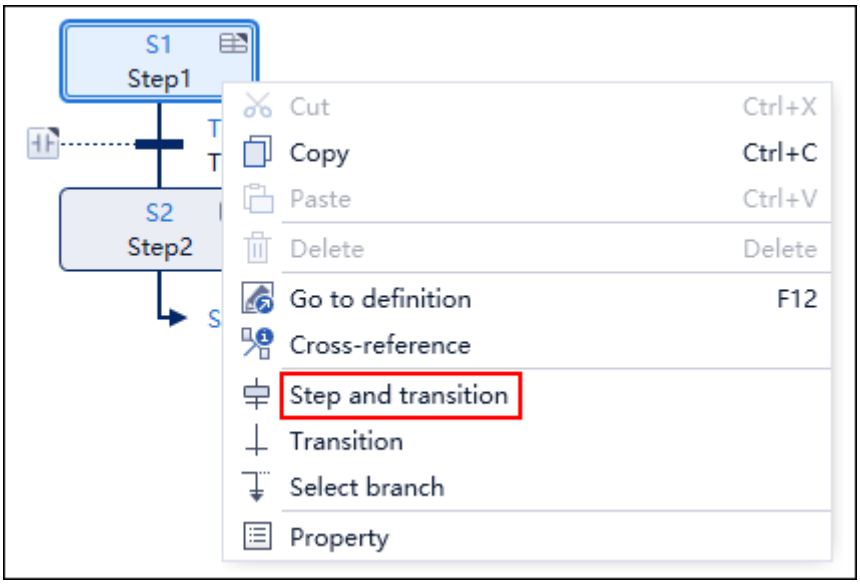
10.1.6.4.3.1 Transition Basic Properties

Click on the side of the transition to expand the transition condition logic editing area. If the current program content is large, it may exceed the display area. Click the "Fit size" icon to fully display all program content within the visible area; click the "Minimize" icon to collapse the condition logic editing area and simplify the interface.

No.	Item	Description
①	Transition number	Transitions are numbered numerically. Each transition number is unique within the same program block. A transition number is automatically generated when a transition is created, which can be modified by users. Value range: 1 to 999.
②	Transition name	The name of the transition, which must be unique within the same program block. A transition name is automatically generated when a transition is created, which can be modified by users. It can include letters, Chinese characters, numbers, and underscores, with a length limit of 64 characters.
③	Transition condition	A transition is essentially a logic result (TRUE or FALSE). Transition logic can be programmed using LD language, but only one LD network segment is allowed, and only comparison operations are supported. Newly created transitions have empty logic by default, but the result is TRUE.
④	Comment	Each transition can have a comment, which is an empty string by default and can be modified by users. It can contain letters, Chinese characters, numbers, and underscores, with a length limit of 128 characters.

10.1.6.4.3.2 Transition Status

A transition condition can be active or inactive.



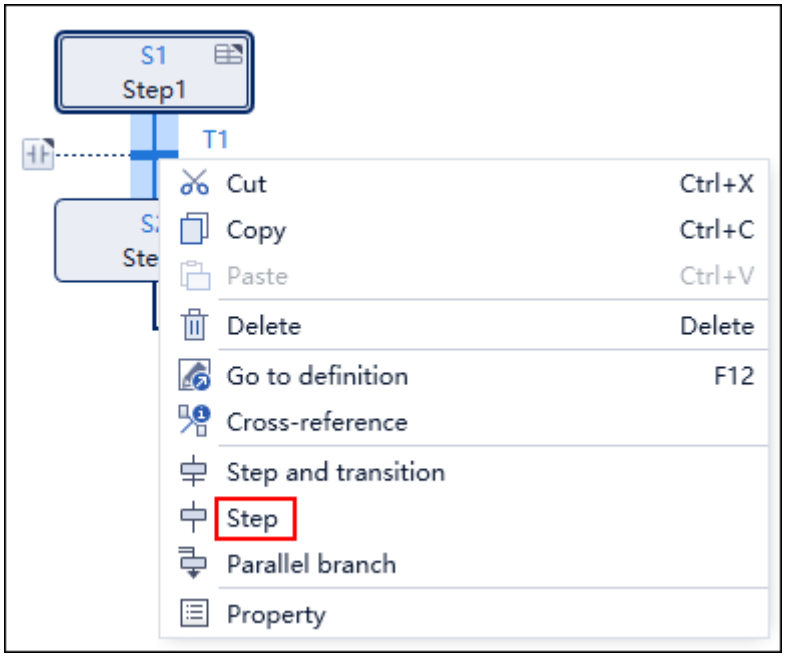
- Active state
  When the step before the transition is active, the transition condition becomes active.
  - Transition condition satisfied
    The transition condition is active, and the transition result is TRUE.
  - Transition condition unsatisfied
    The transition condition is active, and the transition result is FALSE.
- Inactive state
  When the step before the transition is inactive, the transition condition is inactive.

10.1.6.5 Step and Transition Usage

10.1.6.5.1 Adding a Step and Transition

There are multiple ways to add a step and transition, including the right-click menu, SFC editor toolbar, and the right-side toolbox. This section only introduces how to add through the SFC editor toolbar and the right-click menu.

- Method 1: Select a step or transition in the program, click on the toolbar to add a step and transition after the selected step.
- Method 2: Right-click a step or transition in the program, select "Step and transition" to add a step and transition after the selected step.

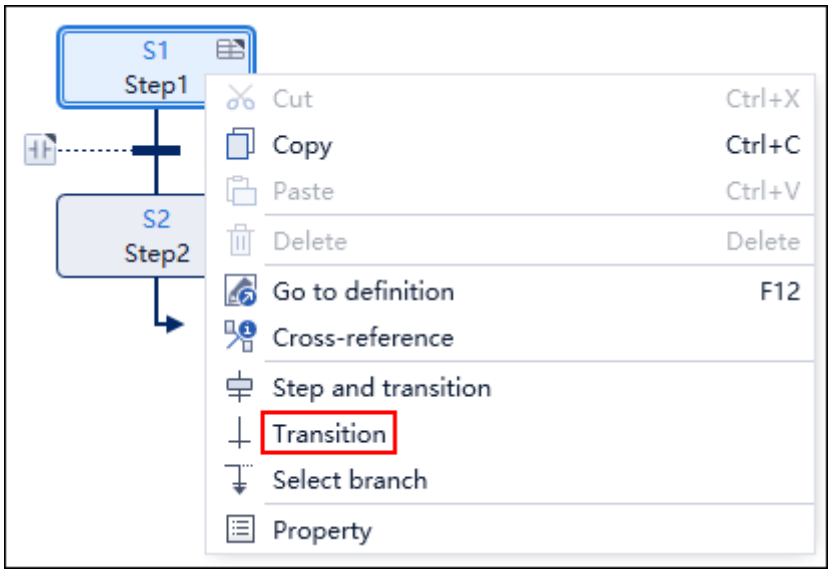


10.1.6.5.2 Adding a Step

There are multiple ways to add a step, including the right-click menu, SFC editor toolbar, and the right-side toolbox.

This section only introduces how to add through the SFC editor toolbar and the right-click menu.

- Method 1: Select a step in the program, click on the toolbar to add a step after the selected step.
- Method 2: Right-click a step in the program, select "Step" to add a step after the selected step.



NOTE

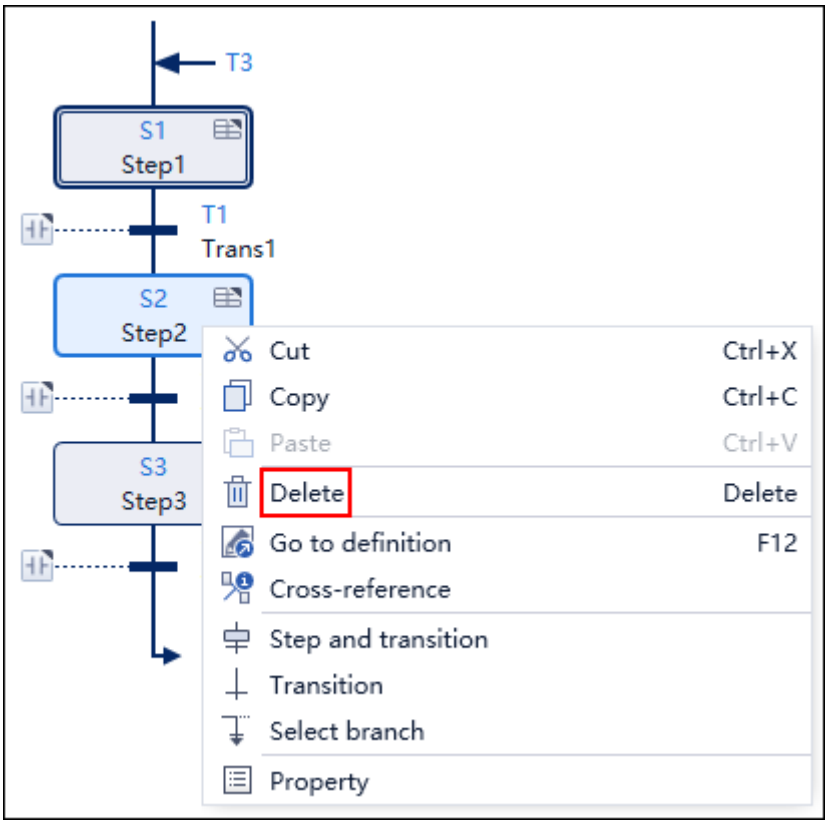
In an SFC program, a maximum of 250 steps can be added.

10.1.6.5.3 Adding a Transition

There are multiple ways to add a transition, including the right-click menu, SFC editor toolbar, and the right-side toolbox. This section only introduces how to add through the SFC editor toolbar and the right-click menu.

- Method 1: Select a transition in the program, click ⊥ on the toolbar to add a transition after the selected transition.
- Method 2: Right-click a transition in the program, select "Transition" to add a transition after the selected transition.

> **NOTE**
>
> In an SFC program, a maximum of 250 transitions can be added.



10.1.6.5.4 Deleting a Step and Transition

Restrictions

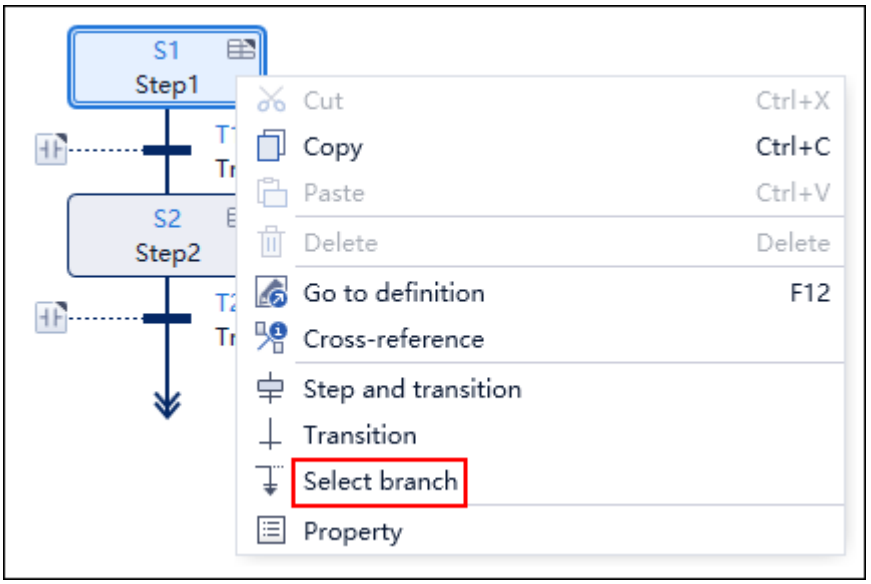
- The initial step cannot be deleted.
- When creating an SFC program, the first step generated by the system by default cannot be deleted.

Procedure

Right-click a step or transition in the program and select "Delete". Use the Shift key or Ctrl key for multiple selection to enable batch deletion.

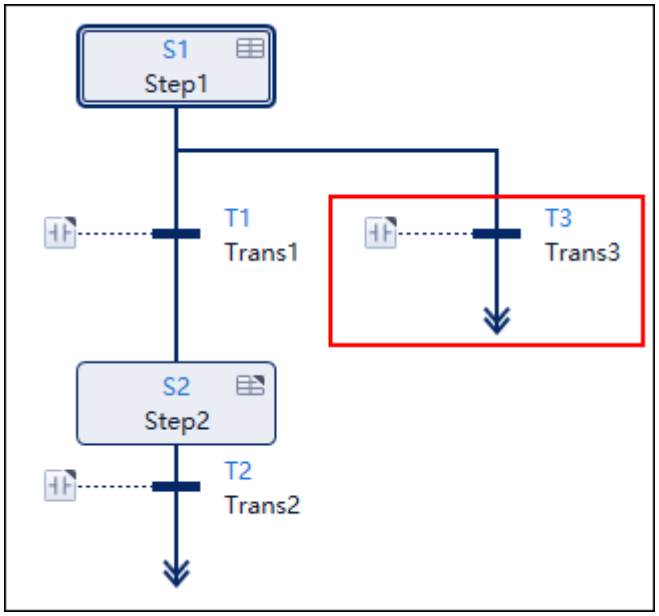
10.1.6.6 Branch Usage

10.1.6.6.1 Adding a Selective Branch



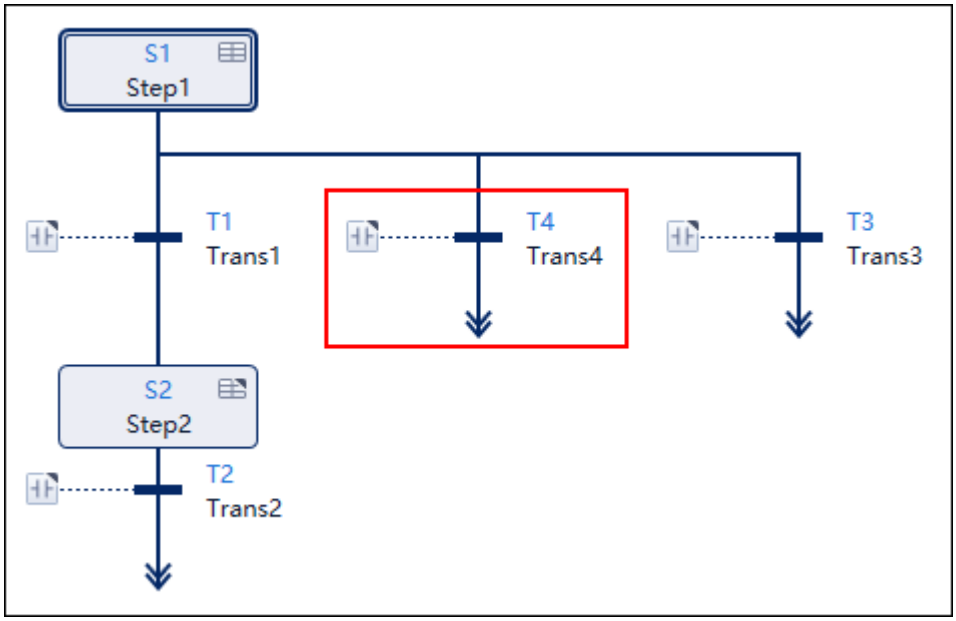
The selective branch can be added only below the step. Each selective branch must start with a transition. The logical relationship between multiple selective branches is OR, meaning the program executes only one of them. If multiple conditions are met simultaneously, execute the leftmost branch.

NOTE

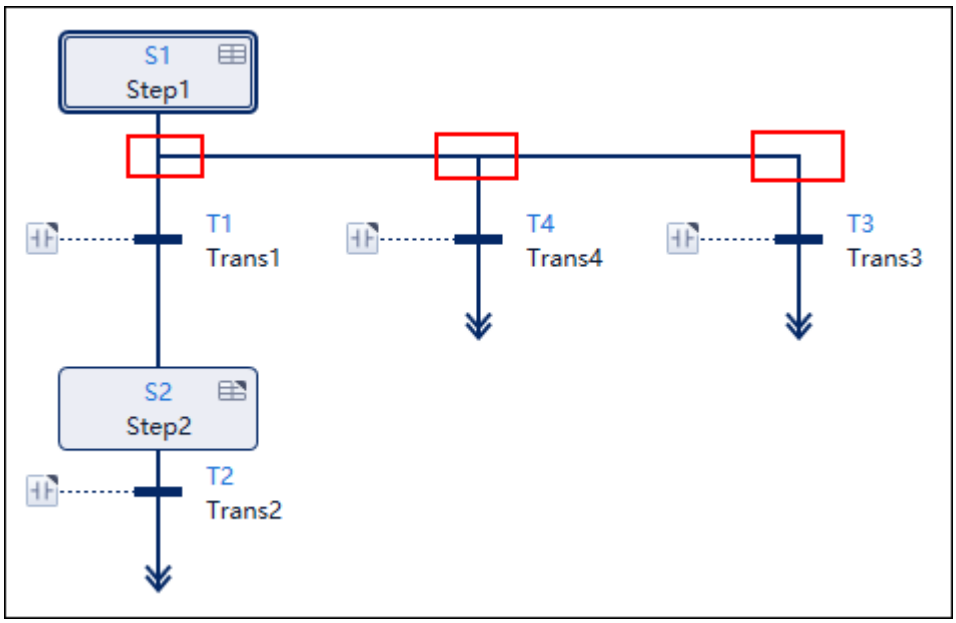


- In an SFC program, a maximum of 125 selective branches can be added.
- There are multiple ways to add an SFC element, including the right-click menu, SFC editor toolbar, and the right-side toolbox. This section only introduces how to add through the SFC editor toolbar and the right-click menu.

Procedure

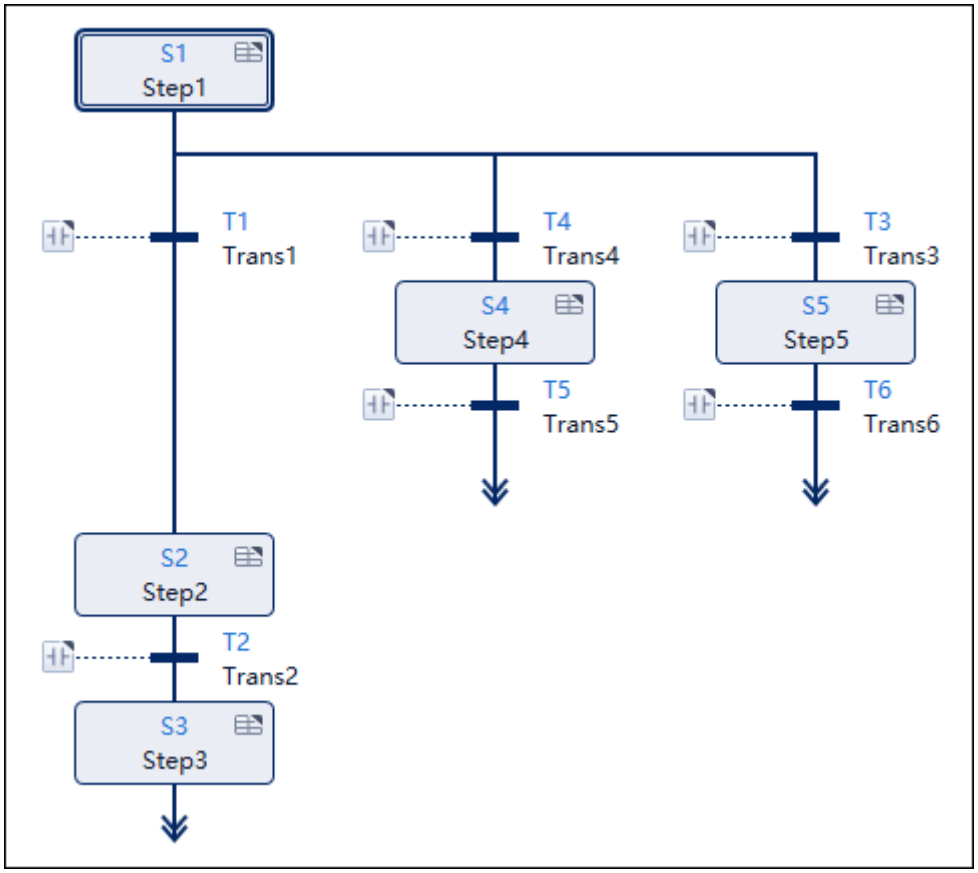


1. Select a step in the program and click on the toolbar. You can also right-click a step and select "Selective branch".



2. A new selective branch is added on the right, which includes a transition, as shown in the following figure.

3. Continue adding selective branches in the following two ways:
   - Keep the current step selected, click on the toolbar or select "Selective branch" from the right-click menu to continue adding new selective branches on the far left, like Trans4 below.

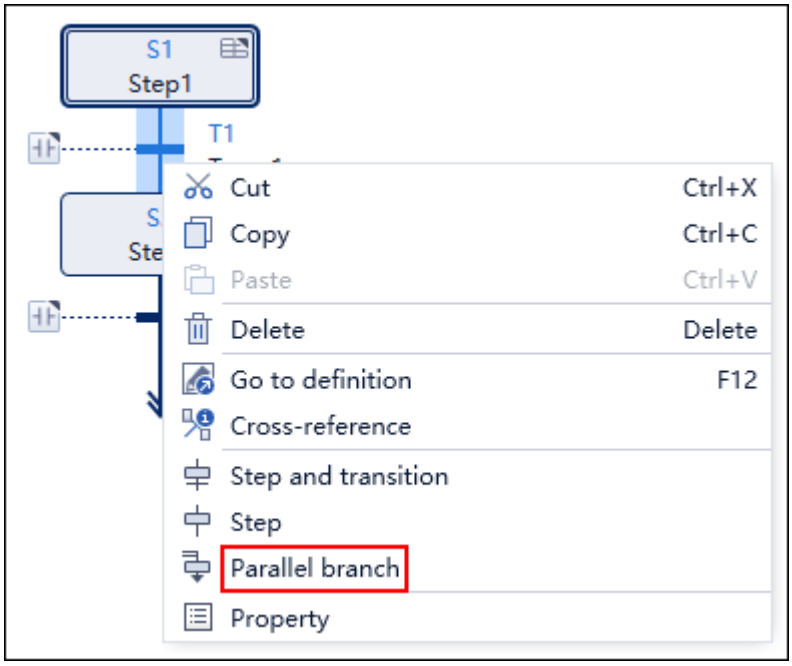


- Select the branch location as shown in the figure, click on the toolbar or select "Selective branch" from the right-click menu to add a new selective branch to the right of the selected branch.

Example Explanation

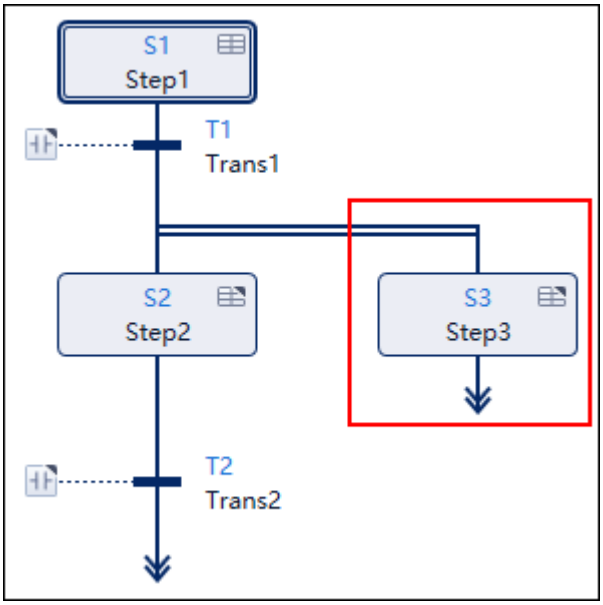
As shown in the figure below, if both Trans1 and Trans4 conditions are met, Step1 is executed, followed by Step2.

10.1.6.6.2 Adding a Parallel Branch



The parallel branch can be added only below the step. Each branch must start with a step. The logical relationship between multiple parallel branches is AND, meaning the program executes all branches simultaneously.

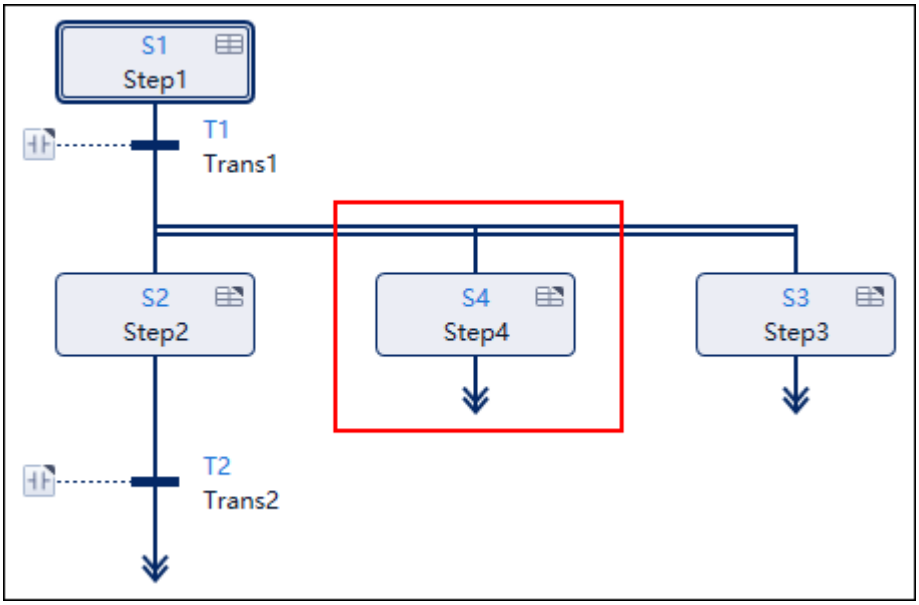
NOTE



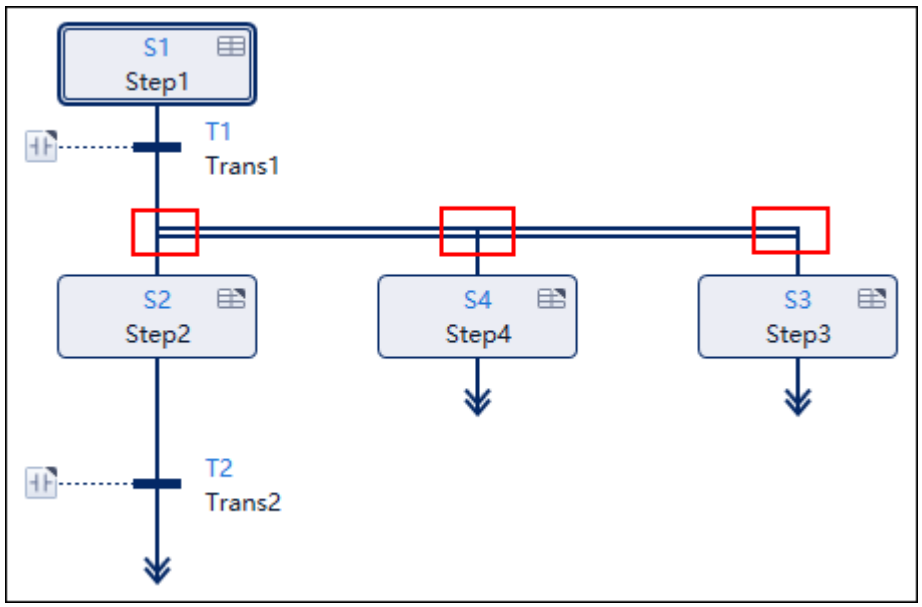
- In an SFC program, a maximum of 249 parallel branches can be added.
- There are multiple ways to add a parallel branch, including the right-click menu, SFC editor toolbar, and the right-side toolbox. This section only introduces how to add through the SFC editor toolbar and the right-click menu.

Procedure

1. Select a transition in the program and click on the toolbar. You can also right-click a transition and select "Parallel branch".



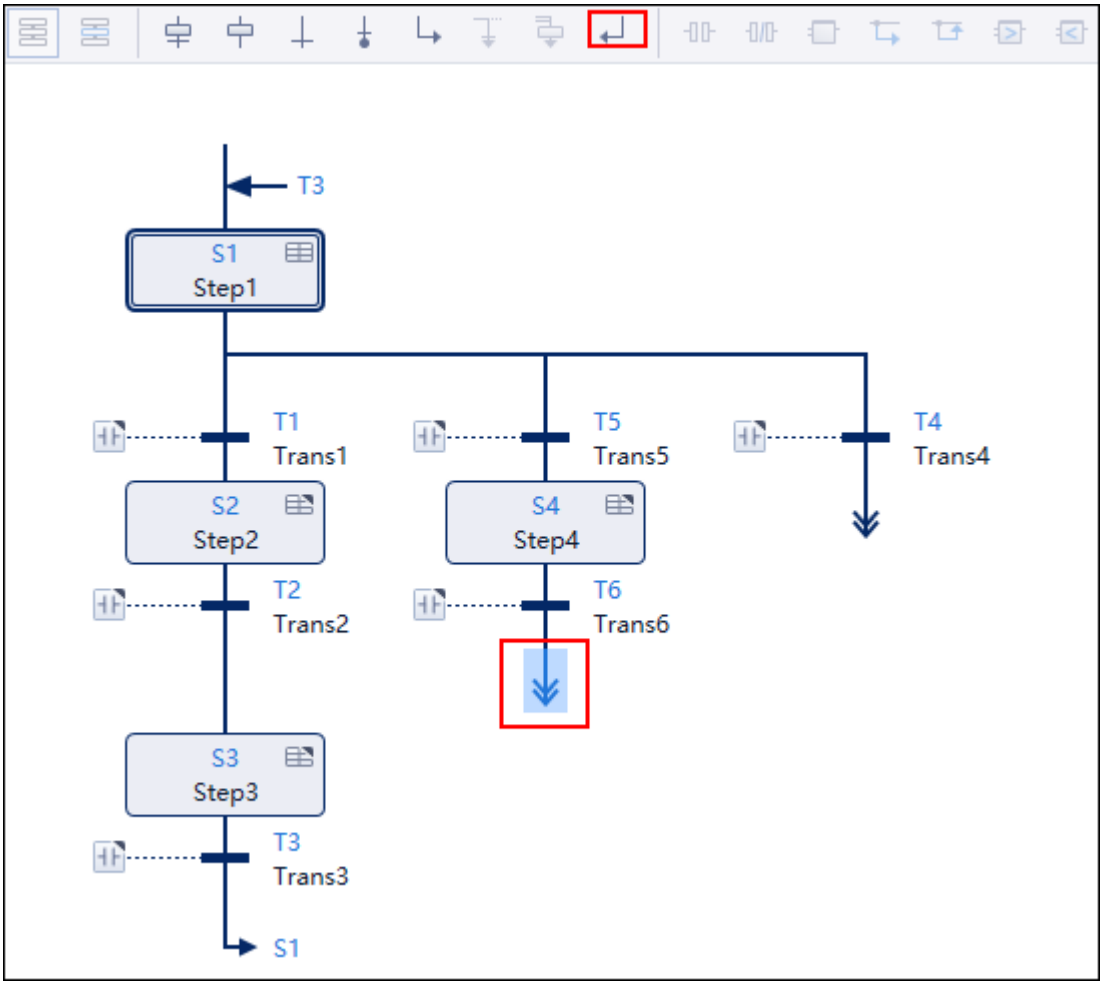
2. A new parallel branch is added on the right, which includes a step, as shown in the following figure.



3. Continue adding parallel branches in the following two ways:

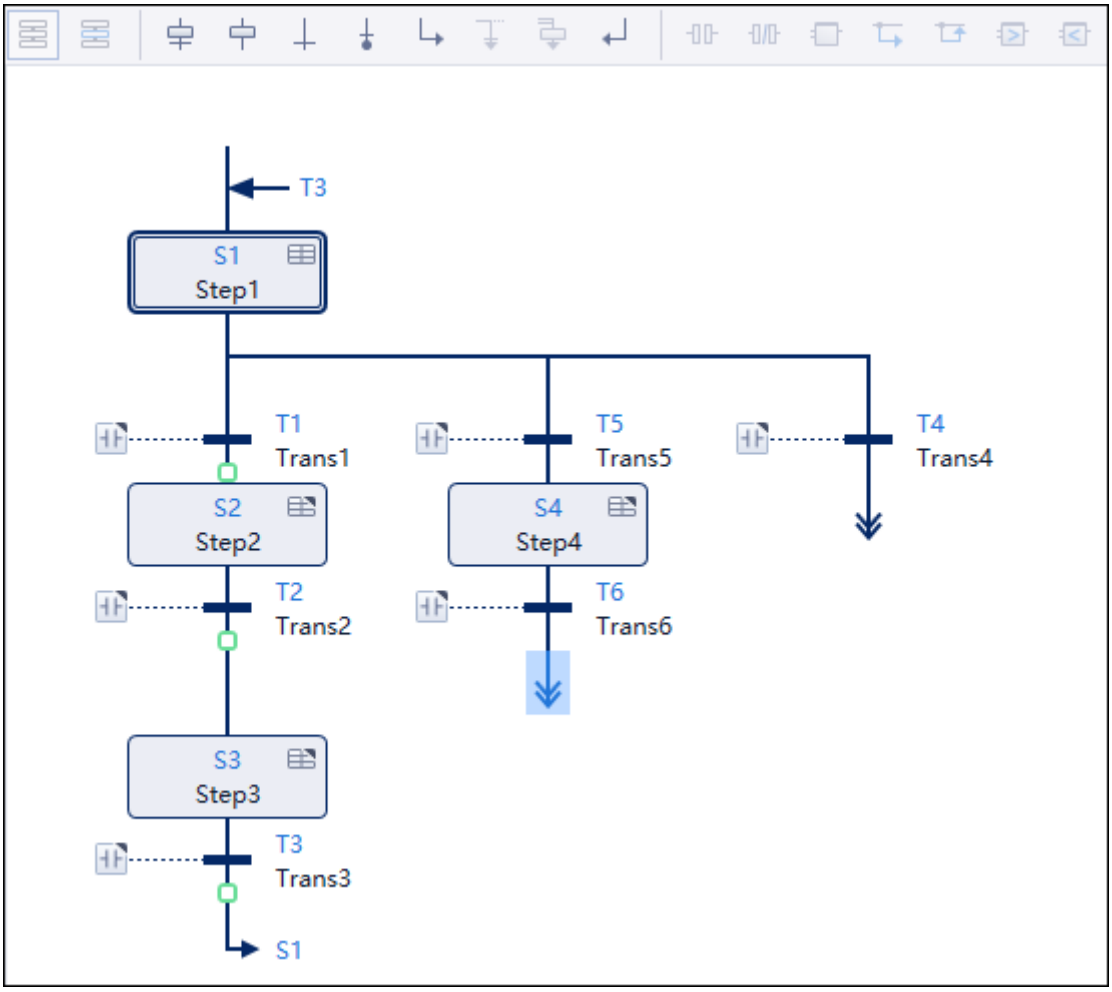
   ◦ Keep the current transition selected, click on the toolbar or select "Parallel branch" from the right-click menu to continue adding new parallel branches on the far left, like S4 below.

- Select the branch location as shown in the figure, click on the toolbar or select "Parallel branch" from the right-click menu to add a new parallel branch to the right of the selected branch.



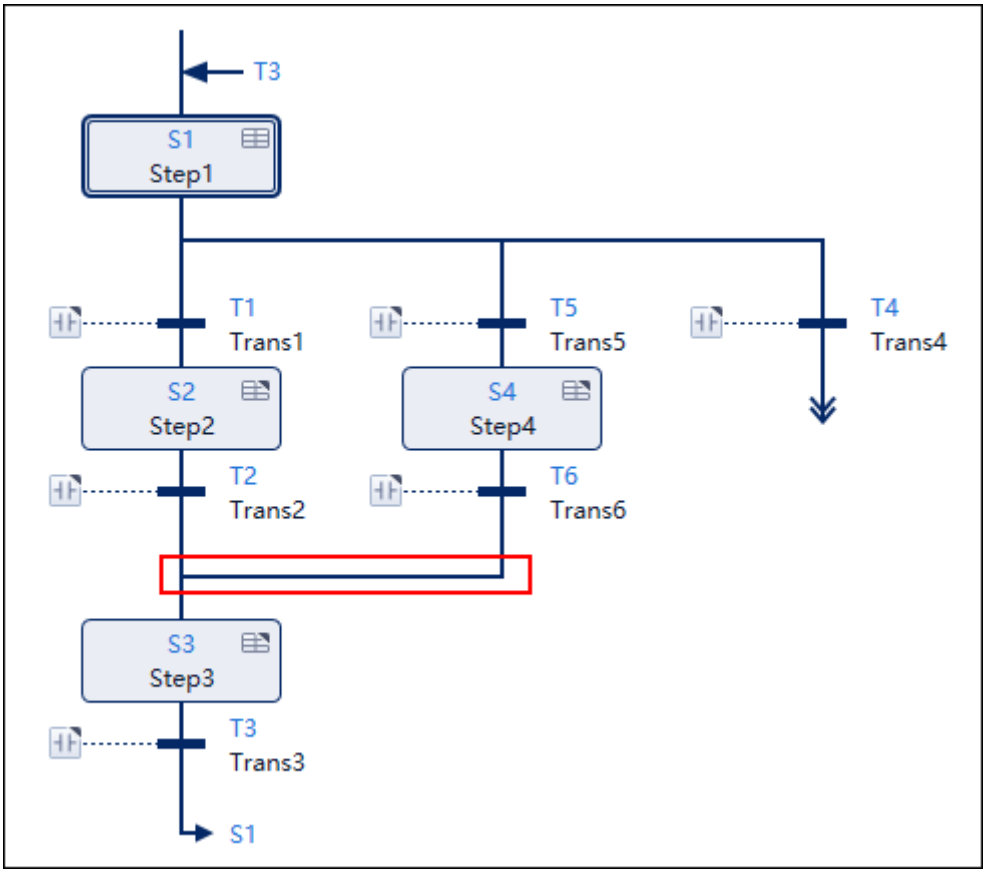
10.1.6.6.3 Closing a Branch

Closing a branch defines its end point and terminates the branch task. There are three methods: return to parent, insert a jump, or insert an end.



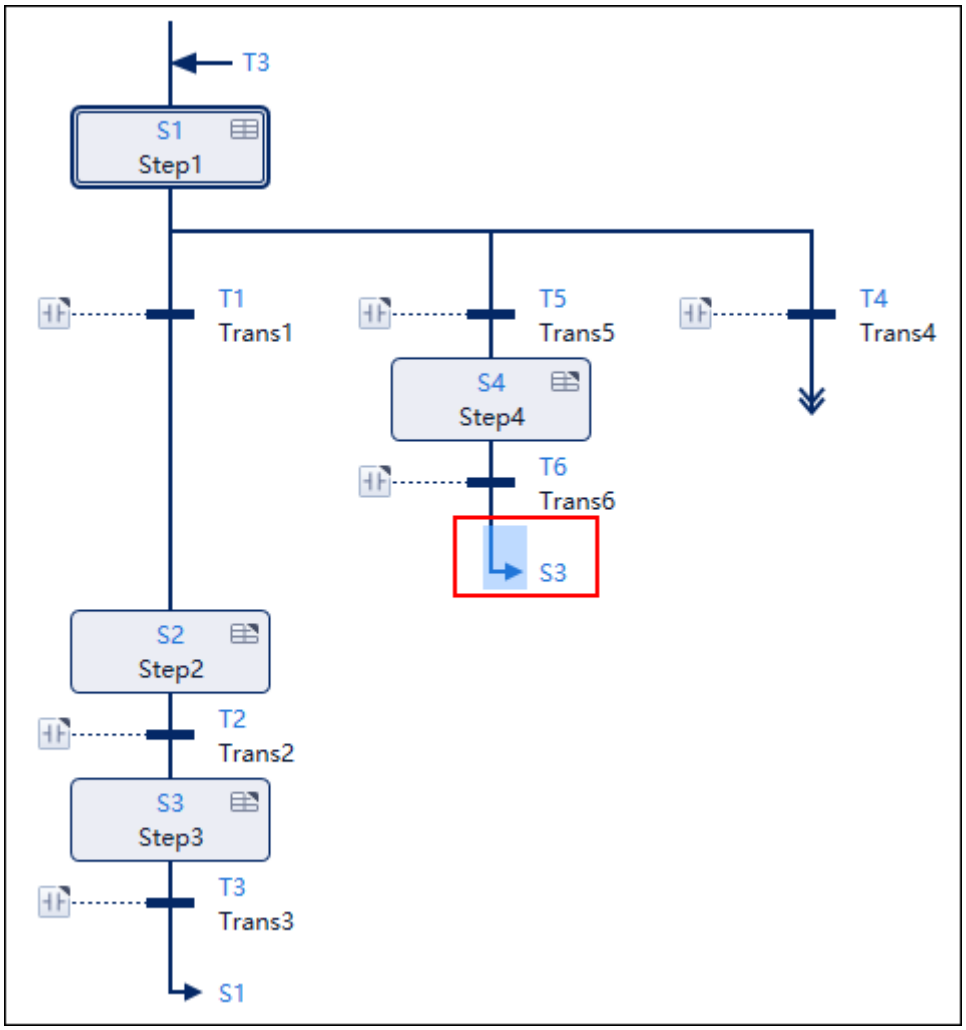
> NOTE
>
> There are multiple ways to add an SFC element, including the right-click menu, SFC editor toolbar, and the right-side toolbox. This section uses only one method as an example. The logic for other methods is similar, and users can choose flexibly.

- **Returning to parent branch**
  - Method 1: Select in a branch, and click on the toolbar, as shown in the following figure.

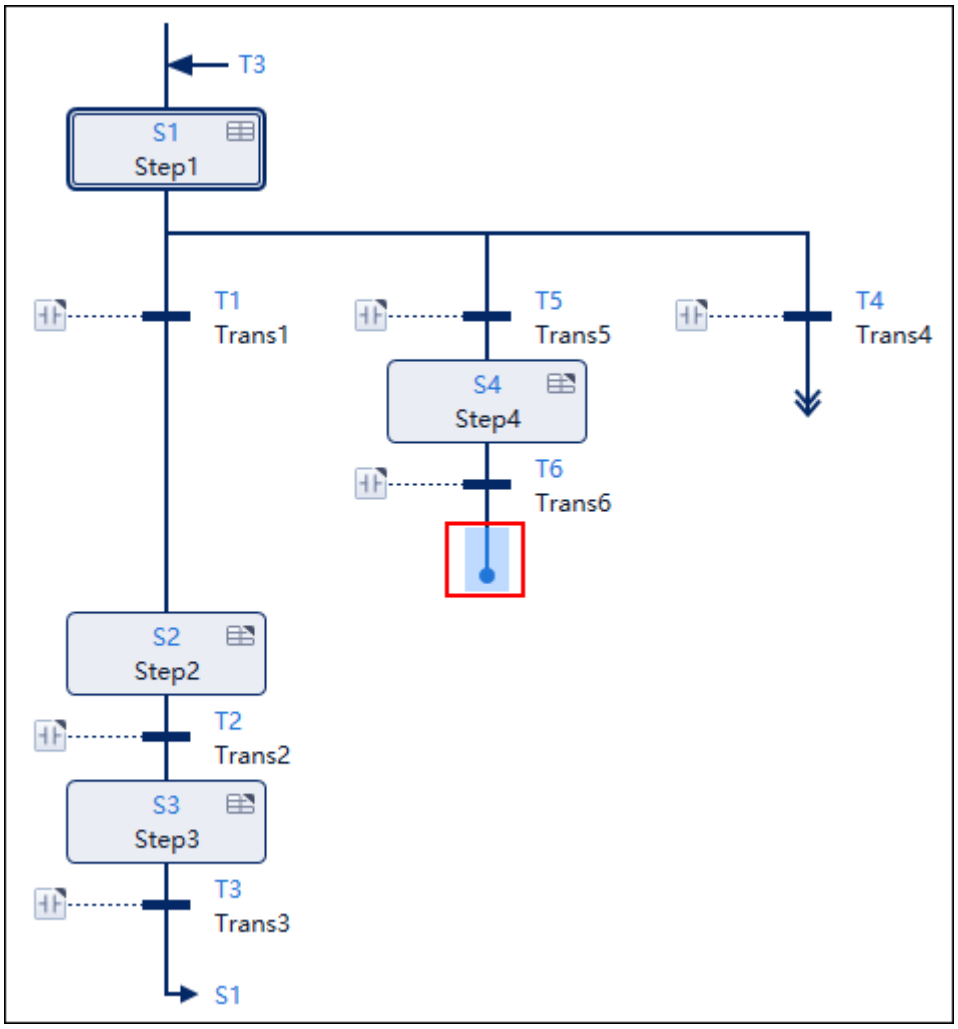


◦ Method 2: Drag and drop

1. Press and hold in a branch. Connectable positions will be highlighted in green, as shown in the figure below.

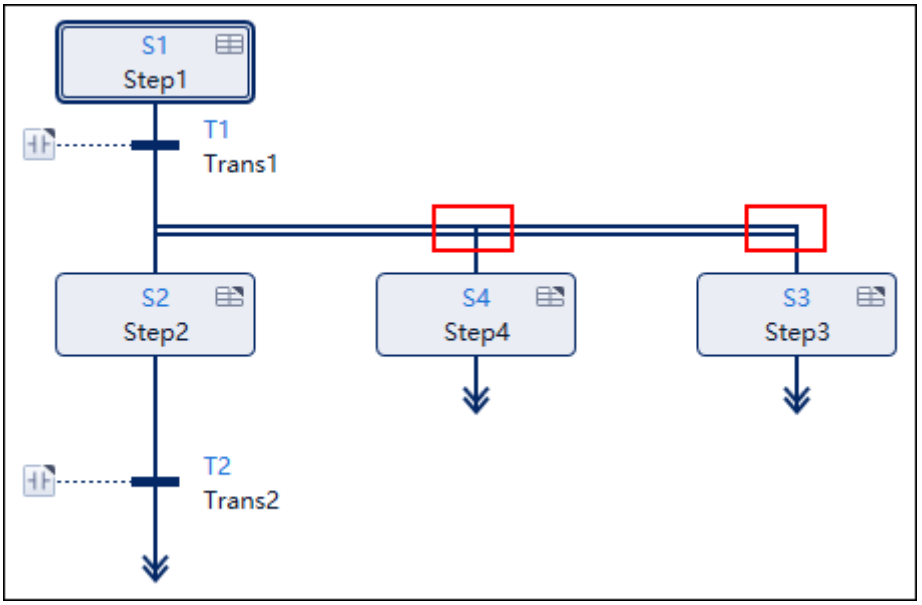


2. Move the mouse to the target position to connect.



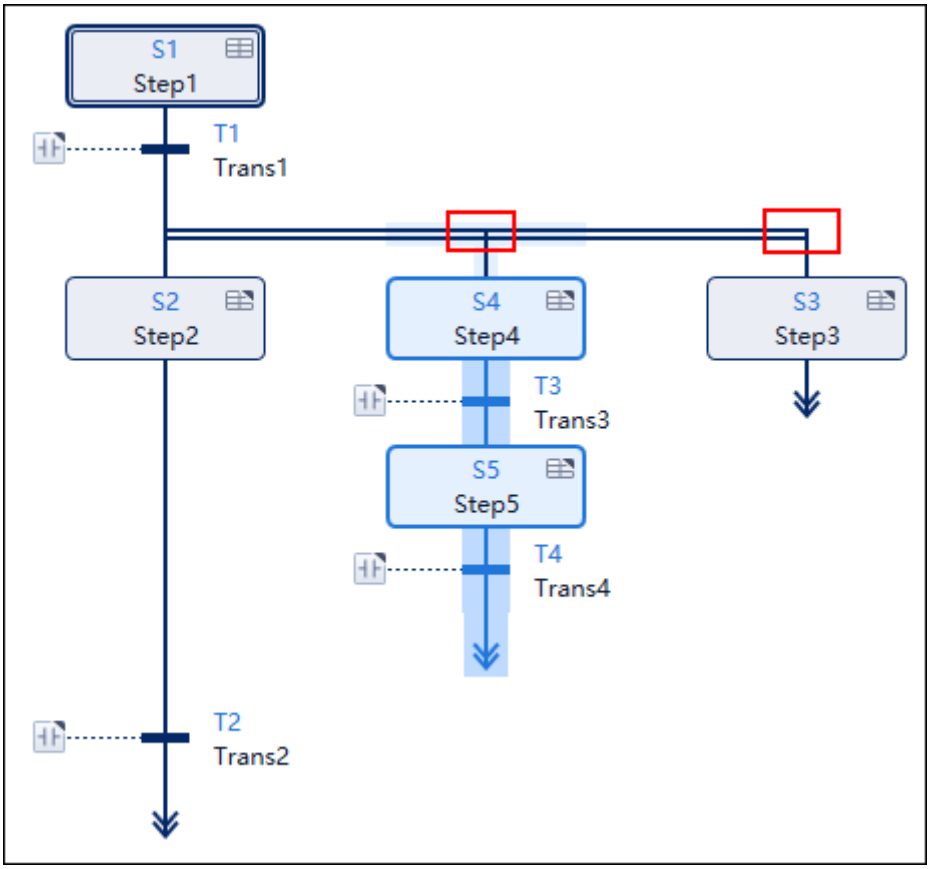
- **Inserting a jump**

Insert a jump to transfer execution to another step.



- **Insert an end**

End the program by inserting an end.



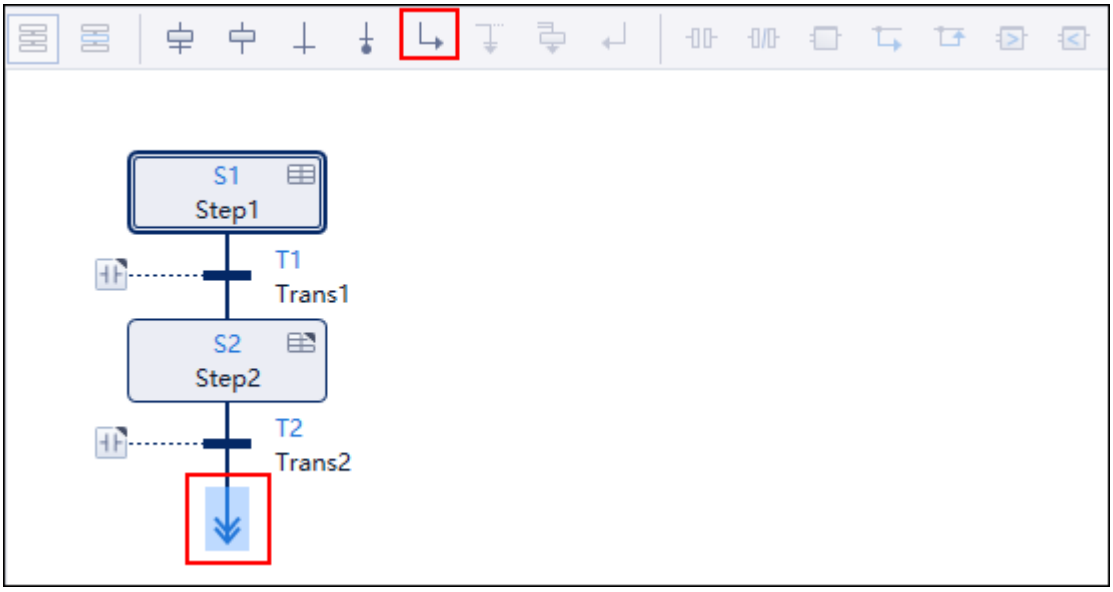
10.1.6.6.4 Deleting a Branch

- Method 1: Right-click the top of the branch and select "Delete".

- Method 2: Double-click the top of the branch to select all branch objects. Right-click the branch and select "Delete".

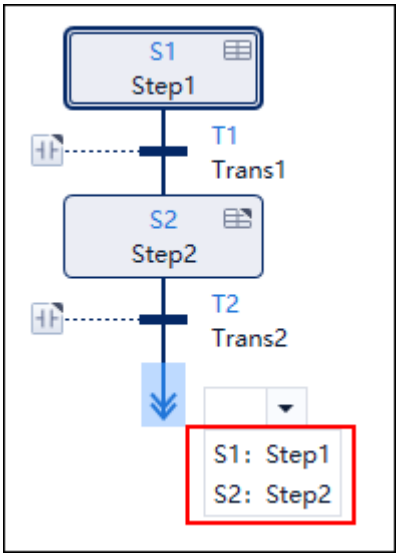
10.1.6.7 Jump Usage

10.1.6.7.1 Adding a Jump



By using the jump function, you can jump from any step directly to a specified step for program loop processing.

> NOTE
>
> There are multiple ways to add an SFC element, including the right-click menu, SFC editor toolbar, and the right-side toolbox. This section uses only one method as an example. The logic for other methods is similar, and users can choose flexibly.



Procedure

1. Select one of the in the program, and click on the toolbar.

> NOTE
>
> A transition must exist before a jump; if missing, please insert a transition first.

Select the target step. The target step is a step within this program block (POU).

10.1.6.7.2 Changing Jump Target

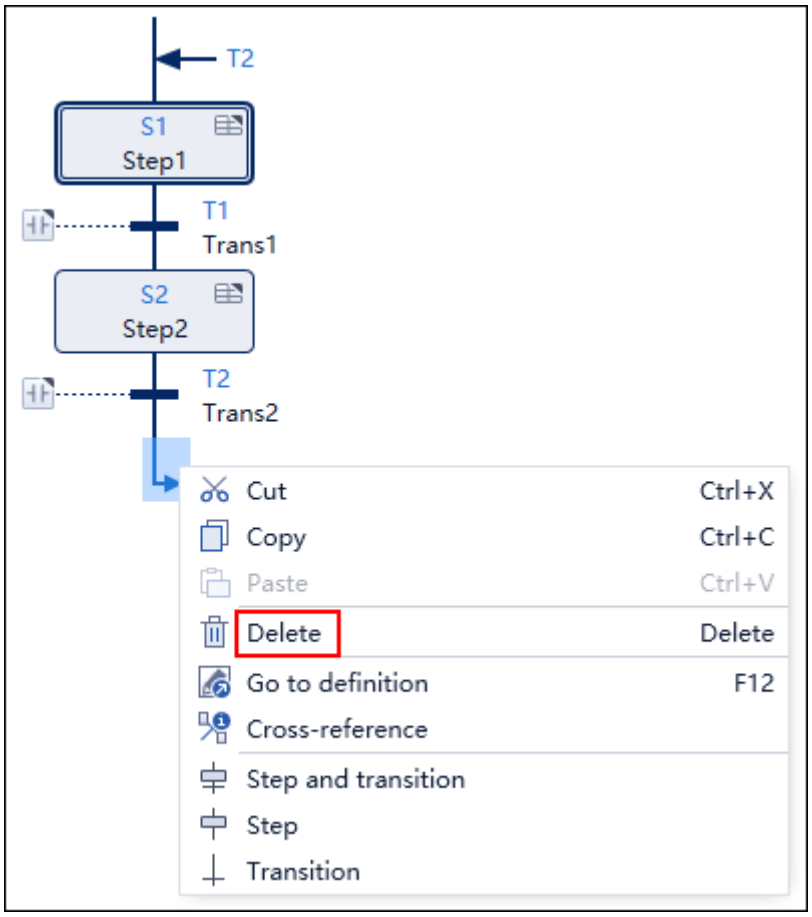
The jump function allows direct navigation to a specified step from any step, and supports changing the target as needed.

Prerequisites

A jump has been added.

Procedure

1. Double-click the current target step number.
2. Select a step as the new jump target.



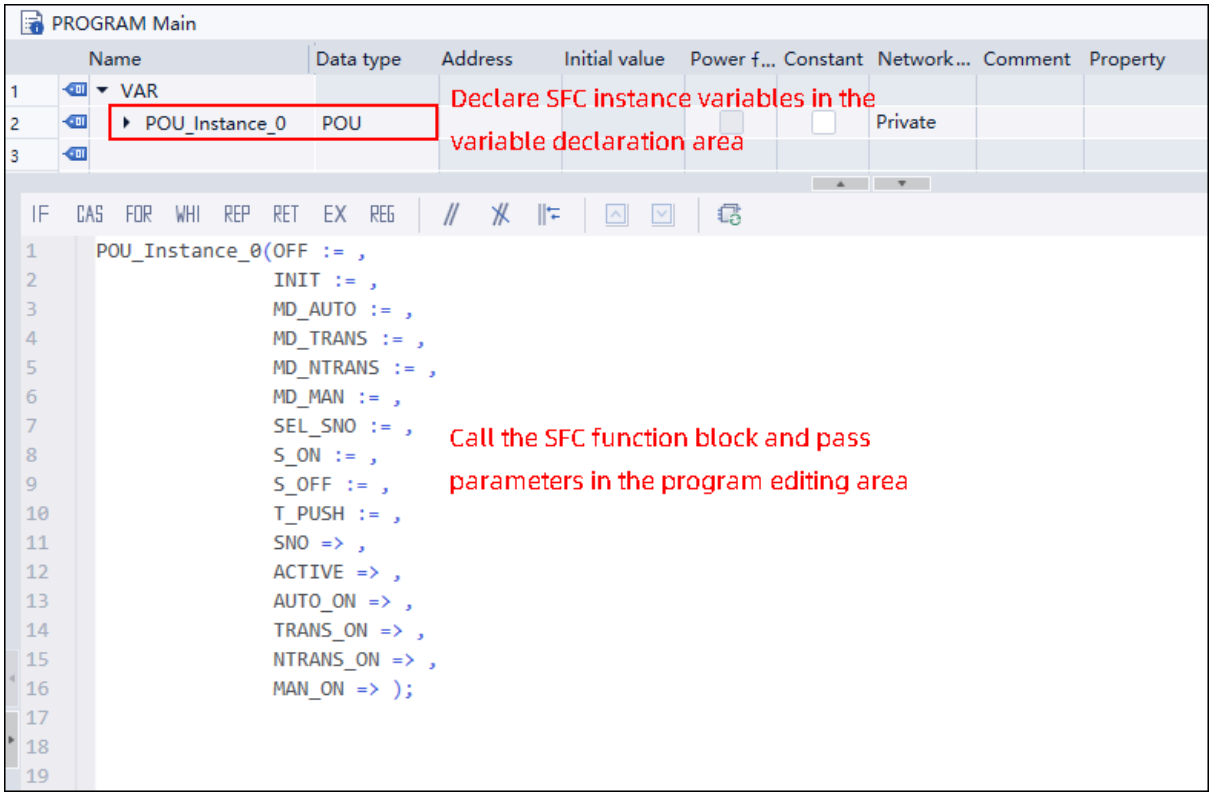
10.1.6.7.3 Deleting a Jump

Prerequisites

A jump has been added.

Procedure

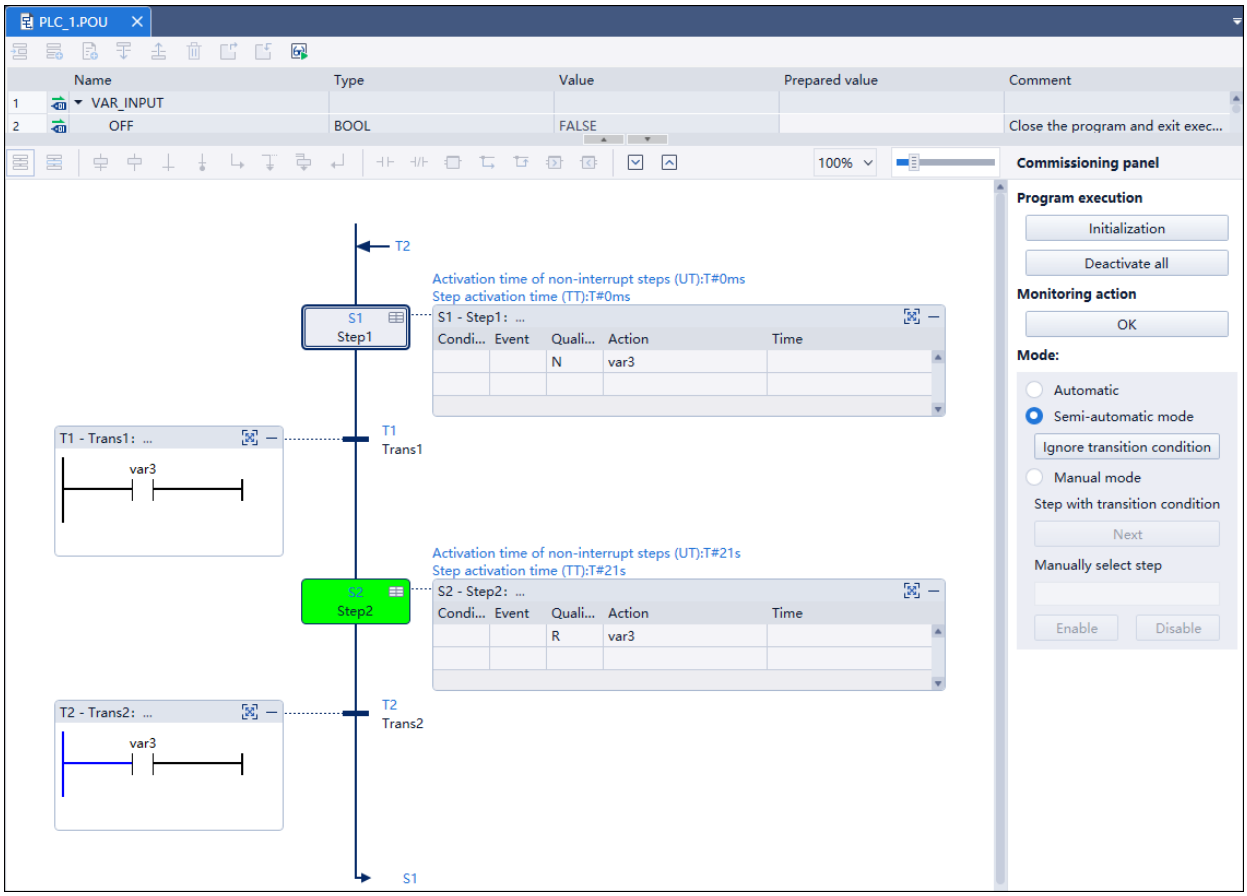
Right-click the added step and select "Delete".



10.1.6.8 SFC Configuration and Commissioning

10.1.6.8.1 SFC Instantiation

SFC instantiation refers to the need for function blocks to be instantiated before use. Function blocks are abstract structure type definitions and not actual data entities; therefore, they cannot be called or executed by a program without instantiation.

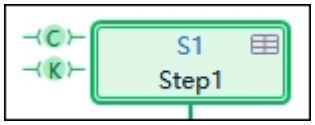


Procedure

1. Create an SFC function block. For details, see 10.1.6.2.1 Creating an SFC Program Block.
2. Instantiate the function block and pass the parameters. For parameter details, see 10.1.6.3.6 SFC Program Block Interface Parameter.

10.1.6.8.2 SFC Commissioning

SFC supports online commissioning.



- **Status Display**

SFC displays step status, transition condition status, condition and monitor result. The steps that define conditions and monitors will display the marks -(C)- and -(K)- next to them.

- Step inactive: Gray background.

- Step active: Green background.

- Step active with monitor result FALSE: Orange background.

- Step active with monitor result TRUE: Red background.

- Transition result TRUE: Green background.

- **Commissioning mode**

  The SFC program supports four operating modes: automatic mode (default), mode with transition conditions, mode ignoring transition conditions, and manual mode. Users can switch operating modes by configuring the input parameters of the SFC program.

  - Auto mode (AUTO)
    Automatically moves to the next step when the transition condition is met.
  - Mode with transition conditions (TAP)
    Automatically moves to the next step only when the transition condition is met and a rising edge is triggered on the input parameter "T_PUSH".
  - Mode ignoring transition conditions (TOP)
    Automatically moves to the next step when the transition condition is met or a rising edge is triggered on the input parameter "T_PUSH".
  - Manual mode (MAN)
    Does not automatically move to the next step when the transition condition is met; it requires manual selection of a step or switching to the next step.

- **Commissioning panel**

  The commissioning panel includes two parts: program initialization settings and operation mode selection.

  - Initial value setting
    - Click the "Initialize" button under "Sequential controller operation" to reset the program status.
    - Click the "Deactivate all" button under "Sequential controller operation" to disable all steps within the program.
    - When an error occurs during monitoring, click the "Confirm" button under "Monitoring action" to continue executing the program.

- Operation mode selection
  - Automatic mode

    Automatically moves to the next step when the transition condition is met.
  - Semi-automatic mode

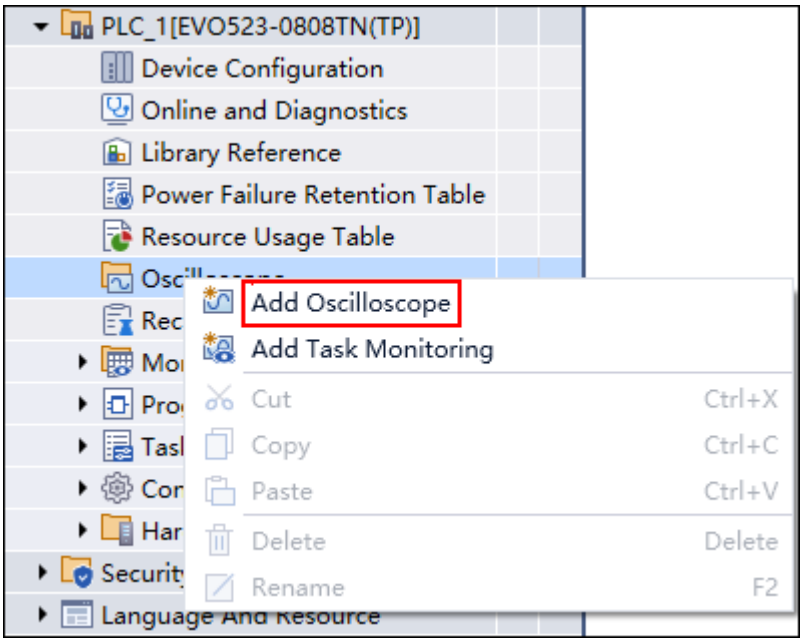
    Automatically moves to the next step when one of the following conditions is met.
    - The transition condition is met.
    - The input parameter "T_PUSH" triggers a rising edge.
    - Manually switch to the next step using the "Ignore transition condition" button.
  - Manual mode

    Users can manually switch to the next step or choose to enable or disable a specific step.

10.2 Oscilloscope

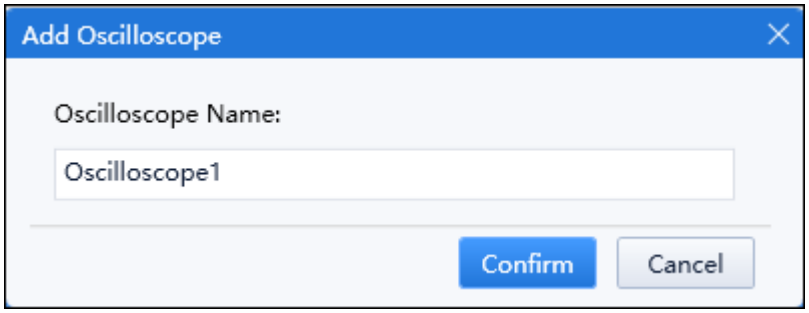
10.2.1 Basic Oscilloscope

10.2.1.1 Adding a Basic Oscilloscope



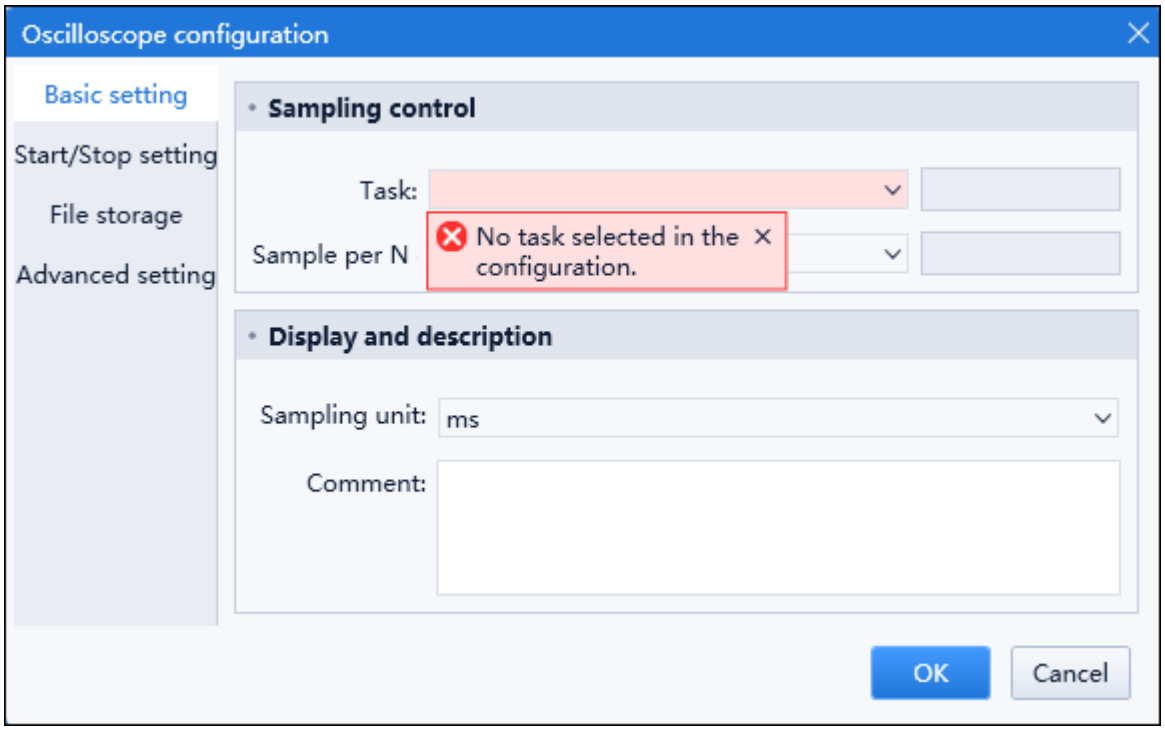
The basic oscilloscope provides real-time visualized monitoring of variables, simulating the functions of a hardware oscilloscope.

Prerequisites



- A PLC device has been added.
- A program has been added, and variables have been created.

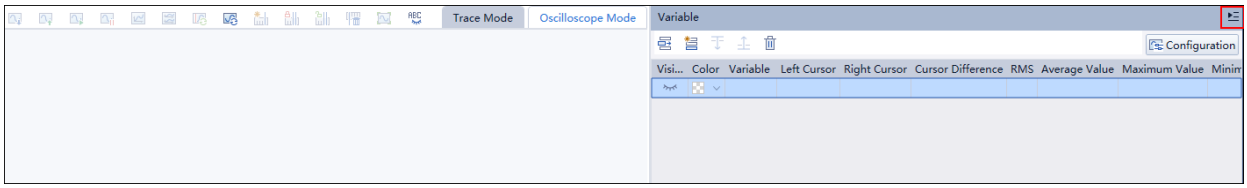
Procedure



1. Right-click "Oscilloscope" in the project tree and select "Add oscilloscope".

2. In the pop-up window, set the name of the oscilloscope and click "Confirm".

3. Click "Configuration" button in the upper right corner of the interface to open the "Oscilloscope configuration" window, set the related parameters (for details, see the oscilloscope configuration introduction in 10.2.1.2 Variable Area).

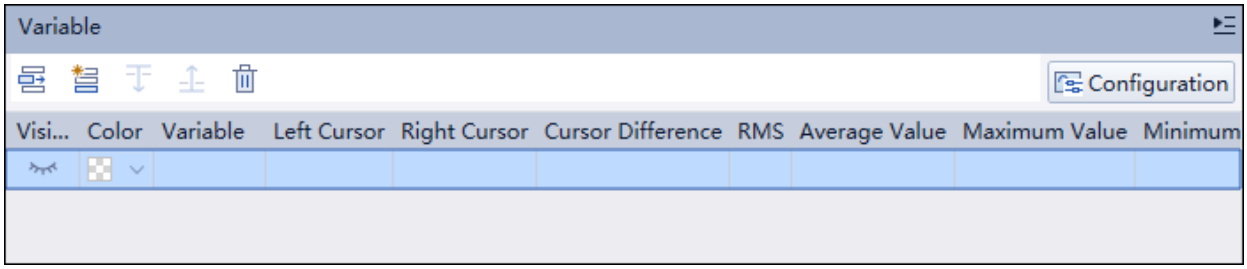


4. Click "OK" to enter the oscilloscope interface.

Result

The oscilloscope interface is divided into two parts: the plot area and the variable area.

The two areas can be resized by dragging the middle divider line. The variable area can be hidden or expanded using the "Collapse" icon, as shown in the figure below.



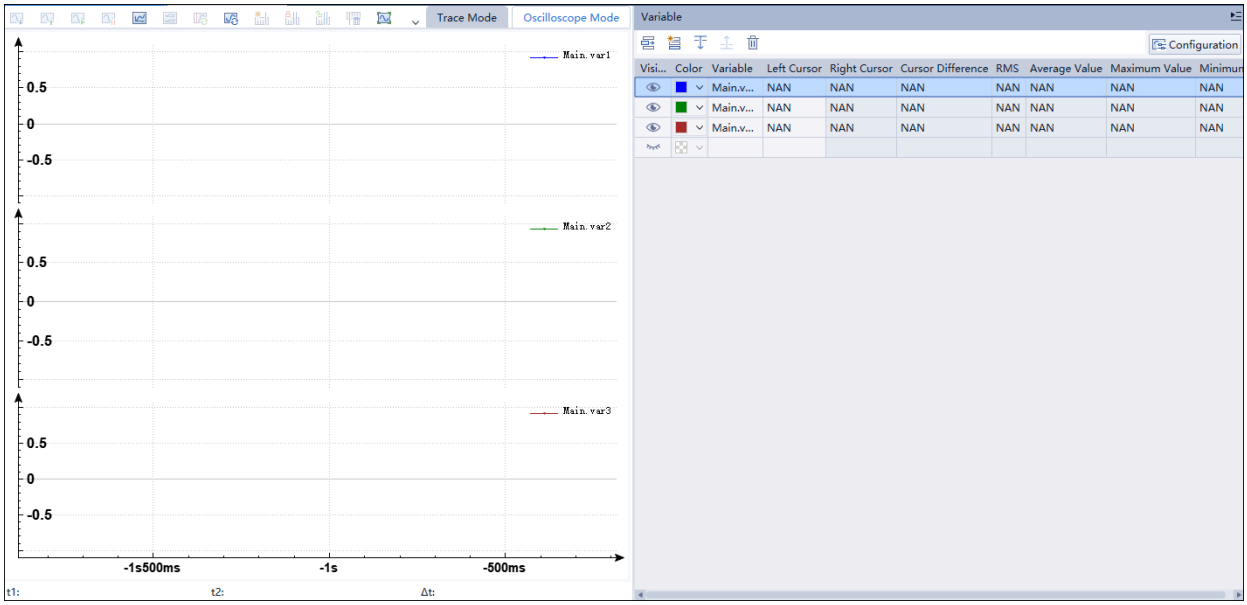
NOTE

The number of oscilloscopes supported varies by product, as shown in the table below.

	EVO400/EVO500	EVO700	EVO800
Max. number of oscilloscopes that can be added	32	64	64
Max. number of oscilloscopes that can be downloaded	32	64	64
Max. number of oscilloscopes that can run simultaneously	5	5	5

10.2.1.2 Variable Area

The variable area includes functions for adding variables and configuring the oscilloscope. The main interface is shown in the figure below.



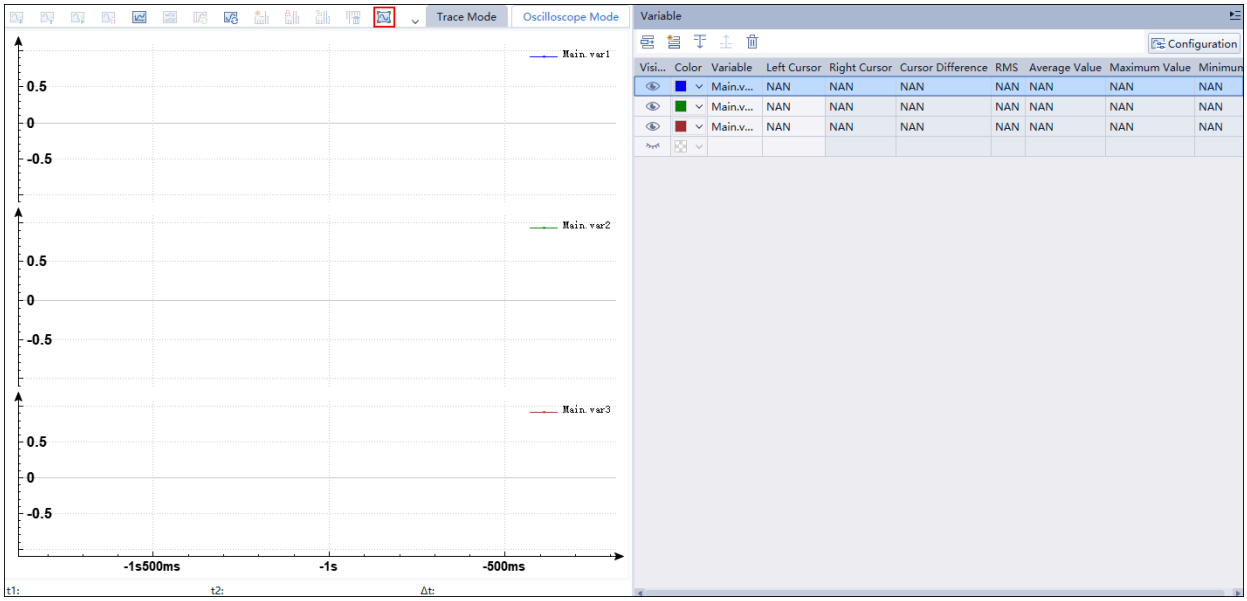
Adding a variable

There are three ways to add a variable:

- Click the "Add row" or "Insert row" icon on the toolbar, then double-click a cell in the "Variable" column to enter the variable name. This method only supports adding one variable at a time.
- Drag the variable directly from the "Details" window to the variable area of the oscilloscope to complete the addition. This method supports batch addition.
- Drag the variable directly from PRG or GV to the variable area of the oscilloscope to complete the addition. This method supports batch addition.

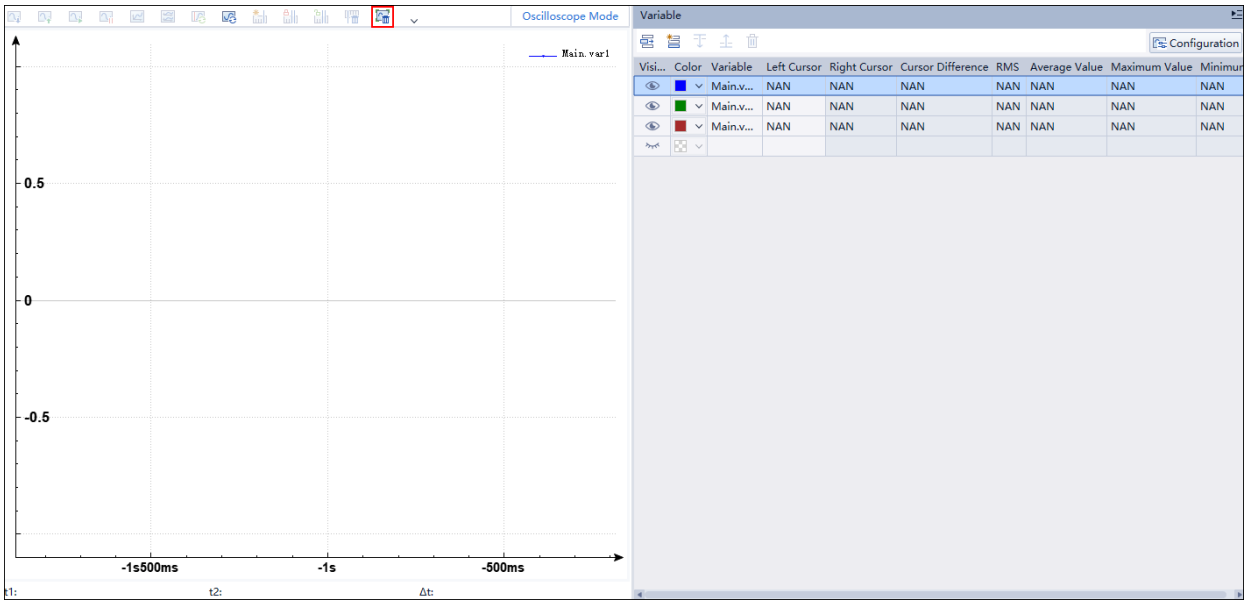
After the variable is added, the corresponding coordinate system will also be generated in the plot area.

NOTE



The number of oscilloscope variables supported varies by product, as shown in the table below.

	EVO400/EVO500	EVO700	EVO800
Max. number of oscilloscope variables that can be added or displayed simultaneously on a single oscilloscope	32	64	64
Max. number of oscilloscope variables that can be added to a single device	128	128	128
Max. number of oscilloscope variables that can be displayed simultaneously on a single device	64	64	64



Viewing variables in multi-channel mode

In multi-channel mode, when there are too many variables, select a variable and click the "Exclusive view" icon on the toolbar. Click the same icon to cancel the exclusive view.

- Before switching to the exclusive view, the plot area displays the views of all variables.

- After switching to the exclusive view, the plot area only displays the view of the selected variable.

NOTE

This operation is supported in both online and offline modes, but note the following:

- In offline mode, the variable exclusive view only supports resetting view, saving oscilloscope data, and cursor-related functions.
- In online mode, the variable exclusive view only supports resetting trigger, resetting view, saving oscilloscope data, and cursor-related functions.

Introduction to the variable area toolbar

Description	Icon	Description
Insert a row		Inserts an empty row above.

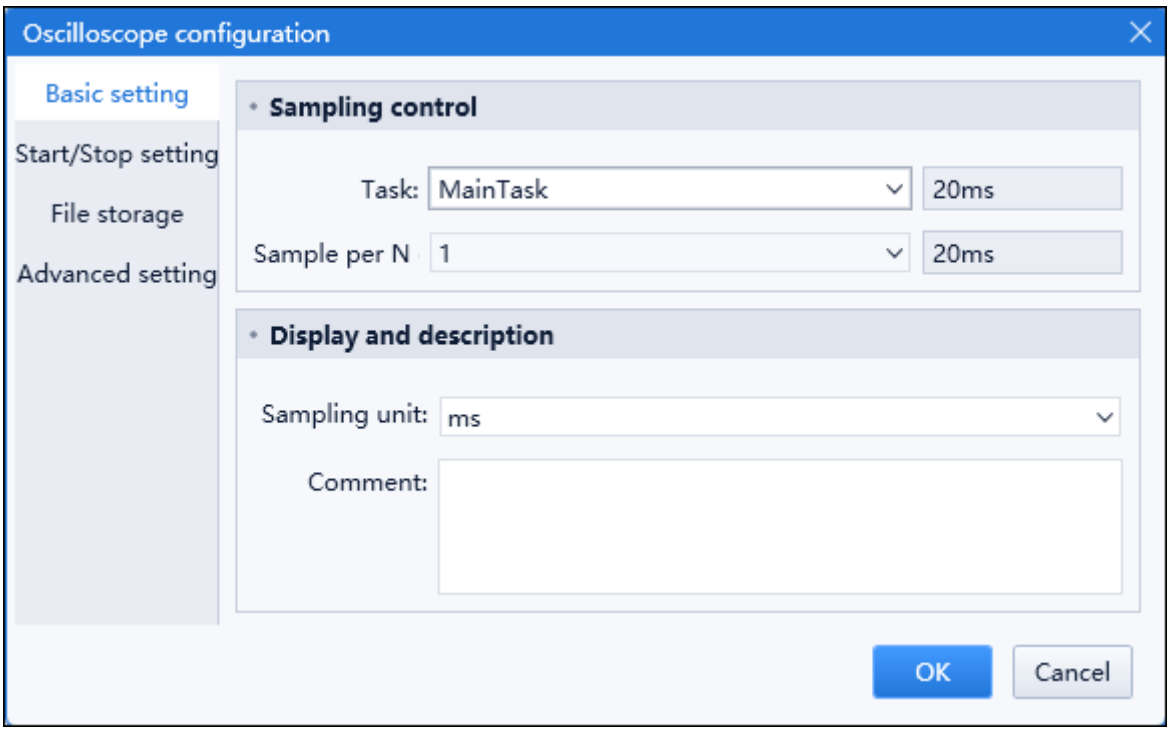
Description	Icon	Description
Add a row		Add an empty row. Oscilloscope variables can be added to the row in the following two ways: • Input with input assistant. • Manual input with intelligent association.
Move down		Moves the selected row down.
Move up		Moves the selected row up.
Delete		Deletes the selected row. It supports batch selection deletion.

Column properties of the variable table

The variable table displays variables added to the oscilloscope, including the following column properties.

Column Properties	Description
Visible	Sets the visibility of the variable in the oscilloscope. When there is only one variable in the variable table, this function is enabled by default.
Color	Sets the color of the variable in the oscilloscope from the drop-down menu.
Variable	Sets the instance path of the variable.
Left Cursor	Displays the value of the left cursor in the oscilloscope after a left cursor is added in the plot area.
Right Cursor	Displays the value of the right cursor in the oscilloscope after a right cursor is added in the plot area.
Cursor Difference	Displays the difference between the left cursor and the right cursor.
RMS	Displays the root mean square of the variable value during the acquisition time.
Average Value	Displays the average value of the variable during the acquisition time.
Maximum Value	Displays the maximum value of the variable during the acquisition time.
Minimum Value	Displays the minimum value of the variable during the acquisition time.

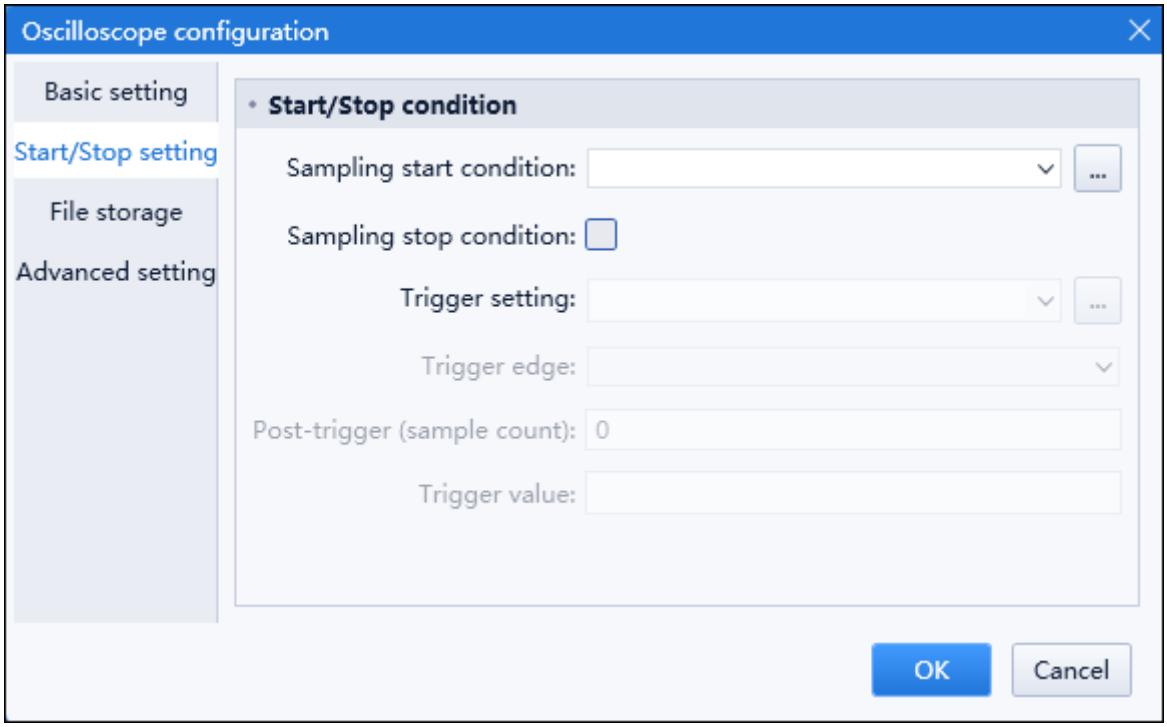
Right-click menu



The right-click menu includes cut, copy, paste, delete, input assistant, and configuration functions.

Function	Description
Cut	Cuts the selected variable.
Copy	Copies the selected variable.
Paste	Pastes the variable.
Delete	Deletes the selected variable.
Input assistant	Opens the "Input assistant" page.
Configuration	Opens the "Oscilloscope configuration" page.

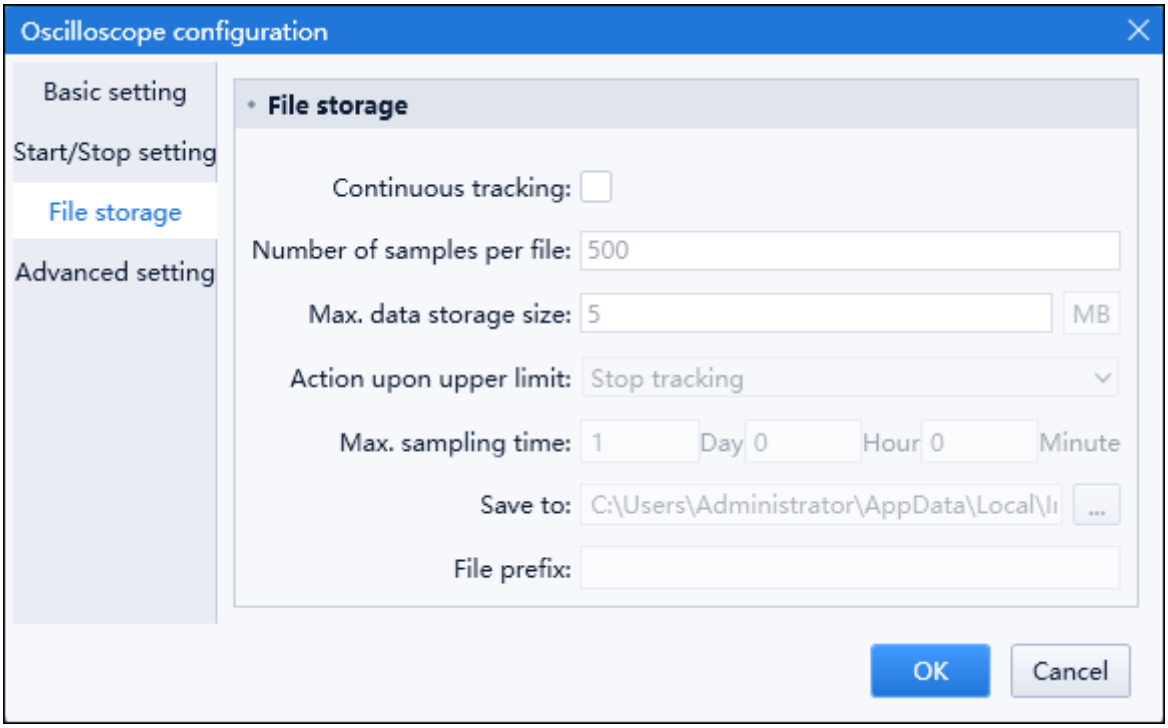
Oscilloscope configuration



This function is used to configure oscilloscope parameters, including basic settings, start/stop settings, file storage, and advanced settings. The configuration interface is shown as follows.

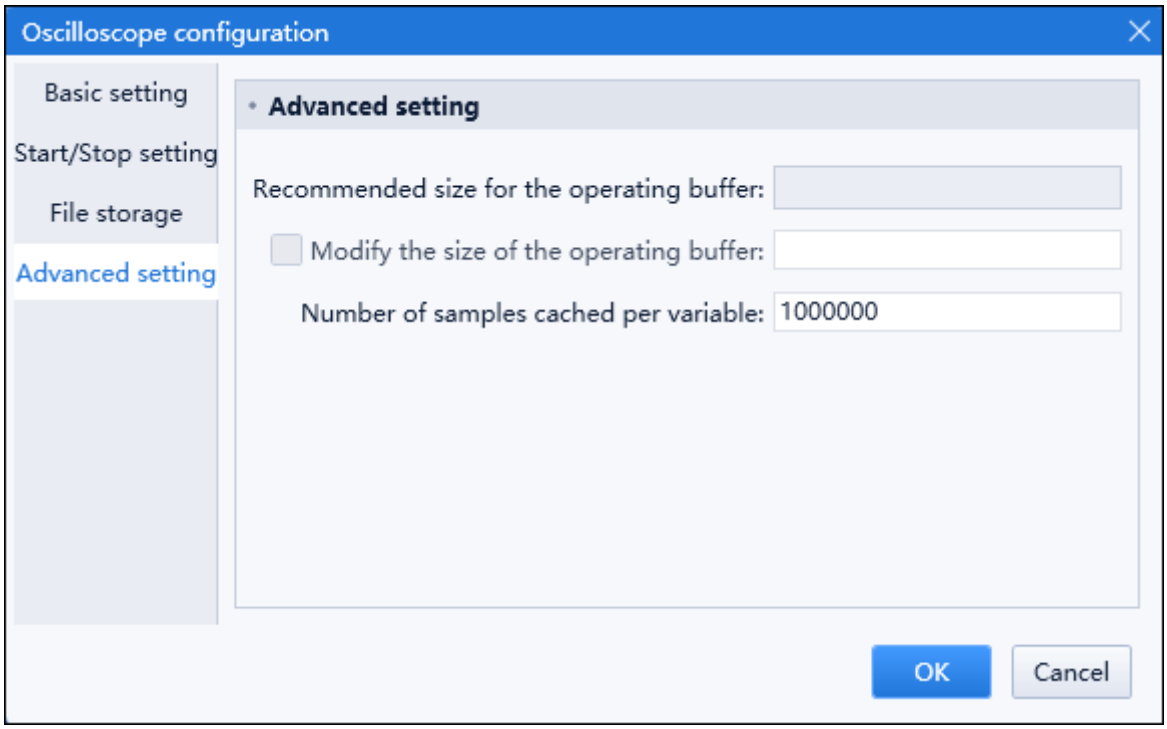
- **Basic settings**

Item	Parameter	Description
Sampling control	Task	Sets the cycle period for the oscilloscope to collect data, configured by selecting tasks from the drop-down menu.
	Measure per N cycles	Sets the sampling multiplier. Select different sampling multiples from the drop-down menu. The actual sampling cycle will be displayed after setting.
Display and description	Sampling unit	Sets the minimum time interval that can be displayed on the X-axis of the channel. Units include ms and μs (default: ms), which can be selected via the drop-down menu.
	Comment	Supports entering oscilloscope comments. After selecting the oscilloscope in the project tree, comments can be displayed via TIPS.



- **Start/Stop settings**

Item	Parameter	Description
Start/Stop conditions	Sampling start condition	Variable or input expression can be selected. When the expression result is TRUE, sampling starts; otherwise, sampling stops.
	Sampling stop condition	After "Sampling stop condition" is checked, the oscilloscope stops collecting and updating real-time data for the variable when the set stop condition (specific variable reaching a specified value) is met.
	Trigger settings	Trigger settings are divided into trigger variables and trigger parameters, which can be set through drop-down menu. • Trigger variable: Determines by specifying a variable in the POU. When the variable meets the configured condition, the oscilloscope stops sampling. • Trigger parameter: Determines by system parameters to stop sampling.



Item	Parameter	Description
	Trigger edge	Trigger edge is divided into rising edge, falling edge, and both rising and falling edges. • Rising edge ◦ For BOOL type trigger variables, triggering occurs when the BOOL value changes from FALSE to TRUE. ◦ For analog trigger variables, triggering occurs when the set value reaches the trigger value from a lower level. • Falling edge ◦ For BOOL type trigger variables, triggering occurs when the BOOL value changes from TRUE to FALSE. ◦ For analog trigger variables, triggering occurs when the set value reaches the trigger value from a higher level. • Rising and falling edges ◦ For BOOL type trigger variables, triggering occurs when the BOOL value changes. ◦ For analog trigger variables, triggering occurs when the set value reaches the trigger value.
	Post-trigger (sample count)	Sets the number of samples to continue collecting after the trigger is activated. The oscilloscope stops once the sample count is reached.
	Trigger value	Sets the trigger value of the specified trigger variable. When the variable reaches the trigger value, the oscilloscope stops sampling. The exact stop time depends on the selected trigger edge type.

- **File storage**

Item	Parameter	Description
File storage	Continuous tracking	• When "Continuous tracking" is checked, data can be collected according to the file storage settings in a custom directory. • When "Continuous tracking" is not checked, there is no need to store oscilloscope data locally and only cached data is displayed.
	Number of samples per file	Sets the number of data items that can be generated per file. After this number is exceeded, a new file needs to be generated to continue collection. The value range is 100 to 30000, with a default value of 500.
	Maximum data storage size	The value range is 5 to 1000000, with a default value of 5 MB.
	When limit is reached	When the maximum data storage is reached, you can choose to stop collection or delete old files through the drop-down menu.
	Maximum sampling time	The oscilloscope stops collection after this sampling time is exceeded. The time range is from 1 minute to 1000 days 23 hours 59 minutes.
	Save to	Sets the save path for the collected files.
	File prefix	Sets the prefix of the generated files. For example, when the prefix is set to XX, files are generated as XX, XX_1, and XX_2.

- **Advanced settings**

Item	Parameter	Description
Advanced settings	Recommended size for the operating buffer	Default is 101.
	Modify the size of the operating buffer	Used to adjust the real-time Runtime buffer; not selected by default. The buffer size range is 10 to 500,000.
	Number of samples cached per variable	The number of samples for each variable cache must be no less than twice the size of the operating buffer and no more than 1,000,000 (default).

10.2.1.3 Plot Area

Trace mode / Oscilloscope mode

Oscilloscope mode displays single-variable data in the oscilloscope.

Trace mode is generated based on the variable list in oscilloscope mode, following the index order of variables (consistent with the display order in the variable table). Each pair of adjacent variables is combined (for example, variables at index 0 and 1 are combined, and variables at index 2 and 3 are combined). If there is an odd number of variables, the last variable will not be combined with any other variable and will be displayed in oscilloscope mode.

Based on the variable list in oscilloscope mode, channels in trace mode are generated by pairing adjacent variables. The channels are divided into combined channels, unpaired channels, and non-combined channels.

Channel	Description
Combined channel	The y-value of the first variable in the pair is used as the x-axis value in trace mode, and the y-value of the second variable is used as the y-axis value, generating the channel in trace mode. The curve color in the combined channel inherits the color of the first variable in the pair from the variable table in oscilloscope mode, so is the color of the second variable in the pair.
Unpaired channel	The unpaired channel contains variables with no adjacent variables for pairing.
Non-combined channel	Variable values are displayed with separate channels. The curve color inherits the color of the variable in oscilloscope mode.

The functions in oscilloscope mode and trace mode is shown in the table below.

Mode	Description	Enabled Feature
Oscilloscope mode	Right-click menu	Cut, delete, input assistant, and configuration are enabled.
	Column properties of the variable table	Left and right cursor value, cursor difference value, and color are enabled.
Trace mode	Right-click menu	Configuration is enabled.
	Column properties of the variable table	Left and right cursor and cursor difference are enabled.

NOTE

- In trace mode, combined channels do not support cursors, upper/lower limit, or Y-axis scaling functions. Non-combined channels support cursors, upper/lower limit, and Y-axis scaling functions.
- Single channel and multi-channel functions are not supported in trace mode. The number of channels is determined by the number of adjacent variable pairs and unpaired variables.

Introduction to the plot area toolbar

Description	Icon	Description
Download		Downloads IEC oscilloscope variables and configuration information to the currently connected target device.
Upload		Uploads the oscilloscope variables and configuration information from the currently connected target device to IEC.
Start		Starts the current oscilloscope operation and the real-time data will be echoed to form the waveform of the oscilloscope variables.
Stop		Stops the current oscilloscope operation, real-time data echoing, and the plot of the oscilloscope variable waveforms.
Single channel		Single channel and multi-channel functions determine the layout of oscilloscope variables. In single channel mode, there is only one display view, and all oscilloscope variable tracing results are displayed in this view.
Multi-channel		In multi-channel mode, each oscilloscope variable has an independent display view, and the tracing results of each variable are displayed separately in their own views.
Reset trigger		After the trigger stops sampling, resetting the trigger can start sampling again.
Reset view		The view can be reset by dragging and zooming.
Add cursor		Cursors are used to measure the waveform values between two points of an oscilloscope variable. • Cursors can be added when the oscilloscope is online and stopped. • Select "Add cursor" and a draggable red line indicating the cursor will be displayed on the corresponding view. • A maximum of two cursors (left cursor and right cursor) are supported per view. • The waveform values of the left and right cursors will be displayed in the variable table.
Lock cursor		• Cursors can be locked when there are two cursors in the current view. • Select "Lock cursor" icon and the relative positions of the two cursors in the current view will be locked. Moving either cursor will cause both cursors to move synchronously.
Unlock cursor		• Locked cursors can be unlocked. • Click the "Unlock cursor" icon and the two locked cursors in the current view will be unlocked.
Delete cursor		• Cursors in the current view can be deleted. • Click the "Delete cursor" icon to delete the cursors from the current view.

Description	Icon	Description
Exclusive view		In multi-channel mode, when there are too many variables, you can select a specific variable for an exclusive view. After switching to the exclusive view, the plot area will only display the view of the selected variable.
Cancel exclusivity		After canceling the exclusive view, the plot area will display the views of all variables.
Hide legend		Hides the legends in the plot area.
Show legend		Show the legends in the plot area.

Right-click menu

Description	Icon	Description
Cut		Cuts variables from the variable table.
Copy		Copies variables from the variable table.
Paste		Pastes variables into the variable table.
Delete		Deletes variables from the variable table.
Input assistant		Opens the "Input assistant" page.
Download		Downloads IEC oscilloscope variables and configuration information to the currently connected target device.
Upload		Uploads the oscilloscope variables and configuration information from the currently connected target device to IEC.
Start oscilloscope		Starts the current oscilloscope operation and the real-time data will be echoed to form the waveform of the oscilloscope variables.
Stop oscilloscope		Stops the current oscilloscope operation, real-time data echoing, and the plot of the oscilloscope variable waveforms.
Single channel		Single channel and multi-channel functions determine the layout of oscilloscope variables. In single channel mode, there is only one display view, and all oscilloscope variable tracing results are displayed in this view.
Multi-channel		In multi-channel mode, each oscilloscope variable has an independent display view, and the tracing results of each variable are displayed separately in their own views.
Reset trigger		After the trigger stops sampling, resetting the trigger can start sampling again.
Reset view		The view can be reset by dragging and zooming.

Description	Icon	Description
Add cursor		Cursors are used to measure the waveform values between two points of an oscilloscope variable. • Cursors can be added when the oscilloscope is online and stopped. • Select "Add cursor" and a draggable red line indicating the cursor will be displayed on the corresponding view. • A maximum of two cursors (left cursor and right cursor) are supported per view. • The waveform values of the left and right cursors will be displayed in the variable table.
Lock cursor		• Cursors can be locked when there are two cursors in the current view. • Select "Lock cursor" icon and the relative positions of the two cursors in the current view will be locked. Moving either cursor will cause both cursors to move synchronously.
Unlock cursor		• Locked cursors can be unlocked. • Select "Unlock cursor" and the two locked cursors in the current view will be unlocked.
Clear cursors		• Cursors in the current view can be deleted. • Select "Delete cursor" to delete the cursors from the current view.
Add upper limit cursor		The upper/lower limits are used to determine a maximum/minimum baseline to help users observe the parts of the oscilloscope variable waveform that exceed the limits. Select "Add upper limit cursor" and a red horizontal line will be drawn on the view.
Add lower limit cursor		Select "Add lower limit cursor" and a green horizontal line will be drawn on the view.
Clear all limit cursors		• Limit cursors can be cleared when there are limits in the current view. • Select "Clear all limit cursors" to clear the limits in the current view.
Load oscilloscope data		Loads local oscilloscope files into IEC and displays them in the interface. The oscilloscope files include the following content: • Configuration information of the oscilloscope object are loaded the configuration interface. • Variable information of the oscilloscope is loaded to the variable table. • Data of the oscilloscope variables is loaded to the corresponding channels.

Description	Icon	Description
Save oscilloscope data		Saves the oscilloscope data in IEC to the local storage. The data can be saved in two formats: ".oscilloscope" and ".csv". • The ".oscilloscope" file is stored in XML form, containing information of the configuration and data of the oscilloscope. • The ".csv" file is stored in TXT form, containing basic configuration data and oscilloscope variable data.
Configuration		Opens the "Oscilloscope configuration" page.

Operations in plot area

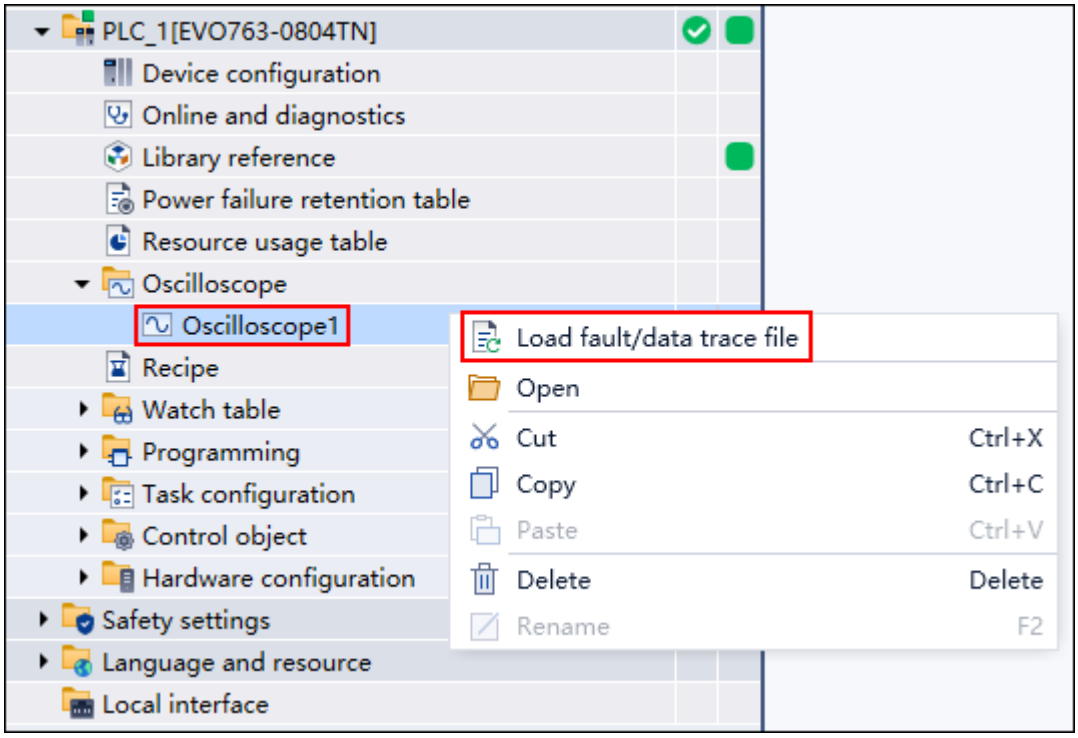
Function	Method
Horizontal movement of X-axis	Hold the left mouse button and drag left/right.
Vertical movement of Y-axis	Hold Ctrl and left mouse button, and drag up/down.
X-axis zoom	Scroll the mouse wheel.
Y-axis zoom	Hold Ctrl and scroll the mouse wheel.

10.2.1.4 Loading Fault/Data Trace Files

The fault/data trace file loading function reads saved faults or program data files for visualized replay of the operation process, enabling analysis and diagnosis of historical operating conditions.

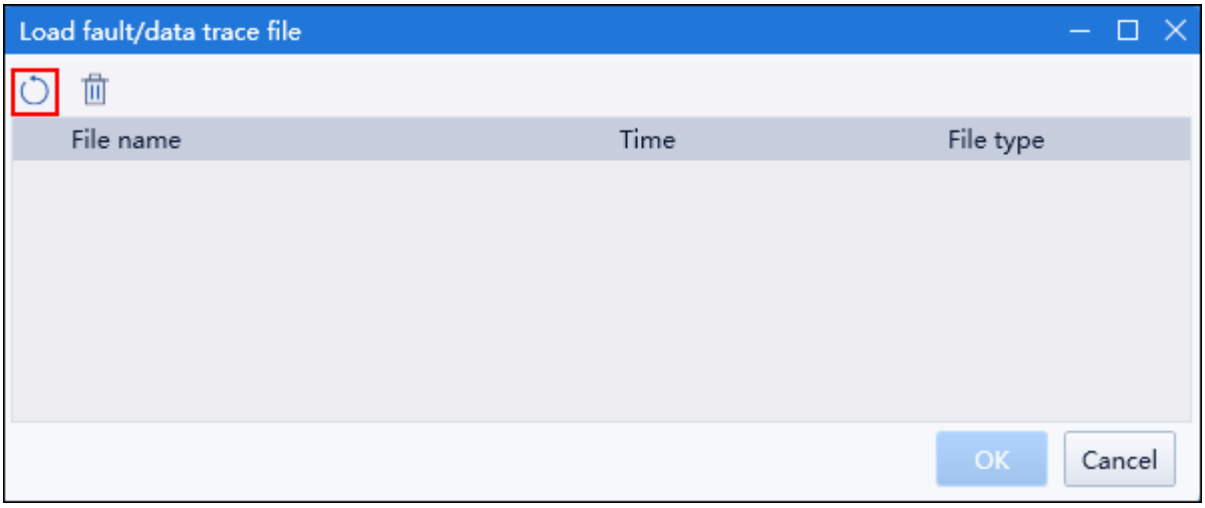
Restrictions

This function is applicable to the following PLC models and firmware versions:



- EVO500, EVO700, and APC series: Firmware version V1.6 and above.
- EVO800 series: Firmware version V1.1 and above.

Prerequisites



- The controller is equipped with an external storage device (SD card or USB drive).
- A basic oscilloscope has been added. For details, see 10.2.1.1 Adding a Basic Oscilloscope.
- The device is in an online status.

Procedure

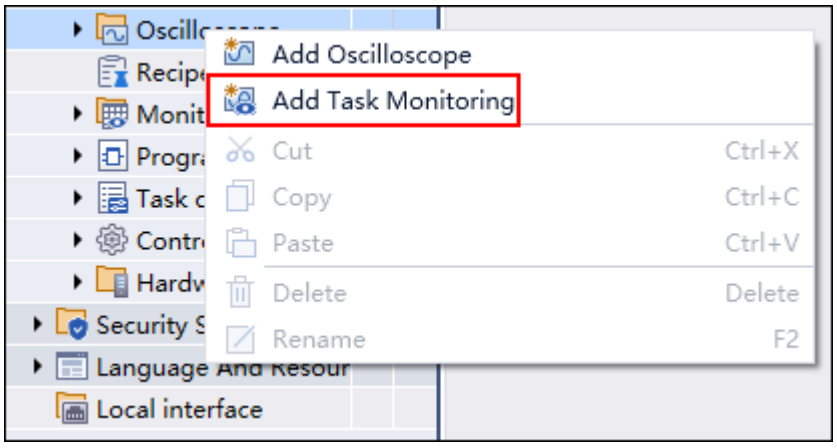
1. Right-click an existing basic oscilloscope in the project tree and select "Load fault/data trace file".

2. Click in the pop-up window. The system will automatically load the saved faults or program data files from the external storage device of the controller.

3. Select the target file from the list and click "OK". A prompt window will appear, indicating loading data will overwrite the current oscilloscope. Click "Yes", and the data from the selected file will overwrite the current content on the oscilloscope. Users can replay historical operating states and analyze oscilloscope data changes for troubleshooting.

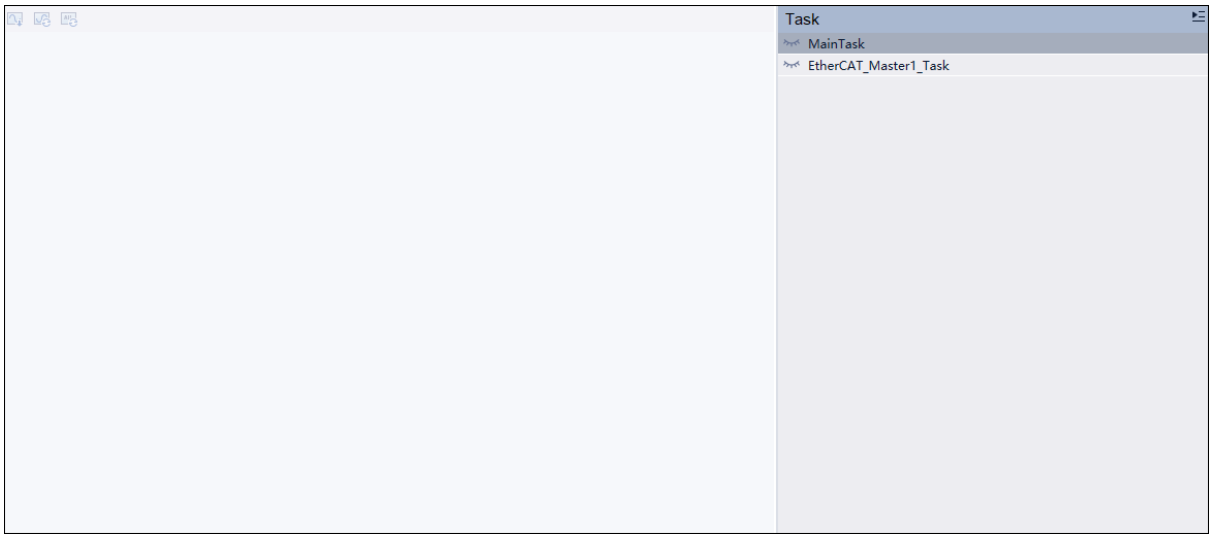
4. If the loaded oscilloscope is closed, a dialog box will appear asking whether to save the trace file. Select based on actual needs and follow the prompts in the dialog box.

10.2.2 Task Oscilloscope



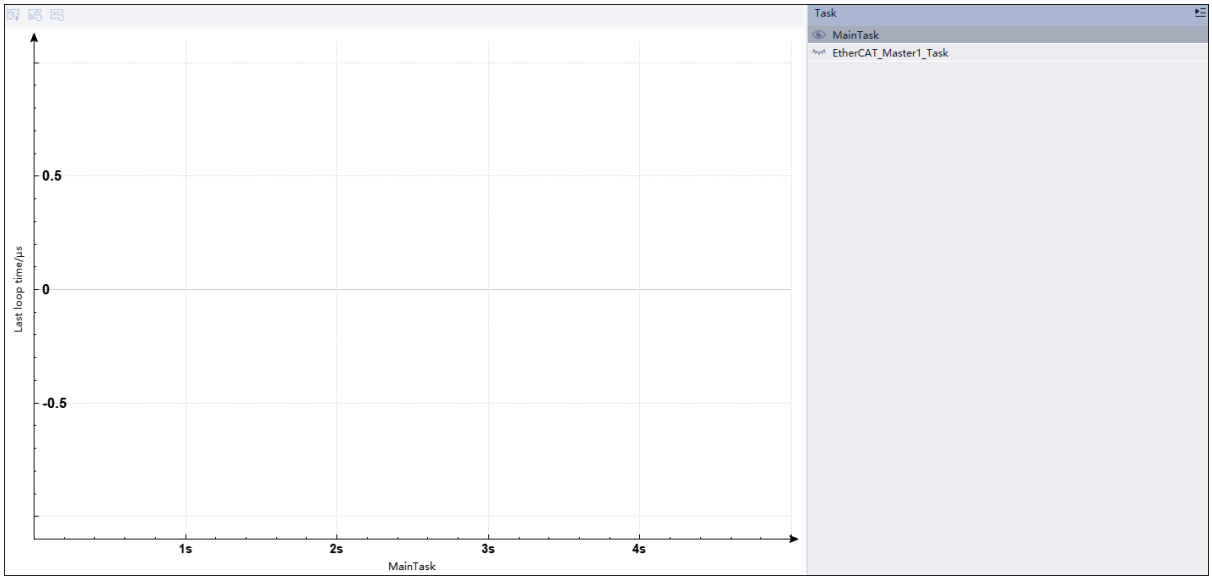
In the task oscilloscope, users can add a target task and monitor the last loop time of the task during online operation.

Prerequisites



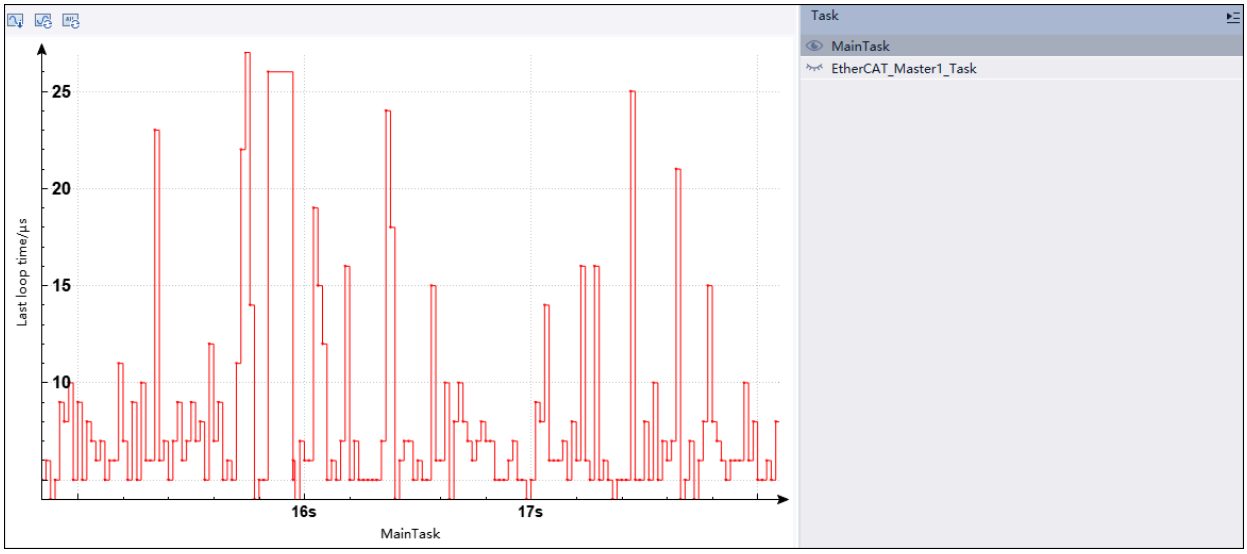
- A program has been created and added to the task.
- The task has been switched to online operation.

Procedure



1. Right-click the "Oscilloscope" node in the project tree and select "Add task monitoring".

2. The task oscilloscope interface is opened. The interface is divided into the task list and the task oscilloscope area, as shown in the figure below.



3. Select the task to be monitored in the task list.

4. Switch to online operation, click the "Download" icon on the toolbar to monitor the jitter information of the "Last loop time" parameter of the task.

Result

The task jitter information (last loop time) collected by the task oscilloscope is shown in the figure below.

Introduction to task oscilloscope functions

Description	Icon	Description	Conditions for Use
Download		Download the task monitoring information to the currently connected target device.	The task is in online status.
Reset view		The view can be reset by dragging and zooming.	The selected channel can be scrolled/dragged.
Reset all views		All channel views can be reset by dragging and zooming.	Channels can all be scrolled/ dragged.

NOTE

- The number of channels in the monitoring page is the same as the number of selected tasks. Each channel generates an X-axis label to indicate the corresponding task.
- Data can only be collected in online status, not in offline status.
- When a monitored task is deleted in the "Task configuration" window, the corresponding monitoring object of the task is also deleted.

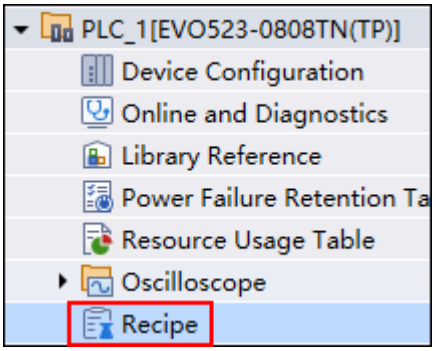
Operations in the task oscilloscope interface

Function	Method
Horizontal movement of X-axis	Hold the left mouse button and drag left/right.
Vertical movement of Y-axis	Hold Ctrl and left mouse button, and drag up/down.
X-axis zoom	Scroll the mouse wheel.
Y-axis zoom	Hold Ctrl and scroll the mouse wheel.

10.3 Recipe

10.3.1 Configuring a Recipe

Recipes can be added in the "Recipe" section of the project tree and can be used for managing initial values of variables.



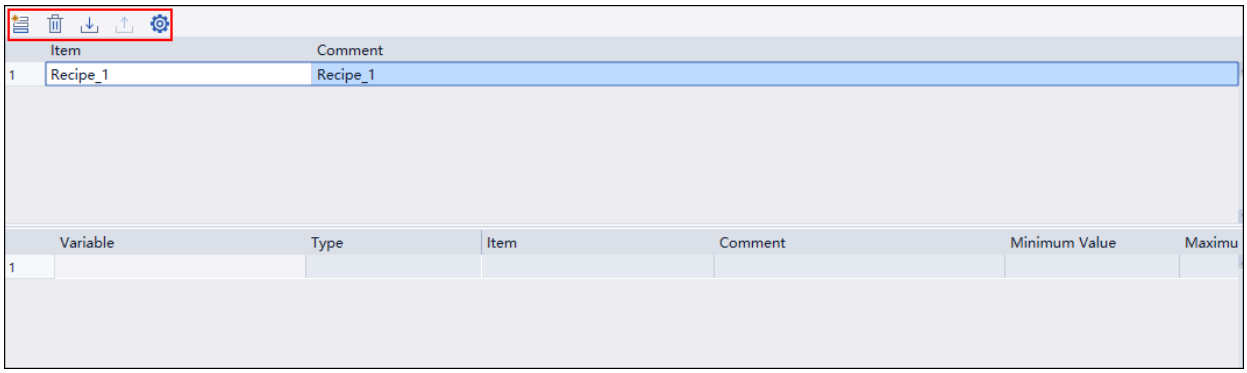
This section introduces how to set recipe-related parameters.

Prerequisites

- A PLC device has been added.
- Variables have been created.

Procedure

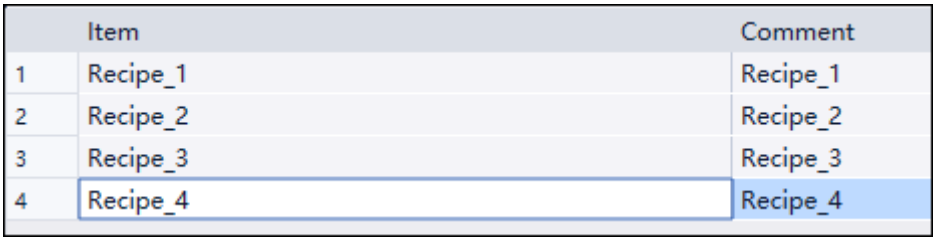
1. Double-click the "Recipe" node in the project tree to open the "Recipe" page.



2. Click the "Add" icon in the upper left corner of the page to open the main recipe interface.

Main recipe interface

The main recipe interface includes a toolbar, a recipe definition list, and a recipe parameter list, as shown in the figure below.



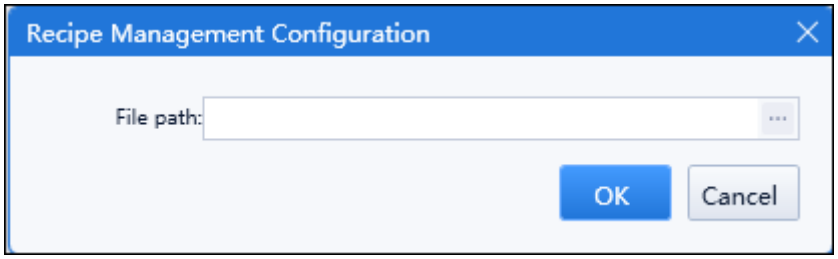
Toolbar

The functions of each icon in the toolbar are described in the table below.

No.	Name	Icon	Description
①	Add		Creates a recipe.
②	Delete		Deletes a recipe.
③	Import		Imports recipes.
④	Export		Exports the recipes in the list.
⑤	Configuration		Opens the recipe configuration page.

Detailed usage instructions for the toolbar functions are as follows.

- **Adding**
  Click the "Add" icon to automatically add a recipe definition to the list, with the default name "Recipe_n" (n is a number), as shown in the figure below.



- **Delete**
  Select a row in the recipe list and click the "Delete" icon. Click "OK" in the pop-up confirmation window to delete the selected recipe.

  Recipes can also be deleted in batches by batch deletion using Ctrl and Shift.

- **Importing**
  Click the "Import" icon to open the "Import recipe" window and select the recipe to import.

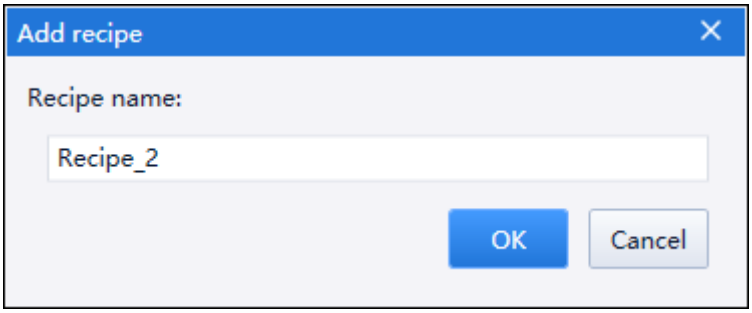
- **Exporting**
  Right-click a recipe and click the "Export" icon. In the pop-up "Export recipe" window, select the save format as "*.txtrecipe". Batch export is not supported.

- **Configuring**
  Click the "Configure" icon to open the "Recipe management configuration" dialog box. Click the "..." button to set the default recipe import and export paths, as shown in the figure below.

Recipe definition list

The recipe definition list interface is shown in the following figure:

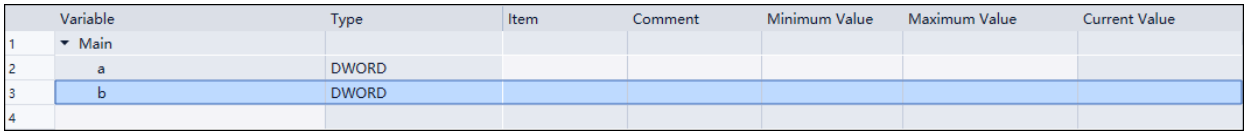
	Item	Comment
1	Recipe_1	Recipe_1
2	Recipe_2	Recipe_2
3	Recipe_3	Recipe_3
4	Recipe_4	Recipe_4



The specific functions of the recipe definition list are as follows:

Function	Description
Right-click menu	Supports copying, pasting, deleting, cutting, and adding recipes.
Data property column	Includes sequence number, name, and comment columns, where the name and comment columns can be modified.
Online status	For online recipes, functions including adding, pasting, deleting, and cutting are grayed out and disabled, while copying is enabled.
Offline status	• For offline recipes, when a recipe is selected, the copying, deleting, and cutting functions are enabled; when no recipe is selected, the copying, deleting, and cutting functions are disabled. Batch operation is supported. • When copying a recipe, the pasting function is enabled; otherwise, it is disabled. • Adding a recipe is enabled. • When deleting a recipe, a confirmation dialog box will pop up. Click "Confirm" to delete the recipe and click "Cancel" to cancel the deletion.

The right-click menu in the recipe definition list is shown in the following figure.



Click "Add recipe definition" and enter the recipe name in the pop-up "Add recipe" window. The default name is "Recipe_n", where n is a number, and automatically increments by 1.

Recipe parameter list

The recipe parameter list (including variable, type, name, comment, minimum value, maximum value, current value) is shown in the following figure.

	Variable	Type	Item	Comment	Minimum Value	Maximum Value	Current Value
1	Main						
2	a	DWORD					
3	b	DWORD					
4							

Descriptions of each parameter:

Column	Description	Precautions
Variable	Variables added in the parameter list	Does not support adding duplicate variables. When there is an empty row, only the "Variable" column can be modified (to add a variable). • Supports adding all global variables (including system variables) under the "Programming" node. • Supports adding all variables in PRGs under the "Programming" node. There are four ways to add variables: • Method 1: Add variables and types through the intelligent input, where you can directly enter the variable name in the edit box and there will be intelligent prompts. • Method 2: Add variables and types through the input assistant. Click the "..." button in the variable edit box to enter the input assistant window and select the variable. • Method 3: Copy and paste data from other recipe parameter tables. • Method 4: Drag and drop data from other recipe parameter tables. Each recipe can add up to 100 variables.
Type	Data types of variables	The following data types are supported: • Basic data types • Custom Type • FB • Array The type column cannot be modified. It is not supported to add constants, I-zone variables, temporary variables, input/output variables, pointer type variables, reference type variables, and Any type variables.
Item	Variable names	Default is empty. Only the last child node (i.e., the basic type variable column) can be modified.
Comment	Variable comments	The comment length should be less than 128 characters. Variable comments are different from the comments in the variable table.

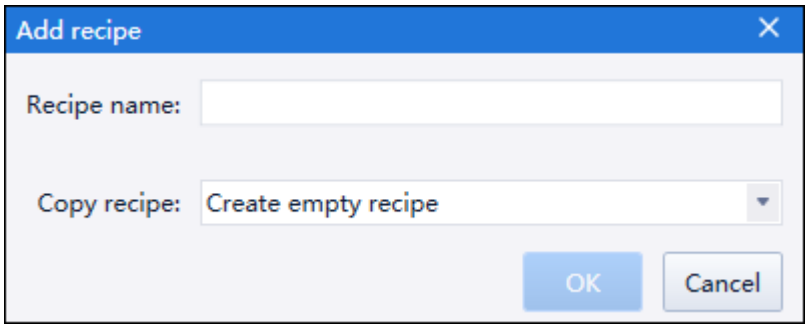
Column	Description	Precautions
Minimum value	Minimum values set for variables	After using the recipe, the value set in the background cannot be less than this value.
Maximum value	Maximum values set for variables	After using the recipe, the value set in the background cannot be greater than this value.
Current value	Current values of the variables in the device	• The current value cannot be modified. • In online mode, the variable value is automatically loaded, or it can be written via the write operation. If maximum/minimum values are set, and the current recipe value is greater/less than the maximum/minimum value, the value written to the PLC is the maximum/minimum value; otherwise, the value written is the current recipe value. • When the current value is forced, the write operation is disabled and the forced value cannot be modified. • When the current value is of BOOL type, the value has a display color.
Recipe column	Variable recipes	For detailed configuration, see 10.3.2 Adding a Recipe.

Descriptions of the right-click menu functions for the recipe parameter list:

Function	Description	Enabled Feature	
		Offline Status	Online Status
Cut	Cuts variables from the parameter table.	Enabled when variables are selected; otherwise, it is grayed out and disabled.	Grayed out and disabled.
Copy	Copies variables from the parameter table.	Enabled when variables are selected; otherwise, it is grayed out and disabled.	Enabled when variables are selected; otherwise, it is grayed out and disabled.
Paste	Pastes variables into the parameter table.	Enabled after cutting or copying; otherwise, it is grayed out and disabled.	Grayed out and disabled.
Delete	Deletes variables from the parameter table.	Enabled when variables are selected; otherwise, it is grayed out and disabled.	Grayed out and disabled.

Function	Description	Enabled Feature	
		Offline Status	Online Status
Go to Definition	Go to the corresponding definition of the selected column property.	• Enabled when the "Variable" column property is selected. • Enabled when the "Type" column property is selected and the type is custom (DUT, FB); other types are not enabled. • Not enabled when any column property other than "Variable" or "Type" is selected.	Enabled when the "Variable" column property is selected.
Cross-reference	Opens the cross-reference table for the selected variables in the monitoring area.	Enabled when the variable name is selected for cross-reference.	Enabled when the variable name is selected for cross-reference.
Adding a Recipe	Adds a recipe for the selected variable.	All enabled.	All enabled.

10.3.2 Adding a Recipe



This section introduces how to add a recipe in the recipe manager.

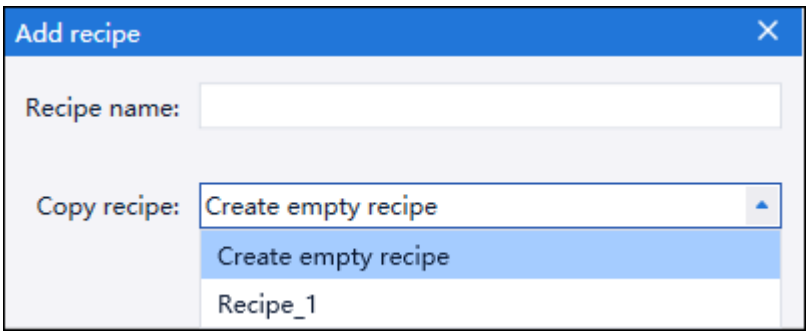
Prerequisites

- The project has been created.
- Recipes have been defined in the recipe manager, and parameters have been added.

Procedure

1. Right-click the recipe parameter list and select "Add recipe" to enter the "Add recipe" page, as shown in the following figure.

2. Set the "Recipe name", select the recipe to be copied in "Copy recipe", and click "OK" to add the recipe.

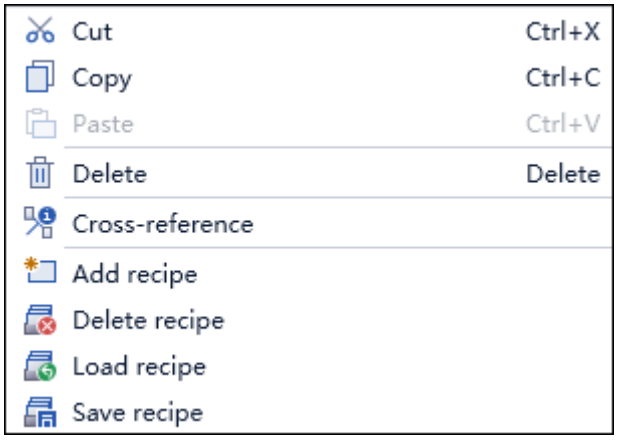


Result

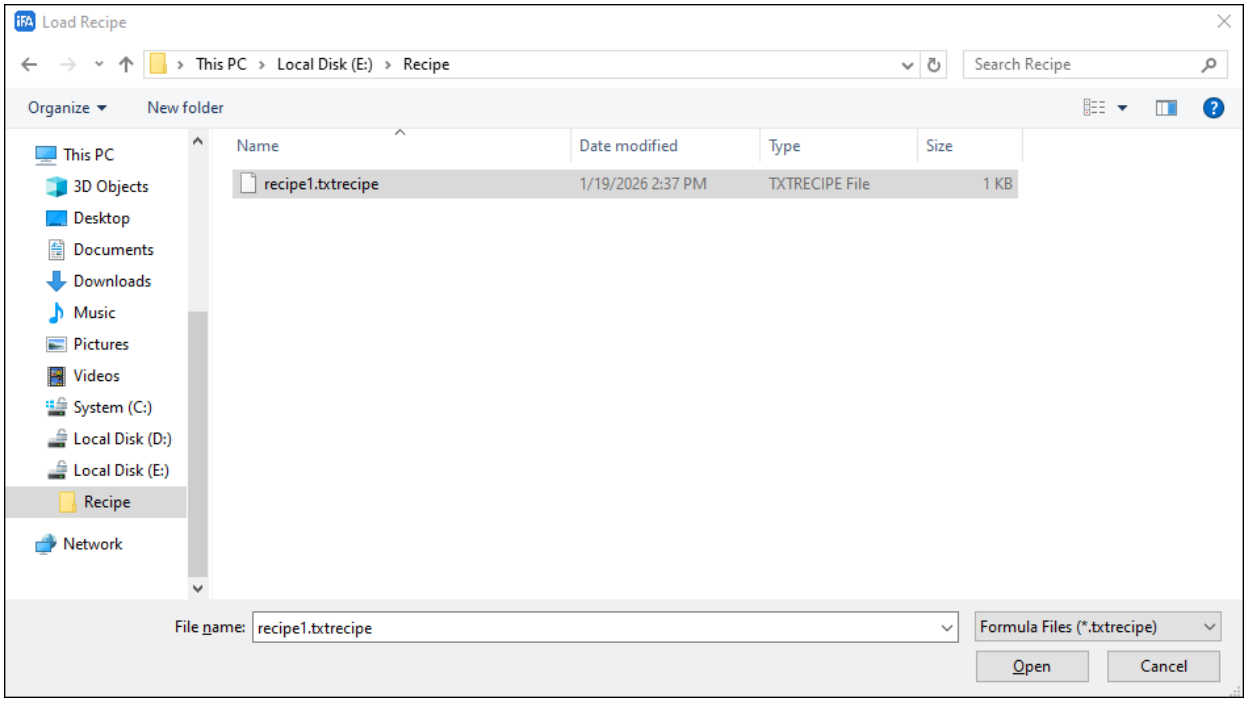
The added recipe is shown in the following figure.

	Variable	Type	Name	Comment	Min. value	Max. value	Current value	Recipe_1
1	Main							
2	a	INT						
3	b	INT						
4								

Descriptions of the "Copy recipe" function

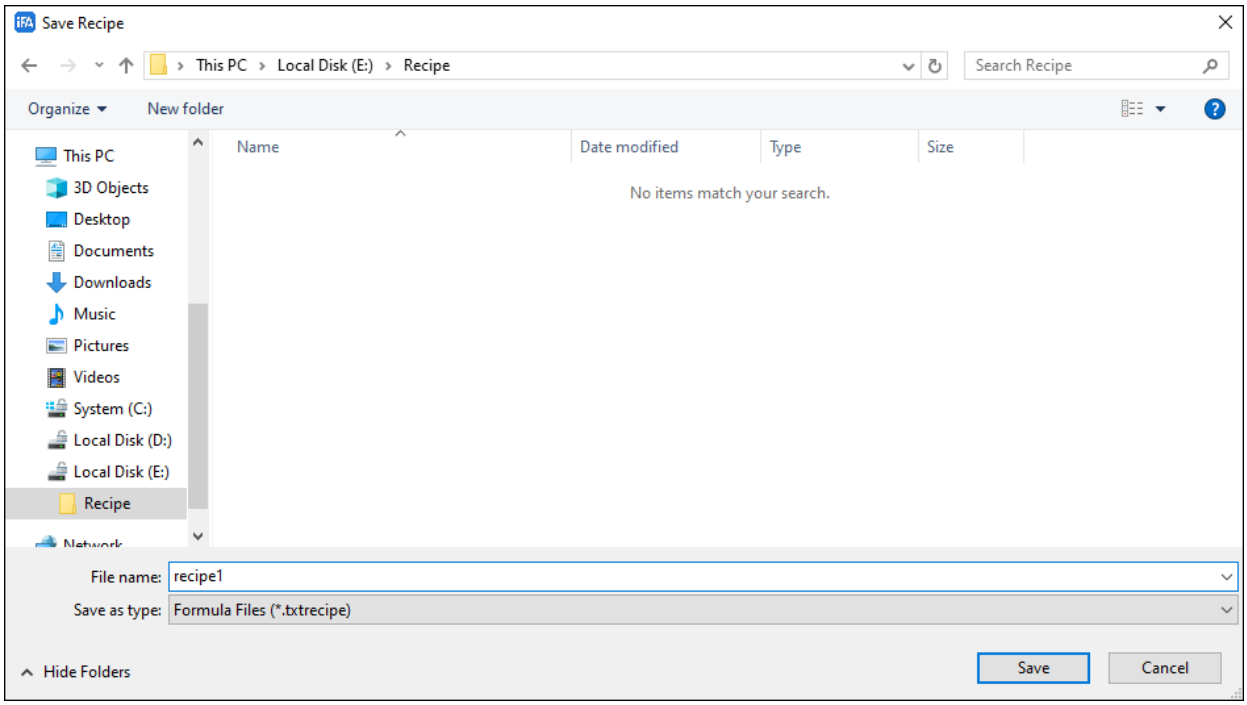


1. The default option in the "Copy recipe" drop-down menu is "Create empty recipe".
2. When there are no recipes in the recipe parameter list, only "Create empty recipe" is displayed in the drop-down menu. When there are recipes in the list, existing recipes are also displayed in the drop-down menu. Custom input is not allowed, as shown in the following figure.



3. When adding a new recipe by selecting an existing recipe, the values of the selected recipe will be copied.

Right-click menu



Right-click the "Recipe" column and the menu is shown in the following figure.

- You can perform cut, copy, paste, delete, and cross-reference operations for the selected variable.
- Add recipe: Adds a new recipe.
- Delete recipe: Deletes the selected recipe. Batch deletion is not supported.
- Load recipe: Loads from a local file, read the parameters of the saved recipe, and write them into the selected recipe, as shown in the following figure.

- Save Recipe: Saves the parameters of the selected recipe to a local file with a save file format of ".txtrecipe", as shown in the following figure.

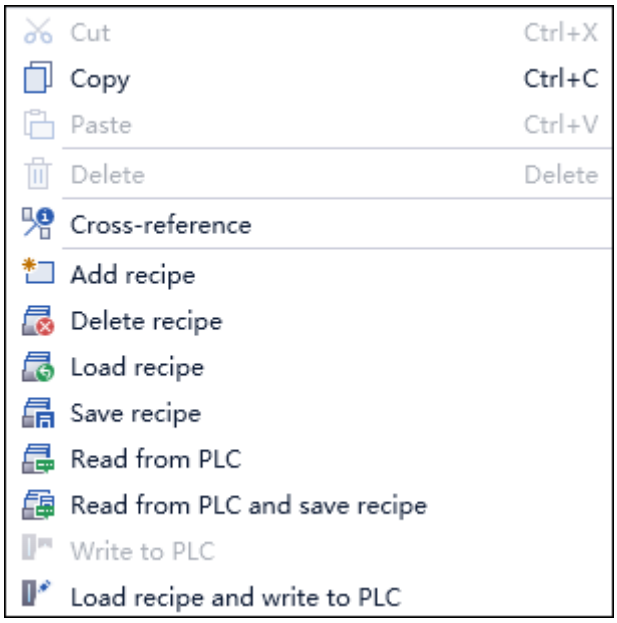
10.3.3 Online Recipe

This section introduces the right-click menu functions of an online recipe.

Prerequisites

- The recipe manager has been created and recipes have been added.
- The recipe has been switched to online status.

Right-click menu functions



After the recipe is switched to online status, the enabling conditions of the right-click menu functions for the recipe definition list and recipe parameters change.

- Recipe definition list
  The functions to add a recipe, paste, cut, and delete in the recipe list are grayed out and disabled, while copy is enabled.
- Recipe parameter table

Description	Enabled Feature	Description
Cut	Grayed out and disabled	/
Copy	Enabled	Copies the selected variable.
Paste	Grayed out and disabled	/
Delete	Grayed out and disabled	/
Cross-reference	Enabled	Opens the cross-reference table for the selected variable.
Adding a Recipe	Enabled	Adds a recipe list.

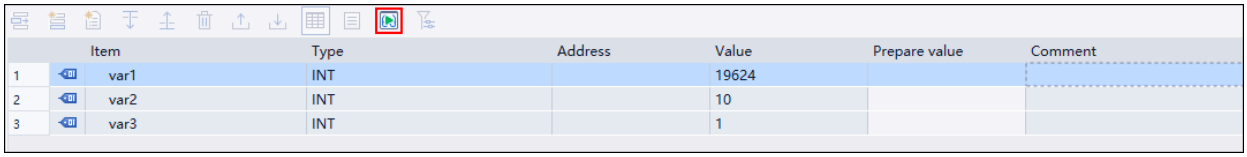
- Recipe list
  The right-click menu functions for the recipe list are shown in the figure below.

The specific functions of the right-click menu are described in the table below.

Description	Enabled Feature	Description
Cut	Grayed out and disabled	/
Copy	Enabled	Copies the selected variable.
Paste	Grayed out and disabled	/
Delete	Grayed out and disabled	/
Cross-reference	Enabled	Opens the cross-reference table for the selected variable.
Adding a Recipe	Enabled	Adds a recipe.
Delete recipe	Enabled	Deletes an existing recipe. Only one recipe can be deleted at a time. Batch selection is not supported.
Load recipe	Enabled	Loads from a local file, reads the parameters of the saved recipe, and writes them into the selected recipe.
Save recipe	Enabled	Saves the parameters of the selected recipe to a local file (which can only be imported after successful compilation).
Read from PLC	Enabled	Reads the current values and writes them into the currently selected recipe.
Read from PLC and save recipe	Enabled	Reads the current values and writes them into the currently selected recipe, then saves the parameters of the selected recipe to a local file.
Write to PLC	Enabled	Writes the values of the currently selected recipe to the current values.
Load recipe and write to PLC	Enabled	Loads from a local file, reads the parameters of the saved recipe, writes them into the selected recipe, and writes the values of the currently selected recipe to the current values.

10.4 Watch Table

10.4.1 Monitoring Variable Table



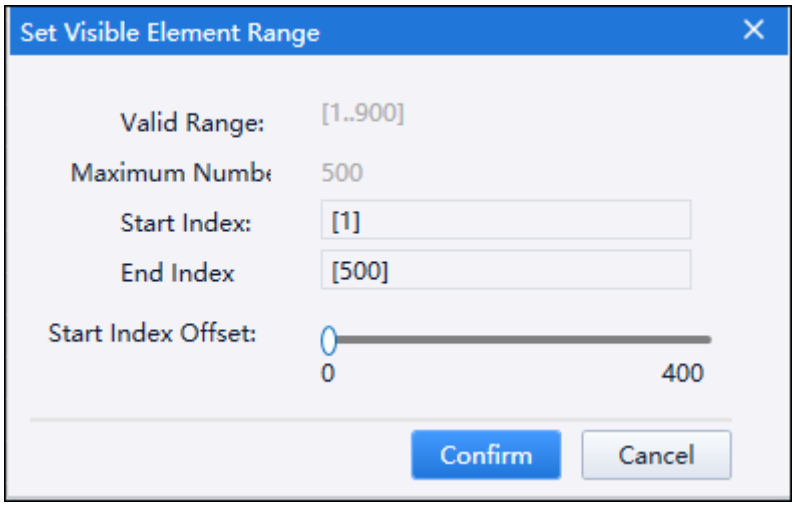
When the device is in online mode, the POU variable table and the global variable table GVL support real-time monitoring.

Prerequisites

- The variable has been added to the variable table.
- The current POU has been called.
- The device is in an online status.

Procedure

1. Switch the device to online mode.
2. Click the monitoring icon in the toolbar of the variable table to enable the independent monitoring function of the variable table, putting the variable table into online status.

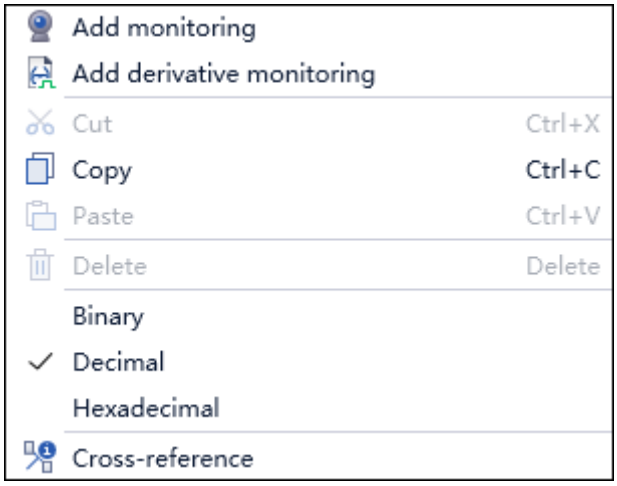


Columns in the online variable table

Column	Description
Name	The variable name
Type	The data type of the variable
Address	The address of the variable
Value	The current real-time value of the variable
Prepared value	The value prepared for writing to the variable • Basic type prepared value: Enter the prepared value by editing the cell. • BOOL/enumeration type prepared value: Select the prepared value from a drop-down list.
Comment	The comment of the variable

Visible element range setting

After the variable table goes online, the maximum number of variables displayed is 500. When this number is exceeded, the "  " icon will be enabled to set the visible element range. Users can set the variable display range through this icon, as shown in the following figure.



NOTE

Since iFA Evolution V1.4.4.5, the viewing function of the variable table has changed:

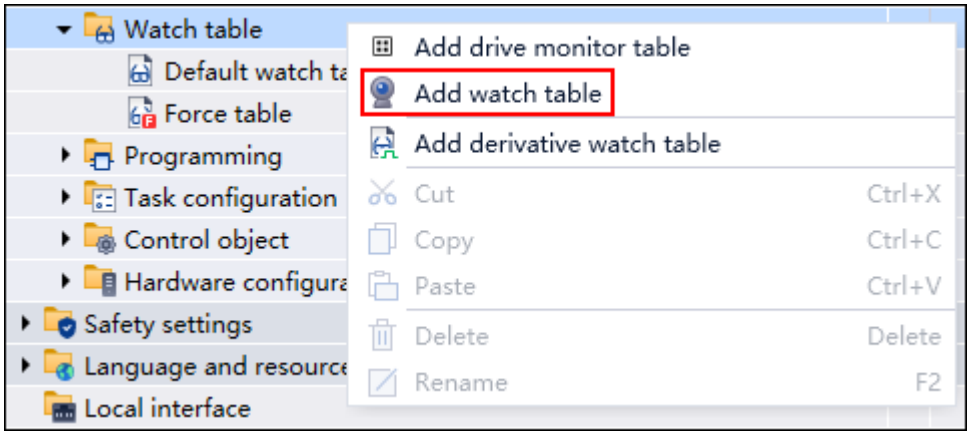
- For versions prior to V1.4.4.5.Patch.20260610: The maximum number of viewable variables is limited to 500.
- For versions V1.4.4.5.Patch.20260610 and later: Users can view all variables with no limit.

Variable table right-click menu

Right-click a variable to open the right-click menu, which is shown in the figure below.

Function	Description
Add watch	Adds the variable to the watch table.
Add derivative monitoring	Adds the variable to the derivative watch table. Note: This operation is available when a derivative watch table already exists and the number of monitored variables is less than 16.
Cut/Paste/Delete	Grayed out and disabled in online status.
Copy	Copies variable to clipboard.
Binary	Displays the value and prepared value of the variable in binary format.
Decimal	Displays the value and prepared value of the variable in decimal format.
Hexadecimal	Displays the value and prepared value of the variable in hexadecimal format.
Cross-reference	Opens the cross-reference table for the variable.

NOTE



In the same POU/GVL, variables can be displayed in binary, decimal, and binary formats.

10.4.2 Monitoring Specified Variables

When the device is in online mode, the watch table allows real-time monitoring of specified variables and addresses. Users can view the data type, current value, and assign a value to the monitored variable through the watch table.

Procedure

1. Right-click "Watch table" in the project tree and select "Add watch table". A maximum of 20 watch tables can be created.

2. Add variables to the watch table.
   a. Click  or  to add or insert a variable row.
   b. Variables can be added to the watch table in both online and offline states with the following methods:
      - Add from variable list: Double-click the text box to enter the variable name, or click "..." to select a variable using the input assistant.
      - Add from variable declaration area (online only): Right-click the variable and select "Add monitoring", or drag and drop the variable directly onto the watch table.
      - Add from program editing area (online only): Right-click the variable and select "Add monitoring".
3. Switch the device to online mode and variable monitoring will be enabled automatically. Click  to switch the variable's disabled or enabled state, with the default being enabled.

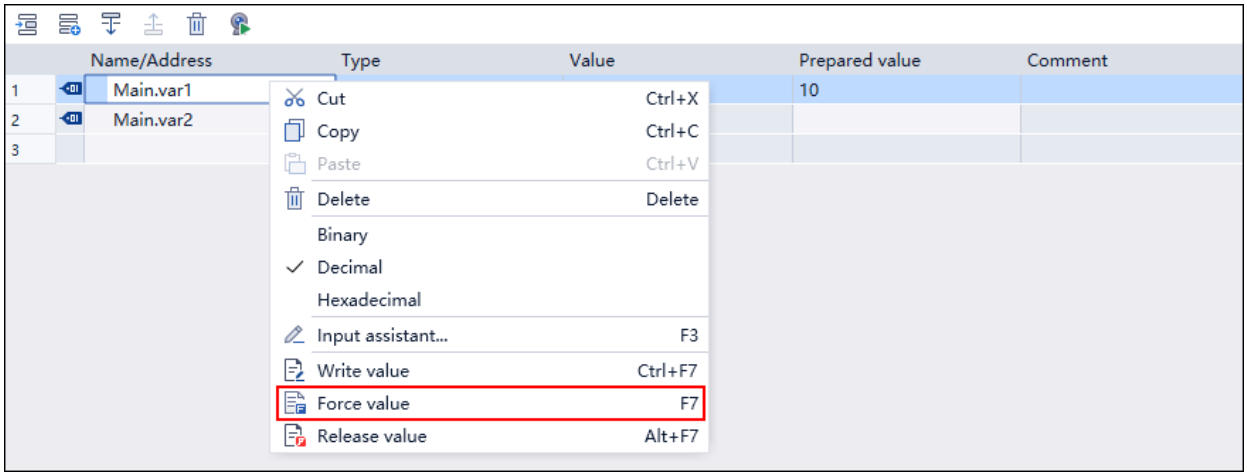
Result

- The watch table displays the variable name/address, type, value, prepared value, and comment.

	Name/Address	Type	Value	Prepared value	Comment
1	Main.var1	INT	11180		
2	Main.var2	INT	11180		
3					

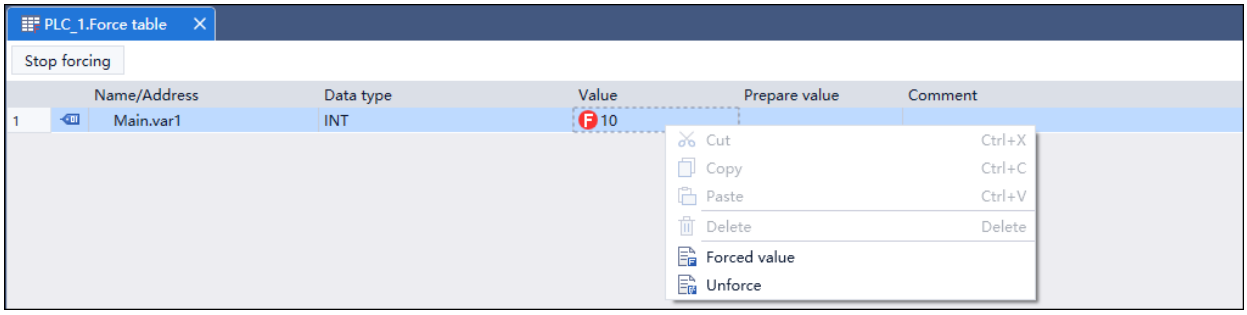
- When the device is offline or monitoring is disabled, variables cannot be monitored, and their values are displayed as <No monitoring>.

	Name/Address	Type	Value	Prepared value	Comment
1	Main.var1	INT	<No monitoring>		
2	Main.var2	INT	<No monitoring>		
3					



Deleting a variable

Right-click a variable and select "Delete" to delete it from the watch table.

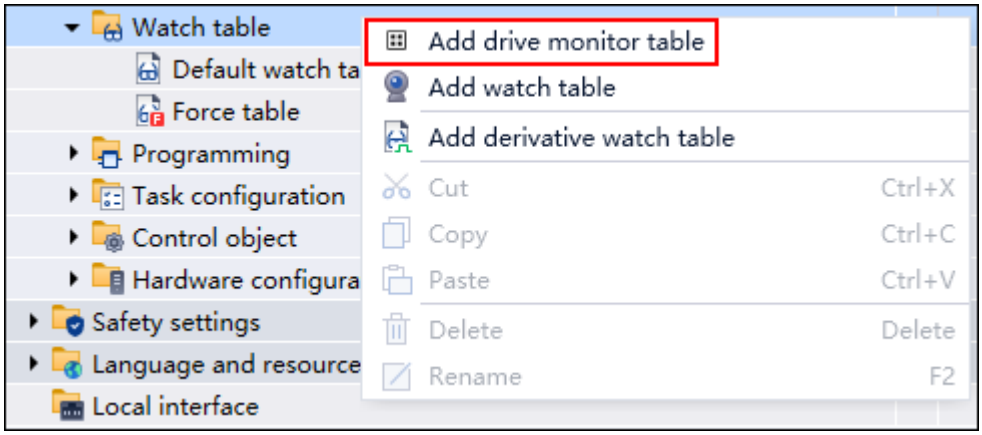


Variable display

Right-click a monitored variable and select "Force value" to add a forced value. The variable will then be displayed by default in the force table under the "Watch table" node in the project tree.

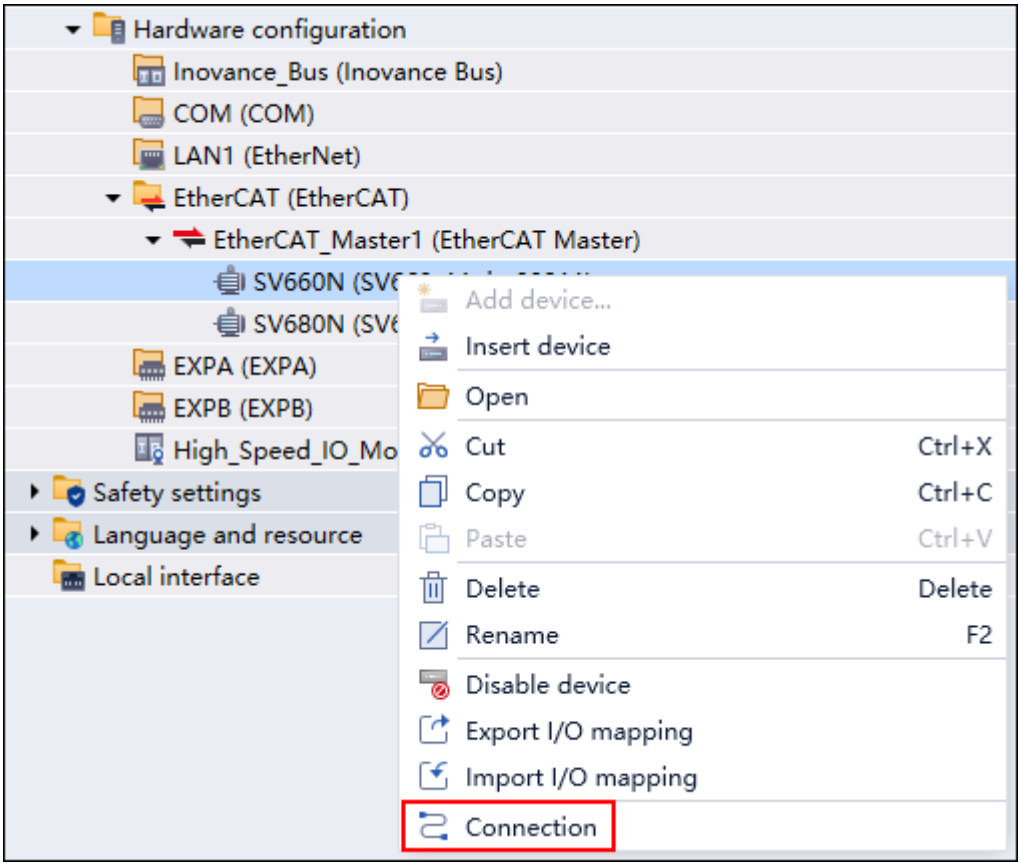
Cancel forcing: Cancel the previously written forced value.

10.4.3 Drive Watch Table



The drive watch table is used to monitor the real-time values of axis parameters during operation of servo slaves, with the monitored axis parameter objects specified by users during configuration.

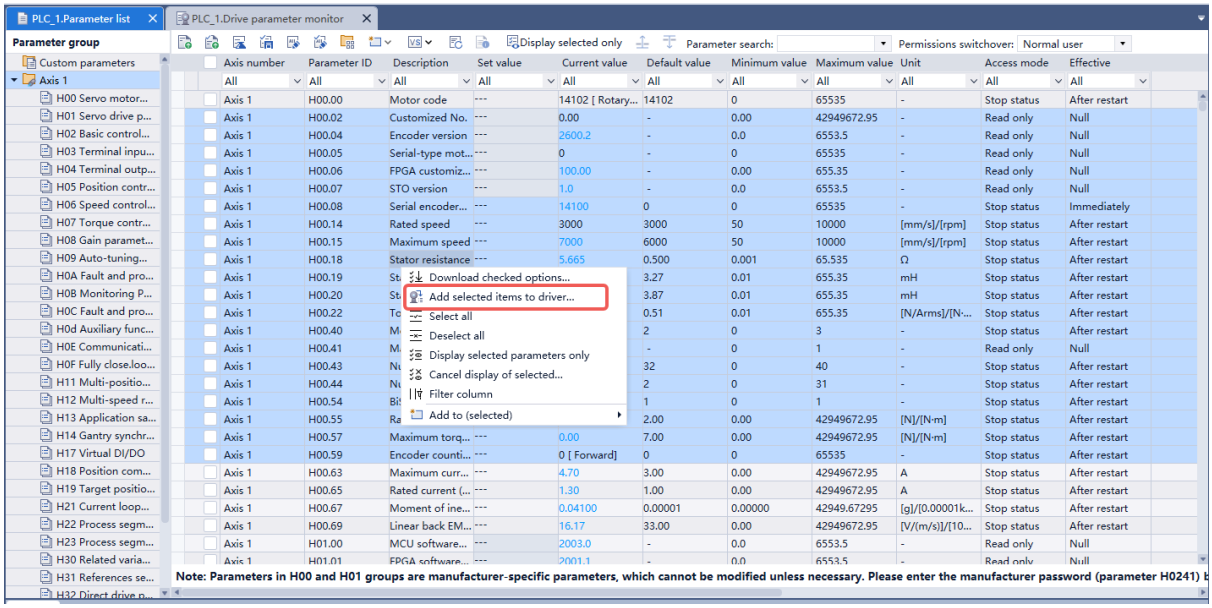
Prerequisites



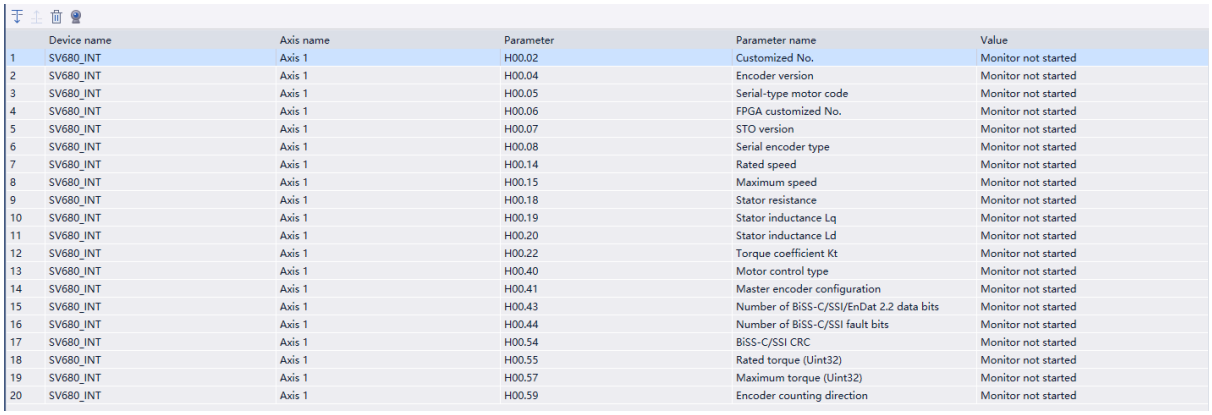
- Supported servo device models are SV660 and SV680.
- The drive watch table supports up to 200 parameters, with no more than 16 servo slaves distributed across them.

Procedure

1. Right-click "Watch table" in the project tree and select "Add drive watch table".



2. Right-click a servo slave and select "Connect" to complete the communication connection between the slave and the PLC. For detailed connection methods, see 17.1.1 EOE Connection.



3. Double-click the "Parameter list" of the slave device to open the configuration interface. Right-click the target axis parameters to monitor (supporting multiple selections) and select "Add the selected to the

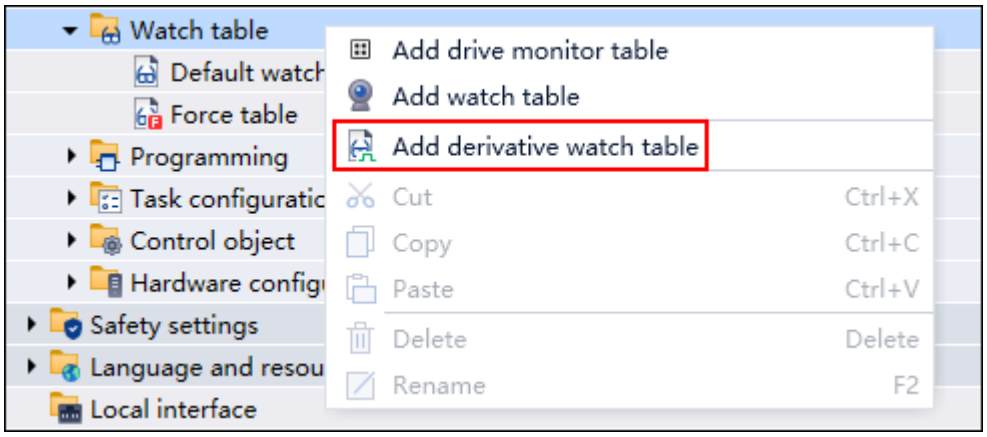
drive monitoring table (current page)" to complete the parameter configuration in the drive watch table.

4. Double-click the added drive watch table in the project tree to open the corresponding interface.

	Device name	Axis name	Parameter	Parameter name	Value
1	SV680_INT	Axis 1	H00.02	Customized No.	Monitor not started
2	SV680_INT	Axis 1	H00.04	Encoder version	Monitor not started
3	SV680_INT	Axis 1	H00.05	Serial-type motor code	Monitor not started
4	SV680_INT	Axis 1	H00.06	FPGA customized No.	Monitor not started
5	SV680_INT	Axis 1	H00.07	STO version	Monitor not started
6	SV680_INT	Axis 1	H00.08	Serial encoder type	Monitor not started
7	SV680_INT	Axis 1	H00.14	Rated speed	Monitor not started
8	SV680_INT	Axis 1	H00.15	Maximum speed	Monitor not started
9	SV680_INT	Axis 1	H00.18	Stator resistance	Monitor not started
10	SV680_INT	Axis 1	H00.19	Stator inductance Lq	Monitor not started
11	SV680_INT	Axis 1	H00.20	Stator inductance Ld	Monitor not started
12	SV680_INT	Axis 1	H00.22	Torque coefficient Kt	Monitor not started
13	SV680_INT	Axis 1	H00.40	Motor control type	Monitor not started
14	SV680_INT	Axis 1	H00.41	Master encoder configuration	Monitor not started
15	SV680_INT	Axis 1	H00.43	Number of BiSS-C/SSI/EnDat 2.2 data bits	Monitor not started
16	SV680_INT	Axis 1	H00.44	Number of BiSS-C/SSI fault bits	Monitor not started
17	SV680_INT	Axis 1	H00.54	BiSS-C/SSI CRC	Monitor not started
18	SV680_INT	Axis 1	H00.55	Rated torque (Uint32)	Monitor not started
19	SV680_INT	Axis 1	H00.57	Maximum torque (Uint32)	Monitor not started
20	SV680_INT	Axis 1	H00.59	Encoder counting direction	Monitor not started

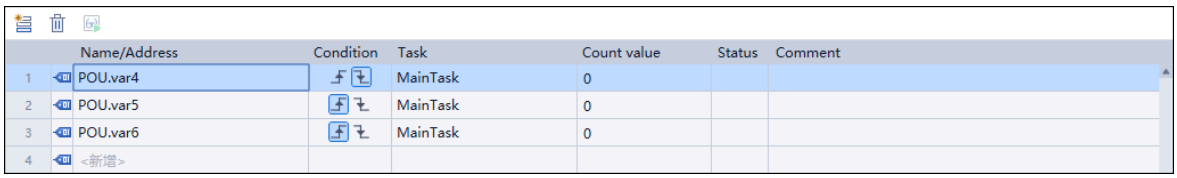
The icons and parameters in the interface are described in the following table.

Name	Description
	Moves the selected row(s) down, supporting simultaneous movement of multiple rows.
	Moves the selected row(s) up, supporting simultaneous movement of multiple rows.
	Deletes the selected row.
	Monitoring switch: When enabled, the PLC reads and displays the real-time values of the servo slave's function codes; when disabled, the PLC does not read real-time values, and displays "-" instead.
Device name	The name of the servo slave in the project; if the name changes, it will automatically synchronize here.
Axis name	The axis number configured internally in the servo, independent of the motion control axis name.
Parameter	Parameter format: H00.00.
Parameter name	Description of the parameter.



Name	Description
Value	The real-time value of the axis parameter can be monitored here, but not written. The value is refreshed every 1 second. Displays the real-time value when the slave communicates normally with the PLC; displays "-" if communication is abnormal.

10.4.4 Derivative Watch Table



Derivative watch tables are used to monitor the number of changes in up to 16 BOOL/BIT variables within a task cycle.

Procedure

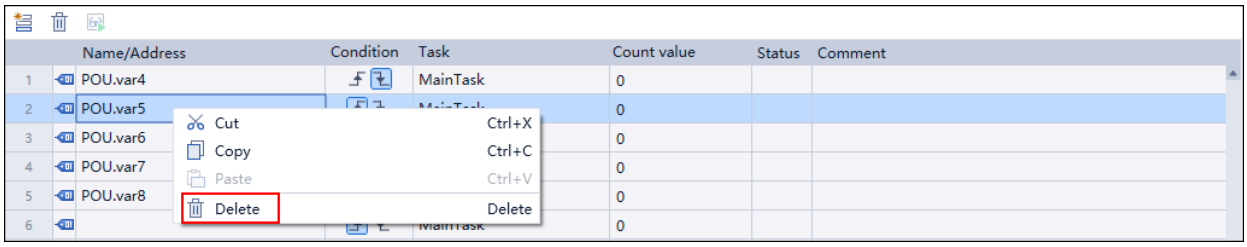
1. Right-click "Watch table" in the project tree and select "Add derivative watch table".

2. Add derivative watch variables.
   a. Click or double-click the derivative variable list text box <新增> to add a derivative watch variable row.
   b. Variables can be added to the derivative watch table in both online and offline states with the following methods:
      - Add from variable list: Double-click the text box to enter the variable name, or click "..." to select a variable using the input assistant.
      - Add from variable declaration area (online only): Right-click the variable and select "Add derivative monitoring", or drag and drop the variable directly onto the derivative watch table.
      - Add from program editing area (online only): Right-click the variable and select "Add derivative monitoring".
   c. Click or in the "Condition" column of the variable row to set the monitoring condition.
   d. Click the "Task" cell of the variable row to select the task to be mounted.

The icons and parameters in the interface are described in the following table.

Name	Description
	Adds a watch variable row.
	Deletes the selected row.

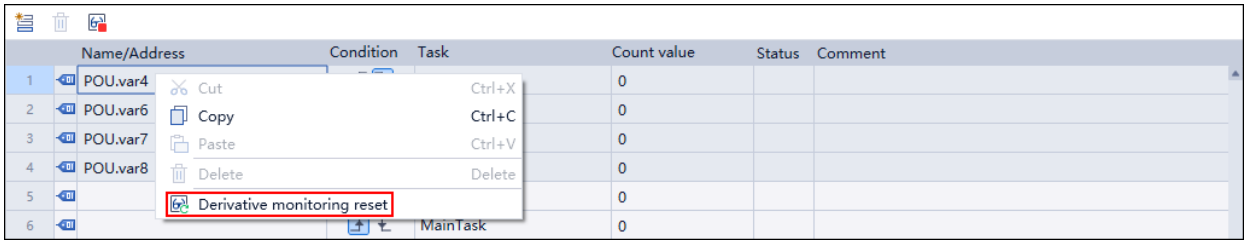
Name	Description
/	Enables or disables the derivative monitor.
Name/Address	Name or address of the monitored variable.
Condition	Conditions for monitoring variables. Click the following icons to select the conditions. Default is rising edge triggered. : Rising edge : Falling edge
Task	Task mounted to the monitored variable. Click to select the task. Default is MainTask.
Count value	Counts how many times the set condition is triggered. Within the task cycle of the monitored variable, the current value is compared with the previous value. A count is incremented when the value changes to match the specified condition. ▪ Only one count is recorded per task cycle even if the value matches the condition multiple times. ▪ No count is recorded if the value at the previous and current evaluation are the same (even if it changed in between).
Status	Monitors the status of the variable. ▪ Condition not triggered: Blank. ▪ Condition triggered: Green/gray icon flashes alternatively for 8s per trigger.
Comment	Comments on the monitored variables.



3. Switch the device to online mode and click to enable the derivative monitor.

NOTE

Derivative monitoring variables can only be added when a derivative monitoring table already exists and the number of monitored variables is less than 16.



Deleting a variable

Right-click a variable and select "Delete" to delete it from the derivative watch table. The monitored variable cannot be deleted when the derivative monitor is enabled.

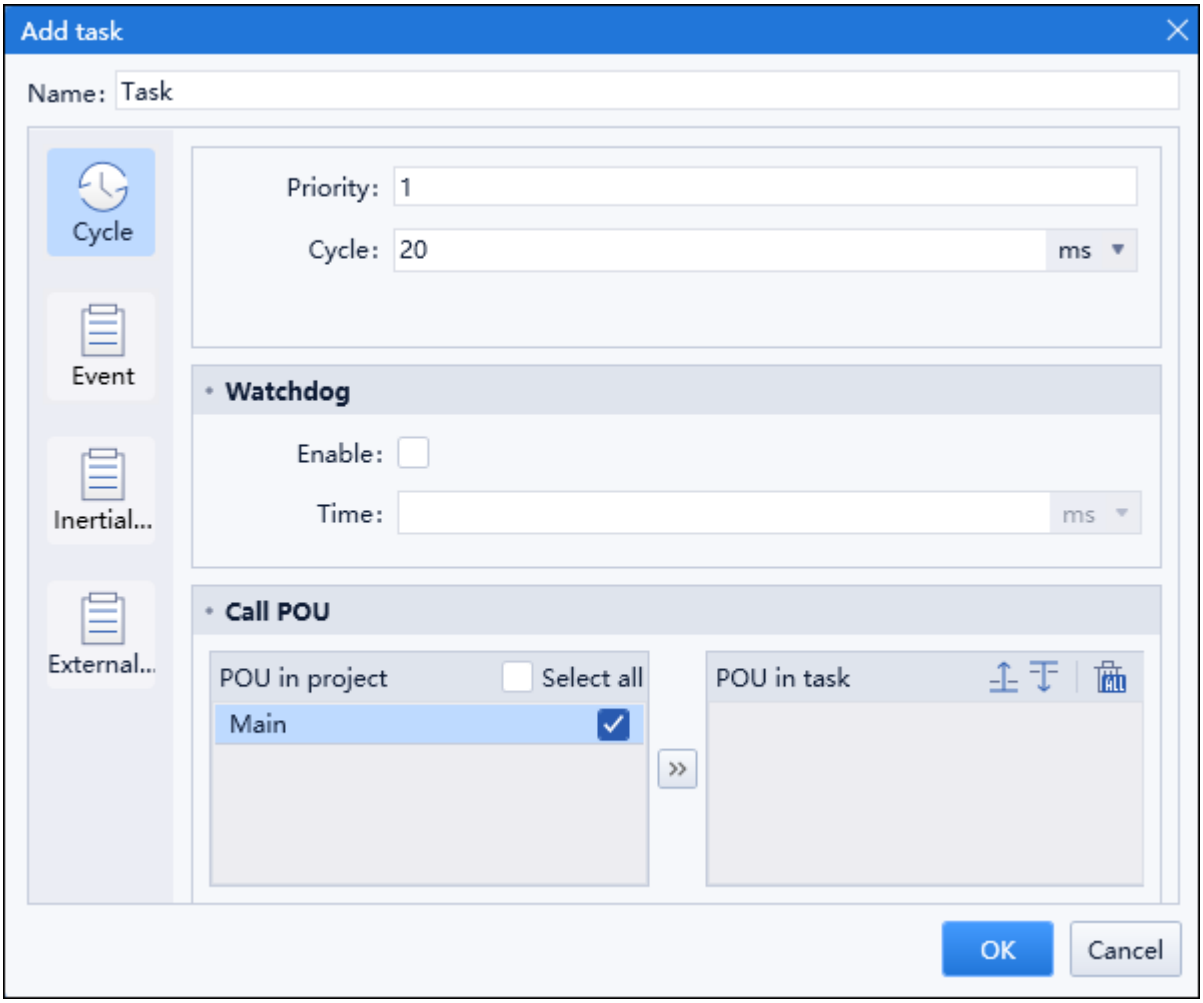
Derivative watch reset

When the device is in online state and the derivative monitor is enabled, right-click the variable and select "Derivative monitoring reset" to resume monitoring (restart counting) for that variable.

10.5 Task Configuration

10.5.1 Adding a Task

A task is the fundamental execution units of the scheduler, and all programs must be assigned to a task to run. Tasks can be managed through the "Task configuration" node in the project tree. The system automatically generates a default task when a PLC device is added; users can also create new tasks as needed. By setting task properties (such as execution cycle, priority, and bound CPU core), users can control the allocation of system resources and program execution.



Prerequisites

- A PLC device has been added.
- A program has been created.
- Before creating a task of the "Event" type, first create a BOOL variable for event trigger.

Procedure

A task supports only one execution type, interval, and priority. Add multiple tasks for different execution characteristics.

1. Right-click the "Task configuration" node in the project tree and select "Add task".
2. In the pop-up window, configure the task name, task type, and related parameters. For details, see 10.5.2 Task Parameter Configuration.

3. Click "OK" to add the task.
4. (Optional) Open the added task in the project tree to edit its parameters. There are two methods to open a task:
   - Method 1: Double-click the task node in the project tree.
   - Method 2: Right-click the task node in the project tree and select "Open".

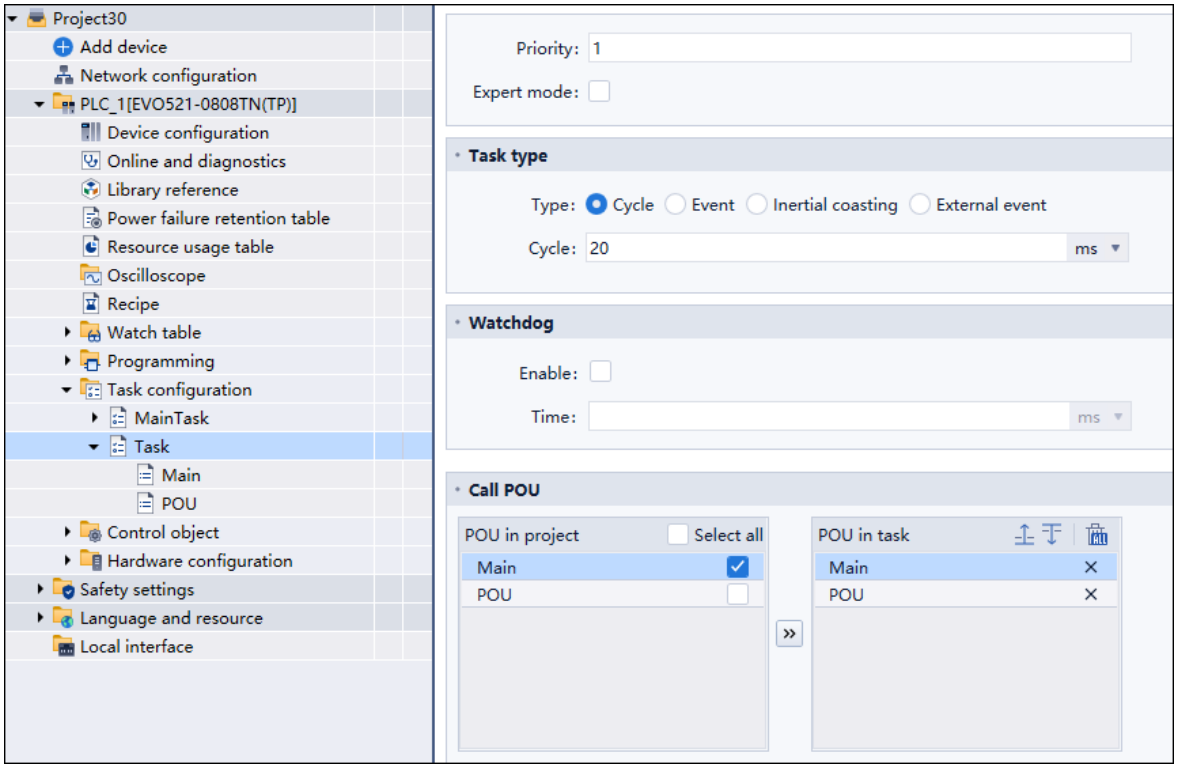


Figure 10-5-1-1 Task configuration interface

10.5.2 Configuring Task Parameters

- **Precedence**

  Priority is the basis for PLC task scheduling, determining the order in which tasks are executed. The execution of a low-priority task may be interrupted by a high-priority task. After the high-priority task has been executed, the low-priority task interrupted previously will be resumed.

  Task priority can be set in the "Add task" or task configuration window. It ranges from 0 to 31 (range for EVO800 series redundant mode is 0 to 15). The smaller the number, the higher the priority. Levels 0 to 15 adopt a priority-based preemptive scheduling strategy, while levels 16 to 31 adopt a time-slice-based round-robin scheduling strategy.

  The system pre-sets different priorities for automatically added tasks (e.g., EtherCAT bus task, CANOPEN interrupt task) to ensure that critical tasks such as motion control are executed first. In applications requiring high-performance motion control (MC), this enables efficient utilization of controllers. The task priority order is as follows (modifying this order is not recommended):

Default Priority	Task name	Description
0	EtherCAT_Master_Task	Only one EtherCAT task is allowed.
2	CANopen	Only one CANopen task is allowed.

- **Expert mode**

  In expert mode, multi-core PLCs can process multiple tasks simultaneously. For multi-core PLC devices, the core for task execution can be configured to assign different tasks to different cores for processing.

  1. Double-click a task node in the project tree to open the task.
  2. In the task configuration interface, select "Expert mode", and select the core for task execution (0 or 1) in the "Assigned core" drop-down menu.

NOTE

- Dynamically allocate cores for task execution based on core utilization rates. To view core utilization, double-click "Online and diagnostics" in the project tree and select "Task monitoring". The core utilization can be viewed in the "CPU and memory monitoring" section.
- Multiple tasks can be assigned to the same core, and the processing order follows the task priority.
- A single task cannot be assigned to multiple cores.
- The EVO800 series supports activating expert mode in single mode, but not in redundant mode.

- **Task type**

1. The task type can be selected in the "Add task" or task configuration interface.

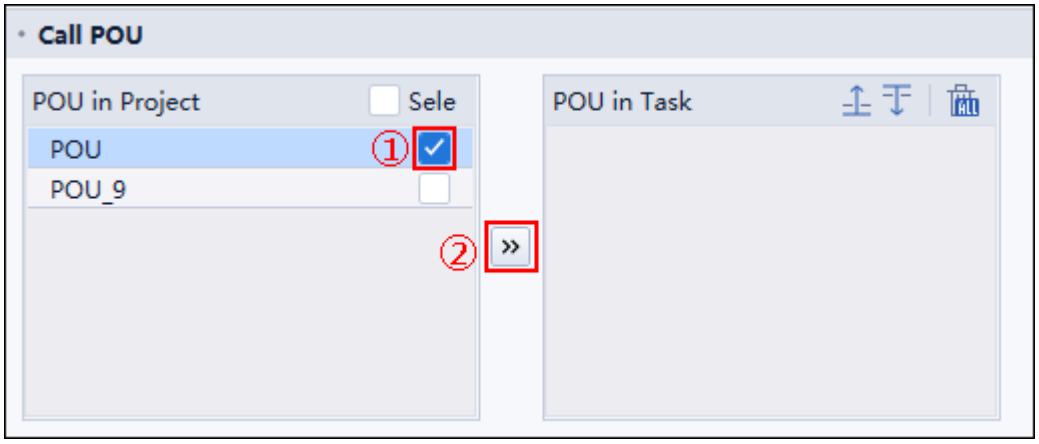
Task type	Note	Execution Characteristics
Periodic	Cycle tasks repeat execution periodically according to the set cycle time.	The POU is executed once at each configured interval.
Event	Event tasks start executing when a specific event is triggered. In iFA software task configuration, set a BOOL variable as the event trigger. When the BOOL type variable is TRUE, the event is triggered, and the task starts executing.	Task execution is triggered once when the preset BOOL variable transitions from 0 to 1, but will not be triggered under other transition combinations such as 0->0, 1->1, and 1->0.
Inertial slide	An inertial coasting task refers to automatically restarting the task in a continuous loop at the beginning and end of task execution.	The task is executed circularly and continuously once the execution is started.
External event	External event tasks are suitable for situations where immediate program response is required when an external signal is input or when the counter axis reaches a set value.	The corresponding POU is executed once when the HSIO status changes or the high-speed counter readings match. External event tasks are not affected by the scan cycle.

NOTE

- The EVO800 series only supports two task types in redundant mode: cycle type and inertial coasting type.
- Only EVO400, EVO500, and APC500 series PLCs support configuring external event tasks.

2. Depending on the selected task type, configure the corresponding parameters. The parameter descriptions for each task type are shown in the table below.

Parameter	Description
Periodic	This parameter is displayed when the task type is "Cycle". Indicates the task execution interval (unit: ms/μs). For slow-changing processes with low real-time requirements (such as conventional logic control), the cycle can be appropriately extended (e.g., to 20 ms); for processes with high real-time requirements (such as interrupt service), a shorter cycle must be configured to ensure system real-time performance. NOTE The minimum task cycle varies for different products. For example, the minimum task cycle for the EVO500 series is 1 ms. For details, see the relevant product manuals.
Offset	This parameter is displayed when the task type is "Cycle". The system uses the highest-priority task as the reference task, and its execution time serves as the time reference point. Other tasks (subordinate tasks) are executed with a set offset delay relative to the execution time of the reference task. Default is 0. The maximum offset can be set to 2147483647, in ms or μs. For example: ▪ If the highest-priority reference task has a cycle of 100 ms, it is executed at 0 ms, 100 ms, 200 ms, etc. ▪ If the subordinate task A has a cycle of 100 ms and has no offset set, it is triggered at 0 ms, 100 ms, 200 ms, etc., simultaneously with the reference task. By setting an offset of 50 ms for the subordinate task A, it is triggered at 50 ms, 150 ms, 250 ms, etc. This avoids the CPU pressure caused by multiple concurrent tasks and ensures real-time response of high-priority tasks. NOTE ▪ Only EVO800 series PLCs (including standalone, redundant, and multi-machine modes) support offset configuration. ▪ To ensure the performance of the highest-priority task, it is recommended to set offsets only when the subordinate task cycle is an integer multiple of the reference task cycle. ▪ Due to various factors such as fluctuations in program logic complexity, system resource competition, or external interference, the execution cycle of tasks may fluctuate within a certain range (task jitter time ±75 μs). Therefore, users need to dynamically adjust the task offset based on the actual runtime results.



Parameter	Description
Event	This parameter is displayed when the task type is "Event". Click the "..." in the edit box, and select a BOOL-type variable in the "Input assistant" pop-up window.
External event	This parameter is displayed when the task type is "External event". Select the external event for task triggering from the drop-down menu. ▪ X0InterruptEvent to X3InterruptEvent are used to receive interrupt events triggered by input ports X0 to X3. ▪ Cmp1InterruptEvent to Cmp16InterruptEvent are used to receive comparison interrupt events of high-speed counter 0 to 3. High-speed counters 0 to 3 can be arbitrarily bound to external events 1 to 16. NOTE When adding multiple external event tasks, external events must not be duplicated; otherwise, a compilation fault will occur.

- **Watchdog**
  The watchdog monitors the actual runtime of the task. If the actual runtime exceeds the limit set by the watchdog, the watchdog mechanism will be triggered, terminating the task execution.
  1. In the "Add task" or task configuration interface page, check "Enable" in the "Watchdog" section.
  2. Set the watchdog time and unit (ms or us).

NOTE

The EVO800 series (single/redundant mode) has watchdog enabled by default, with a default time of twice the task execution cycle. Users can disable the watchdog or reconfigure the time as needed; the configured value should not be less than twice the task cycle.

- **Call POU**
  A task can include multiple POUs. These POUs follow the same execution cycle and are executed in the order they were added to the task.
  1. In the "Add task" or task configuration interface, select the POUs from the "POU in project" list.
  2. Click » to add the selected POU to the current task.

The POUs in the current task can be moved up/down or deleted, as shown in the table below.

Description	Icon	Description
Move up		Move the selected POU upward; this operation synchronously updates the POU order under the corresponding task node in the project tree.
Move down		Move the selected POU downward; this operation synchronously updates the POU order under the corresponding task node in the project tree.
Delete all		Delete all POUs from the "POU in project" list; this operation synchronously removes the corresponding POUs from the task node in the project tree.

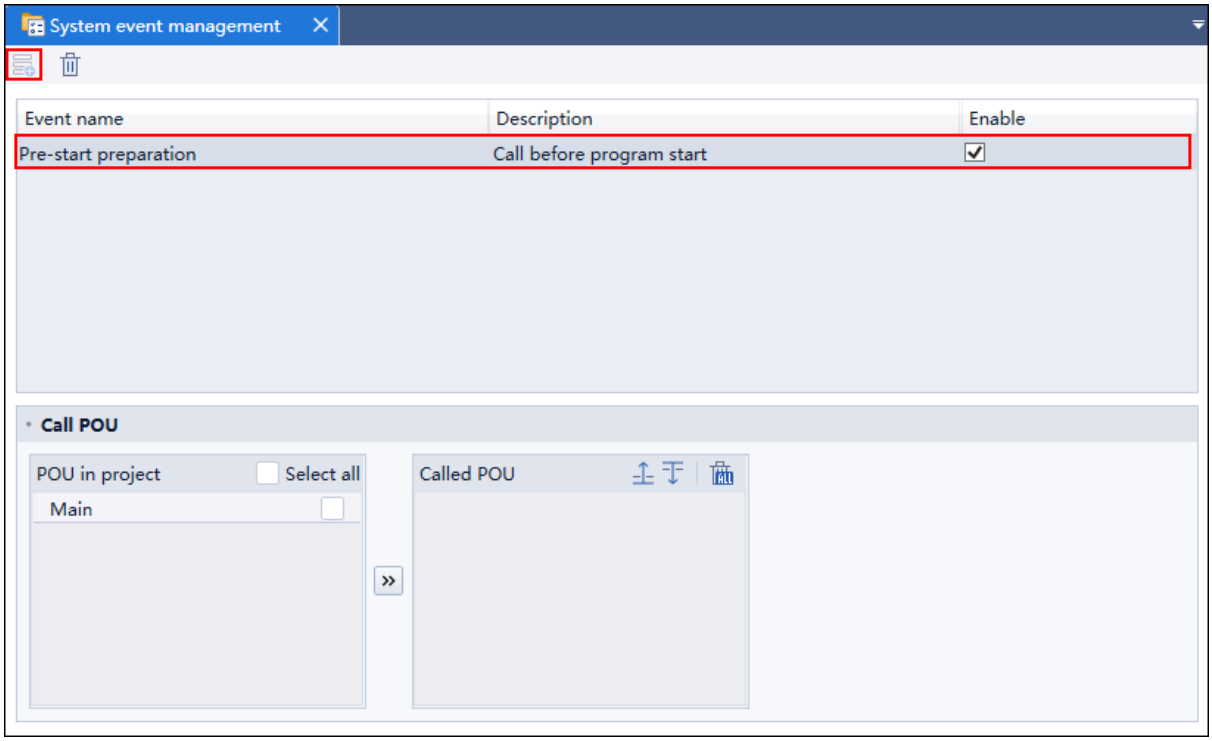
10.5.3 System Event Management

To perform initialization before the PLC starts running the main program, you can add a "Pre-start preparation" event on the "System event management" page and add the initialization program to this event. After the event is activated, the initialization operation will be executed before the formal task begins. The execution rules for the pre-start preparation event are as follows:

1. When the PLC is run for the first time, it is automatically called before all tasks are executed.
2. When the PLC is restarted after stopping, it is regarded as a new operation cycle and is executed with priority again.
3. If users log out and in again after modifying the program (triggering online modification), it will not be executed.
4. If users log out and in again without modifying the program (not triggering online modification), it will not be executed.
5. If online modification is triggered but a full download is executed, it will be executed once.
6. After the device is powered off and on again, it will be executed once.

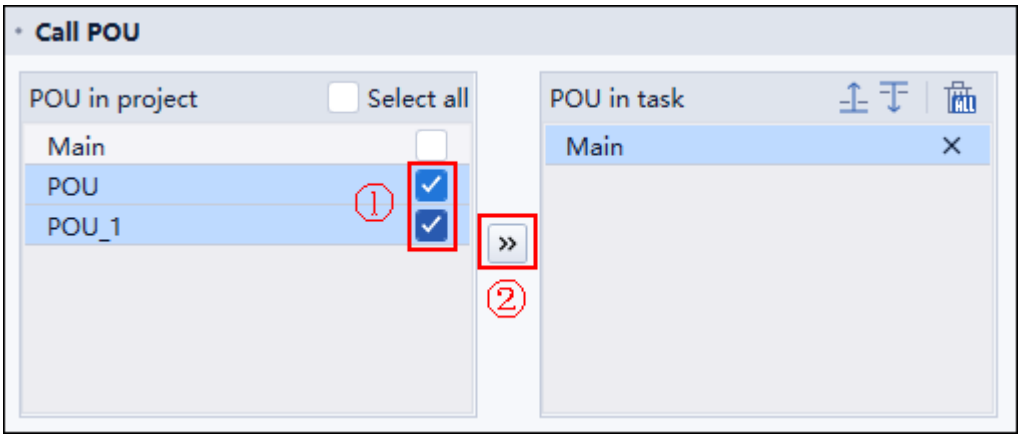
NOTE

In iFA simulation mode, the rules are consistent with the above 1 to 5.



Prerequisites

- A PLC device has been added.
- The initialization program has been created.



Procedure

1. Right-click the "Task configuration" node in the project tree and select "System event management".
2. On the "System event management" page, click to add the "Pre-start preparation" event. This function is activated by default and can be deactivated as needed.

   Only one "Pre-start preparation" event is supported. Click to delete the event.

3. In the "Call POU" area, check the POU(s) in the "POU in project" list (select all is supported) and click to add the selected POU(s) to the "Pre-start preparation" event.

The "Called POU" can be moved up, moved down, or deleted. The specific instructions are shown in the table below.

Description	Icon	Description
Move up		Moves up the selected POU.
Move down		Moves down the selected POU.
Delete all		Deletes all POUs in the list.

10.6 PLC Configuration

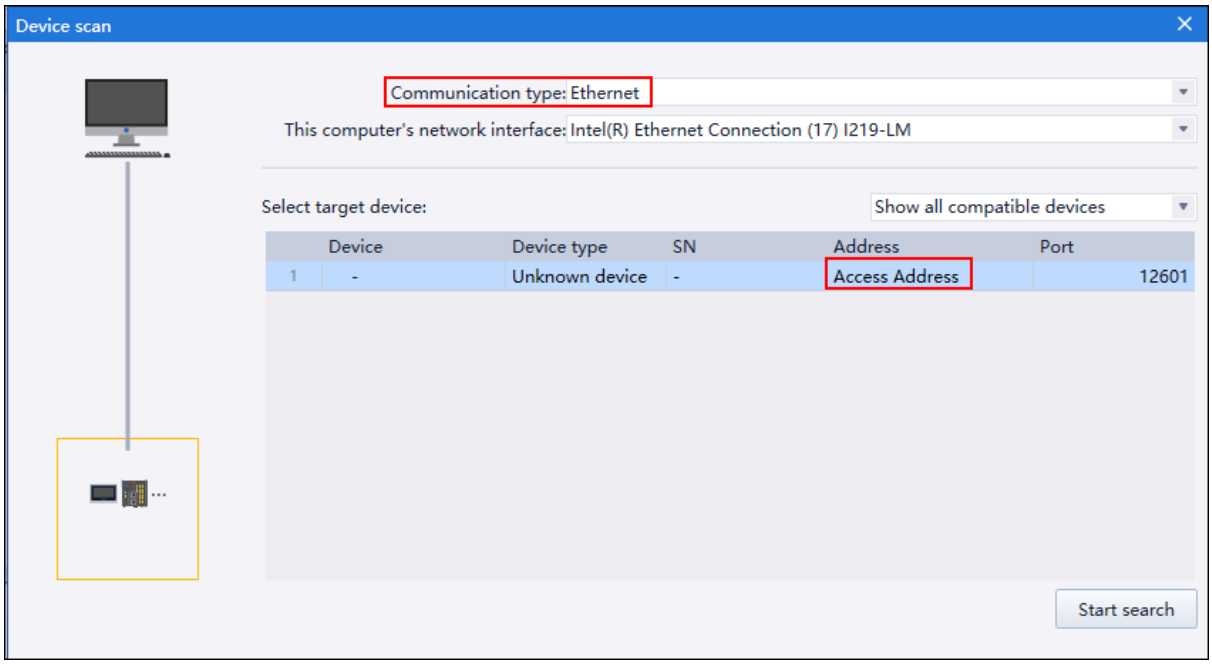
10.6.1 Hardware Configuration and Device Management

10.6.1.1 Device Scanning

When the current PLC needs to connect to devices such as PLCs, HMIs, PACs, PCs, and drives, this function can scan all compatible devices within the same subnet, allowing users to select the target device for connection.

Background

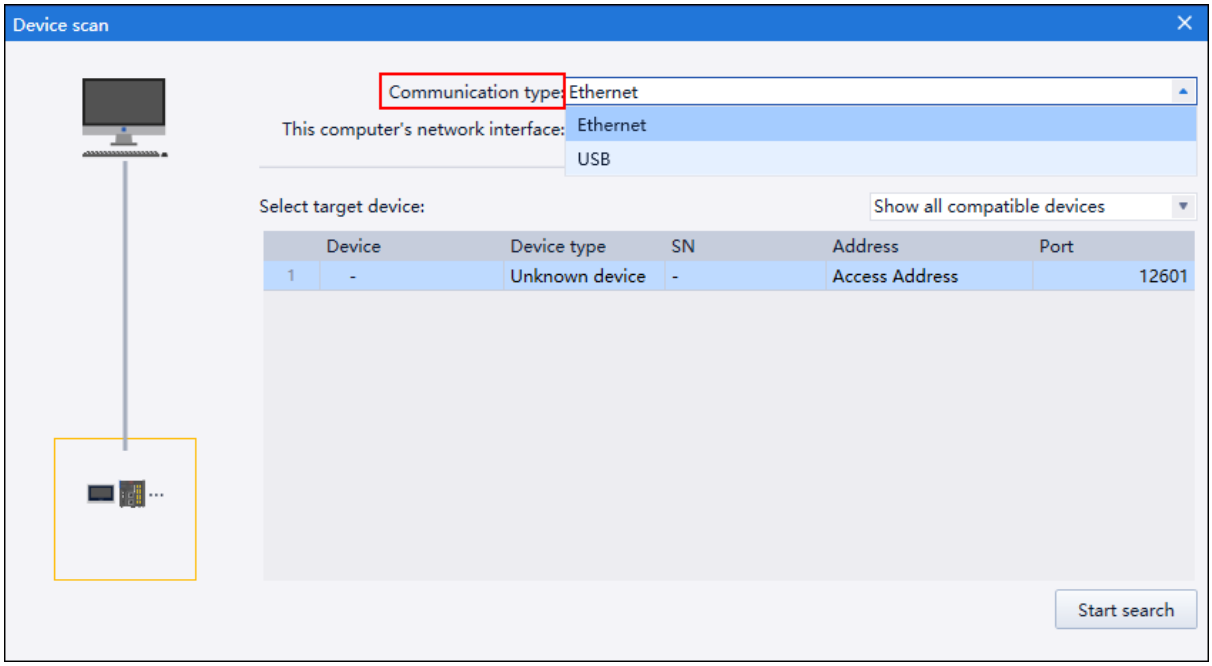
The EVO800 series PLC supports downloading and commissioning through the Ethernet expansion module port. When scanning devices through this port, the current system only supports scanning the PLC to which the connected Ethernet expansion module belongs; other PLCs are not supported for scanning.



Prerequisites

Devices have been configured in the project.

Steps



1. Select a device from the left project tree.
2. Scan the selected device.
   - Method 1: Right-click the selected device and select "Online" to open the "Device scanning" window.
   - Method 2: Click the "Device scanning" icon in the toolbar.
3. Set search conditions.
   - Searching by address

     Select communication type as "Ethernet". Double-click "Access address" and enter the IP address.

   - Searching by communication type

     Select communication type as "Ethernet" or "USB."

USB interface communication constraints:

> CAUTION
>
> For non-administrator users, the USB scanning function is not supported. Switch to administrator or scan the device via Ethernet.

- Supports standard USB 2.0 interface.
- Supports direct one-to-one connection between USB interface and PLC.
- During routine function (such as download and commissioning) communication, multiple USB interfaces on the PC can be used simultaneously (to connect to PLCs). During PLC firmware upgrade, only one of the PC's USB interface is supported, with the rest remaining unused.

4. Execute search.
   Click "Start search" to perform the scan, and select the target device from the results.

   To avoid incorrect connections, ensure that the selected device in the list matches the physical target device. There are two methods to confirm:

   - SN number consistency check: Compare the SN number in the window with that on the physical device, ensuring they match.
   - LED indicator consistency check: When "Flashing LED" is checked in the window, the RUN indicator on the corresponding physical device will flash in response.

5. Connect the device.
   After confirming the information, click "OK" to connect to the physical device.

Scanning operations

Cross-subnet device search and renaming

To configure network settings for devices within a region, use the 7.3.2 network configuration functions to search for all devices in the region and modify device names, IP addresses, and so on.

Filtering devices by network card

For multiple network interfaces on the user's PC, devices can be filtered based on different network interfaces.

- Prerequisites

There are multiple network interfaces on the user's PC.

- Procedure

1. There are two ways to scan devices:
   - Method 1: Right-click the selected device and select "Online" to open the "Device scanning" window.
   - Method 2: Click the "Device scanning" icon in the toolbar.
2. In the "Device scanning" window, click "Start search" and filter the scanned devices based on different network card types from the "PC network interface" drop-down list.

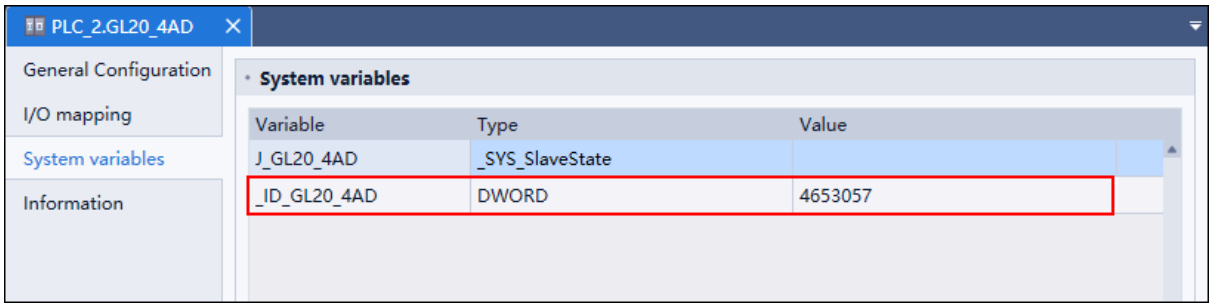
Device memory connection

To quickly connect to a previously connected device, the software supports device memory connection.

- Prerequisites
  - Devices have been configured in the project.
  - The device has been successfully connected in the current project before.
- Procedure

Click the drop-down box next to the "Device scanning" icon in the toolbar to view and select previously connected devices.

10.6.1.2 Viewing Device ID



Device ID is a number used to uniquely identify different devices. It is an essential component for communication, configuration, and maintenance among devices.

Prerequisites

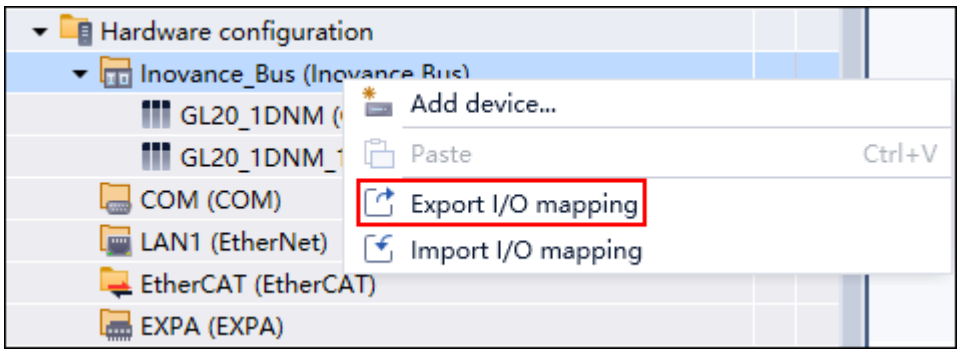
Devices have been configured in the project.

Procedure

1. In the left project tree, double-click a device node to open the device configuration interface (using the I/O module GL20-4AD as an example).
2. Select the "System variable" tab to view the device ID (_ID_Device Name).

10.6.1.3 Exporting I/O Mapping

The I/O mapping table can be exported in CSV format. The export scope is divided into:



- Single device: Export all I/O mappings of a single PLC device.

- Hardware configuration node: Export all I/O mappings under the PLC hardware configuration node.
- Single port node: Export I/O mappings of Inovance_Bus, COM, LAN, EtherCAT, expansion cards, and so on.

Users can edit the exported file according to the format and import the updated configuration. This section introduces the export of I/O mapping for Inovance_Bus (I/O module) as an example.

Procedure

1. Right-click "Inovance_Bus (I/O module)" under the "Hardware configuration" node in the project tree, and select "Export I/O mapping".

2. Select the file storage path, edit the filename as needed, and click "Save".

Result

The exported file "XXX.csv" is shown in the figure below.

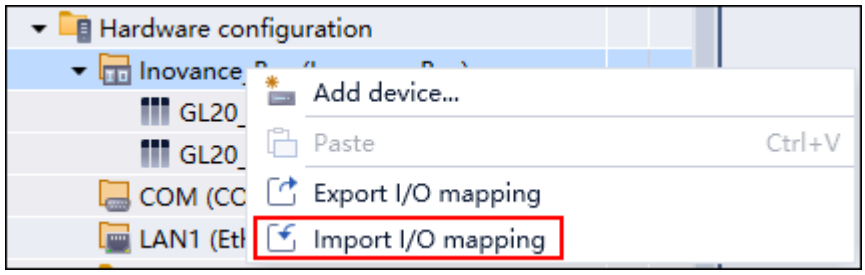
Variable	Variable table	Channel	Device name	Channel address following variable address	Description
		MasterStat	GL20_1DNM	No	
		Bit0	GL20_1DNM	No	
		Bit1	GL20_1DNM	No	
		Bit2	GL20_1DNM	No	
		Bit3	GL20_1DNM	No	
		Bit4	GL20_1DNM	No	
		Bit5	GL20_1DNM	No	
		Bit6	GL20_1DNM	No	
		Bit7	GL20_1DNM	No	
		SlavesState	GL20_1DNM	No	
		SlavesState	GL20_1DNM	No	
		Bit0	GL20_1DNM	No	
		Bit1	GL20_1DNM	No	
		Bit2	GL20_1DNM	No	
		Bit3	GL20_1DNM	No	
		Bit4	GL20_1DNM	No	
		Bit5	GL20_1DNM	No	
		Bit6	GL20_1DNM	No	
		Bit7	GL20_1DNM	No	
		SlavesState	GL20_1DNM	No	
		Bit0	GL20_1DNM	No	
		Bit1	GL20_1DNM	No	
		Bit2	GL20_1DNM	No	
		Bit3	GL20_1DNM	No	

10.6.1.4 Importing I/O Mapping

Importing I/O mapping allows for quick updating of I/O configuration. The import scope is divided into:

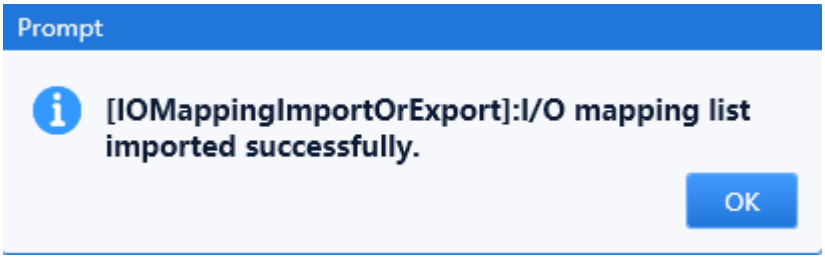
- Single device: Import all I/O mappings of a single PLC device.
- Hardware configuration node: Import all I/O mappings under the PLC hardware configuration node.

- Single port node: Import I/O mappings of Inovance_Bus, COM, LAN, EtherCAT, expansion cards, and so on.



This section introduces the import of I/O mapping for Inovance_Bus (I/O module) as an example.

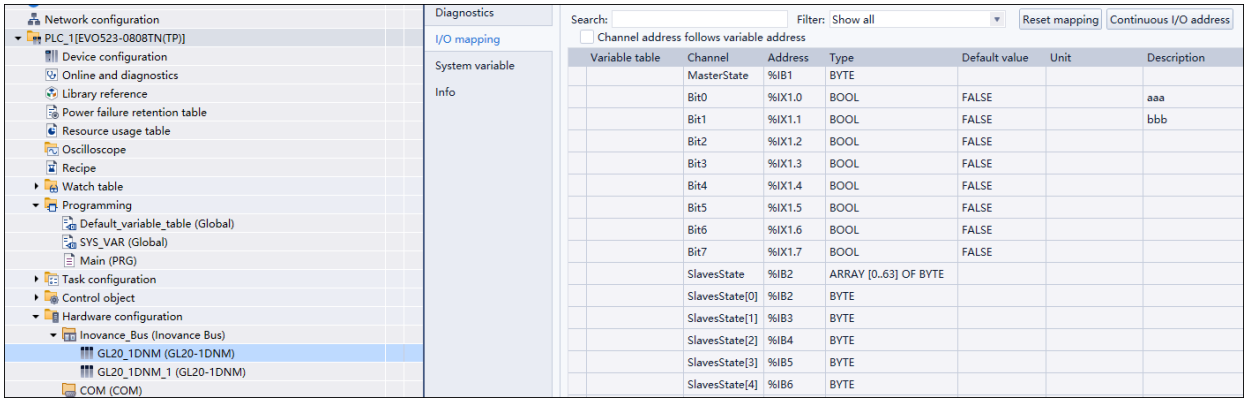
Prerequisites



A file that meets the import conditions already exists.

Procedure

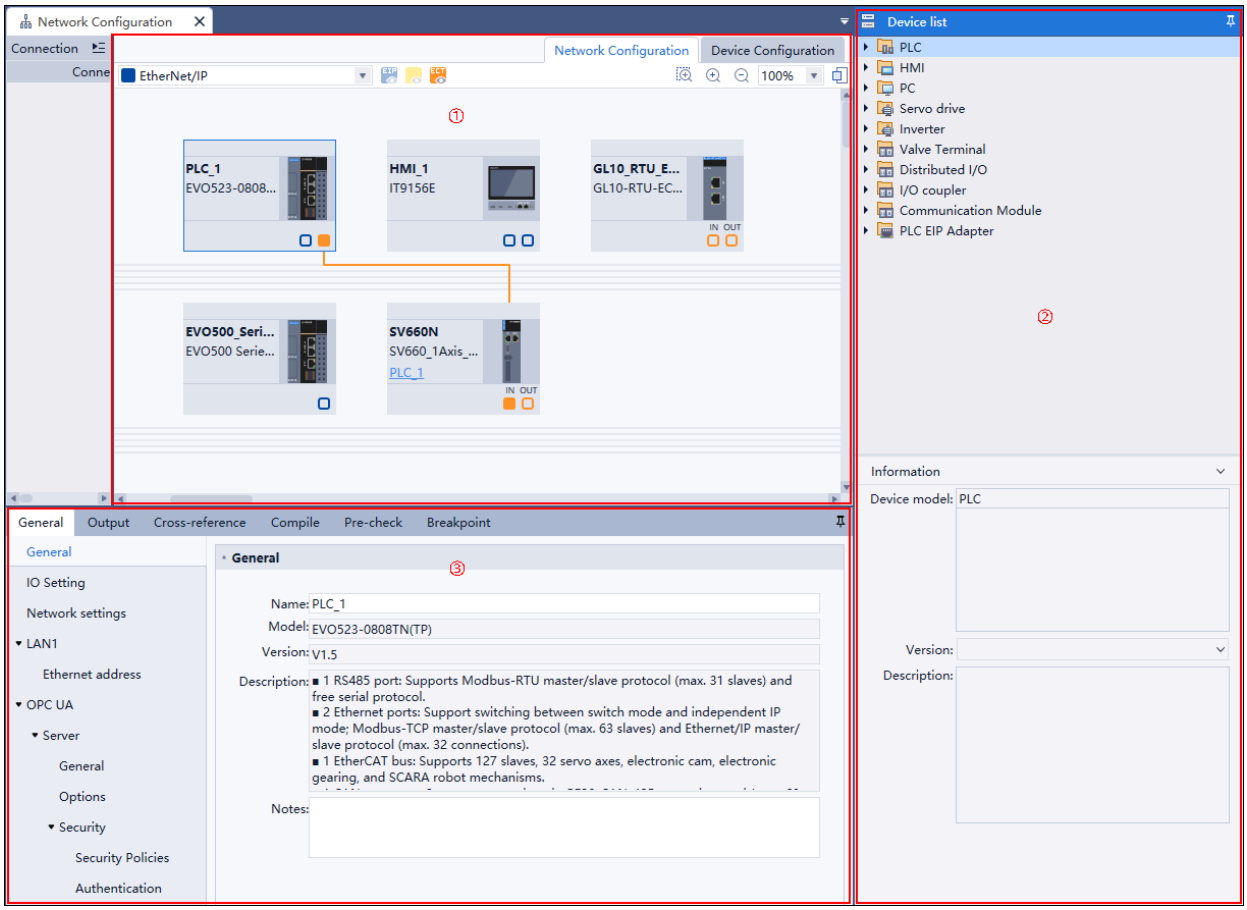
1. Right-click "Inovance_Bus (I/O module)" under the "Hardware configuration" node in the project tree, and select "Import I/O mapping".



2. Select the file to import, and click "Open".
3. After successful import, click "OK" in the pop-up prompt box.

Result

Open the imported I/O mapping table under Inovance_Bus to view the updated configuration, as shown in the figure below.



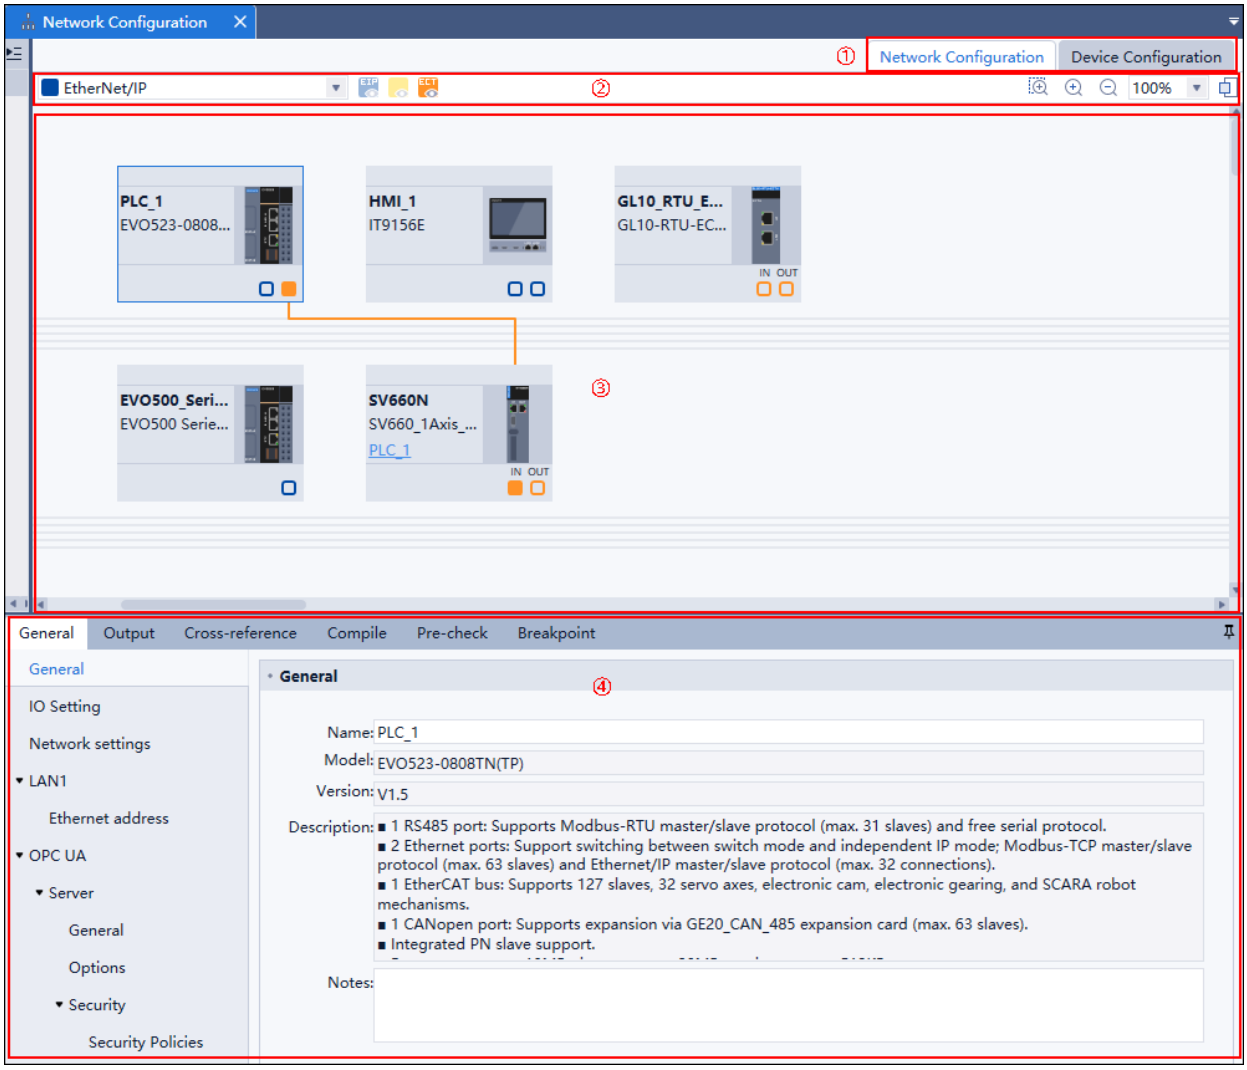
10.6.2 Device and Network Editor

10.6.2.1 Overview

- Functions of the device and network editor
  - The device and network editor is an integrated development environment used for configuring devices and modules, networking, parameter assignment, and other operations.

- Double-click "Device configuration" in the project tree to open the device and network editor.

- Structure of the device and network editor
  - The device and network editor consists of the following components:



No.	Function	Description
①	Device configuration and network configuration	A graphical area including the device view and network view. You can switch views according to your usage requirements.
②	Device List	Drag devices and modules from the device list to the network configuration or device configuration tab.
③	Monitoring area	Contains relevant information about the currently marked object, which can be modified here.

10.6.2.2 Network View

The network configuration view is one of the two workspaces in the device and network editor, used to plan the network structure between devices, and can perform the following tasks:

- Configure and assign device parameters.
- Network devices.
- Modify device names.

As shown in the figure below, it displays the components of the network configuration view:

No.	Function	Description
①	View switch	Switches between device configuration and network configuration views.
②	Toolbar	Performs operations such as zooming in/out.
③	Graphical area	Contains basic configuration operations.
④	Information display area	Displays relevant information about the device.

- **Toolbar**

  The toolbar provides the following functions:

Icon	Description
	Switches protocol. You can switch the supported protocols of the device through the drop-down menu.
	Displays the EtherNet/IP connection selection status. The connection line will be highlighted when selected.

Icon	Description
	Displays the EtherCAT connection selection status. The connection line will be highlighted when selected.
	Zooms in the overall view. Click the "Zoom in" icon to zoom in the effect gradually by 25%, 75%, 100%, 150%, 200%, 300%, and 400%, with the center of the canvas as the zoom center and the current ratio as the starting ratio.
	Zooms in the selected area Click the "Area zoom in" icon. Press and hold the mouse at the starting position of the selected area to be zoomed in, move the mouse to draw a selection box, and release it at the appropriate position. Only the selected area will be zoomed in.
	Zooms out the overall view. Click the "Zoom out" icon to zoom out the effect gradually by 400%, 300%, 200%, 150%, 100%, 75%, and 25%, with the center of the canvas as the zoom center and the current ratio as the starting ratio.
	Micro view Micro view display: Shows an overview of the canvas in map form, with the current workspace highlighted by a gray semi-transparent frame on the map. Micro view operation: You can drag the gray semi-transparent frame, and the content within the frame will be displayed in the workspace simultaneously. Zoom ratio: Zooms the view based on the selected zoom ratio, with the center of the canvas as the zoom center.

- **Graphical area**
  The graphical area of the network configuration displays all devices, networks, connections, and relationships related to the network. In this area, you can add devices from the device list, connect devices through interfaces, and configure communication settings.

  You can also use scroll bars to view the network configuration, or use Ctrl + mouse wheel to set the zoom level of the graphics.
- **Information display area**
  The information display area shows relevant information about the selected device.
- **View switch**
  The view switch supports switching between the device configuration view and the network configuration view.

10.6.2.3 Device View

Device configuration is one of the two workspaces in the device and network editor, used to configure parameters for devices and submodules. The following operations can be performed:

- Configure and assign device parameters.
- Configure and assign module parameters.
- Modify the names of devices and modules.

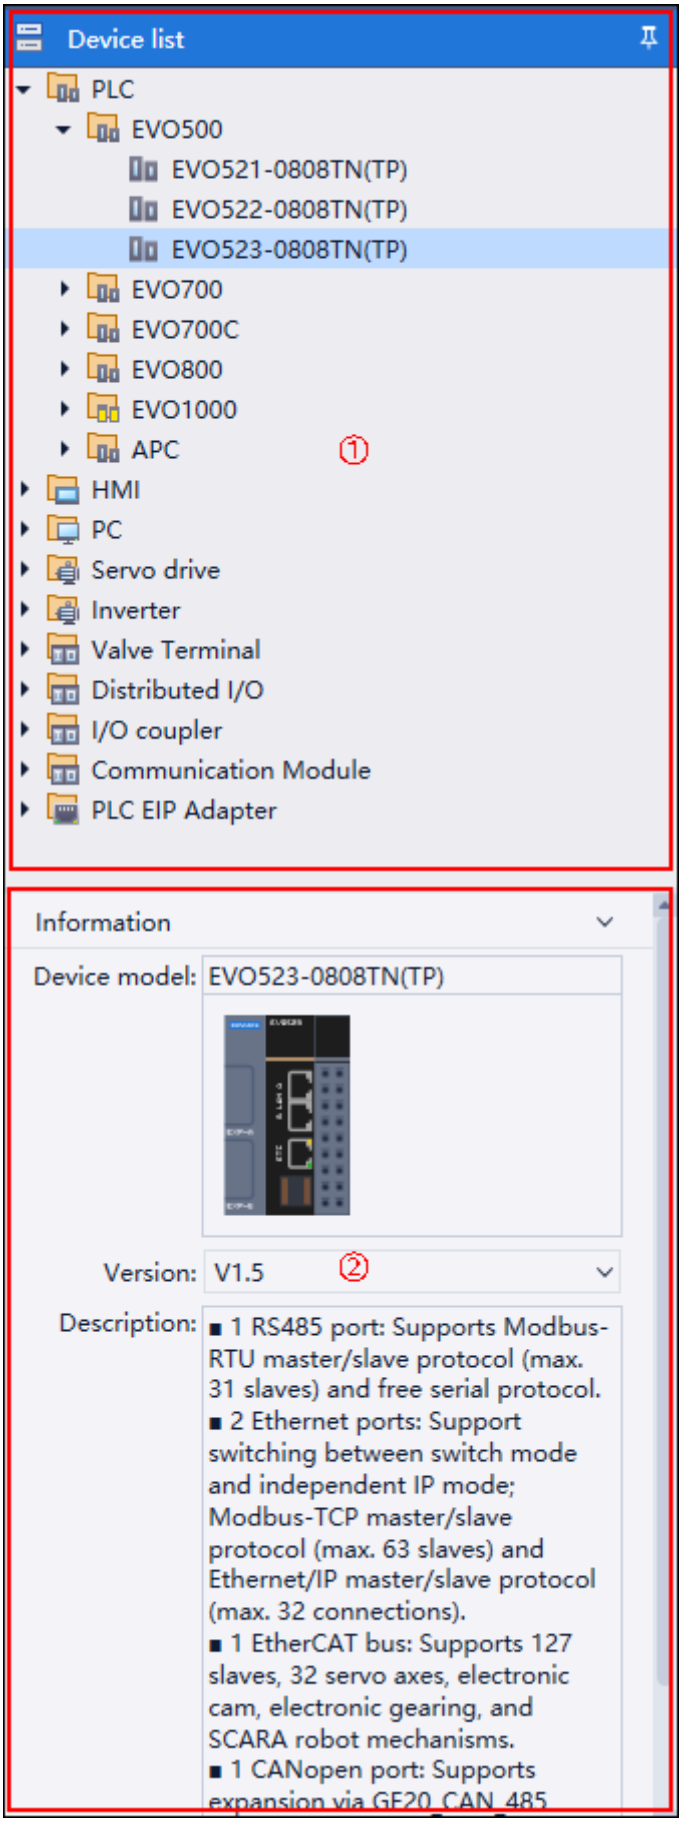
As shown in the figure below, it displays the components of device configuration:

No.	Function	Description
①	View switch	Switches between device configuration and network configuration views.
②	Toolbar	Performs operations such as zooming in/out.
③	Graphical area	Contains basic configuration operations.
④	Information display area	Displays relevant information about the device.

- **Toolbar**

  The toolbar provides the following functions:

Icon	Description
	Switches to the network configuration view. Click the icon to switch to the network configuration view.
	Selects the device. Use the drop-down list to switch between devices in the project within the device configuration. After selecting a device, the device configuration view displays the device graphics, and the device list is updated to show the modules that match the selected device.



Icon	Description
	Shows/hides module labels. Device names can be modified here.
	Zooms in the overall view. See 10.6.2.2 Network Configuration View.
	Zooms in the selected area See 10.6.2.2 Network Configuration View.
	Zooms out the overall view. See 10.6.2.2 Network Configuration View.
	Micro view Micro view display: Shows an overview of the canvas in map form, with the current workspace highlighted by a gray semi-transparent frame on the map. Micro view operation: You can drag the gray semi-transparent frame, and the content within the frame will be displayed in the workspace simultaneously. Zoom ratio: Zooms the view based on the selected zoom ratio, with the center of the canvas as the zoom center.

- **Graphical area**
  The graphical area of the device configuration view displays hardware components, which are assigned to each other via one or more racks if necessary. For devices with racks, users can install other hardware components from the device list into the slots of the rack.
- **Information display area**
  The information display area shows relevant information about the selected device.
- **View switch**
  The view switch supports switching between the device configuration view and the network configuration view.

10.6.2.4 Device List

The device list is located in the toolbox on the right side of the platform, consisting of two parts: the device list and information. The two parts are placed in separate panes that support expansion, collapse, and can be dragged up and down between panes.

- **Structure**

- **Device list**
  The device list categorizes and displays the directory of components, supporting dragging and moving devices or modules from the device list to the graphical area of the device configuration/network configuration view.
- **Information**

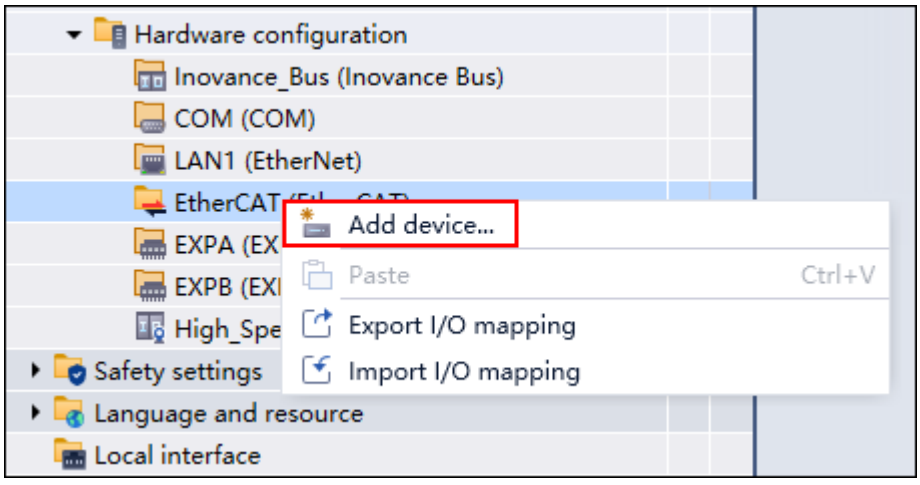
Select a project tree node and the detailed information about the selected device will be displayed in the information pane below. The information pane includes the following content:

Content	Note
Model	The model of the device selected from the project tree node.
Diagram	The diagram of the device selected from the project tree node.
Version	The firmware version of the device selected from the project tree node.
Description	A detailed description of the device selected from the project tree node.

10.6.3 EtherCAT Communication Configuration (EVO500, EVO700, APC500, EVO700C)

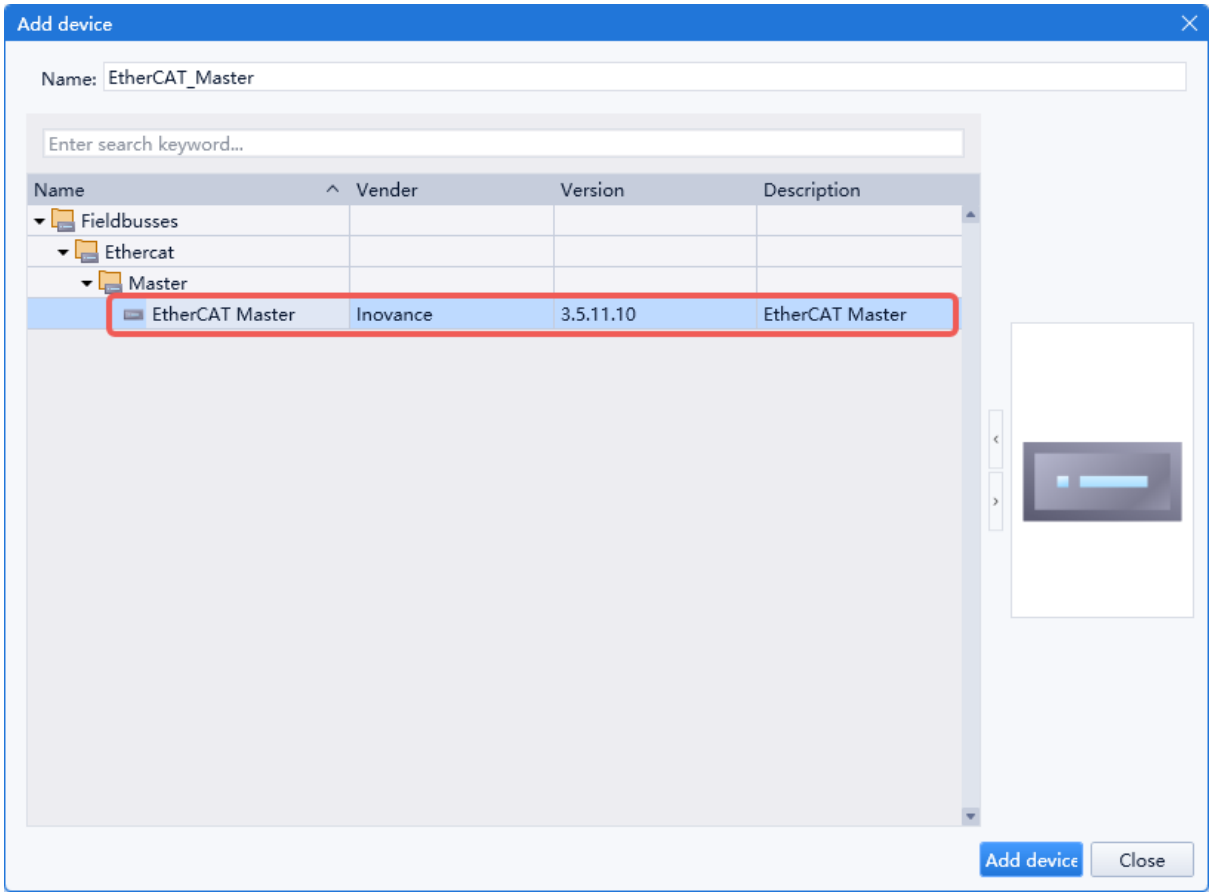
10.6.3.1 Adding an EtherCAT Device

10.6.3.1.1 Adding a Master



The controller supports EtherCAT communication and EtherCAT master devices can be added.

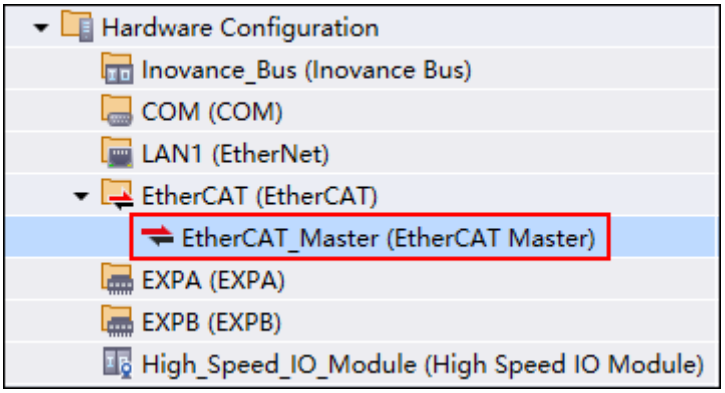
Prerequisites



- A project has been created.
- A device has been added.

Procedure

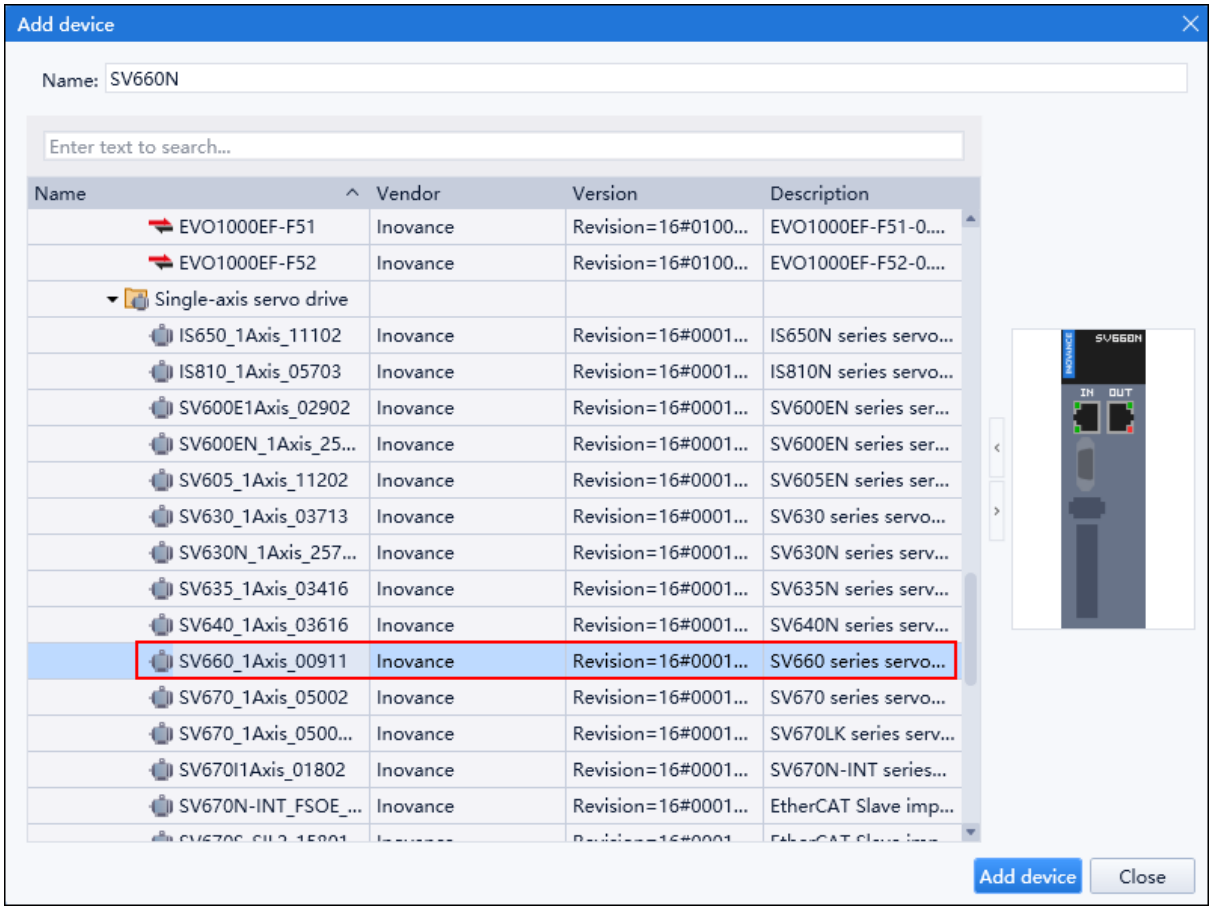
1. Right-click "EtherCAT" under "Hardware configuration" in the project tree and select "Add device".



2. In the pop-up window, select "EtherCAT Master" and click "Add device" to add the EtherCAT master device.

Result

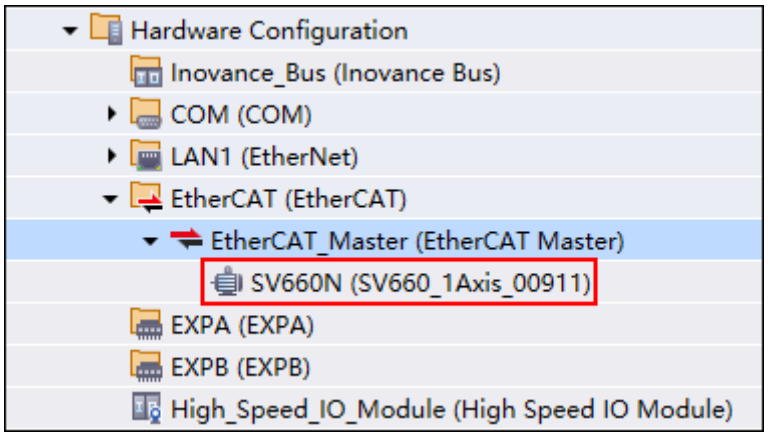
Under the EtherCAT node, you can see the added master device node.



10.6.3.1.2 Adding a Slave

Prerequisites

The EtherCAT master has been added.



Procedure

1. Right-click the "EtherCAT_Master" node and select "Add device".
2. In the pop-up window, select the slave device and click "Add device".

Result

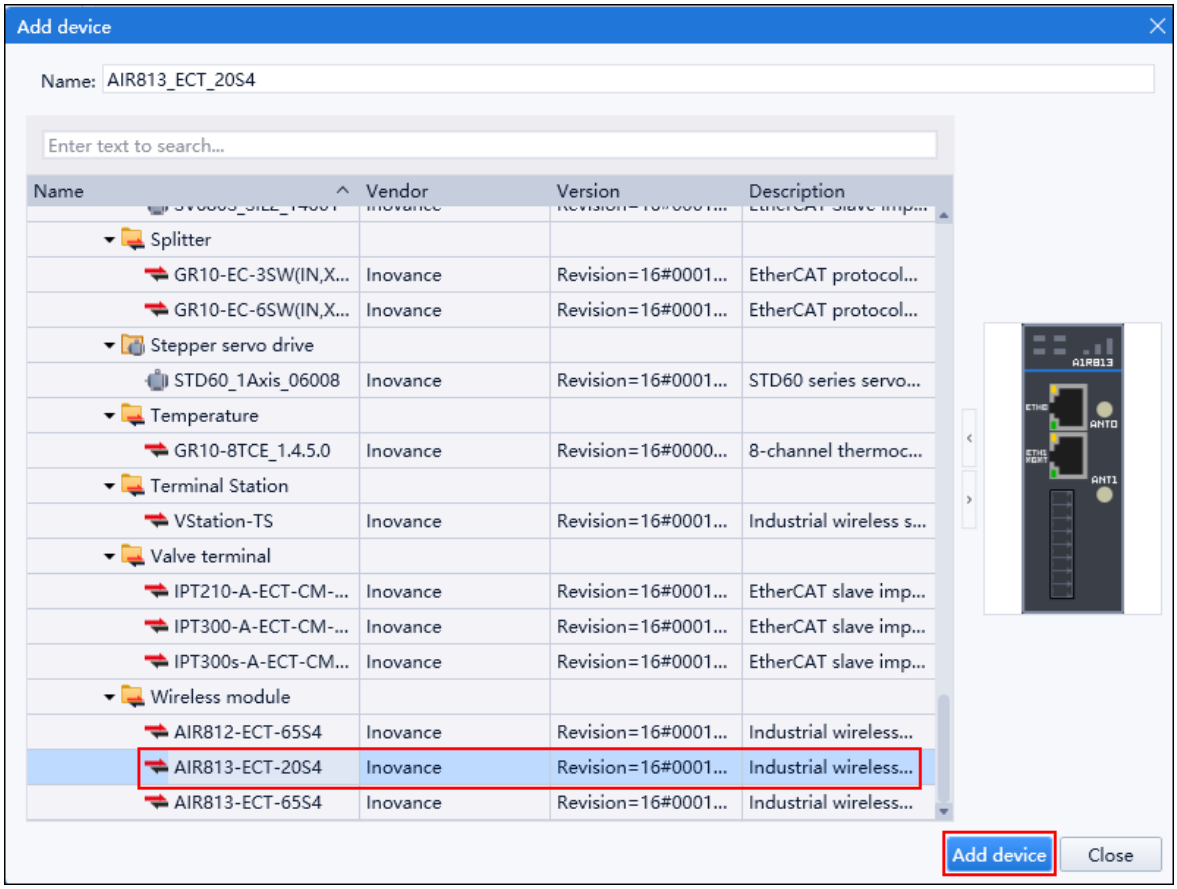
Under the "Hardware configuration > EtherCAT > EtherCAT_Master" node, you can see the added slave devices.

10.6.3.1.3 Adding a Wireless Management Station

Restrictions

- The wireless management station must be the first station of the PLC.
- Ring network is not supported by the wireless management station.
- Only one wireless management station can be added to a single PLC.

Prerequisites



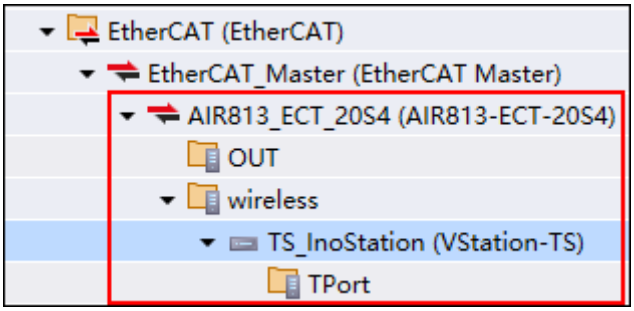
The EtherCAT master has been added.

Procedure

1. Add a wireless management station.

   a. Right-click the "EtherCAT_Master" node, and select "Add device".

   b. In the pop-up window, select a wireless management station, and click "Add device".

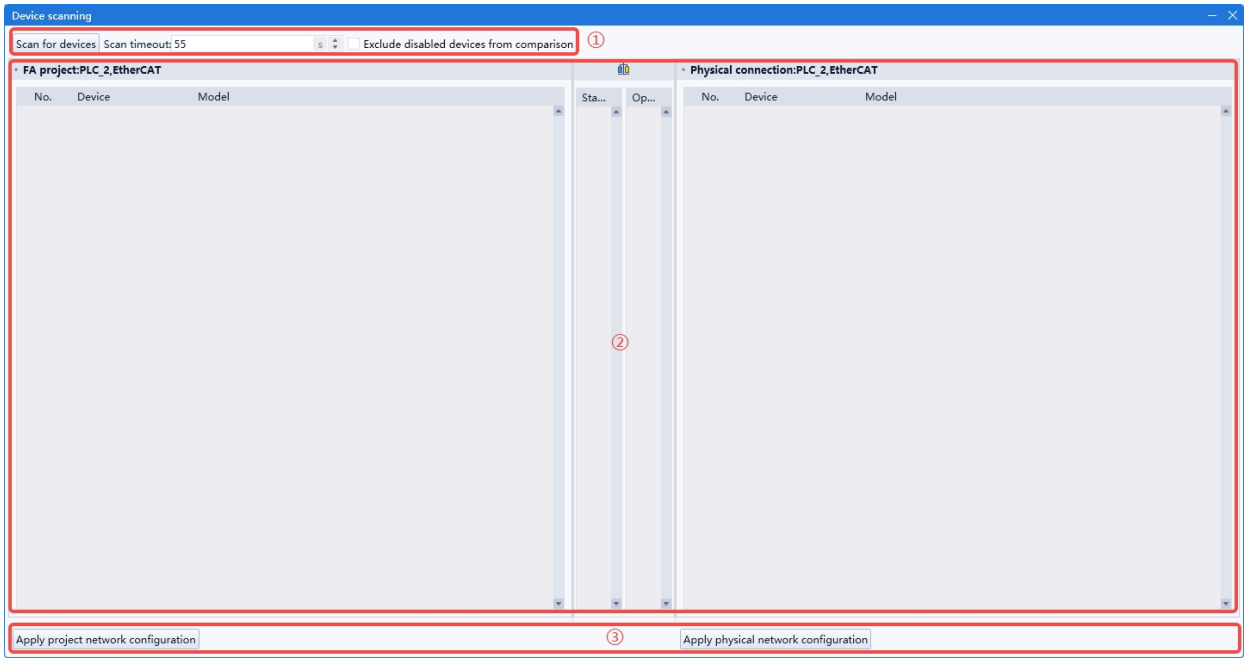


2. Add a terminal station to the wireless port of the management station.

   In the "Add device" window, select a terminal station, and click "Add device".

Result

The added wireless management station and terminal station can be viewed under "Hardware configuration > EtherCAT > EtherCAT_Master".



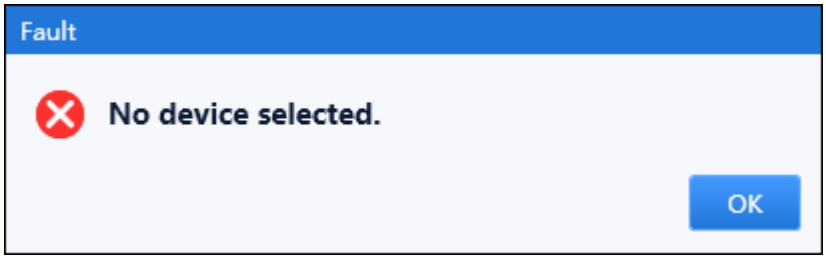
10.6.3.1.4 Adding an Online EtherCAT Slave to Project

Prerequisites

- The PC and PLC have been correctly connected through the gateway.
- The EtherCAT_Master has been configured.

Procedure

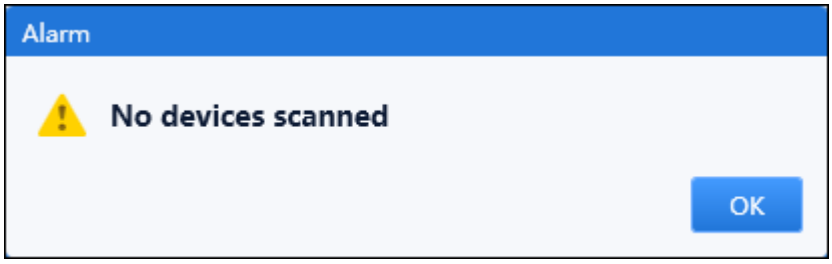
1. Download the project to the PLC.
2. Right-click "EtherCAT_Master", select "Scan for devices", and the device scanning window will pop up.



The items in the above figure are defined as follows:

No.	Function	Description
①	Scan for devices	Scans the devices.
	Scan timeout	Scan duration, with a range from 5s to 300s.

No.	Function	Description
	Exclude disabled devices from comparison	When selected, disabled devices are not involved in device comparison; During device copy, if device comparison succeeds, device configuration is retained; if it fails, the device is deleted. The disabled status of devices is adjusted based on their actual status in the configuration list. For example, if a device in the physical device list is successfully compared, its disabled status is enabled. However, if the originally disabled device exists in the project configuration device list, the disabled status remains upon successful comparison.
	Set alias address	After editing the alias address in the "Write alias address" field, click "Set alias address" to make the address effective.
	Batch assign aliases	Alias addresses are automatically assigned starting from the first slave, incrementing by 1 sequentially. If no alias address is set for the first slave row, the original default alias address is used as the starting address. After editing the alias address in the "Write alias address" field, click "Batch assign aliases" to apply the changes.
②	Copy to the left	Copies scanned devices from the network to the project network.
	Status	Compares the data between the project and physical devices.
③	Apply project network configuration	Applies the device configuration in the project network to the project.
	Apply physical network configuration	Applies the configuration of all scanned devices to the project

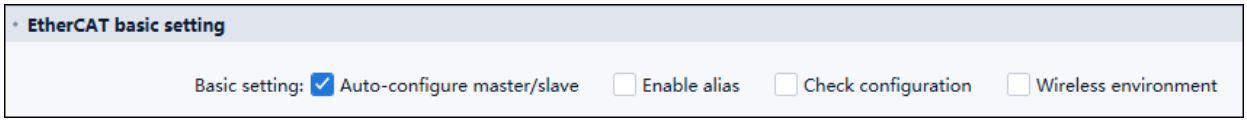


Scanning faults

1. If the PC is not connected to the PLC and you directly scan the slave devices, the following prompt will appear:

Solution: Check the communication connection status between the PC and the PLC.

2. If the PC is connected to the PLC but no slaves are connected under the PLC, the following prompt will appear:



CAUTION

After the EtherCAT bus starts normally, if the project is switched to offline mode, the scan results may fail or be inaccurate when scanning devices online. The reason is that during the scanning process, reading slave information via SDO communication (such as object dictionary 0xF050) may time out, affecting the scan results (SDO communication is asynchronous, and CPU load, bus cycle time, and user program execution time can all affect SDO communication).

10.6.3.2 Configuring Master Parameters

10.6.3.2.1 General Settings

EtherCAT basic settings

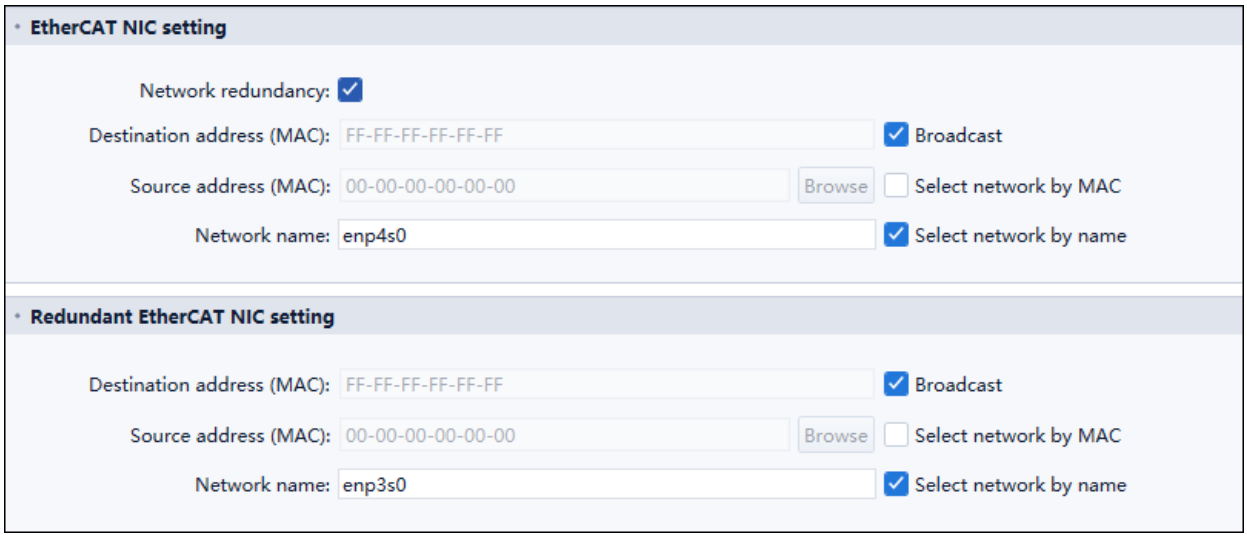
- Auto-configure master/slave
  After selecting this option, the system will automatically complete the main configuration for master and slave. Meanwhile, the "FMMU/Sync" tab in the editor of all slaves will be hidden.

NOTE

- "Auto-configure master/slave" is enabled by default; it is strongly recommended to keep it enabled in standard applications. If disabled, all masters and slaves must be configured manually, requiring the operator to have the necessary expertise.
- When configuring slave-to-slave communication, you must disable "Auto-configure master/slave".

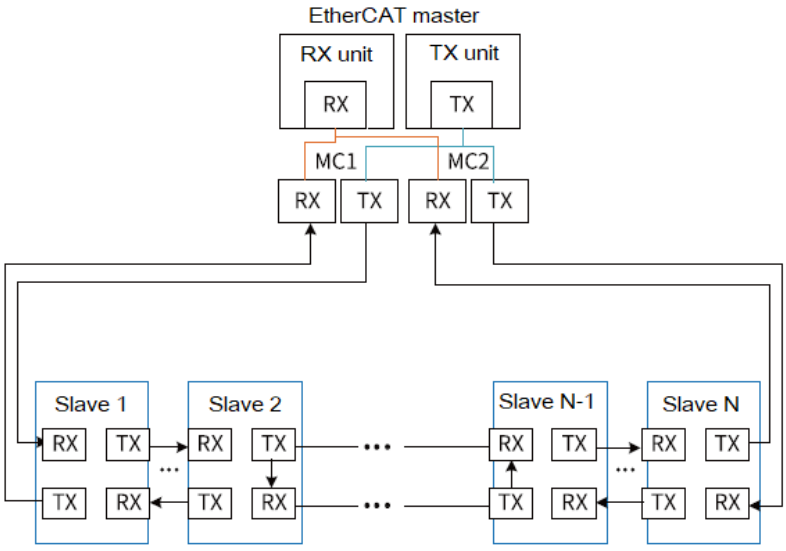
- Enable alias
  Used to manage alias settings for slaves. When selected, the "Alias address" in all slave configurations will be enabled; for details, see 10.6.3.2.6 Overview.
- Check configuration
  Configuration checking typically refers to using an EtherCAT slave configuration tool to check or set various slave parameters. This tool provides various functions, such as reading and modifying slave parameters, displaying slave information, commissioning slave status, and so on.

  The current configuration parameters of the slave can be viewed using the configuration check command, such as the IP address, port number, device name, and so on. By checking the configuration,



you can ensure that the configuration of the slave devices is correct, thus ensuring the normal operation of EtherCAT communication.

- Wireless environment
  After selecting this option, you can discover and add wireless management terminals through scanning; if not selected, wireless management terminals cannot be scanned.

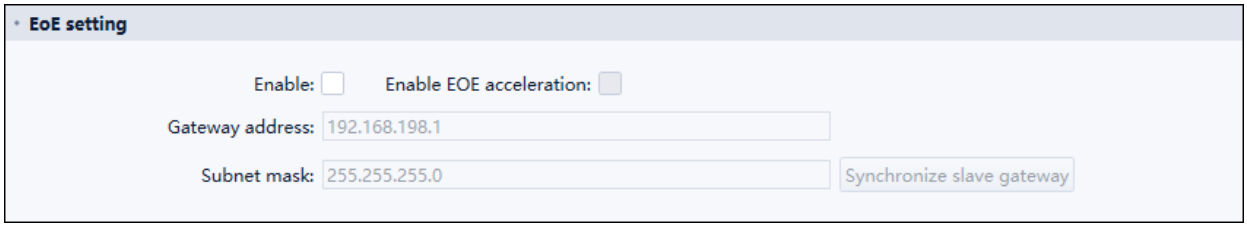


EtherCAT NIC setting

The EVO760 series supports EtherCAT network redundancy function.

After adding an EtherCAT master, double-click it to enter the configuration page. Check the "Network redundancy" option to enable the redundancy function.

In a ring topology, if redundancy is required, enable this option. After enabling, if a single-point fault occurs in the network connection, the EtherCAT network function can still operate normally.



Configuration Item	Description
Destination address (MAC)	The MAC address of the EtherCAT network member receiving the message. If the "Broadcast" option is checked, the broadcast address (FFFFFFFFFFFF) is used.

Configuration Item	Description
Source address (MAC)	The MAC address of the PLC. Select the MAC address of the currently available target device through the "Browse..." button. Each EtherCAT NIC has a unique MAC address. If "Select network by MAC" is checked, this project cannot be used on other devices.
Network name	Network card name. To make the project independent of the device, it is recommended to check "Select network by name".

Redundant EtherCAT NIC setting

If the "Network redundancy" option is enabled, the "Redundant EtherCAT NIC settings" will be displayed. Users can define the relevant settings.

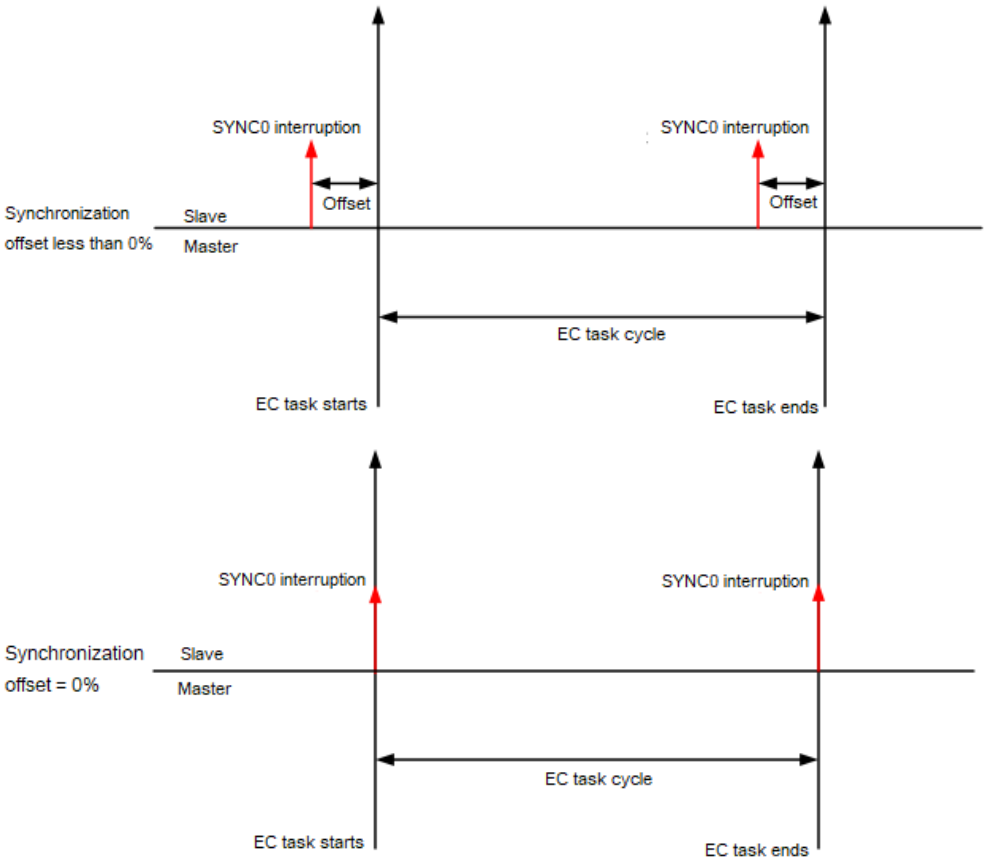
EOE setting

Ethernet over EtherCAT (EoE) allows any Ethernet device to be connected to EtherCAT via a conversion terminal without affecting the real-time performance of EtherCAT. Similar to well-known Internet protocols, such as TCP/IP, VPN, PPPoE (DSL), Ethernet frames are transmitted via the EtherCAT protocol. This setting allows standard network devices to be connected to terminal devices, such as printers or PCs, via a switch.

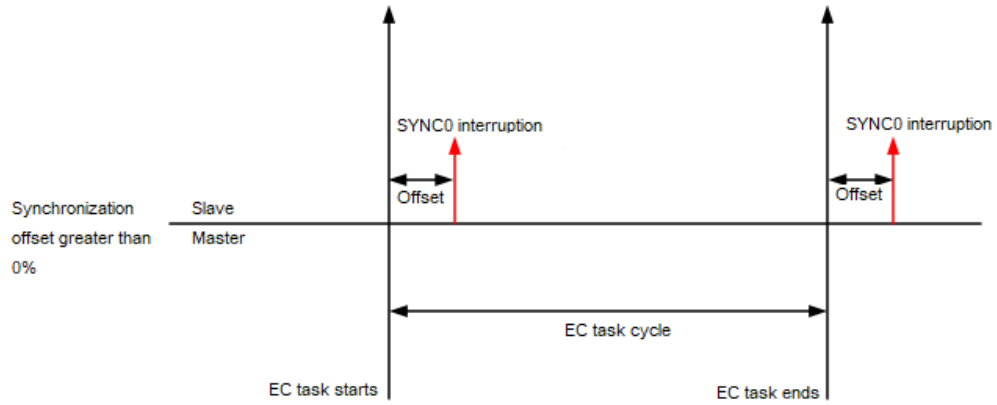
- Enable: Default is disabled. Check "Enable" to modify the gateway address and subnet mask address for EoE.
- Enable EOE acceleration: Default is disabled. Enable it to improve the transmission rate of EOE.

> CAUTION
>
> Enabling this function will consume network resources and increase the system's overall load. If there is no special need, keep it disabled by default.

- Synchronize slave gateway: Click to synchronize the gateway configuration to the slaves.



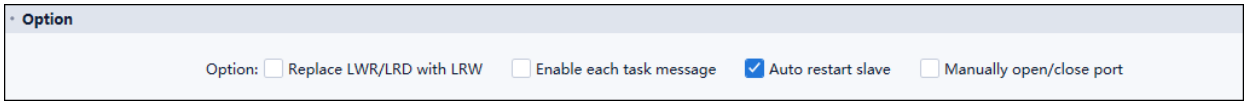
Distributed clock



Distributed clock (DC) enables all EtherCAT devices to share the same EtherCAT system time, thus synchronizing task operations across devices. EtherCAT data exchange is based on a pure hardware mechanism. The master can calculate and measure time offset and transmission delay based on the time difference between the sent data frame and the received data frame, while compensating for the drift of the local clock.

- Sync window monitoring:
- Cycle time
  Indicates the cycle time for executing EtherCAT master functions. It must be the same as the cycle time of the IEC task bound to the EtherCAT master. If the distributed clock function of the slave is enabled, the "Cycle time" will synchronize with the "Distributed clock" value set in the slave device editor.
- Synchronization offset
  Indicates the cycle time offset ratio of the EtherCAT master's IEC task (PLC task) relative to the reference distributed clock (normally the SYNC0 synchronization interrupt). This parameter ranges from -50% to +50%, with a default value of 30%.

  Synchronization offset (%) = (SYNC0 interrupt time - PLC task cycle start time) / PLC task cycle time.



CAUTION

- By default, the PLC task cycle time is equal to the cycle time of the distributed clock of the slave.
- In actual configuration, the following factors must be considered: master clock jitter of the controller (system real-time performance), PLC task execution time, PLC task cycle time, and number of slaves.

- Synchronization window
  Indicates the time monitored by the synchronization window. If all slave synchronization information falls within this time window, the variable xSyncInWindow (IoDrvEtherCAT) is set to TRUE; otherwise, it is set to FALSE.

Options

- Replace LWR/LRD with LRW
  Disabled by default. Check it to enable the slave-slave communication. The logical addressing of the EtherCAT master will use logical memory read/write (LRW) command instead of logical memory read (LRD) and logical memory write (LWR) commands. Enabling LRW mode can save network bandwidth and optimize network load.
- Enable each task message

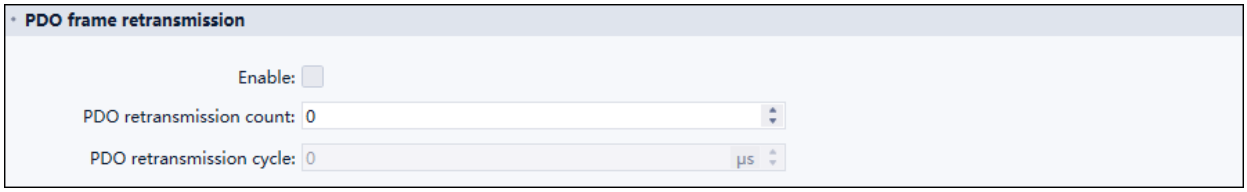
  CAUTION

  Enabling it will increase system load, so it is only intended for problem diagnosis and troubleshooting.

  Disabled by default. This option is used to enable or disable each task message. By default, each task message is disabled to avoid unnecessary interference with the system. If a fault or error occurs during operation, this option can be enabled for troubleshooting.
- Auto restart slave
  Enabled by default. After checking it, when a slave encounters disconnection, communication faults, or other faults, the system will automatically restart the slave to restore communication and system operation. This only applies to scenarios when all slaves encounter disconnection or communication

faults. After restart, if there are servo axes, the axis status will still report communication faults, and the MC_Reset instruction must be used to reinitialize them.

- Manual port control

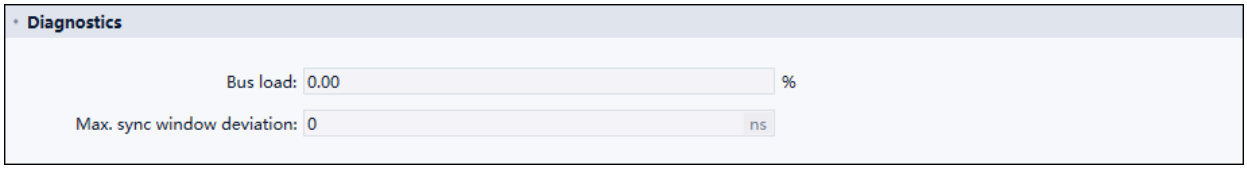


> CAUTION
>
> Enabling it will affect communication, so it is only intended for problem diagnosis and troubleshooting.

An EtherCAT slave supports up to four ports, which will automatically open or close based on whether a connection exists. If a connection exists, the port opens; otherwise, it closes. If the port is open, data frames entering the port are sent to other slaves and return to the port after being processed by other slaves. If the port is closed, data frames flow directly to the next port of the slave.
This option is disabled by default. After enabling, the port can be manually opened or closed, with the main scenarios as follows:

  - Fault diagnosis and troubleshooting: When a network fault occurs, you can manually open or close ports for fault diagnosis and troubleshooting. For example, when a port fails, you can manually close it to determine if it affects the entire network.
  - Security control: By manually opening or closing ports, you can enhance network security. For example, when a port is not needed, you can manually close it to reduce potential security risks.

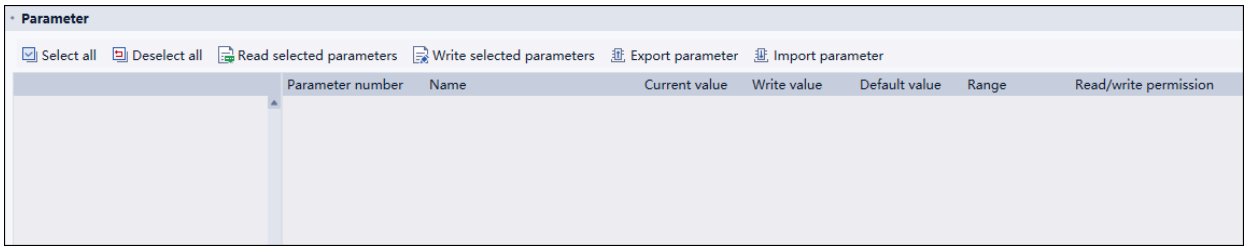
PDO frame retransmission



Disabled by default. Enabling it to re-transmit PDO frames. This feature is mainly used in high-reliability scenarios, but it increases CPU and bus load, so it is disabled by default.

- Enable: This option is automatically checked when the "PDO retransmission count" is set to a value greater than 0, with no need for manual configuration.
- PDO retransmission count: Sets the number of times a PDO frame is retransmitted.
- PDO retransmission cycle: Sets the cycle time for retransmitting PDO frames. Configuration is not supported.

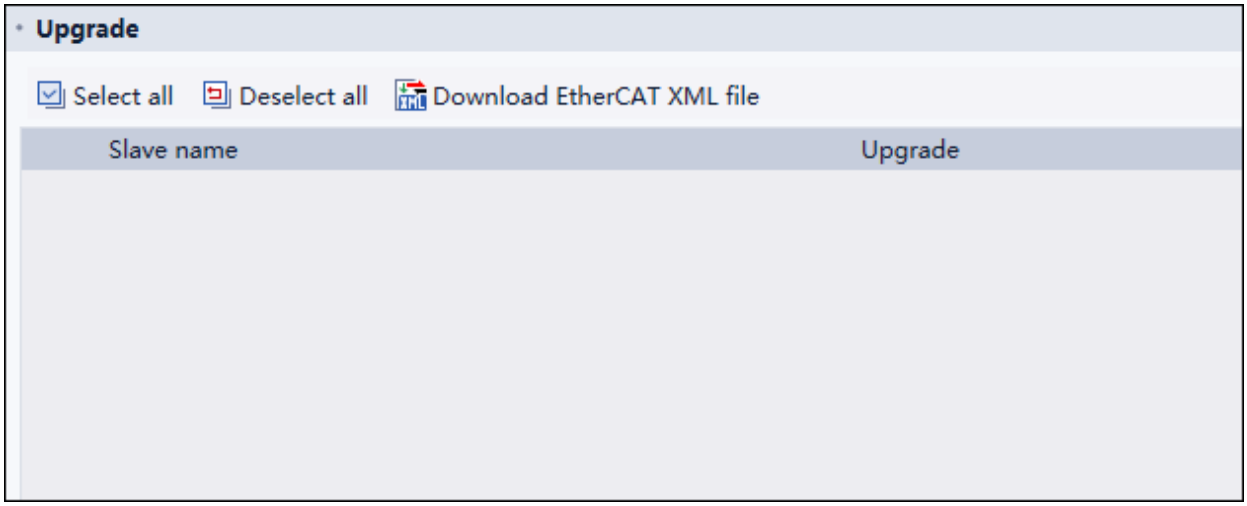
Diagnostics



Visible only in online mode.

- Bus load: The bandwidth utilization of data transmission in the EtherCAT network.
- Max. sync window deviation: The maximum deviation (in ns) between the slave system clock and the reference clock.

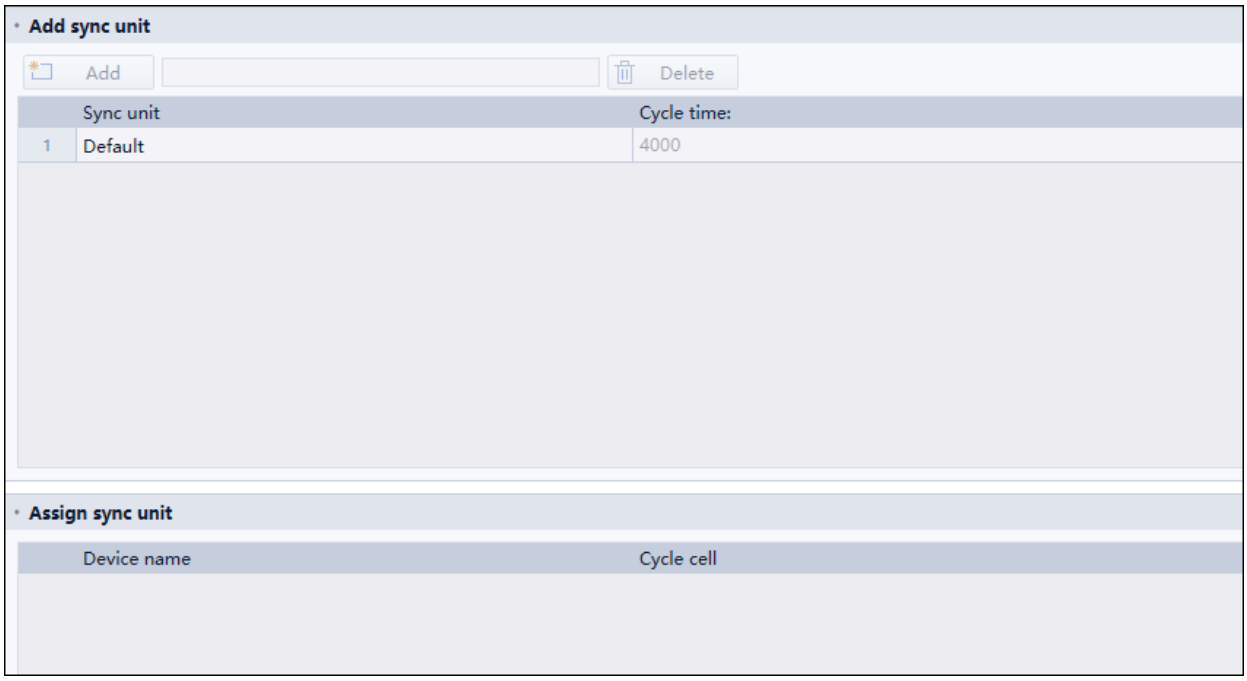
10.6.3.2.2 Parameters



Function codes refer to the manufacturer parameters defined for Inovance servo products. In the master configuration, the manufacturer parameters of multiple product can be read and written in batches, imported, and exported, facilitating commissioning and maintenance.

- Select all: Selects all slaves and axes, as well as the servo function codes under the axes.
- Deselect all: Cancels all selected items.
- Read selected parameters: In the servo operation status, reads the servo function codes with RO, RW, or R properties.
- Write selected parameters: In the servo operation status, writes the servo function codes with W or RW properties.
- Export function code: Exports the servo function codes of all slaves in an Excel file.
- Import parameters: Imports the parameters of all slaves from an external Excel file. If the configuration does not match the file, a fault will be reported.

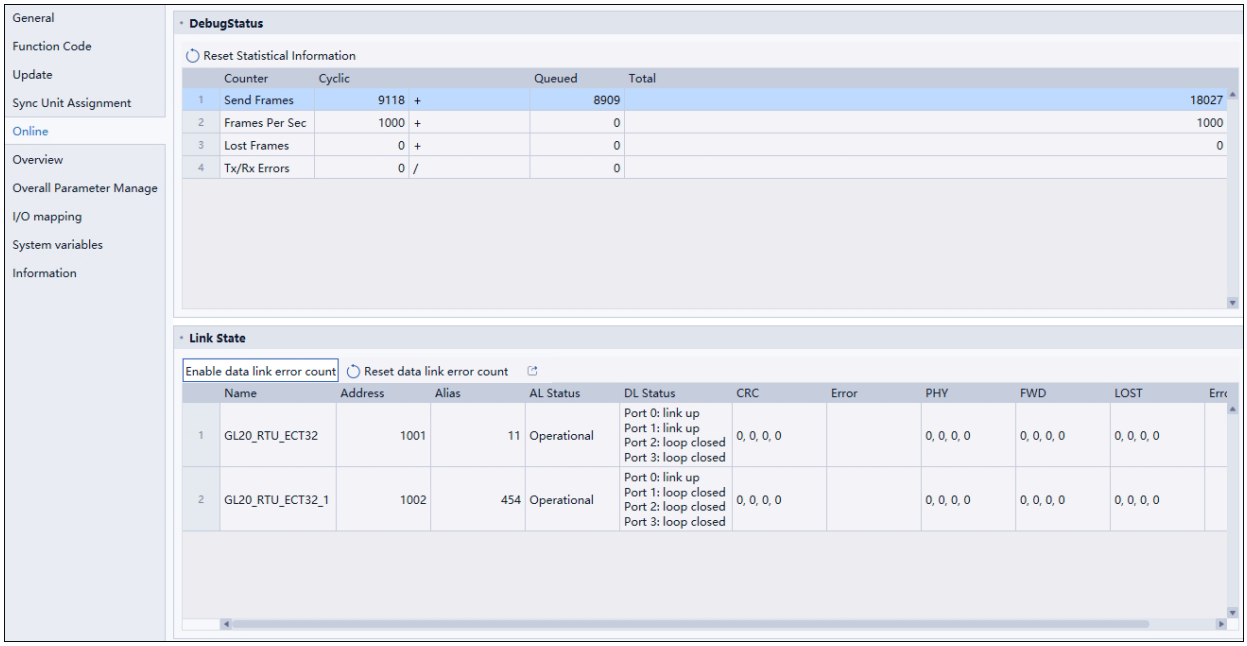
Note: The commissioning function of the master does not support SV660 series and SV680 series products. For details, see the commissioning function in 17.2.2 Parameter List of the drive settings. The drive devices of other series can perform function code debugging after binding the servo axes.



10.6.3.2.3 Upgrade

- Select all: Selects all slave devices.
- Deselect all: Deselects all selected slave devices.
- Download EtherCAT XML file: Downloads the EtherCAT slave XML file from the iFA fully integrated platform to the E2PROM of the slave device. Batch download can be achieved by checking multiple slave devices.

10.6.3.2.4 Unit Synchronization Assignment

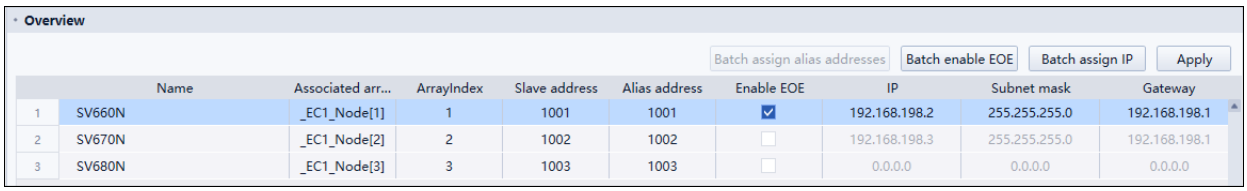


Unit synchronization allocation is mainly used for setting servos to different synchronization units in batches and categorizing them. After allocation, the synchronization unit cycle of the corresponding servos will be adjusted accordingly.

- Add synchronization unit: Enter the name of a synchronization unit and set the cycle time to add it. The cycle time is an integer multiple of the synchronization unit cycle.
- Allocate synchronization unit: Set the cycle of the added synchronization unit through a drop-down box. After setting, this parameter will be synchronized to the DC synchronization unit cycle of the allocated devices.

10.6.3.2.5 Online

After the device switches to online operation, this interface will display the operation status and statistics to better monitor the device's operation.



- Debug status
  Includes "Send frames (total number of frames sent)", "Frames per sec (frames sent per second)", "Lost frames (total number of lost frames)", and "Tx/Rx errors".
  Click "Reset statistics" to clear all current cumulative counts.
- Link status
  - Enable data link error count: After enabling this option, invalid frame count, receive error count, transfer error count, and lost link count are displayed in the "Link status" list.
  - Reset data link error count: After enabling this option, all accumulated error statistics in the "Link status" list are cleared and the counting restarts.
  - Export: Click to save the current link status information in CSV format to the backend.

10.6.3.2.6 Overview

The overview interface displays the address information of all slave devices, supports EoE parameter settings, and allows users to directly complete EoE commissioning.

> NOTE
>
> Before configuring EoE parameters, enable EoE settings in the "General" interface. Once enabled, "IP", "Subnet mask", and "Gateway" become editable.

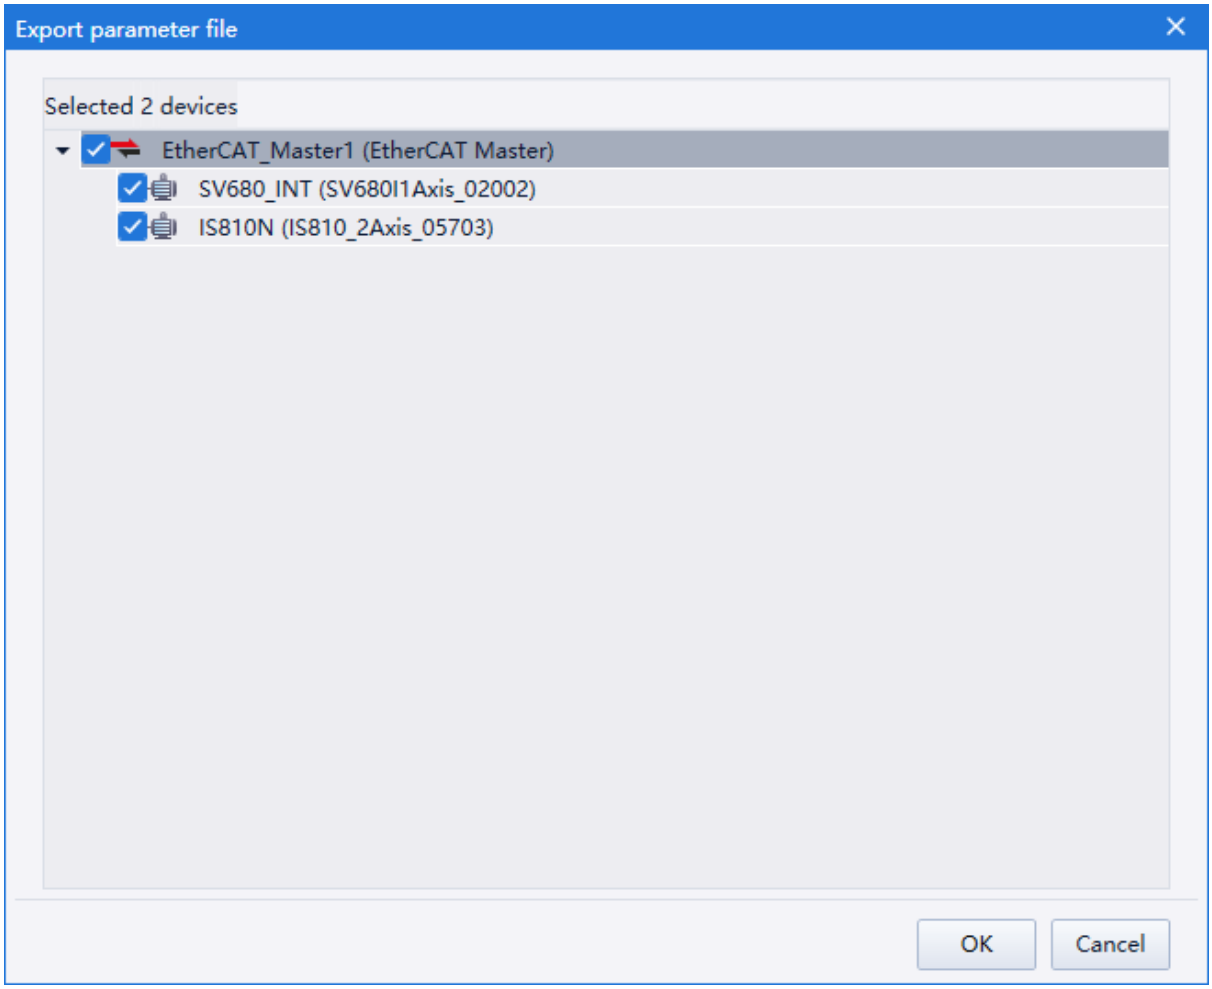
Parameter	Description
Name	Displays the names of all slaves under the master, which cannot be modified.

Parameter	Description
Associated array	Also known as the slave array. Used to centrally manage all EtherCAT slave devices in the bus network. Each EtherCAT master corresponds to a slave array, which stores the corresponding EtherCAT slave system variable information.
Data index	The index of the associated array (typically the slave number). Supports manual editing by the user.
Slave address	Displays the address information of the slave station, which cannot be modified.
Alias address	• When the "Enable alias" option in the "General" tab is not checked, the alias address cannot be modified. • When the "Enable alias" option is checked, batch modification of aliases is supported, and the device aliases must be unique (no duplicates allowed). After the alias settings are completed, they are automatically synchronized to the alias configuration parameters of the sub devices.
Enable EOE	When EoE is enabled, if any of the "IP", "Subnet mask", or "Gateway" is empty, they will be automatically assigned based on EoE setting in the "General" interface.
IP	IP address: Supports user input or modification.
Subnet mask	Subnet mask address: Supports user input or modification.
Gateway	Gateway address: Supports user input or modification.

- Batch assign alias addresses: Automatically sets alias addresses from 1 to 30000 according to the configuration order.
- Batch enable EoE: Enables all devices supporting EoE, with gateway not assigned by default.
- Batch assign IP: Assigns gateways to all EoE-enabled devices based on the EoE setting.
- Apply: Saves all modified settings.

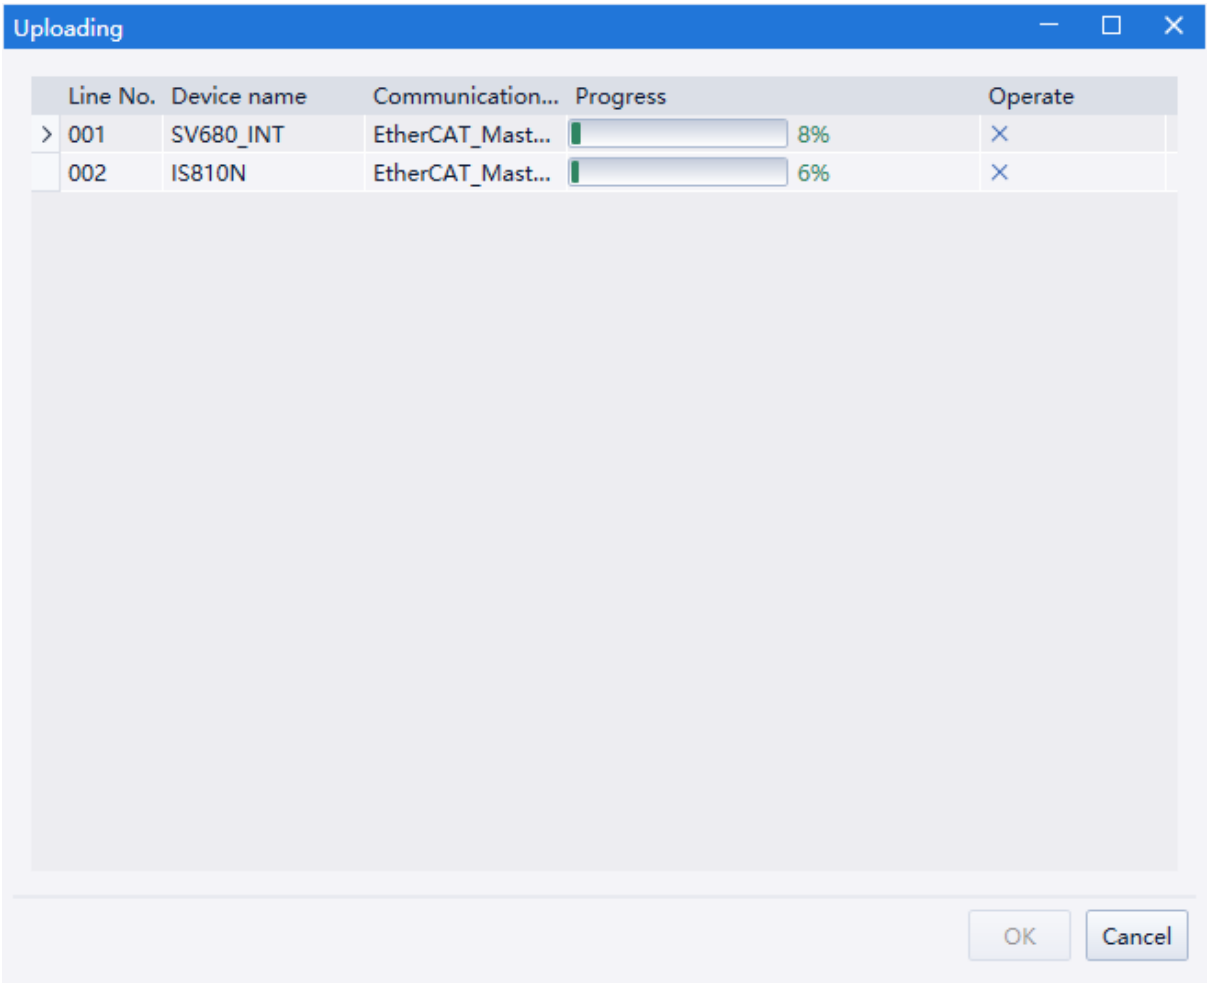
When devices are online, the above buttons will not be displayed.

10.6.3.2.7 Machine Parameter Management



10.6.3.2.7.1 Machine Recipe Management

Machine recipe import

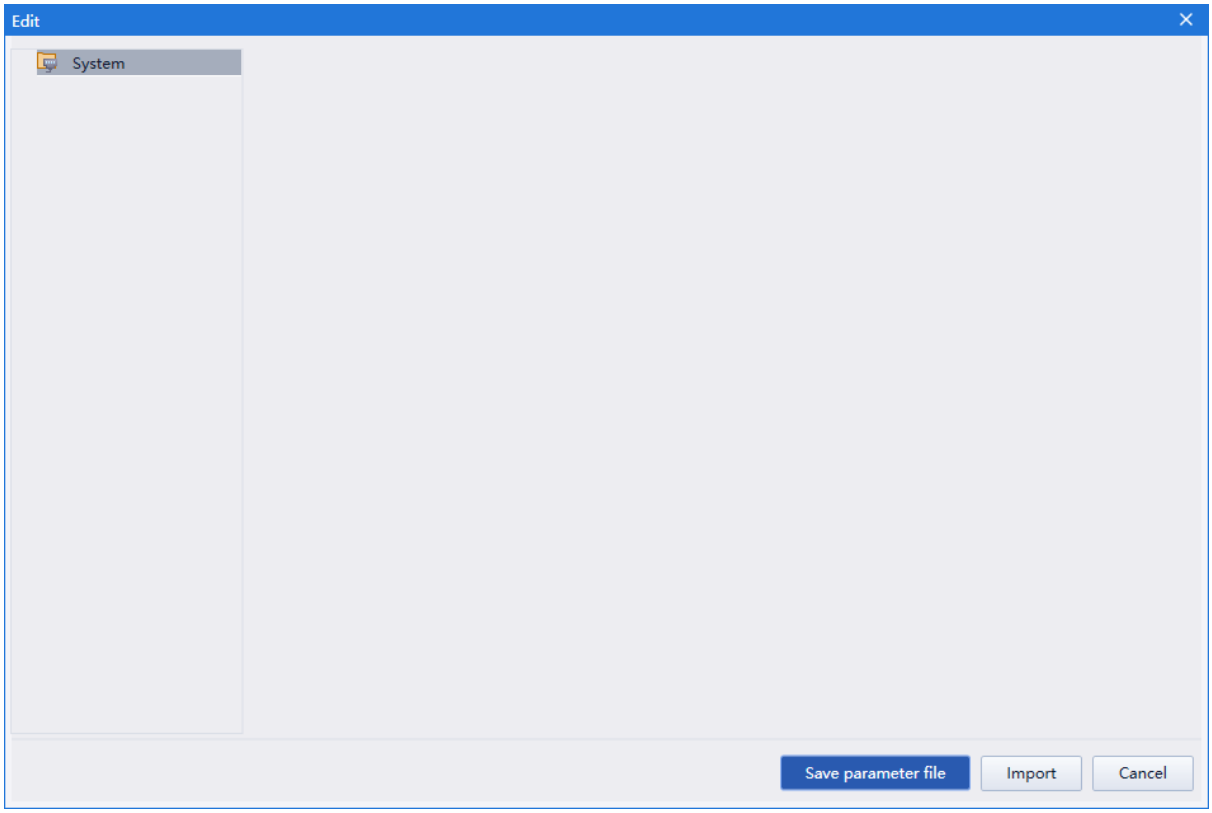


Click "Import", select a file with the .inoDat extension, and select the recipe to be imported into the software.

Machine recipe export

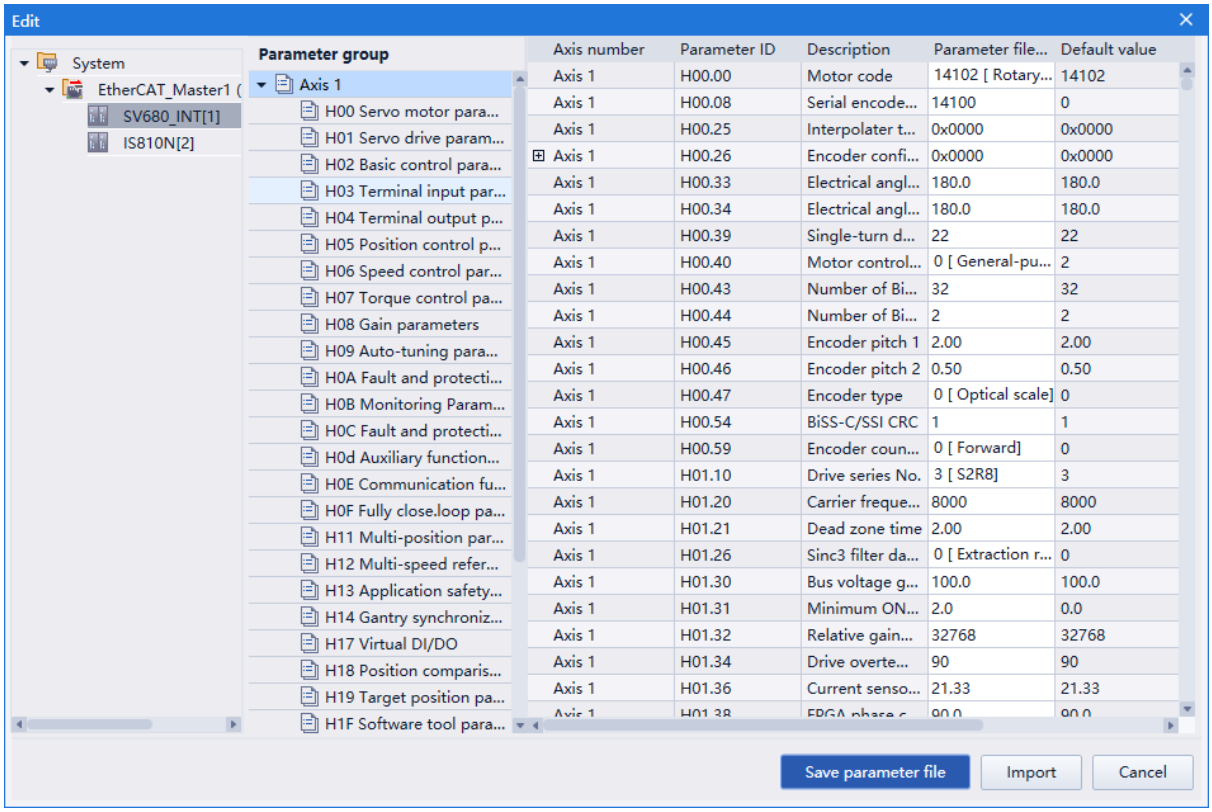
1. Click "Export" and the "Export recipe" window pops up.

2. Select the device to export the recipe, and click "OK" to start exporting.



3. After all export progress bars are complete, select the storage location for the recipe.

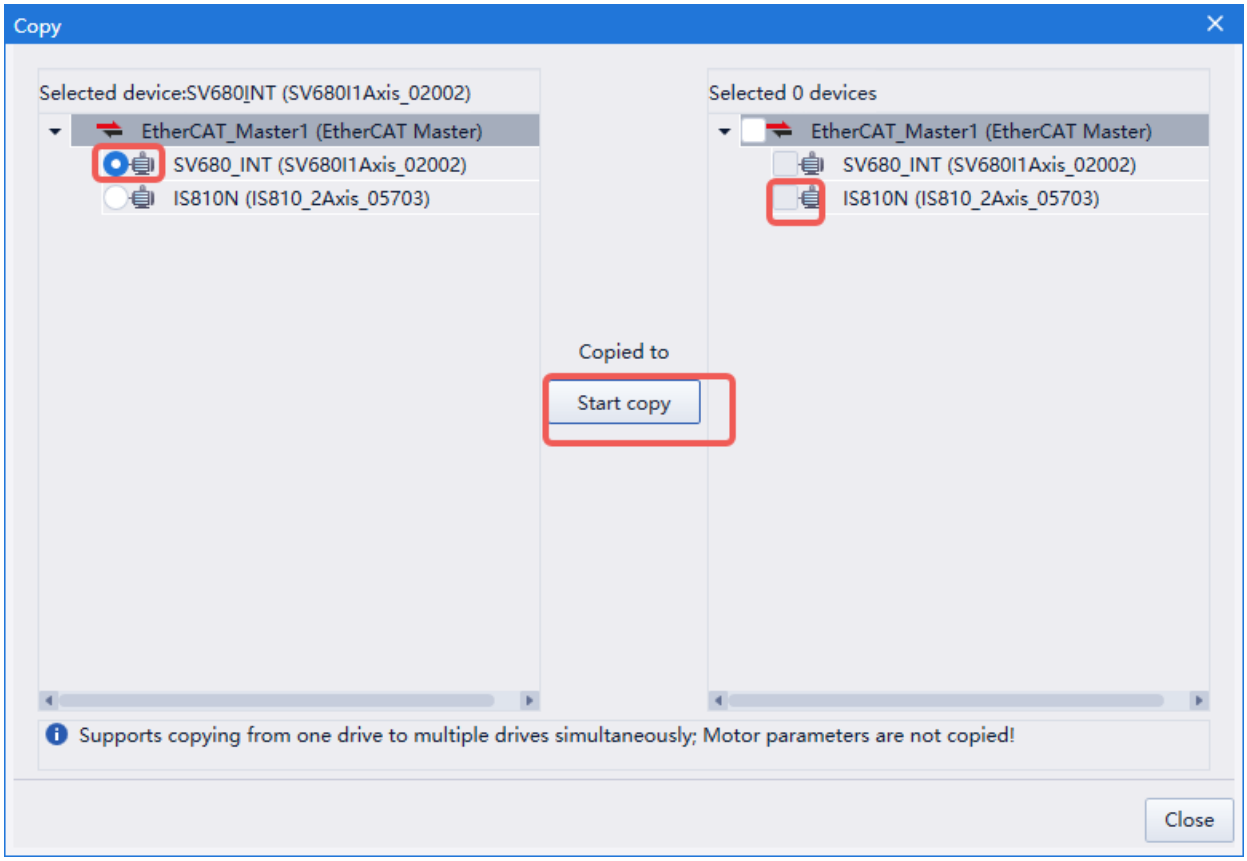
Offline recipe modification



This function is used to modify the *.inoDat type recipe files that have been saved locally.

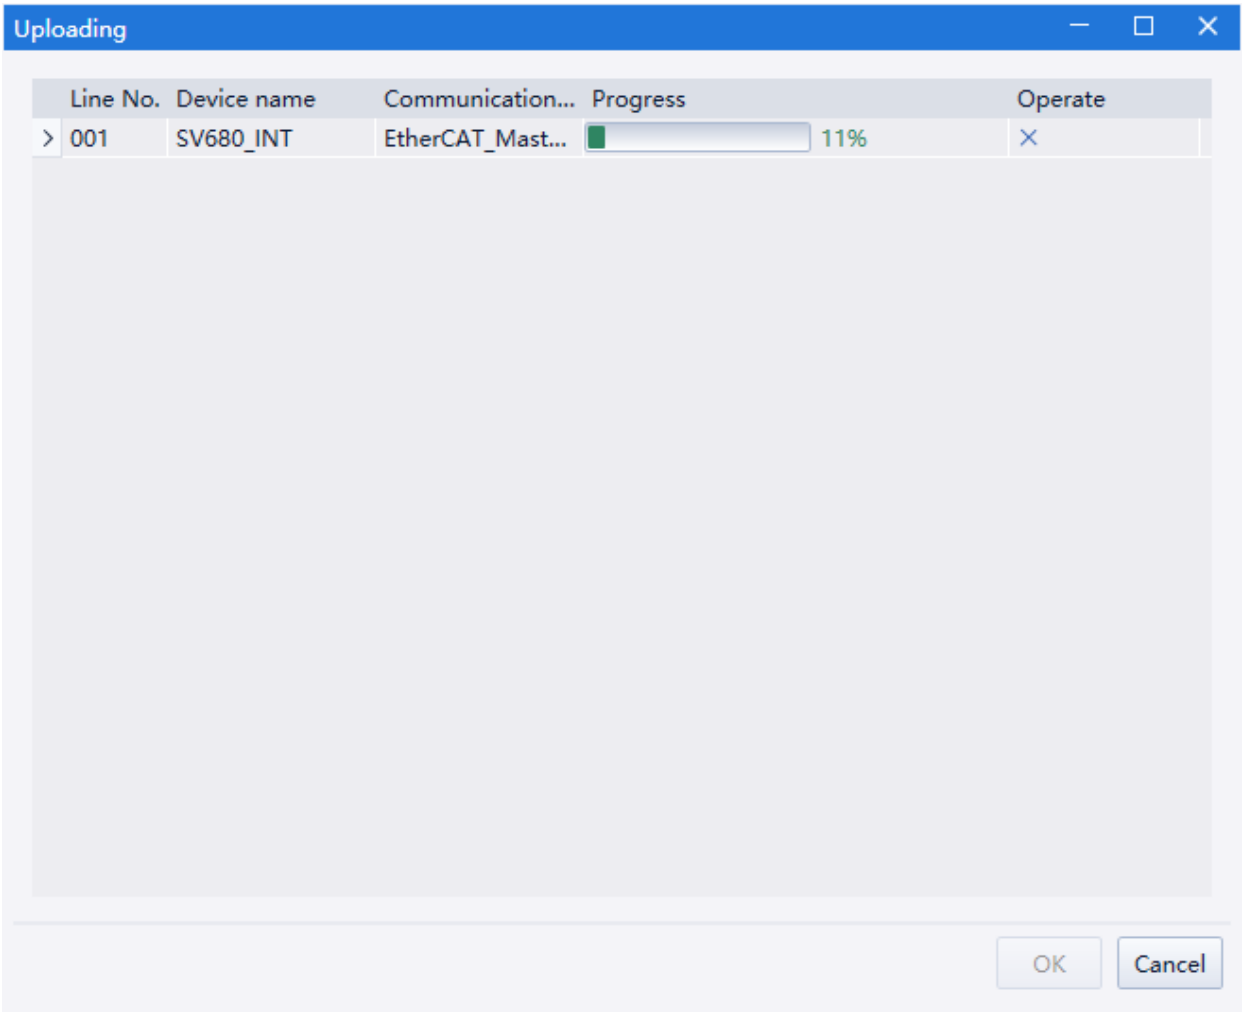
1. Double-click "EtherCAT_Master (EtherCAT_Master)", select the "Machine parameter management" interface, and click "Offline recipe modification".

2. Click "Import" to import the local recipe, as shown in the figure below.



3. After opening the recipe, double-click the corresponding device on the left in the pop-up "Edit recipe" window to open and edit the recipe for the corresponding device.

10.6.3.2.7.2 Machine Parameter Management

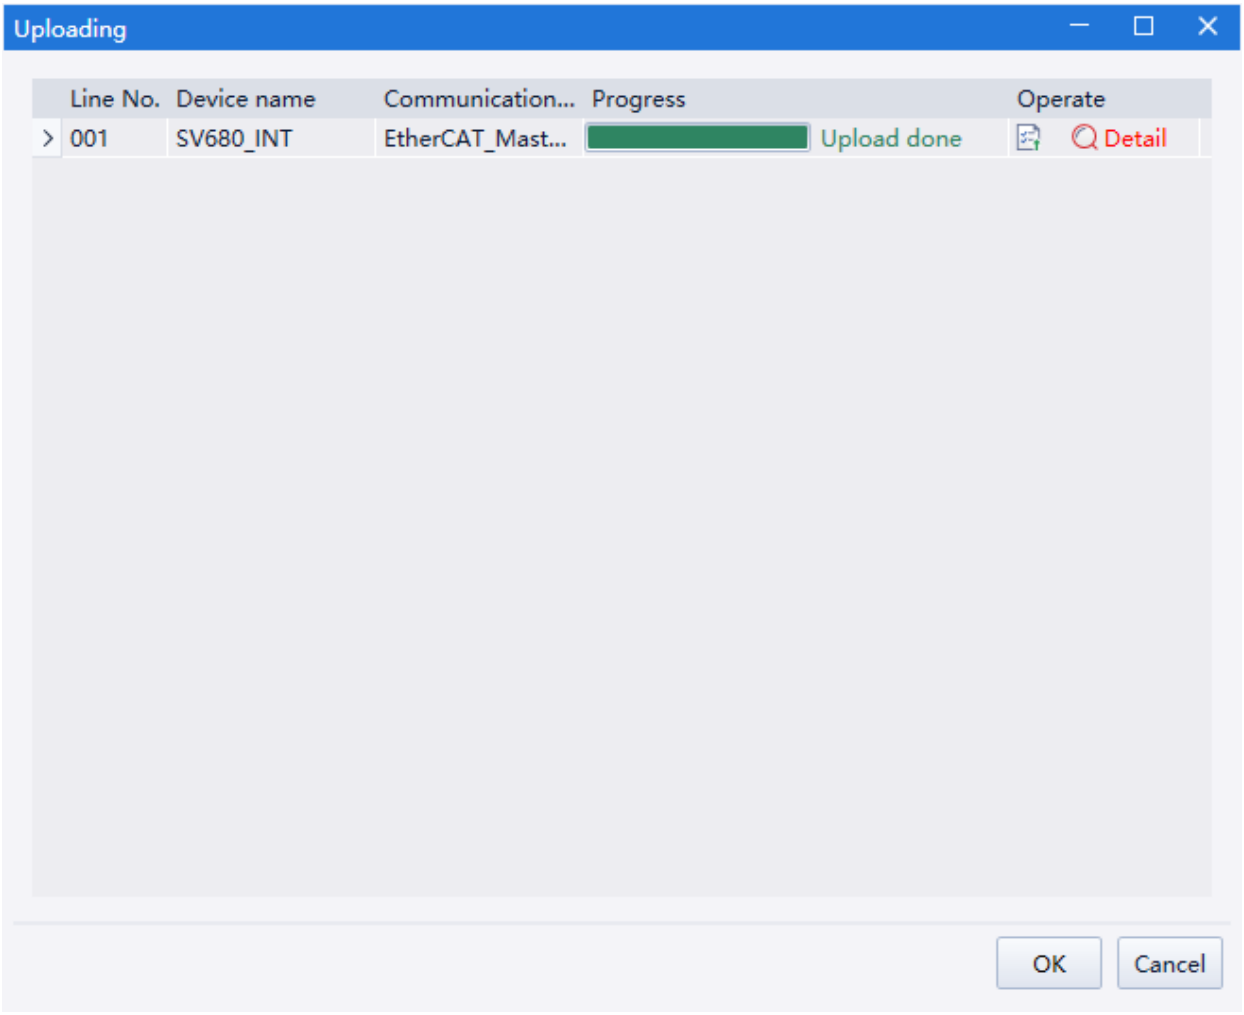


Online parameter copy

This function can copy parameters from one device (excluding motor parameters and non-modifiable parameters) to multiple devices of the same series type simultaneously. As shown in the figure below, the left side is the source device, and the right side is the target device. Click "Start copy" to copy the parameters from the source device to target device.

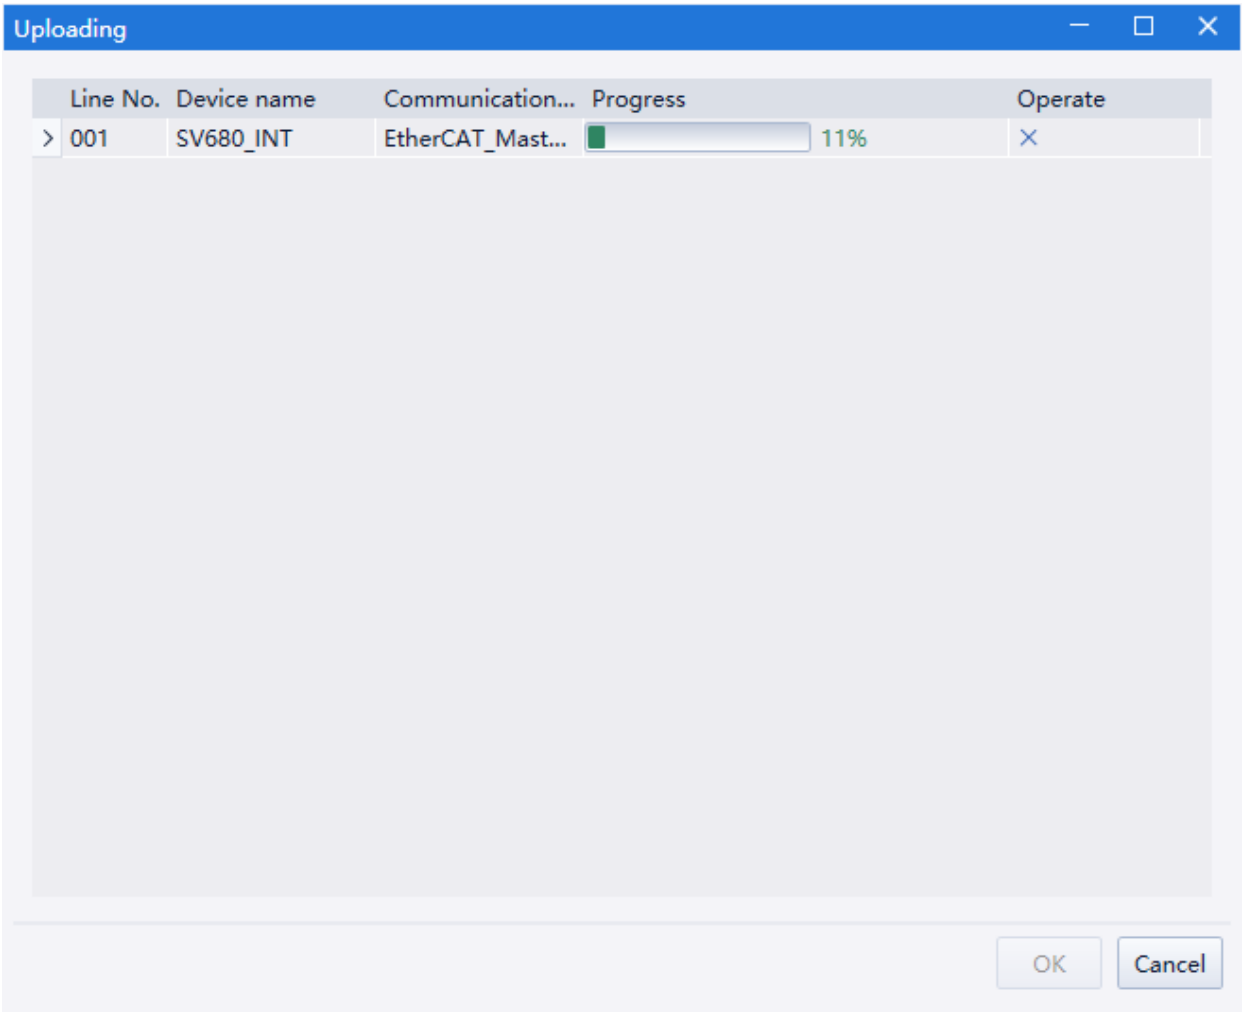
The copy process is divided into two steps, namely the upload of source device parameters and the copy of target device parameters, as shown in the figure below.

- **Source device parameter upload**

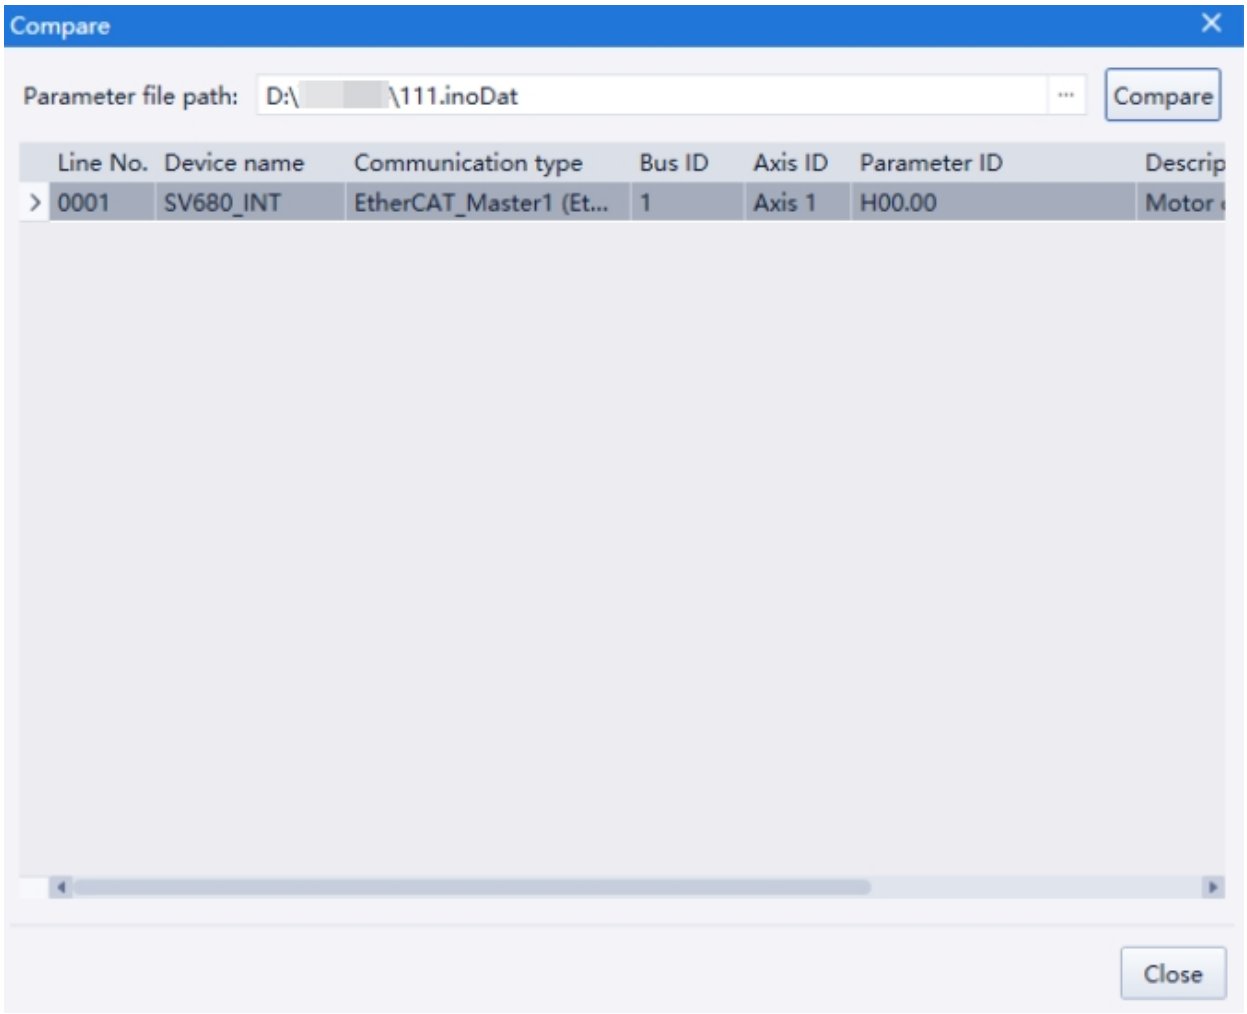


NOTE

Source device parameter upload failures will be indicated in the right "Operation" column. Click to view detailed information.



- **Target parameter copy**



This step copies the parameters uploaded to the source device to the target device.

Online machine comparison

By loading saved recipes, this function compares the data saved in the recipe with the current values of the device, displaying functional codes with differences to help users determine whether to import the recipe into the drive.

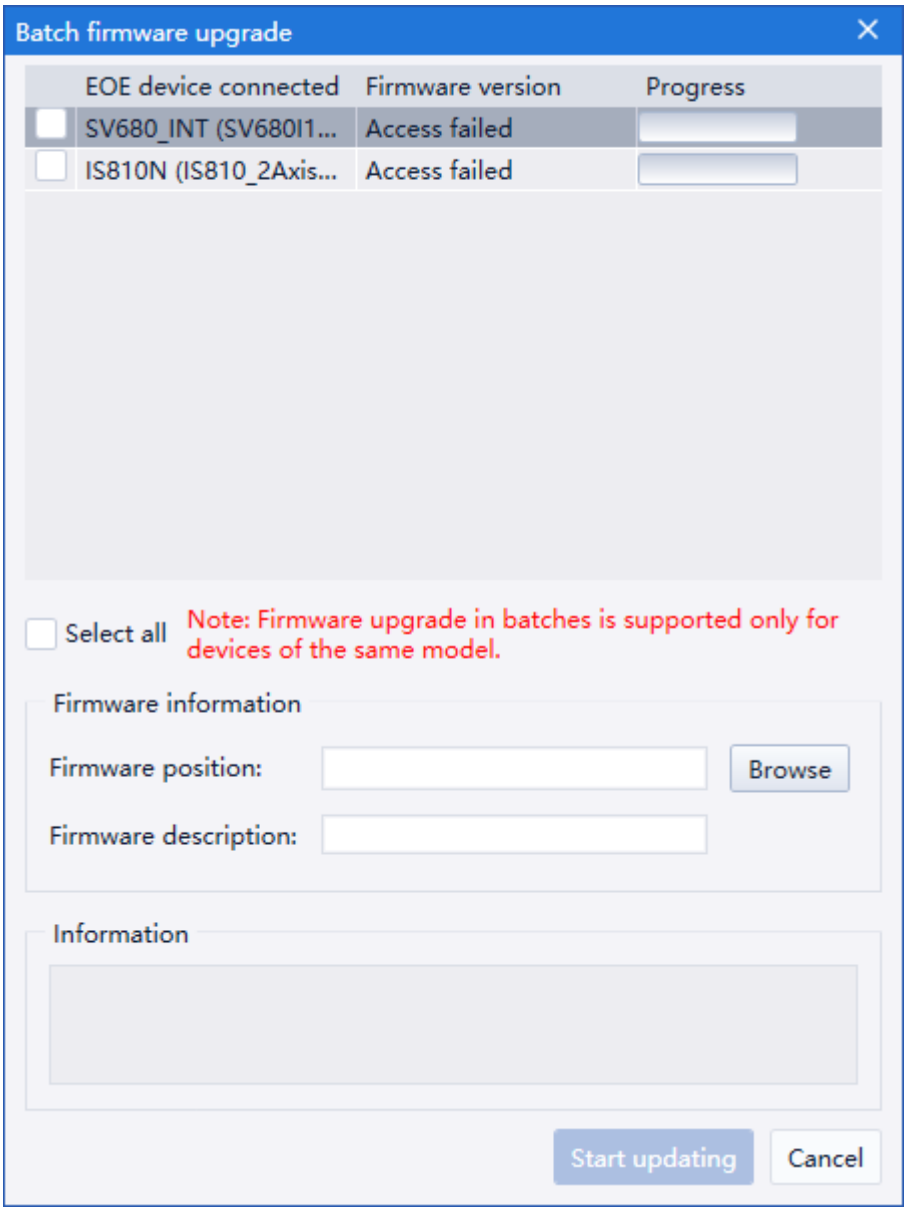
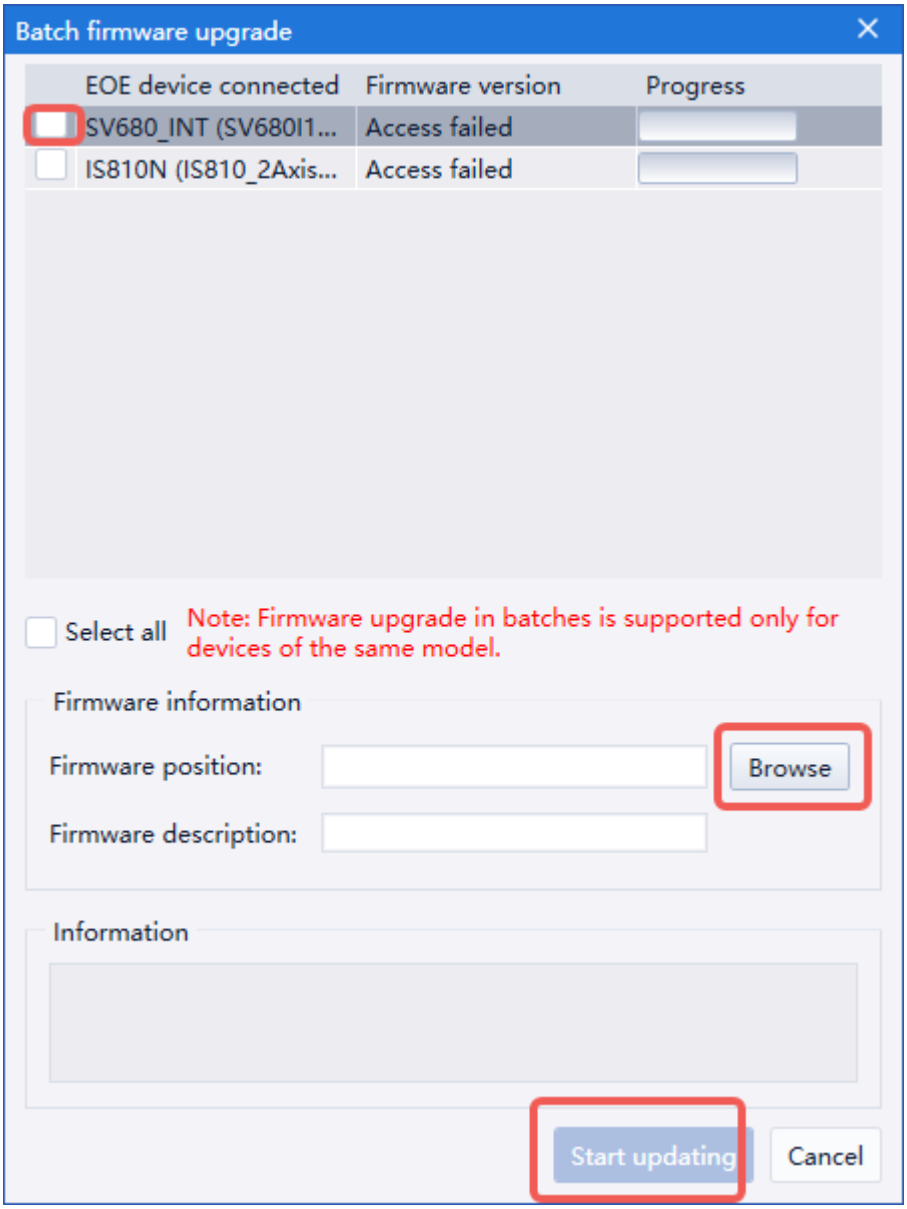
10.6.3.2.7.3 Batch Firmware Upgrade



Function description

This function can be used to perform batch firmware burning for multiple devices of the same model.

It is currently not supported by MD800 and MD810 series models.

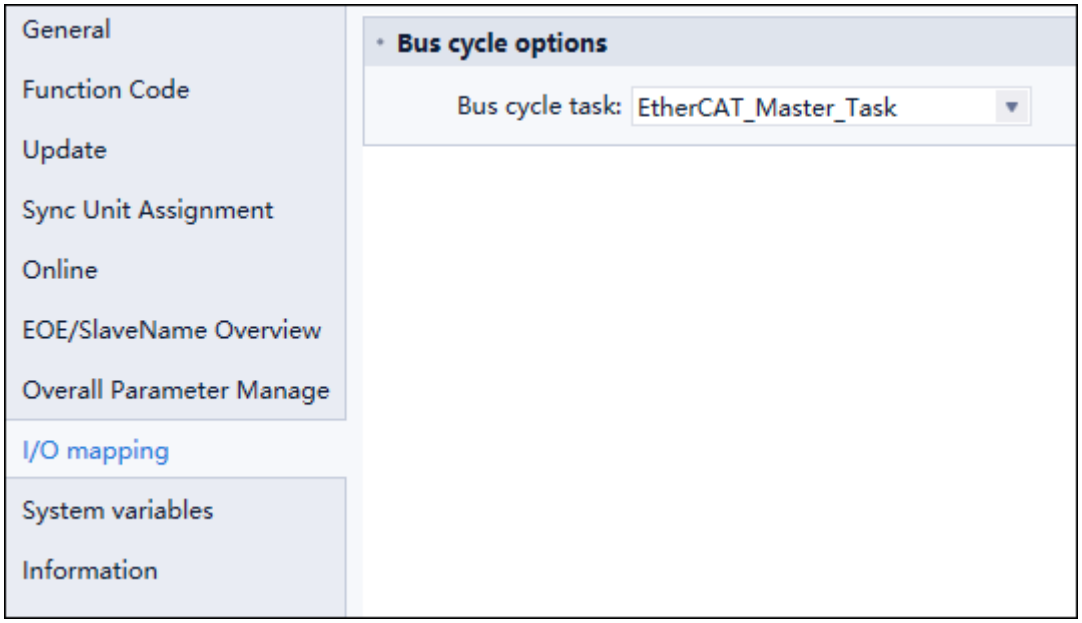


Procedure

1. Double-click "EtherCAT_Master (EtherCAT_Master)", select the "Machine parameter management" interface, and click "Batch firmware burning".
2. The system will automatically read the current firmware versions of each device.

3. Click "Browse" to add the appropriate firmware bin file, check the relevant devices, and click "Start update". The system will automatically read the firmware description information.

> NOTE
>
> Only devices of the same model can be upgraded in batch.



4. After the burn is complete, a success message box will pop up.

NOTE

- After the burn starts, the FA servo integration will automatically disconnect the device.
- After a successful burn, the device needs to be powered on again to connect devices for use.
- If the burn fails, try again. If it fails twice consecutively, contact Inovance technical support.

10.6.3.2.8 I/O Mapping

After adding the corresponding devices under EtherCAT, the I/O mapping is set to a fixed value and cannot be modified.

- Bus cycle task: The system executes bus tasks at a fixed cycle, and the bus cycle task supports modification. The default is EtherCAT_Master Task, and the refresh cycle of I/O mapping for different tasks varies.

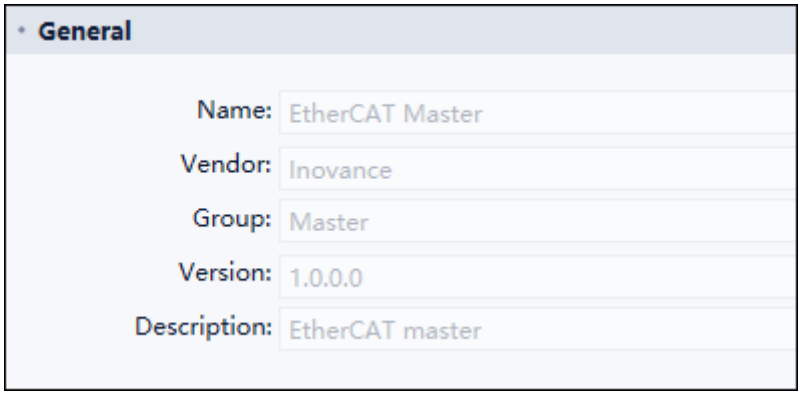
10.6.3.2.9 System Variables

In the "System variable" tab of the EtherCAT master, an instance (variable) of type ETC_Master is specified for EtherCAT I/O, supporting control of devices connected to the EtherCAT master via user programs, and displaying the device ID value of this master.

System variable

Variable	Type	Value
EtherCAT_Master1	ETC_Master	
_EC1_Node	ARRAY[1..127] OF ETC_Slave	
_ID_EtherCAT_Master1	DWORD	1376257

The following table describes the members of the ETC_Master type structure.

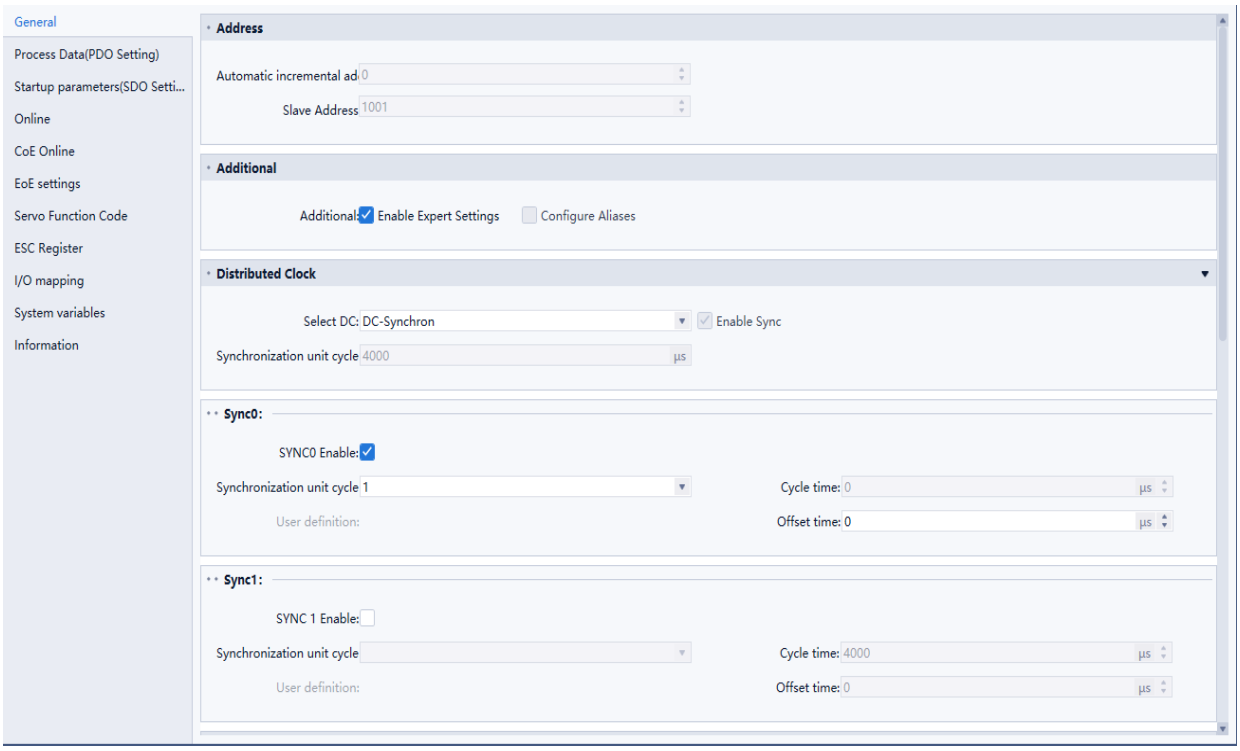


Variable	Data Type	Description
SyncFinished	BOOL	Master synchronization status, indicating whether ECAT master synchronization is completed.
LostFrameCount	UDINT	Number of lost frames.

NOTE

When master synchronization is completed, the variable EtherCAT_Master.SyncFinished is set to TRUE, indicating that the ECAT master has started successfully. This can be used as a condition for executing subsequent ECAT communication-dependent programs.

10.6.3.2.10 Information



This interface displays basic information about the master, including name, vendor, group, version, and description.

10.6.3.3 Configuring Slave Parameters

10.6.3.3.1 General Settings

Double-click a slave node (servo device) to open the slave configuration window. The "General" interface of the EtherCAT slave provides basic configuration information for the slave, as shown in the figure below.

Address

If the "Auto-configure master/slave" option in the master device editor is not checked, the following options can be configured:

- Automatic incremental address: The automatic incremental address (16-bit) is determined by the physical topology position of the slave in the network. This address is only used when the EtherCAT master starts up. It assigns EtherCAT slave addresses to slaves at corresponding physical topology positions through sequential addressing.

During sequential addressing, the auto-increment address of the slave is determined by its connection position in the physical topology network, represented by a negative number. Sequential addressing sends data frames containing sub-messages. As each data frame passes through a slave device, the auto-increment address in the sub-message automatically increments by 1. When a physical slave receives the data frame, it addresses its own message by checking whether the auto-increment address in the sub-message is 0. This mechanism of updating internal address variables in the slave through data frames is called "sequential addressing" or "auto-increment addressing".

- Slave address: The configuration address (nominal address) of the slave, assigned by the master during startup. This address is independent of the actual position in the network, and the address of the slave is unrelated to its connection order within the segment. After disabling a slave device in hardware configuration, the address of the slave device is set to 0, and it is reassigned according to the current specifications when the slave is re-enabled.

Additional settings

- Enable expert settings: If this option is checked, you can configure distributed clocks, startup checks, timeouts, DC cycle unit control, watchdogs, and other functions.
- Configure aliases: This reflects the status of the "Enable alias" option in the general settings of the EtherCAT master, and cannot be modified here.

Distributed clock

- Enable sync: If this option is checked, it indicates that the "Distributed clock" function is used.
- Synchronization unit cycle (μs): If the "Distributed clock" function is enabled, the synchronization unit cycle value will default to the same as the EtherCAT master's cycle time.
- Select DC: This drop-down menu provides all settings related to distributed clocks in the device description file, generally including free operation, SM event synchronization, DC synchronization, and so on. The setting items are described in the table below:

ID	Item	Description
1	Free operation mode	In this mode, the local control cycle is generated by a local timer interrupt. The cycle time can be set by the master. This is an optional function for the slave.
2	SM event synchronization	A local cycle is triggered when a data input or output event occurs. The master can write the transmission cycle of the process data frame to the slave. The slave can then check whether the cycle time is supported or perform local optimization of the cycle time. The slave can choose to support this function. Synchronization typically occurs with the data output event. If a slave has only input data, synchronization occurs with the data input event.
3	DC synchronization	A local cycle is triggered by the SYNC event. The master must complete the transmission of the data frame before the SYNC event. Therefore, the master clock must also be synchronized to the reference clock.

ID	Item	Description
4	Sync0 and Sync1	Slave synchronization signals 0 and 1. The distributed clock control unit of the slave (an internal function of the EtherCAT-specific communication chip) can generate two synchronization signals, Sync0 and Sync1. These signals provide interrupt flags to the application layer of the slave or directly trigger the update of output data.
5	Sync0 enablement and Sync1 enablement	Check these options to enable the Sync0 and Sync1 synchronization signals. • Synchronization unit cycle: If this option is checked, slave synchronization cycle time = master cycle time × selected coefficient. • The "Cycle time (μs)" item indicates the current set cycle time of the slave.
6	User-defined DC mode	If this option is selected in the "Select DC" drop-down menu, user-defined synchronization cycle time in microseconds can be entered in the "Offset time" fields for Sync0 and Sync1.

Diagnostics

Visible only in online mode.

Current status: Displays the current status of the slave's communication state machine. Possible values include: Initialization, Pre-operational, Safe-operational, Operational, Boot (not supported by Inovance servo). If the current status is operational, it indicates that the slave configuration has been correctly completed.

Option

Option: If a slave device is defined as "optional", no fault messages will be generated to prevent the device from not being present in the bus system. To enable this option, a station address must be stored in the slave device, so the "station alias" address must be defined and written into the EEPROM. This option is only valid when the "Auto-configure master/slave" option is checked in the EtherCAT master general settings and the EtherCAT slave supports this function.

Start check

By default, the system automatically checks the identity of the supplier and the product ID at startup based on the current configuration. You can also check the "Check version number" option to check the specified version. If a mismatch is detected, the bus will stop running and no further actions will be performed. This setting is used to prevent the download of incorrect configurations.

Timeout

By default, the following operations are not defined as timeouts. To observe whether these operations exceed a specific time, you can set them here.

- SDO access: Sets the timeout time for SDO (Service Data Object) access from the EtherCAT master protocol to the slave.
- I -> P: Sets the timeout time for the transition of the slave communication state machine from "Initialization" to "Pre-operational".

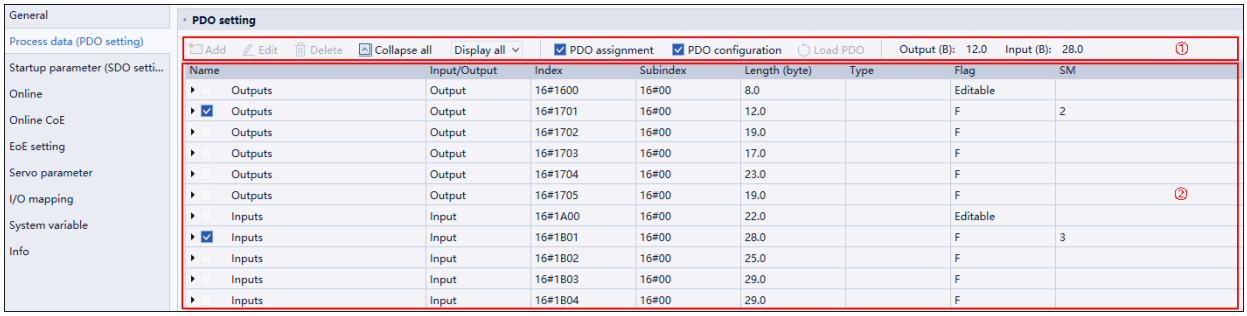
- P -> S / S-> O: Sets the timeout time for the transition of the slave communication state machine from "Pre-operational" to "Safe-operational", or from "Safe-operational" to "Operational".
- Detect port -> Open port: After the slave is connected, sets the timeout time for detecting and opening the port.

DC cycle unit control

This option is assigned to the local microprocessor to select the options defined by the distributed clock function. The control function is implemented in register 0x980 of the EtherCAT slave, with optional settings being: Periodic unit, Latch 0, and Latch 1.

Watchdog

- Watchdog multiplier: Sets the multiplier of the watchdog timer to determine its minimum timing increment. The default value is 2498. The minimum timing increment of the watchdog timer is 100 μs.
- PDI watchdog: After enabling the PDI watchdog, if the PDI (Physical Device Interface) communication time of the EtherCAT slave exceeds the set value, the watchdog will be triggered.
- PD watchdog: Sets the PD watchdog.



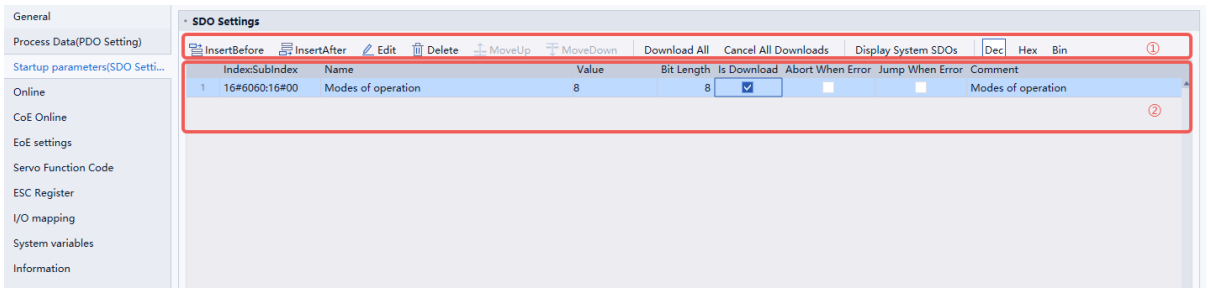
Slave alias

The settings of slave alias are only valid when "Option" is checked and the slave device supports alias addresses (defined by the device description file). If the corresponding alias address of the slave is configured, there is no need to change the configuration in the user program when adjusting its position in the physical topology network, and the slave can still operate normally. Note: After modifying the alias address of the slave, the user program must be re-downloaded for the alias to take effect. Additionally, some slaves must be powered off and restarted for the alias to take effect. For details, see the user guides of relevant slave devices.

- Disable: If this option is checked, the slave will not detect the alias address.
- Configure site alias (ADO 0x0012): When the slave device supports alias addresses and "Option" is checked, writing the alias address is supported only in online operation mode.
- Write EEPROM: This command is visible only in online mode. It allows the defined address to be written to the EEPROM of the slave. If the slave does not support the written address, this command is invalid and the slave cannot operate in site alias form.
- Actual address: This field is visible only in online mode. The actual address of the slave is displayed, which can be used to check whether the "Write EEPROM" command is successful.
- Display device identification (ADO 0x0134): Reserved.
- Data word (2 bytes): Reserved.

10.6.3.3.2 Process Data (PDO Configuration)

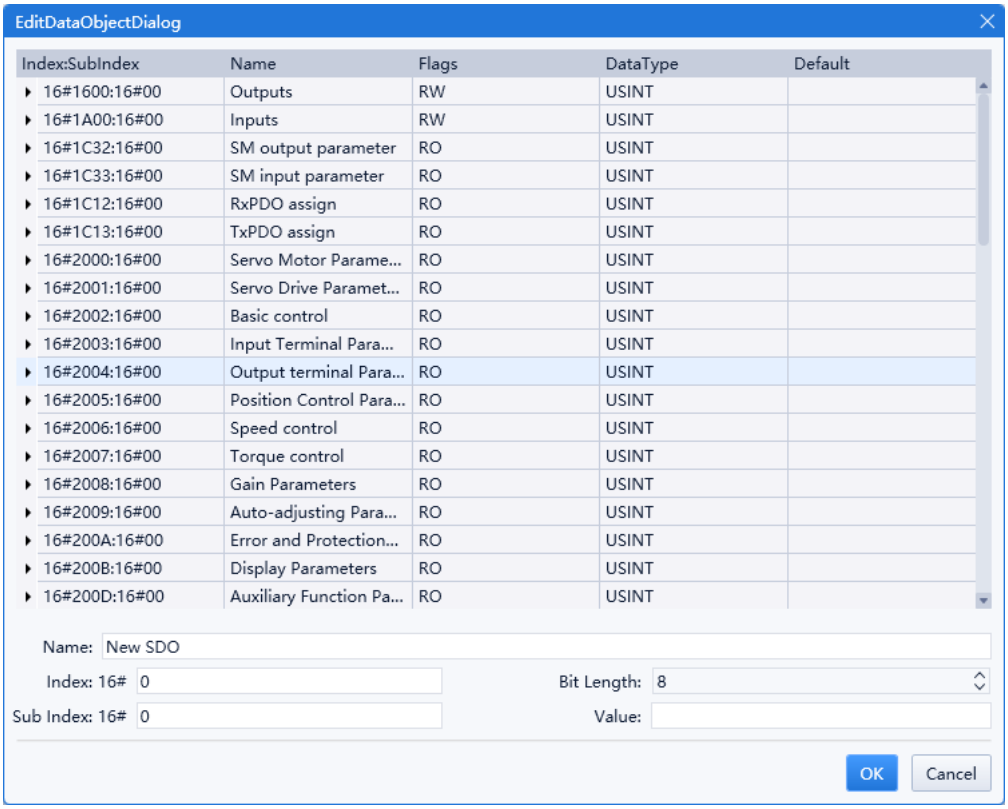
In actual automated control systems, there are normally two forms of data exchange between application programs: time-critical and non-time-critical. Time-critical indicates that specific actions must be completed within a designated time window; if not, it may lead to control failure. The process of periodically sending time-critical data is called periodic process data communication. Non-time-critical data can be sent non-periodically using MailBox data communication in EtherCAT.



No.	Function	Description
①	Toolbar	Supports adding, editing, deleting, and filtering PDO entries.
②	PDO display area	Displays detailed information about PDO.

- Adding: Adds PDO items based on the properties of the current PDO group (editable properties only). Users can choose to add one set or multiple sets of data.
- Edit: Edits the selected PDO item based on the properties of the current PDO group (editable properties only).
- Delete: Deletes the selected PDO item based on the properties of the current PDO group (editable properties only).
- Collapse all: Collapses all entries in the PDO display area with one click.
- Filter box: Filters the PDO display area to display all, display output PDO entries, or display input PDO entries.
- PDO allocation/PDO configuration: In the configuration of the GR10_4ADE module, PDO allocation and configuration refer to assigning PDO objects to the corresponding input/output channels and setting PDO parameters to ensure correct communication between the module and the CANopen network.
- Load PDO: When the slave is in operation, the current PDO group data of the slave can be uploaded to the backend.

10.6.3.3.3 Startup Parameters (SDO Configuration)

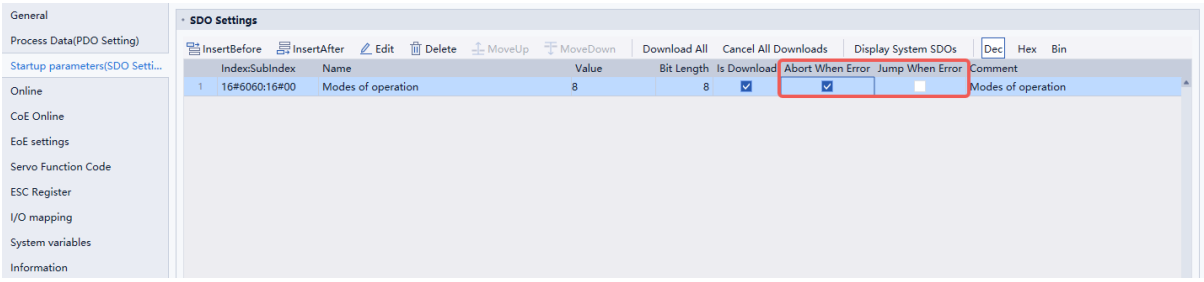


Startup parameters can be transmitted to the slave through SDO (Service Data Object) when the system starts. They include basic configuration parameters required for the slave startup, as shown in the following figure.

No.	Function	Description
①	Toolbar	Supports inserting, editing, deleting, downloading, canceling download, and setting display mode for SDO entries.

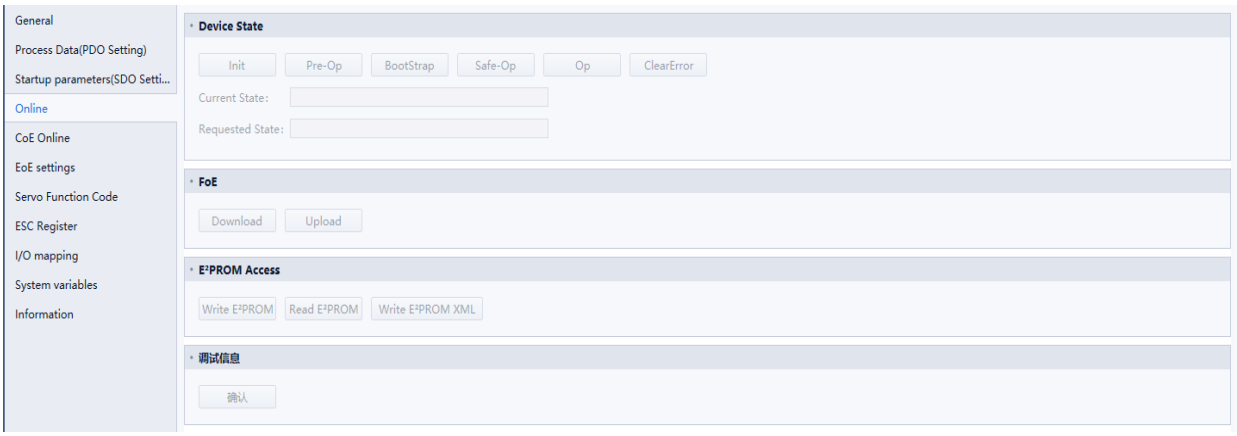
No.	Function	Description
②	SDO entry display area	Displays detailed information of SDO entries.

- Insert before: Adds an SDO entry to the startup parameter list before the currently selected entry. The object dictionary selection box that pops up is shown below. After selecting the SDO to add, you can modify its name, index, sub-index, bit length, and value in the edit bars below, then click "OK" to create a new startup parameter.



- Insert after: Adds an SDO entry to the startup parameter list after the currently selected entry.
- Edit: Edits the parameters of the currently selected entry. Read-only parameters cannot be edited, such as system parameters.
- Delete: Deletes the currently selected entry.
- Move up/Move down: The order of the SDO list (from top to bottom) represents the order in which startup parameters are transmitted to the module. The "Move up" and "Move down" buttons can change the transmission order.
- Download all (SDO)/Cancel all downloads (SDO): Click "Cancel all downloads" to deselect the download property of all entries. Click "Download all" to select the download property of all entries. You can also select the download property of some entries for partial download.
- Display system parameters: Displays the parameters added to the SDO after PDO allocation and PDO configuration are checked, for comparison only.
- Value display mode: The values in the "Value" column of the SDO entry display area can be displayed in decimal, hexadecimal, or binary.

Note: When a fault occurs during the SDO transmission process, it can be resolved through the following options:



- Exit on error: If this option is selected, the SDO transmission will exit if an error is detected.

- Skip on error: If this option is selected, the SDO transmission will skip to the next line and continue if an error is detected.

10.6.3.3.4 Online

The slave online configuration editor can only be used after logging into the device. The related functions and interface are as follows.

- **Device state**

The EtherCAT state machine coordinates the status relationships between the master and slave applications during initialization and operation, as shown in the following figure. The EtherCAT operation transition sequence is: Initialization -> Pre-operational -> Safe-operational -> Operational. The following table introduces each status transition relationship.

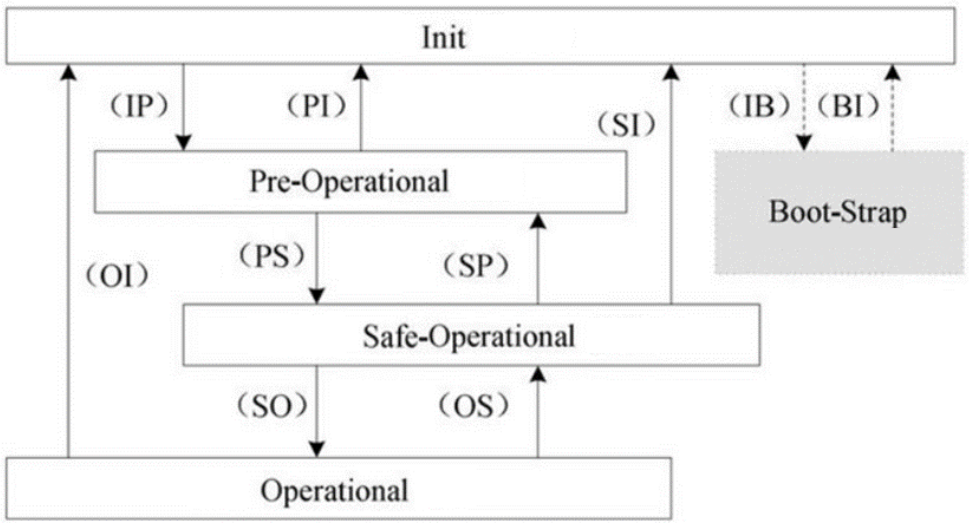


Figure 10-6-3-3-4-1 EtherCAT status transition relationship

No.	Status Transition	Local Management Service
①	IP	Starts mailbox communication.

No.	Status Transition	Local Management Service
②	PI	Stops mailbox communication.
③	PS	Starts input updating.
④	SP	Stops input updating.
⑤	SO	Starts output updating.
⑥	OS	Stops output updating.
⑦	OP	Stops output/input updating.
⑧	SI	Stops output updating and mailbox communication.
⑨	OI	Stops output/input updating and mailbox communication.
⑩	IB	Starts boot mode.
⑪	BI	Restart the device

- Clear error: Click this button to clear the error in the current status.
- Current status: Displays the current operating status of the device.
- Request status: Displays the currently requested status. When selecting another status and the transition has not been completed, this bar will display the requested but uncompleted status.

- **FoE**

  Used to transmit firmware files to the slave for firmware upgrades.

  Click the "Boot status" button to transit the slave to boot mode. Click "Download"/"Upload" to download or upload firmware files and a dialog box pops up. Enter a string and password to execute the file transfer. This information is provided by the slave device and recorded in the slave's data table. Avoid power outages or status switches during firmware upgrades.

- **E2PROM interface**

  The configuration of the slave can be read from or written to the E2PROM.

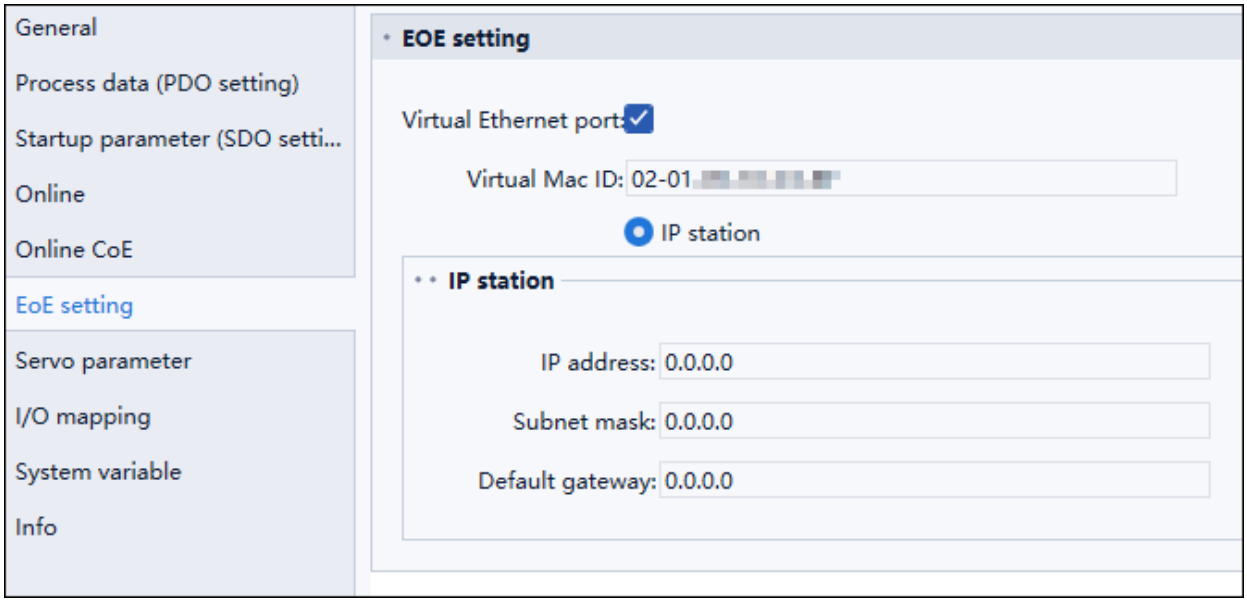
  Similar to firmware file transfer, this operation will also pop up a dialog box to open or save the file. Users can use the "Write E2PROMXML" command to directly write the slave configuration from an XML file to the device. This command is only valid if there is configuration data in the XML file (in the <configuration data> section).

- **Commissioning**

  Click "Clear" to clear all fault codes from the slave.

10.6.3.3.5 Online CoE

The values of online CoE can only be read when the bus is operating normally and the PLC is logged in, as shown in the following figure.



- The interface displays the index, item, flag, type, and value information of the data.
- The flags include RO (read-only) and RW (read-write).
- Click "Read this page" to read the values of the parameters on the current page.
- Click "Auto upload" to automatically read the values of the parameters from the device.
- Select "Offline files from ESI" or "Online device" to switch the source of the data in the list.

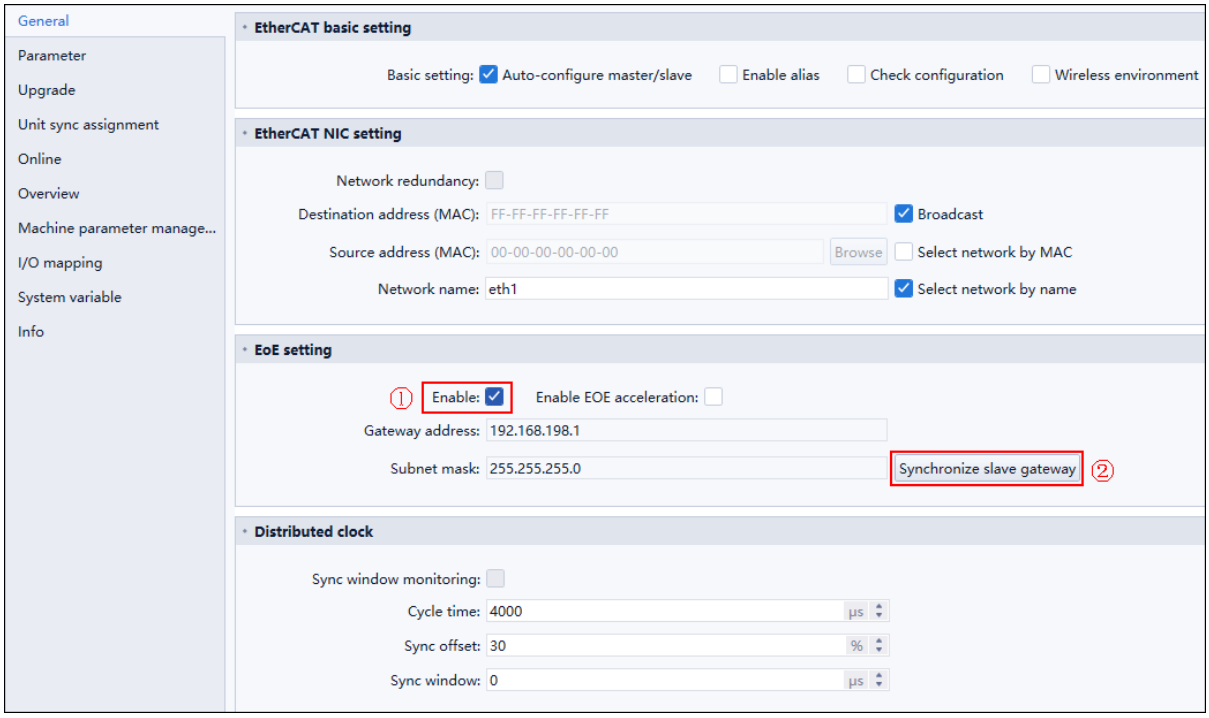
10.6.3.3.6 EoE Settings

This function is currently not supported for the MD800 and MD810 series products.

EtherNET over EtherCAT (EoE) allows any EtherNET device to be connected to EtherCAT via a conversion terminal without affecting the real-time performance of EtherCAT. Similar to well-known Internet protocols, such as TCP/IP, VPN, PPPoE (DSL), Ethernet frames are transmitted via the EtherCAT protocol.

- This setting allows standard network devices to be connected to end devices (such as printers, PCs) via a switch by enabling "Virtual Ethernet port" and set the "IP station".

For special slave devices that support EoE, communication can be set. The following dialog box will only pop up when the device supports EoE.



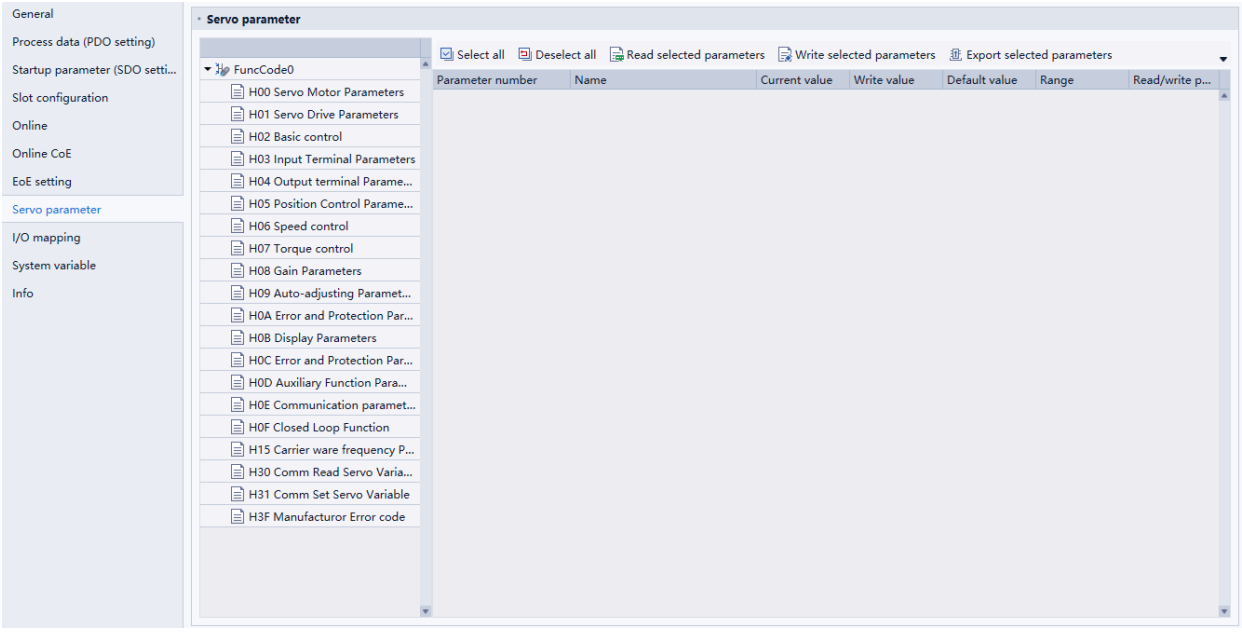
- Virtual Ethernet port: Enables the EoE function of the slave device. If this option is checked, a special "Virtual Mac ID" must be defined.
- Virtual MacID: Automatically assigned by the system, which can be manually modified by users. If a MacID duplication occurs, a compilation fault will occur.
- IP station: Configures the device as an IP interface. When this option is selected, the Ethernet communication parameters must be set.

  Ethernet communication parameters must be set based on the parameters of the virtual Ethernet adapter. The entries for IP address, subnet mask, and default gateway are each allocated four bytes to identify the slave in the network and support modifications to the default settings.

NOTE

The IP address must be in the same subnet as the virtual Ethernet adapter. For example, if the Ethernet adapter's address is 192.168.1.1 and the subnet mask is 255.255.255.0, then the IP address must be within the range of 192.168.1.2 to 192.168.1.254.

- After configuring the EoE settings of the slave, double-click the master node "EtherCAT_Master (EtherCAT Master)", check "Enable" in the "EoE settings" section of the general settings, and then click "Synchronize slave gateway" to complete the EtherCAT configuration, as shown in the figure below:



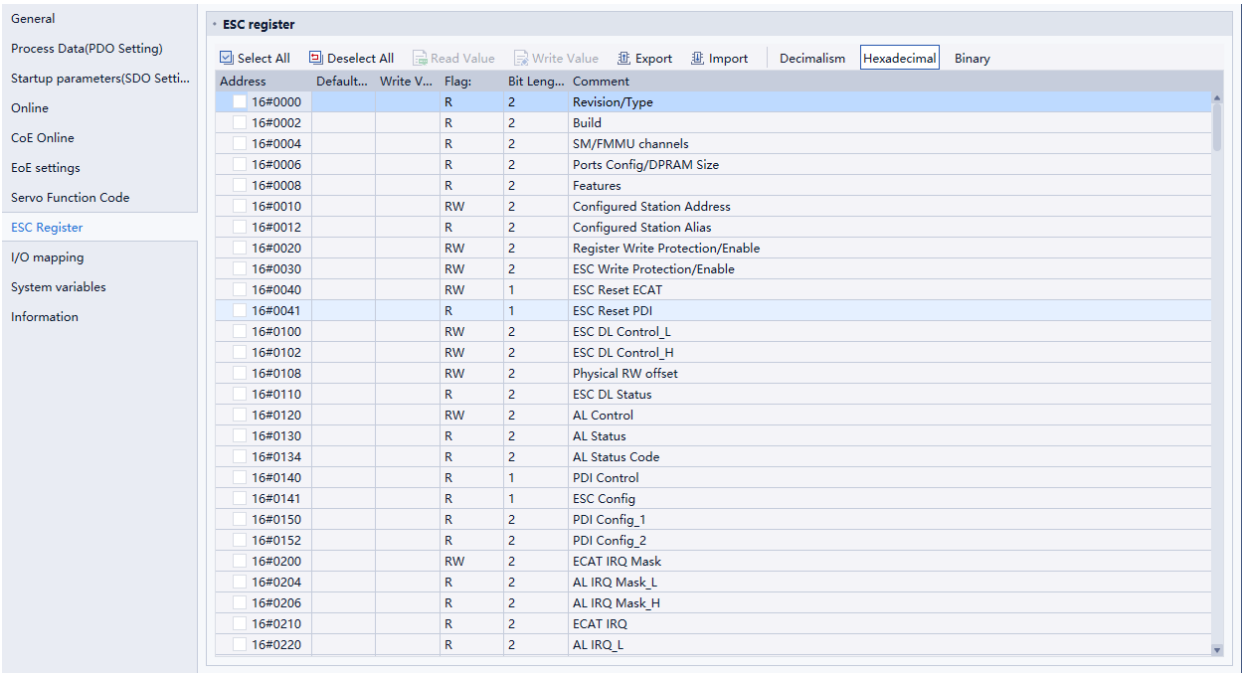
NOTE

The gateway address cannot be in the same subnet as the PLC's IP address. If they are in the same subnet, it is recommended to modify it manually.

Only devices that support the EoE function can be configured.

10.6.3.3.7 Servo Parameters

Servo function codes refer to the manufacturer parameters defined for Inovance servo products. Under the "Servo parameter" tab of slave configuration, the manufacturer parameters of multiple product can be read and written in batches, imported, and exported, facilitating commissioning and maintenance.

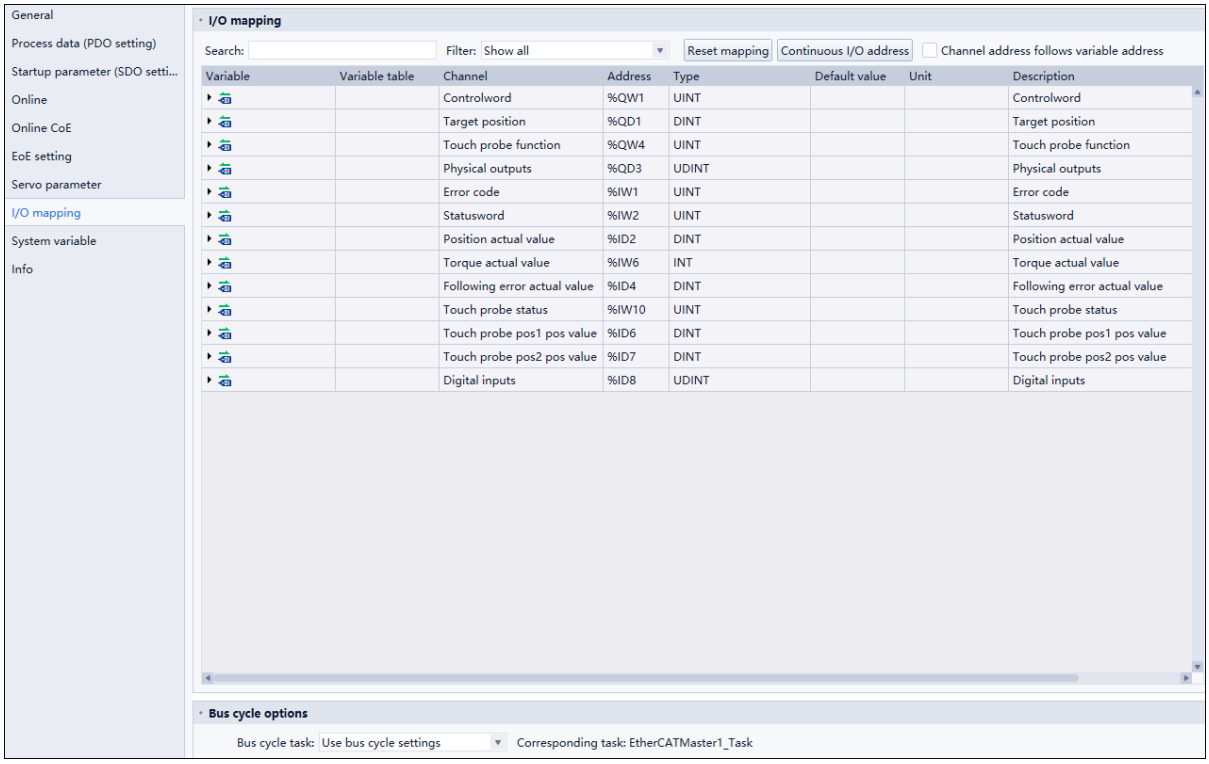


- Select all: Selects all slaves and axes, as well as the servo function codes under the axes.
- Deselect all: Cancels all selected items.

- Read selected parameters: In the servo operation status, reads the servo function codes with RO, RW, or R properties.
- Write selected parameters: In the servo operation status, writes the servo function codes with W or RW properties.
- Export selected parameters: Exports the selected servo parameters in an Excel file.
- Import parameters: Imports the parameters of all slaves from an external Excel file. If the configuration does not match the file, a fault will be reported.

10.6.3.3.8 ESC Register

The ESC register is used to read the values of the ESC chip register addresses in advanced commissioning, as shown in the figure below. For descriptions of each function and parameter, see the table below.



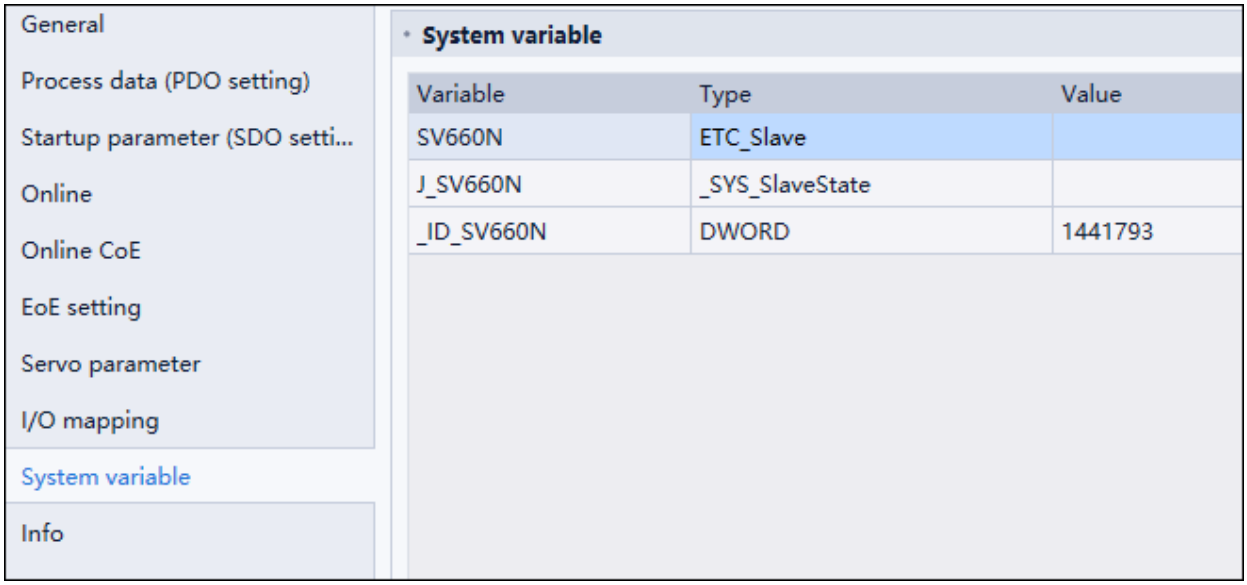
Currently, only the SV680N series device supports this feature.

Parameter	Description
Select all	Selects all parameters in the list.
Deselect all	Deselects all parameters in the list.
Read value	Reads the values of the selected items in operation status.
Writing a Value	Writes the values with write property in operation status.
Export	Exports the selected items as an .xml file and save it to the local disk.
Import	Imports an .xml file from the local disk that meets the format requirements.
Display format	Switches the display format to decimal, hexadecimal, or binary.

10.6.3.3.9 I/O Mapping

The "I/O mapping" interface is shown in the figure below, and detailed explanations of the parameters are provided in the table below.

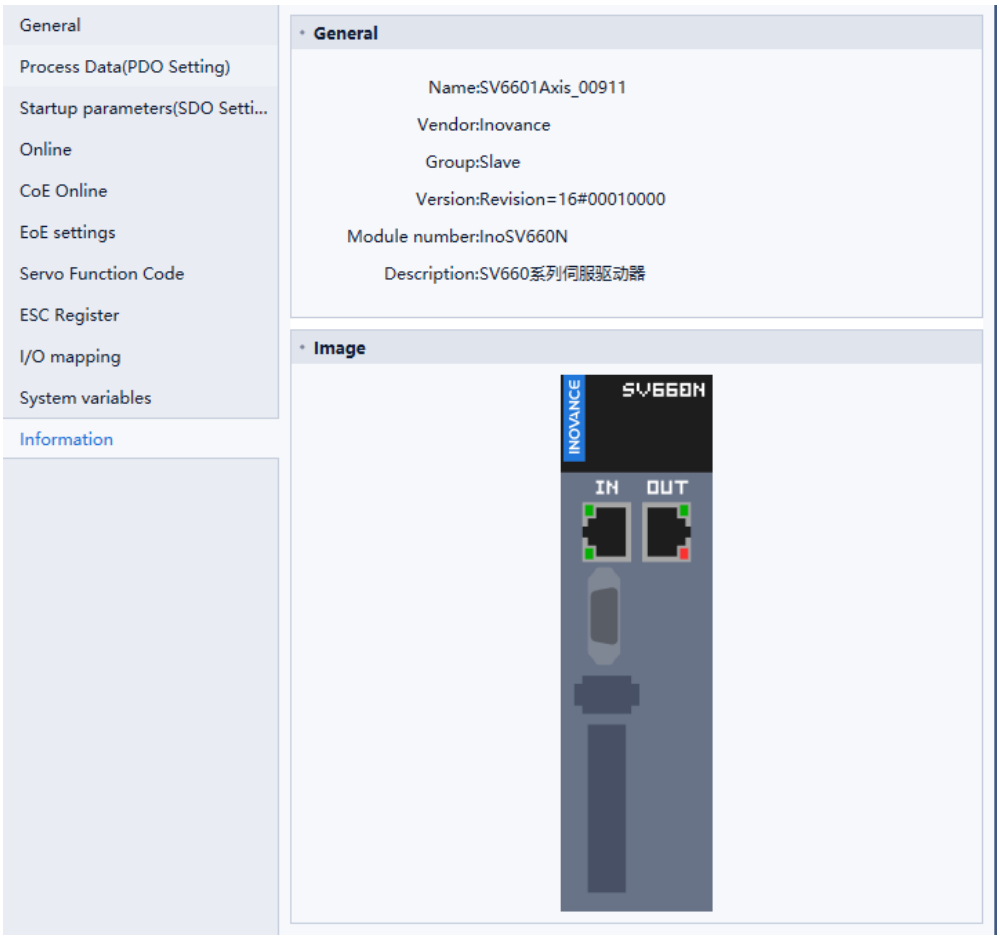
Parameter	Description
Search	Searches for the corresponding I/O mapping channel based on keywords.
Filter	Displays the corresponding variables based on the filtering option.
Reset mapping	Clears the mapped variable information.
Continuous I/O address	Clears the device's I/O address and reassign it to a continuous address.



Parameter	Description
Channel address follows variable address	This option is not checked by default. If "Channel address follows variable address" is not selected: The I/O mapping channel address is fixed, and the variable type must strictly match the channel type. This mode only supports binding standard data types. After the variable is bound to the channel, the channel address will be automatically assigned to the variable. If "Channel address follows variable address" is selected: Binding can be completed when the channel byte size matches the variable byte size. This mode supports binding standard data types, structures, unions, and enumerations as custom types. After the variable is bound to the channel, the I/O mapping channel address will be removed, and the channel address will automatically follow the variable address.

Parameter	Description
Variable	Configures the variables for I/O mapping, which can be performed in the following two ways: • Mapping the I/O mapping channel to an existing variable (standard data type) Double-click the cell in the "Variable" column, and click "...". Select the existing variable to be mapped in the pop-up "Input assistant" interface and click "OK". • Mapping the I/O mapping channel to an existing variable (struct/union/array) 1. Select "Channel address follows variable address". 2. Double-click the cell in the "Variable" column, and click "...". Select the user-defined instance to be mapped in the pop-up "Input assistant" interface and click "OK". 3. When binding a user-defined type to the first channel, select the binding method in the dialog box. ▪ Bind the structure directly to this channel: After selected, the variable is bound only to this channel. ▪ Bind the elements in the structure sequentially to all channels of this device: After selected, the variables in the struct are automatically bound to all channels of the device in order; when the struct variable has multiple levels of nesting, only the first-level variables are bound sequentially. • Mapping the I/O mapping channel to a new variable Double-click the cell in the "Variable" column, enter the name of the new variable, and press the Enter key. The new variable will be synchronized to the default variable table. The name of the new variable must comply with IEC programming standards, otherwise it will result in a compilation fault.
Variable table	Identifies the type of variable table for I/O mapping variables.
Channel	Indicates the bit number of the current I/O mapping channel.

Parameter	Description
Address	Indicates the address assigned to the current I/O mapping variable. To customize the I/O address, double-click the cell in the "Address" column to modify it.
Type	Indicates the data type of the current I/O mapping variable.
Default value	Indicates the default value of the current I/O mapping variable.
Unit	Indicates the unit of the current I/O mapping variable.
Description	Indicates the description information of the current I/O mapping variable.
Prepared value	Indicates the value pre-written or forced for the current I/O mapping variable. Double-clicking the cell in the "Prepared value" column for modification. After modification, use "Ctrl+F7" or "F7" to write the value or force it to be uploaded to the I/O mapping variable.
Bus cycle task	This function is applicable to virtual axes. The "Bus cycle task" must be bound to the called EtherCAT task (default is "Use bus cycle settings", which is applicable to a single master). It is prohibited to call the same virtual axis under multiple EtherCAT tasks.



10.6.3.3.10 System Variables

In the "System variable" tab of the EtherCAT slave, instances (variables) of type ETC_Slave and _SYS_SlaveState are specified for servo slaves I/O, supporting control of devices connected to the EtherCAT slave via user programs, and displaying the device ID value of this slave.

10.6.3.3.11 Information

This interface displays the general information and image of the device, as shown in the following figure:

10.6.3.4 Disabling/Enabling an EtherCAT Device

Disabling EtherCAT device

In iFA software, a certain EtherCAT device can be disabled through commands or variable setting, thus "detaching" from the control system while retaining its configuration parameters and I/O mapping

information. If a device fails and needs to be replaced, this function can reduce the time required for replacement.

- Disabling operation and effect
  A device can be disabled through commands or variable setting, each with different scopes. Command disabling applies to all devices except PLCs Variable setting requires that there be corresponding variables in SYS_VAR.
  - Command disabling
    Right-click an EtherCAT master/slave node in the project tree and select "Disable device".
    You can also open the network configuration interface, right-click a slave device and select "Disable device".
    After disabling, it is necessary to perform a 10.8.3 full download of the PLC to make the disabling operation effective.
  - Variable setting
    When adding each EtherCAT slave, a corresponding variable is created in **SYS_VAR**, following the naming rule: J_device model.
    Setting member The member **bDisableEnable** disables the slave, and the setting method supports writing values in **SYS_VAR** or assigning values in user programs.

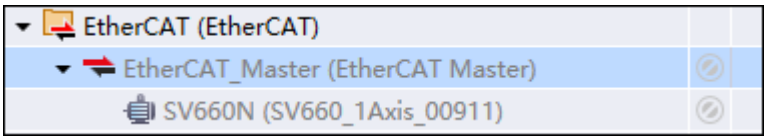
GLOBAL SYS_VAR

	Name	Data type	Address	Retain	Network publish	Comment	Attributes
1	VAR_GLOBAL						
2	LAN1_EIPSingle_STATUS	Array[1..32] OF IoStand...			Private		attribute 'device_created'
3	LAN1_EIPSlave_STATUS	Array[1..16] OF EtherNe...			Private		attribute 'device_created'
4	_EC1_Node	ARRAY[1..127] OF Ether...			Private		attribute 'device_created'
5	J_SV660N	IoStandard._SYS_SlaveS...		☑	Private		attribute 'device_created'
6	bDisableEnable	BOOL			Private		

After disabling, it is necessary to sequentially download, power off, and power on the PLC to make the disabling operation effective.

> **CAUTION**
>
> Powering off the PLC will result in the loss of values for temporary variables and variables with power-off retention set to FALSE.

- Disabling result
  The disabled devices are marked with the icon for differentiation.



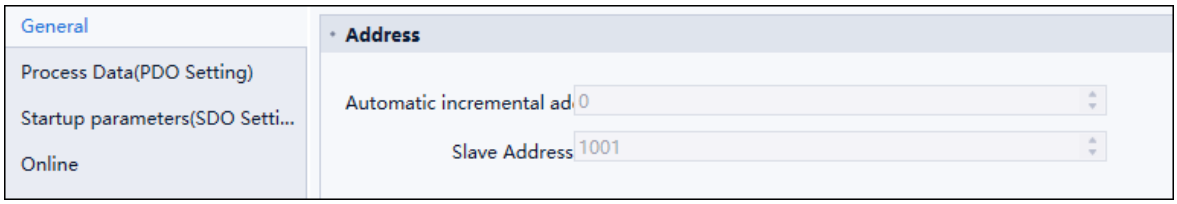


Figure 10-6-3-4-1 Icon in project tree

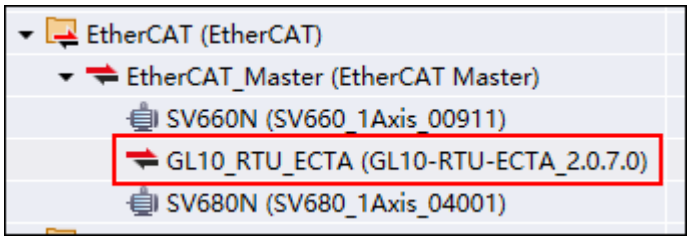

Figure 10-6-3-4-2 Icon in network configuration view

- Disabling Impact
  - If an EtherCAT slave device is addressed by address, after being disabled, iFA software will reassign addresses to subsequent devices. If it is addressed by alias, disabling has no impact on other slave devices.

  - When EtherCAT slave devices have inconsistent models, the physical device that is disabled must be removed from the control system to ensure the normal operation of other slaves.
    As shown in the figure below, three slave devices consist of two models. After the middle device is disabled, it needs to be physically removed to ensure the normal operation of the other two slaves.

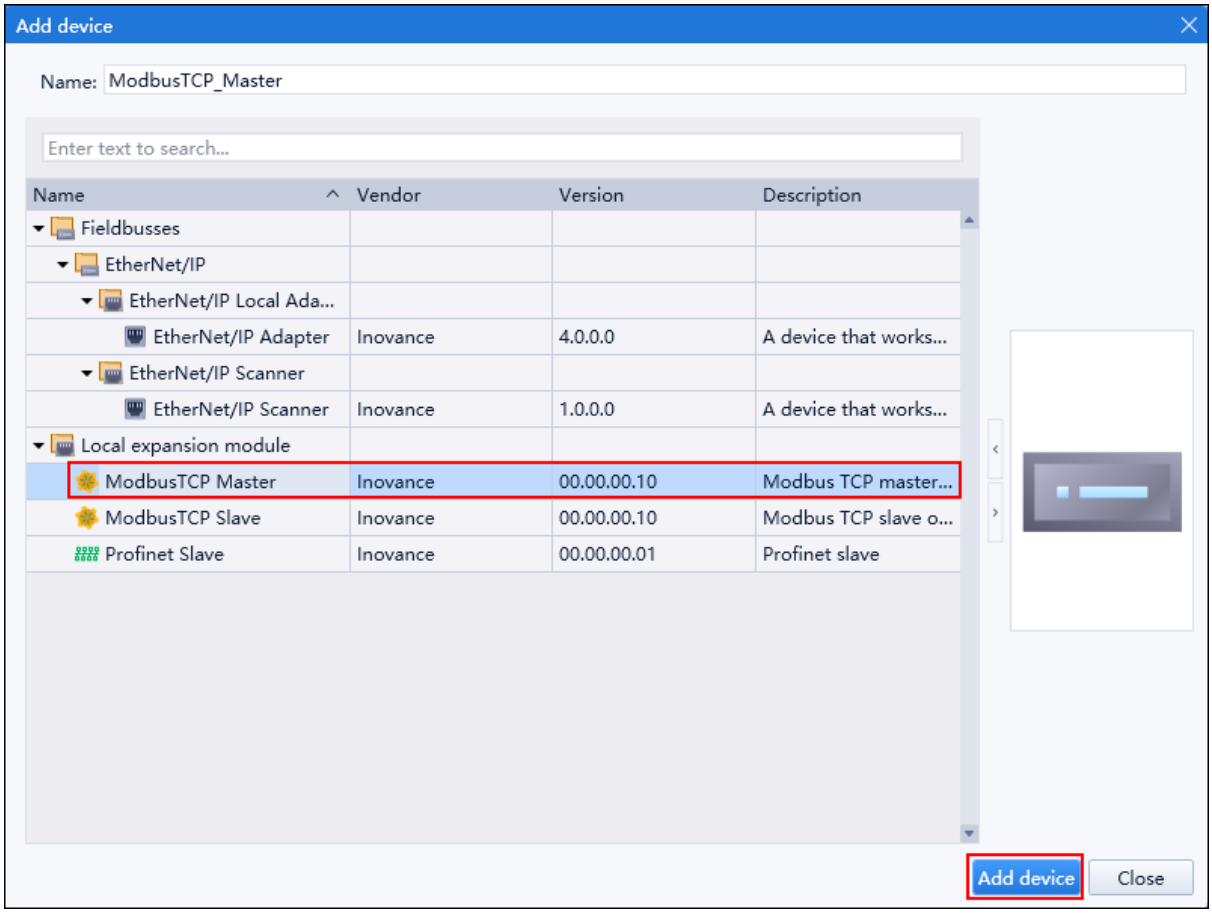
Enabling EtherCAT device

The disabling and enabling of EtherCAT devices are a set of mutually corresponding operations. Only when the device is disabled is the enabling command visible.

The enabling operation and its effect are exactly the same as the disabling operation.

A device needs to be disabled and enabled in the same way. That is, if the device is disabled by setting a variable, it must be enabled by resetting the variable. If it is disabled using a command, it must also be enabled using a command.

10.6.4 EtherNet Communication Configuration

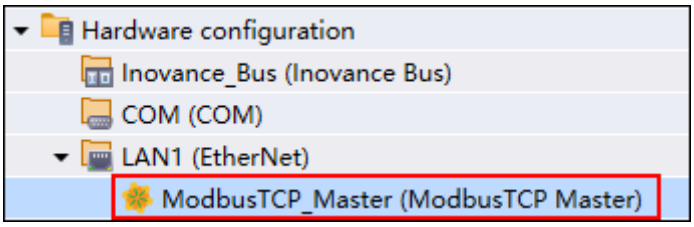


10.6.4.1 Modbus TCP Device Configuration

10.6.4.1.1 Adding a Modbus TCP Device

Adding a Modbus master device

Procedure



1. Click "Hardware configuration" in the project tree on the left.
2. Right-click "LAN1(EtherNet)" and select "Add device".
3. The pop-up "Add device" window is shown in the figure below.

4. Double-click "ModbusTCP master" or select it and click "Add device" to add the Modbus master.

Result

The added Modbus master is displayed under the "Hardware configuration" node.

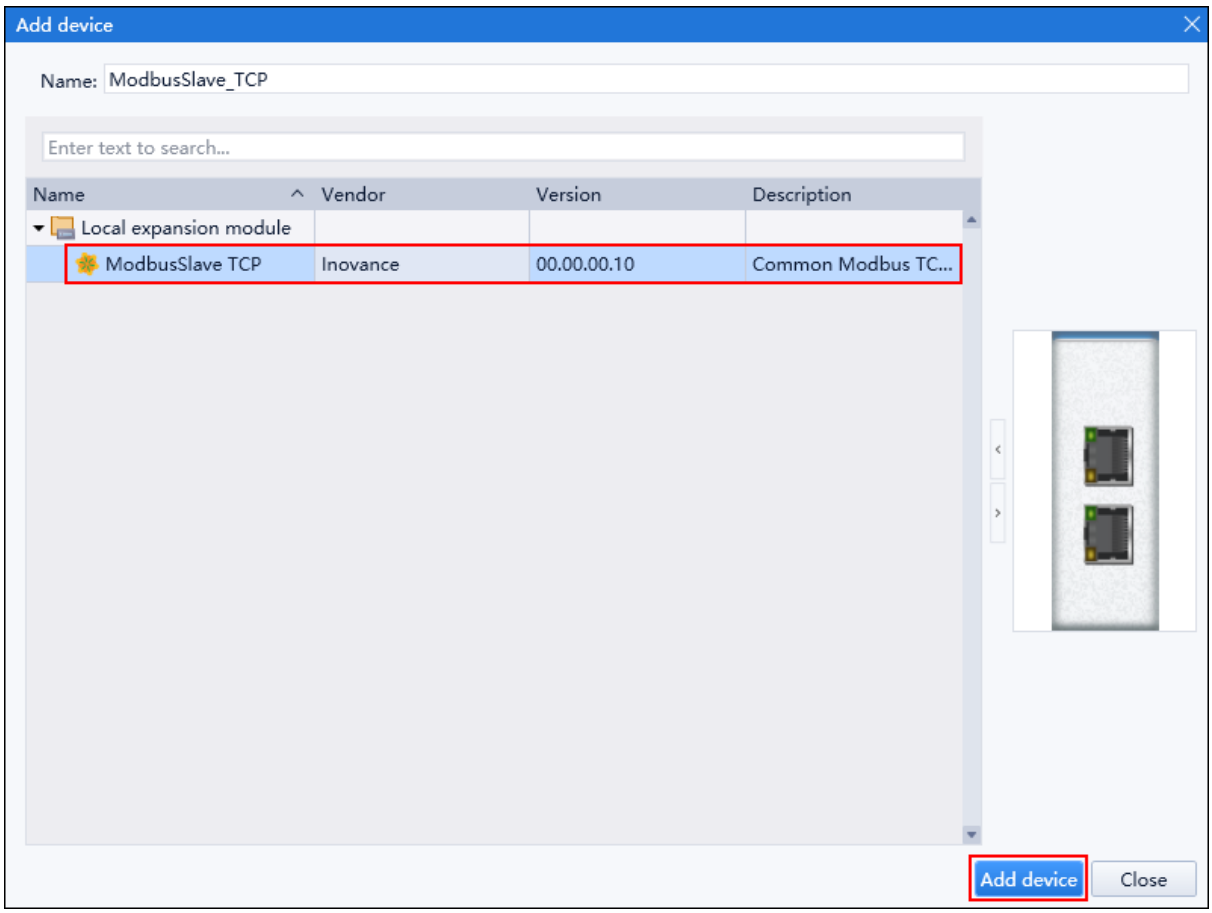
Adding a Modbus slave device

Steps

1. Click "Hardware configuration" in the project tree on the left.
2. Right-click "LAN1(EtherNet)" and select "Add device".
3. The "Add device" window pops up.
4. Double-click "ModbusTCP slave" or select it and click "Add device" to add the Modbus slave.

Result

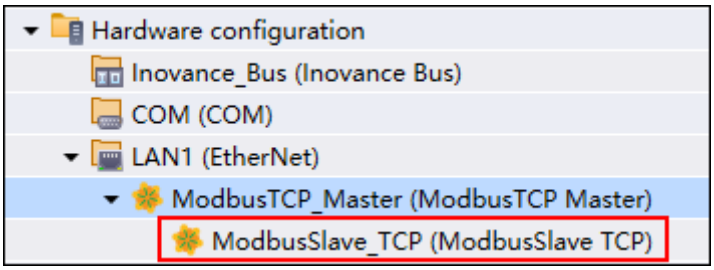
The added Modbus slave is displayed under the "Hardware configuration" node.



Mounting a Modbus slave under the Modbus master

Prerequisites

A Modbus master has already been added to the current device.



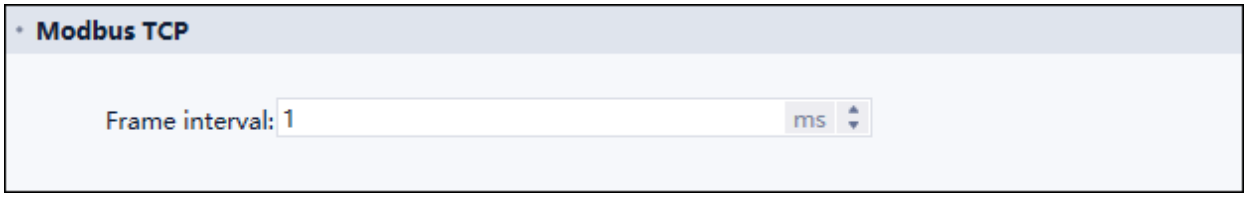
Procedure

1. Right-click the Modbus master device and select "Add device".
2. In the pop-up "Add device" window, select "ModbusSlave TCP".

Result

The corresponding master and slave devices are displayed under the "Hardware configuration" node.

10.6.4.1.2 Configuring a Modbus TCP Master

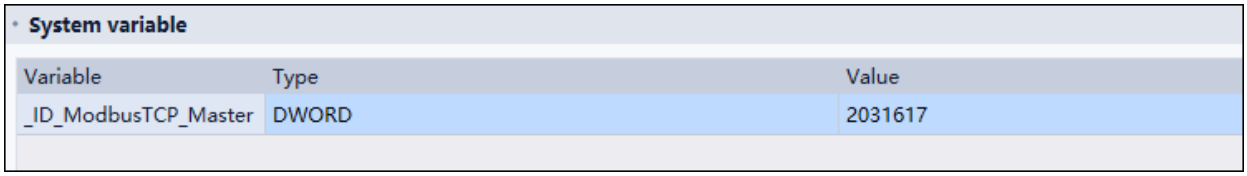


10.6.4.1.2.1 Modbus TCP Master Configuration

Prerequisites

The master device has been added.

Procedure



Double-click the Modbus TCP master device node to open the master configuration interface.

Modbus TCP master configuration is relatively simple, only requiring the frame interval to be set. In general, there is no need to change this setting.

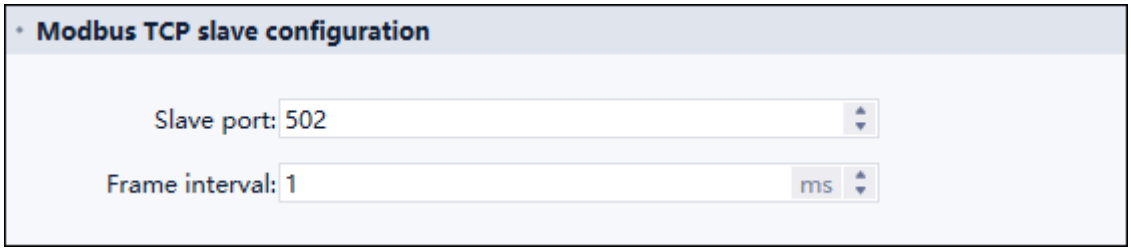
10.6.4.1.2.2 System Variables

The device ID value of the Modbus TCP master is displayed in the "System variable" interface.

10.6.4.1.2.3 Information

The "Information" tab displays the following information for the current module: name, vendor, version, module number, and description.

10.6.4.1.3 Configuring a Modbus TCP Slave

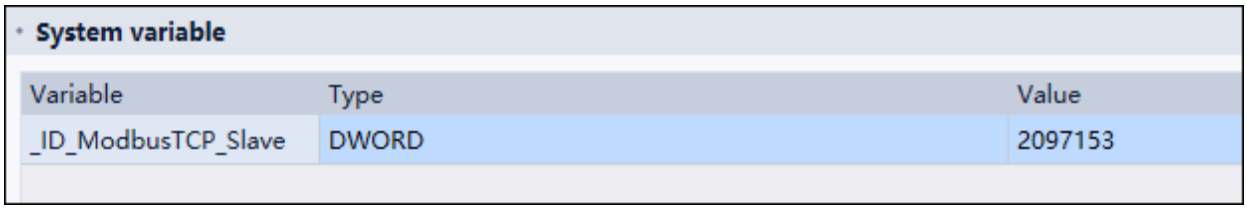


10.6.4.1.3.1 Modbus TCP Slave Settings

Prerequisites

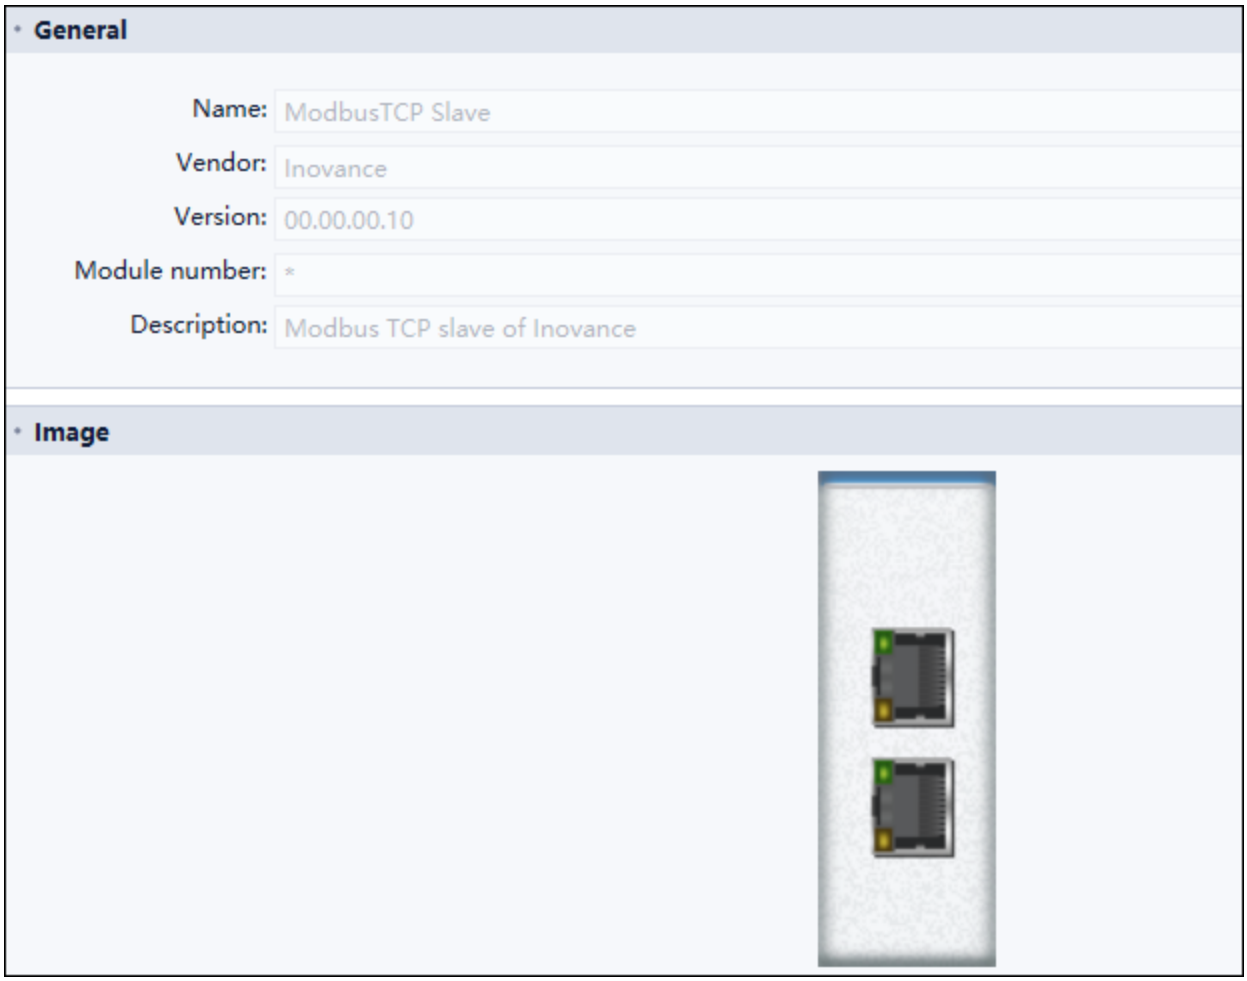
A slave device has been added.

Procedure



Double-click the Modbus TCP slave device node to open the slave configuration interface.

Item	Description
Slave port	The port number on which the slave listens Range: 1 to 65535. **Note:** System ports are prohibited from being used. System ports include 21, 22, 23, 44818, 2222, 34980, 48000, 12601 to 12610, 1260 to 1263, 8889, 4840, and 60000 to 62000.
Frame interval	The interval between the last received data frame and the next transmitted frame.



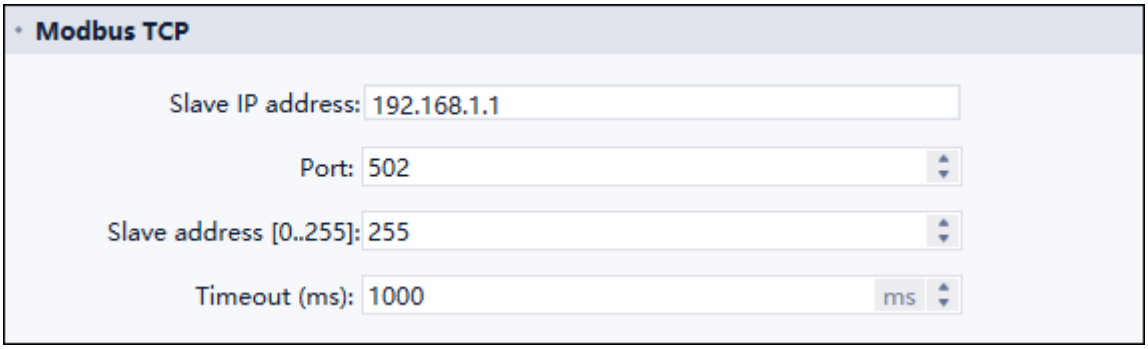
10.6.4.1.3.2 System Variables

The device ID value of the Modbus TCP slave is displayed in the "System variable" interface.

10.6.4.1.3.3 Information

The "Information" tab displays the following information for the current module: name, vendor, version, module number, description, and image.

10.6.4.1.4 Configuring a Modbus TCP Slave Under the Master

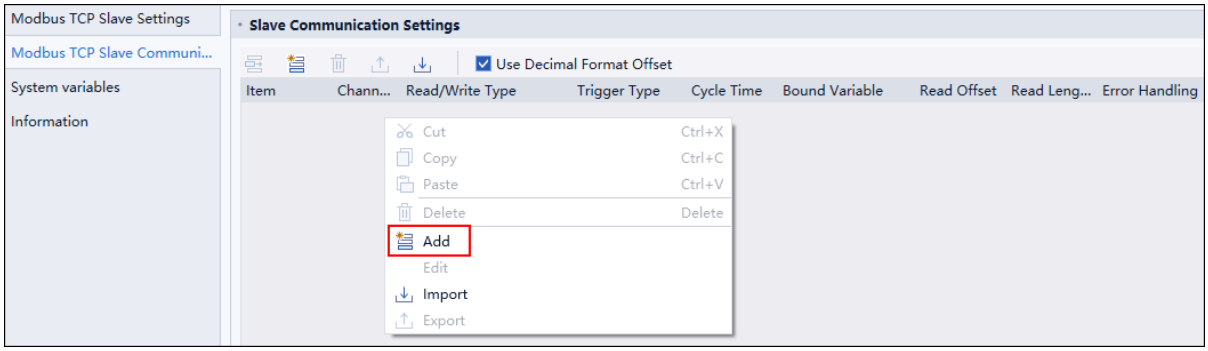


10.6.4.1.4.1 Modbus TCP Slave Settings

Prerequisites

A slave device has been added and mounted on the master.

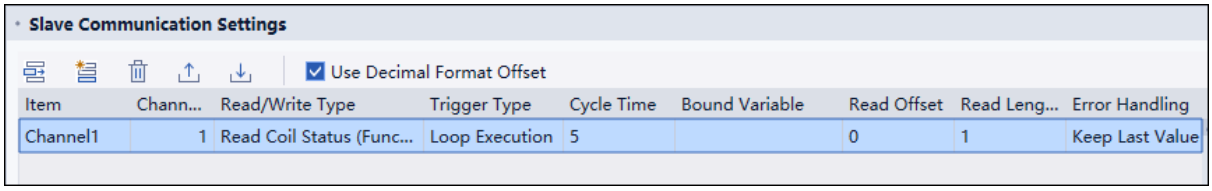
Procedure



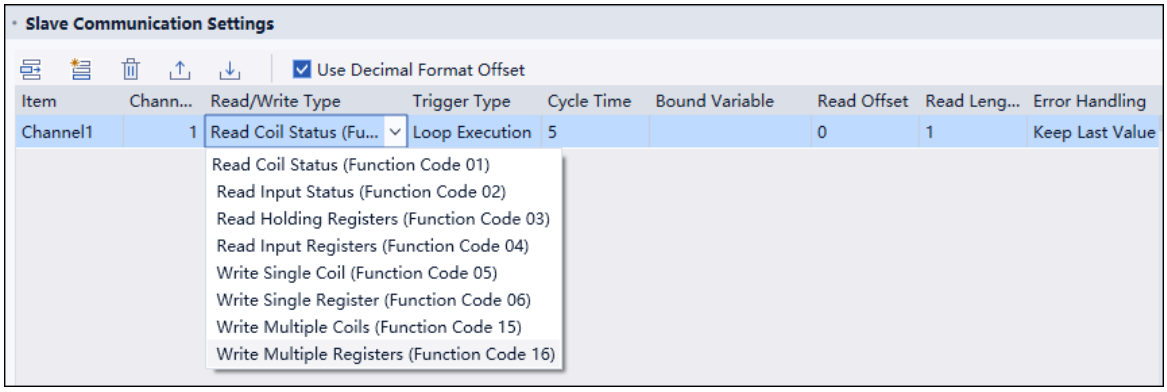
Double-click the added slave device node to open the slave configuration interface.

Item	Description
Slave IP address	The IP address of the Modbus slave in the actual hardware configuration.
Port	The port to access the peer slave. Range: 1 to 65535. **Note:** System ports are prohibited from being used. System ports include 21, 22, 23, 44818, 2222, 34980, 48000, 12601 to 12610, 1260 to 1263, 8889, 4840, and 60000 to 62000.
Slave address [0..255]	The Modbus application layer address corresponding to the slave.
Timeout period	Indicates the response time for a single connection to the slave, with a range from 2 ms to 1000 ms and a default value of 1000 ms. If the slave does not respond within this period, the master will terminate the request after sending the specified number of retry requests and display a fault message. **Note**: The timeout time must be greater than the longest CPU scan cycle, otherwise a fault will occur.

10.6.4.1.4.2 Modbus TCP Slave Communication Settings



1. In the "Modbus TCP slave communication settings" tab interface, right-click in the blank area on the right and select "Add" to add a communication entry.



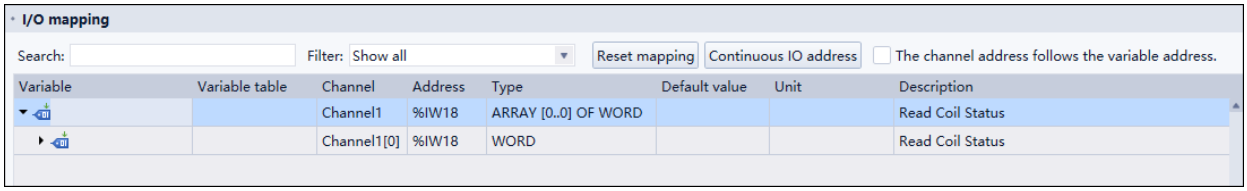
Different devices support different numbers of added channels, as shown in the table below.

Product Series	Firmware Version	Number of channels
EVO400, EVO500, EVO700, EVO700C, and APC series	V1.5 and above	A single slave can support up to 200 channels, and the total number of channels added by all slaves cannot exceed 512.
	V1.4 and below	A single slave can support up to 60 channels.
EVO800 series	V1.1 and above	A single slave can support up to 200 channels, and the total number of channels added by all slaves cannot exceed 512.
	V1.0	A single slave can support up to 60 channels.

2. The added entry is shown in the figure below.

- Item: The name of the entry
- Channel number: The sequence number corresponding to this entry
- Read/Write type: Configures the function code, which can be set to: read coil status (function code 01), read input status (function code 02), read holding register (function code 03), read input register (function code 04), write single coil (function code 05), write single register (function code 06), write multiple coils (function code 15), write multiple registers (function code 16).

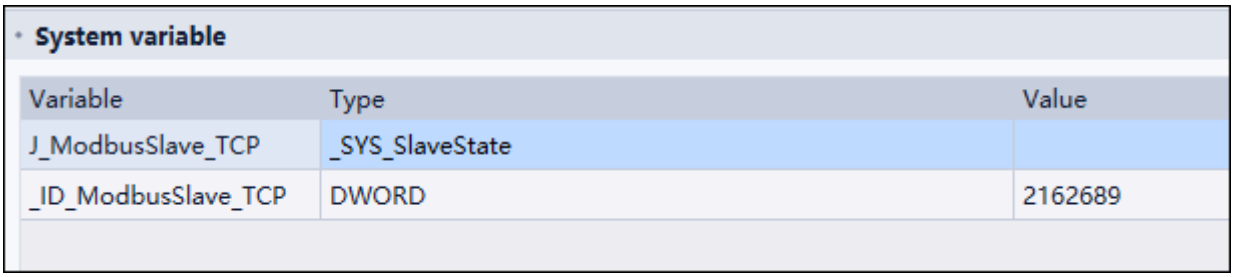
- Trigger type: The trigger type corresponding to this entry, supporting cyclic execution and level triggering (for EVO500 series PLCs, only version V1.3 and above support level triggering).
- Cycle time: The cycle time cannot be edited in level triggering mode.



- Bound variable: You can manually input or bind global variables in the project using the input assistant. After binding, the channel data access status can be controlled through the program. The variable type must be BOOL. Non-BOOL types are not supported. One channel can only bind one variable. After executing a trigger command, the BOOL variable value is set to FALSE. The command is effective only once and only when the variable status is TRUE.
- Read offset: The offset position based on the read start address
- Read length: The length of the read operation
- Fault handling: The handling method when a fault occurs
- Write offset: The write offset position
- Write length: The length of the write operation
- Retry count: The number of times to retransmit when encountering network issues
- Comment: Comment information

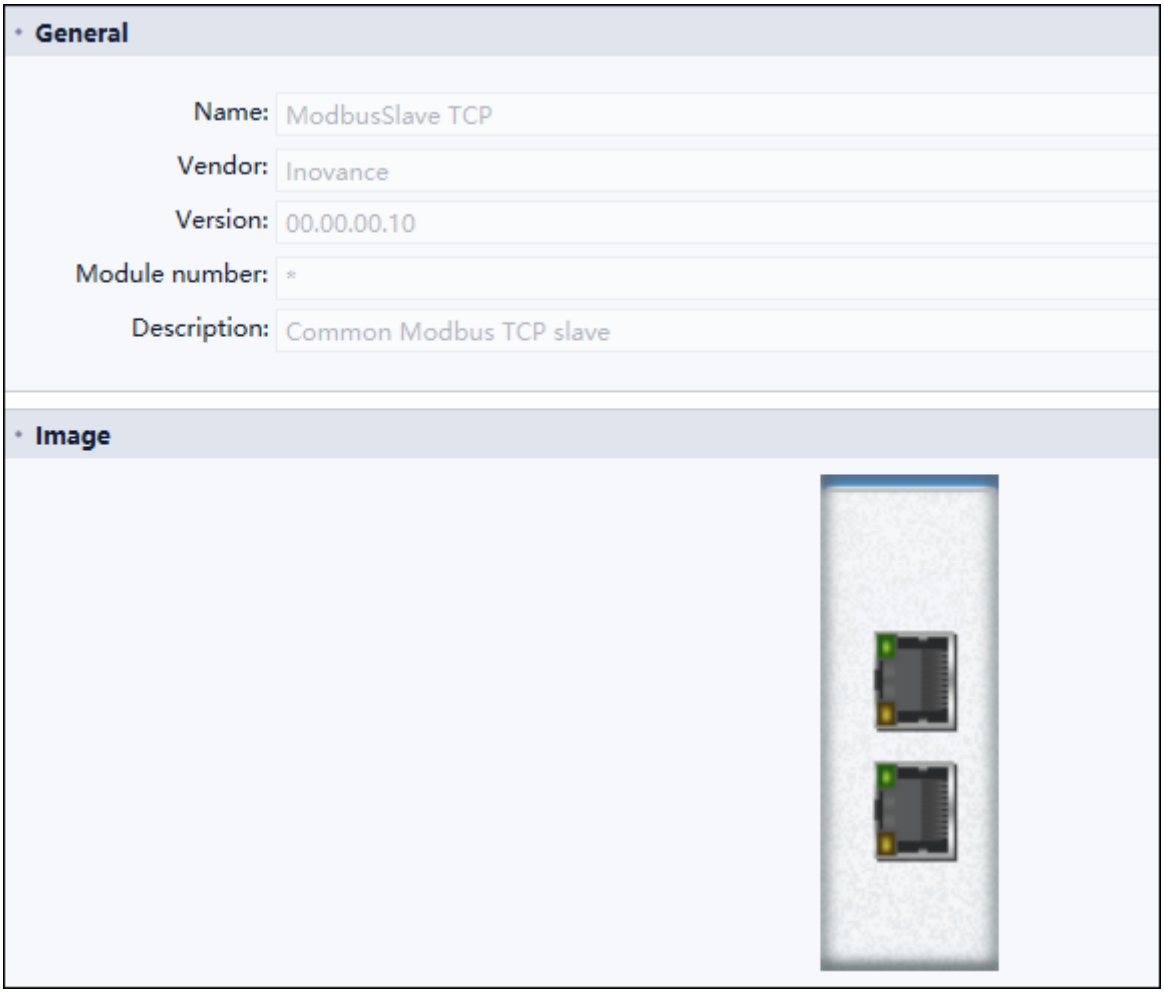
For details about the entries in this interface, see the Modbus protocol.

10.6.4.1.4.3 I/O Mapping



After configuring the Modbus TCP slave communication settings, you can configure the Modbus-related I/O settings. The number of I/O configuration entries in the "I/O mapping" tab is consistent with the number of entries in the "Modbus TCP slave communication settings" tab.

For details about the configuration parameters, see 10.6.3.3.9 I/O Mapping.



10.6.4.1.4.4 System Variables

In the "System variable" tab, an instance (variable) of type _SYS_SlaveState is specified for the slave I/O and the device ID values of the mounted Modbus TCP slaves are displayed.

10.6.4.1.4.5 Information

The "Information" tab displays the following information for the current module: name, vendor, version, module number, description, and image.

10.6.4.1.5 Modbus TCP Variable Addressing

Coil

Coil is a bit variable with only two statuses, 0 and 1. This PLC (taking the EVO500 series as an example) includes variables in the Q area and I area.

Variable Name	Command Code	Starting Address	Number of coils	Note
QX0.0-QX8191.7	0x01, 0x05, 0x0f	0	65536	Accessible through the universal standard Modbus protocol
IX0.0-IX8191.7	0x2	0	65536	Accessible through the universal standard Modbus protocol

Register

Register is a 16-bit (word) variable. Take the EVO500 series as an example, the PLC includes only variables in M area.

Variable Name	Command Code	Starting Address	Number of Registers	Note
MW0-MW65535	0x03, 0X04, 0x06, 0x10	0	65536	Accessible through the universal standard Modbus protocol

NOTE

The soft elements of the EVO400/EVO500 series contain three types: Q area, I area, and M area. They can be accessed by bit, byte, word, and double word, such as: %QX, %QB, %QW, %QD. The conversion rules are as follows:

QB0 = (QX0.0 to QX0.7)
QW0 = (QB0 to QB1) =((QX0.0 to QX0.7) + (QX1.0 to QX1.7))
QD0 = (QW0 to QW1) = (QB0 to QB3) = ((QX0.0 to QX0.7) + (QX1.0 to X1.7) + (QX2.0 to QX2.7) + (QX3.0 to QX3.7))

Register address indexing rule

Bit Addressing	Byte Addressing	Word Addressing	Dword Addressing		Bit Addressing	Byte Addressing	Word Addressing	Dword Addressing
QX0.0	QB0	QW0	QD0		MX0.0	MB0	MW0	MD0
QX0.1					MX0.1			
QX0.2					MX0.2			
QX0.3					MX0.3			
QX0.4					MX0.4			
QX0.5					MX0.5			
QX0.6					MX0.6			
QX0.7					MX0.7			
QX1.0	QB1				MX1.0	MB1		
QX1.1					MX1.1			
QX1.2					MX1.2			
QX1.3					MX1.3			
QX1.4					MX1.4			
QX1.5					MX1.5			
QX1.6					MX1.6			

Bit Addressing	Byte Addressing	Word Addressing	Dword Addressing		Bit Addressing	Byte Addressing	Word Addressing	Dword Addressing
QX1.7					MX1.7			
QX2.0	QB2	QW1			MX2.0	MB2	MW1	
QX2.1					MX2.1			
QX2.2					MX2.2			
QX2.3					MX2.3			
QX2.4					MX2.4			
QX2.5					MX2.5			
QX2.6					MX2.6			
QX2.7					MX2.7			
QX3.0	QB3				MX3.0	MB3		
QX3.1					MX3.1			
QX3.2					MX3.2			
QX3.3					MX3.3			
QX3.4					MX3.4			
QX3.5					MX3.5			
QX3.6					MX3.6			
QX3.7					MX3.7			
QX4.0	QB4	QW2	QD1		MX4.0	MB4	MW2	MD1
QX4.1					MX4.1			

NOTE

The starting address of EVO400/EVO500's word-type register is an even byte address. The starting address of DWord-type register aligns with even word addresses, and its index number is in a 2x relationship, making address calculation convenient.

10.6.4.1.6 Modbus TCP Communication Frame Format

- Reading coils

Use the 0x01 command code to read Q variables.

Request frame format: transaction meta identifier + protocol identifier + length + slave address + 0x01 + starting address of coil + number of coils

No.	Definition of Data (Byte)	Number of Bytes	Note
1	Transaction meta identifier	2 bytes	Identifier of the Modbus request/response transaction
2	Protocol identifier	2 bytes	0 = Modbus protocol
3	Length	2 bytes	Number of following bytes
4	Slave address	1	Range: 1 to 247
5	0x01 (command code)	1	Read coils.
6	Head address of coils	2 bytes	Upper bits are followed by lower bits.
7	Number of coils (N)	2 bytes	Upper bits are followed by lower bits.

Response frame format: transaction meta identifier + protocol identifier + length + slave address + 0x01 + number of bytes + status of coils

No.	Definition of Data (Byte)	Number of Bytes	Note
1	Transaction meta identifier	2 bytes	Identifier of the Modbus request/response transaction
2	Protocol identifier	2 bytes	0 = Modbus protocol
3	Length	2 bytes	Number of following bytes
4	Slave address	1	Range: 1 to 247
5	0x01 (command code)	1	Read coils.
6	Number of bytes	1	Value: [(N + 7) / 8]
7	Coil status	[(N + 7) / 8] bytes	Eight coils are indicated by one byte. If the last byte has less than eight bits, enter 0 for undefined bits. The first eight coils are indicated by the first byte, and the coil with the smallest address is indicated by the least significant bit, and so on.

- Reading registers

Use the 0x03 command code to read M variables.

Request frame format: transaction meta identifier + protocol identifier + length + slave address + 0x03 + starting address of register + number of registers

No.	Definition of Data (Byte)	Number of Bytes	Note
1	Transaction meta identifier	2 bytes	Identifier of the Modbus request/response transaction
2	Protocol identifier	2 bytes	0 = Modbus protocol
3	Length	2 bytes	Number of following bytes
4	Slave address	1	Range: 1 to 247
5	0x03 (command code)	1	Read registers.
6	Head address of registers	2 bytes	Upper bits are followed by lower bits.
7	Number of registers (N)	2 bytes	Upper bits are followed by lower bits.

Response frame format: transaction meta identifier + protocol identifier + length + slave address + 0x03 + number of bytes + register value

No.	Definition of Data (Byte)	Number of Bytes	Note
1	Transaction meta identifier	2 bytes	Identifier of the Modbus request/response transaction
2	Protocol identifier	2 bytes	0 = Modbus protocol
3	Length	2 bytes	Number of following bytes
4	Slave address	1	Range: 1 to 247
5	0x03 (command code)	1	Read registers.
6	Number of bytes	1	Value: N*2
7	Register value	N x 2	One register value is indicated by two bytes. Upper bits are followed by lower bits. The register with a smaller address is indicated by the first byte.

- Writing a single coil

Use the 0x05 command code to write Q variables.

Request frame format: transaction meta identifier + protocol identifier + length + slave address + 0x05 + coil address + coil state

No.	Definition of Data (Byte)	Number of Bytes	Note
1	Transaction meta identifier	2 bytes	Identifier of the Modbus request/response transaction
2	Protocol identifier	2 bytes	0 = Modbus protocol
3	Length	2 bytes	Number of following bytes

No.	Definition of Data (Byte)	Number of Bytes	Note
4	Slave address	1	Range: 1 to 247
5	0x05 (command code)	1	Writes a single coil.
6	Address of the coil	2 bytes	Upper bits are followed by lower bits.
7	Coil status	2 bytes	Lower bits are followed by upper bits. A non-zero value is valid.

Response frame format: transaction meta identifier + protocol identifier + length + slave address + 0x05 + coil address + coil state

No.	Definition of Data (Byte)	Number of Bytes	Note
1	Transaction meta identifier	2 bytes	Identifier of the Modbus request/response transaction
2	Protocol identifier	2 bytes	0 = Modbus protocol
3	Length	2 bytes	Number of following bytes
4	Slave address	1	Range: 1 to 247
5	0x05 (command code)	1	Writes a single coil.
6	Address of the coil	2 bytes	Upper bits are followed by lower bits.
7	Coil status	2 bytes	Lower bits are followed by upper bits. A non-zero value is valid.

- Writes one register.

Use the 0x06 command code to write M variables.

Request frame format: transaction meta identifier + protocol identifier + length + slave address + 0x06 + register address + register value

No.	Definition of Data (Byte)	Number of Bytes	Note
1	Transaction meta identifier	2 bytes	Identifier of the Modbus request/response transaction
2	Protocol identifier	2 bytes	0 = Modbus protocol
3	Length	2 bytes	Number of following bytes
4	Slave address	1	Range: 1 to 247
5	0x06 (command code)	1	Writes a single register.
6	Register address	2 bytes	Upper bits are followed by lower bits.
7	Register value	2 bytes	Upper bits are followed by lower bits. A non-zero value is valid.

Response frame format: transaction meta identifier + protocol identifier + length + slave address + 0x06 + register address + register value

No.	Definition of Data (Byte)	Number of Bytes	Note
1	Transaction meta identifier	2 bytes	Identifier of the Modbus request/response transaction
2	Protocol identifier	2 bytes	0 = Modbus protocol
3	Length	2 bytes	Number of following bytes
4	Slave address	1	Range: 1 to 247
5	0x06 (command code)	1	Writes a single register.
6	Register address	2 bytes	Upper bits are followed by lower bits.
7	Register value	2 bytes	Upper bits are followed by lower bits. A non-zero value is valid.

- Writing multiple coils

Use the 0x0f command code to write multiple consecutive Q variables.

Request frame format: transaction meta identifier + protocol identifier + length + slave address + 0x0f + starting address of coil + number of coils + number of bytes + coil state

No.	Definition of Data (Byte)	Number of Bytes	Note
1	Transaction meta identifier	2 bytes	Identifier of the Modbus request/response transaction
2	Protocol identifier	2 bytes	0 = Modbus protocol
3	Length	2 bytes	Number of following bytes
4	Slave address	1	Range: 1 to 247
5	0x0f (command code)	1	Writes multiple single coils.
6	Head address of coils	2 bytes	Upper bits are followed by lower bits.
7	Number of coils (N)	2 bytes	Upper bits are followed by lower bits. The maximum is 1968.
8	Number of bytes	1	Value: [(N + 7) / 8]
9	Coil status	[(N + 7) / 8] bytes	Eight coils are indicated by one byte. If the last byte has less than eight bits, enter 0 for undefined bits. The first eight coils are indicated by the first byte, and the coil with the smallest address is indicated by the least significant bit.

Response frame format: transaction meta identifier + protocol identifier + length + slave address + 0x0f + head address of coils + number of coils

No.	Definition of Data (Byte)	Number of Bytes	Note
1	Transaction meta identifier	2 bytes	Identifier of the Modbus request/response transaction
2	Protocol identifier	2 bytes	0 = Modbus protocol
3	Length	2 bytes	Number of following bytes
4	Slave address	1	Range: 1 to 247
5	0x0f (command code)	1	Writes multiple single coils.
6	Head address of coils	2 bytes	Upper bits are followed by lower bits.
7	Number of coils	2 bytes	Upper bits are followed by lower bits.

- Writing multiple registers

Use the 0x10 command code to write multiple consecutive M variables.

Request frame format: transaction meta identifier + protocol identifier + length + slave address + 0x10 + starting address of register + number of registers + number of bytes + register value

No.	Definition of Data (Byte)	Number of Bytes	Note
1	Transaction meta identifier	2 bytes	Identifier of the Modbus request/response transaction
2	Protocol identifier	2 bytes	0 = Modbus protocol
3	Length	2 bytes	Number of following bytes
4	Slave address	1	Range: 1 to 247
5	0x10 (command code)	1	Writes multiple registers.
6	Head address of registers	2 bytes	Upper bits are followed by lower bits.
7	Number of Registers	2 bytes	Upper bits are followed by lower bits.
8	Number of bytes	1	Value: N*2
9	Register value	N*2 (N*4) bytes	-

Response frame format: transaction meta identifier + protocol identifier + length + slave address + 0x10 + register address + register value

No.	Definition of Data (Byte)	Number of Bytes	Note
1	Transaction meta identifier	2 bytes	Identifier of the Modbus request/response transaction
2	Protocol identifier	2 bytes	0 = Modbus protocol
3	Length	2 bytes	Number of following bytes

No.	Definition of Data (Byte)	Number of Bytes	Note
4	Slave address	1	Range: 1 to 247
5	0x10 (command code)	1	Writes multiple registers.
6	Head address of registers	2 bytes	Upper bits are followed by lower bits.
7	Register value	2 bytes	Upper bits are followed by lower bits.

10.6.4.1.7 Common Modbus TCP Faults

The main faults that occur when a Modbus TCP master connects to a Modbus TCP slave are as follows:

- The Modbus TCP master fails to establish communication with the Modbus TCP slave due to incorrect IP configuration.
- The Modbus TCP master accesses an illegal address on the Modbus TCP slave, resulting in a faulty response.
- The Modbus TCP master attempts to write to a register on the Modbus TCP slave, but the register only supports read operations, causing the master to receive a fault response from the slave.

Fault response frame format

Fault response frame format: transaction meta identifier + protocol identifier + length + slave address + (command code+0x80) + fault code + CRC check

This fault frame applies to all operation command frames.

No.	Definition of Data (Byte)	Number of Bytes	Note
1	Transaction meta identifier	2 bytes	Identifier of the Modbus request/response transaction
2	Protocol identifier	2 bytes	0 = Modbus protocol
3	Length	2 bytes	Number of following bytes
4	Slave address	1	Value range: 1 to 247
5	Command code + 0x80	1	Fault command code
6	Fault code	1	1 to 4
7	CRC code	2 bytes	Lower bits are followed by higher bits.

Fault code list

Fault Code	Description	Cause	Solution
0x9E360000	Fault recovery	-	Channel fault has been recovered.

Fault Code	Description	Cause	Solution
0x9E360072	Illegal data address	The accessed peer data address does not exist or is out of bounds.	Check if the data access address or data length exceeds limits.
0x9E360074	Unsupported command code	The accessed peer command code is not supported.	Check if the slave supports the command code requested by the master.
0x9E360075	Receiving timeout	• The communication link is faulty. • The peer device is not operational.	1. Check if the master IP address or port is configured correctly. 2. Check if the Modbus TCP network of the peer device is working properly. 3. Check if the Modbus TCP of the peer device has started normally. 4. Optimize the wiring by eliminating potential interference sources.
0x9E360076	Illegal data value	The data value is illegal.	Check if the response data from the peer slave is faulty.
0x9E360077	Buffer overflow	Buffer overflow	Check if the number of requested coils or registers exceeds the maximum supported by Modbus TCP.
0x9E360078	Frame fault	The data frame is faulty.	Check if the length of the response data frame of the peer slave or the data frame itself is faulty.

Fault Code	Description	Cause	Solution
0x9E36009A	Modbus TCP cannot connect to the device.	Modbus TCP link is faulty.	1. Check if the master IP address or port is configured correctly. 2. Check if the network of the peer device can work normally. 3. Check whether the wiring is disconnected. 4. Optimize the wiring by eliminating potential interference sources.
0x9E35009B	Modbus TCP master IP address declaration failed	EtherNet port IP address does not match the device network port IP address.	Check if the EtherNet port IP address is set correctly.
0x9E3E009B	Modbus TCP slave IP address declaration failed	EtherNet port IP address does not match the device network port IP address.	Check if the EtherNet port IP address is set correctly.
0x9E36009C	Modbus TCP slave port occupied	The slave started on the PC occupies the Modbus TCP port configured by iFA Evolution.	Close the slave started on the PC to release the occupied port.

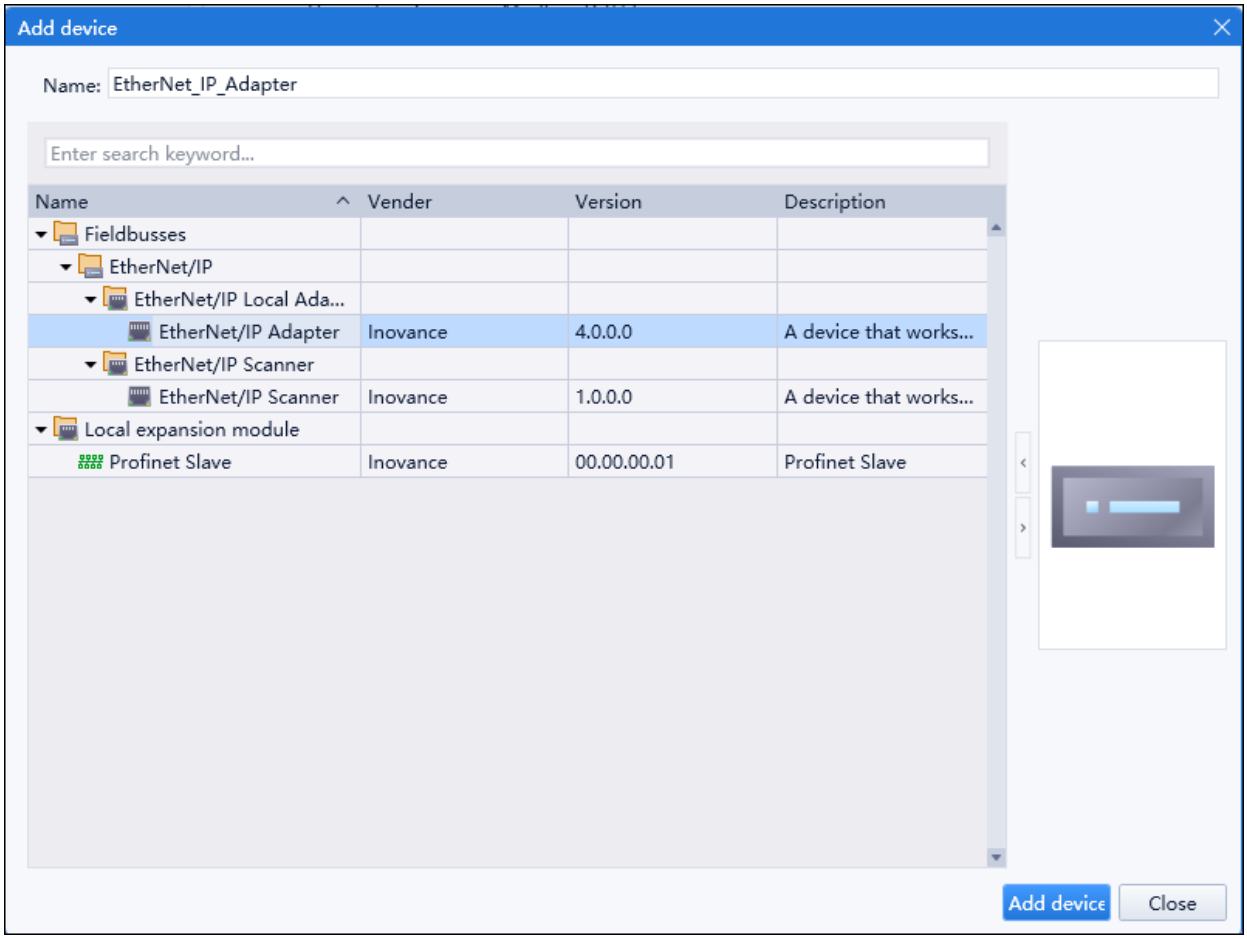
10.6.4.2 EtherNet/IP Device Configuration

10.6.4.2.1 Adding an EtherNet/IP Device

Adding an adapter

The adapter acts as the target end device.

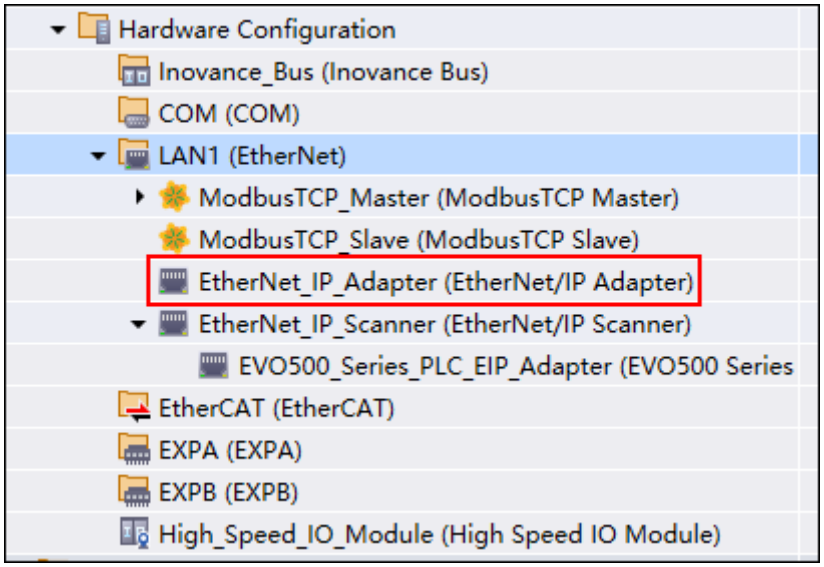
Prerequisites



The selected device supports EIP communication.

Procedure

1. Click "Hardware configuration" in the project tree on the left.



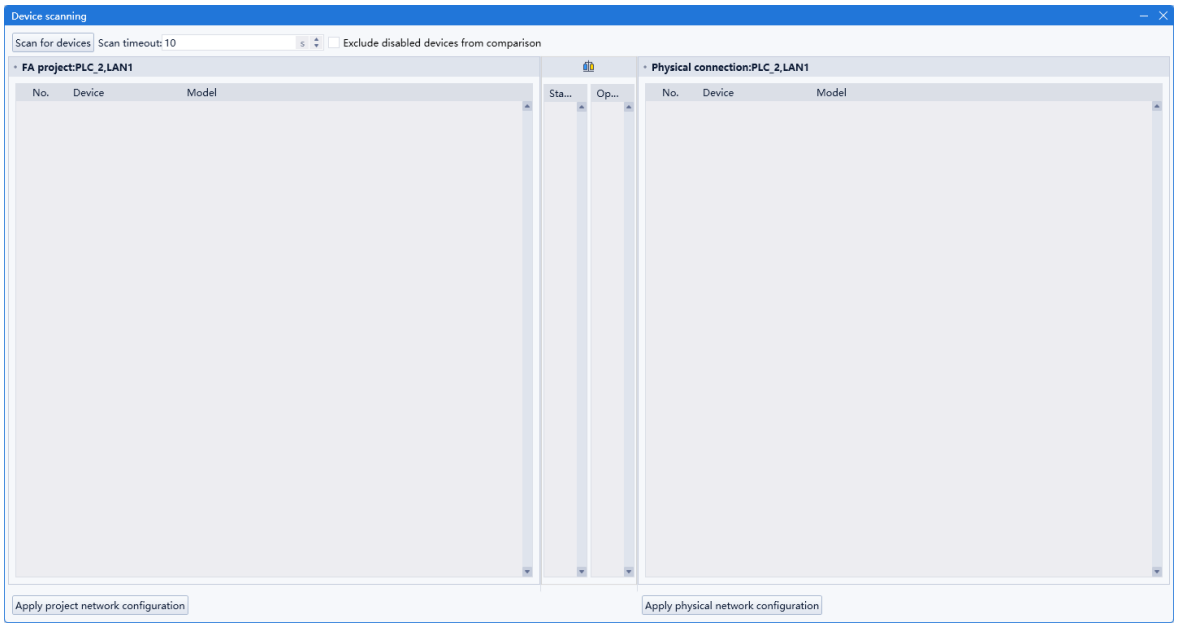
2. Right-click "LAN1(EtherNet)" or "LAN1_EVO800_CM_EN(EtherNet)", and select "Add device".

3. Double-click "EtherNet/IP Adapter", or select it and click "Add device" to add the adapter.

Result

The added adapter is displayed under "Hardware configuration".

Adding a scanner



The scanner acts as the originator device.

Prerequisites

The selected device supports EIP communication.

Procedure

1. Click "Hardware configuration" in the project tree on the left.
2. Right-click "LAN1(EtherNet)" or "LAN1_EVO800_CM_EN(EtherNet)", and select "Add device".
3. Double-click "EtherNet/IP Scanner", or select it and click "Add device" to add the scanner.
4. Add a remote adapter.
   - Adding offline
     Right-click the "EtherNet/IP_Scanner" node and select "Add device", then double-click the target device (such as EVO500) in the pop-up window.
   - Adding online
     Right-click the "EtherNet/IP_Scanner" node and select "Scan for devices".

   - Scan timeout: The default scan timeout time is 10 seconds, with a range of 5 to 300. Within this time, scanned devices will be displayed in the right list.
   - Ignore disabled device comparison: If checked, disabled devices do not participate in the comparison. However, they are included in the comparison operation during device copying. If device comparison is successful, the device configuration is retained; otherwise, the device is deleted. The disabled status of devices is adjusted based on their actual status in the configuration list. For example, if a device in the physical device list is successfully compared, its disabled status is enabled. However, if the originally disabled device exists in the project configuration device list, the disabled status remains upon successful comparison.
   - Status: Compares the data between the project and physical devices.
   - Action: Copies scanned devices from the network to the project network.
   - Apply project network configuration: Applies the configuration of the devices in the project network to the project.
   - Apply physical network configuration: Applies the configuration of all scanned devices to the project.

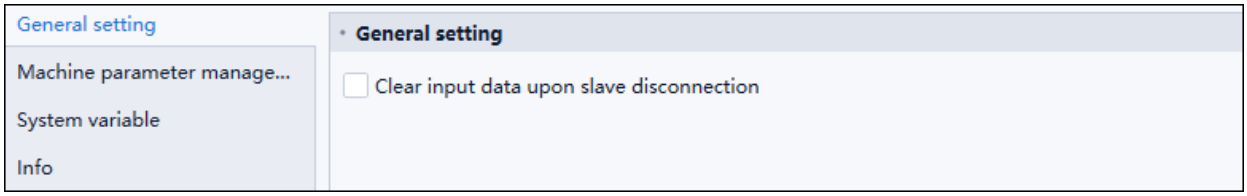
   Select target devices as needed and apply them to the project.

   A remote adapter refers to a remote target end device, which can only be added after it is added to iFA by installing the EDS file. For details, see 8.15 Device Library Usage.

Result

The added scanner and remote adapter are displayed under "Hardware configuration".

10.6.4.2.2 EtherNet_IP_Scanner Configuration



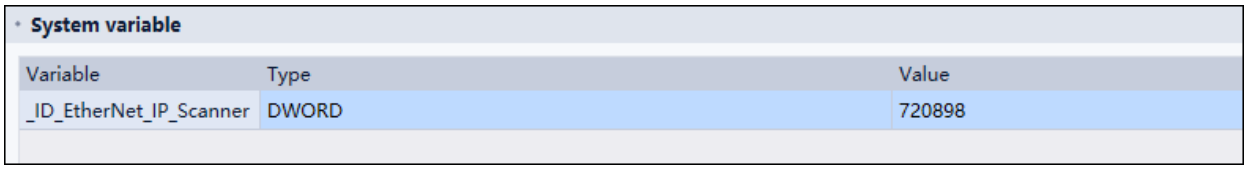
10.6.4.2.2.1 Scanner Settings

Prerequisites

A scanner device has been added.

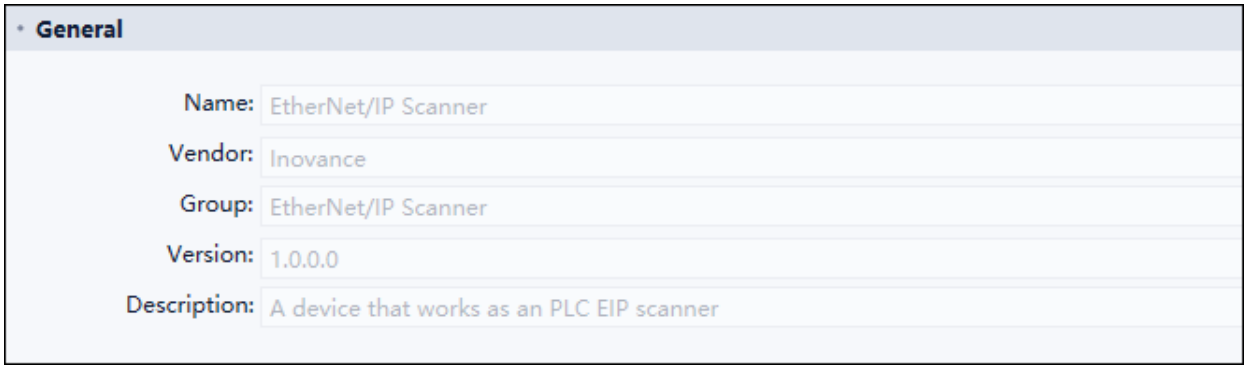
Procedure

Double-click the added scanner node in the project tree to open the configuration interface.



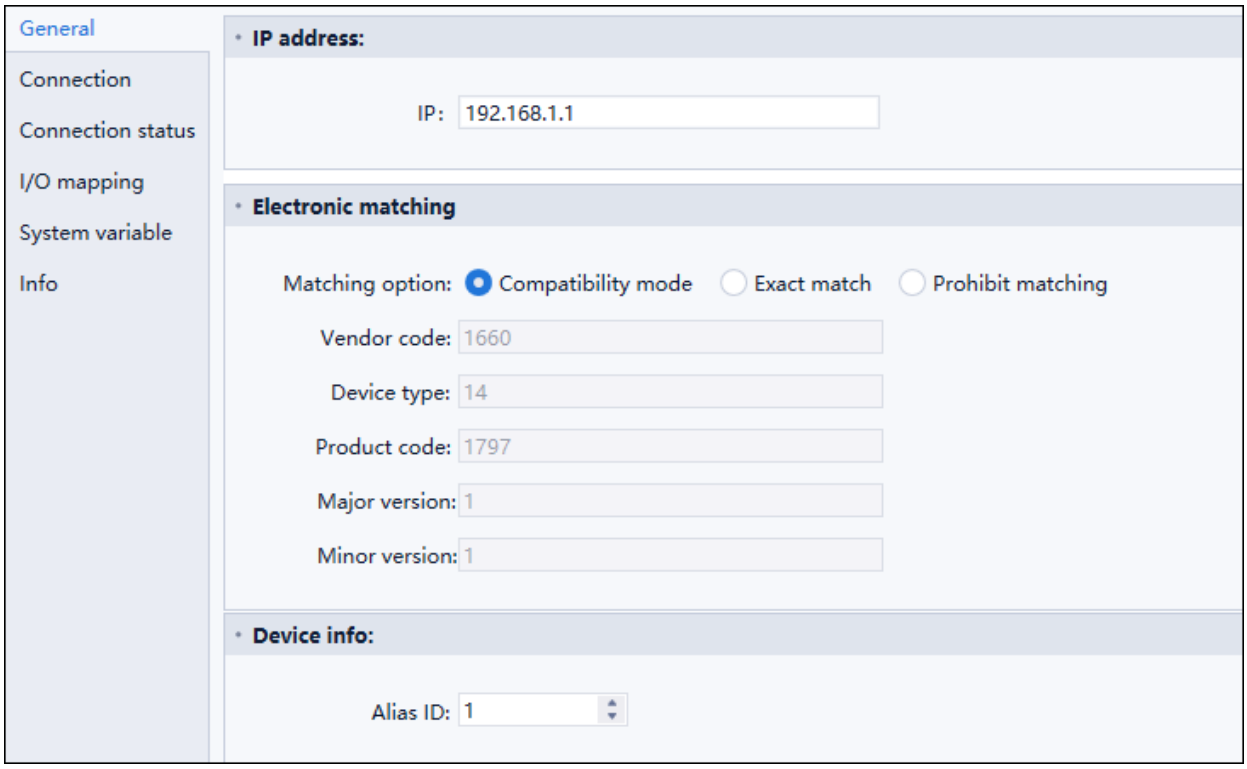
General settings

Clear input data when slave line is disconnected: By default not selected. When selected, if any slave device loses communication, its corresponding input data area will be cleared.



System Variables

Displays the device ID value of the scanner.



Information

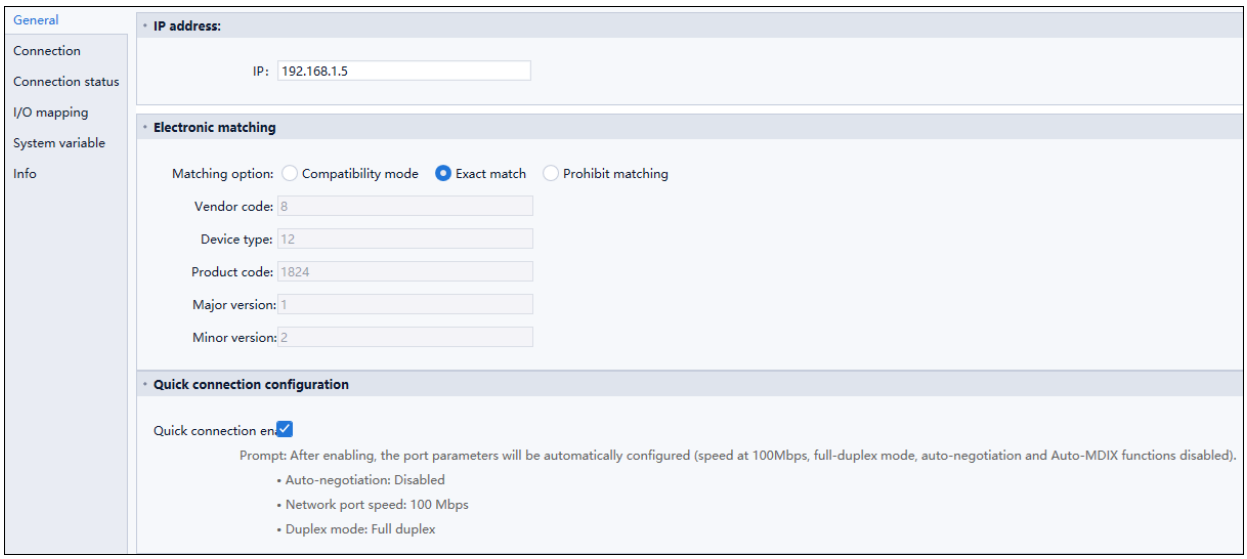
Displays basic information of the scanner, including name, vendor, group, version, and description.

10.6.4.2.2.2 General Settings of Remote Adapters

Double-click the remote adapter node added under **EtherNet_IP_Scanner** to open the general settings interface.

- IP address
  Enter the IP address of the local adapter, which is the IP address of the PLC it belongs to.
- Electronic matching
  This function is used to reduce the risks of misusing devices in control systems. It can compare the devices defined in the project with the installed devices. If the match fails, a fault will occur.
  The following properties are compared.
  Vendor code: The code of the device manufacturer
  Device type: A numeric code
  Product code: A specific product type
  Major version: A number representing the device's major functions
  Minor version: A number representing device's updates
  - Compatibility mode: Conditional matching. Communication can only be established if the version number of the installed device is the same as or higher than that of the defined device, with the following prerequisites:
    The "Vendor code", "Device type", and "Product code" of the installed device are exactly the same as

those of the defined device.
If the major versions are the same, the minor version of the installed device must be the same as or higher than that of the defined device.



- Exact match: Complete matching. Communication can only be established if all electronic matching information is completely consistent.
- Prohibit matching: Ignores electronic matching information and establishes communication directly.

> **WARNING**
>
> The "Prohibit matching" option should be used with particular caution. Improper use of this option can lead to personal injury, property damage, or economic loss.
> It is strongly recommended not to check the use "Prohibit matching" option.

- Device info
  Set the alias ID of the remote adapter, used to configure the IP address of the remote adapter via instructions.
- Quick connection configuration (EVO700, EVO700C, EVO800, APC760C)
  When the remote adapter device supports the quick connection feature compliant with the ODVA specification, the adapter device can power on, connect to the EtherNet/IP Scanner, and start I/O data exchange within less than 500 ms.

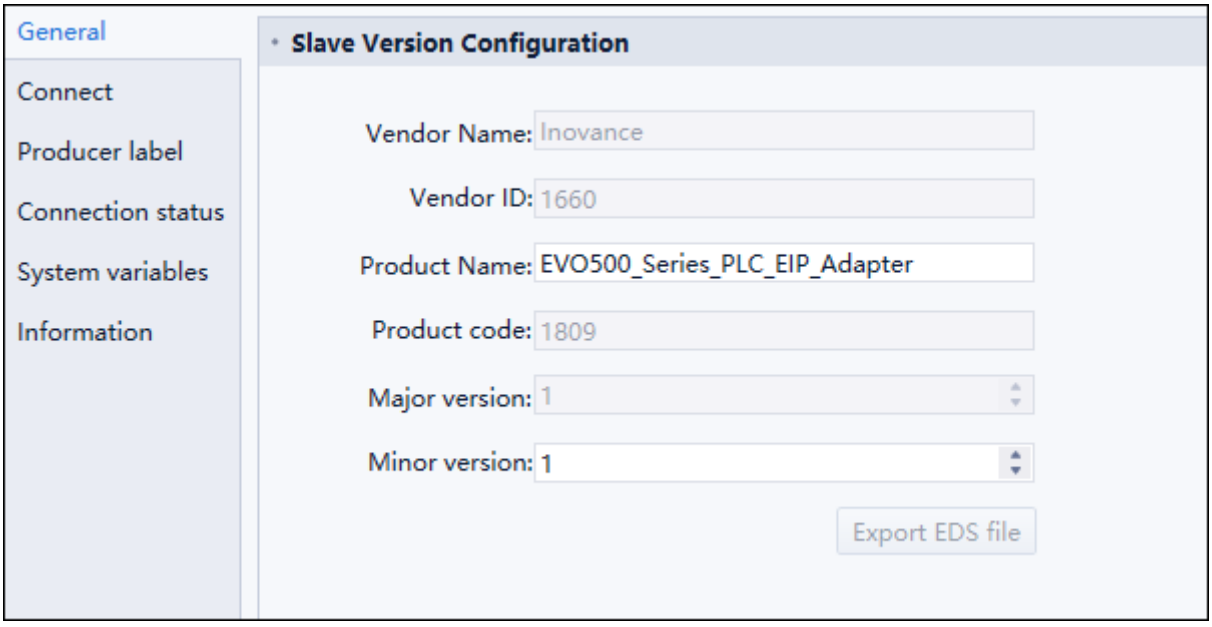
  iFA software can automatically detect and display whether the adapter device supports quick connection. Enabling this feature activates the related configuration options of the PLC, allowing the PLC to quickly connect to adapter slaves and exchange I/O data at the software level.

> **CAUTION**
>
> Enabling quick connection will disable address conflict detection on the network port by default. Potential address conflict detection issues may not be prompted or handled. When no quick connection device is enabled on this port, the address conflict detection function will be automatically reactivated.

NOTE

- The quick connection function is currently not supported by third-party remote adapter devices. For such devices, refer to their user guides to enable quick connection.
- The quick connection function only modifies the PLC at the software level to meet the requirements for quick connection. Additionally, the network port configuration connected to the quick connection device must be adjusted to reduce negotiation time. If the quick connection device is directly connected to the PLC, refer to 10.11.22 Network Port Configuration for modifications; if the quick connection device is connected to the PLC through a switch, modify the corresponding switch port configuration. The following network port settings must be applied:
  - Speed: 100 Mbps.
  - Duplex mode: Full duplex.
  - Auto-negotiation: Disabled.
  - Auto wiring sequence: Disabled.

10.6.4.2.2.3 I/O Mapping



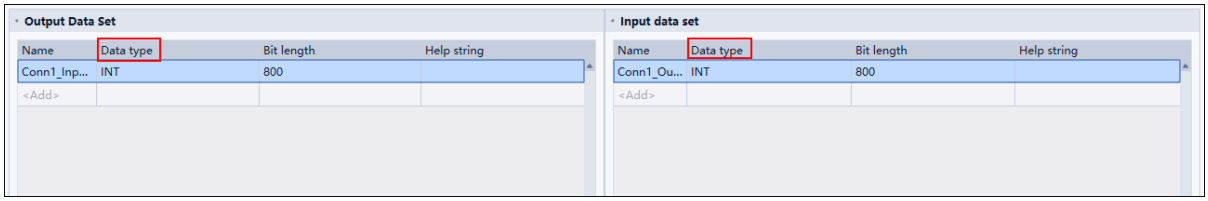
Refer to the 10.6.4.2.3.2 I/O Mapping configuration of the local adapter.

10.6.4.2.3 EtherNet_IP_Adapter Configuration

Configure this machine as the target device.

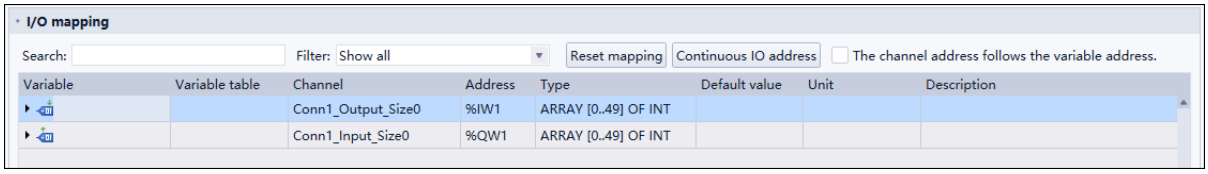
10.6.4.2.3.1 General Settings of Local Adapters

Double-click the added adapter in the project tree to open the adapter configuration interface.



Product name: Supports renaming. When exporting the EDS file, the new name is recorded.

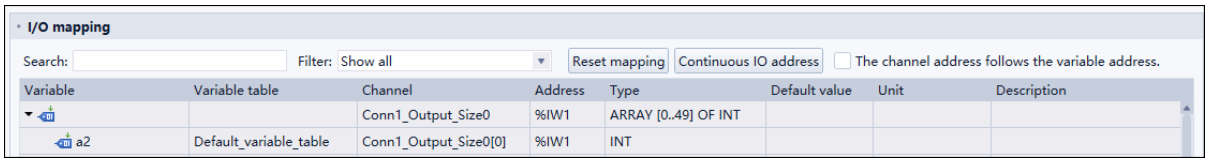
Minor version: When the physical device version is upgraded, this is used to manually adjust the records in the EDS file to align the physical device with the file content.



Export EDS file: Exports the current device configuration as an EDS file, which ensures consistency of information when used on the scanner end.

10.6.4.2.3.2 I/O Mapping

1. After configuring the connection information, especially the T->O size and O->T size, configure the data type to be transmitted in the "Connect" tab.

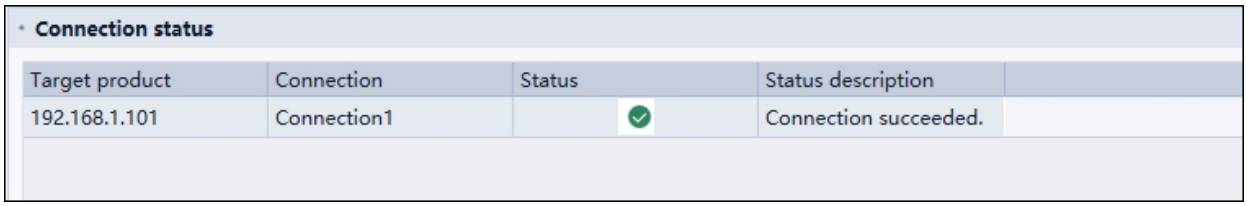


2. The configured variable information is displayed in the "I/O mapping" tab. The channel information corresponds to the established variable information, and a default address has been assigned, which can be modified.

3. The search function can be used to conveniently and quickly find variables. Filtering can be applied for partial display.

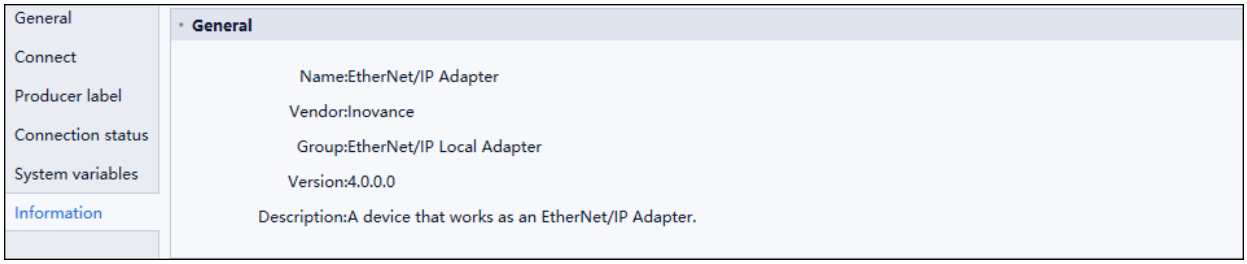
4. Click "Continuous IO address" to reassign the addresses of the variables to consecutive I/O addresses.

5. Create a mapping relationship. When creating a mapping, pay attention to the read/write permissions of the variables and ensure they match the variable addresses. I area addresses are used for input, and Q area addresses are used for output. If the relationship is incorrect, a compilation fault will be reported.



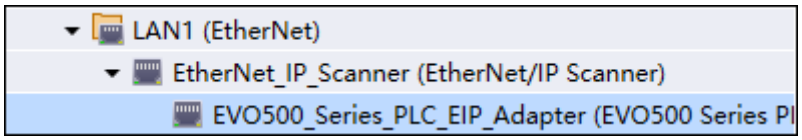
6. The "Reset mapping" button can quickly reset the entire variable mapping table.

7. The "Channel address follows variable address" option can be used to configure the allocation of I/O mapping addresses.
   - If it is not checked, the I/O mapping channel address is fixed. After binding a variable to the channel, the channel address is assigned to the variable.
   - If it is checked, binding is allowed only if the channel byte size matches the bound variable's byte size. After binding, the I/O mapping channel address is deleted, and the channel address follows the variable address.



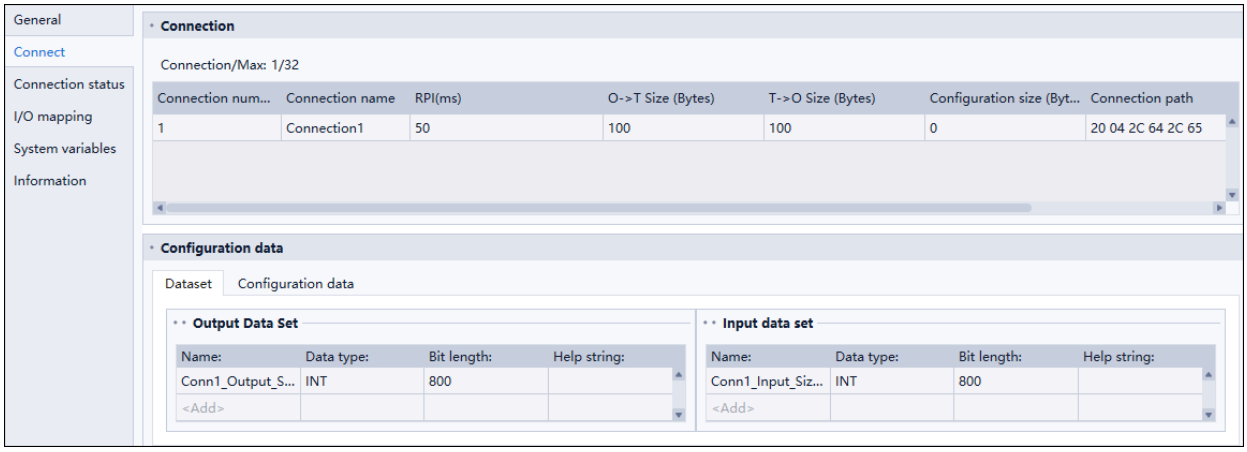
10.6.4.2.3.3 Connection Status

After switching the device to online, it starts listening for client connections. Once a client is connected, the relevant information can be viewed in the "Connection status" tab.



10.6.4.2.3.4 Information

This tab displays the following information for the current module: name, vendor, group, type, ID, version, description, and so on.



10.6.4.2.4 Connection Configuration (Class1)

Configuring the remote adapter under scanner

When adding an EtherNet/IP remote adapter, a connection path is generated by default, as shown in the figure below.

- Connection

  The "Connection" tab is used to configure connection parameters and count the total number of connections.

  - Connection parameter configuration

    Double-click a connection row to open the parameter configuration window.

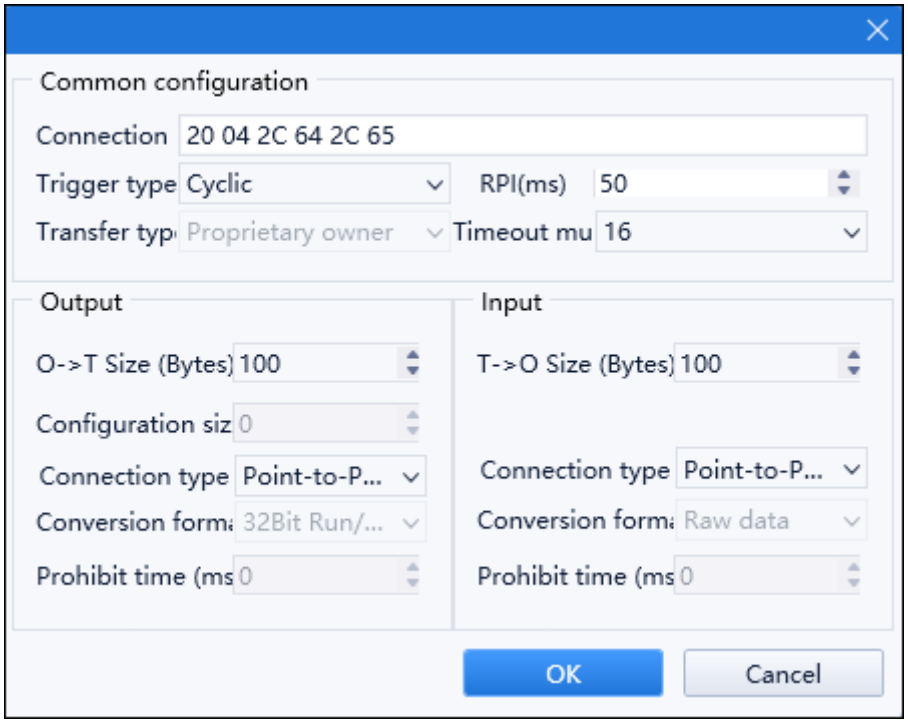


Table10-6-4-2-4-1 Connection configuration table

Category	Parameter	Note
Connection path	Composite configuration - Instance ID	Supports integers, with a range of 0 to 9999. Applicable to Generic_EtherNetIP_device devices.
	Composite consumption (O-->T) - Connection point	Consistent with the ID in the target settings, applicable to Generic_EtherNetIP_device devices.
	Composite production (T-->O) - Connection point	Consistent with the ID in the target settings, applicable to Generic_EtherNetIP_device devices.
General configuration	Connection path	Usually automatically calculated by the software, typically no need to change.
	Trigger type	Cyclic: Sends data according to the RPI cycle. State change: Triggers an immediate sending when data values change during each PLC scan cycle.
	RPI (ms)	Indicates the requested packet interval. The RPI of each node can be set independently without affecting each other.
	Transfer type	Proprietary Owner: Sets both the data transmission from the originator (O) to the target (T) and the data reception from the target (T) to the originator (O). Input only: Sets only the data reception from the target (T) to the originator (O). Listen only: Listens to multicast data without providing configuration or scheduling information for EtherNet/IP devices. Note: "O" refers to the originator and "T" refers to the target.

Category	Parameter	Note
	Timeout multiplier	If data is not received for multiple consecutive RPI cycles, communication is considered to have timed out. The timeout time is equal to the RPI multiplied by the timeout multiplier.
Output/Input	O->T size/T->O size	Displays byte size, which is automatically calculated based on data type and can be adjusted manually. The total number of bytes is constrained by the device's EDS file.
	Configuration size	Indicates the byte size of configuration data. The total number of bytes is constrained by the device's EDS file.
	Connection type	Multicast: Data is produced simultaneously to multiple consumers. Point-to-point: Data is produced individually to one consumer.
	Conversion format	Reads the content of the device's EDS file.
	Prohibit time (ms)	Configurable when "Trigger type" is set to "Upon status change". Indicates the minimum cycle for data refresh, must not be greater than the RPI value. The value ranges from 0 ms (the prohibit time is not effective) to 255 ms.

  - Connection count
    The connections consist of the connection rows (Class1 type) added under the corresponding network port, such as LAN1 (Ethernet), and the service message labels (Class3 type).
    The total number of connections is not fixed and depends on the PLC model. The EVO523 series PLC supports 32 connections.
    Right-click the blank space and select "Create connection" to add a new connection.

- Configuration data
  - Data set
    A connection will automatically generate corresponding input/output data sets. Users can manually configure the data sets, including changing names, data types, and adding or deleting data sets. These changes will be synchronized in real-time to the "I/O mapping" tab.
    The maximum total byte size of input and output data sets is 1444 bytes.
  - Configuration data
    The configuration data depends on the EDS file of the device. For example, the Generic_EtherNetIP_device supports adding configuration data, with a maximum total byte size of 1444 bytes.

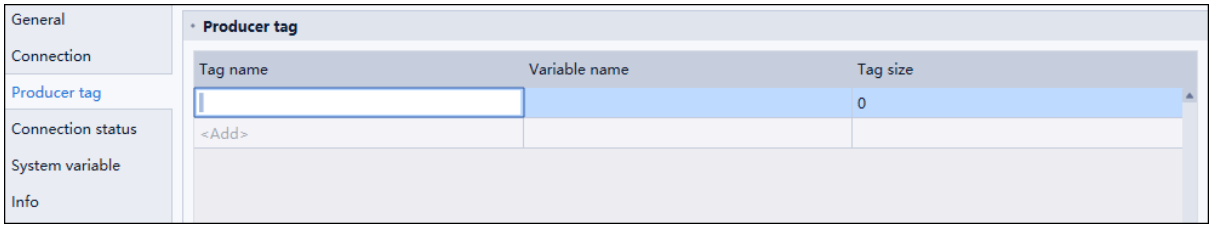
Configuring local adapter

In the "Connection" tab, create a connection.

You can modify the size and name of the input and output data sets, and these changes will be synchronized in real-time to the "I/O mapping" tab.

10.6.4.2.5 Communication Between Producer and Consumer Labels

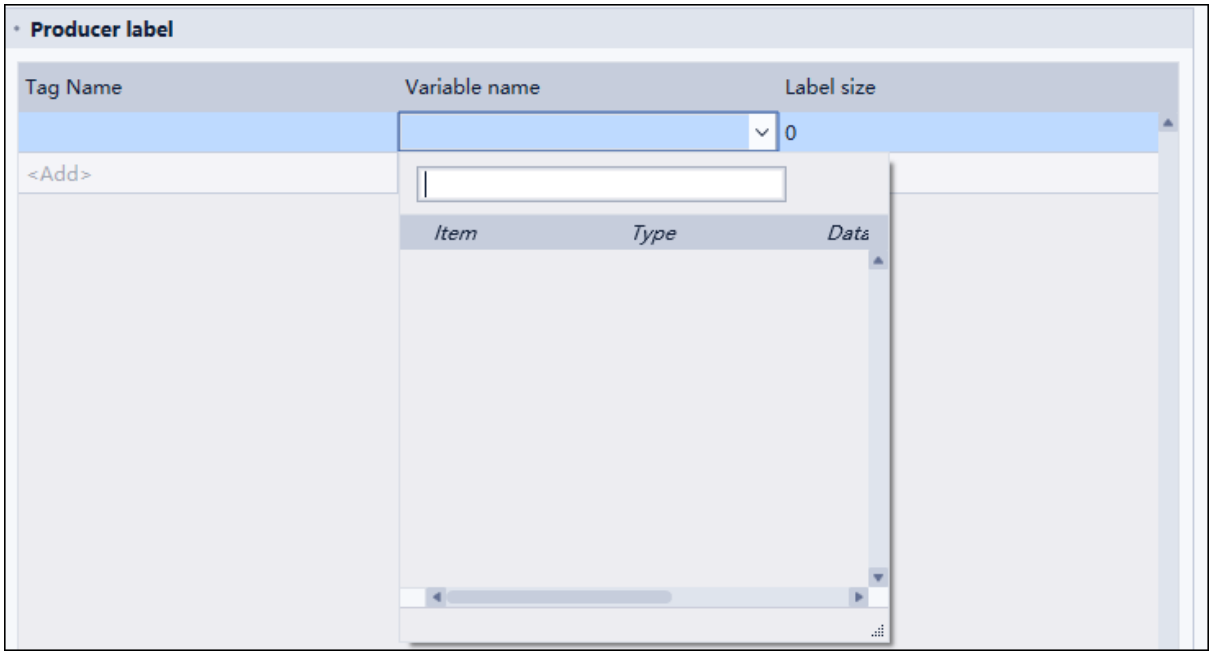
The definitions of producer and consumer labels are as follows:



Label Type	Description
Producer label	A label provided by one controller for use by other controllers. Multiple controllers can consume (receive) data simultaneously. Without using logic, a producer label can send its data to one or more consumer labels (consumers). The producer label sends data according to the RPI of the consumer label.
Consumer label	A label that receives data from a producer label. The data type of the consumer label must match that of the producer label, including any array dimensions. The RPI of the consumer label determines the data update cycle.

Communication between producer and consumer labels requires configuration on both the local adapter and the remote adapter, and the content and order of the configurations must be exactly the same.

Configuring producer labels



To configure producer labels in the local adapter, follow these steps:

1. Create a label.
   Click "<Add>" in the "Producer tag" tab to create a communication tag.

2. Associate variables with the label.

   Double-click a cell in the "Variable name" column to make it selectable.

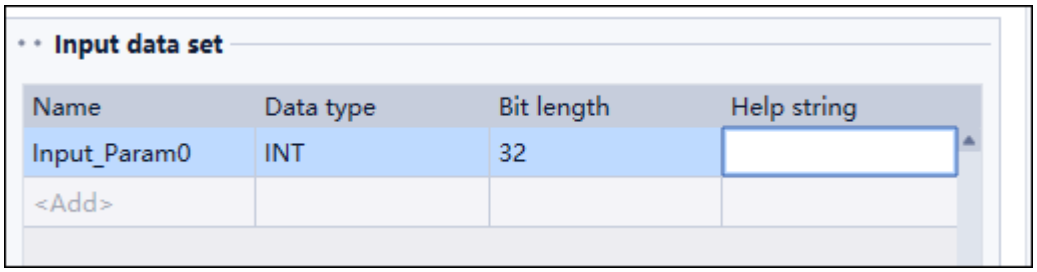
   Select the target variable from the drop-down menu to complete the association.

   The variables added here must meet the following requirements:

   - 10.1.1.8.1 Standard data types, structures, and unions are supported.
   - The network public property supports **read-only** or **read-write**.
   - Constants, function blocks, and their members are not supported.
   - Variables in SYS_VAR(Global) are not supported.
   - Temporary variables are not supported.

   Label name: Supports modification. It requires a combination of letters, numbers, and underscore characters, with a maximum length of 128 characters. When the new name duplicates an existing label name, a "_1" suffix will be automatically added to avoid renaming.

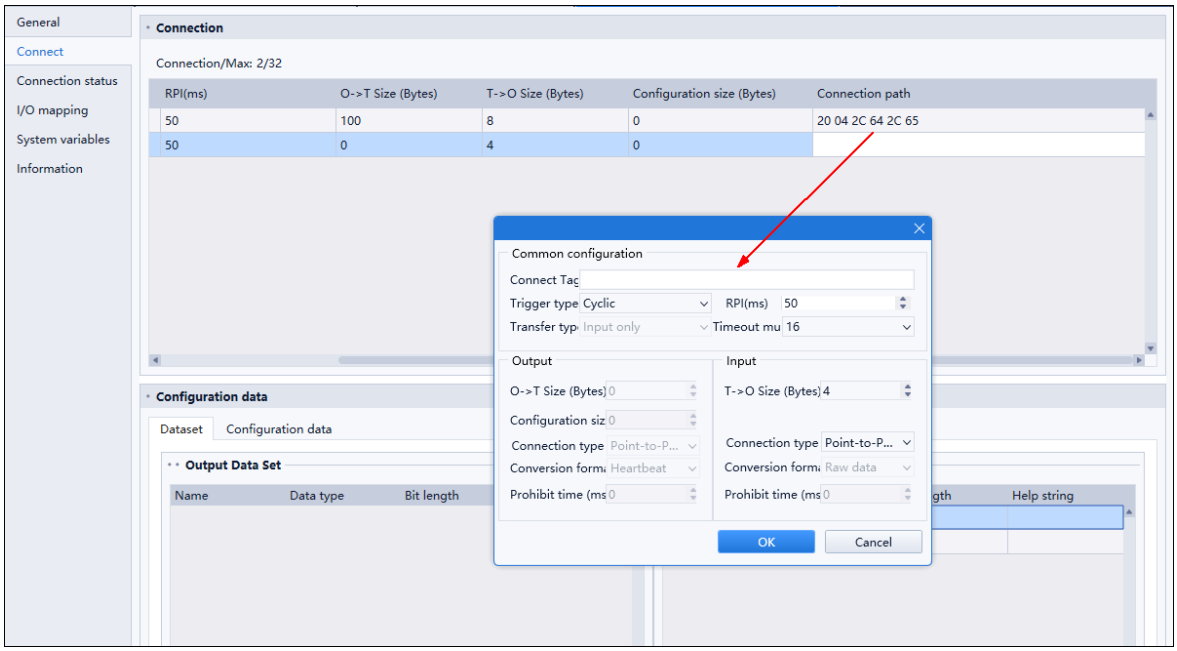
Configuring consumer labels



To configure consumer labels in the remote adapter, follow these steps:

1. Create a label.

   In the "Connection" tab, right-click the blank area and select "Create tag connection".



This will simultaneously generate a corresponding data row in the **input dataset area** of the current tab and a corresponding mapping row in the "I/O mapping" tab.

2. Set label information.
   - Connection

     Double-click the connection row to open the modification window.

     The "Connection path" in the connection row and the "Connection label" in the modification window are the same. Enter the label name of the producer label here.

     For other parameters, see the connection configuration table on the Connection Configuration (Class1) page.

   - Input dataset area

     Configure the name and data type of the label in the input dataset area, ensuring they match the content in the producer label exactly.

     Help string is used for remarks and does not participate in communication.

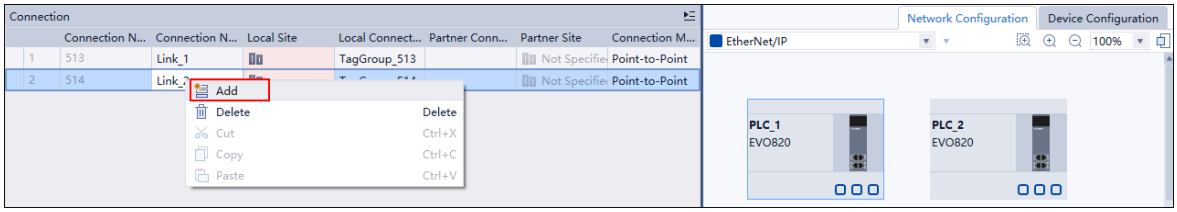
     These changes will be synchronized in real-time to the "I/O mapping" tab.

3. Associate variables in I/O mapping.

Double-click the cell containing the icon , click to open the input assistant, and select the variable to complete the association.

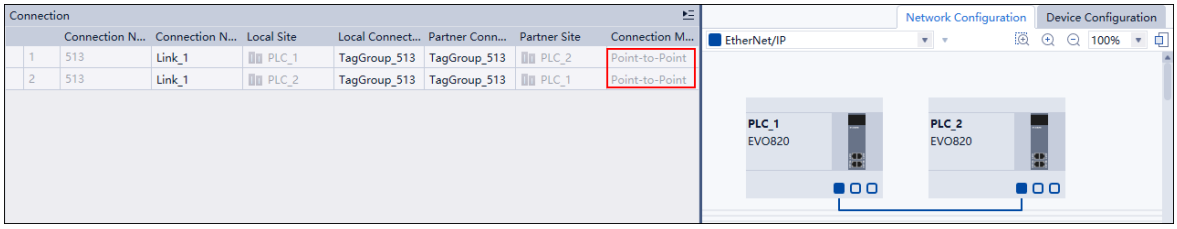
The network public property of the associated variables is not restricted.

With the above steps, the configuration for communication between producer and consumer labels is complete.



10.6.4.2.6 Communication Between PLCs

Multiple sets of PLC devices configured in the iFA Evolution software can communicate with each other via Ethernet, backplate, and other methods. The following uses the EVO800 series PLC as an example.



Configuring Ethernet communication

When communicating via Ethernet, the selected devices must support EIP communication.

1. Establish a connection.
   - Right-clicking creation
     Right-click in the connection table in the network configuration view, and select "Add" to create an unspecified connection channel and set the data communication method.

   - Drag-and-drop creation
     In the network configuration view, drag and drop to connect the CPU ports/Ethernet expansion module ports between devices. Since multicast is unidirectional one-to-many communication with one data sender and multiple data receivers, it does not support drag-and-drop creation. The connection type automatically generated by dragging is point-to-point. After a connection is created, it cannot be modified. If created incorrectly, it needs to be deleted and recreated.

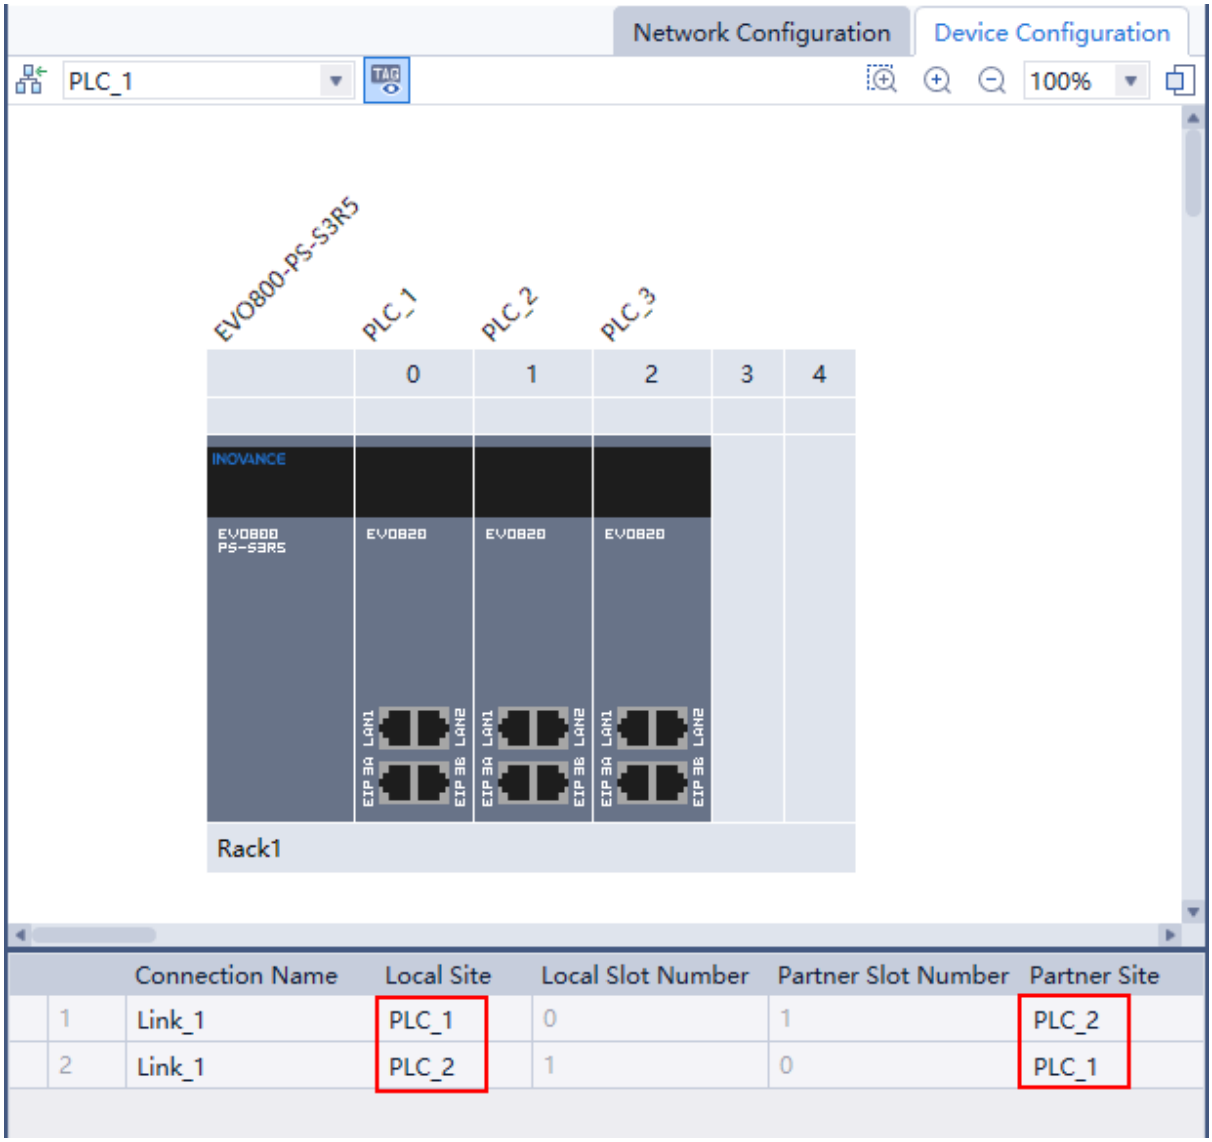
     After a connection is established through right-clicking or dragging, all generated connections are displayed in the same table. If both communication parties are included in iFA, the table displays two connections, each pointing from one end to the other, with the connection method defaulting to "point-to-point" and not supporting modification. If the communication partner is not included in iFA, the table displays only one connection, and the connection method supports selecting "point-to-point" or "multicast".

     For scenarios where both communication parties are included in iFA, the connection ID is automatically generated. If the partner is "unspecified", the ID is automatically generated but allows manual modification. This ID is used to identify the connection, including identifying point-to-point and multicast. The data sender generates the ID, and the data receiver initiates a connection request based on this ID to establish the ID and confirm the identity of the connection partner. The columns in the connection table is shown below.

2. After a connection is successfully created, click the connection to view or modify the relevant information in the "General" tab at the bottom of the interface.
   The refresh time only applies to the data receiver, and each data provider associated with a connection ID does not need to set a refresh time. The connection is automatically activated when the CPU/Ethernet expansion module has multiple interfaces, such as multiple Ethernet interfaces. The "Interface" entry supports drop-down selection, with the default interface being the one used to create the connection. When the CPU/Ethernet expansion module has only one interface for communication, the "Interface" entry is grayed out.

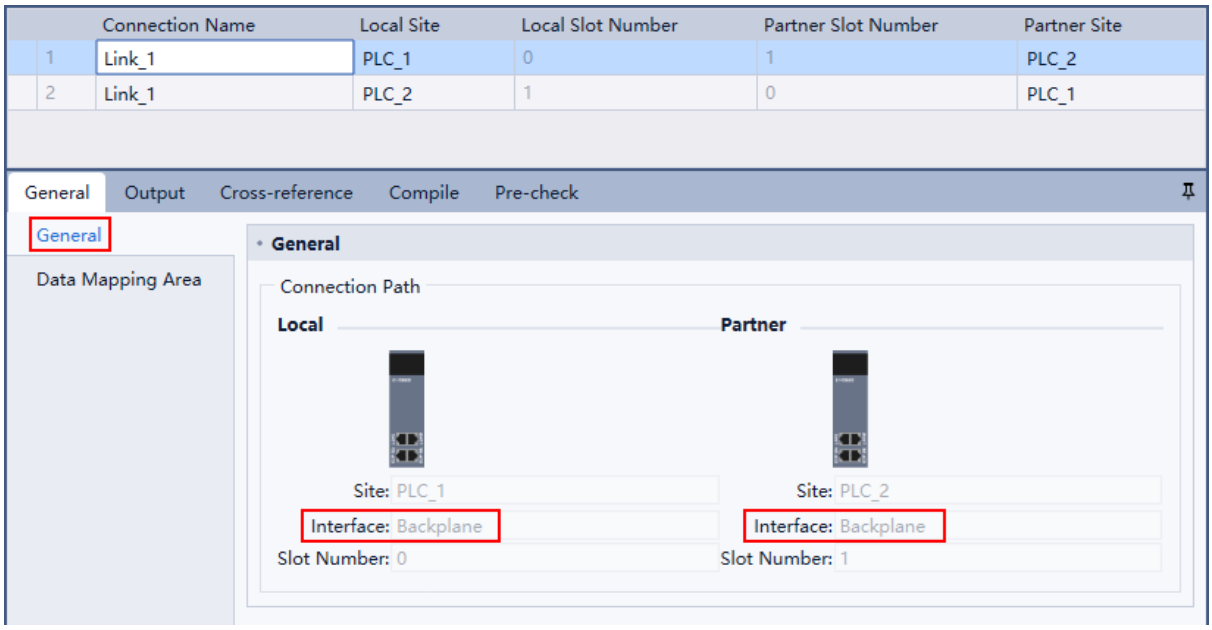
3. In the "Data mapping area" tab, set the total size of data interaction required by both communication parties (number of bytes sent/received). For Ethernet communication, the maximum communication data volume per direction for a single connection is 1444 bytes. Configure the data mapping relationship between the parties through binding variables. For point-to-point communication where both parties are within iFA, the schematic diagram is as follows:

   - Each transmission area can be assigned a name, which has no direct association with PLC variables and serves as an explanation for the transmission area on the local PLC side.
   - Variables: Users can select a PLC variable by dragging or mouse selection. The variable must be network-public with a fixed length, or at least readable for output variables and writable for input variables, otherwise it cannot be dragged or selected.
     - In the detailed view, select one or more variables and add them to the data mapping area by dragging and dropping.
     - In the variable table, select one or more variables to copy and paste into the data mapping area.
   - Offset: Automatically calculates the offset of each variable's data area relative to the starting position in the entire transmission area (byte stream).
   - Length: iFA automatically calculates and displays the total data length of the selected variables for user reference.
   - Communication direction: Click to switch the direction, which indicates the direction of data transmission.

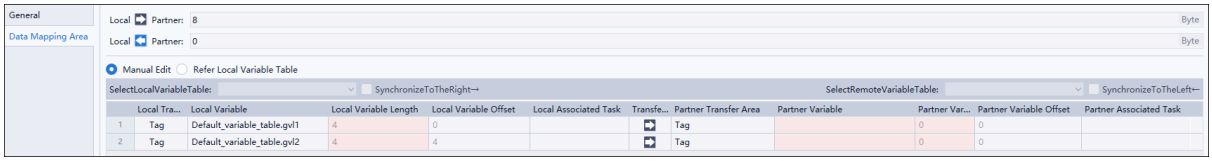


Configuring backplate communication

After configuring the EVO800 series multi-machine (single rack multi-CPU) mode, multiple CPUs within a single rack support communication via the backplate.



1. In the connection table area below the device view, right-click and select "Add" to create a new connection.



2. In the created connections, select the communication partner through the drop-down lists of the local site and partner site columns. Since the communication partner in this scenario is the same rack CPU, the local sites and partner sites in both connections correspond to each other.

3. After the connection settings, click the connection to view the detailed information about the connection in the "General" tab below, where the interface type is backplate.

4. In the "Data mapping area" tab, configure the data mapping relationship between the communication parties by binding variables. Click the cell in the "Transfer direction" column to switch the data transfer direction.

Associated tasks: Select variables from the drop-down list to bind the variables with the tasks created in the PLC. No variable is bound by default. When a task is bound locally, the partner must also bind a task, otherwise a fault will occur.

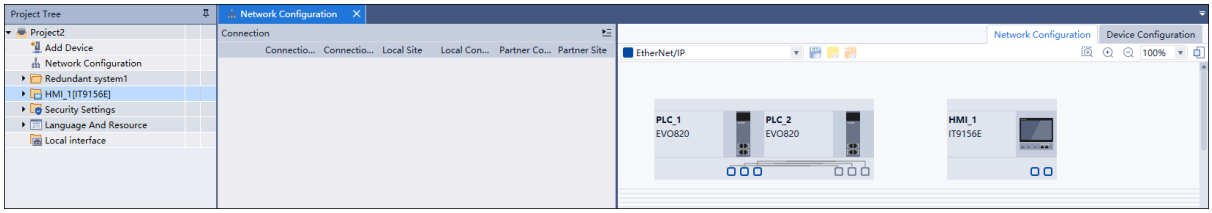
10.6.4.2.7 Communication with HMI

The PLC devices configured in the iFA Evolution software support communication with other devices (such as HMIs) via the EtherNet/IP protocol.

The software supports communication configuration for the following two scenarios:

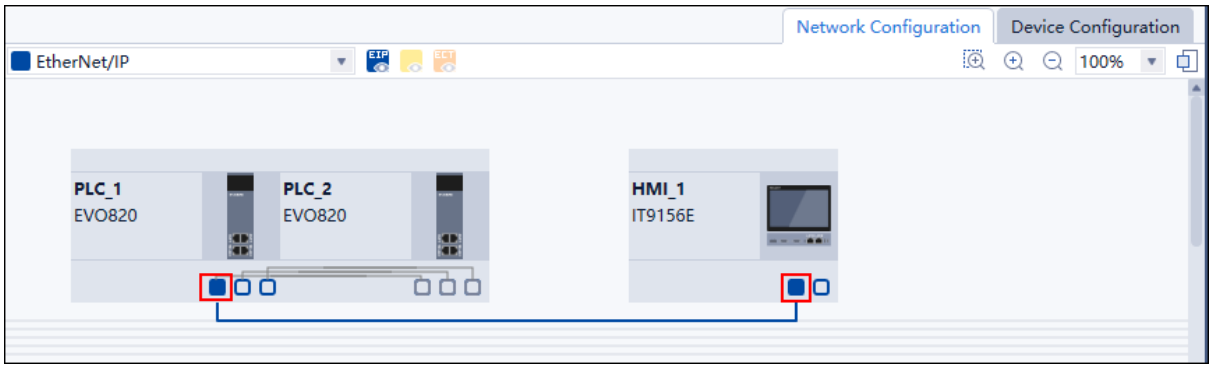
- PLC and HMI are in the same project.
- PLC and HMI are in different projects.

This section uses the communication connection between the LAN1 port of the EVO820 redundant system and the LAN1 port of the HMI as an example.



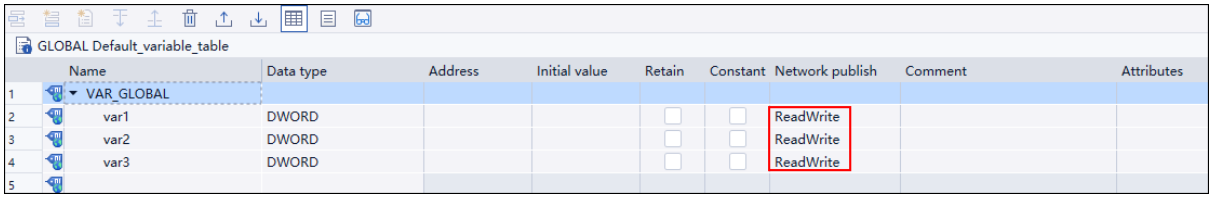
Communication configuration for PLC and HMI in the same project

Prerequisites



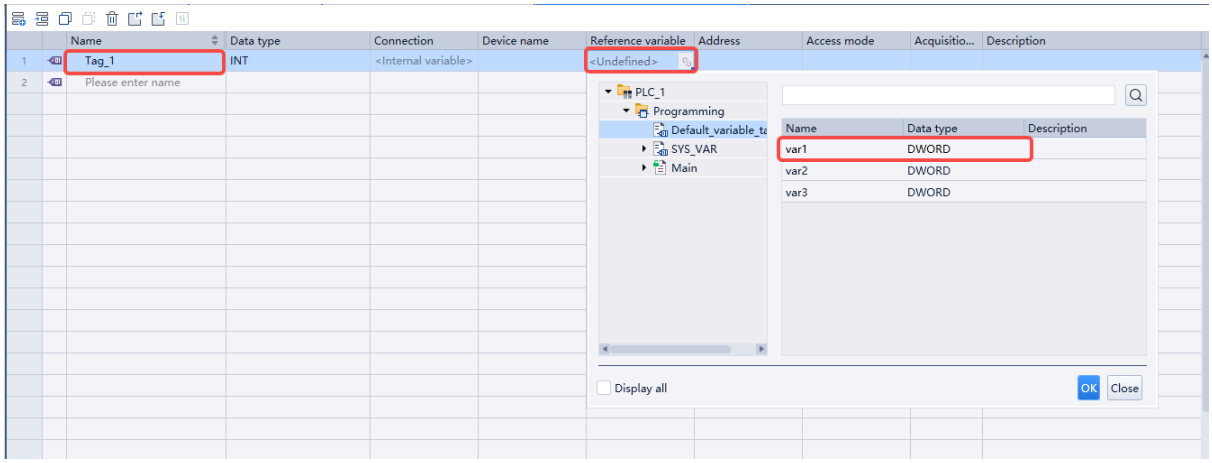
- PLC and HMI have been created. For specific operations, see 7 Project Deployment.
- The IP addresses of the LAN1 port of the EV820 redundant system and the HMI have been set in the same subnet. For specific operations, see 10.11.5 Network Settings.

Procedure

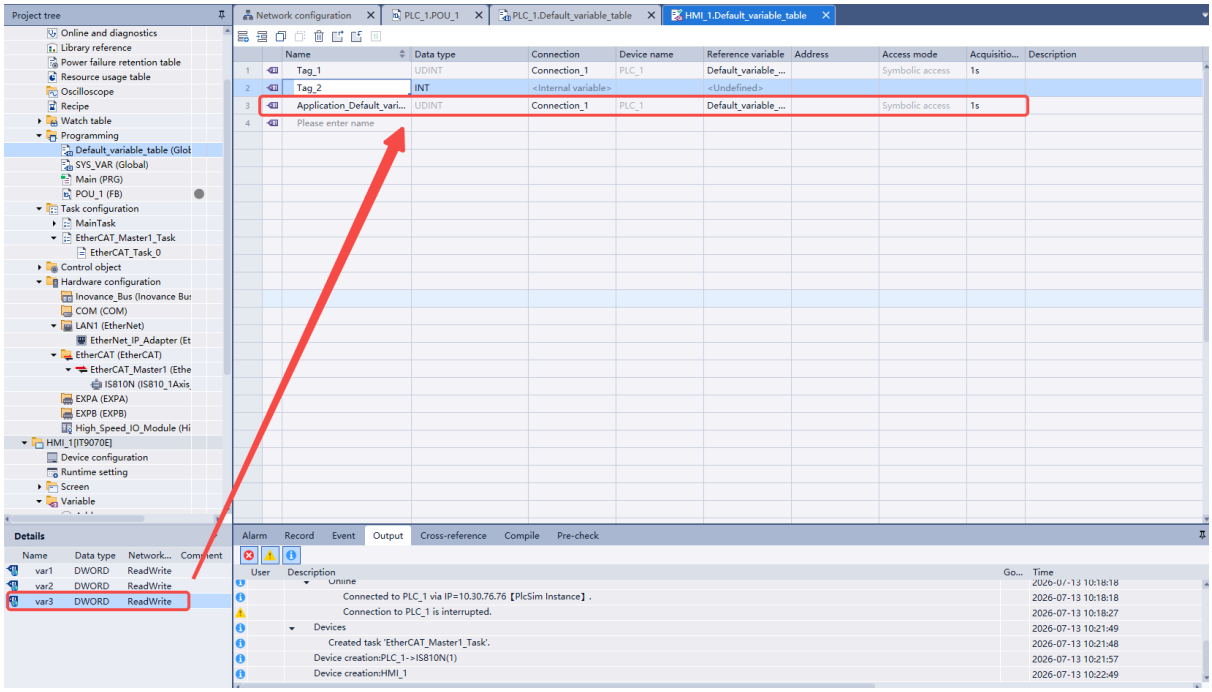


1. Double-click "Network configuration" in the left project tree to open the "Network configuration" view.

2. Drag the LAN1 port of IT9156E HMI_1 to the LAN1 port of EVO820 PLC_1 to establish an EtherNet/IP connection.



3. In the project tree, under the redundant system node "PLC_1 > Programming > Default variable table", double-click the variable to be read or written and change the network public property to "Read/Write".



4. In the variable table of HMI_1, reference the variables from the PLC_1 variable table whose network public property has been changed to "Read/Write".

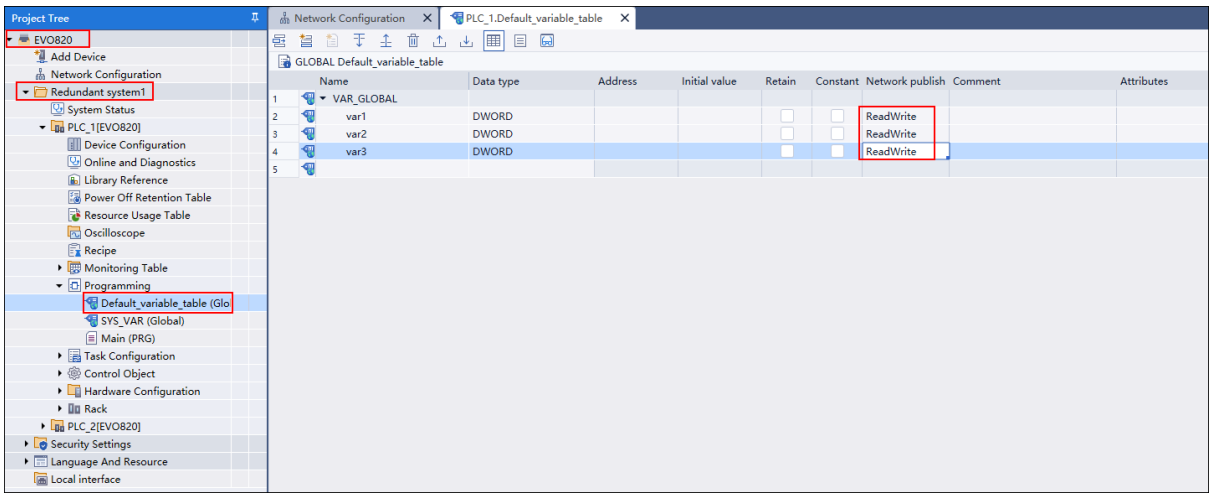
5. In the project tree, under "HMI_1 > Variables > Default variable table", click the cell in the "Reference variable" column, select the variable from the PLC_1 variable table, and click "OK" to associate the referenced variable.

6. In the project tree, under the redundant system node "PLC_1 > Programming > Default variable table", drag the variable in the "Details" window to the HMI_1 variable table to associate the referenced variable.

7. Compile and download the projects for PLC_1 and HMI_1.

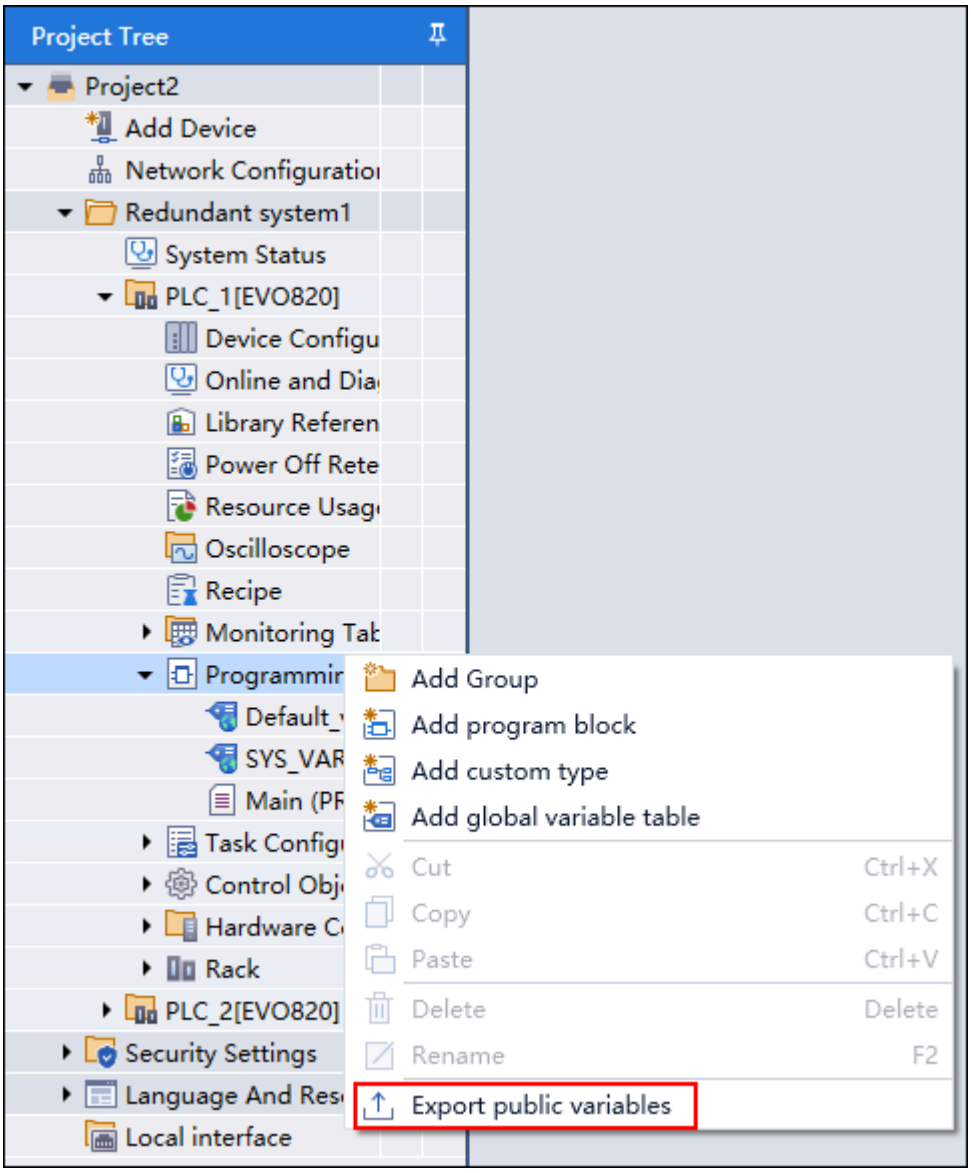
8. Observe the variable values on the HMI screen.

Communication configuration for PLC and HMI in different projects



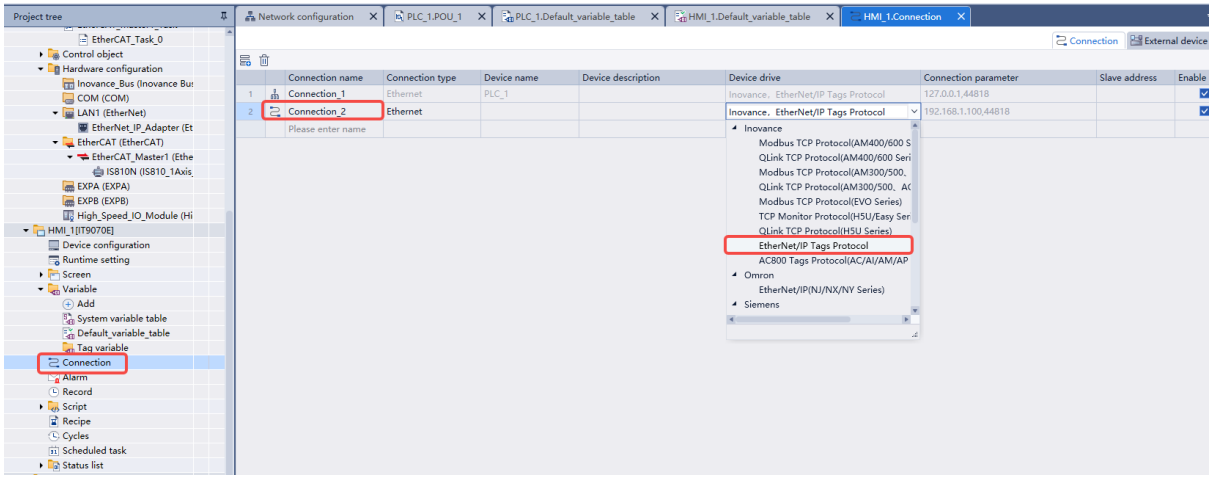
Prerequisites

- PLC and HMI have been created. For specific operations, see 7 Project Deployment.

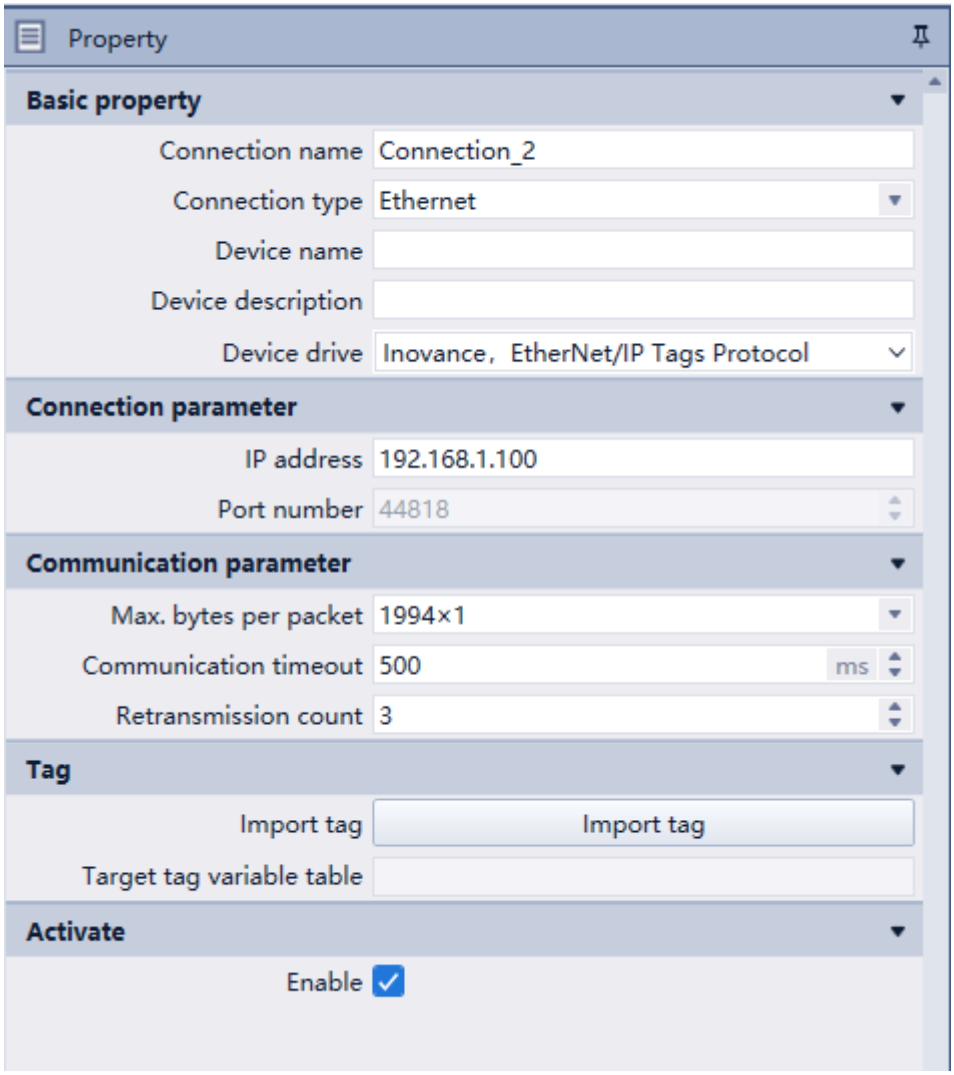


- The IP addresses of the LAN1 port of the EV820 redundant system and the IT9156E have been set in the same subnet. For specific operations, see 10.11.5 Network Settings.

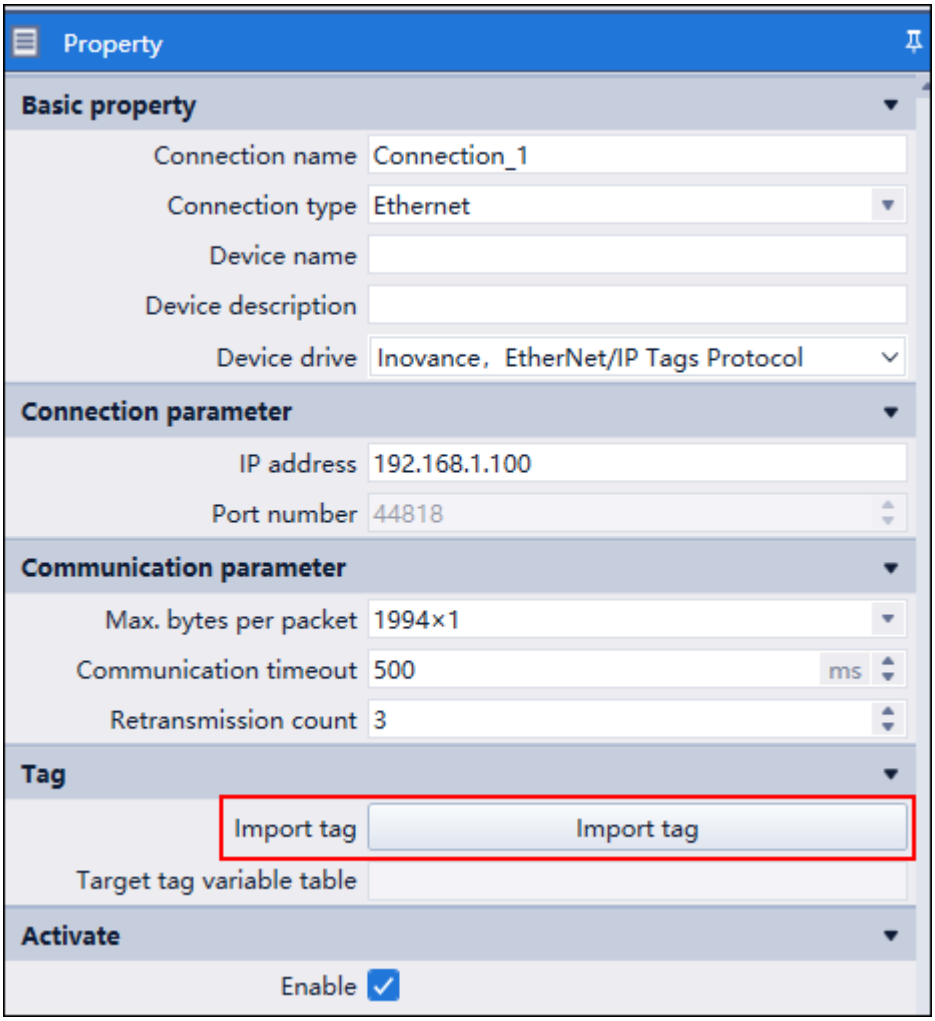
Procedure



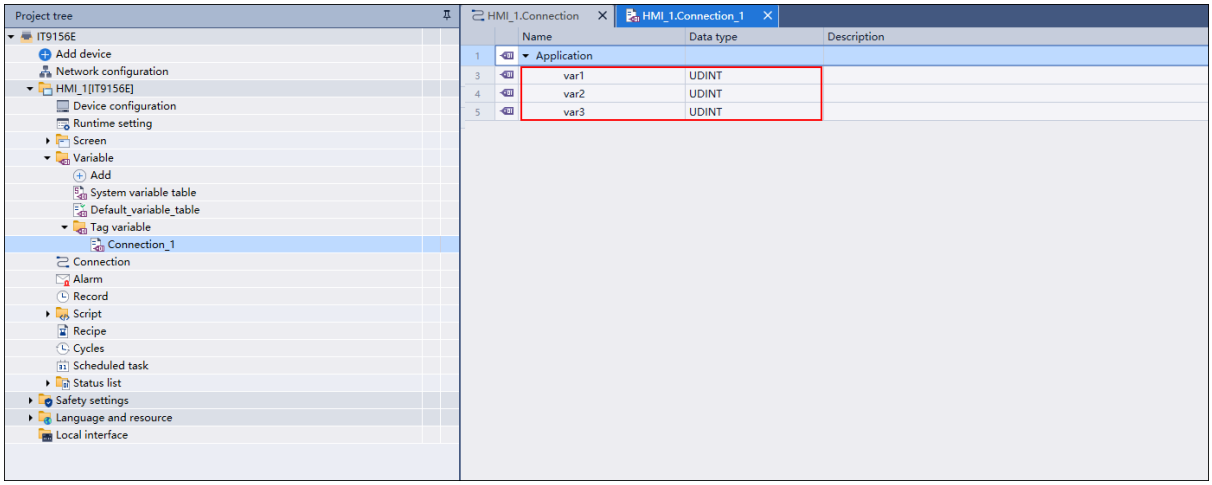
1. In the project tree, under the redundant system node "PLC_1 > Programming > Default variable table", double-click the variable to be read or written and change the network public property to "Read/Write".



2. Right-click "Programming" under the redundant system node "PLC_1" in the project tree, and select "Export public variables" to export the public variables. The default filename for the public variables is "plc.PLC_1.Application.xml".



3. In the HMI project tree, double-click "Connections" and set the connection name to create the connection. Select "Inovance, EtherNet/IP Tags Protocol" for the device driver.



4. In the "Property" area of the HMI project on the right side of the interface, set the IP address of the LAN1 port of the EVO820 device to be connected.

5. Click "Import tag" to import the public variables file plc.PLC_1.Application.xml exported from the EVO820 project to the IT9156E project.

After successful import, the public variables defined in the EVO820 project are displayed in the HMI project.

6. Compile and download the projects for PLC_1 and HMI_1.
7. Observe the variable values on the HMI screen.

Data encoding and transmission methods

The variable types used in EIP label communication mainly include basic data types, BOOL types, STRING types, and structure types. The following explains the encoding and transmission methods for these data types respectively.

Basic data types

For basic data types, the encoding and data size for each type are as follows:

Type	Encoding (Hex)	Description
SINT	C2	8-bit integer
INT	C3	16-bit integer
DINT	C4	32-bit integer
LINT	C5	64-bit integer
USINT	C6	8-bit unsigned
UINT	C7	16-bit unsigned
UDINT	C8	32-bit unsigned
ULINT	C9	64-bit unsigned
REAL	CA	32-bit floating-point
LREAL	CB	64-bit floating-point
BYTE	D1	8-bit bit string
WORD	D2	16-bit bit string
DWORD	D3	32-bit bit string
LWORD	D4	64-bit bit string

BOOL types

For BOOL types, 0xC1 encoding is used for transmission. A BOOL variable occupies one byte, with the least significant bit being valid. For BOOL[n], each BOOL occupies one byte. Take BOOL[17] as an example, if n elements are requested, n bytes will be returned; if the entire array is requested, 17 bytes will be returned.

STRING types

For STRING types, 0xD0 encoding is used for. During data transmission, variable-length transmission is performed according to the actual length of the string. For example, a variable of type STRING[128] containing "ABCDEFG" will transmit 7 bytes of data.

NOTE

- The null terminator "\0" is not included in the transmission.
- STRING type does not support reading or writing the entire array at once; only one element can be accessed at a time.

Structure types

When transmitting structures, byte alignment issues are involved. The following explains the alignment rules for different structure members.

- **Members of basic data types**

LINT: Starts and ends on a 64-bit boundary.
DINT: Starts and ends on a 32-bit boundary.
REAL: Starts and ends on a 32-bit boundary.
INT: Starts and ends on a 16-bit boundary.
SINT: Starts and ends on an 8-bit boundary.

Array: Elements in an array are closely arranged and aligned according to the data type of the basic elements in the array.
Structure: A structure is aligned to an integer multiple of the length of its largest member.

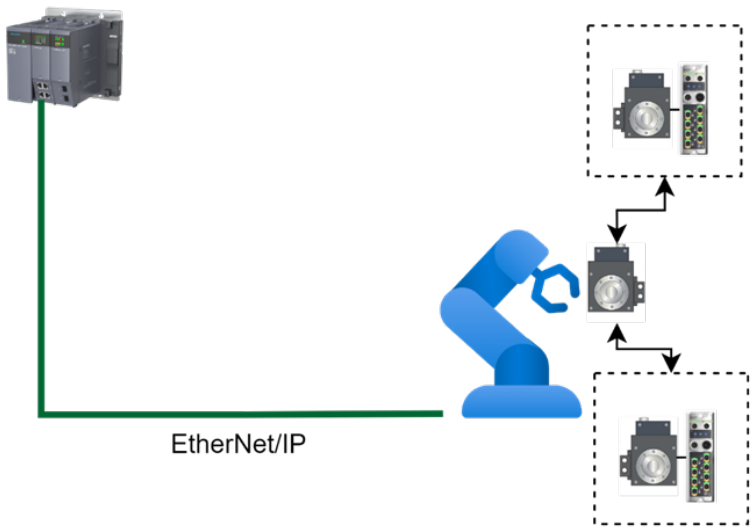
- **Members of BOOL type**

BOOL type: When the member is of BOOL type, it is aligned to 2 bytes, occupying 2 bytes, with the least significant bit being valid.

BOOL[n] type: When the member is a BOOL array, each BOOL is tightly arranged by bits, with a total length of 16 bits (i.e., aligned to 2 bytes). For example, BOOL[16] occupies 2 bytes, BOOL[10] also occupies 2 bytes, while BOOL[17] occupies 4 bytes. Bits are valid sequentially from the least significant to the most significant.

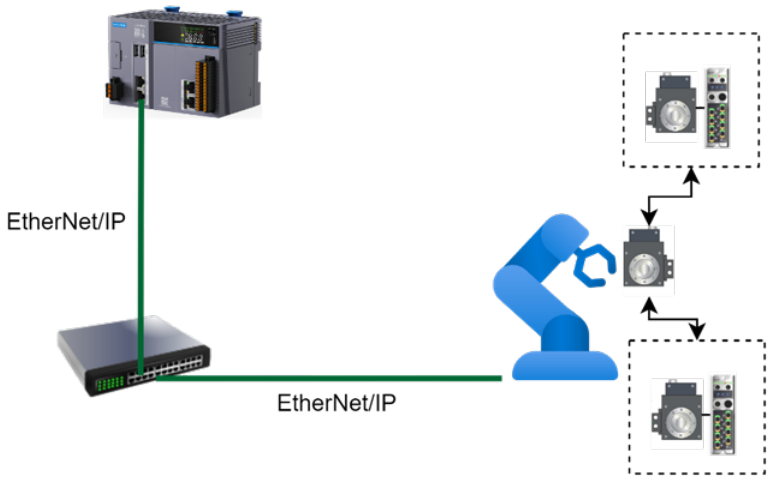
- **Members of STRING type**

A STRING type can specify a length, such as STRING<25> and STRING<100>. Strings in structures can be considered as arrays of SINT, aligned to 1 byte, and transmitted according to its maximum length. For example, STRING<25> occupies 25 bytes and STRING<100> occupies 100 bytes.



> NOTE
>
> EIP label communication supports up to 8 levels of structure nesting.

10.6.4.2.8 Quick Connect Communication (EVO700, EVO700C, EVO800, APC760C)

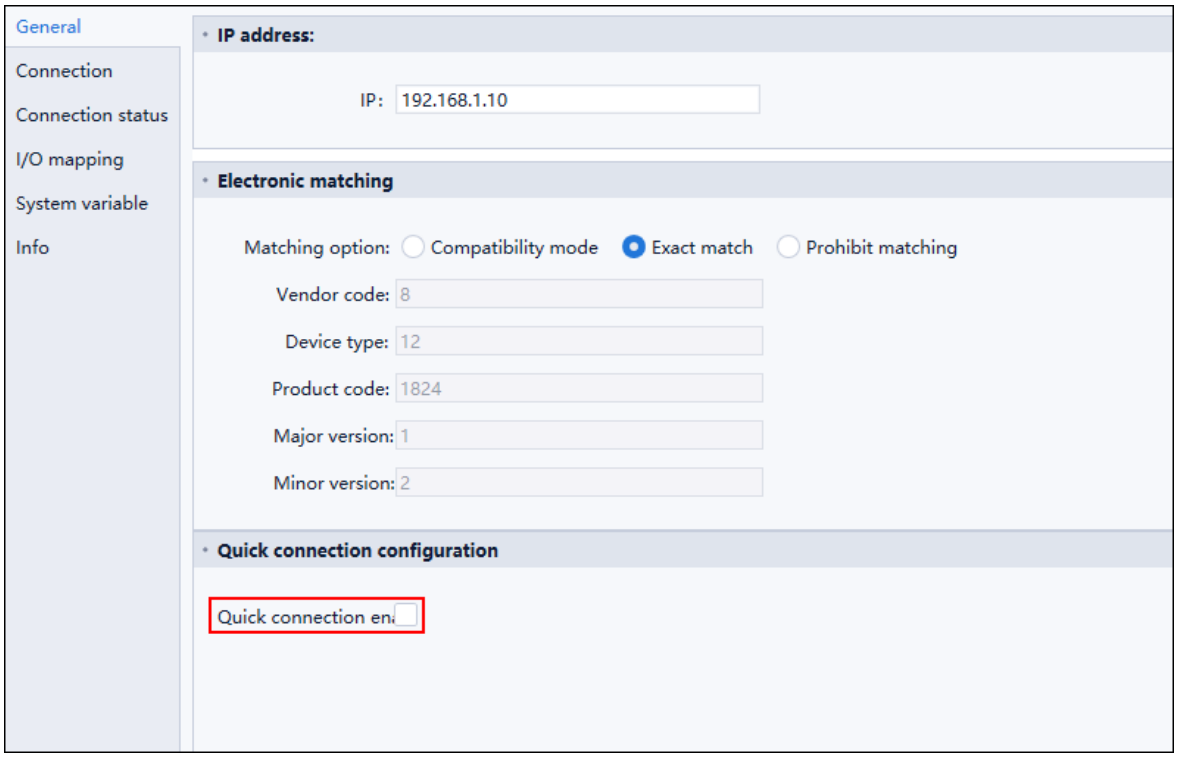


The PLC devices configured in iFA Evolution software support fast power-on and integration into EtherNet/IP networks when connected to ODVA-compliant EtherNet/IP target devices with the quick connection function.

Typical quick connection topologies can be simplified into the following two forms:

- Method 1: The PLC connects directly to the quick connection adapter device via its local Ethernet port on the EtherNet/IP network (requires network port configuration on the PLC).

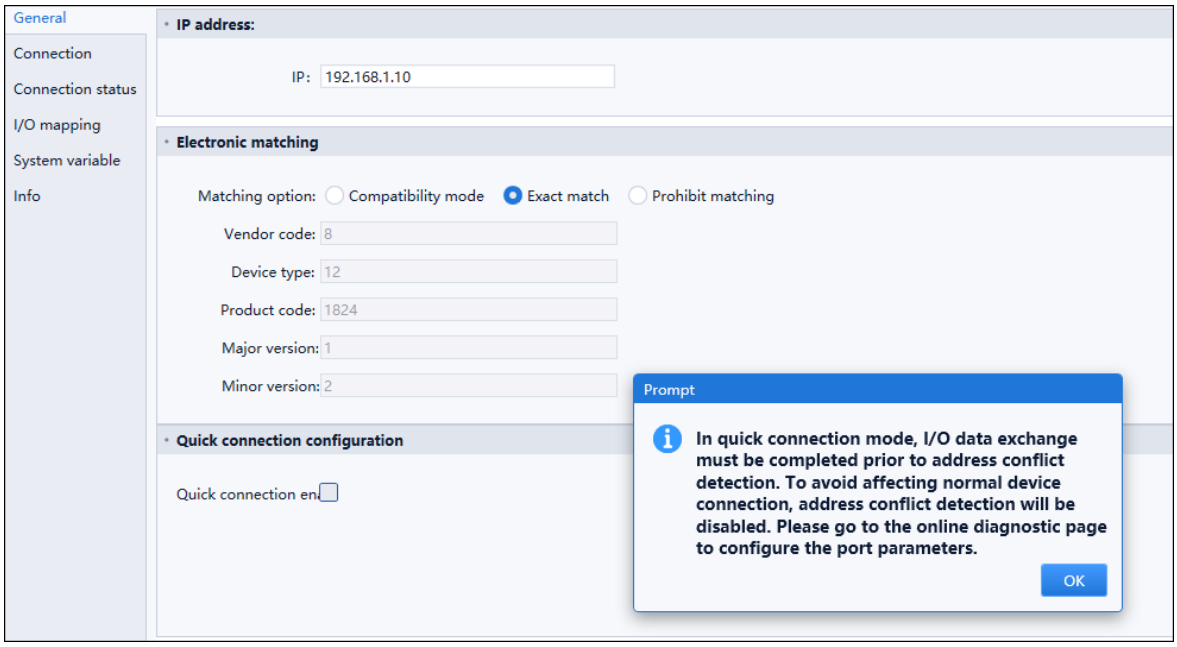
- Method 2: The PLC device communicates with the quick connection adapter through a managed switch. The switch must support adjustment of its port configuration parameters, and the link establishment time must be less than 300 ms when using the quick connection port configuration.



Quick connection communication configuration

Prerequisites

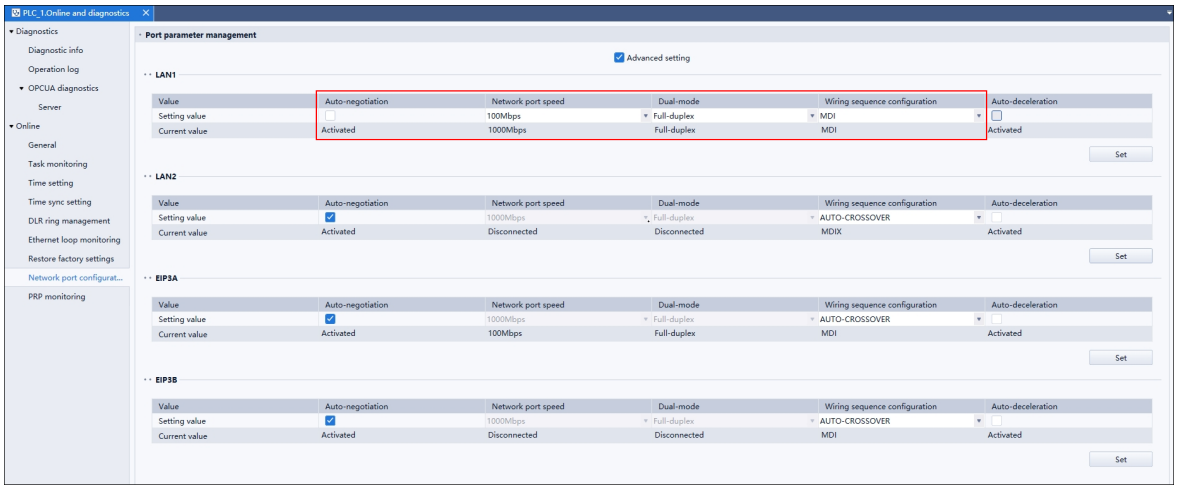
To implement quick connection via EtherNet/IP, both the selected PLC and the remote adapter device must support the EIP quick connection function. If a managed switch is used, it must support modifying port parameters.



Procedure

1. Enable the quick connection function.
   a. Add an ODVA-compliant remote adapter device that supports quick connection under the PLC project. The quick connection switch is displayed in the "General" settings interface.

> **NOTE**
>
> The configuration steps for the quick connection slave device are the same as those for a common remote adapter device. Refer to 10.6.4.2.2.2 General Settings of Remote Adapters and 10.6.4.2.4 Connection Configuration (Class1) for general configuration and Class1 connection configuration.



b. Enable quick connection and click "OK" in the pop-up prompt box.

2. Modify port parameters.

To reduce the negotiation time of the quick connection adapter device on the network, the port parameters of the connected peer device must be modified.

- If the peer device is a PLC, refer to 10.11.22 Network Port Configuration to modify the corresponding port parameters. Disable auto-negotiation, set the port speed to 100 Mbps, duplex mode to full-duplex, and wiring sequence to fixed MDI or MDIX.

- If the peer device is a managed switch, manually modify the corresponding port parameters through the Web interface or command-line control.

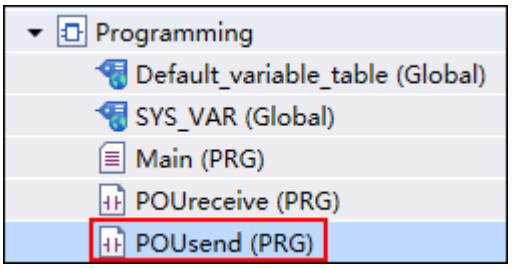
NOTE

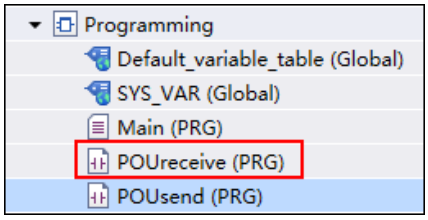
- Modifying the port parameters is mandatory. If a switch is connected to the quick connection device and the switch does not support modifying the above configuration items, the port negotiation time may be delayed, potentially failing to meet the performance requirements of quick connection.
- When configuring the wiring sequence, attention must be paid to the matching relationship with the network cable (twisted-pair cable); otherwise, connection failure may occur.
  There are two types of network cable wiring sequences, used to match MDI and MDI-X interfaces:
  - Straight-through cable
    Pin assignments are identical at both ends (T568A<--> T568A or T568B<--> T568B).
  - Crossover cable
    One end uses T568A pin assignment, the other uses T568B (T568A<--> T568B).

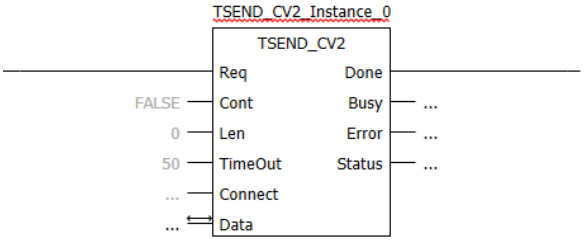
The following table shows the wiring sequence type of device interfaces and the supported cable types:

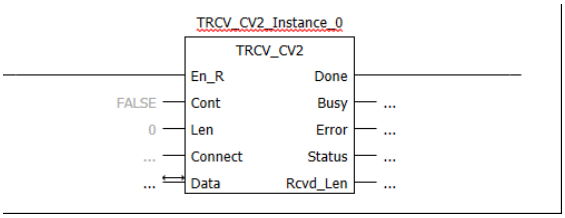
No.	Device Interface Type	Supported Cable Type
1	MDI<-->MDI-X	Straight-through cable
2	MDI-X<-->MDI-X	Crossover cable
3	MDI<-->MDI	Crossover cable

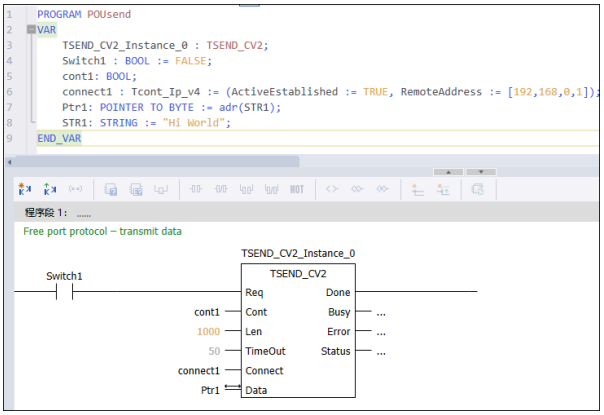
- If a switch is used to connect quick connection devices, ensure that other switch functions (such as VLAN, QoS queues, and STP) do not interfere with data communication between the port connected to the PLC and the port connected to the quick connection adapter.

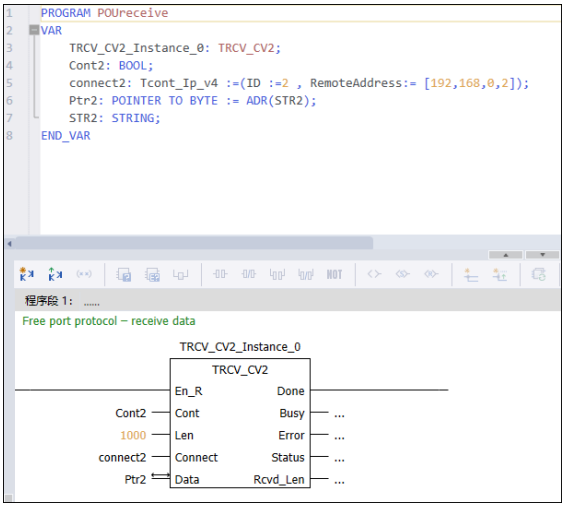












3. Quick connection communication
   After enabling quick connection and configuring port parameters, power on and off the quick connection adapter device connected to the EtherNet/IP network for quick power on, port negotiation, and integration into the EtherNet/IP network for Class1 I/O data exchange.

10.6.4.3 Free Network Port Communication

The free port protocol is used to achieve character data communication between PLC devices and third-party devices, with the physical interface being a network port. The transmission and reception communication of this protocol is completed by the dedicated library NetFreePort. For detailed instructions on the function blocks, see the instruction manual.

This section takes transmitting "Hi, World" at irregular intervals as an example to explain the configuration process.

Step	Transmitter	Receiver
1	Create a PLC project.	
2	Reference the NetFreePort library. For reference operations, see 12.3 Library Reference.	

Step	Transmitter	Receiver
3	Create a PRG type POU in LD language, named POUsend. 	Create a PRG type POU in LD language, named POUreceive. 
4	Add a normally open contact and a TSEND_CV2 function block instance in POUsend. 	Add a TRCV_CV2 function block instance in POUreceive. 
5	Name the normally open contact Switch1. Declare these variables between VAR and END_VAR and connect them to the function blocks. For parameter settings, see 18.4.8.5 TSEND_CV2. 	Declare these variables between VAR and END_VAR and connect them to the function blocks. For parameter settings, see 18.4.8.4 TRCV_CV2. 
6	Check that the port numbers (RemotePort, LocalPort) are the same for both the receiver and transmitter. Ensure that the IDs of the transmitting or receiving blocks are not duplicate.	
7	Call POUsend in MainTask.	Call POUreceive in MainTask. Set the task cycle of POUreceive to be at least twice that of POUsend to avoid receiving delays.
8	Download the controller and start running.	

Step	Transmitter	Receiver
9	Write TRUE to Switch1.	Observe the value changes of STR2. If the value is 'Hi, World', the configuration is successful.

During commissioning, pay attention to the status code of **Status**, and refer to the relevant explanations in instructions 18.4.8.5 TSEND_CV2 or 18.4.8.4 TRCV_CV2.

10.6.4.4 Disabling/Enabling an EtherNet Device

Disabling devices under the LAN1 (EtherNet) node

In iFA software, a certain EtherNet device can be disabled through commands or variable setting, thus "detaching" from the control system while retaining its configuration parameters and I/O mapping information. If a device fails and needs to be replaced, this function can reduce the time required for replacement.

- Disabling operation and effect
  A device can be disabled through commands or variable setting, each with different scopes. Command disabling applies to all devices except PLCs Variable setting requires that there be corresponding variables in SYS_VAR.
  - Command disabling
    Right-click a device under the "LAN1 (EtherNet)" node in the project tree and select "Disable device".
    In the "Network configuration" window, right-click an EtherNet/IP remote adapter and select "Disable device".
  - Variable setting
    When adding a device under the "LAN1 (EtherNet)" node, a corresponding variable is created in **SYS_VAR**, following the naming rule: J_device model.
    Setting member The member **bDisableEnable** disables the slave, and the setting method supports writing values in **SYS_VAR** or assigning values in user programs.

    GLOBAL SYS_VAR

	Name	Data type	Address	Retain	Network publish	Comment
1	VAR_GLOBAL					
2	LAN1_EIPSingle_STATUS	Array[1..32] OF IoStand...		☐	Private	
3	LAN1_EIPSlave_STATUS	Array[1..16] OF EtherNe...		☐	Private	
4	J_ModbusSlave_TCP	IoStandard._SYS_SlaveS...		☑	Private	
5	bDisableEnable	BOOL		☑	Private	从站禁用变量

    Devices that support automatic variable creation include:
    - Remote slave devices added when the current PLC acts as a Modbus TCP Master.
    - Remote adapter devices added when the current PLC acts as an EtherNet/IP scanner.

After disabling, it is necessary to perform a 10.8.3 full download of the PLC to make the disabling operation effective.

- Disabling result
  The disabled devices are marked with the icon for differentiation.

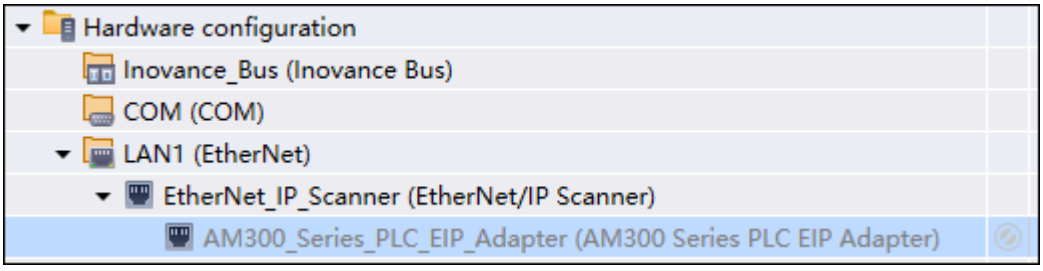


Figure 10-6-4-4-1 Icon in project tree

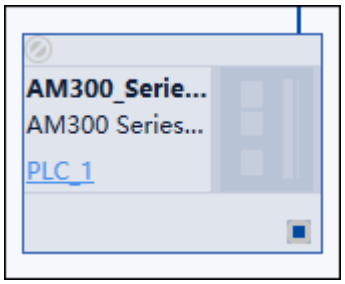

Figure 10-6-4-4-2 Icon in network configuration view

Enabling devices under the LAN1 (EtherNet) node

The disabling and enabling of LAN1 (EtherNet) devices are a set of mutually corresponding operations. Only when the device is disabled is the enabling command visible.

The enabling operation and its effect are exactly the same as the disabling operation.

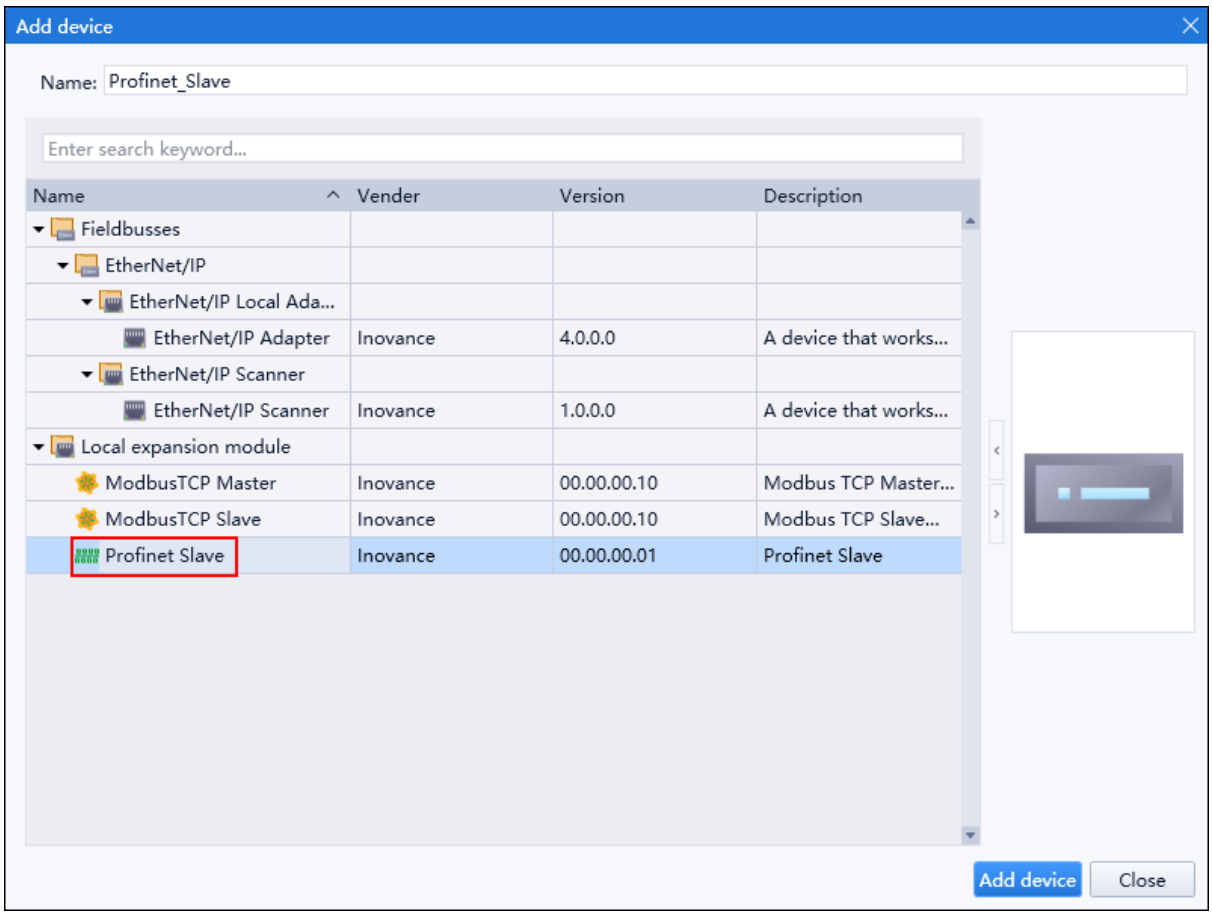
A device needs to be disabled and enabled in the same way. That is, if the device is disabled by setting a variable, it must be enabled by resetting the variable. If it is disabled using a command, it must also be enabled using a command.

10.6.5 PROFINET Communication Configuration (EVO400, EVO500, EVO700, APC500, EVO800)\

10.6.5.1 Overview

PROFINET is introduced by PROFIBUS International (PI) and is a new generation of automation bus standards based on industrial Ethernet technology. PROFINET provides a complete network solution for the field of automation communication, covering hot topics such as real-time Ethernet, motion control, distributed automation, functional safety, and network security. As a cross-vendor technology, it is fully compatible with industrial Ethernet and existing fieldbus technologies (such as PROFIBUS), protecting existing investments.

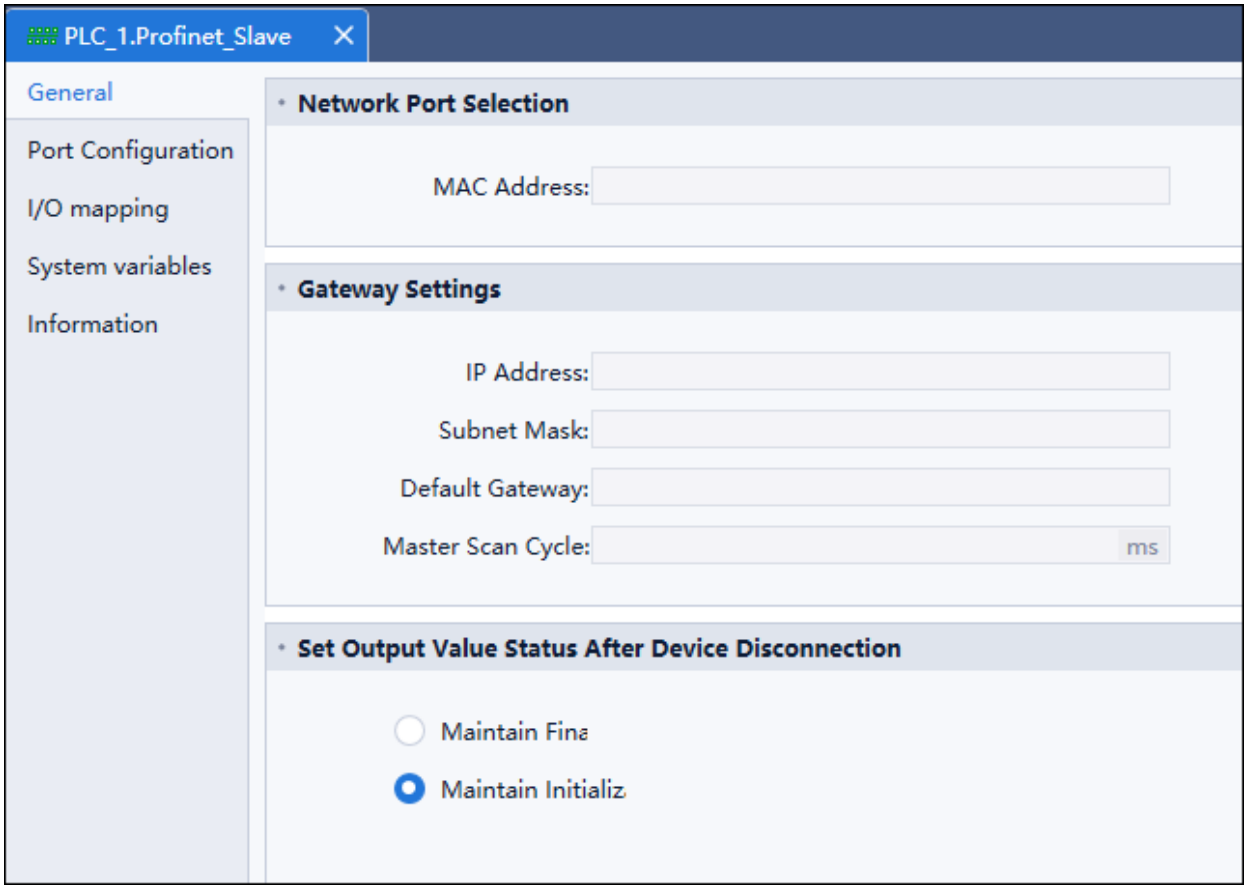
PROFINET communication is abbreviated as PN communication. The following section will explain it in the following two modes:



- PN communication between EVO500 series PLCs (as PROFINET slaves) and Siemens PLC masters
- PN communication between PN expansion modules of EVO800 series PLCs (as master) and GL20 series I/O devices

10.6.5.2 PN Slave Configuration(EVO400,EVO500,EVO700,APC500)

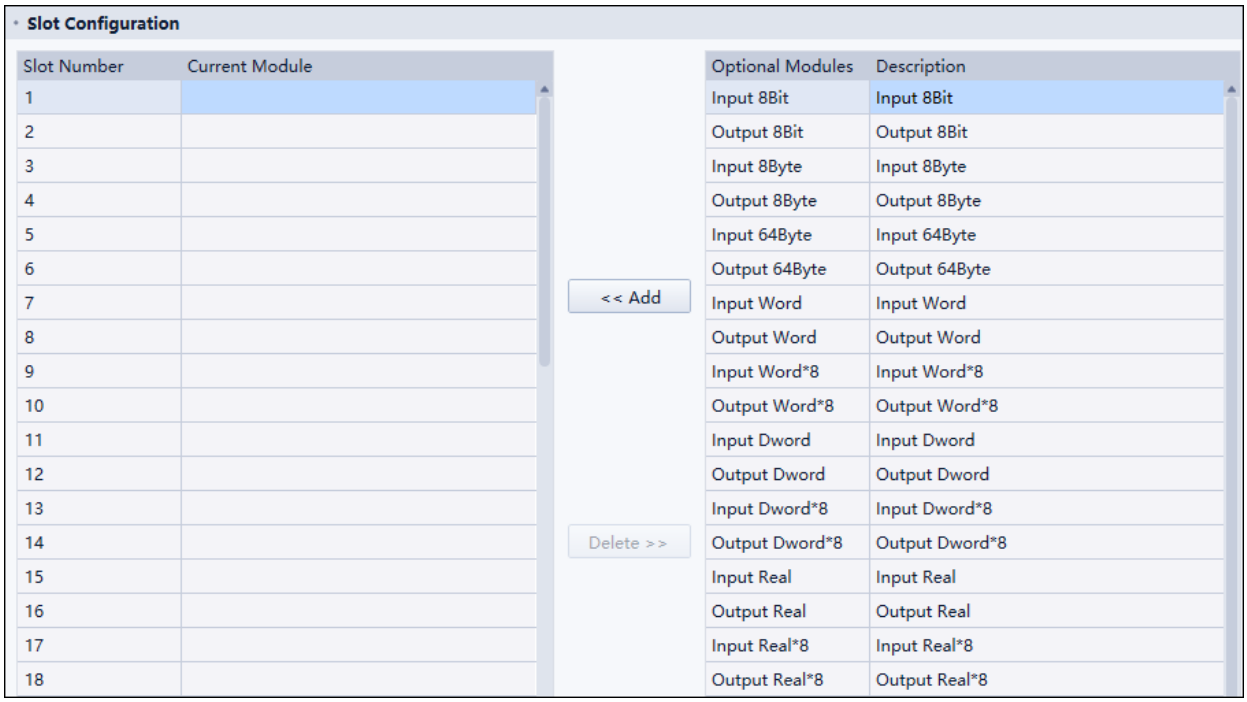
10.6.5.2.1 PN Slave Configuration



Procedure

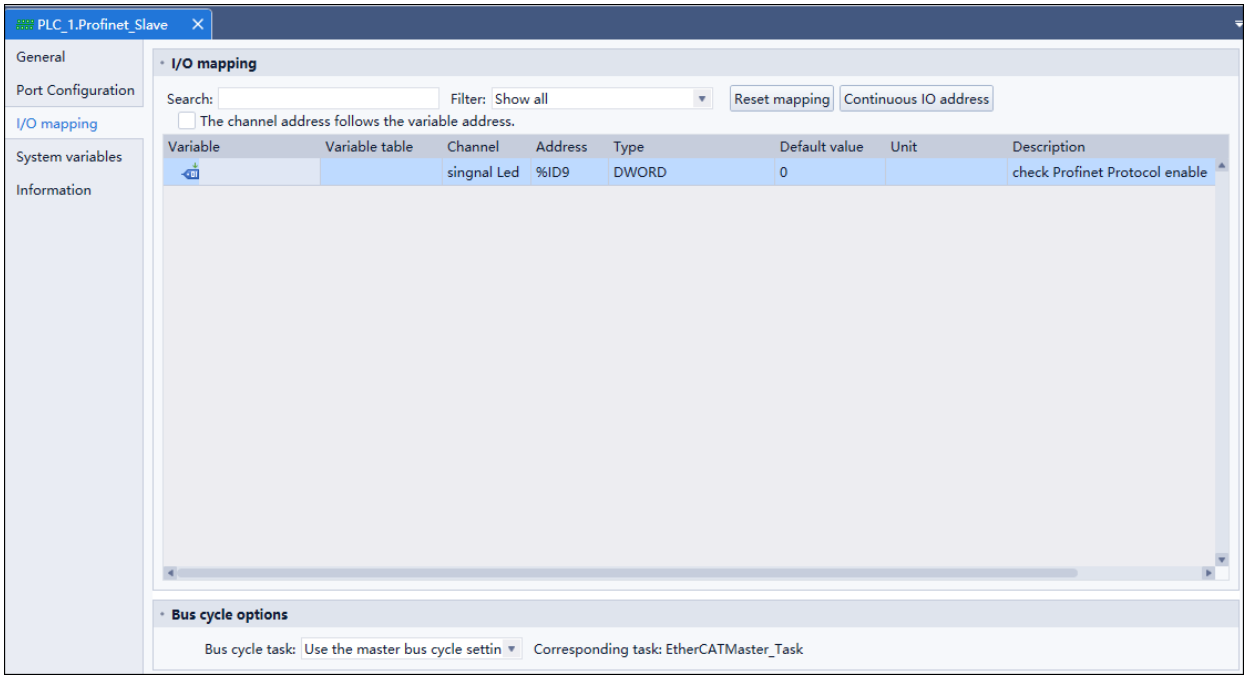
1. Select the device for connection.
   Add a device supporting the PN protocol in the project tree. The EVO500 series (firmware version V1.3) is used as an example. PN communication protocol is not supported when an independent IP address is configured for each EtherNet port. The default mode is "Switch". For details, see 10.6.14.2 Network Settings (EVO400, EVO500).
2. Configure and add the PN slave device.

3. Configure parameters.
   Double-click the PN slave device under the "Hardware configuration" node in the left project tree to enter the parameter settings interface.



General configuration

Option		Function	Note
Network port selection		Displays information about the LAN port.	"MAC address" displays the actual MAC address of the local network port and cannot be modified. For the EVO500 series PLC, only the MAC address of the LAN1 port is displayed.
Gateway setting	IP address	Displays the IP information assigned to the slave by the master.	Automatically scans the gateway information of the device. This cannot be modified.
	Subnet mask		
	Default gateway		
	Master scan cycle	Displays the master scan cycle for communication.	• Displays 0 when no communication is taking place. • Displays real-time data when communication is active. The recommended master scan cycle for PN task is 4 ms. Values below 4 ms may cause inconsistent data refresh.



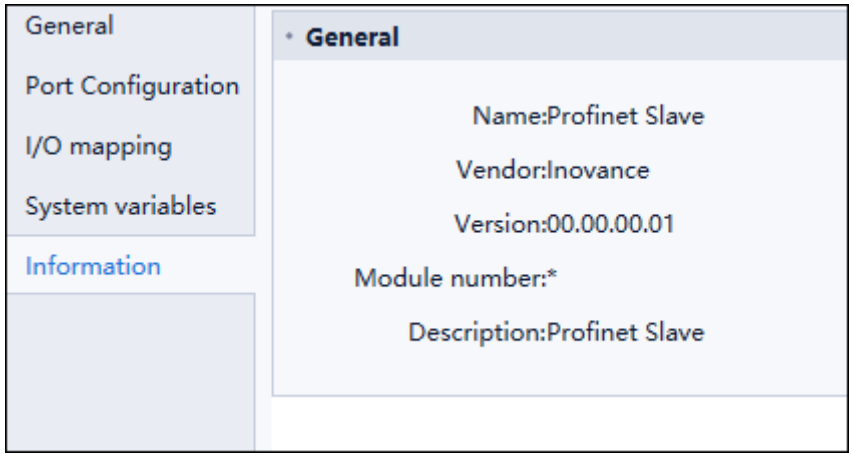
Option	Function	Note
Set the output value status upon device disconnection	Used to set the output value status when the device is disconnected.	• Maintain final state: When disconnected, output data remains at the last output value. • Maintain initialization state: When disconnected, all output data is cleared to zero. Note: When the master is in the STOP state, it is not considered a communication failure, and I/O data exchange proceeds normally.

Port configuration

- Select a blank slot on the left, select the I/O module type on the right, and click "Add" or double-click the selected module to add it to the corresponding slot. Once a module is added, it does not support overwriting addition.
- Select a device on the slot and click "Delete" or use the shortcut key "Delete" to remove the module.

I/O mapping

- I/O mapping
  Includes slave I/O signals and module I/O mapping. When an I/O module is added in port configuration, the corresponding module appears in the I/O mapping table. If no module is added, only slave I/O mapping is displayed by default. For detailed interface parameters, see 10.6.3.3.9 I/O Mapping.
- Bus cycle options
  Bus cycle task: Displays all task names. Default is "Inherit from bus cycle setting", corresponding to MainTask.



NOTE

Since CPU utilization affects the real-time performance of PN communication, it is recommended to set the watchdog time of the PN master as follows:

- When CPU utilization is below 50%, it is recommended to set the watchdog time to 20 ms.
- When CPU utilization is between 50% and 80%, it is recommended to set the watchdog time to 28 ms.
- When CPU utilization is above 80%, it is recommended to set the watchdog time to 36 ms.

Information

Displays basic device information.

10.6.5.2.2 PROFINET I/O Module

The PN slave communicates with the PN master through I/O modules, which can be divided into three major categories based on the direction of data transmission within the module: Input, Output, and InOut.

- The Input type is a module that transmits data from the slave to the PN master, and the transmitted data is PdIndata.
- The Output type is a module that transmits data from the master to the slave, and the transmitted data is PdOutdata.
- The InOut type is a module where data can be transmitted between the master and slaves, and the transmitted data includes both PdIndata and PdOutdata.

In PN communication, I/O modules must be configured in the master and slaves with corresponding slot numbers and data types for communication. Unmatching configuration of the I/O modules can result in data transmission failure, but this does not affect the functionality of other I/O modules. Up to 64 I/O modules can be configured for a PN slave, and the maximum PdIndata and PdOutdata data length that can be transmitted in a single frame is 1024 bytes. The specific types of I/O modules and their corresponding relationships are as follows:

Table10-6-5-2-2-1 Input type I/O modules

I/O Module for PN Slave	I/O Module for PN Master	Description
Input 64Byte	Input 64Byte	Inputs 64 bytes of data to the master.
Input 8bit	Input 8bit	Inputs 1 byte of data to the master.
Input 8Byte	Input 8Byte	Inputs 8 bytes of data to the master.
Input Dword	Input Dword	Inputs 4 bytes of data to the master.
Input Dword *8	Input Dword *8	Inputs 32 bytes of data to the master.
Input Real	Input Real	Inputs 4 bytes of data to the master.
Input Real *8	Input Real *8	Inputs 32 bytes of data to the master.
Input Word	Input Word	Inputs 2 bytes of data to the master.
Input Word *8	Input Word *8	Inputs 16 bytes of data to the master.

Table10-6-5-2-2-2 Output type I/O modules

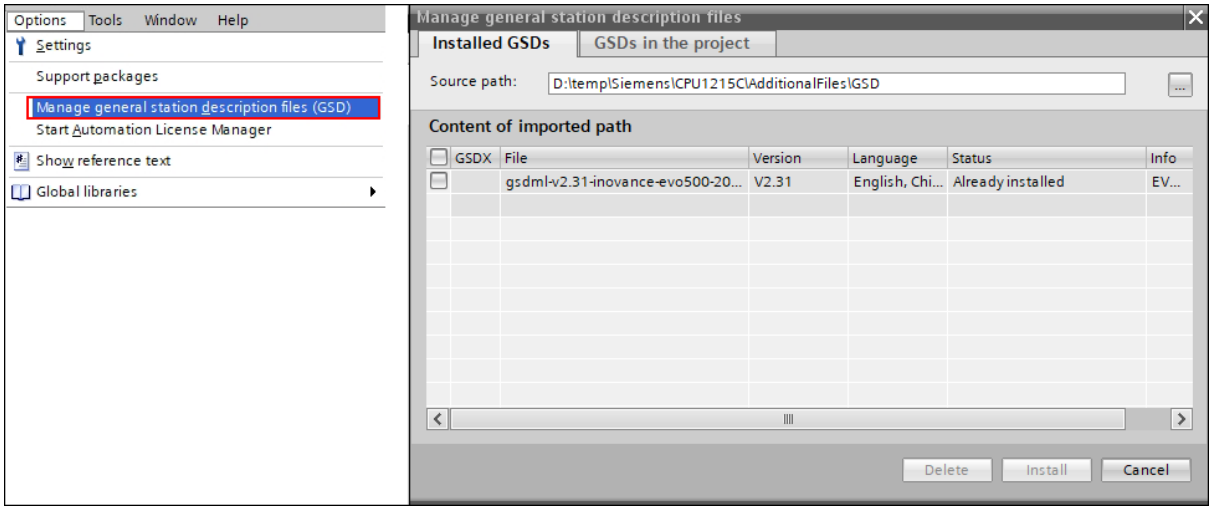
I/O Module for PN Slave	I/O Module for PN Master	Description
Output 64Byte	Output 64Byte	Outputs 64 bytes of data from the master.
Output 8bit	Output 8bit	Outputs 1 byte of data from the master.
Output 8Byte	Output 8Byte	Outputs 8 bytes of data from the master.
Output Dword	Output Dword	Outputs 4 bytes of data from the master.
Output Dword *8	Output Dword *8	Outputs 32 bytes of data from the master.

I/O Module for PN Slave	I/O Module for PN Master	Description
Output Real	Output Real	Outputs 4 bytes of data from the master.
Output Real *8	Output Real *8	Outputs 32 bytes of data from the master.
Output Word	Output Word	Outputs 2 bytes of data from the master.
Output Word *8	Output Word *8	Outputs 16 bytes of data from the master.

Table10-6-5-2-2-3 InOut type I/O modules

I/O Module for PN Slave	I/O Module for PN Master	Description
InOut 64Byte	InOut 64Byte	Exchanges 64 bytes of data between master and slave.
InOut 8bit	InOut 8bit	Exchanges 1 byte of data between master and slave.
InOut 8Byte	InOut 8Byte	Exchanges 8 bytes of data between master and slave.
InOut Dword	InOut Dword	Exchanges 4 bytes of data between master and slave.
InOut Dword *8	InOut Dword *8	Exchanges 32 bytes of data between master and slave.
InOut Real	InOut Real	Exchanges 4 bytes of data between master and slave.
InOut Real *8	InOut Real *8	Exchanges 32 bytes of data between master and slave.
InOut Word	InOut Word	Exchanges 2 bytes of data between master and slave.
InOut Word *8	InOut Word *8	Exchanges 16 bytes of data between master and slave.

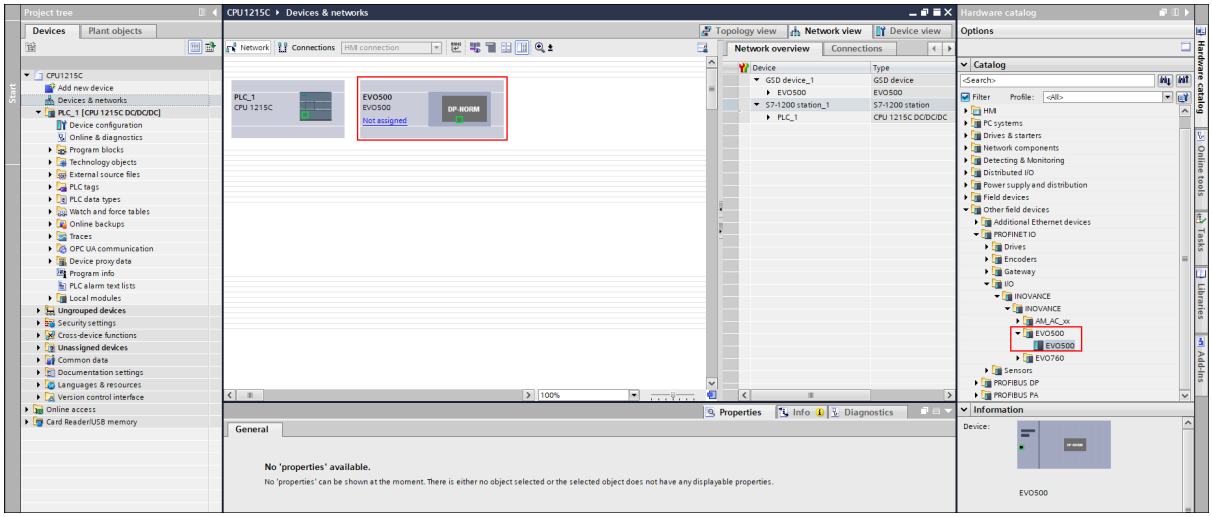
10.6.5.2.3 TIA Portal and PN Master Configuration



This section introduces the PN slave configuration using a Siemens device as the master and the EVO500 series PLC as an example.

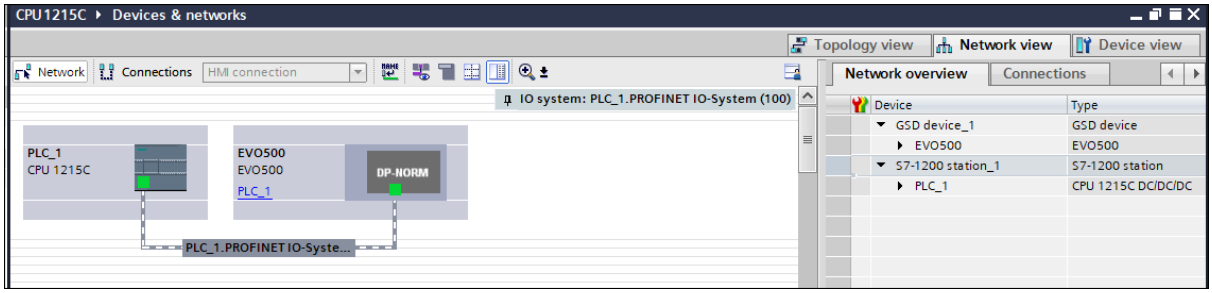
Prerequisites

The GSD file for the EVO500 series device has been obtained.



Procedure

1. Import and install the GSD file for the PN device.
   In TIA Portal, select "Options > Manage general station description files (GSD) (D)", select the path where the GSD file is located, and install the required PN GSD file from the automatically retrieved list.

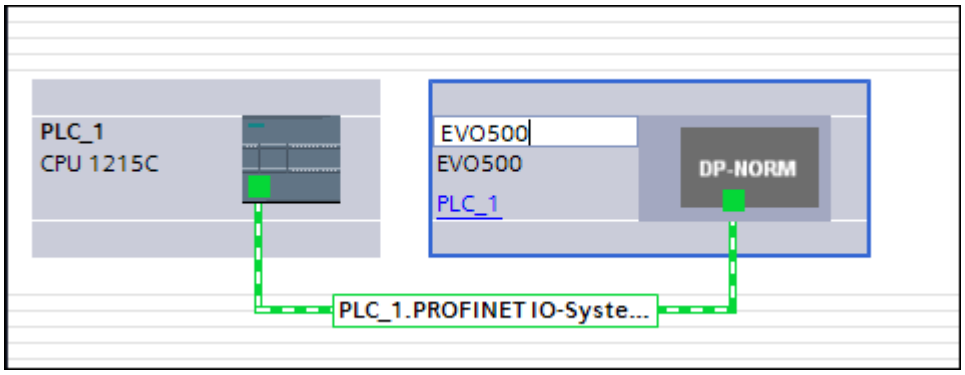


2. Configure and add the PN slave device.

   Click "Devices and networks", then double-click or drag the "EVO500" from the "Hardware catalog" into the network view.

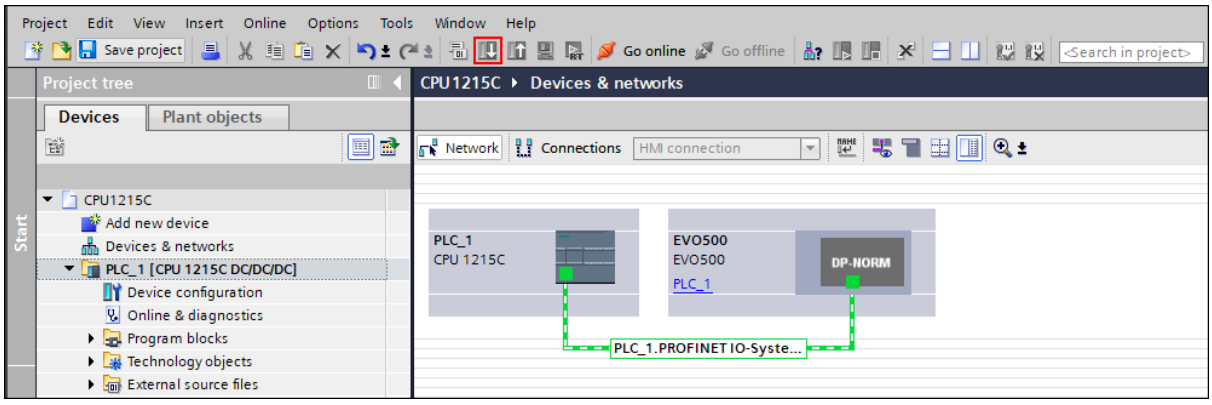
   In the network view, click the green box of the PLC device and drag the connection to the green box of the EVO500 device.

> **NOTE**
>
> When the EVO500 device is configured as a PROFINET slave, the TIA Portal software automatically assigns an IP address to the EVO500 device via the PROFINET bus. The assigned IP address must not be the same as that of the EVO500 device itself, otherwise the actual IP address of the EVO500 device will become invalid.



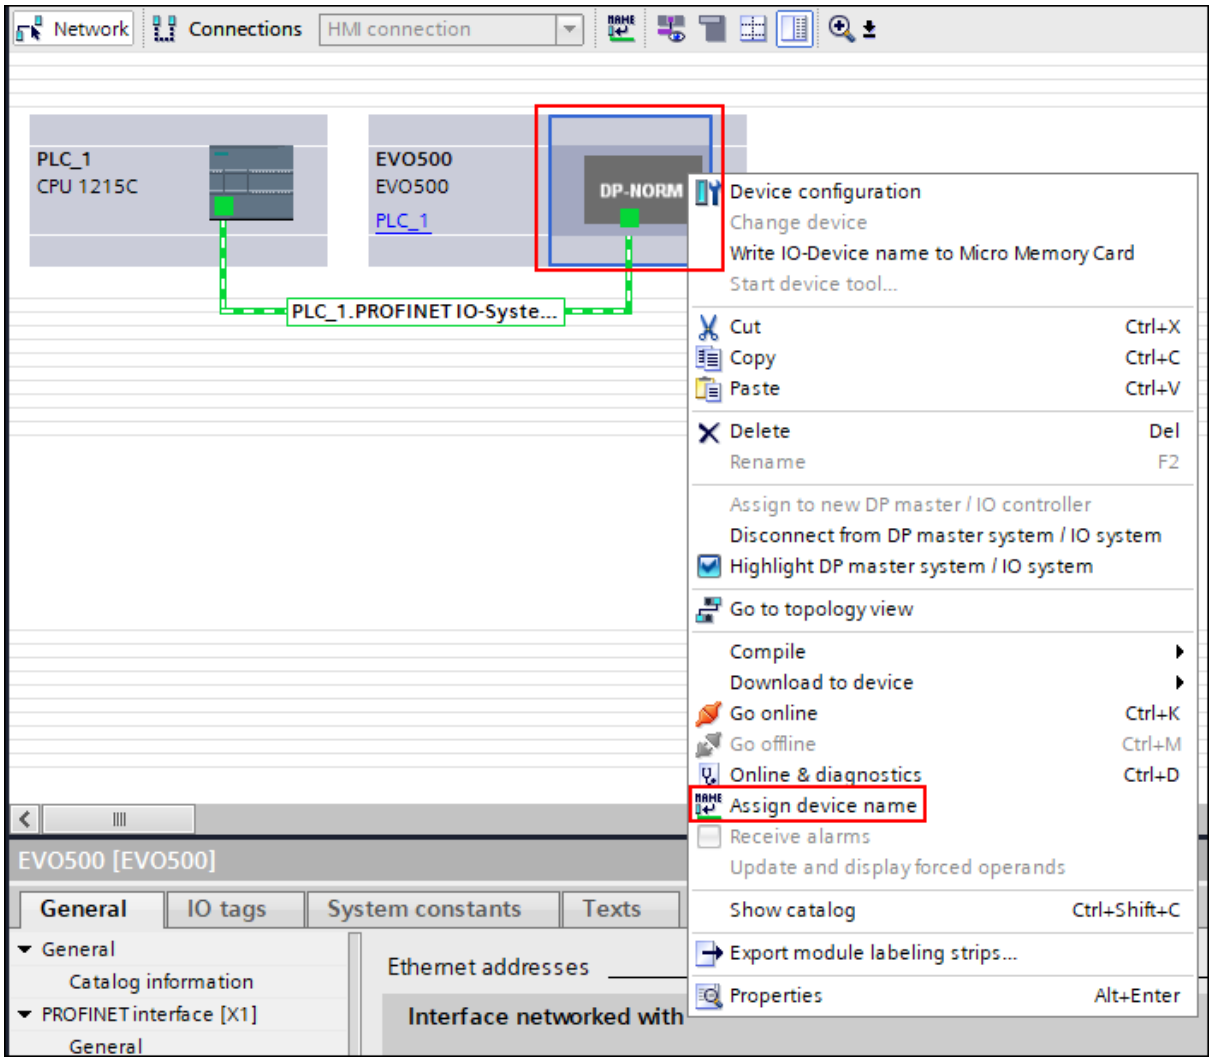
3. Configure the I/O modules.

Click "Device view", then double-click or drag the required I/O modules from the "Hardware catalog" into the "Device overview".



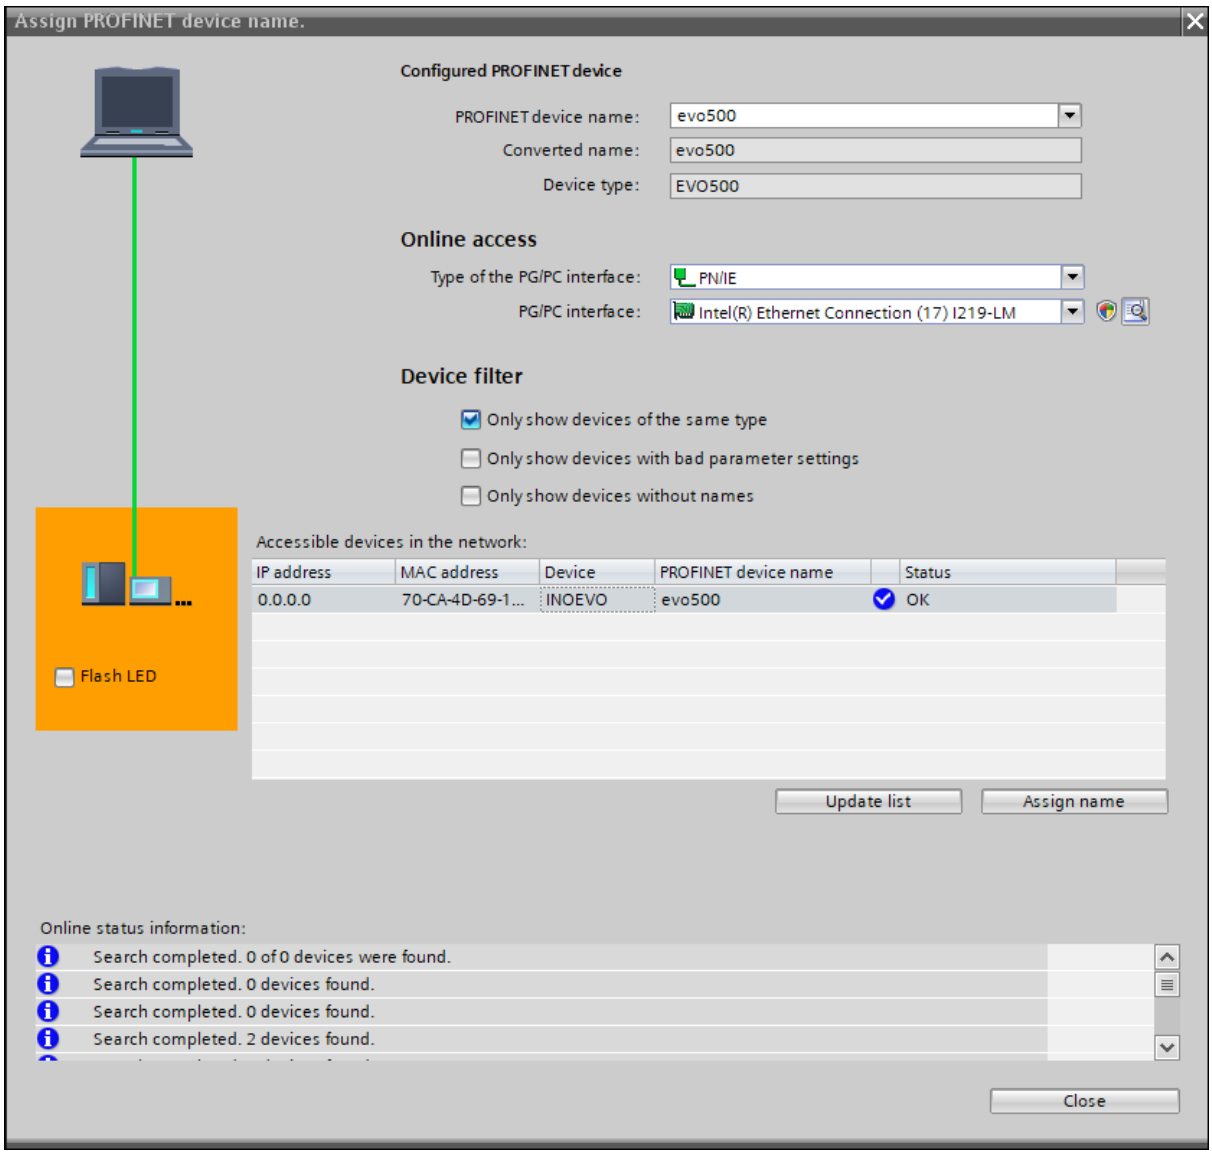
4. Rename the device.

   Double-click the text name to rename the device.



5. Download the configured project to the master PLC.

   Compile and download the configured project to the master PLC.



6. Assign a PROFINET device name to the actual PN slave device.

Right-click the EVO500 device in the configuration, and select "Assign device name" to assign the name.

In the "Assign PROFINET device name" dialog box, click "Update list", select the corresponding EVO500 device from the list, then click "Assign name" to complete the configuration on the PN master (TIA Portal).

NOTE

The IP address of the PROFINET slave device must not be the same as that of the device itself.

10.6.5.2.4 PN Slave Troubleshooting

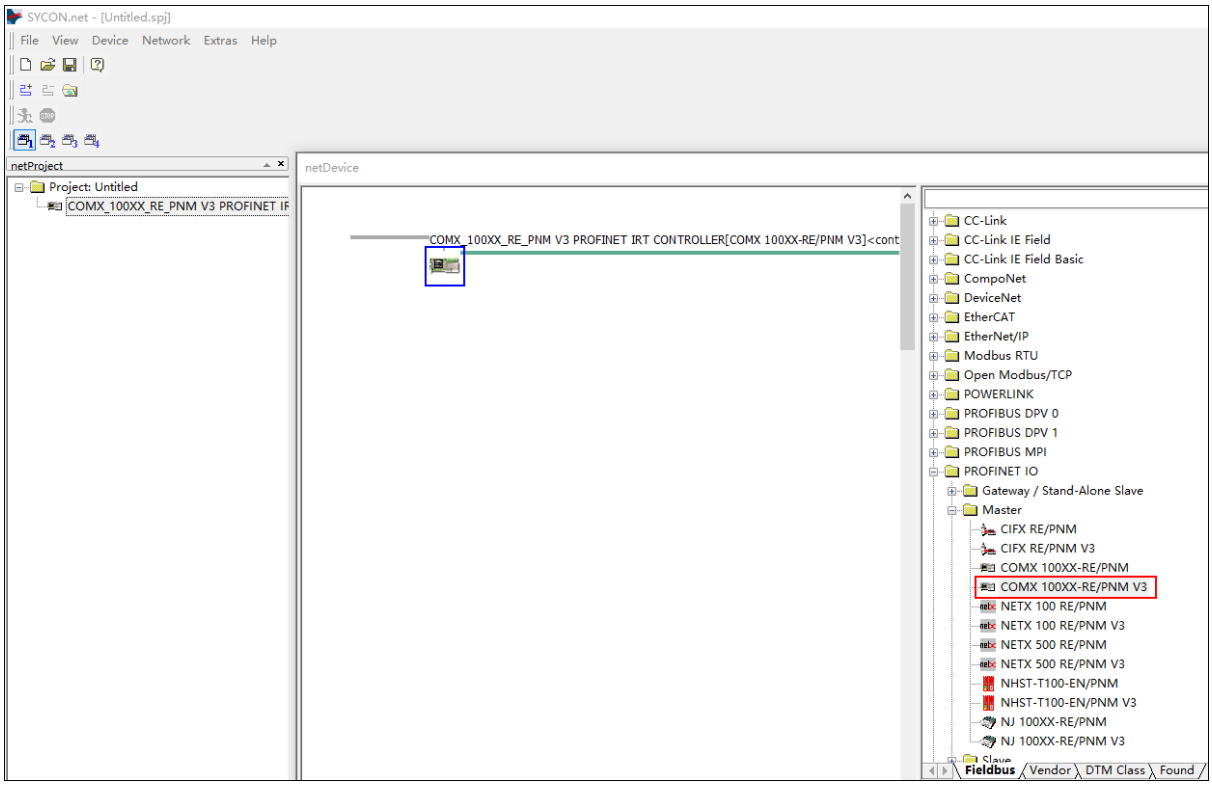
The PN slave troubleshooting include fault information for the PN slave and its I/O submodules.

Fault Code	Diagnostic Information	Definition	Solution
0x00	-	No fault	-

Fault Code	Diagnostic Information	Definition	Solution
0x70	MODULE_ID_ERROR	The I/O module types between the master and slaves do not match.	1. Check whether the I/O module types between the master and slaves are compatible. 2. Check whether the corresponding I/O modules between the master and slaves exist.
0x71	MODULE_INPUT_LEN_MISMATCH	The input data slot length of the corresponding modules between the master and slaves does not match.	Overridden by fault 0x70, the solution is as follows: 1. Check whether the I/O module types between the master and slaves are compatible. 2. Check whether the corresponding I/O modules between the master and slaves exist.
0x72	MODULE_OUTPUT_LEN_MISMATCH	The output data slot length of the corresponding modules between the master and slaves does not match.	Overridden by fault 0x70, the solution is as follows: 1. Check whether the I/O module types between the master and slaves are compatible. 2. Check whether the corresponding I/O modules between the master and slaves exist.
0x80	MASTER_PLC_STOP	The PN master PLC is in STOP status.	Communication requires the PN master PLC to be in RUN status.
0x81	NETWORK_ERROR	The network between the PN master and slaves is not connected.	Check whether the network ports between the PN master and slaves are properly connected. 1. Ensure the slave is working properly. 2. Check whether the wiring is disconnected. 3. Optimize the wiring by eliminating potential interference sources.

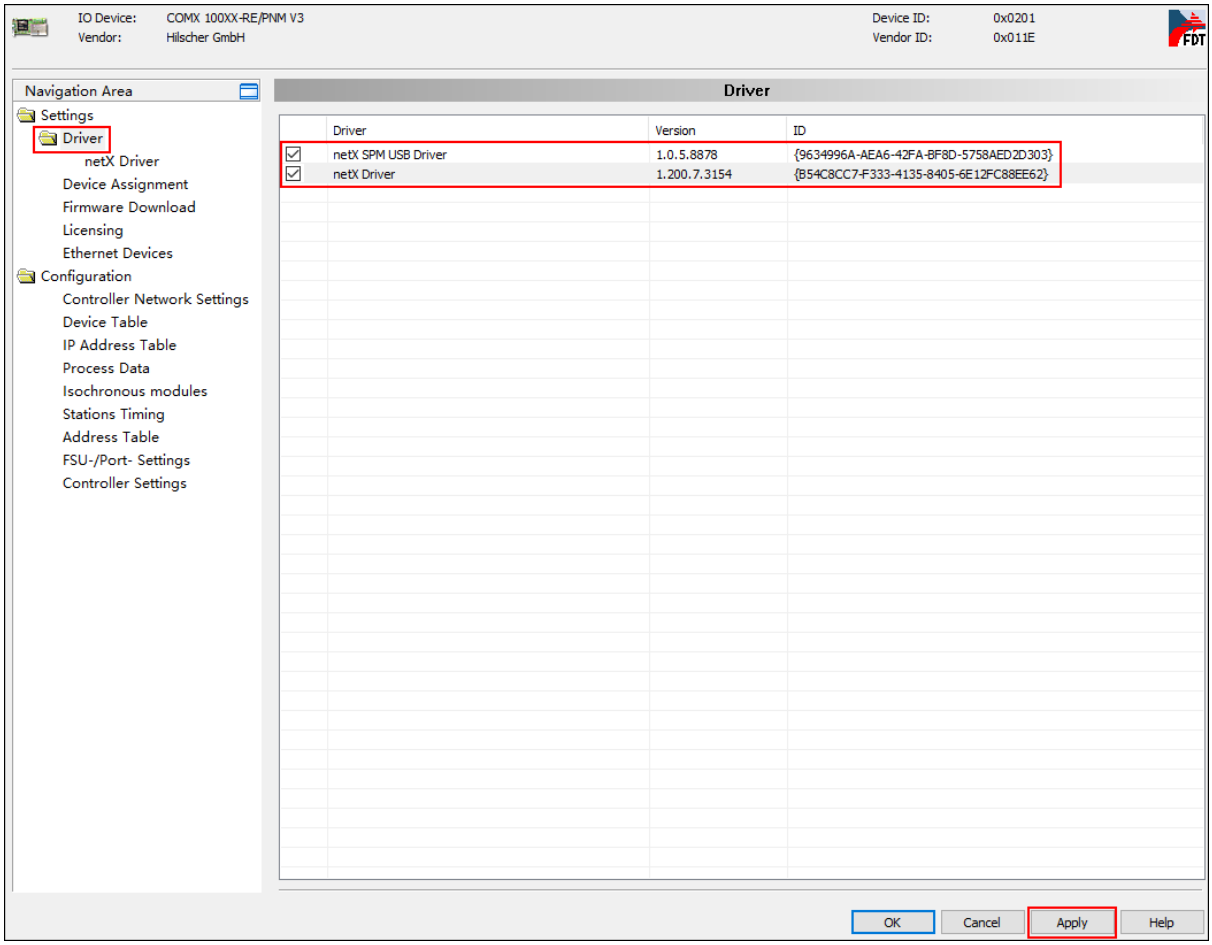
10.6.5.3 PN Master Configuration (EVO800)

10.6.5.3.1 PN Master Configuration (SYCON.net)



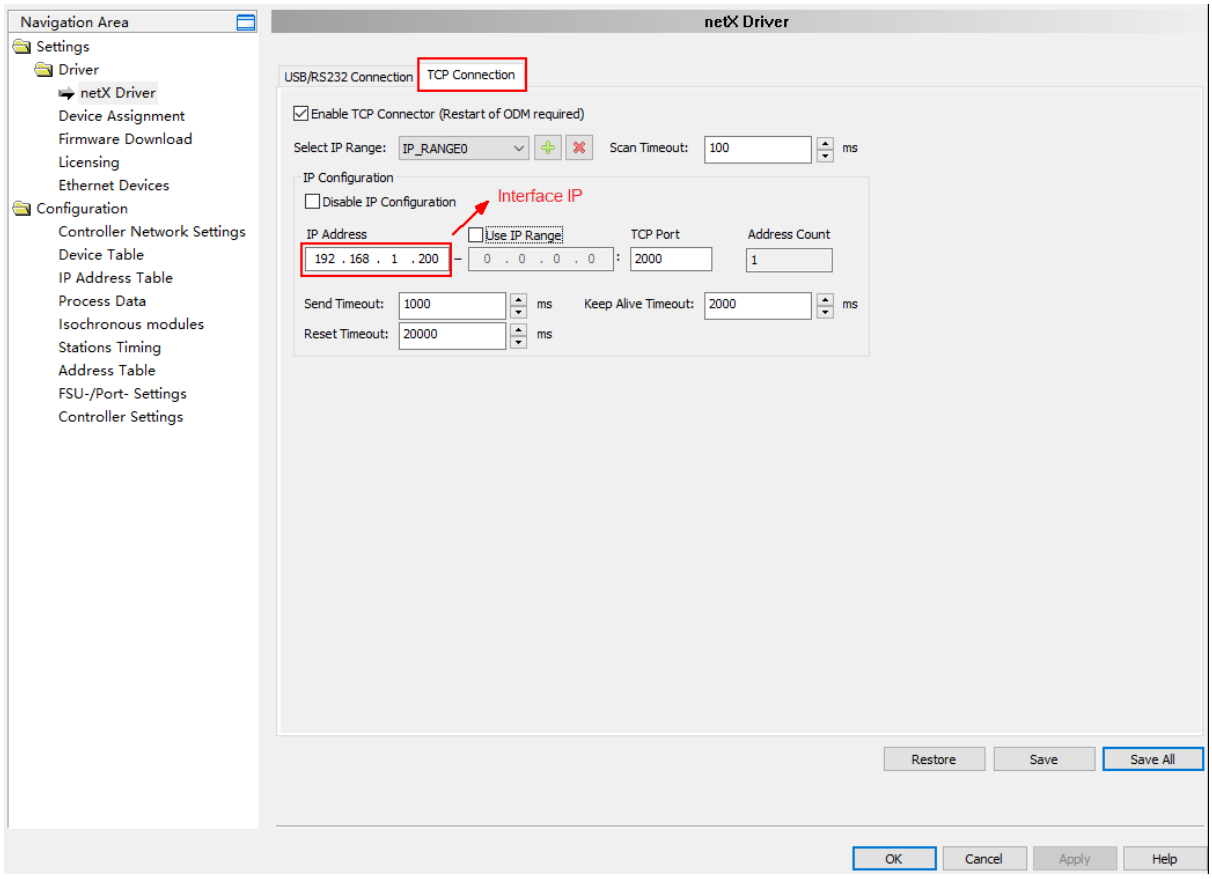
This section introduces how to configure the PN master and its slaves using the SYCON.net software.

Prerequisites

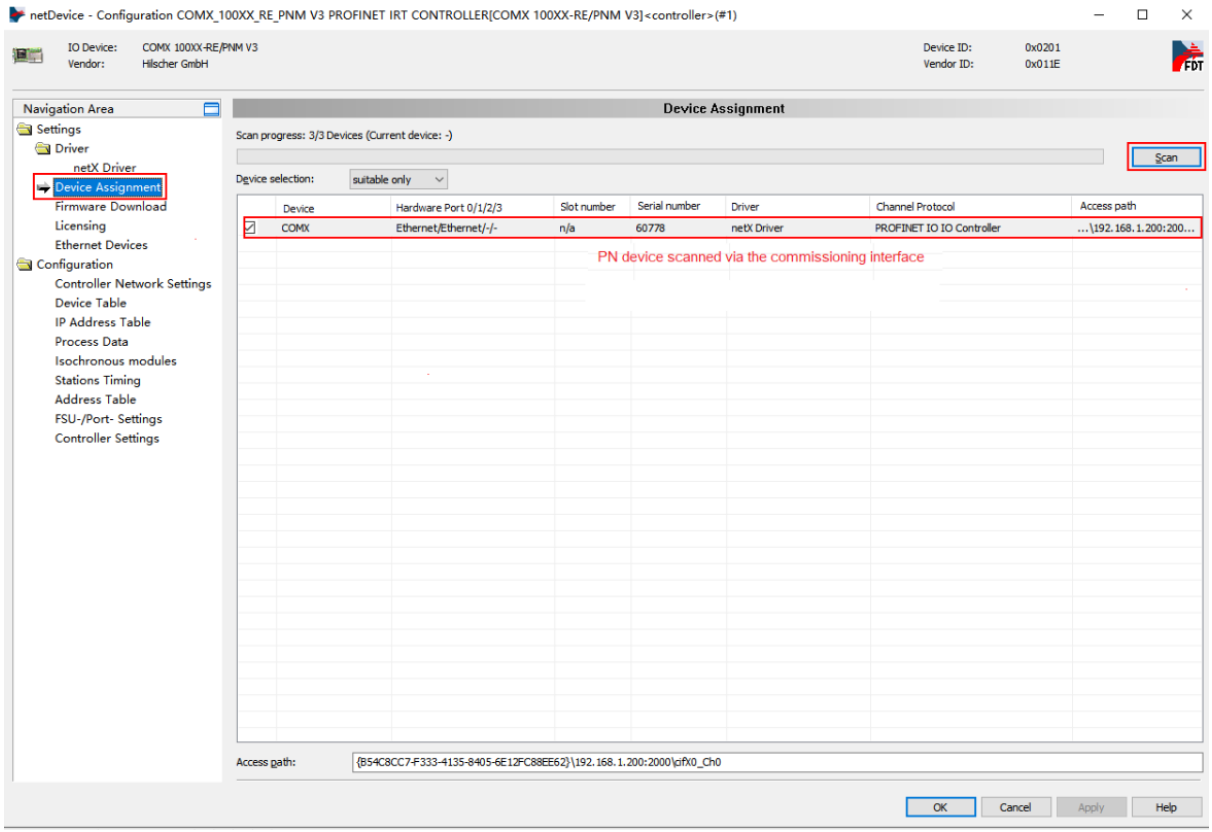


- SYCON.net software has been installed.
- The slave device description file has been obtained.
- Hardware connection has been completed.
  PN can connect to the PC via the commissioning interface. The default IP of the commissioning interface is 192.168.1.200 (ensure that the local network is configured in the 192.168.1.XX subnet).

PN master configuration



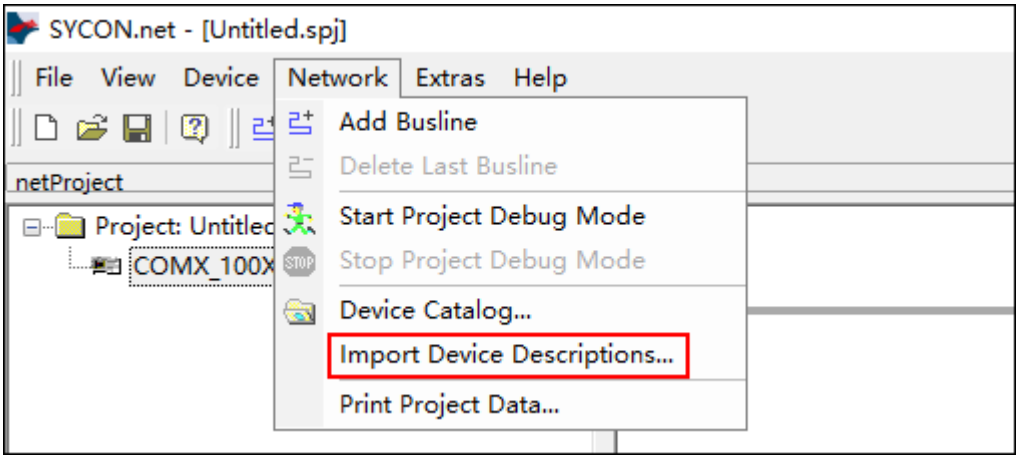
1. Launch the SYCON.net software as the admin.
2. Add a PN master. On the "Fieldbus" tab on the right of the interface, select "PROFINET IO > Master > COMX 100XX-RE/PNM V3" and drag it into the "netDevice" window, connecting it to the gray data line.



3. After adding the master, double-click the master icon to open the configuration page. On the "Driver" tab, check the configuration items as shown below, and click "Apply".

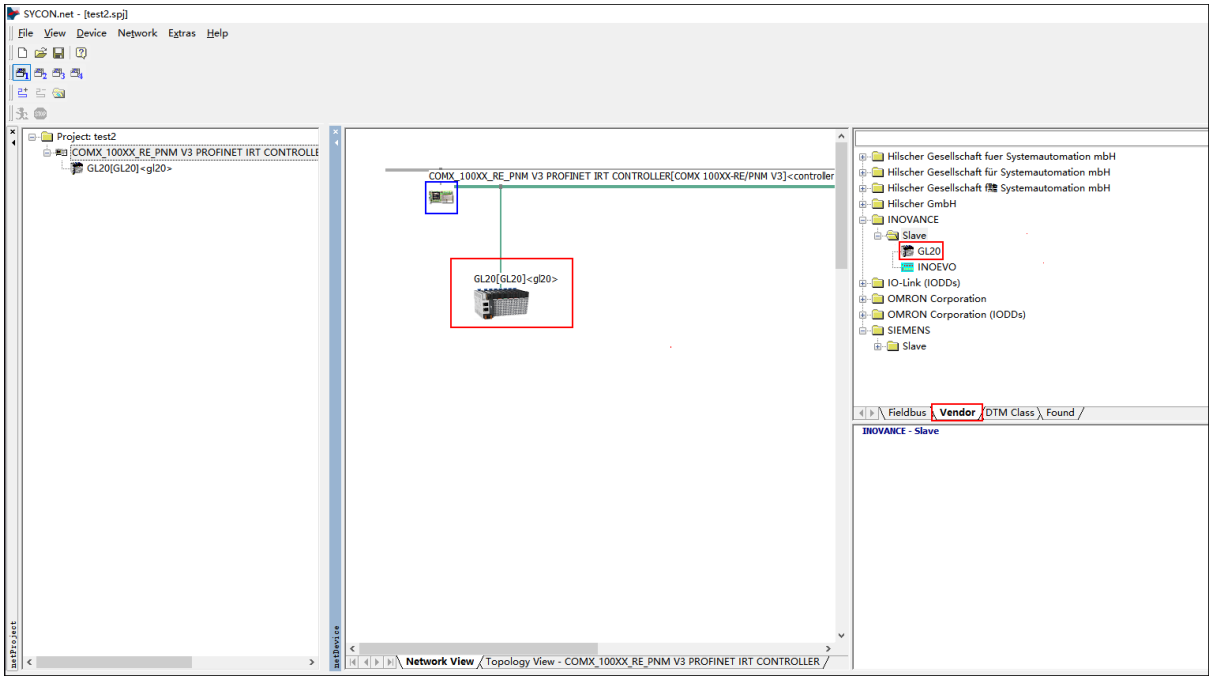
4. When connecting to the master via Ethernet, select "Driver > netXDriver" on the configuration page. On the "TCP Connection" tab, configure the following parameters: Click  in the "Select IP Range" area, set the IP range to "IP_RANGE0"; set "IP Address" to "192.168.1.200"; set "TCP Port" to "2000".

5. Select the "Device Assignment" tab, click "Scan". Once the PN module is found, click "Apply", then click "OK".



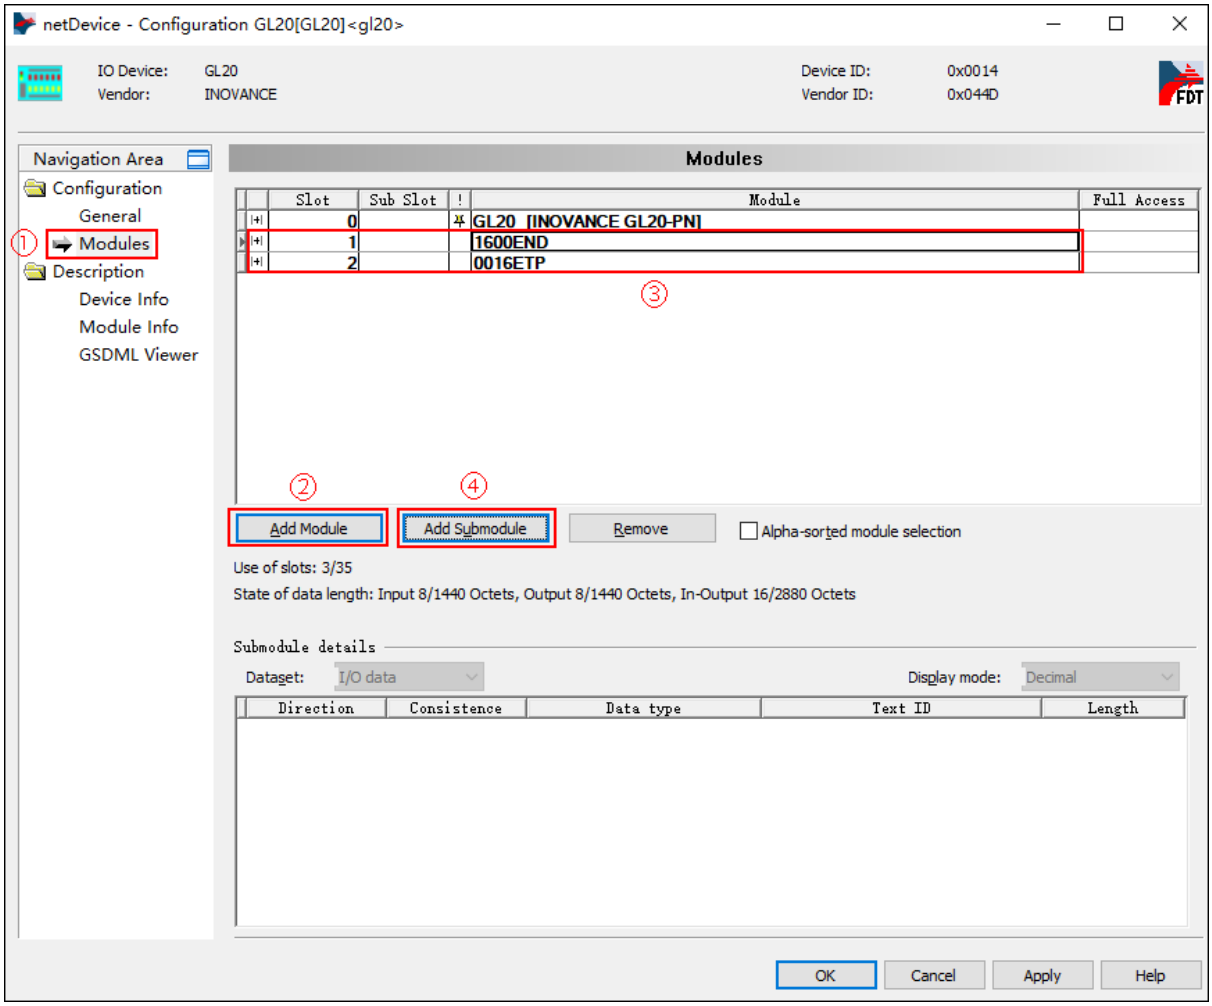
PN slave configuration

Taking the addition of a GL20-RTU-PN slave as an example.



1. Import the slave device description file.

   In the menu bar, select "NetWork > Import Device Description" to import the slave device description file. You can view the added device on the "Vendor" tab on the right of the interface.

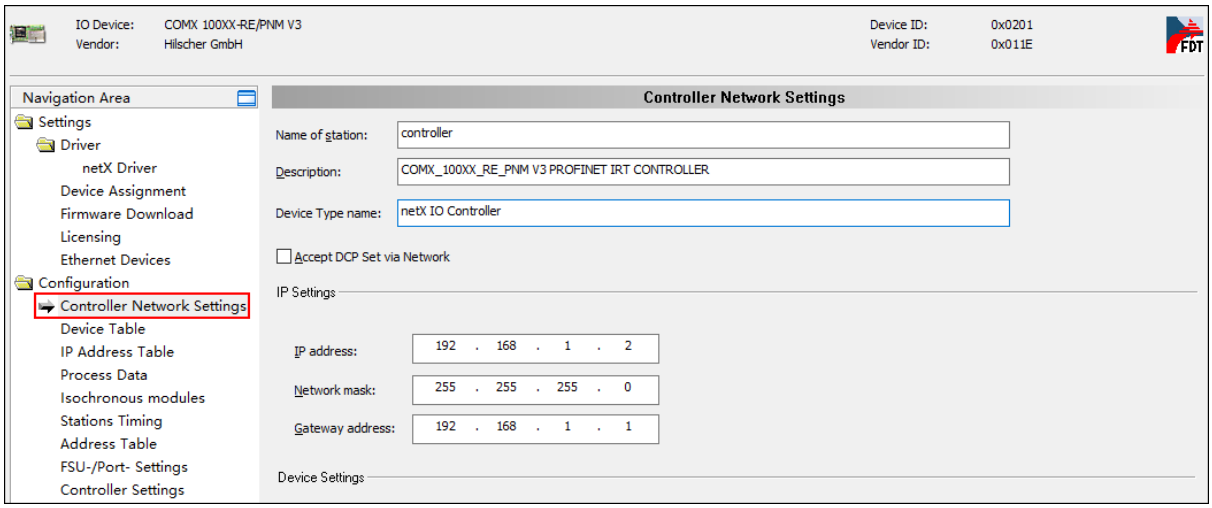


2. Add the GL20-RTU-PN slave.

   On the "Vendor" tab, select "INOVANCE > Slave > GL20", and drag it under the master.

3. Add submodules.

   Double-click the added GL20-RTU-PN and select the "Modules" tab. Click "Add Module", select the submodule type, and click "Add Submodule" to add the submodule.

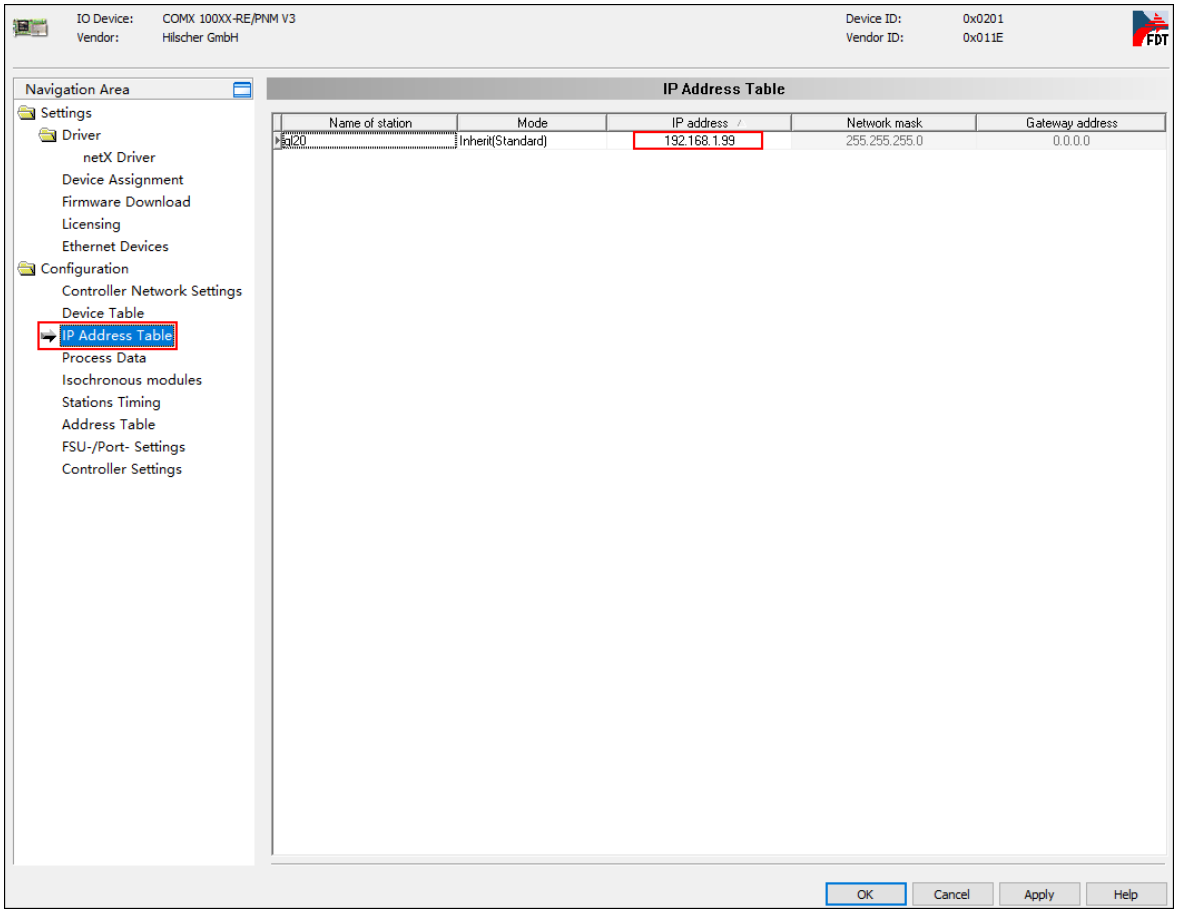


Master/Slave address configuration

1. Set the IP address for the master.

   Double-click the master icon to open the master configuration page. Select "Controller Network Settings"

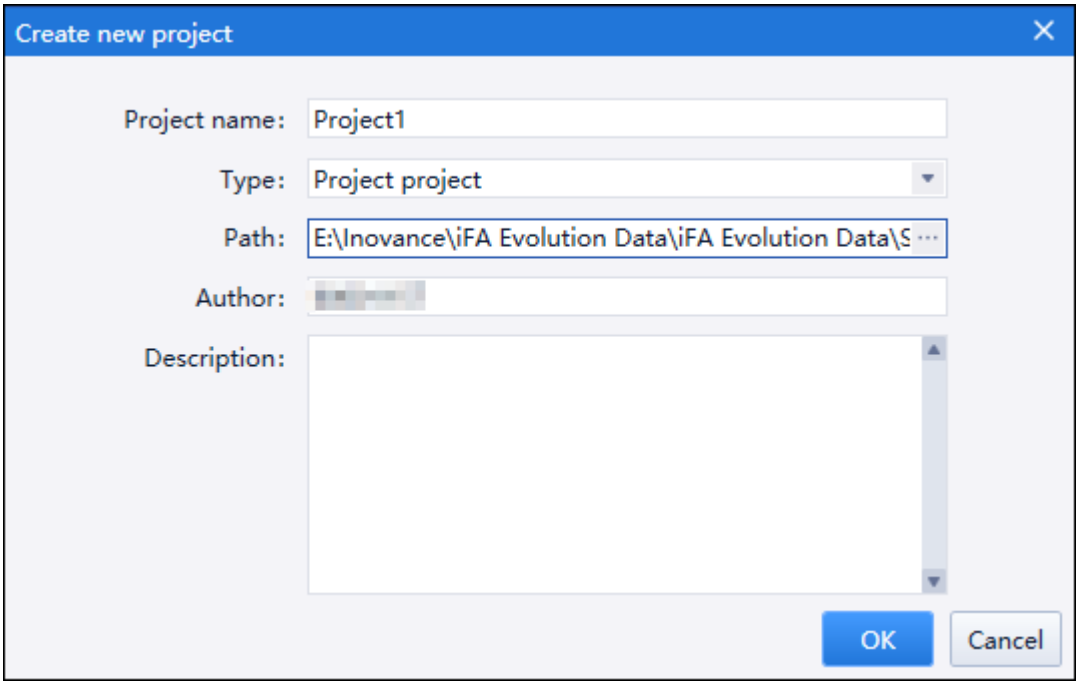
to configure the parameters related to master IP address.



2. Scan and set the slave devices.

a. Select the "Device Table" tab, set the slave device names, and click "OK".

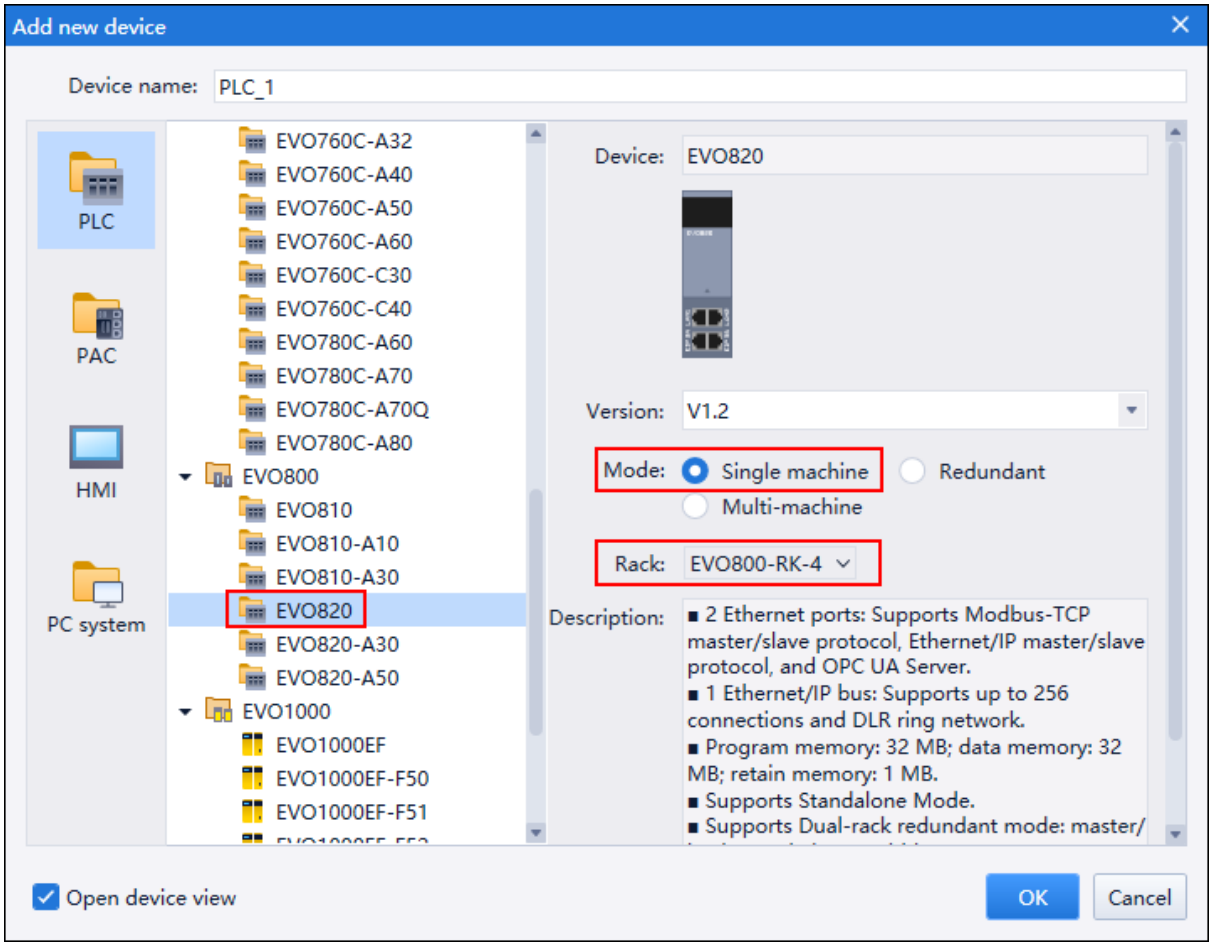
b. Select the "IP Address Table" tab, set the slave IP addresses, and click "OK".



10.6.5.3.2 PN Master Configuration (iFA)

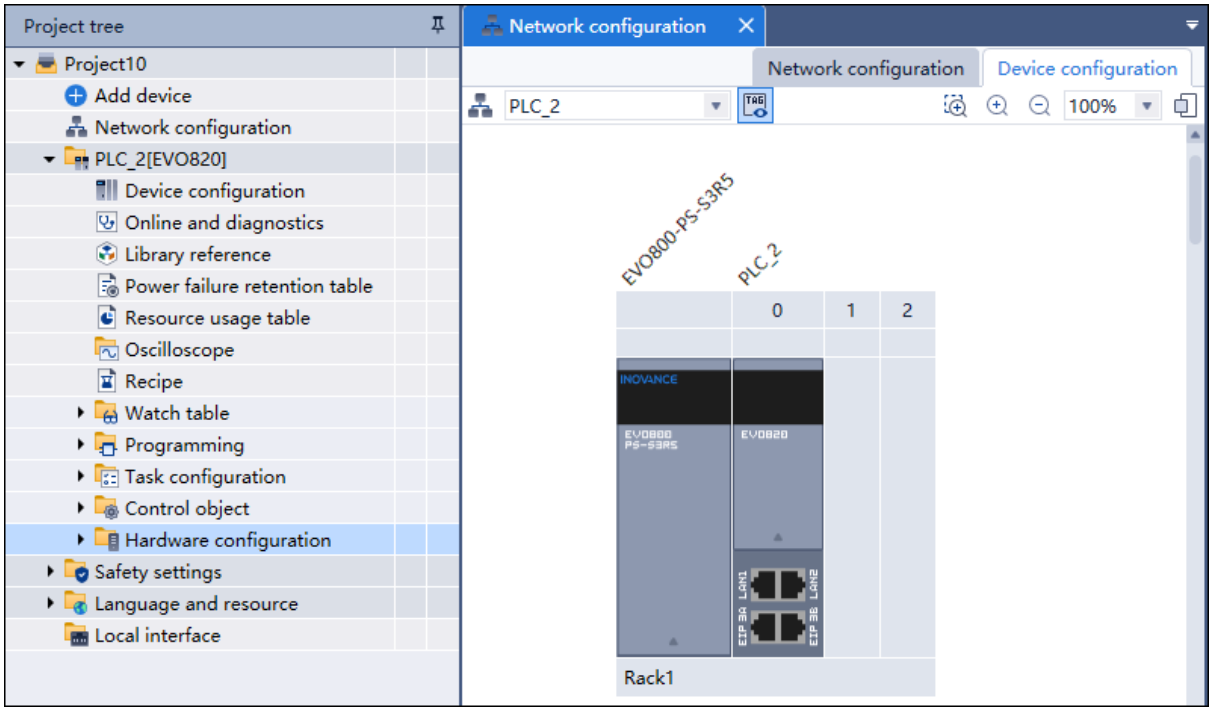
Prerequisites

- All products in the configuration example have been installed, wired, and powered on.
- The PC installed with iFA Evolution is connected to the LAN1 port of the EVO820 control module via a network cable.



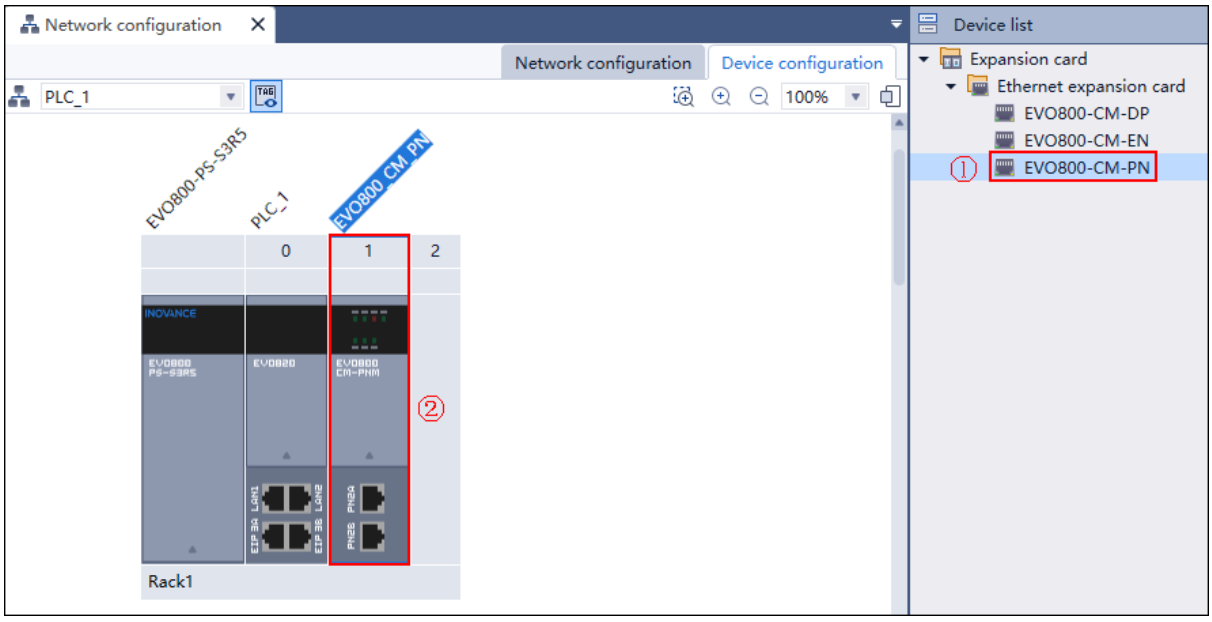
Procedure

1. Create a new project.
   In the menu bar, select "Project > New". Enter the project information (select "Engineering project" for "Type"), and click "OK".

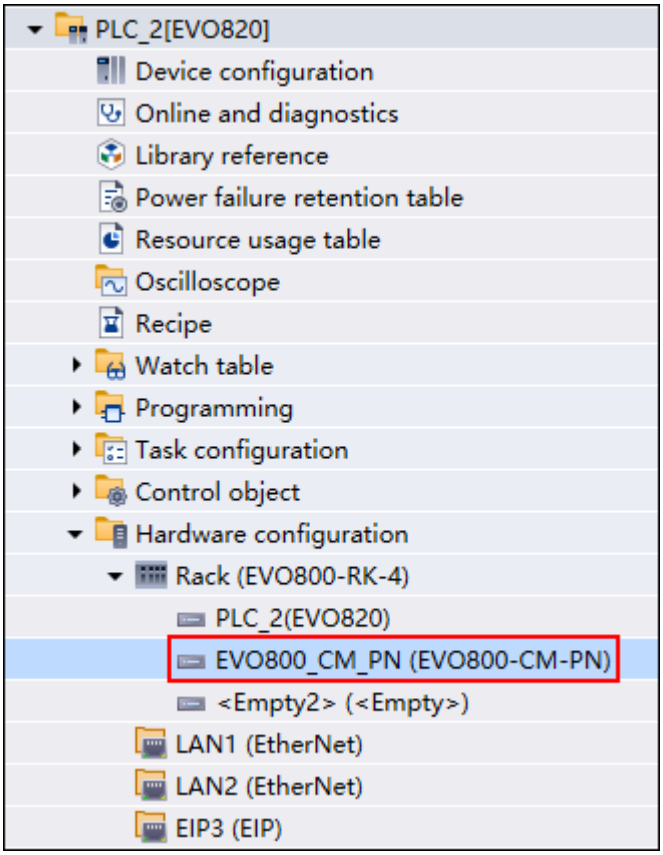


2. Add a new device.

   Double-click "Add device" in the project tree, click "EVO820" in the opened dialog box, enter the device name, "Mode" is set to "Single machine" by default, select the proper "Rack", and click "OK".

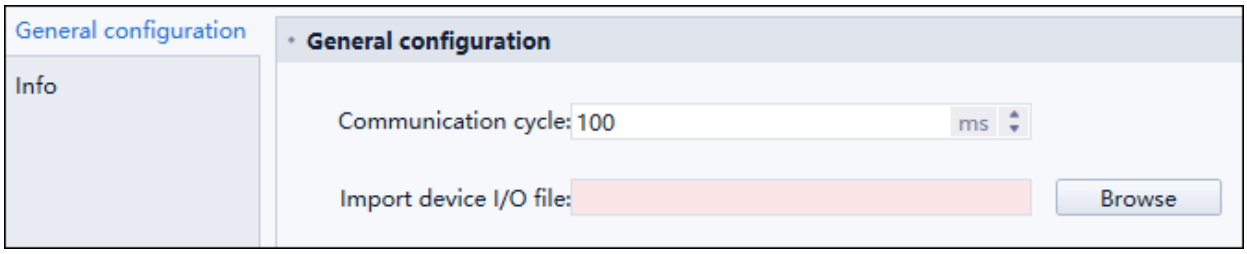


The newly added EVO820 device appears in the project tree.

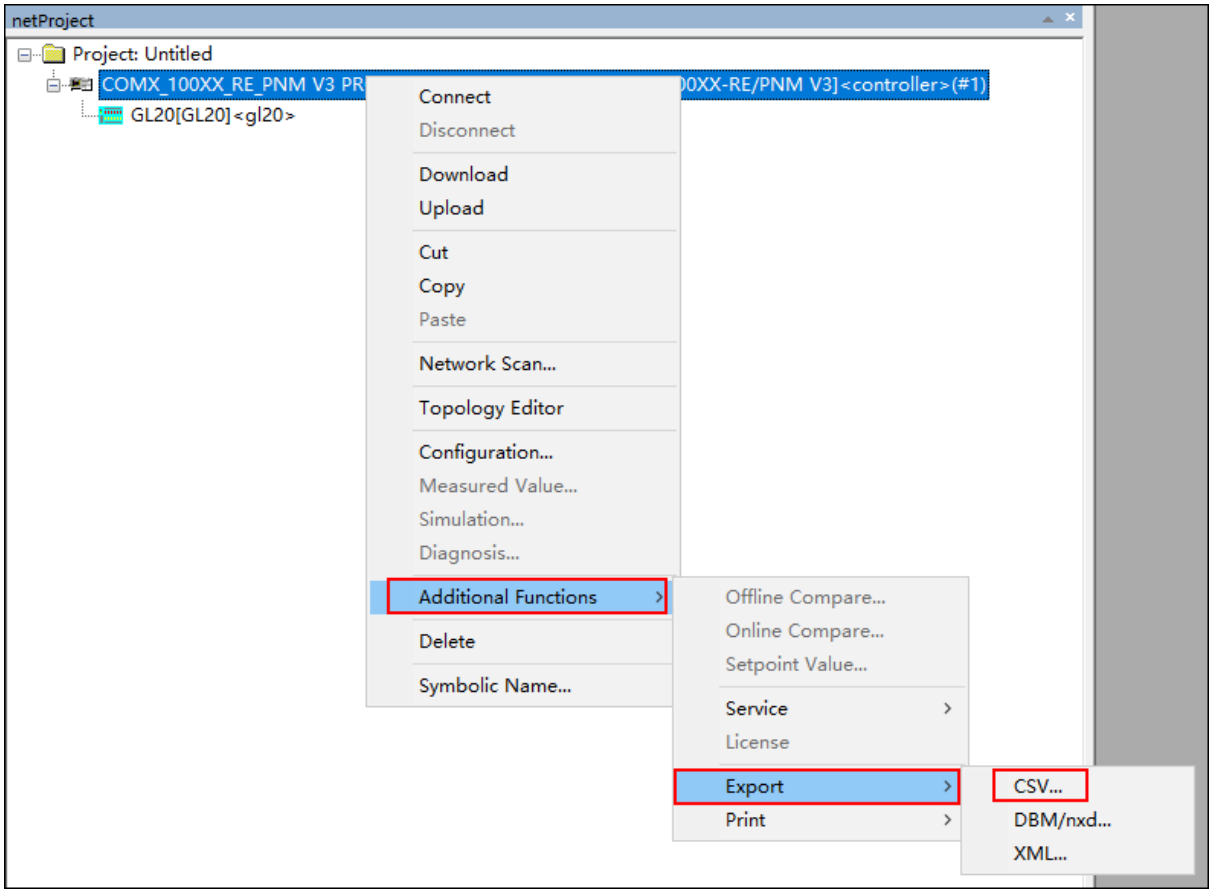


3. Add the EVO800-CM-PN module.

   In the project tree, double-click "Device configuration", then double-click "EVO800-CM-PN" in the "Device list" to add the PN master expansion module.



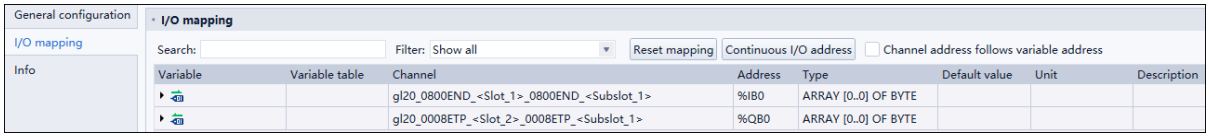
The newly added PN master expansion module appears in the project tree.



10.6.5.3.3 PN Master Configuration

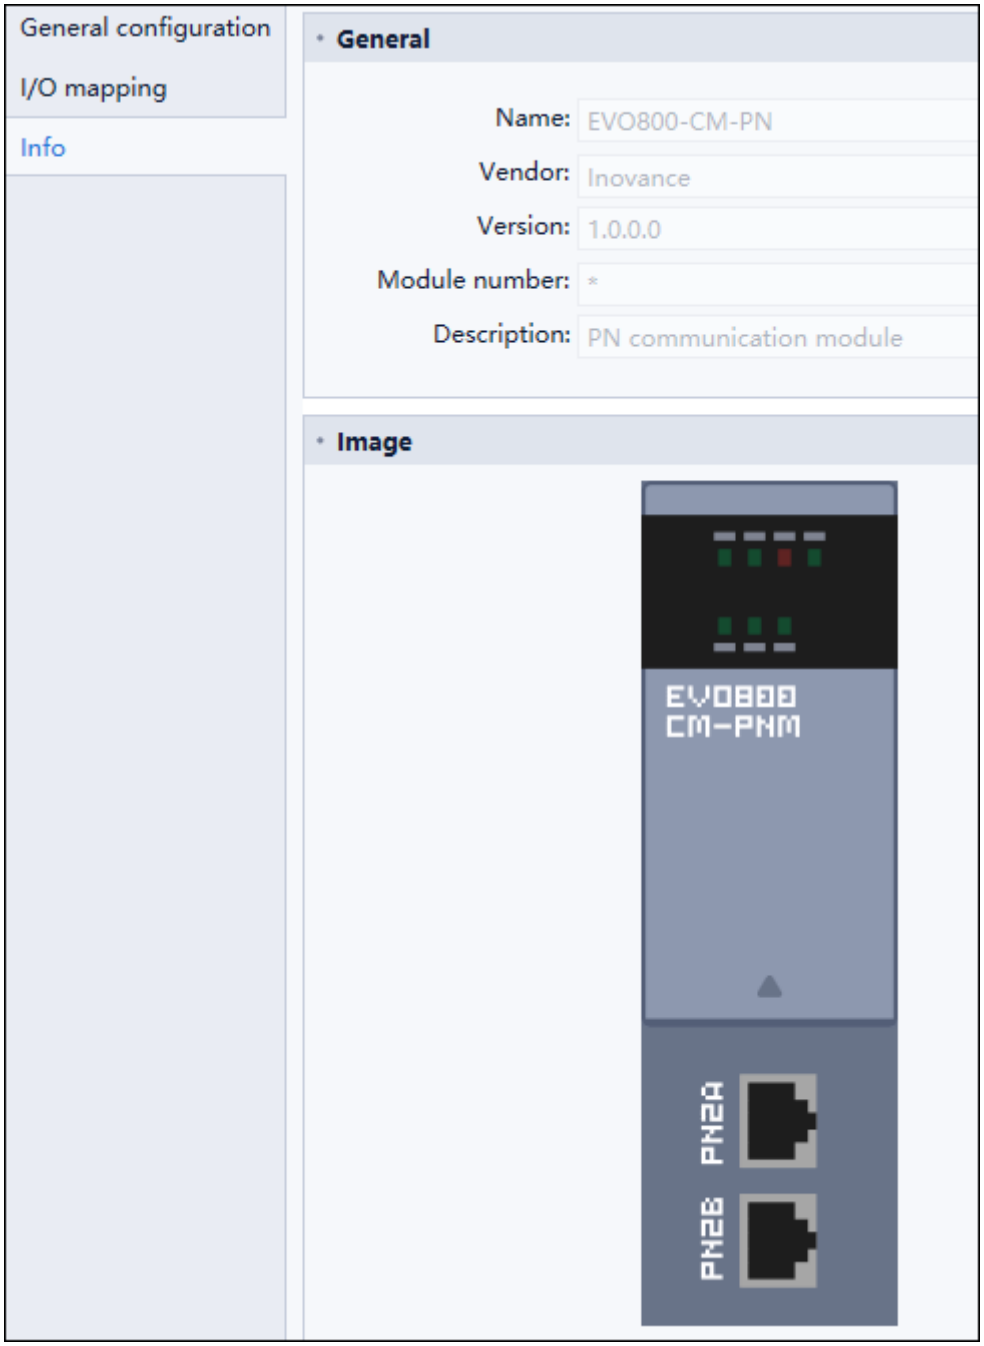
10.6.5.3.3.1 General Configuration

Double-click the PN master node to enter the master parameter configuration interface.



- Communication cycle: The backplate communication cycle between the PLC and the PN module. Default: 100 ms.
- Import device I/O file: Click "Browse" to select a CSV file (exported from SYCON.net software) for import.
  To export the I/O configuration file of the PN module from SYCON.net:
  After configuring the master, right-click the master, and select "Additional functions > Export > CSV" to save the file in CSV format.

10.6.5.3.3.2 I/O Mapping

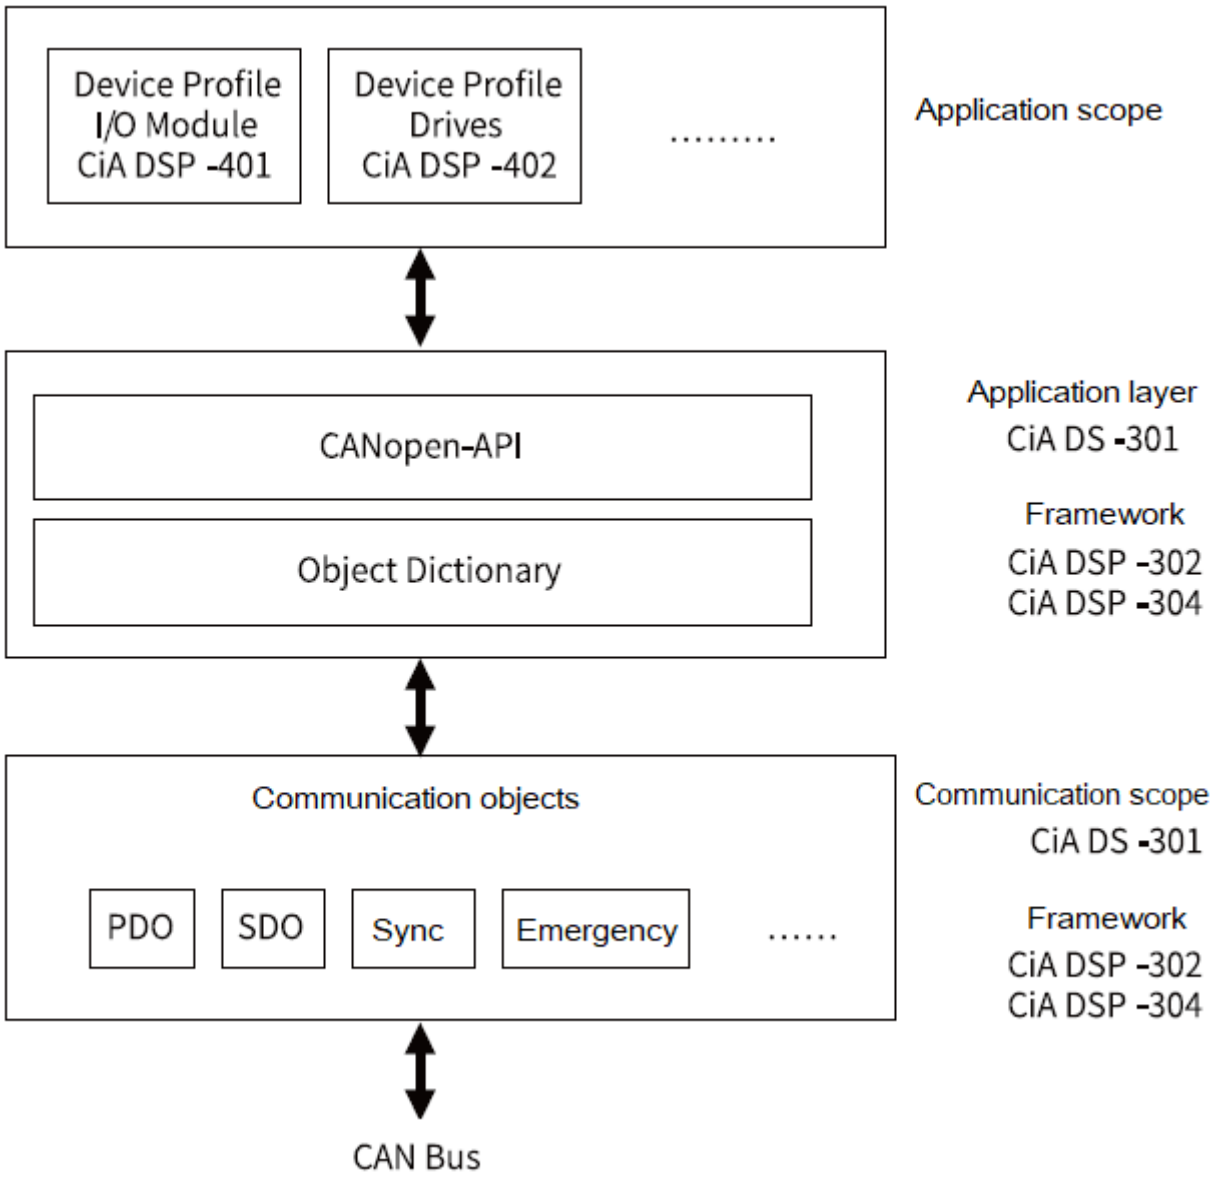


After importing the device I/O configuration file on the general configuration page, you can view the I/O settings related to PN communication, as shown in the figure below:

For details about the configuration parameters, see 10.6.3.3.9 I/O Mapping.

10.6.5.3.3.3 Information

This interface displays the general information and image of the device, as shown in the following figure.



10.6.6 CANopen Communication Configuration (EVO400, EVO500, EVO700, APC500)

10.6.6.1 Usage Workflow

Introduction

CANopen is a family of industrial communication protocols for distributed automation control devices based on the CAN (Controller Area Network) bus. It was promoted and developed by the manufacturers and user association CiA (CAN in Automation), and standardized by the end of 2002 under the standard number CENELEC EN 50325-4. CANopen defines application layer protocols, communication layer protocols, and various application protocols, featuring openness, reliability, and flexibility. It is widely used in fields such as mechanical engineering, robotics, building automation, and automotive electronics. The following figure shows the overall architecture of CANopen.

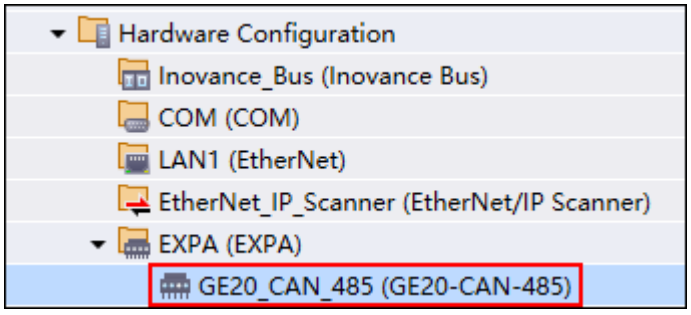
The application layer provides applications with acknowledged and unacknowledged services and defines communication objects. Those services can be used to request data from a server. Communication objects are used during data exchange. They are used to exchange process data and service data, process management, or system clock synchronization, fault status management and node state control/ monitoring. A communication object is defined by a structure, transmission type, and CAN identifier. The typical parameters of communication objects include: CAN identifiers used for data transmission, transmission type of messages, inhibit time or event time, which are all defined by the communication protocol.

Each CANopen device uses an object dictionary as its primary data structure. The object dictionary serves as the primary medium for data exchange between the application layer and CAN bus communication. The object dictionary can be accessed from both the application layer and the CAN bus side via specific messages. These access entries can be regarded as variables or programmer-defined areas.

Each entry in the object dictionary has an index and a sub-index. Using the index structure, entries in the object dictionary can be accurately located.

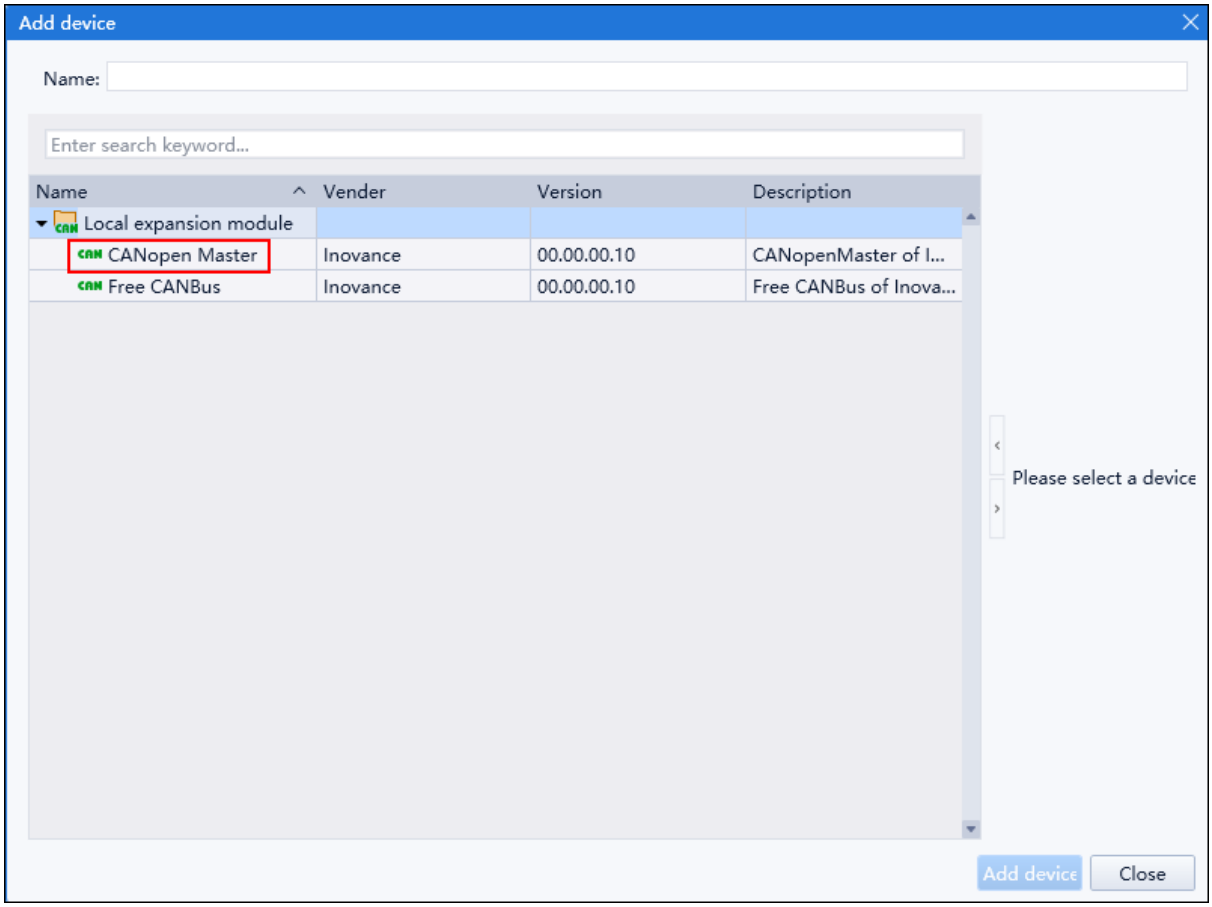
The CANopen protocol stack provides standard API functions to define entries in the object dictionary, including their read and write attributes. The object dictionary can also be accessed through communication objects via the CAN bus.

In object dictionaries, attributes of each portal must be defined, including the data type, access permission, data transmission for process data objects (PDOs), and variable range.



- PDO (Process data object) is used to transmit process data in real time.
- Service data objects (SDOs) are used to access the object dictionary of a device, set parameters, or transmit non-real-time data.
- The SYNC message, which does not contain any data, is sent from the producer to CAN network cyclically to trigger transmission of the PDO data.
- The Emergency message is triggered by internal fatal faults of the device, which consists of emergency fault code, fault register, and manufacturer-specific faults.

The CiA DS-301 specification defines the application layer and communication protocol. The CiA DSP-302 specification defines the framework for programmable CANopen devices. The CiA DSP-304 specification defines the framework for secure redundant data transmission. Specific device data descriptions are defined in application protocols composed of individual device protocols, such as the CiA DSP-401 specification defining the data format for I/O modules, and the CiA DSP-402 specification defining the data format for drive control.

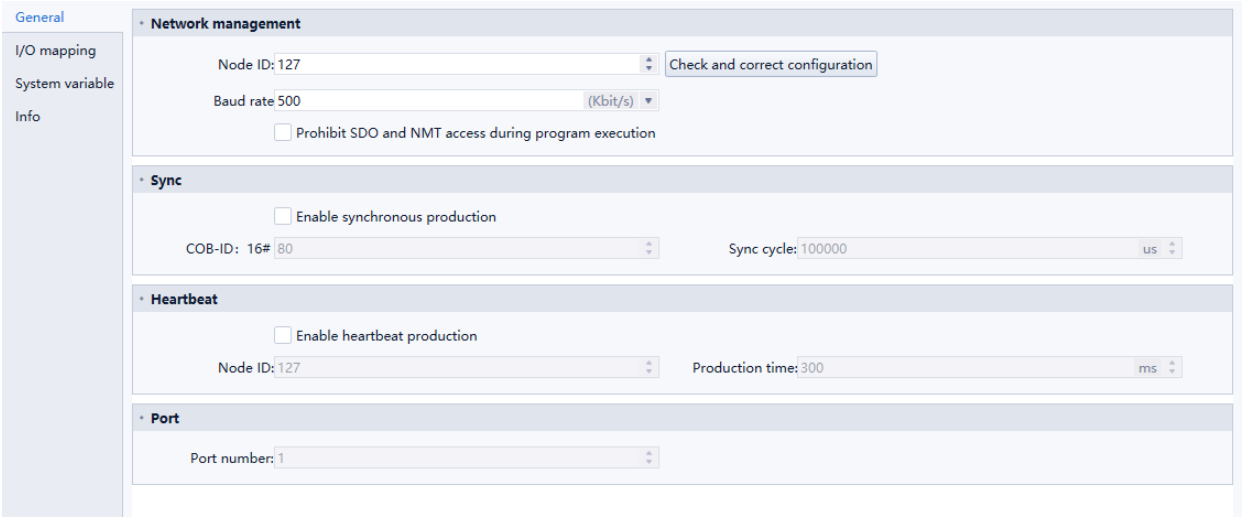


CANopen usage process

The general CANopen usage process is as follows, illustrated using the EVO500 series PLC:

1. Add a PLC device supporting the CANopen protocol to the project tree.
2. In the left project tree, add a CANopen master under the "Hardware configuration" node.
   For controllers with a CAN port, select the CAN bus node and add a CANopen master.
   For controllers without a CAN port, such as the EVO500 series, add a CAN module via an expansion card.

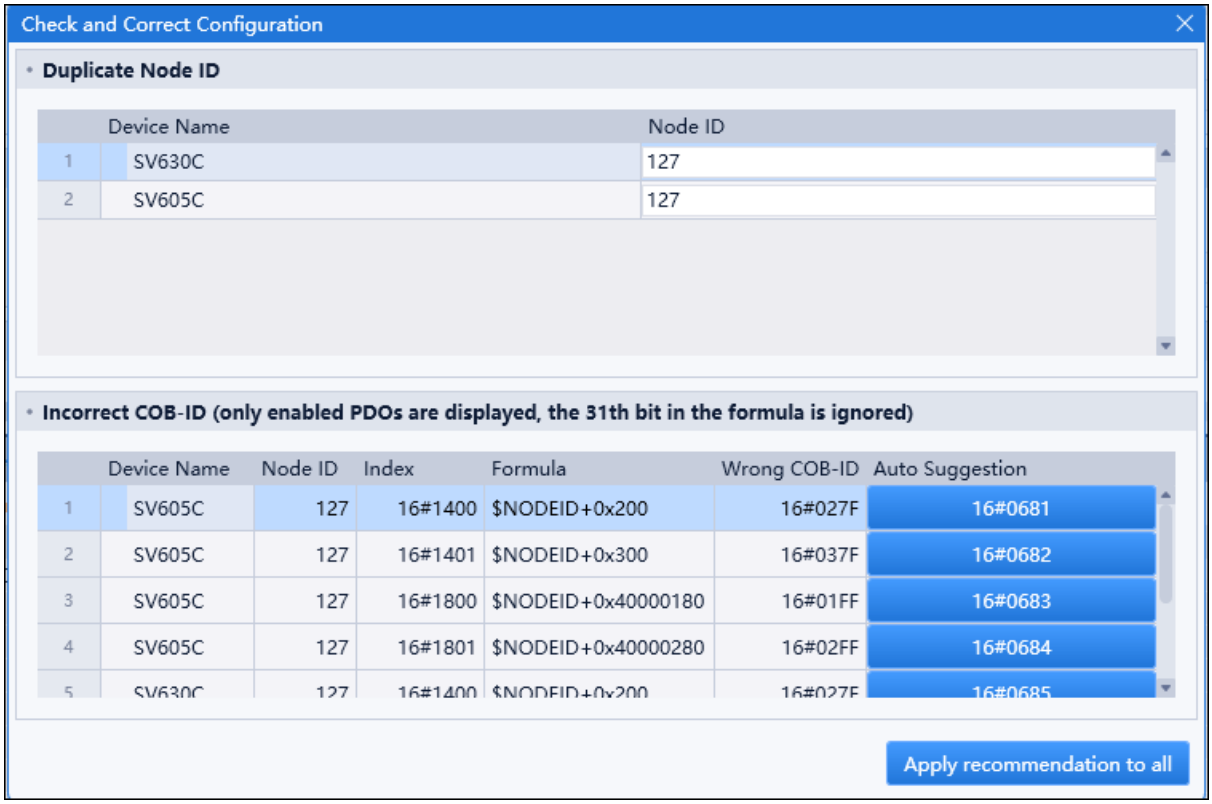
   Right-click the CAN module and select "Add device" to add a CANopen master.



After adding the CANopen master, the CANopen bus task is automatically added. By default, the CANopen bus uses this task for I/O refresh.

3. Add CANopen slave devices and modules to the master according to the hardware structure.
   A CANopen slave refers to a remote CANopen device. For third-party slaves, import them by installing an EDS file in "Menu bar > Tools > Device library", then add the third-party slave.
4. Set configuration parameters of the master, slave, and module properly. Generally, the slave node ID, PDO, and mapping are generated automatically based on the EDS file. Special configurations may involve manual modification.

10.6.6.2 CANopen Master Configuration



10.6.6.2.1 General Settings

Double-click the master node to open the CANopen master configuration interface.

Network management

- Node ID
  A decimal number indicating the unique identifier of the master in the CANopen network. Default is 127, with a range from 1 to 127.
- Check and correct configuration
  When multiple slaves are added to a CANopen system, the EDS files of different slaves may have default COB-ID configurations or manually modified node IDs, causing duplicate node IDs or COB-ID conflicts on the slave or master side. Click "Check and correct configuration", then click "Apply to all" in the pop-up window to resolve duplicate node IDs or conflicting COB-IDs.

  - Duplicate node ID: This box contains a list of all slave devices with the same node ID. Node ID conflicts between master and slave are also displayed in this list. Users can reassign new node IDs by editing the "Node ID" column. After modification, duplicate node IDs are automatically cleared.

- Incorrect COB-ID: This box displays a list of all slave devices with conflicting or invalid COB-IDs. COB-IDs in PDO can be modified in two ways:
  - Click the button in the "Auto suggest" column to modify the COB-ID for the current slave index according to the value displayed on the button.
  - Click "Apply to all" to modify all incorrect COB-IDs according to the values displayed in the "Auto suggest" column.

- Baud rate
  The baud rate used for transmission on the bus. Unit is kbit/s. The following baud rates can be set: 10, 20, 50, 100, 125, 250, 500 (default), 800, and 1000.

> NOTE
>
> If the CPU module is at the beginning or end of the network, the matching resistor on the CANopen port must be set to ON. Communication distance is related to baud rate, so a reasonable baud rate must be set.

- Prohibit SDO/NMT access during program execution
  If this item is checked, the slave cannot be accessed via SDO or NMT during program execution. For example, SDO and NMT access to the slave cannot be performed in the user program or on the slave commissioning page.

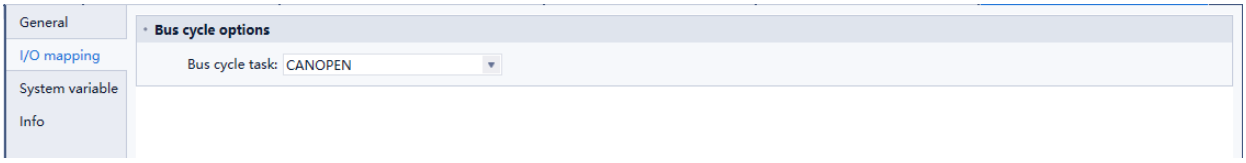
Sync

- Enable sync production
  If enabled (default: disabled), the master will send synchronous messages. Only one slave in a CANopen bus system can enable synchronous production. Synchronous type PDO sends messages according to the set type after the synchronous message is sent.
- COB-ID
  Communication object identifier, used to identify the synchronous message ID. The value is 16#80 and cannot be modified. If the slave enables synchronous production, the same COB-ID is used for identification.
- Sync period
  Synchronous messages are sent at time intervals defined by the synchronous period. The unit is microseconds, with a range from 2000 μs to 4294967000 μs. It must be an integer multiple of the bus task time.

Heartbeat

Heartbeat is another node protection mechanism: Unlike the node watchdog function, heartbeat can be triggered by either the master or the slave. Typically, the master sends heartbeats to the slave devices. The slave sets the node ID of the master to be monitored, enabling the slave to monitor the master.

- Enable heartbeat production
  If enabled (default: disabled), the master will send heartbeat messages.
- Node ID
  The unique identifier for sending heartbeat messages. Default is the master node ID, with a range from 1 to 127.



- Production time
  The time interval for sending heartbeat messages (unit: milliseconds), with a range from 2 ms to 32767 ms. It must be an integer multiple of the bus task time. Default is 300 ms.

Port

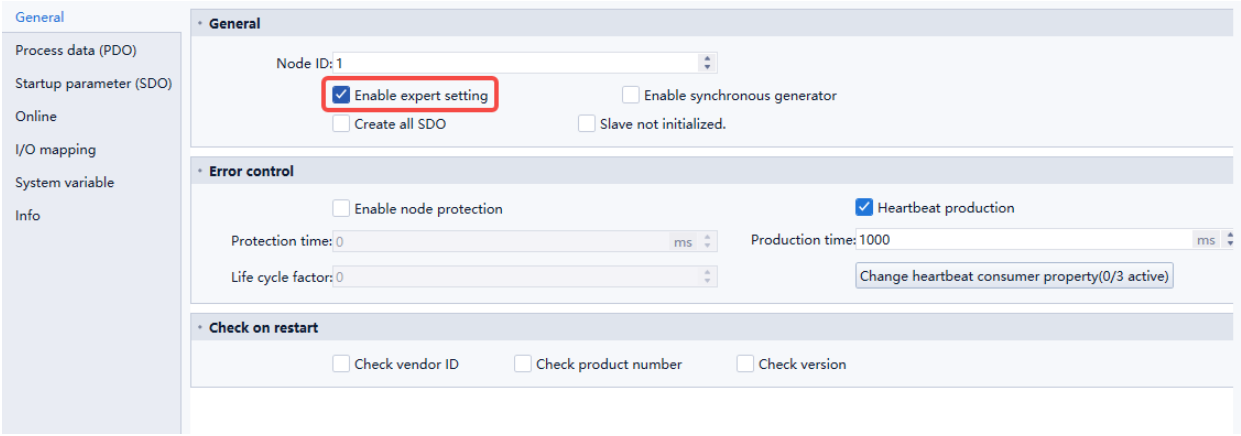
- Port number
  Used to distinguish between different CAN ports when multiple CAN ports exist.

10.6.6.2.2 I/O Mapping

All task names and bus cycle settings will be displayed in the bus cycle options. For CANopen communication, it is recommended to prioritize the default CANOPEN task.

10.6.6.2.3 System Variables

In the "System variable" tab, an instance (variable) of type _SYS_SlaveState is specified for the master and the device ID value of the master is displayed.



10.6.6.2.4 Information

The "Information" tab displays the following information for the current module: name, vendor, group, version, module number, and description.

10.6.6.3 CANopen Slave Configuration

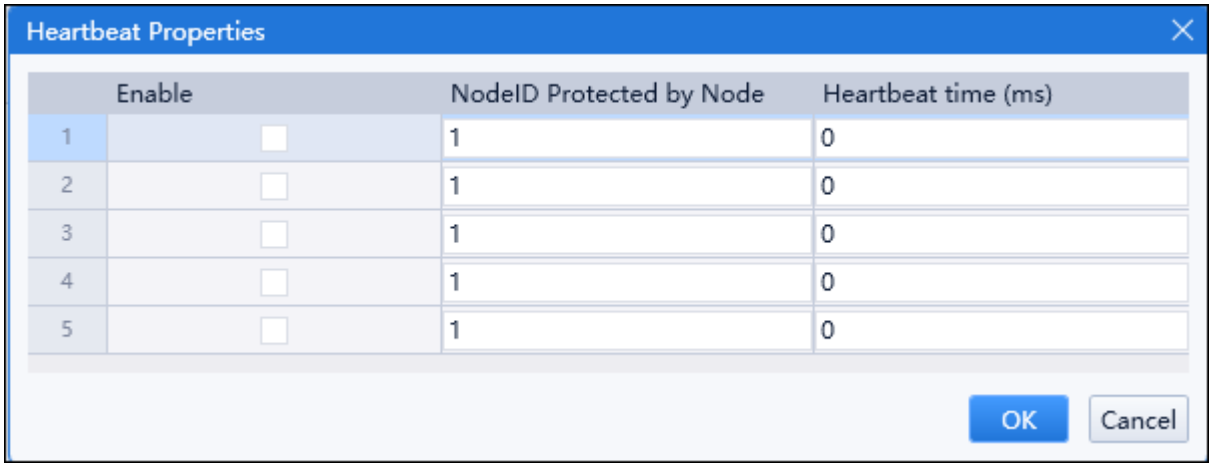
10.6.6.3.1 General Settings

Double-click the slave node to open the CANopen slave configuration interface.

General Settings

- Node ID
  The unique identifier of the slave in the CANopen network ranges from 1 to 127 (decimal), and must match the slave's own identifier (such as a DIP switch).
- Enable expert settings
  Enable this option to configure expert parameters, such as node protection, heartbeat production, emergency messages, restart checks, PDO mapping operations, system SDO display, and SDO exception jumps.
- Enable sync generator
  If this option is enabled (default: disabled), the slave will send synchronization information. A CANopen bus system can only have one enabled sync producer. Synchronization transmission parameters use the master's synchronization configuration parameters.
- Create all SDOs
  Enable to create SDO objects in the object dictionary with writable attributes, such as object access attributes being RW, WO, RWR, RWW. The created SDOs are displayed in the service data object interface.
- Slave uninitialized
  If enabled, SDO parameters are not sent at startup.

Error control



Used to detect the online status of nodes, including node protection and heartbeats.

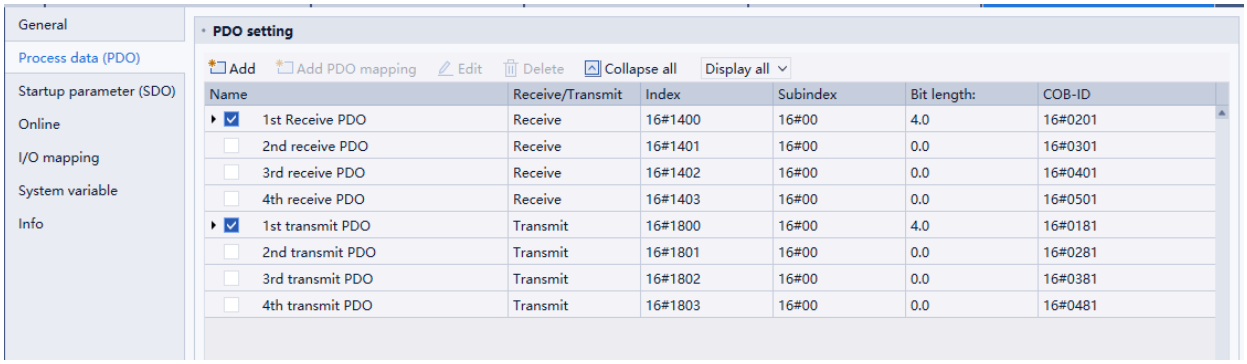
Node protection is used by the master to detect the online status of the slave. The master periodically sends node protection information, and the slave responds to the information. If the slave does not respond within the node protection time (protection time × lifecycle factor), the master considers the slave lost.

Heartbeats can be produced by the slave or the master. The producer broadcasts heartbeat messages on the CAN bus, and the consumer consumes the heartbeat. If a node is set to consume heartbeats and does not detect the heartbeat production corresponding to the node ID within the set heartbeat consumption time, it considers the node lost. Typically, slaves consume the master's heartbeat to detect the online status of the master.

- Enable node protection
  Node protection and heartbeat production are mutually exclusive. The master periodically sends node protection frames during the protection time. If the slave does not provide a response containing a specific protection COB-ID (communication object ID) within the node protection time (protection time × lifecycle factor), the slave is considered to be offline.

- Protection time
  The interval at which the master sends node protection frames, ranging from 10 ms to 65535 ms. It must be an integer multiple of the bus task cycle.
- Lifecycle factor
  Used in conjunction with protection time. If the slave does not respond within the node protection time (protection time × lifecycle factor), the master considers the slave lost. The value range is from 1 to 255.
- Heartbeat production
  Check this option to enable heartbeat production by the slave, which sends heartbeat production frames at the production time interval. This setting is mutually exclusive with node protection.
- Production time
  The interval at which the slave sends heartbeat production frames, ranging from 10 ms to 32767 ms. It must be an integer multiple of the bus task cycle.
- Change heartbeat consumer properties
  Click this button to set the heartbeat producers consumed by the slave. By heartbeat consumption configuration, the slave can check the online status of the corresponding heartbeat-producing slave. Typically, the slave consumes the heartbeat produced by the master.

The heartbeat consumption configuration list is used to configure the heartbeat producers being consumed. Configuration is only possible after enabling "Heartbeat production". After enabling, the "NodeID protected by node" (range: 1 to 127) defaults to the master's heartbeat production node ID. If heartbeat production is disabled for the master, this NodeID is 0. Heartbeat time defaults to 1.5 times the master's heartbeat production time, ranging from 1 to 65535.



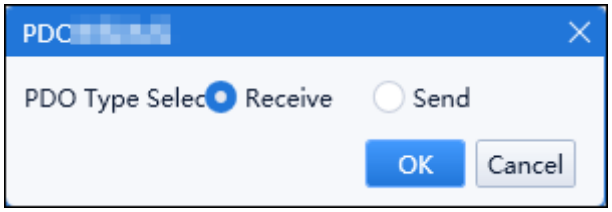
Check on restart

- Check supplier ID
  If this option is checked, the slave will check whether the vendor ID (index 1018, sub-index 01) in the object dictionary matches the slave's own vendor ID. If they do not match, the slave cannot operate normally.
- Check product number
  If this option is checked, the slave will check whether the product number (index 1018, sub-index 02) in the object dictionary matches the slave's own product number. If they do not match, the slave cannot operate normally.
- Version check
  If this option is checked, the slave will check whether the version (index 1018, sub-index 03) in the object dictionary matches the slave's own version. If they do not match, the slave cannot operate normally.

10.6.6.3.2 Process Data (PDO)

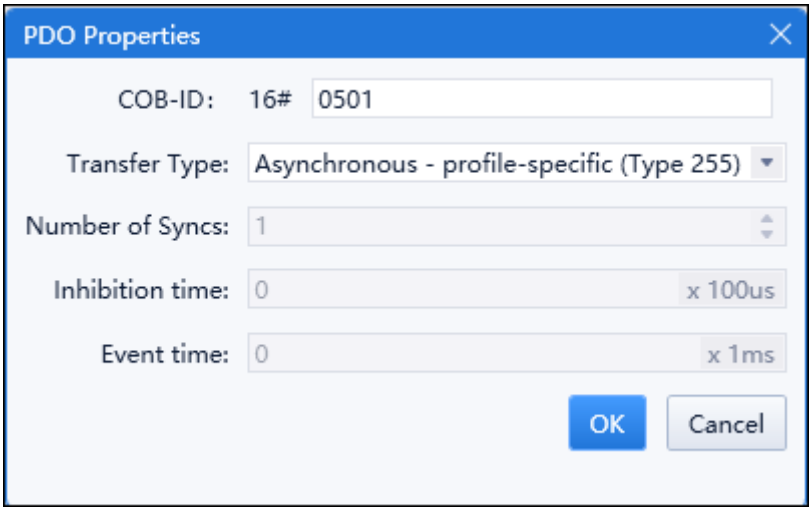
PDO (Process Data Object) is used for real-time data transmission between the master and slaves, where the received PDO is the real-time data sent from the master to the slave.

PDO includes communication parameters and mapping parameters. The communication parameters include COB-ID, transmission type, transmission control, and so on. The PDO mapping parameter indicates that the PDO transmission data comes from the index and sub-index of the object dictionary.



Name	Receive/Transmit	Index	Subindex	Bit length:	COB-ID
1st Receive PDO	Receive	16#1400	16#00	4.0	16#0201
2nd receive PDO	Receive	16#1401	16#00	0.0	16#0301
3rd receive PDO	Receive	16#1402	16#00	0.0	16#0401
4th receive PDO	Receive	16#1403	16#00	0.0	16#0501
1st transmit PDO	Transmit	16#1800	16#00	4.0	16#0181
2nd transmit PDO	Transmit	16#1801	16#00	0.0	16#0281
3rd transmit PDO	Transmit	16#1802	16#00	0.0	16#0381
4th transmit PDO	Transmit	16#1803	16#00	0.0	16#0481

Add



Click "Add" to select the PDO type in the pop-up window.

The added PDO is appended to the end of the list by default. The maximum number of received PDOs in the slave is determined by the number of object dictionary entries from index 1400 to 1600. PDOs exceeding this limit cannot be added. The name and index of the added PDO are automatically obtained from the object dictionary based on usage order and cannot be modified. Select the PDO type in the pop-up "PDO type selection" window. For details, see "PDO properties".

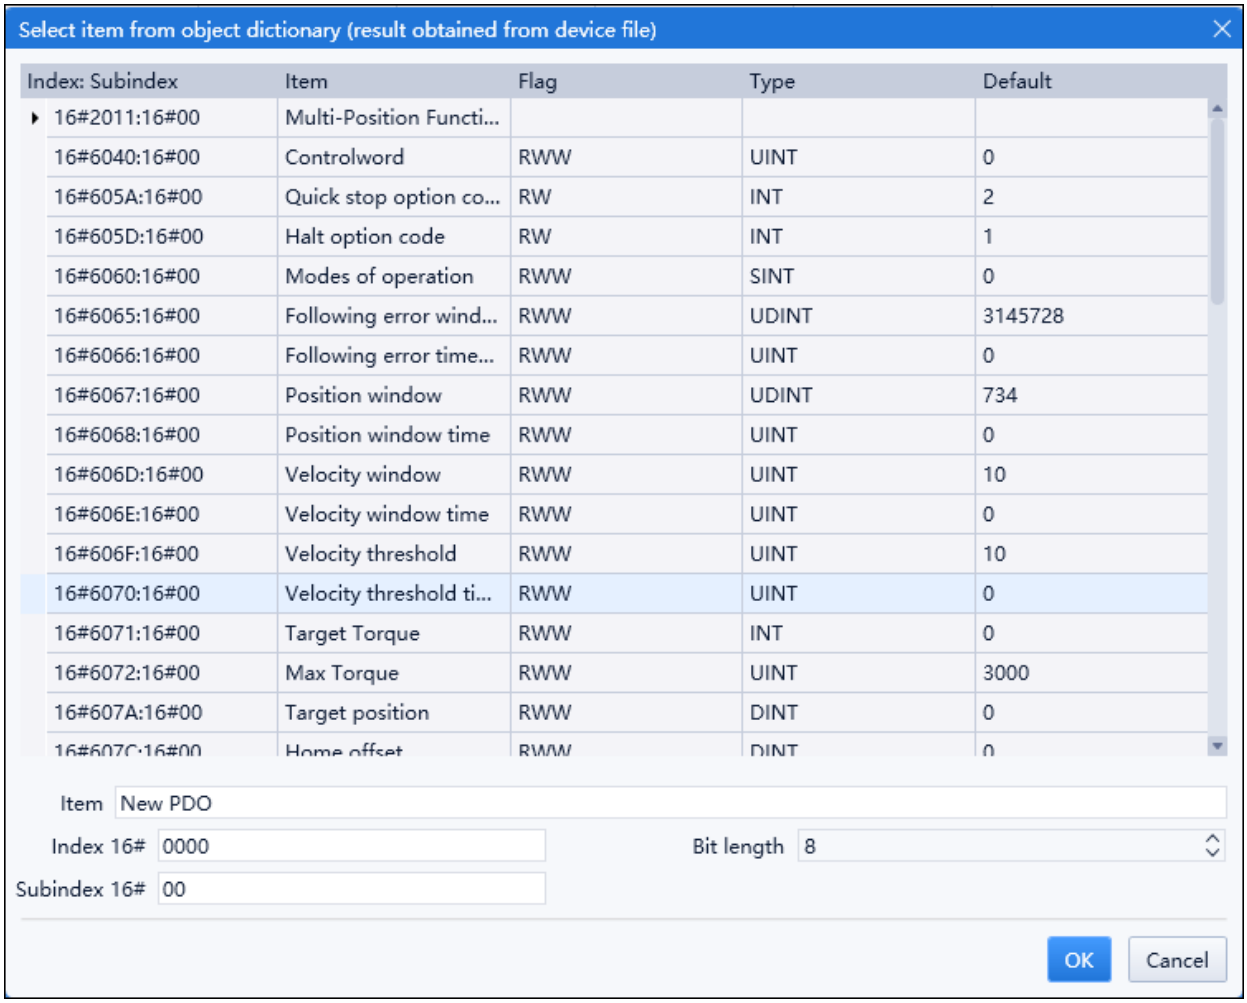
- Receive PDO: The receive PDO comes from the objects in the object dictionary starting from index 1400 and ending at index 1600. The default communication parameters for each PDO come from its corresponding subindexes. The objects that can be mapped by the receive PDO come from objects in the object dictionary that allow write access, such as RW, RWW, and WO.
- Transmit PDO: Indicates the real time data sent by the slave to the master. The transmit PDO comes from the objects in the object dictionary starting from index 1800 and ending at index 1A00. The default communication parameters for each PDO come from its corresponding subindexes. The objects that can be mapped by the transmit PDO come from objects in the object dictionary that allow write access, such as RW, RWR, RO, and CONST.

PDO properties

- COB-ID: Synchronous message ID with a range of 180-57F; 681-6DF.
- Transfer type:
  - Synchronous - Non-cyclic (Type 0): The transfer is triggered by a remote frame or by specific events defined in the device sub-protocol for certain objects.
  - Synchronous - Cyclic (Type 1-240): The transfer is triggered after every 1 to 240 SYNC messages.
  - Asynchronous - Manufacturer specified (Type 254): The transfer is triggered by specific events defined by the manufacturer for certain objects.
  - Asynchronous - Device file specified (Type 255): The transfer is triggered by specific events defined in the device sub-protocol for certain objects.

> NOTE
>
> In non-expert mode, only PDO communication parameters can be modified. PDOs and PDO mappings cannot be added or deleted.

The following table introduces different PDO transmission modes defined by the transmission type, which is part of the PDO communication parameter object and is defined by an 8-bit unsigned integer.



Transmission Type	Trigger Conditions for PDO Communication (B = both needed; O = one or both)			PDO Transmission
	Sync	RTR	Event	
0	B	-	B	Synchronous, non-cyclic
1 to 240	O	-	-	Synchronous, cyclic
241 to 251	-	-	-	Reserved
252	B	B	-	Synchronous, after RTR
253	-	O	-	Asynchronous, after RTR

Transmission Type	Trigger Conditions for PDO Communication (B = both needed; O = one or both)			PDO Transmission
	Sync	RTR	Event	
254	-	O	O	Asynchronous, vendor-specific event
255	-	O	O	Asynchronous, sub-protocol specific event
Note: SYNC - upon receiving a SYNC-object RTR - upon receiving a remote frame Event - such as a value change or timer interrupt When the transmission type is from 1 to 240, this number represents the number of SYNC objects between two PDOs.				

The default transmission type of each PDO comes from the object corresponding to PDO subindex 02 in the object dictionary. If the write permission of the corresponding object dictionary is not granted, the transmission type cannot be changed.

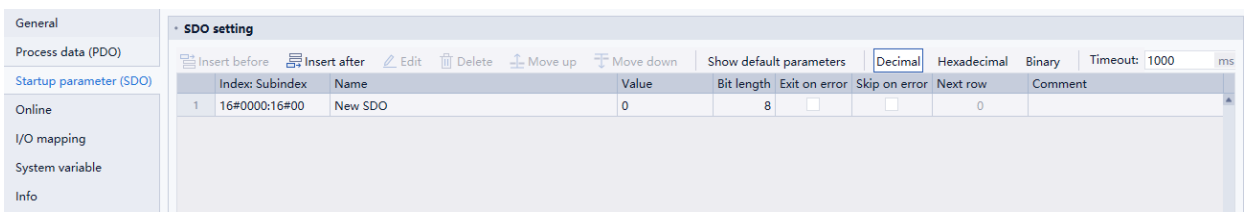
- Number of syncs: Indicates the number of sync frames the slave receives before it can start processing PDO data transmission. It depends on the transmission type and can be modified only when the transmission type is within the range of 1 to 240.
- Inhibition time: Indicates the product of the minimum interval between the transmission of two messages by the same PDO and 100 μs. This parameter prevents PDOs from being sent too frequently when a value is changed.
- Event time: Indicates the interval time (in ms) between two messages transmitted via the same PDO. The default event time for each PDO is derived from the object at sub-index 05 of the corresponding PDO in the object dictionary. If the write permission of the corresponding object dictionary is not granted, the event time cannot be changed.

Adding a PDO mapping

Add a PDO mapping to the currently selected PDO, which is added after the current PDO. The maximum length of PDO mapping is 64 bits. The PDO mapping comes from the object dictionary. The objects that can be mapped by the receive PDO come from objects in the object dictionary that allow write access, such as RW, RWW, and WO.

Editing

Edit the currently selected PDO communication parameters or PDO mapping parameters. If the PDO is selected, the PDO is edited. If the PDO mapping is selected, the PDO mapping is edited.



Delete

Delete the currently selected PDO or PDO mapping. If the PDO is selected, the PDO is deleted. If the PDO mapping is selected, the PDO mapping is deleted.

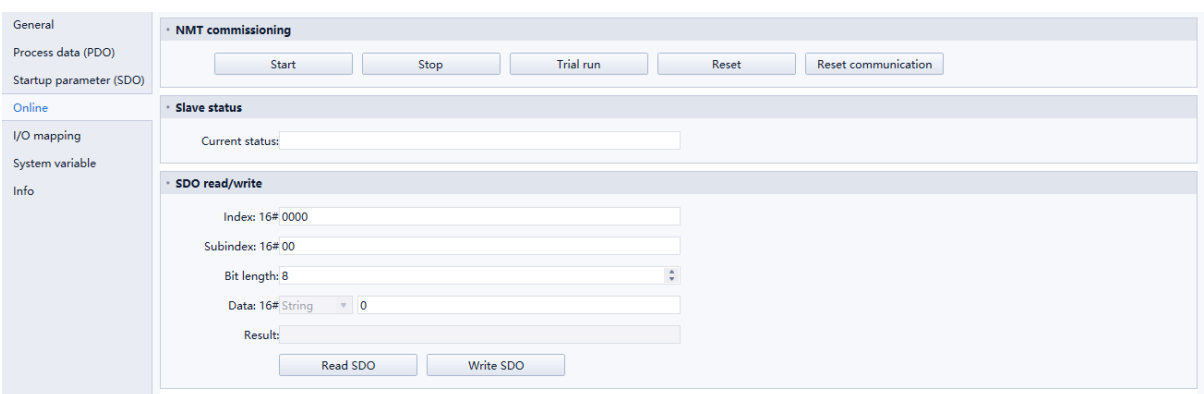
10.6.6.3.3 Startup Parameter (SDO)

SDOs are used to transmit data during slave initialization and operation. Settings on the "Service Data Object" page are written to the slave during slave initialization.

The SDO configuration interface allows you to configure selected SDOs, modify the transmission order of SDOs, and define the handling method when solutions occur during SDO transmission.

In the SDO configuration interface, click "Insert before" or "Insert after" to add an SDO before or after the selected entry. The added SDOs can be modified and moved up or down. Double-click the "Value" cell to modify the SDO value.

When SDO configuration faults occur, you can set the fault handling method. Select "Exit upon error" to directly exit configuration when a fault occurs, and no further SDOs will be configured. Select "Skip upon error" to directly jump to the selected line and continue execution downward when a fault occurs. If neither of these options is selected, the default handling method is "Skip upon error".

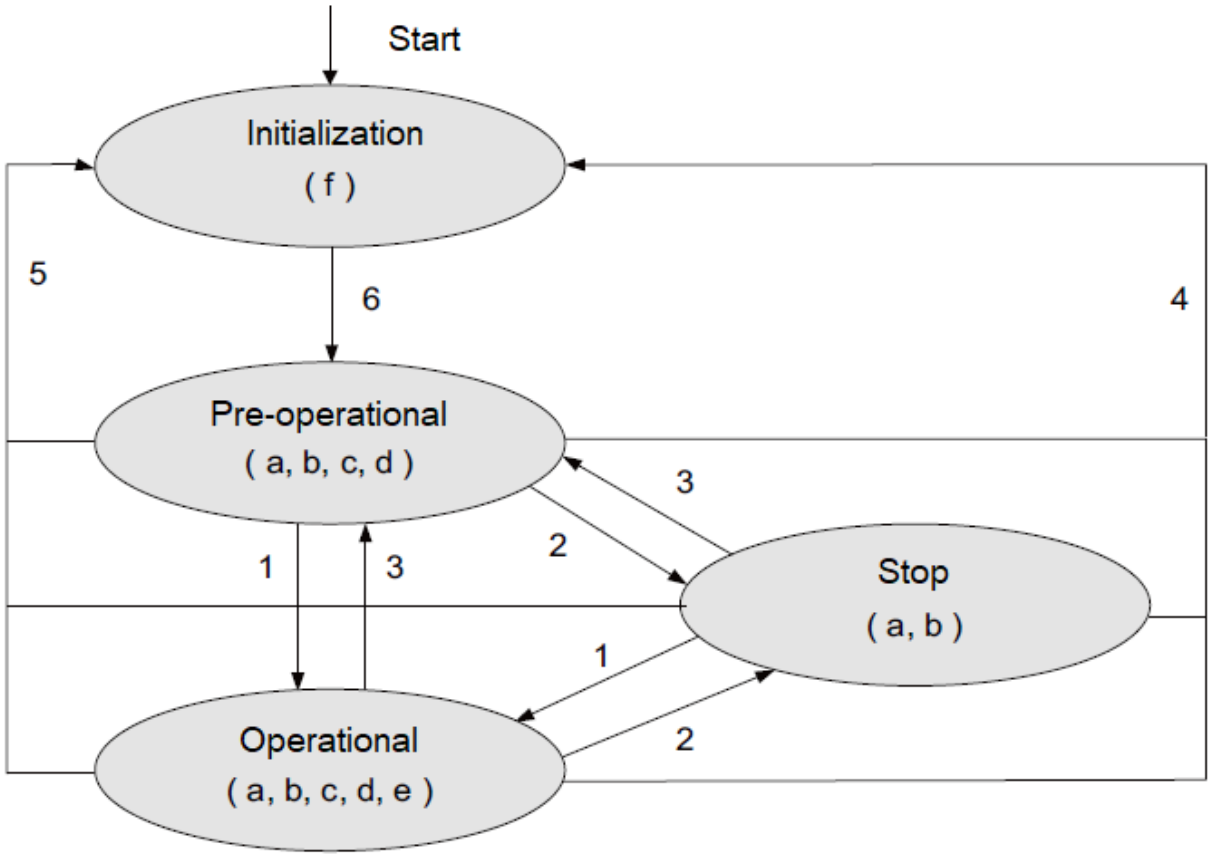


Sub-Function	Function description
Insert before	Insert an SDO parameter before the selected SDO entry. Note that all system SDOs are by default arranged at the top. It is not allowed to insert SDOs in the middle of system SDOs.
Insert after	Insert an SDO parameter after the selected SDO entry.
Edit	Edit the selected editable SDO.
Delete	Delete the selected editable SDO.
Move up	Move up the selected editable SDO. It cannot be moved above system SDOs.
Move down	Move down the selected editable SDO.
Timeout	The timeout time for SDOs. The default is 1000 ms, with a range from 0 ms to 4294967 ms.

NOTE

- Only in expert mode will the system SDOs and fault handling be displayed.
- When configuring SDO fault handling, be cautious with line jump processing. An upward jump may result in an infinite loop in SDO configuration.

10.6.6.3.4 Online



The online interface is used for master NMT control, SDO read/write, and diagnostic information acquisition.

NMT commissioning

NMT provides network management services (such as node initialization, start-up, stop, and failure detection). The services are implemented using a master-slave communication mode (with only one NMT master node).

The status of a slave node during startup can be represented by the following status transition diagram.

Note:

- a: NMT; b: Node guard; c: SDO; d: Emergency; e: PDO; f: Boot-up status transition (commands 1 to 5 are initiated by NMT service)
- NMT command words:

  1: Start_Remote_node (0x01, start node)

  2: Stop_Remote_Node (0x02, stop node)

  3: Enter_Pre-Operational_State (0x80, enter pre-operational)

  4: Reset_Node (0x81, reset node)

  5: Reset_Communication (0x82, reset communication)

  6: After device initialization, the system automatically enters Pre-Operational status and sends Boot-up messages.

Initialization includes application data initialization and communication initialization. Reset_Node resets all data of the slave node, while Reset_Communication only resets communication-related data.

The device completes initialization, enters the Pre_Operational state, and sends a Boot-up message. The NMT service can switch all or part of the nodes to different operating statuses at any time.

Description	Sub-Function	Function description	Scope of Features
NMT	Start	Run the slave node; PDO communication can only occur in the operational status.	When the slave node is in pre-operational or stopped status, click "Start" to switch it to operational status.
	Stop	Stop the slave node operation; in this status, all communication is stopped except node protection and heartbeat.	When the slave node is in pre-operational or operational status, click "Stop" to switch it to stopped status.
	Test run	The slave node enters pre-operational status; in this status, SDO communication is possible but PDO communication is not. After the slave node is initialized, it automatically enters pre-operational status.	When the slave node is in operational or stopped status, click "Test run" to switch it to pre-operational status.
	Reset a bit	First reset application configuration, then reset communication configuration data; after reset, the system automatically enters pre-operational status.	-
	Reset communication	Reset the slave communication configuration data. After reset, the system automatically enters pre-operational status.	-

SDO read/write

SDO is used to transfer large-volume, low-priority data between devices. Typical application scenarios include configuring devices on a CANopen network. It is mainly used during slave node operation to read or write SDO object values. To read or write an SDO object, the object index, sub-index, and bit length must be determined. When writing, the value must also be provided.

- Index: SDO read/write index, with a range from 16#0 to 16#FFFF.
- Sub-index: SDO read/write sub-index, with a range from 16#0 to 16#FF.
- Bit length: SDO read/write bit length, with options 8, 16, 24, and 32.
- Data: SDO read/write value; the first edit box contains hexadecimal value, the value after "=" is decimal. For SDO write operations, the value range is related to the bit length, with minimum value 0 and maximum value being the maximum representable by the bit length.
- Result: SDO read/write result; if read/write is faulty, a fault message is displayed.

10.6.6.3.5 I/O Mapping

For detailed information about I/O mapping, see 10.6.3.3.9 I/O Mapping.

10.6.6.3.6 System Variables

System variables specify variables for slaves, such as an instance (variable) of type J_SV605C_V1_0, supporting control of devices connected to the CANopen master via user programs. The device ID of the corresponding slave is also displayed.

10.6.6.3.7 Information

The "Information" tab displays the following information for the current module: name, vendor, group, version, description, and image.

10.6.6.4 CANopen Module

In CANopen slave configuration, a CANopen slave node can connect to two types of devices:

Modular devices: When connected to a CANopen slave node, the module comes with its own I/O mapping list. There is no need to use the CANopen slave I/O mapping dialog box; the slave node's PDO mapping is automatically added when the module is added.

Non-modular devices: The slave node dialog box includes an I/O mapping dialog box, and PDO mapping cannot be automatically configured.

10.6.6.5 CANopen Parameter Configuration

Configuration is an important part of the Inovance iFA programming software. If drives from other manufacturers are to be used, their EDS files must first be imported. Confirm that the drive program from other manufacturers strictly follows the CANopen communication specifications and the CIA402 standard. Correct parameter settings must be completed before calling the CANopen402 function block. Details are as follows:

Master configuration

Master configuration mainly includes communication baud rate, synchronization mode, synchronization period, heartbeat, and heartbeat interval time.

- Communication baud rate: The higher the baud rate, the higher the communication efficiency, but the shorter the communication distance. The default baud rate is 500 kbps.
- Synchronization mode: The periodic synchronization function must be selected; otherwise, the function block will not operate.
- Synchronization period: For systems with only CANopen axes and three slaves (receive/transmit PDO data < 8 bytes), it is recommended to configure a 4 ms period. It is recommended that the synchronization period match the CANopen task scan cycle time in the program.

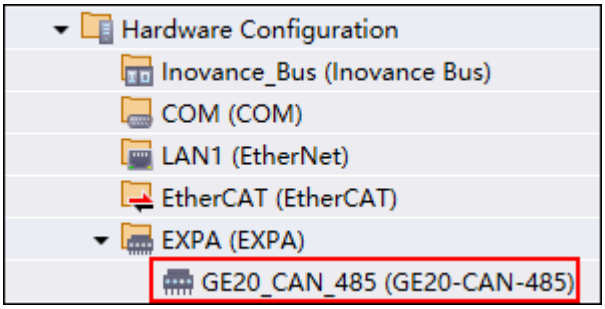
- Heartbeat: The master sends a heartbeat frame at each heartbeat interval to allow the slave to monitor whether the master has gone offline. This function must be used in conjunction with the slave. Some slaves do not support heartbeat monitoring, so this function is disabled by default.
- Heartbeat time: The master sends a heartbeat frame to the slave at the set interval, with a default value of 300 ms. It takes effect only when the heartbeat function is enabled.

Slave configuration

Slave configuration mainly includes node ID, heartbeat, heartbeat time, PDO synchronization method, and synchronization object dictionary configuration.

- Node ID (station number): A basic communication parameter for the slave. The station number must match the actual physical station number.
- Heartbeat: The slave sends heartbeat frames to the specified station number, primarily used to allow other stations to monitor the communication status of this station. By default, this function is enabled.
- Heartbeat time: The slave sends heartbeat frames to the specified station number at the set interval. The default is 1000 ms and takes effect only when the heartbeat function is enabled.
- PDO synchronization method: The default is asynchronous mode, which must be changed to synchronous periodic mode.

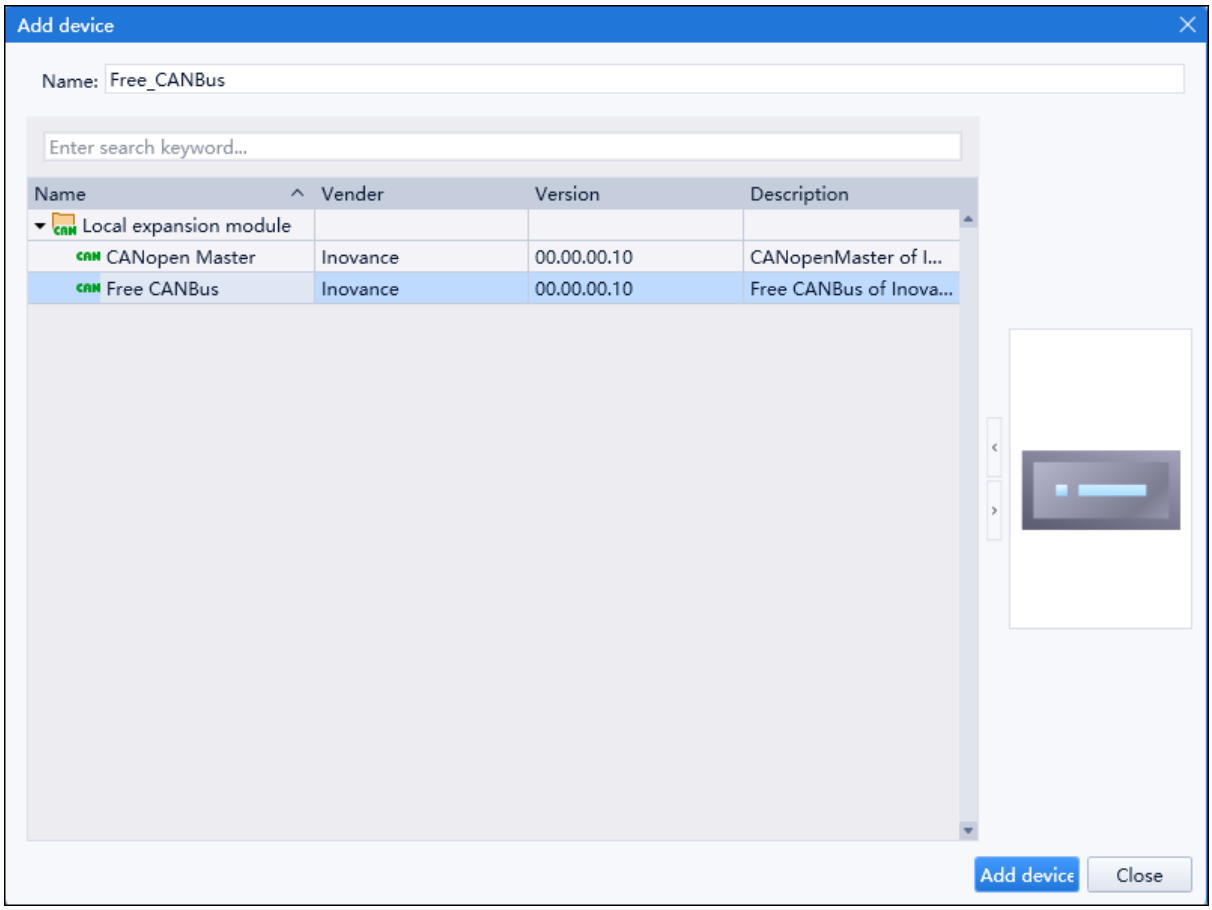
PDO object dictionary configuration: The PDO object dictionary ensures that data is exchanged once per bus cycle between the master and slaves. The more entries, the more efficient the status exchange between master and slaves. However, an excessive number of PDOs will increase bus load, potentially causing bus data transmission delays, and in severe cases, communication failure. For axis control devices, based on application experience, the mandatory configuration items for transmit and receive PDOs are 6040, 6041, 6060, 6061, 607A, 6064 (6063), 60FF, 606C, 6081. Optional items are 6083, 6084, 607C, 6098.



10.6.6.6 Programming Interface

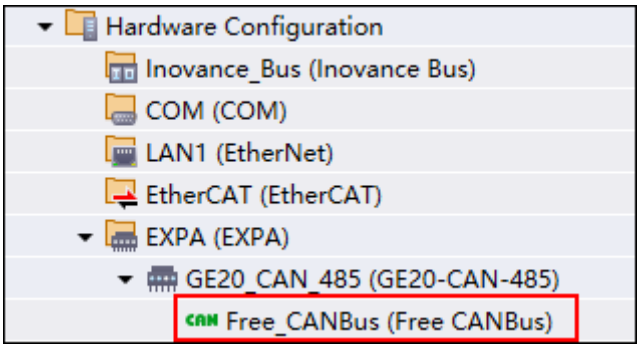
For details, see the 18.4.11 CANopen Communication Commands.

10.6.7 CAN Free Communication Configuration (EVO400, EVO500, EVO700, APC500)



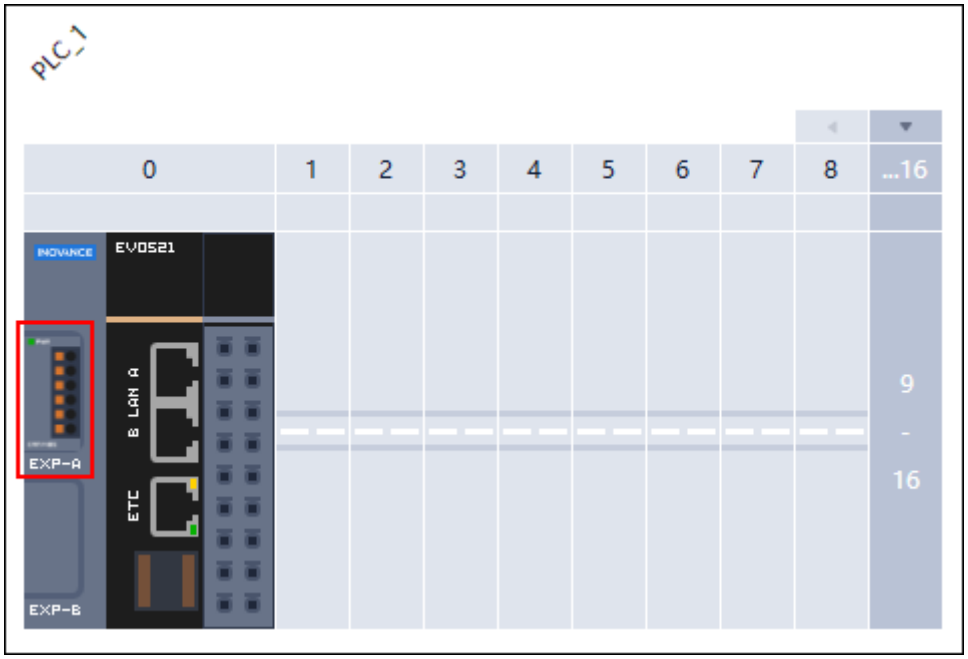
10.6.7.1 Network Configuration (EVO400, EVO500, APC500)

1. Right-click "EXPA (EXPA)" under the "Hardware configuration" node in the left project tree and select "Add device".
2. Select "GE20_CAN_485" in the pop-up window and click "Add device".
   After adding the expansion card, the corresponding CAN port "GE20_CAN_485(GE20-CAN-485)" is automatically generated.



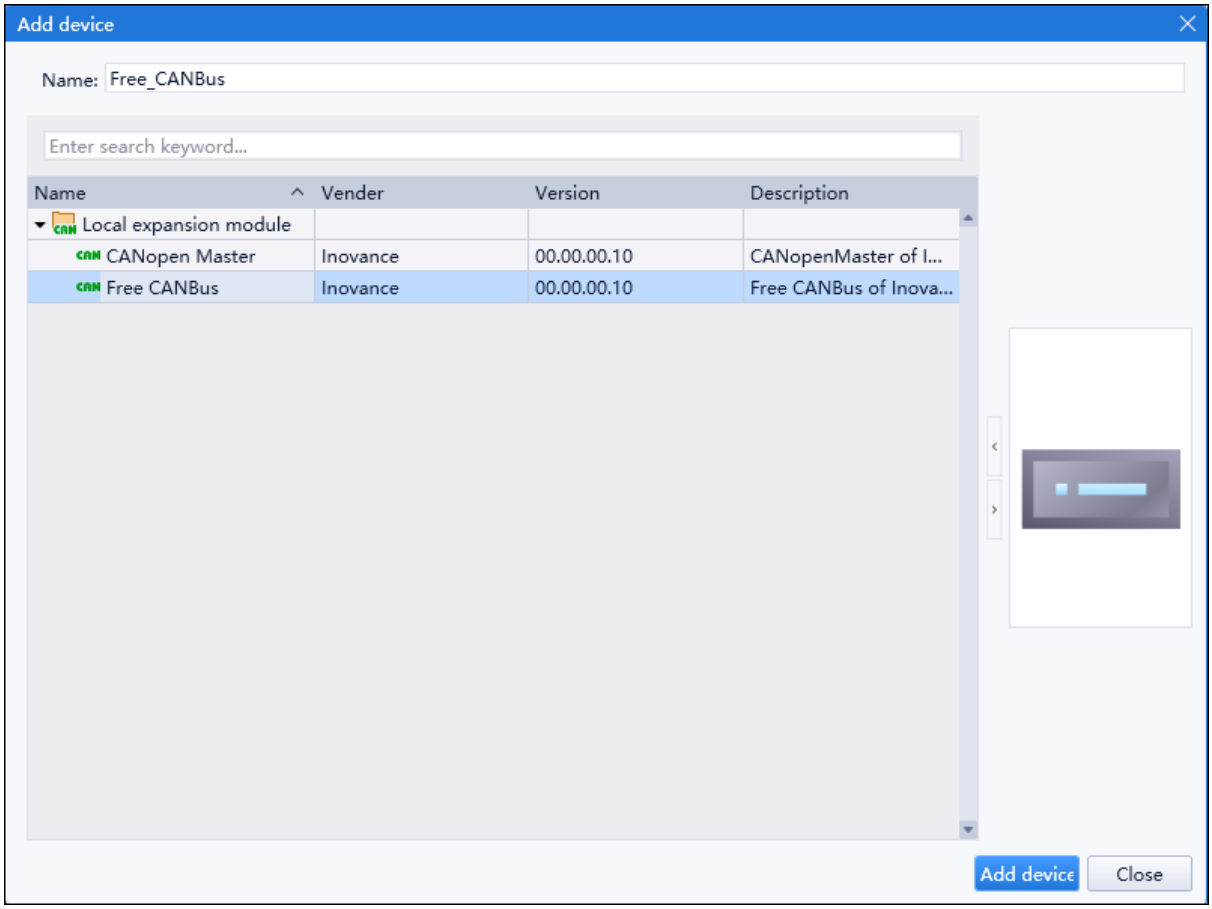
3. Right-click "GE20_CAN_485(GE20-CAN-485)" and select "Add device".

4. Select "Free CANBus" and click "Add device" to configure the CAN free protocol network.



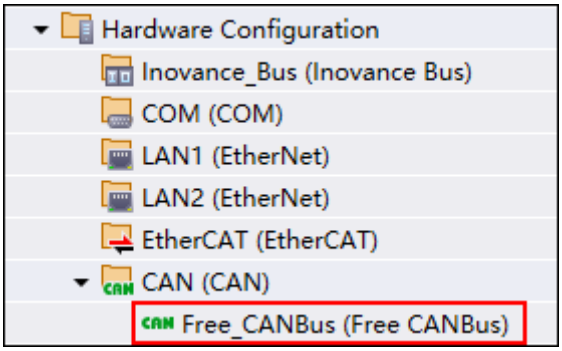
Result

The added CAN free protocol node is displayed in the left project tree.



The device configuration view is updated synchronously, and the EXPA port of the expansion card shows that the CAN free protocol has been added.

10.6.7.2 Network Configuration (EVO700)



1. Right-click "CAN (CAN)" under the "Hardware configuration" node in the left project tree and select "Add device".

2. Select "Free CANBus" and click "Add device" to configure the CAN free protocol network.

Result

The added CAN free protocol node is displayed in the left project tree.

10.6.7.3 CAN Free Protocol Configuration

Network Settings

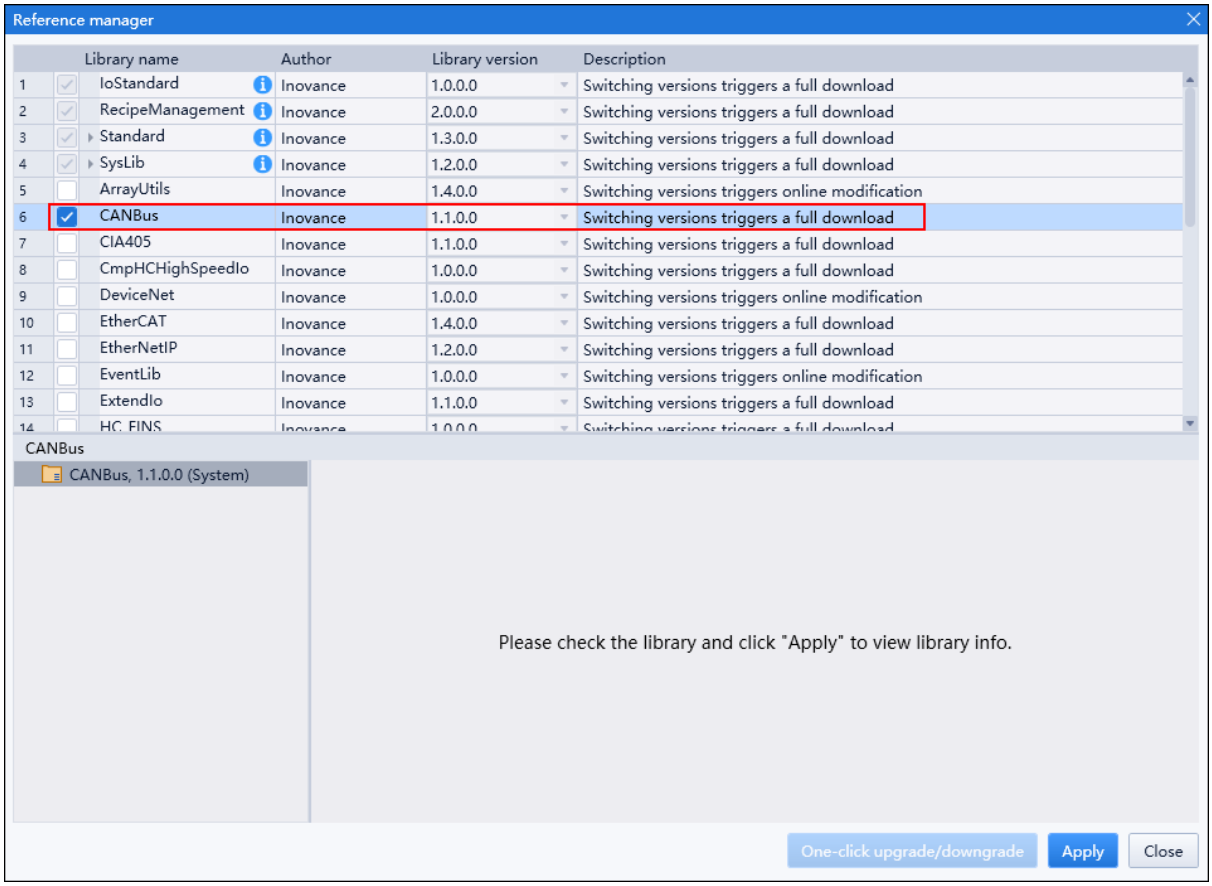
Port number

Used to distinguish between different CAN ports when multiple CAN ports exist.

Baud rate

Baud Rate: The baud rate used for transmission on the bus. Unit is kbps. The following baud rates can be set: 10, 20, 50, 100, 125, 250, 500 (default), 800, and 1000.

Information

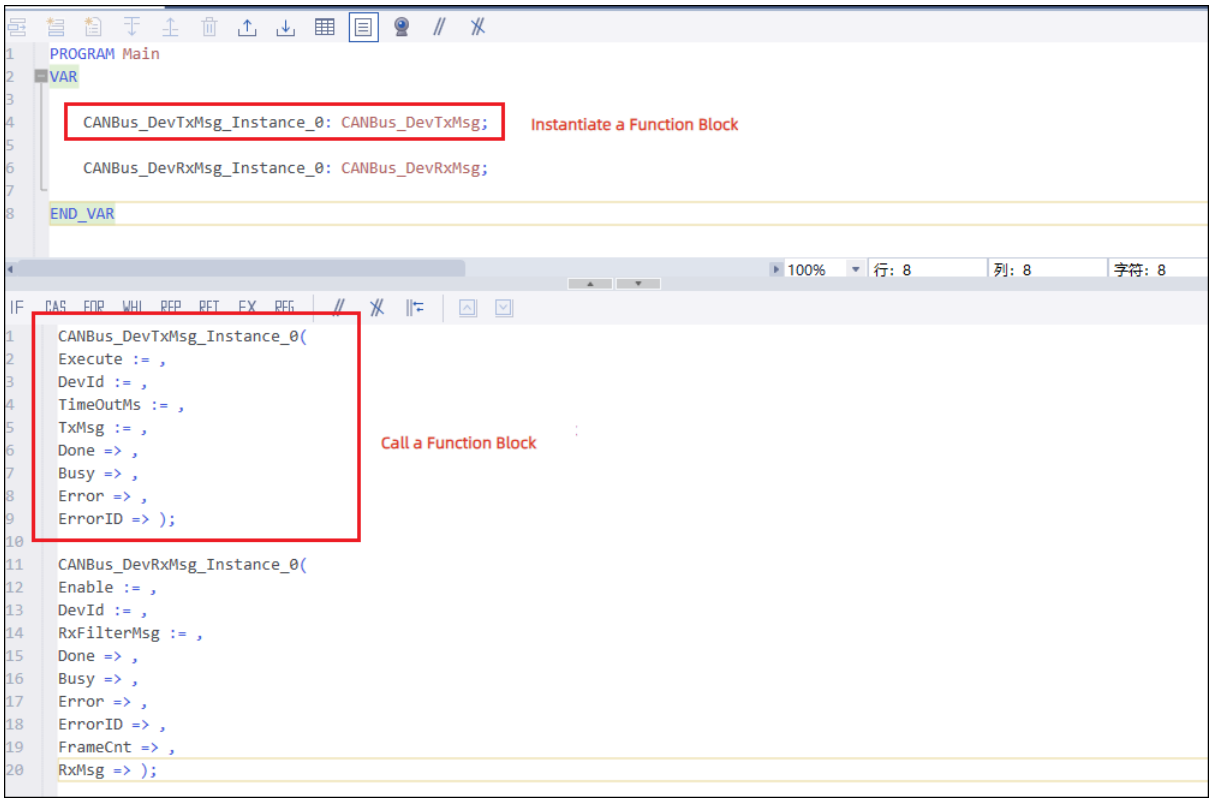


If the current device is available, the following basic information will be displayed: name, vendor, type, version number, module number, and description.

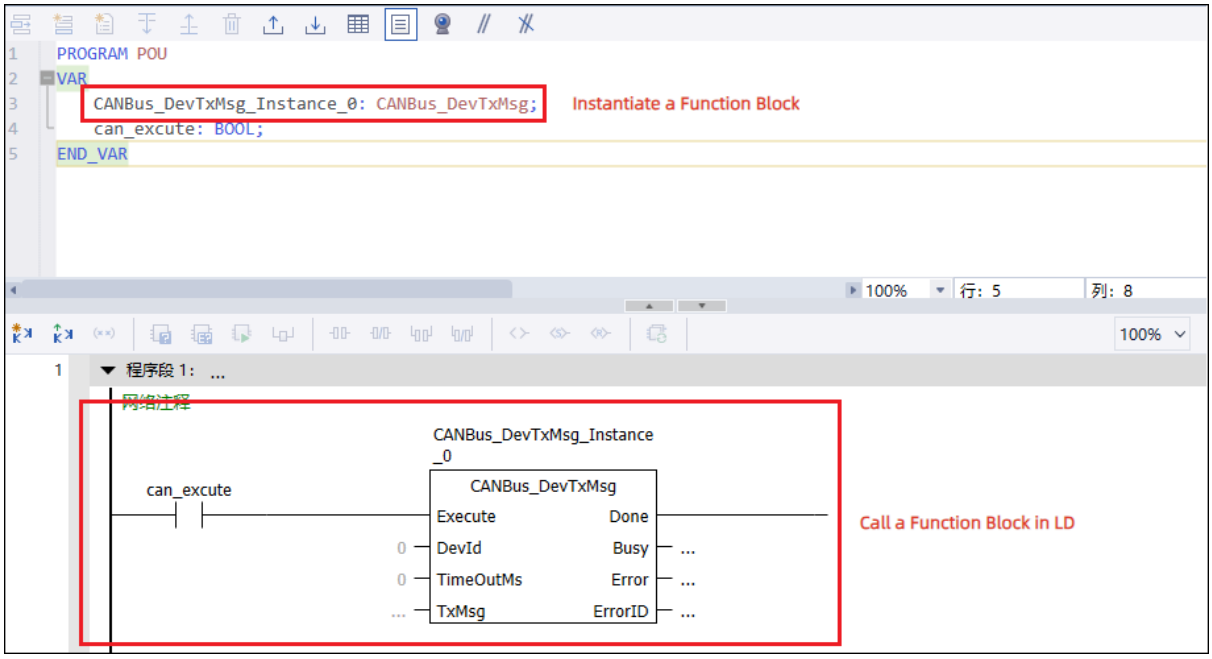
10.6.7.4 Usage Example

CAN free protocol only supports configuration through the CAN Bus function block.

The following example illustrates how to add a CAN Bus function block.



1. Double-click "Library reference" in the left project tree to open the "Reference manager" window.
2. Select "CANBus" and click "Apply" to reference the CANBus library into the project.



3.

Open the program editing page, double-click the function block instruction in the right toolbox under "Communication and diagnostics > CANBus instructions" to use and instantiate the instruction.

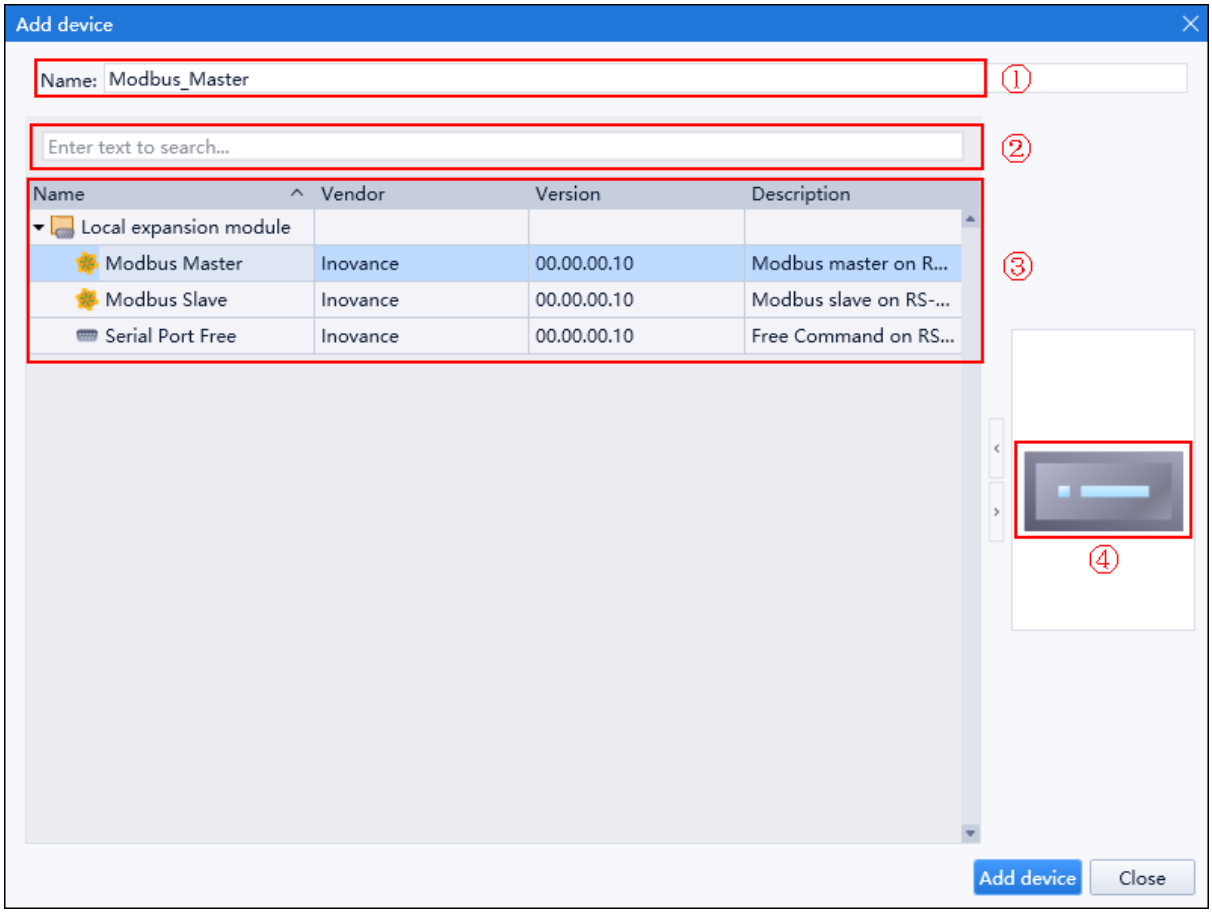
The CAN Bus function block instruction supports ST language and LD language, as shown in the figures below.

10.6.8 COM Communication Configuration (EVO400, EVO500, EVO700, APC500)

10.6.8.1 Modbus RTU Device Configuration

10.6.8.1.1 Adding a Modbus RTU Device

Specifying the current device as a Modbus master device



Specify the current controller as a Modbus master device to add a Modbus master. Other types of devices can be added under the master as Modbus slaves; the added slaves must match the actual hardware configuration. When the PLC goes online, the configuration information will be sent to the corresponding PLC. If the actual hardware connection sequence does not match the hardware configuration in the project, faults may occur.

Prerequisites

The master device supports serial communication.

Procedure

1. Click "Hardware configuration" in the left project tree to expand the list.
2. Right-click "COM" and select "Add device".
3. In the pop-up "Add device" window, select the master device and click "Add device" to add the Modbus master device. The "Add device" window is shown below.

No.	Description
①	Displays the name of the selected device; if no device is selected, no name is displayed.
②	A quick search box used for fast searching when there are many devices.
③	Devices supported by the current serial port.
④	Device preview image.

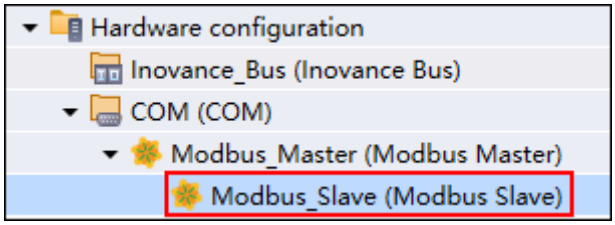
Result

The added Modbus master device can be viewed under "Hardware configuration > COM" in the left project tree.

Mounting a Modbus slave under the Modbus master

Mount a slave under Modbus.

Prerequisites



The Modbus master device has been added.

Procedure

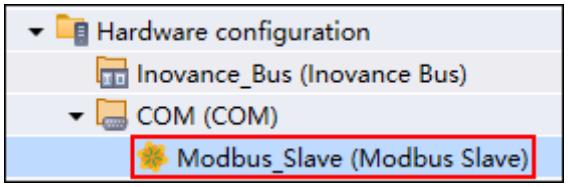
1. Right-click "Modbus_Master" under "Hardware configuration > COM", and select "Add device".
2. In the pop-up "Add device" window, select "Modbus slave" and click "Add device", or double-click "Modbus_Slave" to add the slave device.

Result

The added Modbus slave device can be viewed under "Hardware configuration > COM > Modbus_Master".

Specifying the current device as a Modbus slave device

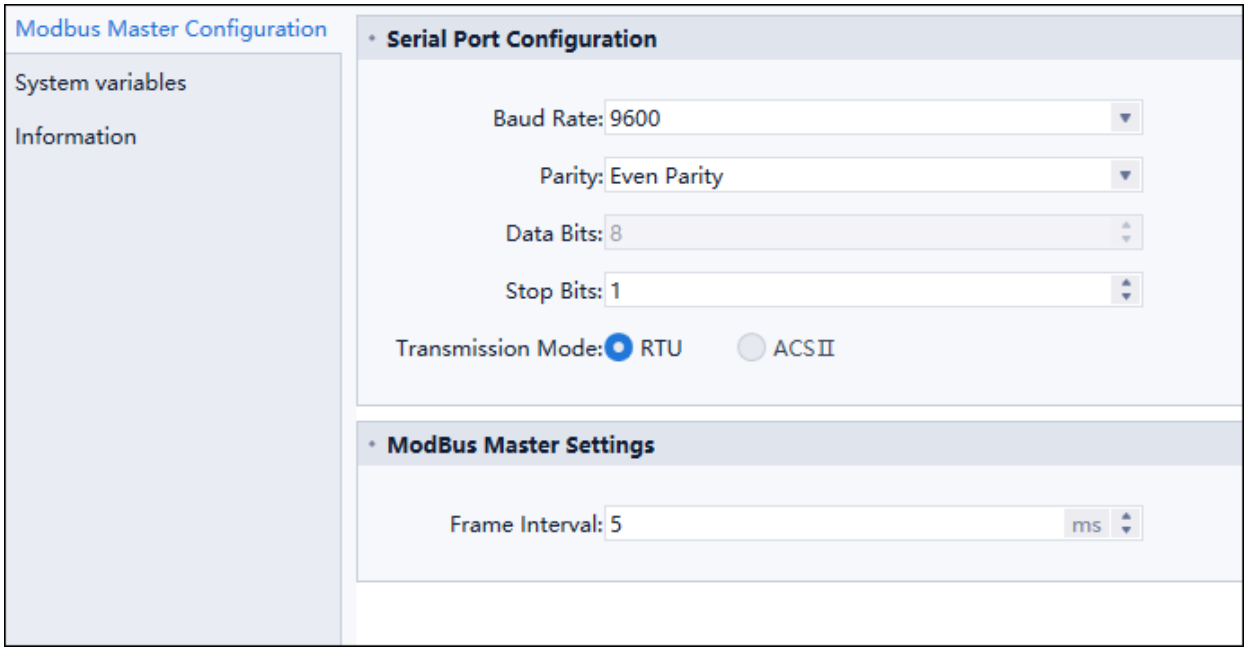
Prerequisites



The current device supports serial communication.

Procedure

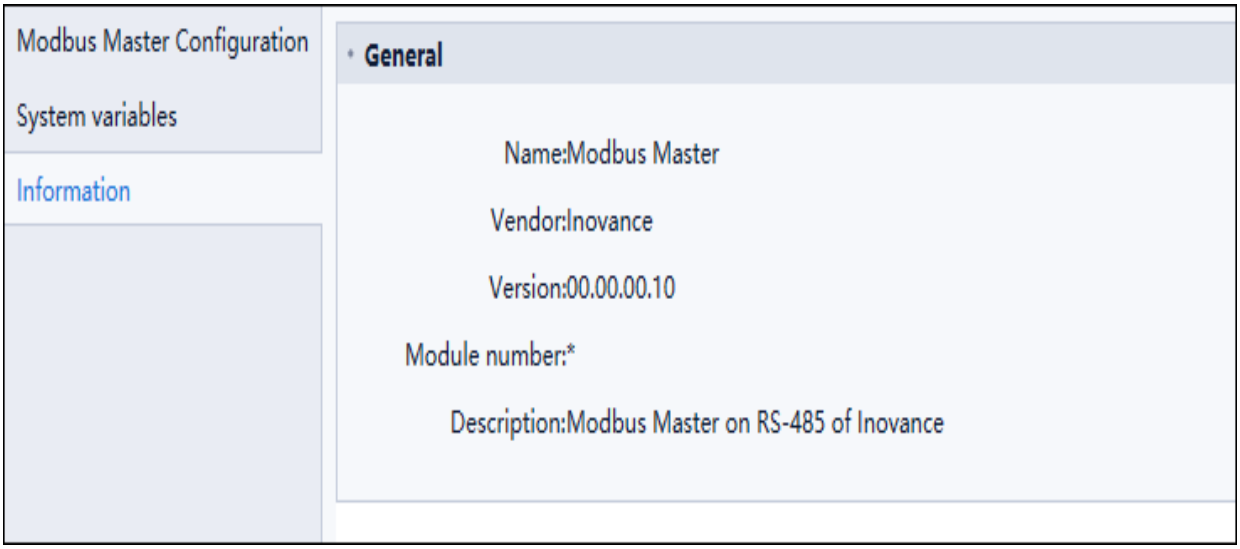
1. Right-click "COM" under the "Hardware configuration" node in the left project tree, and select "Add device".
2. In the pop-up "Add device" window, select "Modbus slave" and click "Add device", or double-click "Modbus_Slave" to add the slave device.



Result

The added Modbus slave device can be viewed under "Hardware configuration > COM" in the left project tree.

10.6.8.1.2 Configuring a Modbus RTU Master



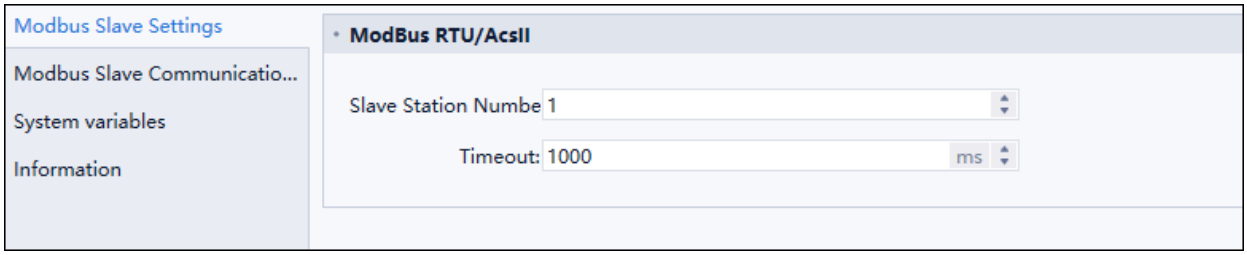
10.6.8.1.2.1 Modbus RTU Master Configuration

Item	Description
Baud rate	Communication speed
Parity check	Check method for communication frames
Data bit	Actual number of data bits contained in a communication frame
Stop bit	Last bit that identifies a single data packet during communication
Transmission mode	Binary encoding or ASCII encoding.
Frame interval	Time interval the master waits between receiving the previous response data frame and sending the next request data frame.

10.6.8.1.2.2 Information

The "Information" tab of the Modbus master configuration interface displays the following information for the current module: name, supplier, type, ID, version, module number, description, and so on.

10.6.8.1.3 Configuring a Modbus RTU Slave

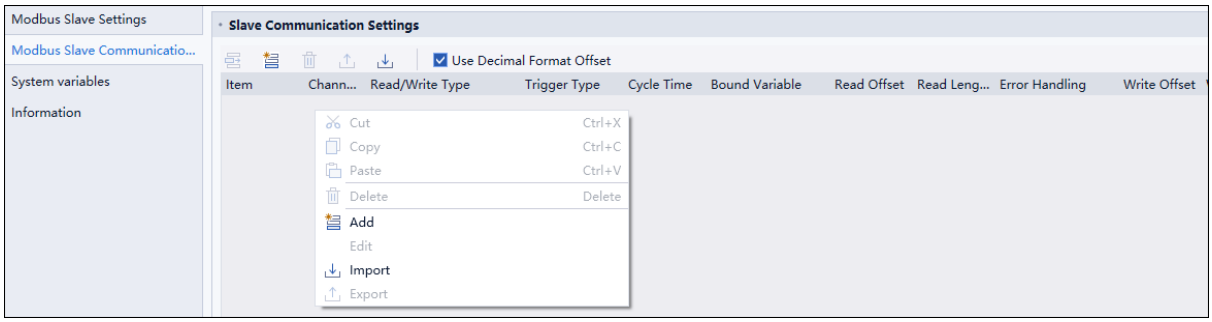


10.6.8.1.3.1 Modbus RTU Slave Configuration

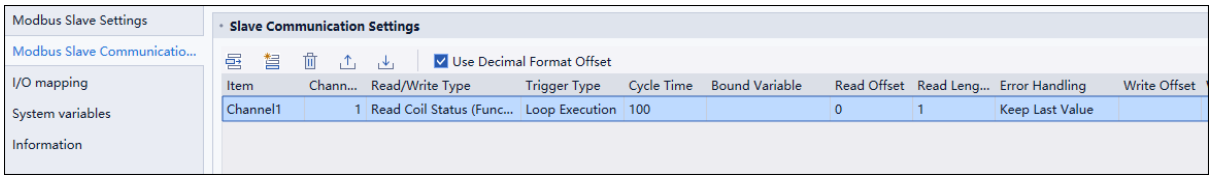
Prerequisites

The master device has been added.

Procedure

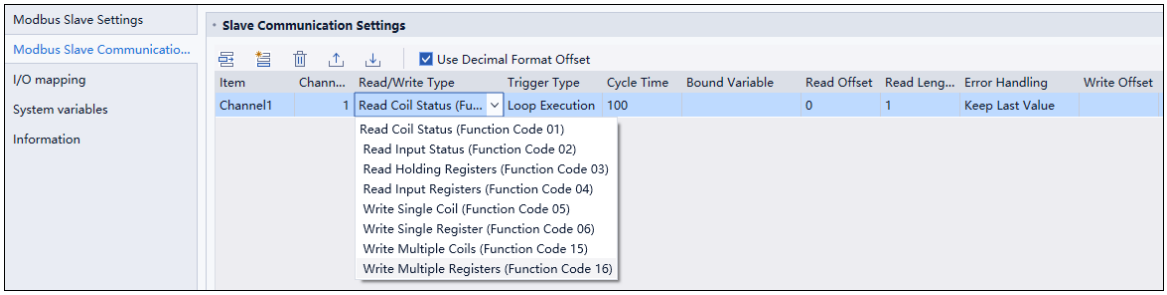


Double-click "Modbus_Slave" under "Hardware configuration > COM > Modbus_Master" in the left project tree to open the slave configuration page.



Item	Description
Slave number	Indicates the station number of the current device.
Timeout period	Indicates the response time for a single connection to the slave, with a range from 2 ms to 1000 ms and a default value of 1000 ms. If the slave does not respond within this period, the master will terminate the request after sending the specified number of retry requests and display a fault message. **Note**: The timeout time must be greater than the longest CPU scan cycle, otherwise a fault will occur.

10.6.8.1.3.2 Modbus RTU Slave Communication Configuration



1. In the "Modbus slave communication settings" tab, right-click in the blank area on the right and select "Add" to add a communication entry. Up to 60 channels can be added.

2. The added entry is shown in the figure below.

   - Item: The name of the entry
   - Channel number: The sequence number corresponding to this entry
   - Read/Write type: Configures the function code, which can be set to read coil status (function code 01), read input status (function code 02), read holding register (function code 03), read input register (function code 04), write single coil (function code 05), write single register (function code 06), write multiple coils (function code 15), write multiple registers (function code 16).

   - Trigger type: The trigger type corresponding to this entry, supporting cyclic execution and level triggering (for EVO500 series PLCs, only version V1.3 and above support level triggering).
   - Cycle time: The cycle time cannot be edited in level triggering mode.

- Bound variable: You can manually input or bind global variables in the project using the input assistant. After binding, the channel data access status can be controlled through the program. The variable type must be BOOL. Non-BOOL types are not supported. One channel can only bind one variable. After executing a trigger command, the BOOL variable value is set to FALSE. The command is effective only once and only when the variable status is TRUE.
- Read offset: The offset position based on the read start address
- Read length: The length of the read operation
- Fault handling: The handling method when a fault occurs
- Write offset: The write offset position
- Write length: The length of the write operation
- Retry count: The number of times to retransmit when encountering network issues
- Comment: Comment information

> CAUTION
>
> For details about the entries in this interface, see the Modbus protocol.

10.6.8.1.3.3 System Variables

The system variables can be configured to specify an instance (variable) of type _SYS_SlaveState for the slave I/O.

10.6.8.1.3.4 Information

The "Information" tab of the Modbus master configuration interface displays the following information for the current module: name, supplier, type, ID, version, module number, description, and so on.

10.6.8.1.4 Modbus RTU Variable Addressing

Coil

Coil is a bit variable with only two statuses, 0 and 1. This PLC (taking the EVO500 series as an example) includes variables in the Q area and I area.

Variable Name	Command Code	Starting Address	Number of coils	Note
QX0.0-QX8191.7	0x01, 0x05, 0x0f	0	65536	Accessible through the universal standard Modbus protocol
IX0.0-IX8191.7	0x2	0	65536	Accessible through the universal standard Modbus protocol

Register

Register is a 16-bit (word) variable. Take the EVO500 series as an example, the PLC includes only variables in M area.

Variable Name	Command Code	Starting Address	Number of Registers	Note
MW0-MW65535	0x03, 0x04, 0x06, 0x10	0	65536	Accessible through the universal standard Modbus protocol

NOTE

The soft elements of the EVO400/EVO500 series contain three types: Q area, I area, and M area. They can be accessed by bit, byte, word, and double word, such as: %QX, %QB, %QW, %QD. The conversion rules are as follows:

QB0 = (QX0.0 to QX0.7)
QW0 = (QB0 to QB1) =((QX0.0 to QX0.7) + (QX1.0 to QX1.7))
QD0 = (QW0 to QW1) = (QB0 to QB3) = ((QX00 to QX0.7) + (QX1.0 to X1.7) + (QX2.0 to QX2.7) + (QX3.0 to QX3.7))

Register address indexing rule

Bit Addressing	Byte Addressing	Word Addressing	Dword Addressing		Bit Addressing	Byte Addressing	Word Addressing	Dword Addressing
QX0.0	QB0	QW0	QD0		MX0.0	MB0	MW0	MD0
QX0.1					MX0.1			
QX0.2					MX0.2			
QX0.3					MX0.3			
QX0.4					MX0.4			
QX0.5					MX0.5			
QX0.6					MX0.6			
QX0.7					MX0.7			
QX1.0	QB1				MX1.0	MB1		

Bit Addressing	Byte Addressing	Word Addressing	Dword Addressing		Bit Addressing	Byte Addressing	Word Addressing	Dword Addressing
QX1.1					MX1.1			
QX1.2					MX1.2			
QX1.3					MX1.3			
QX1.4					MX1.4			
QX1.5					MX1.5			
QX1.6					MX1.6			
QX1.7					MX1.7			
QX2.0	QB2	QW1			MX2.0	MB2	MW1	
QX2.1					MX2.1			
QX2.2					MX2.2			
QX2.3					MX2.3			
QX2.4					MX2.4			
QX2.5					MX2.5			
QX2.6					MX2.6			
QX2.7					MX2.7			
QX3.0	QB3				MX3.0	MB3		
QX3.1					MX3.1			
QX3.2					MX3.2			
QX3.3					MX3.3			
QX3.4					MX3.4			
QX3.5					MX3.5			
QX3.6					MX3.6			
QX3.7					MX3.7			
QX4.0	QB4	QW2	QD1		MX4.0	MB4	MW2	MD1
QX4.1					MX4.1			

NOTE

The starting address of EVO400/EVO500's word-type register is an even byte address. The starting address of DWord-type register aligns with even word addresses, and its index number is in a 2x relationship, making address calculation convenient.

10.6.8.1.5 Modbus RTU Communication Frame Format

- Reading coils
  Use the 0x01 command code to read Q variables.

  Request frame format: slave address + 0x01 + head address of coils + number of coils + CRC code

No.	Definition of Data (Byte)	Number of Bytes	Note
1	Slave address	1	Range: 1 to 247
2	0x01 (command code)	1	Read coils.
3	Head address of coils	2 bytes	Upper bits are followed by lower bits.
4	Number of coils (N)	2 bytes	Upper bits are followed by lower bits.
5	CRC code	2 bytes	Lower bits are followed by higher bits.

Response frame format: slave address + 0x01 + number of bytes + state of coils + CRC code

No.	Definition of Data (Byte)	Number of Bytes	Note
1	Slave address	1	Range: 1 to 247
2	0x01 (command code)	1	Read coils.
3	Number of bytes	1	Value: [(N + 7) / 8]
4	Coil status	[(N + 7) / 8] bytes	Eight coils are indicated by one byte. If the last byte has less than eight bits, enter 0 for undefined bits. The first eight coils are indicated by the first byte, and the coil with the smallest address is indicated by the least significant bit, and so on.
5	CRC code	2 bytes	Lower bits are followed by higher bits.

- Reading registers
  Use the 0x03 command code to read M variables.

  Request frame format: slave address + 0x03 + head address of registers + number of registers + CRC code

No.	Definition of Data (Byte)	Number of Bytes	Note
1	Slave address	1	Range: 1 to 247

No.	Definition of Data (Byte)	Number of Bytes	Note
2	0x03 (command code)	1	Read registers.
3	Head address of registers	2 bytes	Upper bits are followed by lower bits.
4	Number of registers (N)	2 bytes	Upper bits are followed by lower bits.
5	CRC code	2 bytes	Lower bits are followed by higher bits.

Response frame format: slave address + 0x03 + number of bytes + register value + CRC code

No.	Definition of Data (Byte)	Number of Bytes	Note
1	Slave address	1	Range: 1 to 247
2	0x03 (command code)	1	Read registers.
3	Number of bytes	1	Value: N*2
4	Register value	N x 2	One register value is indicated by two bytes. Upper bits are followed by lower bits. The register with a smaller address is indicated by the first byte.
5	CRC code	2 bytes	Lower bits are followed by higher bits.

- Writing a single coil
  Use the 0x05 command code to write Q variables.

  Request frame format: slave address + 0x05 + head address of the coil + state of the coil + CRC code

No.	Definition of Data (Byte)	Number of Bytes	Note
1	Slave address	1	Range: 1 to 247
2	0x05 (command code)	1	Writes a single coil.
3	Address of the coil	2 bytes	Upper bits are followed by lower bits.
4	Coil status	2 bytes	Lower bits are followed by higher bits. A non-zero value is valid.
5	CRC code	2 bytes	Lower bits are followed by higher bits.

Response frame format: slave address + 0x05 + head address of the coil + state of the coil + CRC code

No.	Definition of Data (Byte)	Number of Bytes	Note
1	Slave address	1	Range: 1 to 247
2	0x05 (command code)	1	Writes a single coil.
3	Address of the coil	2 bytes	Upper bits are followed by lower bits.
4	Coil status	2 bytes	Lower bits are followed by higher bits. A non-zero value is valid.

No.	Definition of Data (Byte)	Number of Bytes	Note
5	CRC code	2 bytes	Lower bits are followed by higher bits.

- Writes one register.
  Use the 0x06 command code to write M variables.

  Request frame format: slave address + 0x06 + head address of the register + register value + CRC code

No.	Definition of Data (Byte)	Number of Bytes	Note
1	Slave address	1	Range: 1 to 247
2	0x06 (command code)	1	Writes a single register.
3	Register address	2 bytes	Upper bits are followed by lower bits.
4	Register value	2 bytes	Upper bits are followed by lower bits. A non-zero value is valid.
5	CRC code	2 bytes	Lower bits are followed by higher bits.

  Response frame format: slave address + 0x06 + head address of the register + register value + CRC code

No.	Definition of Data (Byte)	Number of Bytes	Note
1	Slave address	1	Range: 1 to 247
2	0x06 (command code)	1	Writes a single register.
3	Register address	2 bytes	Upper bits are followed by lower bits.
4	Register value	2 bytes	Upper bits are followed by lower bits. A non-zero value is valid.
5	CRC code	2 bytes	Lower bits are followed by higher bits.

- Writing multiple coils
  Use the 0x0f command code to write multiple consecutive Q variables.

  Request frame format: slave address + 0x0f + head address of coils + number of coils + number of bytes + state of coils + CRC code

No.	Definition of Data (Byte)	Number of Bytes	Note
1	Slave address	1	Range: 1 to 247
2	0x0f (command code)	1	Writes multiple single coils.
3	Head address of coils	2 bytes	Upper bits are followed by lower bits.
4	Number of coils (N)	2 bytes	Upper bits are followed by lower bits, with a maximum value of 1968.
5	Number of bytes	1	Value: [(N + 7) / 8]

No.	Definition of Data (Byte)	Number of Bytes	Note
6	Coil status	[(N + 7) / 8] bytes	Eight coils are indicated by one byte. If the last byte has less than eight bits, enter 0 for undefined bits. The first eight coils are indicated by the first byte, and the coil with the smallest address is indicated by the least significant bit, and so on.
7	CRC code	2 bytes	Lower bits are followed by higher bits.

Response frame format: slave address + 0x0f + head address of coils + number of coils + CRC code

No.	Definition of Data (Byte)	Number of Bytes	Note
1	Slave address	1	Range: 1 to 247
2	0x0f (command code)	1	Writes multiple single coils.
3	Head address of coils	2 bytes	Upper bits are followed by lower bits.
4	Number of coils	2 bytes	Upper bits are followed by lower bits.
5	CRC code	2 bytes	Lower bits are followed by higher bits.

- Writing multiple registers

  Use the 0x10 command code to write multiple consecutive M variables.

  Request frame format: slave address + 0x10 + head address of registers + number of registers + number of bytes + register value + CRC code

No.	Definition of Data (Byte)	Number of Bytes	Note
1	Slave address	1	Range: 1 to 247
2	0x10 (command code)	1	Writes multiple registers.
3	Head address of registers	2 bytes	Upper bits are followed by lower bits.
4	Number of registers (N)	2 bytes	Upper bits are followed by lower bits.
5	Number of bytes	1	Value: N*2
6	Register value	N*2 (N*4)	-
7	CRC code	2 bytes	Lower bits are followed by higher bits.

Response frame format: slave address + 0x10 + head address of coils + number of coils + CRC code

No.	Definition of Data (Byte)	Number of Bytes	Note
1	Slave address	1	Range: 1 to 247
2	0x10 (command code)	1	Writes multiple registers.

No.	Definition of Data (Byte)	Number of Bytes	Note
3	Head address of registers	2 bytes	Upper bits are followed by lower bits.
4	Number of registers (N)	2 bytes	Upper bits are followed by lower bits.
5	CRC code	2 bytes	Lower bits are followed by higher bits.

10.6.8.1.6 Common Modbus RTU Faults

The main faults that occur when a Modbus master connects to a slave are as follows:

- The Modbus master configuration is inconsistent with the Modbus slave configuration, preventing the establishment of communication between the master and slave.
- The Modbus master accesses an illegal address on the Modbus slave, resulting in a faulty response.
- The Modbus master attempts to write to a register on the Modbus slave, but the register on the slave only supports reading and not writing, causing the master to receive a faulty response from the slave.

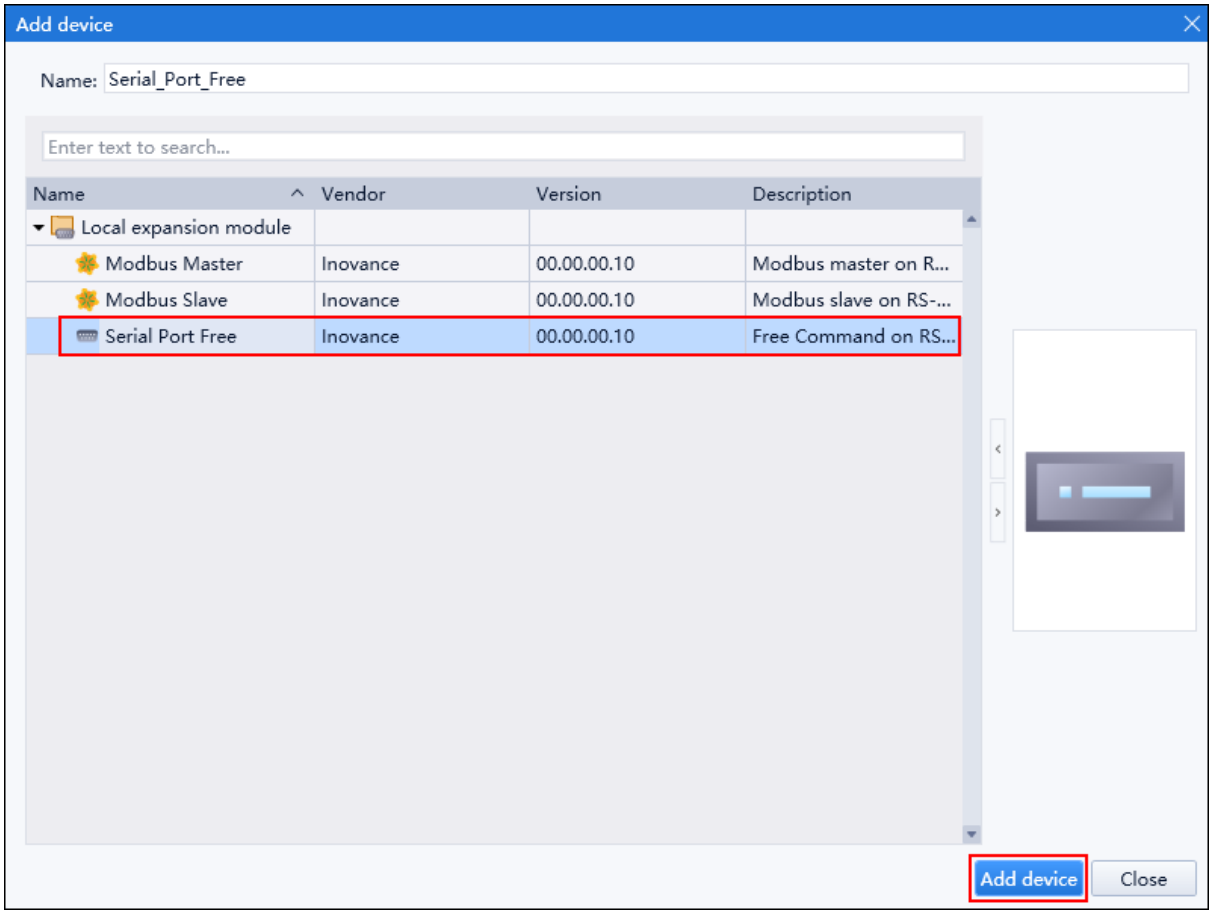
Fault response frame format

Fault response frame format: slave address + (command code + 0x80) + fault code + CRC code

This fault frame applies to all operation command frames.

No.	Definition of Data (Byte)	Number of Bytes	Note
1	Slave address	1	Value range: 1 to 247
2	Command code + 0x80	1	Fault command code
3	Fault code	1	1 to 4
4	CRC code	2 bytes	Lower bits are followed by higher bits.

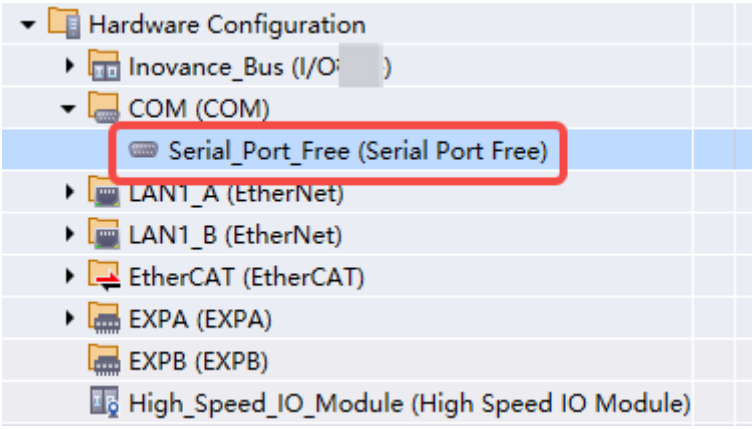
10.6.8.2 Free Serial Communication



10.6.8.2.1 Adding Serial_Port_Free

Prerequisites

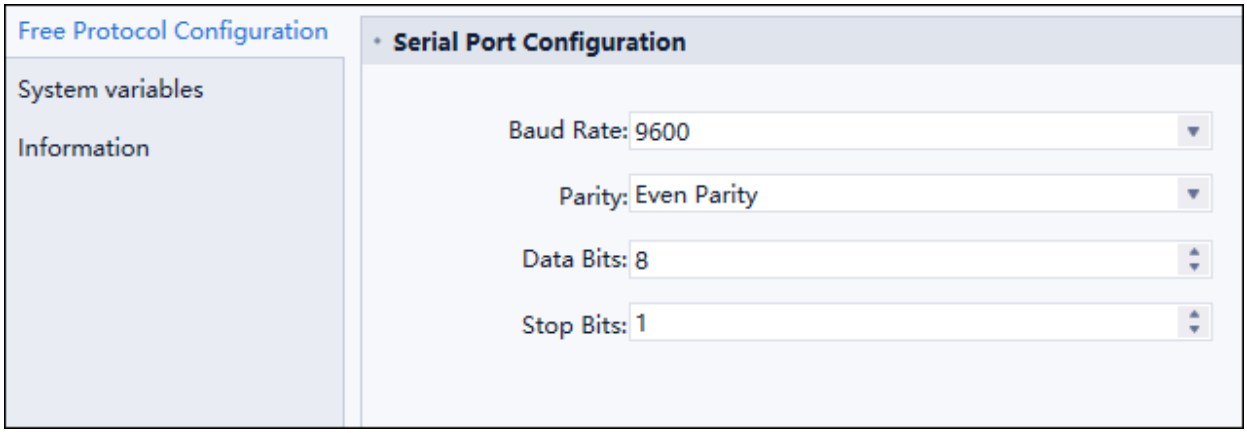
The selected device supports serial communication.



Procedure

1. Click "Hardware configuration" in the left project tree to expand the list.
2. Right-click "COM" and select "Add device".
3. The "Add device" window pops up. Double-click the "Serial port free" entry, or select it and click "Add device".

Result

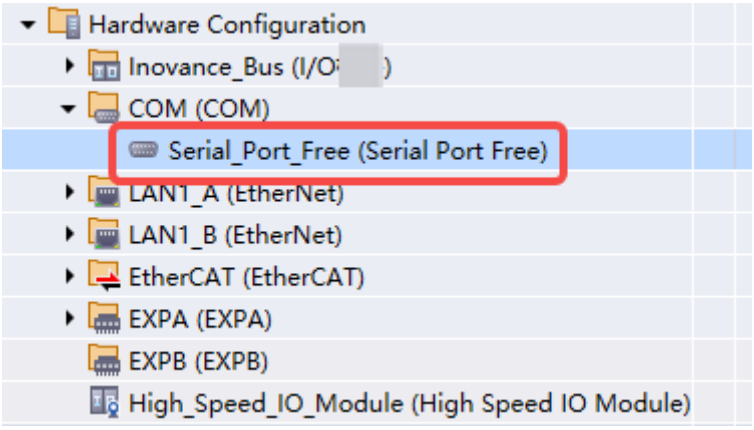


The added free serial port can be viewed in the project tree.

10.6.8.2.2 Configuring Serial_Port_Free

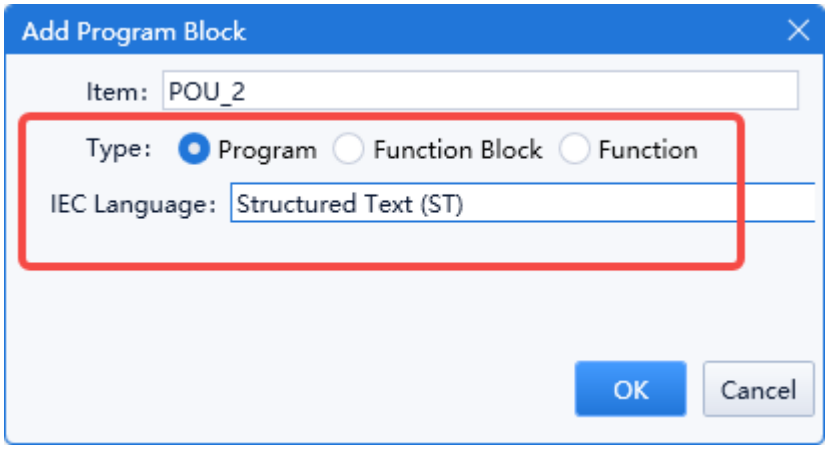
The corresponding free serial port has been added in the hardware configuration.

Double-click the added free serial port to open the serial port configuration interface. Commonly used configuration options are displayed in the configuration interface.



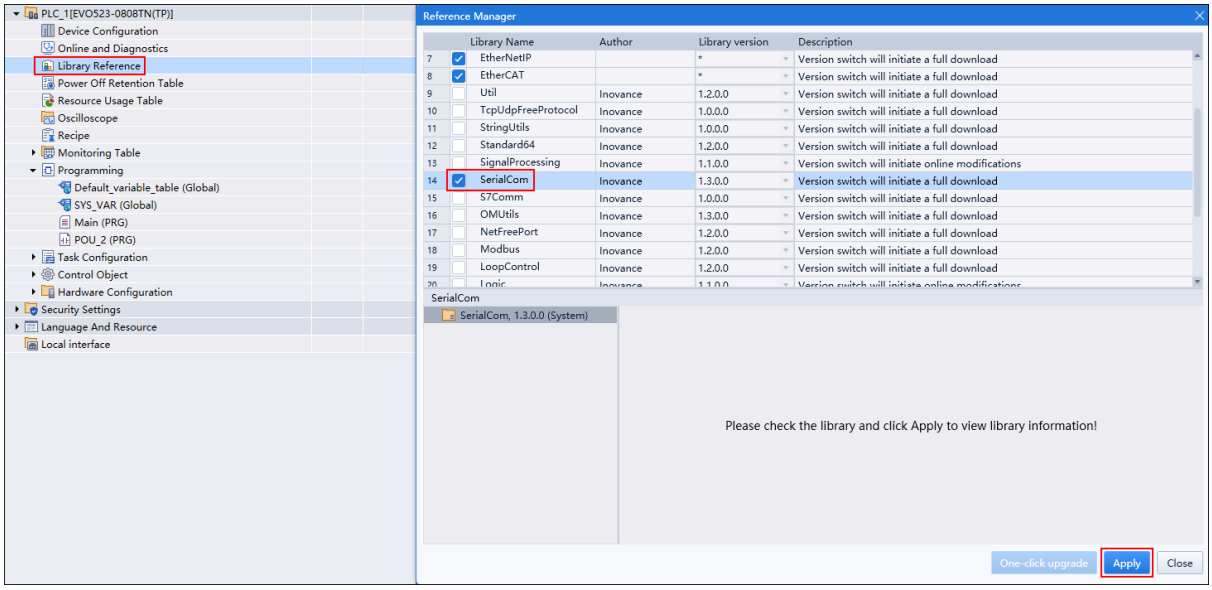
Item	Description
Baud rate	Communication speed
Parity check	Check method for communication frames
Data bit	Actual number of data bits contained in a communication frame
Stop bit	Last bit that identifies a single data packet during communication

10.6.8.2.3 Transmitting/Receiving Data Through Free Serial Port



Prerequisites

The corresponding free serial port has been added and configured.



Procedure

1. Create a PLC programming task. Under the "Programming" node in the project tree, add a program block, select "Program" as the programming type, and set the IEC language to "Structured text (ST)".

2. Add the corresponding library reference. Double-click the "Library reference" node in the project tree. In the pop-up "Reference manager" interface, and select the "SerialCom" library.

3. The added library can be viewed in the "Toolbox" on the right side of the interface.

4. Call these functions to implement data communication. For detailed function descriptions, see 18.4.7 Free Serial Port.

10.6.8.3 Disabling/Enabling a COM Device

Disabling the device under the COM node

In iFA software, a certain COM device can be disabled through commands or variable setting, thus "detaching" from the control system while retaining its configuration parameters and I/O mapping information. If a device fails and needs to be replaced, this function can reduce the time required for replacement.

- Disabling operation and effect
  A device can be disabled through commands or variable setting, each with different scopes. Command disabling applies to all devices except PLCs Variable setting requires that there be corresponding variables in SYS_VAR.
  - Command disabling
    Right-click a device under the "COM" node in the project tree and select "Disable device".
  - Variable setting
    When the current PLC is set as a Modbus RTU Master, the added remote slave devices will have corresponding variables created in **SYS_VAR**, with variable naming rule: J_device model.
    Setting member The member **bDisableEnable** disables the slave, and the setting method supports writing values in **SYS_VAR** or assigning values in user programs.

	Name	Data type	Address	Retain	Network publish	Comment
1	VAR_GLOBAL					
2	LAN1_EIPSingle_STATUS	Array[1..32] OF IoStand...			Private	
3	LAN1_EIPSlave_STATUS	Array[1..16] OF EtherNe...			Private	
4	J_Modbus_Slave	IoStandard._SYS_SlaveS...			Private	
5	bDisableEnable	BOOL			Private	

    After disabling, it is necessary to perform 10.8.3 a full download of the PLC to make the disabling operation effective.

- Disabling result
  The disabled devices are marked with the icon for differentiation.

Enabling the device under the COM node

The disabling and enabling of COM devices are a set of mutually corresponding operations. Only when the device is disabled is the enabling command visible.

The enabling operation and its effect are exactly the same as the disabling operation.

A device needs to be disabled and enabled in the same way. That is, if the device is disabled by setting a variable, it must be enabled by resetting the variable. If it is disabled using a command, it must also be enabled using a command.

10.6.9 FINS TCP&UDP Communication Configuration

10.6.9.1 Overview

FINS (Factory Interface Network Service) is an industrial automation control network protocol used for communication between clients and servers. FINS is an application-layer protocol. When using Ethernet communication, data is sent and received as UDP/IP or TCP/IP packets over the default port 9600.

The EVO500, EVO700, EVO760C, and EVO780C series PLCs integrate FINS protocol communication and support read/write access to the M memory area. Currently, these PLCs only act as FINS TCP/UDP servers and can exchange data with Omron, Keyence, and other PLC brands.

The FINS server function is disabled by default. The user must manually call the FINS_Server function block to enable or disable FINS communication. After the PLC stops running, FINS communication will no longer be accessible.

10.6.9.2 FINS Parameters and Addresses

Parameters

When accessing the I/O memory area (M area) of EVO500 and EVO700 series PLCs via FINS protocol commands, the communication command codes are shown in the table below.

Table10-6-9-2-1 FINS communication command code

Type	Primary Command	Secondary Command	Function	Description
I/O memory area (M area) read/write	01	01	Memory reading	Reads data from consecutive I/O memory area.
	01	02	Memory writing	Writes data to consecutive I/O memory area.

Address

The PLC soft components are mapped to the M area (fixed code: 0x82), with an addressing range of 0 to 32767. Access is performed in word components. The table below shows the soft component address mapping supported by the FINS protocol.

Variable	Address Range	Number of Soft Elements	Note
%MW0 to %MW32767	0x0000 to 0x7FFF (0 to 32767)	32768	16-bit register

NOTE

When reading/writing a large number of devices, it is recommended that the FINS TCP/UDP client split the data read/write into multiple packets.

10.6.9.3 FINS Protocol Configuration

Prerequisites

- The default communication port 9600 cannot be modified.
- The maximum number of FINS TCP/UDP client connections is 32.
- The maximum number of network nodes for the FINS protocol is 254.
- The maximum number of consecutive components that can be read via the FINS protocol is 2000 words.
- The last byte of the IP address must be within the range of 1 to 254 and cannot be set to 0 or 255.

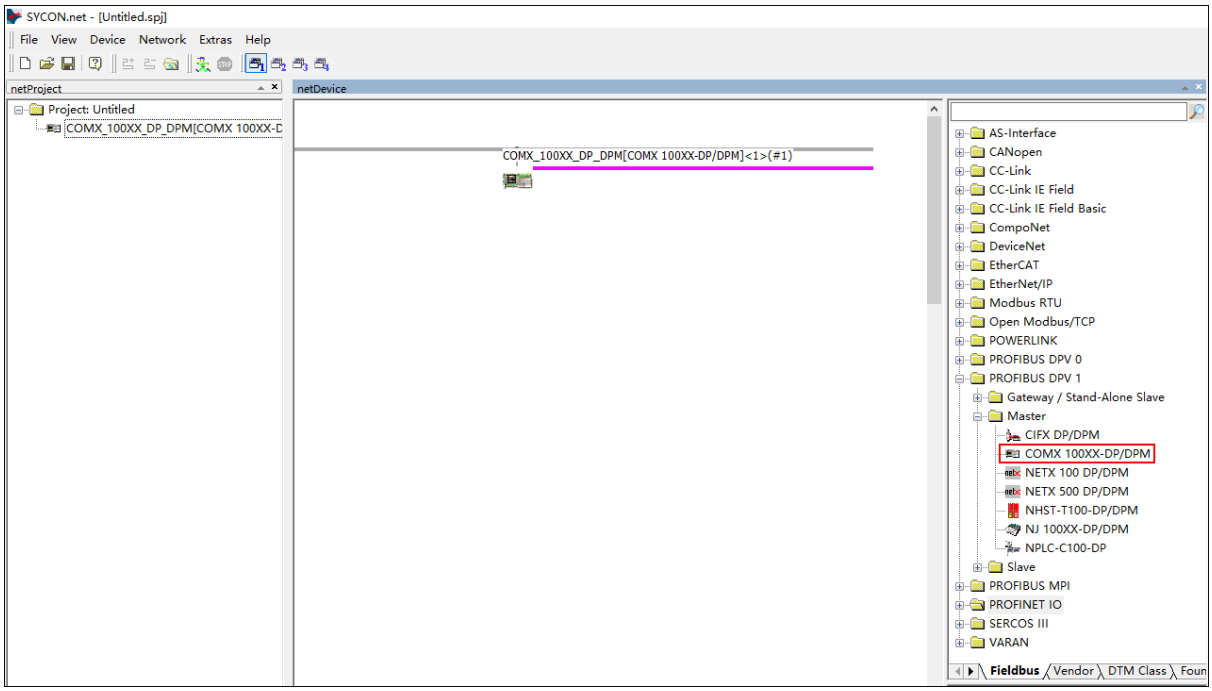
Command	RD-CMD (Read Command)	RD-ACK (Read Response)	WR-CMD (Write Command)	WR-ACK (Write Response)
FINS TCP	34 bytes	30 bytes + 2*N	34 bytes + 2*N	30 bytes
FINS UDP	18 bytes	14 bytes + 2*N	18 bytes + 2*N	14 bytes

NOTE

N does not exceed 2000.

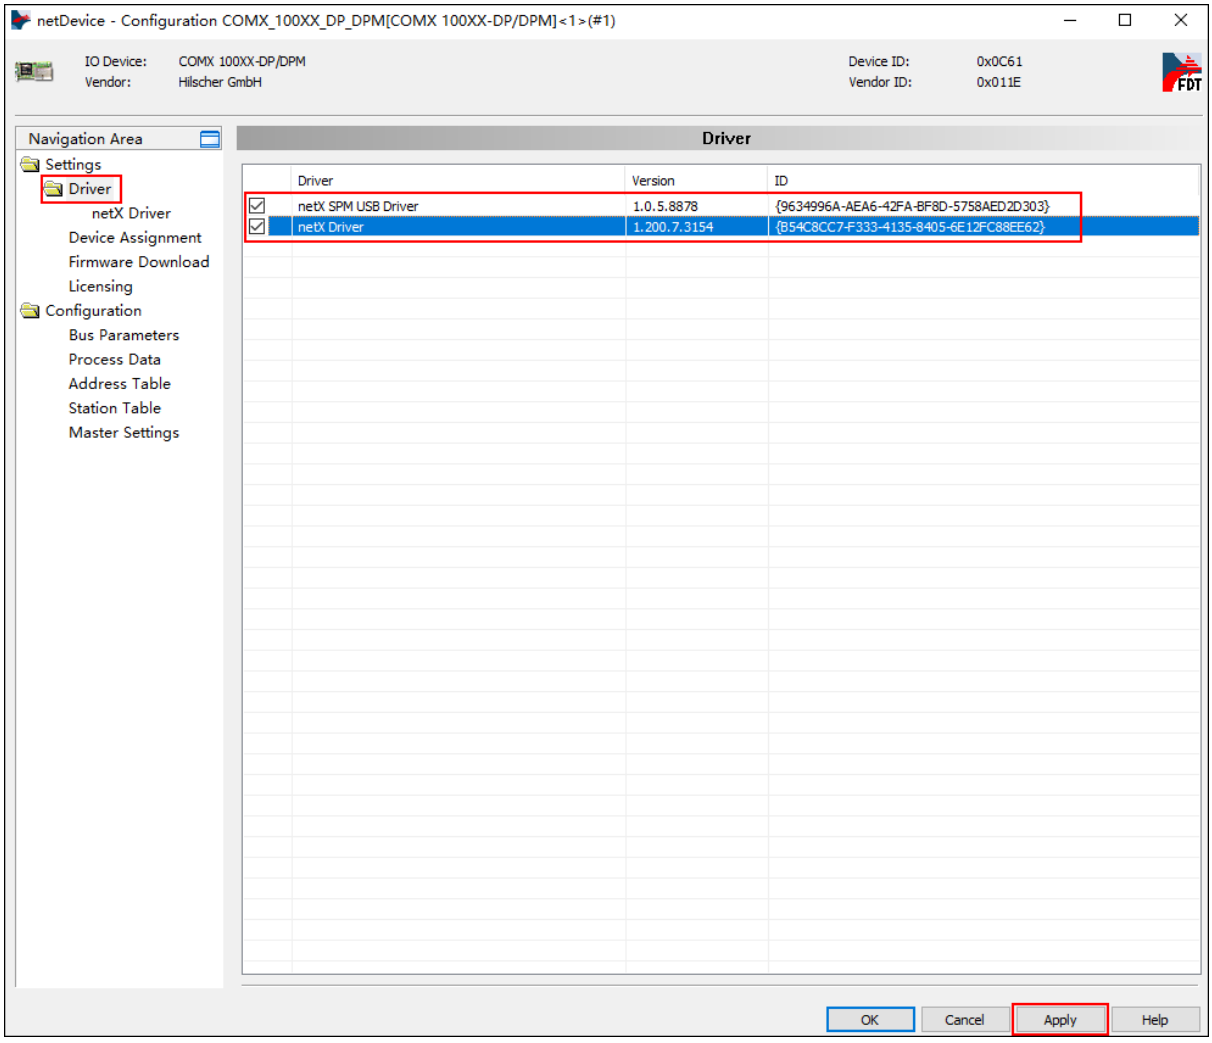
10.6.10 DP Communication Configuration (EVO800)

10.6.10.1 DP Master Configuration (SYCON.net)



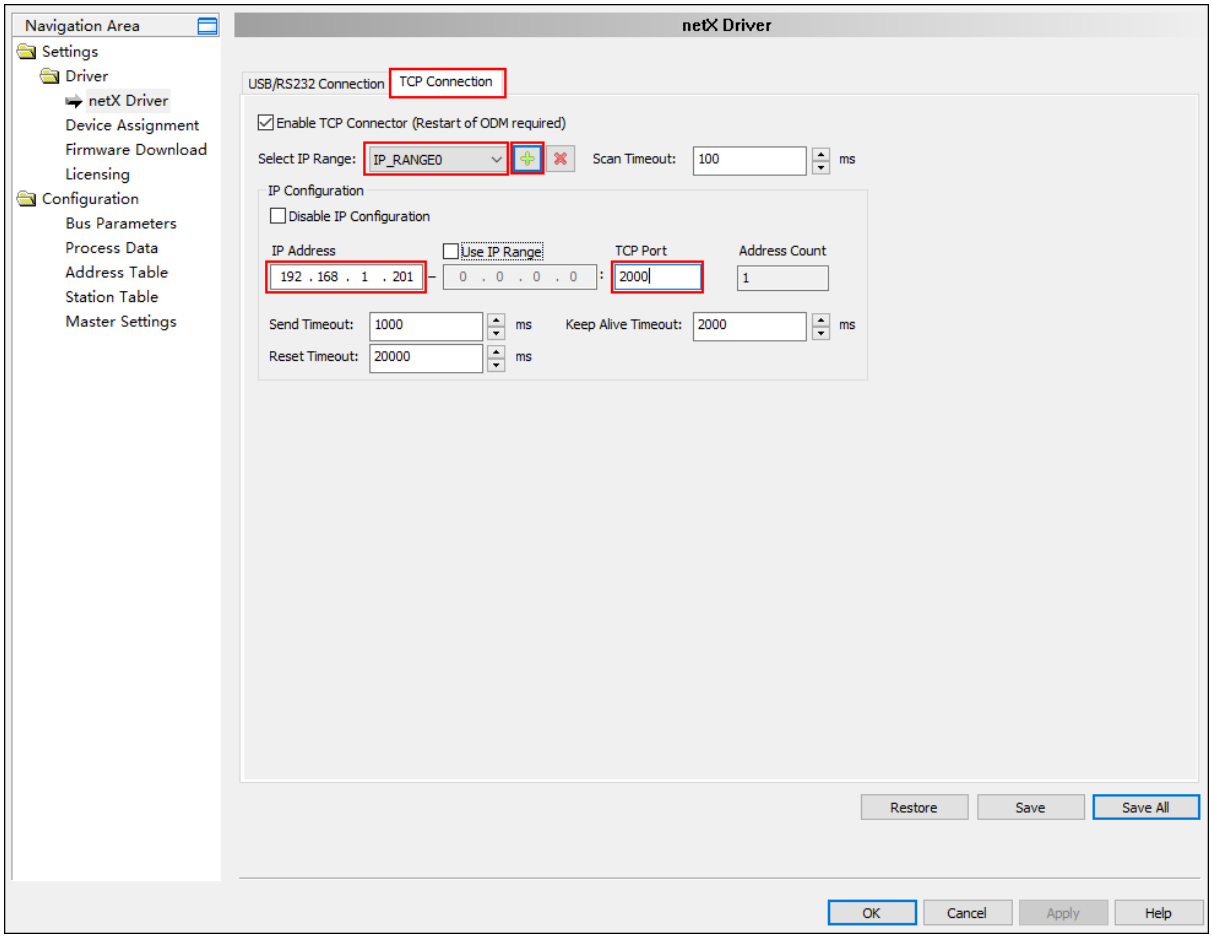
This section introduces how to configure the DP master and its slaves using the SYCON.net software.

Prerequisites

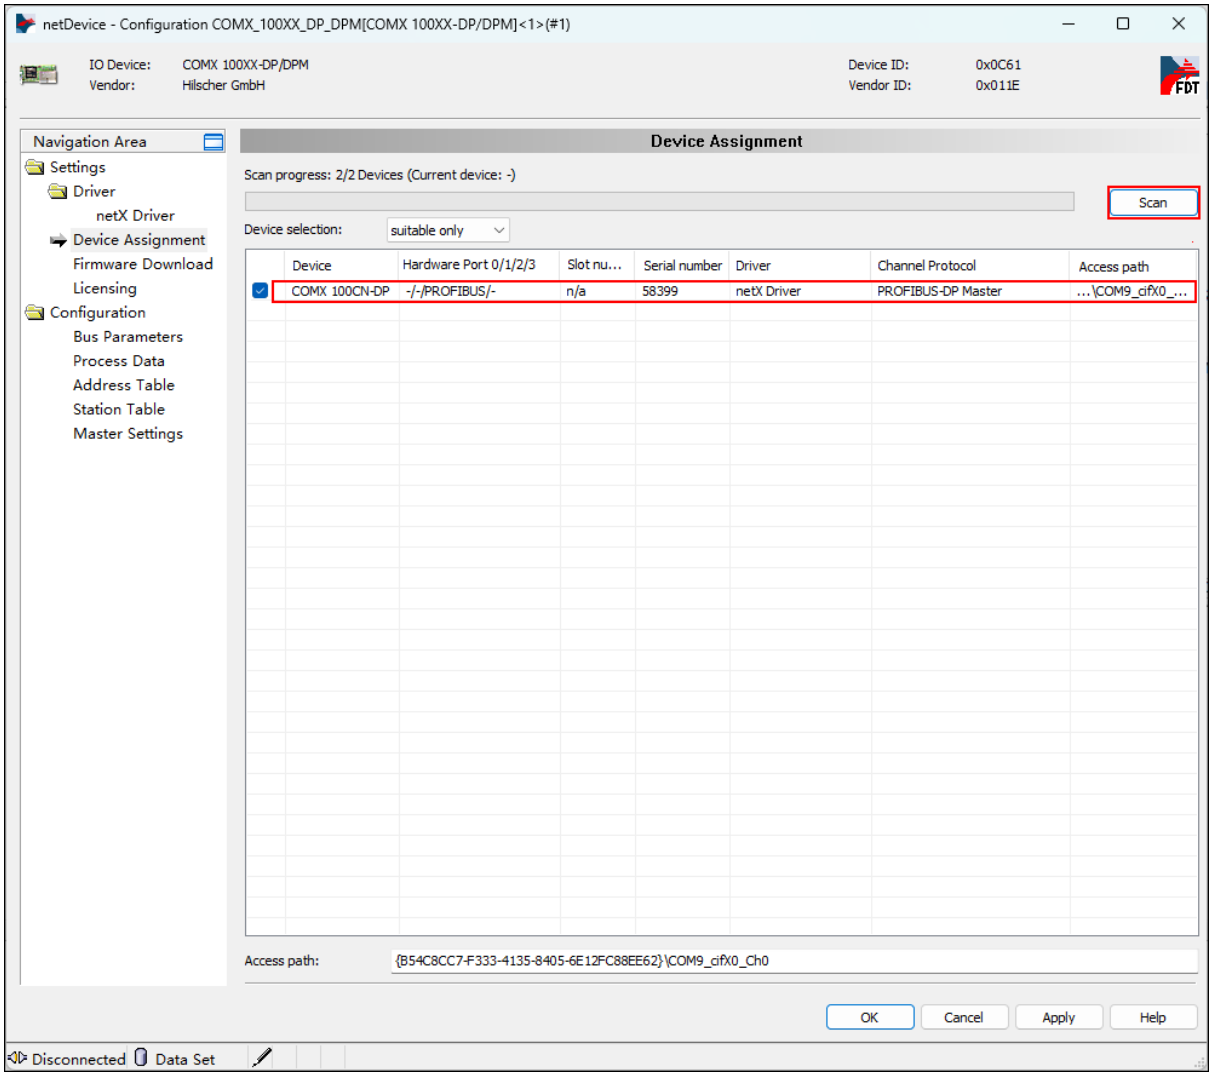


- SYCON.net software has been installed.
- The slave device description file has been obtained.
- Hardware connection has been completed.
  The DP can connect to the PC via the commissioning interface. The default IP of the commissioning interface is 192.168.1.201 (ensure that the local network is configured in the 192.168.1.XX subnet).

DP master configuration



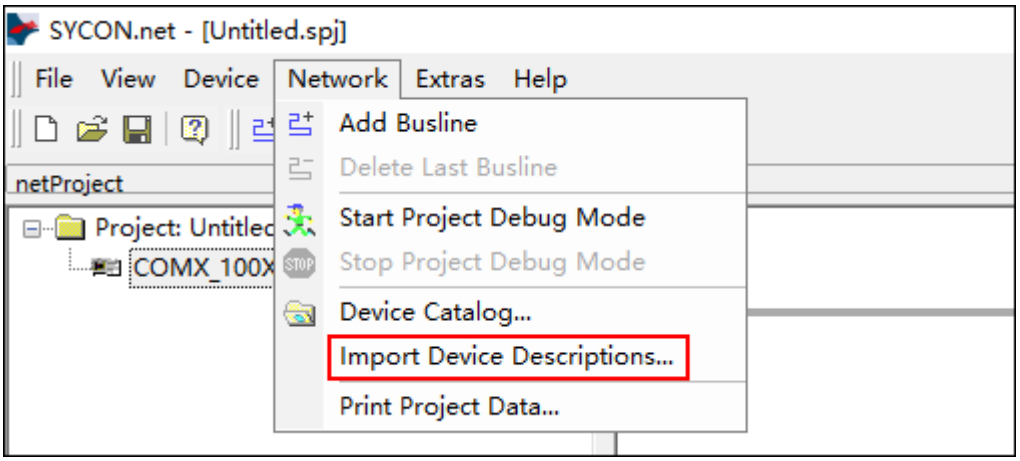
1. Launch the SYCON.net software as the admin.
2. Add a DP master. On the "Fieldbus" tab on the right of the interface, select "PROFIBUS DPV 1 > Master > COMX 100XX-DP/DPM" and drag it into the "netDevice" window, connecting it to the gray data line.



3. After adding the master, double-click the master icon to open the configuration page. On the "Driver" tab, check the configuration items as shown below, and click "Apply".

4. When connecting to the master via Ethernet, select "Driver > netXDriver" on the configuration page. On the "TCP Connection" tab, configure the following parameters: Click in the "Select IP Range" area,  set the IP range to "IP_RANGE0"; set "IP Address" to "192.168.1.201"; set "TCP Port" to "2000".

5. Select the "Device Assignment" tab, click "Scan". Once the DP module is found, click "Apply", then click "OK".



DP slave configuration

Using the addition of the IM155-5 DP ST V3.0 slave as an example.

1. Import the slave device description file.

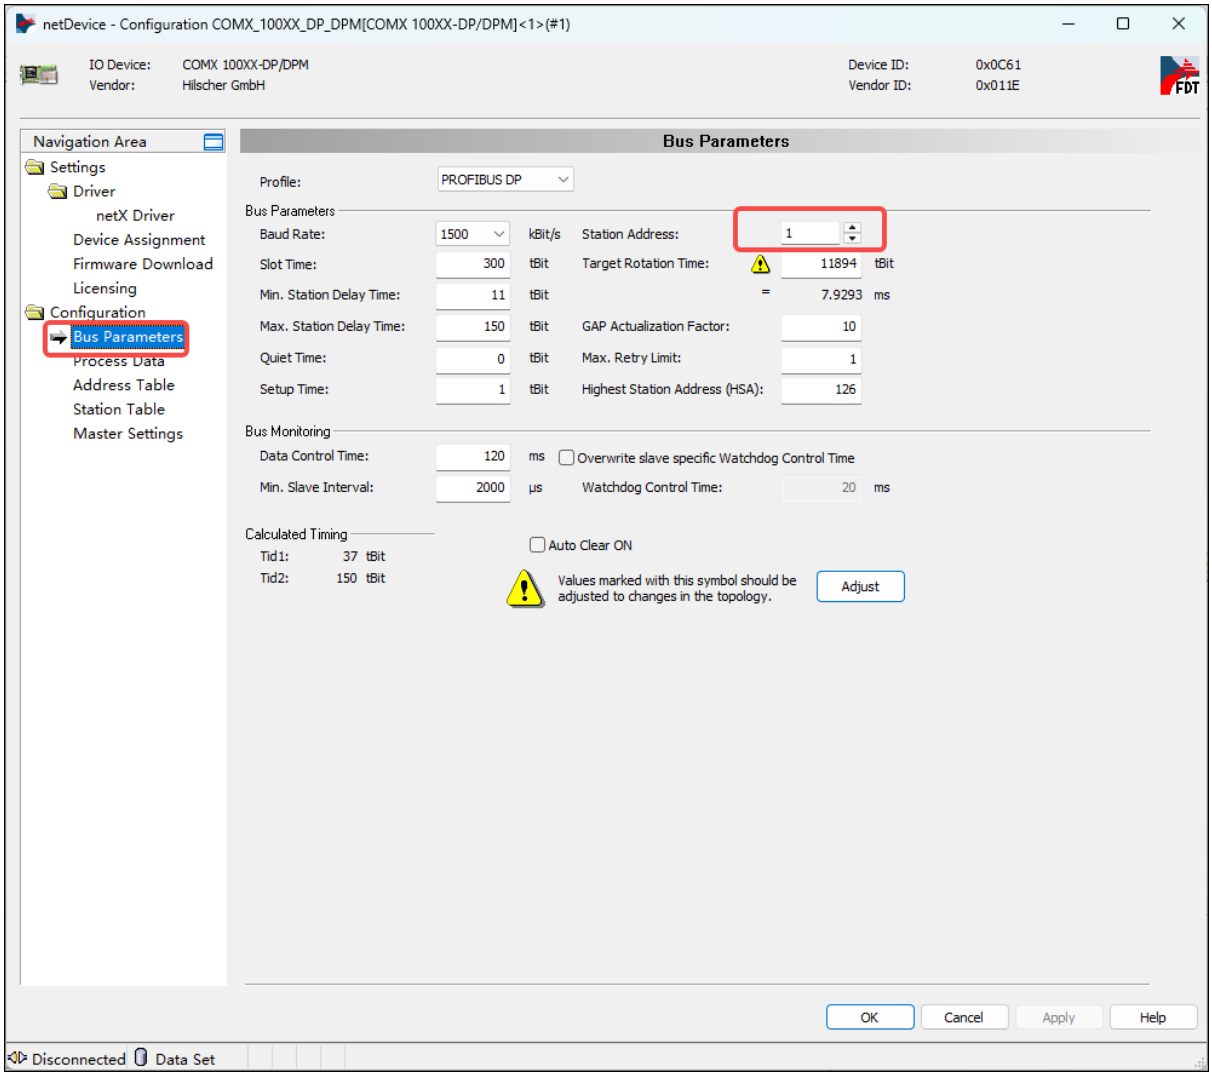
   In the menu bar, select "NetWork > Import Device Description" to import the slave device description file.

   You can view the added device on the "Vendor" tab on the right of the interface.

2. Add a slave.

   On the "Vendor" tab on the right of the interface, select "SIEMENS > Slave > IM155-5 DP ST V3.0", and drag

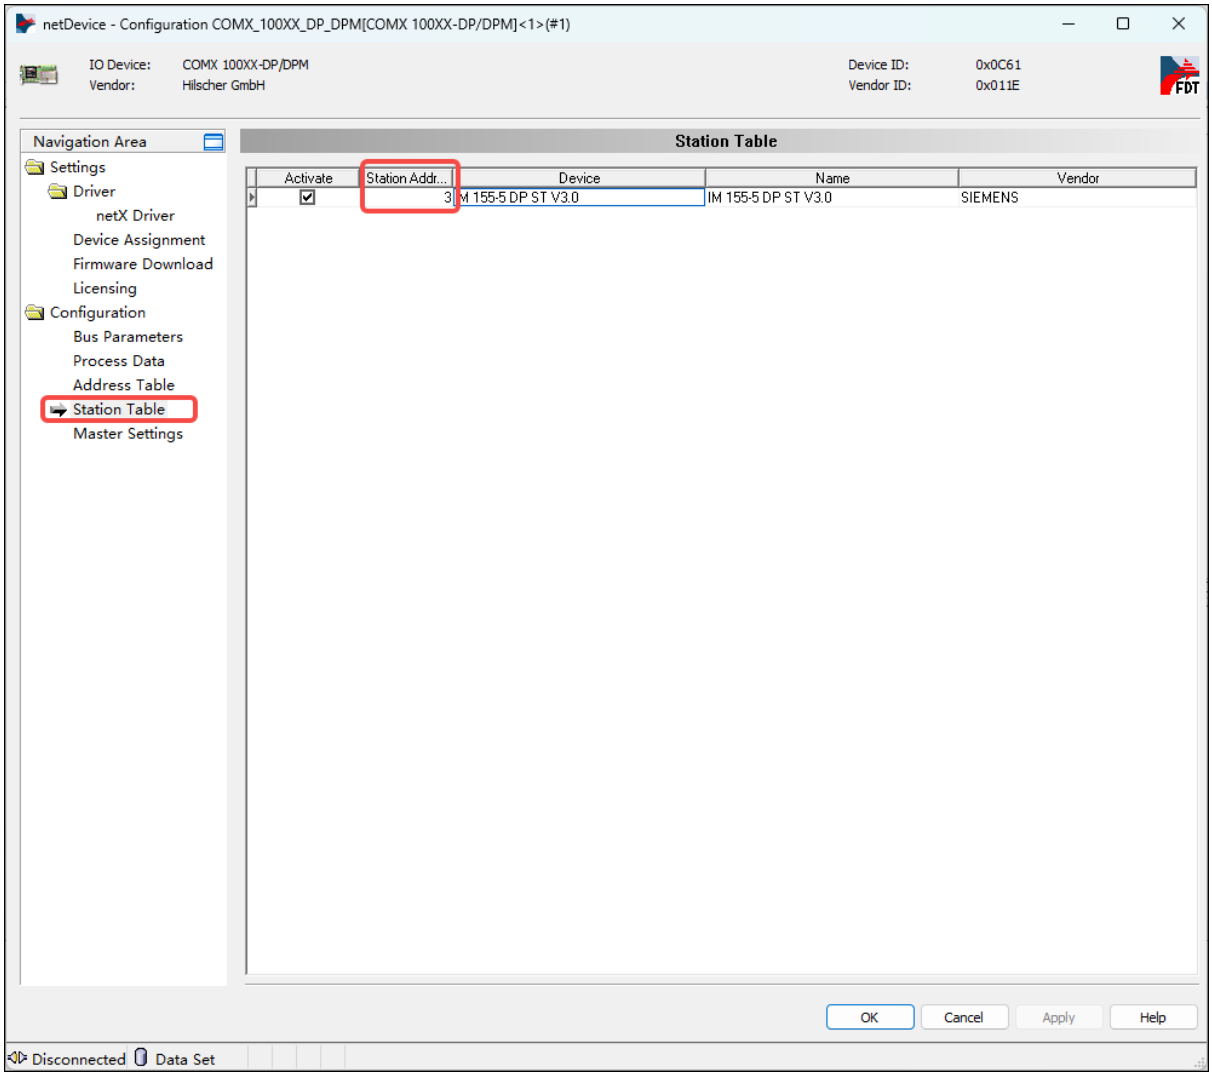
it under the master.



3. Configure the slave.

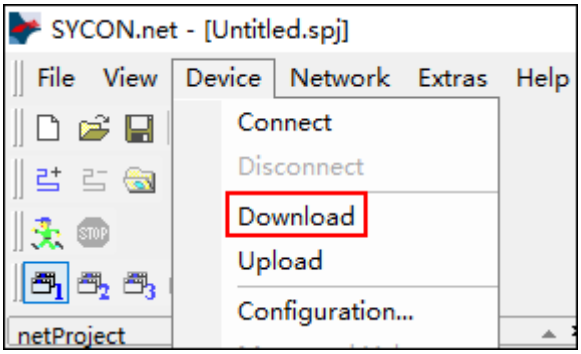
Double-click the slave icon to open the configuration page. On the "Modules" tab, double-click the corresponding slave model to add it, and click "Apply".

Master/Slave address configuration



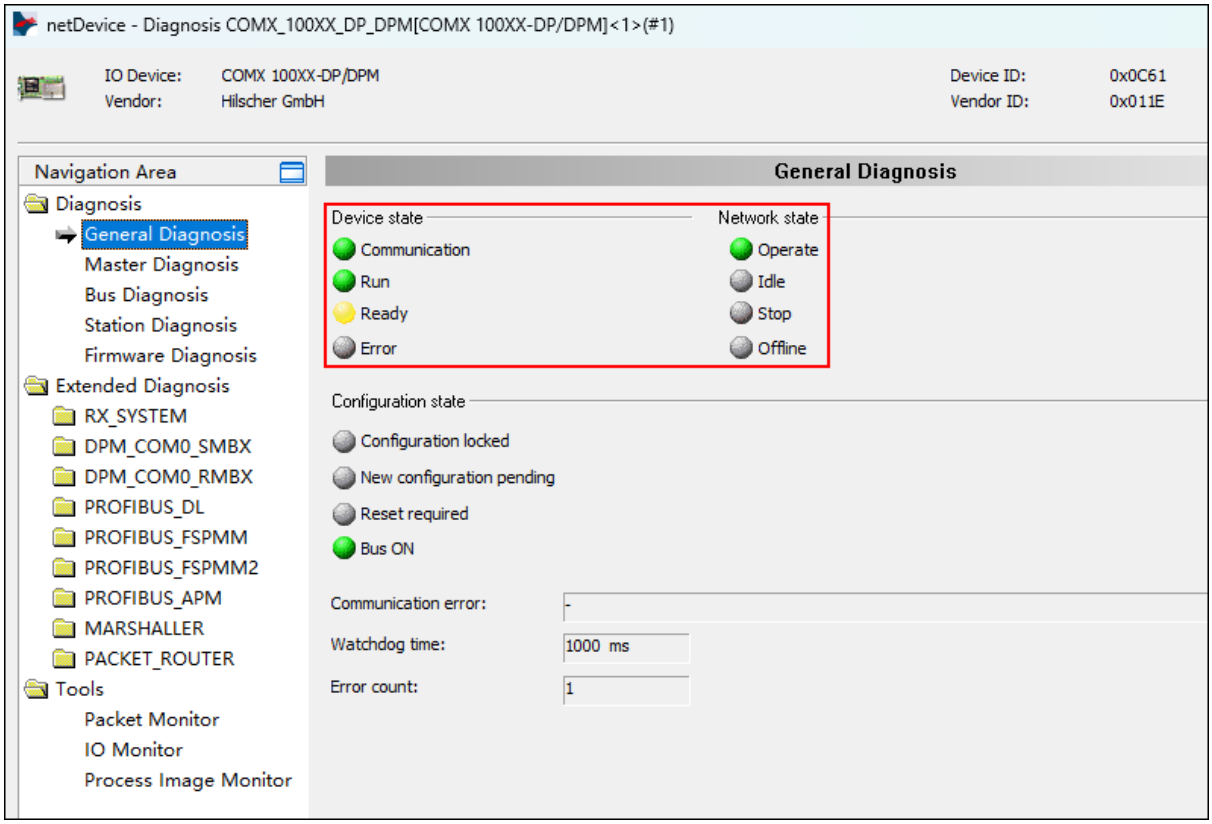
1. Double-click the master icon to open the master configuration page. Select "Bus Parameters"; the default station address of the master is 1.

2. Select "Station Table", change the slave address to 3, click "Apply", then click "OK".

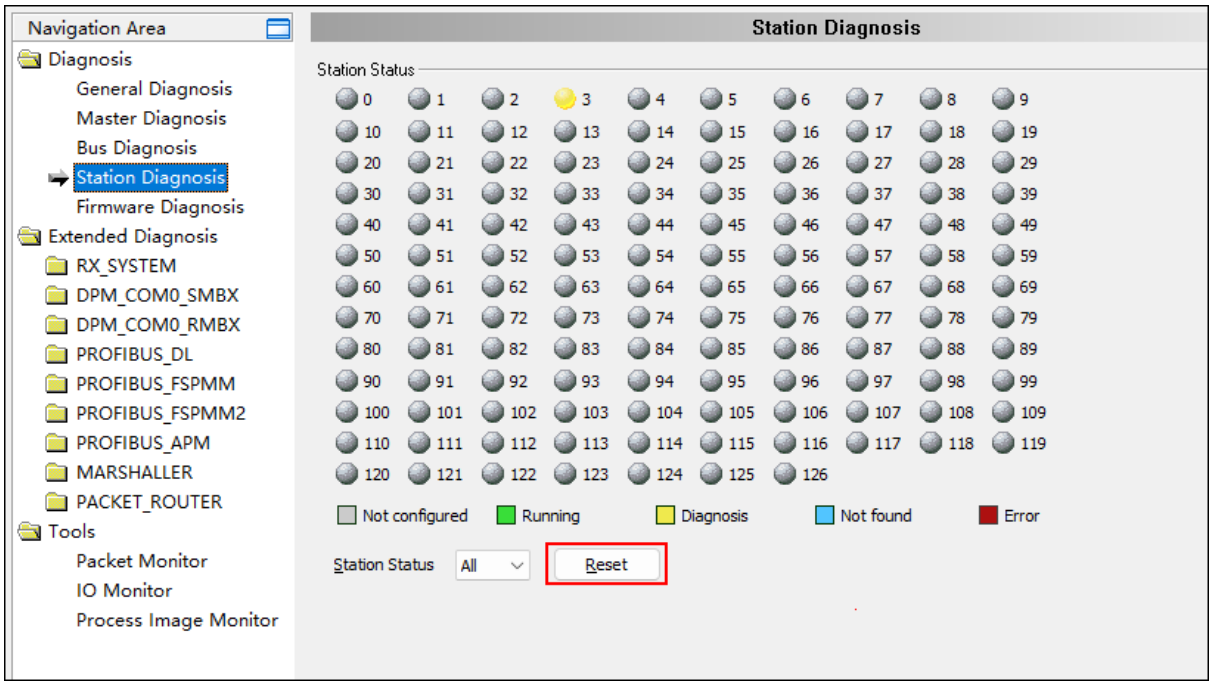


NOTE

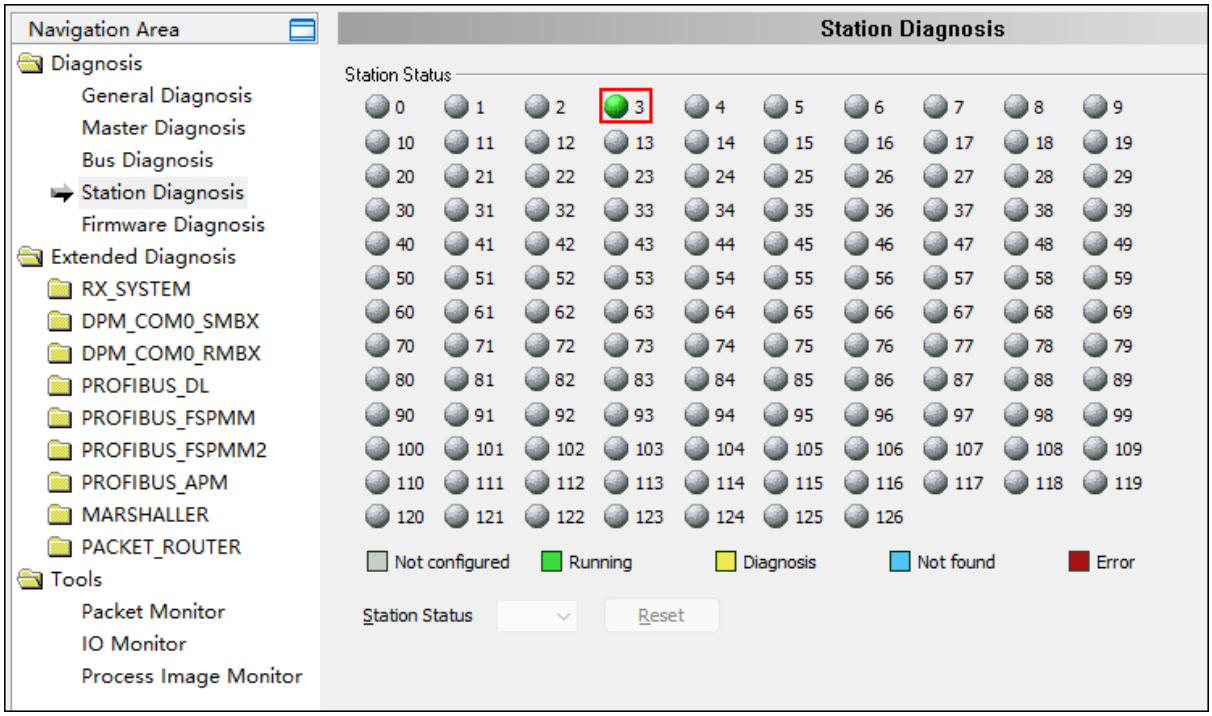
The slave address setting shall match the DIP switch setting of the actual connected slave.



Configuration download

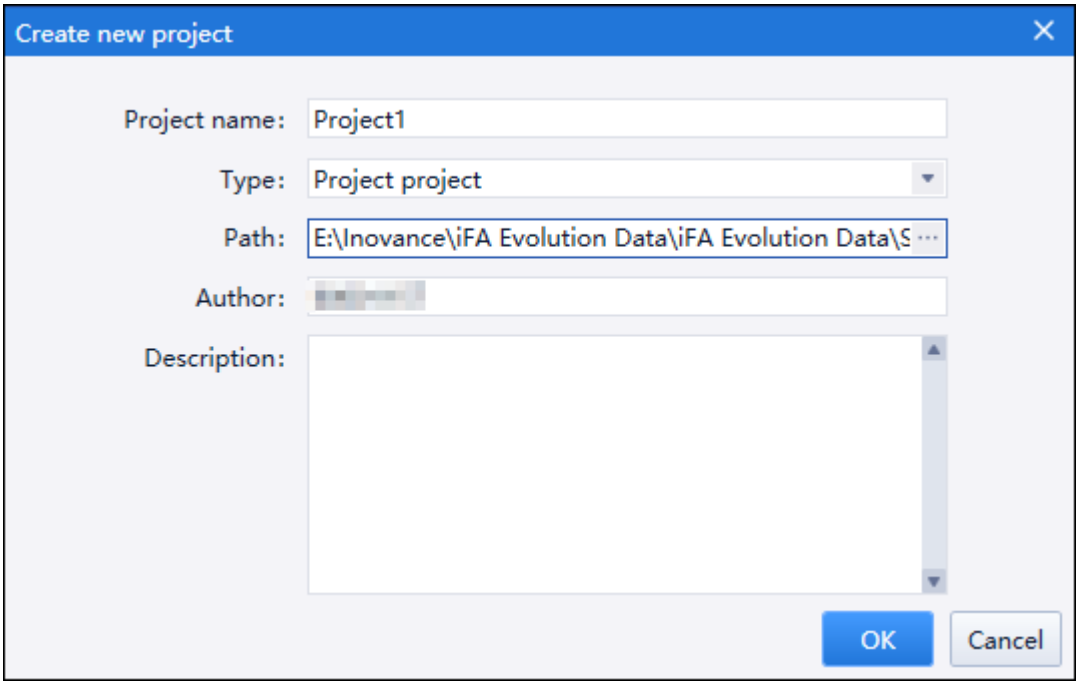


1. Select "Device > Download" from the menu bar to download the configuration to the device.



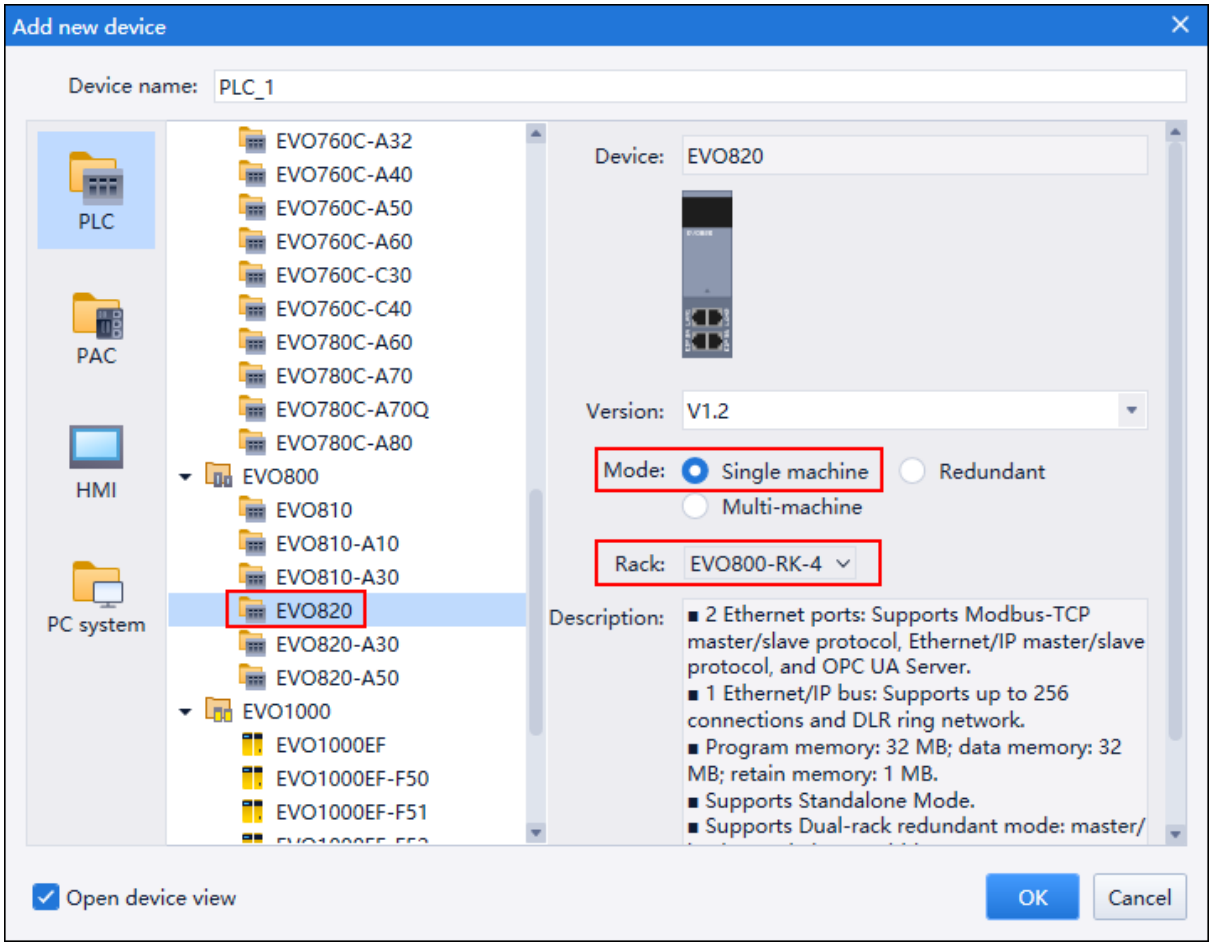
2. Check whether the configuration and communication are successful.
   Double-click the master icon to view diagnostic information on the "General Diagnosis" tab. As shown below, the master is operating normally.

3. Select "Station Diagnosis" to check the slave operation. A yellow light indicates that the slave has reported diagnostic information to the master. Click "Reset" and the light turns green, indicating normal communication and successful configuration.



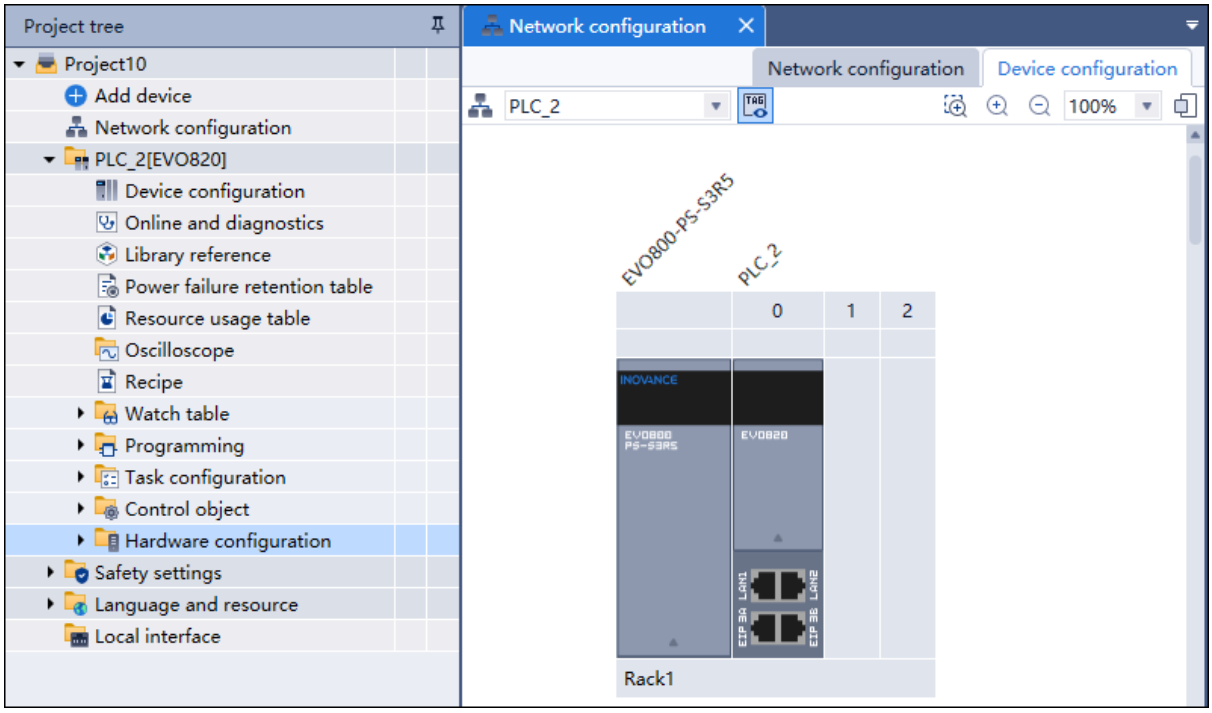
10.6.10.2 DP Master Configuration (iFA)

Prerequisites



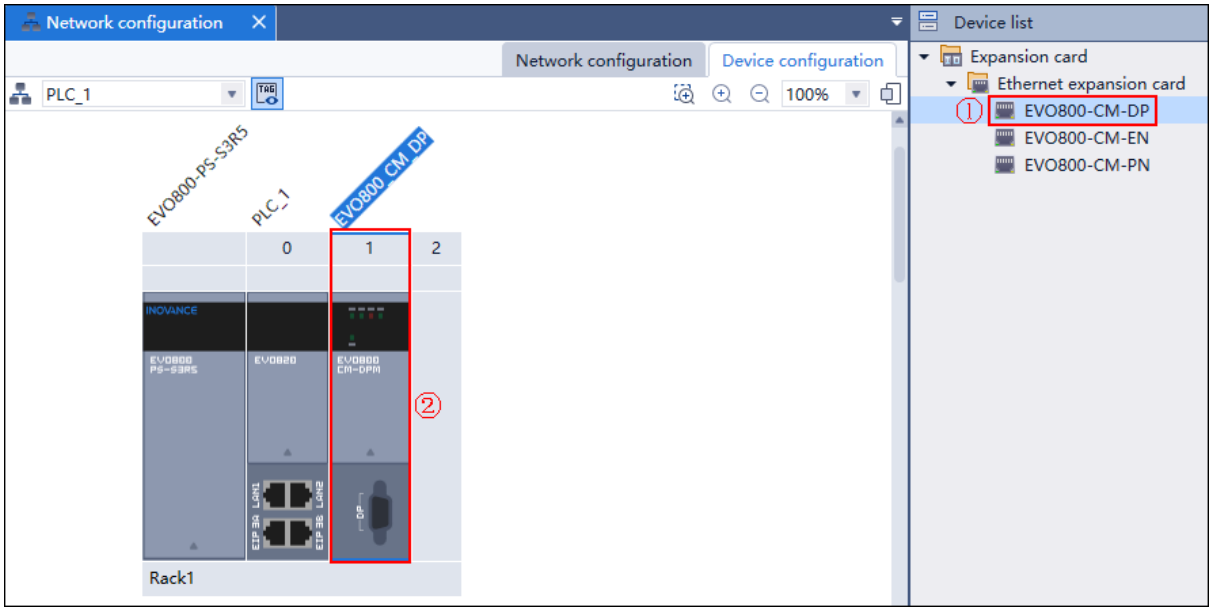
- All products in the configuration example have been installed, wired, and powered on.
- The PC installed with iFA Evolution is connected to the LAN1 port of the EVO820 control module via a network cable.

Procedure

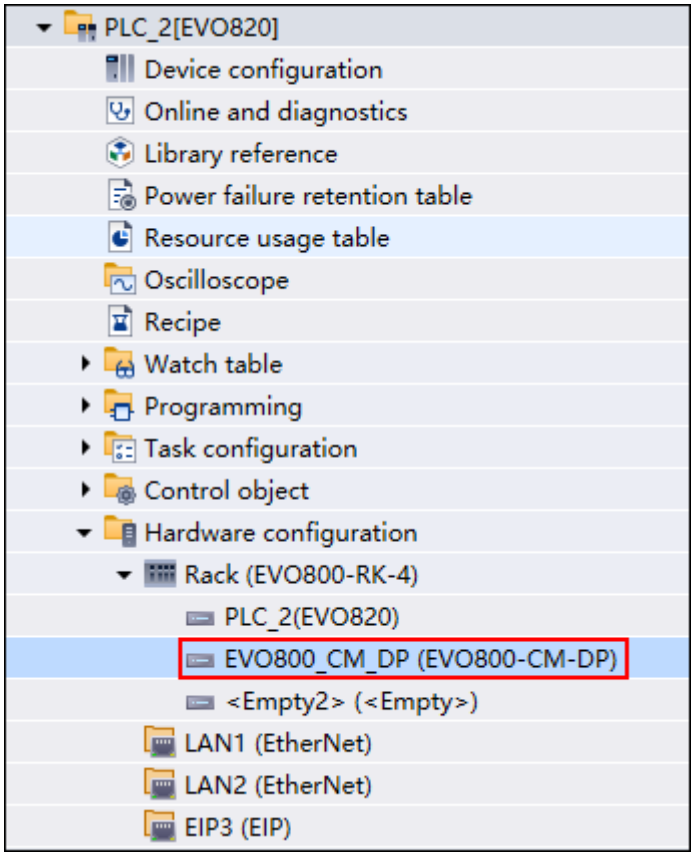


1. Create a new project.
   In the menu bar, select "Project > New". Enter the project information (select "Engineering project" for "Type"), and click "OK".

2. Add a new device.
   Double-click "Add device" in the project tree, click "EVO820" in the opened dialog box, enter the device name, "Mode" is set to "Single machine" by default, select the proper "Rack", and click "OK".

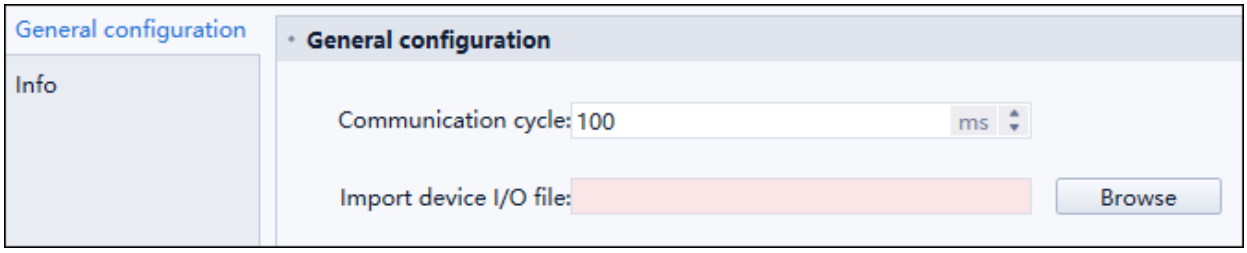


The newly added EVO820 device appears in the project tree.

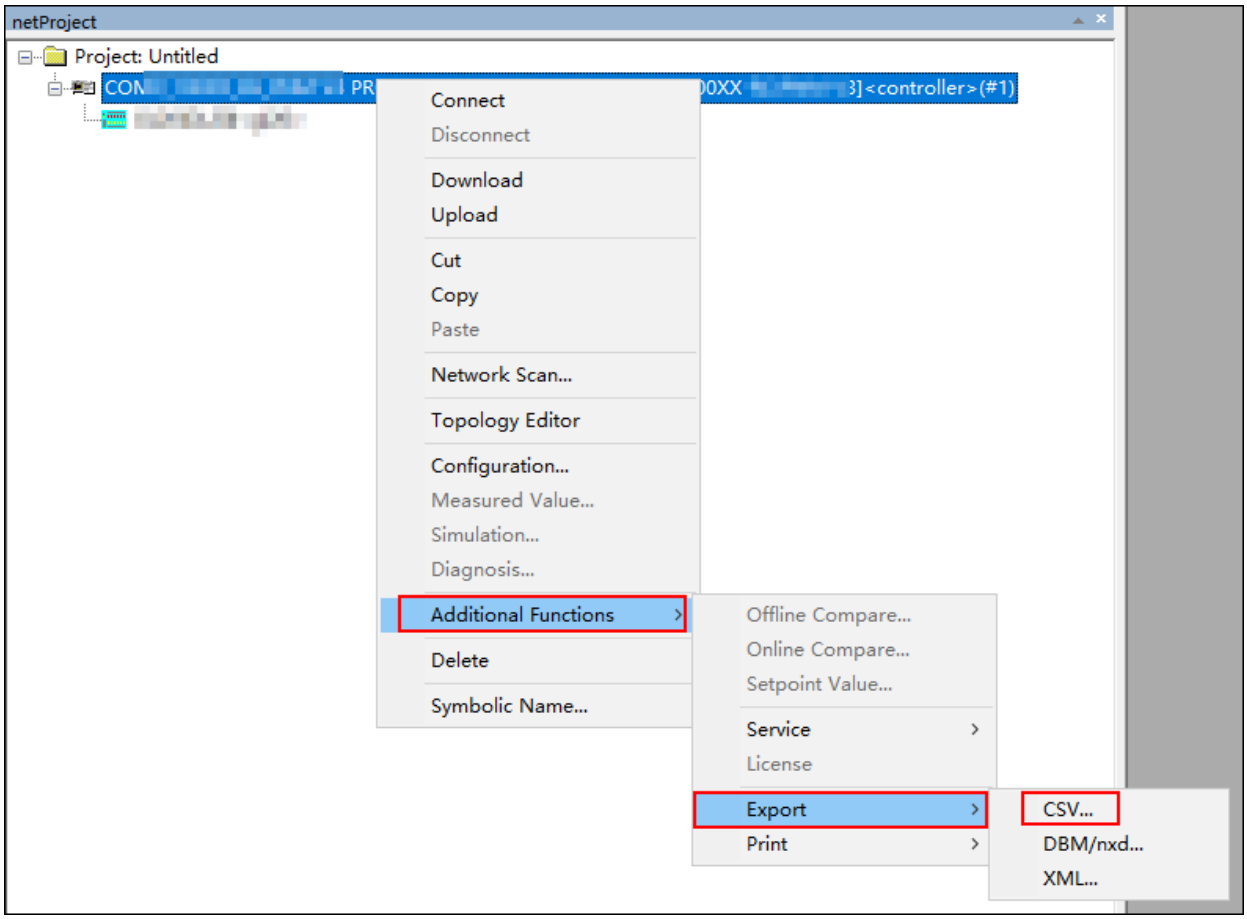


3. Add the EVO800-CM-DP module.

   In the project tree, double-click "Device configuration", select the target slot, then double-click "EVO800-CM-DP" in the "Device list" to add the DP master expansion module.



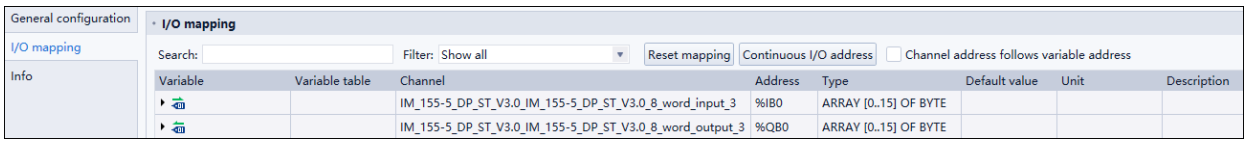
The newly added DP master expansion module appears in the project tree.



10.6.10.3 DP Master Configuration

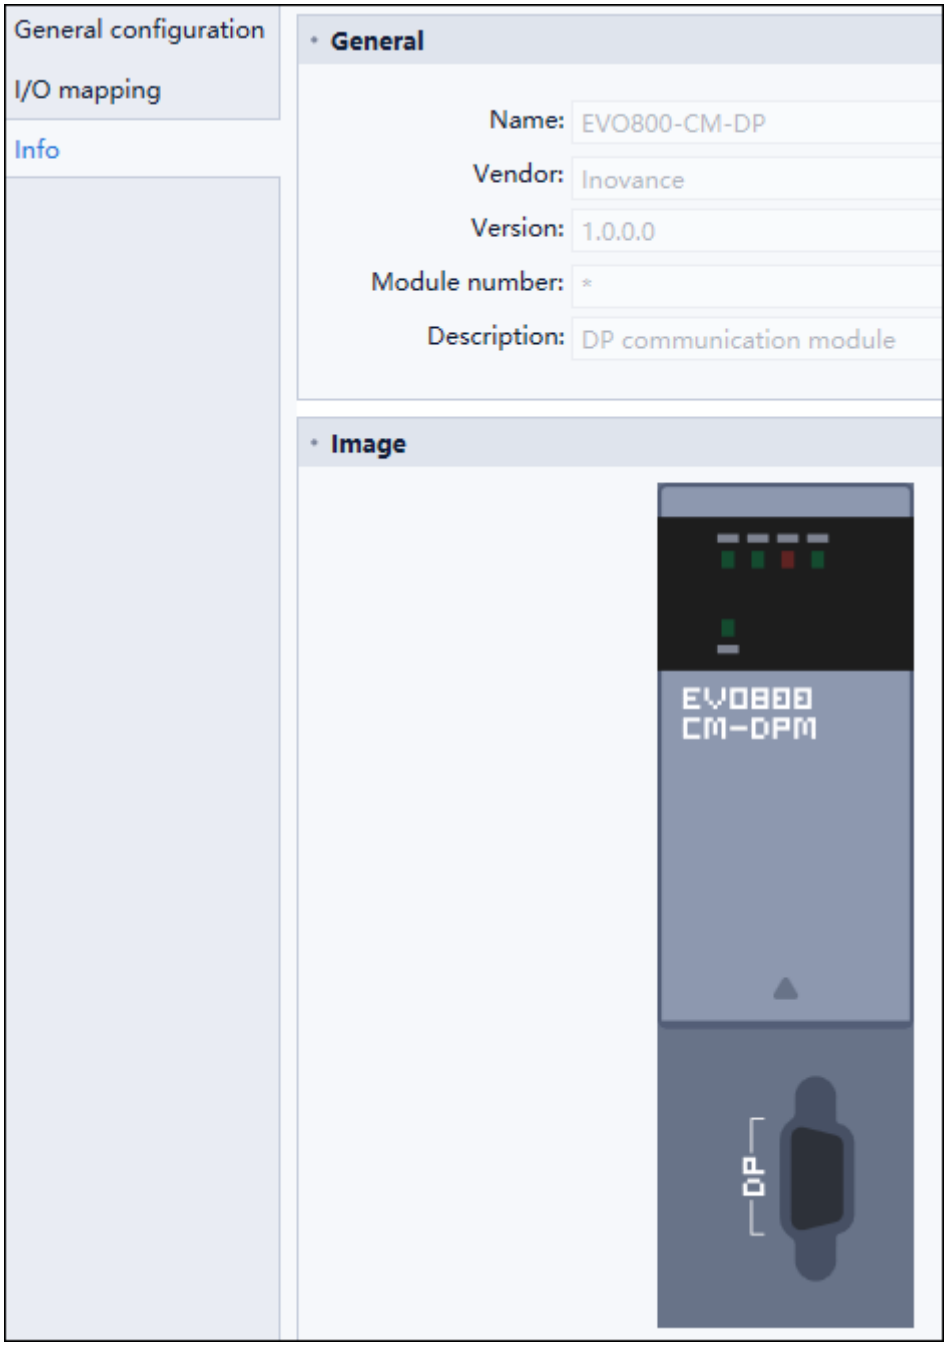
10.6.10.3.1 General Configuration

Double-click the DP master node to enter the master parameter configuration interface.



- Communication cycle: The backplate communication cycle between the PLC and the DP module. Default: 100 ms.
- Import device I/O file: Click "Browse" to select a .csv file (exported from SYCON.net software) for import.
  To export the I/O configuration file of the DP module from SYCON.net:
  After configuring the master, right-click the master, and select "Additional functions > Export > CSV" to save the file in CSV format.

10.6.10.3.2 I/O Mapping

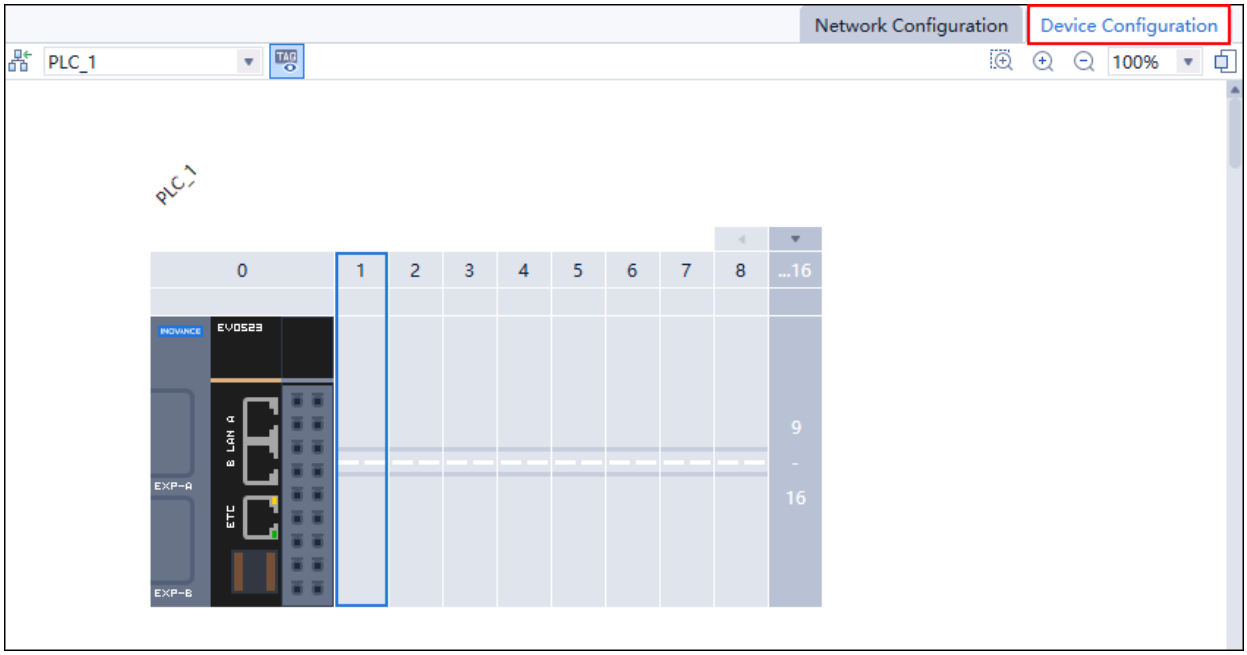


After importing the device I/O configuration file on the general configuration page, you can view the I/O settings related to DP communication, as shown in the figure below:

For details about the configuration parameters, see 10.6.3.3.9 I/O Mapping.

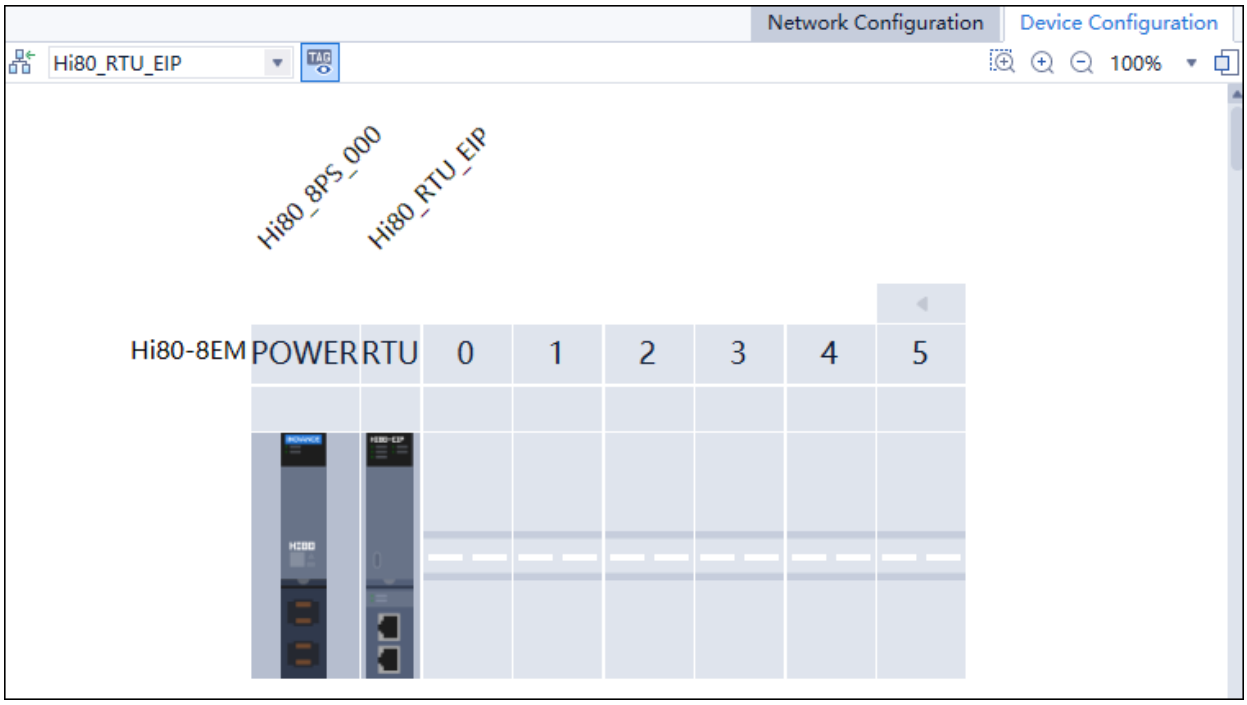
10.6.10.3.3 Information

This interface displays the general information and image of the device, as shown in the following figure:



10.6.11 I/O Module Configuration

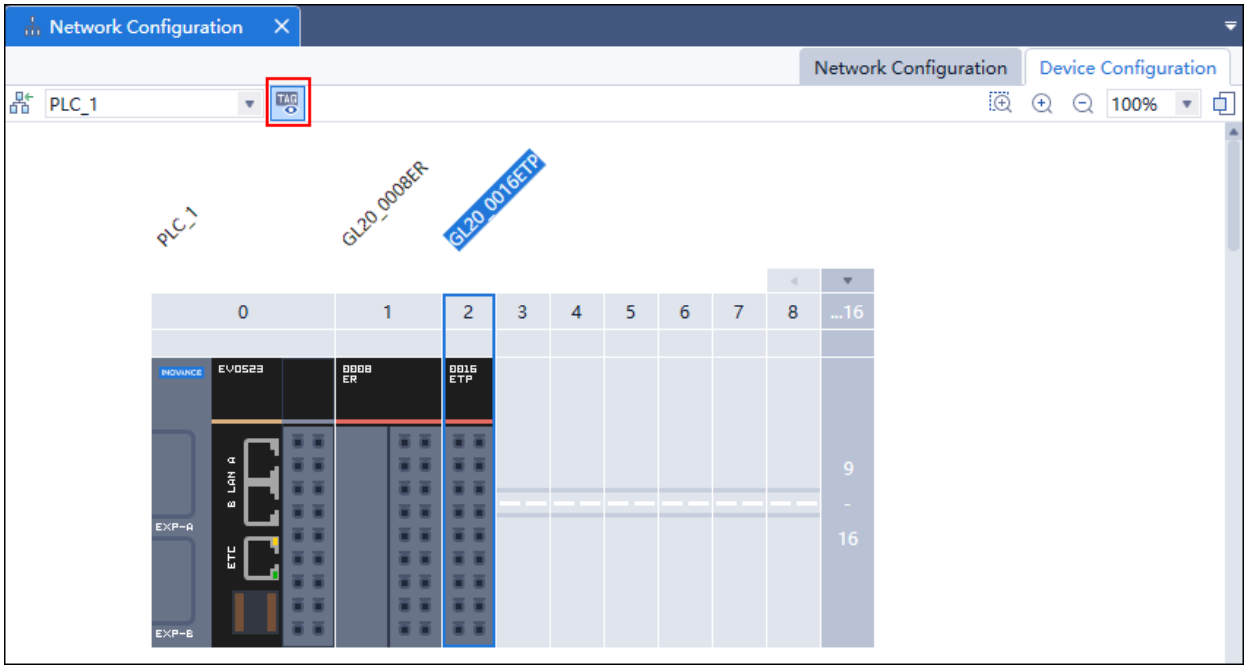
10.6.11.1 Rack Overview



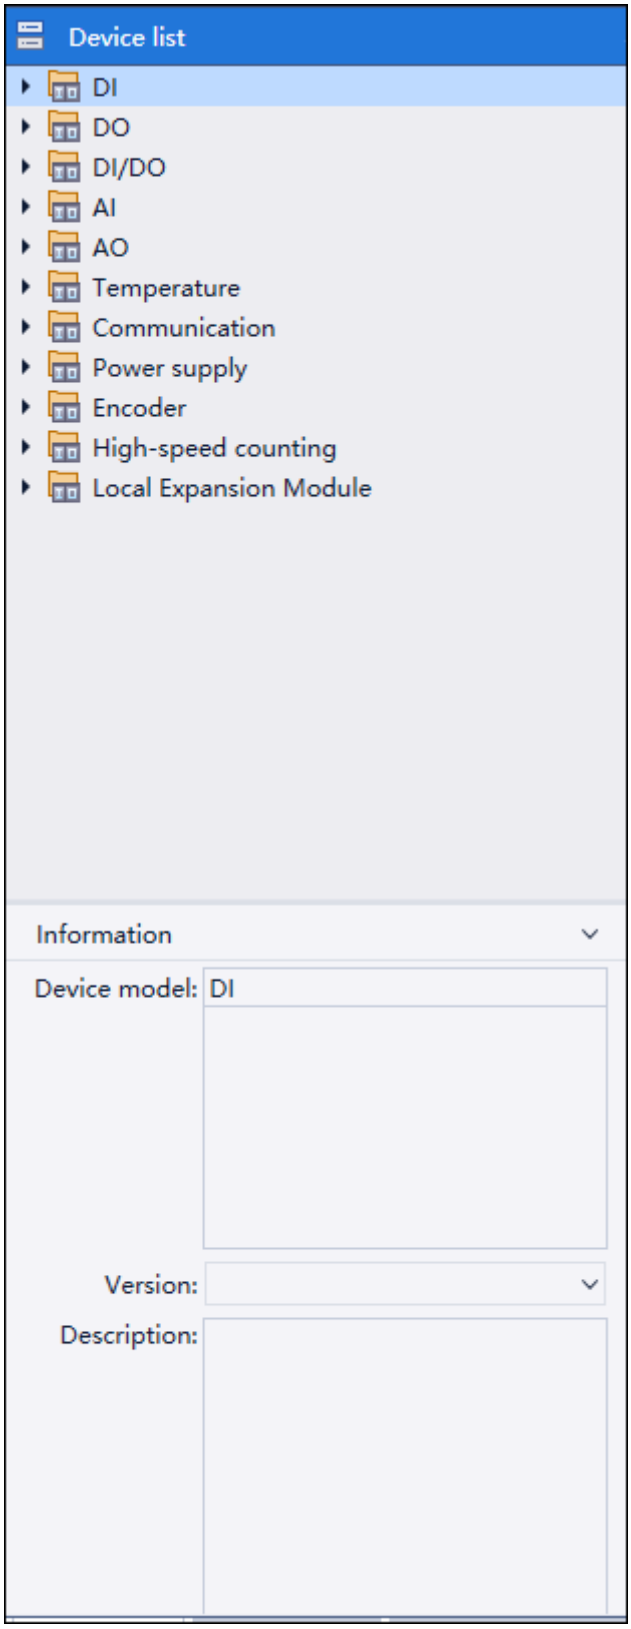
To mount modules after the main device, a rack (i.e., a mounting rail) must be used to secure the modules to the rack and connect them to the CPU, couplers, power supply, or other modules via the backplate bus.

Creating a rack

After adding a device, a rack suitable for the selected device is automatically created. The available slots in the rack are displayed in the device configuration view, and the number of available slots depends on the type of device used.



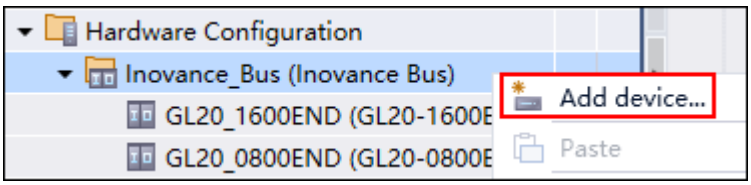
When adding a rack with a backplate bus (such as the Hi80/Hi50 series), the system automatically creates a power supply and an RTU communication module before slot 0. Depending on the selected module, the rack supports different backplates and numbers of slots. If a module is inserted into a slot, its properties can be viewed in the monitoring window.



Rack structure

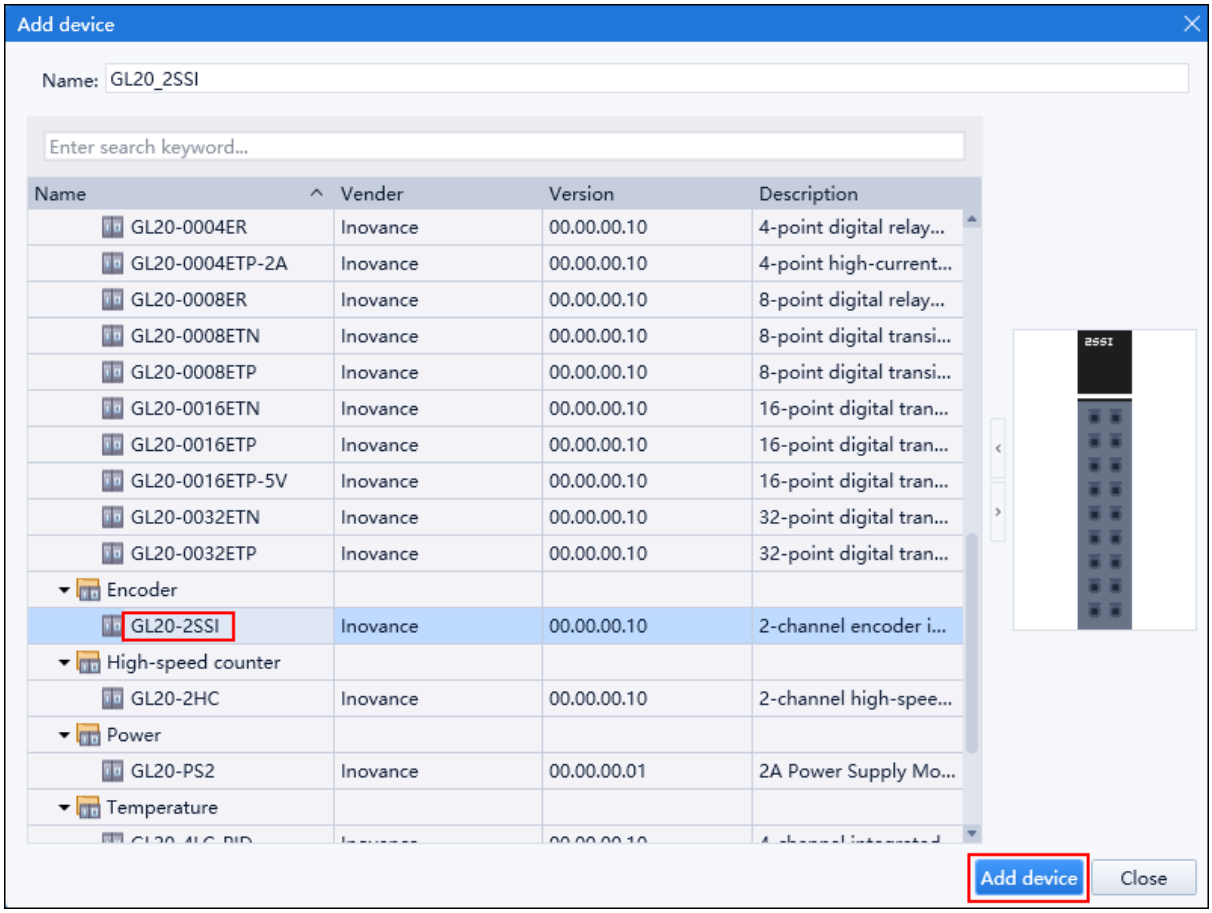
There are empty slots to the right of the device. The slot numbers are located above the slots and a brief description is displayed above the inserted device and modules. Use the "Display label" icon on the toolbar to display or hide the brief description of the device.

In the right device list, the slots that allow insertion of these modules are displayed.



PLC local rack I/O modules is also known as local I/O modules. For the EVO500 series products, the CPU rack supports up to 16 local I/O modules by default for expansion. These modules include digital input modules (DI), digital output modules (DO), digital input/output modules (DIO), analog input modules (AI), analog output modules (AO), temperature modules (PT), power supply modules, and local expansion modules.

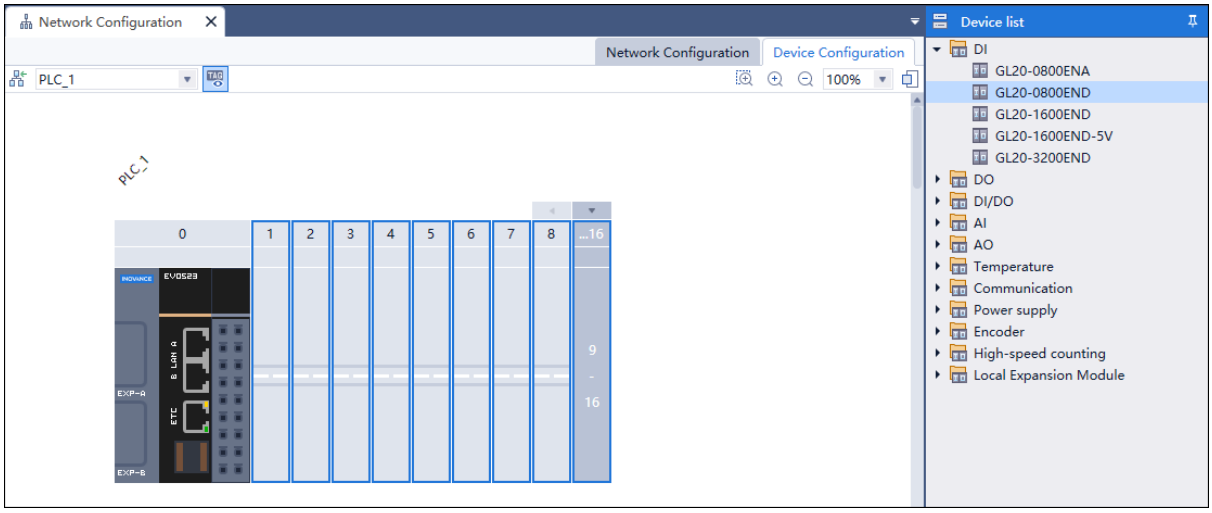
10.6.11.2 Adding a Local I/O Module



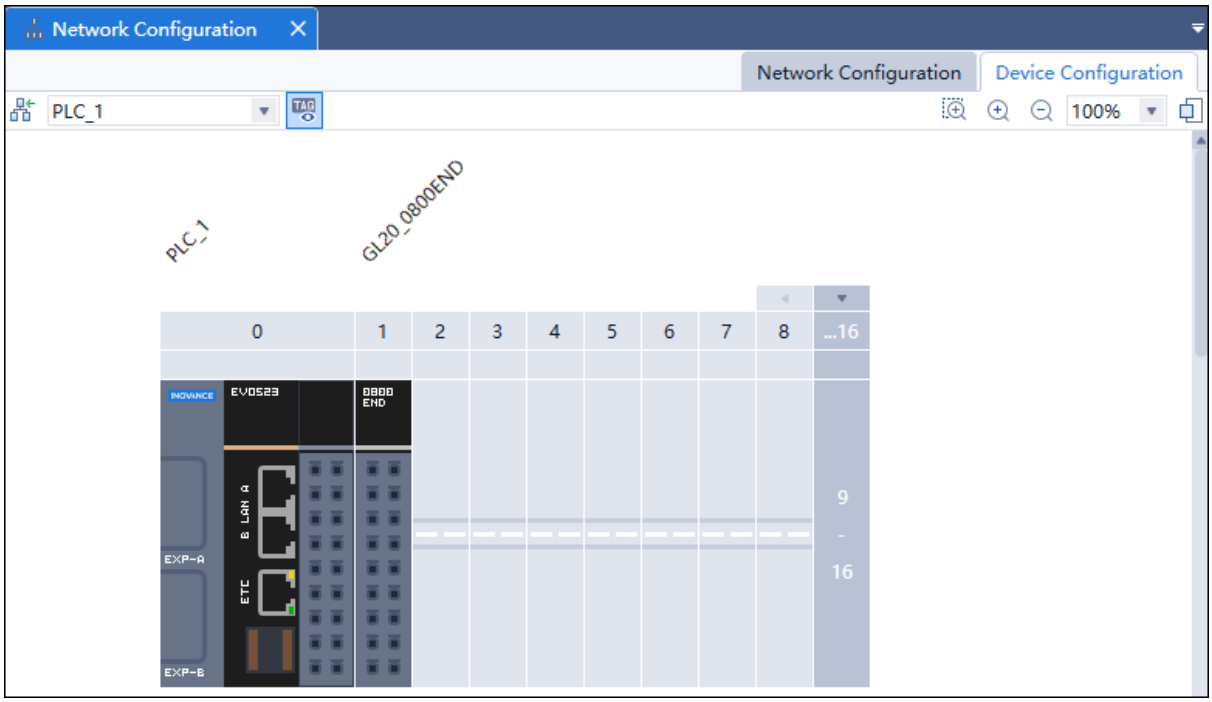
Local I/O modules can be added through the project tree or the device configuration view. The specific steps are as follows:

Method 1: Adding a module through the project tree

1. Expand the "Hardware configuration" list in the left project tree.
2. Right-click "Inovance_Bus (I/O Modules)" and select "Add device".



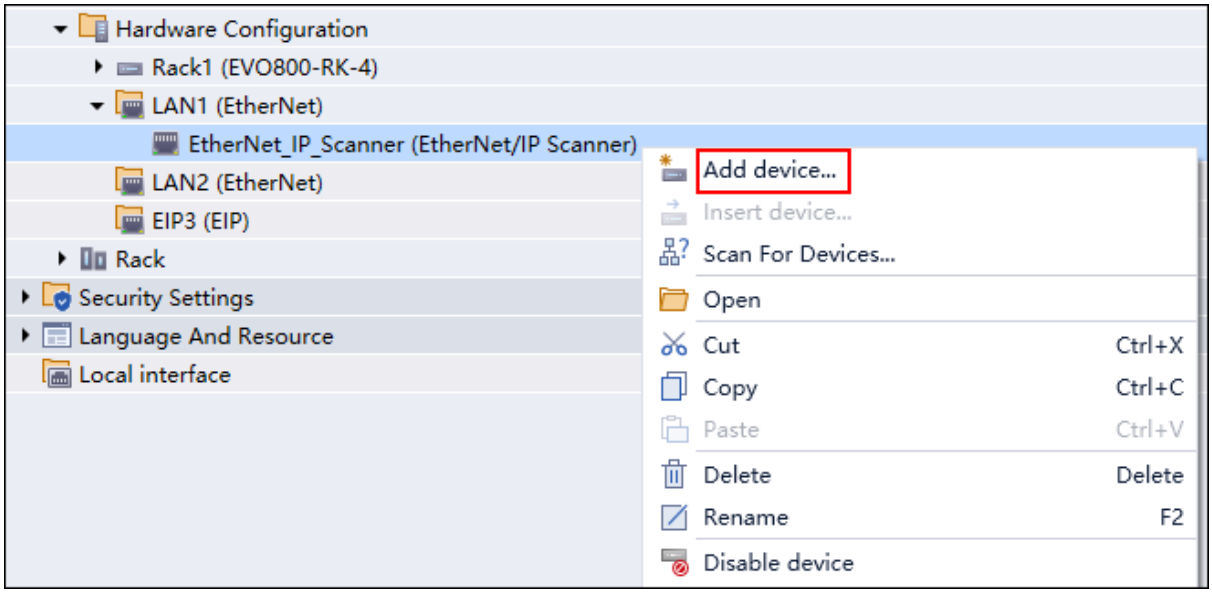
3. In the pop-up window, select the module and click "Add device", or double-click the module to complete the addition.



Method 2: Adding a module through the device configuration view

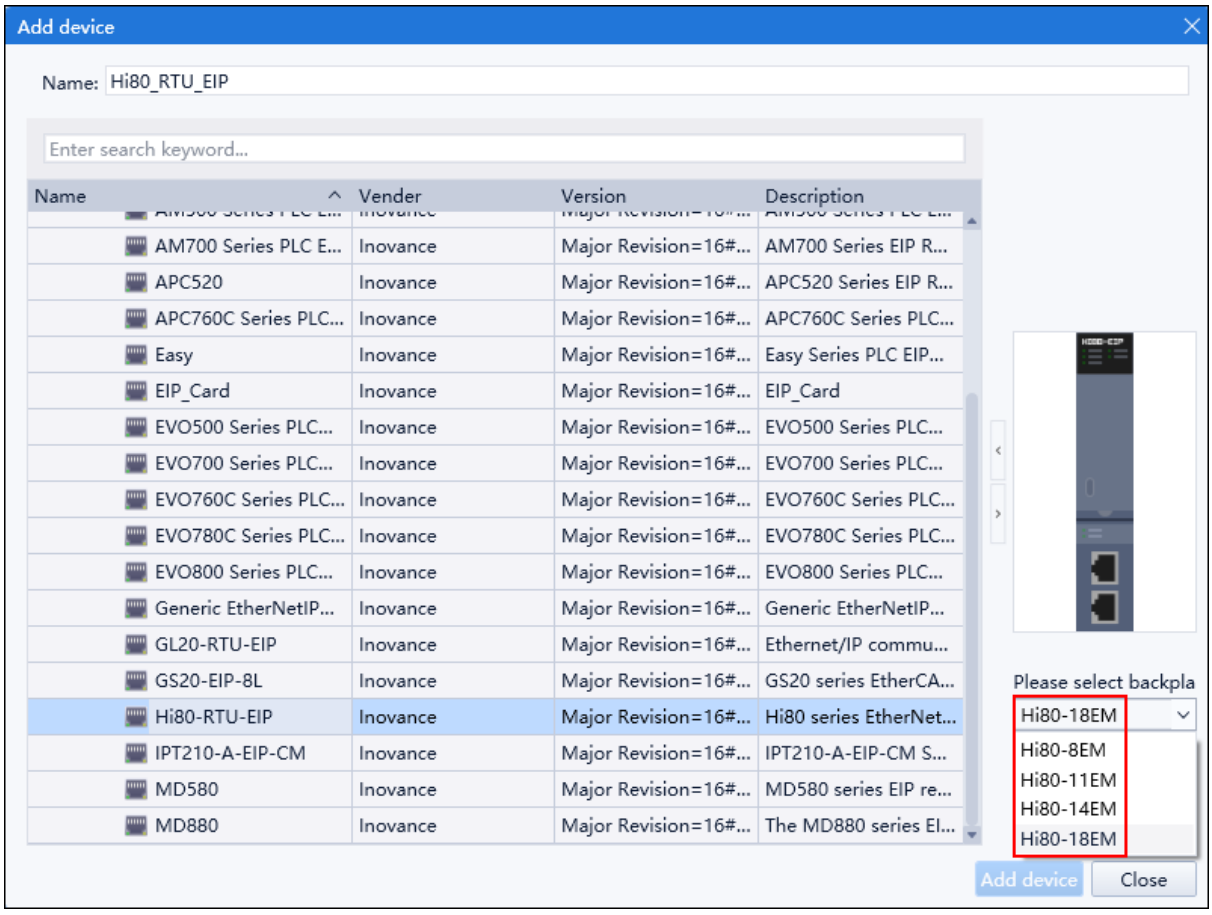
1. In the project tree, double-click the "Device configuration" node.
2. Switch to the device configuration view.
3. In the right device list, select the module. When a module is selected, the insertable slots for the module are highlighted in the configuration diagram.

4. In the device list, double-click the module to add it to the first available slot. You can also drag the module from the device list to an available slot in the device configuration view.



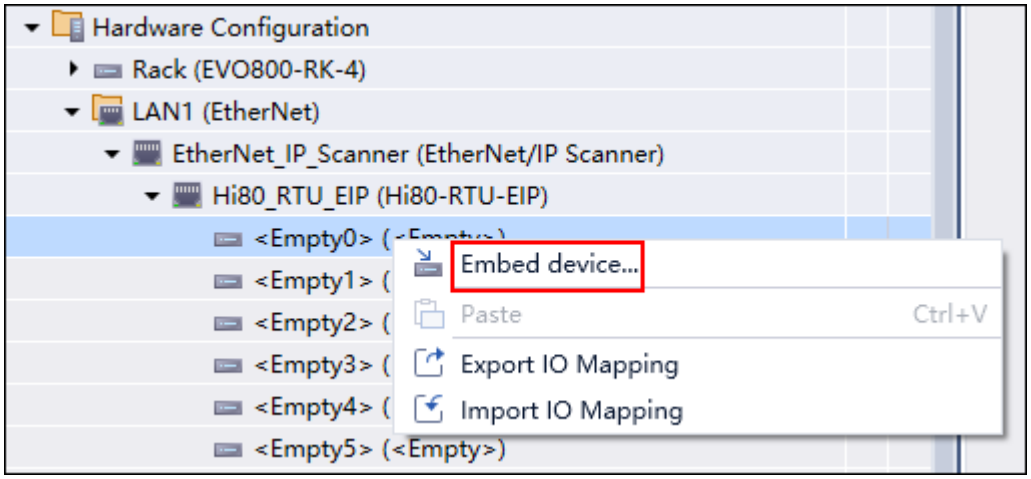
5. To change the module slot, drag the module in the device configuration view to the target slot.
6. The added module can be copied and pasted using the right-click menu or keyboard shortcuts.
   Only one module can be copied and pasted in the device list. Multiple modules can be copied and pasted in the device configuration view.

10.6.11.3 Adding a Remote I/O Module

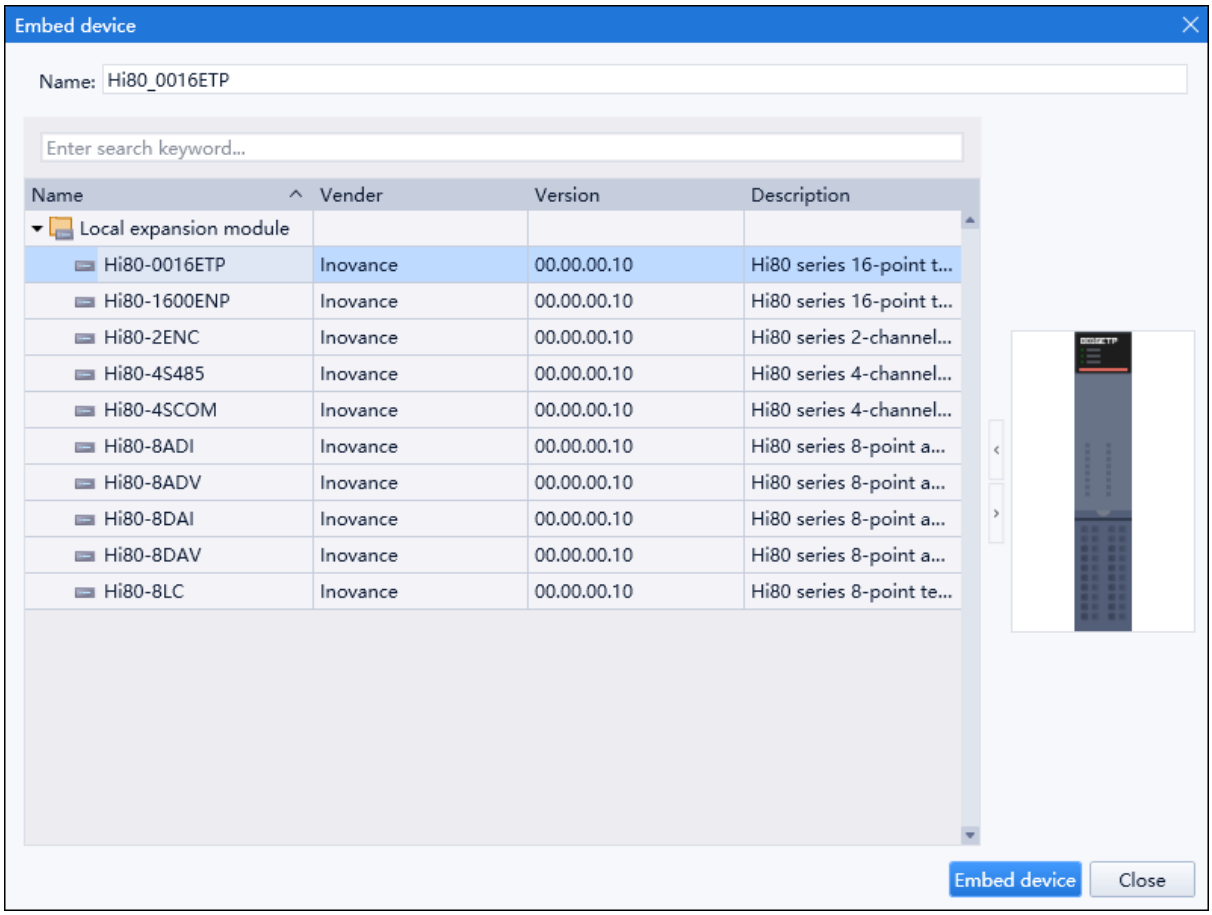


A remote IO module can be added through the project tree, device scanning, or network configuration view. The following example illustrates adding the Hi80-RTU-EIP module. The method for adding modules of other fieldbus types is similar.

Method 1: Adding a device through the project tree

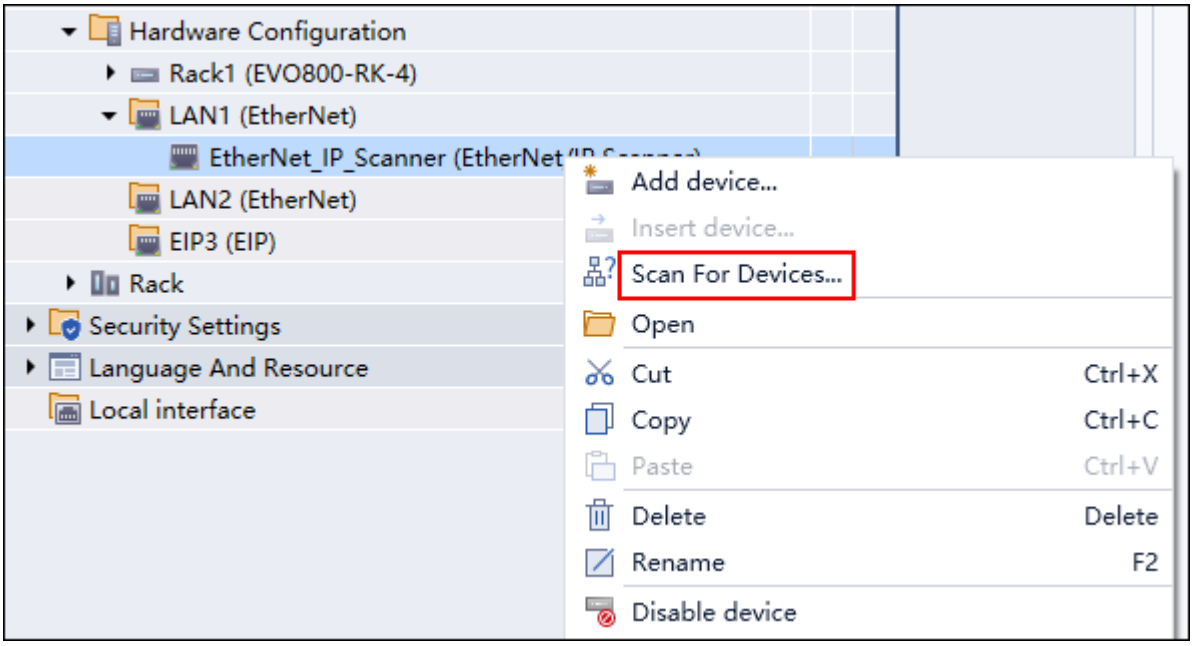


1. Expand the "Hardware configuration" list in the left project tree.
2. Right-click "LAN1(EtherNet)" and select "Add device".
3. Double-click "EtherNet/IP Scanner", or select it and click "Add device" to add the scanner.
4. Right-click the added scanner in the project tree and select "Add device".



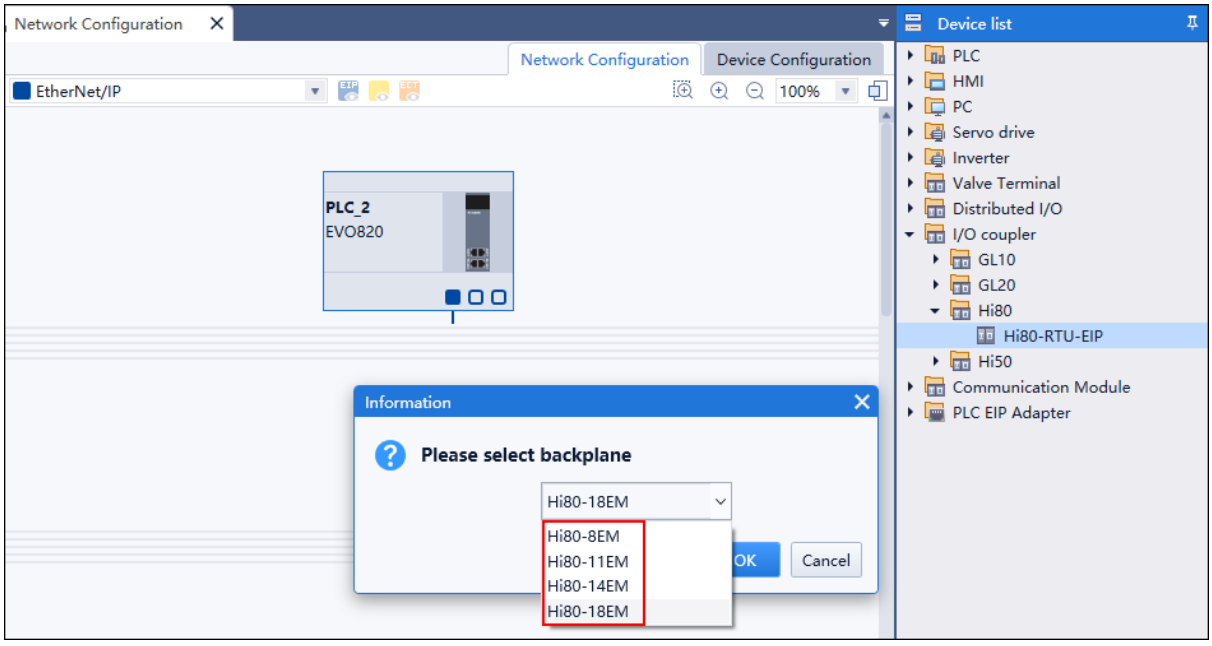
5. In the pop-up window, select the Hi80-RTU-EIP module, select a backplate in the drop-down menu on the right, and click "Add device", or double-click the module to complete the addition.

6. Right-click a slot of the Hi80-RTU-EIP module in the project tree and select "Embed device".



7. In the pop-up window, select the module and click "Embed device", or double-click the module.

Method 2: Adding a device through device scanning



1. Expand the "Hardware configuration" list in the left project tree.
2. Right-click "LAN1(EtherNet)" and select "Add device".
3. Double-click "EtherNet/IP Scanner", or select it and click "Add device" to add the scanner.
4. Right-click the added scanner in the project tree and select "Scan for devices".

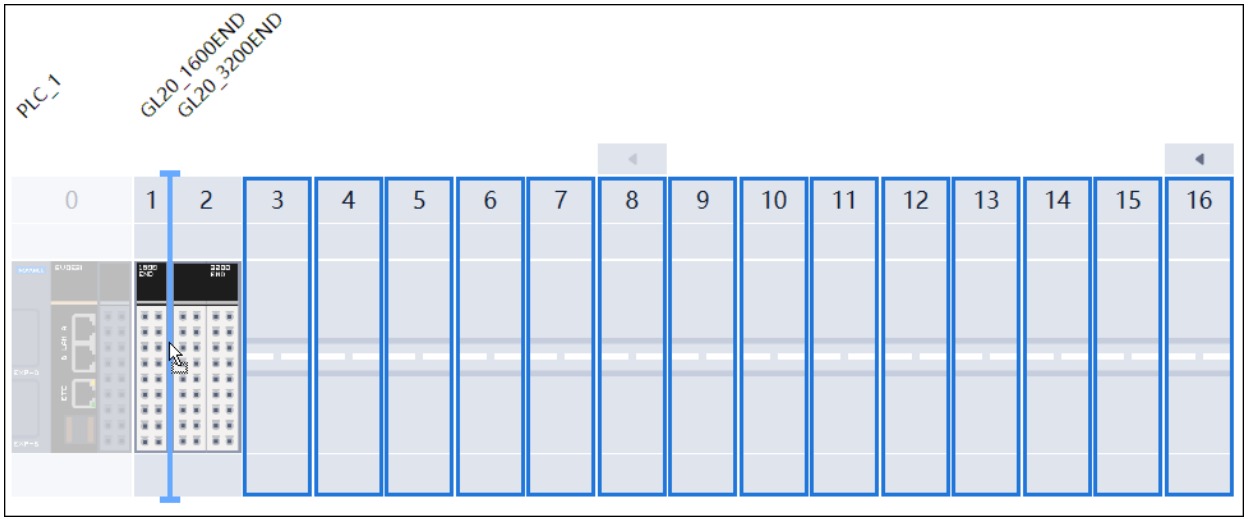
5. In the pop-up window, click "Scan for devices" and wait for the scan results.
6. Click the icon in the operation column of the Hi80-RTU-EIP module to add the target module to the left FA project area.
7. Click "OK" in the pop-up window.
8. Click "Apply project network configuration" to add the remote I/O module to the project.

Method 3: Adding via network configuration view

1. In the project tree, double-click the "Device configuration" node.
2. Switch to the network configuration view.
3. Select a module from the right "Device list" and add it by double-clicking or dragging-and-dropping.
4. In the pop-up window, select the backplate and click "OK".

10.6.11.4 Deleting a Module

The deletion operation of the module is the same as that of a regular slave device. The recommended method for deleting a module is as follows:



1. Double-click "Device configuration" in the project tree.
2. In the device configuration view, select a module on the PLC rack.
3. Press the Delete key to delete it.

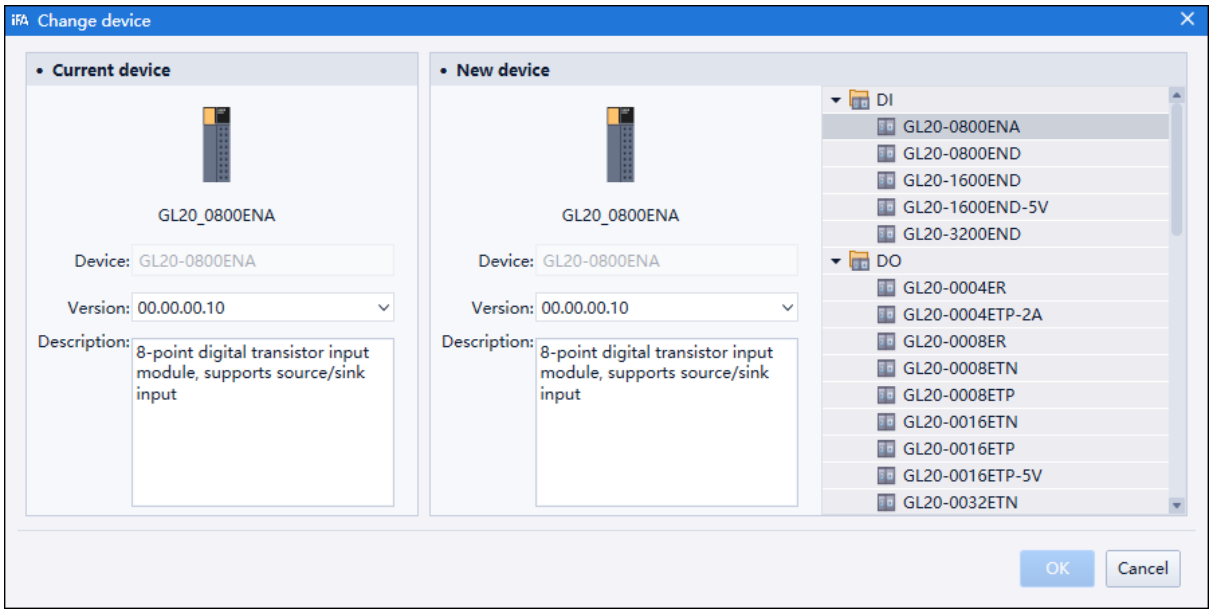
When a module is deleted, the variables mapped to its channels will be released. At the same time, the module will be automatically deleted from "Hardware configuration > Inovance_Bus".

> NOTE
>
> After deleting an I/O module, the addresses of the associated I/O variables will be rearranged.

10.6.11.5 Inserting a Module

- Dragging and dropping from the device list
  Drag a sub-module from the device list to insert it into existing slots.

After successful insertion, the module that has been moved will be highlighted.



- Dragging and dropping from the device view
  Drag a sub-module from the device configuration view and insert it into another slot.

> NOTE
>
> After inserting an I/O module, the addresses of the associated I/O variables will be rearranged.

10.6.11.6 Replacing a Module

- Modifying by the right-click menu
  In the device configuration view, right-click a sub-device and select "Change device".

In the pop-up "Change device" window, the selected sub-module can be replaced with the new device.

- Modifying by dragging and dropping
  Drag a device from the "Device list" to the slot in device configuration diagram. If the slot is occupied, the "Change device" window pops up, where you can replace the original sub-module with the newly selected one.

10.6.11.7 Moving a Module

- Moving to an empty slot
  : In the device configuration view, drag a sub-module to move it to another empty slot.
- Moving to an occupied slot
  : In the device configuration view, drag a sub-module to move it to an occupied slot to swap the positions of the two modules. The sub-modules whose positions have changed are highlighted.

10.6.11.8 Disabling/Enabling an I/O Module

Disabling local or remote I/O modules

In iFA software, a certain I/O module can be disabled through commands or variable setting, thus "detaching" from the control system while retaining its configuration parameters and I/O mapping information. If a device fails and needs to be replaced, this function can reduce the time required for replacement.

- Disabling operation and effect
  A device can be disabled through commands or variable setting.
  - Command disabling
    Right-click an I/O module in the project tree and select "Disable device".
    Right-click an I/O module in the device configuration view and select "Disable device".
    After disabling, it is necessary to perform a 10.8.3 full download of the PLC to make the disabling operation effective.
  - Variable setting
    When adding each I/O module, a corresponding variable is created in **SYS_VAR**, following the naming rule: J_device model.
    Setting member The member **bDisableEnable** disables the slave, and the setting method supports

writing values in **SYS_VAR** or assigning values in user programs.

	Name	Data type	Address	Retain	Network publish	Comment
1	VAR_GLOBAL					
2	LAN1_EIPSingle_STATUS	Array[1..32] OF IoStand...			Private	
3	LAN1_EIPSlave_STATUS	Array[1..16] OF EtherNe...			Private	
4	J_GL20_3200END	IoStandard._SYS_SlaveS...			Private	
5	bDisableEnable	BOOL			Private	

After disabling, it is necessary to sequentially download, power off, and power on the PLC to make the disabling operation effective.

> CAUTION
>
> Powering off the PLC will result in the loss of values for temporary variables and variables with power-off retention set to FALSE.

- Disabling result

  The disabled devices are marked with the icon for differentiation.

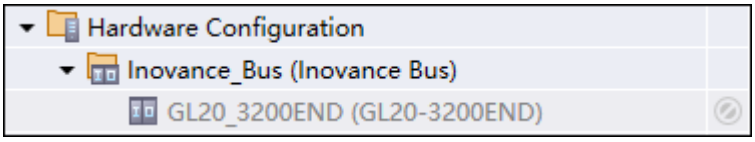


Figure 10-6-11-8-1 Icon in project tree

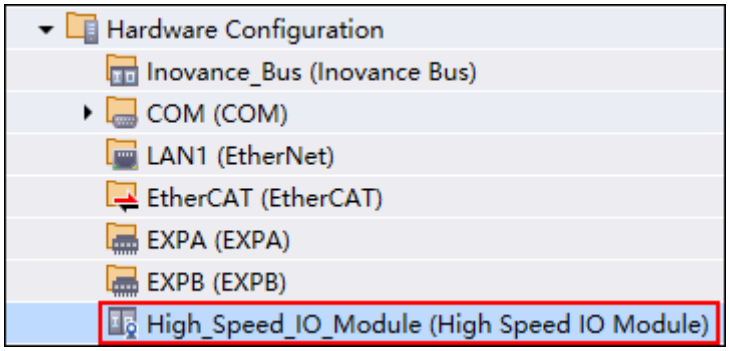
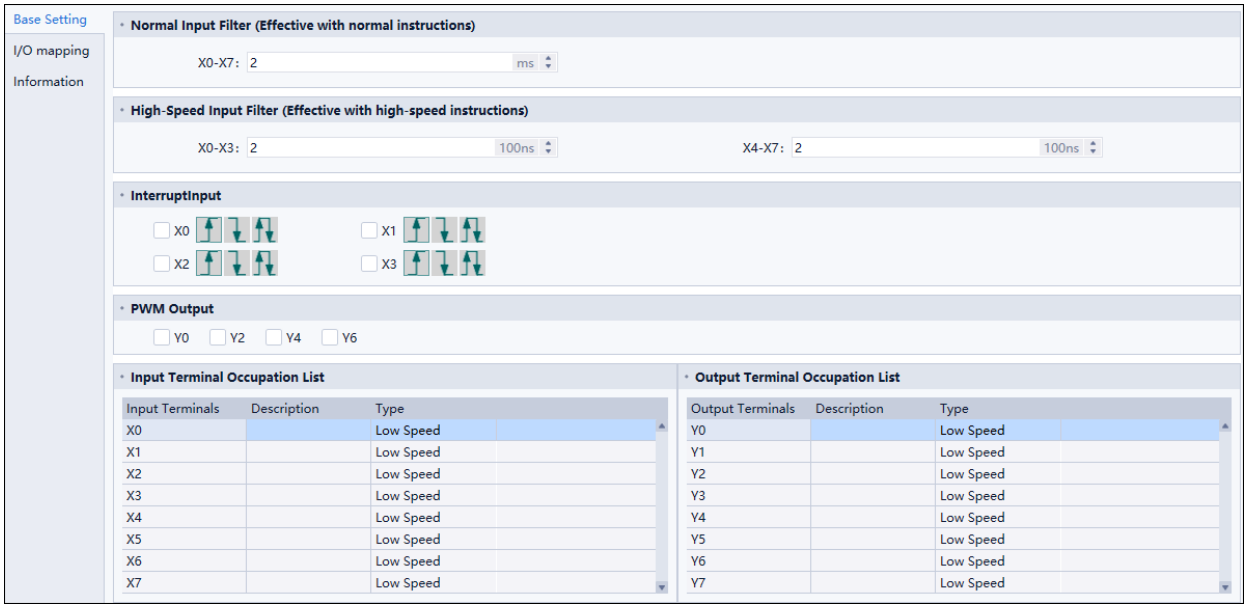
Enabling local or remote I/O modules

The disabling and enabling of I/O modules are a set of mutually corresponding operations. Only when the module is disabled is the enabling command visible.



The enabling operation and its effect are exactly the same as the disabling operation.

A module needs to be disabled and enabled in the same way. That is, if the module is disabled by setting a variable, it must be enabled by resetting the variable. If it is disabled using a command, it must also be enabled using a command.



10.6.12 High Speed I/O Module Configuration (EVO400, EVO500, EVO700)

10.6.12.1 Opening High-Speed I/O Module Interface

In the project tree, double-click "High_speed_I/O_module" under the "Hardware configuration" node.

Open the corresponding configuration interface.

Filter parameters: Configure filter values for input signals, and display terminal usage status.

I/O mapping: Assign variables to terminals to acquire field signals, and support address changes.

Information: Display basic background information of the device for user reference.

10.6.12.2 Configuring a High-Speed I/O Module

Filter parameter

The filter setting for the input signals is used to remove waveform signals above the reference frequency, thereby achieving signal stability and accuracy.

Set the reference waveform frequency and the system will filter out waveform signals above the reference frequency. Then, the reference waveform frequency is converted into a waveform period. For example, to filter out waveform signals above 500 Hz, the waveform period corresponding to 500 Hz is 2 ms.

Terminal occupation list

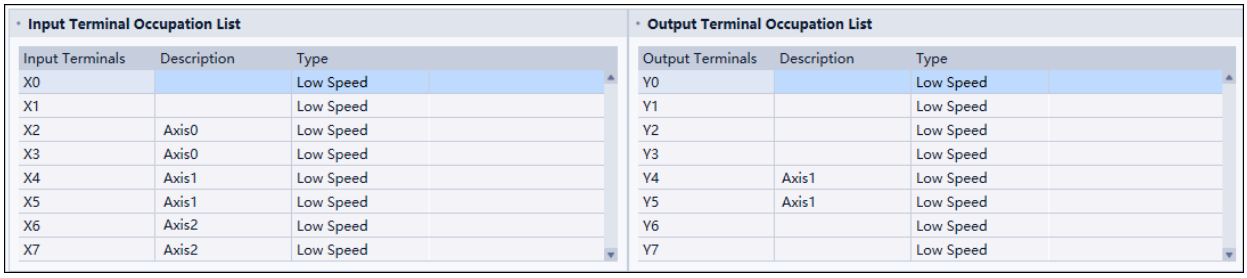


Figure 10-6-12-2-1 Configuration interface for EVO523 PLC

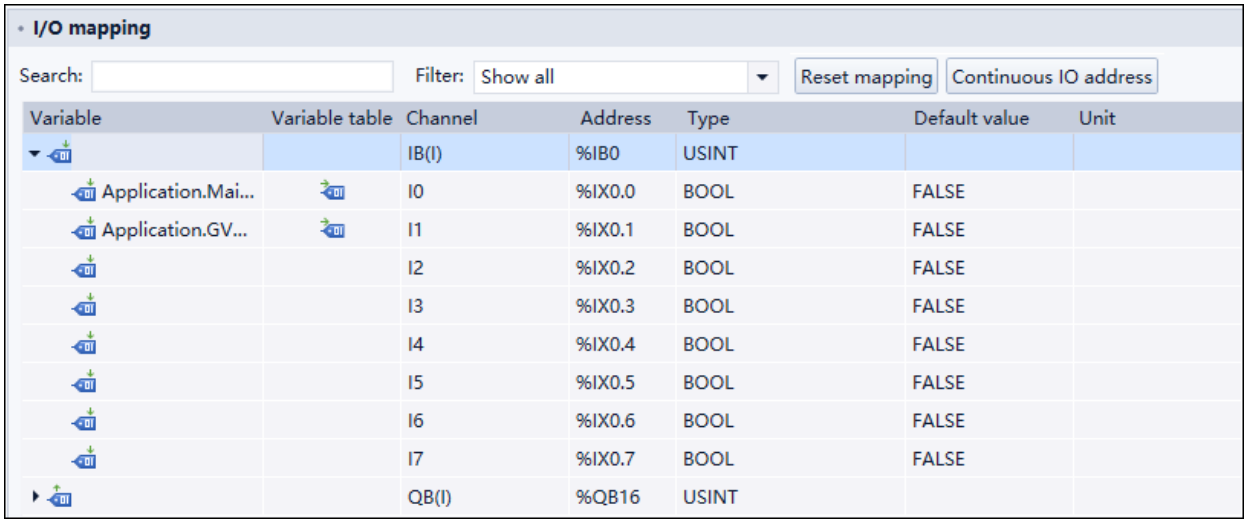
The list displays the high-speed and low-speed signal occupancy status of input/output terminals. High-speed I/O terminals connected to axis signals will be displayed as high-speed, while other signals will be displayed as low-speed.

High-speed I/O terminals support connection of signals from **local encoder axes** and **local pulse axes**. The signal configuration interface is concentrated on the **Axis basic settings** and **Mode/Parameter settings** tabs.

I/O Mapping

The "I/O mapping" tab is used to assign variables to channels to enable data transfer.



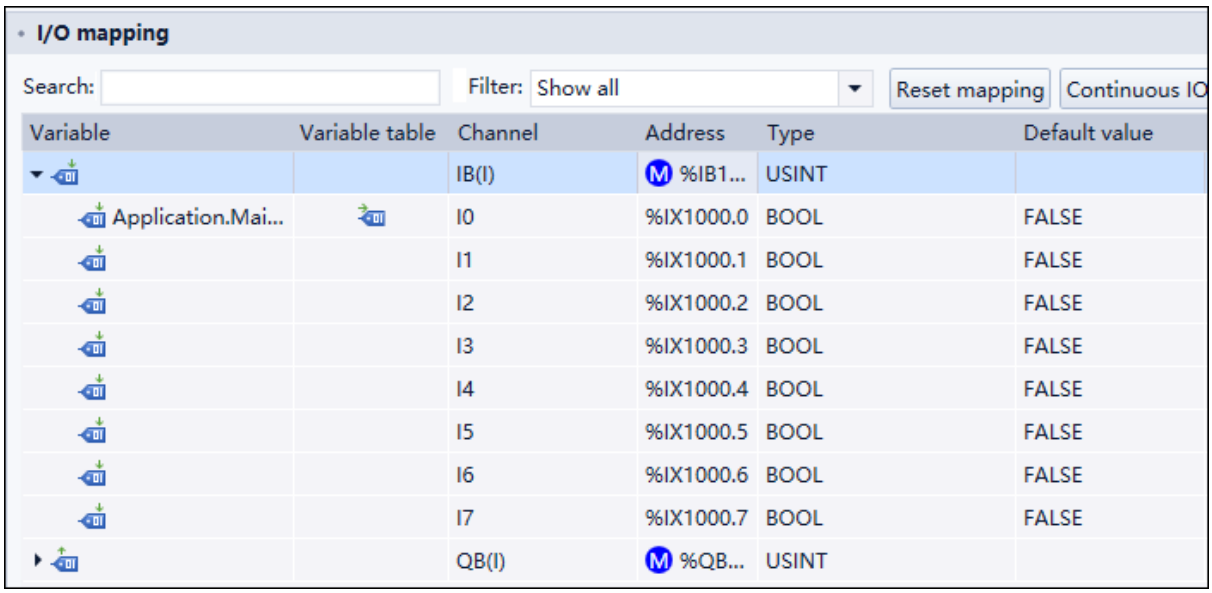


Figure 10-6-12-2-1 Configuration interface for EVO523 PLC

- Channel variables
  Variables support searching and filtering for viewing.
  Click "Reset mapping" to clear mapped variable information.

- Channel address
  Channel addresses support manual modification and system reassignment.
  Manual modification is effective for the parent node. After modification, it will be marked with **M**.
  System reassignment is completed using the "Continuous I/O address" button. If the initial default address is not occupied, the address remains unchanged; otherwise, a new continuous address will be assigned.

- Bus cycle options
  Used to assign tasks for high-speed I/O signals, which should be consistent with the tasks configured for the axis and axis control program to avoid compilation faults.
  The following diagrams illustrate the configuration of the three tasks, all of which are EtherCATMaster_Task.

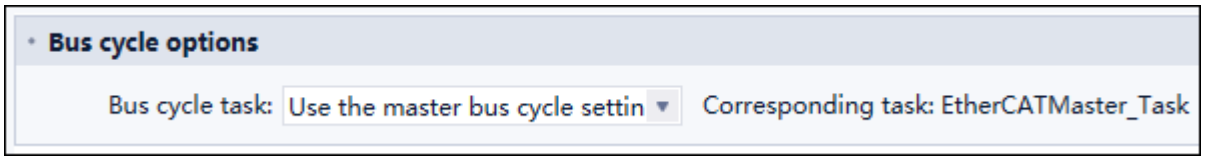

Figure 10-6-12-2-3 Task configuration for high-speed I/O signals

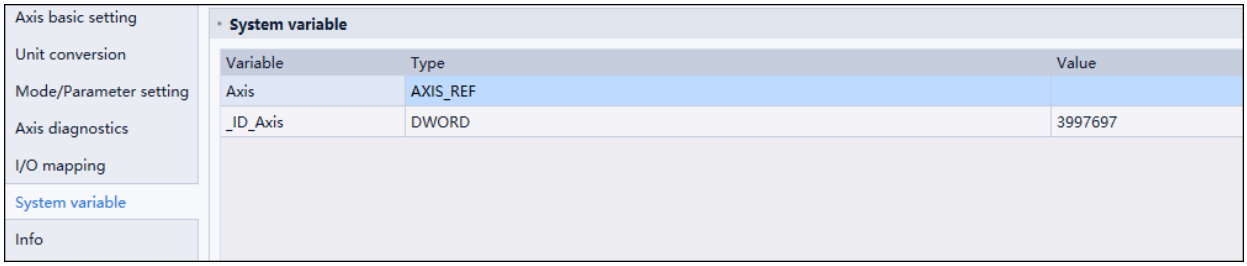

Figure 10-6-12-2-4 Task configuration for axis

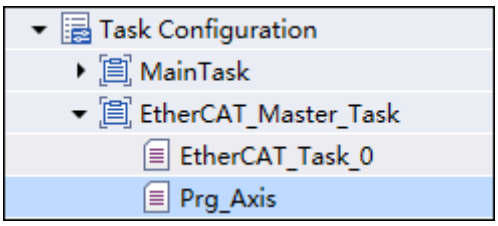

Figure 10-6-12-2-5 Task configuration for axis control program

NOTE

The three task configurations shall be consistent; otherwise, a device compilation fault will occur.

10.6.12.3 Disabling/Enabling a High-Speed I/O Module

Disabling a high-speed I/O module

Disabling a high-speed I/O module: With the physical module remaining unprocessed, disconnect the module from the system at the software level to stop its operation, preventing it from receiving or transmitting signals.

Right-click the "High_speed_I/O_module" node and select "Disable device". The node turns gray and is marked with .

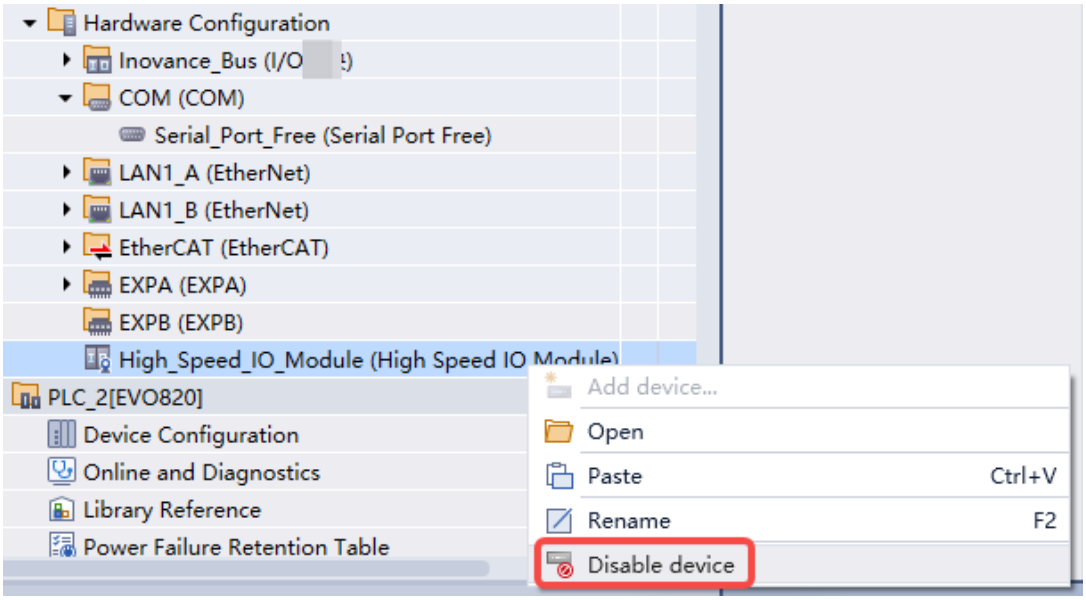

Figure 10-6-12-3-1 Disable command

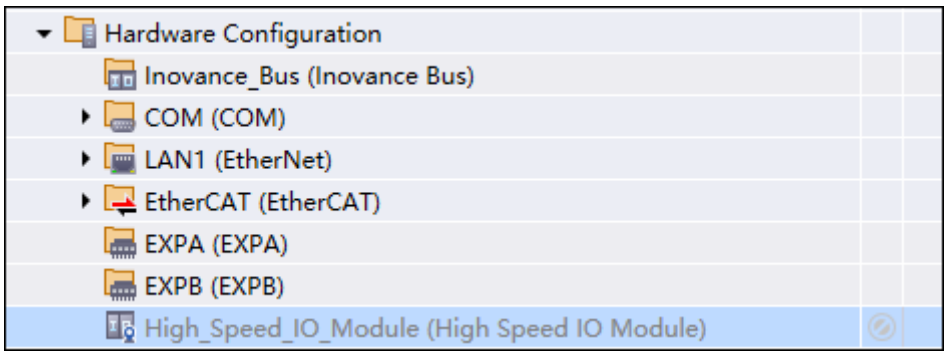

Figure 10-6-12-3-2 Disabled status

After disabling, it is necessary to perform a 10.8.3 full download of the PLC to make the disabling operation effective.

Enabling a high-speed I/O module

Enabling a high-speed I/O module: Restore the module within the system so that it can receive and transmit signals.

Right-click the "High_speed_I/O_module" node and select "Enable device". The node turns black and the mark disappears.

After enabling, it is necessary to perform a 10.8.3 full download of the PLC to make the disabling operation effective.

10.6.13 EXPA/EXPB (Local Expansion Module) Configuration (EVO400, EVO500, APC500)

10.6.13.1 Adding/Deleting a Local Expansion Module

Adding a local expansion module

A PLC supports adding two expansion modules.

The procedure of adding a local expansion module is the same as adding a slave device. The recommended procedure is as follows:

1. In the project tree, double-click the "Device configuration" node.
2. Switch to the device view.
3. Double-click a local expansion module in the device list.

The selected module will automatically be inserted into the left position of the PLC. At the same time, the added module is automatically displayed under "Hardware configuration > EXPA/EXPB" in the project tree.

To add a local expansion module through the device list, follow these steps:

1. Double-click "Device configuration" in the project tree.
2. Open the device view and select the left expansion slot on the PLC.
3. In the device list, select a local expansion module and double-click or drag and drop to add it.

To add a local expansion module in the project tree, follow these steps:

1. Right-click the EXPA/EXPB node under "Hardware configuration" in the project tree.
2. In the right-click menu, select "Add device" and select a local expansion module.

Deleting a local expansion module

When deleting a local expansion module, the variables mapped to the channels will be released.

The procedure of deleting a local expansion module is the same as deleting a slave device. The recommended procedure is as follows

1. Double-click "Device configuration" in the project tree.
2. In the device configuration view, select a module on the PLC rack.
3. Press the Delete key to delete it.

At the same time, the module is automatically deleted from "Hardware configuration > EXPA/EXPB" in the project tree.

10.6.13.2 Disabling/Enabling a Local Expansion Module

Disabling a local expansion module

Disabling a local expansion module: With the physical module remaining unprocessed, disconnect the module from the system at the software level to stop its operation, preventing it from receiving or transmitting signals.

Right-click the child node of EXPA/EXPB and select "Disable device". The child node will turn gray and be marked with .

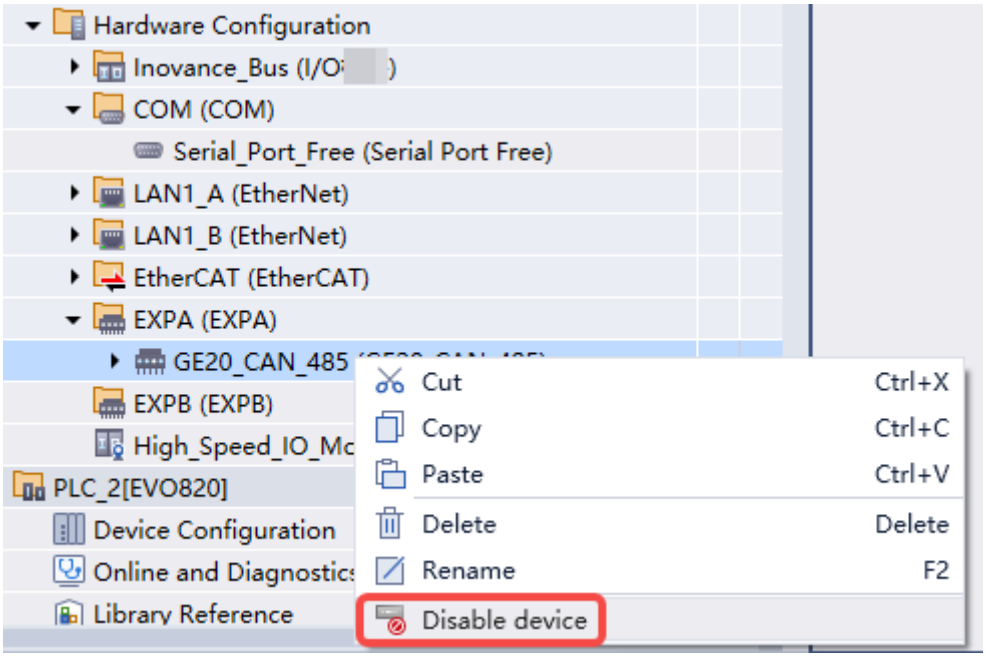

Figure 10-6-13-2-1 Disable command

Figure 10-6-13-2-2 Disabled status

After disabling, it is necessary to perform a 10.8.3 full download of the PLC to make the disabling operation effective.

Enabling a local expansion module

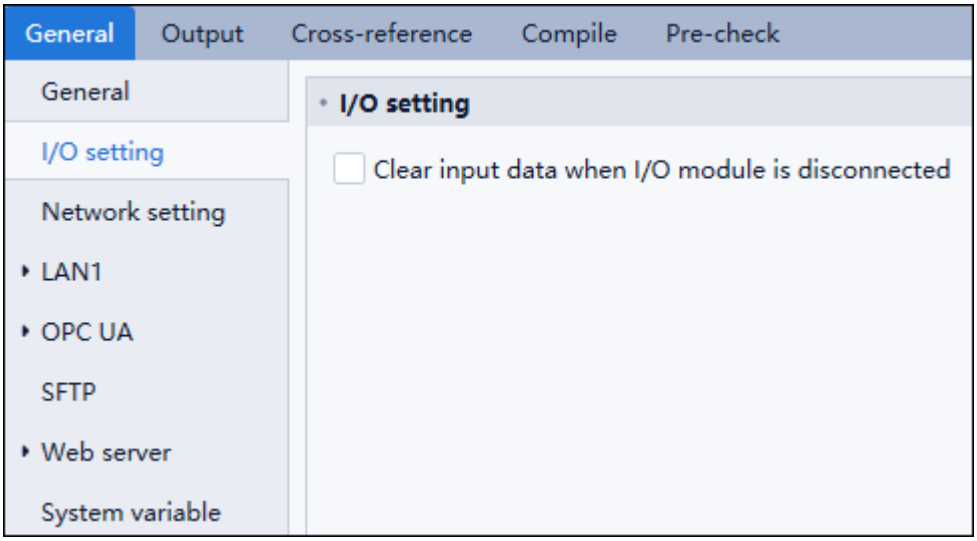
Enabling a local expansion module: Restore the module within the system so that it can receive and transmit signals.

Right-click the child node of EXPA/EXPB and select "Enable device". The child node will turn black and the mark disappears.

After enabling, it is necessary to perform a 10.8.3 full download of the PLC to make the disabling operation effective.

10.6.14 PLC Property Configuration

10.6.14.1 I/O Settings (EVO400, EVO500, EVO700)



I/O settings are used to configure how input data is handled when a module disconnects during local I/O module configuration.

Prerequisites

PLC devices support configuration of local I/O modules.

Procedure

1. Double-click "Device configuration" in the left project tree and go to the "Network configuration" tab.
2. Select the PLC device diagram. In the "General" tab of the monitoring area below, select "I/O setting" to open the configuration interface.

Clear input data when I/O module is disconnected: Disabled by default. When enabled, if any I/O module loses communication, its corresponding input data area will be cleared.

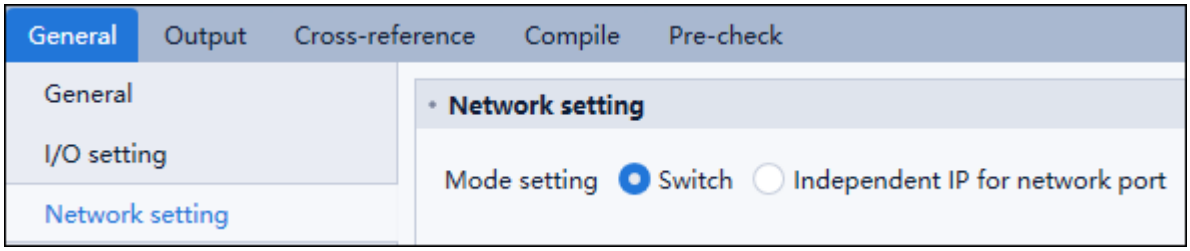
> NOTE
>
> The I/O settings of the PLC device apply to all modules connected under the local I/O module.

10.6.14.2 Network Settings (EVO500)

Enable the corresponding product features by configuring different network modes for EVO500 series PLCs.

Restrictions

The following conditions must be met simultaneously:



- EVO500 series PLC with firmware version V1.3 or above.
- Device purchased in or after July 2025.

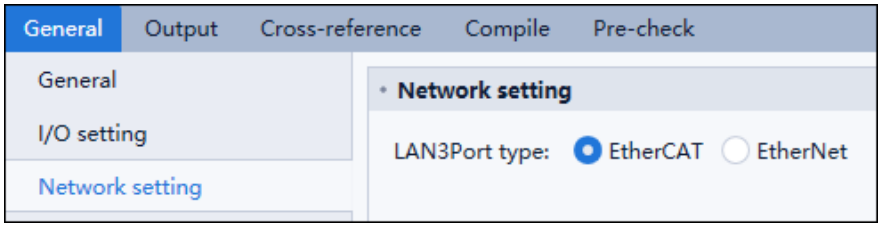
Description

- Neither switch mode nor dual independent network port mode should be connected to a switching network to form a ring network.
- After switching from switch mode to dual independent network port mode, Port A inherits the IP address from switch mode, and Port B defaults to 192.168.2.88.
- After switching modes, the configuration environment EIP needs to re-select the network interface.
- After switching modes, the network will disconnect. Ensure the operation is performed in a safe environment.

Procedure

1. Double-click "Device configuration" in the left project tree and go to the "Network configuration" tab.
2. Select the PLC device diagram, and select mode through the "Network setting" tab in the monitoring area.

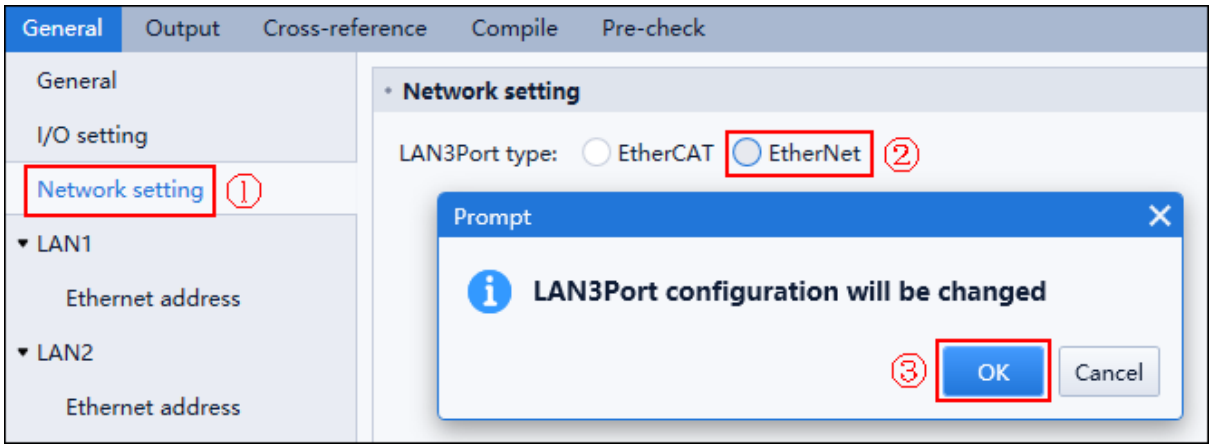
Mode	Note
Switch	The default is switch mode, where only LAN1 port can be configured.
Independent IP for network port	◦ LAN1_A The IP address remains the original settings. For example, after switching from switch mode to "Independent IP for network port", the IP 10.44.122.1 remains unchanged. ◦ LAN1_B When switching from independent IP mode to switch mode, all data and configurations on the LAN1_B port are deleted. ▪ If "Set IP address in the project" is checked, the IP follows the project settings and does not support setting a gateway. For detail, see 10.6.14.4 Ethernet Address Settings. ▪ If "Use the IP address directly from the device" is checked, the default IP address 192.168.2.88 is used for the first setup in independent IP mode, and subsequent setups retain the original settings.



Feature comparison

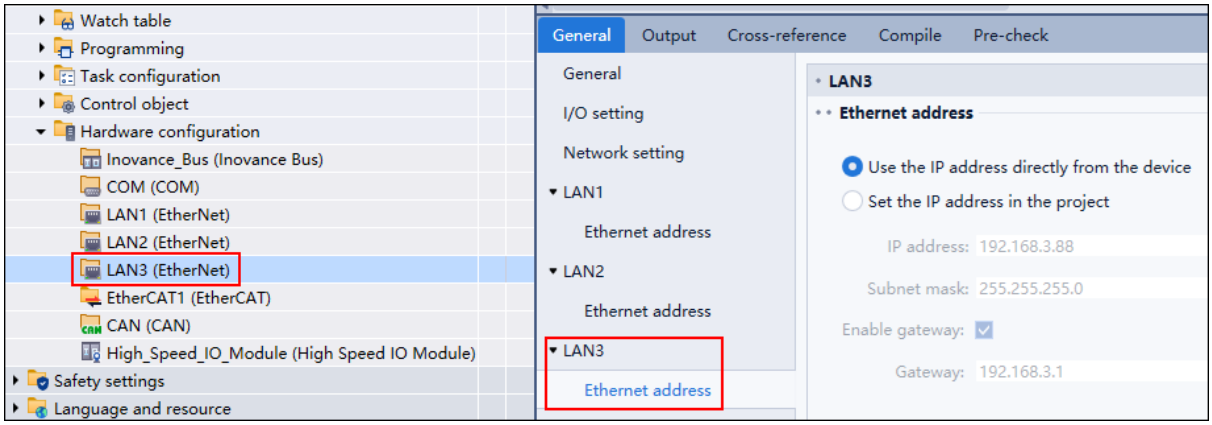
The impact of functions under the two modes is shown in the table below:

EVO500 Network Port Configuration	Switch Mode	Independent IP for Network Port	
Port number	LAN1	LAN1_A (100 Mbps)	LAN1_B (100 Mbps)
EthernetIP	Supports master and slaves	Supports master and slaves	Supports master and slaves
ModbusTCP master	Support master	Support master	Support master
ModbusTCP slave	Support slave	Only one port can be configured	
OPC UA	Supported	Only one port can be configured	
CANopen	Not supported	Not supported	Not supported
EtherCAT	Not supported	Not supported	Not supported
PROFINET	Support slave	Not supported	Not supported

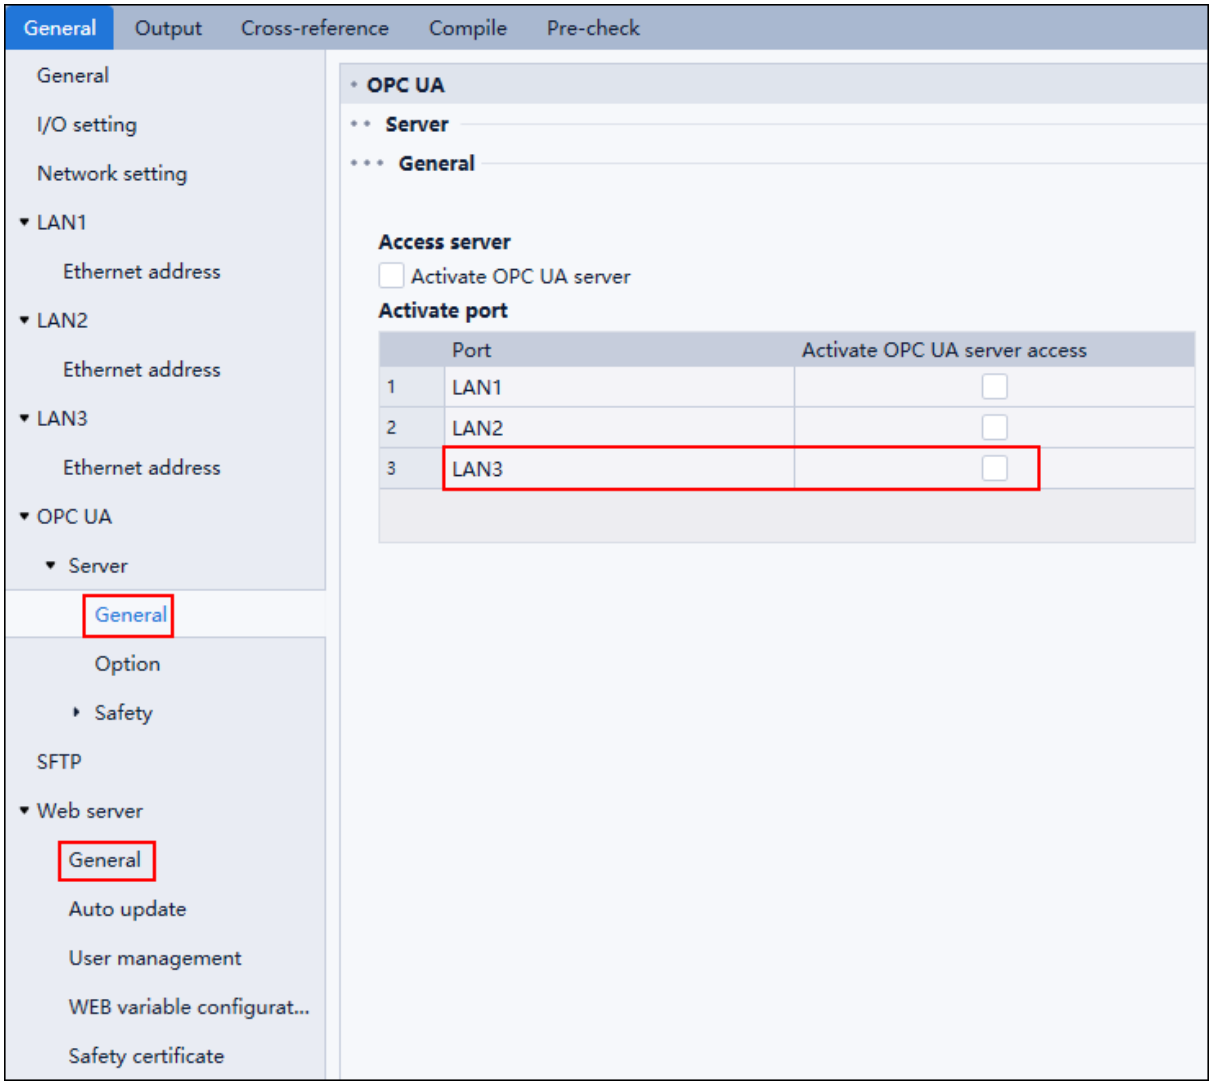


10.6.14.3 Network Port Switching

The LAN3 port of the EVO760 series PLC defaults to EtherCAT type. When the firmware version is V1.5 or above, the LAN3 interface supports free switching between EtherCAT and Ethernet types. By switching different types of network ports, different product features can be enabled.

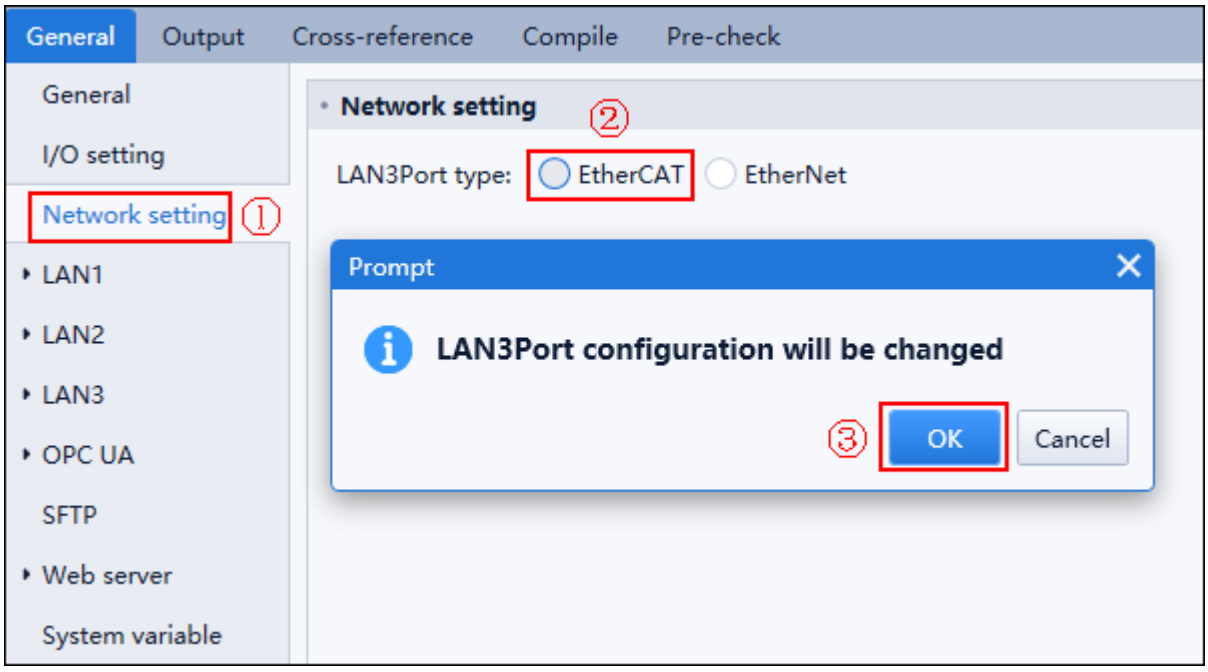


LAN3 network port configuration



1. On the "General > Network setting" tab, select "Ethernet" as the type for the LAN3 network port.
2. A window pops up, indicating LAN3 configuration will be added. Click "OK" to switch the LAN3 interface to Ethernet type.

3. A "LAN3 (EtherNet)" node is added in the project tree. A LAN3 Ethernet address configuration tab is added on the "General" configuration interface, enabling three independent IPs.



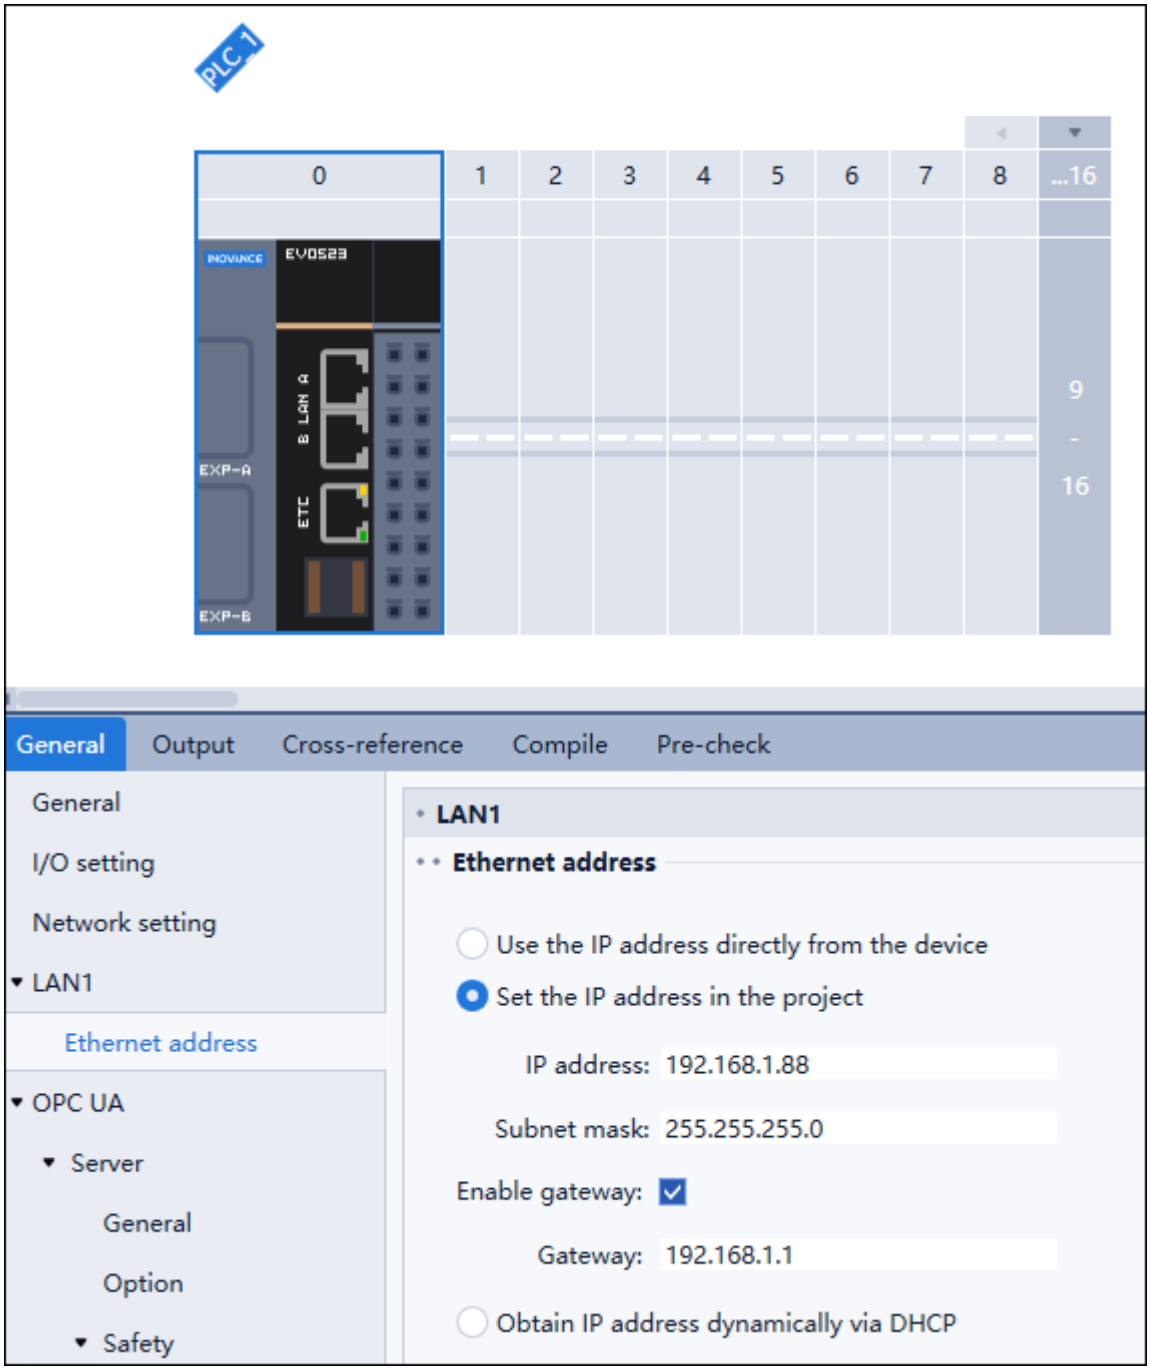
4. A LAN3 port option is added to the "OPC UA > General" and "Web server > General" tabs, which can be activated as access ports for OPC UA and Web server.

5. On the "General > Network setting" tab, select the LAN3 port configuration as the "Ethercat" type.

6. A window pops up, indicating LAN3 configuration will be deleted. Click "OK".

7. When the LAN3 interface is switched to the EtherCAT type, the LAN3 configuration in the project tree and general settings will be deleted.

Device update



- When switching between devices of the same series (e.g., EVO762 to EVO763), the network port type remains unchanged, and the conversion is performed directly.
- When switching between devices of different series (e.g., EVO760 to EVO760C), the conversion is performed based on the actual port types supported. If a device does not support a certain port type, the corresponding port configuration is deleted.

10.6.14.4 Ethernet Address Settings

The Ethernet address of the PLC is a unique identifier for communication. Duplicate IP addresses are not allowed within a system.

Ethernet address setting

1. Double-click "Device configuration" in the left project tree and go to the "Network configuration" tab.
2. Select the PLC device diagram. On the "General" tab in the monitoring area below, select "Ethernet address" of the target network port.

3. Configure the Ethernet address, with parameters described in the table below.

Parameter		Description
Use the IP address directly from the device		When checked, the pre-set static IP on the device is used. The device IP address, subnet mask, and gateway can be modified in the 17.1.2 Network setting interface. The changes will automatically synchronize here after the device goes online.
Set the IP Address in the Project	IP address	Configures the IP address. When the project is downloaded, this address is automatically written to the PLC. If the PLC has multiple network ports, their IP addresses must not be on the same subnet.
	Subnet mask	Auto-adapts based on IP address and supports manual modification.

<table>
<tr><th colspan="2">Parameter</th><th>Description</th></tr>
<tr><td rowspan="2"></td><td>Enable gateway</td><td>After checked, the router function is enabled, and the gateway address can be set. Checked by default.

NOTE
◦ For multi-port devices, only one default gateway can be enabled at a time.
◦ Devices and firmware versions that support enabling the gateway function are as follows:
▪ EVO500/EVO700: V1.7 and above.
▪ EVO400: V1.5 and above.
▪ APC series: V1.7 and above.
▪ EVO800: V1.2 and above.</td></tr>
<tr><td>Gateway</td><td>The gateway and device IP address must be in the same network segment.</td></tr>
<tr><td colspan="2">Obtain IP Address Dynamically via DHCP</td><td>The controller can dynamically obtain an IP address through a DHCP server. If there is no DHCP server in the network, the IP address is empty (0.0.0.0).
When DHCP acquisition fails, the solution is as follows:
◦ For single-port devices: Connect the device via USB, select "Set IP address in the project", and download the configuration.
◦ For multi-port devices: Select "Set IP address in the project" and download the configuration through other available network ports of the device.

NOTE
◦ After enabling this option, it takes approximately half a minute to take effect; please wait during the first project download.
◦ After setting the DHCP mode, if the device's IP address changes due to network changes, a different DHCP server, or network cable unplugging/replugging, the user must either re-power on the device or re-download the project with the DHCP mode enabled to apply the new IP address.</td></tr>
</table>

The device-level firmware versions that support the DHCP dynamic acquisition function are listed in the table below.

Product Series	Firmware Version		
	V1.0 to V1.4	V1.5	V1.6
EVO400 series	Not supported	Supported	Supported
EVO500 series	Not supported	Supported	Supported
EVO700	Not supported	Supported	Supported
APC520 series	Not supported	Supported	Supported
EVO760C series	Not supported	Not supported	Supported
EVO780C series	Not supported	Not supported	Supported
APC760C series	Not supported	Not supported	Supported

In PROFINET communication mode, the IP address of the PROFINET slave device must not be the same as that of the main device; otherwise, the actual IP address of the main device will become invalid.

Network features of different address setting method

The relationship between the three Ethernet address setting methods and network function is shown in the table below:

Function	Use the IP Address Directly from the Device	Set the IP Address in the Project	Obtain IP Address Dynamically via DHCP
Network setting	Network-based IP setting supported	Network-based IP setting not supported	Network-based IP setting not supported
Instruction setting	Network-based IP setting supported	Network-based IP setting not supported	Network-based IP setting not supported
HMI tag connection	HMI requires manual communication IP configuration	IP is automatically updated on the HMI after modification	HMI requires manual communication IP configuration
C2C			
Redundant PLC	Network-based IP setting supported	Network-based IP setting not supported	Network-based IP setting not supported
Mode Switching	A full download is triggered after mode switching.		

10.6.14.5 OPC UA Server Configuration

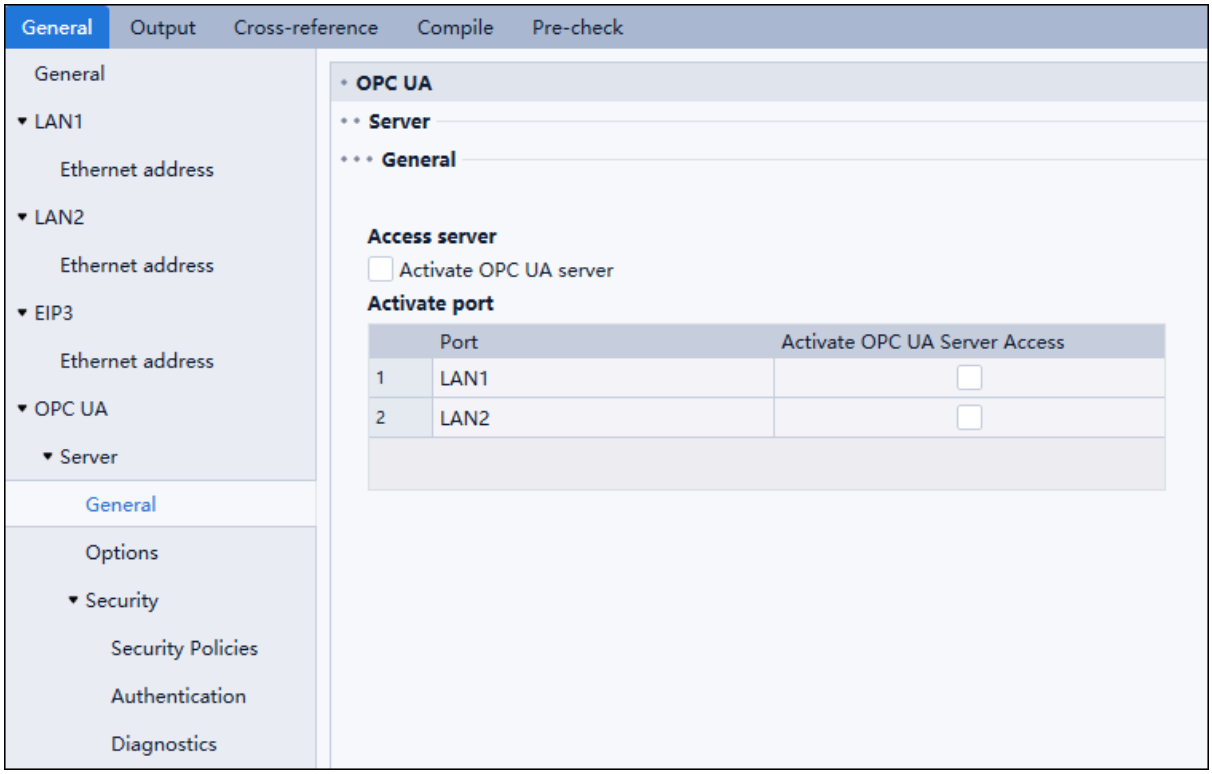
10.6.14.5.1 Overview

The OPC UA protocol is divided into two parts: OPC UA server and client.

The OPC UA server provides standardized data access services across platforms and systems, ensuring secure and reliable data exchange from sensors to the cloud.

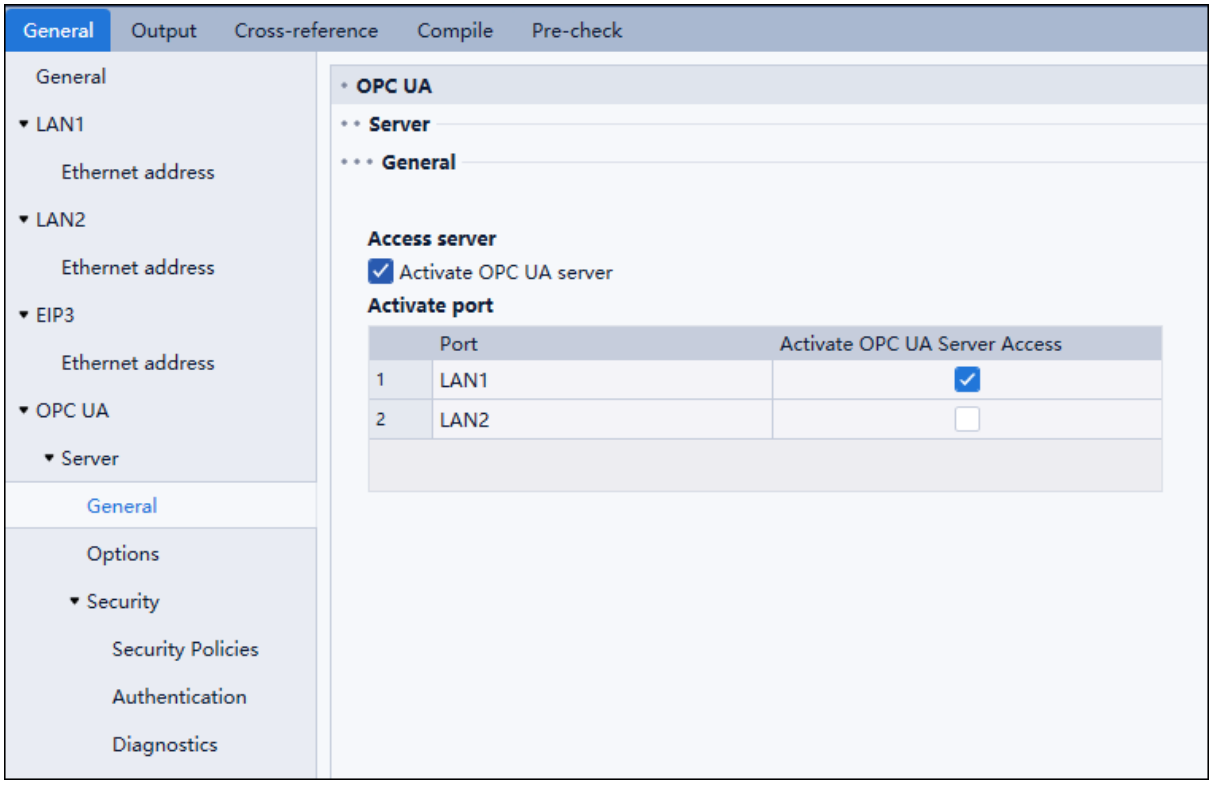
The core functions of the OPC UA server include the following:

- It provides a unified data model that supports the description of complex information structures, enabling the transmission of real-time data, historical data, and rich metadata.
- It implements secure communication mechanisms, supporting various authentication and encryption modes, including anonymous access, username and password authentication, and certificate authentication.
- It has a wide range of applications, suitable for industrial automation, the Internet of Things (IoT), smart manufacturing, and other fields, facilitating interoperability between different levels of equipment, such as PLCs, SCADA systems, MES systems, and ERP system integration.
- It allows any device to act as a data provider, enabling seamless data sharing among products from different manufacturers, enhancing the transparency and efficiency of the entire production process.
- By being built-in or attached to devices and PLCs, or running on separate computers, the OPC UA server acts as the central hub for industrial data, promoting the informatization and intelligence of enterprises.



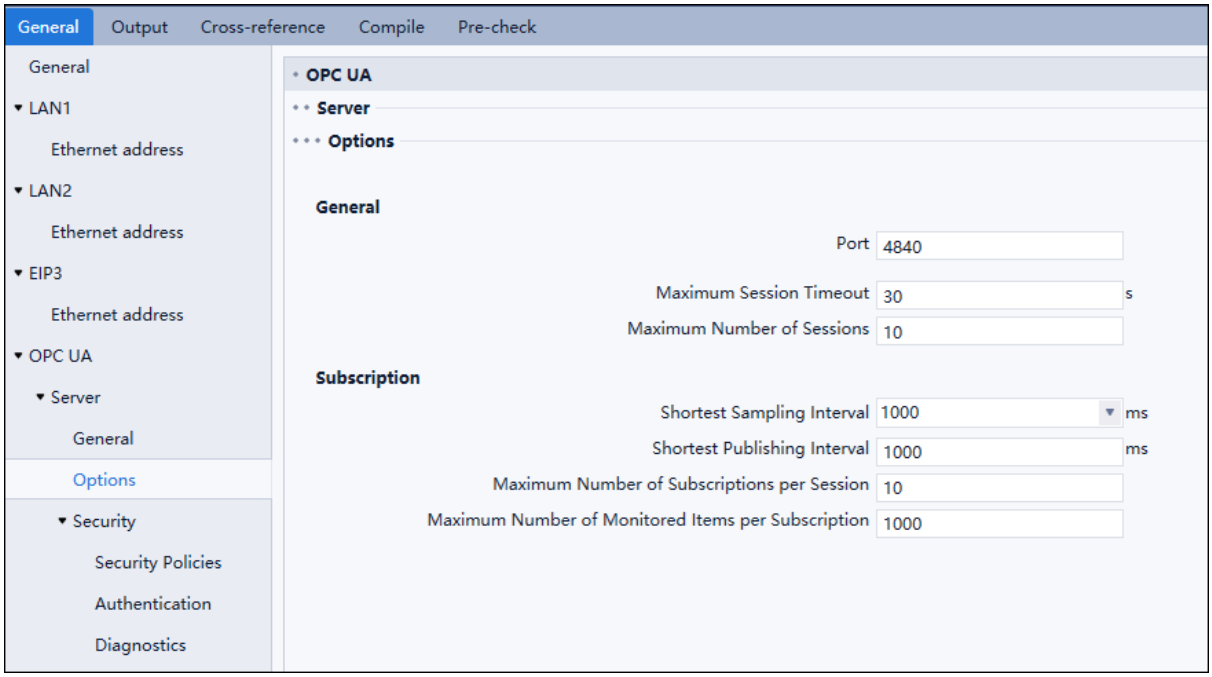
10.6.14.5.2 Configuring OPC UA Server

Prerequisites



A PLC device has been added.

Procedure



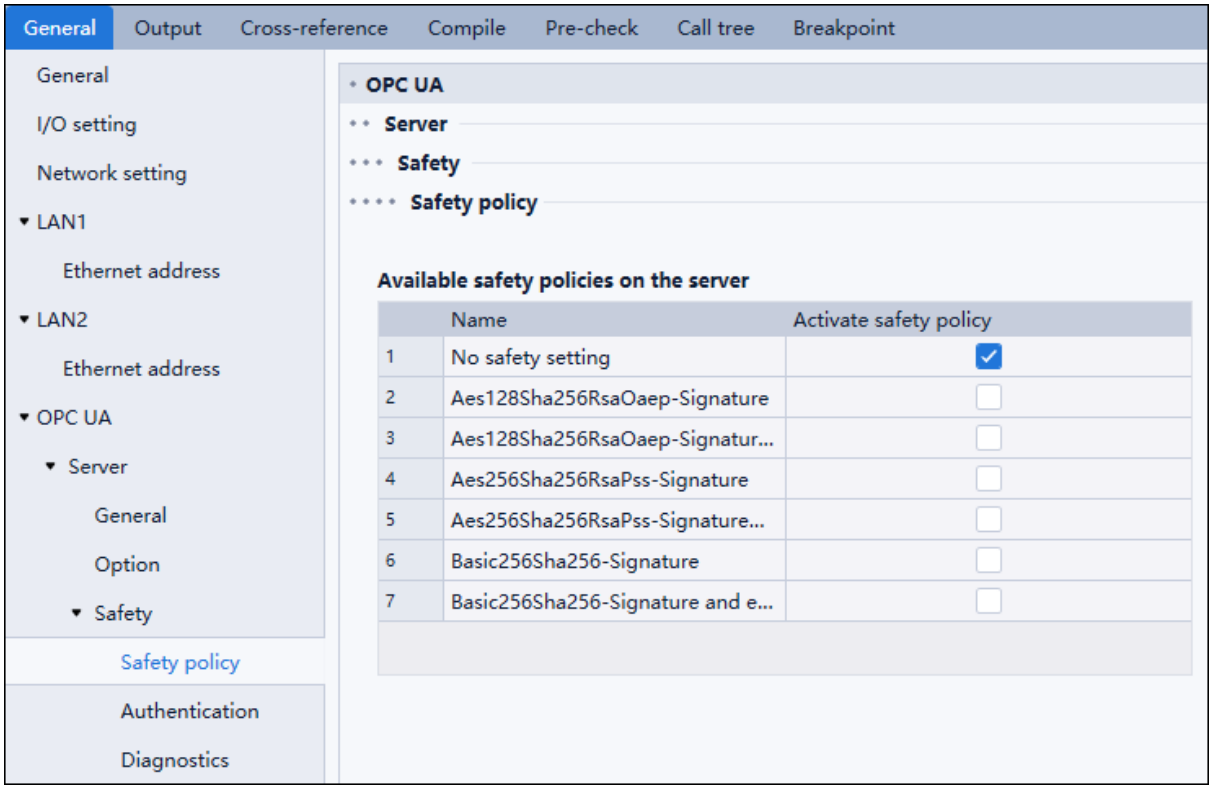
1. Double-click "Network configuration" in the project tree to open the network configuration view. Select the corresponding PLC device, and the "General" tab appears in the monitoring area, where you can configure the OPC UA server.

2. Check "Activate OPC UA server" to configure and enable the OPC UA server, and activate the access port in the port list.

3. The OPC UA server parameters can be configured under "General > OPC UA > Server > Options".

The parameter configuration is described in the table below.

Parameter	Note	Setting Method
Port	Sets the port number for the OPC UA server.	Default value: 4840; range: 1024 to 49151. The following special ports cannot be set: ◦ Modbus TCP: 502 ◦ FINS: 9600 ◦ EtherNet/IP: 44818, 2222 ◦ EtherCAT: 34980 ◦ Label communication: 12939, 12940



Parameter	Note	Setting Method
Maximum session timeout	Sets the maximum duration before the OPC UA server closes a session if no data exchange occurs.	Default value: 30s; range: 5s to 600000s.
Maximum number of sessions	Sets the maximum number of sessions that the OPC UA server can start and operate simultaneously, which depends on the performance of the PLC.	Default value: 10; range: 1 to 20.
Shortest sampling interval	Sets the time interval at which the OPC UA server records PLC variable values and compares them with previous values to check for changes.	Default value: 1000 ms. Range for EVO400/EVO500 series: 100 ms, 250 ms, 500 ms, 1000 ms, 5000 ms, 10000 ms. EVO700 series value range: 100 ms, 250 ms, 500 ms, 1000 ms, 2000 ms, 5000 ms, 10000 ms. EVO800 series value range: 100 ms, 250 ms, 500 ms, 1000 ms, 2000 ms, 5000 ms, 10000 ms.
Shortest publishing interval	Sets the interval loop rate at which the OPC UA server subscription channel publishes notifications to the client.	Default value: 1000 ms; range: 500 ms to 20000000 ms.
Maximum number of subscriptions per session	Sets the maximum number of subscriptions allowed in each session.	Default value: 10; range: 1 to 20.
Maximum number of monitored items per subscription	Sets the maximum number of monitored elements that the server assembles into a notification package for each subscription. As monitoring consumes resources, this item depends on the PLC performance.	Default value: 1000. EVO400/EVO500 series value range: 100 to 5000. EVO700 series value range: 100 to 10000. EVO800 series value range: 100 to 10000.

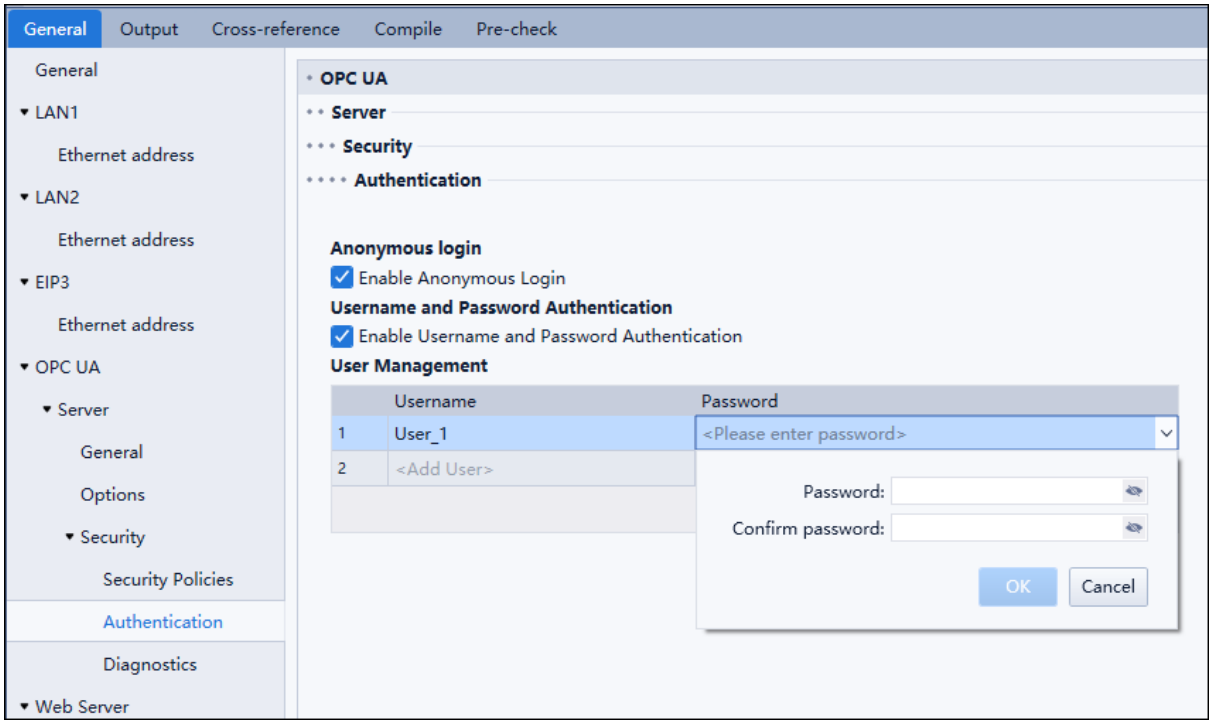
The total number of all monitored items for EVO800 series products does not exceed 20000. At the same time, the number of monitorable items is affected by the sampling interval; under the same number of monitored items, the smaller the sampling interval, the greater the system load. To ensure system functionality and execution efficiency, it is recommended to control the number of monitored items based on the sampling interval within the following quantities.

Sampling Interval	Maximum Number of Monitored Items
100 ms	1000

Sampling Interval	Maximum Number of Monitored Items
250 ms	2500
500 ms	5000
1000 ms	10000

4. The encryption policy of the OPC UA server can be configured under "General > OPC UA > Server > Safety > Safety policy" in the monitoring area.

The security policy is the message security mechanism allowed during communication between the OPC UA server and the client, implemented by setting the message signature, message encryption, and the algorithms for signing and encryption. You can select no security policy, or select one or more security policies. The specific security policy information is shown in the table below.



Parameter	Description
No security settings	No security policy connection and no security settings
Aes128Sha256RsaOaep - Sign	Use signing to ensure data integrity (prevent tampering, etc.) Use Aes128Sha256RsaOaep as the signing algorithm
Aes128Sha256RsaOaep - Sign and encryption	Use signing and encryption to ensure data integrity (prevent tampering, etc.) and reliability (prevent eavesdropping, etc.) Use Aes128Sha256RsaOaep as the signing and encryption algorithm

Parameter	Description
Aes256Sha256RsaPss - Sign	Use signing to ensure data integrity (prevent tampering, etc.) Use Aes256Sha256RsaPss as the signing algorithm
Aes256Sha256RsaPss - Sign and encryption	Use signing and encryption to ensure data integrity (prevent tampering, etc.) and reliability (prevent eavesdropping, etc.) Use Aes256Sha256RsaPss as the signing and encryption algorithm
Basic256Sha256 - Sign	Use signing to ensure data integrity (prevent tampering, etc.) Use Basic256Sha256 as the signing algorithm
Basic256Sha256 - Sign and encryption	Use signing and encryption to ensure data integrity (prevent tampering, etc.) and reliability (prevent eavesdropping, etc.) Use Basic256Sha256 as the signing and encryption algorithm

NOTE

- Depending on the hardware device, supported security policies vary, with different policies providing different security encryption methods. For detailed security policies of different products, refer to the relevant product manuals.
- It is recommended to use no security policy during initial commissioning. After commissioning, select a security policy compatible with the device or factory's security concept, and disable other security policies.

5. The user authentication of the OPC UA client can be configured under "General > OPC UA > Server > Safety > Authentication" in the monitoring area.

The parameters for authentication are described in the table below.

Parameter	Description	Setting Method
Enable anonymous login	With anonymous login enabled, users do not need to prove their identity (anonymous access), and the OPC UA server will not check the authorization of the client user.	By default, anonymous login is enabled.
Enable username and password authentication	By enabling this item, users must prove their identity (non-anonymous access), the OPC UA server will check whether the client user has the permission to access the server, and authenticate through a username and correct password.	This item is disabled by default. After checking "Enable username and password authentication", you can edit user information in the "User management" list below.
Add user	Adds a new user.	Up to 100 users can be added. You can set the username and password.

NOTE

It is recommended to enable anonymous login only during the initial commissioning phase. After commissioning, enable "Username and password authentication" to ensure communication security.

Result

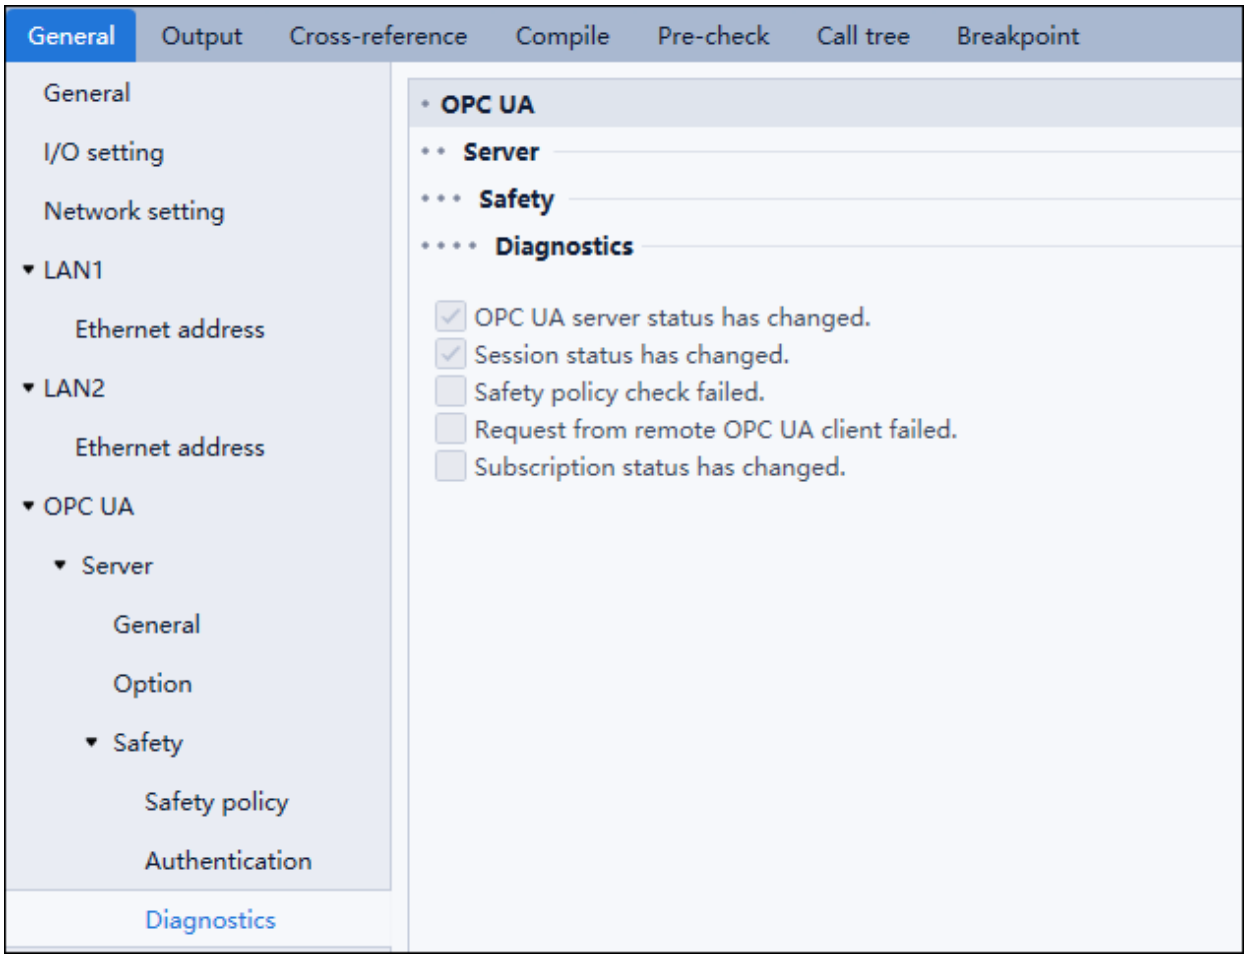
After configuring the OPC UA server parameters, download and start the device (for details, see 10.8 PLC Download). Once the PLC device is online, start the OPC UA server.

Precautions

- When the PLC runs the OPC UA server for the first time, or for the first time after IP address modification, the OPC UA server certificate file needs to be regenerated, which requires a waiting time of 1s to 2s.
- When the OPC UA server is running, if the IP address of the PLC is modified via the background or system variables, it is necessary to restart the server, or power off and on the device for the modification to take effect.

10.6.14.5.3 OPC UA Diagnostics

iFA software supports OPC UA self-diagnosis functions, which can be used to view fault information in OPC UA connections and diagnose devices and networks, making it easier to locate issues.



Diagnostic function configuration

Prerequisites

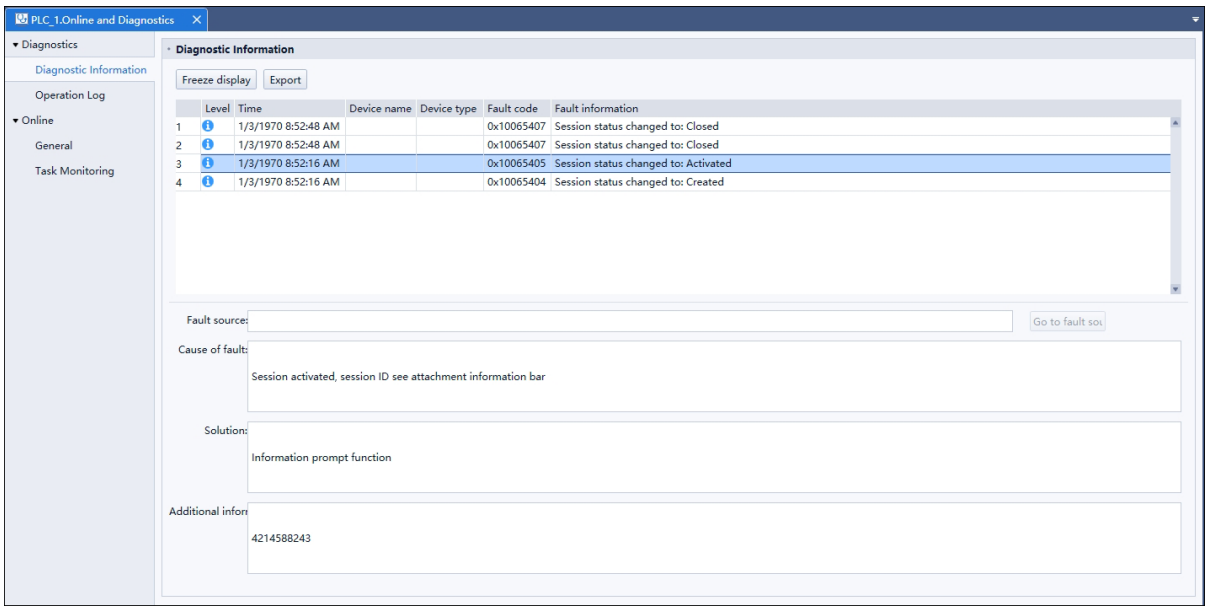
OPC UA server has been configured.

Function entry

The diagnostic function can be configured under "General > OPC UA > Server > Safety > Diagnostics" in the monitoring area.

The diagnostic scenarios include the following:

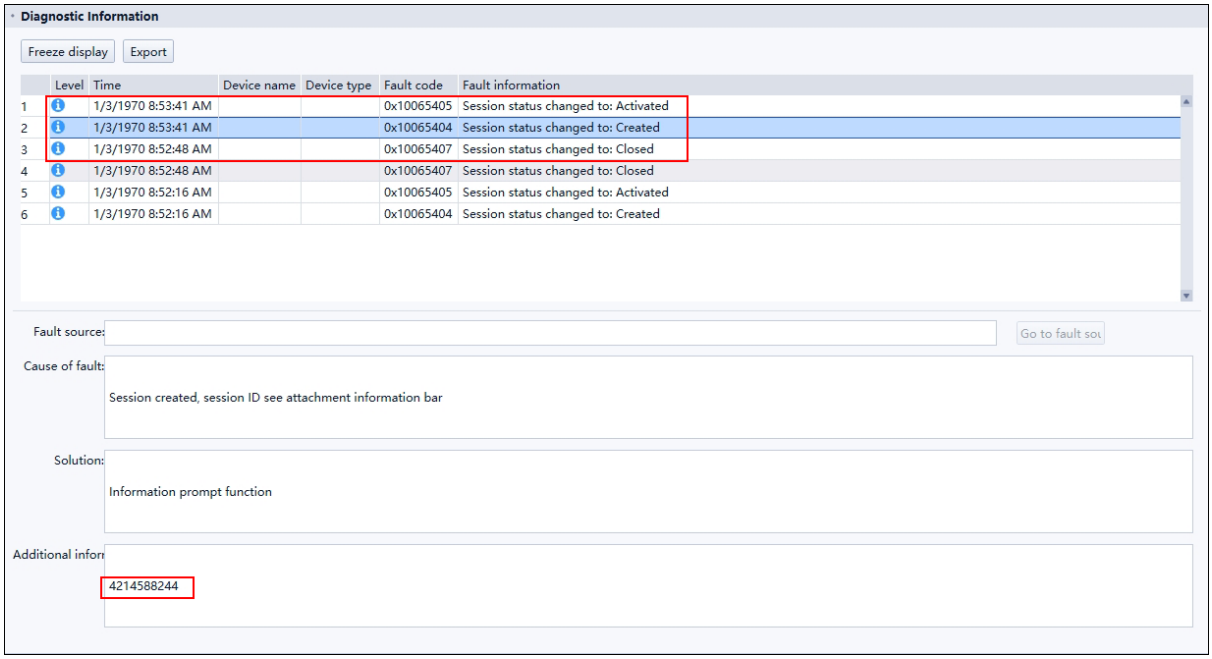
- OPC UA server status has changed: Supports diagnosing changes in server operation, stop, and timeout statuses, and reporting with diagnostic code.



- Session status has changed: Supports diagnosing session status changes for connected sessions, including creation, activation, timeout, and closure, and reporting with diagnostic code.
- Security policy check failed: This diagnostic function is not currently supported.
- Remote OPC UA client request failed: Supports diagnosing failures of OPC UA client requests. Upon a failure, the count of rejected requests is increased in the session tab and the diagnostic code is reported.
- Subscription status has changed: Clients and servers establish subscriptions during sessions. This function supports diagnosing subscription status changes, and reporting with diagnostic code.

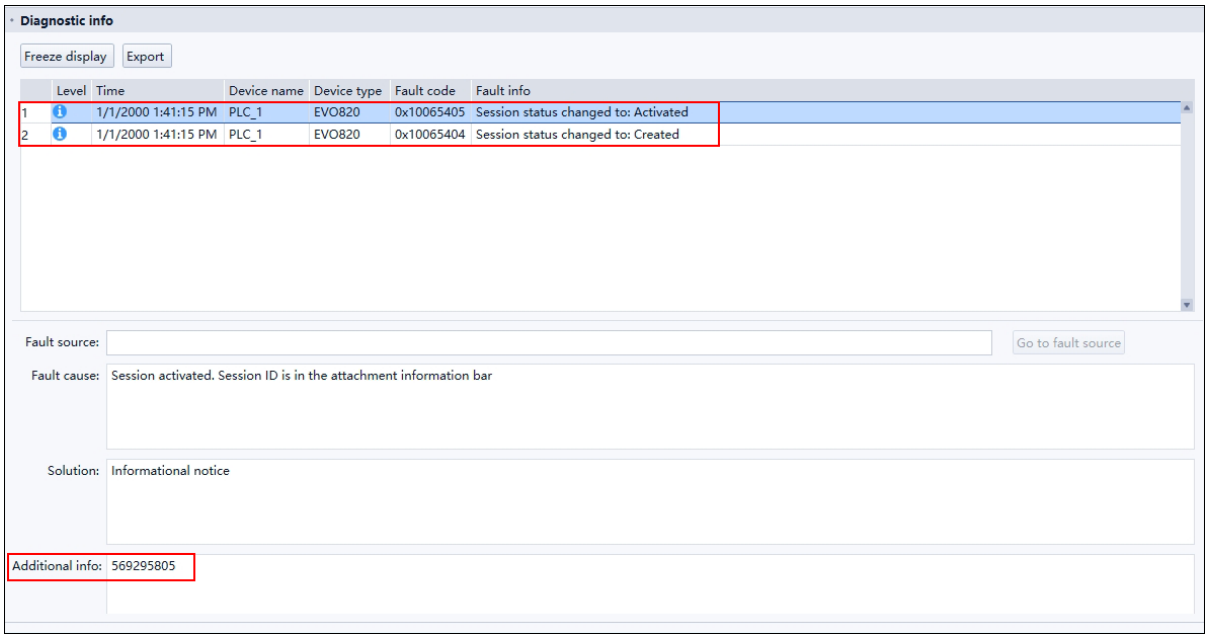
Viewing diagnostic code

Function entry



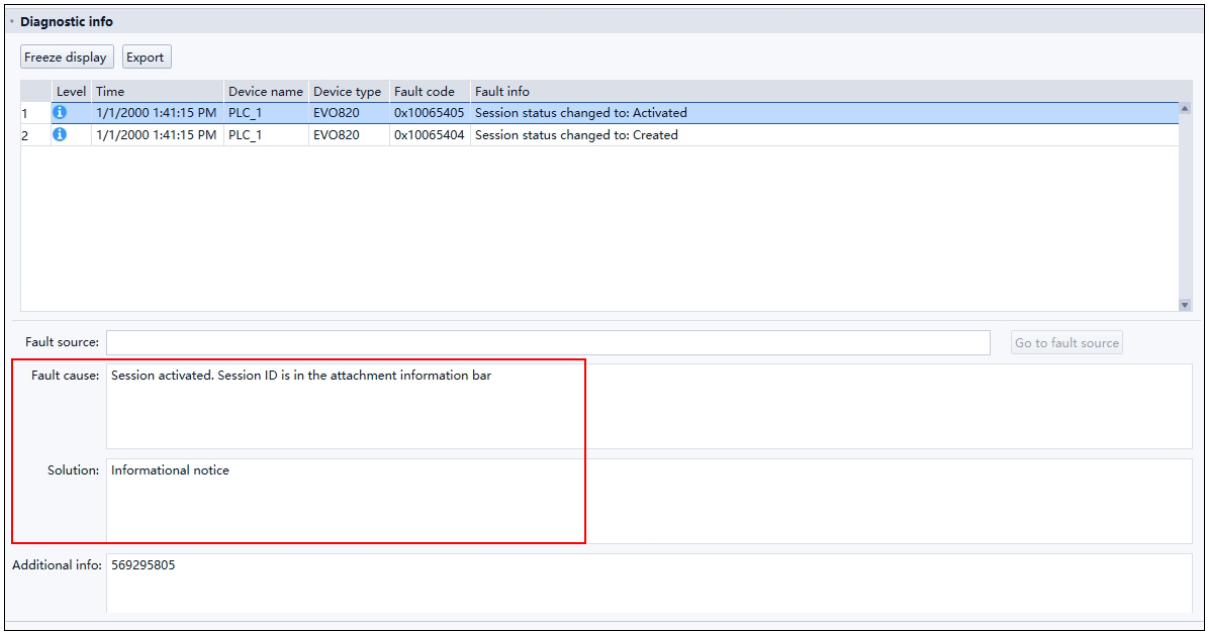
Double-click "Online and diagnostics" in the project tree to open the "Online and diagnostics" interface.

- Viewing diagnostic information
  The diagnostic information of the OPC UA server can be viewed under "Diagnostic > Diagnostic information", including information prompts and fault prompts. Information prompts include session information and subscription information prompts. Click "Freeze display" in the upper left corner to view specific session and subscription information, which allows you to see session and subscription status transitions. Additional information below include the session ID and subscription ID. Click the specific fault information to view the cause and solution of the fault.



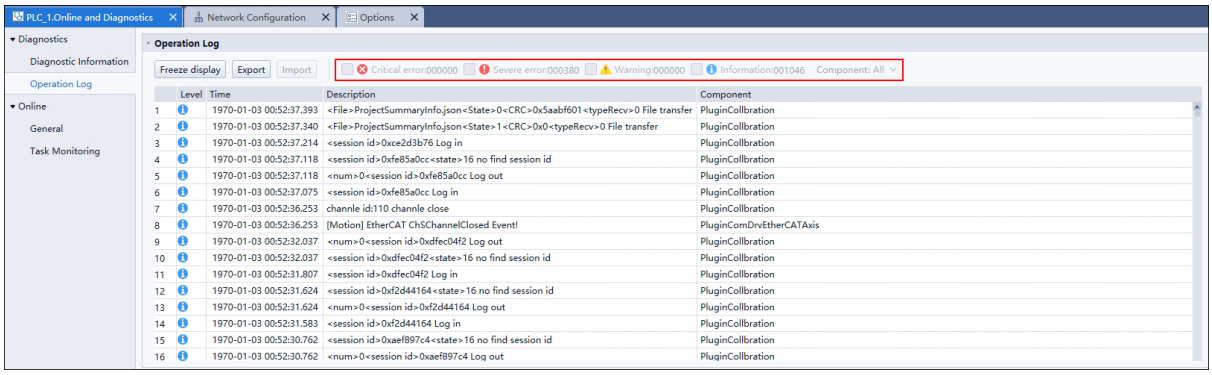
Session status:

Session status displays transitions between session creation, activation, and closure statuses, with specific session IDs attached in the additional information below.



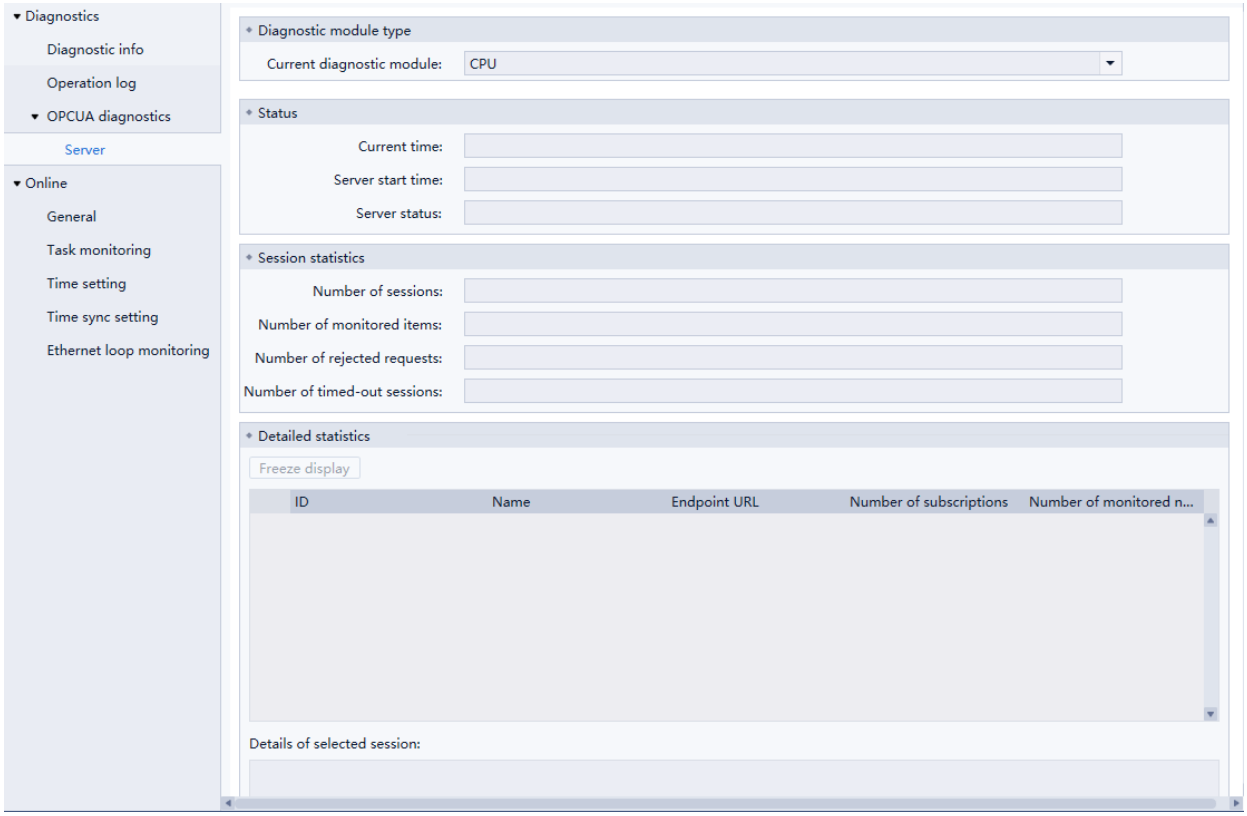
Subscription status:

The subscription status displays the creation and normal status of the subscription, and the corresponding subscription ID will be shown in the information prompt below.



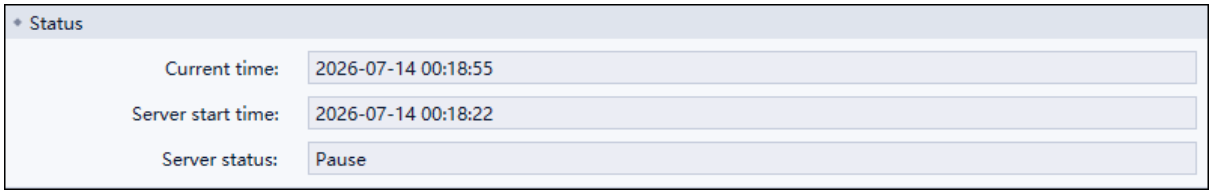
Fault status:

Displays specific information, causes, and corresponding solutions of faults.



- Viewing operation logs

  Switch the component to PluginOPCUAServer to filter and view the operation logs created by the OPC UA server. The statistics above show the number of critical faults, severe faults, warnings, and information messages. Select a specific fault type to view the corresponding fault logs.

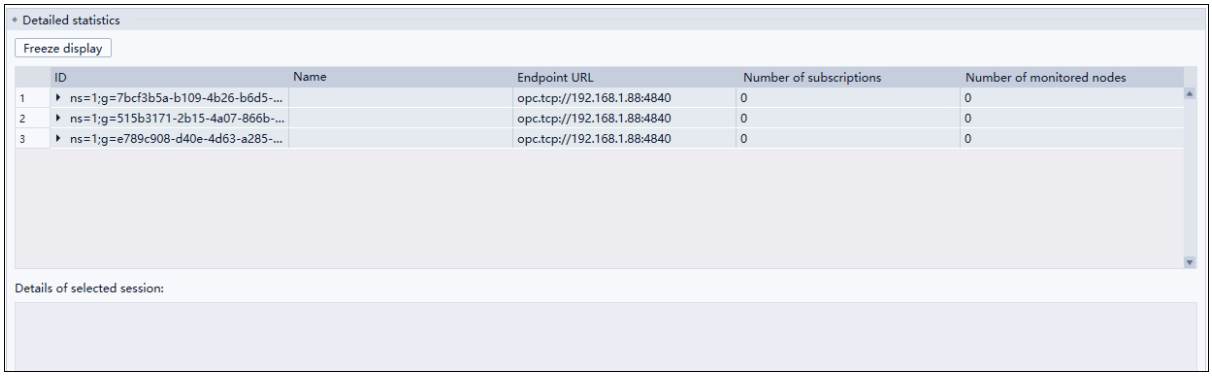


Viewing server status monitoring and self-diagnostic information

Select the module to be diagnosed from the drop-down list of "Current diagnostic module".

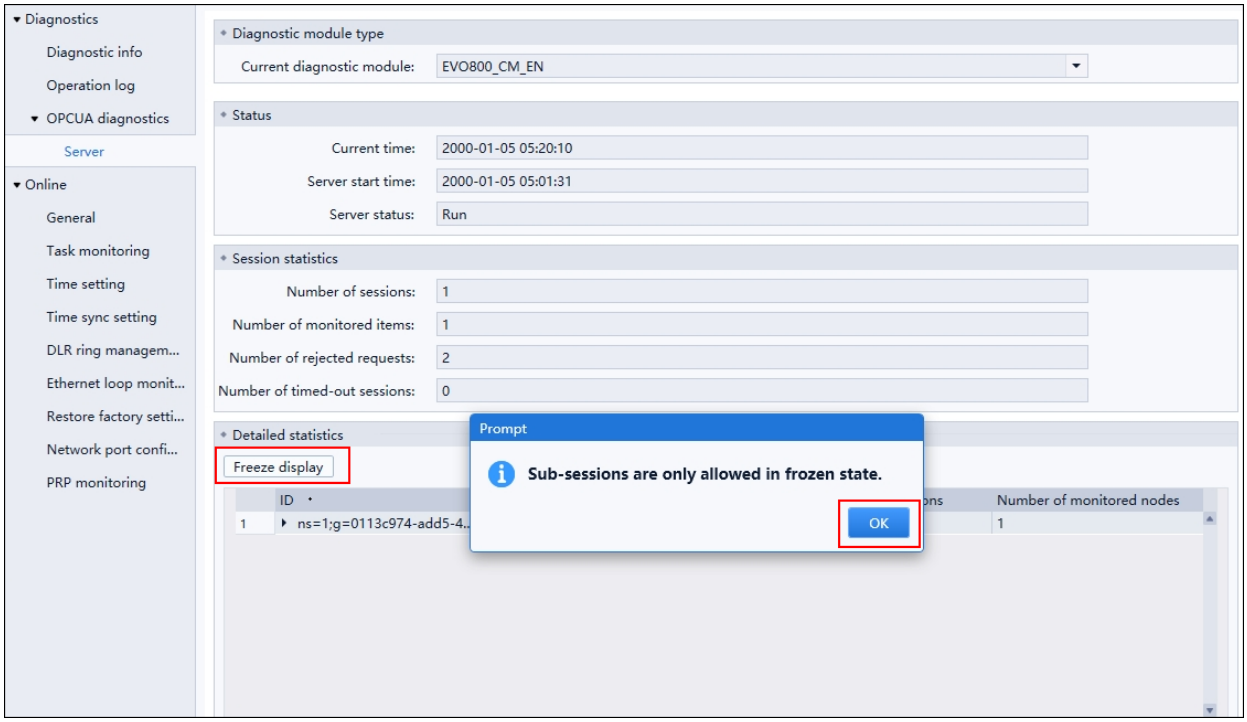
- Status

  Supports monitoring the status of the OPC UA Server. Includes the current enabled status of the server, current time, and server start time.



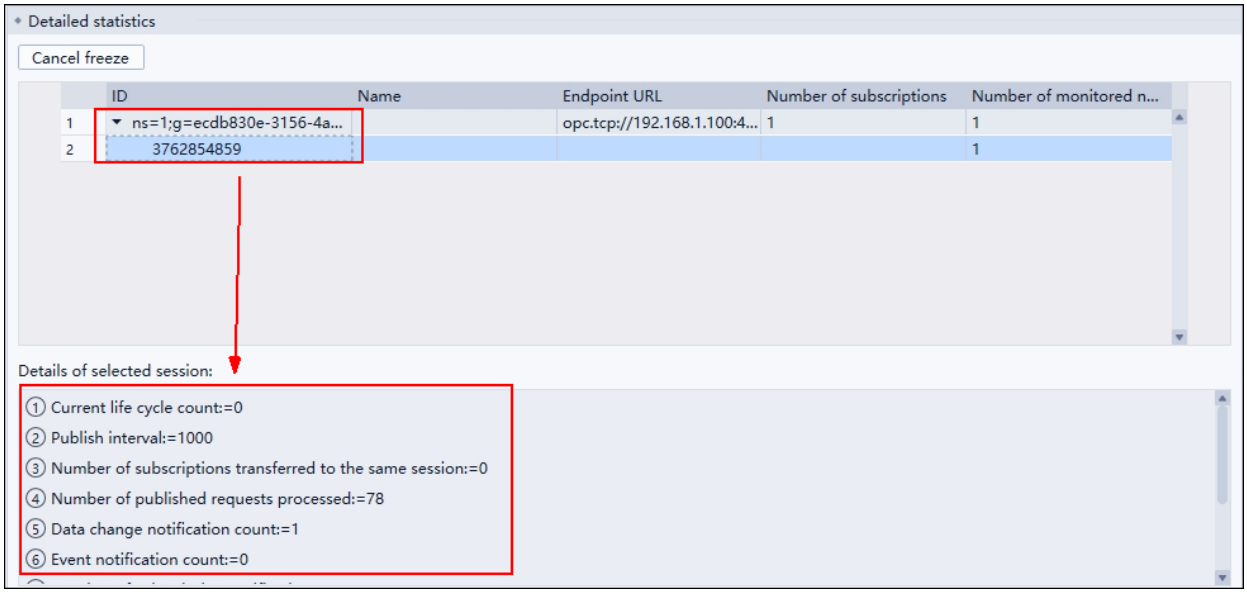
- Session statistics

  Supports viewing the number of sessions, monitored items, rejected requests, and timed-out sessions on the interface.



- Details

  Displays specific session/subscription diagnostic information, including the IDs, names, and the number of subscriptions and monitored items in the current established sessions/subscriptions.



Precautions

To view detailed session information, freeze the current window to expand the sub-session information card for details.

After freezing, select a detailed session to view its description in the selected session details below.

10.6.14.5.4 Fault Codes

Fault Code	Level	Description	Cause
0x10065000	Information	Normal connection with no fault	/
0x10065001	Fatal	Out of memory	Insufficient memory
0x10065002	Critical	Socket failed to open	Insufficient permissions, insufficient system resources, occupied port number, and so on
0x10065003	Critical	Unspecified IP	Socket bound without specifying an IP
0x10065004	Critical	Socket failed to be bound	Insufficient permissions, insufficient system resources, occupied IP address or port number, and so on
0x10065006	Critical	hostname too long	hostname length exceeds 512 bytes.
0x10065008	Critical	Invalid EndpointUrl	The configured server endpoint Url is invalid.
0x10065009	Warning	Empty security policy	Security policy is not correctly configured.
0x1006500A	Warning	Failed to set security policy	Security policy is not correctly configured.
0x1006500B	Warning	Mismatch between security mode and security protocol	When the security mode is not None, the security protocol is None (cannot be None).
0x1006500D	Alarm	OPC UA network anomaly	OPC UA network connection is disconnected, or the remote network is unreachable.
0x1006500E	Warning	Port settings out of limit	In the issued configuration parameters, the port setting exceeds the limit range and has been set to the default value.
0x1006500F	Warning	Maximum session timeout out of limit	In the issued configuration parameters, the maximum session timeout exceeds the limit range and has been set to the default value.
0x10065010	Warning	Maximum number of sessions out of limit	In the issued configuration parameters, the maximum number of sessions exceeds the limit range and has been set to the default value.
0x10065011	Critical	Sampling interval out of limit	In the issued configuration parameters, the sampling interval exceeds the limit range.
0x10065012	Warning	Publishing interval out of limit	In the issued configuration parameters, the publishing interval exceeds the limit range and has been set to the default value.

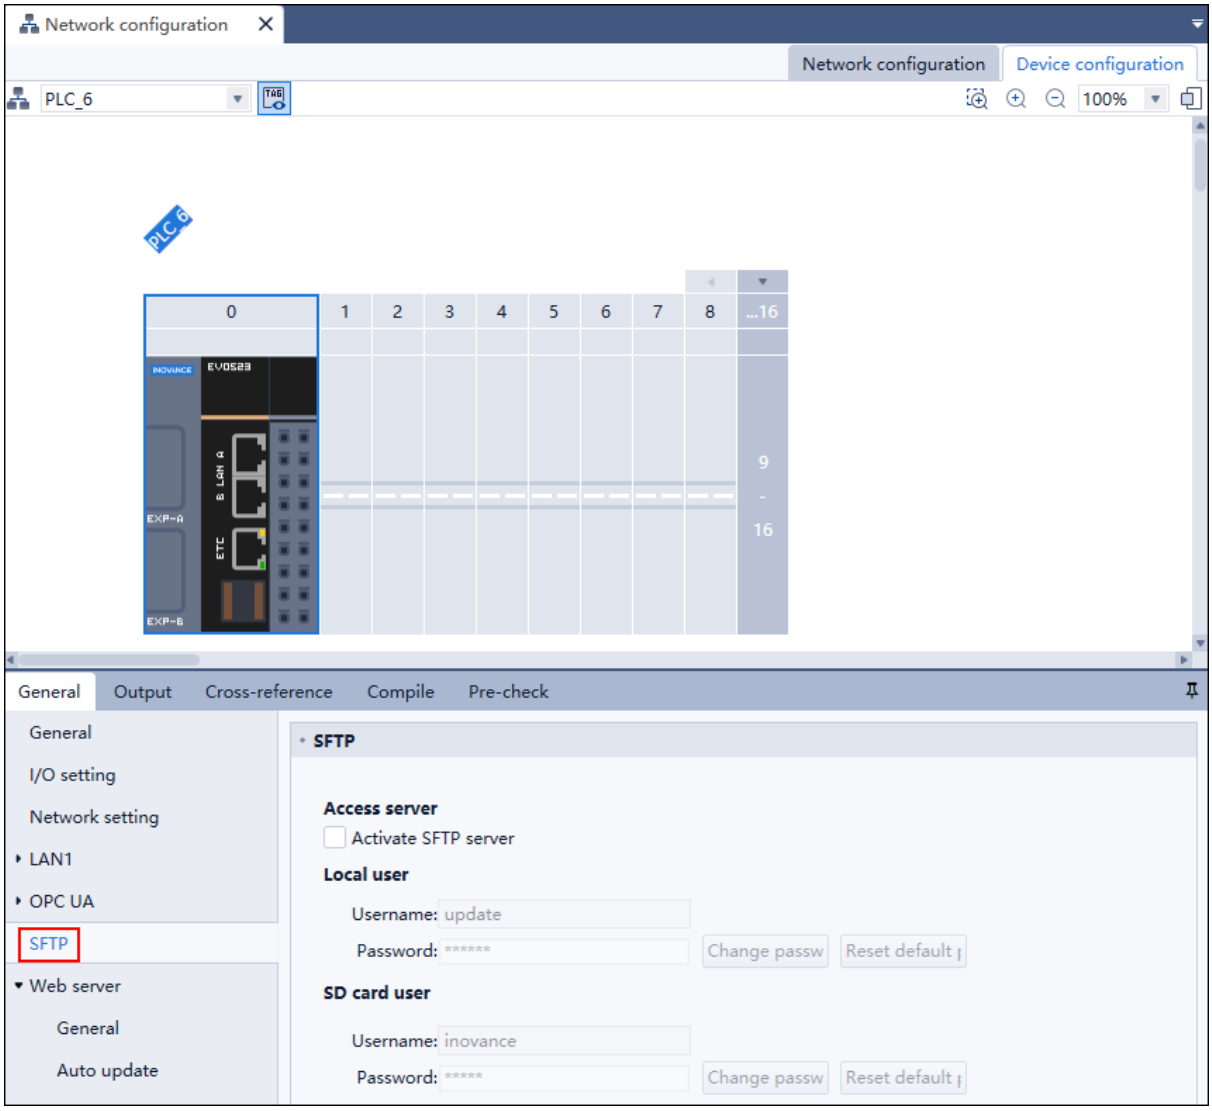
Fault Code	Level	Description	Cause
0x10065013	Warning	Maximum number of subscriptions per session out of limit	In the issued configuration parameters, the maximum number of subscriptions per session exceed the limit range and have been set to the default value.
0x10065014	Warning	Maximum number of monitored items per subscription out of limit	In the issued configuration parameters, the maximum number of monitored items per subscription exceed the limit range and have been set to the default value.
0x10065015	Fatal	Configuration file not exist	The ini configuration file is missing from the device.
0x10065016	Warning	Server certificate about to expire	The server certificate is about to expire.
0x10065201	Fatal	Out of memory	Insufficient memory
0x10065401	Fatal	Out of memory	Insufficient memory
0x10065402	Warning	Excessive sessions	The number of session connections exceeds the limit.
0x10065404	Information	Session status changed to: Created	The session is created.
0x10065405	Information	Session status changed to: Activated	The session is activated.
0x10065406	Information	Session status changed to: Timeout	The session is timed out.
0x10065407	Information	Session status changed to: Closed	The session is closed.
0x10065601	Fatal	Out of memory	Insufficient memory
0x10065602	Warning	Excessive read/write operations	When reading or writing properties and historical data, the number of read/write requests in a single frame exceeds the upper limit.
0x10065603	Warning	Node value unreadable	When reading the value property of a variable, the read permission of the node is disabled.
0x10065605	Warning	No data in indexRange	When reading node properties, the specified indexRange has no data.
0x10065606	Warning	Node value unwritable	When writing the value property of a variable, the write permission of the node is disabled.

Fault Code	Level	Description	Cause
0x10065801	Fatal	Out of memory	Insufficient memory
0x10065802	Warning	Excessive subscriptions	When creating or transferring subscriptions, the number of subscriptions in a single session exceeds the limit.
0x10065803	Information	Subscription status changed to: Creating	The subscription is normal, whose ID is displayed in the attachment information section.
0x10065804	Information	Subscription status changed to: Normal	The subscription is normal, whose ID is displayed in the attachment information section.
0x10065805	Information	Subscription status changed to: Late	The subscription is overdue, whose ID is displayed in the attachment information section.
0x10065806	Information	Subscription status changed to: Closed	The subscription is closed, whose ID is displayed in the attachment information section.
0x10065807	Warning	Excessive monitored nodes	The number of monitored nodes exceeds the limit.
0x10065C01	Fatal	Out of memory	Insufficient memory

10.6.14.6 SFTP Server Configuration

By configuring an SFTP server, users can transfer files with the PLC using standard SFTP clients or commands. This function is primarily used for remote user program upgrades.

Restrictions



SFTP server configuration is only applicable to EVO500, EVO700, EVO760C, EVO780C, and APC series PLCs, and requires firmware version V1.6 or above.

Prerequisites

A PLC device has been added.

Procedure

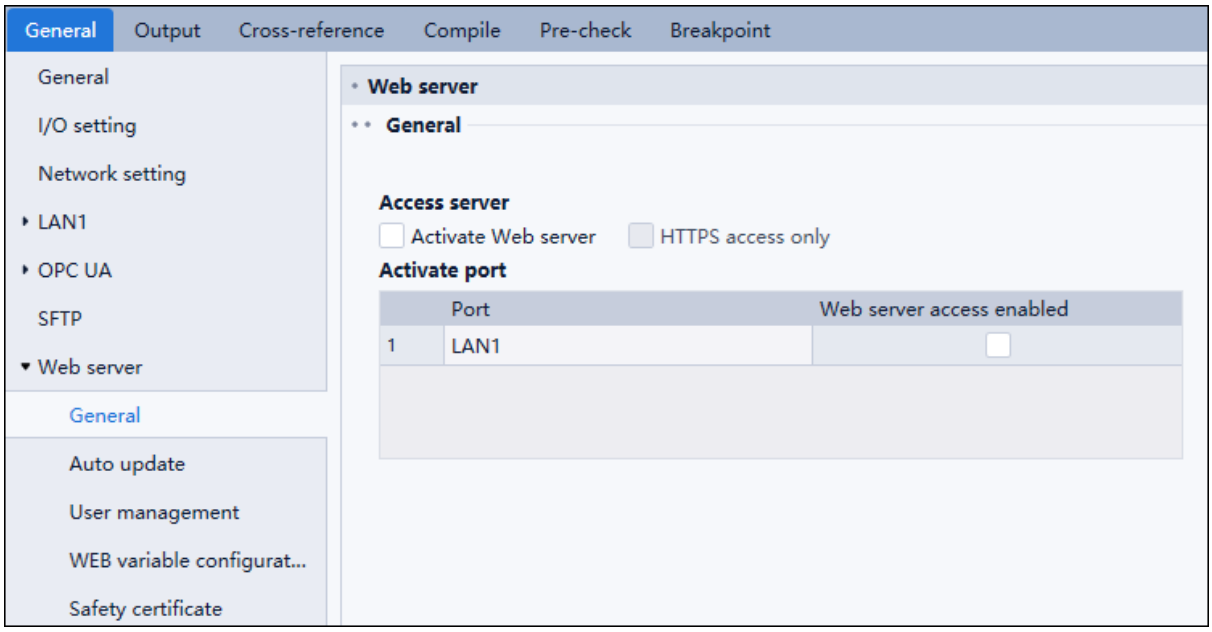
1. Double-click "Device configuration" in the left project tree and go to the "Network configuration" tab.
2. Select the PLC device diagram. In the "General" tab of the monitoring area below, select "SFTP" to open the SFTP server configuration interface.

3. Check "Activate SFTP server" to enable the SFTP server function of the PLC. Two built-in accounts are provided:

Parameter	Description
Local account	Has read/write access to the PLC storage path and can be used for user program upgrades. Default username and password are as follows: ◦ Username: update (non-modifiable) ◦ Password: 123456 (modifiable)
SD card account	Has read-only access to the SD card path, mainly for file transfer. Default username and password are as follows: ◦ Username: inovance (non-modifiable) ◦ Password: admin (modifiable)

4. (Optional) The password for either account can be changed or reset as follows:
   - Click "Change password". In the pop-up dialog, enter the current password and the new password, then click "OK".
     The new password must contain at least one digit, one uppercase letter, and one lowercase letter.

- Click "Reset default password", enter the current password in the dialog box, and click "OK" to restore the account password to default.

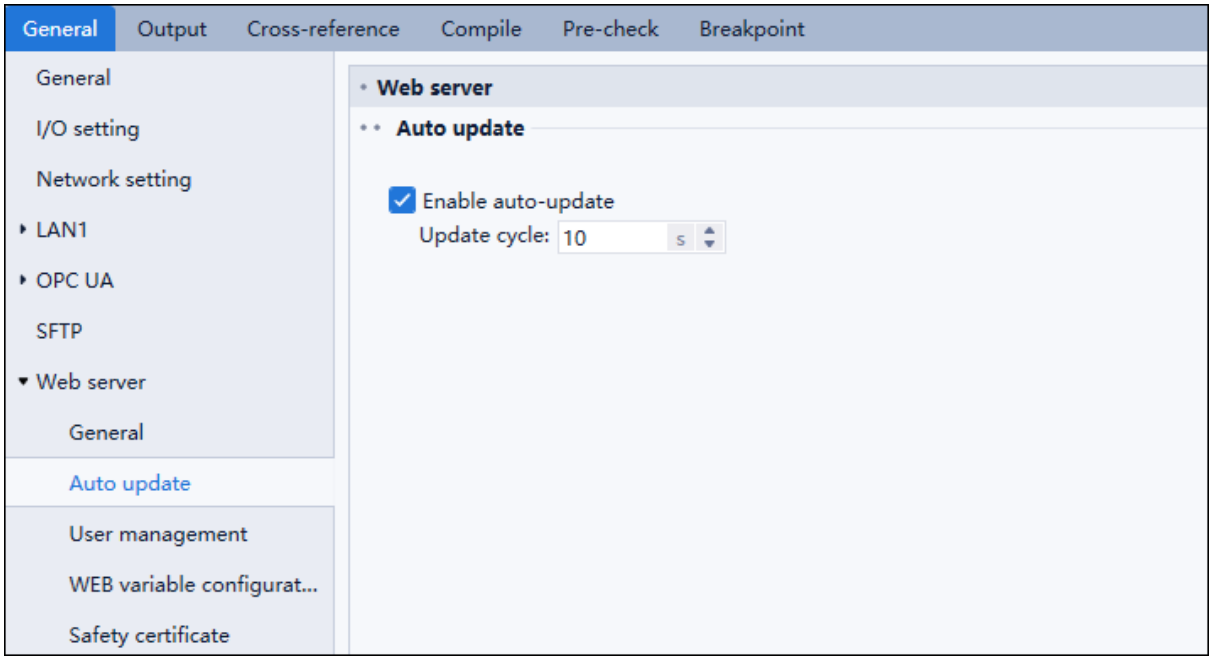


10.6.14.7 Web Server Configuration

Prerequisites

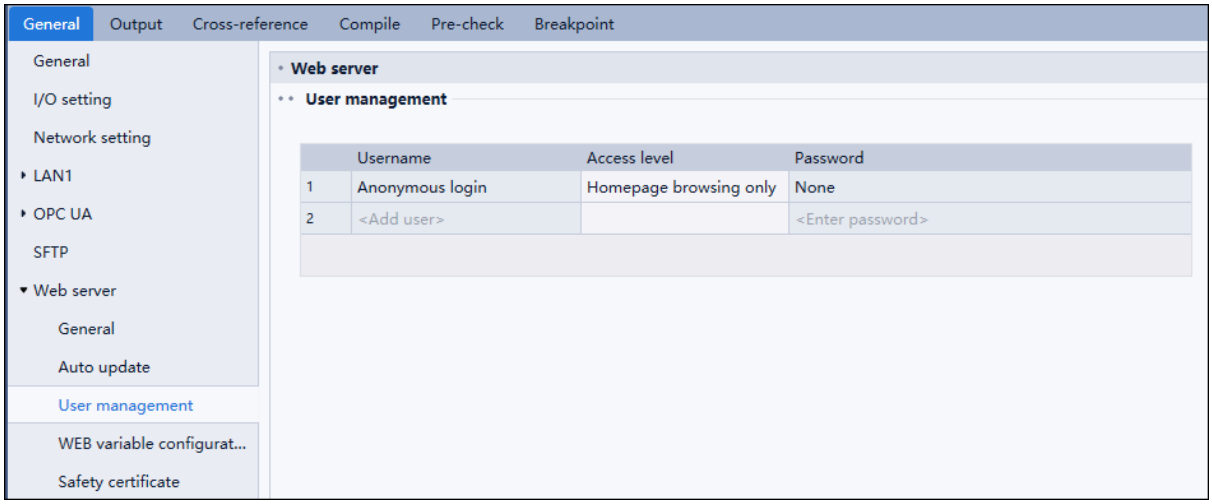
A PLC device has been added.

Procedure



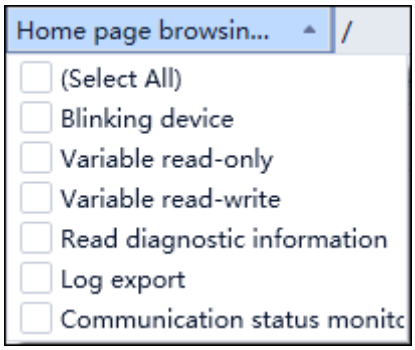
1. Open the Web configuration interface.
   Double-click "Network configuration" or "Device configuration" in the left project tree to open the network configuration interface. Click the PLC device and the Web server can be configured under "General > Web server" in the monitoring area below.

   When the Web is activated, users can log in to the Web server via "http://<address>". For details, see 10.1 1.12 Web Diagnostics and Monitoring.



2. Activate the Web server.
   Check "Activate Web server" and activate the access port in the port list. If "HTTPS access only" is checked, only HTTPS access is supported.

3. Configure automatic updates.
   In the "Auto update" tab, check "Enable auto-update" and the Web server will update data in real-time according to the set "Update cycle".

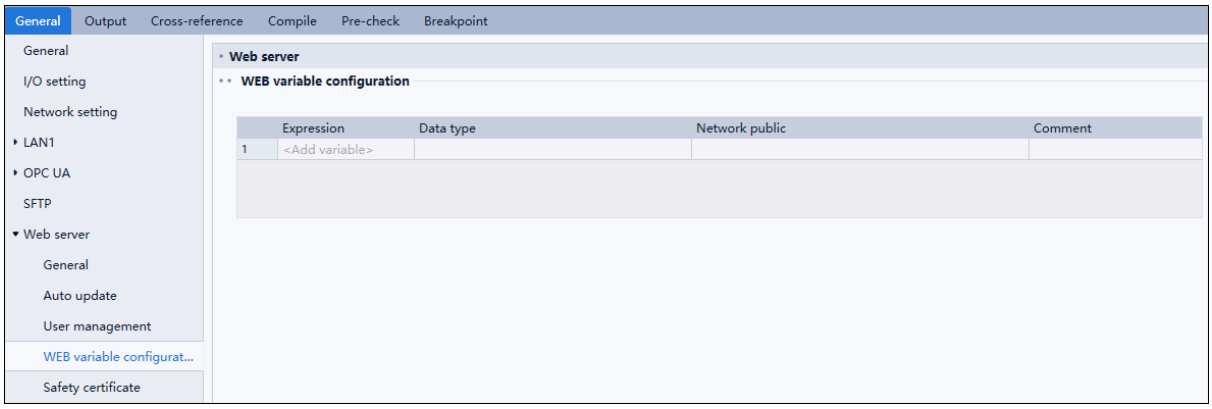


4. Configure user management.

   By default, all users can log in anonymously with permissions limited to homepage browsing. The anonymous permissions can be customized by users.

In the "User management" tab, user accounts can be added to increase access permissions; the number of users that can be created is 1 to 20.

Parameter	Note
Username	Required field, default name is "User_1". Composed of letters (case-insensitive), numbers, Chinese characters, and special characters. Supported special characters include ~`!@#$ %^&*()-_=+[]{}|\;:,.<>/?!　（）、。：；“” The maximum character length is 128.



Parameter	Note
Access level	The Web interface only supports the corresponding access levels. The options in the drop-down list of "Access level" are as follows: 
Password	Composed of letters (case-sensitive), numbers, Chinese characters, and special characters. Supported special characters include ~`!@#$%^&*()-_=+[]{}|\;:,.<>?/ The password must contain numbers, uppercase letters, and lowercase letters. Character length: 8 to 32.

5. Configure Web variables.

   When configuring variables in the "Web variable configuration", full name addition of variables is supported. Click "..." to add variables in the pop-up input assistant.

   The software interface supports displaying properties of variables, such as expressions, data types, network public property, and annotations.

   Only read-write and read-only variables are supported, with a limit of 100 variables. For variables containing sub-elements such as arrays and structures, their sub-elements are also counted.

6. Configure the security certificate.

   The server certificate is used for identity verification when users access the server.

The default name for the certificate is Webserver. Users can select the certificate from a drop-down box.

NOTE

The EVO500 series PLC only supports Web server functionality from version V1.4.2.5 and above.

10.6.15 Ethernet Expansion Module Property Configuration

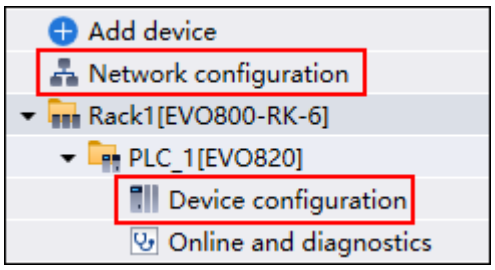
Ethernet expansion module property configuration is downloaded to a PLC module via a PLC project. The PLC module then synchronizes this configuration to the Ethernet expansion module via rack communication.

CAUTION

iFA Evolution does not support downloading directly to the Ethernet expansion module itself.

10.6.15.1 Setting Ethernet Address

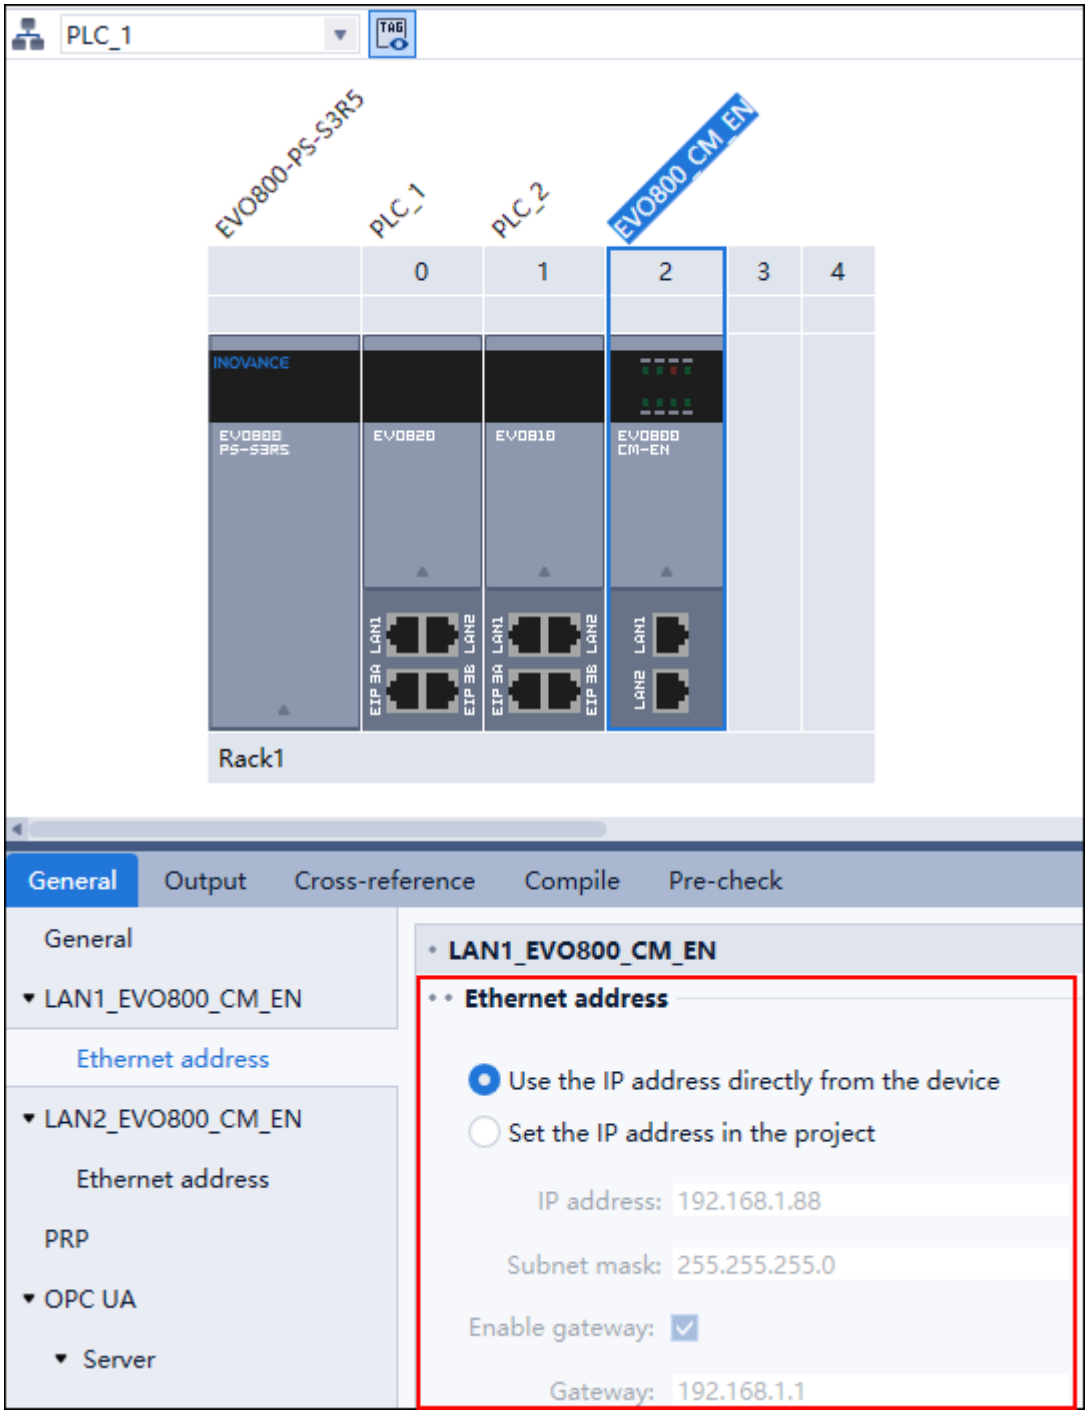
This section describes how to set IP addresses for the LAN1 and LAN2 ports of the Ethernet expansion module via its properties. IP addresses can also be configured through the toolbar: "Online > Network setting" (see 10.11.5 Network Setting for details). After the device goes online, the changes are automatically synced back to this interface.



Background

- The two ports of the expansion module cannot be on the same network segment. For example, when the IP address of LAN1 is 162.168.0.1, the IP address of the LAN2 cannot be set to 192.168.0.2.
- The expansion module ports can be on the same network segment as the PLC's built-in port. For example, when the IP address of LAN1 on the Ethernet expansion module is 192.168.0.1, the IP address of the LAN1 on the PLC can be set to 192.168.0.10.

Procedure

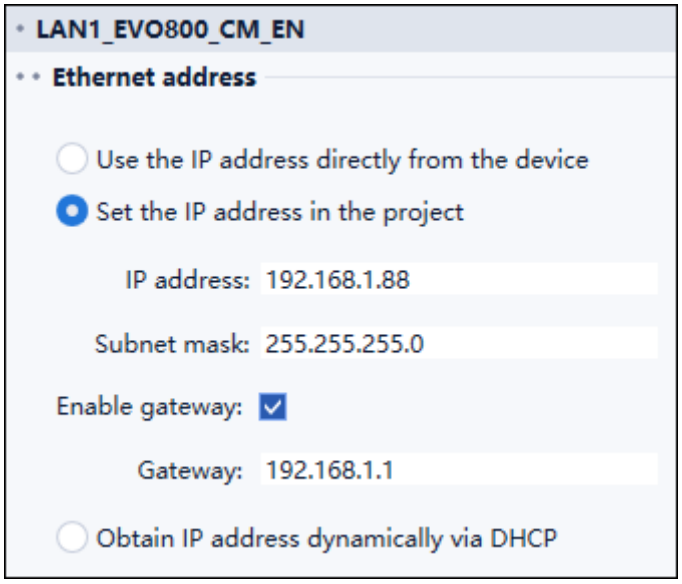


1. Open the configuration interface.

Double-click "Network configuration" or "Device configuration" in the project tree to open the configuration window.

2. Open the IP address setting interface.

   Switch to the network view or device view. Click the Ethernet expansion module diagram, and click the "Ethernet address" under LAN1 or LAN2 port on the "General" tab.



3. Set the IP address.

   - Use the IP address directly from the device.

     The IP address follows that set by the device and cannot be modified.

◦ Set the IP address in the project.

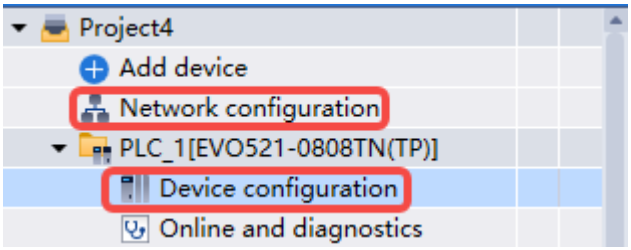
Parameter	Description
IP address	The two ports of the expansion module cannot be in the same network segment, but they can be in the same network segment as the PLC's built-in Ethernet port. Set them according to the actual network planning.
Subnet mask	Auto-adapts based on IP address and supports manual modification.
Gateway	The gateway's IP address must be in the same subnet as the "IP address".

10.6.15.2 Setting PRP

This section describes how to activate PRP and set PRP IP addresses via Ethernet expansion module properties. After PRP is enabled, the two network ports present only one PRP IP address (virtual IP) externally. The PRP IP address can also be set via "Online > Network setting" (see 10.11.5 Network Settings for details). After the device goes online, the changes are automatically synced back to this interface.

Background

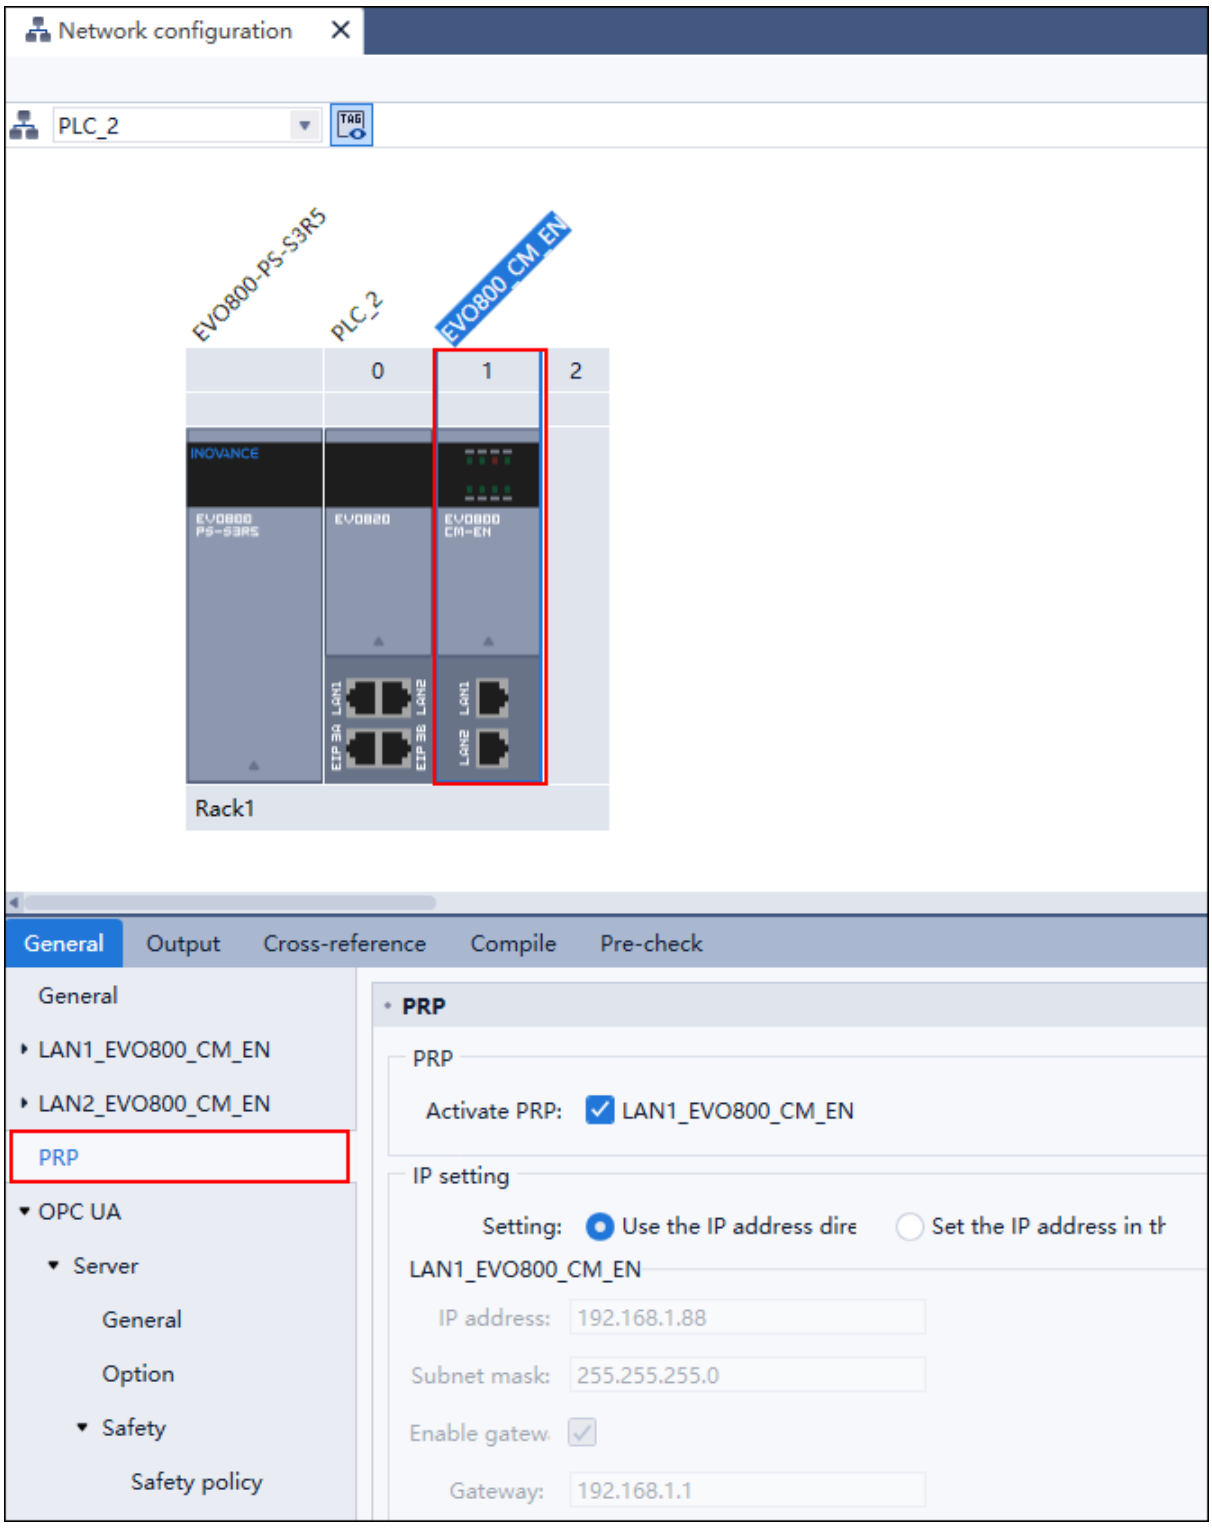
PRP (Parallel Redundancy Protocol) is a redundancy protocol based on dual-network parallel transmission (compliant with IEC 62439-3). Identical data frames are sent via two independent Ethernet ports, with valid frames selected by the receiver per preset rules for zero-switch-delay high-availability communication. Upon link failure of one port, communication switches seamlessly to the other port automatically to ensure uninterrupted system communication.



PRP core features:

- Dual-network redundancy: Two physically isolated networks (LAN A/LAN B) are required.
- Frame identification: A six-byte RCT is appended to the end of Ethernet frames, containing serial numbers and path identifiers.
- Seamless switchover: The optimal path is automatically selected upon faults, with recovery time less than 1 ms.

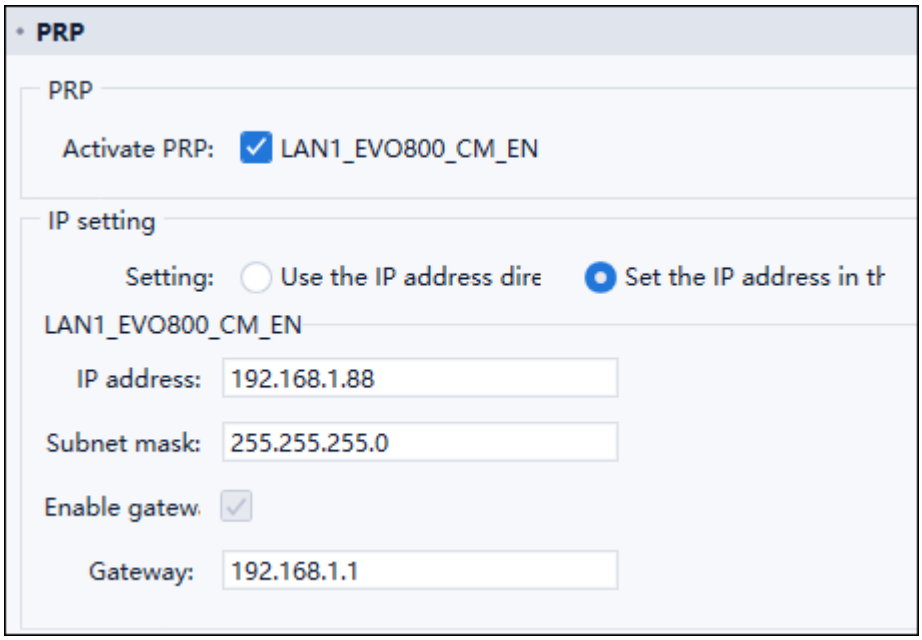
Procedure



1. Open the configuration interface.

Double-click "Network configuration" or "Device configuration" in the project tree to open the configuration window.

2. Open the PRP setting interface.



Switch to the network view or device view. Click the Ethernet expansion module diagram, and click "PRP" on the "General" tab.

3. Check "Activate PRP".

> **NOTE**
>
> After activating PRP, communication with external devices is only possible via the LAN1 port. That is:
>
> - Slaves can only be connected under the LAN1 port.
> - External communication services (Web Server, OPC UA Server, Modbus TCP Server, etc.) are only available through LAN1.

4. Set the PRP IP address.
   - Use the IP address directly from the device.
     The IP address follows that set by the device (through 10.11.5 Network setting) and cannot be modified.
   - Set the IP address in the project.

Parameter	Description
IP address	The PRP IP address of the Ethernet expansion module: the two network ports present only one virtual IP address externally. The PRP IP address of the Ethernet expansion module's network port and the IP address of the PLC module's network port can be set to the same subnet or to different subnets. Configure them according to actual network planning.
Subnet mask	Auto-adapts based on IP address and supports manual modification.
Enable gateway	Takes effect when checked.
Gateway	The gateway's IP address must be in the same subnet as the "IP address".

5. (Optional) To monitor PRP, see 10.11.23 PRP Monitoring for details.
6. (Optional) To view diagnostic information, see 10.11.20 Diagnostic Information for details.

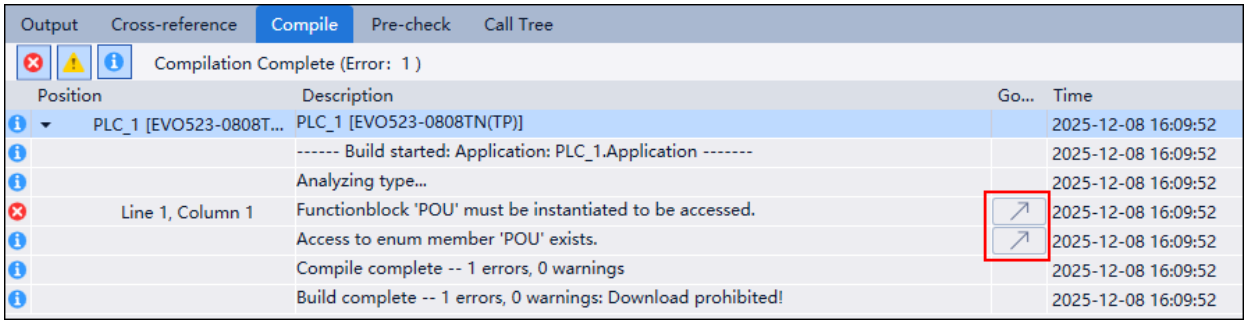
10.6.15.3 Configuring OPC UA Server

The configuration related to the Ethernet expansion module's OPC UA server is the same as that of the PLC's OPC UA server. For specific operations, see 10.6.14.5 OPC UA Server Configuration.

NOTE

PLC public variables can be accessed externally via the OPC UA service on the Ethernet expansion module.

10.6.15.4 Configuring Web Server



The Web server configuration related to the Ethernet expansion module is the same as that of the PLC's Web server. See 10.6.14.7 Web Server for specific operations.

10.7 PLC Compilation

10.7.1 Overview

After the program is written, it needs to be compiled before downloading. The compile command checks the syntax of the written program and only compiles the programs added to the task. If the created POU is not added to the task, the compile command does not perform a syntax check on that POU. If the program is directly switched to online, the system will execute the compile command by default (equivalent to manually executing the compile command first), and execute the connection login command if no syntax error is detected. Similarly, during compilation, no syntax check is performed on POUs that are not added to the task. Code will be generated when executing the login command.

After the compile command is executed, the generated information is displayed in the "Compile" tab in the monitoring area, where you can view the number and location of faults or alarms. Through the monitoring area, you can view and search for faults or alarms, and modify the program according to the prompt information.

- Double-click the faults or alarms in the monitoring area to locate.
- Right-click a fault or alarm in the monitoring area and select "Go to" to locate the specific position.
- Click the  icon after a fault or alarm to locate the specific position.

10.7.2 Pre-Check

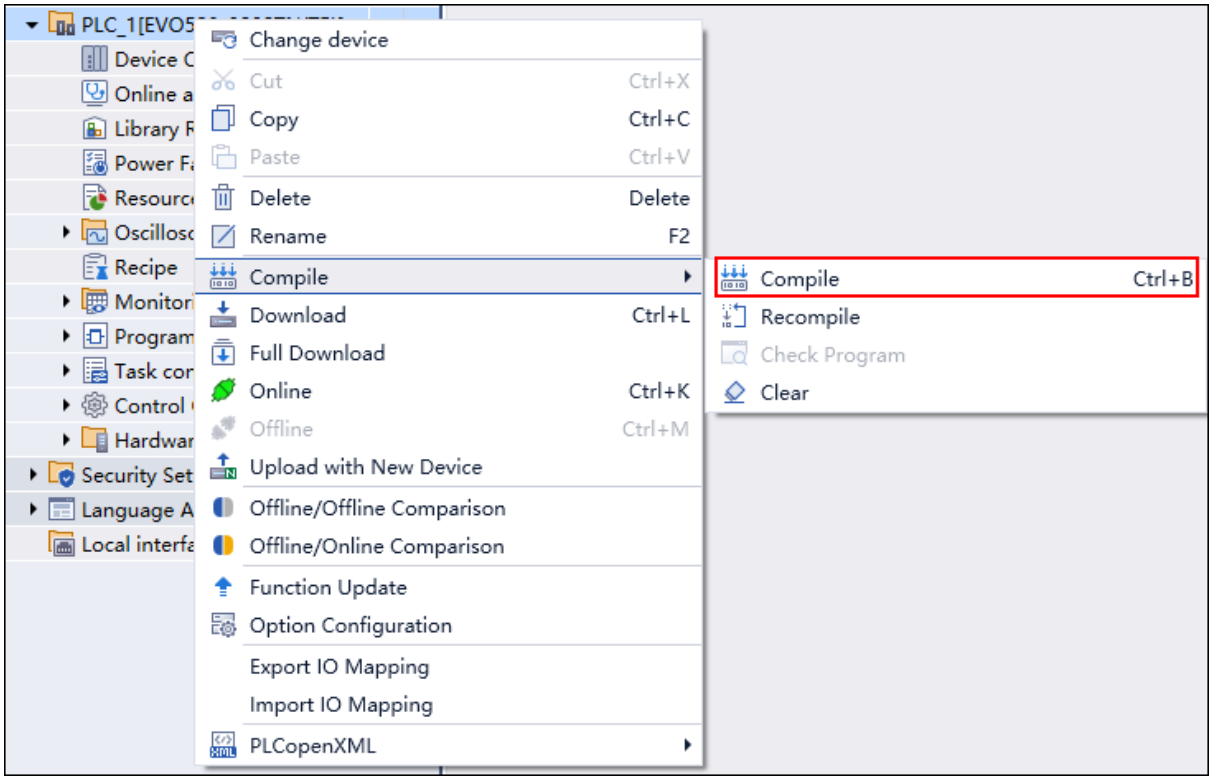
The pre-check function is used to check for syntax errors in the user-configured project in real time and provide prompts. When the user configuration content changes, the compiler will automatically trigger a pre-check to alert the user to syntax errors in the code in advance.

The pre-check aims to provide a quick preliminary check mainly based on syntax, to verify whether the project configuration conforms to the syntax rules. It can also check for basic types associated with the configuration (excluding user-defined types).

The pre-check mainly covers two parts: the variable area and the program area.

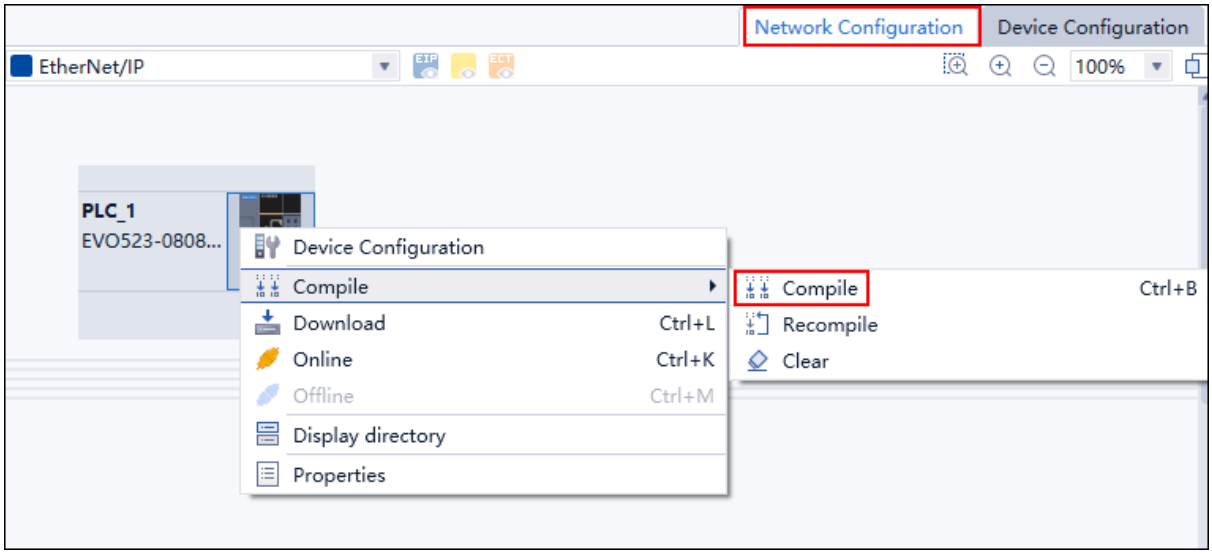
- The variable area can be displayed in table view or text view. In the table view, the system checks the validity of each property field of the variables. In the text view, the system checks the validity of each property field of the variables and the syntax of the variable declaration statements. The specific check points are as follows:
  - Whether the variable declaration statement conforms to the syntax rules for declaring variables.
  - Whether the variable name is a valid identifier and whether it is duplicated.
  - Whether the data type is valid.
  - Whether the address is valid.
  - Whether the initial value is within the valid range of the type.
  - Whether the variable supports power failure retention.
- The program area includes two languages: graphical language and text language. In the graphical language mode, the system checks the validity of the content associated with each component of the graphical language In the text language mode, the system checks the syntax and validity of the text content. The specific check points are as follows:
  - Whether statements and expressions conform to syntax rules.
  - Whether the variables referenced by statements and expressions exist.
  - Whether the variable types associated with expressions conform to syntax rules.
  - Whether the expression types match.
  - Whether the number and types of formal parameters and actual parameters in function calls match.
  - Whether the constant subscripts in array access are within the upper and lower bounds.
  - Whether type conversions conform to the rules.
  - Whether the label of the jump target exists.

10.7.3 Compilation



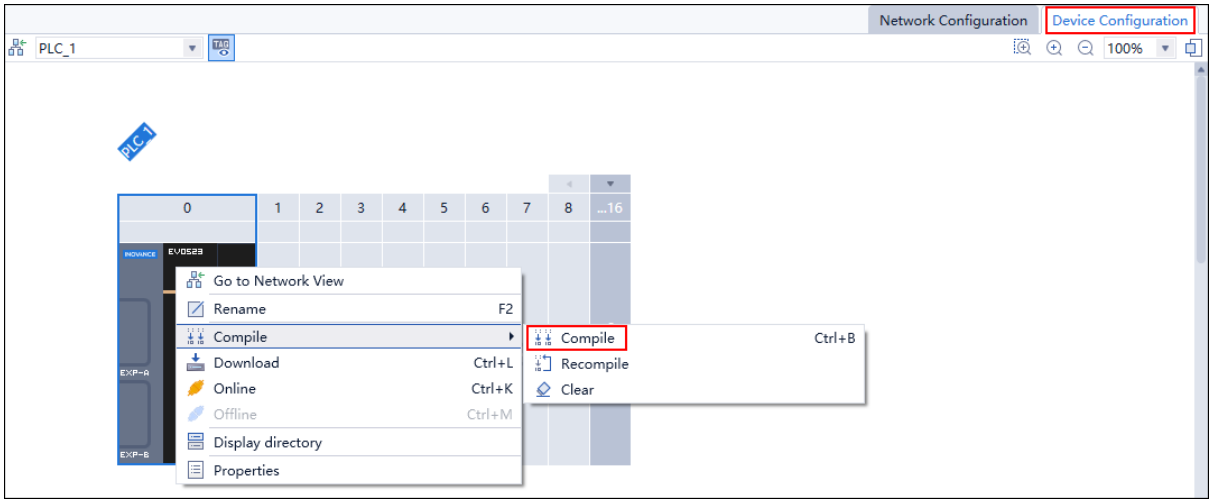
Compile all code into code that the PLC can execute.

Prerequisites

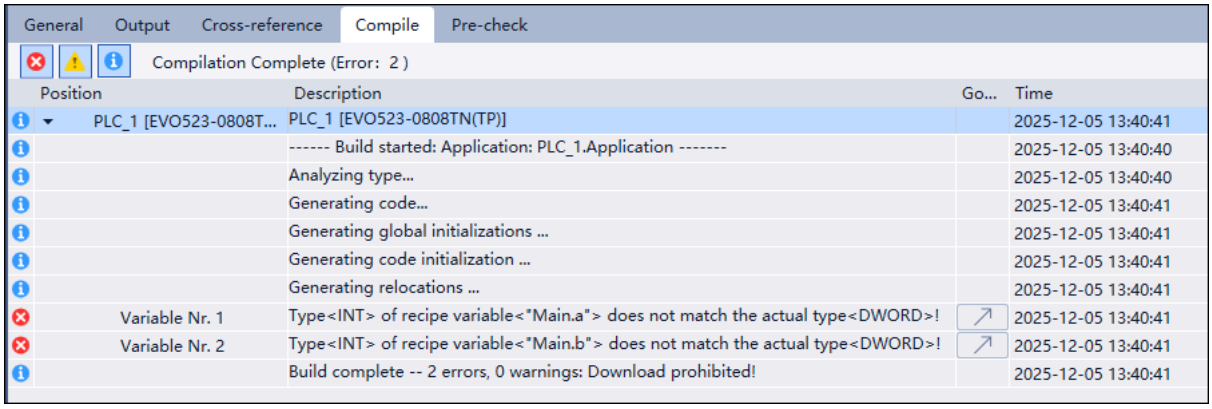


There are compilable programs in the project.

Procedure



1. There are several ways to compile the project.
   - Toolbar: In the project tree, select the corresponding PLC project and click the "Compile" icon on the toolbar.
   - Menu bar: In the project tree, select the corresponding PLC project and select "Compile > Compile" in the menu bar.
   - Right-click menu: Right-click the corresponding PLC project in the project tree and select "Compile > Compile" to download the project to the device, as shown in the following figure:



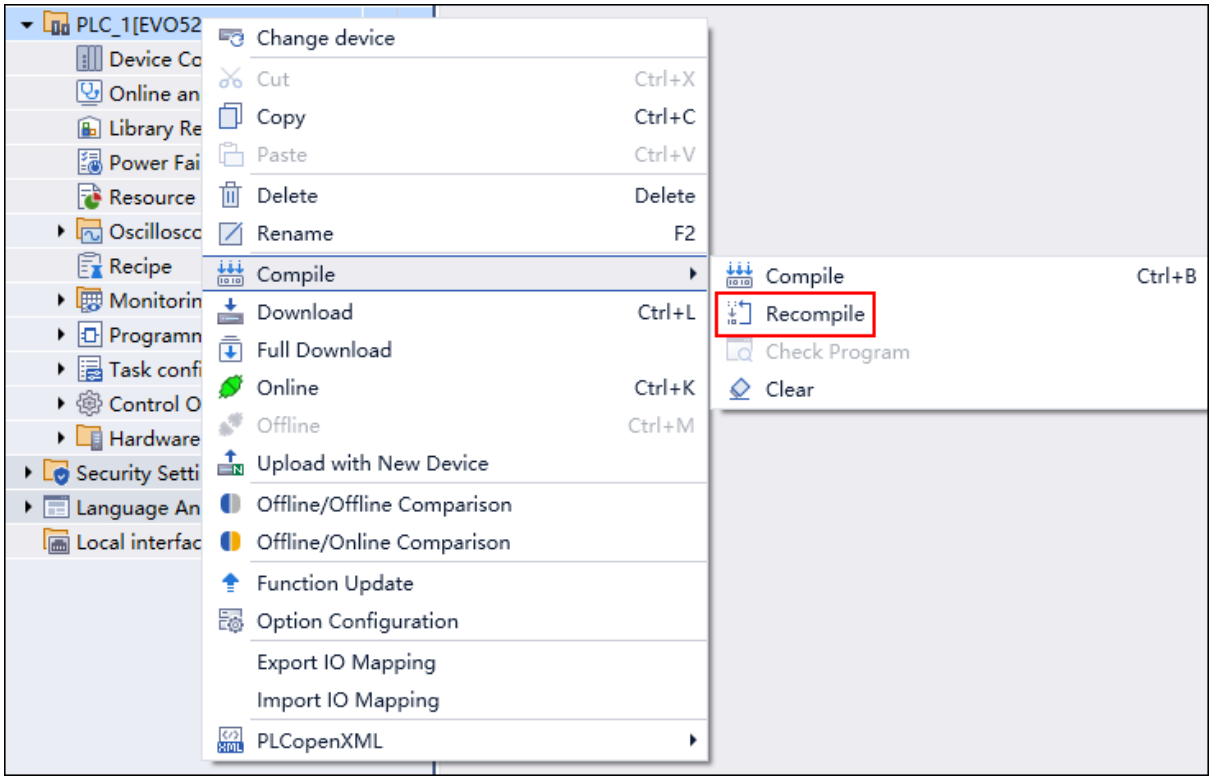
- Shortcut key Ctrl+B: After selecting the device, when the compile icon is enabled, press Ctrl+B on the keyboard to compile.
- Network view: In the "Network configuration" interface, right-click the corresponding PLC and select "Compile > Compile".

- Device view: In the "Device configuration" interface, right-click the corresponding PLC and select "Compile > Compile".

2. View the compilation information.
   After compilation, the corresponding compilation information is displayed in the "Compile" tab in the monitoring area, which includes faults, alarms, and information. Click the icons to hide/show the corresponding information. When a compilation is abnormal, there will be a corresponding prompt. Double-click the prompt to locate the specific position.

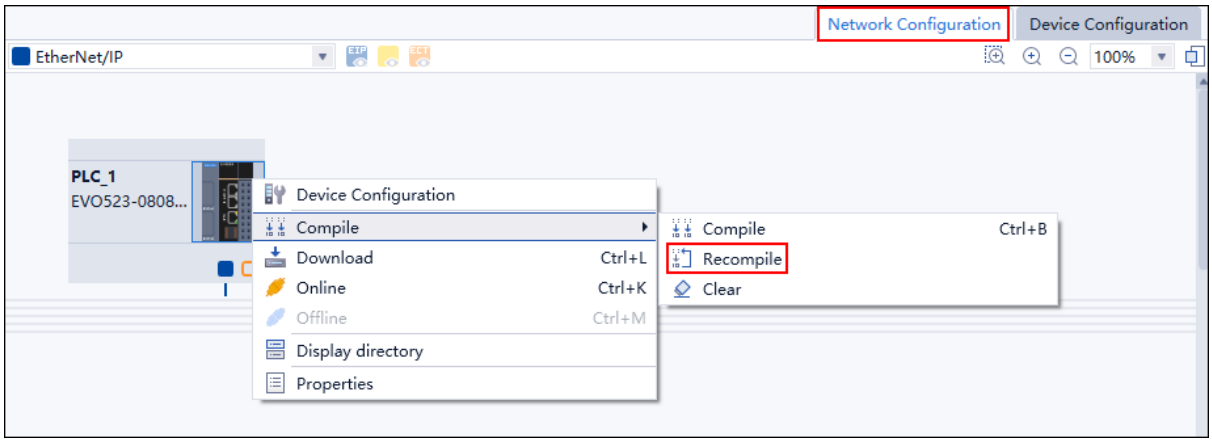
10.7.4 Recompilation

Clear the previous compilation information and re-run the compilation command.



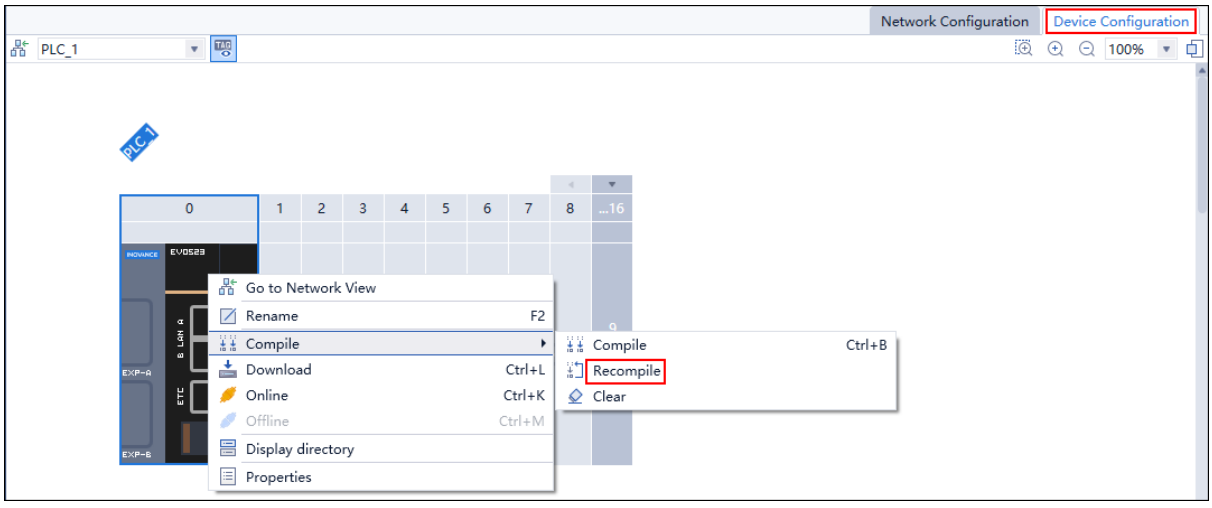
> **NOTE**
>
> Under the premise that the source code remains unchanged, recompiling, clearing, and full clearing operations will not affect the consistency of the compilation, and the project remains online.

Prerequisites

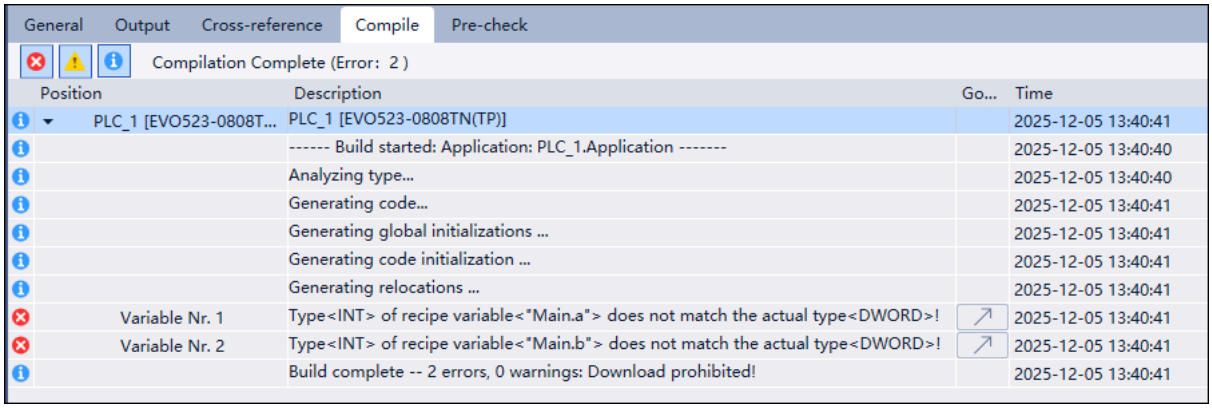


The device is in an offline status.

Procedure



1. Execute the recompilation command.
   There are several ways to recompile.
   - Menu bar: In the project tree, select the corresponding PLC project and select "Compile > Recompile" in the menu bar.
   - Right-click menu: Right-click the corresponding PLC project in the project tree and select "Compile > Recompile" to download the project to the device, as shown in the following figure:



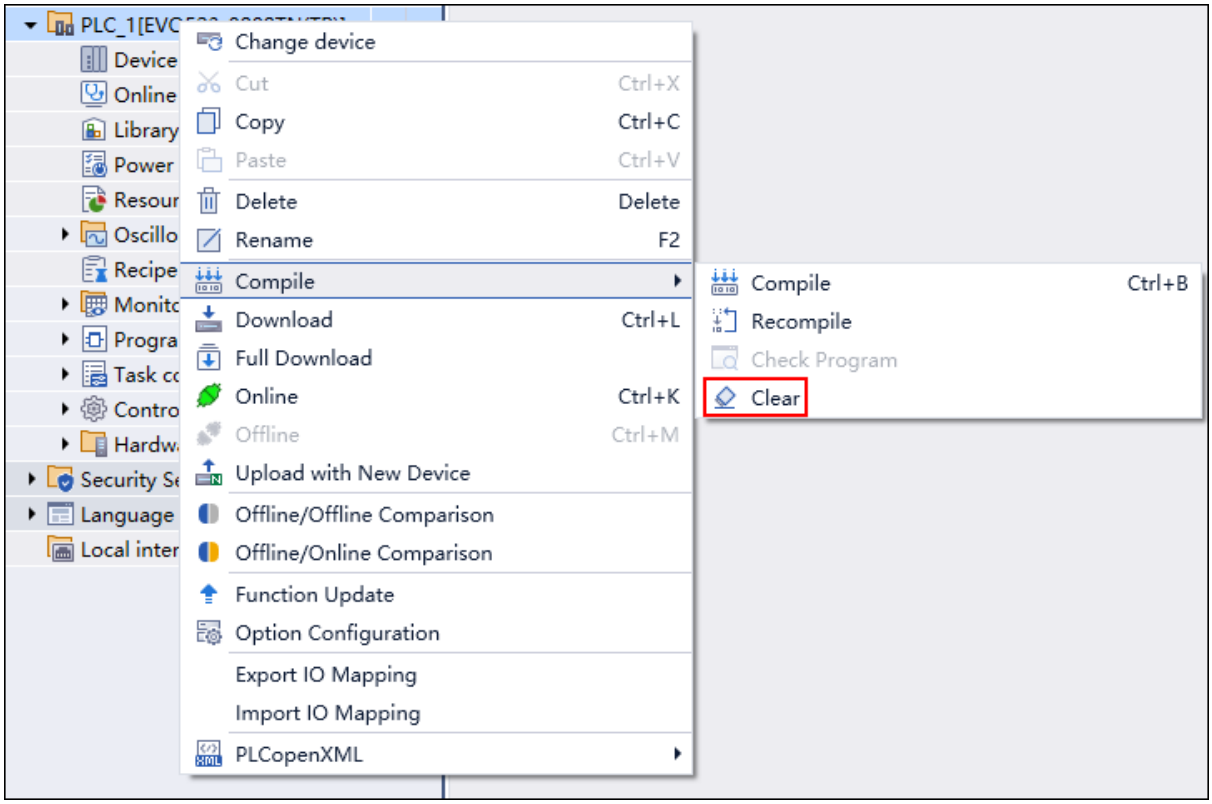
- Network view: In the "Network configuration" interface, right-click the corresponding PLC and select "Compile > Recompile".

- Device view: In the "Device configuration" interface, right-click the corresponding PLC and select "Compile > Recompile".

2. View the compilation information. After recompilation, the corresponding compilation information will be displayed in the "Compile" tab in the monitoring area.

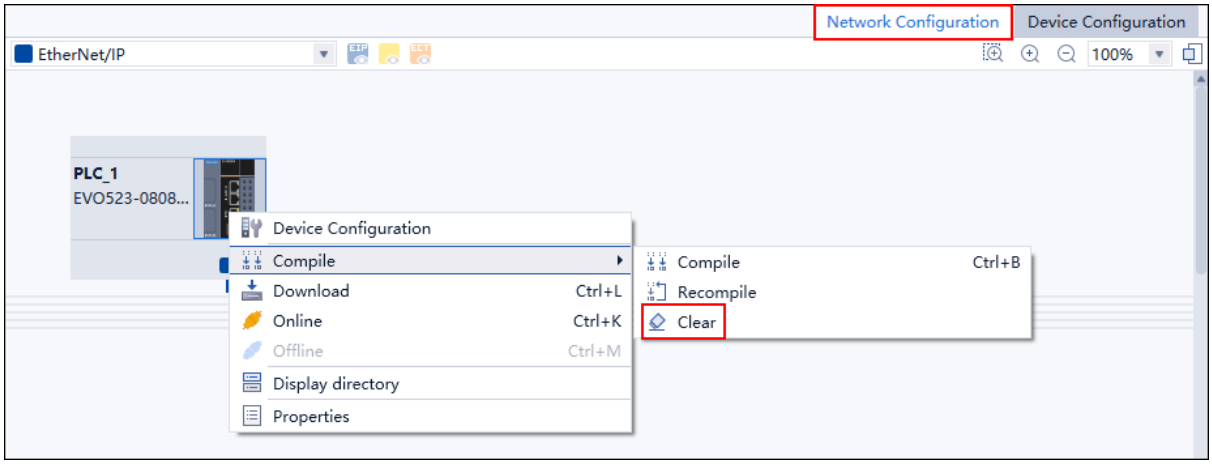
10.7.5 Clearing

Clear the compilation information of the current device (excluding library information). If you log in to the device again, the compilation information needs to be regenerated.



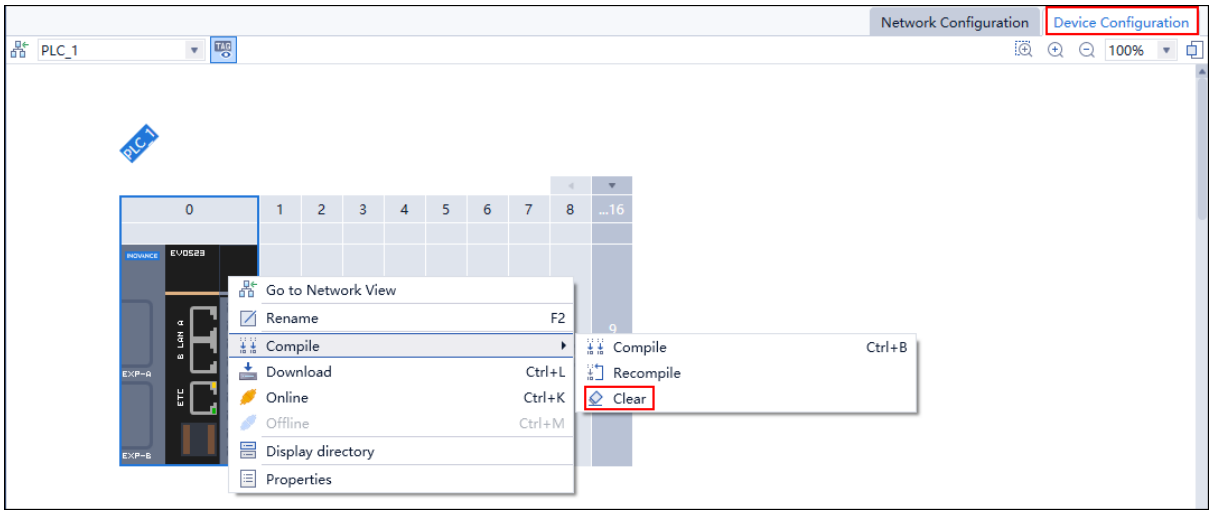
> **NOTE**
>
> Under the premise that the source code remains unchanged, recompiling, clearing, and full clearing operations will not affect the consistency of the compilation, and the project remains online.

Prerequisites



The current device is in an offline status.

Procedure



1. There are several ways to clear the compilation information of the project.
   - Menu bar: In the project tree, select the corresponding PLC project and select "Compile > Clear" in the menu bar.
   - Right-click menu: Right-click the corresponding PLC project in the project tree and select "Compile > Clear", as shown in the following figure:

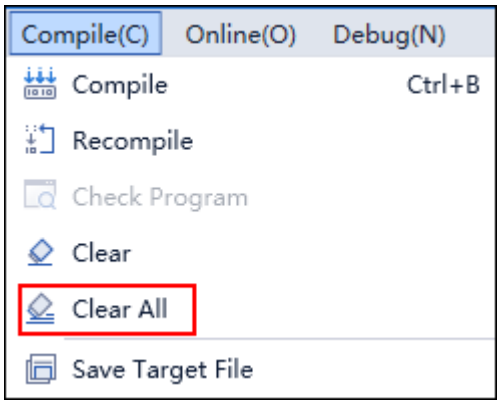
◦ Network view: In the "Network configuration" interface, right-click the corresponding PLC and select "Compile > Clear".

◦ Device view: In the "Device configuration" interface, right-click the corresponding PLC and select "Compile > Clear".

2. In the pop-up "Confirm to clear" window, click "OK" to perform the clear operation.

10.7.6 Clearing All

Clear all compilation information, download information, and reference information from all devices, and refresh the compilation information for all libraries and project data.



> NOTE
>
> Under the premise that the source code remains unchanged, recompiling, clearing, and full clearing operations will not affect the consistency of the compilation, and the project remains online.

Prerequisites

All current devices are in an offline status.

Procedure

1. Select "Compile > Clear All" in the menu bar to clear all related information.

2. In the pop-up "Confirm to clear" window, click "OK" to perform the clearing all operation.

10.7.7 Option Configuration

10.7.7.1 Compilation Options

The software supports configuring compilation options before compilation.

Function entry

Right-click a PLC project node in the project tree and select "Option configuration" to open the configuration interface.

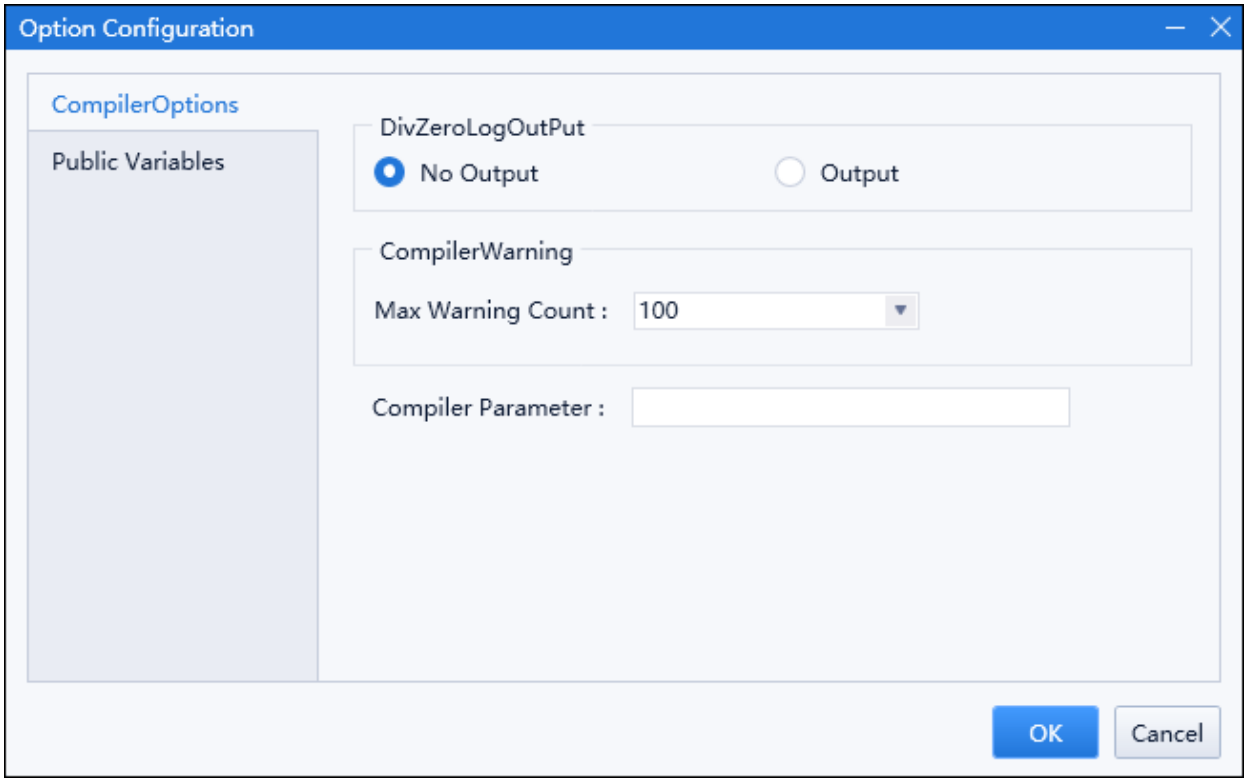


Figure 10-7-7-1-1 Compilation option configuration interface of EVO800 PLC

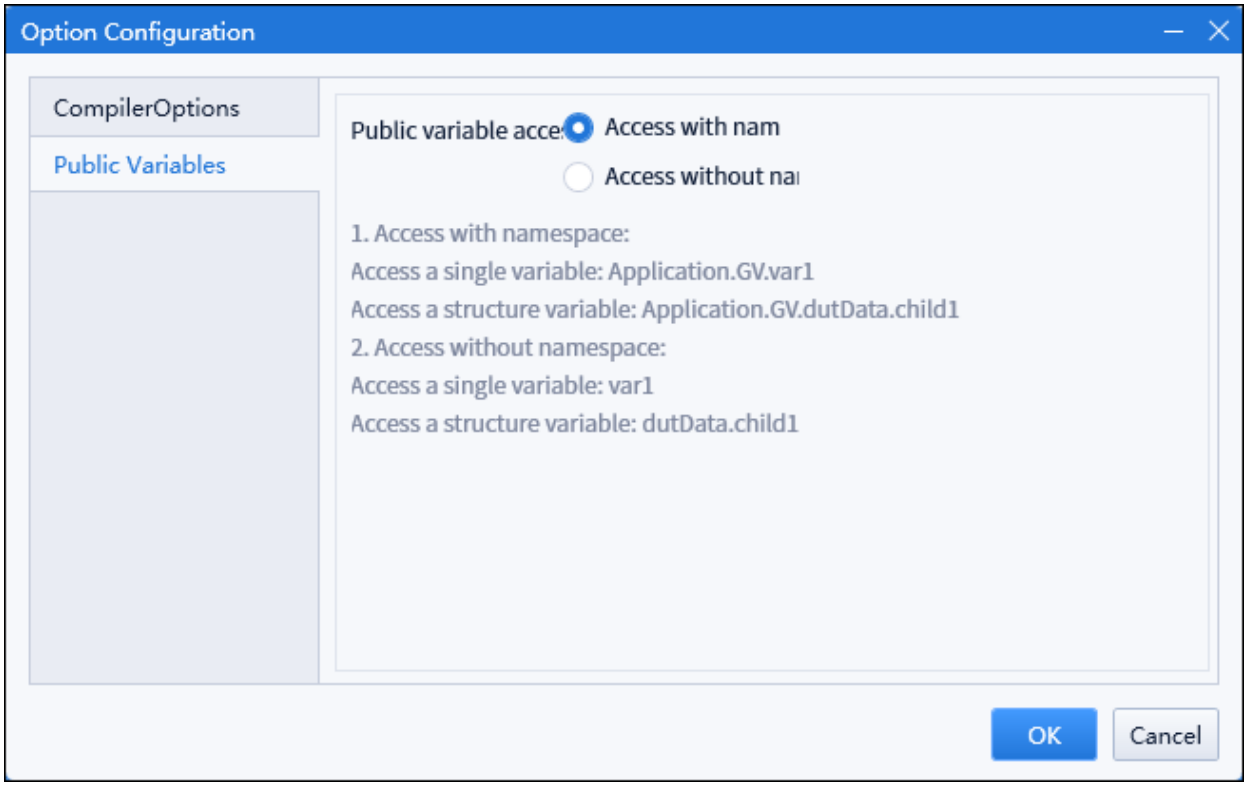
- Division by zero diagnostic information
  - No output: Do not output diagnostic information.
  - Output: Output diagnostic information.
- Configuration
  - Support pointer: If checked, using pointers will trigger an alarm; if unchecked, the use of pointers is prohibited, and any usage will result in a fault.
- Compilation alarm
  - Maximum number of alarms: Configurable to 100/200; after configuration, compilation can only report the corresponding number of pre-compilation messages.
- Compiler parameter
  Indicates developer parameters Users do not need to pay attention.

NOTE



The EVO400/EVO500 series PLC does not support pointer settings.

10.7.7.2 Public Variables

Software supports configuring public variables before compilation.

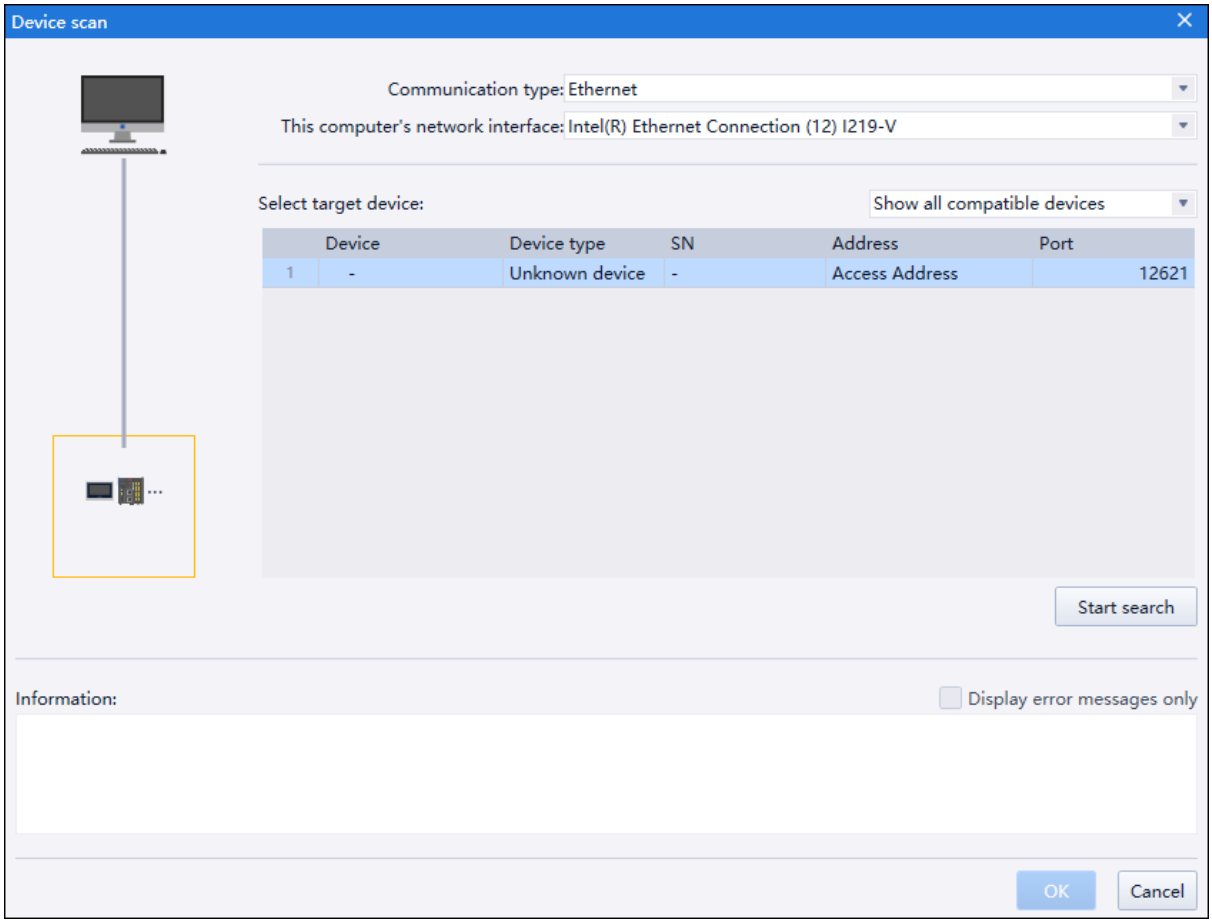
Function entry

Right-click a PLC project node in the project tree and select "Option configuration > Public variables" to open the configuration interface.

- Public variable access configuration
  - Access with namespace: If checked, users can access network public variables in this device using "Application.Namespace.VariableName", which supports duplicate variable names.
  - Access without namespace: If checked, users can directly access network public variables in this device using "VariableName", and duplicate variable names are not supported.

NOTE

The EVO500 series PLC V1.2 version currently does not support the public variable configuration feature.



10.8 PLC Download

10.8.1 PLC Connection

Before downloading the PLC, establish a connection between the computer and the PLC, and set the connection method, IP address, and other communication parameters.

Device scanning

1. Select "Online > Download" in the menu bar to open the "Device scanning" window.

2. Set communication parameters.
   Select the communication type and the network interface of this computer, then click "Start search".
   The virtual PLC only supports Ethernet communication type. For details, see 10.13.2 Establishing a Simulation Environment.

3. Check the target controller information.
   Verify the name, SN code, IP address, port information of the target PLC, or check whether the RUN indicator of the target object flashes to ensure proper connection.
   The virtual PLC does not support connection check via RUN indicator or SN code comparison.

NOTE

The EVO800 series PLC supports downloading and debugging via the Ethernet port of the Ethernet expansion module. When performing device scanning through the Ethernet expansion module port, only the PLC to which the currently connected Ethernet expansion module belongs can be scanned; other PLCs cannot be scanned.

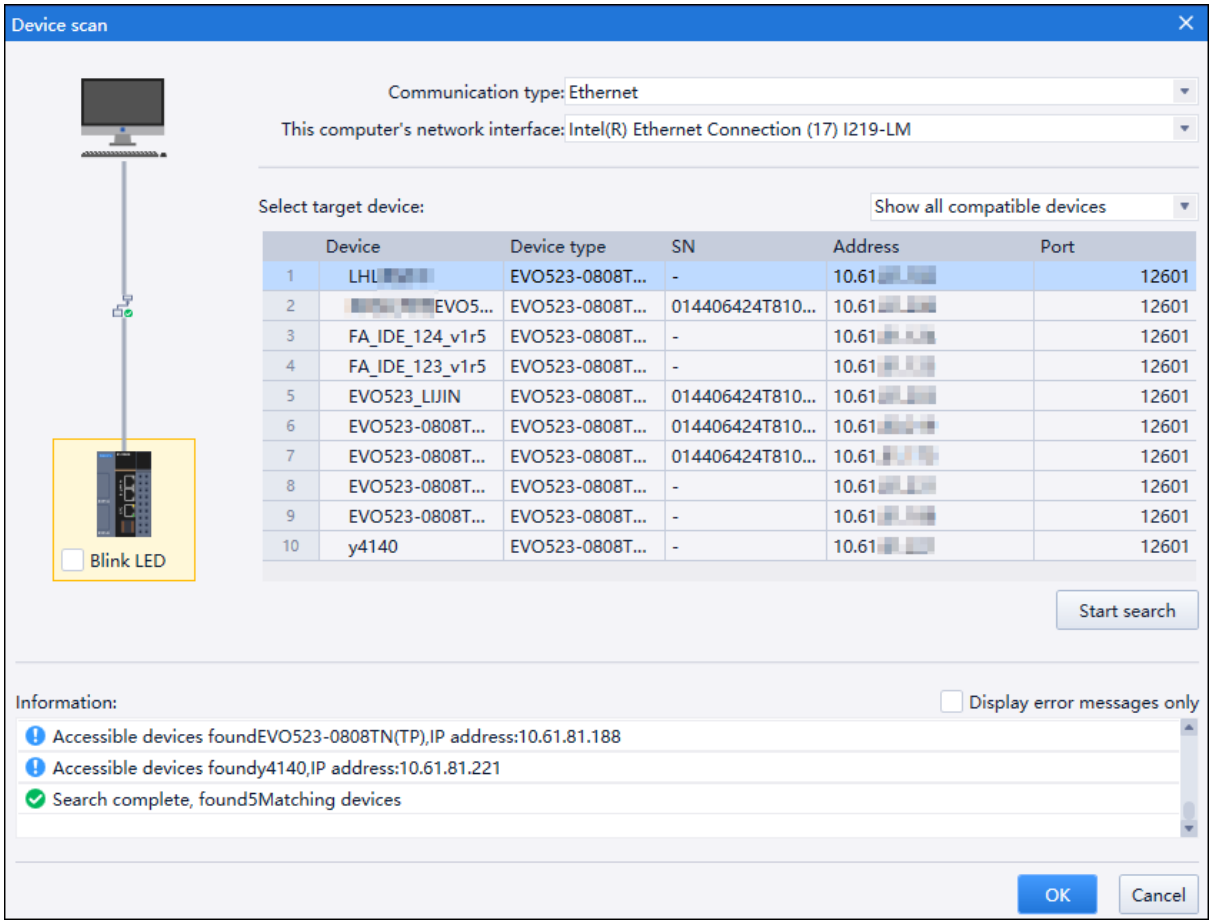


Figure 10-8-1-1 Physical PLC search results

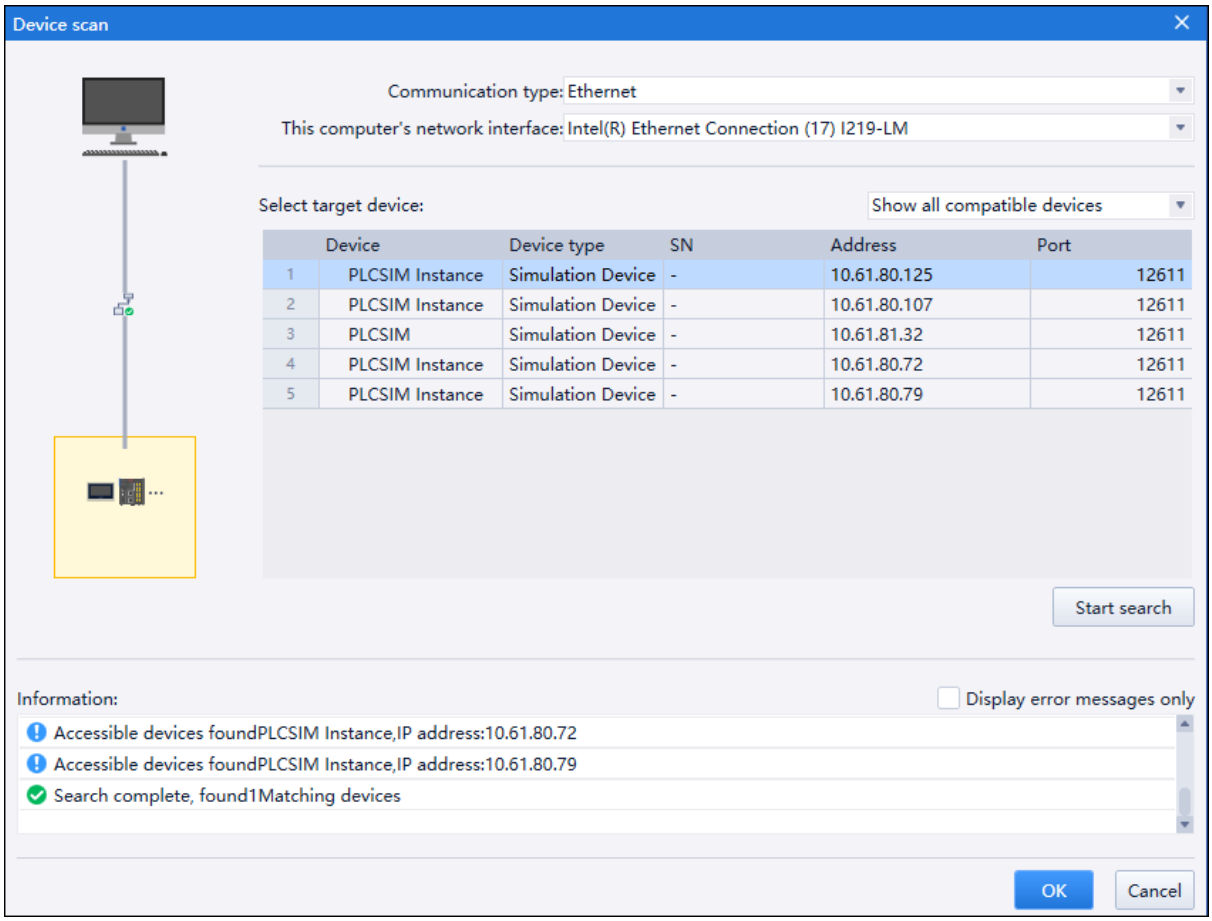

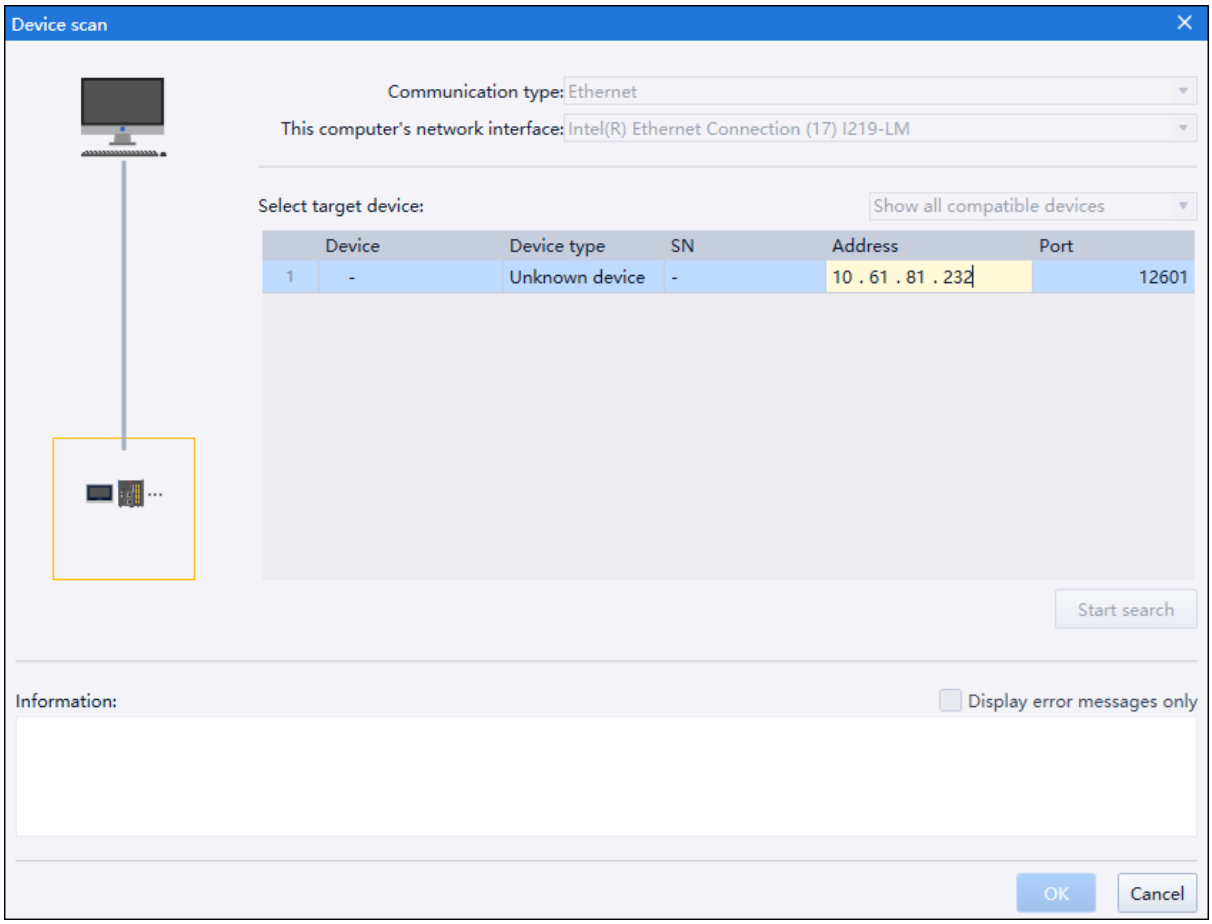

Figure 10-8-1-2 Virtual PLC search results

4. Confirm the connection object.

   Select the target PLC and click "OK" to establish the connection between the computer and the target PLC.

Direct connection

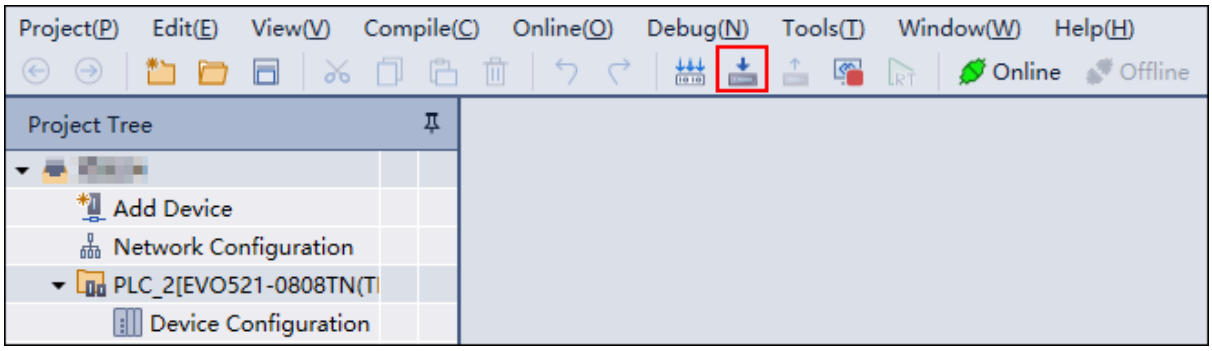
1. Select "Online > Download" in the menu bar to open the "Device scanning" window.
2. Double-click the address area, enter the IP address of the target device, and click any other area to directly connect to the target device.

10.8.2 Download Permission Check

The upload/download operations of the PLC are restricted by both software user permissions and PLC access permissions. The upload/download operations are supported only when both permissions are satisfied.

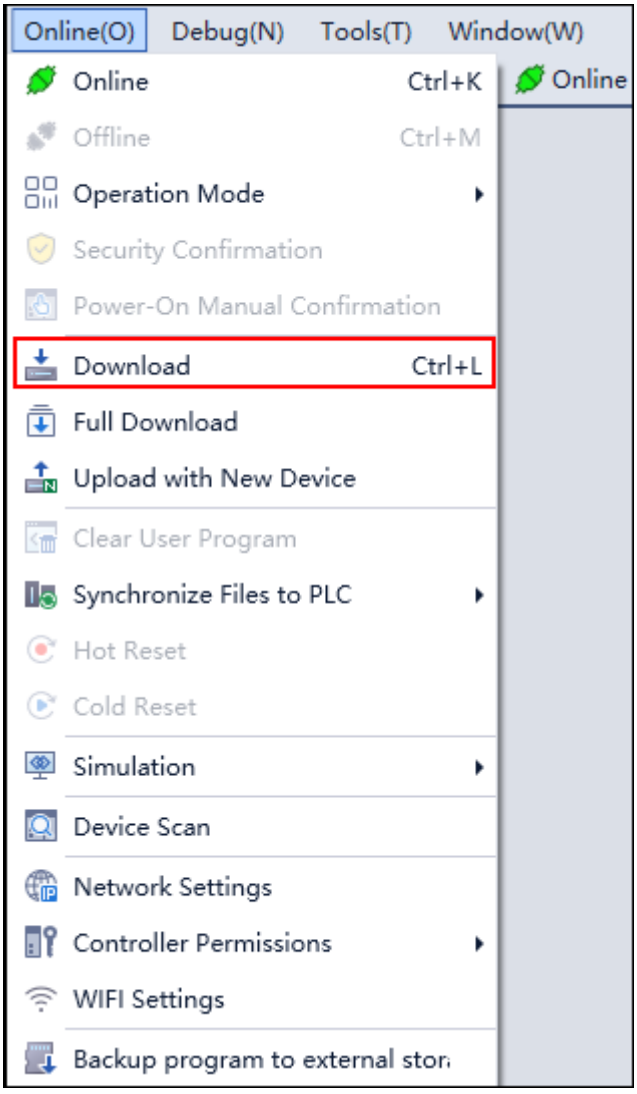
- User login permission of the iFA software
  Users logged in to the software must have the permission to download PLC projects. For details, see 9.1 Permission Management.
- PLC access permission
  If 10.11.24 upload/download permissions are set for the PLC, password verification will be performed during the execution of upload/download commands.
- PLC operation permission

Users need to log in to the software to execute the PLC operations with the corresponding permissions. For details, see 10.11.6 PLC Permission Settings.



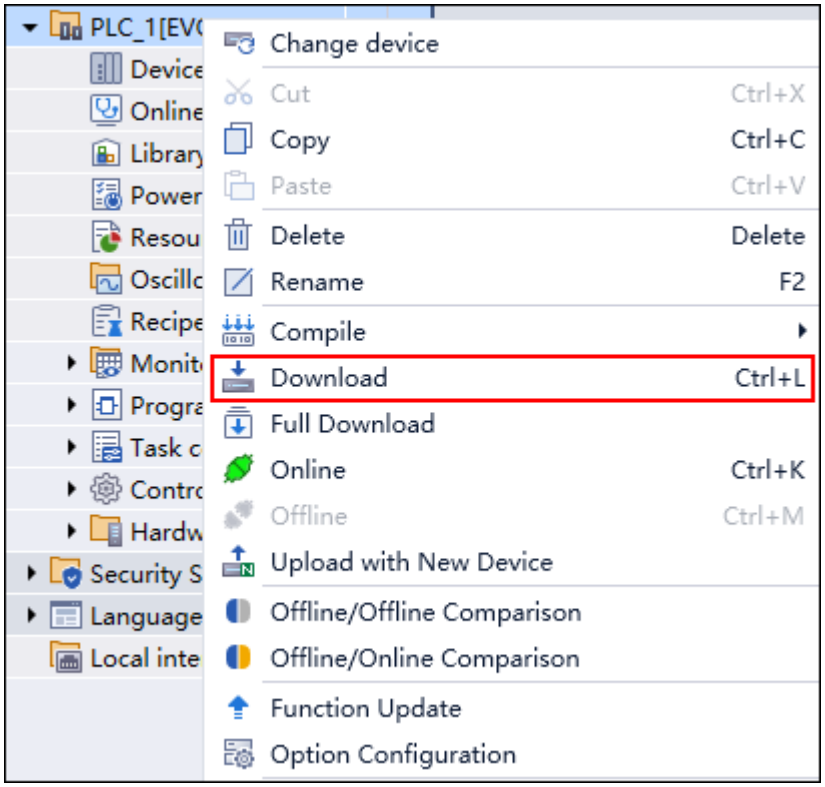
10.8.3 Full Download

Prerequisites



- A program or hardware configuration has changed.
- The project is in offline mode.

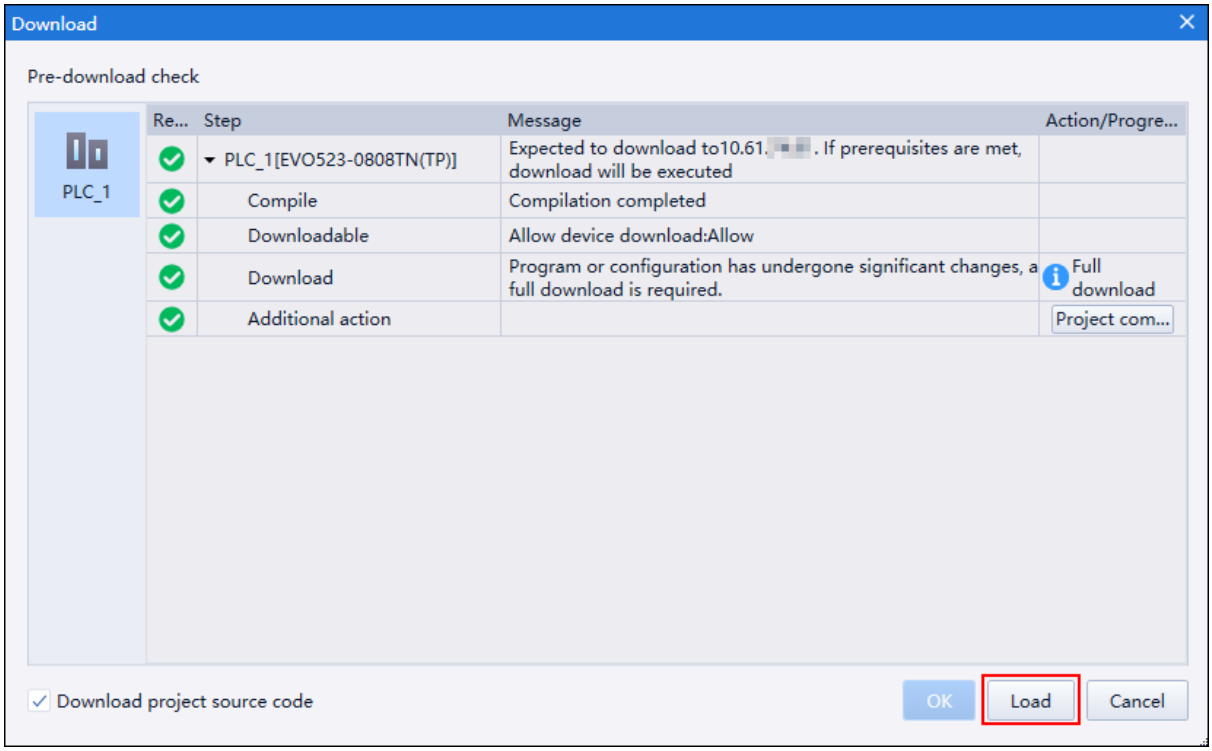
Procedure



1. Click "Download".
   There are three download entries: the toolbar, the menu bar, and the right-click menu of the PLC node in the project tree.
   - Toolbar: Select the corresponding PLC project in the project tree, then click the "Download" icon in the Toolbar, as shown in the figure below.

   - Menu bar: Select the corresponding PLC project in the project tree, then click "Online > Download" in the menu bar, as shown in the figure below.

   - Right-click menu: Right-click the corresponding PLC project in the project tree, then select "Download", as shown in the figure below.



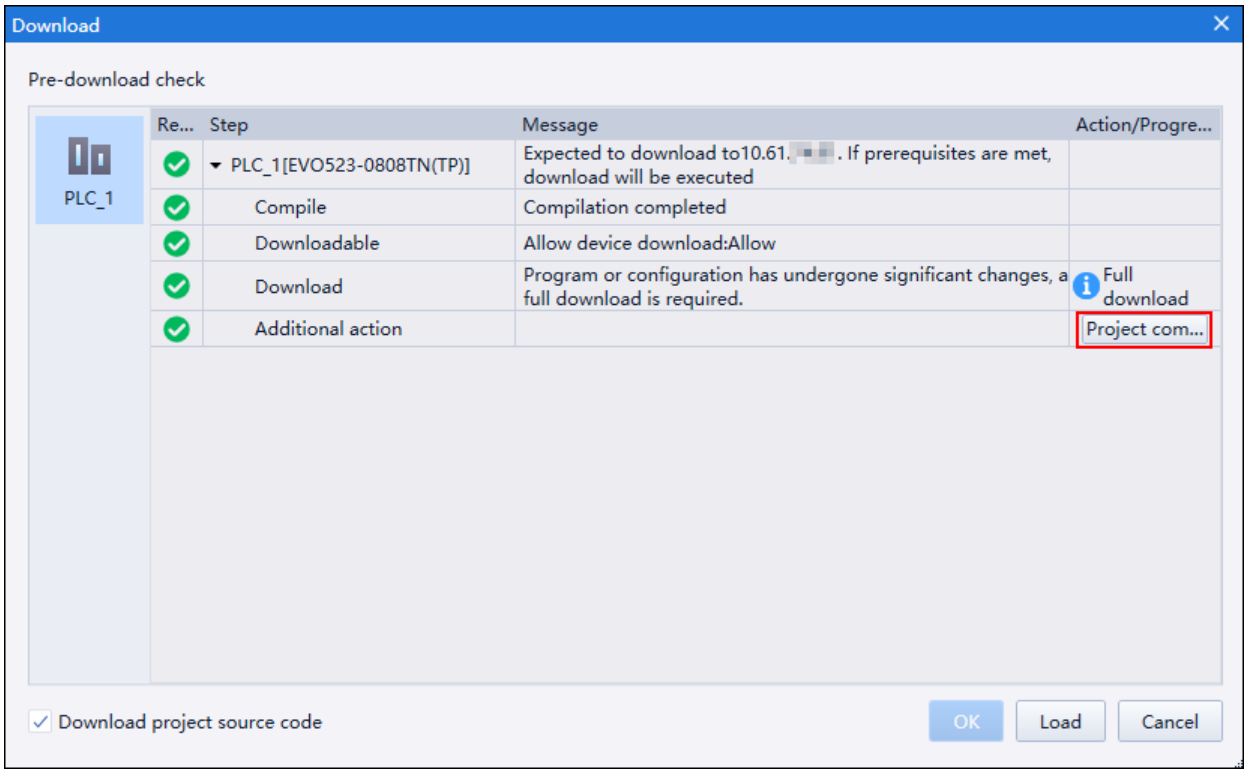
2. Configure download options.

   In the pop-up device scanning window, click "Start search". Select the target device to download, then click "OK", as shown in the figure below.

3. Check before downloading.

   Before downloading, a series of checks will be performed, and information such as the IP address of the target device will be prompted. After configuration, click "Load", as shown in the figure below:

The main check items are as follows:



- Check whether shutdown is required
  For programs that must stop the PLC before downloading, users must select the "Stop device" action before downloading.
- Automatic compilation before downloading
  If compilation has not been performed before downloading, compilation will be automatically executed.
- Confirm whether to download project source code
  By default, "Download project source code" is checked, which will download the project source code to the PLC. If unchecked, the project source code will not be downloaded to the PLC.
- Check for encryption permissions downgrade
  A security prompt will be issued if the encryption permissions are downgraded before downloading.
- Prompt about modified content
  A notification will be displayed before downloading, indicating the modified content, allowing users to review the changes.
- Check for password
  If a password has been set for the PLC, users must enter the password before downloading; otherwise, downloading is not allowed.

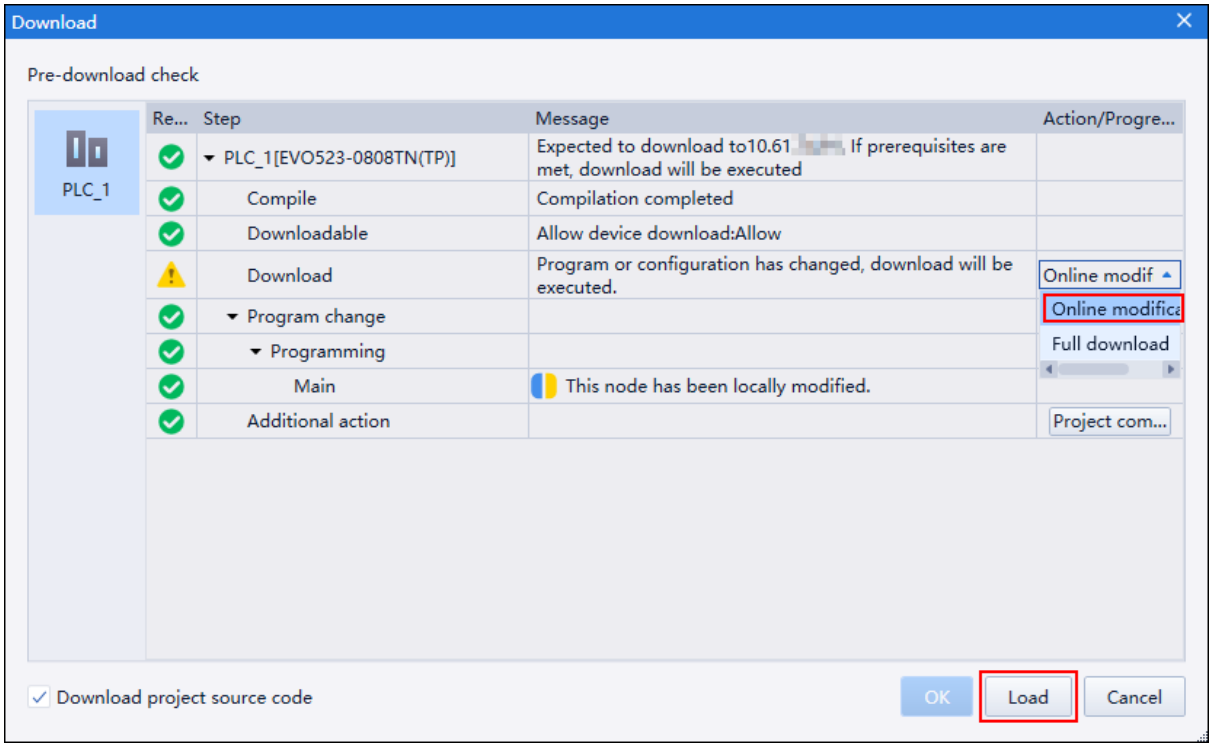
4. Actions after downloading
   After download completes, an option to start the device will appear. Select "Start device" to run the downloaded project; select "No action" to only download the project to the device without starting it, as shown in the figure below.

Project comparison

When downloading a project, click "Project comparison" to view differences in project contents. For details, see 10.12 PLC Project Comparison.

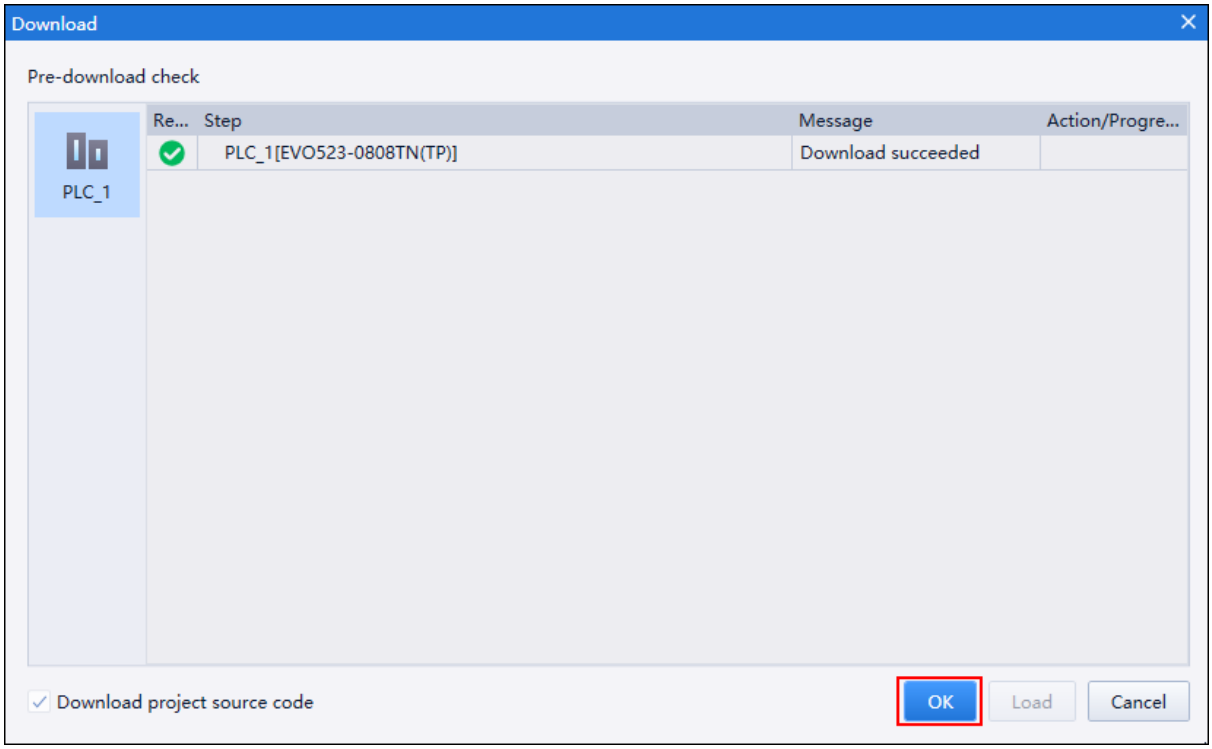
After starting the project comparison, the download operation is canceled and must be restarted to download the project to the device.

10.8.4 Online Modification/Monitoring without Modification



When the project is offline and needs to connect to an online controller, there are two modes:

- Online modification mode: Allows online modification and download of project objects that are not under monitoring in the controller, without stopping the PLC.



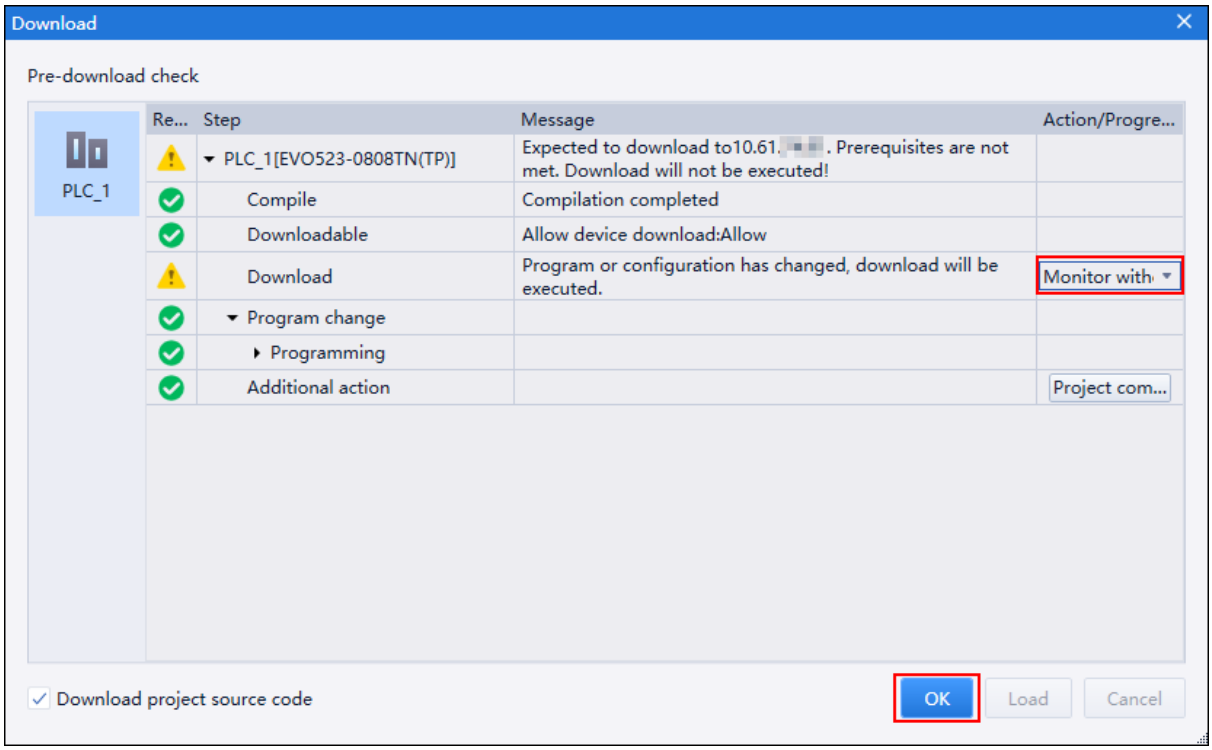
- Monitor without modification mode: Allows online monitoring of data changes from the last project downloaded to the controller.

Online change

1. Compile the project and click "Download" after compilation. If online modification is feasible, the dialog box for download pre-checks will appear, confirming related check items and providing a prompt for the modification content.
2. Select "Online modification" and click "Load" to download the current modification to the device.

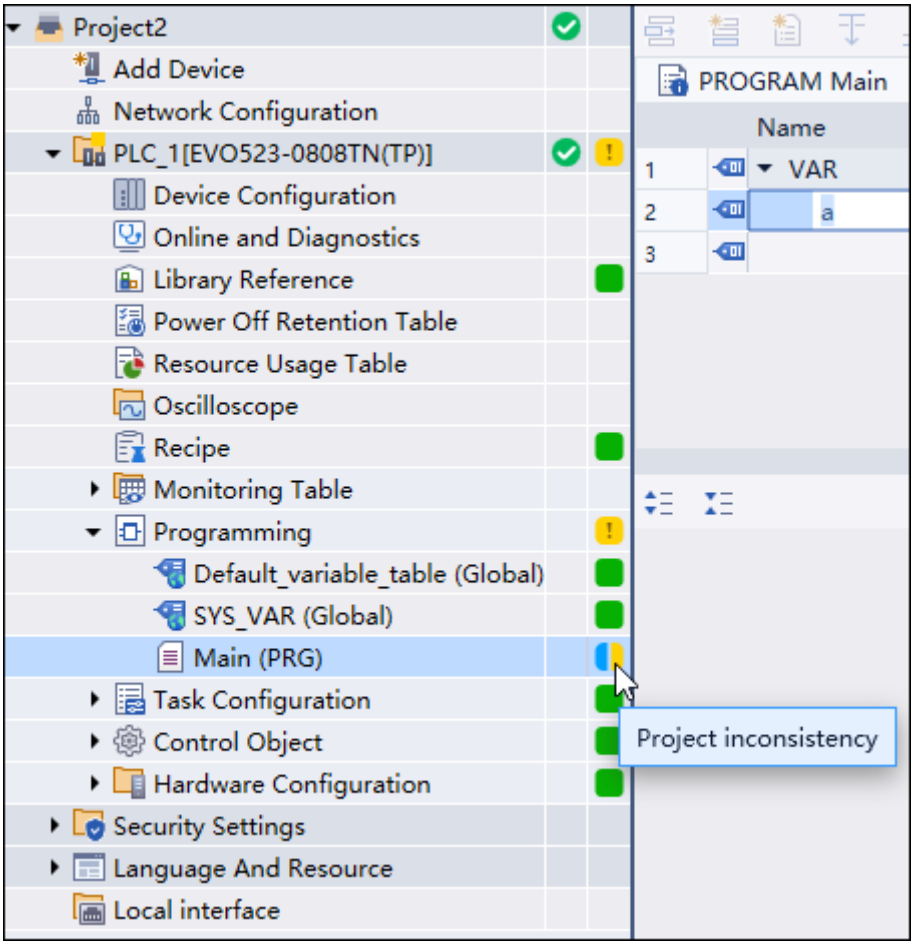
3. After download, a success message appears.

Monitoring without modifying



> **NOTE**
>
> This feature is only available in software versions V1.4.4.5 and earlier.

Prerequisites

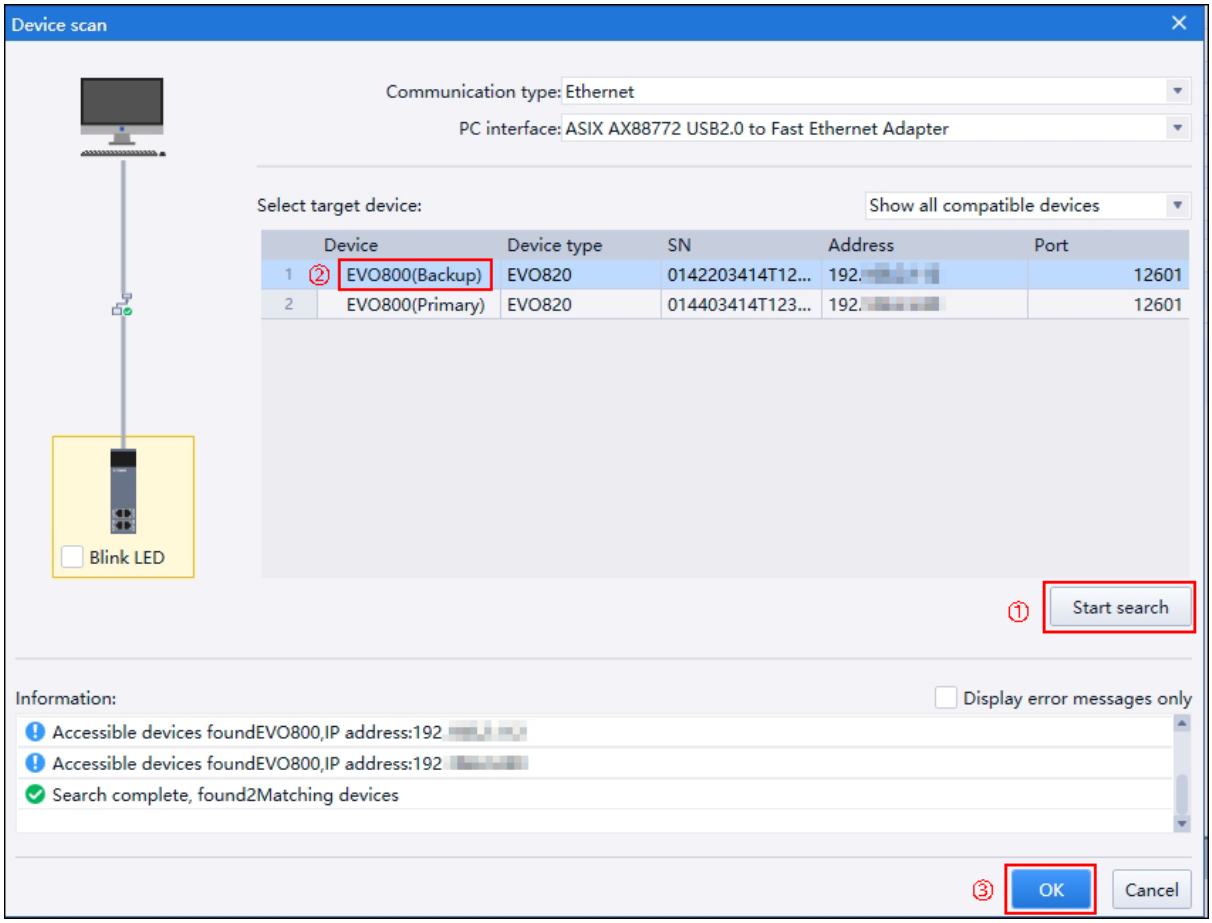


- A program or hardware configuration has changed.
- The project is in offline mode.

Procedure

1. Edit the project and click the "Online" icon in the menu bar. The dialog box for download pre-checks will pop up.
2. Select "Monitor without modification".

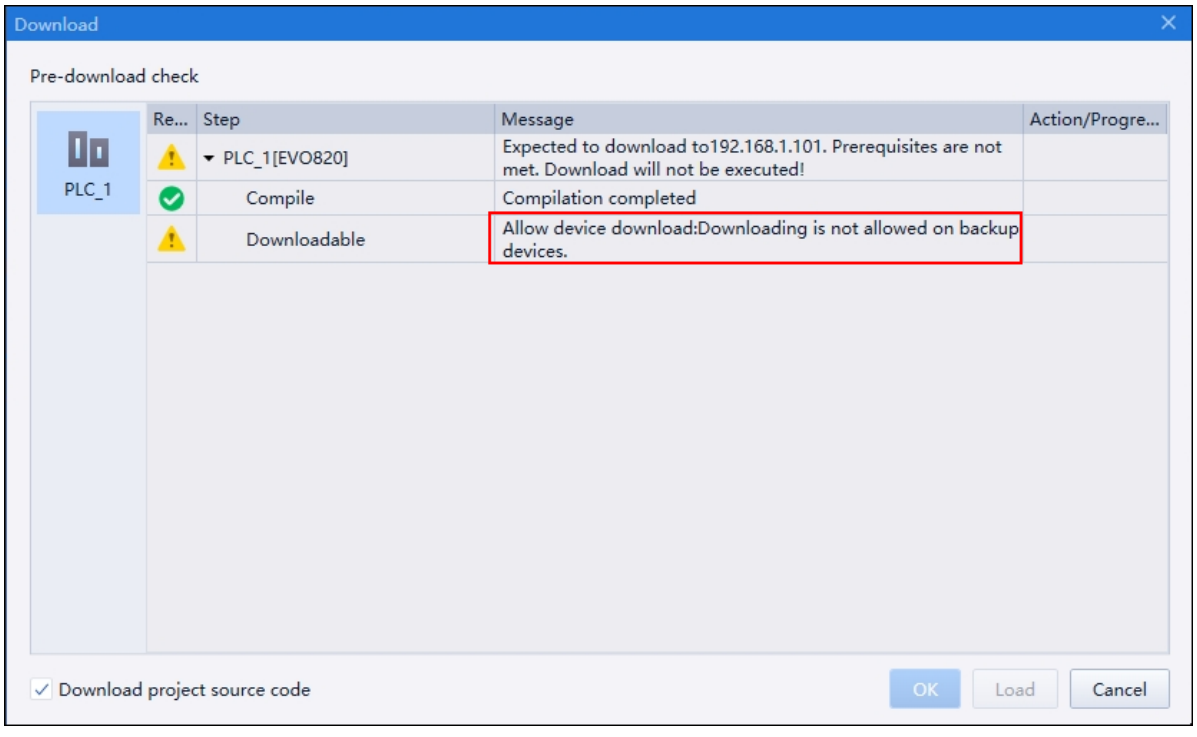
3. The device enters online status, and the project tree displays the data changes in the project, as shown in the figure below.



10.8.5 Redundant System Download (EVO800)

The EVO820 series PLC supports dual-rack redundancy mode. When downloading programs to a redundant system, only the main device can be selected for download. After download, the PLC host synchronizes the new program to the PLC backup unit.

Procedure



1. Right-click the first PLC device under the redundant system in the left project tree, then select "Download".
2. In the pop-up device scanning window, click "Start search", select the target PLC main device, then click "OK" to begin the download.

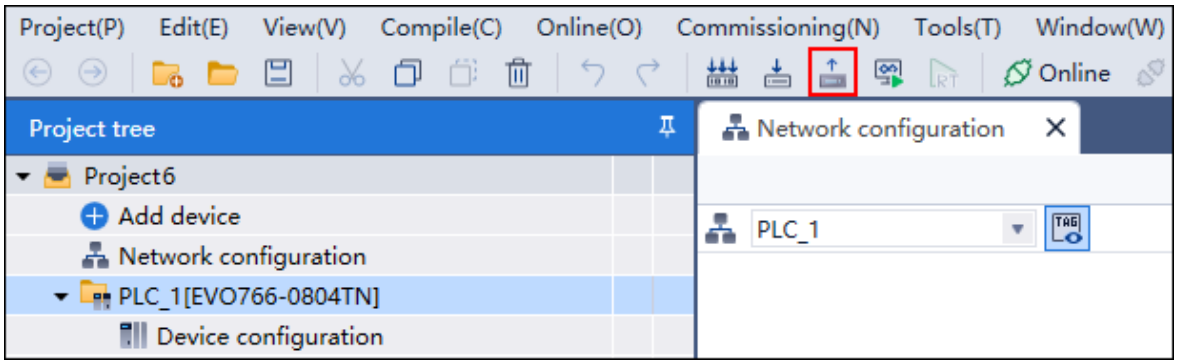
3. The subsequent download procedure is the same as for a single device. For details, see 10.8.3 Full Download and 10.8.4 Online Modification/Monitoring without Modifying.

NOTE

A redundant system only allows downloading to the main device. When attempting to connect to the backup device, the download interface will display a message indicating that downloading is not allowed, as shown in the figure below.

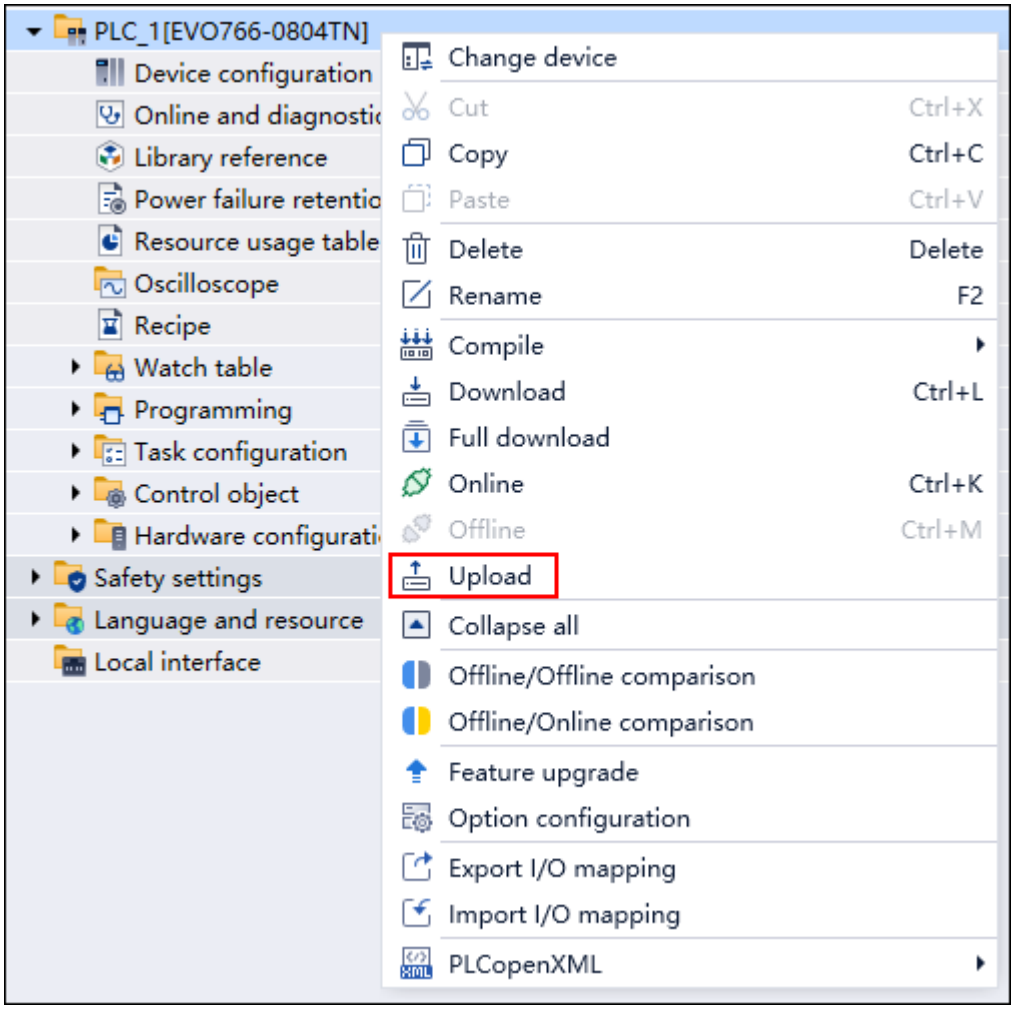
10.9 PLC Upload

10.9.1 Uploading



This function overwrites the existing devices in the software with the project source code (including source code, compilation information files, device configuration files, etc.) from the device.

Prerequisites

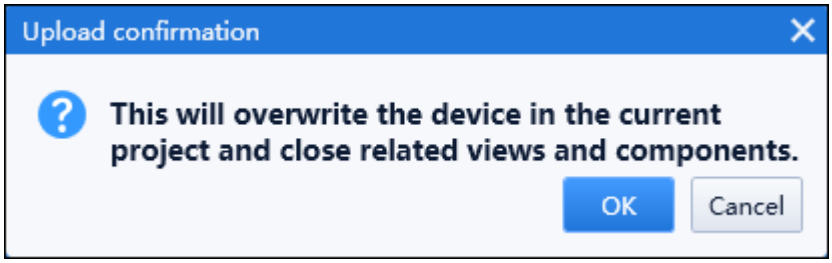


The project is in offline mode.

Procedure

1. Click "Upload".
   There are two upload entries: the toolbar and the right-click menu of the PLC node in the project tree.
   - Toolbar: Select the corresponding PLC project in the project tree, then click the "Upload" icon in the Toolbar, as shown in the figure below:

   - Right-click menu: Right-click the corresponding PLC project in the project tree, then select "Upload", as shown in the figure below:



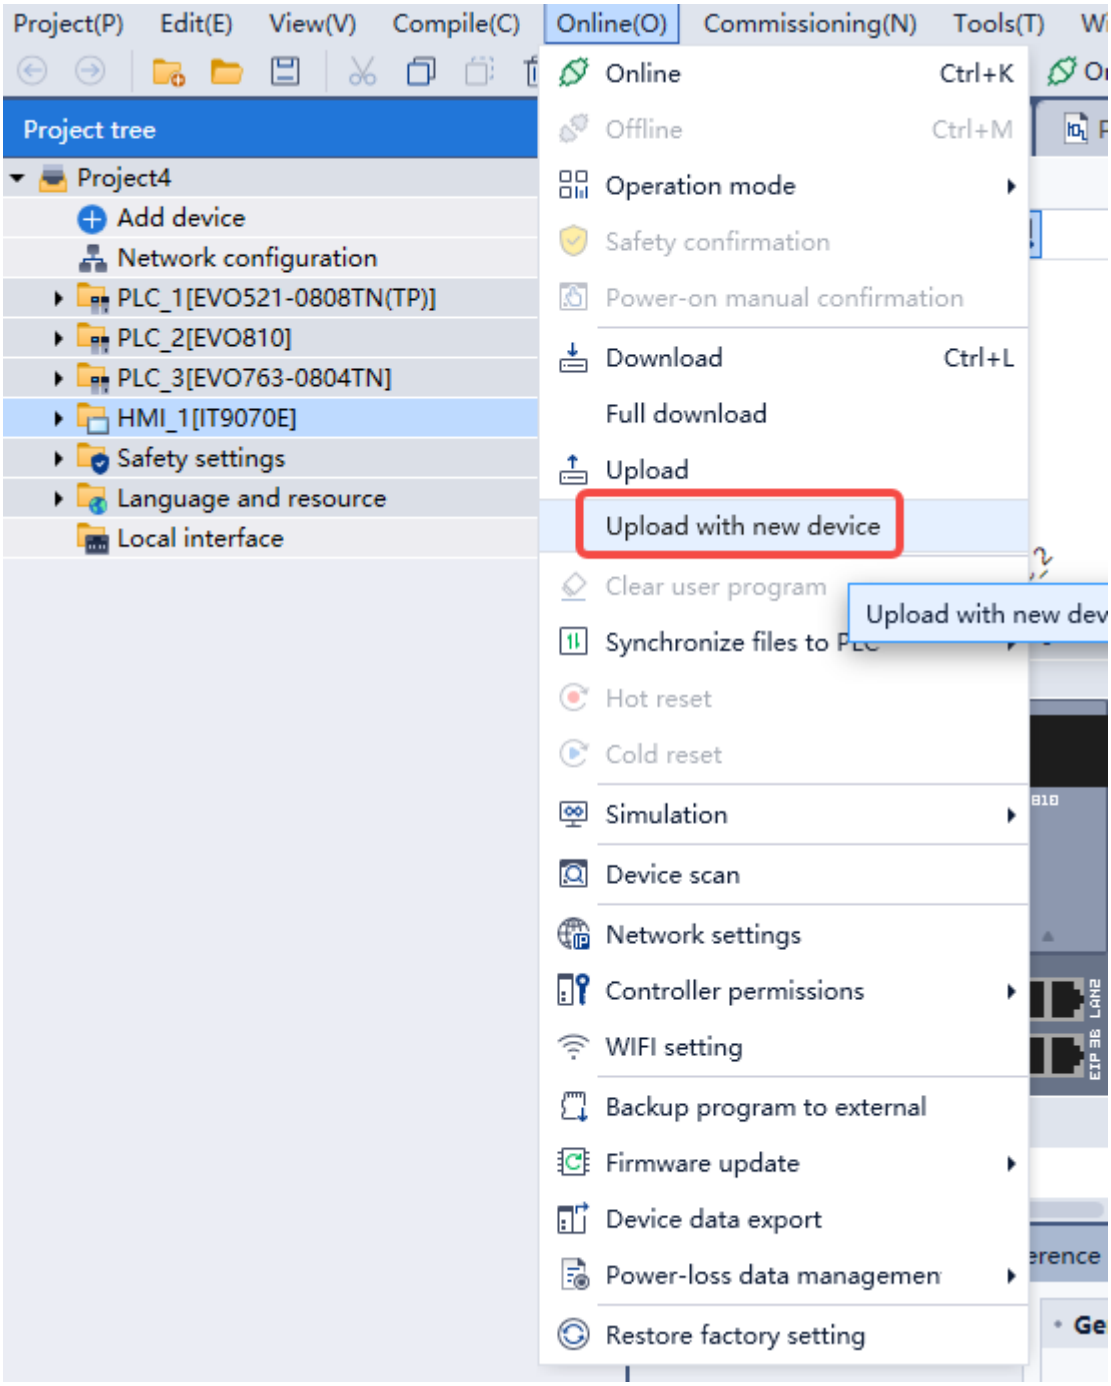
2. Upload configuration.

   In the pop-up device scanning window, click "Start search". Select the target device to upload, then click "OK", as shown in the figure below.

3. Checks before uploading.
   The system will automatically perform the following checks before uploading:
   - Whether the controller model and firmware version of the project in the PLC match the controller model and firmware version selected in the project.
   - Whether the device ID of the project in the PLC matches the device ID selected in the project.
   - Whether the project in the PLC contains source code.
4. Actions after uploading.
   - If all the above checks pass, the "Upload confirmation" window will pop up, prompting that the operation will overwrite the device in the current project and close related views and components. Click "OK" to complete the upload.

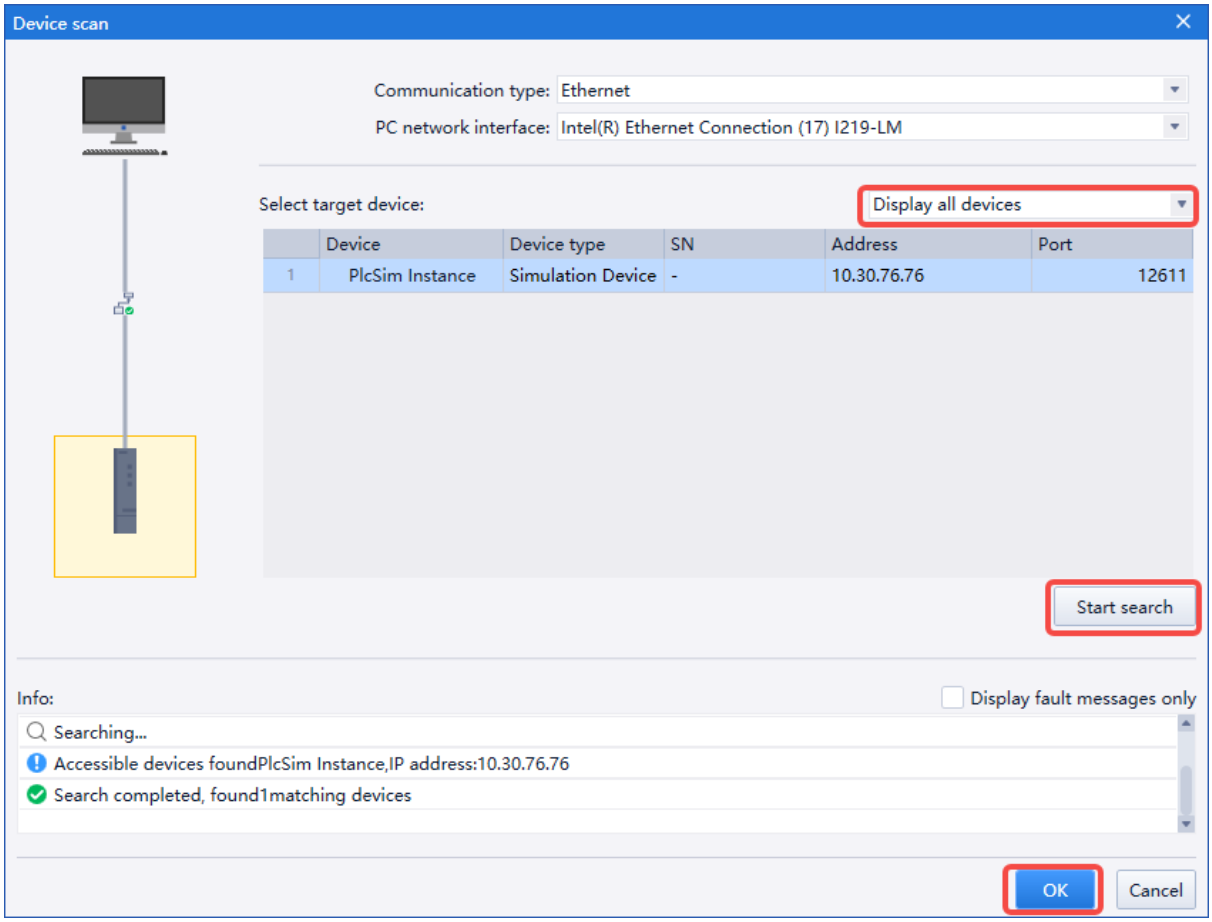
   - If any check fails, an "Error" window will pop up, indicating the reason for the error. Please troubleshoot and handle the issue based on the prompt message in the pop-up window.

10.9.2 Uploading with a New Device



This function uploads the project source code (including source code, compilation information files, device configuration files, etc.) from the device to the software in the form of a new device.

Prerequisites



The software has established communication with the device.

Procedure

1. Select "Online > Upload with new device" in the menu bar.

2. In the pop-up device scanning window, click "Start search". The system will automatically scan for all devices and support filtering by device type. Select the target device to be uploaded and click "OK" to upload, as shown in the figure below:

3. Before uploading, the system will automatically check whether the current project contains a device with the same name or identical configuration.
4. Actions after uploading.
   - If the corresponding device does not exist in the iFA software, the "Upload confirmation" window will pop up, prompting a new device will be created in the current project. Click "OK" to complete the upload.
   - If the project contains a PLC with the same name as the current PLC, a fault will be reported, prompting that the device already exists.
   - If the project content in the PLC is the same as the current project content, a fault will be reported, prompting that the device already exists.

10.10 PLC Commissioning

10.10.1 PLC Start/Stop

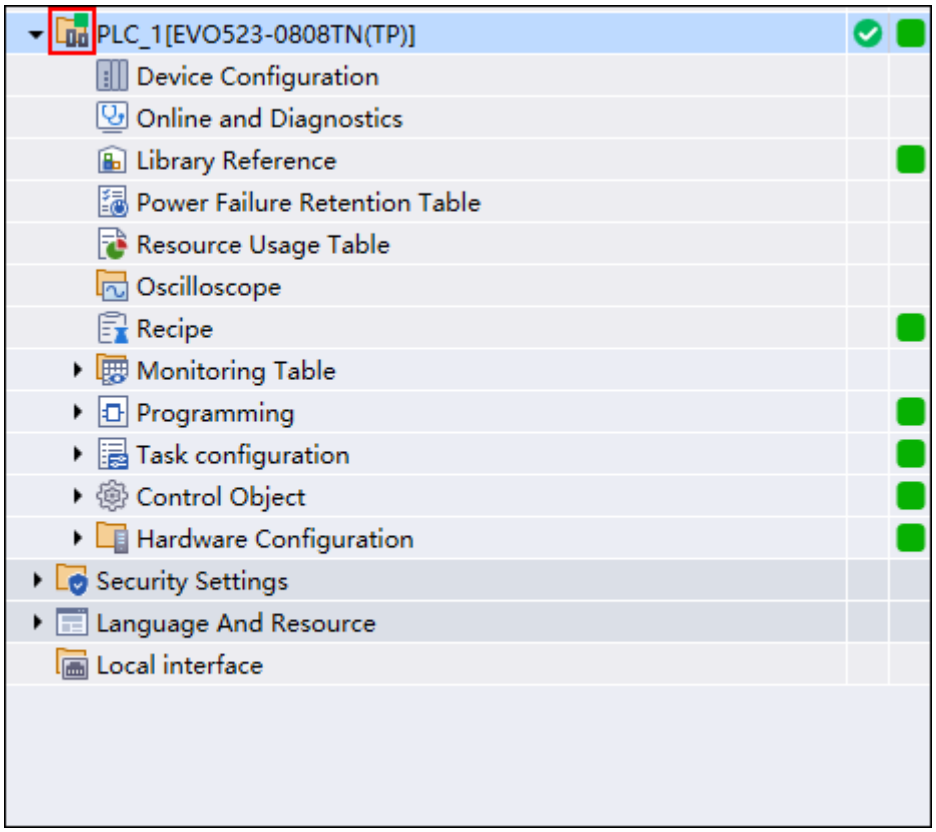
Device startup

Create and deploy the application, and start the service to initiate the application.

Prerequisites

The project has been downloaded to the device.

Procedure



Click the "Start" icon in the toolbar; or select "Commissioning > Start" in the menu bar.

NOTE

If not in simulation mode or no breakpoints are set, a dialog box will appear asking whether to switch the PLC to RUN mode. Click "OK" to start the device.

Result

After the device starts successfully, the device identifier in the project tree changes from yellow to green.

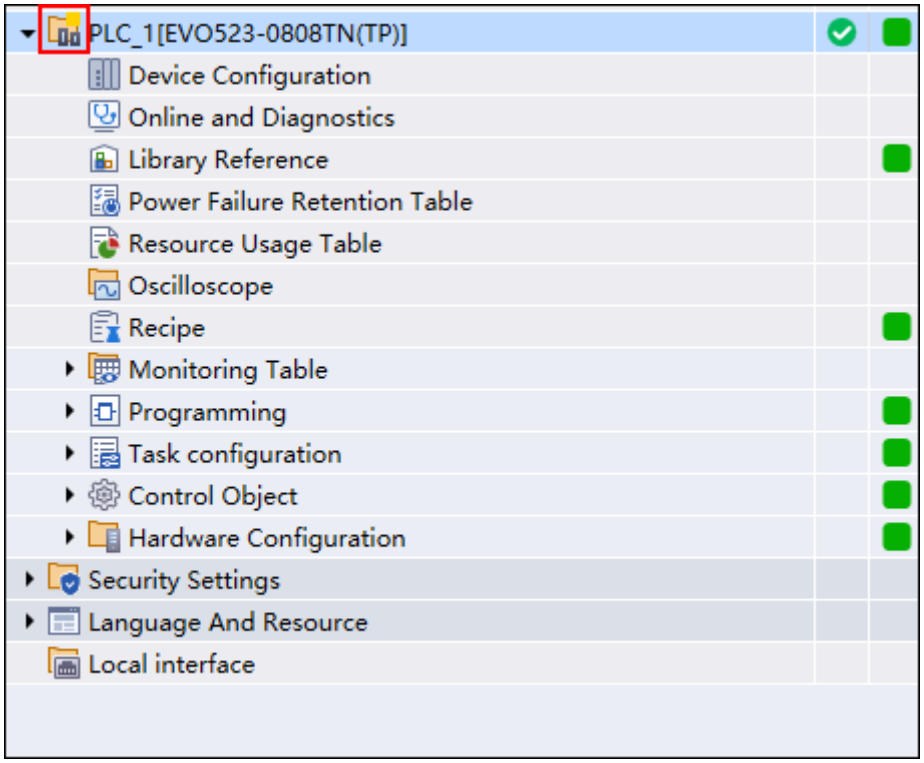
Device stop

Create and deploy the application stop service to stop the application. After the device is started, the stop icon becomes enabled.

Prerequisites

The device has started.

Procedure



Click the "Stop" icon in the toolbar; or select "Commissioning > Stop" in the menu bar.

NOTE

Click the "Stop" icon, and a dialog box will appear asking whether to switch the PLC to STOP mode. Click "OK" to stop the device.

Result

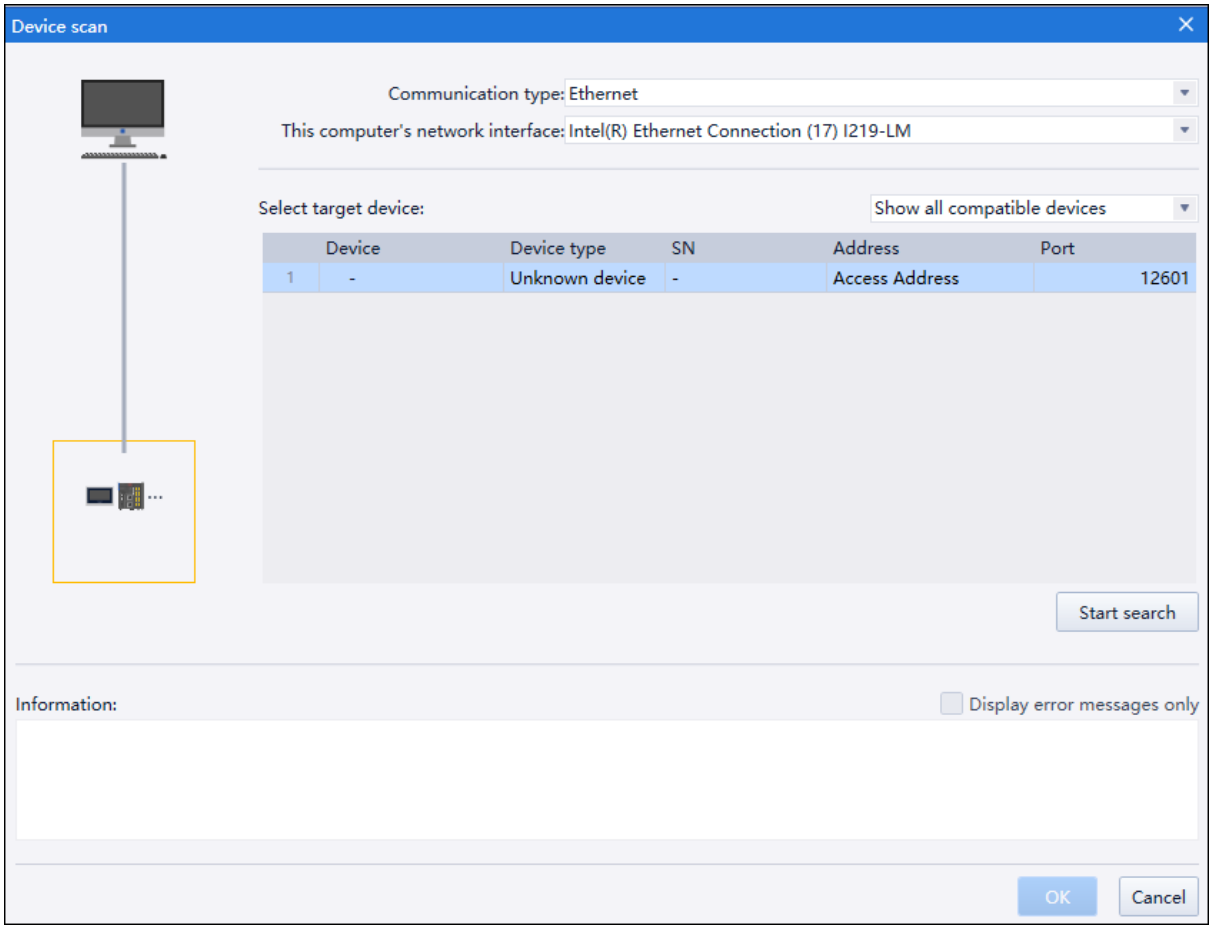
After the device stops successfully, the device identifier in the project tree changes from green to yellow.

NOTE

When the device is manually switched from RUN status to STOP status, the power failure retention variables maintain their previous values, while other variables are reinitialized.

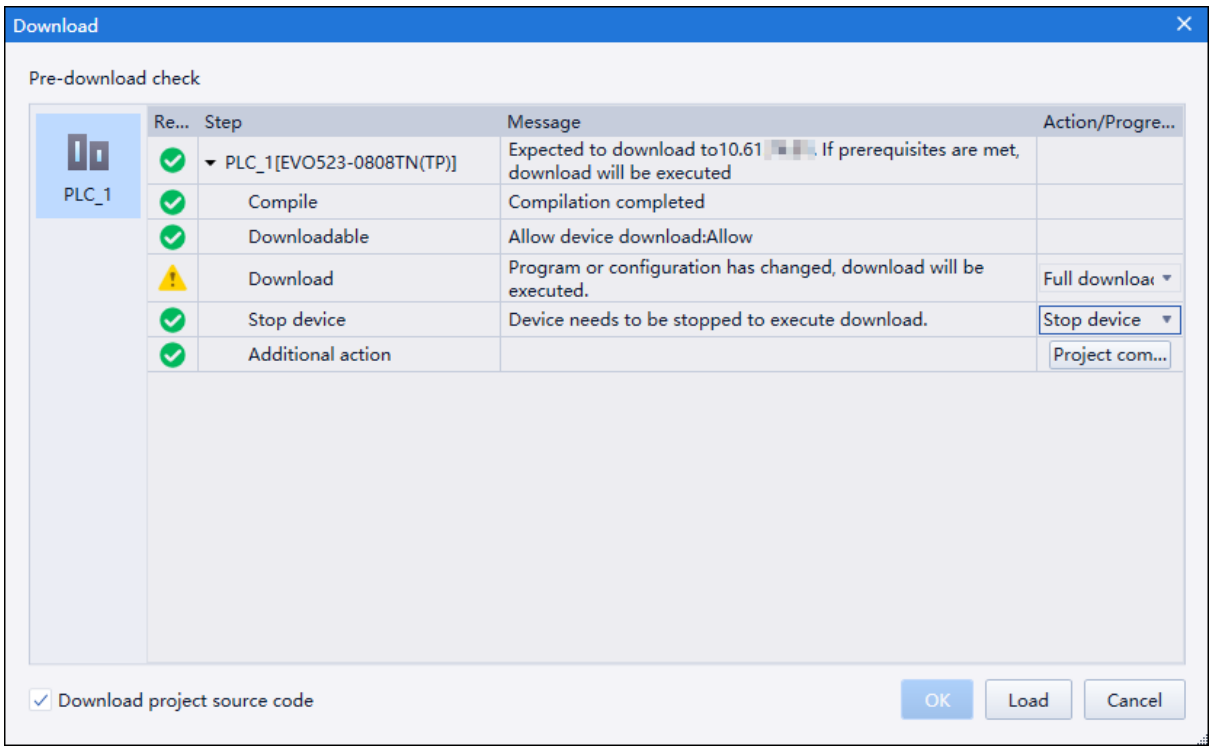
10.10.2 PLC Online/Offline

The online function is used to establish a connection to the device.



Prerequisites

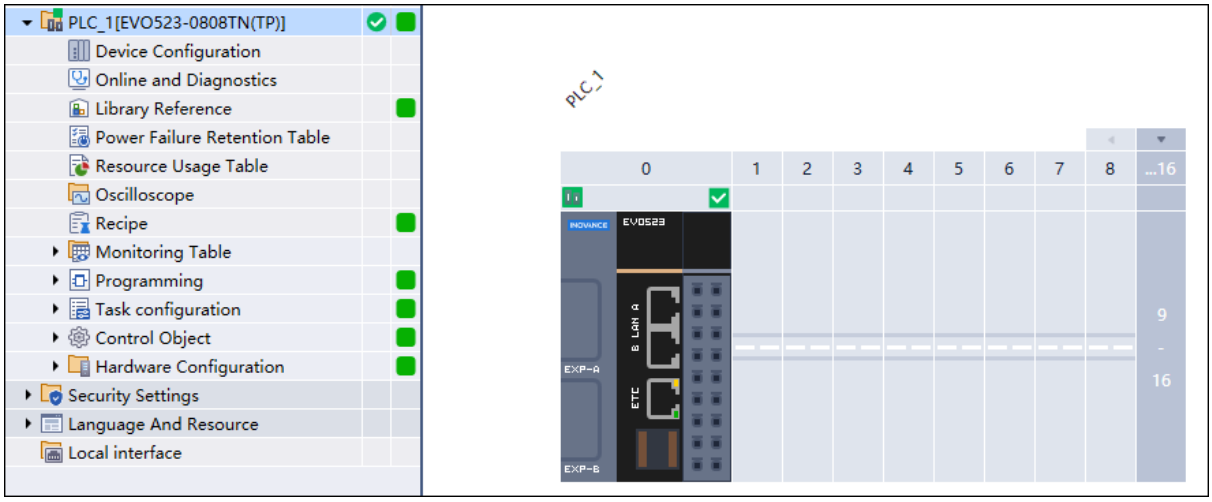
- The project has been downloaded to the device.
- The device is in an offline status.



Procedure

1. Online function entry
   - After selecting the device node in the project tree, click the "Online" icon in the menu bar.
   - Right-click the device node in the project tree and select "Online".
   - After selecting the device, use the Ctrl+K shortcut key to go online; use the Ctrl+M shortcut key to go offline.
   - In the network view/device view, right-click the device and select "Online".

   The online function does not support batch operations for multiple projects. It can only be enabled for a PLC device node or its child node in the project tree. Click "Online" to establish a connection to the device.
2. Go online
   - If the device has not been configured for connection, click "Online" and the following connection configuration window will pop up.



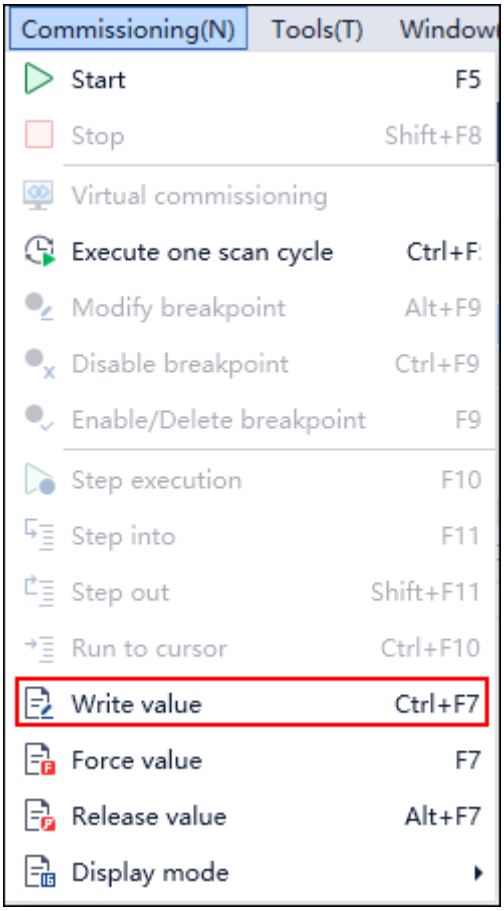
◦ After configuring the connection path, the dialog box for download ore-checks will appear. After downloading, a connection to the device is established.

3. In online mode

After going online, the device identifiers in the project tree and device configuration view will change, as shown in the figure below.

NOTE

- For the EVO800 series redundant system, only the first PLC device under the redundant system in the project tree can be selected to perform the online operation.
- During the online process, in the "Device scanning" window, you can select either the main device or backup device to establish a connection and go online. After going online, the diagnostic information and operation logs will display relevant information about the connected (main or backup) devices.
- For online projects in versions V1.4.3.5 and earlier, after upgrading the software version and going online directly, the project comparison column in the left project tree will display icon differences, which can be ignored. This column can be synchronized by performing re-download or online modification.



10.10.3 Value Display and Calculation

10.10.3.1 Writing a Value

When the PLC is in online running status, values can be written to variables.

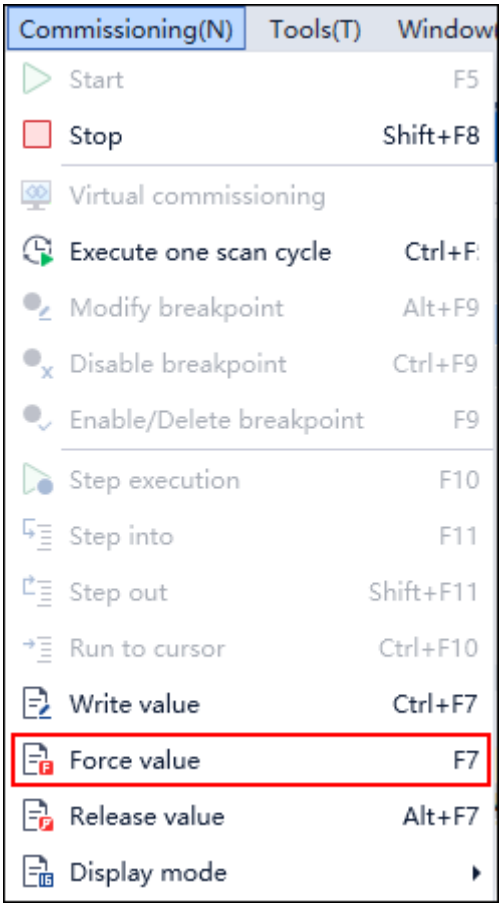
Writing method

- After editing the prepared value, execute the write operation by selecting "Commissioning > Write value" in the menu bar.

- After editing the prepared value, use the shortcut key Ctrl+F7 to execute the write value operation.
- After editing the prepared value, click the "Write value" icon in the toolbar to execute the write value operation.

Result

After writing the value, the value of the variable in the variable declaration area and the program editing area will change to the edited prepared value.



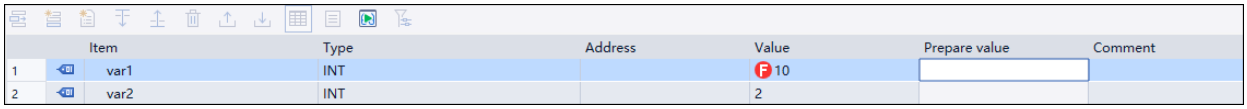
> NOTE
>
> For expressions containing POU calls, their online values cannot be viewed directly. Enter specific index numbers in the watch table to view online data.

10.10.3.2 Forcing a Value

When the PLC is in online running status, a forced value can be written to a variable.

Forcing method

- After editing the prepared value, execute the force value operation by selecting "Commissioning > Force value" in the menu bar to change the variable to the forced status.



- After editing the prepared value, use the shortcut key F7 to execute the force value operation and change the variable to the forced status.

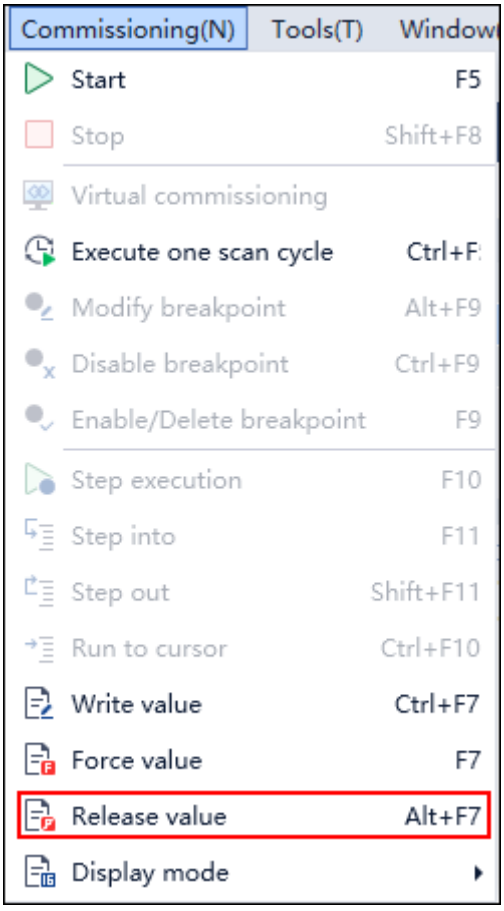
Result

After writing the forced value, the identifier is added at the front of the value. This identifier indicates that the value is a forced value, and the identifier appears in both the variable declaration area and the program editing area.

- Variable declaration area

	Item	Type	Address	Value	Prepare value	Comment
1	var1	INT		10		
2	var2	INT		2		

- Program editing area

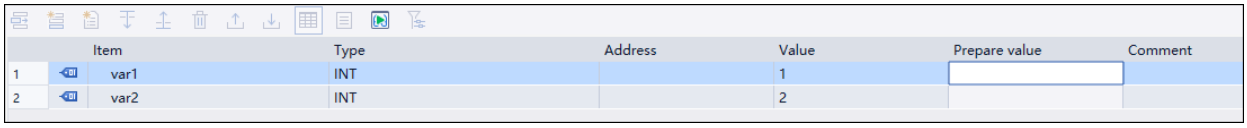


10.10.3.3 Releasing a Value

When the PLC is in online running status, executing the value release operation will release the existing prepared values and forced values, and cancel the forced statuses.

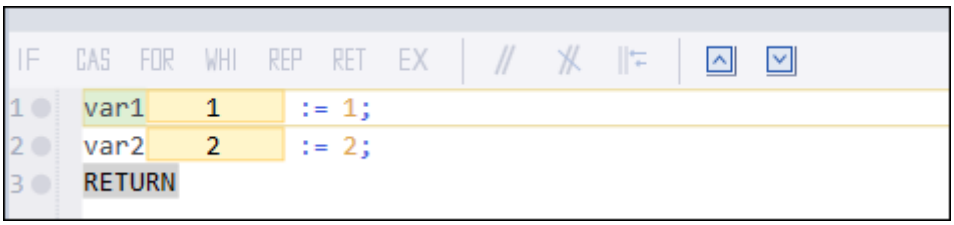
Releasing method

- Select "Commissioning > Release value" in the menu bar to release the forced values.



- The forced values can also be released using the shortcut key Alt+F7.

Result

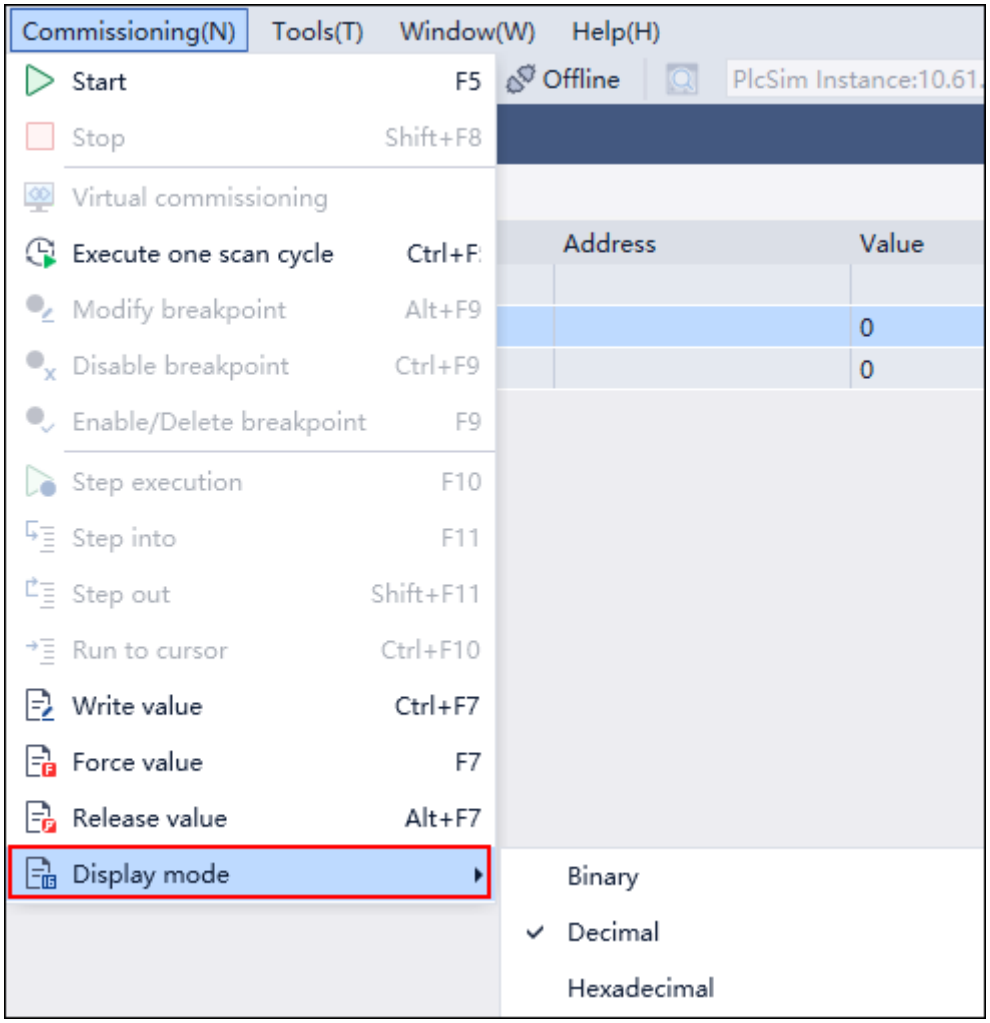


After the forced values are released, the corresponding identifiers disappear.

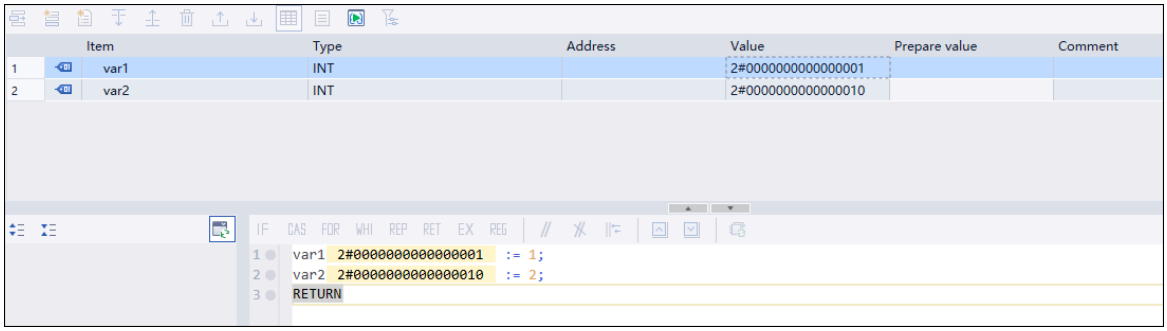
- Variable declaration area

	Item	Type	Address	Value	Prepare value	Comment
1	var1	INT		1		
2	var2	INT		2		

- Program editing area



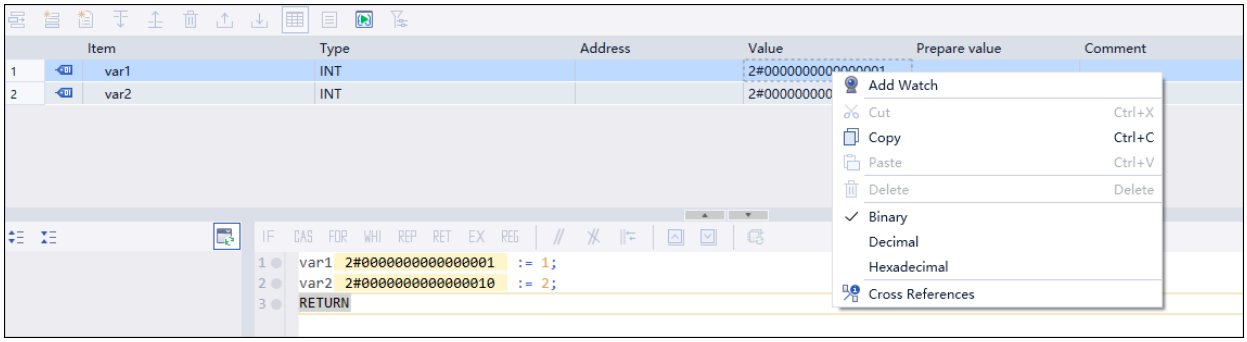
10.10.3.4 Display Modes



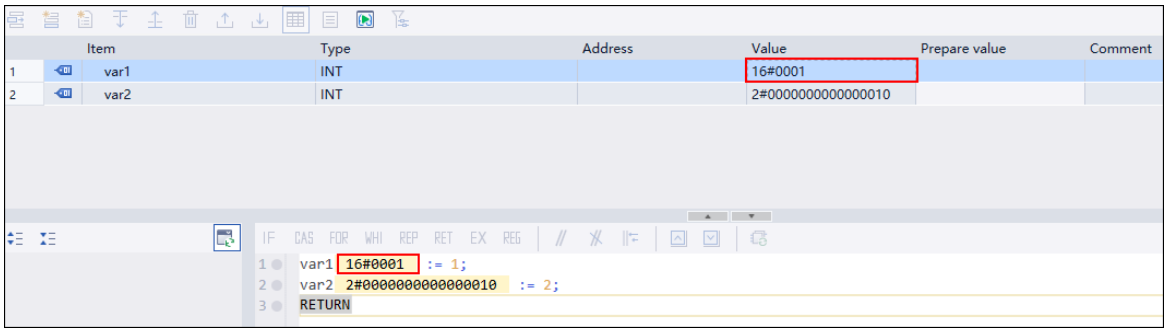
The display mode function allows switching variable values to different number bases for display. For example, this function can be used to switch a variable to binary format for observing the status of each bit.

Switching method

- Select "Commissioning > Display mode" in the menu bar to switch the display mode.



After switching, all variables are displayed in the selected format, as shown in the figure below for binary display.



NOTE

Using this method will change the display mode for all variables.

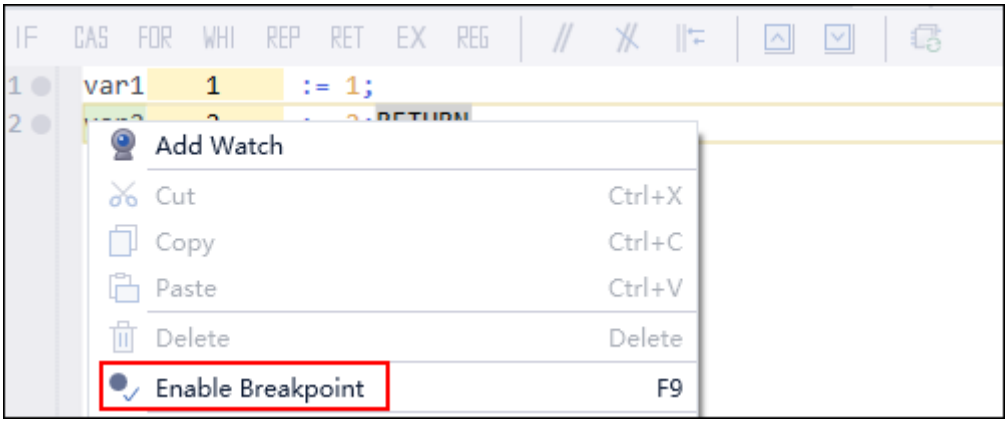
- In online mode, right-click a variable and select a different display mode; the variable's value will then be displayed in the selected mode.

After switching, the variable is displayed in the selected mode, as shown in the figure below.

NOTE

The display mode selected from the menu bar overrides the current variable's display mode.

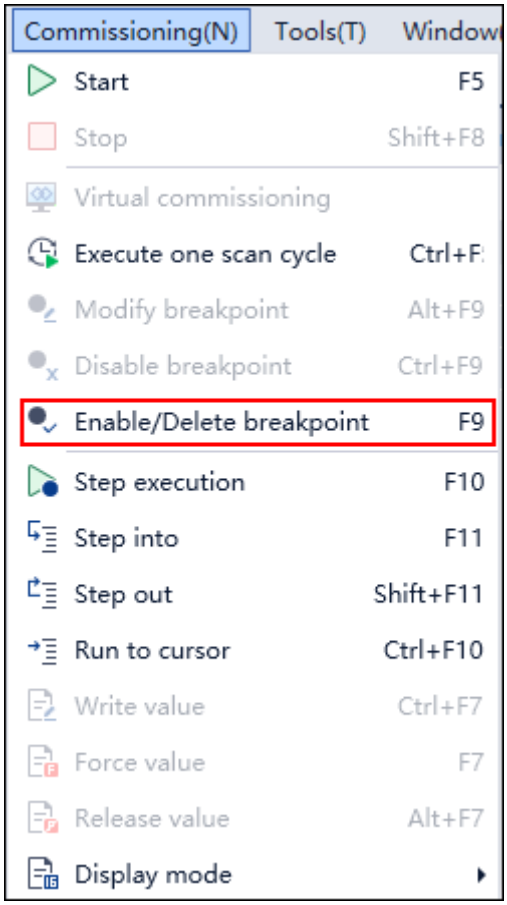
10.10.4 Breakpoint Commissioning



10.10.4.1 Enabling a Breakpoint

Prerequisites

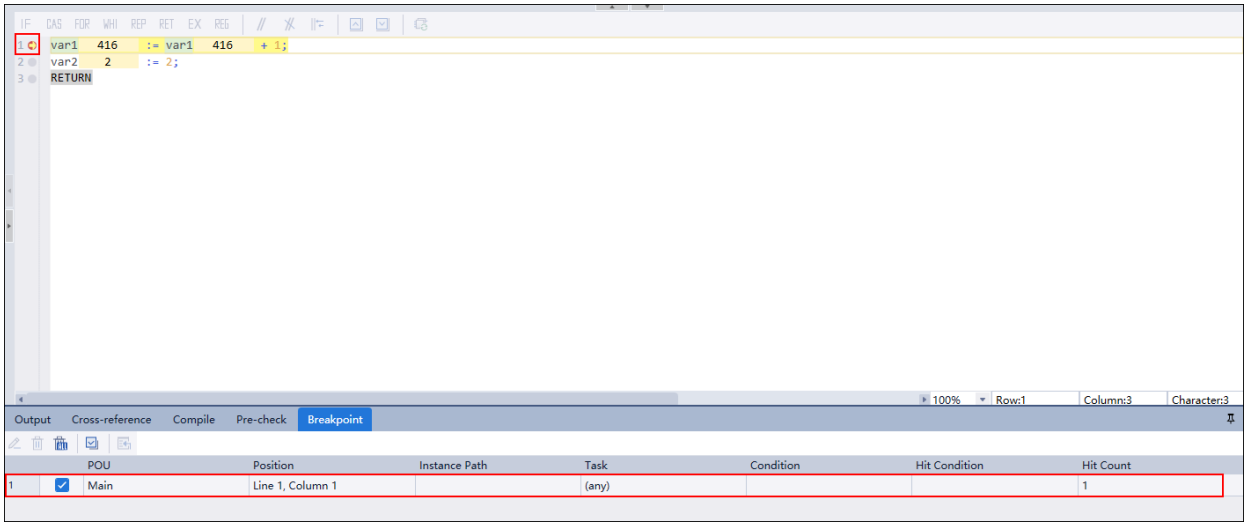
The device is in an online status.



Enabling method

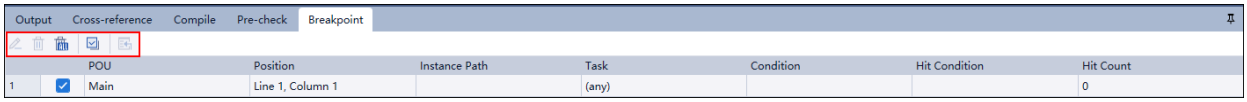
- Move the mouse to a statement with no enabled breakpoint (the compiler determines whether this location is valid for setting a breakpoint). Right-click and select "Enable breakpoint" to enable a breakpoint.

- Click to configure the breakpoint area (the beginning of an ST line) and add an enabled breakpoint.



- Click a statement with no enabled breakpoint (the compiler determines whether this location is valid for setting a breakpoint), and select "Commission > Enable/Disable breakpoint" in the menu bar to enable a breakpoint.

- Click a statement with no enabled breakpoint (the compiler determines whether this location is valid for setting a breakpoint), and press the keyboard shortcut F9 to enable a breakpoint.



Result after enabling a breakpoint

- A breakpoint identifier appears before the corresponding statement, and a new variable (checked) is added to the breakpoint monitoring view, as shown in the figure.

The breakpoint monitoring window displays the following columns:

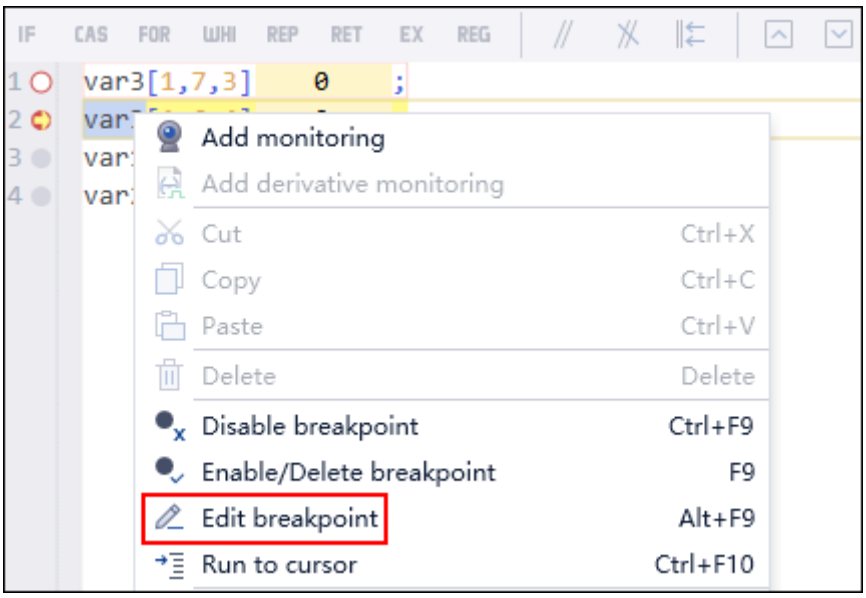
Name	Description
POU name	The name of the POU where the breakpoint is set, which corresponds to the POU name in the offline view
Breakpoint location	The location where the breakpoint is set, such as a specific line and column in the ST text
Instance path	The instance name of the FB type POU where the breakpoint is set
Task	The tasks in which the breakpoint is hit, defaulting to any task
Condition	Breakpoint hit condition, defaulting to always break upon hit; this condition can be a BOOL variable or an expression that evaluates to a BOOL value
Hit condition	Conditions related to the number of hits

As shown in the above figure, the breakpoint monitoring window toolbar supports modifying a breakpoint, deleting a breakpoint, deleting all breakpoints, enabling/disabling all breakpoints, and navigating to breakpoint location.

Icon	Name	Description
	Modify a breakpoint	In the breakpoint monitoring window, select the corresponding POU and click this icon to modify the breakpoint. For details, see 10.10.4.2 Modifying a Breakpoint.
	Deleting a Breakpoint	In the breakpoint monitoring window, select the corresponding POU and click this icon to delete the breakpoint. For details, see 10.10.4.3 Deleting a Breakpoint.
	Delete all breakpoints	Click this icon to delete all breakpoints at once.
	Enable/Disable all breakpoints	Click this icon to enable/disable all breakpoints at once. For details, see 10.10.4.1 Enabling a Breakpoint and 10.10.4.4 Disabling a Breakpoint.
	Navigate to breakpoint location	In the breakpoint monitoring window, select the corresponding POU and click this icon to jump directly to the breakpoint location.

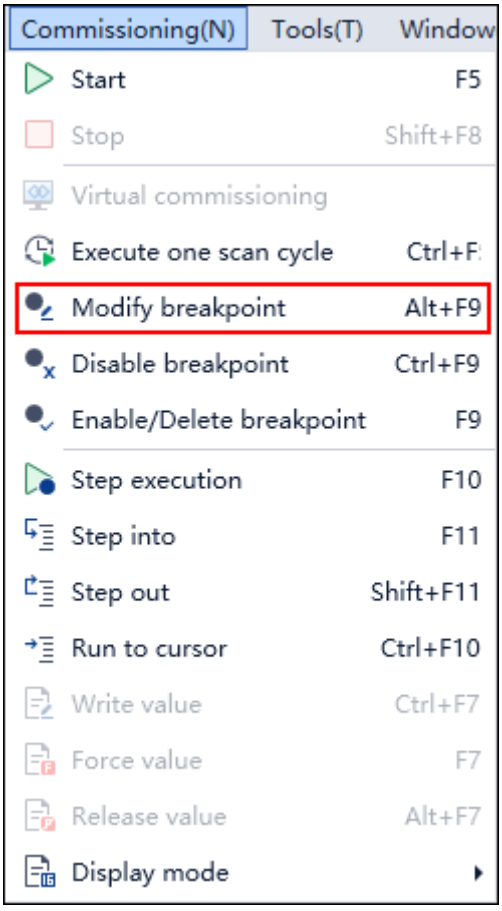
CAUTION

- When the breakpoint view switches from online to offline, the list is cleared; when switching back to online, the breakpoints from the current PLC are reloaded, and the reloaded breakpoints are disabled by default.
- When multiple PLCs are online simultaneously, the breakpoint list switches when switching between PLC1 and PLC2.



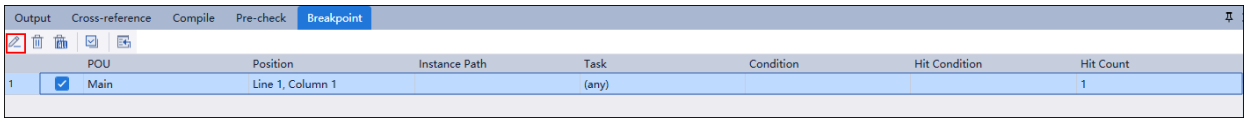
10.10.4.2 Modifying a Breakpoint

Prerequisites

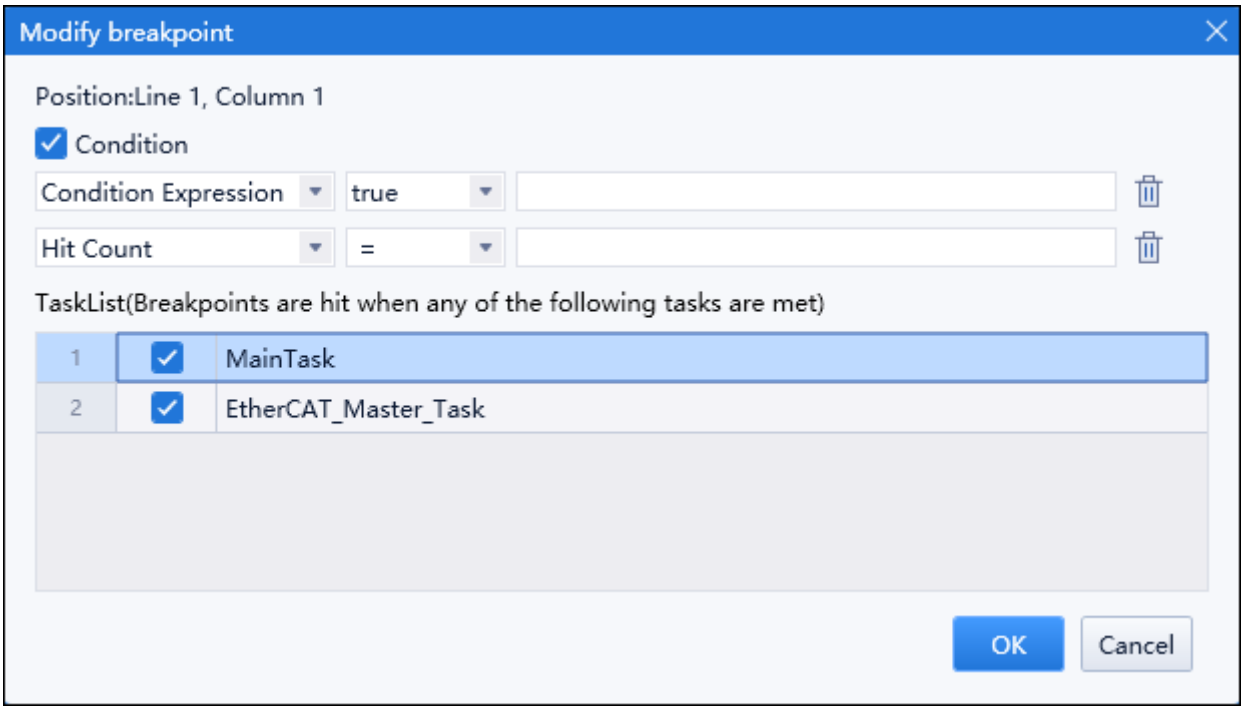


The breakpoint is enabled.

Modifying method

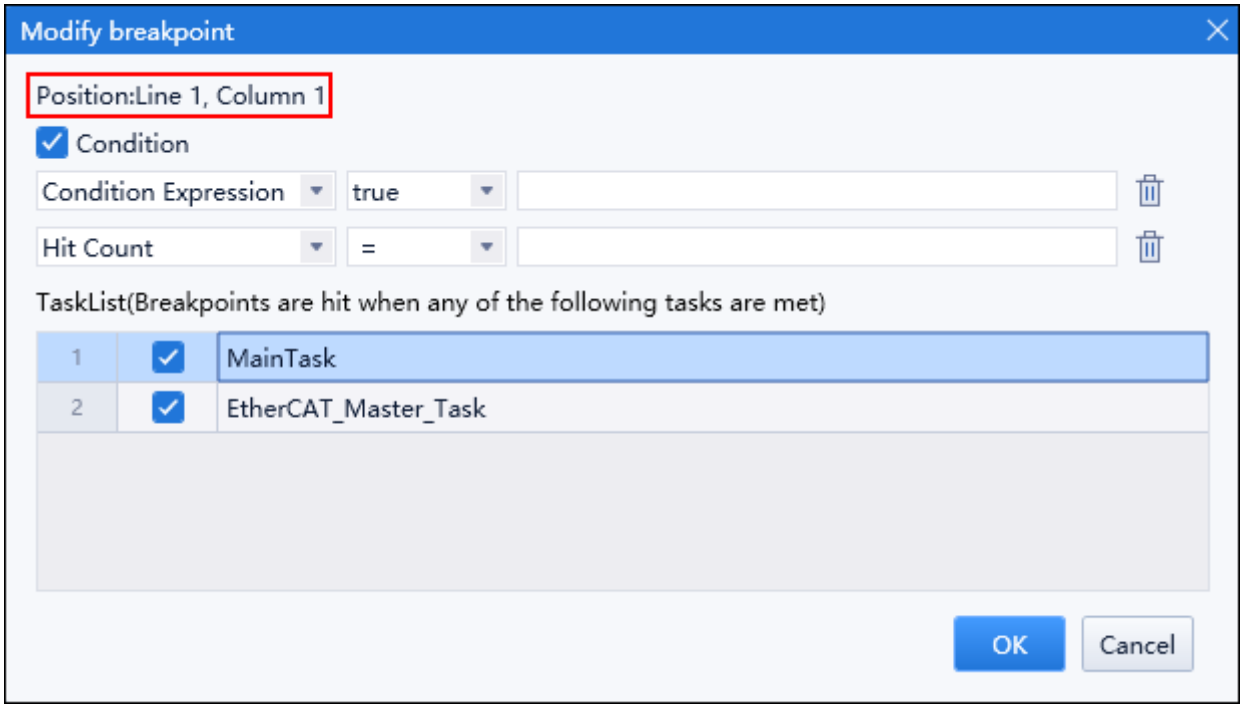


- Move the mouse to a statement location with an enabled/disabled breakpoint, right-click and select "Modify breakpoint" to open the breakpoint modification window.

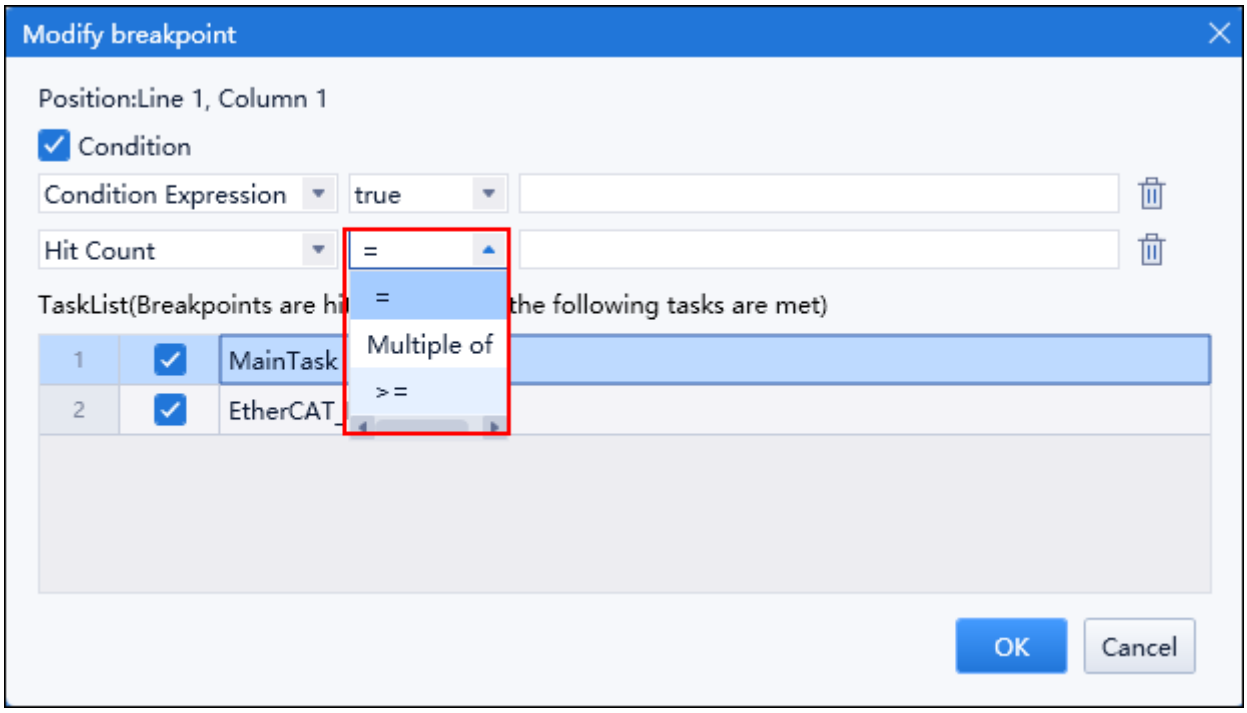


- Click a statement location with an enabled/disabled breakpoint and select "Commissioning > Modify breakpoint" from the menu bar to open the breakpoint modification window.

- Click a statement location with an enabled/disabled breakpoint and use the shortcut key Alt+F9 to open the breakpoint modification window.
- After adding a breakpoint, its information is displayed in the breakpoint monitoring window, where you can modify the breakpoint. In the breakpoint monitoring window, select the corresponding POU and click the "Modify breakpoint" icon in the toolbar.

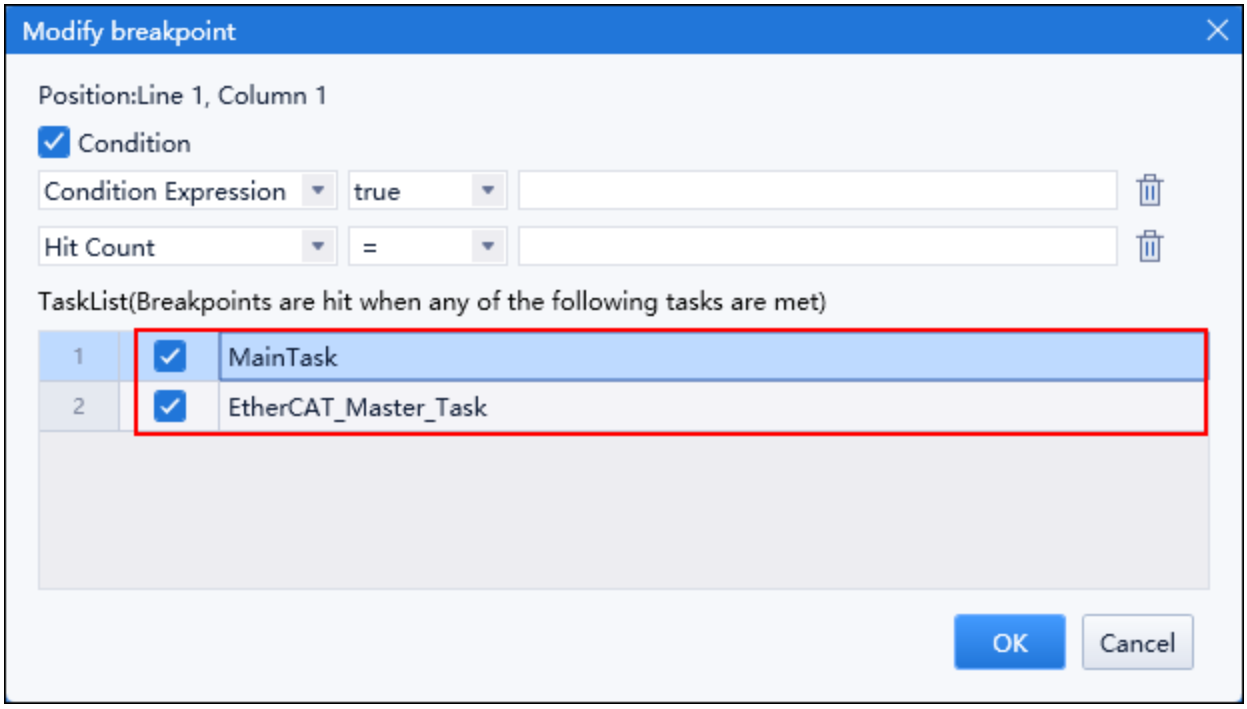


The following figure is the breakpoint modification window.



The breakpoint modification window contains the following items:

- Location information



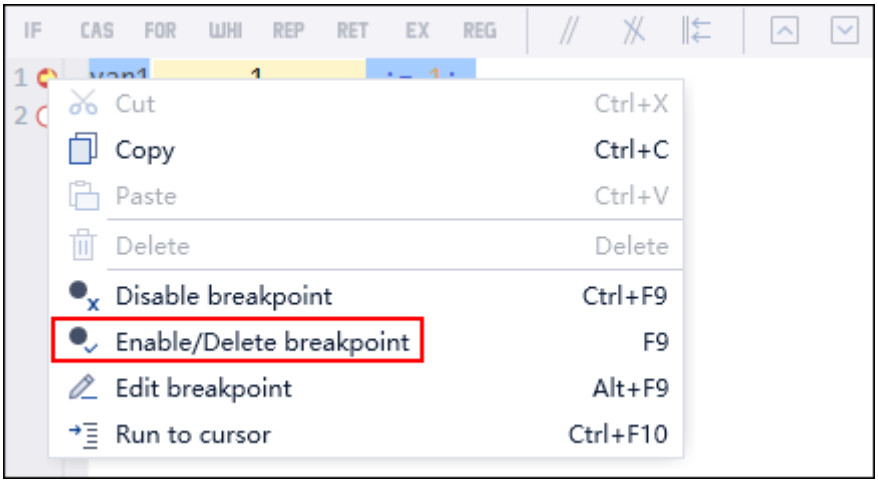
- Condition: Condition expression and hit count

Hit count	Determines when to stop the program based on how many times the breakpoint location has been executed.
Not configured	Always stop the program upon reaching the breakpoint location
Equal to n	Stop when the hit count reaches n
Multiple of n	Stop when the hit count is a multiple of n
Greater than or equal to n	Stop when the hit count is greater than or equal to n

- Task

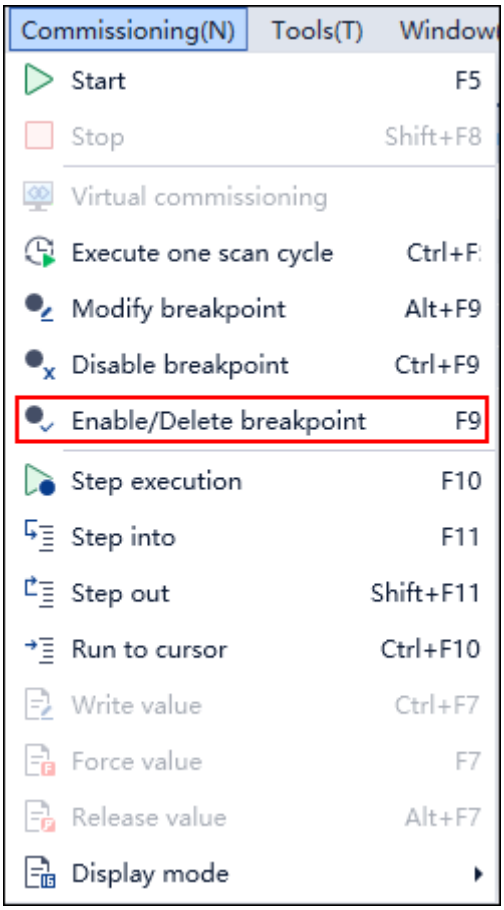
CAUTION

- Expression condition: The breakpoint is hit when the condition expression evaluates to true. The condition expression can be a complex expression but must be of BOOL type after validation.
- You can select either the expression condition or the hit count condition, or set both. (Note: When both the expression condition and the hit count condition are set, the breakpoint is hit when the number of hits satisfying the expression condition reaches the hit count condition.)
- Task: All tasks are displayed in the list. Users can select one or more tasks at which the breakpoint will stop. If not set, the breakpoint will be hit in any task. (Note: When multiple tasks are selected, if one of the tasks is deleted, the corresponding data in the breakpoint view will be refreshed; if the breakpoint is set for only one task, when that task is deleted, the breakpoint will be deleted synchronously. When all tasks are selected, the task option in the view is not selected by defaulted, and the list of selected tasks is not expanded.)



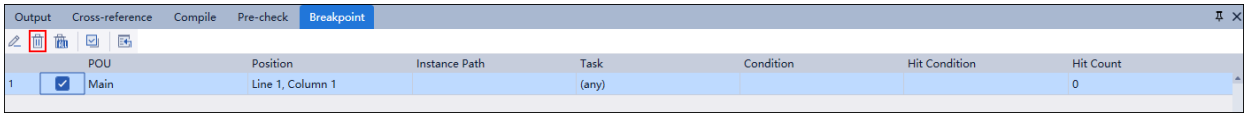
10.10.4.3 Deleting a Breakpoint

Prerequisites



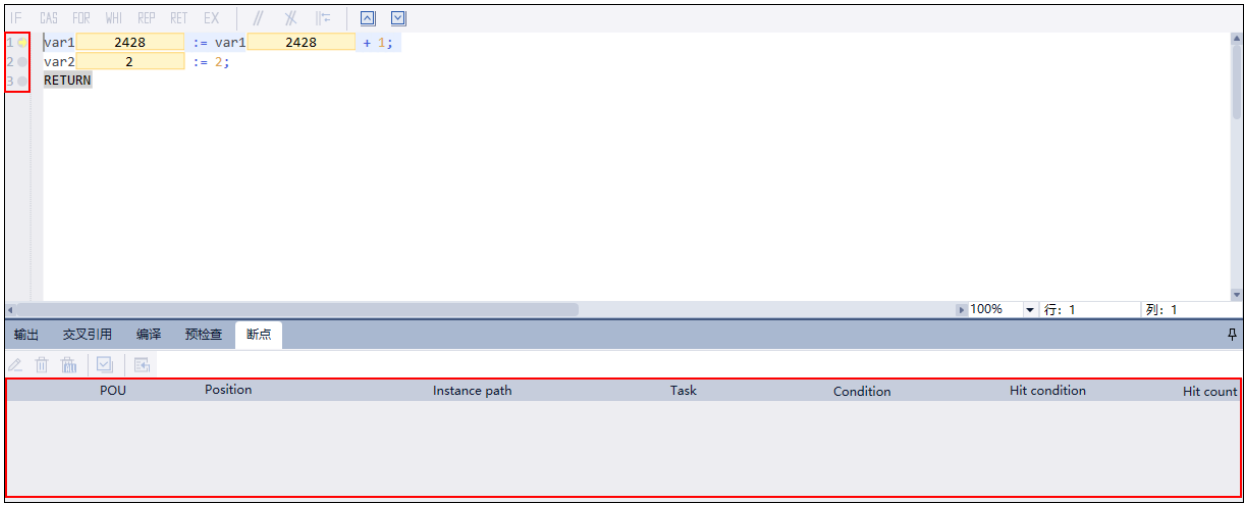
The breakpoint is enabled.

Deleting method



- Move the mouse to a statement location with an enabled breakpoint, right-click and select "Enable/Delete breakpoint" to delete the breakpoint.

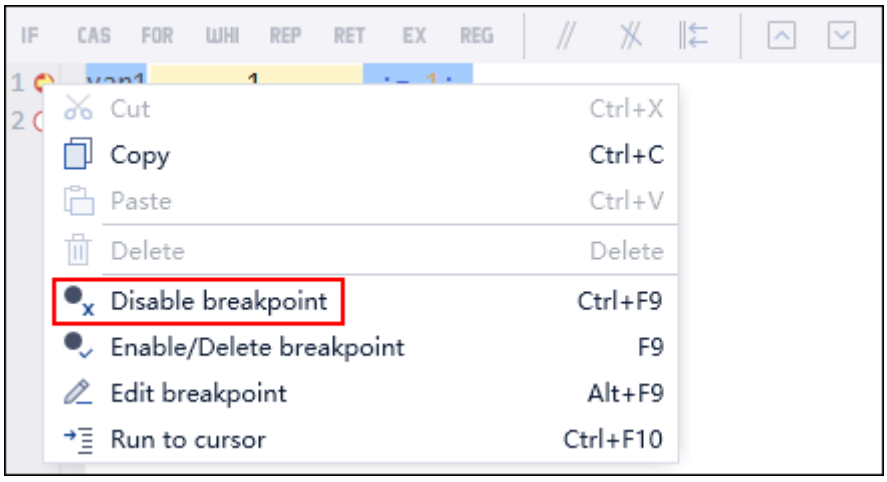
- Click a statement location with an enabled breakpoint and select "Commissioning > Enable/Delete breakpoint" to delete the breakpoint.



- Click a statement location with an enabled breakpoint and press the shortcut key F9 to delete the breakpoint.
- After adding a breakpoint, its information is displayed in the breakpoint monitoring window, where you can delete the breakpoint. In the breakpoint monitoring window, select the corresponding POU and click the "Delete breakpoint" icon in the toolbar.

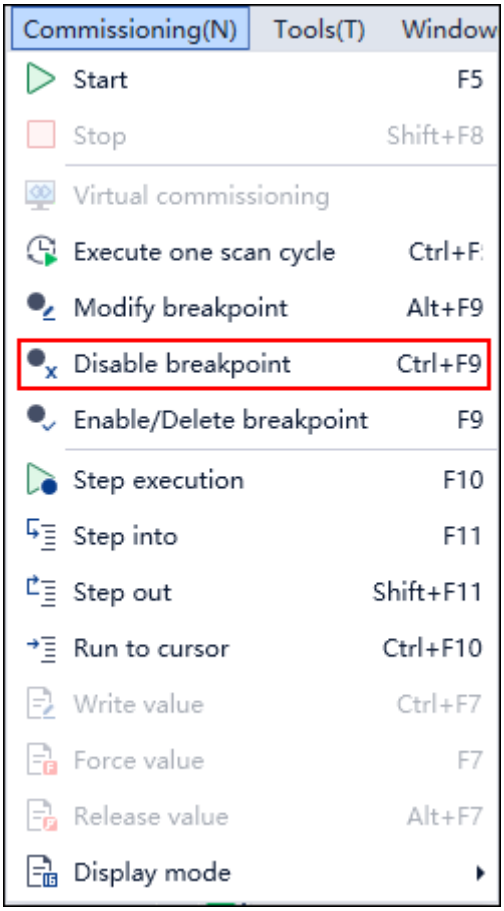
Result after deleting a breakpoint

The identifier in front of the statement disappears, and the corresponding breakpoint disappears from the breakpoint monitoring window.



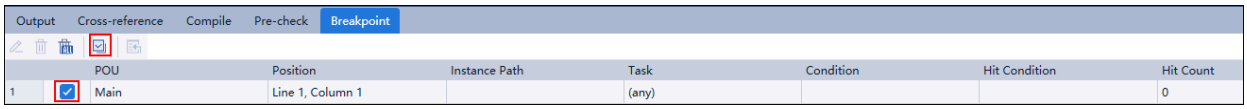
10.10.4.4 Disabling a Breakpoint

Prerequisites



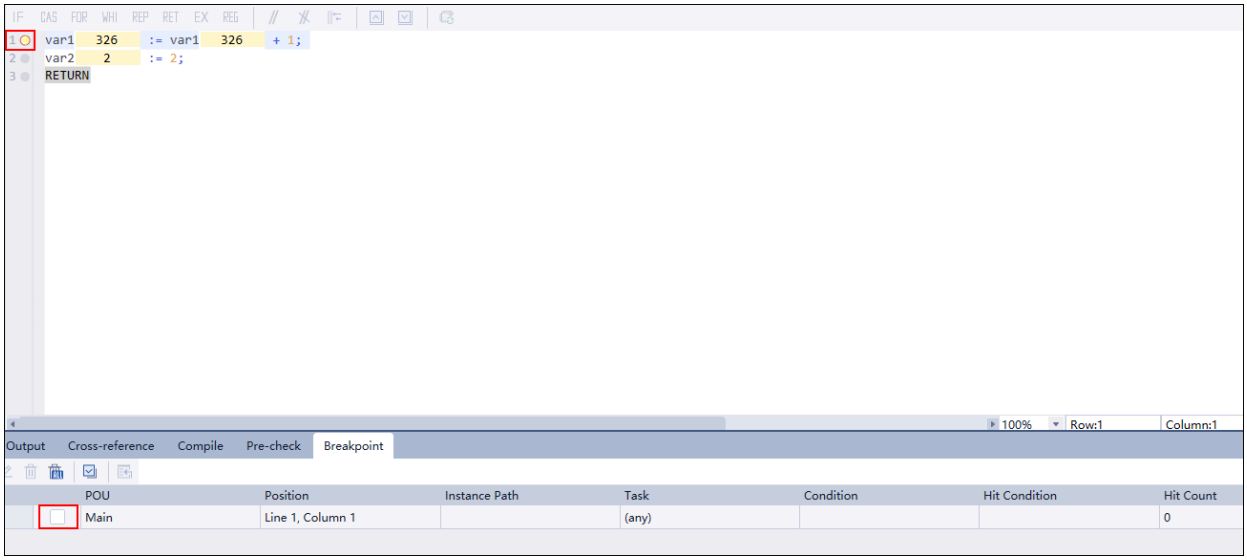
A breakpoint has been set and is enabled.

Disabling method



- Move the mouse to a statement location with an enabled breakpoint, right-click and select "Disable breakpoint" to disable the breakpoint.

- Move the mouse to a statement location with an enabled breakpoint, select "Commissioning > Disable breakpoint" from the menu bar, and the breakpoint disabling window will pop up.



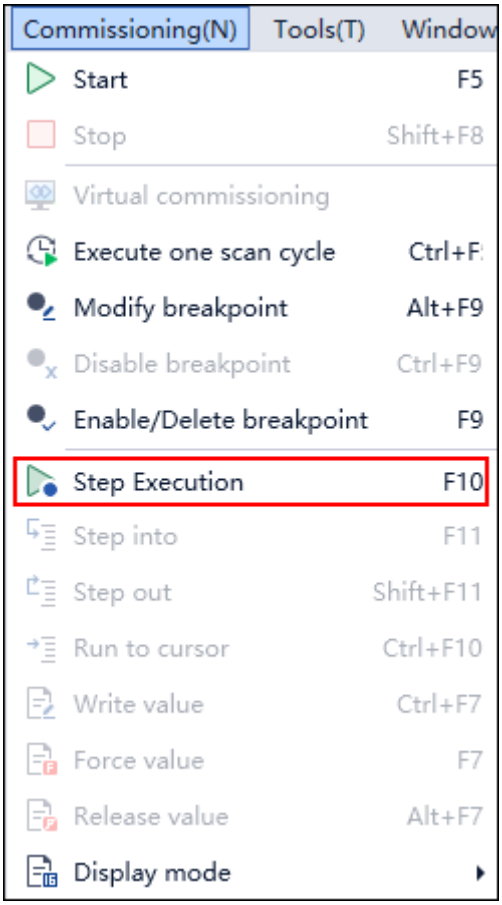
- Select an enabled breakpoint and click the breakpoint area (the beginning of an ST line) to disable the breakpoint.
- Move the mouse to a statement location with an enabled breakpoint and use the shortcut Ctrl+F9 to disable the breakpoint.
- After adding a breakpoint, its information is displayed in the breakpoint monitoring window, where you can disable the breakpoint in the following two ways:
  - Click the "Enable/Disable breakpoint" icon in the toolbar.
  - Uncheck the checkbox to the left of the breakpoint.

Result after disabling a breakpoint

A red hollow circle indicating a disabled breakpoint appears before the corresponding statement, and the corresponding POU in the breakpoint monitoring window is no longer checked.

10.10.5 ST Program Commissioning

10.10.5.1 Step Execution



Execute one statement in the order of program statements, without entering methods/functions.

Prerequisites

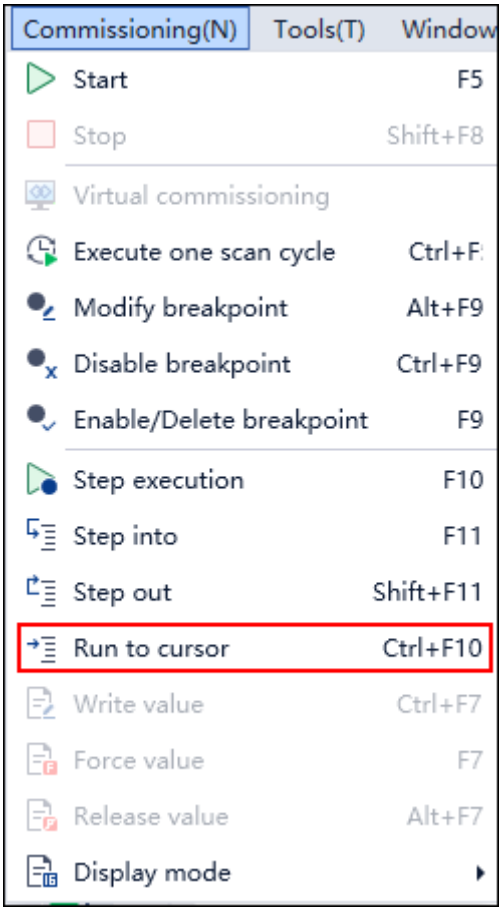
The program is in breakpoint commissioning status.

Process

- Move the mouse to the statement location and select "Commissioning > Step execution" in the menu bar to execute the statement.

- Move the mouse to the statement location and use the shortcut key F10 to execute the statement.
- Move the mouse to the statement location and click the "Step execution" icon in the toolbar to execute the statement.

10.10.5.2 Running to Cursor



The program runs to the location of the cursor. If there is a breakpoint between the stop statement and the cursor, it runs first to the breakpoint in between.

Prerequisites

The program is in breakpoint commissioning status.

Process

- Move the mouse to the statement location, select "Commissioning > Run to cursor" in the menu bar, and the program will run to the location of the cursor.

- Move the mouse to the statement location and use the shortcut key Ctrl+F10.
- Move the mouse to the statement location and click the "Run to cursor" icon in the toolbar.

10.10.5.3 Displaying Current Statement

Use this function to jump to the statement where the pointer stops during breakpoint commissioning.

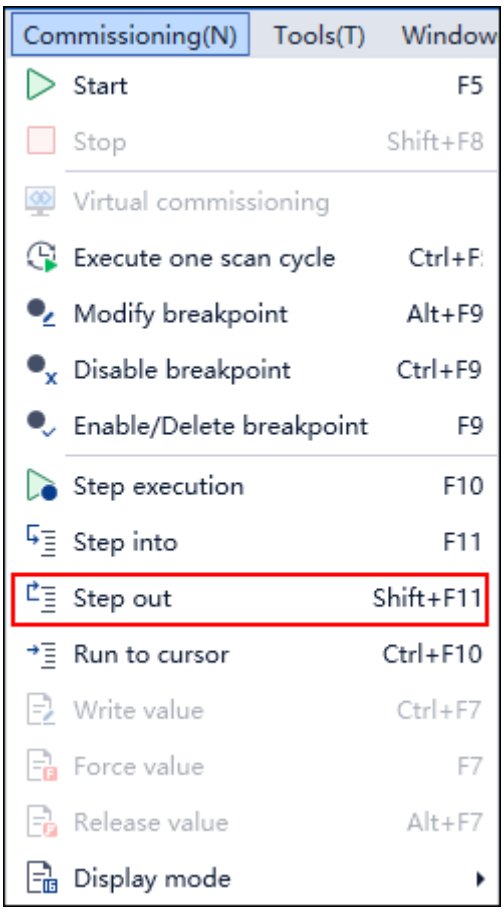
Prerequisites

The program is in breakpoint commissioning status.

Process

Click the "Display current statement" icon in the toolbar to jump to the statement where the pointer stops.

10.10.5.4 Stepping Out



Statement exits the method/function directly. If there are breakpoints between the stop statement of the method/function and the end, the program first runs to the intermediate breakpoints. If there are no intermediate breakpoints, it exits the call hierarchy level by level.

Prerequisites

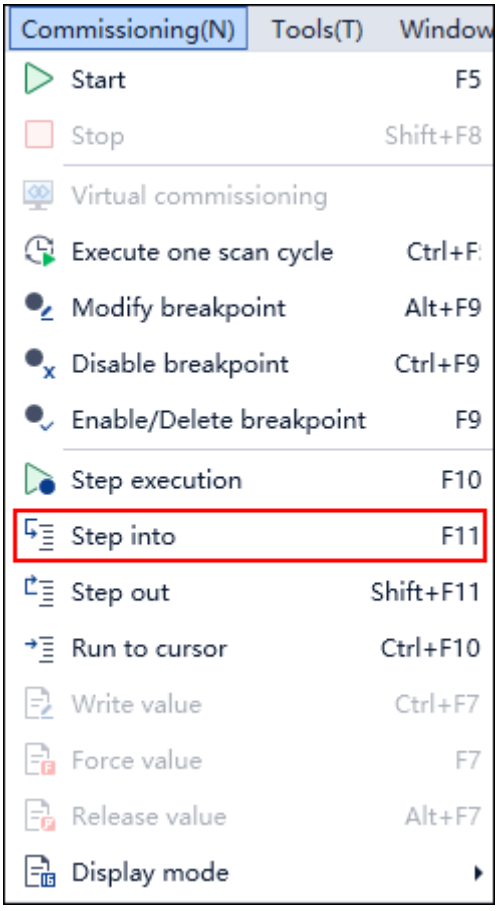
The program is in breakpoint commissioning status.

Process

- Move the mouse to the statement location, select "Commissioning > Step out" in the menu bar, and program exits the call hierarchy level by level.

- Move the mouse to the statement location and use the shortcut key Shift+F11.
- Move the mouse to the statement location and click the "Step out" icon in the toolbar.

10.10.5.5 Stepping Into



Execute one statement in the order of program statements and enter methods/functions encountered during execution.

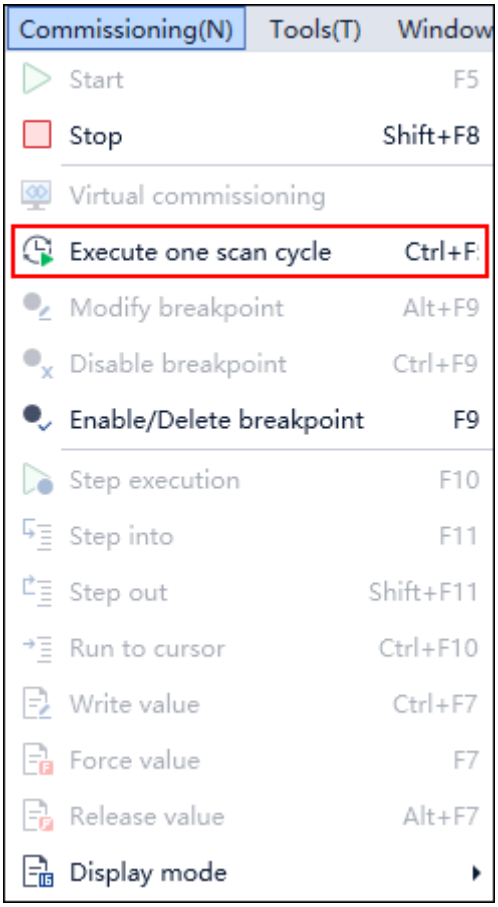
Prerequisites

The program is in breakpoint commissioning status.

Process

- Move the mouse to the statement location, select "Commissioning > Step into" in the menu bar, and the program executes one statement in the order of program statements.

- Move the mouse to the statement location and use the shortcut key F11.
- Move the mouse to the statement location and click the "Step into" icon in the toolbar.



10.10.5.6 Executing One Scan Cycle

The program runs for one cycle. If the pointer stop position is not at the start of the program, it runs from the current position to the end. If there are breakpoints between the stop pointer and the end position, the breakpoints will be triggered.

Process

- Select "Commissioning > Execute a scan cycle" in the menu bar and the program runs for one cycle.

- Use the shortcut key Ctrl+F5 to run the program for one cycle.
- Click the "Execute a scan cycle" icon in the toolbar to run the program for one cycle.

10.10.6 PID Function Block Commissioning Wizard

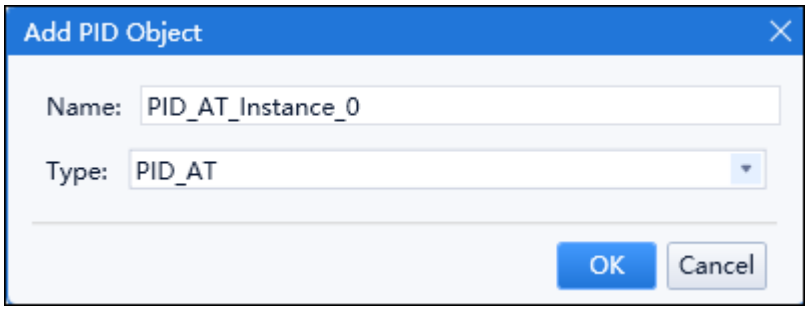
10.10.6.1 Overview

The PID_AT and PID_ATC commands support configuration and commissioning functions.

- Configuration: Provides parameter names, upper and lower limits, grayed-out properties, and personalized displays, making complex command configurations simpler.
- Commissioning: For online command commissioning, this interface displays commonly used parameters for commissioning. Users can operate these parameters and see the commissioning results intuitively.

10.10.6.2 Adding a PID Function Block

Prerequisites

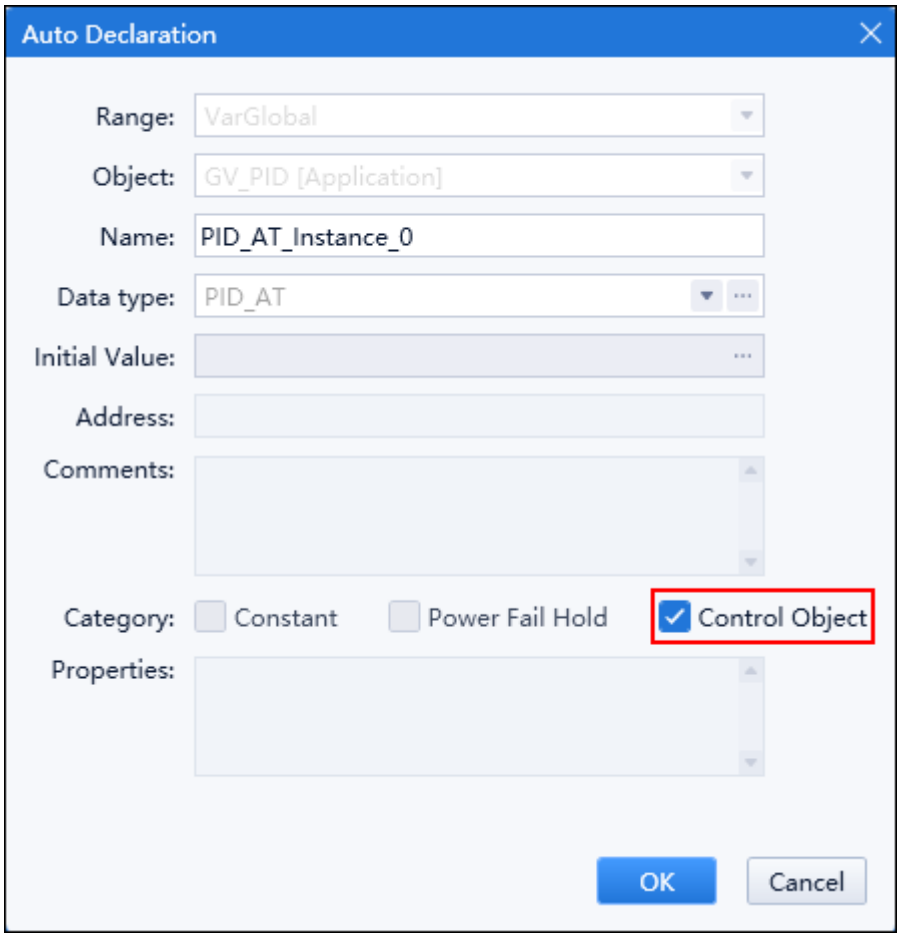


- A project has been created.
- The device has been added.

Procedure

- Adding through the project tree
  1. Select "Control object > PID" in the left project tree.

2. Right-click the "PID" node, select "Add PID object", and a dialog box will pop up.

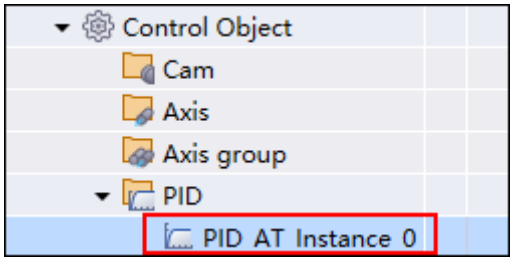


3. Enter the name and type of the PID object, and click "OK" to complete the addition.

- Automatic declaration in program editing area

1. Create a POU (only PRG and FB are supported) under "Programming" in the left project tree.

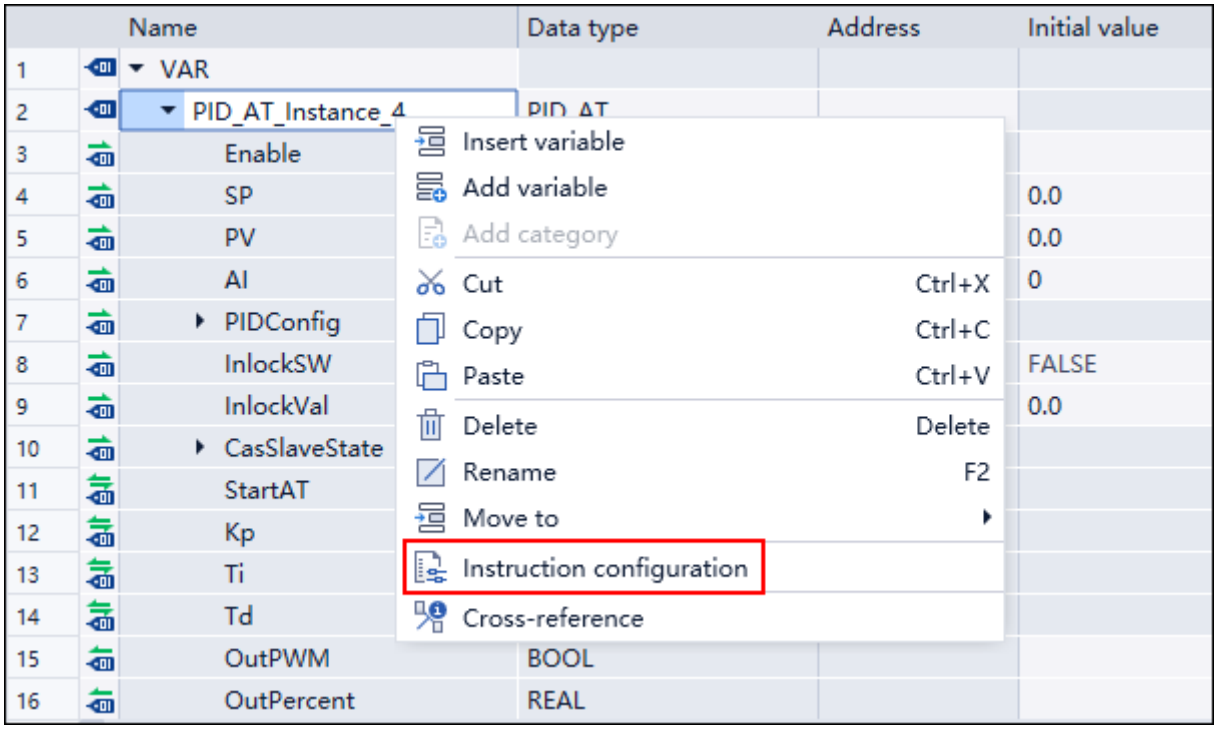
2. Open a POU (PRG or FB) under "Programming". Double-click a PID object from the toolbox or drag it to the program editing area, and the "Auto declaration" dialog box for the PID object will pop up. Check "Control object" and click "OK" to add it under the "Control object > PID" node without creating a variable in the POU.



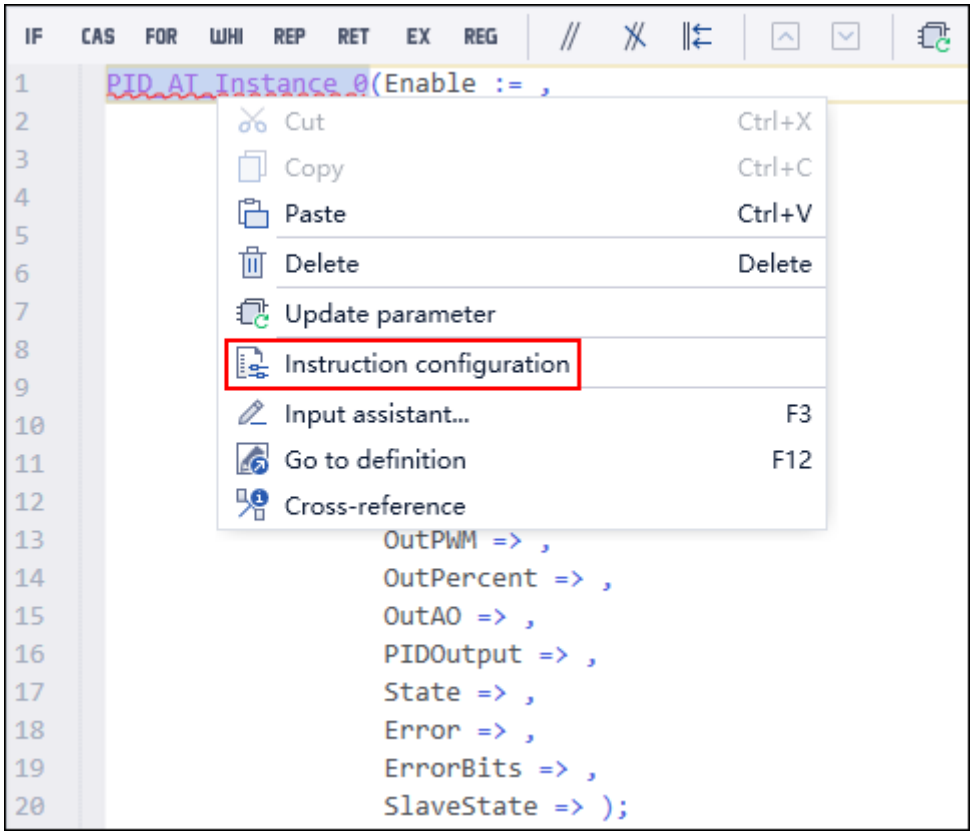
NOTE

When adding a PID object through automatic declaration in the program editing area, if "Control object" is not checked, it will be added as a regular variable, which will be added to the corresponding POU or global variable table.

Result

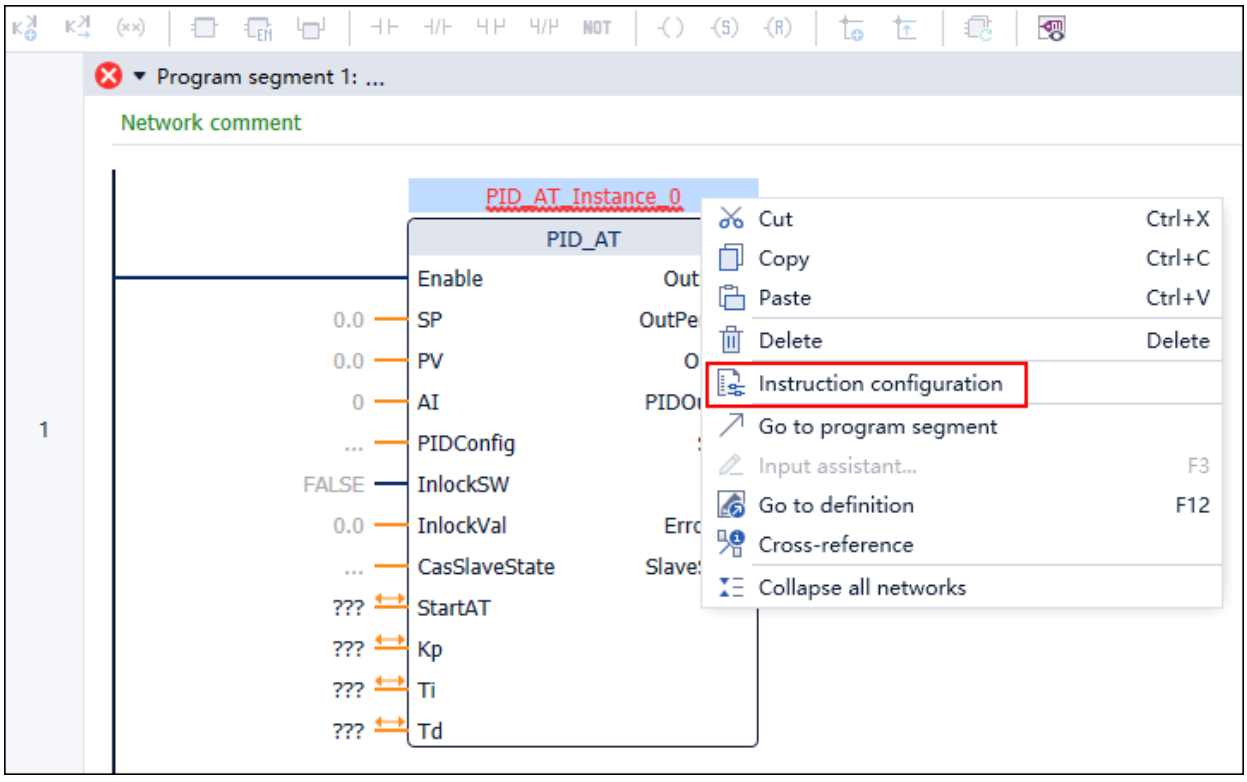


The added PID object can be viewed under the PID node.



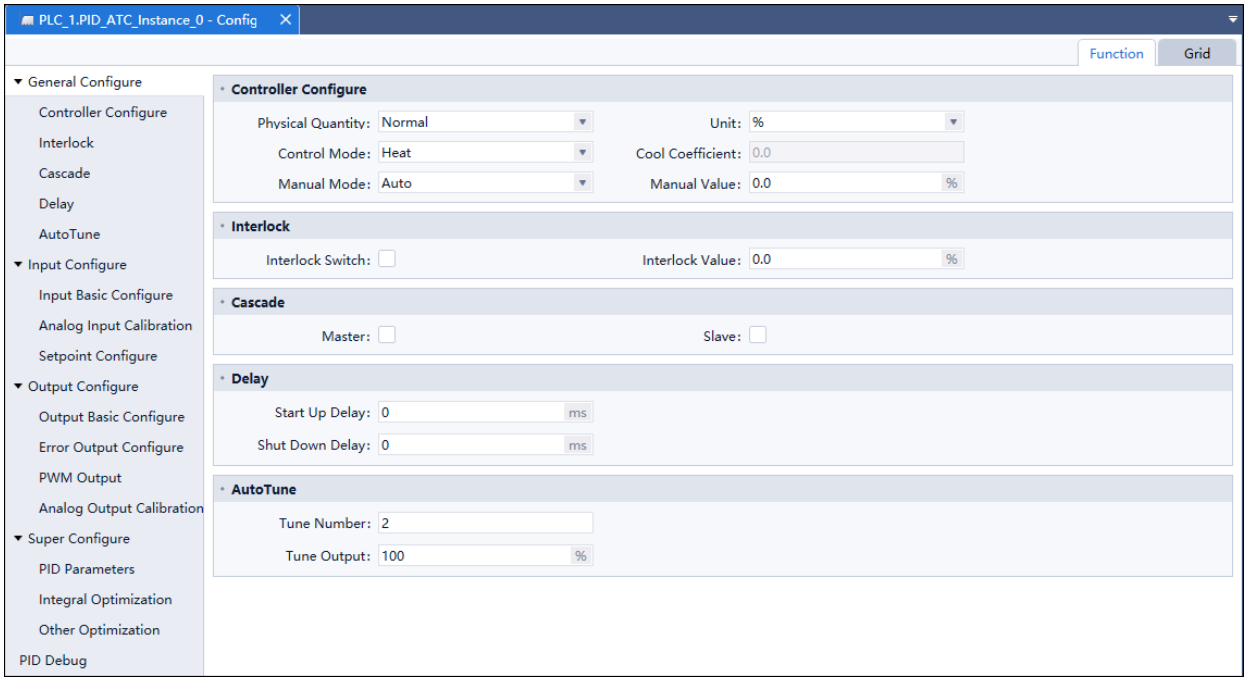
10.10.6.3 Configuration and Commissioning

Function entry

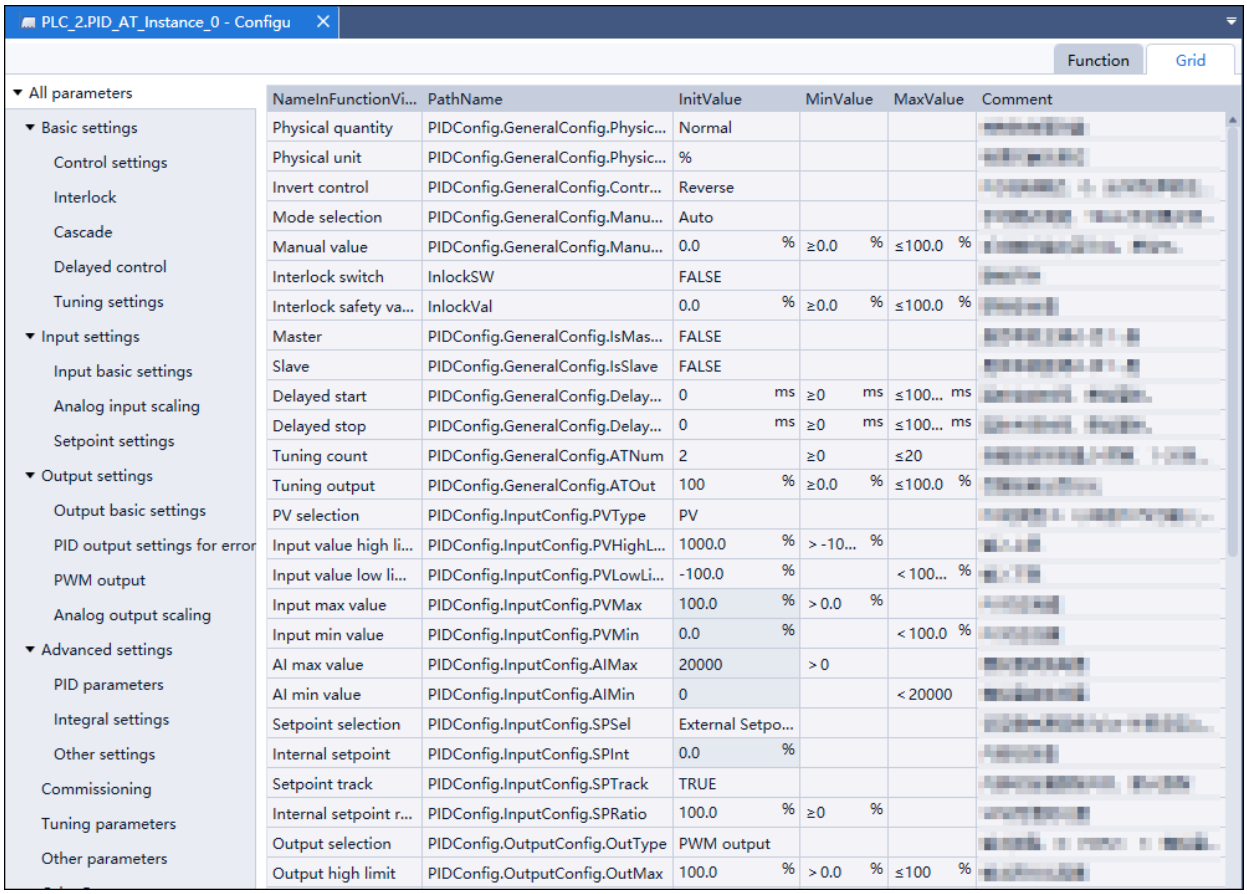


- Double-click the PID object node added under the PID node to open the configuration and commissioning interface.
- After creating a PID object instance, right-click the instance and select "Instruction configuration" to open the configuration and commissioning interface.
  - Variable table: Right-click the PID object instance row in the variable table and select "Instruction configuration".

  - ST: Right-click the PID object instance name in the ST programming area and select "Instruction configuration".



- LD: Right-click the PID object instance name in the LT programming area and select "Instruction configuration".

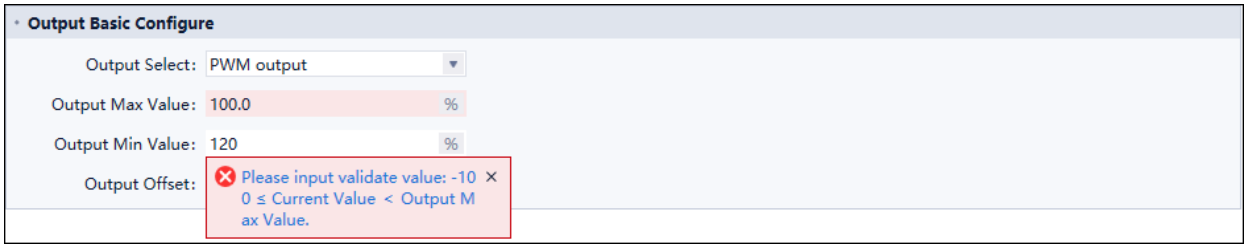


Configuration

The configuration and commissioning interface can be displayed in function view or parameter view. You can switch the display mode using the button in the upper right corner.

- Function view
  - Click each parameter category on the left, and the corresponding configuration parameters will be displayed on the right.

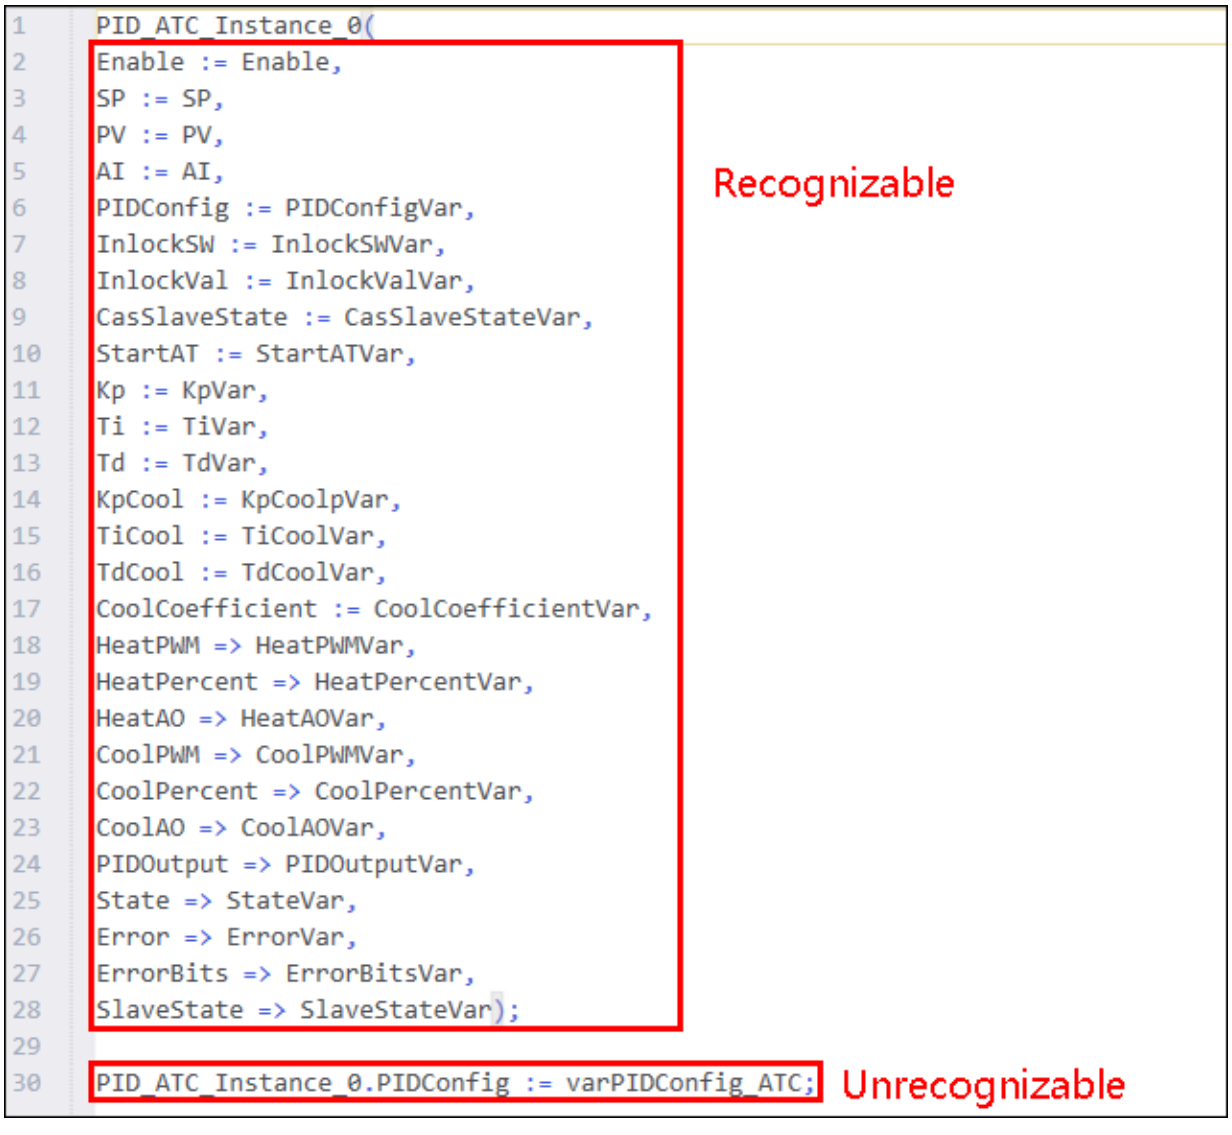
- Parameter view
  - Click each parameter category on the left, and the corresponding configuration parameters will be displayed on the right, showing more detailed information, including parameter names in the function view, names in the FB, initial values, minimum values, maximum values, and comments.



NOTE

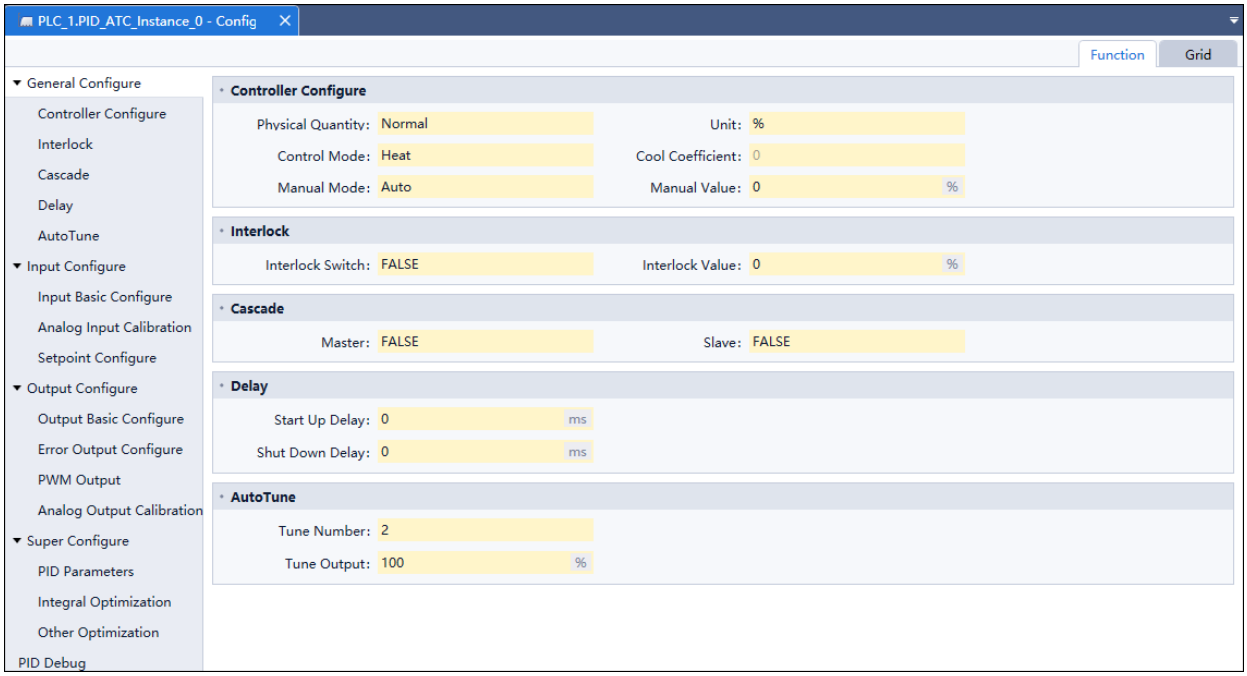
For details and configurations of PID_AT and PID_ATC parameters, see 18.3.1 PID Control.

Offline editing



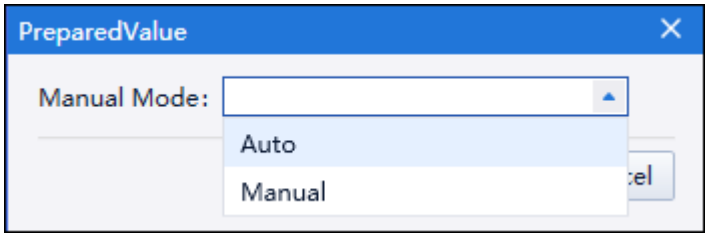
- Parameters can be edited in both function view and parameter view.
- Parameter editing supports undo and redo.
- If the input parameter exceeds the limit, a fault message will be displayed (which is only shown in the configuration interface and will not cause a compilation fault).

- If a parameter is bound to another variable in the programming area, editing the parameter value will change the bound variable.

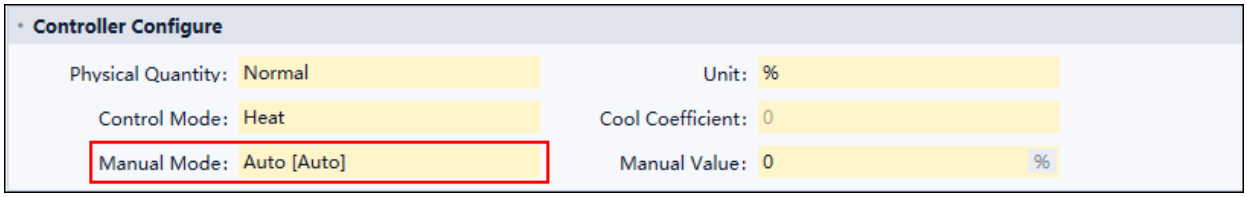


CAUTION

Variables bound to internal parameter pins of function blocks are supported for recognition, while those bound to external pins are not supported.



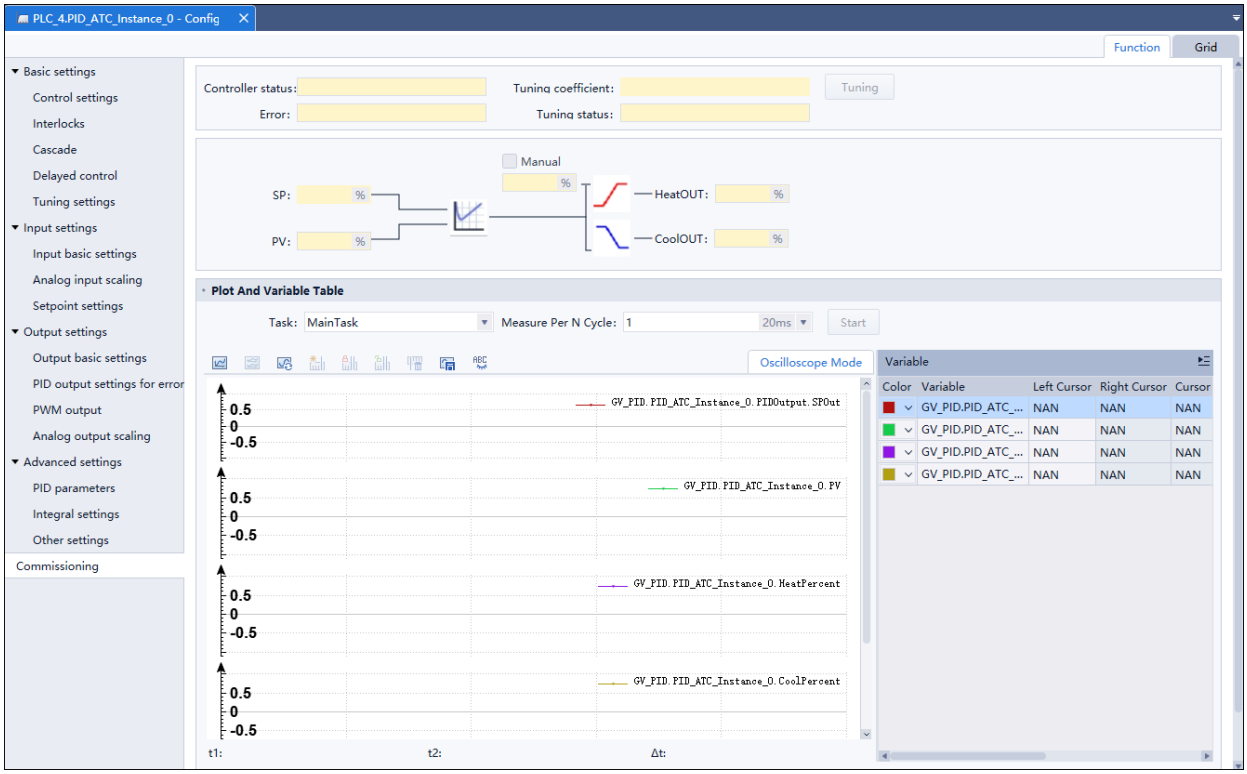
Online monitoring



- Function view

  - The input box displays real-time monitored values (decimal).
  - Double-click an ungrayed input box and the prepared value window will pop up.

  - Enter the prepared value, click "OK," and the input box will simultaneously display the monitored value and the prepared value.



- Parameter view
  - In online mode, there are "Monitored value" and "Prepared value" columns in the parameter view, displaying real-time monitored values (in decimal) and input prepared values.

Commissioning

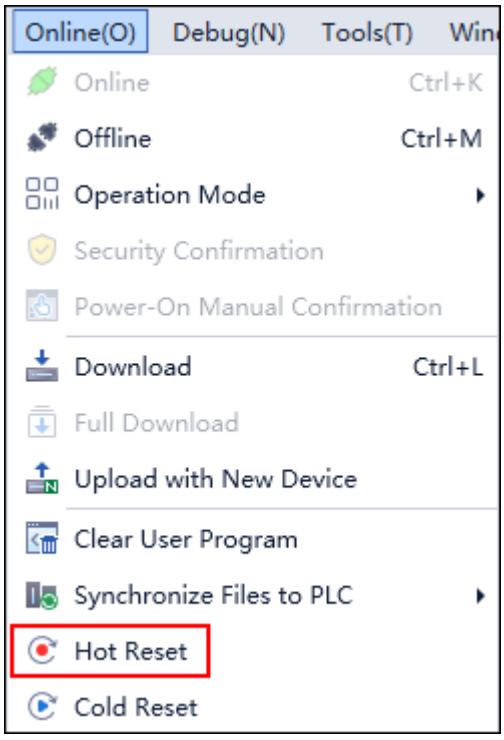
- The commissioning interface displays commonly used parameters during commissioning. On this interface, users can operate these parameters and see the commissioning results intuitively.
- The commissioning parameters for each command vary, so are the corresponding commissioning interfaces.
- The following figure shows the "PID_ATC" command interface. On this interface, you can operate the parameters related to the "PID_ATC" command, start the oscilloscope with one click, and observe the commissioning results.

Parameter	Description
PLC state	Corresponding to variable State; for display only.
Error bits	Corresponding to variable ErrorBits; for display only. If there is a parameter fault, an icon will appear after the monitored value box. Hovering the mouse over it will show detailed fault code and descriptions.
Auto-tuning coefficient	Corresponding to editable variable PIDConfig.GeneralConfig.ATCoefficient; supports value writing and value forcing in online status.
Auto-tuning state	Corresponding to variable PIDOutput.ATState; for display only.
StartAT	Corresponding to variable StartAT; click to write the prepared value. Call the "Write value" command to trigger tuning (set StartAT=TRUE), and the StartAT button will be grayed out. After successful tuning, it will be rewritten as FALSE, and the StartAT button can be triggered again. To stop tuning during the process, set "StartAT" to "Tuning complete" in the "Other parameters" tab in the parameter view of the command configuration interface, and then call the "Write value" command.
SP	Current setpoint; for display only.
PV	Current actual PV value; for display only.
OUT	Corresponding to variable OutPercent; for display only.
Manual	Corresponding to variable PIDConfig.GeneralConfig.ManualEnable; check to write the prepared value. Call the "Write value" command to write the value TRUE, triggering manual mode. In manual mode, double-click the manual value text box to write the prepared value, and the operation variable is PIDConfig.GeneralConfig.ManualValue. ManualValue. In automatic mode, the prepared value cannot be written to the manual value box.
Task	The task can be any user-created task or EtherCAT task.

Parameter	Description
Measure per N cycles	The sampling period (task cycle × N)
Start/Stop	Click "Start" to begin sampling with the oscilloscope. Each time you click "Start", the previous oscilloscope data will be cleared, and a new session will begin. When the oscilloscope is running, switching to offline mode or closing the commissioning interface will automatically stop the oscilloscope first. Click "Stop" to halt oscilloscope sampling.

10.11 PLC Online Operations

10.11.1 Hot Reset



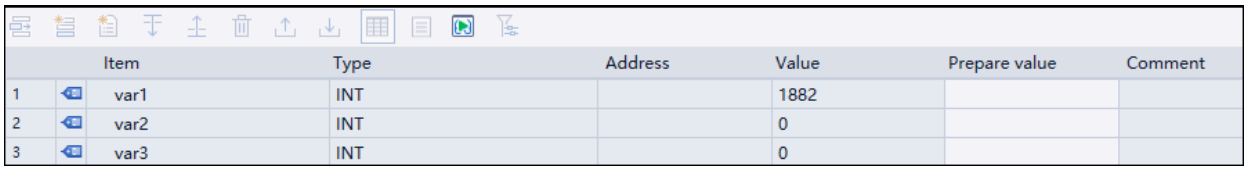
After a hot reset, all variables of the currently active application, except for power failure retention variables, will be reinitialized. If a variable has an initial value, its value will revert to the initial value after a hot reset. Other variables will be set to their standard initial values (such as 0).

Prerequisites

- The program has been downloaded to the PLC device.
- The current project is in online mode.

Procedure

1. Select "Online > Hot reset" in the menu bar.



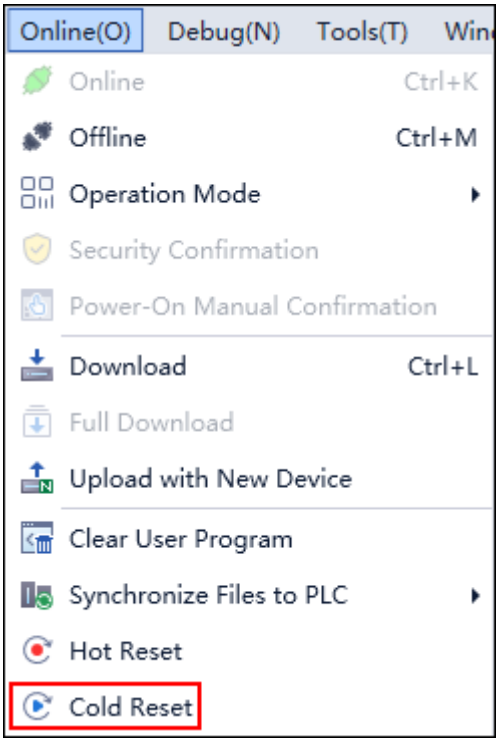
2. In the pop-up window, click "OK" to perform the online hot reset.

Operation result

After a hot reset, all variables of the currently active application, except for power failure retention variables, will be reinitialized.

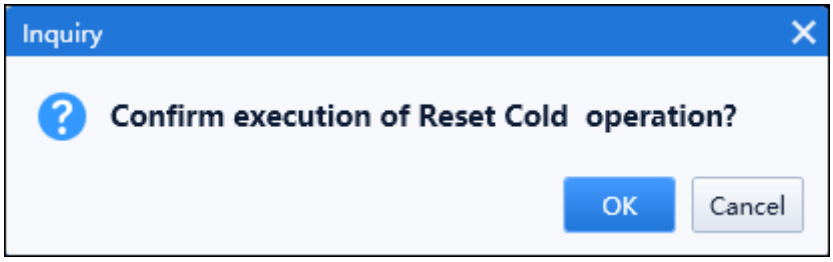
		Item	Type	Address	Value	Prepare value	Comment
1		var1	INT		1882		
2		var2	INT		0		
3		var3	INT		0		

10.11.2 Cold Reset



After a cold reset, all variables of the currently active application, except for power failure retention variables, will be reinitialized. If a variable has an initial value, its value will revert to the initial value after a cold reset. Other variables will be set to their standard initial values (such as 0).

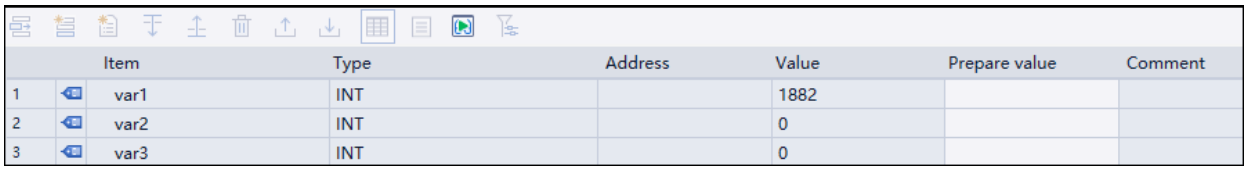
Prerequisites



- The program has been downloaded to the PLC device.
- The current project is in online mode.

Procedure

1. Select "Online > Cold reset" in the menu bar.



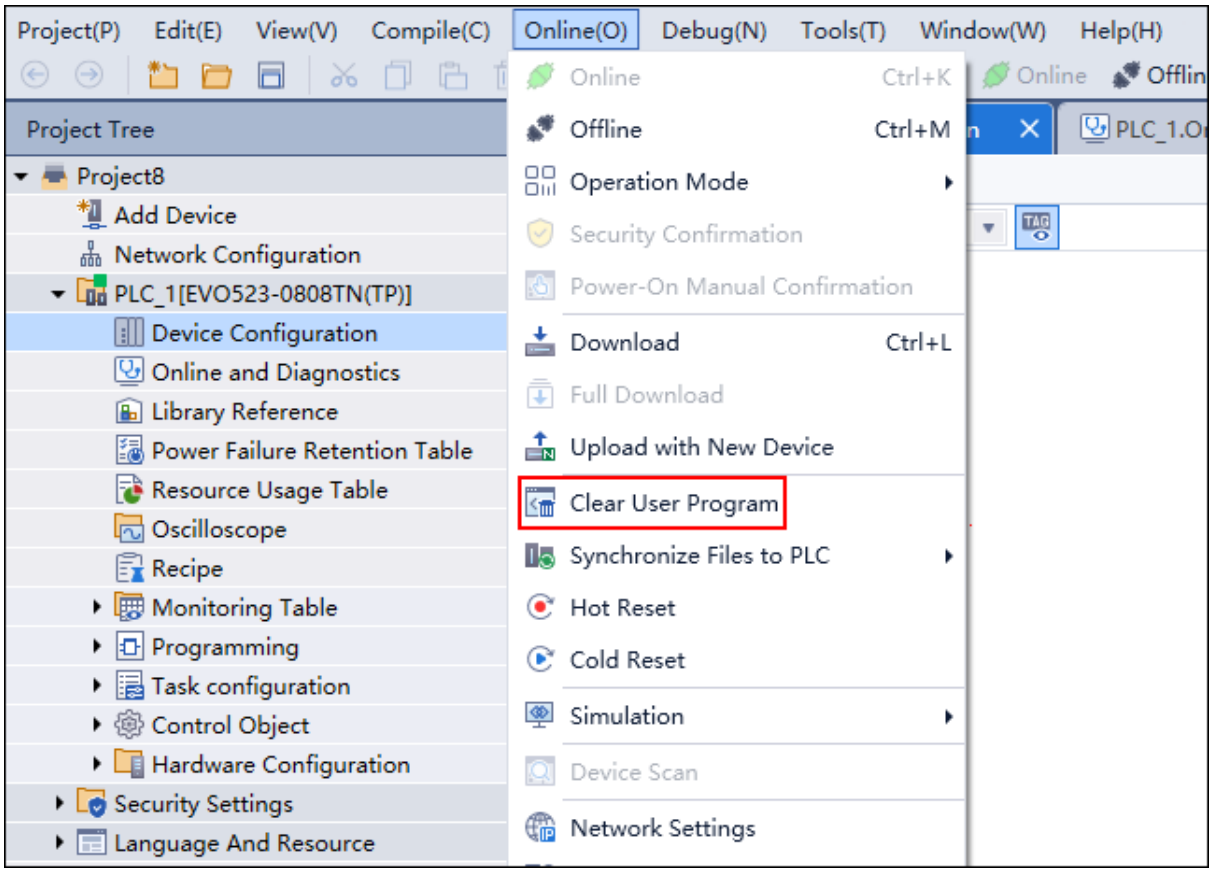
2. In the pop-up window, click "OK" to perform the online cold reset.

Operation result

After a cold reset, all variables of the currently active application, except for power failure retention variables, will be reinitialized.

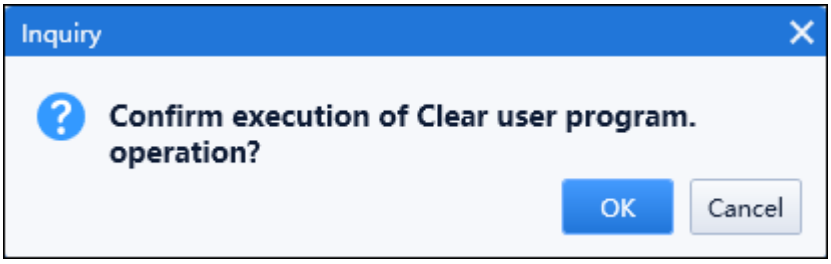
		Item	Type	Address	Value	Prepare value	Comment
1		var1	INT		1882		
2		var2	INT		0		
3		var3	INT		0		

10.11.3 Clearing User Program



After clearing user programs, the programs in the PLC will be cleared, and the device will be switched to the offline status.

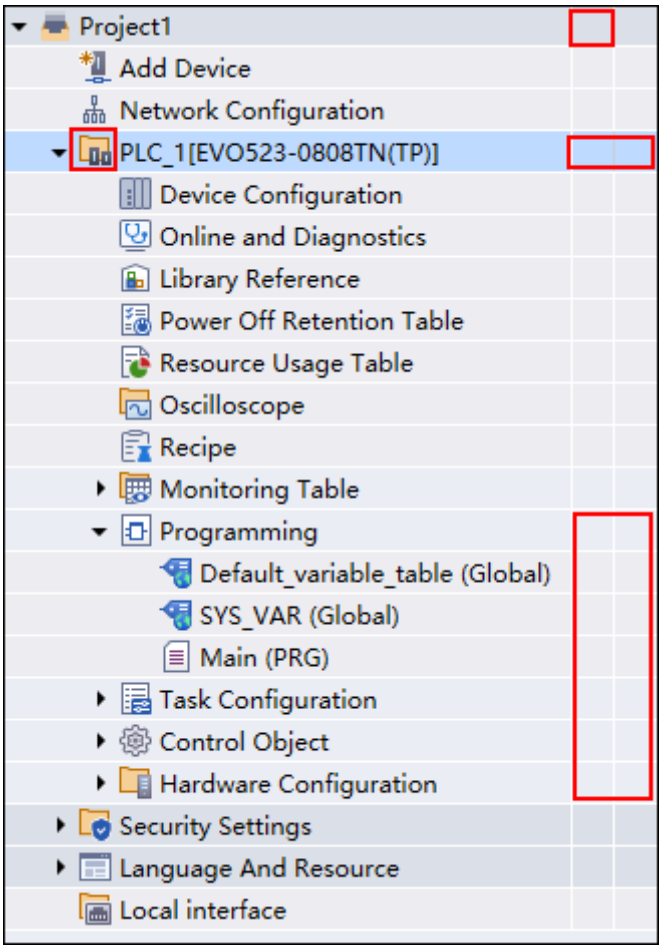
Prerequisites



The device is in an online status.

Procedure

1. Select "Online > Clear user program" in the menu bar.



2. In the pop-up window, click "OK" to clear user programs.

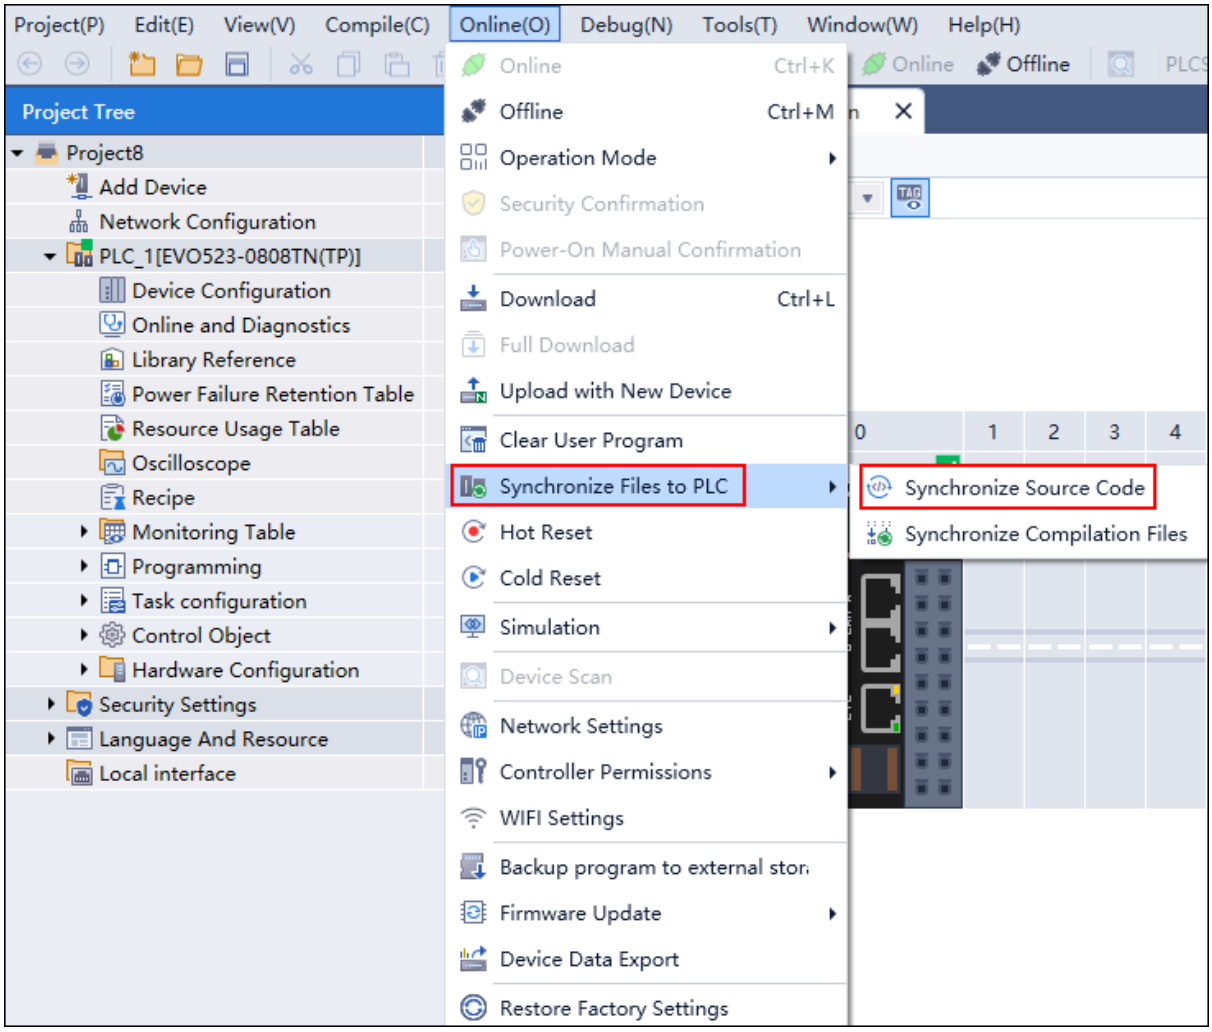
Operation result

After clearing user programs, the PLC project will switch to an offline status, and the green identifier for the corresponding device in the project tree will disappear.

10.11.4 Synchronizing Files to PLC

This function is used to synchronize files to the PLC, including two source code and compilation files.

Synchronizing source code



Synchronize project source code to the PLC.

Prerequisites

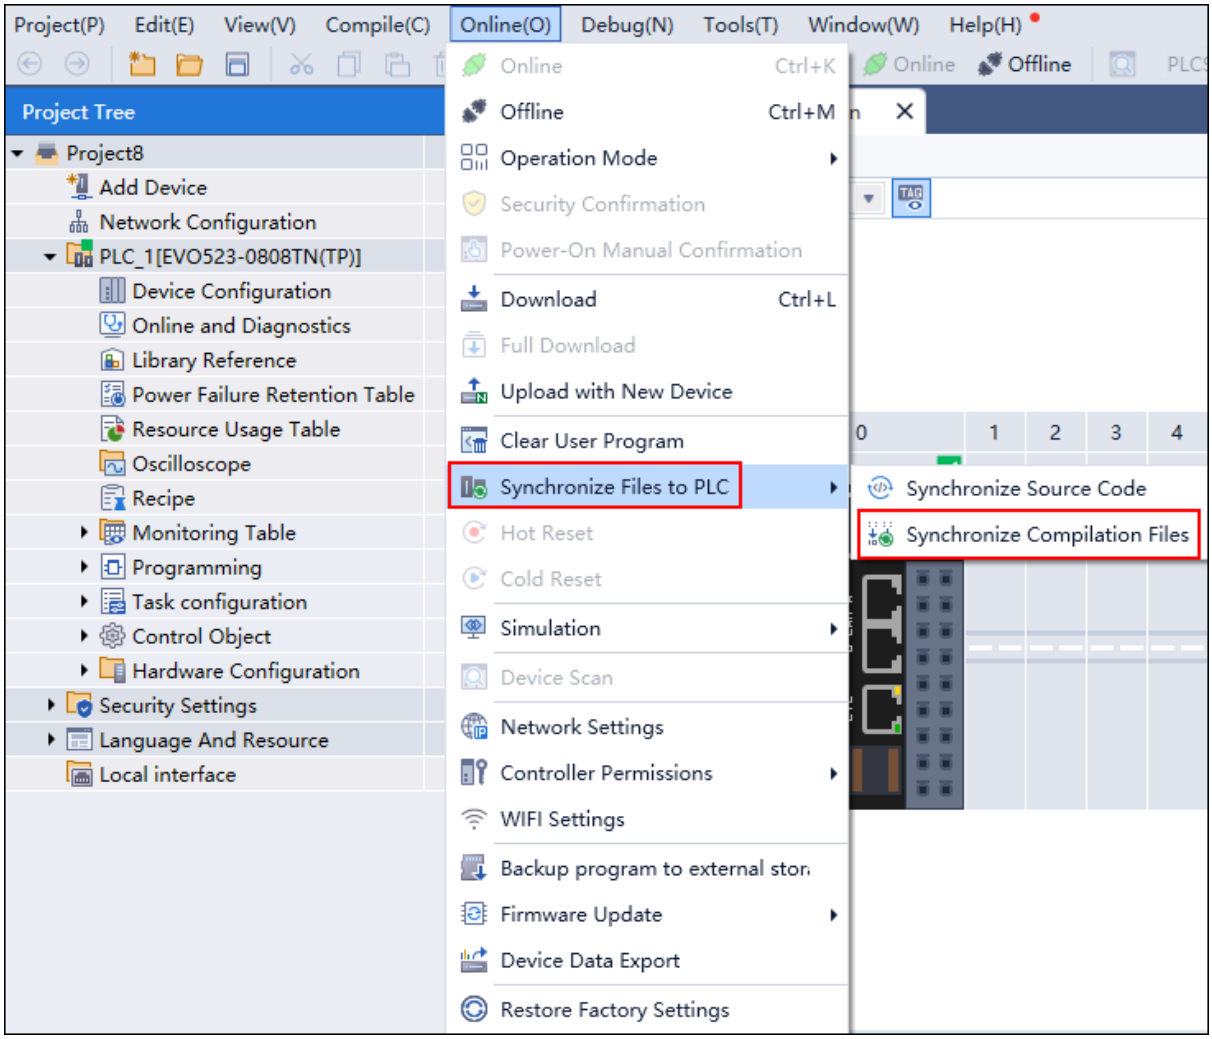
- The current project is in online mode.
- The user program has not changed.

Procedure

1. Select "Online > Synchronize files to PLC > Synchronize source code" in the menu bar to download the project source code to the PLC.

2. The download result will be displayed in the monitoring area.

Synchronizing compilation files



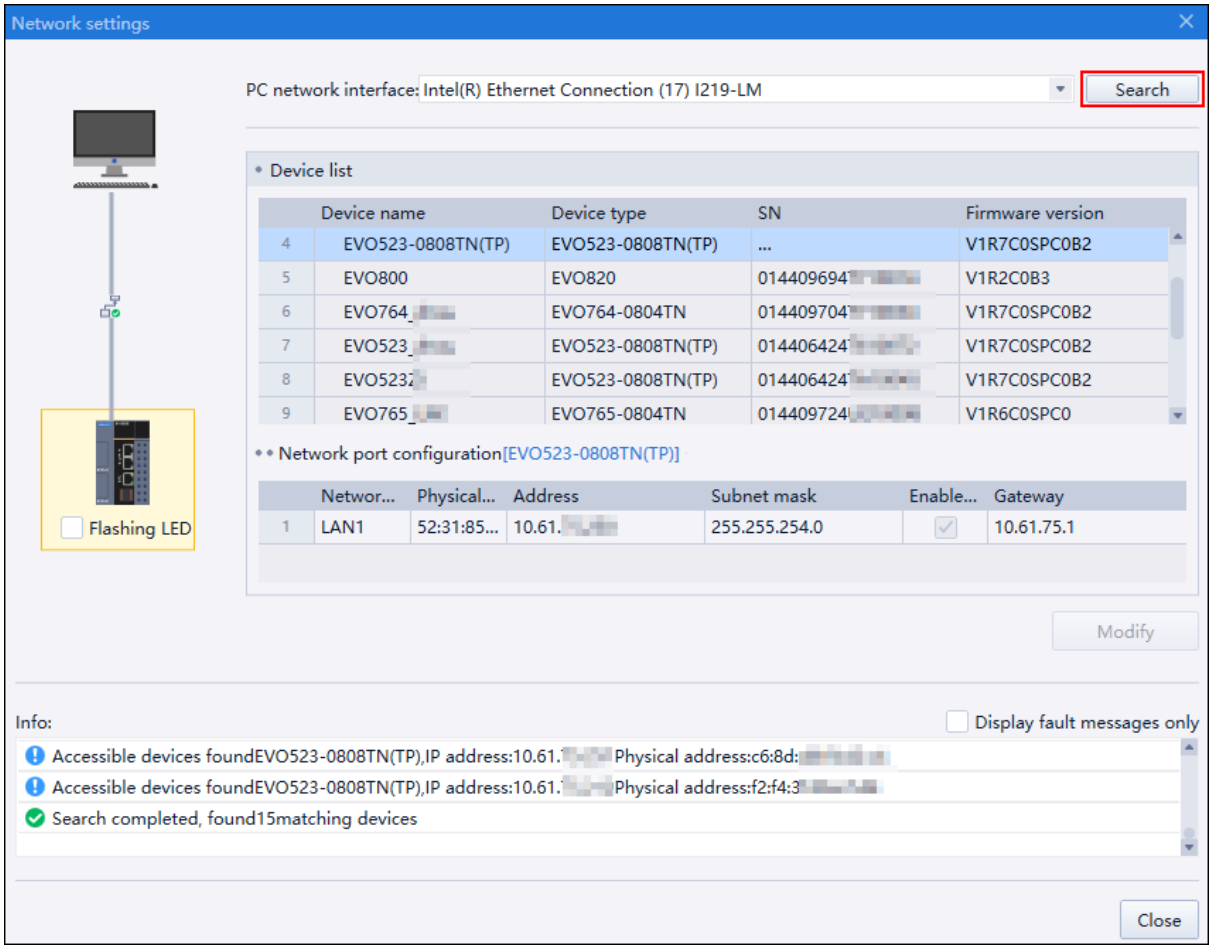
Synchronize compilation files to the PLC.

Prerequisites

- The current project is in online mode.
- The user program has not changed.

Procedure

1. Select "Online > Synchronize files to PLC > Synchronize compilation files" in the menu bar to download the compilation files to the PLC.

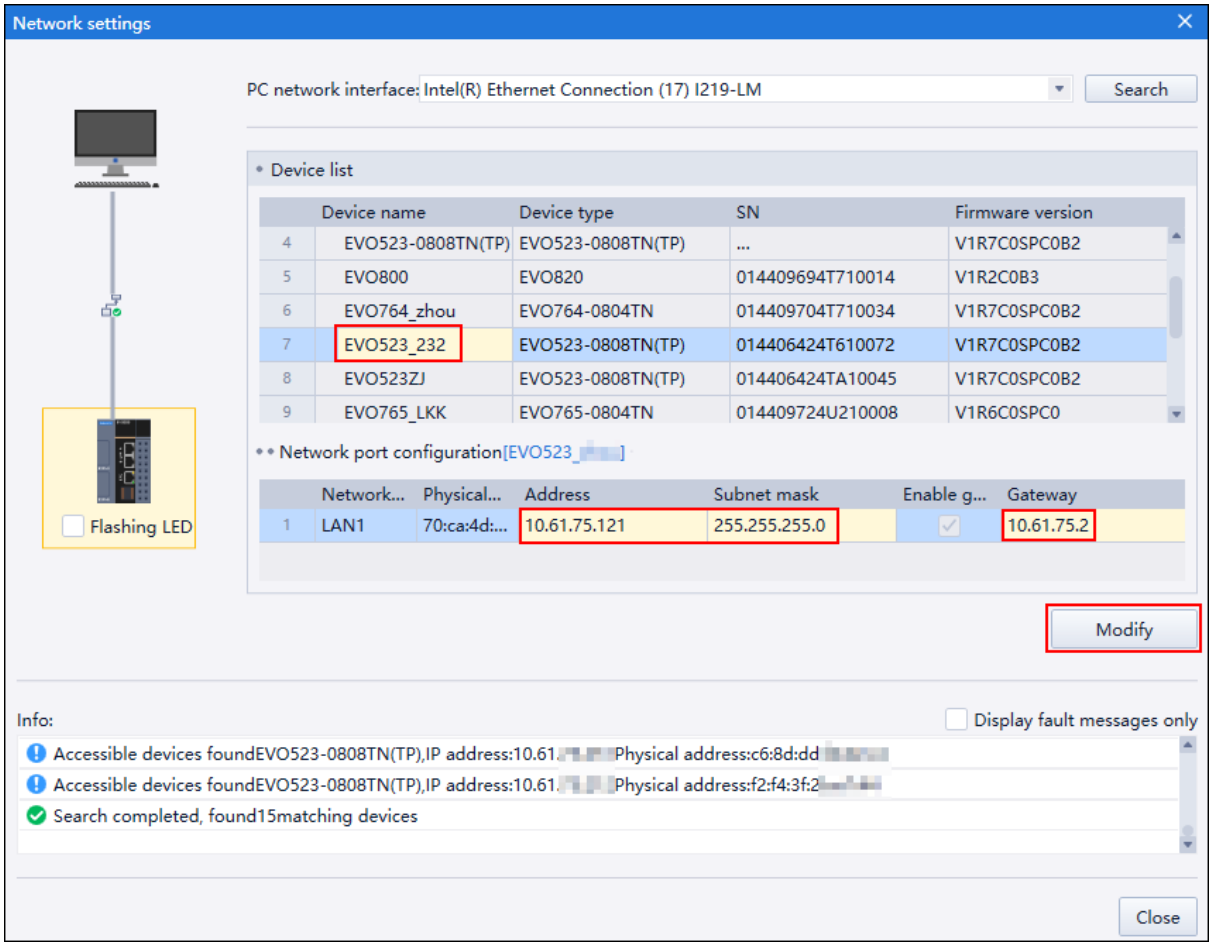


2. The download result will be displayed in the monitoring area.

10.11.5 Network Settings

1. Select "Online > Network setting" in the menu bar to open the network settings interface.
2. Click "Search for devices" to view all devices in the same subnet and across subnets.

> NOTE
>
> The EVO800 series PLC supports downloading and commissioning through the Ethernet expansion module port. When scanning devices through this port, the current system only supports scanning the PLC to which the connected Ethernet expansion module belongs; other PLCs are not supported for scanning. Regardless of whether iFA Evolution is connected to the PLC or to the expansion module: In single or redundant mode, the IP addresses of both the PLC and the expansion module can be set. In single-rack multi-PLC mode, only the IP addresses of the current group (the expansion module and its associated PLC) can be set.



3. Confirm the device.

   Ensure the device selected online matches the target device in the physical environment to avoid connection faults. There are two methods to confirm:

   - SN number consistency check: Compare the SN number in the window with that on the physical device, ensuring they match.
   - LED indicator consistency check: When "Flashing LED" is checked in the window, the **RUN** indicator on the corresponding physical device will flash in response.

4. Edit device information.

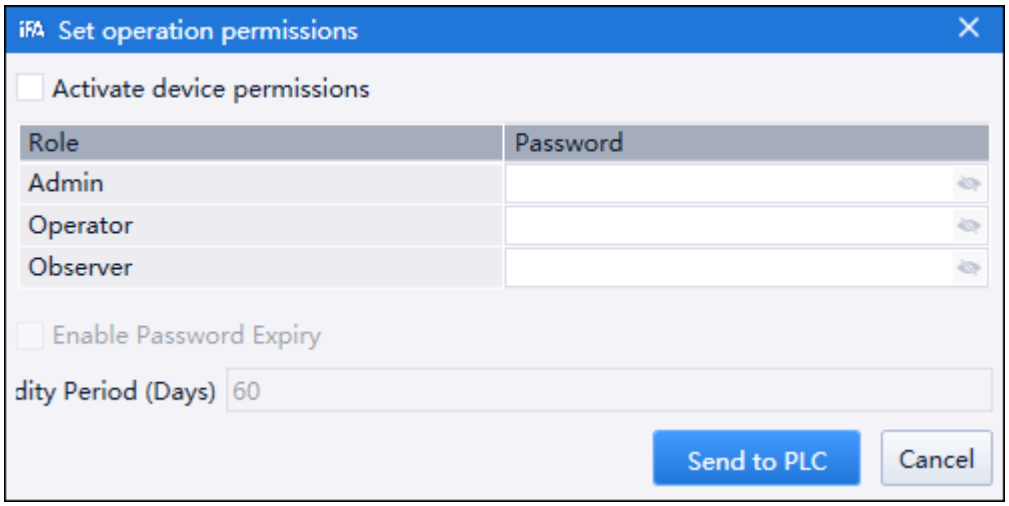
   Double-click to edit the device name, address, subnet mask, and gateway. Then, click "Modify device info" to apply the changes.

The information bar will display the modified content and the operation result.

NOTE

- The gateway address must be in the same network segment as the device's IP address.
- For multi-port devices, only one default gateway can be enabled at a time.
- Devices and firmware versions that support enabling the gateway function are as follows:
  - EVO500/EVO700: V1.7 and above.
  - EVO400: V1.5 and above.
  - APC series: V1.7 and above.
  - EVO800: V1.2 and above.

10.11.6 PLC Permission Configuration



The controller permission configuration function is used to set operation permissions for PLCs. After permissions are set, users must select the appropriate role and pass authentication when connecting to the device (for downloading, going online, etc.). Once authenticated, they can perform the relevant operations.

Prerequisites

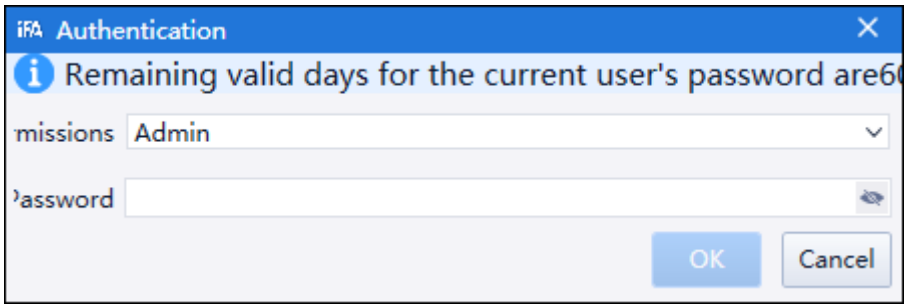
Only the administrator can configure controller permissions. Ensure the current user is an administrator.

Operation permission settings

1. In the iFA menu bar, select "Online > Controller permission > Set operation permissions".
2. On the "Device scanning" page, click "Start search", select the target PLC, and click "OK".
3. Set permissions for the PLC. The parameters are described in the table below.

Parameter	Description
Activate device permissions	When checked, device permission configuration is enabled.
Password	After "Activate device permissions" is checked, you can enter passwords for each role. The password length is 8 characters and must include at least one number, uppercase letter, and lowercase letter.
Enable password validity	When checked, you can configure the password validity period. Each time you log in to the device, the remaining days are displayed. When the password is expired, users can only log in as the administrator. After successful login, they must change the passwords for administrators, operators, and observers. No other operations can be performed until the password change is successful.
Password validity period (days)	Default is 60 days. The configurable range is 1 to 3650 days.

4. After settings, click "Send to PLC" and the permission settings take effect.



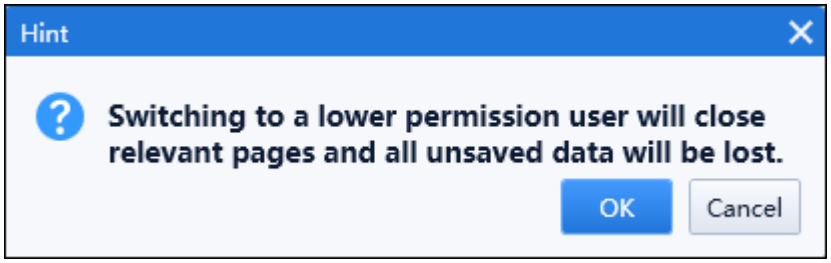
NOTE

- To cancel permission configuration, uncheck "Activate device permissions" in the "Operation permission settings" window, then click "Send to PLC".
- When the software version used by the user is lower than V1.5.2.5 and the connected device is a standard PLC (including EVO400, EVO500, EVO500C, EVO700, EVO700C, and APC series with firmware version V1.7 or later, and EVO800 with firmware version V1.2 or later), if the device has been set with password permission, the software will not be able to connect to this device. To connect, upgrade the software to V1.5.2.5 or later.

Connecting to a controller

Before connecting to a device that has permissions set (e.g., downloading, going online), authentication is required. The download operation is used as an example:

1. Click the "Download" icon on the iFA toolbar.
2. On the "Device scanning" page, click "Start search", select the target PLC, and click "OK".
3. In the pop-up "Authentication" window, select the operation permission, enter the password, and click "OK".



> **NOTE**
>
> During commissioning, to avoid entering passwords when connecting to the device, you can set the PLC device's online retention duration. Within this duration, connecting to the device does not require re-entering the password. For details, see 6.1 General Settings.

Switching roles

For a device with permissions set, use the "Switch user" function to change the current user's operation permissions.

1. In the iFA menu bar, select "Online > Controller permission > Switch user".
2. On the "Device scanning" page, click "Start search", select the target PLC, and click "OK".
3. In the prompt box that appears, click "OK".

4. In the pop-up "Authentication" window, select the operation permission, enter the password, and click "OK" to switch permissions.

Description

The table below describes the permission scope for controllers of different roles.

Permission Scope	Role		
	Administrator	Operator	Observer
Upload/Download	√	×	×
Modify administrator password	√	×	×
Modify role password	√	×	×
WIFI settings[1]	√	√	×
Main/Backup switching[1]	√	√	×
DLR ring network	√	√	×
Time data settings	√	×	×
Online comparison	√	×	×
CPU reset	√	×	×
CPU start/stop	√	×	×
Firmware upgrade	√	×	×
SD card upgrade	×	×	×
Clearing user programs	√	×	×
Trace monitoring	√	√	√
Breakpoint commissioning	√	×	×
Online program modification	√	×	×
Online program monitoring	√	√	√
Variable Monitoring	√	√	√
Variable modification	√	√	×
Variable forcing	√	√	×
Exporting device data	√	×	×
Log clearing	√	×	×
Program and configuration backup[2]	√	×	×

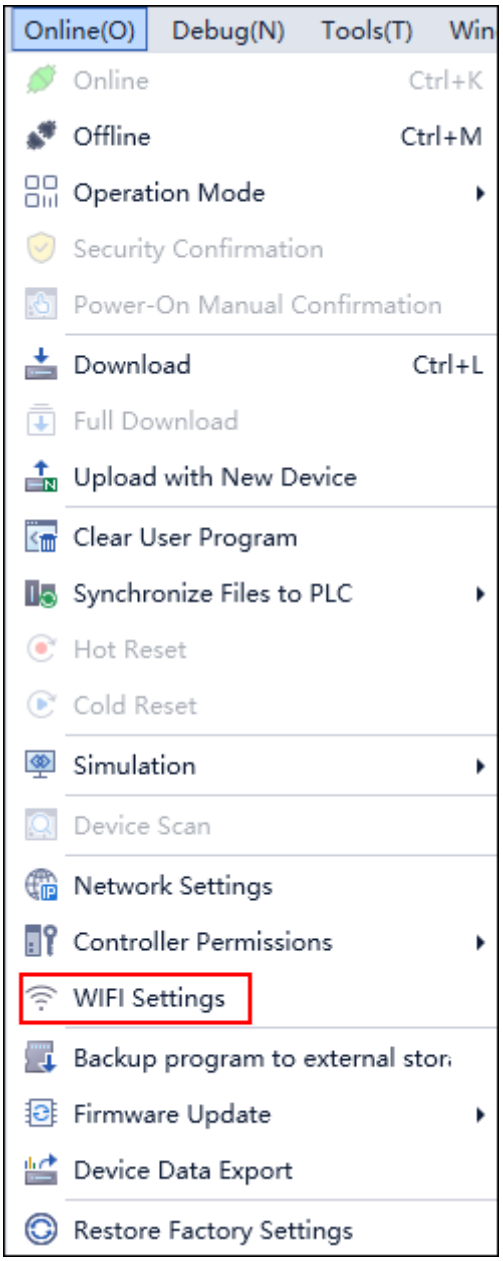
√ indicates that the permission is supported, × indicates that the permission is not supported.

NOTE

All PLCs support the permissions unless otherwise specified.

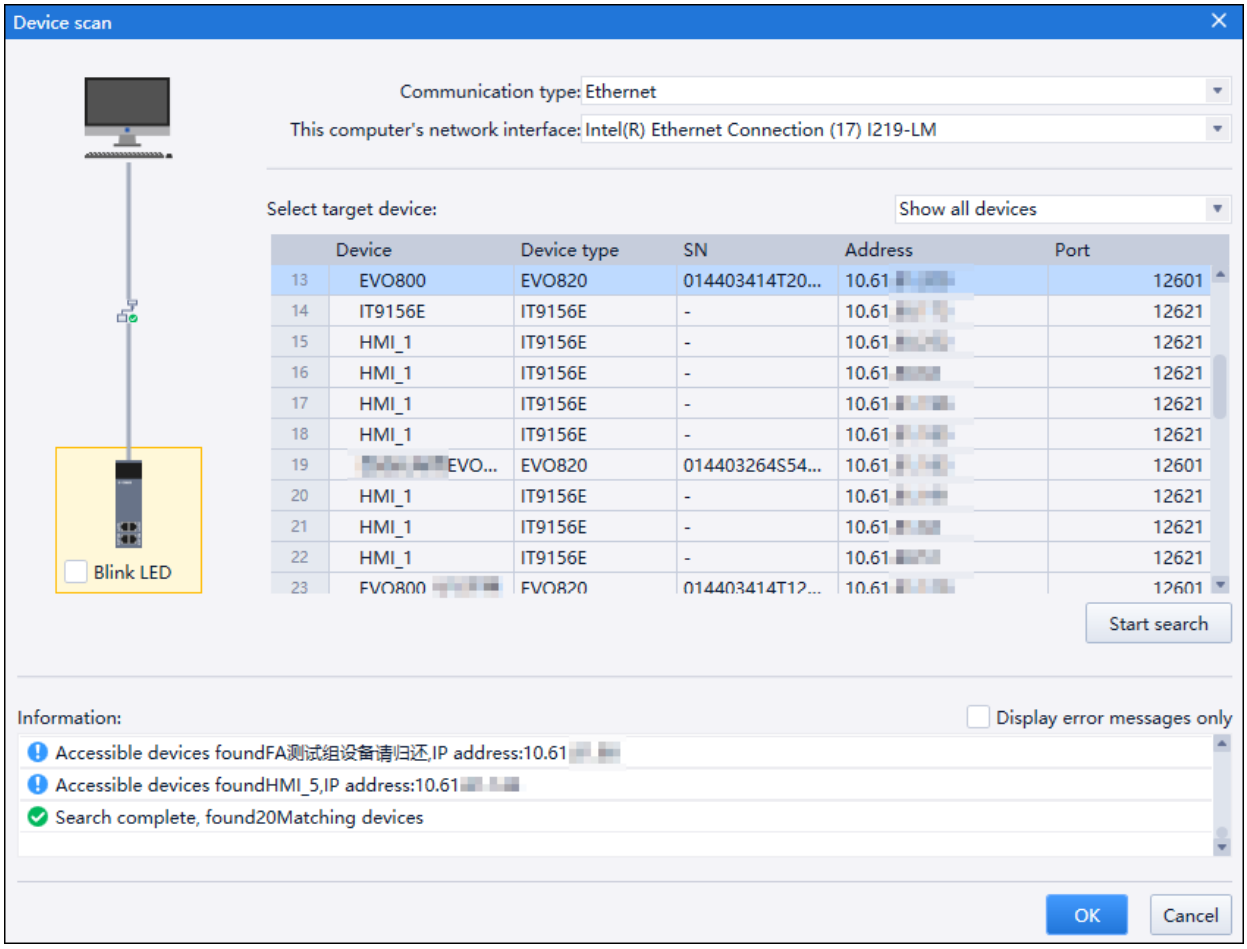
[1]: This permission is only supported by EVO800 series PLCs.

[2]: This permission is only supported by EVO800 series and EVO1000 series PLCs.



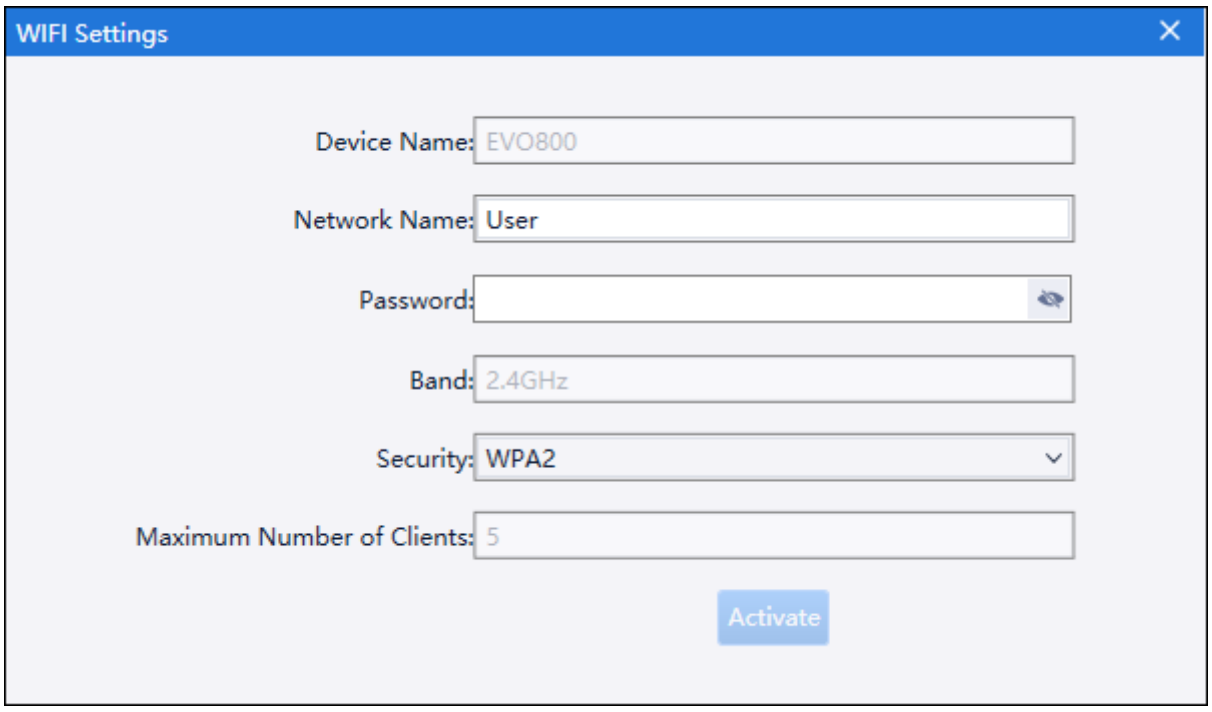
10.11.7 WIFI Settings (EVO820)

iFA supports setting the WIFI parameters of a PLC and activating or deactivating it without relying on a project. Currently, only the EVO820 series PLC supports this feature.



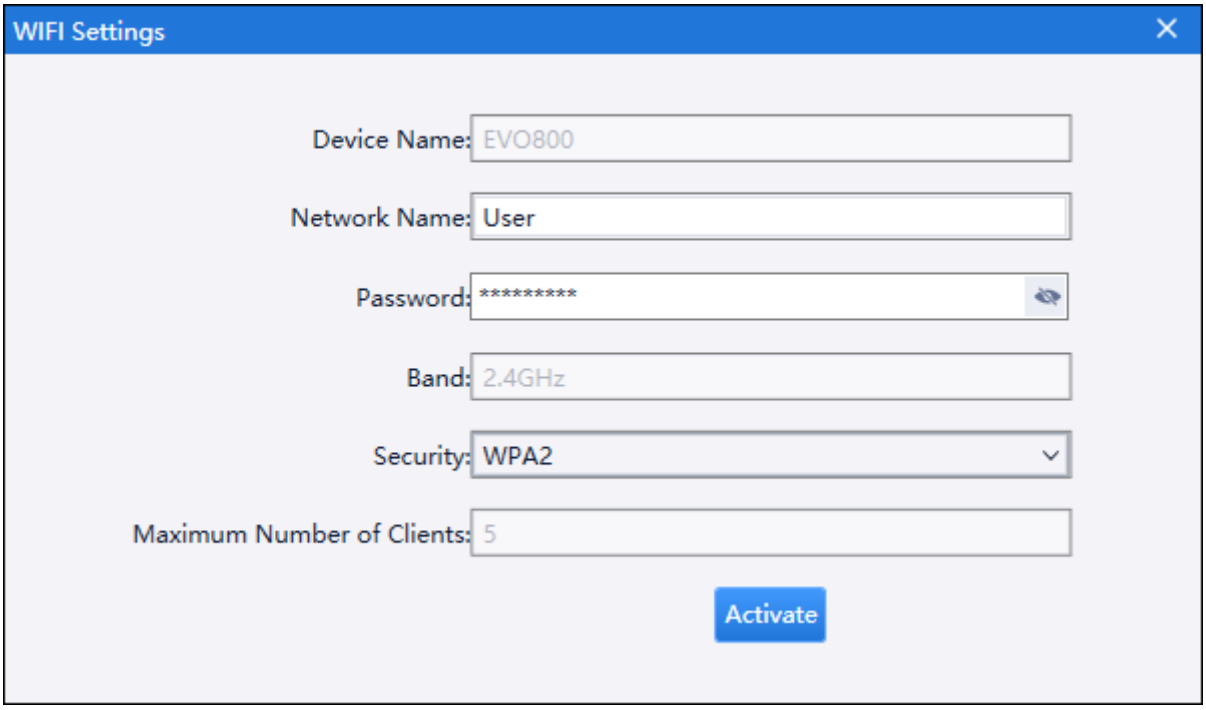
There are two ways to set this up.

- Select "Web diagnostics and monitoring > WIFI settings" in iFA Web. For details, see 10.11.12 Web Diagnostics and Monitoring.
- Select "Online > WIFI settings" in the menu bar.

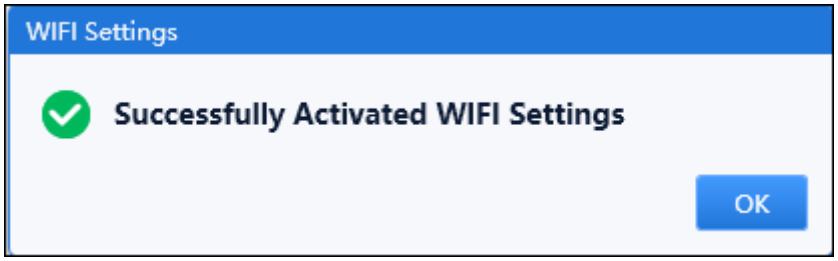


Select "Online > WIFI settings" in the menu bar, as shown in the figure below.

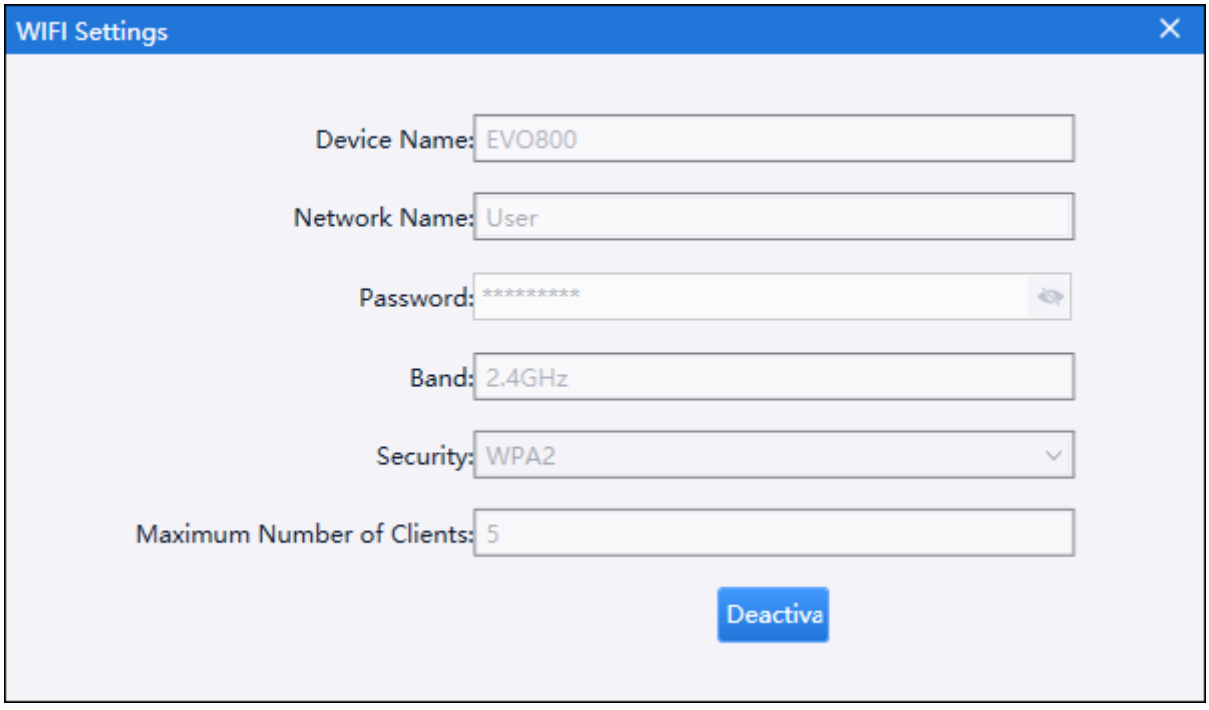
In the pop-up device scan interface, select the EVO800 series PLC.



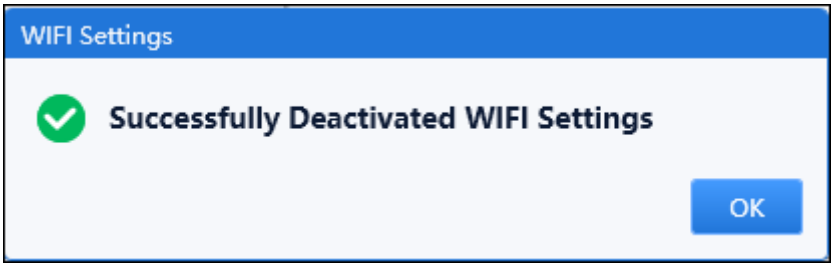
Click "OK" to enter the WIFI settings interface.



- Device name: The name of the selected device
- Network name: The WIFI network name, which supports customization. The default is InovancePLC.
- Password: The initial WIFI password is empty. Set it according to the prompts.
- Frequency band: The default is 2.4 GHz and cannot be modified.
- Security: Supports WPA2 (default) and WPA3.
- Maximum number of clients: The default is 5 and cannot be modified.



After setting the parameters in the WIFI settings interface, the activation button becomes enabled.



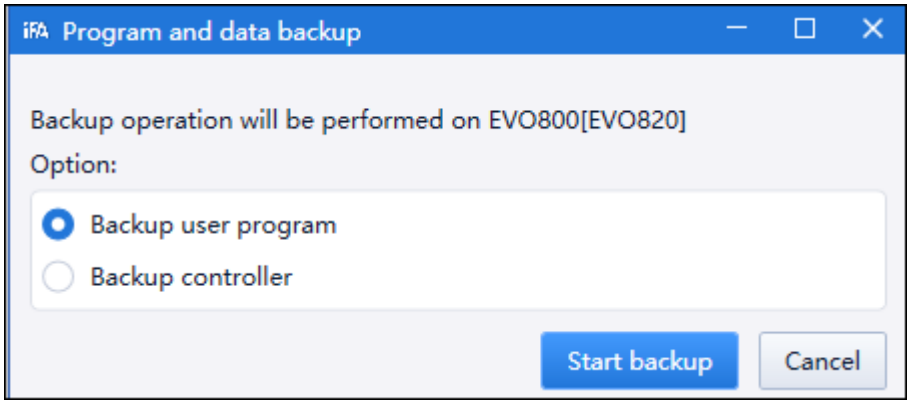
Click the activation button, and a dialog box indicating successful activation will pop up.

Select the device that has successfully activated WIFI, and a dialog box for turning off WIFI will pop up.

Click the close button, and a dialog box indicating successful WIFI closure will pop up.

WIFI settings apply to standalone large-scale PLCs, and main/backup devices of a redundant system. If the PLC is configured with permissions, enter the device password first to obtain the setting permission.

10.11.8 Backing up Program to External Storage



Back up the running program and data from the PLC device to an external storage device.

Prerequisites

- The current device supports program and data backup functions.
- An external storage device (SD card or USB drive) is installed on the current PLC device.
- The current PLC device is in a STOP status.

Backing up program to external storage

1. Select "Online > Backup program to external storage" in the menu bar.
2. In the pop-up "Device scanning" window, click "Start search".
3. Select the target device, click "OK", and the "Program and data backup" window appears.
4. Users can choose either "Backup user program" or "Backup controller".

   - Backup user program: Backs up the user program files.
   - Backup controller: Performs a complete backup of the controller, including system configuration (time, time zone, date, device gateway, etc.) in addition to user program files.
5. Click "Start backup". After completion, a window pops up, indicating successful backup.

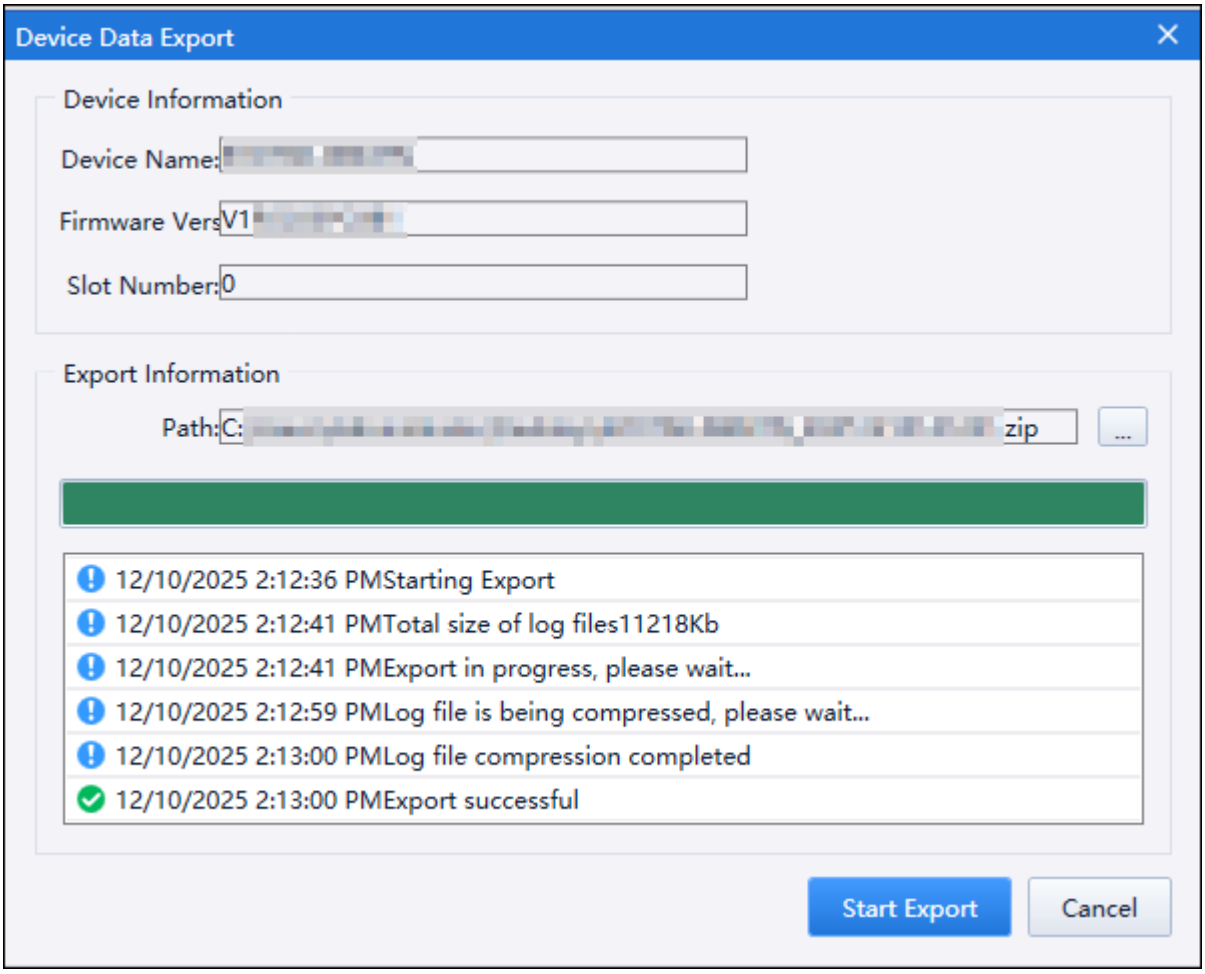
Restoring from external storage

1. Insert the SD card containing the backup files into the card slot of the target PLC.
2. Power off and on the PLC.
   During power-on, the PLC will automatically read the backup data from the SD card and perform the restore operation.
3. If the PLC's segment code screen displays "100", it indicates that the restore operation is completed.

NOTE

- Before backing up, it is recommended to format the SD card or USB drive to avoid issues during the backup process.
- The EVO500 series PLC firmware V1.2 version does not currently support backup functions.
- The EVO760 series PLC only supports backup using a USB drive, and only one USB drive can be inserted. If two USB drives are inserted, the backup fails.
- The EVO800 series PLC supports backup in both single and multi-machine modes, but in redundant mode, only the main device supports backup, while the backup device does not support backup.
- The EVO1000 series PLC currently only supports backing up user programs by default and does not allow user selection.
- During the backup process, do not remove the USB drive, as this may cause backup abnormalities.
- When restoring the PLC, it supports inserting two USB drives simultaneously:
  - If both USB drives contain backup files, the file from the first inserted USB drive will be restored by default.
  - If only one USB drive contains backup files, the backup file will be selected for restoration.
- If device permissions have been set and activated, this operation is subject to permission control. For details, see 9 Project Security Protection.

10.11.9 Exporting Device Data



The data recorded in the device, such as device operation logs, can be exported through the device data export function for analysis.

Prerequisites

The IP addresses of the PLC device and the PC is in the same local network segment.

Procedure

1. Select "Online > Device data export" to enter the device scan page.
2. Select the PLC device to be exported, and enter the export page.

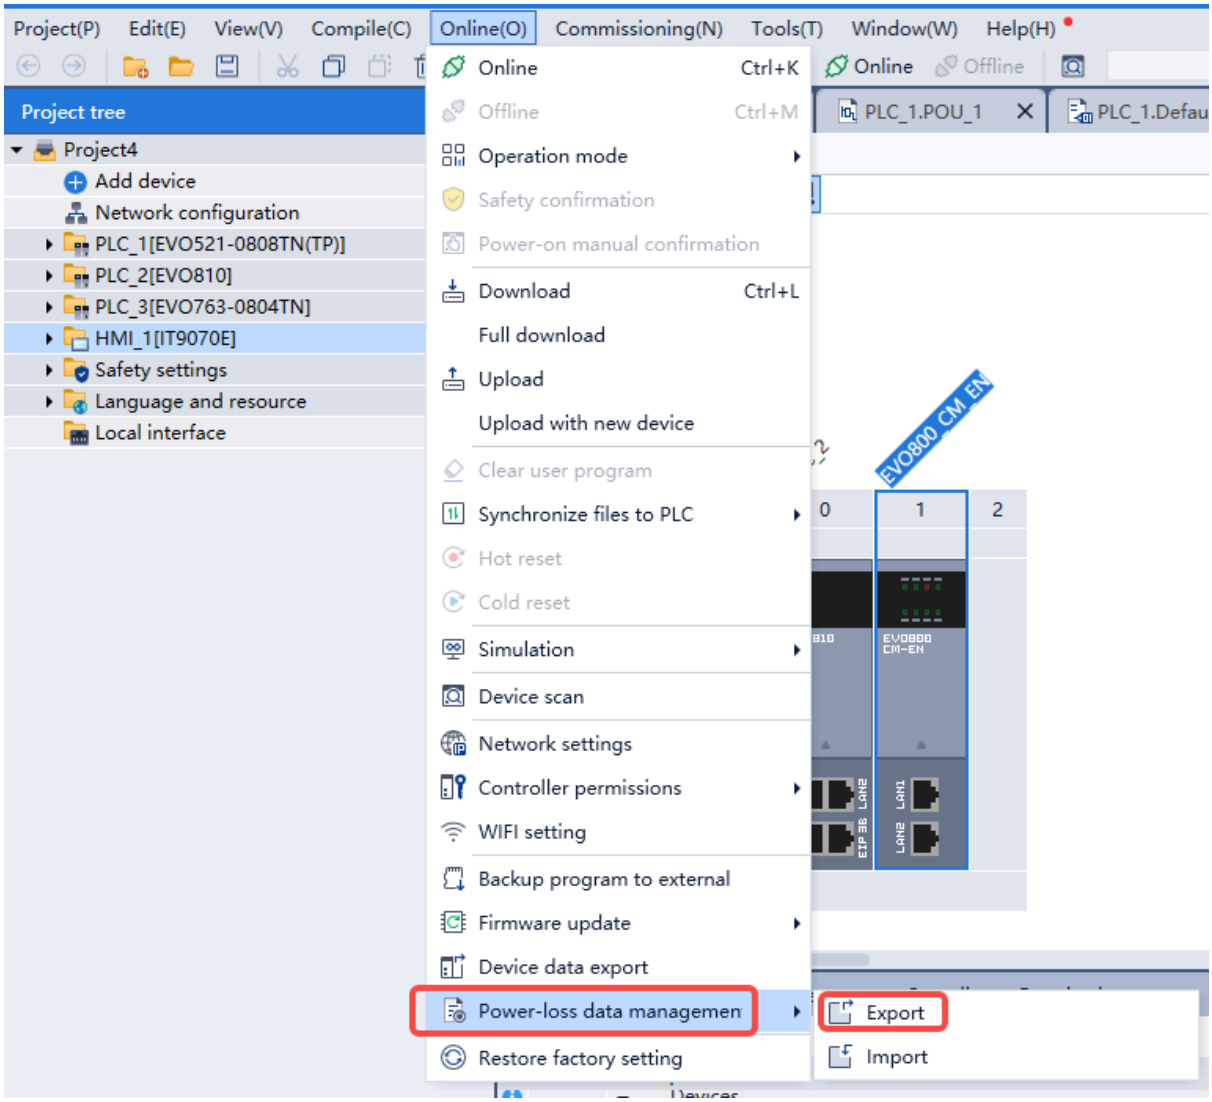
Device name: The name of the current device

Firmware version: The version number of the device firmware

Slot number: The slot number where the device is located

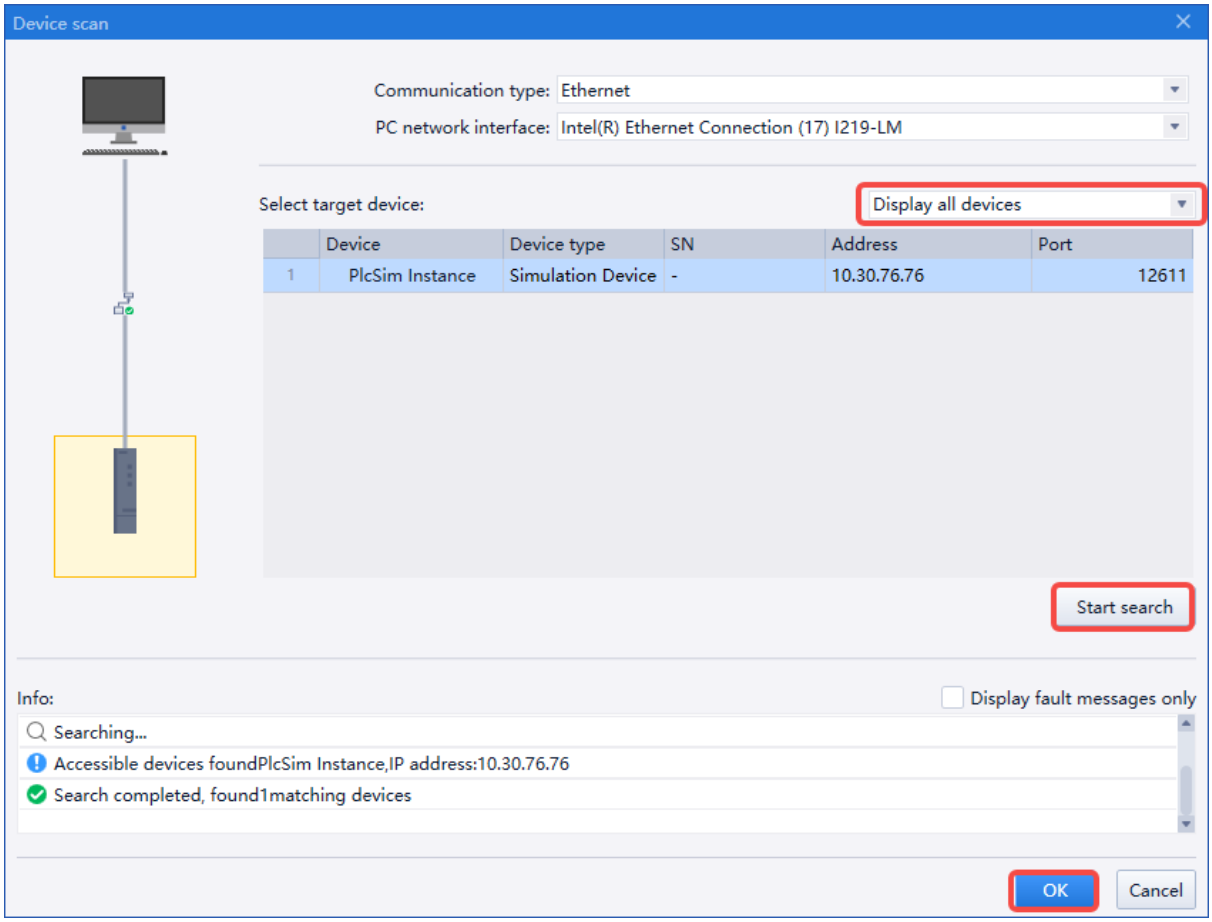
3. Select the path for the export file and click "Export" to start the device file upload process, which will generate a .zip file in the selected path.
   Path: Select the storage location of the export file on the PC's disk. The default file name that supports user modification is "current device name + date and time", such as "PLC1_20240118120012".

NOTE



Only one PLC device can be exported at a time.

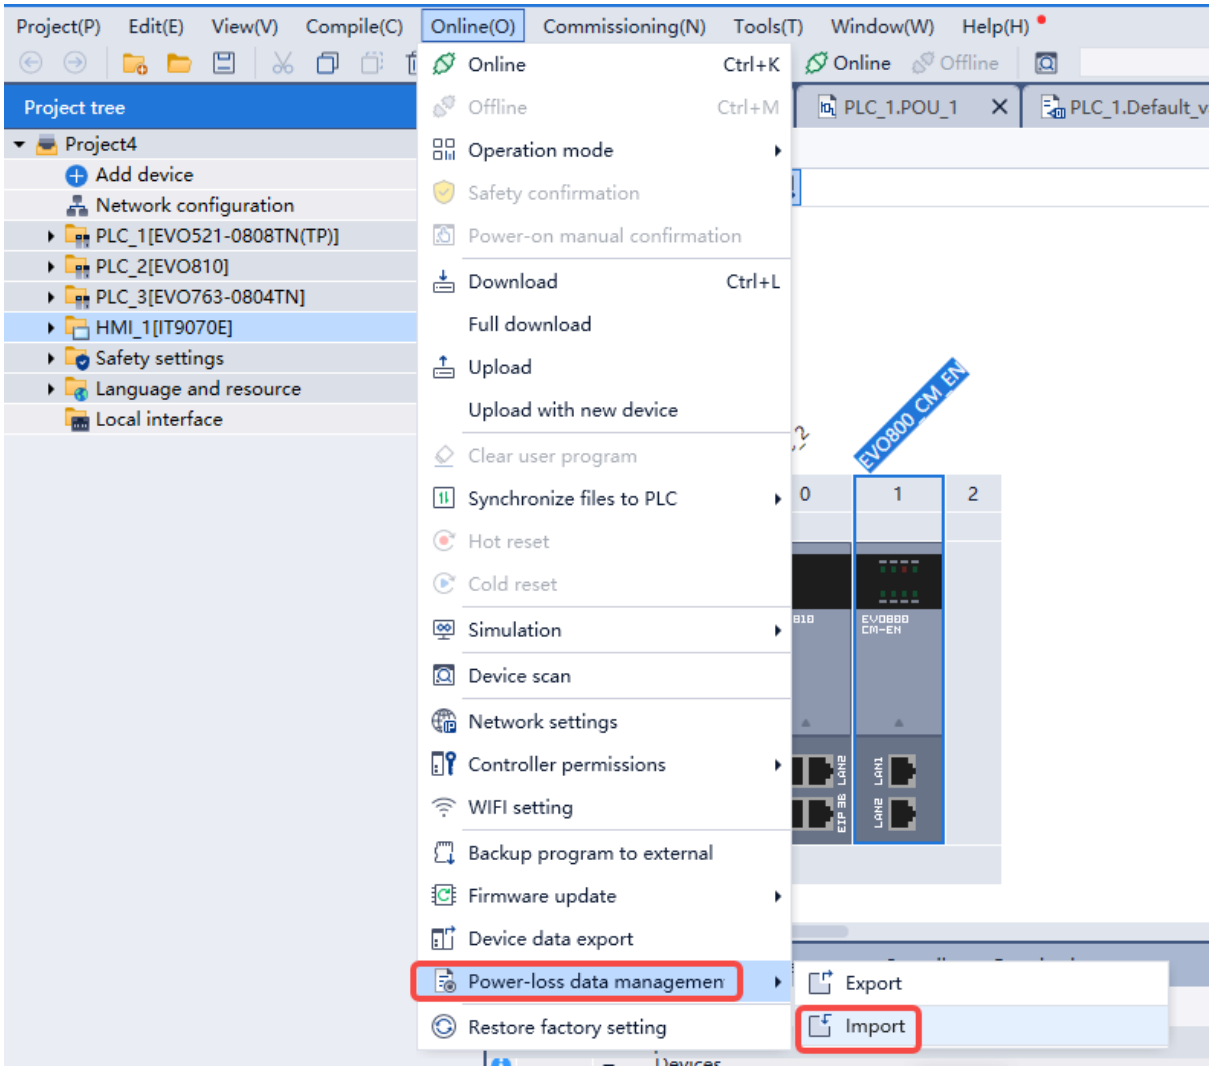
10.11.10 Power Failure Data Management



Power failure data management is used to back up and restore the device's data upon power failure to prevent information loss due to unexpected power outages. You can back up the device's power failure data using the export operation, and restore the backed-up data to the device using the import operation.

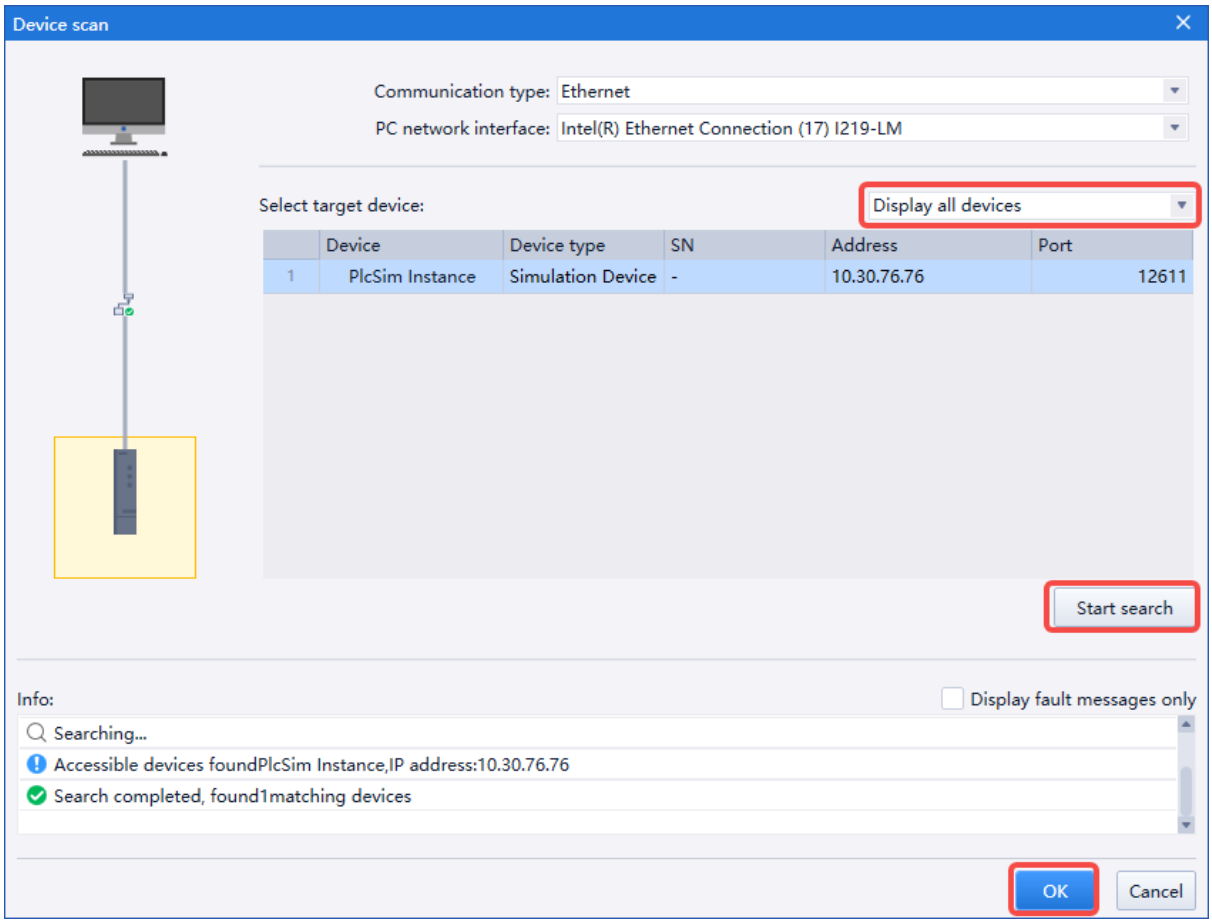
Export

1. Select "Online > Power failure data management > Export" in the menu bar.



2. In the pop-up device scanning window, click "Start search". The system will automatically scan for all devices and support filtering by device type. Select the target device for data export and click "OK", as shown in the figure below:

3. In the pop-up dialog box, select the folder for data export. The system will display a pop-up message: "Executing, please wait...". If the execution succeeds, the system will prompt that the power failure data has been successfully uploaded. If the execution fails, a fault will be reported. Please troubleshoot and handle the issue according to the prompt information.
4. The exported power failure data will be saved in the specified folder, with the default file name "PersistentBackup.rgfile".



Import

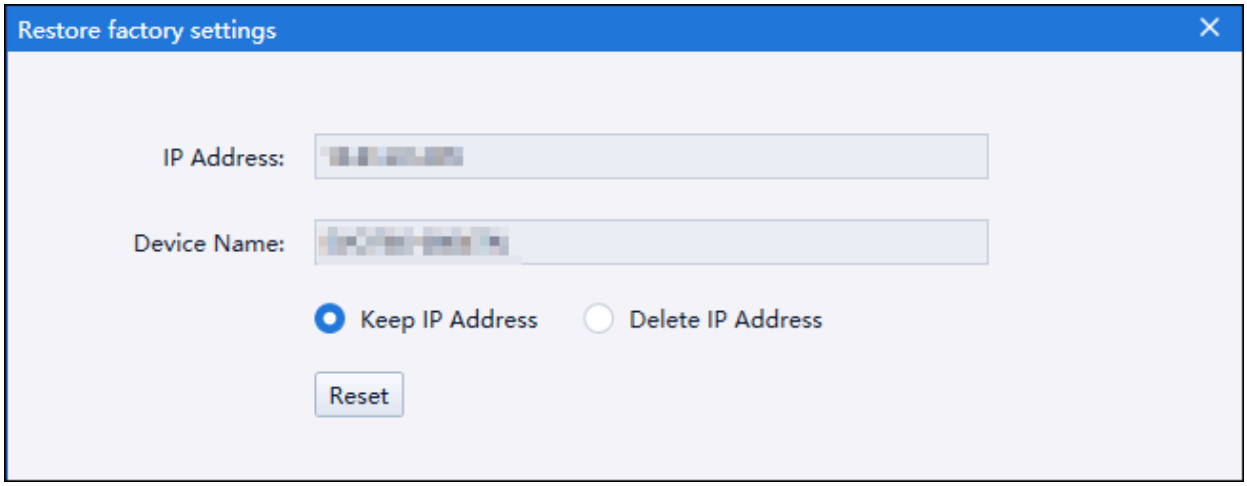
1. Select "Online > Power failure data management > Import" in the menu bar.

2. In the pop-up device scanning window, click "Start search". The system will automatically scan for all devices and support filtering by device type. Select the target device for data import and click "OK", as

shown in the figure below:

3. In the pop-up dialog box, select the power failure data file in .rgfile format to be restored and click "Open".
4. After successful import, the system prompts that power failure data has been transferred to the PLC. Power off and restart the device to restore the data. If the execution fails, a fault will be reported. Please troubleshoot and handle the issue according to the prompt information.

10.11.11 Restoring Factory Settings (EVO800, EVO1000)



Restore the factory settings for the currently connected PLC device, which can be in single mode or redundant mode.

This function can be performed in the following two ways.

Restoring factory settings through the menu bar

Procedure

1. Select "Online > Restore factory setting" to enter the device scan page.
2. Select the target PLC device to enter the factory restoration page.

Restoring factory settings through "Online and diagnostics"

Prerequisites

- A project has been created and a PLC device has been added.
- The device has been switched to online.

Procedure

1. Double-click "Online and diagnostics" in the left project tree and select the "Restore factory setting" tab page.
2. Select the target PLC device to enter the factory restoration page.

Function description

Keep IP address: Maintain the IP address set by users without making any changes.

Delete IP address: Clear users program and restore the IP to the initial IP (192.168.1.88).

Restoring factory settings will reset the default time to 8:00 A.M., January 1, 2000.

NOTE

- The factory restoration operation can only be performed on the currently connected PLC device.
- Both the main device and backup device support deleting the IP for factory restoration.
- When two PLCs are in redundant operation mode, restoring the factory settings of the master device does not affect the slave device.

10.11.12 Web Diagnostics and Monitoring

The web server supports the following browsers:

PC:

- Google Chrome 63.0 or later
- Mozilla Firefox 67.0 or later
- Microsoft Edge 18.0 or later
- MacOS Safari 12.0 or later

Mobile:

- iOS Safari 13.0 or later
- Android Chrome 80.0 or later
- Android Firefox 68.0 or later

> NOTE
>
> Web diagnostics and monitoring functions are supported only on EVO500 series PLCs from V1.4.2.5 and later.

User Login

Enter the device's IP address in the browser, and log in to the 10.6.14.7 web interface using the username and password set on the user management tab of the web server.

If anonymous login has been set in the permission settings of the user management, select "Anonymous access" and no username or password is required.

Home Page

After logging in, go to the main page of web diagnostics and monitoring.

Item		Description
Product information		Specific model information of the product, and the current RTC time /time zone of the controller
System status		Device operating status
CPU operation		The device flashes based on online PLC. Click the "Device flashing" button once and the device will flash for 5s.
Device information (in EVO800 series redundant mode, the main/ backup device status will be displayed; in single mode of EVO700 series and other devices, device information will not be displayed)		Displays the optical fiber status information of the main/backup devices.
Device image		Displays the device image.
Basic information	Project name	Name of the project created by the user
	Controller version	Controller firmware version
	Product model	Specific product model, such as EVO800
	SN code	PLC hardware serial number
	Main control module (Displayed in EVO800 redundant mode)	For redundant control modules, the model of the main control module is displayed, such as EVO820.

Item		Description
	Redundant synchronization module (Displayed in EVO800 redundant mode)	For redundant control modules, the model of redundant module is displayed, such as EVO800-RM.
	Last compilation time	The last project compilation time in the controller (including incremental compilation)
	Last download time	The last project download time in the controller (including online modifications)

Online diagnosis

Displays diagnostic information of the current device.

When the online diagnostic information section shows blank content, manually clear the browser cache and refresh the web server to retrieve the latest online diagnostic information.

Function	Description
Search	By entering a fault code in the search input box, the corresponding fault information is displayed.
Advanced filtering	Use the drop-down box to select fault level and the filtered fault information is displayed accordingly. Fault levels include critical fault, severe fault, alarm, information, and unknown.
Freeze display	Diagnostic information can be frozen for display. After freezing, diagnostic information will no longer be refreshed in real time.
Export controller log	Click to export current diagnostic information, which is saved to a user-defined local path.
Previous page/Next page	Click next or previous page to navigate through diagnostic information.
View fault details	Click the fault level to display detailed fault information, including the cause of the fault code and recommended solutions.
Sort	Sorting can be performed by level, time, or in ascending/descending order.

Variable monitoring

Monitor changes in variable values.

Function	Description
Write	After clicking "Write", the input prepared value will be written, and the value in the variable table will be synchronized and refreshed. Variable write rules: • INT/LINT/SINT/SINT/DINT/WORD/DWORD/LWORD: Enter decimal data. • BOOL: Select TRUE or FALSE. • TIME: TIME type supports input format "XX (unit)", such as 1 h, 1 m, 1 s, 1 ms, and combinations of units h/m/s/ms. For numeric input without a unit, the default unit is ms. • Ltime: Supports input format "XX (unit)", such as 1 d, 1 h, 1 m, 1 s, 1 ms, 1 us, and combinations of units d/h/m/s/ms/us. For numeric input without a unit, the default unit is ms. • Time of DAY: Click the calendar to select time. • DateAndTime/Date: Click the calendar to select date and time. • Enumeration: Select enumeration values from the drop-down list.
Read	Refreshes variable values.
Previous page/Next page	Click next or previous page to navigate through variable information.
Search	Enter an expression to search; supports fuzzy search.

Network port communication information

Displays the network port communication information of the device. The information is read-only, uneditable, and refreshed every 1 second.

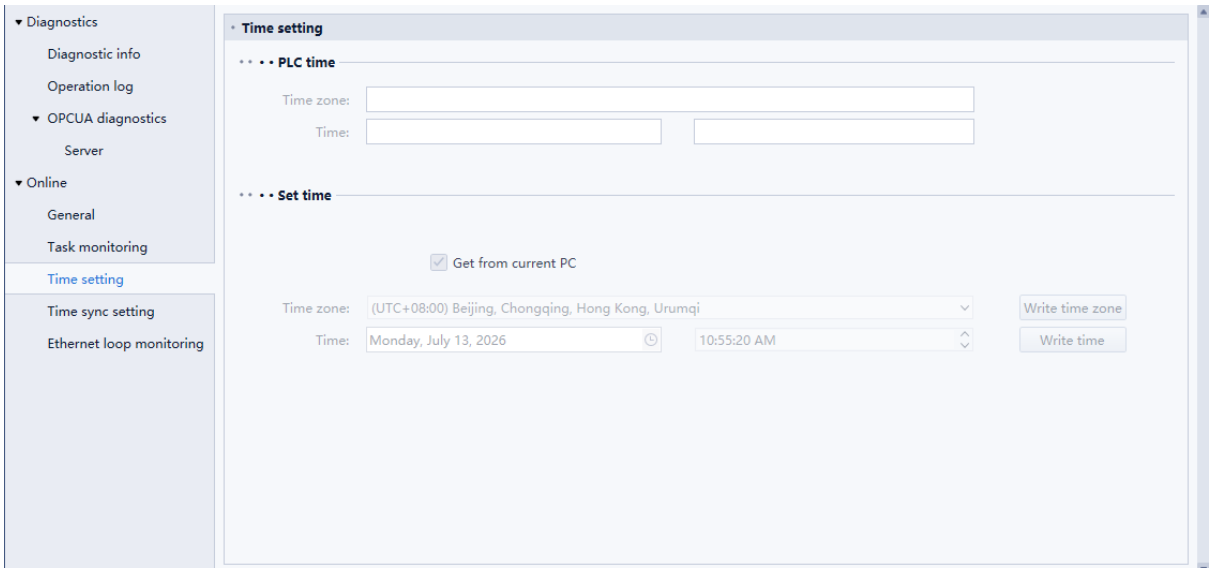
Parameter	Description
Port	The port refers to the actual physical port of the device.
Port IP	The IP address of the port.
Subnet mask	The subnet mask of the port.
Connected device information	The IP address of the connected device. If connected via a personal PC, the PC's IP address is displayed.
Communication type	The protocol type used by the device. Currently supports communication protocols such as EIP/OPCUA/WEB/Modbus TCP.
Connection status	Displays whether the device's connection status is normal or faulty. • For active connection, the slave status matches the project tree status, and the PLC acts as the master (such as EIP master and Modbus TCP/RTU master). • For passive connection, the connection status displays "Connected", and the PLC acts as a slave (such as EIP slave, Modbus TCP/RTU slave, WEB, OPCUA server, or HMI-CLASS3 connection).

Wi-Fi configuration

Currently, only EVO800 series PLCs support Wi-Fi settings, and the function is the same as "Wi-Fi settings" under "Online" in the menu bar.

Parameter	Description
Network name	The prefix is fixed as the PLC device name, and the suffix can be customized by the user. It can include English letters, Chinese characters, numbers, and underscores, but cannot start with a number or end with a number or underscore.
Password	The Wi-Fi password is initially empty, which can be set according to the password naming requirements. The password can consist of letters, numbers, and special characters, and must include at least one digit, one uppercase letter, and one lowercase letter, with a length between 8 and 32 characters.
Frequency band	The default is 2.4 GHz and cannot be modified.
Security	Supports WPA2 (default) and WPA3. • WPA2: Uses AES encryption technology to provide reliable network protection. • WPA3: Enhances encryption algorithms to resist brute password attacks and offline attacks, significantly improving privacy and security.
Max. number of clients	The default is 5 and cannot be modified; new connections will be rejected if more than 5 clients are connected, while existing connections remain unaffected.
Wi-Fi activation status	Activation is only allowed when network name, password, security settings, and client count are correctly entered. After activation, the parameter page becomes grayed out and cannot be edited.

10.11.13 Time Settings



Time settings are used to set the time reference for the PLC, which is supported when the PLC is online.

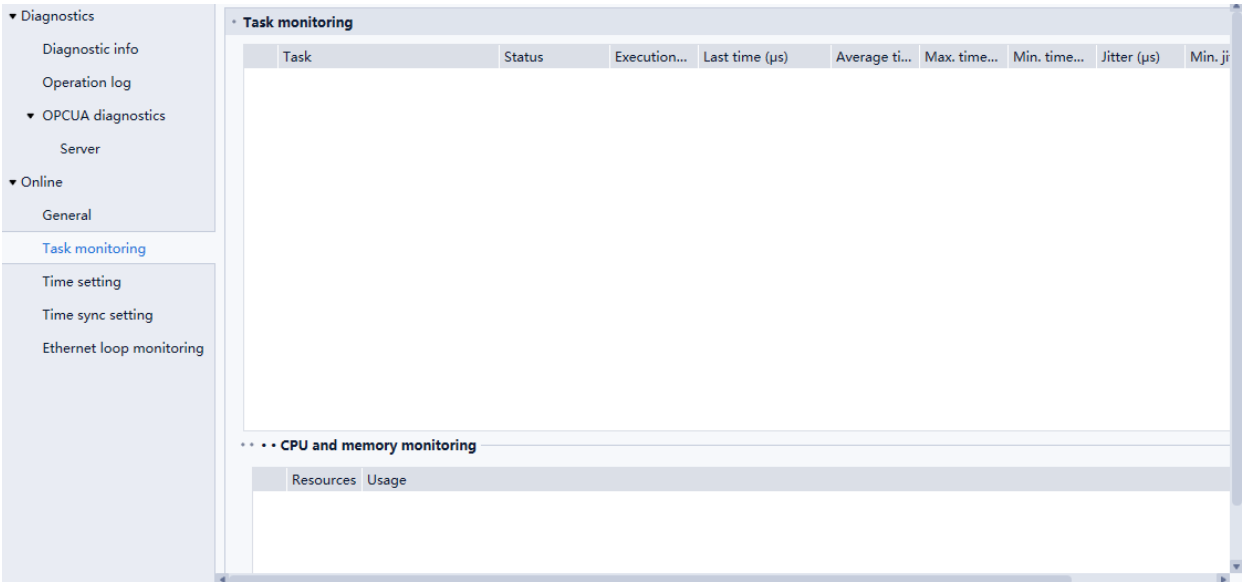
Prerequisites

- The device is in an online status.
- The PLC has a built-in battery or an RTC clock card.

Procedure

1. Double-click "Online and diagnostics" in the project tree.

2. Set the time.



- PLC time: The current time and time zone of the PLC, with a refresh cycle of 1 second.
- Set time: The desired time reference for the PLC, which can be obtained from the current computer or by entering the corresponding time zone and time.

NOTE

To use the RTC (Real-Time Clock) function, ensure that the PLC has a built-in battery. If the PLC does not have this feature (such as EVO500), a dedicated RTC clock card (such as GE20-RTC) must be selected to achieve the time retention function after power failure.

10.11.14 Task Monitoring

Double-click "Online and diagnostics" in the project tree.

- Task monitoring
  The "Task monitoring" tab displays the information of tasks currently contained in the PLC and the running status of each task.
- CPU and memory monitoring

  The explanation for CPU usage is as follows:

  - 0% to 80%: CPU usage is normal. The PLC runs relatively stably, and functions such as logic execution, bus synchronization, I/O refresh, data synchronization, and data saving can be used normally.
  - 80% to 100%: CPU usage is high or has reached its limit, reducing the stability of the PLC's operation.

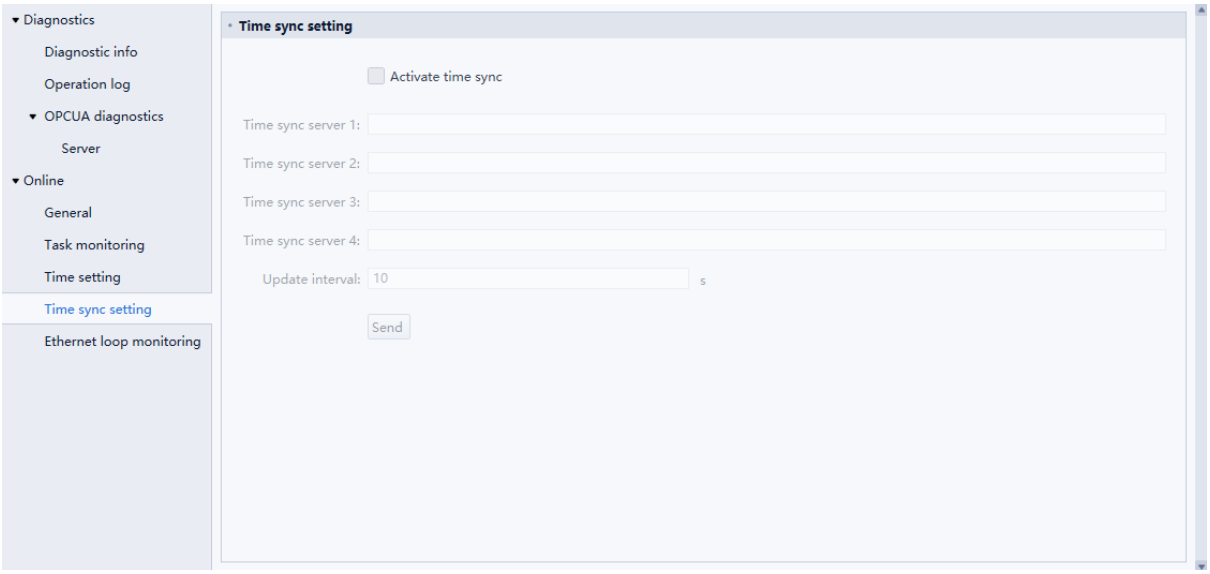
    Main impacts of high CPU usage

    - The stability of EtherCAT operation cannot be guaranteed, and there may be issues with EtherCAT slaves dropping out or losing synchronization.
    - In severe cases, it may cause the PLC to enter a false alarm status, making it impossible to log in to the PLC.
    - Power failure storage data cannot be saved.
    - EIP/OPC UA/Modbus and other related communication services may experience slow data refresh or disconnection risks.
    - Online modification or PLC program download may become slower or fail.
    - Monitored PLC variable values may experience slow refresh or inability to refresh.

10.11.15 Time Synchronization Settings

The time synchronization function allows all devices in the network to obtain time from the same source, ensuring time consistency across all devices.

Prerequisites



The device is in an online status.

Procedure

1. Double-click "Online and diagnostics" in the project tree on the left.

2. Go to the "Online > Time sync setting" tab.

3. Check "Activate time sync", configure the valid IPs for time sync servers and the update interval, and click "Send".

Parameter	Description
Activate time sync	Unchecked by default. When checked, it activates the time synchronization function.
Time sync server 1/2/3/4	Enter valid IP addresses for time sync servers. At least one IP address must be provided. If all four are configured, the priority order is 1 > 2 > 3 > 4.
Update interval	The interval for time synchronization updates. Range: 10s to 86400s (1 day).

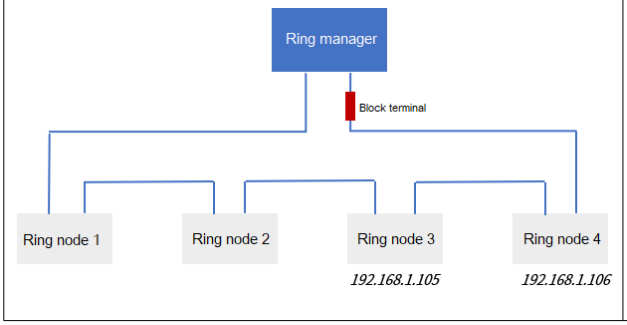
4. After time synchronization, a pop-up displays "Execution succeeded".

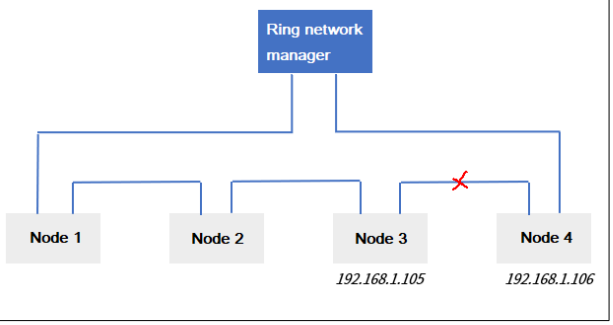
NOTE

- If the current program contains the 18.4.1.34 SysHC_NtpClient(NTP calibration) instruction and it is enabled, this configuration will fail. Please disable the NTP instruction before configuring on this page.
- The EVO800 series PLC only supports setting the time for the main device (PLC), which then synchronizes the time to the backup device.
- If both time synchronization settings and time settings are active, the time setting information is only effective within the update interval of the time synchronization settings. For example, if the time written is 20:00:00 and the NTP synchronization update interval is 10 minutes, the written time will be maintained for a maximum of 10 minutes, after which the new round of NTP synchronization will overwrite 20:00:00 with the server time.
- NTP synchronization is specific to the device and is independent of the software system.

10.11.16 DLR Ring Network Management (EVO800)

Set the communication parameters of the DLR ring network during the online operation of the PLC, and monitor its real-time operating status. Currently, only the EVO800 series PLC supports this function.





Prerequisites

- The ring network has been established.
- The current PLC is the ring network manager.
- The EVO800 series PLC is in online operation mode.

Function entry

Double-click "Online and diagnostics" in the project tree.

Real-time monitoring of the ring network:

The ring network is running well	A break has occurred in the ring network
	

When opening this interface, the system reads the current status of the ring network; it then refreshes every 1 second until the interface is closed.

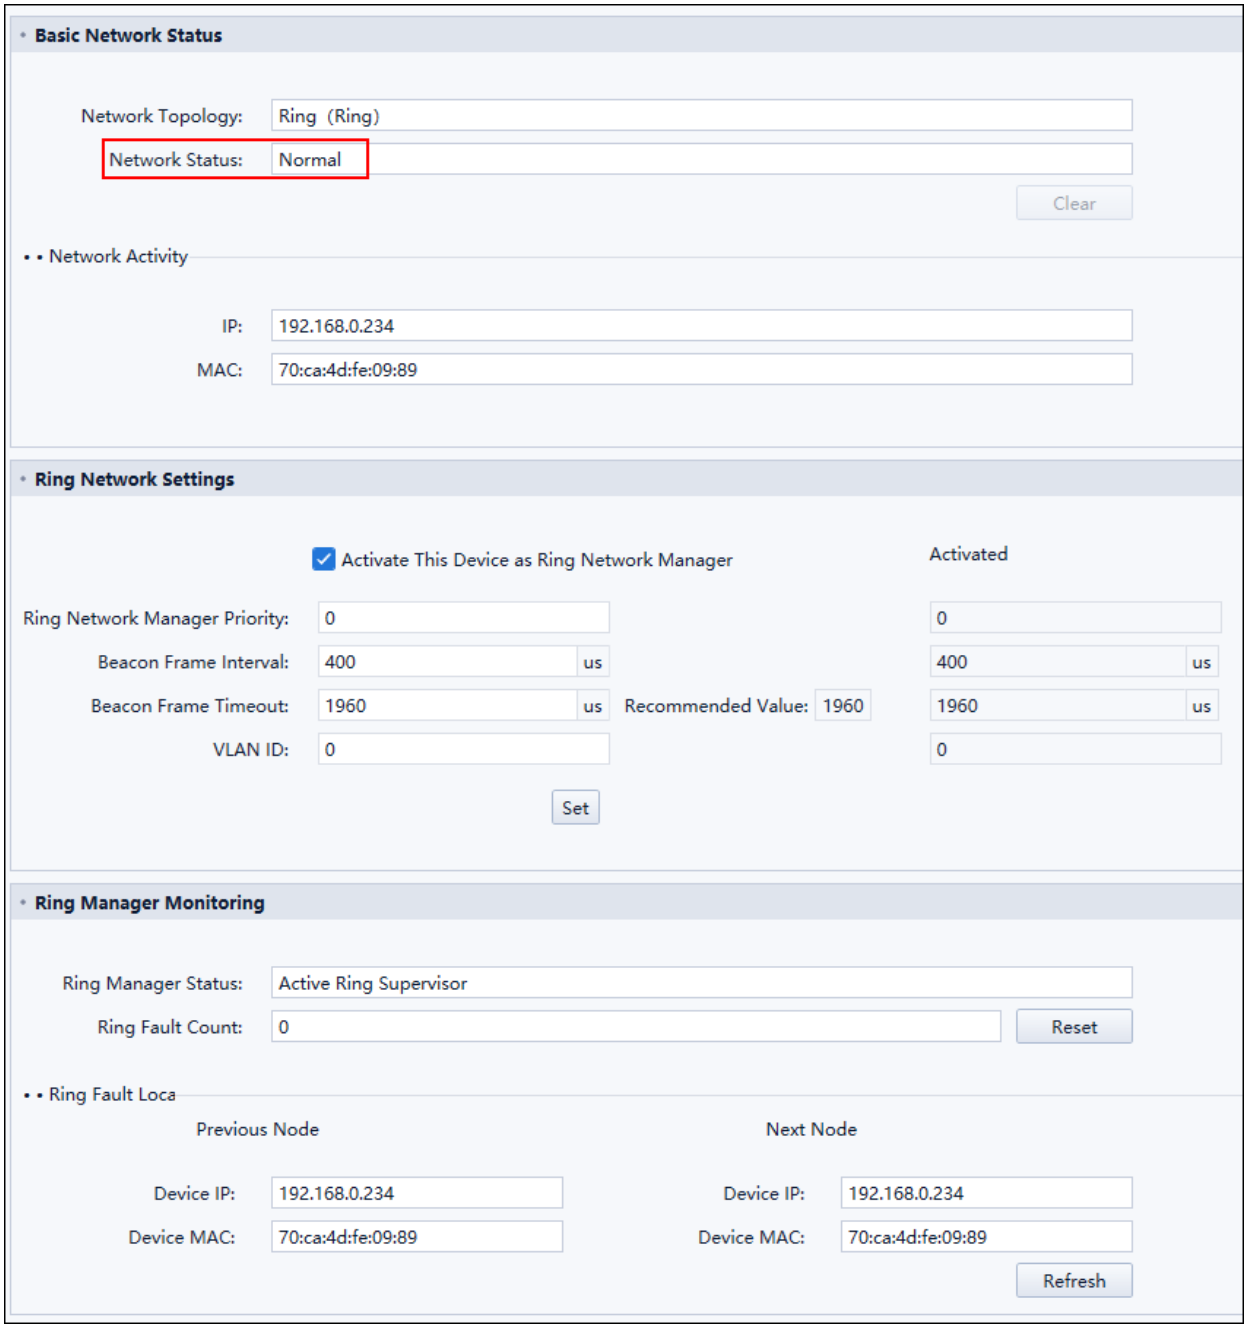


Figure 10-11-16-1 Monitoring results when the ring network is running well

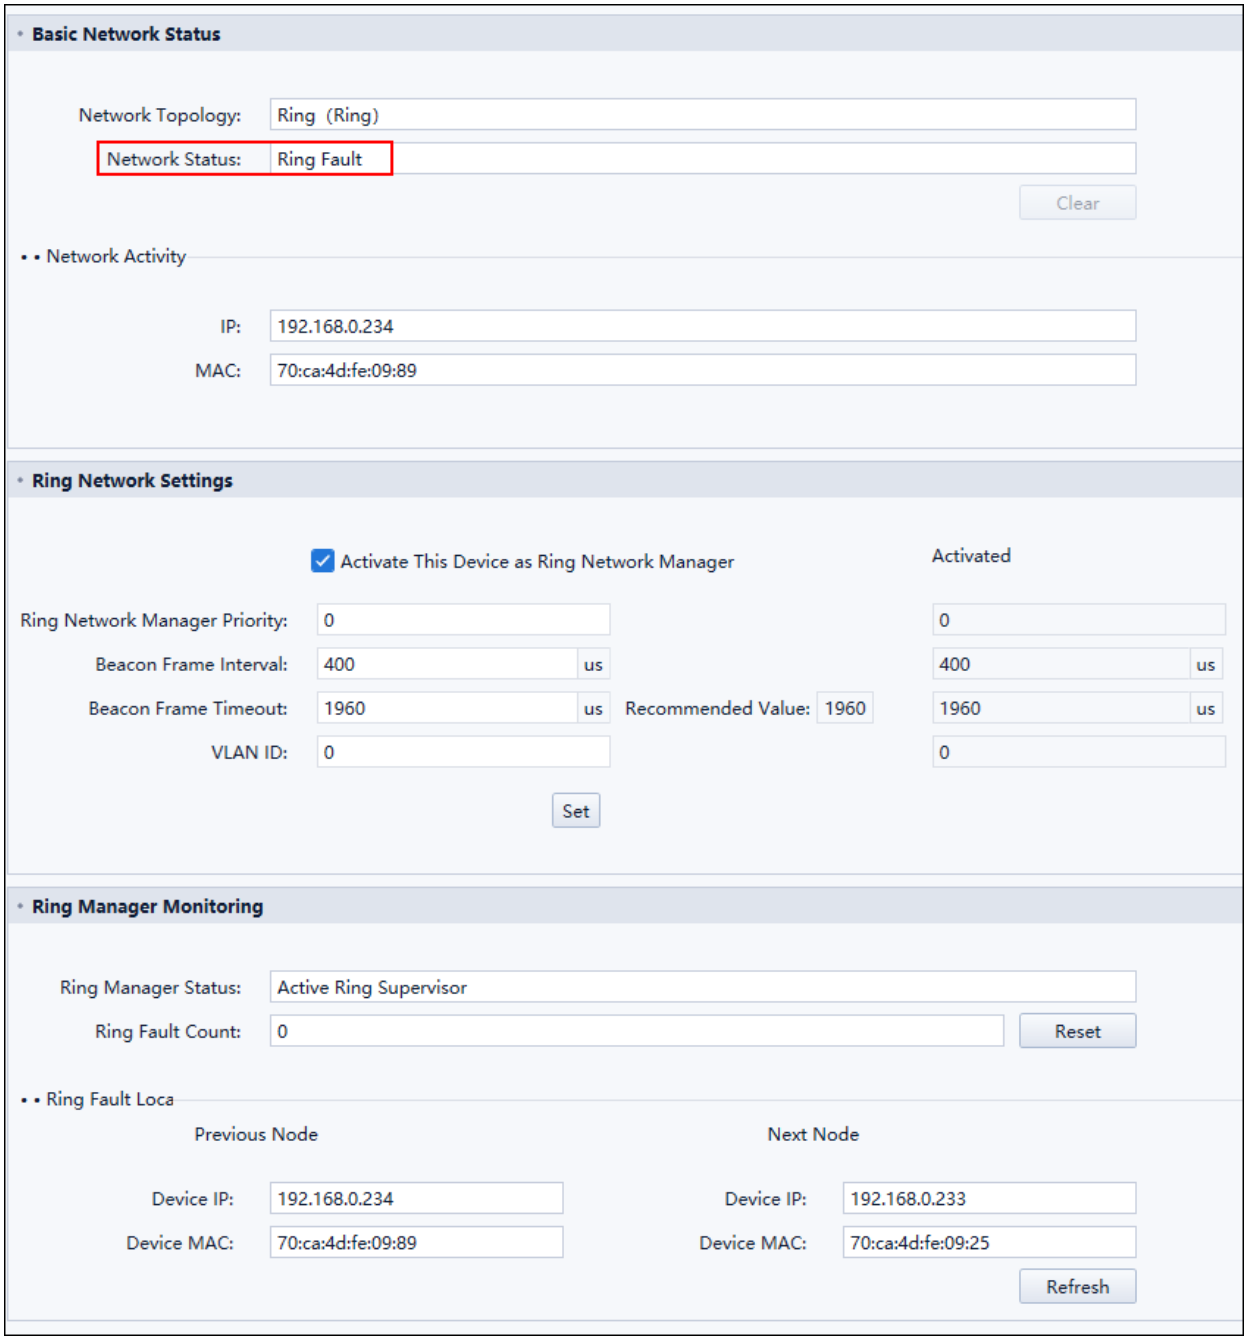

Figure 10-11-16-2 Monitoring results when a break occurs in the ring network

	Item	Description	Remarks
Basic network status	Network topology	Supports ring topology and linear topology. • Ring topology: Related to the configuration of devices in the network. As long as one device in the network is enabled as a ring network manager, it will become a ring network; • Linear topology: If no device in the network is enabled as a ring network manager, it will become a linear network.	-

	Item	Description	Remarks
	Network status	Current network operating status, with five statuses: • Normal: There is an active ring network manager, and the network is running well without any faults. • Ring fault: (Case 1) There is an active ring network manager, and a fault has occurred in the ring network; (Case 2) No ring network manager is active. • Unexpected loop detected: A network storm has occurred in the ring network. • Partial network fault: A partial network fault occurs when transmission is lost in only one direction on the network. • Rapid fault/restore cycle: Link faults occur more than five times within 30 seconds.	-
	Network activity	Displays the IP and MAC addresses of the current ring network manager.	-
Ring network settings	Activate this device as ring network manager	For a ring network, at least one ring network manager must be configured; otherwise, it becomes a linear network.	The area is divided into two parts: Left side: New value input, click to apply settings. Right side: Current value monitoring.
	Ring network manager priority	When multiple nodes are activated, the node with the highest priority number, ranging from 0 (low) to 255 (high), becomes the active ring network manager, and other ring network management devices automatically become backup devices.	
	Beacon frame interval	The time interval at which the ring network manager sends beacon frames, with a range from 100 μs to 100 ms.	

	Item	Description	Remarks
	Beacon frame timeout	The total waiting time for the manager node or ring network node after the ring network manager sends a beacon frame. Range: 200 μs to 500000 μs, with a default of 1960 μs. The timeout time must be at least twice the interval. If the entered value is less than twice the interval, the system automatically sets it to twice the interval. Note: The system supports up to 50 node configurations by default. When the total number of nodes exceeds 50 by adding switches to expand the topology structure or when the configuration data frame length exceeds 1000, the DLR (Device Level Ring) timeout time should be extended accordingly to ensure network stability.	
	VLAN ID	In most cases, there is no need to change the VLAN ID. When using DLR dedicated switches in the ring network, VLAN ID needs to be set to a unique value from 0 to 4094.	
Ring manager monitoring	Ring manager status	Displays the role and status of the current device in the ring network: Backup Active ring supervisor Normal ring node Non-DLR topology Bad current ring parameters	-
	Ring fault count	Cumulative number of the detected ring faults. Click "Reset" clear the fault count.	-
	Ring fault location	Displays ring network fault information, including status and the breakpoint location between two devices.	-

10.11.17 Ethernet Loop Monitoring

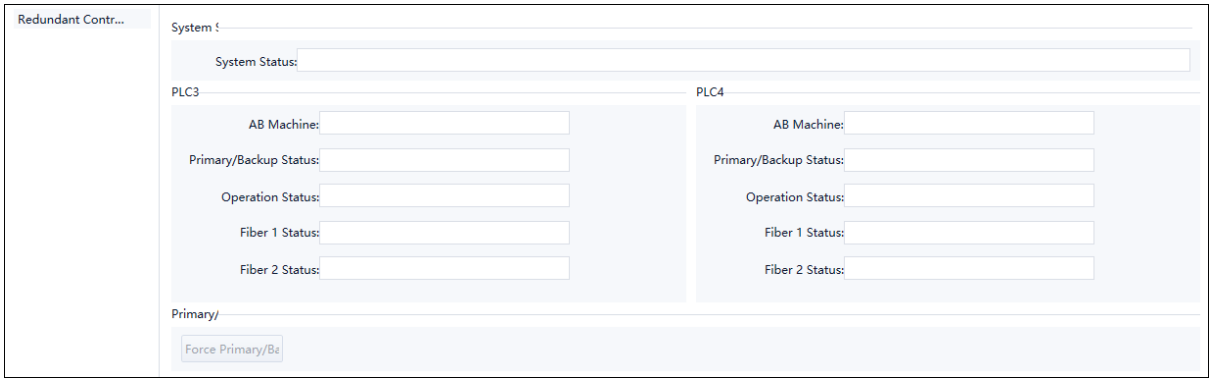
During online operation of the PLC, the iFA software periodically monitors whether a loop fault has occurred in its Ethernet network. Information about loop fault occurrence or elimination is recorded in the diagnostic information and operation logs.

Double-click "Online and diagnostics" in the project tree.

This interface displays all Ethernet ports on the current PLC device, with port names matching the actual PLC device for easy identification.

- Actual cycle: Displays the currently executing cycle.
- Set cycle: The setting range is 100 ms to 30000 ms.
- Monitoring operation: Includes the "Activate monitoring" button and indicators showing real-time monitoring status. Click "Activate monitoring" to monitor the loop status, and the indicator turns on; otherwise, monitoring is disabled and the indicator turns off.

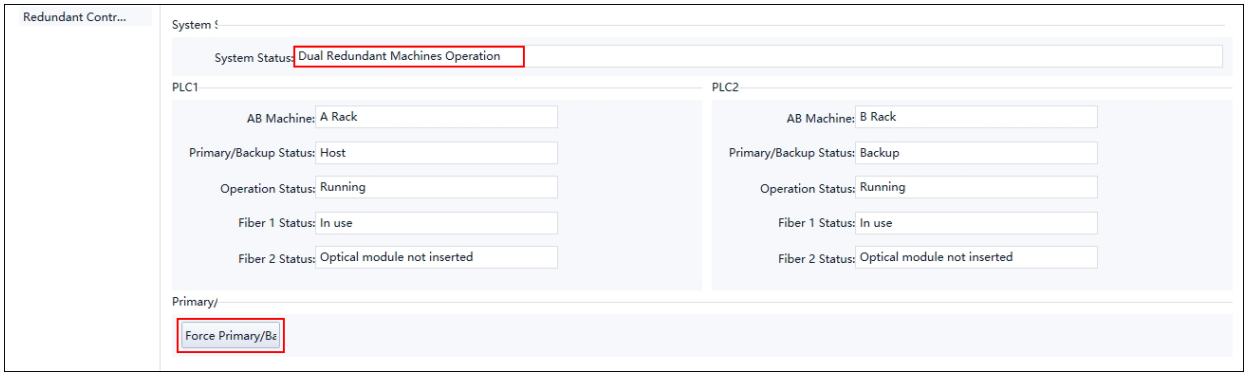
10.11.18 Monitoring Main/Backup Device Status (EVO800)



Redundant system supports online switching between the main and backup devices, and monitoring the status of the devices.

Prerequisites

- A redundant device has been added.
- The main or backup device has been switched to online status.



Procedure

1. Double-click the redundant system node in the left project tree to enter the system status tab.
2. View device status.

   - A/B device: Unknown, A device, B device
   - Main/backup status: Unknown, main device, backup device
   - Operating status: Unknown, running, stopped, commissioning
   - Fiber 1 status: Not inserted, faulty, in use, on backup
   - Fiber 2 status: Not inserted, faulty, in use, on backup

When the redundant system configuration is complete and the redundant PLC is online, the system status is redundant dual-machine operation. At this point, users can manually switch the main/backup status of the current PLC device.

Click the force switch button and confirm the switch in the pop-up window to switch the main/backup status of the current PLC.

After successful forced switching, click the "Online" icon and the main device rack has changed from the original A rack to the B rack, and the backup device rack has changed from the B rack to the A rack.

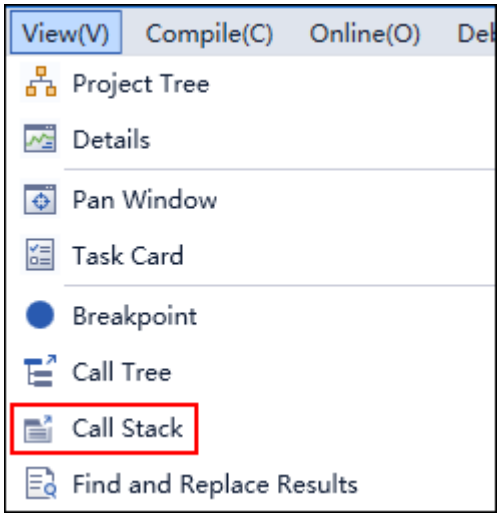
NOTE

By default, as long as the redundant system is running normally, any changes to the main device's program or hardware configuration due to downloading will be automatically synchronized to the backup device.

10.11.19 Calling a Stack

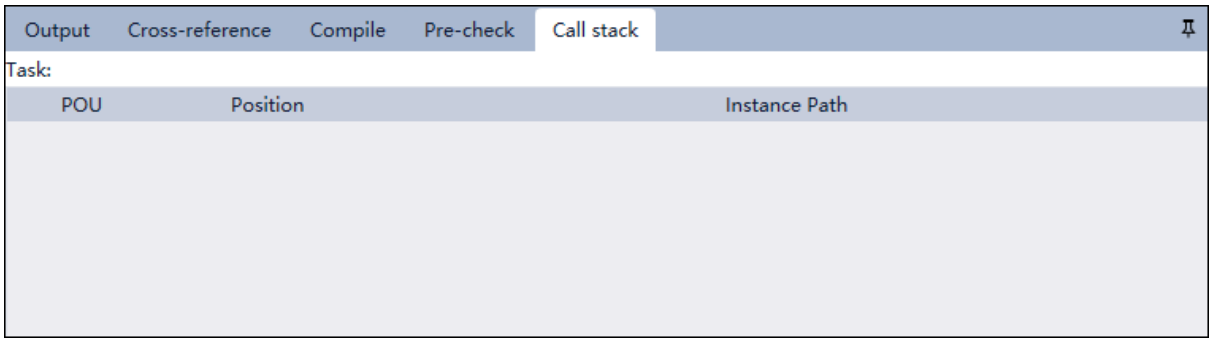
The "Call stack" interface displays the current PLC call status in real time. When debugging the program step by step in online mode, the "Call stack" interface provides real-time information during single-step program execution, showing the complete call path of the current position reached.

The "Call stack" interface supports the function of double-clicking a stack entry to locate the corresponding position, and identifies the stack top and the viewing stack. The stack list displays the POU name, corresponding position, and instance path of each layer (the instance path is the same as the POU name for non-FB instances).



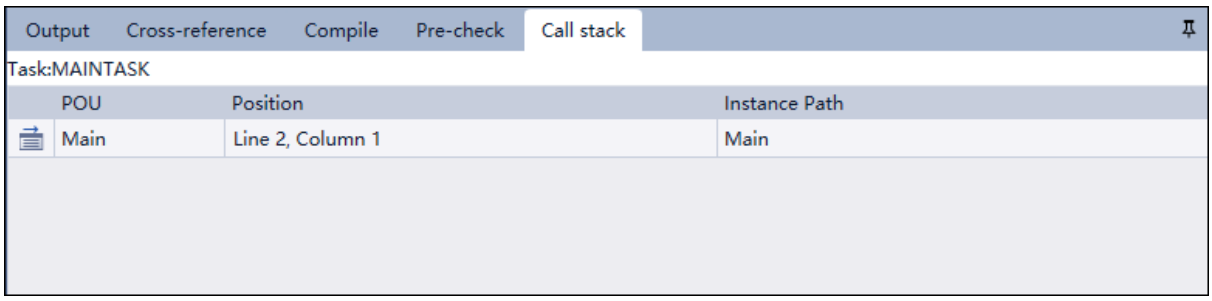
The call stack is displayed as a list of positions, with each position described by POU name, location, and instance path. In the text editor, the location is indicated by line and column numbers; in the graphical editor, the location is indicated by network or element numbers.

Prerequisites



The device is in online mode and is in breakpoint commissioning status.

Procedure

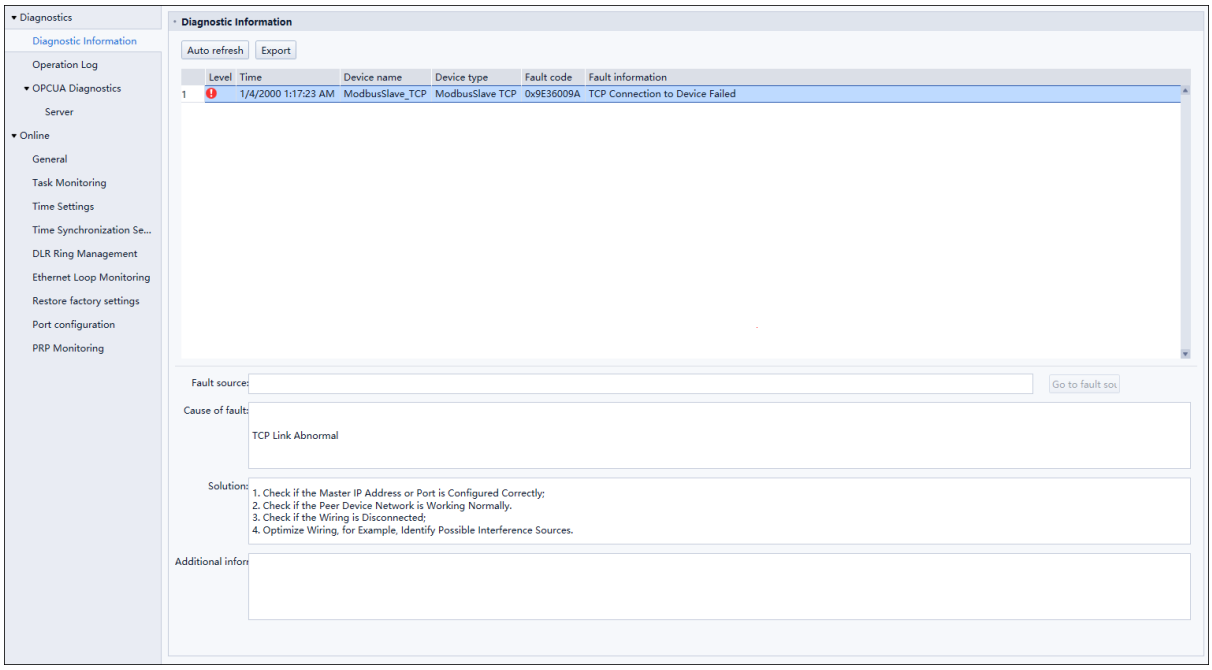


1. Select "View > Call stack" in the menu bar to display the "Call stack" interface.

2. In the monitoring area, click "Call stack" to open the corresponding interface, as shown in the figure below.

3. When debugging the program step by step in online mode, the "Call stack" interface displays the current step's POU name, location, and instance path, as shown in the figure below.

NOTE



The call stack displays up to a maximum of 10 levels.

10.11.20 Diagnostic Information

Diagnostic information is fault data automatically recorded and generated by the device during operation, including basic fault information, fault causes, and recommended solutions. Through diagnostic information, users can quickly understand the device's abnormal status, accurately locate the root cause of the problem, and complete repairs, thereby ensuring stable device operation.

Viewing diagnostic information

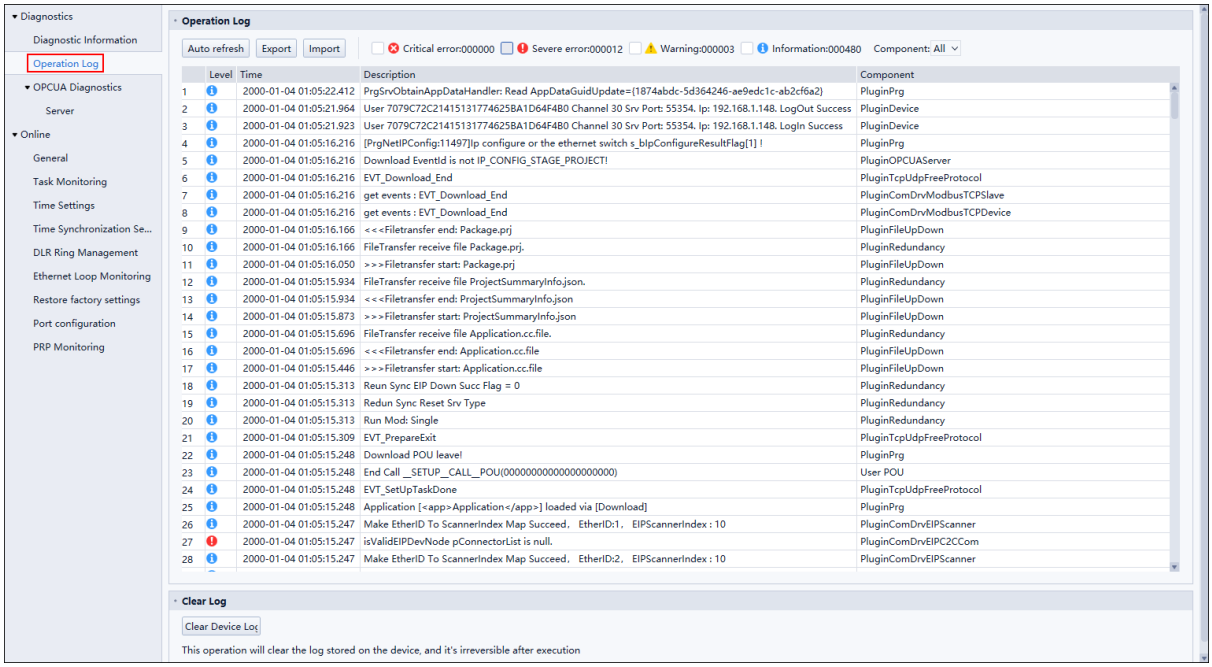
1. Double-click "Online and diagnostics" in the project tree.
2. On "Diagnostic information" tab, view device diagnostic information, including fault level, time, device name, device type, fault code, and fault information.

3. Select a fault entry to display specific details such as the fault source, cause, and solution. Click "Go to fault source" to accurately locate the fault position.
4. (Optional) Above the list, click "Freeze display" to show only the existing diagnostic information without updating newly generated faults. Click "Auto refresh" to resume real-time updates.

Exporting diagnostic information

Above the list, click "Export", select the save path and set the file name, then click "Save" to export the current diagnostic information in .csv format.

10.11.21 Operation Log



The operation log records log information during the device's operation, including device status, faults, alarms, program execution data, communication status, and user operation records. When a device is faulty, the log helps quickly locate the fault and reproduce the scenario. In addition, the real-time recorded operation data can be used for preventive maintenance, performance evaluation, and optimization.

Prerequisites

The device has been switched to online.

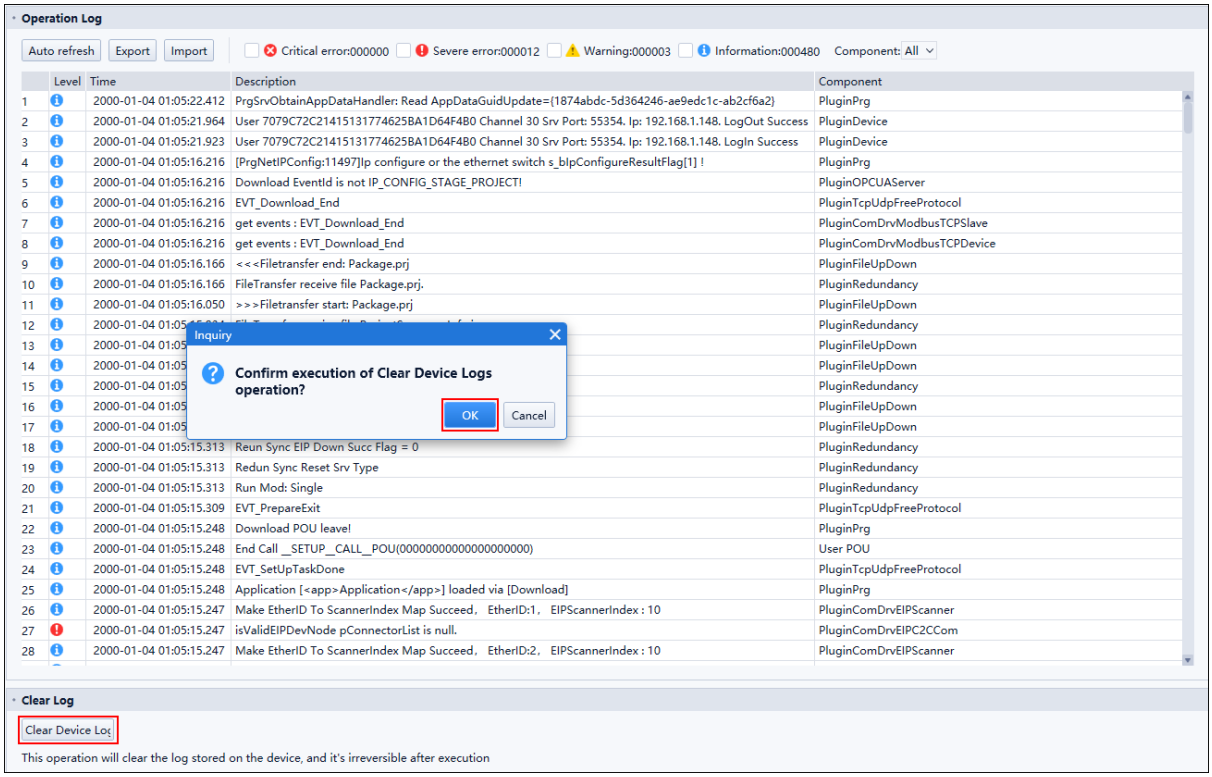
Viewing Operation Logs

1. Double-click the "Online and diagnostics" node in the left project tree to open the "Online and diagnostics" page.
2. On the "Operation log" tab, view the device's current log information, including level, time, description, and associated component.

3. (Optional) Above the list, click "Freeze display" to show only the existing operation logs without updating newly generated logs. Click "Auto refresh" to resume real-time updates.
4. (Optional) In the frozen display state, you can filter by log level and associated component: Check the corresponding fault level to display only logs of that level; select the corresponding component from the "Component" dropdown list to display only logs for that component in the list.

Importing/Exporting logs

- **Export**
  Click "Export", select the save path and set the file name, then click "Save" to export the current operation log in .csv format.
- **Import**
  In the frozen display state, click "Import", select a .csv format log file in the pop-up window to import and display the locally saved log file.



Clearing device logs

When the device is connected to a physical PLC device via iFA and switched to online mode, you can clear device logs. This operation is not supported when the device is connected to a virtual PLC.

CAUTION

This operation cannot be undone. Please proceed with caution.

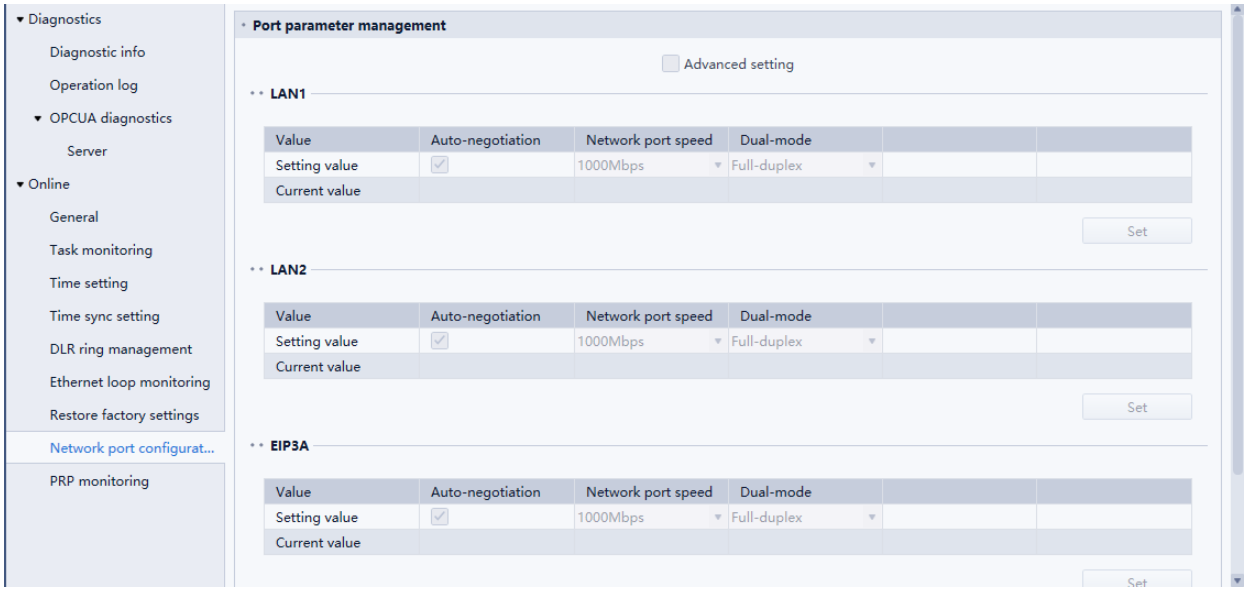
1. On the "Operation log" page, click "Clear device logs".
2. Click "OK" in the pop-up window to clear the operation log information stored in the PLC device.

10.11.22 Network Port Configuration

This tab is used to configure the network port parameters while the PLC is online, and monitor the current network port operation status.

Restrictions

Network port configuration applies to the following PLC models and firmware versions:



- EVO800 series: Firmware version V1.1 or above.
- EVO700C series: Firmware version V1.6 or above.
- APC760C series: Firmware version V1.6 or above.

Prerequisites

The device is in an online status.

Function entry

Double-click the "Online and diagnostics" node in the left project tree, and select the "Online > Network port configuration" tab.

This interface displays the configured values and current values of all Ethernet port parameters of the current PLC. The Ethernet port names are consistent with the actual PLC, making it easier for engineers to identify the Ethernet ports.

Select "Advanced settings" to display the configured values and current values of the "Wiring sequence configuration" and "Auto-deceleration" parameters.

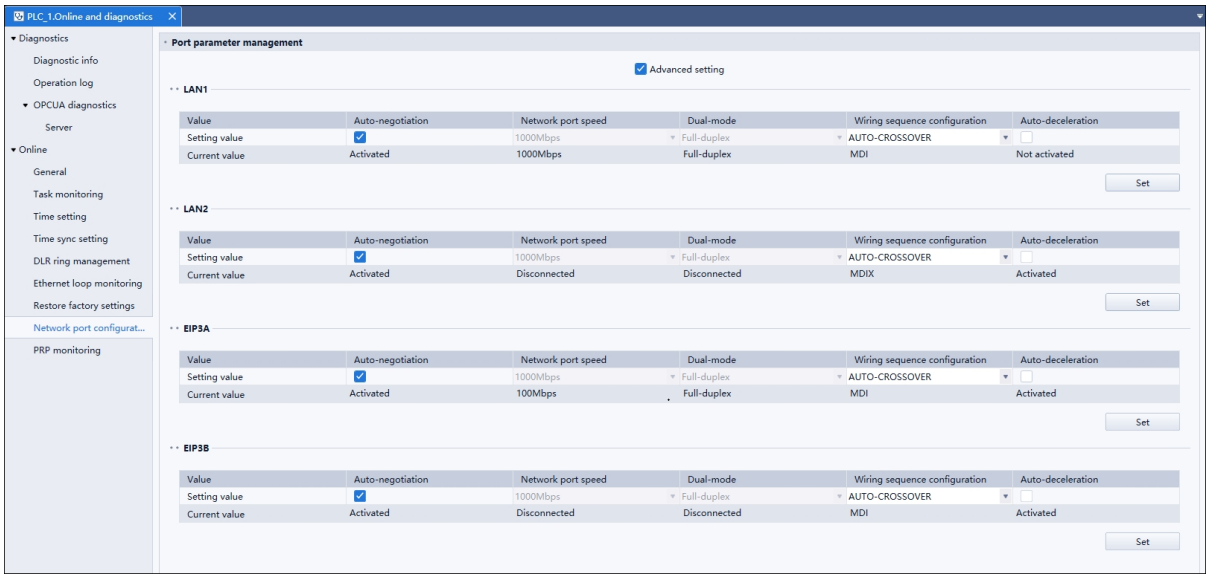


Figure 10-11-22-1 Network port configuration interface of EVO800 PLC

Table10-11-22-1 Network port parameter description

Parameter	Description
Auto-negotiation	Based on the IEEE 802.3u standard, this feature automatically negotiates the optimal speed and duplex mode with the peer device. This is enabled by default.
Port speed	Defines the physical transmission rate of the Ethernet port (bits per second). Supported rates include 10 Mbps, 100 Mbps, and 1000 Mbps (default).

Parameter	Description
Duplex mode	Controls the data transmission direction. Default is full duplex. • Full duplex: Simultaneous transmission and reception. • Half duplex: Alternative transmission and reception.
Wiring sequence configuration (MDI/MDI-X)	Defines the electrical connection method between the port and the transmission medium (such as twisted pair and fiber). Default is AUTO-CROSSOVER. • AUTO-CROSSOVER: The two connected devices negotiate to determine pin assignments (such as whether pins 1 and 2/3 and 6 are used for transmitting or receiving signals). • MDIX: Uses pins 1 and 2 for receiving signals, and pins 3 and 6 for transmitting signals. • MDI: Uses pins 1 and 2 for transmitting signals, and pins 3 and 6 for receiving signals.
Auto-deceleration	When the port repeatedly fails to connect after a certain number of attempts, the PHY (Physical layer) chip can automatically reduce the speed to complete the connection. This feature is enabled by default.

Procedure

1. Open the "Network port configuration" interface and modify setting values of basic network port parameters. After selecting "Advanced settings", wiring sequence and auto-deceleration can be configured.

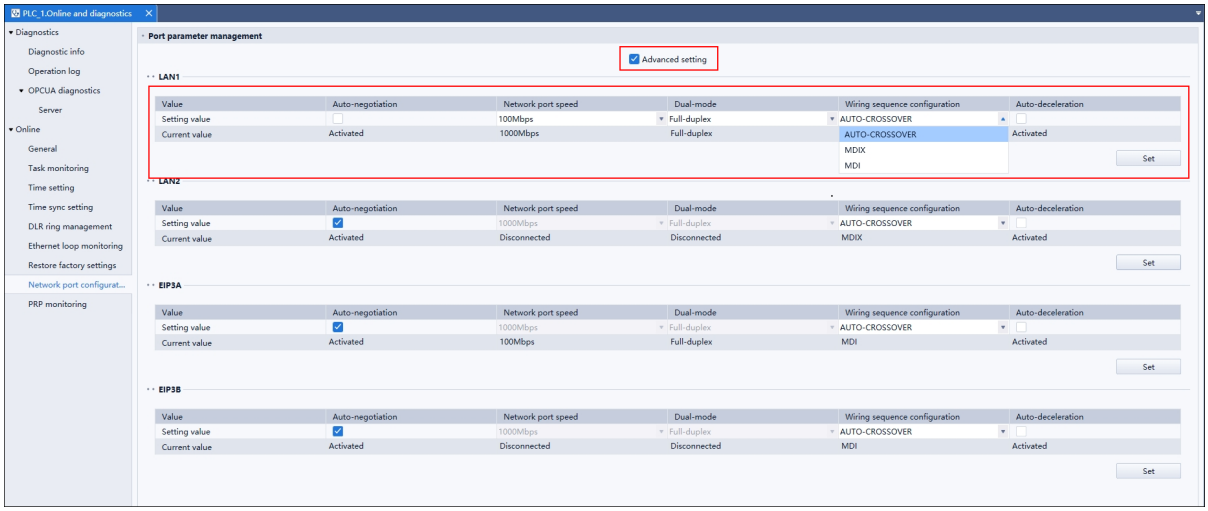

Figure 10-11-22-1 Network port configuration interface of EVO800 PLC

2. After completing the parameter settings, click the "Set" button. In the pop-up prompt window, click "OK" to send the configuration instruction to the PLC and complete the parameter modification of the corresponding port.
3. After modification, the corresponding PLC port will re-negotiate according to the set parameters and display the current set parameters in real time.

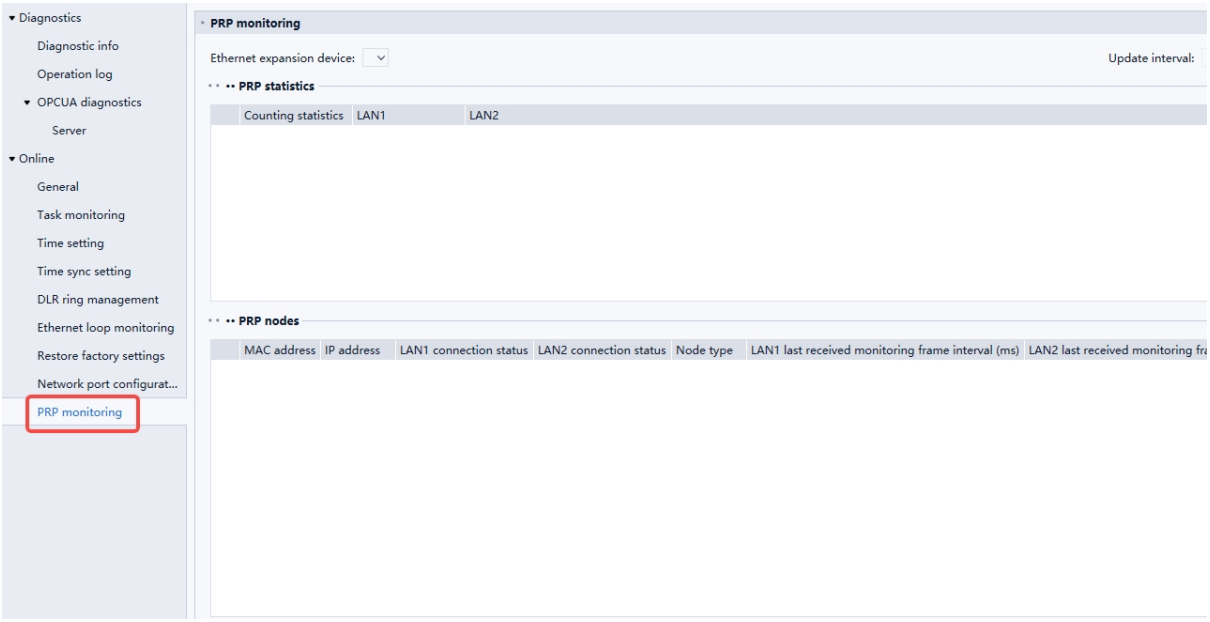
NOTE

- The current values in the "Network port configuration" tab display the negotiation results between the PLC port and the connected device, which are related to the peer device configuration, cable material, PHY characteristics, and other factors.
- If a specific network port on the current device does not support network port configuration, the current value will not be displayed for that port. Clicking the "Set" button will display an "Execution failed" prompt.

CAUTION

- Modifying Ethernet port parameters will cause the port to undergo a link down and link up process. This will inevitably impact current communication services, manifesting as temporary interruption and subsequent recovery of all communication connections on this port.
- If the configured port is currently being used for monitoring, modifying its parameters may cause the device to go offline.

10.11.23 PRP Monitoring



After the EVO800 series Ethernet expansion module activates the PRP function and the PLC goes online, PRP information can be monitored online.

Prerequisites

The device is in an online status.

Procedure

1. Double-click "Online and diagnostics" in the project tree, select "Online > PRP" in the opened interface to enter the PRP monitoring interface.
   When PRP is activated, the default data update interval between iFA Evolution and the PLC is 3s. The status information of all nodes in the network is automatically refreshed. The update interval can be set from 1s to 10s.

2. Select the device to monitor from the "Ethernet expansion device" drop-down list and set the update interval.
3. View PRP statistical information. The related parameters are shown in the table below.

Parameter	Description
Transmitted package count	Number of packets transmitted via LAN1/2.
Received package count	Number of packets received via LAN1/2.
Unique received frame count	Number of unique PRP frames received by the port.
Duplicated received frame count	Number of duplicate PRP frames received by the port.
Incorrect port count	Number of packets received by the port that do not belong to that port. For example, LAN1 receives a packet with tag lan_id = LANB (which corresponds to LAN2).
Alarm count	Number of PRP faults/alarms.
Warning occurs?	Indicates whether a PRP fault/alarm has occurred, including events such as no PRP frame received or an incorrect PRP suffix, etc. ◦ 0: No fault/alarm has occurred. ◦ 1: A fault/alarm has occurred.

4. View PRP node information. The related parameters are shown in the table below.

Parameter	Description
MAC address	The MAC address of the peer PRP node (a PRP node has only one MAC address externally).
IP address	The IP address of the peer PRP node (a PRP node has only one IP address externally).

Parameter	Description
LAN1 connection status	The status indicating whether the LAN1 or LAN2 port has received PRP packets. ◦ True: The port has received PRP packets. ◦ False: The port has not received PRP packets.
LAN2 connection status	
Node type	PRP node type. ◦ Dual-node connection: The node device supports PRP mode. ◦ Virtual dual-node connection: The node device does not support PRP mode and connects via a PRP management switch.
LAN1 last received monitoring frame interval (ms)	The interval between the received monitoring frame and the previous frame.
LAN2 last received monitoring frame interval (ms)	

10.11.24 Uploading/Downloading Permission Settings (EVO500)

The permission settings function is used to manage the password for external access (upload/download) to the physical controller.

NOTE

This function is only applicable to the EVO500 series with firmware version V1.2.

Prerequisites

- The physical controller is online.
- The PLC project is online.

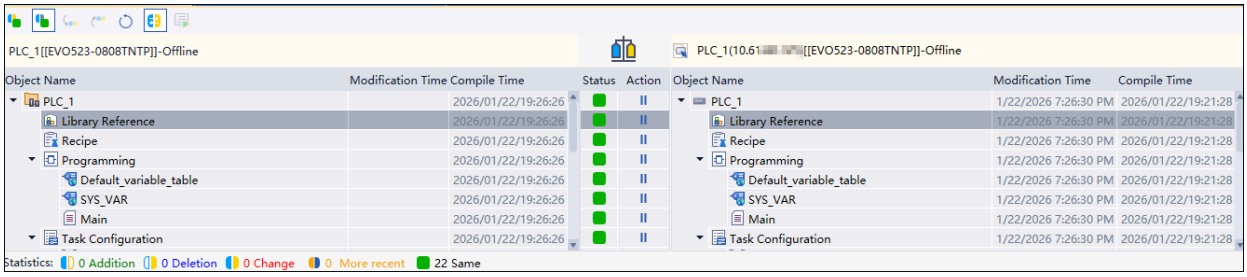
Adding a password

1. Right-click a PLC project node in the project tree and select "Permission setting" to open the "Upload/Download password setting" window.
2. Set the permission password.
   Upload/Download password: When checked, the password management permission is activated; when unchecked, the corresponding permission is revoked.
   Enter/Confirm password: The password for accessing the controller. Supports letters, numbers, and special characters, with a length between 6 and 8 characters.
3. Click "OK".
   The permission and password settings for managing controller access are configured and active. Password verification is required during the execution of download or upload commands.

Canceling password verification

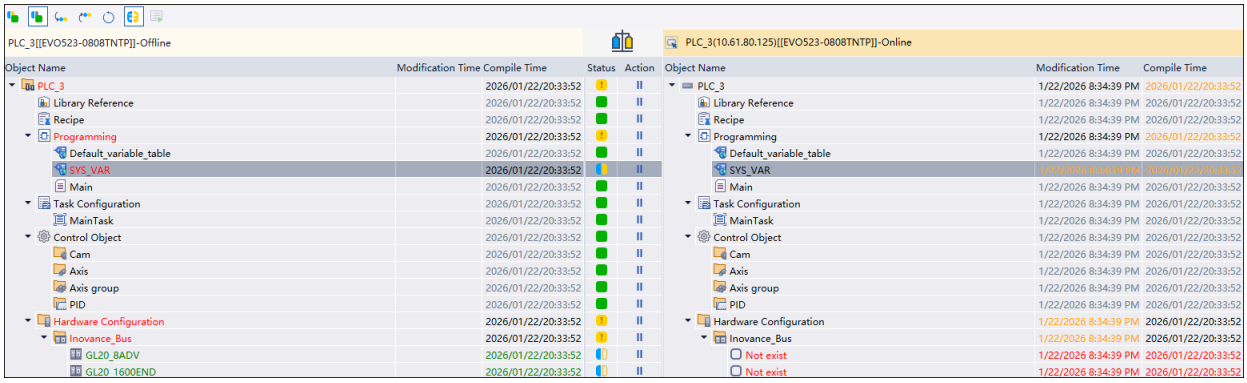
1. Right-click a PLC project node in the project tree and select "Permission setting" to open the "Upload/Download password setting" window.
2. Cancel permission settings
   Uncheck "Upload/Download password", and no password will be required when accessing the controller. This setting takes effect immediately.

Changing password



1. Right-click a PLC project node in the project tree and select "Permission setting" to open the "Upload/Download password setting" window.
2. Change password
   Click the "Change password" button and set the new password in the pop-up window. The new password takes effect immediately.

10.12 PLC Project Comparison



10.12.1 Overview

PLC project comparison is a comparison of equipment content and coverage, helping users quickly locate differences between two project contents. This feature supports comparison between offline projects, and between online and offline projects.

Offline/offline comparison

Offline/online comparison

The comparison editor includes toolbar, project selection panel, left comparison table, right comparison table, status area, action area, and comparison result area.

Toolbar

Icon	Description	Description
	Shows differences in objects.	Switches to detailed comparison view.
	Shows only different comparison results.	Shows only different comparison results.
	Shows all comparison results.	Shows all comparison results, including identical and different items.
	Next difference	Selects the next different object.
	Previous difference	Selects the previous different object.
	Refresh	Refreshes the view.
	Synchronizes scrolling	Enables/disables synchronized scrolling between left and right comparison tables.
	Executes action	Executes the selected action item in the action area of the comparison view.

Status area

Icon	Description
	Contains differing sub-items.
	The project nodes on both sides are identical.
	The project nodes on both sides are different.
	The project node on the left side does not exist on the right side.
	The project node on the right side does not exist on the left side.

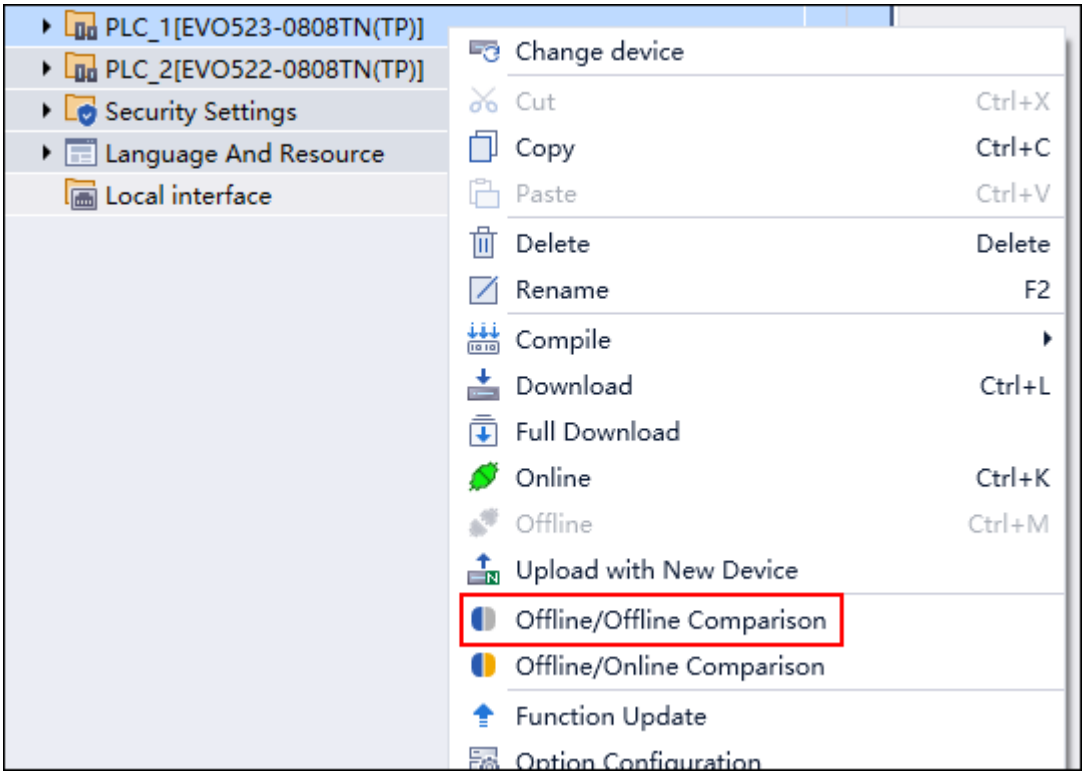
Action area

Icon	Action description
	No action.
	Copies the right project information to the left.
	Copies the left project information to the right. This action is supported only in offline/offline comparison.
	Downloads all left project information to the PLC. This action is supported only in offline/online comparison.

Comparison result area

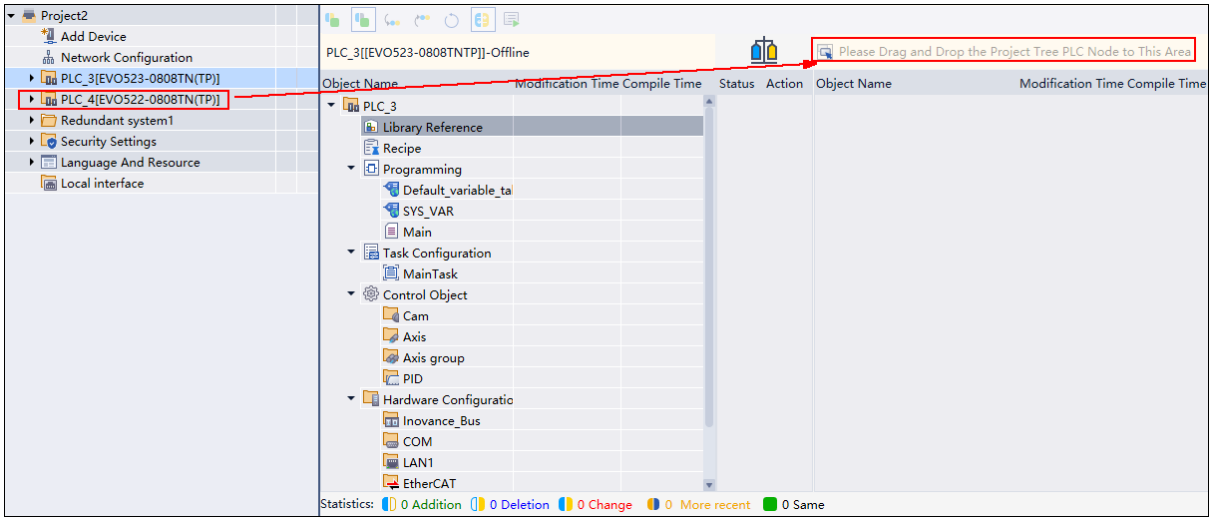
Icon	Description
	Additional items in the left project information
	Missing items in the left project information
	Modified items in both sides
	More recent items
	Identical items in both sides

10.12.2 Offline/Offline Comparison



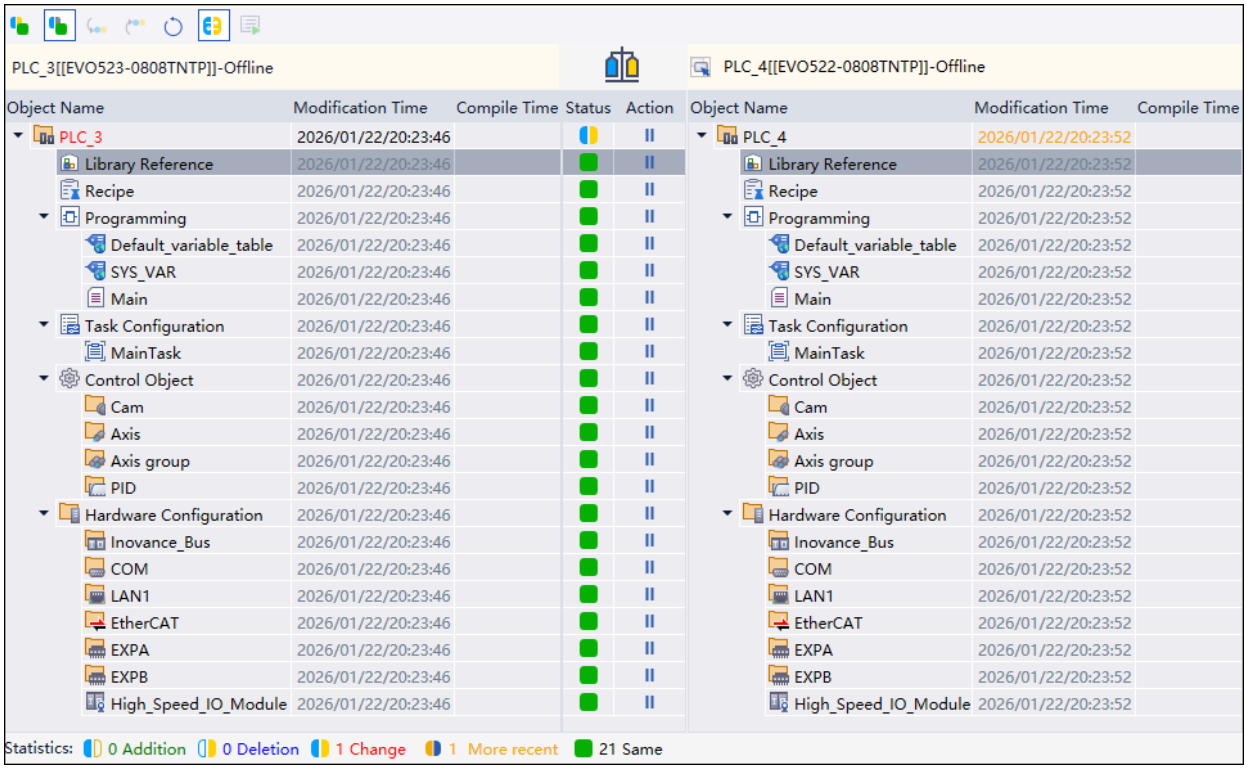
Offline/offline comparison is suitable for comparing offline PLC projects with the same product series.

Prerequisites



- The project is in offline mode.
- At least two PLC project nodes exist in the project tree.
- Comparison is supported between PLC projects of the same product series or different products.

Procedure

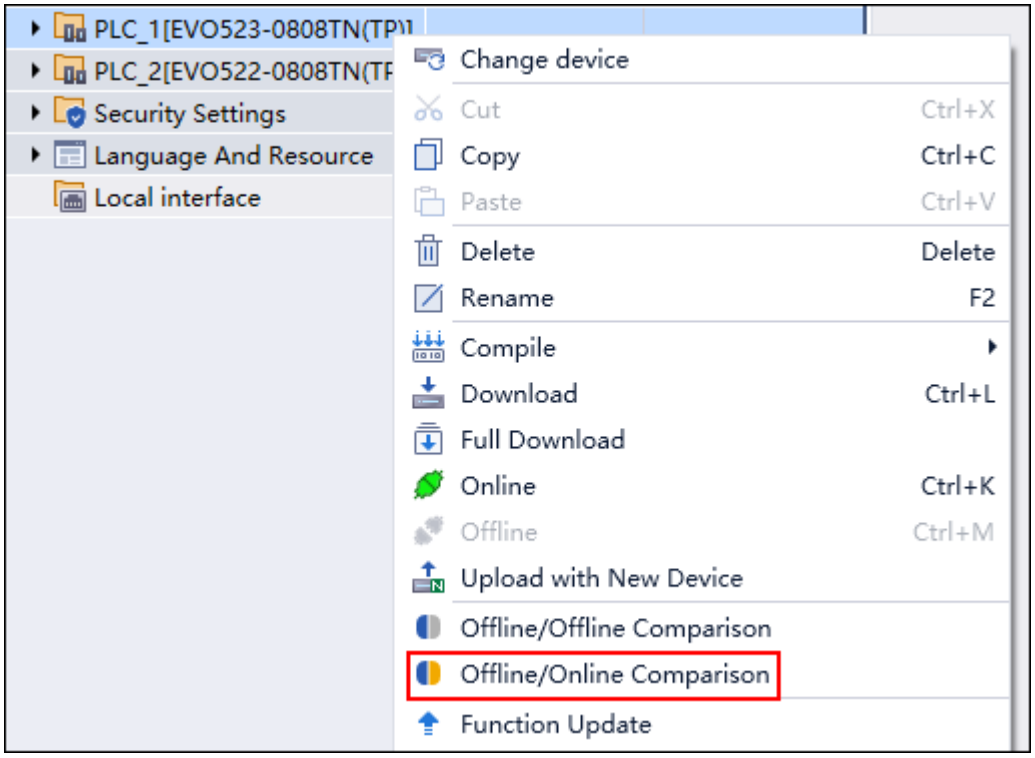


1. Right-click a PLC node in the project tree and select "Offline/offline comparison" to enter the comparison interface.

2. Drag the project to be compared into the right area.

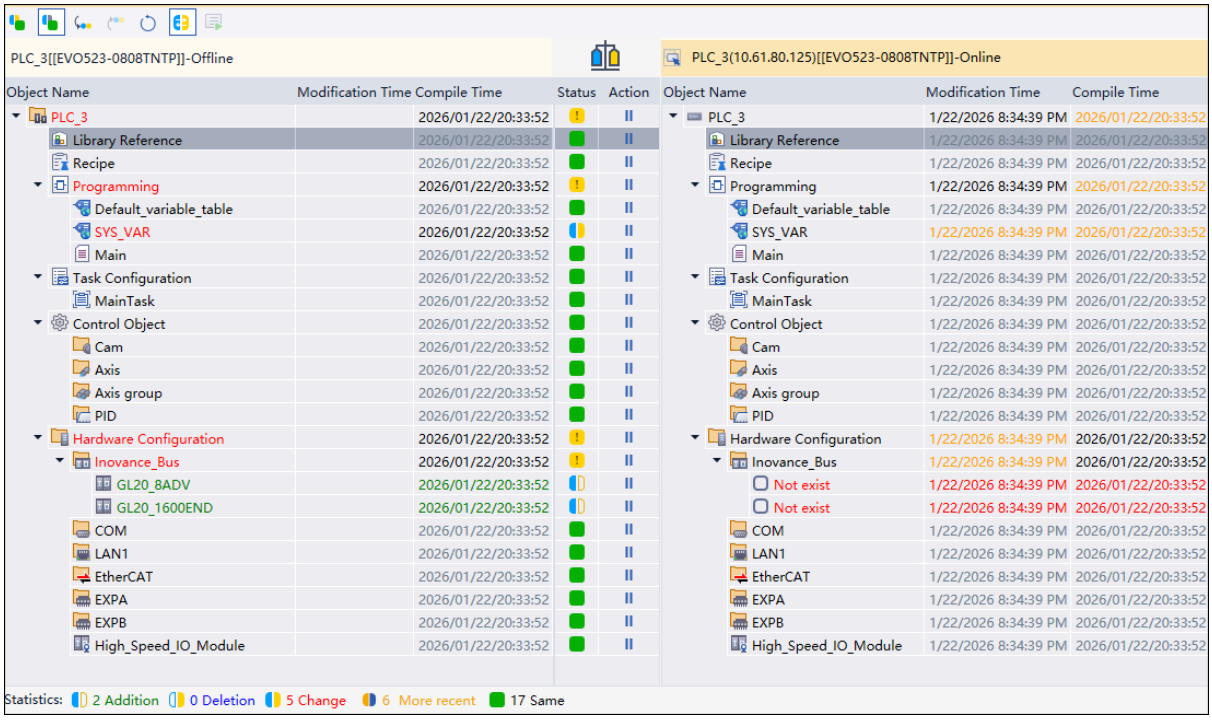
Function view

10.12.3 Offline/Online Comparison



Offline/online comparison is suitable for comparing offline and online PLC projects with the same product series.

Prerequisites



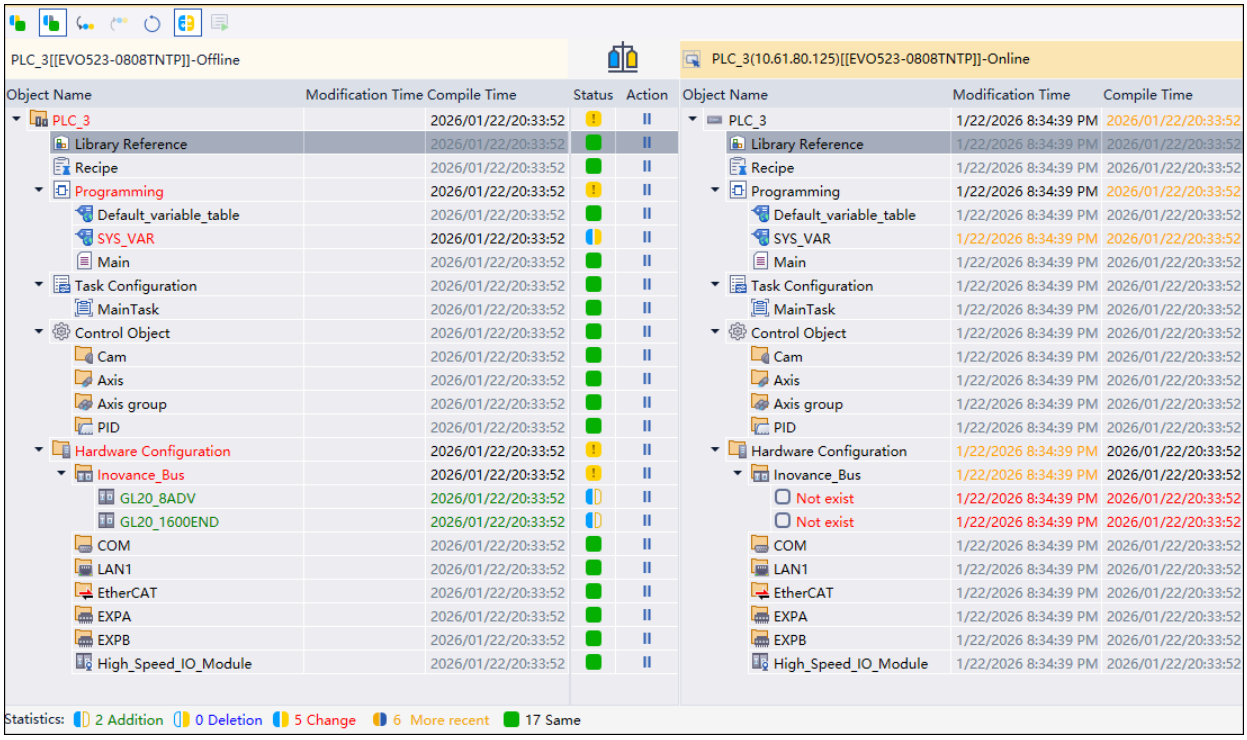
- At least one PLC project node exists in the project tree.
- The PLC project can successfully connect to the PLC, or this project is already in online state.
- Comparison is only supported between PLC projects of the same product series.

Procedure

1. Right-click a PLC node in the project tree and select "Offline/online comparison".

2. Enter the comparison interface and perform object comparison.

10.12.4 Viewing and Processing Comparison Results



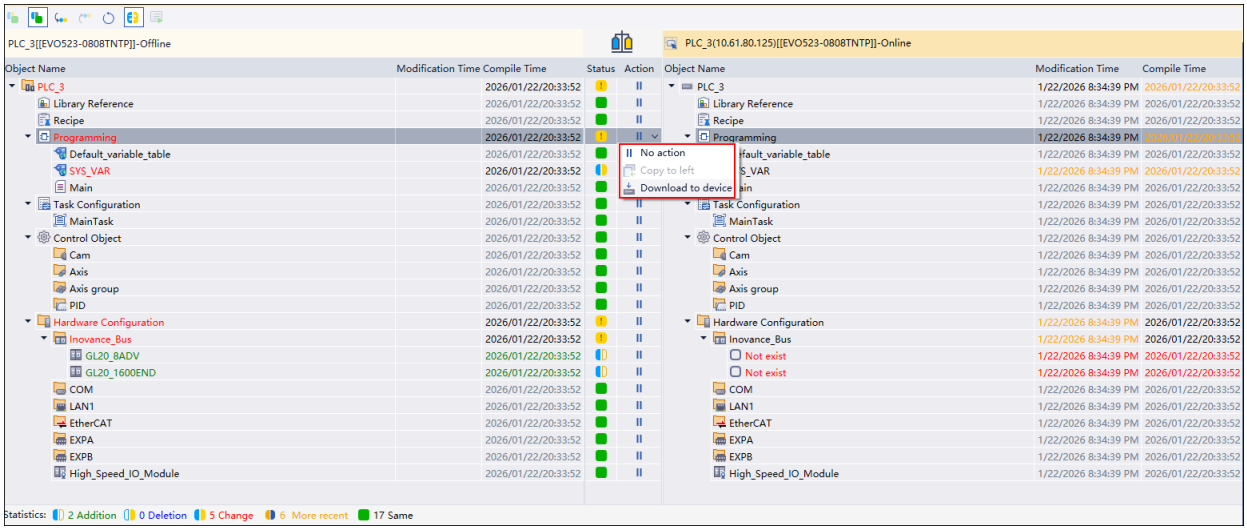
This function is mainly used to view and process the comparison objects and comparison blocks.

Comparison object

The comparison results for various program objects can be viewed and processed.

Viewing method

Right-click a PLC node in the project tree and select "Offline/offline comparison" or "Offline/online comparison" to open the comparison view and directly view the comparison results. Take offline/online comparison as an example.



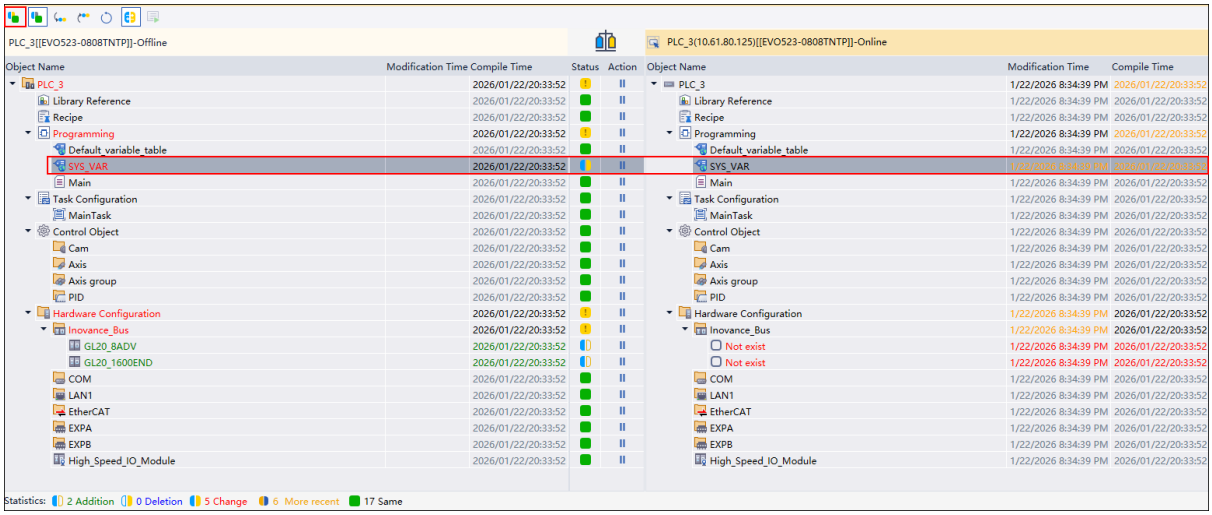
For details about the toolbar, status area, action area, and result area, see 10.12.1 Overview.

Processing method

Select the objects with differences, and click an action to perform the corresponding action.

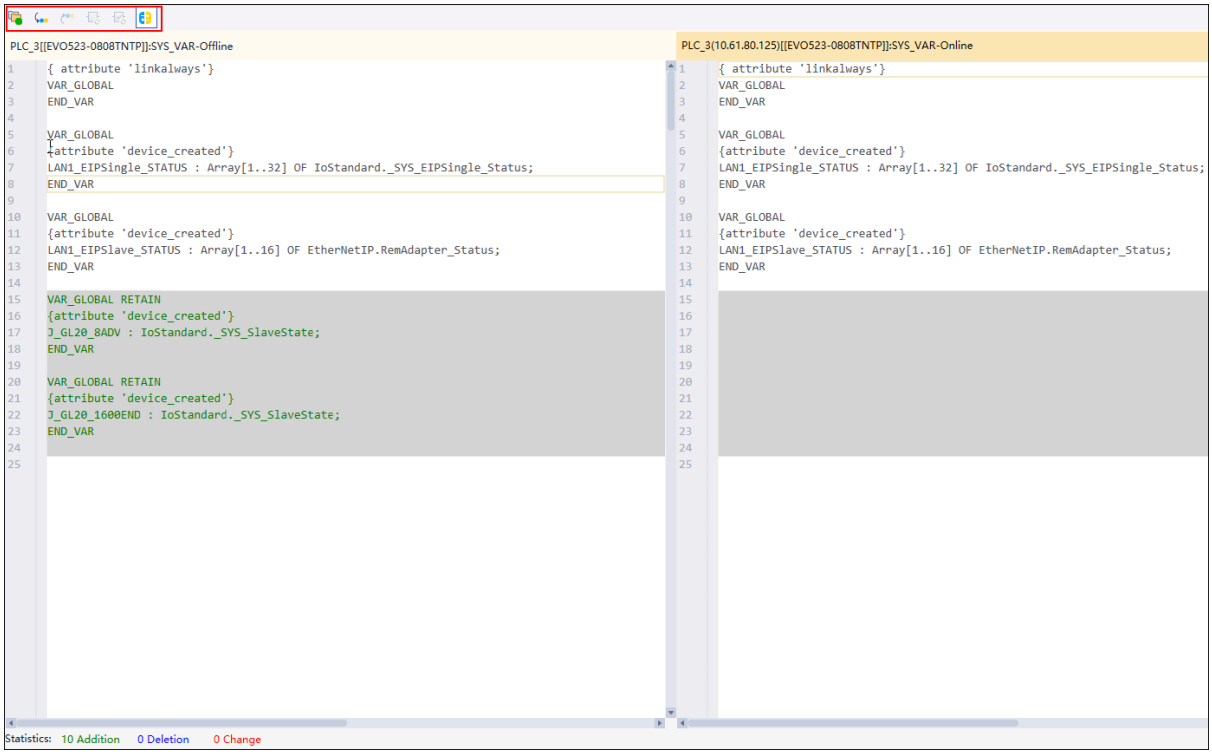
Offline/offline comparison results cannot be downloaded to the device. For details about actions, see 10.12.1 Overview.

NOTE



The selected action can be applied to an individual node or the entire branch. When selecting a higher-level branch, the selected action will be synchronized for all its sub-branches.

Comparison blocks



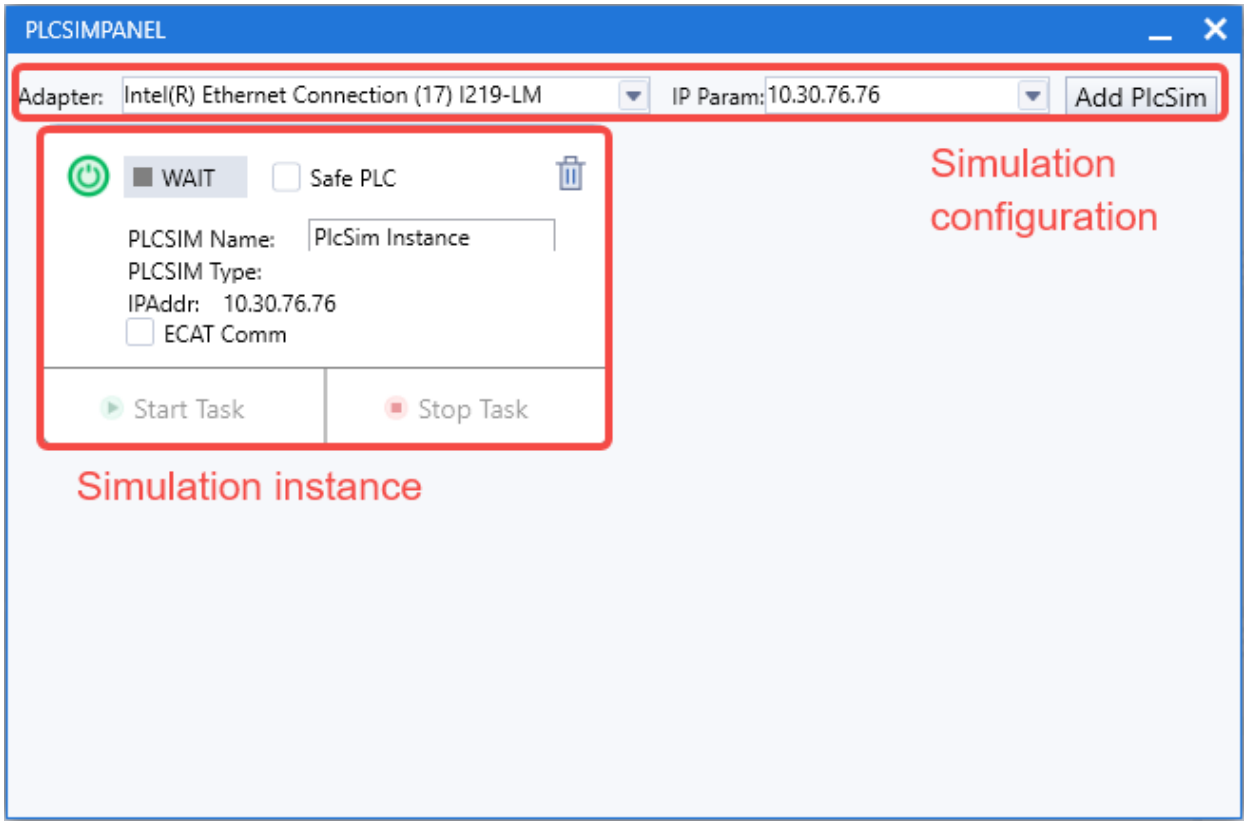
Project comparison supports detailed views of comparison objects, allowing viewing and processing results for each comparison block.

Procedure

1. Right-click a PLC node in the project tree and select "Offline/offline comparison" or "Offline/online comparison" to open the comparison view.
2. Click the "Shows differences in objects." icon in the toolbar or double-click the comparison object to open the detailed view of each comparison object

3. Modify the comparison block using the icons in the toolbar.

Descriptions of the toolbar



Icon	Description	Description
	Shows differences in the projects.	Switches to the detailed view of project comparison.
	Next difference	Selects the next different object.
	Previous difference	Selects the previous different object.
	Synchronize block	Synchronizes all different blocks.

Icon	Description	Description
	Synchronize selected	Synchronizes the selected different blocks.
	Synchronizes scrolling	Enables/disables synchronized scrolling between left and right comparison blocks; this icon remains synchronized with the "Synchronize scrolling" icon in the comparison overview view.

10.13 PLC Simulation Mode

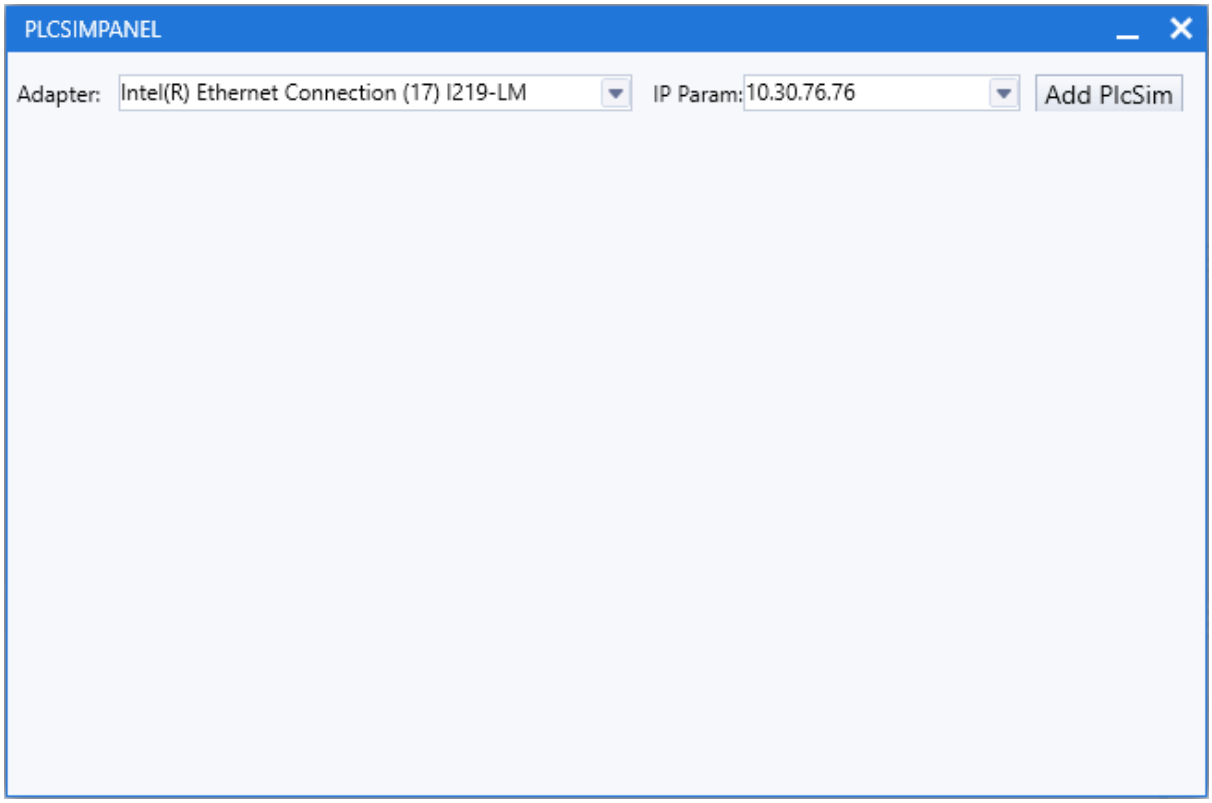
10.13.1 Simulation Panel Overview

Click in the iFA toolbar to open the simulation panel. The simulation panel consists of two parts: the simulation configuration area and the simulation instance management area, as shown in the figure below:

- Simulation configuration area
  Select the physical network card and IP address to establish the simulation network connection. Click "Add simulation" to create a simulation instance.
- Simulation instance management area
  Manage simulation instances, control simulation execution, and view simulation status.

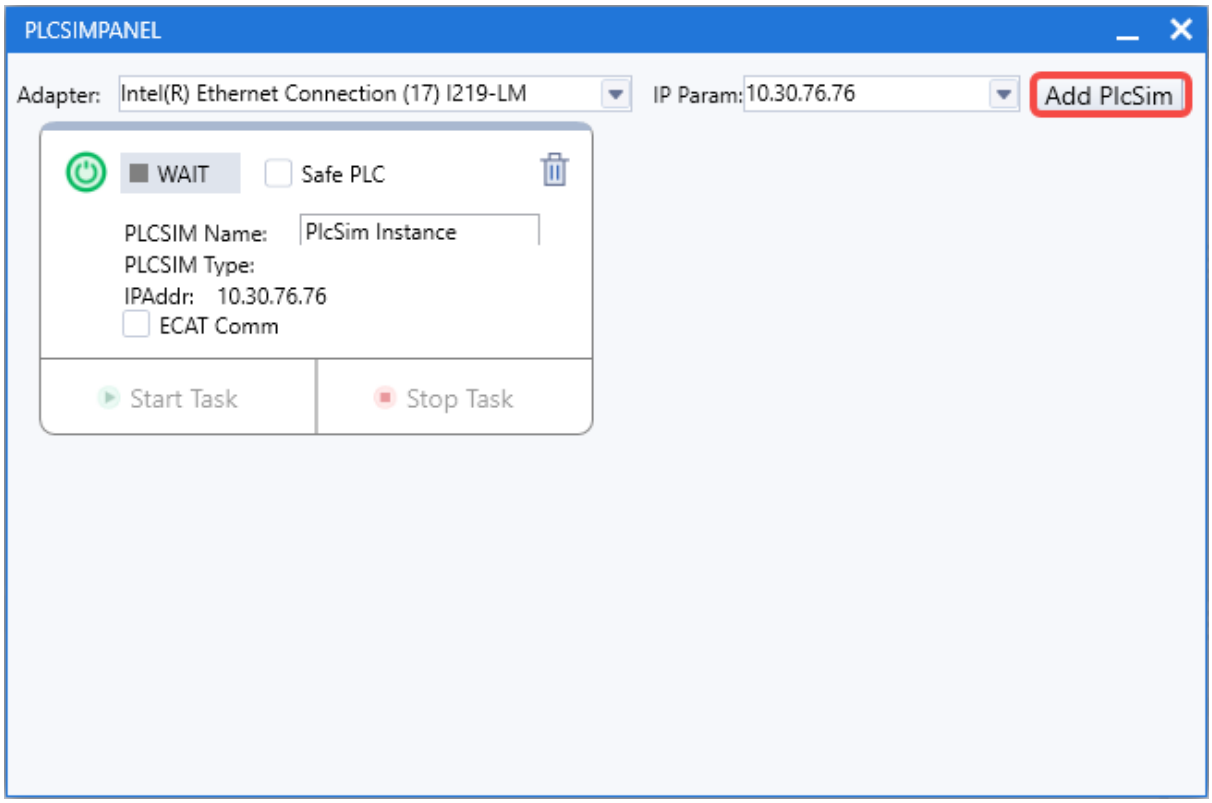
Function	Description
Start/Stop	Starts and stops the virtual PLC. Start: Click and the virtual PLC enters the Ready state. The PLC can be used normally at this time. Users can perform scanning, connecting, downloading, and online operations via the iFA software. Stop: Click to stop the PLC simulation. All connections to iFA are disconnected, and all ongoing simulation operations are terminated.
Status indicator	Indicates the current status of the simulated PLC. WAIT: Wait state. After the virtual PLC is created, the indicator is in the wait state. It indicates that it has not been started and is waiting for users to power it on. READY: Ready state. After the virtual PLC is powered on, the indicator changes to the ready state. It indicates that it is ready and users can download the PLC program for simulation. STOP: Stop state. After the PLC program is compiled and downloaded, the indicator is in stop state. It indicates that the program is loaded but not running. Users can click "Start task" to begin simulation. START: Run state. When the PLC program is running, the indicator is in the run state. It indicates that simulation is in progress.
Safety PLC	Enables the Safety PLC. This option is unchecked by default.
Delete	Deletes the virtual PLC instance object. When the current simulation object is no longer needed, this icon can be used to delete the object.
PLCSIM name	User-defined name of the virtual PLC simulation.
PLCSIM simulation model	Displays the model of the current simulation. After the virtual PLC simulation is successfully created, the simulation model will be confirmed by the system and displayed in the simulation object.
IP address	Displays the IP address bound to the simulation upon creation.
ECAT communication	Check to enable ECAT communication. Disabled by default. During ECAT axis simulation, both real axes and virtual axes are simulated. If ECAT communication is not enabled, all axes in the iFA project will be simulated in virtual axis mode. If ECAT communication is enabled, axes will be simulated according to their actual configuration in the iFA project.
Starts task	After a virtual PLC instance object is created, the PLC logic program is built through software. Once the iFA program is completed, it is downloaded to the virtual PLC object, and this button can be used to start the PLC logic program. If an invalid PLC logic program is downloaded to the current virtual PLC or if the PLC logic program is already running, this button will be disabled and operation is prohibited.
Stop task	After a virtual PLC instance object is created, the PLC logic program is built through software. Once the iFA program is completed, it is downloaded to the virtual PLC object, and this button can be used to pause the PLC logic program. If an invalid PLC logic program is downloaded to the current virtual PLC or if the PLC logic program is already in a stopped state, this button will be disabled.

10.13.2 Establishing a Simulation Environment



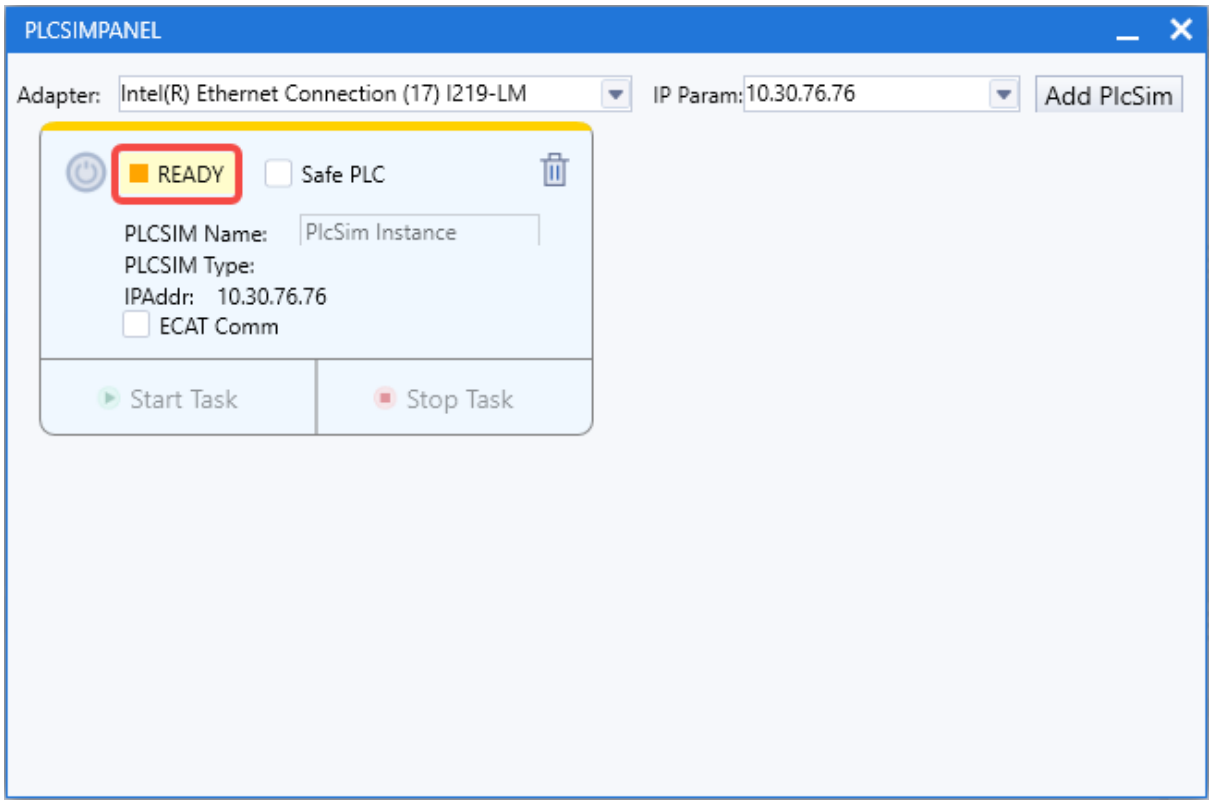
PLCSIM virtual PLC simulation relies on iFA integrated software and must be started by iFA. The simulation environment must be set up before performing simulation operations.

Prerequisites

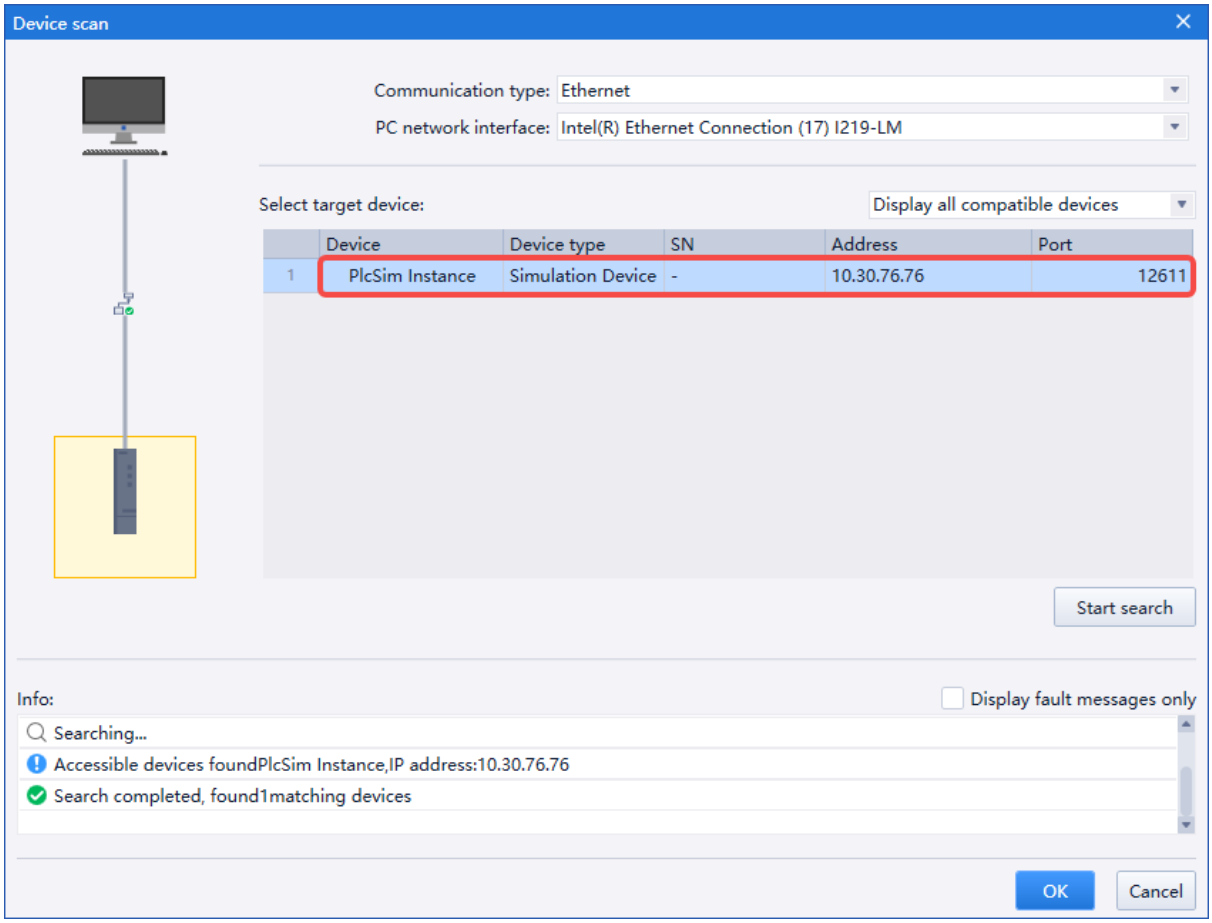


- A project has already been created in iFA, and a PLC device has been added.
- Configure the PLC logic execution program in the program editing interface.

Procedure

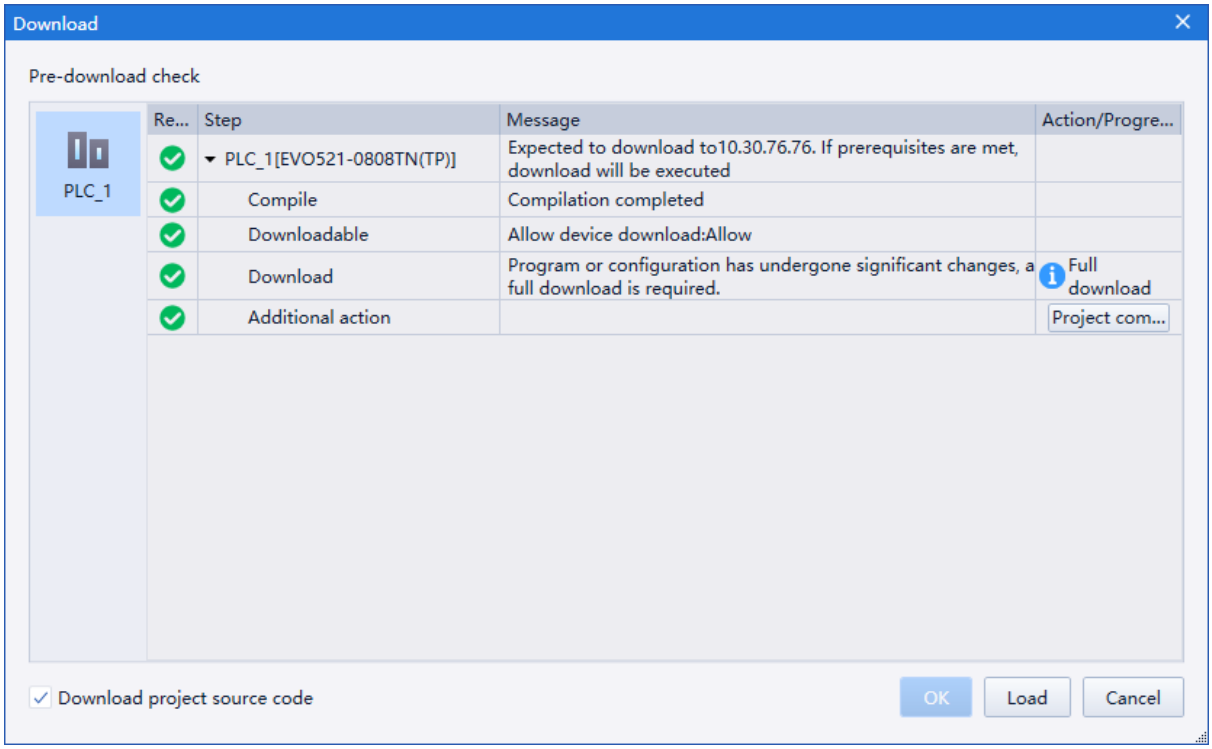


1. Click "Start simulation" on the toolbar to open the simulation panel.

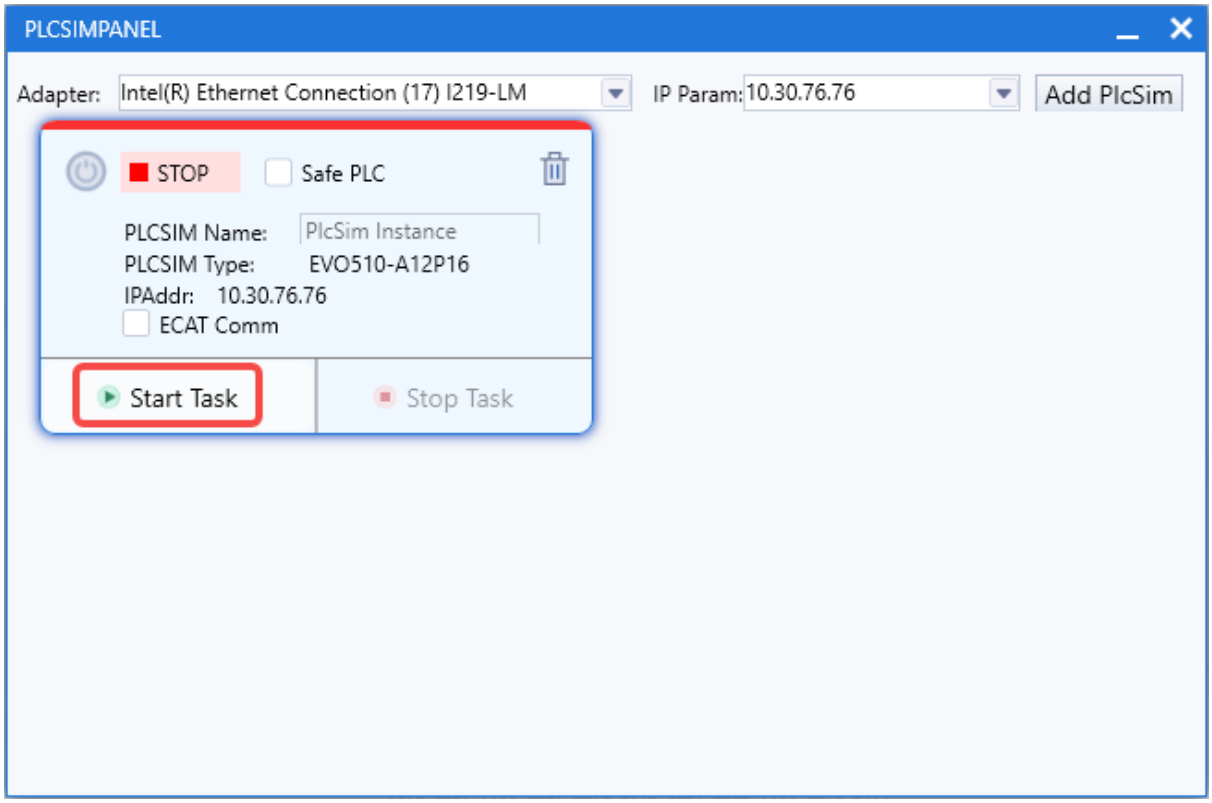


2. Click "Add simulation" to create a virtual PLC simulation instance object.

3. Click and the virtual PLC enters the Ready state. The PLC can be used normally at this time.



4. Select "Online > Device scan" from the menu bar. In the "Device scanning" window, click "Start search", select the simulation device of the virtual PLC, and click "OK".



5. Click the "Compile" icon on the toolbar to compile the PLC logic program.

6. Click the "Download" icon on the toolbar. In the "Download" window, click "Load" to download the successfully compiled program to the virtual PLC.

7. Click the "Online" icon on the toolbar to go online.

8. Click "Start task" in the simulation panel to execute the program in the virtual PLC and start logic simulation.

10.13.3 Simulation Function Description

Supported simulation features

The main functions of PLCSIM are embodied in the virtual PLC instance object, specifically including the following functions:

Simulation Functions	Description
Logic and program simulation	The virtual PLC object can simulate the logical ST programs and LD programs of the PLC, and supports software algorithm library instructions, PID algorithm instructions, axis motion control instructions, and compiler algorithm instructions. It also supports logical power-off commissioning for ST programs, power failure retention, as well as simulation of oscilloscope and recipe functions.

Simulation Functions	Description	
Communication simulation	EIP simulation	EIP protocol supports the virtual PLC to act as a scanner and adapter for communication simulation. The virtual PLC can work as an adapter slave or a scanner master. When the virtual PLC acts as an adapter slave device, it supports Class1 implicit I/O connections and label connections, enabling data exchange access for I/O; it also supports Class3 and UCMM explicit communication with label access, allowing the scanner to access public label variables within the virtual PLC. When the virtual PLC acts as a scanner master, it supports importing EDS device files into the scanner and adding slave device connections or label connections, and building explicit Class3 and UCMM service label communication to access public labels variables on the adapter side.
	Modbus simulation	The virtual PLC supports simulation of Modbus protocol as both master and slave. The virtual PLC simulation object can operate independently as a master or slave, or simultaneously as both. When simulating as a Modbus master or slave, it supports standard Modbus function codes, allowing read and write operations on memory areas and status areas.
	OPC UA simulation	The virtual PLC can simulate an OPC UA protocol service device. During OPC UA simulation, the virtual PLC currently only supports label access from the OPC UA clients, enabling read and write operations on public network variables in the virtual PLC program.
	EtherCAT simulation	The virtual PLC supports simulation of an EtherCAT as a master. Slaves can be added through the EtherCAT master. Currently, only servo EtherCAT slaves are supported, while I/O is not supported. It can drive the motion of servo EtherCAT slave physical axes via EtherCAT, and the current servo master supports motion control simulation for up to eight axes with a 10 ms cycle.

Simulation Functions	Description
Axis simulation	The virtual PLC axis simulation supports two modes: real axis and virtual axis. Real axis: Simulates the motion control for physical servo axes of devices. Virtual axis: Simulates the motion control of theoretical axes, without the need for external physical servo axes. Currently, the virtual PLC supports simulation of axis control instructions and component configuration. It can build axis control configuration programs through the motion control library and perform program simulation. It also supports axis group simulation, enabling motion control simulation of multiple axes in one group. In real axis simulation, the virtual PLC simulates not only EtherCAT real axis devices but also virtual EtherCAT slave devices, enabling motion control simulation of virtual devices.

NOTE

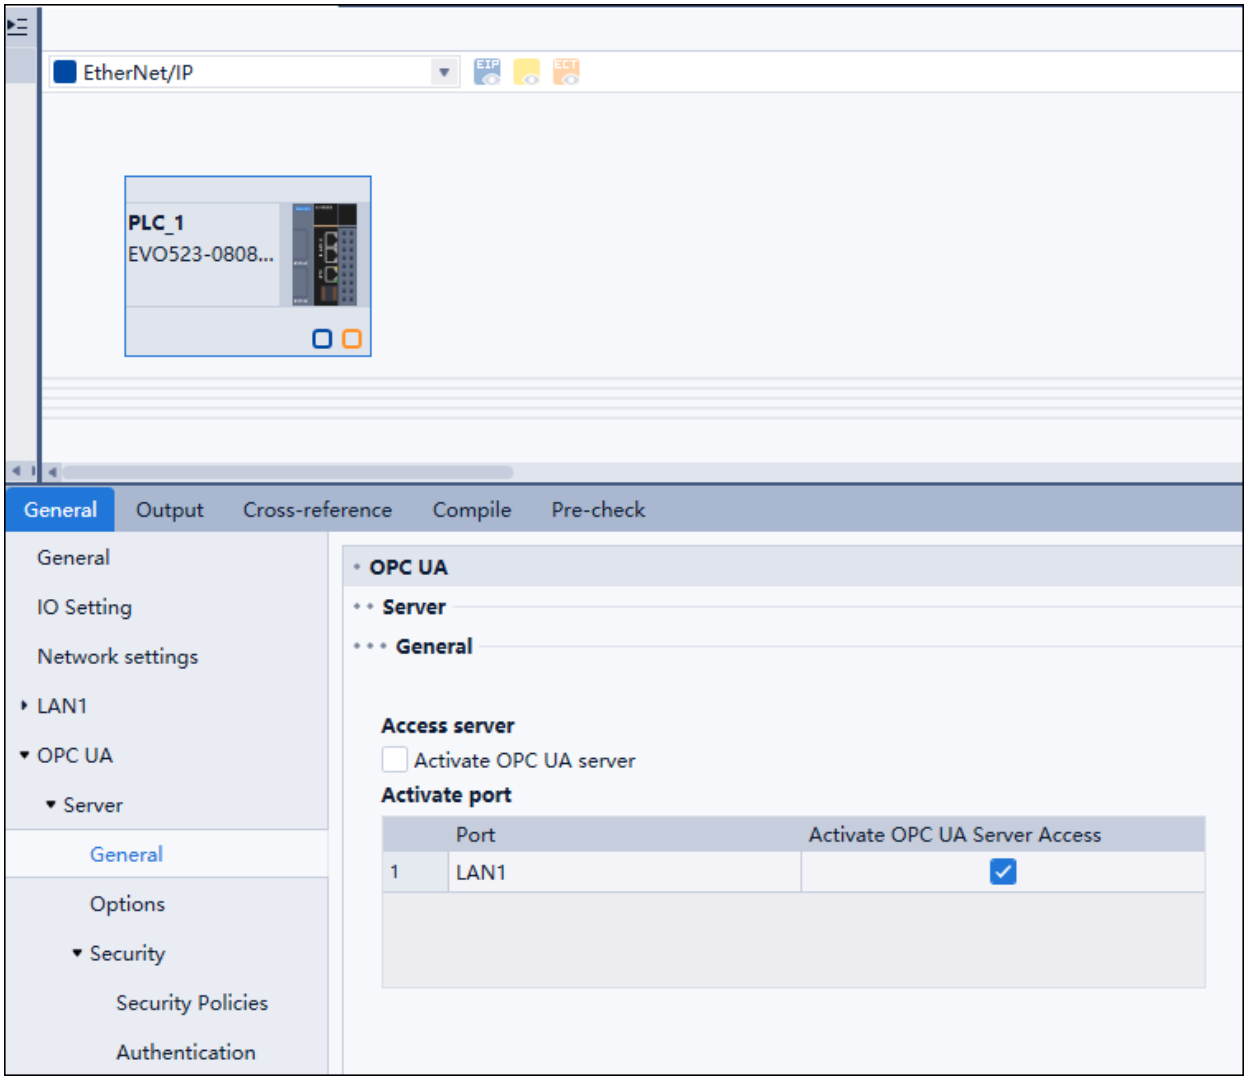
In communication simulation, the simulated instance object must have the same IP address as the current PC.

Use restrictions

PLCSIM simulation is implemented on the Windows system platform. Some functions cannot be supported for simulation, and certain functions may have boundary errors during simulation, as shown below.

- Task priority
  Windows is a non-real-time system, and the system priority settings differ significantly from those in Linux, so task priority simulation is not supported.
- Oscilloscope
  When the execution cycle of an IEC task is less than 40 ms, the values of POU variables obtained by the oscilloscope will have errors, with larger errors occurring at smaller task cycles.
- Instruction
  - There are differences in the instruction results between the X86 and ARM platforms. The differing instructions are as follows:

Differing Instruction	Note
REAL_TO_<TYPE>	<TYPE> data types include: BYTE, SINT, USINT, INT, UINT, DINT, UDINT, LINT, WORD, DWORD, TIME, DATE, DT.
LREAL_TO_<TYPE>	<TYPE> data types include: BYTE, SINT, USINT, INT, UINT, DINT, UDINT, LINT, WORD, DWORD, TIME, DATE, DT, TOD, STRING, WSTRING.
TRUNC	ST language operator for rounding.
TRUNC_INT	ST language operator for rounding.



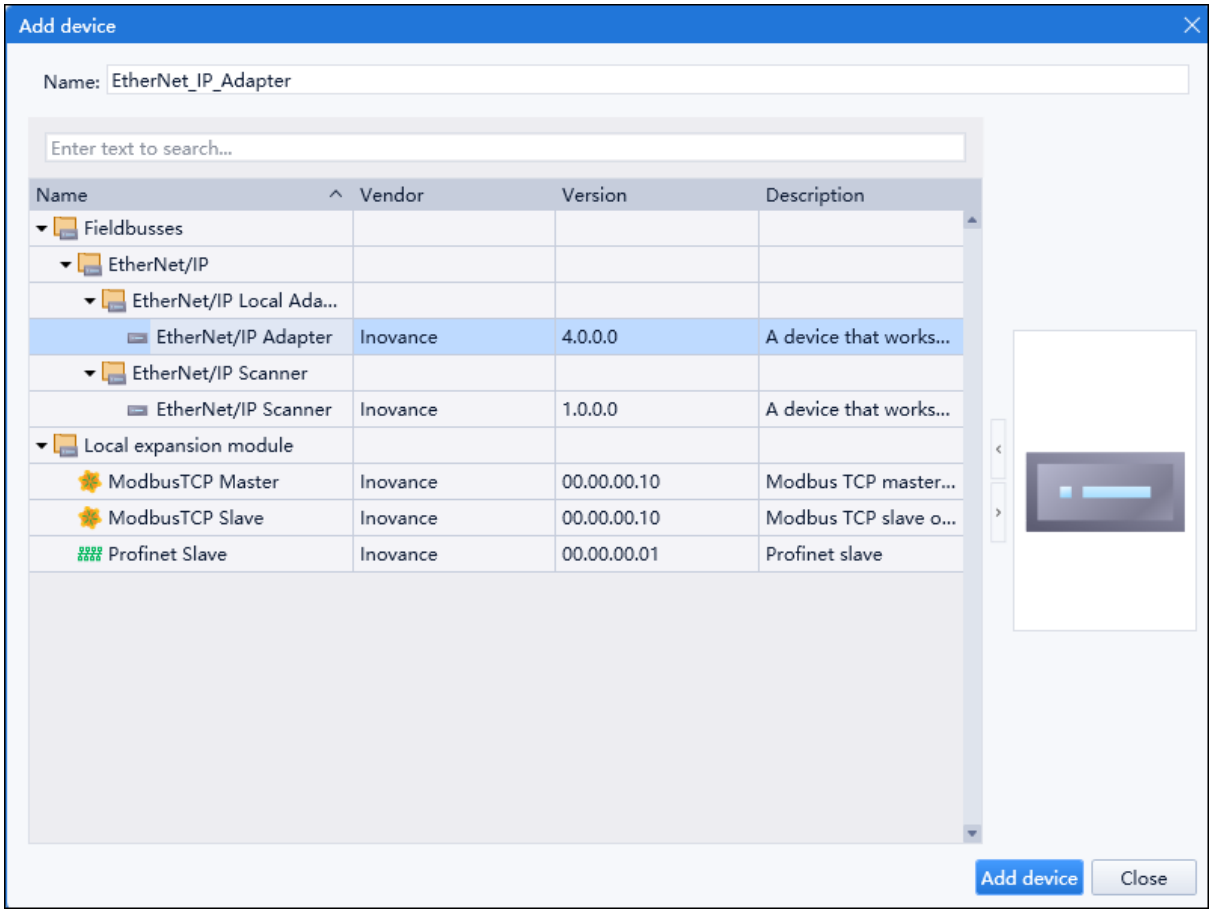
- The following instructions in the library do not support simulation:
  CANBus, CIA405, CmpHCHighSpeedIo, ExtendIo, HC_FINS, IOBlockHandle, MelsecServer, NetFreePort, S7Comm, SerialCom, SftpClient, SysHCPlcInfo, TcpUdpFreeProtocol.

- POU call
  In multi-task simulation mode, calling the same POU from multiple tasks is not supported. If no synchronization lock exists in the logic for the POU, resource contention issues may occur.
- Simulation duration
  After PLCSIM creates a PLC simulation, the simulation duration cannot exceed 8 hours. If it exceeds 8 hours, the PLC simulation will automatically exit.

10.13.4 Simulation Commissioning

10.13.4.1 OPCUA Communication Protocol Simulation

The simulation virtual PLC has OPC UA service capabilities, enabling access by OPC UA client to public network variables in the PLC program. The OPC UA communication protocol is enabled and its related parameters are configured via the iFA software, then downloaded to the virtual PLC instance object in PLCSIM, achieving OPC UA communication protocol simulation for the virtual PLC.
The OPC UA protocol stack parameter configuration is shown in the following figure:

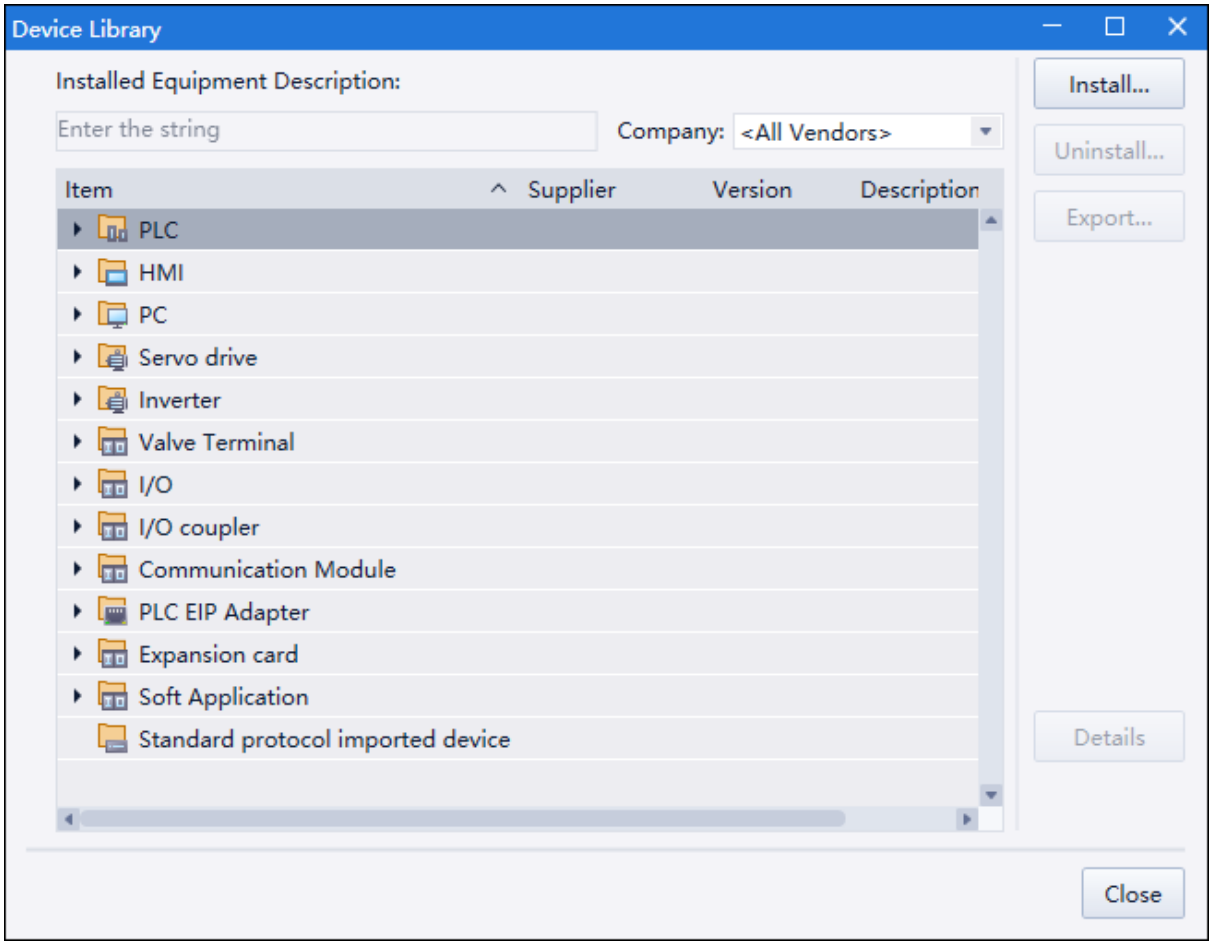


NOTE

OPC UA functionality depends on the .ini configuration file. Currently, OPC UA does not support Chinese paths; therefore, when using OPC UA functionality, PLCSIM must not be installed using a path containing Chinese characters.

10.13.4.2 EtherNet/IP Communication Protocol Simulation

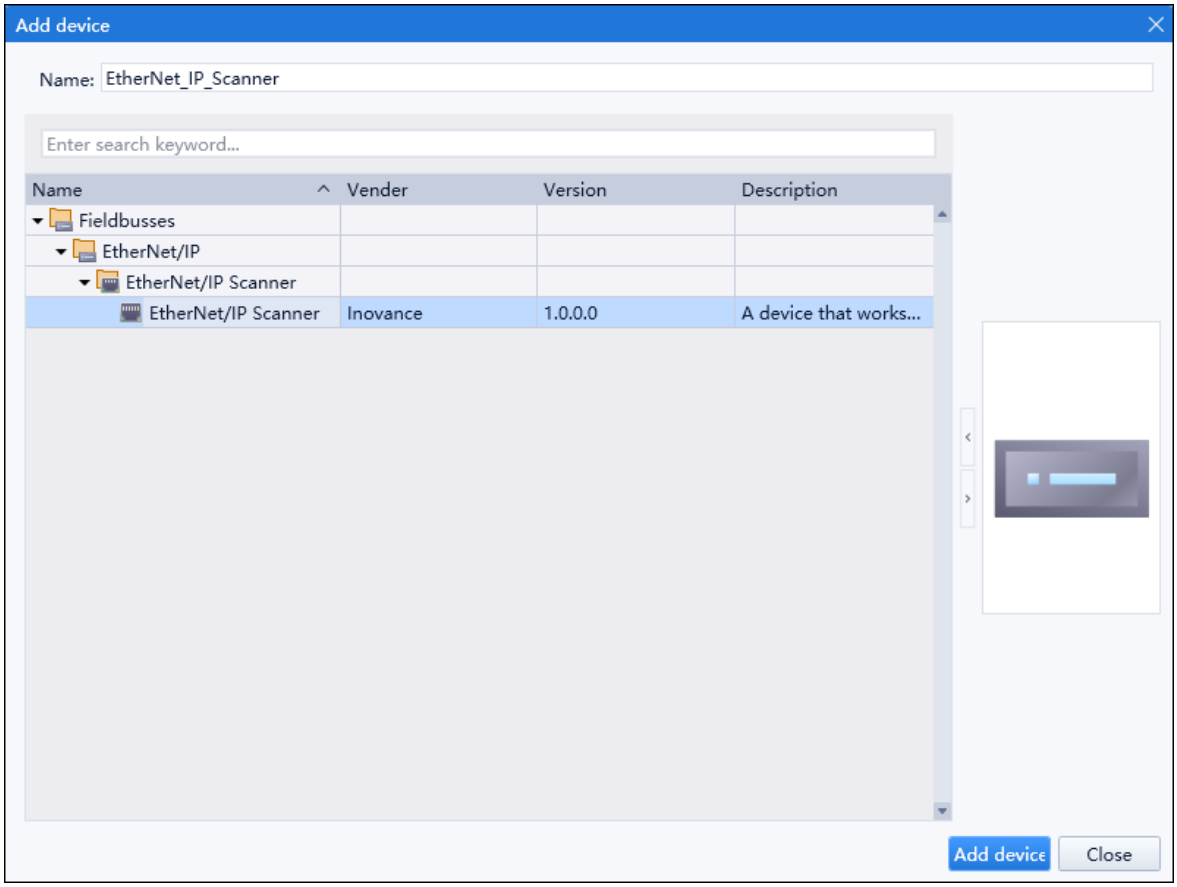
EtherNet/IP (short for EIP) network communication operates in master-slave mode. To simulate EIP communication functions, it is necessary to build a master or slave for the EIP device. Configure the IP address of the EIP device in the slave or master device, and establish a Class1 or Class3 connection. I/O or label data for Class1 and Class3 connections are displayed in the I/O mapping area as communication data. The EIP device configuration is shown in the figure below:



1. Right-click "LAN1 (EtherNet)" under "Hardware configuration" in the project tree and select "Add device". EIP devices include the master scanner and the slave adapter. A virtual PLC can function as both a master and a slave. The EIP device addition interface is shown in the figure below.

2. Select to add an EIP slave device adapter, and add an I/O connection within the adapter. After the connection is created, export the EDS file from the adapter.

   After the simulation program starts, the master device can connect to the slave device of the adapter, enabling I/O data exchange.



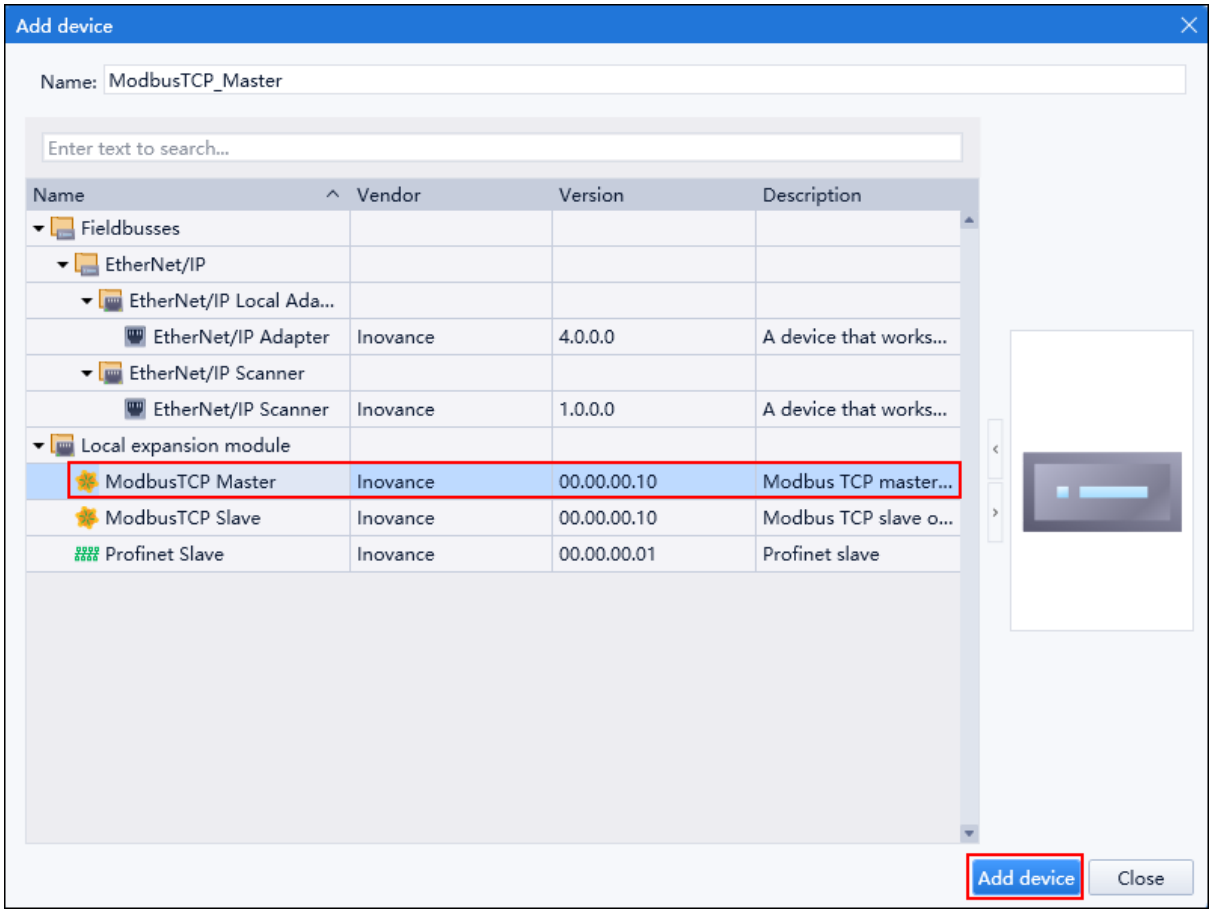
3. Add the EDS file exported in Step 2. Select "Tools > Device library" in the menu bar, as shown in the figure below.

4. After adding the EDS device file, add an EIP master scanner to the network node, and add a slave under the scanner device.

   a. Right-click "LAN1 (EtherNet)" in the project tree and select "Add device".

   b. Select "EtherNet/IP Scanner" and click "Add device".

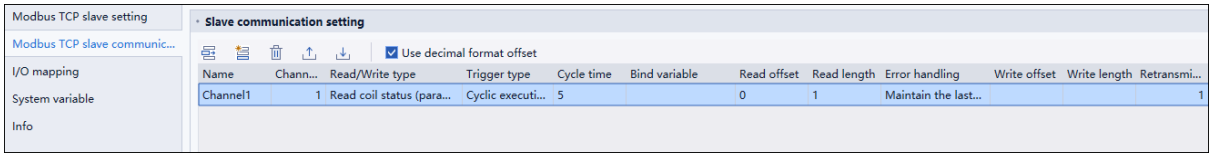
5. After adding the EIP slave device, double-click the slave device, set the slave IP address in the "General" tab, and add I/O connections in the "Connection" interface.



After configuring the remote slave IP and connection settings, re-download the program and start the simulation to establish the EIP I/O connection and complete I/O data exchange.

10.13.4.3 Modbus TCP Communication Protocol Simulation

ModbusTCP devices and EIP devices both use a master-slave communication mode.

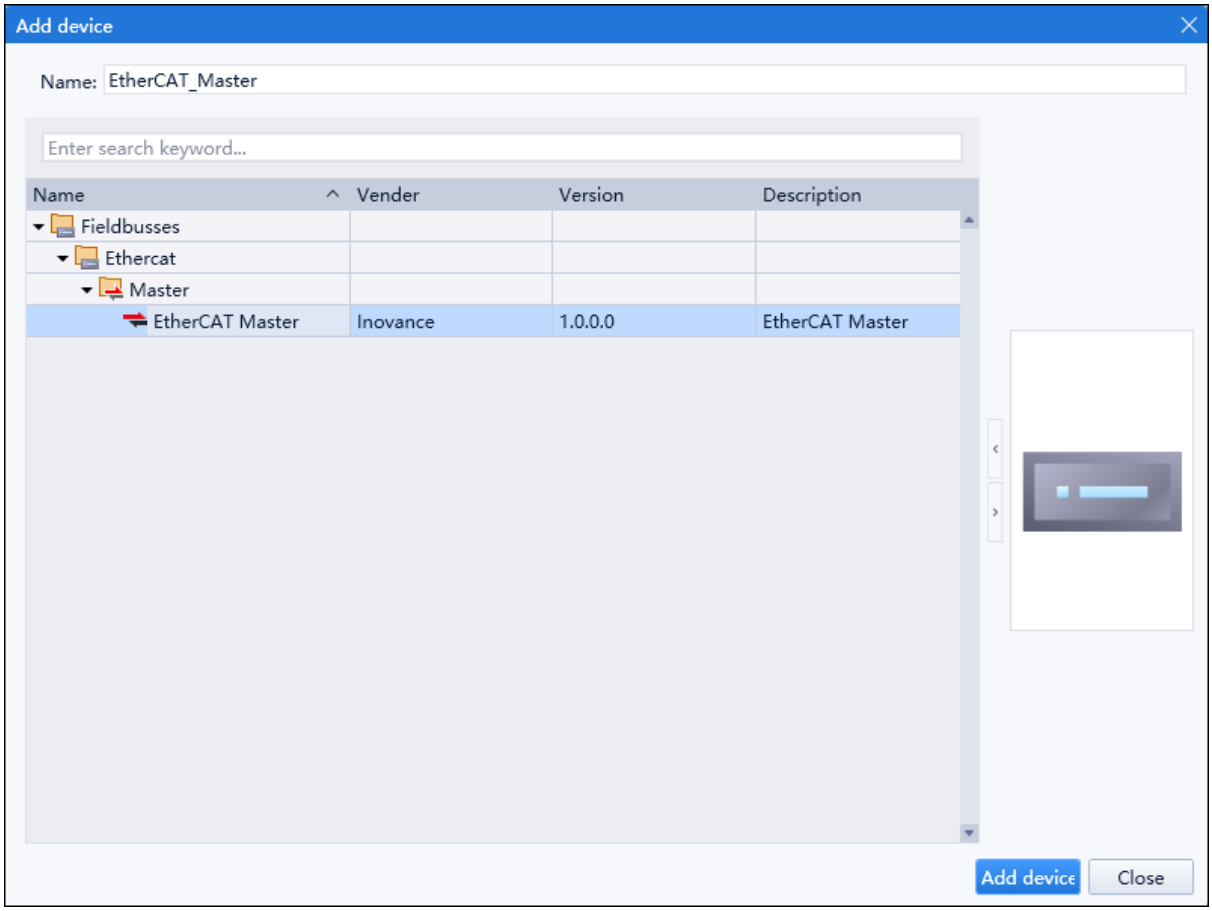


The procedure of adding a ModbusTCP device is similar to adding an EIP device. Right-click the network node, select the ModbusTCP master/slave to add it to the iFA device tree. The creation and operation of a ModbusTCP device are as follows.

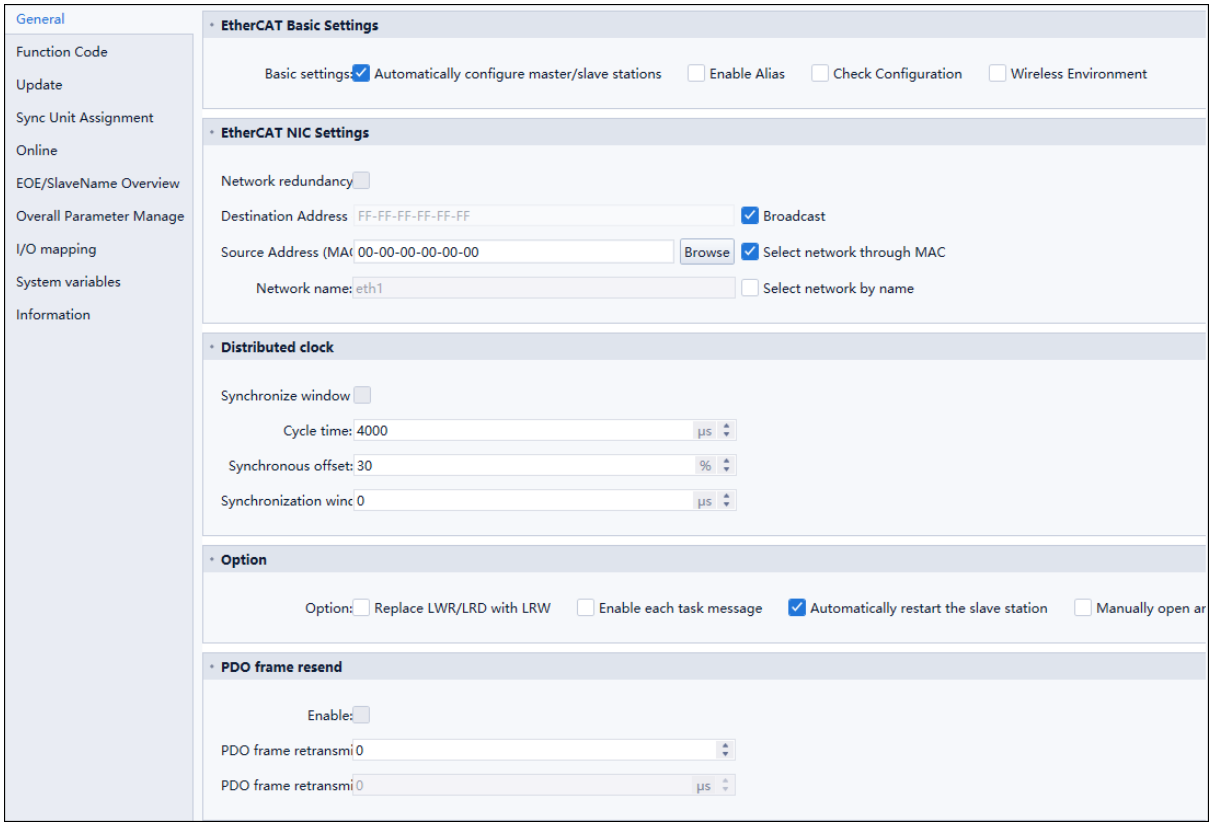
1. Right-click "LAN1 (EtherNet)" in the left project tree and add a ModbusTCP master and slave.

2. To add a slave device to the ModbusTCP master, right-click the "ModbusTCP_Master" node and select "Add device".

3. Add I/O communication channels to the slave device. The communication channels of the slave device support instruction codes 01, 02, 03, 04, 05, 06, 15, and 16. Re-download the virtual PLC to enable ModbusTCP simulation communication. The I/O configuration for Modbus device communication is shown in the following figure.



10.13.4.4 EtherCAT Communication Protocol Simulation



EtherCAT simulation supports only masters and servo devices, not I/O coupler devices.

The simulation cycle of the PLCSIM EtherCAT master supports a minimum of 10 ms. For EtherCAT simulation of drive real axes, up to 8 physical real axes can be simulated. The configuration steps for EtherCAT master in iFA are as follows:

1. Add an EtherCAT device: Right-click the "EtherCAT" node under "Hardware configuration" in the project tree, select "Add device", and select the EtherCAT master device, as shown in the figure below:

2. Configure the EtherCAT master parameters: Select the physical network card for EtherCAT communication, and set the EtherCAT device cycle to no less than 10 ms. The configuration of the EtherCAT master network card is shown in the figure below:

3. Add servo devices and configure the relevant parameters on the servo node.

4. Re-download the program to perform simulation of the servo real axes.

> NOTE
>
> The EtherCAT network cannot be selected using the network names.

10.14 Multi-User Collaboration

10.14.1 Overview

The multi-user collaboration feature allows multiple users to connect to the same PLC simultaneously to complete configuration and program development tasks. It mainly supports operations such as monitoring, commissioning, online modification, online comparison, program upload, and download.

> NOTE
>
> - This feature is only applicable to the EVO700 series PLCs with firmware version V1.7 or above
> - Multi-user collaboration is only supported for projects from the same source. Collaboration is not allowed for projects from different sources.
> - Same-source projects share the same original project, while different-source projects do not. If the original project is opened after a device version change or software upgrade, it will no longer be considered a same-source project.

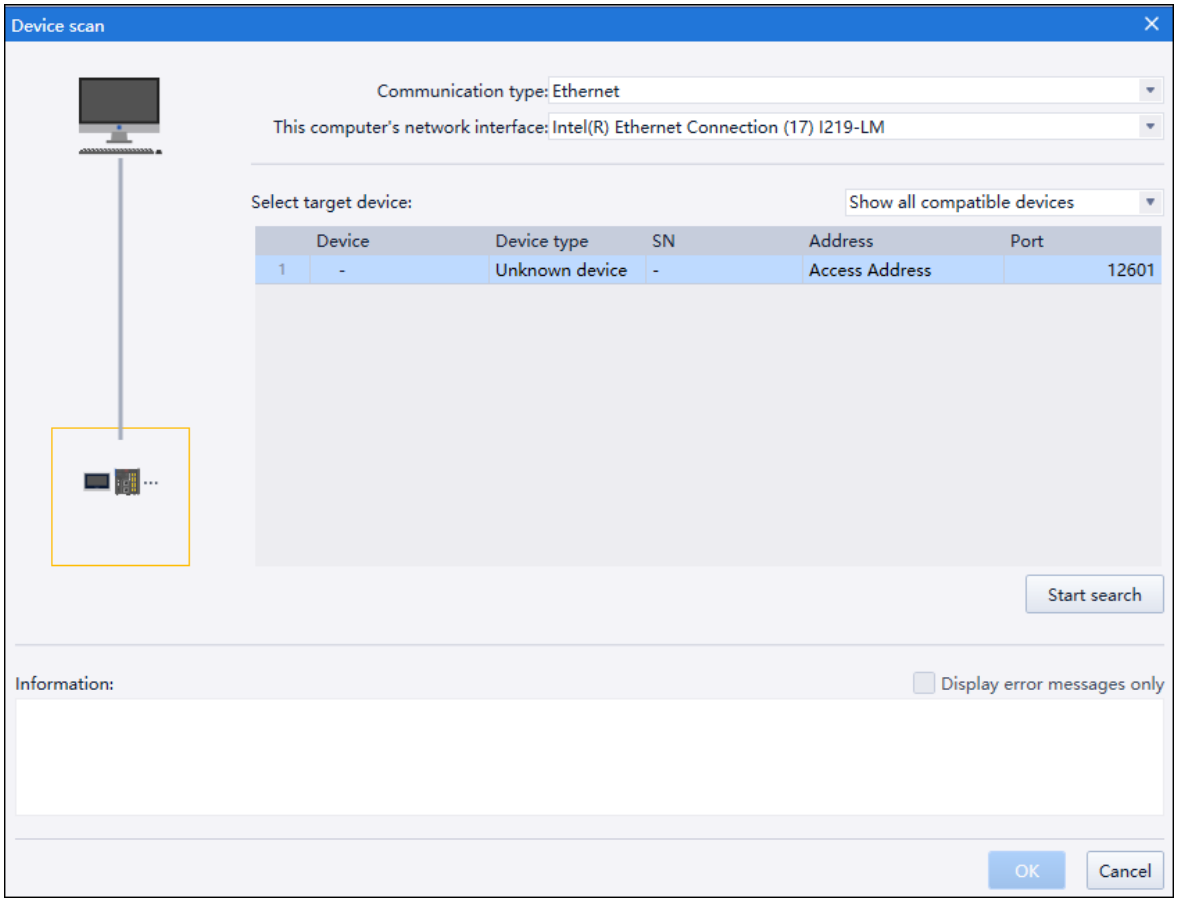
During multi-user collaboration, the PLC acts as the server, allowing different programmers to download their control logic to the PLC via the iFA software. Other programmers can upload the latest PLC logic back to iFA. It is recommended that team members plan the division of work in advance to complete programming tasks efficiently and orderly through teamwork. For example, after member A finishes programming and downloads the program to the PLC, member B uploads the PLC program to their local environment and continues programming, and so on.

10.14.2 Multi-User Online Editing

To accommodate multi-user collaboration scenarios, the system separates device online operations from program download. When users perform online operations, iFA only logs in to the selected device without triggering a download. When online conditions are met, iFA can directly log in to the PLC. Compared to the previous online download mode, the new mode has the following features:

- The operation involves additional steps, but the compilation and download speed is significantly improved.
- Avoids program overwrite conflicts caused by multiple user logins; supports real-time online collaboration among multiple users (including program modification, real-time monitoring, and synchronized download).
- User modifications can be automatically synchronized across multiple terminals in real time.

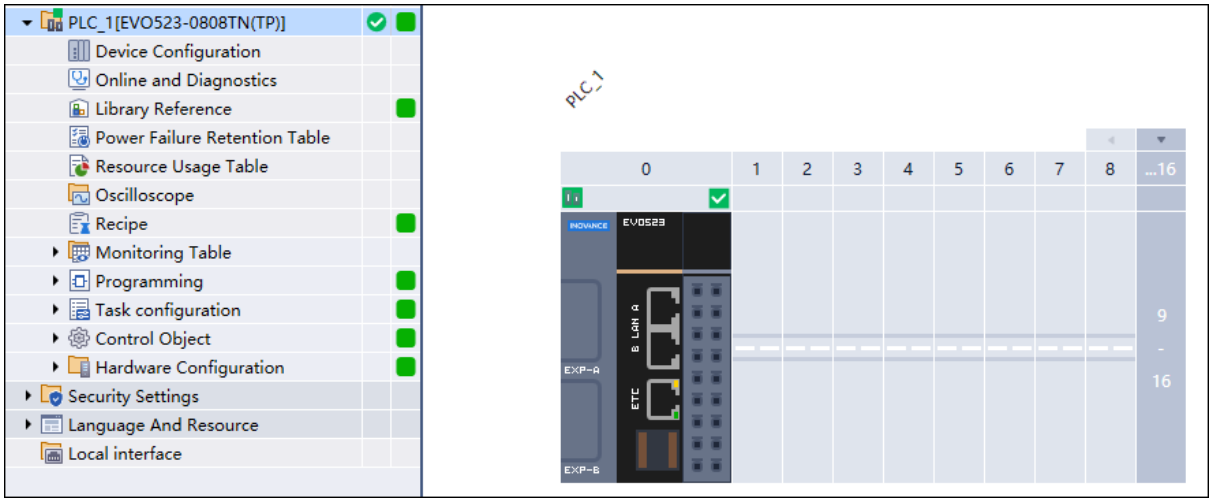
Restrictions



A device supports up to five users logging in simultaneously. If it is exceeded, the system displays a pop-up message, indicating that the login limit is reached and the device supports a maximum of five concurrent logins.

Prerequisites

- Device types are consistent and versions are compatible.
- Project files are from the same source project.



Procedure

1. Go online.
   - After selecting the device node in the project tree, click the "Online" icon in the menu bar.
   - Right-click the device node in the project tree and select "Online".
   - After selecting the device, use the Ctrl+K shortcut key to go online; use the Ctrl+M shortcut key to go offline.
   - In the network view/device view, right-click the device and select "Online".
2. (Optional) If a device connection has not been established, configure the device connection.
   - In the pop-up "Device scanning" window, click "Start search".

- Select the target device and click "OK".

3. (Optional) If online conditions are not met, an error prompt will appear. Troubleshoot and resolve the issue based on the prompted reasons.
4. After going online, the device identifiers in the project tree and device configuration view will change, as shown in the figure below.

Result

Users can view the current number of logged-in users in real time, compare differences between the local project and the controller project, and perform online editing.

- Number of logged-in users

Users can view the current number of online users in the status bar of the software interface. For details, see 5.2 Project View.

- Project comparison

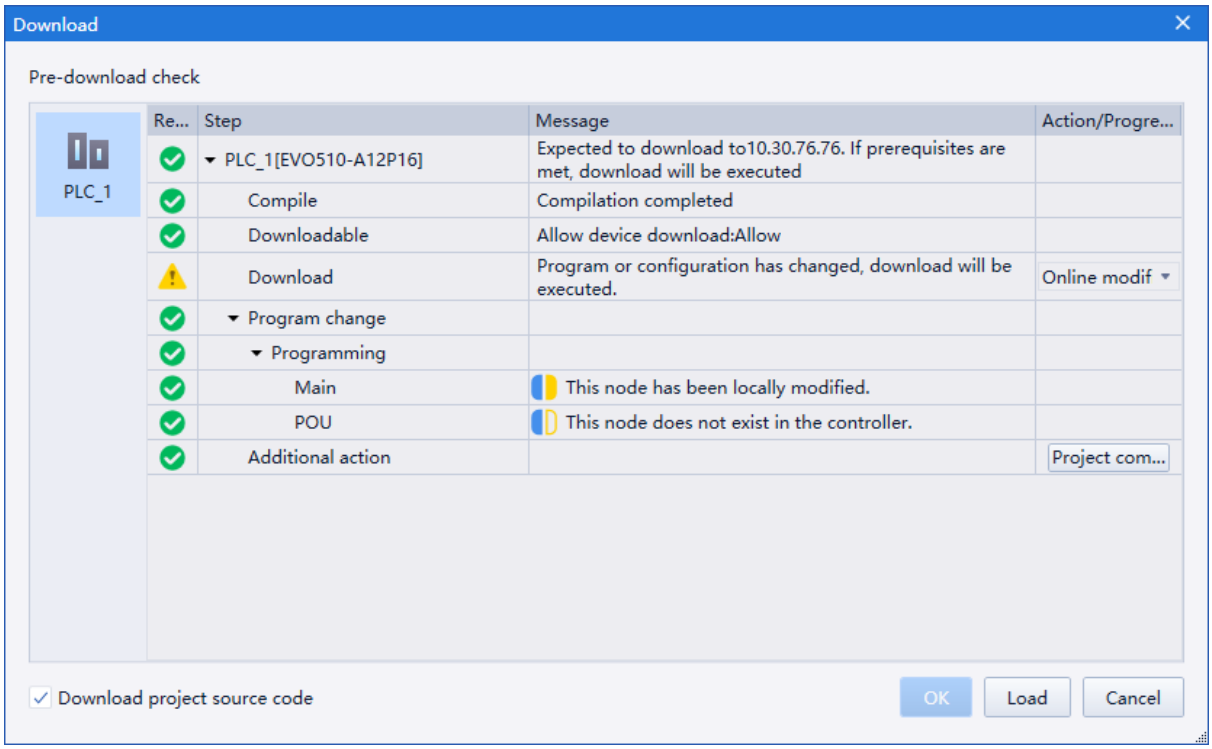
After the device is online, the status bar on the right of the project tree will display the difference status between the local project and the controller project in real time. If a node supports detailed comparison, double-click its status icon to jump to the corresponding comparison view. The descriptions of each status icon are shown in the table below.

Status	Description
	Projects are consistent.
	Projects are inconsistent; double-click to view the detailed comparison for this node.
	Exists only locally.
	Exists only on the controller.
	Content or number of child nodes are inconsistent.

In addition to the above methods, you can also view project differences through the project comparison function. For details, see 10.12.3 PLC Project Comparison > Offline/Online Comparison.

- Online editing

After the device is online, users can perform online editing to modify variables and programs in real time.



10.14.3 Multi-User Download Synchronization

Multi-user download is a core feature in multi-user collaborative scenarios. It is used to resolve potential conflicts and overwriting issues when multiple users download projects to the same controller at the same time. This feature allows multiple users to initiate download tasks simultaneously. The system performs conflict detection during execution and provides clear status prompts to guide users, ensuring the consistency and correctness of the project version in the controller.

Procedure

1. Click  on the toolbar to open the "Download" window. Before the download, compilation and a series of checks are automatically performed.
   When the current project is inconsistent with the project in the controller, the prompt "Program or

configuration has changed, download will be executed" is displayed.

2. Under "Program change", view the program change details and select the appropriate action (currently only changes to programming and task configuration nodes are displayed).
   - Download on sync: Synchronize and download the local program or configuration to the controller.
   - Upload on sync: Synchronize and upload the controller program or configuration to the local system.

Icon	Prompt	Action/Progress
	This node does not exist in the controller.	Default: Download on sync; not modifiable.
	This node does not exist in the project tree.	Default: Upload on sync; not modifiable.
	The node has been modified by others.	Default: Upload on sync; not modifiable.
	This node has been locally modified.	Default: Download on sync; not modifiable.
	This node has been modified by multiple parties.	Options: Download on sync or upload on sync.

3. Click "Download after sync" or "Download without sync".
   - Download after sync: Based on the controller's program or configuration, locally synchronize nodes marked as "Upload on sync"; download the program or configuration of nodes marked as "Download on sync" to the controller.
   - Download without sync: Download the current local program or configuration to the controller, overwriting the controller configuration. This action is independent of the node actions in "Program change".
4. After download, a success message appears. If the download fails, an error prompt will appear. Please troubleshoot and handle the issue according to the prompt.

NOTE

- Before downloading, please carefully confirm that the synchronization items are correctly selected. Synchronization operations cannot be undone. Please proceed with caution!
- Before downloading, please verify the code. In multi-user collaboration, promptly synchronize modifications by others to avoid overwriting.
- In multi-user collaboration, in addition to the automatic project synchronization download method described above, manual synchronization can also be used: Manually upload the programs generated by other users to the local system, and then download the entire project from the local system to the PLC. There are three ways to manually synchronize the project. You can flexibly choose based on your actual situation.
  - Synchronize the current project information in the PLC by uploading only differences. For specific operations, see 10.14.5 Upload Only Differences.
  - Synchronize the current project information in the PLC using the project comparison feature. For specific operations, see 10.12.3 Offline/Online Comparison and 10.12.4 Viewing and Processing Comparison Result in the "PLC Project Comparison" chapter.
  - Synchronize the current project information in the PLC using the project comparison feature in the "Download" window that pops up when logging in to the PLC. For operations after project comparison, see 10.12.3 Offline/Online Comparison and 10.12.4 Viewing and Processing Comparison Result in the "PLC Project Comparison" chapter.

10.14.4 Multi-User Commissioning

When multiple users are simultaneously performing online commissioning on the same controller, the system ensures orderly operation and data consistency through collaboration rules and state management mechanisms, preventing conflicts between commissioning operations. The following table lists all mutually exclusive operations. When performing an operation in the left column, ensure that no other user is performing the corresponding operation in the right column.

When performing this operation	Ensure no other user is performing the following operations
Download	Download, upload, force, release, write, commissioning, clear user program, start, stop, sync source code, sync compilation information, online login, incremental file upload
Incremental file upload	Download, clear user program, sync source code, sync compilation information
Source code upload (Upload as new device)	Download, upload source code, clear user program, sync source code
Forcing a value	Download, clear user program
Releasing a value	Download, clear user program
Writing a value	Download
Execute	Download, clear user program
Stop	Download, clear user program

When performing this operation	Ensure no other user is performing the following operations
Commissioning	-
Clearing user programs	Download
Cold reset	Download, clear user program
Hot reset	Download, clear user program
Sync source code (Download iFA project to PLC)	Download, go online, sync source code, upload source code, incremental file upload
Sync compilation information (Download iFA compilation information to PLC)	Download, sync compilation information, go online, incremental file upload
Go online	Download, sync source code, sync compilation information

Axis commissioning

In a multi-user collaborative commissioning environment, the system uses permission control to ensure the security and data consistency of the axis commissioning process.

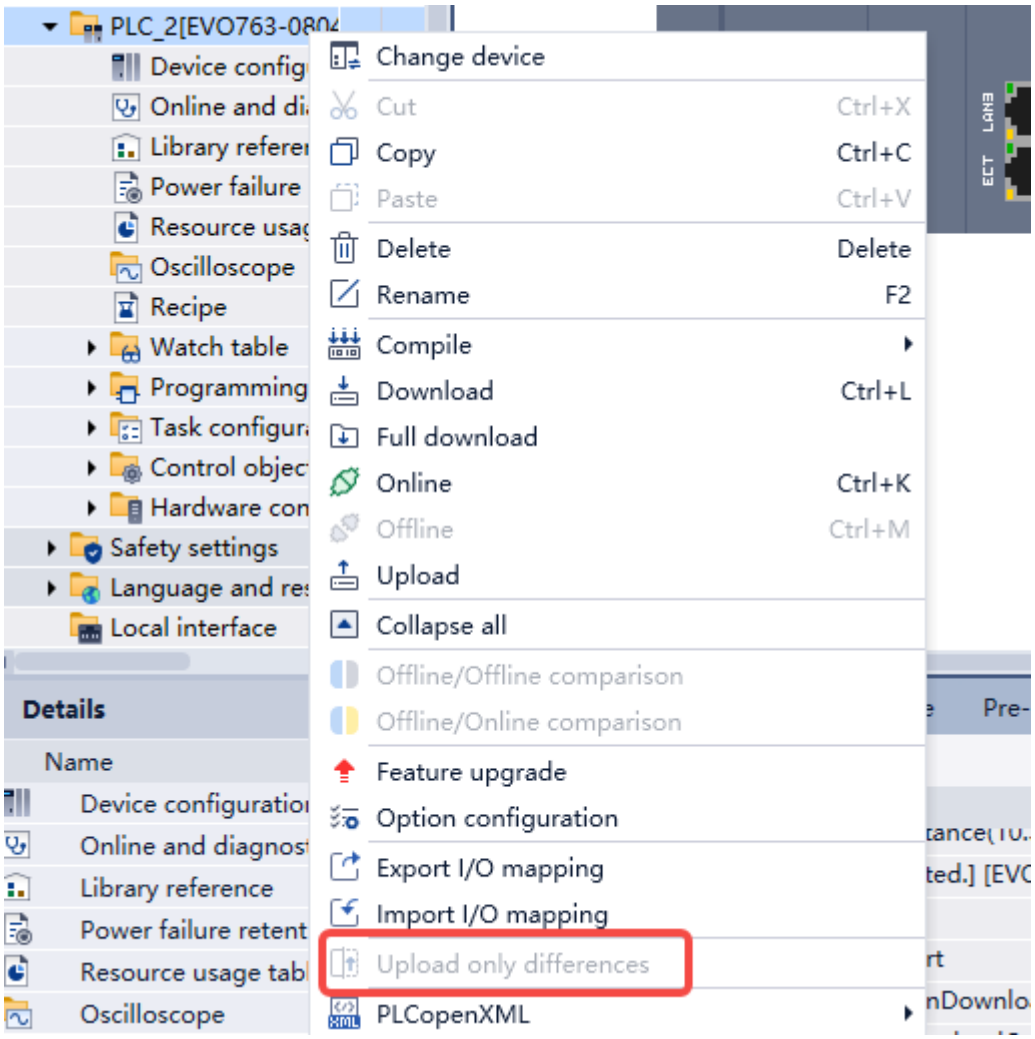
Restrictions

- Allowed operations: Different users can perform commissioning on different axes simultaneously.
- Prohibited operations: Only one user can perform commissioning on the same axis simultaneously. If another user attempts to perform commissioning on an axis that is already occupied, the system will prohibit the operation and display a prompt.

Precautions

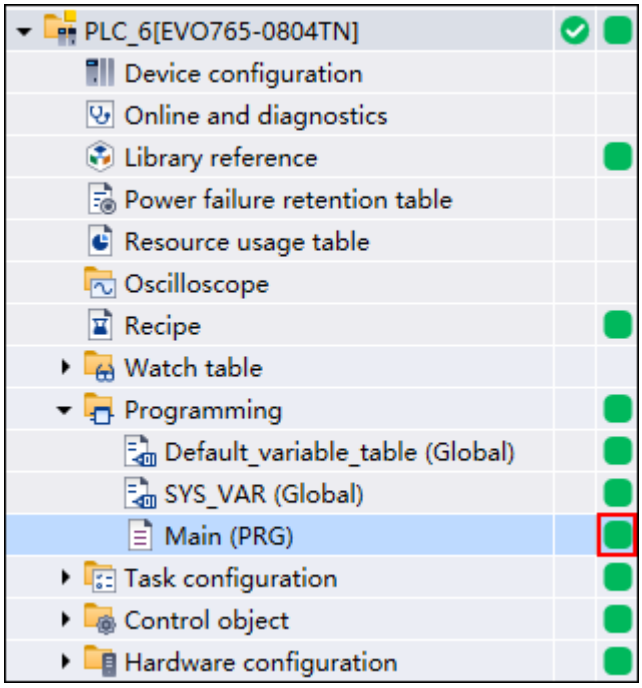
- When User A is performing commissioning on an axis and communication is abnormally interrupted (e.g., iFA unexpectedly closed or LAN cable disconnected), the system will automatically exit User A's commissioning state, allowing User B to perform commissioning
- If User A has opened axis X and entered the commissioning state, User B's commissioning attempt on the same axis X will be prohibited. User B must wait until User A exits the commissioning state.

10.14.5 Uploading Only Differences



This feature is used to synchronize changes in the controller to the local project.

Prerequisites



- Currently, the node types that support difference synchronization are programming nodes, PID configuration nodes, and task configuration nodes in control objects.
- The node exists only in the controller and is not present in the local project.
- The node has not been modified in the local project, but it has been modified in the controller.

Procedure

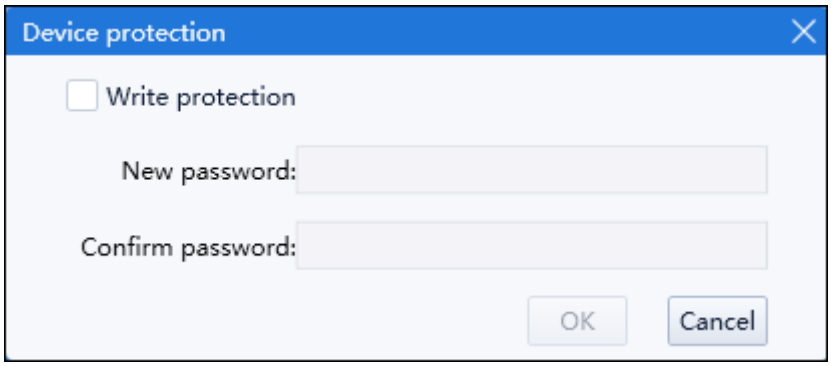
1. Right-click the device name in the project tree and select "Upload only differences".

2. After execution, the comparison status icon in the project tree changes to , indicating that the local project is consistent with the project in the controller.

11 Safety PLC Programming

Safety PLC programming complies with the following standards:

- LD and FBD languages defined by IEC 61131-3
- T3 tool requirements defined by IEC 61508-3
- IEC 62061 SIL CL 3 and ISO 13849-1 PL e/Cat.4 certifications



11.1 Safety PLC Access Protection

11.1.1 PLC Configuration Write Protection

In the iFA project, the safety PLC supports individual write protection settings. The write protection ensures that all content within this safety PLC (including hardware configuration and programs) can only be viewed and cannot be modified.

Setting write protection

In the left project tree, right-click a safety PLC project node, and select "Set/Delete access protection" to open the device protection interface.

Check "Write protection" to activate the password input fields. Enter a valid and consistent password, confirm it, and click "OK" to apply the setting.

Deleting write protection

- Method 1: In the left project tree, right-click a safety PLC project node, and select "Set/Delete access protection". Uncheck "Write protection", a password verification window will appear. Enter the correct password and click "OK" to apply.
- Method 2: In the left project tree, right-click a safety PLC project node, and select "Disable/Enable access protection". A password verification window will appear. Enter the correct password and click "OK" to apply.

11.1.2 PLC Permission Configuration

The method and criteria for configuring PLC permissions in a safety PLC are the same as those for a standard PLC. For details, see 10.11.6 PLC Permission Configuration in the "PLC Programming" chapter.

11.2 Programming Basics

11.2.1 Variables

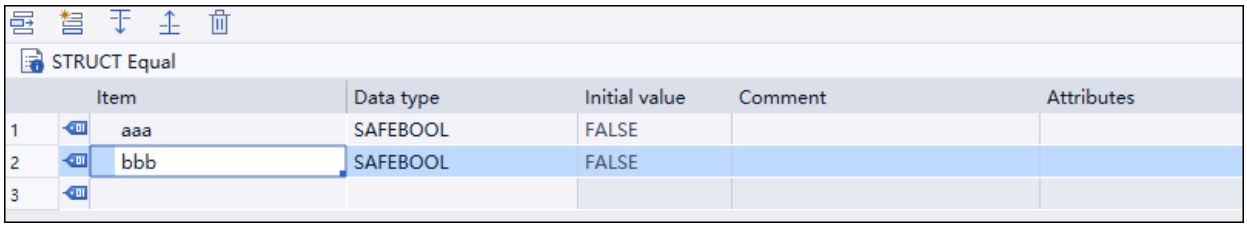
11.2.1.1 Data Types

11.2.1.1.1 Standard Data Types

Data Type	Value Range	Memory Usage (Byte)	Input Example
BOOL	TRUE, FALSE	1	TRUE FALSE
BYTE	0 to 255	1	BYTE#2#00001111
WORD	0 to 65535	2	WORD#61680 DWORD#2#0000_0000_1111_0000_1111_1111_0000_1111
DWORD	0 to 4294967295	4	
INT	-32768 to 32767	2	100 INT#2#00000000_01100100 INT#8#144 INT#10#100 INT#16#64 -100
DINT	-2147483648 to 2147483647	4	
TIME	T#0d0h0m0s0ms to T#49d17h2m47s295ms	4	T#10d_20h_30m_20s_630ms T#61m5s T#3s20ms TIME#10d_20h_30m_20s_630ms TIME#6d_10m
DATE_AND_TIME	DT#1970-01-01-00:00:00 to DT#2106-02-07-06:28:15	4	Start with DT# or dt#, and followed by a date and time in yyyy-mm-dd-hh:mm:ss format. dt#2007-07-01-05:40:25

11.2.1.1.2 Safety Data Types

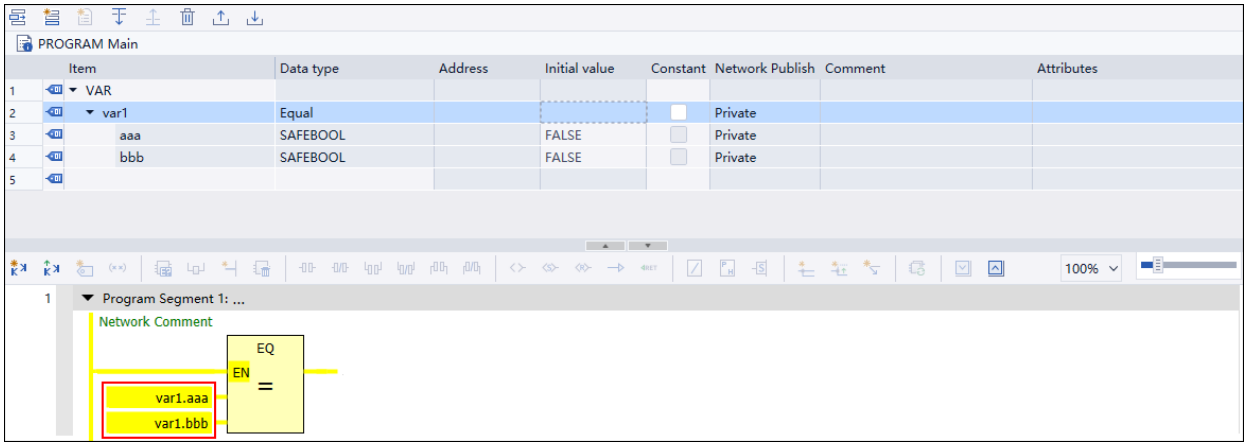
Data Type	Value Range	Memory Usage (Byte)	Input Example
SAFEBOOL	TRUE, FALSE	1	TRUE FALSE



Data Type	Value Range	Memory Usage (Byte)	Input Example
SAFEBYTE	0 to 255	1	BYTE#2#00001111
SAFEWORD	0 to 65535	2	WORD#61680 DWORD#2#0000_0000_1111_0000_1111_1111_0000_1111
SAFEDWORD	0 to 4294967295	4	
SAFEINT	-32768 to 32767	2	INT#2#00000000_01100100 INT#10#100 INT#16#64
SAFEDINT	-2147483648 to 2147483647	4	
SAFETIME	T#0d0h0m0s0ms to T#49d17h2m47s295ms	4	T#10d_20h_30m_20s_630ms T#61m5s T#3s20ms TIME#10d_20h_30m_20s_630ms TIME#6d_10m
SAFE_DATE_AND_TIME	DT#1970-01-01-00:00:00 to DT#2106-02-07-06:28:15	4	Start with DT# or dt#, and followed by a date and time in yyyy-mm-dd-hh:mm:ss format. dt#2007-07-01-05:40:25

11.2.1.1.3 User-Defined Types

In safety PLC programming, custom data types only support structures (STRUCT) with one level.



Structure definition

In the project tree, right-click "Programming" and select "Add user-defined type". Select "Struct" in the pop-up window. Click "OK" and the DUT editor is automatically opened. Create a structure named Equal in the DUT editor, as shown below.

Structure usage

After a structure is created, create a variable in the program with the type set to the newly created structure name, that is Equal. In the "PROGRAM Main" window, enter "VariableName." (the variable name followed by a dot). The system will automatically display a dropdown list of the structure's members. Select to perform read or write operations on the structure, as shown below.

11.2.1.1.4 Data Type Conversion

The safety PLC data type conversion is as follows:

- Safety data remains a safety type after data type conversion. Standard data remains a standard type after conversion.
- Safety type can be automatically converted to standard type, but standard type cannot be converted to safety type.
- Conversion of specified data types is supported. The iFA software provides explicit conversion instructions for users. For details, see 11.10.1.6 Conversion Operators.

> NOTE
>
> Signal from a safety type variable can be input into a standard type variable, but signal from a standard type variable cannot be input into a safety type variable.

11.2.1.2 Variable Declaration

This section only covers the functional differences between variable declarations in safety PLCs and standard PLCs; for other general functions, see 10.1.1.9 Variable Declaration in the "PLC Programming" chapter.

11.2.1.2.1 Variable Declaration Properties

A variable has eight properties: ID (name), data type, address, initial value, constant, network public property, comment, and property.

- ID
  ID is the variable's name. When naming variables, keep the following in mind:
  - It cannot include spaces or special characters.
  - It cannot be a predefined keyword.
  - Names are case-insensitive.
  - The maximum length is 128 characters.
  - Names cannot be defined repeatedly.

- Data type

  Refer to 11.2.1.1 Data Type for the data types supported by the safety PLC.

- Address

  Address is displayed only and not editable; it is automatically generated by the software.

- Initial Value

  The initial value of a variable varies depending on its data type and can be customized during variable declaration.

- Constant

  A constant is a value that does not change.

- Network public property

  The network public property can be used to display the network public status of a variable.

  - When the "Private" option is selected, the variable does not support access by third-party equipment or software.
  - When the "Read/Write", "Read-Only", or "Write-Only" option is selected, the variable supports access by third-party equipment or software.
    - Read/Write: The data of the variable can be modified or viewed.
    - WriteOnly: The data of the variable can only be modified, but cannot be viewed or read.
    - ReadOnly: The data of the variable can only be viewed or accessed, but cannot be modified.

    Network public property restrictions:
  - The number of public read-only variables is limited to 512, so is the number of public write-only variables.
  - The above public variables include both safety variables and standard variables.
  - For the above read-only and write-only variables with public property "Read/Write", each type occupies one count.

- Comment

  Used to add annotations to variables, making them easier to understand.

- Properties

  Properties are used for differentiated handling of individual variables. For example, when a user needs to permanently display a certain variable in decimal format, this can be achieved by setting the variable's attribute 'displaymode' := 'dec'. The following are commonly used properties:

No.	Keyword	Value	Note
1	displaymode	'bin', 'dec', 'hex'	Specifies the base for displaying the online value of a variable, supporting binary, decimal, and hexadecimal formats.

No.	Keyword	Value	Note
2	visibility	none	Visibility check for variables/notations; if it includes "none," it is hidden.
3	qualified_only	/	When this marking is added to a global variable, it must be accessed using the global variable group name followed by a dot.

11.2.1.2.2 Variable Address Range

The following table shows the address ranges of PLC variables.

Storage Area	Address Range (Byte)
I area	0 to 8191
Q area	0 to 8191

11.2.1.2.3 Default Variable Table

When adding a safety PLC device to the project, a "Default variable table (Global)" node is automatically created under the device. Double-click this node to open the corresponding window.

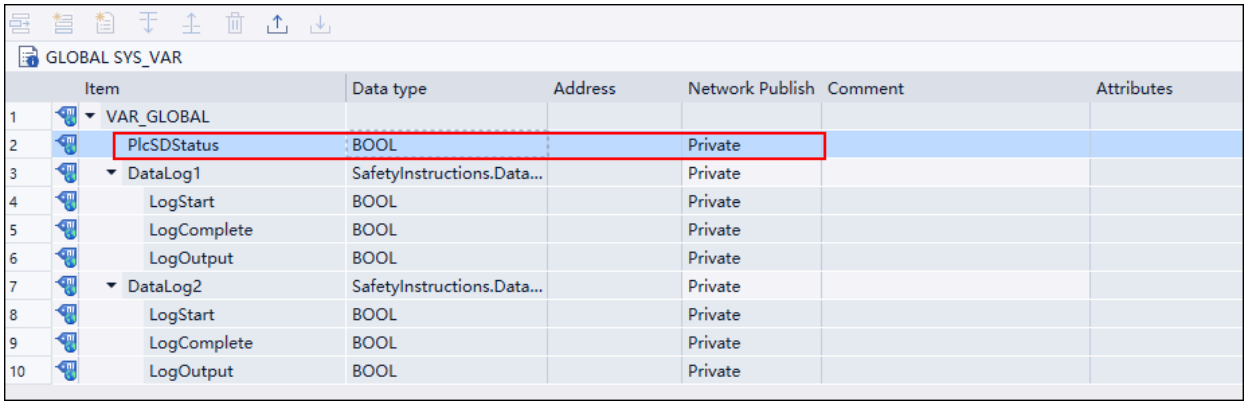
The default variable table does not support copying or deletion, and the node name cannot be modified.

The default variable table supports import and export operations. For details, see sections 10.1.1.10.6 Variable Input and 10.1.1.10.7 Variable Output.

When creating new variables in I/O mapping, they are automatically added to this table.

11.2.1.2.4 System Variable Table

When adding a safety PLC device to the project, a "SYS_VAR(Global)" node is automatically created under the device. Double-click this node to open the corresponding window.



The system variable table is the variable table created by default, which does not support copying or deletion, and the node name cannot be modified.

The system variable table supports export. For details, see section 10.1.1.10.7 Variable Export. Variable import is not supported.

System variables consist of two parts:

- SD card status variables

Variables related to the PLC hardware configuration of the SD card status. By default, the corresponding variable PlcSDStatus is created in the system variable table. Variable name and data type cannot be modified. Users can modify the network public property of variables according to requirements. For details, see 11.2.1.2.1 Variable Declaration Property.

- Data record status variables

Variables related to the PLC hardware data record. By default, corresponding variables are created in the system variable table, named PlcSDStatus, DataLog1, and DataLog2. Variable names and data types cannot be modified, and their network public properties only support private and read-only. Users can modify the network public property of variables according to requirements. For details, see 11.2.1.2.1 Variable Declaration Property. This requires that users has configured data record and enabled this feature. The current data record operation status can be obtained through the structure SafetyInstructions.DataLog, and variables LogStart, LogComplete, and LogOutput.

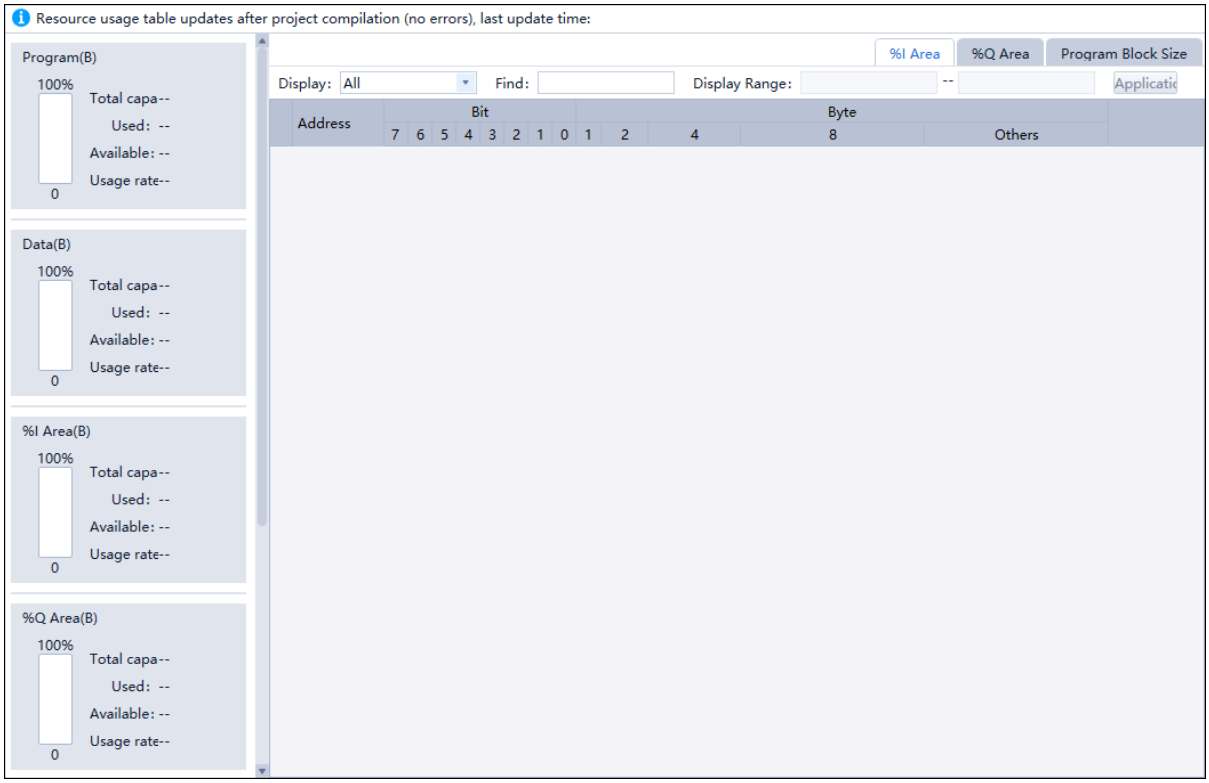


Table11-2-1-2-4-1 Descriptions of safety data record system variables

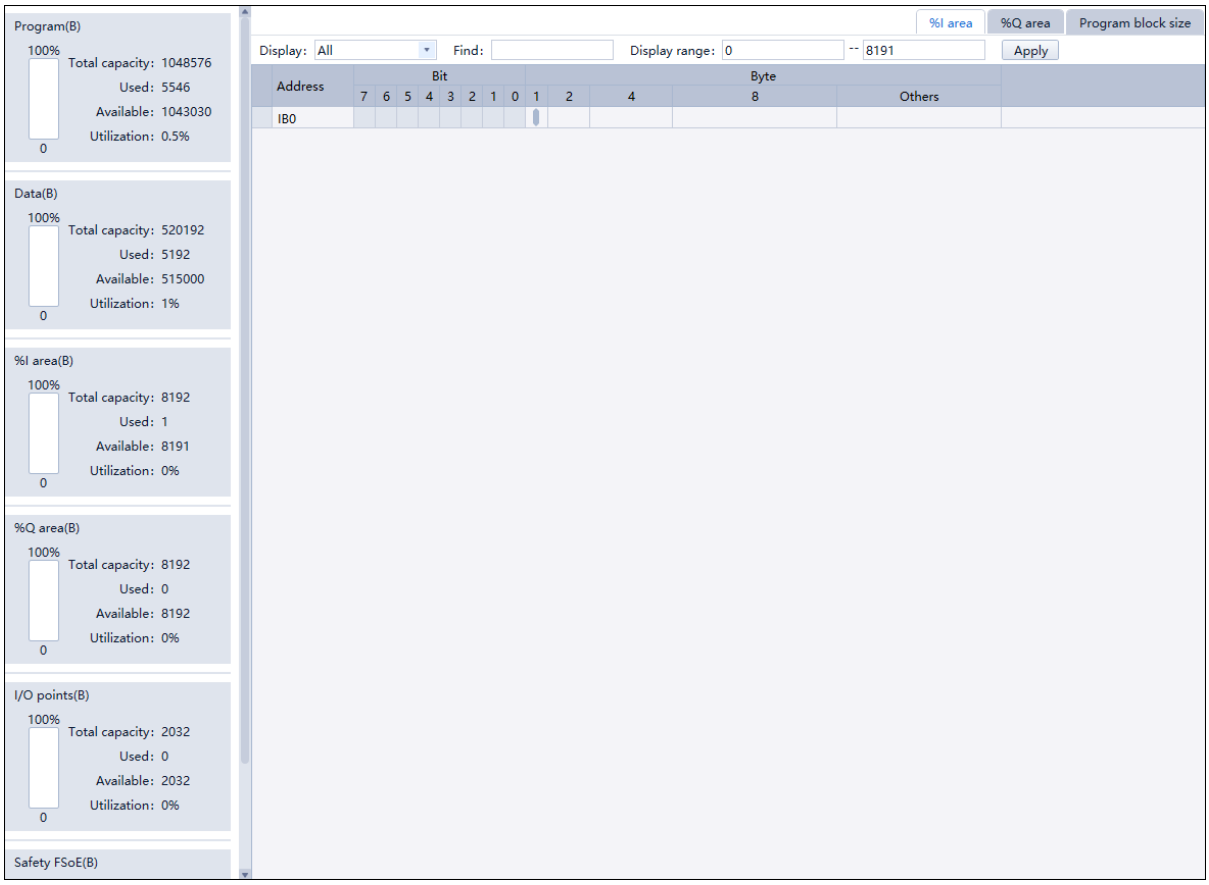
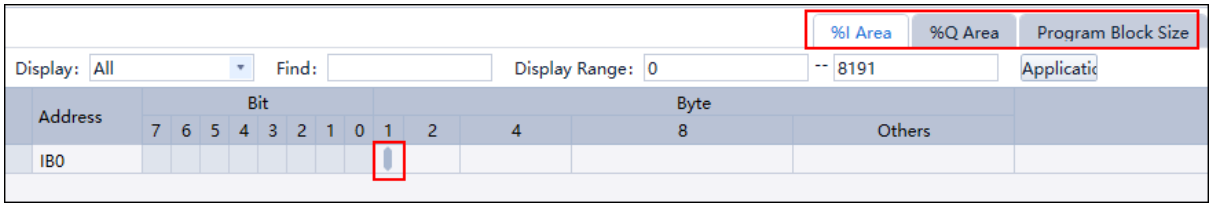
Variable Name	Data Type	Description
PlcSDStatus	BOOL	TRUE: SD card status of the communication unit is normal FALSE: SD card status of the communication unit is faulty
DataLog1.LogStart	BOOL	TRUE: Safety data record 1 is currently running FALSE: Safety data record 1 has stopped
DataLog1.LogComplete	BOOL	TRUE: Safety data record 1 has completed FALSE: Safety data record 1 has not completed
DataLog1.LogOutput	BOOL	TRUE: Safety data record 1 has completed writing to file FALSE: Safety data record 1 has not completed writing to file
DataLog2.LogStart	BOOL	TRUE: Safety data record 2 is currently running FALSE: Safety data record 2 has stopped
DataLog2.LogComplete	BOOL	TRUE: Safety data record 2 has completed FALSE: Safety data record 2 has not completed
DataLog2.LogOutput	BOOL	TRUE: Safety data record 2 has completed writing to file FALSE: Safety data record 2 has not completed writing to file



11.2.1.2.5 Resource Usage Table

The resource usage table is mainly used to display the status of the program, including the overall resource usage of the program, data, I area, Q area, I/O connections, and the safety CIP/FSoE, as well as specific displays of the I area, Q area, and program block size.

- Equipped with an EIP communication unit

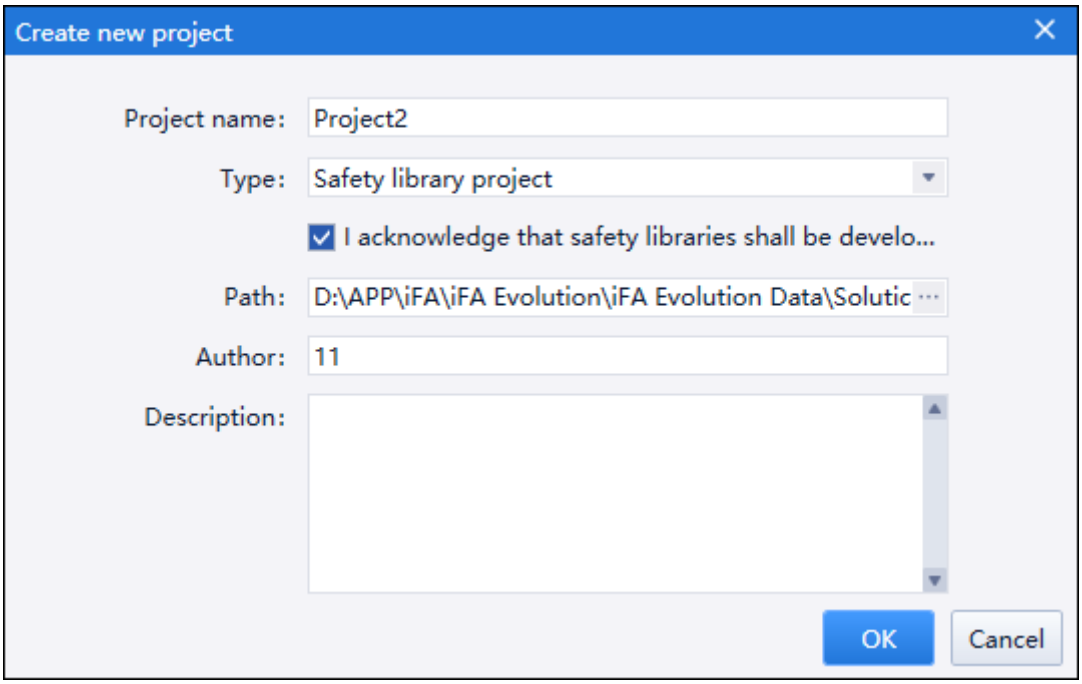


- Equipped with an ECT communication unit

1. The resource usage table is not generated in real-time but is updated after the project is compiled (without faults). The updated results after compilation need to be saved so that they can be viewed the next time the project is opened. Variables that have not been assigned absolute addresses will not be counted or displayed in the resource usage table. The resource usage table only shows the usage of defined variables in the program. Undefined and unused variables are not displayed in the address conflict table on the right side, but only in the statistical information on the left side. Variables declared with address information AT are also included in the display and statistics.

2. The left side displays the overall resource usage using six cards, including program, data, I area, Q area, I/O connections, and safety CIP. The "Display" filter in the tabs of the I area, and Q area can be divided into four categories:
   - All: Lists all defined (configured, used, or coupled) variables.
   - Used: Lists all used variables and addresses (including direct addresses).
   - Idle: Lists all defined but unused variables.
   - Conflict: Lists all variables detected to have address conflicts or overlaps.
3. The right side displays the resource usage status of the I area, Q area, and program block sizes.

4. Hover the mouse over a variable to view the variable name. Right-click a variable and select "Go to definition" to jump to the declaration location of this variable; select "Cross-reference table" to view the usage information of this variable.



11.2.1.3 Variable Operations

The variable operations in safety PLCs are the same as those in standard PLCs. For details, see 10.1.1.10 Variable Operationsin the "PLC Programming" chapter.

11.2.2 Library Reference

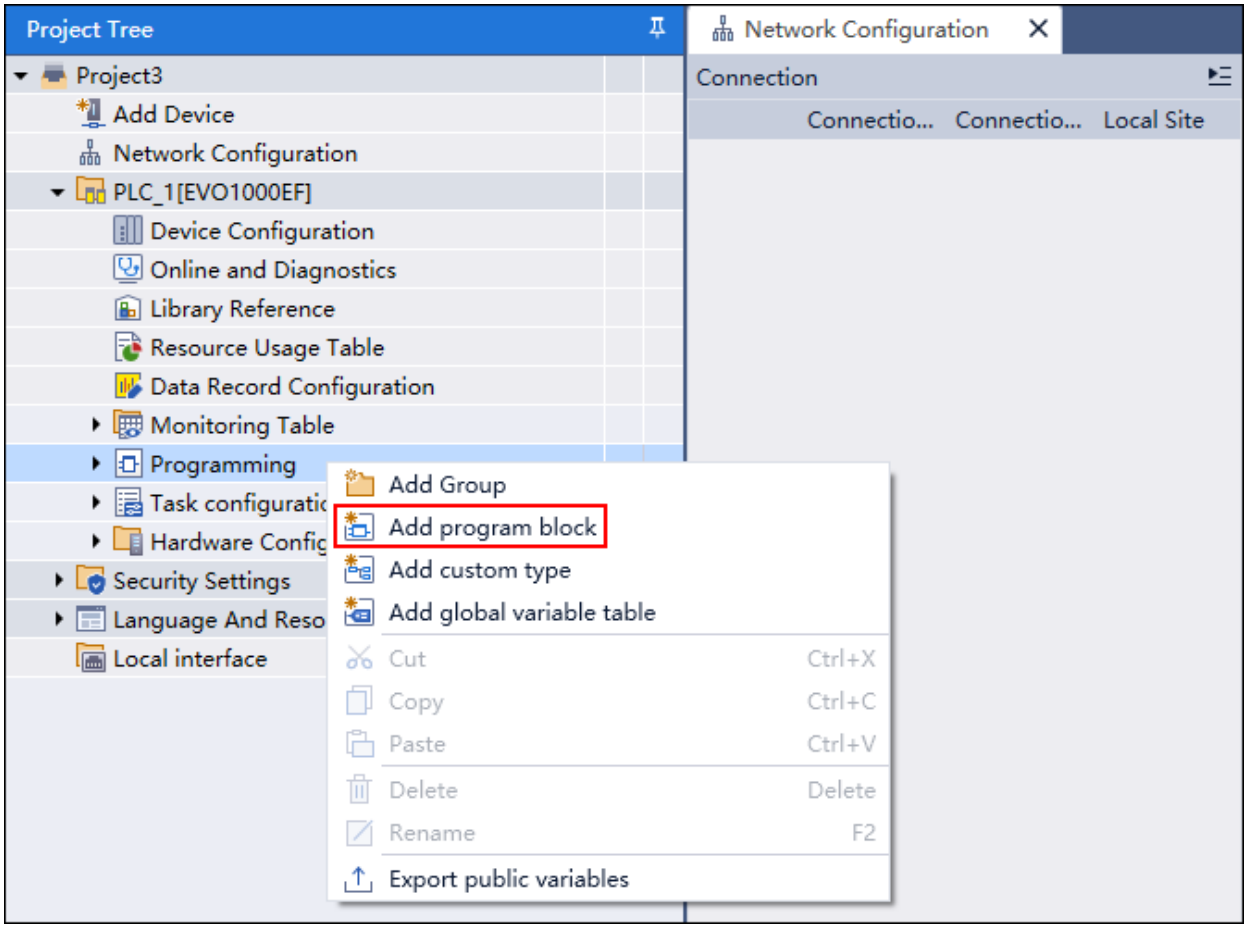
The library reference operations in safety PLCs are the same as those in standard PLCs. For details, see 12.3 Library Reference in the "PLC Programming" chapter.

The safety PLC supports the use of safety libraries. After selecting a safety library project, the user must check the risk acknowledgement alarm before clicking "OK".

11.2.3 Program Block

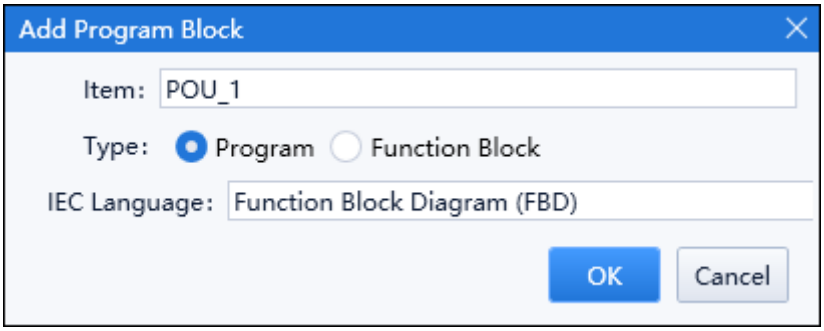
This section only covers the functional differences between the program blocks in safety PLCs and standard PLCs; for other general functions, see 10.1.2 Program Block in the "PLC Programming" chapter.

11.2.3.1 Program



11.2.3.1.1 Adding a User Program

Prerequisites



- A project has been created.
- A device has been added.

Procedure

1. Right-click "Programming > Add program block".

2. In the "Add program block" window, set the program name, select "Program" as the type, and select the corresponding IEC language, as shown in the figure below.

Property	Description
Name	Indicates the program name. It supports letters, numbers, and underscores (_), and must start with a letter or underscore. Underscores cannot be used consecutively or at the end. The program name is case-insensitive, with a maximum length of 128 bytes. For example, __POU, PO__U, and POU_ are invalid names, while P_O_U is considered valid.
Type	Indicates the program block type. To add a user program, select "Program" here.
IEC Language	Supports LD and FBD programming languages.

3. Click "OK" to add the user program POU. The user program has a "(PRG)" suffix. When a user program is added, iFA will automatically open its editor. The editor is divided into the variable declaration area and the program editing area, which can be collapsed and expanded using and .

NOTE

When a POU is being compiled, the system will check the upper limit based on device requirements. For specific limitations, see the device specifications.

11.2.3.1.2 Calling a User Program

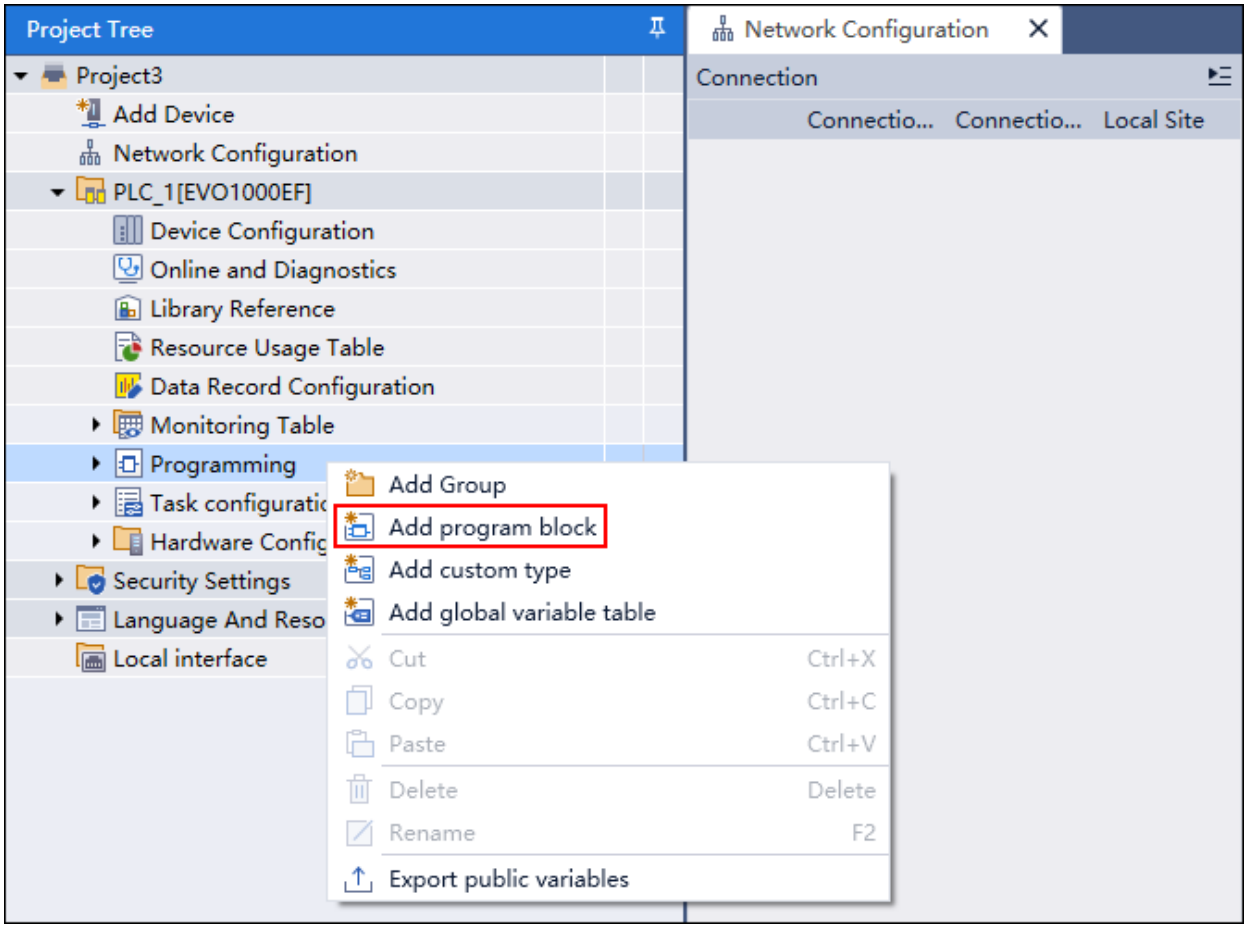
Before a user program is downloaded to the controller, it needs to be called first; otherwise, the program will not be executed.

User program calls are mainly managed in "Task configuration". For details, see 11.4.6 Task Configuration.

NOTE

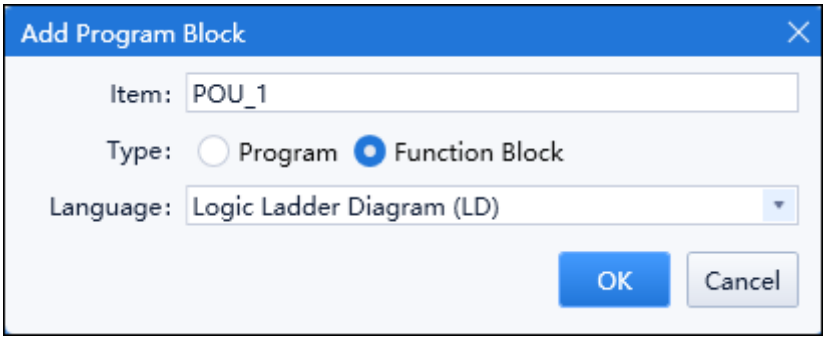
If a user program is added without being called, and the compiler detects that the program has not changed (using the incremental download mechanism), the program download will not be triggered.

11.2.3.2 Function Block



11.2.3.2.1 Adding a User Function Block

Prerequisites



- A project has been created.
- A device has been added.

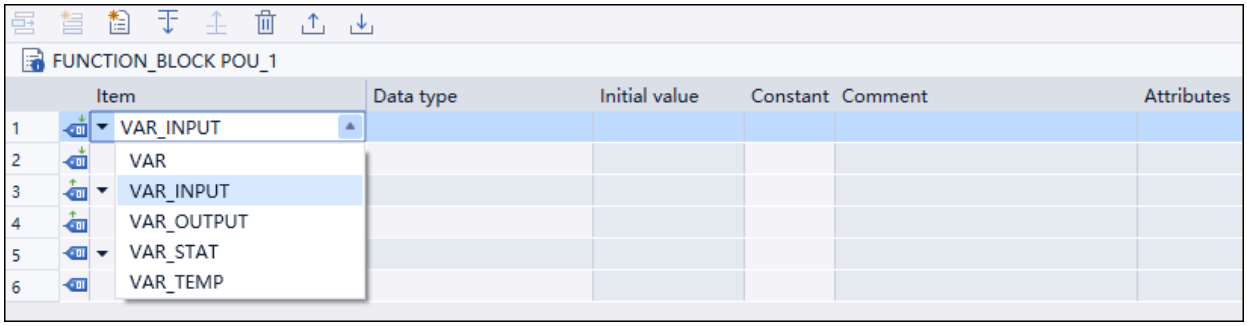
Procedure

1. Right-click "Programming > Add program block".

2. In the "Add program block" window, set the function block name, select "Function block" as the type, and select the corresponding IEC language, as shown in the figure below.

Property	Description
Name	Indicates the name of the function block. It supports letters, numbers, and underscores (_), and must start with a letter or underscore. Underscores cannot be used consecutively or at the end. The program name is case-insensitive, with a maximum length of 128 bytes. For example, __POU, PO__U, and POU_ are invalid names, while P_O_U is considered valid.
Type	Indicates the program block type. To add a user function, select "Function block" here.
IEC Language	Supports LD and FBD programming languages.

3. Click "OK" to add the user function block POU. The user function block has a "(FB)" suffix. When a user function block is added, iFA will automatically open its editor. The editor is divided into the variable declaration area and the program editing area, which can be collapsed and expanded using and .



NOTE

When a POU is being compiled, the system will check the upper limit based on device requirements. For specific limitations, see the device specifications.

11.2.3.2.2 Using a User Function Block

Variable declaration in function blocks

The variable types that can be declared in FB include local variables (VAR), input/output variables (VAR_IN_OUT), input variables (VAR_INPUT), output variables (VAR_OUTPUT), static variables (VAR_STAT), and temporary variables (VAR_TEMP). All properties of the variables are configurable.

Instantiation of function blocks

A function block is an abstract structure definition in the IEC61131-3 standard and must be instantiated to become an executable data entity. An uninstantiated function block cannot be called or executed by a program. An instantiated function block has the following characteristics:

- Possesses private data storage space.
- Executes specific functions according to predefined logic.
- Equipped with fully encapsulated and independent structural variables.

Through the instantiation process, the function block is transformed from a type definition into a specific data entity, thereby achieving its designed functionality.

The instantiation of a function block is like defining a variable. When the program needs to call this function block, it only needs to declare a variable of the FB type. The program reads and writes to the function block through this variable during execution.

A POU can only call the same FB instance once.

11.2.4 Safety LD Language Programming

11.2.4.1 Overview

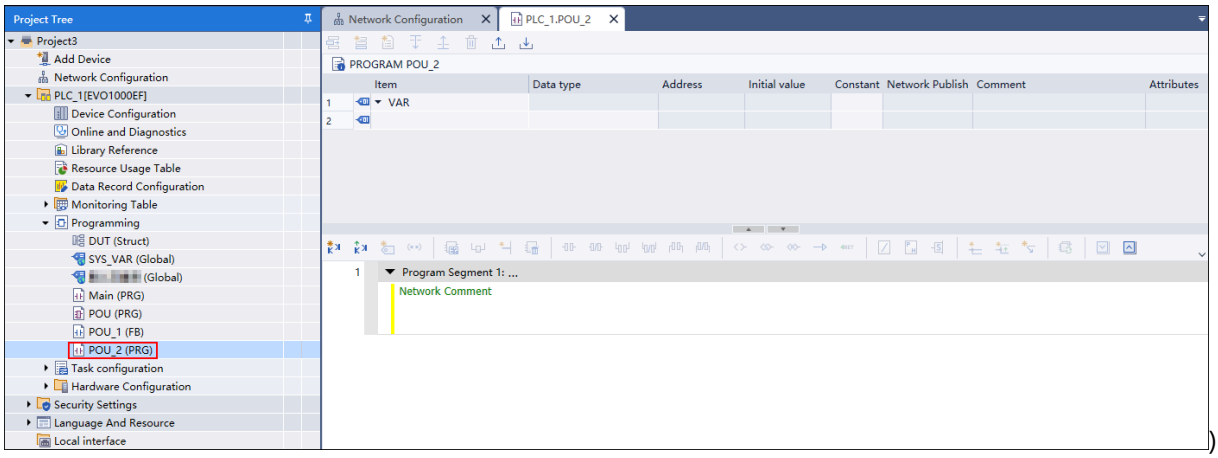
A ladder diagram is a graphical programming language.

It features two vertical power rails on its left and right sides. The left power rail provides a power flow that passes through various contacts, functions, function blocks, coils, and other components along horizontal rungs from left to right. The right power rail serves as the endpoint of the power flow.

Each contact represents the status of a Boolean variable, each coil represents the status of an actual device, and functions or function blocks correspond to the standard libraries in IEC 61131-3 or user-created functions or function blocks.

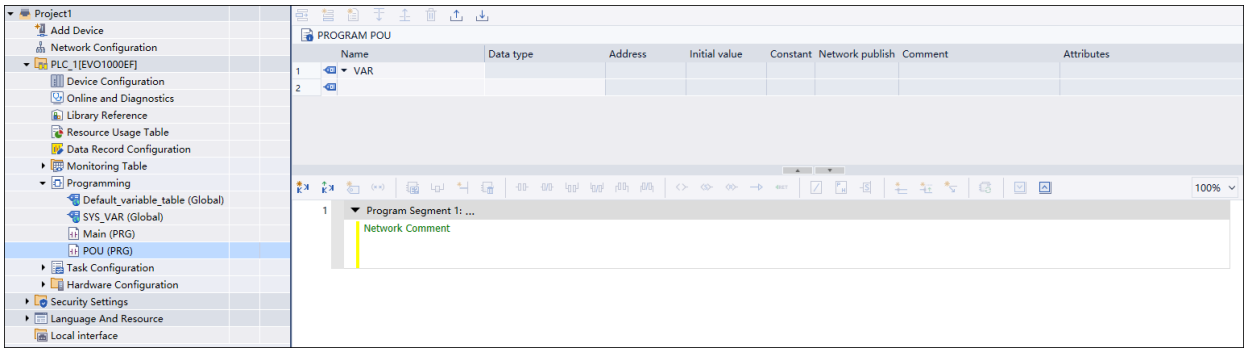
In ladder diagram programming, although relay components such as coils and contacts are used, they are not actual physical relays but rather storage units (soft relays) within the PLC. Each soft relay corresponds to a storage unit in the PLC's memory mapped register, and its status (TRUE/FALSE) determines the logical behavior of the soft relay:

- TRUE (ON) status: When the storage unit is in TRUE status, the corresponding soft relay coil is "energized", with its normally open contacts closed and its normally closed contacts opened.
- FALSE (OFF) status: When the storage unit is in FALSE status, the soft relay coil is "de-energized", with its normally open contacts remain opened, and its normally closed contacts remain closed.



Since these components exist only in the program, they are typically referred to as programming elements, not actual physical relays.

11.2.4.2 Opening the Safety LD Editor



Prerequisites

A safety LD program block has been added.

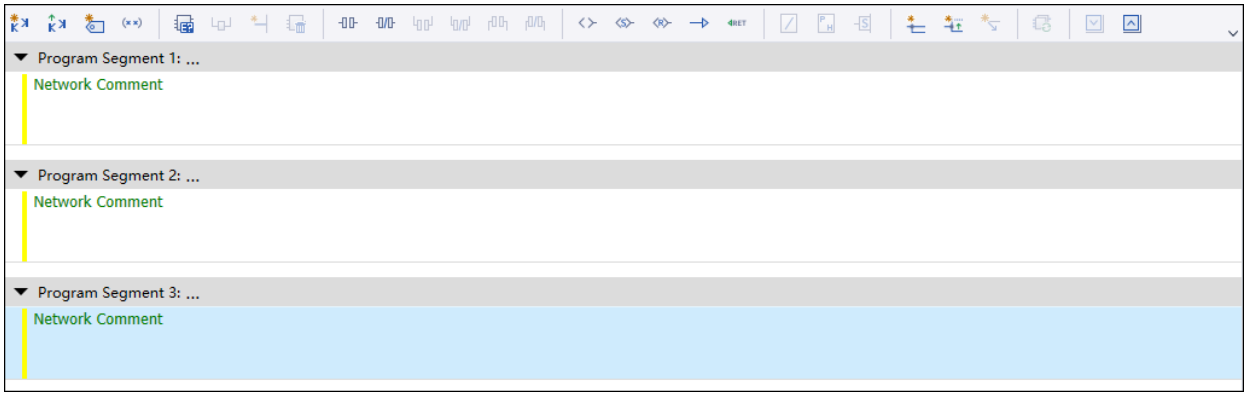
Procedure

- Double-click a safety LD language program block under the "Programming" node (node identifier: 

) to open the safety LD editor.
- Right-click a safety LD language program block under the "Programming" node and select "Open" to open the safety LD editor.

The safety LD editor is divided into the variable declaration area and the program editing area, which can be collapsed and expanded using and .

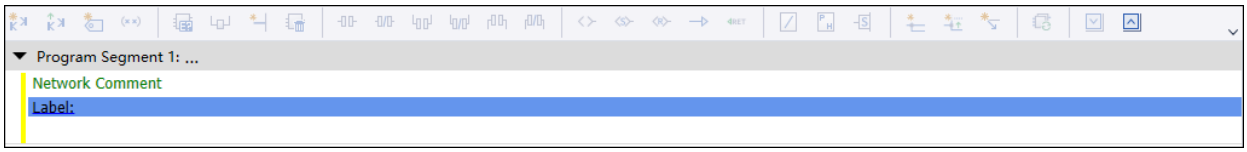
11.2.4.3 Setting the Safety LD Editor



The method and standard for setting the safety LD editor are the same as those for the standard PLC. For details, see 10.1.3.3.2 LD Editor Settings.

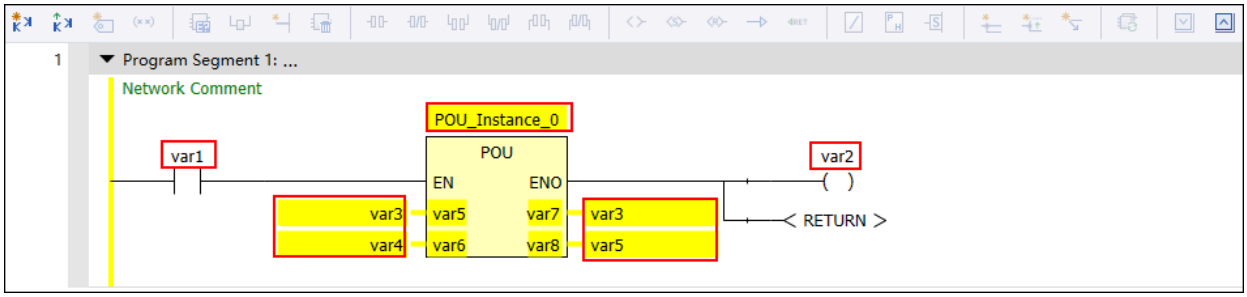
11.2.4.4 Safety LD Elements

Main elements



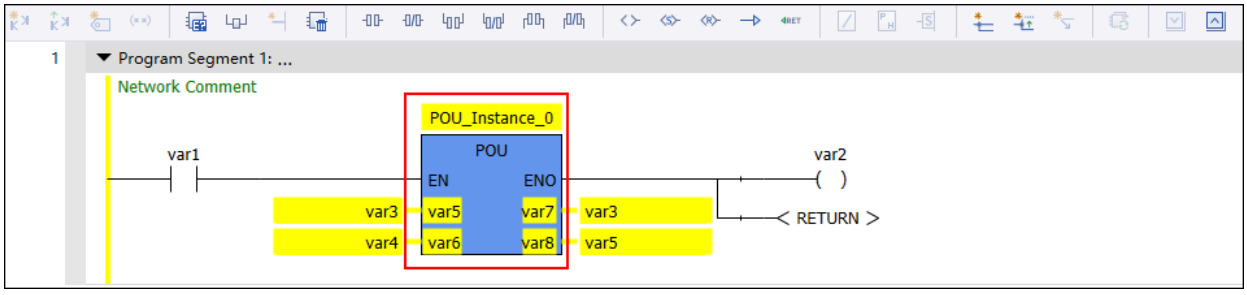
- **Network**

  Each network element contains a program, and the graphical configuration result of the entire network is also a program. Although the entire user program can be implemented within a single network, this is not recommended. To comply with programming standards and facilitate program inspection, it is recommended to split the user program into different networks by function, with each network implementing a specific function. This not only improves programming efficiency but also enhances system stability and scalability.



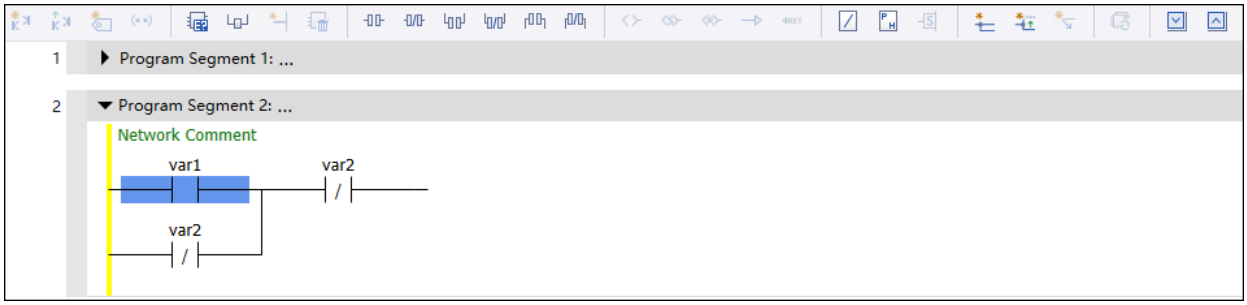
- **Label**

  Labels are used to indicate the specific location to which the program jumps.



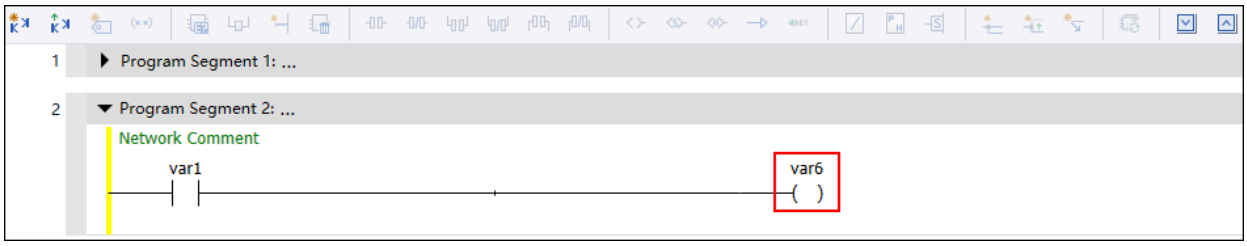
- **Operand**

  Operands are the editable text data, such as variable text corresponding to contacts, coils, block input and output pins, type text of the block, and instance text of the block. Users can change operands to target variables as needed.



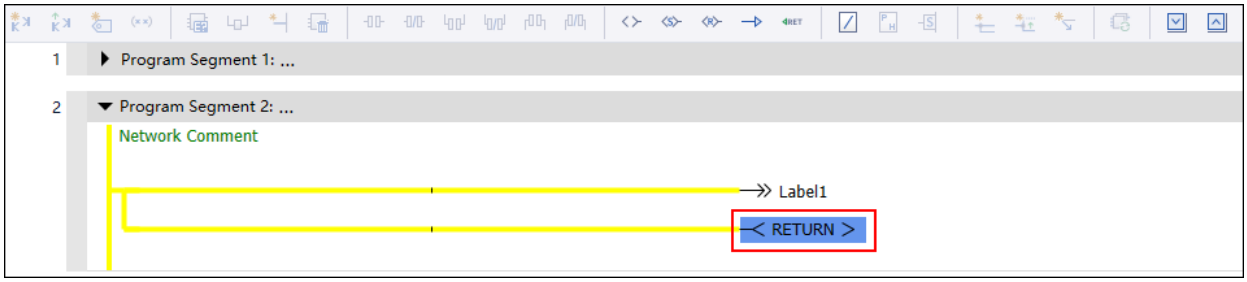
- **Block**

  A block is a packaging of functionality, used to simplify program complexity. It is recommended to encapsulate major functions into FBs and call them in the program. This not only reduces the reading difficulty of the main program but also improves the reusability of functions.



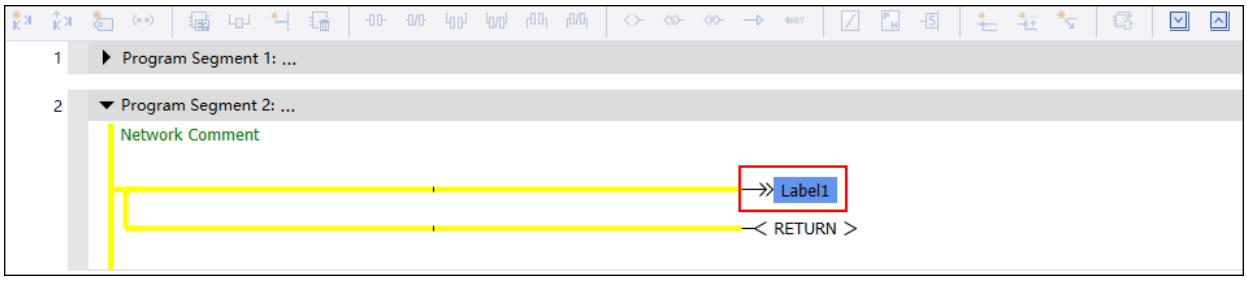
- **Contact**

  A contact is an element controlled by a BOOL or SAFEBOOL variable, determining whether the logic proceeds to the right. When the variable corresponding to the contact is TRUE, the program proceeds to the right; otherwise, execution is interrupted at the contact.



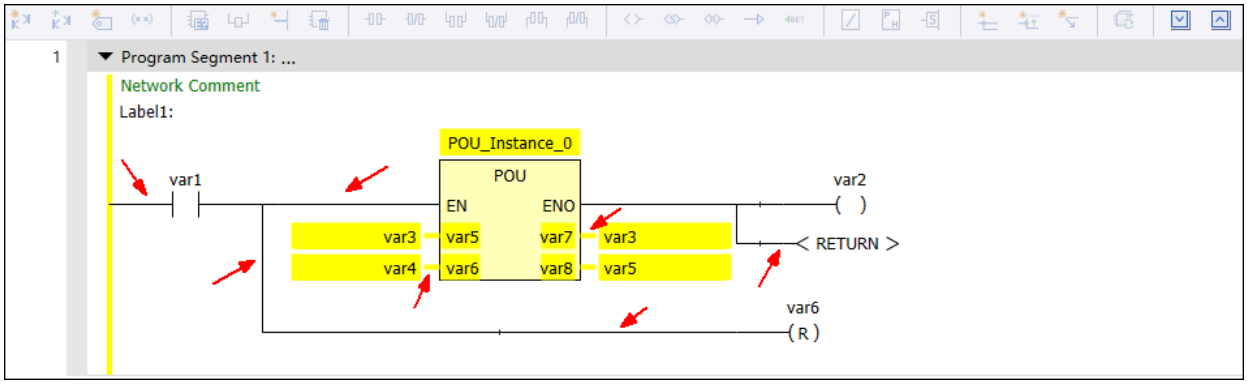
- **Coil**

  A coil is an element used to receive data from the previous configuration result. It assigns the configuration result from the left to the coil variable, achieving data transfer and assignment.



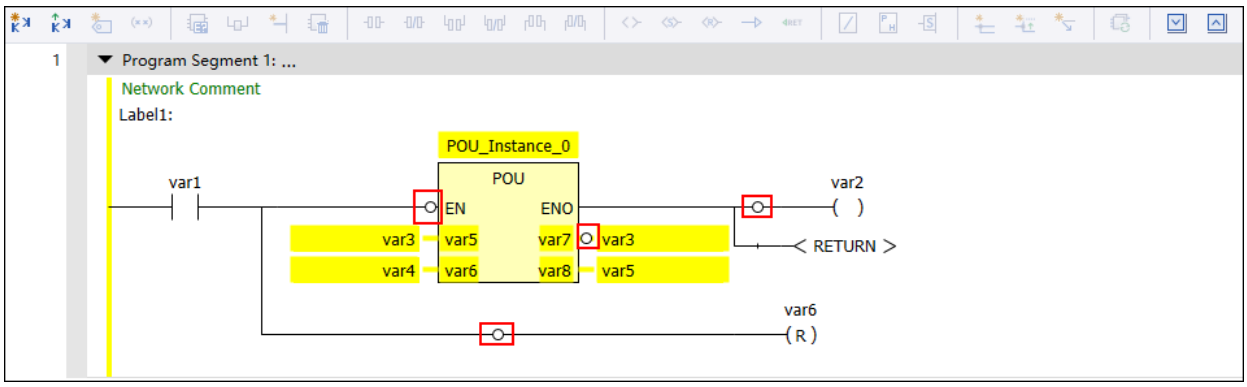
- **Return**

  The return element is used to terminate program execution. Once a return element is encountered, all subsequent program code will no longer be executed.



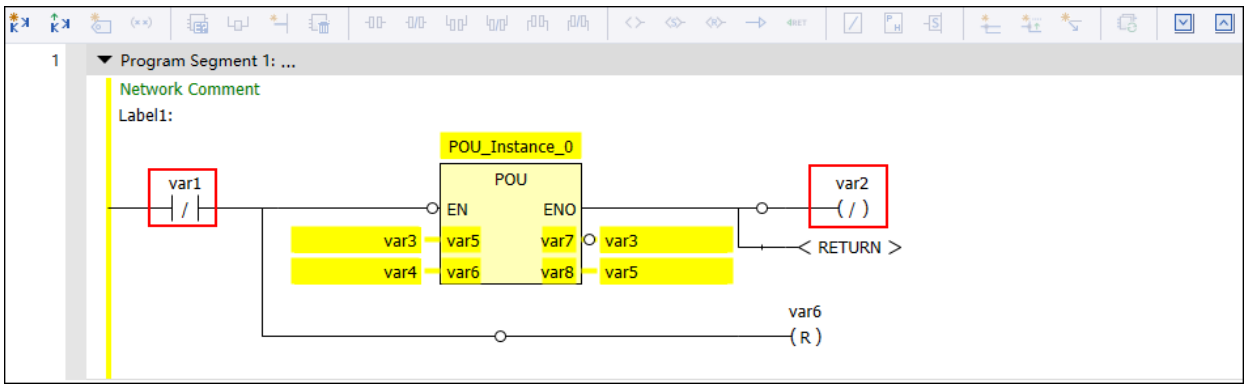
- **Jump**

  The jump element is used to transfer program execution from the current position to another specified location.



- **Connection**

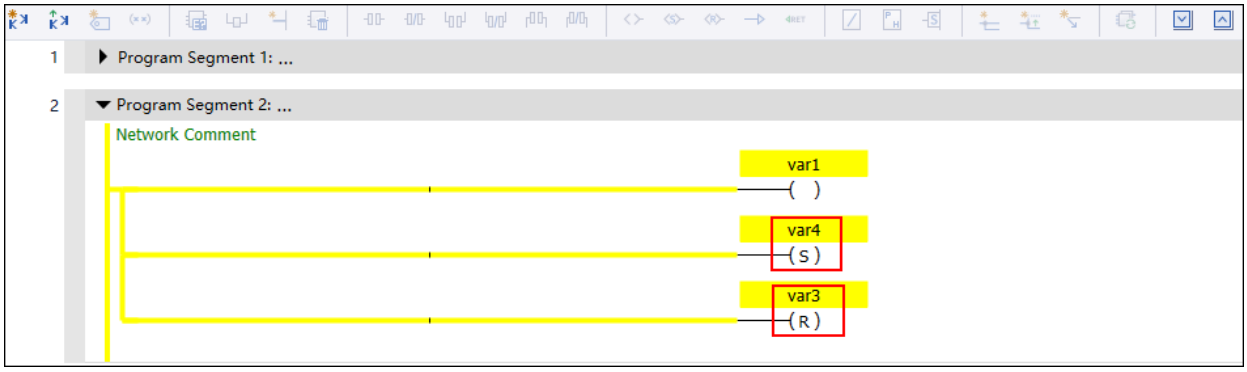
  A connection is a line that connects two positions. Connection lines mainly include contact connections, input/output connections of operation blocks, connections between coils, terminal connections, branch terminal connections, and vertical connections.



Auxiliary element

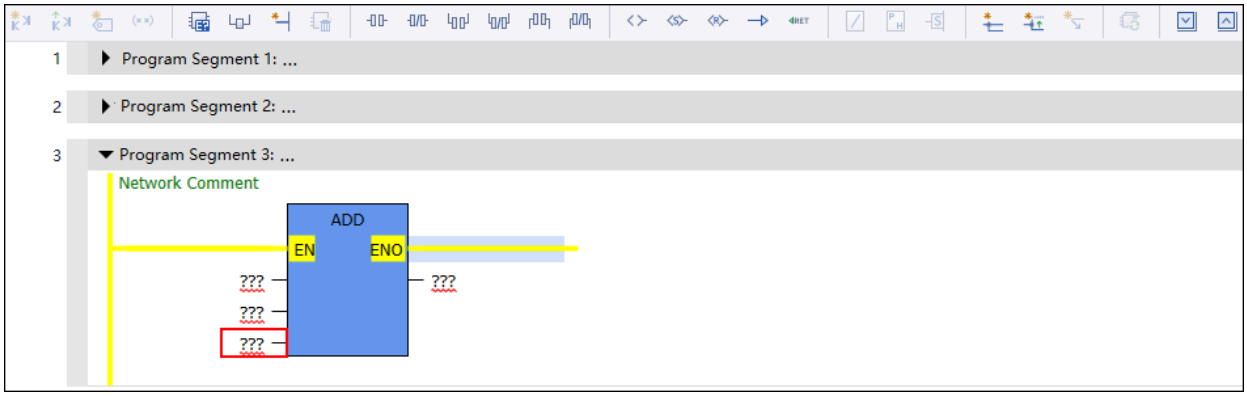
- **Inversion**
  - Supports inverting the block pin of BOOL or SAFEBOOL type.

  - Supports inverting contacts and coils.



- **Edge detection**

  Supports setting rising/falling edges for contacts.



- **Set/Reset**

  Supports set and reset operations for coils.

- **Input pin**

  For blocks supporting multiple inputs, input pins can be added.

11.2.4.5 Safety LD Programming

Safety LD allows users to add required elements to the network using commands from the toolbar. It also supports directly dragging user-defined program blocks from the toolbox and dropping them into the network to create corresponding block instances.

Adding elements by commands

Elements that can be added via commands include: network, label, block, input pin, contact, coil, return, jump, inversion, edge detection, set/reset, and branch.

- Commands in the toolbar

  Commands in the toolbar are fixed. Depending on the selected element, different commands are enabled. Only enabled commands support adding corresponding elements around the selected element, which cannot be achieved by disabled commands by default.

- Commands in the right-click menu

  Commands in the right-click menu vary depending on the selected element. Only the commands that are visible for the selected element can be used to add corresponding elements around it.

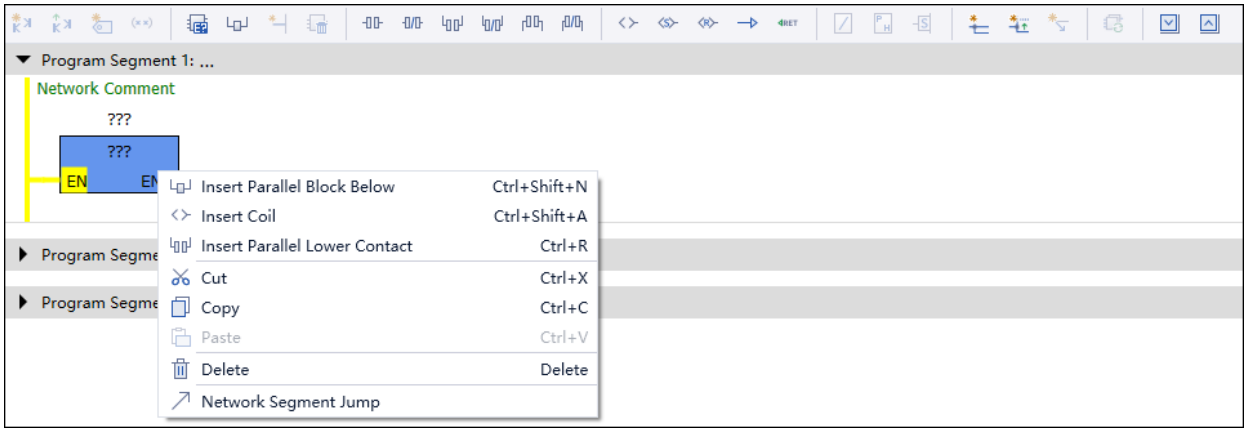


Table11-2-4-5-1 Icons and descriptions of commands

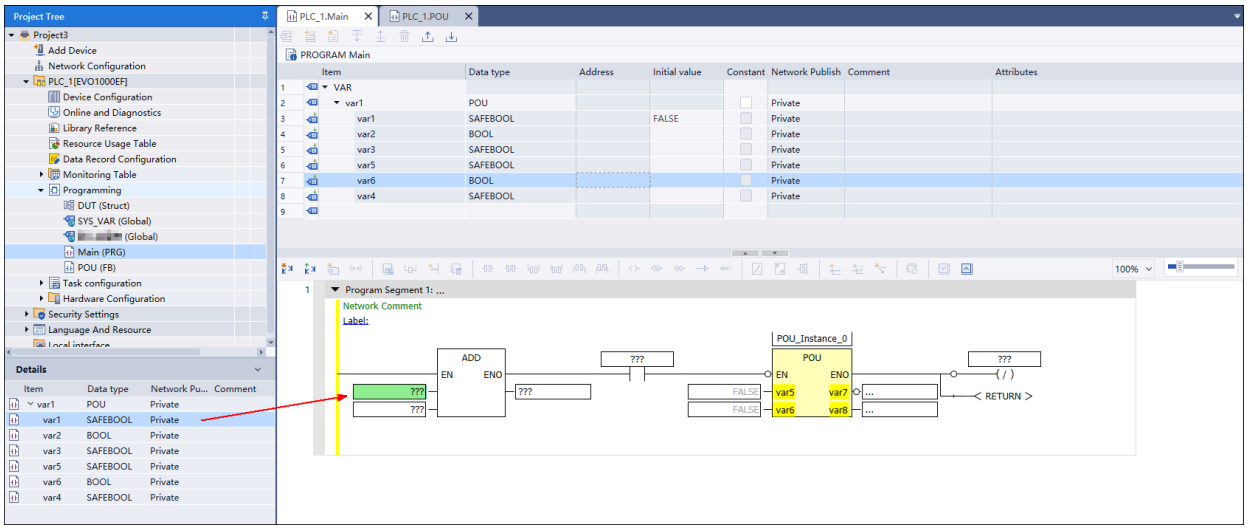
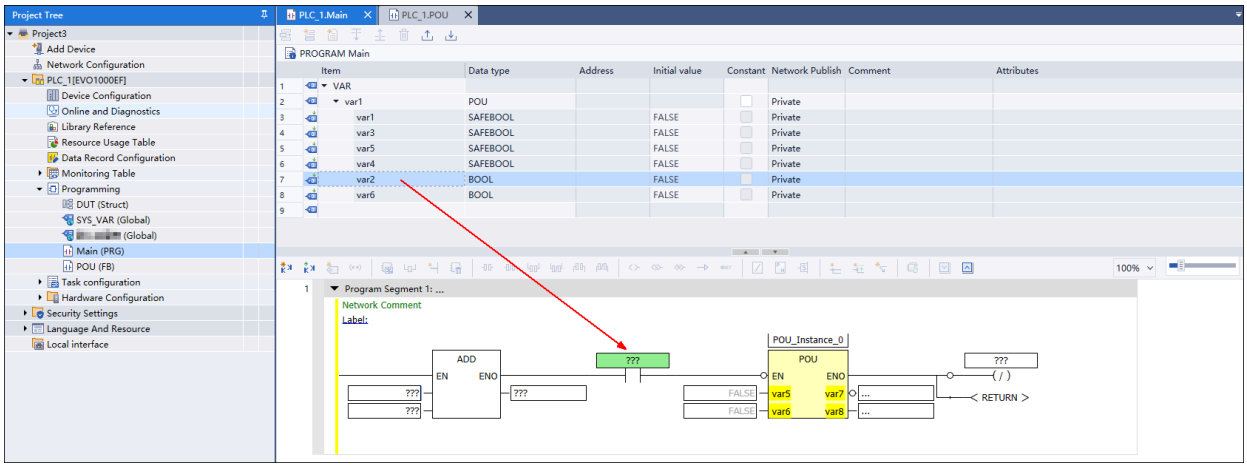
Type	Icon	Description
Add/Insert network		Adds/Inserts a network.
Insert label		Adds a label to network.
Toggle network comment		Comments or uncomments the selected network.
Insert EN/ENO empty block		-
Insert parallel block below		-
Add input		-
Remove unused pins		Deletes unconfigured pins for FB call blocks.
Insert an NO contact		Inserts a normally open, normally closed, or upper/lower normally open/closed contact.
Insert a coil		Inserts a coil, set coil, or reset coil.
Insert jump		-
Insert return		-
Inversion		Inverts a contact or a BOOL connection.
Edge detection		Sets edge detection for a contact.
Set/Reset		Performs set/reset operation for a coil.
Insert a branch		Inserts a branch above or below.
Set branch start point		-
Update all parameters		When parameters are changed at the FB declaration but not at the call site, this icon can update the block at the call site.



Type	Icon	Description
Expand all networks		-
Collapse all networks		-

Adding elements by dragging

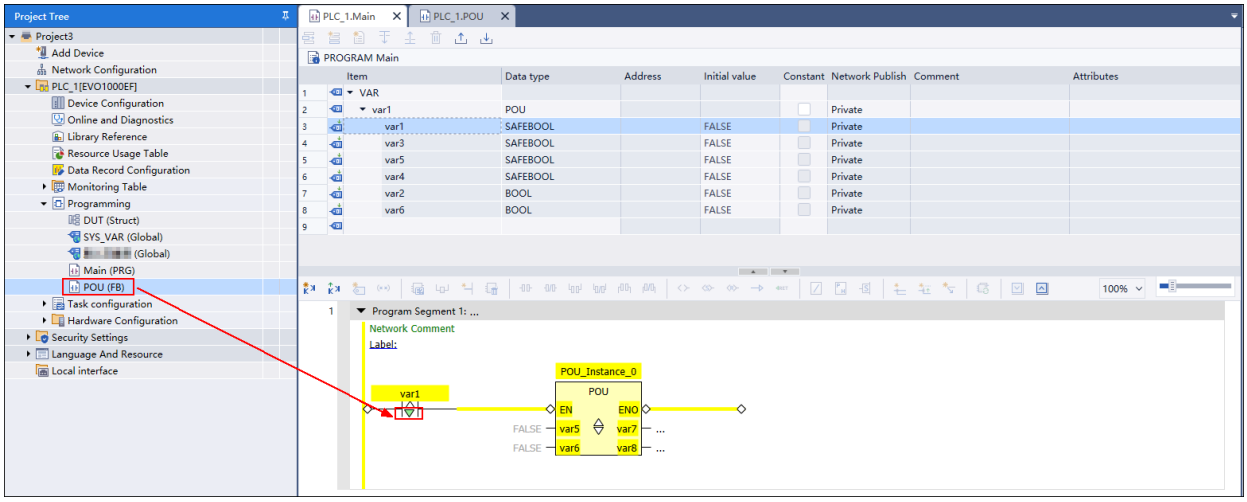


Instance variables from the "Details" window and the variable declaration area can be dragged to block input/output pins, contact, or coil variables for addition or modification. Blocks from the project tree or toolbox can be dragged to the editor for addition. Elements within the editor to another location in the editor. Currently, variables within the editor cannot be dragged.

- Dragging variables

  Drag instance variables from the "Details" window to the operand variable locations in the editor.

  Drag variables from the variable declaration area to the operand variable locations in the editor.



- Dragging elements from the toolbox

  When dragging an element from the toolbox to the editor, the available locations are highlighted with a diamond-shaped mark. Hover over these locations and they will be displayed in green. Release the mouse to add the selected element to the corresponding location.

- Dragging elements from the project tree

  When dragging an element from the project tree to the editor, the available locations are highlighted with a diamond-shaped mark. Hover over these locations and they will be displayed in green. Release the mouse to add the selected element to the corresponding location.

- Dragging elements in the editor

  When dragging an element in the editor to another network or another location within the same network, the available locations in the target network are highlighted with a diamond-shaped mark. Hover over these locations and they will be displayed in green. Release the mouse to move the selected element to the corresponding location.

  If you keep pressing Ctrl during dragging and dropping, the element at the source location will not be deleted and a new element will be added at the target location after. If Ctrl is not pressed during dragging and dropping, the element at the source location will be deleted.

11.2.4.6 Graphic Configuration Modification

11.2.4.6.1 Modifying Text Data

After adding a network, contact, coil, or block, the system provides corresponding text data for them:

- For networks: Includes network title and comment.
- For contacts and coils: Includes variable text.
- For blocks: Includes block type, block instance, and block input/output text.

Users can modify these text data as follows:

- For network titles and labels, double-click the title or label to modify the text.

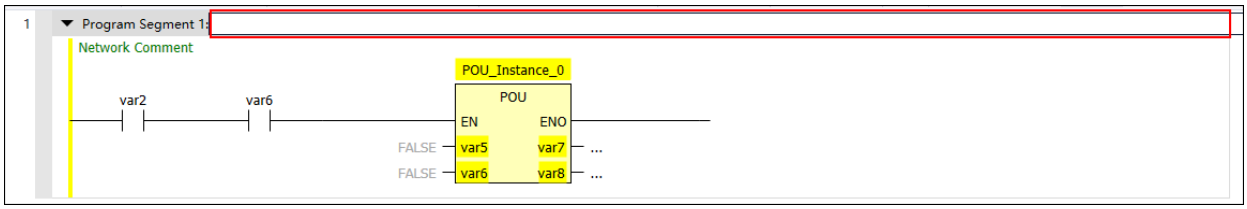


Figure 11-2-4-6-1-1 Modifying network title

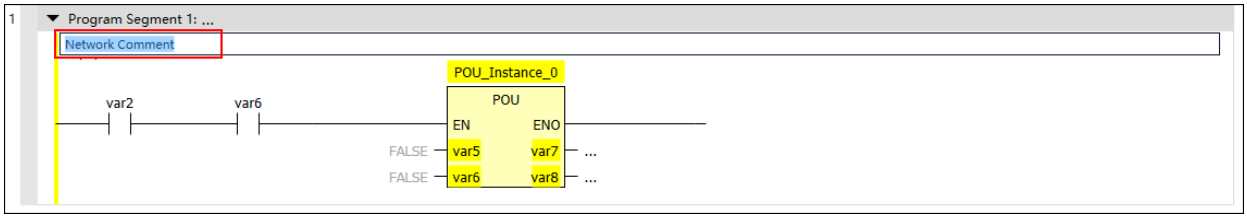

Figure 11-2-4-6-1-2 Modifying network label

- For text of contacts, coils, and blocks, drag a variable to the corresponding location or double-click the text for modification. After modification, the text will be successfully updated.

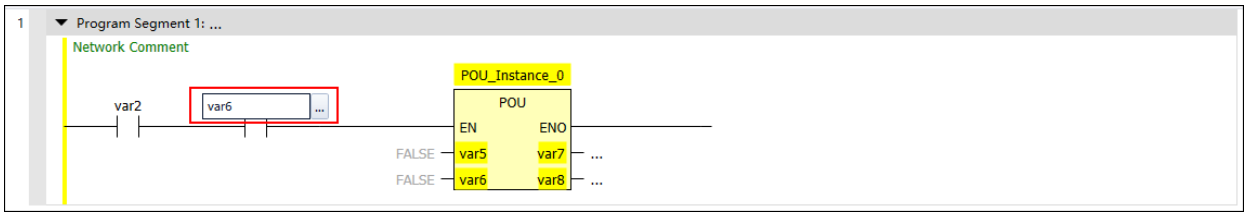

Figure 11-2-4-6-1-3 Modifying contact text

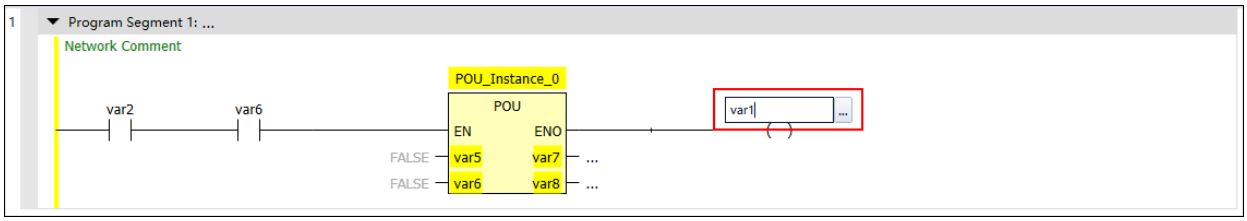

Figure 11-2-4-6-1-4 Modifying coil text

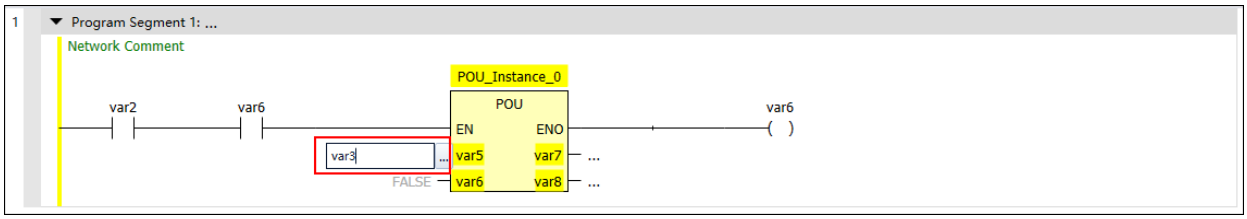

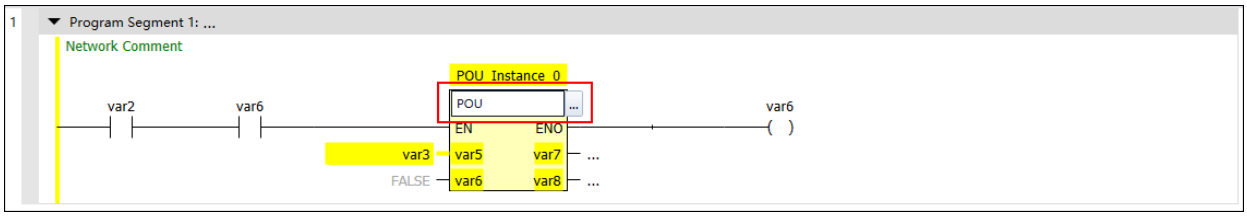

Figure 11-2-4-6-1-5 Modifying block text

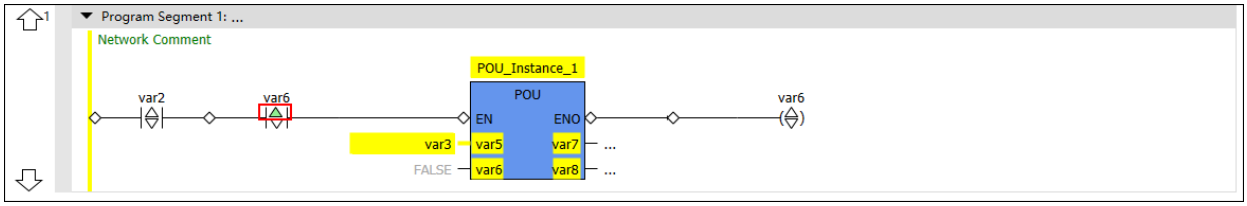


11.2.4.6.2 Modifying Block Type

Double-click a block type to modify its type.

11.2.4.6.3 Moving an Element

To move an element in the editor, you can delete it and then add it to the target position, or directly drag it to the target position. As shown in the figure, a block POU can be dragged to another location.

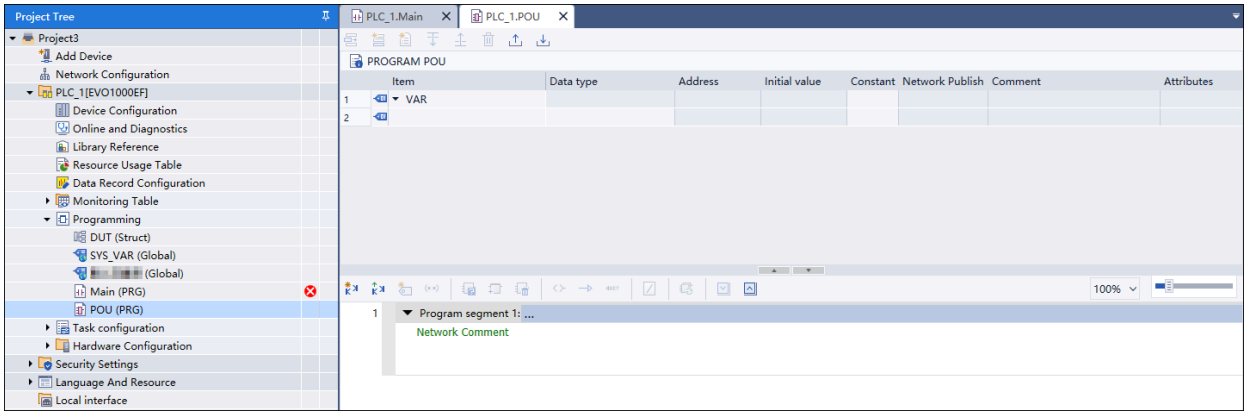
11.2.5 Safety FBD Language Programming

11.2.5.1 Overview

Function Block Diagram (FBD) is a widely used and intuitive graphical programming language. It uses graphical symbols (such as boxes and lines) to represent program logics, similar to electronic circuit diagrams.

The basic building blocks of a program are function blocks. Each function block represents a predefined operation or function, such as logical operations (AND, OR, NOT), mathematical operations (ADD, SUB, MUL, DIV), timers (TON, TOF), counters (CTU, CTD), comparators (GT, LT, EQ), and user-defined complex functions.

Function blocks have input terminals (usually on the left) and output terminals (usually on the right). The logic of program execution is represented by connection lines, which connect the output of one function block to the input of another, clearly illustrating the direction of data flow (from left to right or from top to bottom). The execution order of the program is primarily determined by data flow.

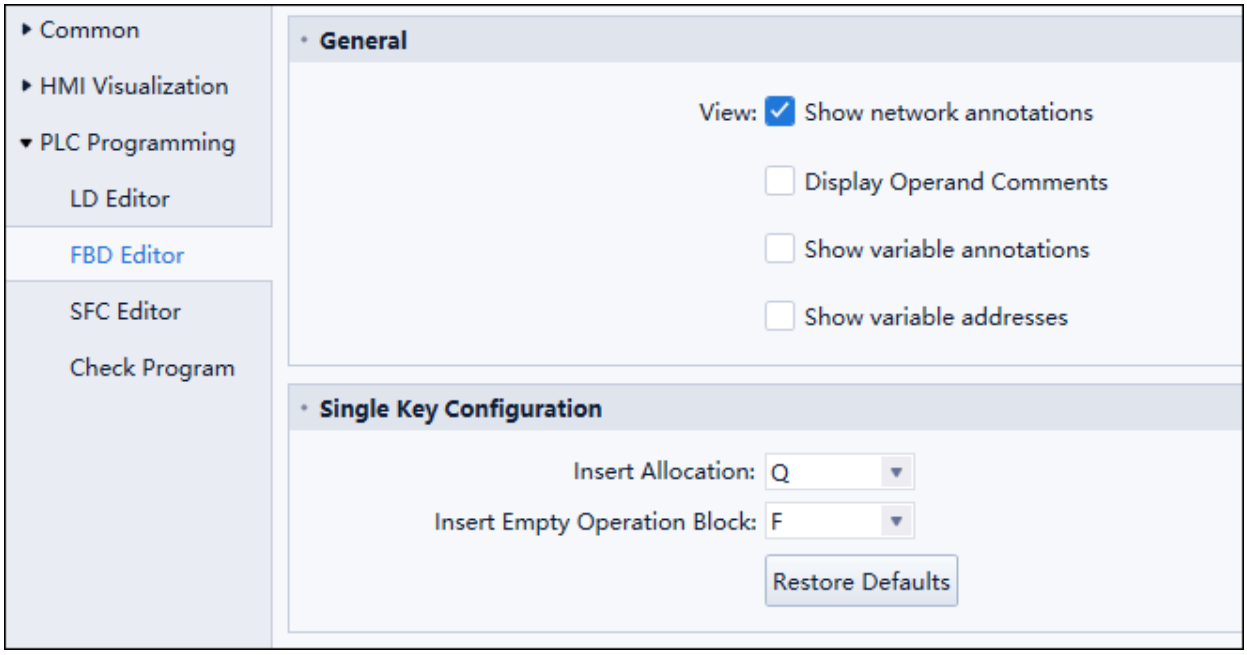


11.2.5.2 Opening the Safety FBD Editor

Prerequisites

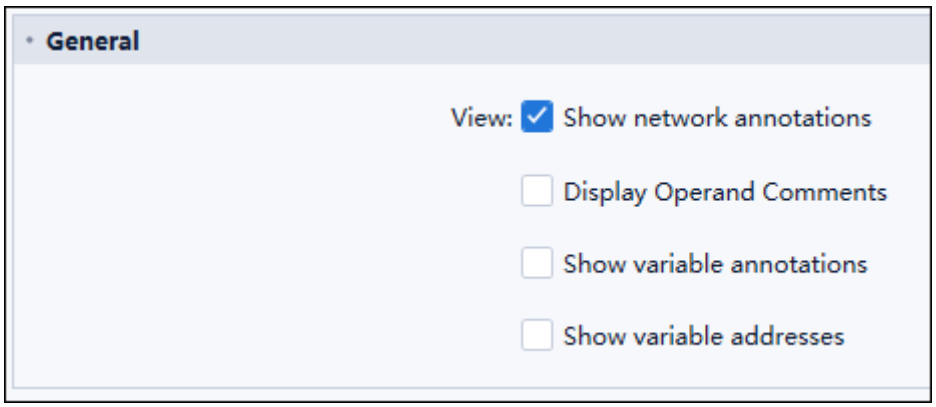
The safety FBD program block has been added.

Procedure



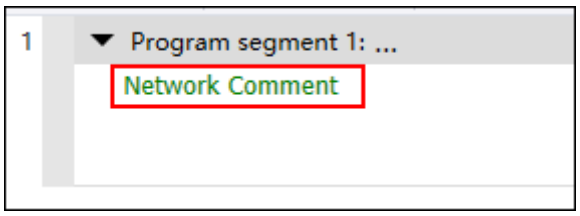
- Double-click a safety FBD language program block under the "Programming" node (node identifier: ) to open the safety FBD editor.
- Right-click a safety FBD language program block under the "Programming" node and select "Open" to open the safety FBD editor.

The safety FBD editor is divided into the variable declaration area and the program editing area, which can be collapsed and expanded using and .



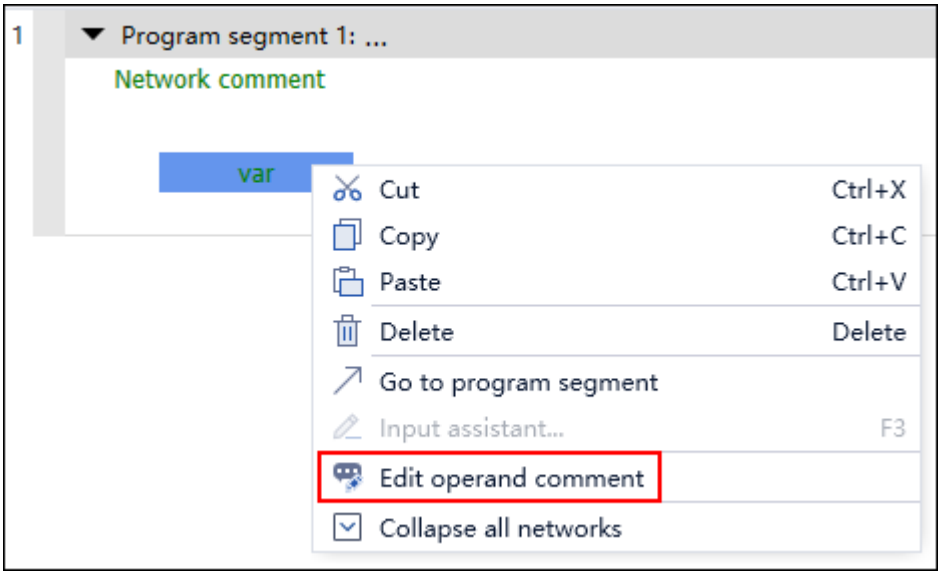
11.2.5.3 Setting the Safety FBD Editor

In the software menu, select "Tools > Options > FBD editor".

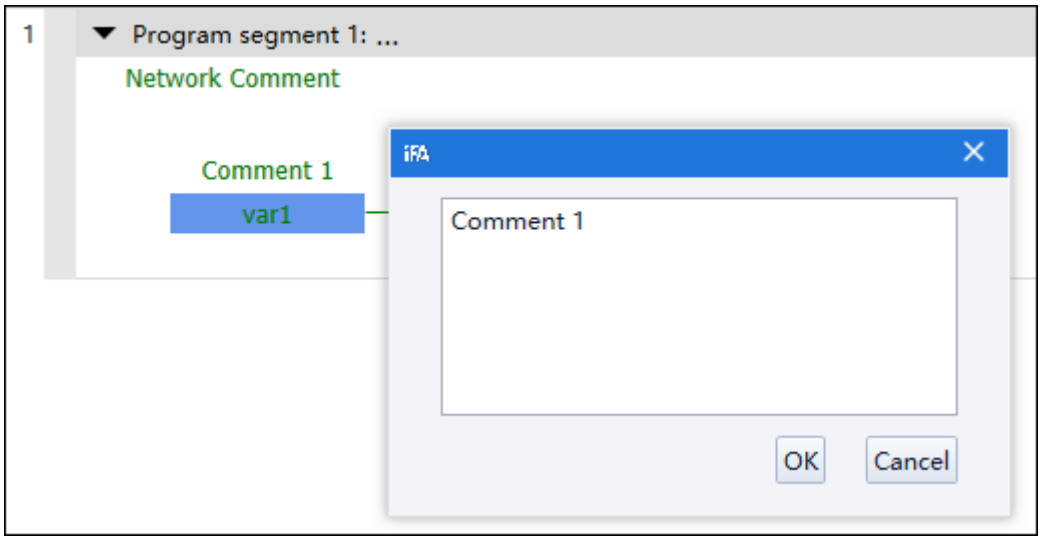


General

Sets the view range of the information in the FBD editor.

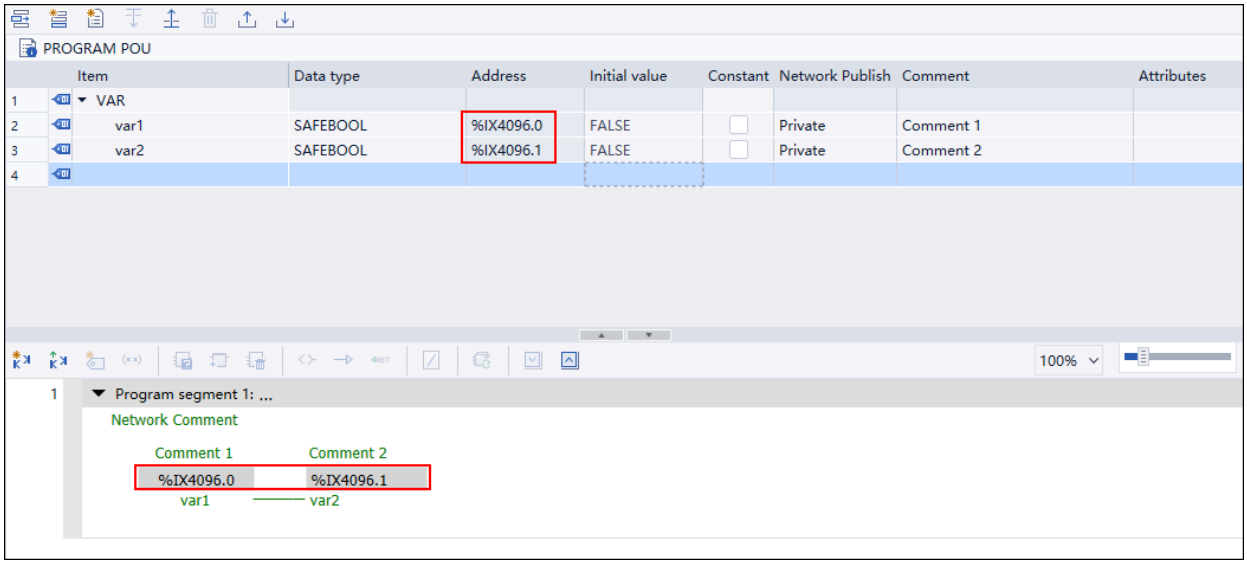


- Show network annotations: Sets the visibility of network annotations.



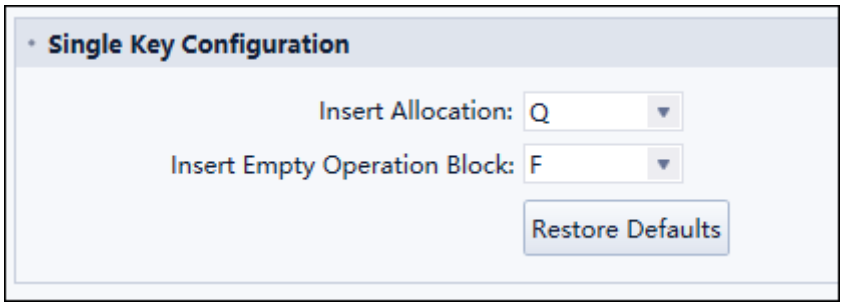
- Show operand annotations: Sets the visibility of operand annotations.

  1. After checking "Display operand comment", right-click an operand in the editor and select "Edit operand comment".



2. The entered annotation will be displayed above the operand. If "Display operand comment" is unchecked, the annotation will not be displayed.

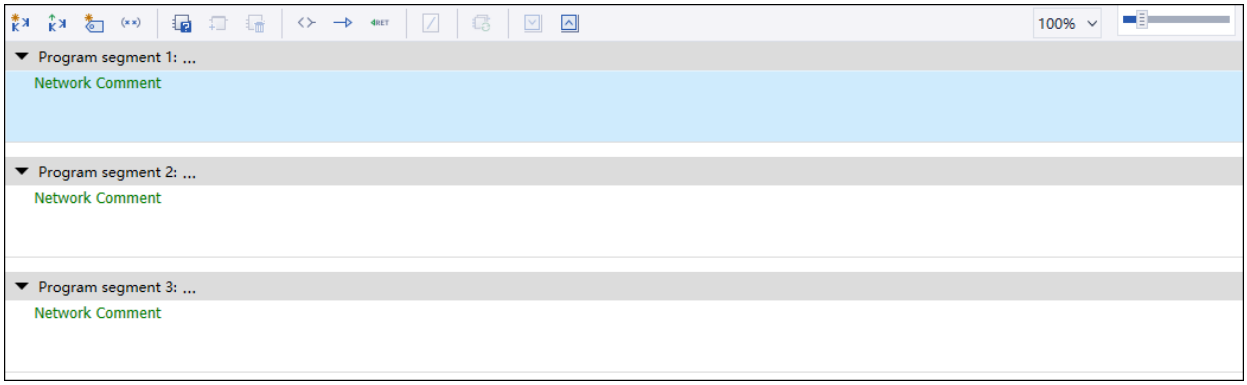
- Show variable annotations: Sets the visibility of variable annotations.



- Show variable addresses: Sets the visibility of variable addresses.

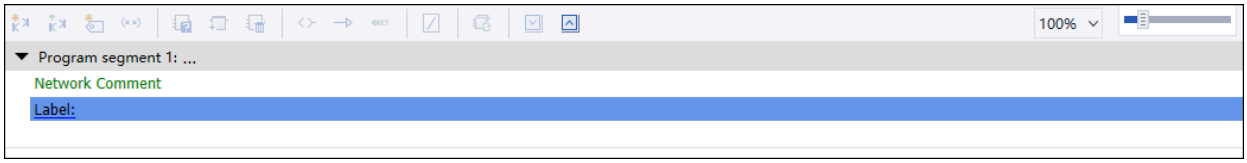
Single key configuration

The items in the "Single key configuration" section sets commonly used shortcut keys for FBD program editing, selected from drop-down lists. Click "Restore defaults" to reset all shortcut keys to their default values.



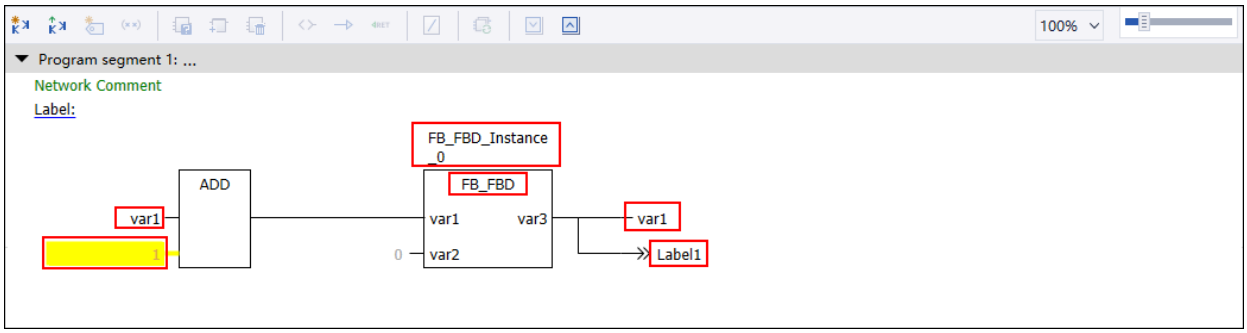
11.2.5.4 Safety FBD Elements

Main elements



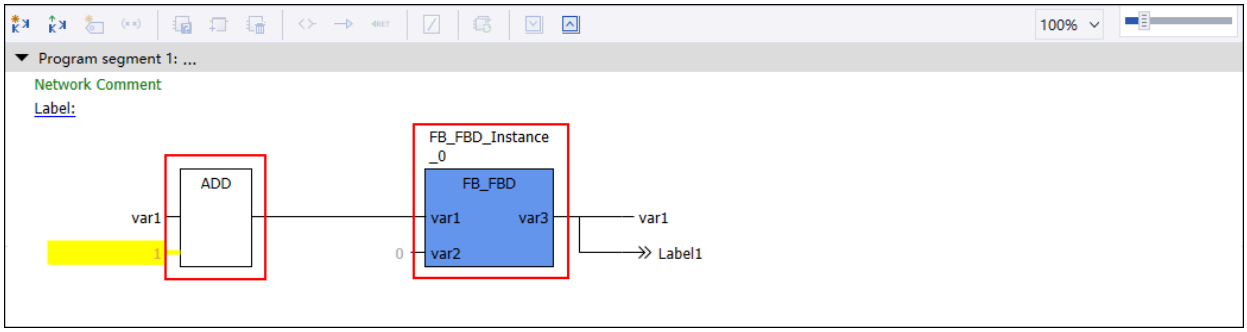
- **Network**

  Each network element contains a program, and the graphical configuration result of the entire network is also a program. Although the entire user program can be implemented within a single network, this is not recommended. To comply with programming standards and facilitate program inspection, it is recommended to split the user program into different networks by function, with each network implementing a specific function. This not only improves programming efficiency but also enhances system stability and scalability.



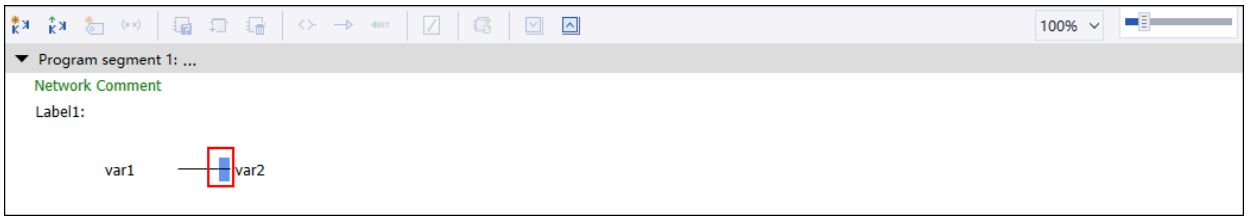
- **Label**

Labels are used to indicate the specific location to which the program jumps.



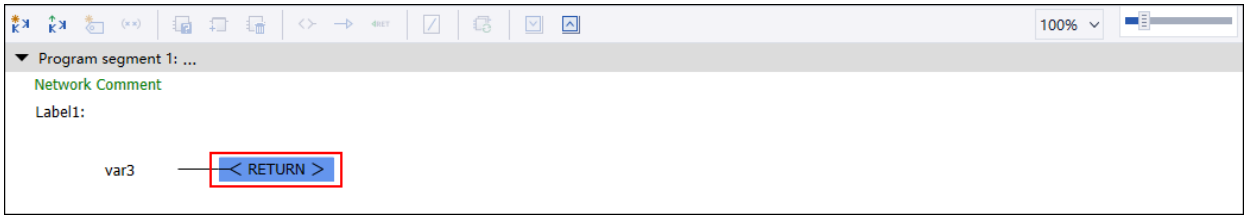
- **Operands**

  Operands are the editable text data, such as variable text corresponding to block input and output pins, type text of the block, and instance text of the block. These texts are all editable, allowing users to change them to target variables as needed.



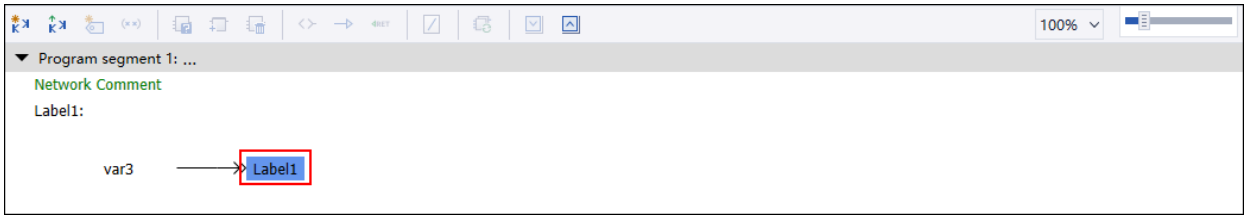
- **Block**

  A block is a packaging of functionality, used to simplify program complexity. It is recommended to encapsulate major functions into FBs and call them in the program. This not only reduces the reading difficulty of the main program but also improves the reusability of functions.



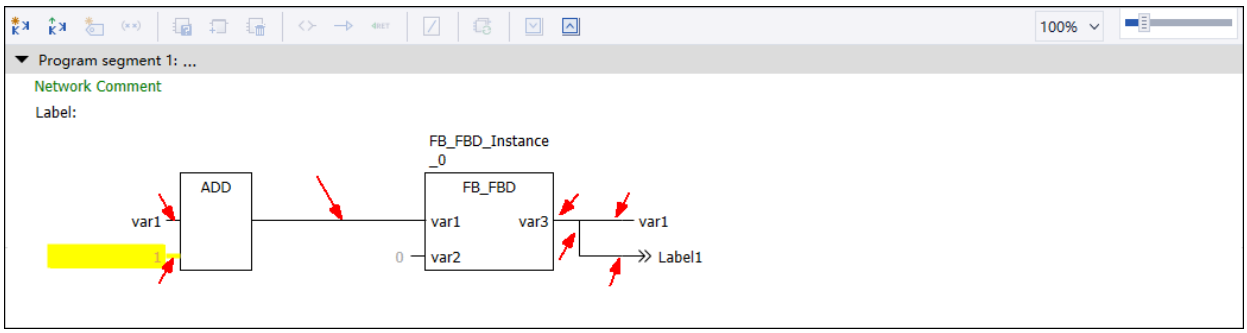
- **Assignment**

  Used to assign a value to another value. As shown in the figure below, var2 := var1 means to assign the value to var1 to var2.



- **Return**

  The return element is used to terminate program execution. Once a return element is encountered, all subsequent program code will no longer be executed.



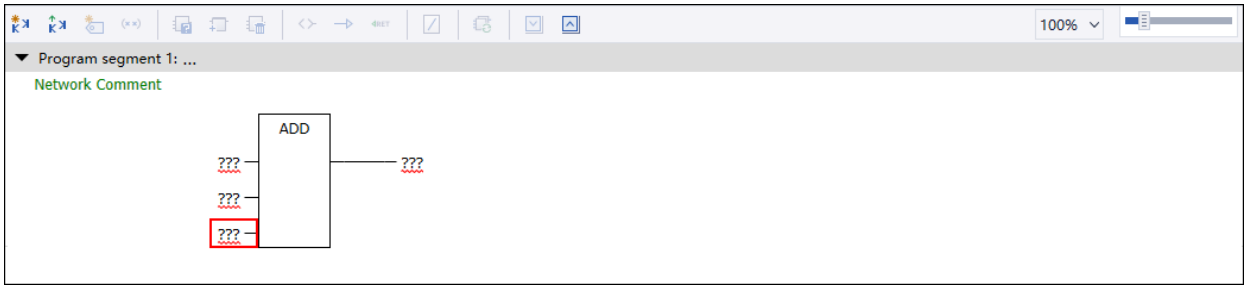
- **Jump**

  The jump element is used to transfer program execution from the current position to another specified location.

- **Connection**

  A connection is a line that connects two positions. Connection lines mainly include contact connections, input/output connections of operation blocks, connections between coils, terminal connections, branch terminal connections, and vertical connections.

Auxiliary element

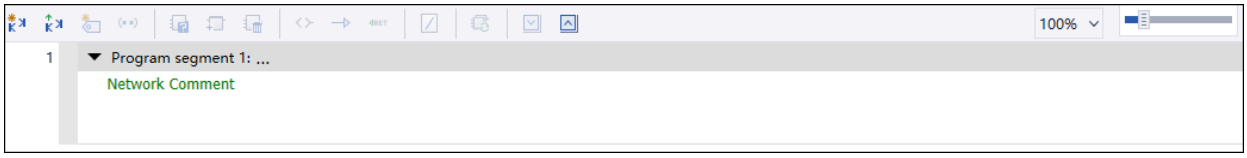


- **Inversion**

  Supports inverting the block pin of BOOL or SAFEBOOL type.

- **Input pin**

  For blocks supporting multiple inputs, input pins can be added.



11.2.5.5 Safety FBD Programming

Safety FBD allows users to add required elements to the network using commands from the toolbar. It also supports directly dragging user-defined program blocks from the toolbox and dropping them into the network to create corresponding block instances.

Adding elements by commands

Elements that can be added by commands include: network, label, block, input pin, assignment, return, jump, and inversion.

- Commands in the toolbar

Commands in the toolbar are fixed. Depending on the selected element, different commands are enabled. Only enabled commands support adding corresponding elements around the selected element, which cannot be achieved by disabled commands by default.

- Commands in the right-click menu

Commands in the right-click menu vary depending on the selected element. Only the commands that are visible for the selected element can be used to add corresponding elements around it.

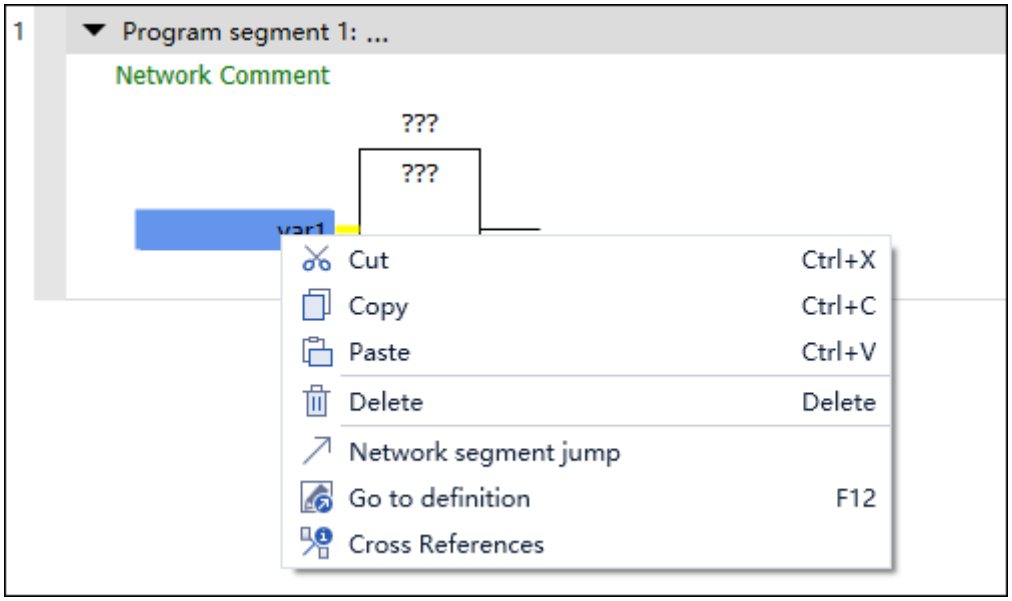


Table11-2-5-5-1 Icons and descriptions of commands

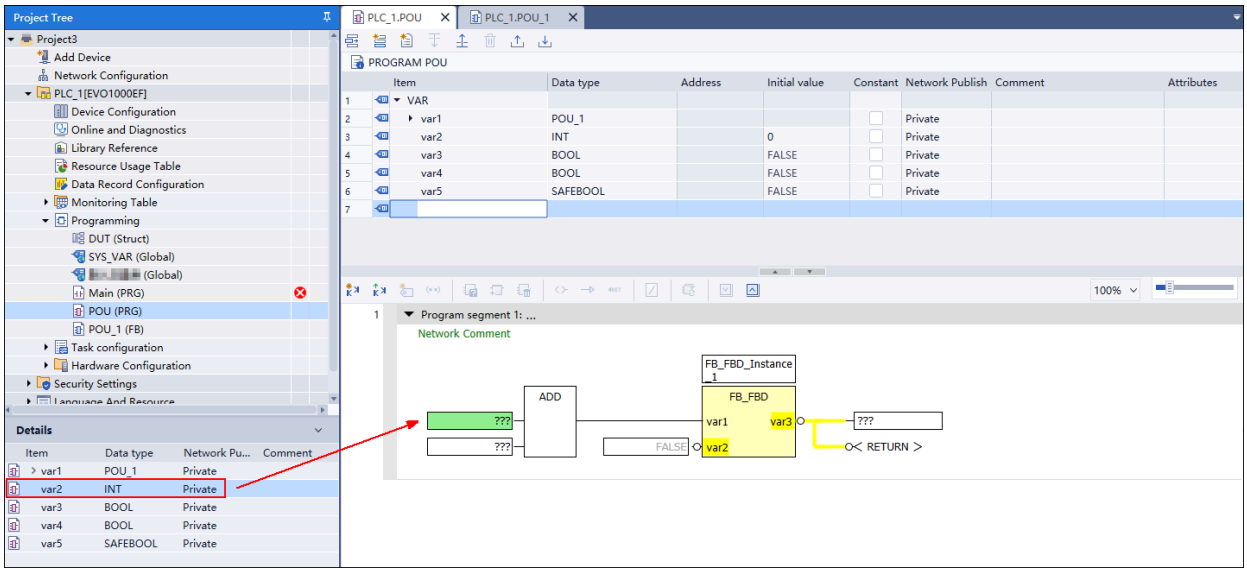
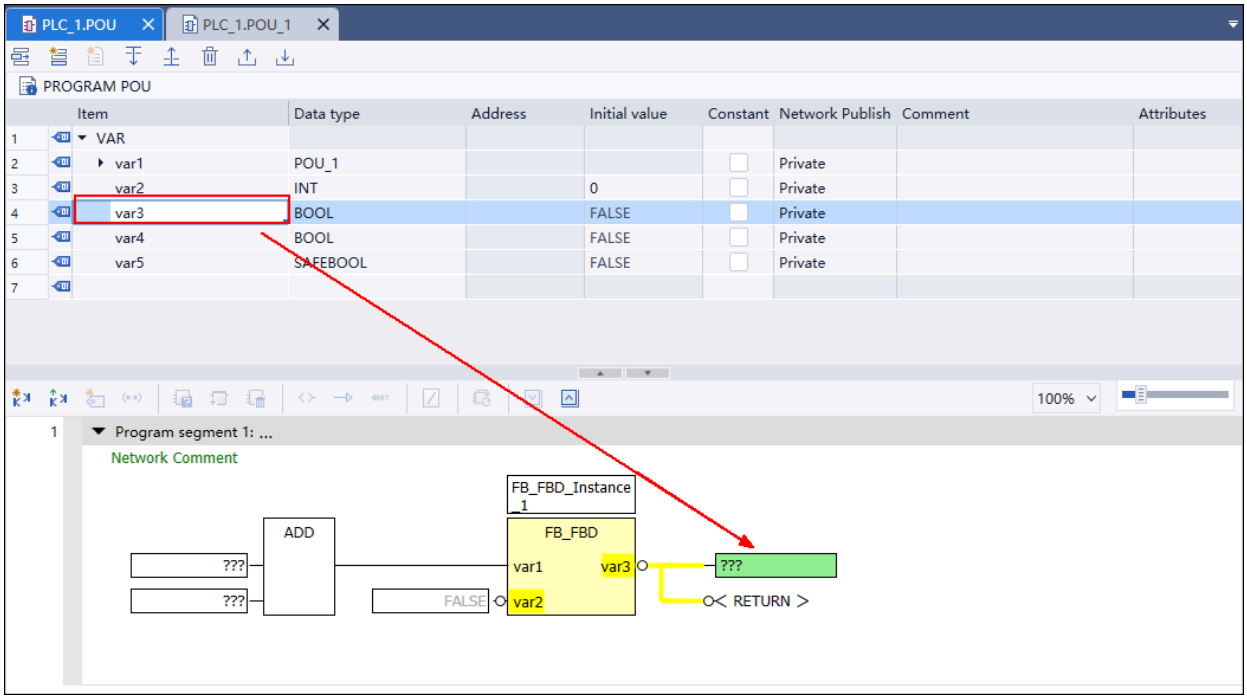
Type	Icon	Description
Add/Insert network		Adds/Inserts a network.
Insert label		Adds a label to network.
Toggle network comment		Comments or uncomments the selected network.
Insert empty function block		-
Add input		-



Type	Icon	Description
Insert input		-
Remove unused pins		Deletes unconfigured pins for FB call blocks.
Insert assignment		-
Insert jump		-
Insert return		-
Inversion		Inverts a contact or a BOOL connection.
Update all parameters		When parameters are changed at the FB declaration but not at the call site, this icon can update the block at the call site.
Expand all networks		-
Collapse all networks		-

Adding elements by dragging

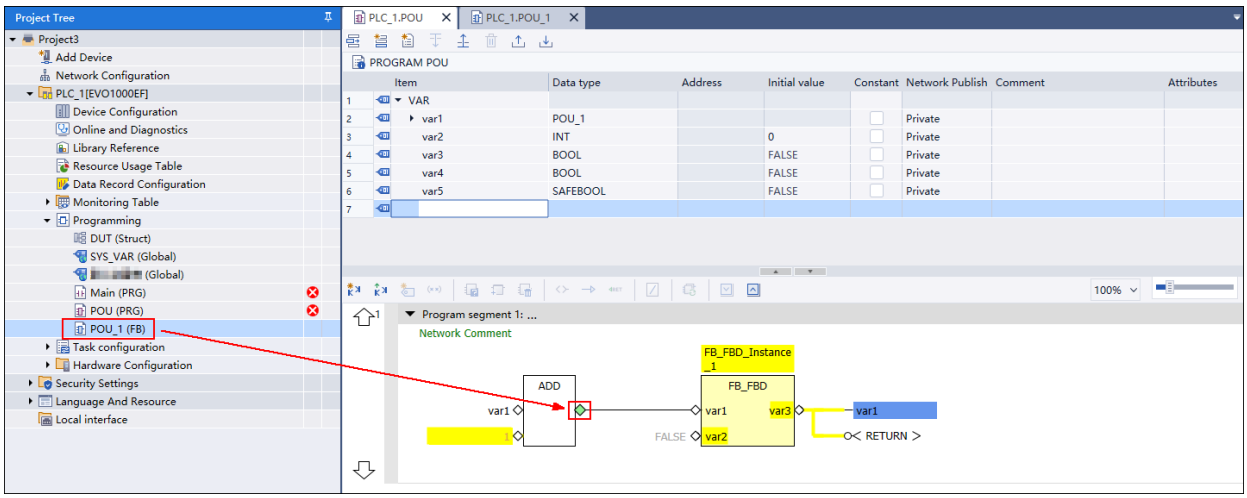


Instance variables from the "Details" window and the variable declaration area can be dragged to block input/output pins for addition or modification. Blocks from the project tree or toolbox can be dragged to the editor for addition. Elements within the editor to another location in the editor. Currently, variables within the editor cannot be dragged.

- Dragging variables

  Drag instance variables from the "Details" window to the operand variable locations in the editor.

  Drag variables from the variable declaration area to the operand variable locations in the editor.



- Dragging elements from the toolbox

  When dragging an element from the toolbox to the editor, the available locations are highlighted with a diamond-shaped mark. Hover over these locations and they will be displayed in green. Release the mouse to add the selected element to the corresponding location.

- Dragging elements from the project tree

  When dragging an element from the project tree to the editor, the available locations are highlighted with a diamond-shaped mark. Hover over these locations and they will be displayed in green. Release the mouse to add the selected element to the corresponding location.

- Dragging elements in the editor

  When dragging an element in the editor to another network or another location within the same network, the available locations in the target network are highlighted with a diamond-shaped mark. Hover over these locations and they will be displayed in green. Release the mouse to move the selected element to the corresponding location.

  If you keep pressing Ctrl during dragging and dropping, the element at the source location will not be deleted and a new element will be added at the target location after. If Ctrl is not pressed during dragging and dropping, the element at the source location will be deleted.

11.2.5.6 Graphic Configuration Modification

11.2.5.6.1 Modifying Text Data

After adding a network, assignment, or block, the system provides corresponding text data for them:

- For networks: Includes network title, comment, and label text.
- For assignments: Includes variable text.

- For blocks: Includes block type, block instance, and block input/output text.

Users can modify these text data as follows:

- For network titles and labels, double-click the title or label to modify the text.

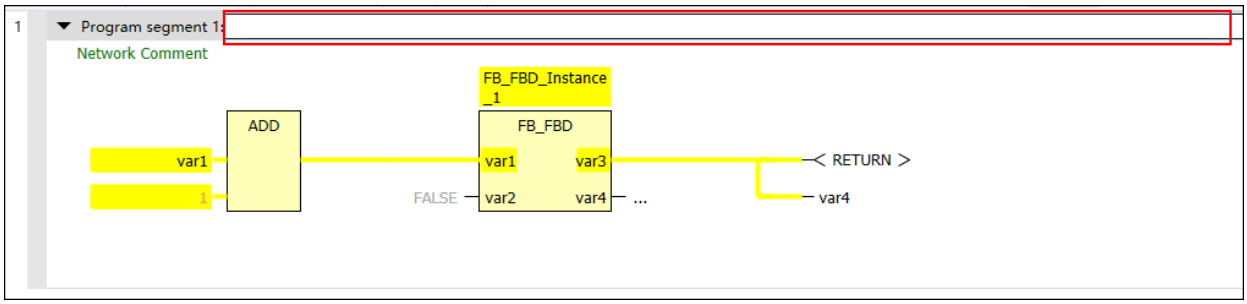


Figure 11-2-5-6-1-1 Modifying network title

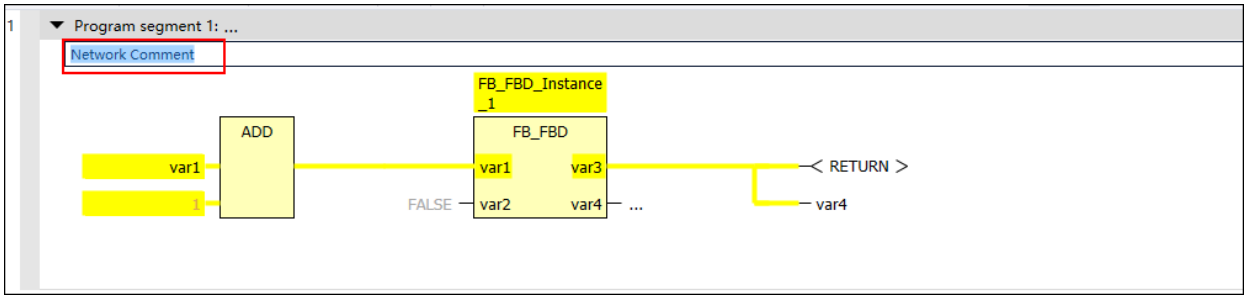

Figure 11-2-5-6-1-2 Modifying network label

- For assignment and block text, drag a variable to the corresponding location or double-click the text for modification.

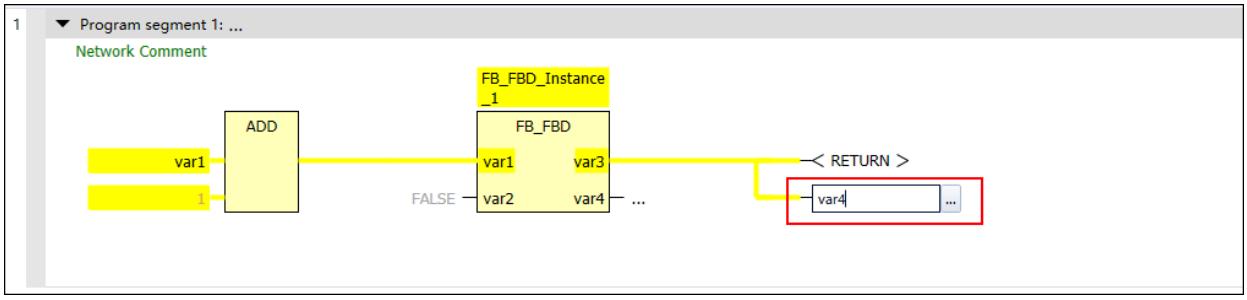

Figure 11-2-5-6-1-3 Modifying assignment text

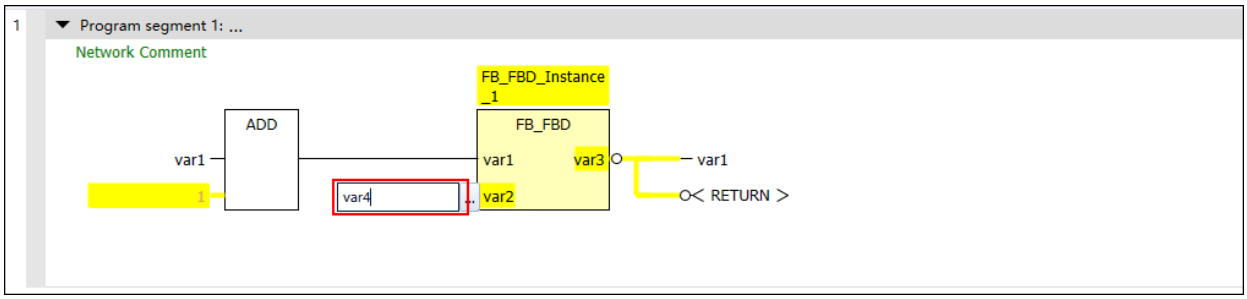

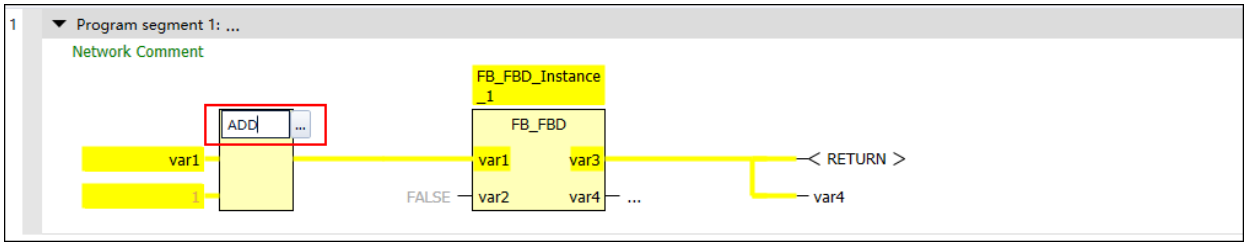

Figure 11-2-5-6-1-4 Modifying block text

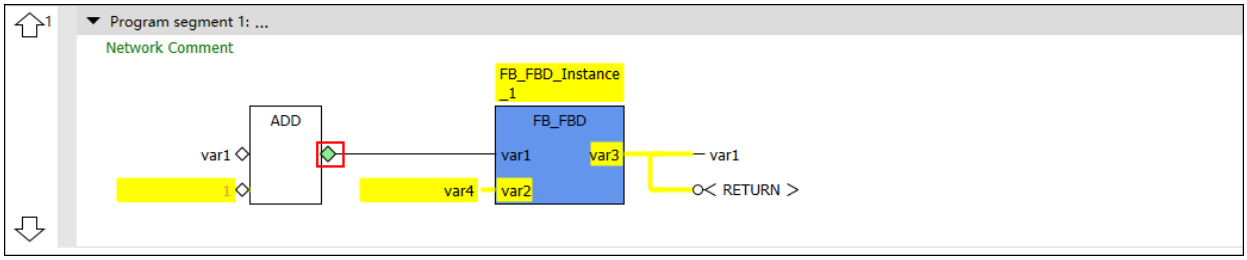


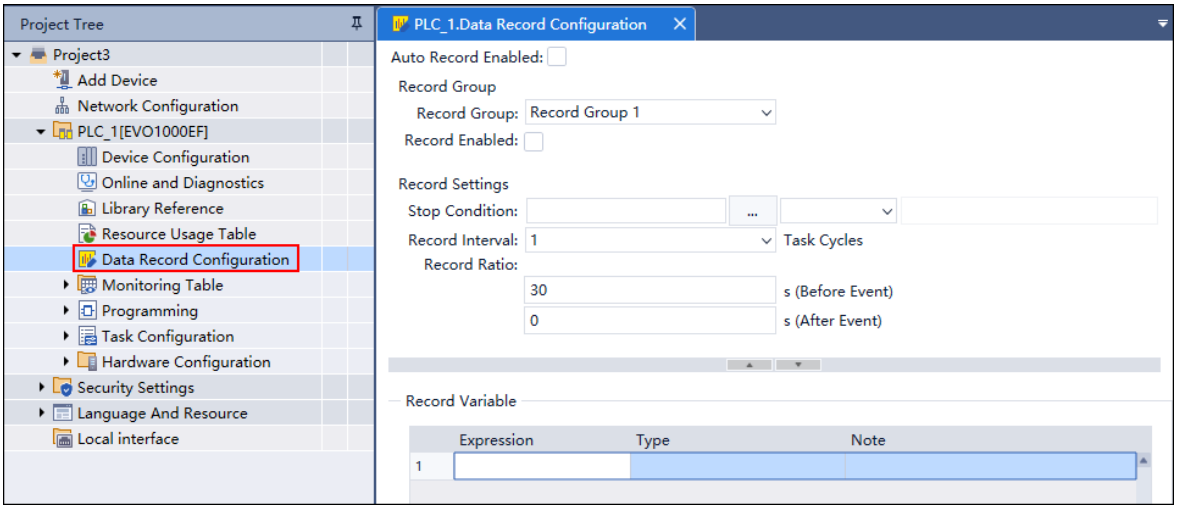
11.2.5.6.2 Modifying Block Type

Double-click a block type to modify its type.

11.2.5.6.3 Moving an Element

To move an element in the editor, you can delete it and then add it to the target position, or directly drag it to the target position. As shown in the figure, a block POU can be dragged to another location.

11.3 Data Record Configuration



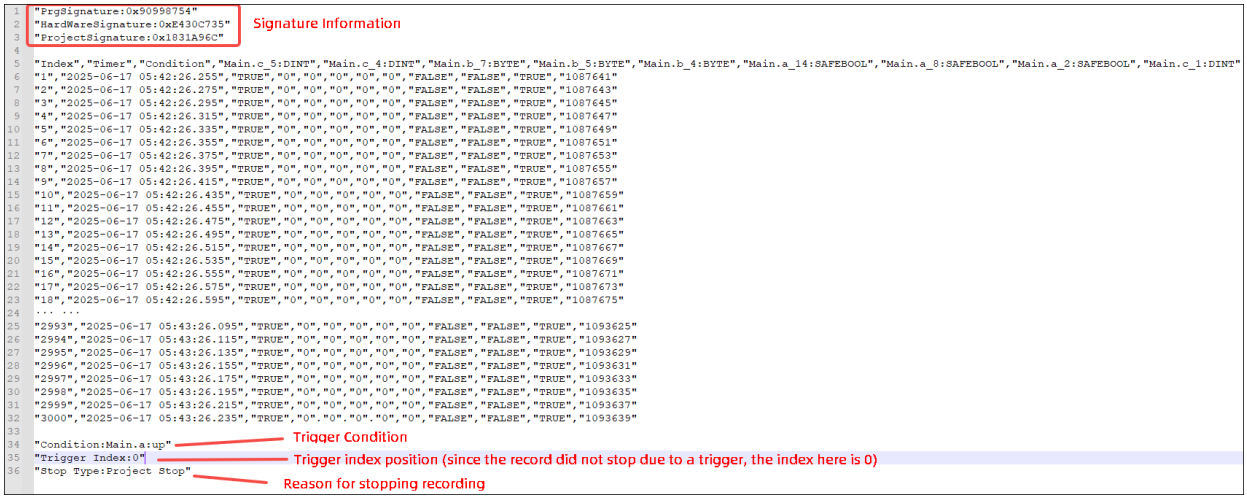
The safety PLC supports recording historical values of variables. During operation, the PLC records variable values to the SD card in the communication unit according to conditions predefined in the "Data record configuration". The recordable data range includes safety PLC's external public variables and device variables. Each variable can record up to 3,000 pieces of data. The iFA Evolution software only supports setting data recording conditions and does not support reading or displaying recorded historical data.

Prerequisites

- A qualified SD card (with more than 10% available space) has been inserted into the communication unit of the safety PLC.
- A project has been created and a safety PLC device has been added.
- A program has been added, and variables have been created.

Procedure

1. Double-click "Data record configuration" in the project tree.
2. Set data recording conditions.



Item		Description
Auto recording enabled		If checked, the safety data will be automatically recorded after the PLC program starts. Both record group configurations will take effect simultaneously.
Record group	Record group	Select the record group to be configured.
	Recording enabled	Set whether to enable the selected recording group configuration.
Recording settings	Stop recording condition	Set the trigger condition for stopping recording. Each recording group can specify a variable. When the condition is met, recording will complete the remaining according to the set recording rate before stopping. ◦ BOOL variable: TRUE (rising edge), FALSE (falling edge). ◦ Non-BOOL variables: Select one of the following options and set a constant value. ▪ [=]: Equal to constant value ▪ [≠]: Not equal to constant value ▪ [>]: Greater than constant value ▪ [<]: Less than constant value ▪ [≥]: Greater than or equal to constant value ▪ [≤]: Less than or equal to constant
	Recording interval	Set the interval period between two consecutive recordings, with a range of 1 to 10 task cycles.
	Recording ratio	The data recorded before and after the moment when the stop recording condition is met. By default, only the data before the stop condition is recorded; no data is recorded after the condition. When one time (before or after the event) is modified, the other is automatically calculated. The sum of both times should not exceed the total recordable time of the buffer. Total recordable time = 3000 × recording cycle × recording interval. For example, with a recording cycle of 10 ms and a recording interval of 1, the total recordable duration for 3000 variables is 30 seconds.

Item	Description
Record variable	Set the variables to be recorded (up to 100 variables allowed). Variables are added from the safety PLC variable table. Only public variables or device variables can be selected. The data type and comment of the selected variables are referenced from the variable table and cannot be edited. ◦ Single variable addition is supported via intelligent suggestion input and input assistant. ◦ Batch variable addition is supported by dragging one or multiple variables from the variable table or "Details" window to the record variable table. **NOTE** Direct addition of complex variables with parent-child structures is not supported. In such cases, variables can only be added individually.

3. After configuration, download the project (including the safety data recording configuration file) to the safety PLC. After the PLC starts running, it will execute the safety data recording according to the configuration.

Result

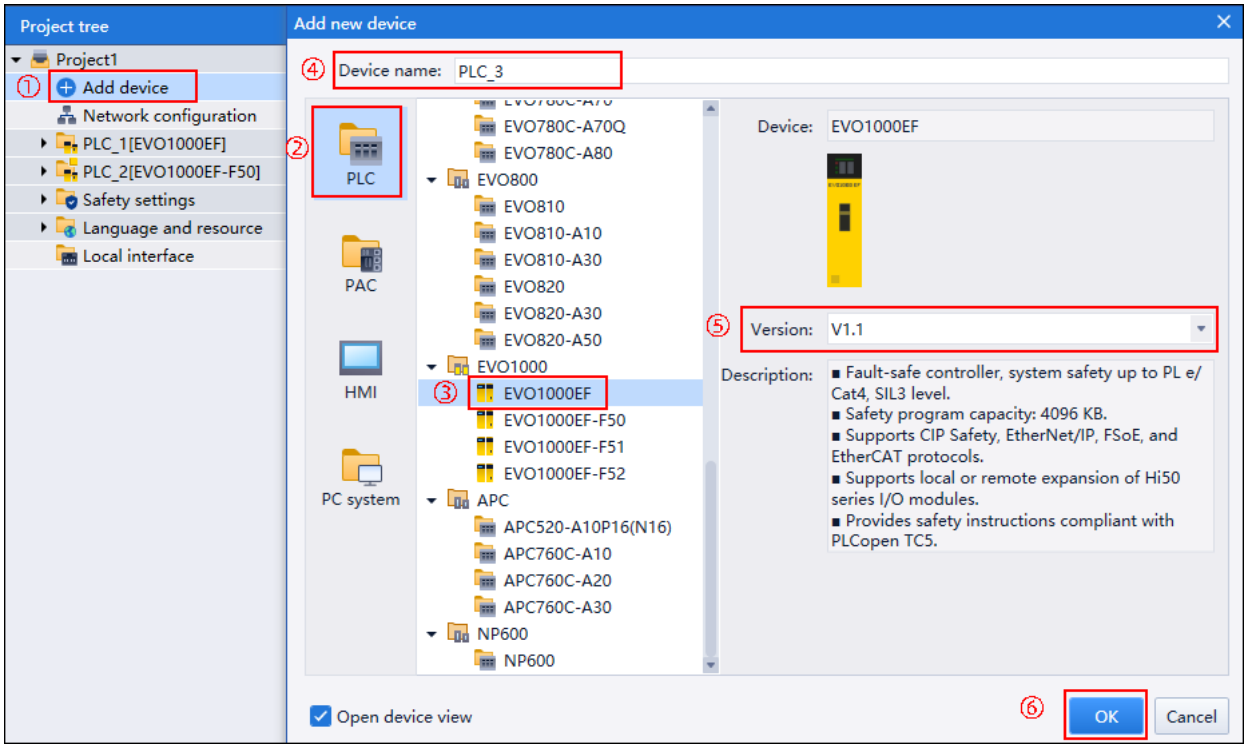
After safety data recording, a TXT file is generated in a fixed format and stored on the SD card in the communication unit. Recorded information includes project signature, data information, recording time, trigger condition, and reason for stopping recording. Open the generated TXT file. The recorded content is shown in the figure below.

11.4 PLC Configuration

11.4.1 Hardware Configuration and Device Management

11.4.1.1 Adding a Safety PLC and Communication Unit

Taking the EVO1000EF as an example for the safety PLC and the EVO1000EF EIP as an example for the communication unit, the method for adding other models of safety PLCs and communication units is the same.



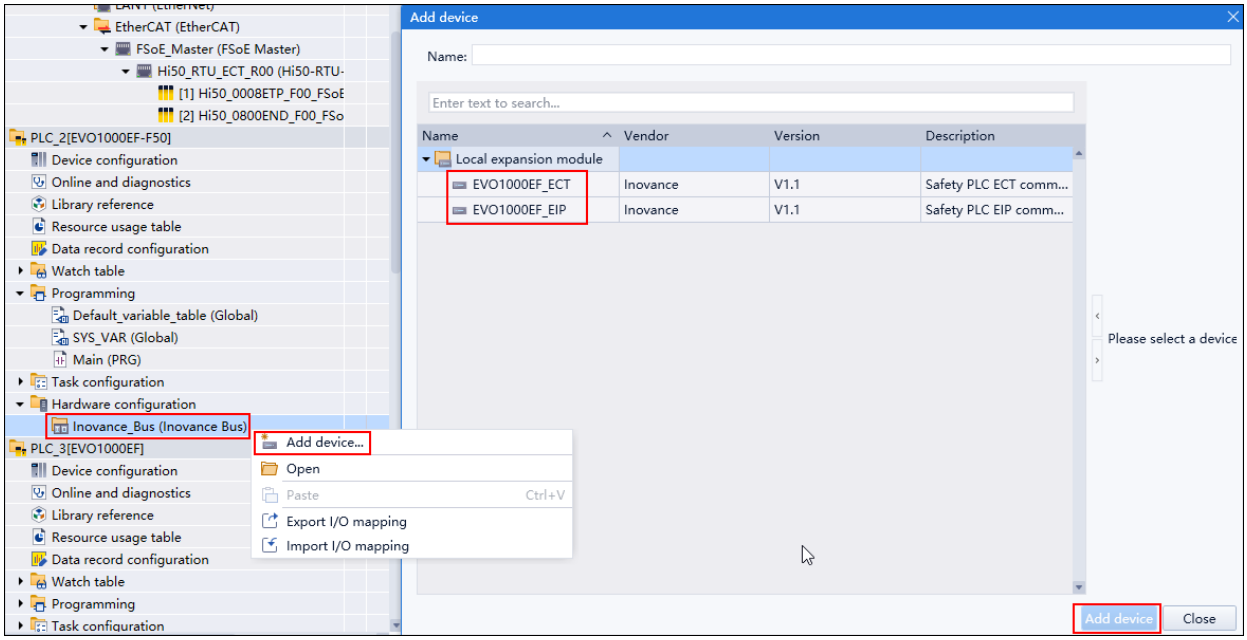
> NOTE
>
> During EtherCAT communication, local failsafe I/O and remote failsafe I/O (including couplers) can only be created, deleted, and renamed under a standard PLC. Whether it is local or remote I/O for the safety PLC, its slot number must be displayed in the project tree.

Adding a safety PLC

To add a safety PLC, follow the steps below. For details, see 7.2.1 Adding a Device.

1. Double-click the "Add device" node in the project tree.
2. Select the PLC device to add, such as "PLC > EVO1000 > EVO1000EF".
3. Modify the "Device name" as needed, select the "Version", and click "OK" to add the new device.

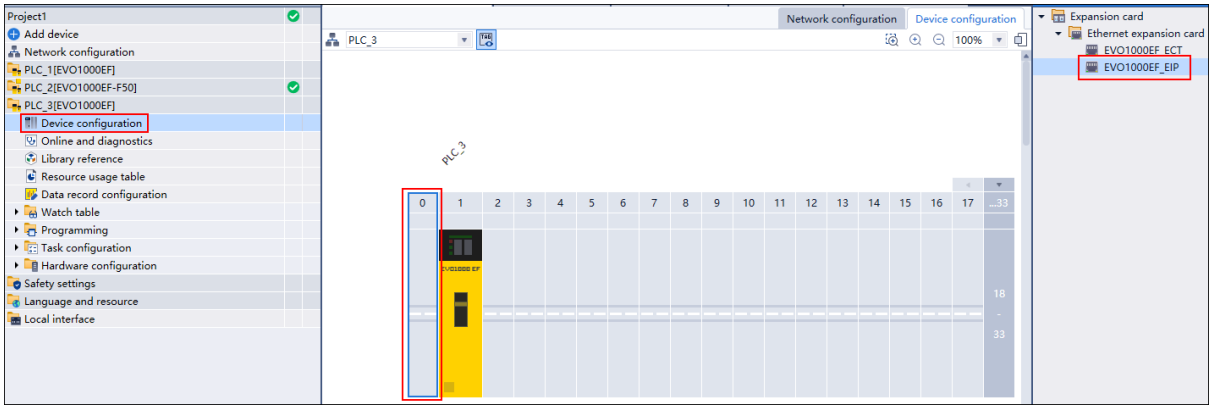
> NOTE
>
> - Version V1.0: The safety PLC is equipped with an EIP communication unit.
> - Version V1.1: You must manually add an EIP or ECT communication unit.



Communication Module Addition

For safety PLC V1.1, you must manually add an EIP or ECT communication unit. Communication units can be added via the project tree view or the device view.

Method 1: Adding via the project tree



1. Right-click the "Inovance_Bus" node under "Hardware configuration" node of the safety PLC device, and select "Add device".
2. Select the communication unit as needed, such as "EVO1000EF_EIP", and click the "Add device" button.

Method 2: Adding via the device view

1. Double-click "Device configuration" of the safety PLC device in the project tree.
2. Select a communication unit under "Device list > Expansion card > Ethernet expansion card", such as the "EVO1000EF_EIP" module. When the module is selected, the device view highlights the border of the slot, indicating where the module can be inserted.

3. Double-click a module to add it to the nearest available slot on the PLC, or select a module and drag it to the desired location in the device view, then release the mouse button to complete the addition.

11.4.1.2 Device Scanning

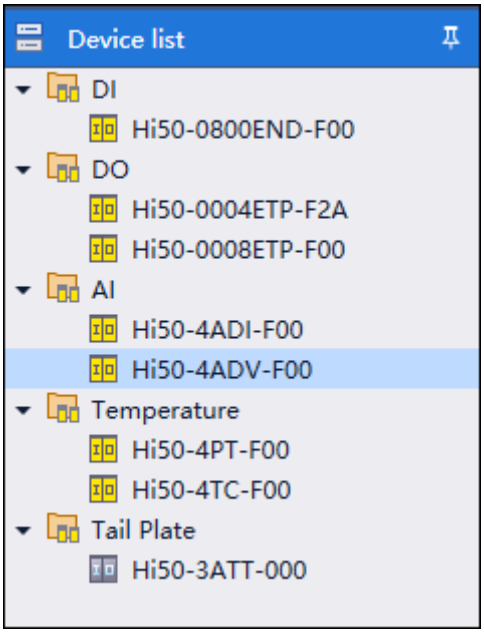
The device scanning method in the safety PLC is the same as that in the standard PLC. Only the functional differences are described here. For other general functions, see 10.6.1.1 Device Scanning in the "PLC Programming" chapter.

For safety PLCs, the "Communication type" adds the "EOE" method. The operation method is the same as the "Ethernet" method.

11.4.2 Failsafe I/O Module Configuration

11.4.2.1 Rack Overview

To mount modules after the main device, a rack (i.e., a mounting rail) must be used to secure the modules to the rack and connect them to the CPU, couplers, power supply, or other modules via the backplate bus.



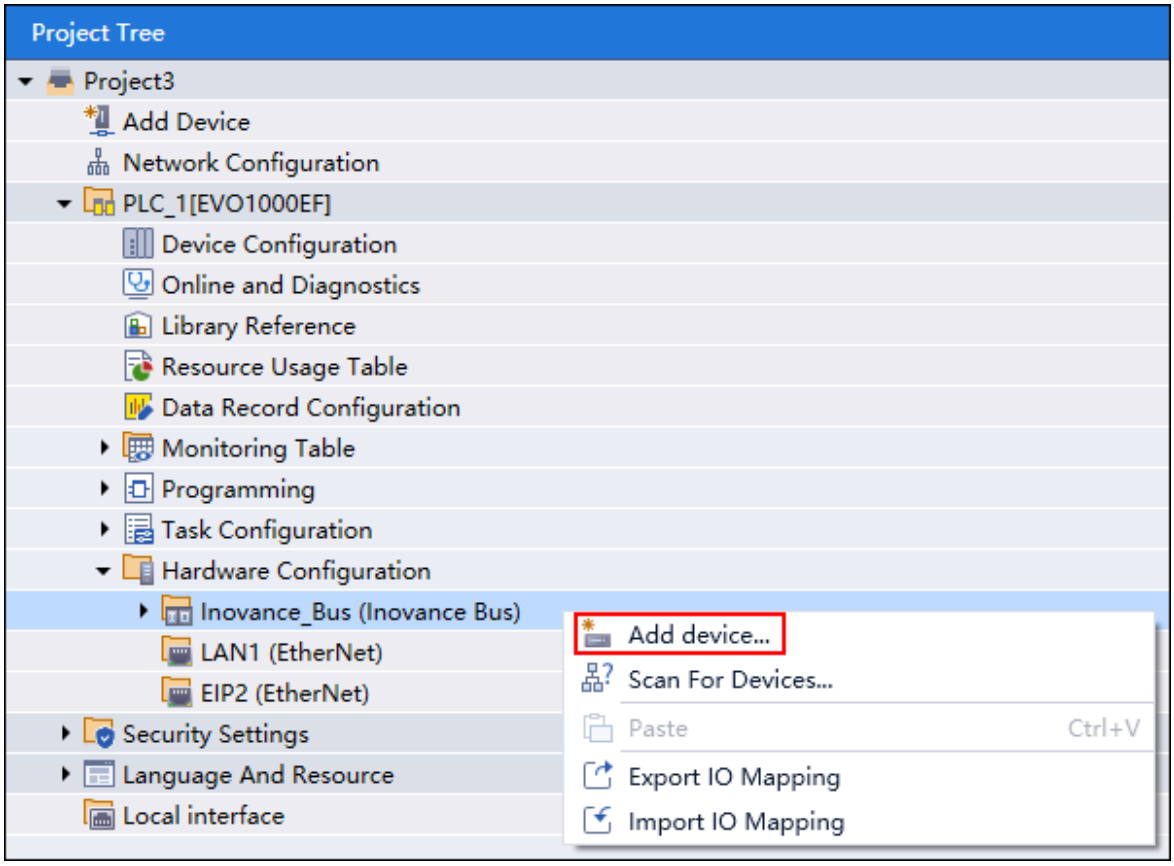
Creating a rack

After adding a device, a rack suitable for the selected device is automatically created. The available slots in the rack are displayed in the device configuration view, and the number of available slots depends on the type of device used.

Rack structure

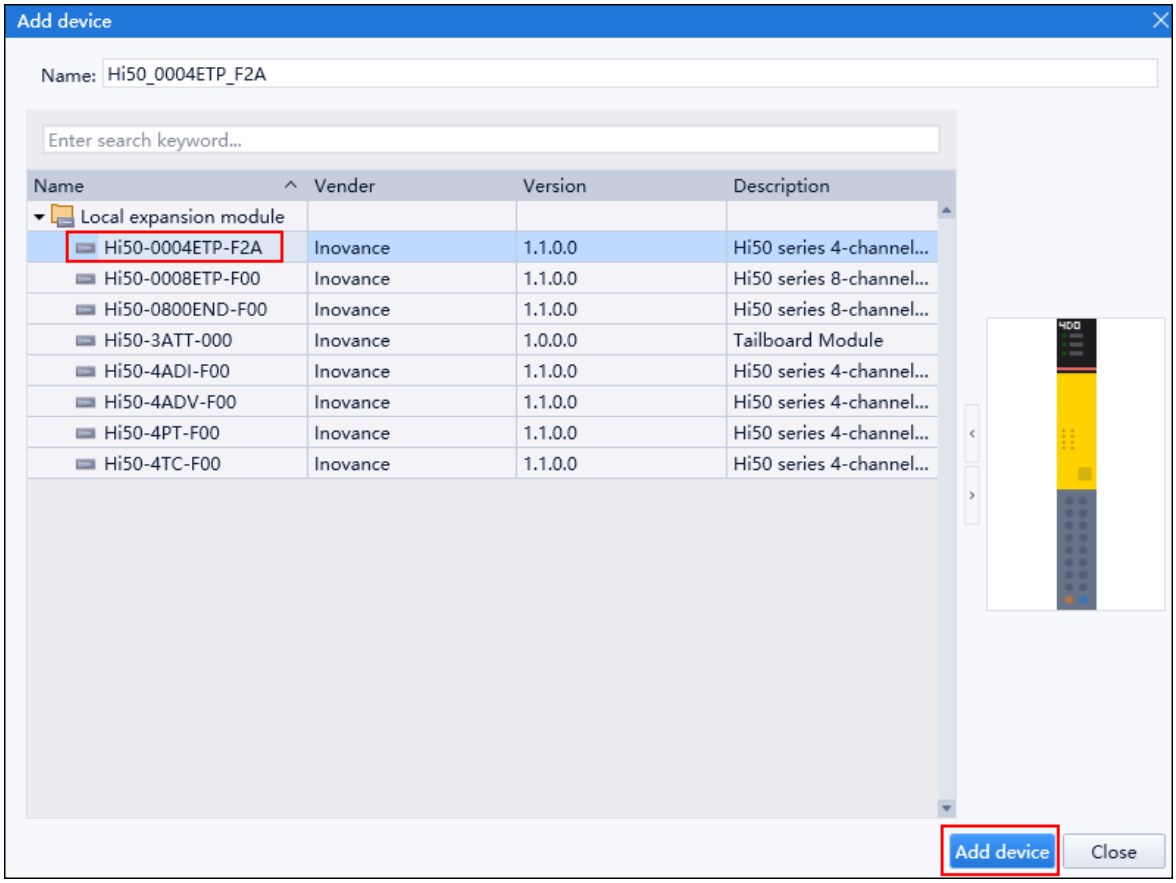
There are empty slots to the right of the device. The slot numbers are located above the slots and a brief description is displayed above the inserted device and modules. Use the "Display label" icon on the toolbar to display or hide the brief description of the device.

In the right device list, the slots that allow insertion of these modules are displayed.



PLC local rack I/O modules are referred to as local I/O modules. For EVO1000 series PLC, the CPU rack defaults to supporting up to 31 local I/O modules, including safety digital input modules (DI), safety digital output modules (DO), safety current analog input modules (ADI), safety voltage analog input modules (ADV), safety thermal resistor analog input modules (PT), and safety thermocouple analog input modules (TC).

11.4.2.2 Adding a Module

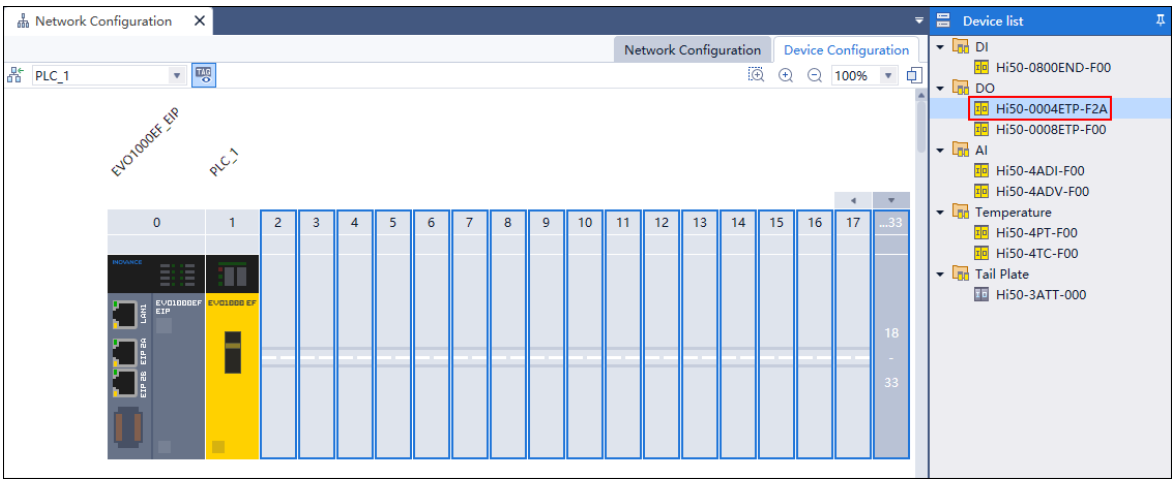


The following describes the methods for adding modules via the project tree, device configuration view, and device scanning, as well as specific restrictions for adding tail plate modules:

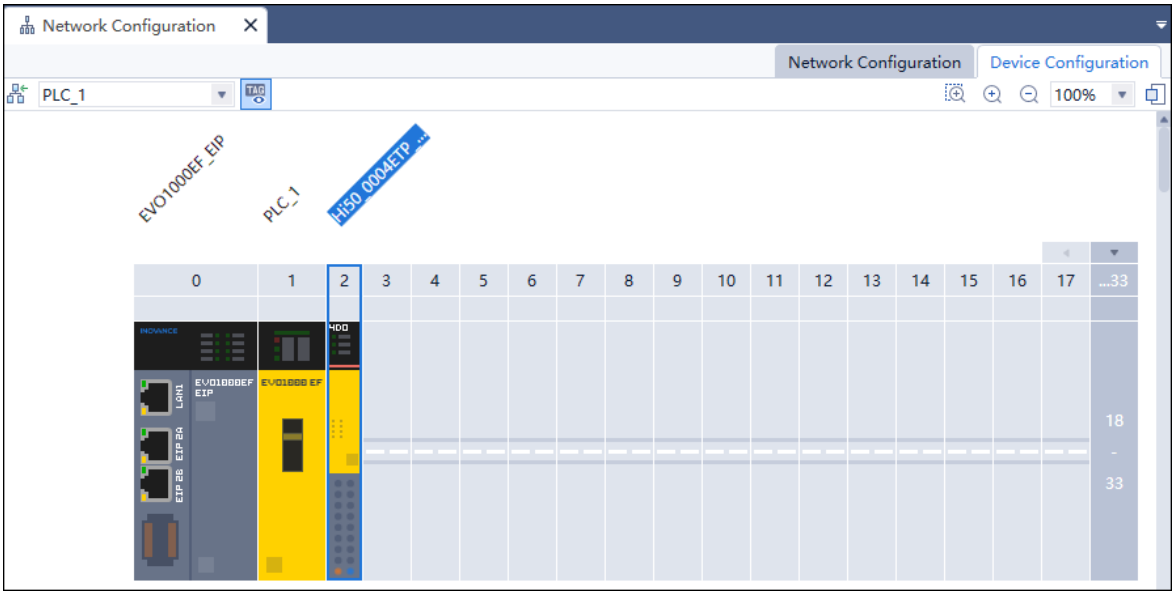
Method 1: Adding a module through the project tree

1. Expand the "Hardware configuration" list in the left project tree.
2. Right-click "Inovance_Bus (Inovance Bus)" and select "Add device".

3. In the pop-up window, select the module and click "Add device", or double-click the module to complete the addition.



4. After the module is added, the result will be synchronized in the device configuration view.



Method 2: Adding a module through the device configuration view

1. Double-click the "Device configuration" node in the left project tree.

2. In the right device list, select the module. When a module is selected, the insertable slots for the module are highlighted in the configuration diagram.

3. In the device list, double-click a module to add it to the nearest available slot adjacent to the PLC. You can also drag the module from the device list to an available slot in the device configuration view.

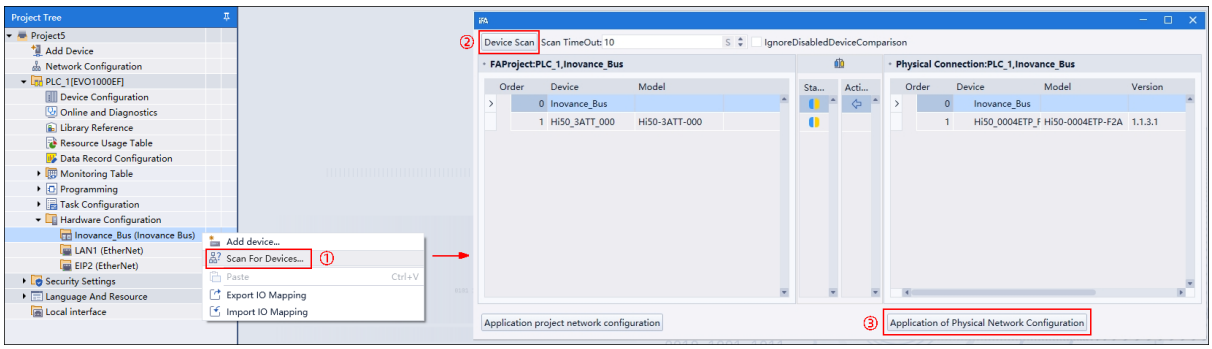
4. To change the module slot, drag the module in the device configuration view to the target slot.

5. The added module can be copied and pasted using the right-click menu or keyboard shortcuts.
   Only one module can be copied and pasted in the device list. Multiple modules can be copied and pasted in the device configuration view.

6. After the module is added, the result will be synchronized under the "Hardware configuration > Inovance_Bus (Inovance Bus)" node in the project tree.

Method 3: Adding a module through device scanning

The iFA Evolution software provides an automatic scanning function for safety I/O modules, allowing users to directly add modules by scanning.



Prerequisites

- A blank project containing the "CIP_Safety_Scanner" node has been deployed to the target safety PLC.
- The user program of the safety PLC is in the stopped state.

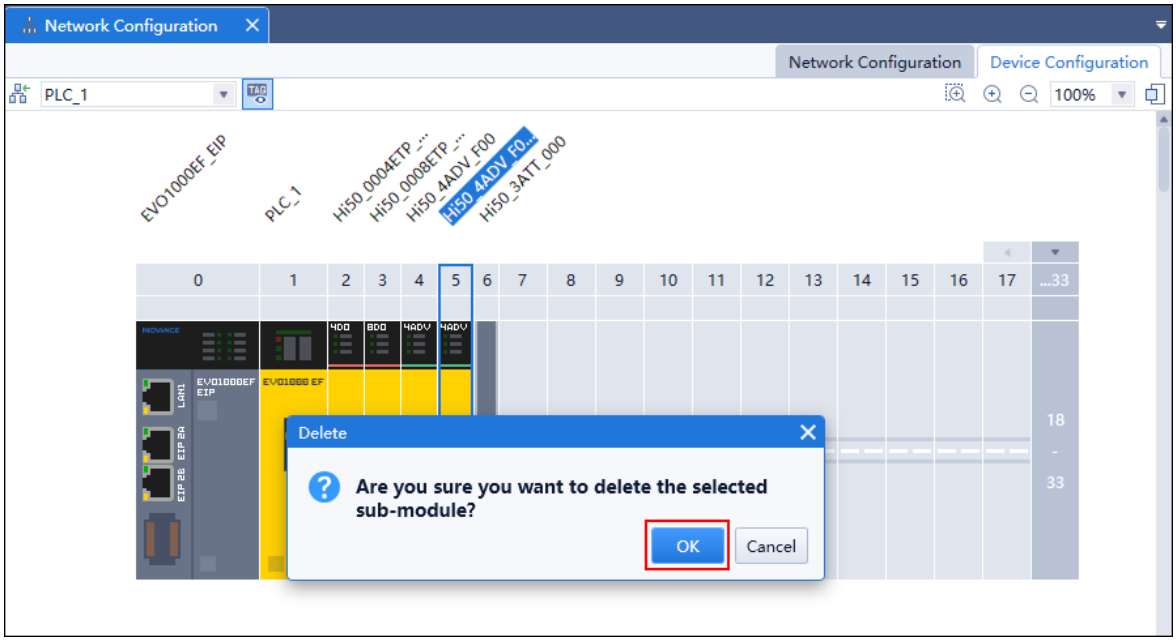
Procedure

1. Right-click the "Inovance_Bus" node under "Hardware configuration" node, and select "Scan for devices".

2. In the pop-up window, click "Device scanning" and synchronize all scanned I/O modules into the current project.
3. In the pop-up confirmation window, click "Yes" to restore the synchronized device configuration to default.
4. Click "OK" to add the safety I/O module to the project.

Adding a backplate module

The Hi50-3ATT-000 module is a backplate module for the CPU rack of the safety PLC and the I/O modules of the Hi50 coupler rack. This module is only used for display in the device view and requires no configuration. Additionally, no information about this module will be included when downloading the project.



The method for adding a backplate module is the same as for other I/O modules. The following are the restrictions for this module:

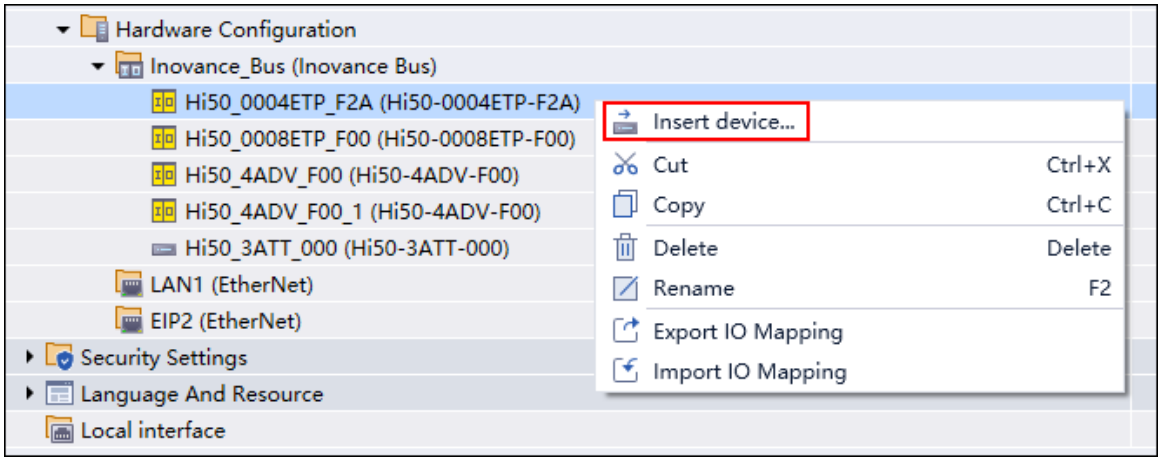
- Only one backplate module is supported in a rack.
- The backplate module can only be added to the slot immediately to the right of the last I/O module.
- If no I/O modules are added to the rack, the backplate module can only be added to the slot immediately to the right of the CPU module (slot 2).
- After adding a backplate module to the rack, no other I/O modules can be added to the slots to the right of this module. To add more modules, the backplate module must first be manually removed.
- After a backplate module is added, it cannot be moved. When there are no available slots to the left of the backplate module, no other I/O modules can be inserted. To insert another module, you must either manually delete the backplate module or delete the modules on the left to free up a slot.
- The last slot in the rack (slot 33) is reserved for the backplate module; no other I/O modules can be inserted into this slot.
- If a backplate module is not manually added during configuration, it will be automatically added during compilation.

11.4.2.3 Deleting a Module

The deletion procedure of a module is the same as that of a regular slave device. The recommended method for deleting a module is as follows:

1. Double-click the "Device configuration" node in the left project tree.
2. In the device configuration view, select a module on the PLC rack; multiple selections are supported.
3. Press the Delete key, then click "OK" in the pop-up window to delete the module.

When a module is deleted, the variables mapped to its channels will be released. At the same time, the deleted module will be removed from the "Hardware configuration > Inovance_Bus (Inovance Bus)" node in the project tree.



> **NOTE**
>
> After deleting an I/O module, the addresses of the associated I/O variables will be rearranged.

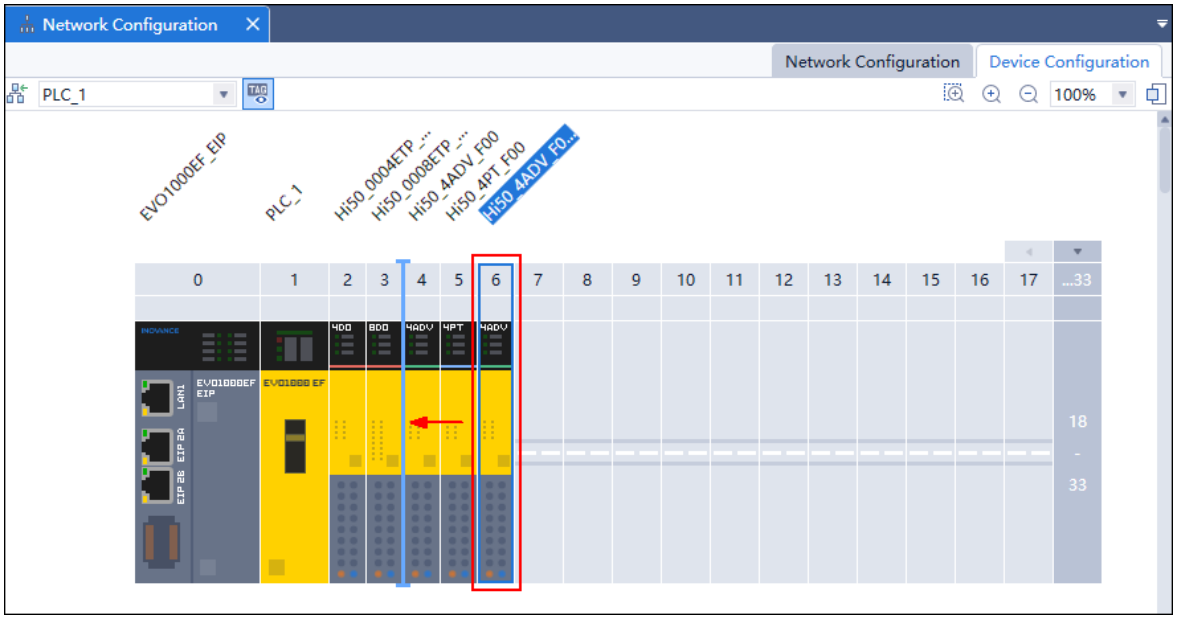
11.4.2.4 Inserting a Module

The module can be inserted in the following three ways:

- **Inserting through the project tree**

  Right-click an existing module under "Hardware configuration > Inovance_Bus (Inovance Bus)" and select "Insert device".

  The inserted module is placed by default in the slot to the left of the selected module.

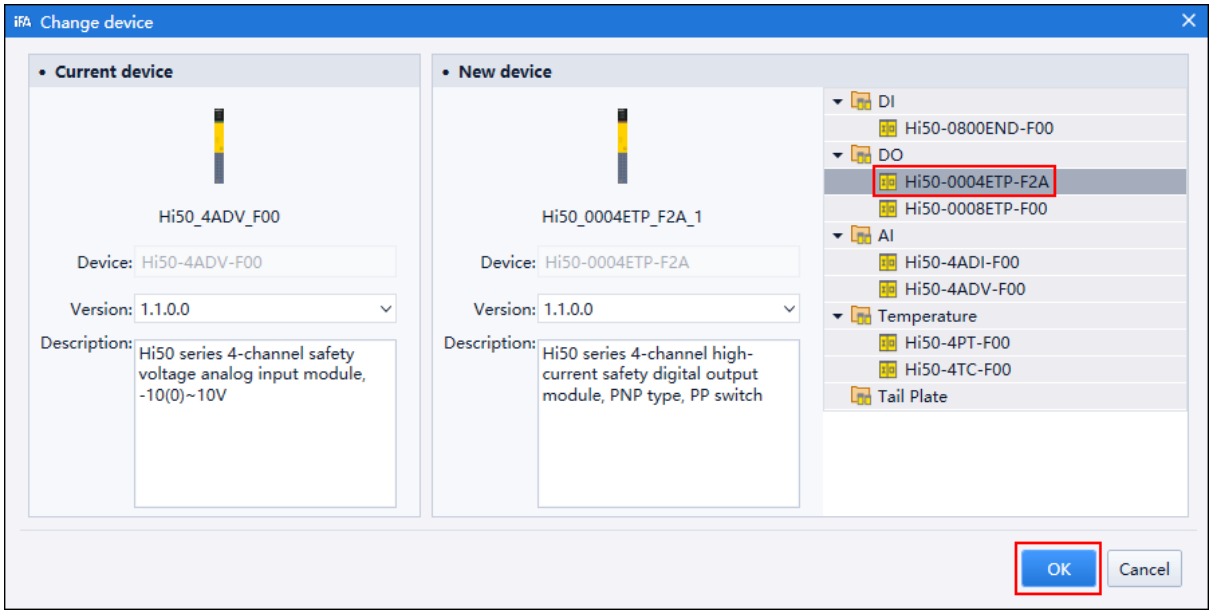


- **Dragging and dropping from the device list**

  Drag a sub-module from the device list to insert it into existing slots.

After successful insertion, the module whose location has been adjusted is highlighted.

- **Dragging and dropping from the device view**
  Drag a sub-module from the device configuration view and insert it into another slot.



NOTE

- After inserting an I/O module, the addresses of the associated I/O variables will be rearranged.
- When a backplate module has been added to the rack, no other I/O modules can be inserted to the right of the backplate module. If there are no available slots to the left of the backplate module, no other I/O modules can be inserted either.

11.4.2.5 Replacing a Module

The module can be replaced in the following two ways:

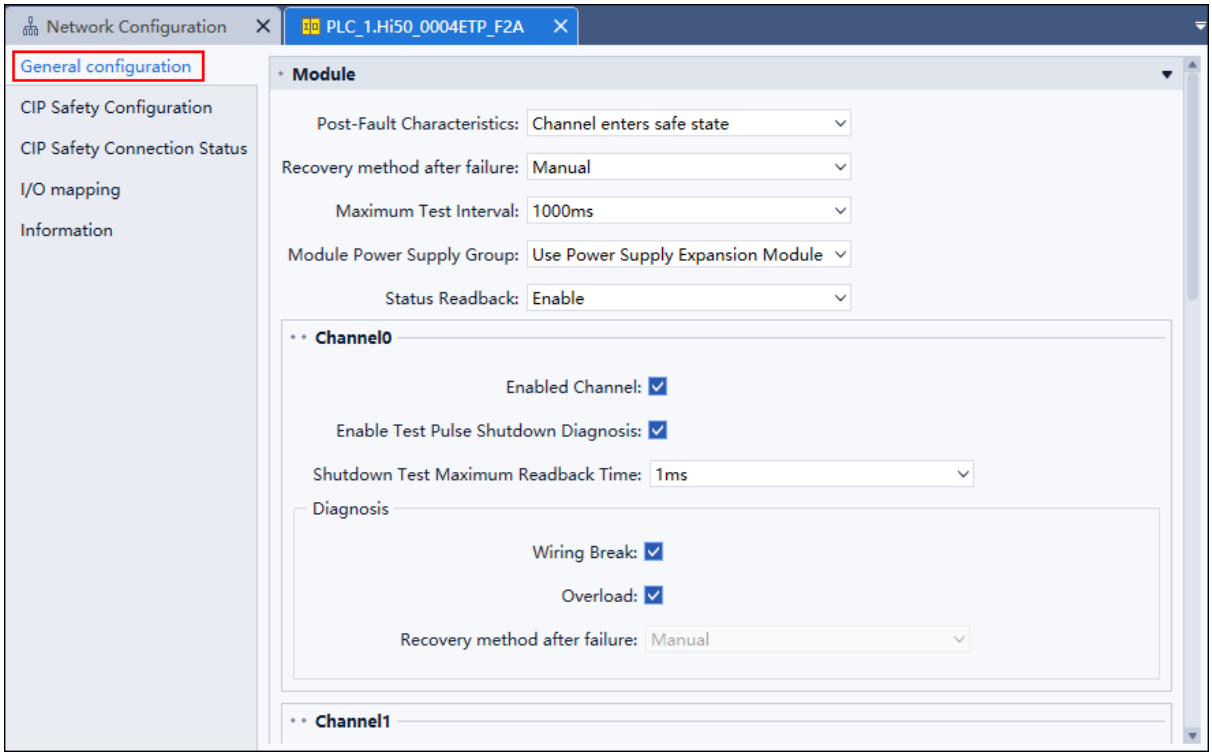
- **Replacing through the right-click menu**
  In the device view, right-click the module to be replaced and select "Change device". Select the new device in the pop-up dialog box, and click "OK" to complete the module replacement.

- **Dragging and dropping from the device view**
  In the device list, drag the new module onto the module to be replaced in the device configuration view. After releasing the mouse, the "Change device" dialog box appears. Click "OK" to complete the module replacement.

11.4.2.6 Moving a Module

The module movement includes the following two scenarios:

- **Moving to an empty slot**
  In the device configuration view, drag a module to move it to another empty slot.
- **Moving to a non-empty slot**
  In the device configuration view, drag a module to move it to another non-empty slot to switch the positions of the two modules. After releasing the mouse, the modules whose positions have been changed are highlighted.



11.4.2.7 Failsafe I/O Module Configuration

The iFA Evolution software supports parameter configuration for each failsafe I/O module. The following describes the specific configuration items:

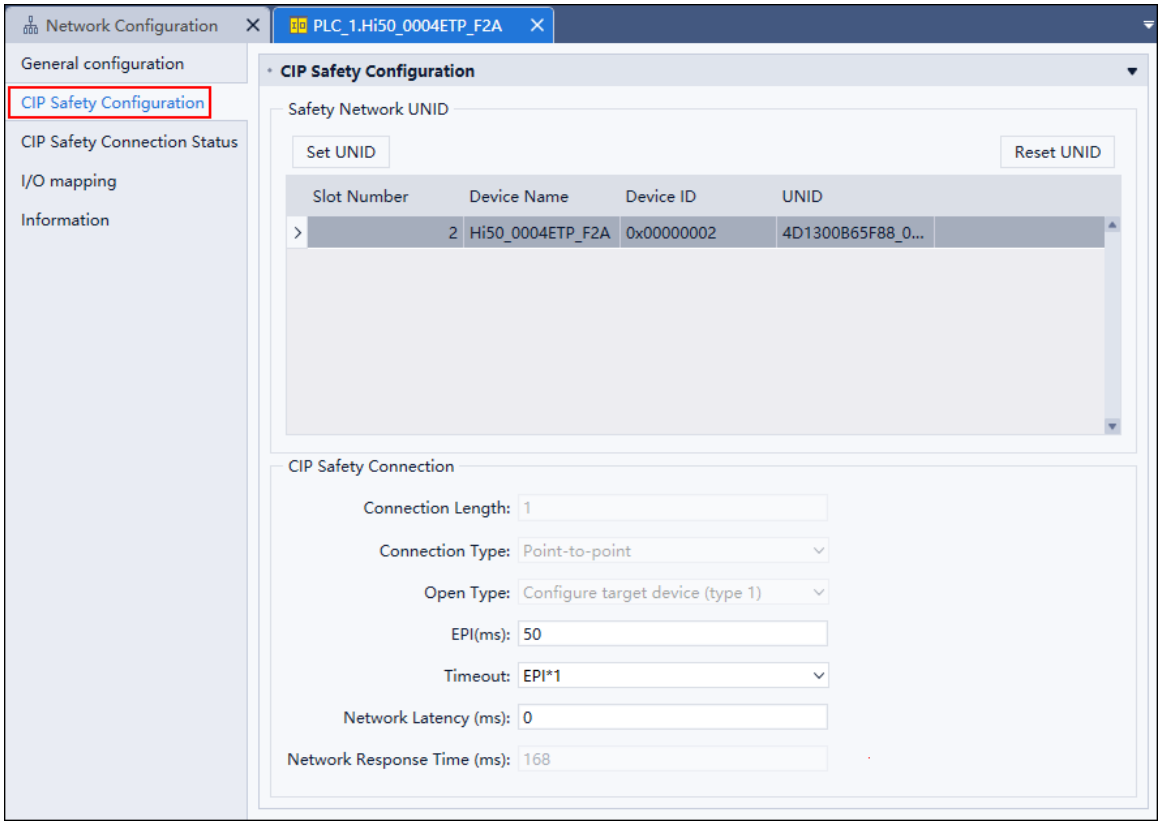
General configuration

This tab is used to configure module-level general settings and channel settings.

1. In the project tree or device configuration view, double-click the failsafe I/O module to be configured. The following takes the Hi50-0004ETP-F2A module as an example.
2. In the configuration page, select the "General configuration" tab to configure module parameters and channel parameters.

Parameter		Description
Module general configuration	Post-fault character	Includes two modes: module enters safe state/channel enters safe state
	Recovery method after fault	Includes three modes: custom/manual/automatic ◦ When set to manual or automatic, the channel parameter "Recovery method after fault" is consistent with the setting. ◦ When set to custom, the channel parameter "Recovery method after fault" can be set to automatic or manual. When "Post-fault character" is set to "Module enters safe state", the "Custom" option is not visible.
	Maximum test interval	Options: 100 ms, 200 ms, 500 ms, 1000 ms (default), 2000 ms, 5000 ms, 10000 ms
	Module power supply group	Supports using power supply expansion modules (default) or power supply start modules.
	Status readback	Enables or disables the status readback function. When enabled, input connections of output modules are activated.
Channel (0 to 3) configuration	Enable channel	Sets whether the channel is enabled.
	Enable shutdown test pulse diagnosis	Enables or disables the shutdown test pulse diagnosis function.
	Shutdown test maximum readback time	Options: 0.5 ms, 1 ms (default), 2 ms, 3 ms, 4 ms, 5 ms
	Wiring break	Enables or disables disconnection diagnosis.
	Overload	Enables or disables overload diagnosis.

Parameter		Description
	Recovery method after fault	◦ When the module parameter "Post-fault recovery method" is set to automatic or manual, this setting follows accordingly and cannot be modified. ◦ When the module parameter "Post-fault recovery method" is set to custom, this setting supports manual selection between automatic and manual.
Safety signature	Safety configuration CRC	Displays the safety configuration CRC information of the module.
	Safety configuration timestamp	Displays the safety configuration timestamp information of the module.

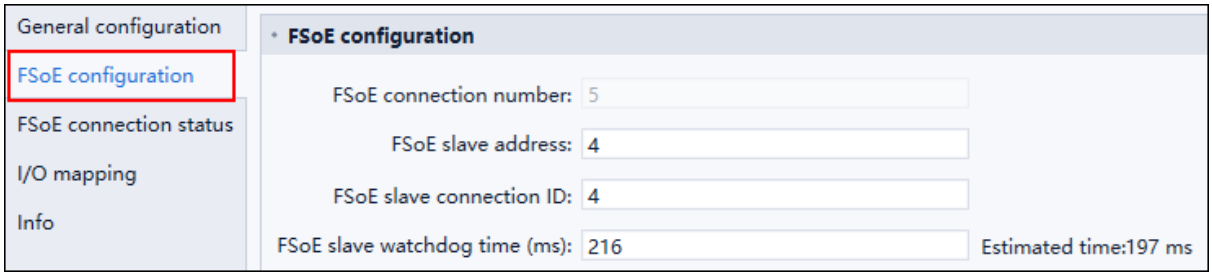


See the Hi50 series failsafe I/O module manuals for parameter definitions and functions of each failsafe I/O module.

CIP Safety configuration

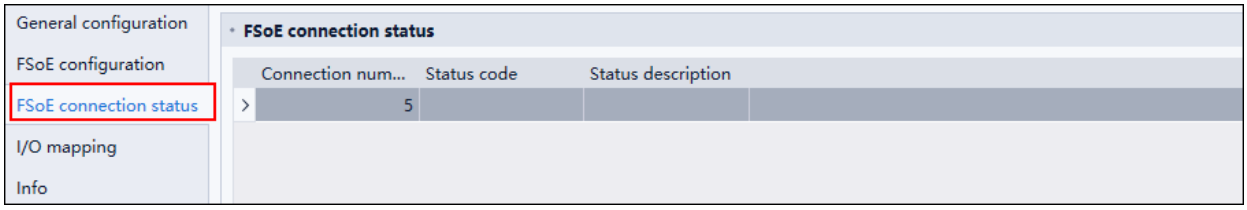
This tab is used to configure the CIP Safety communication parameters for failsafe I/O modules, including EPI, timeout multiplier, network latency, and so on.

1. Double-click the failsafe I/O module to be configured in the project tree or device configuration view.
2. In the configuration page, select the "CIP Safety configuration" tab to configure the CIP Safety connection parameters of the module.
   - EPI (ms): Indicates the cycle of CIP Safety communication between the safety PLC and the safety I/O module. This parameter must be an integer multiple of the task cycle. For example, if the task cycle is 50 ms, this parameter must be 50 ms, 100 ms, 150 ms, and so on. By default, this parameter equals the task cycle.
   - Timeout: Indicates the timeout multiplier for CIP Safety communication between the safety PLC and the safety I/O module. Options include EPI*1 (default), EPI*2, EPI*3, and EPI*4.
   - Network latency (ms): Indicates the network delay time, which should be configured based on the network environment. Default is 0 ms.
   - Network response time (ms): Indicates the timeout time for CIP Safety communication between the safety PLC and the safety I/O module. If no communication response is received within this time, the safety PLC and safety I/O module will enter a safe status and cannot be modified. This parameter is used to calculate the system response time.



FSoE configuration

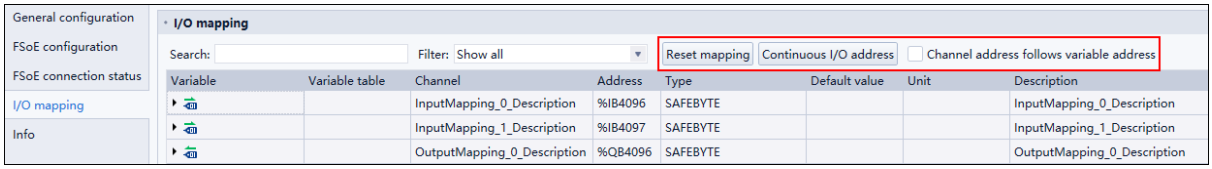
This tab is used to configure the FSoE communication parameters for the failsafe I/O module.



1. Double-click the failsafe I/O module to be configured in the project tree or device configuration view.
2. On the "FSoE configuration" tab, configure the FSoE connection parameters for the module.

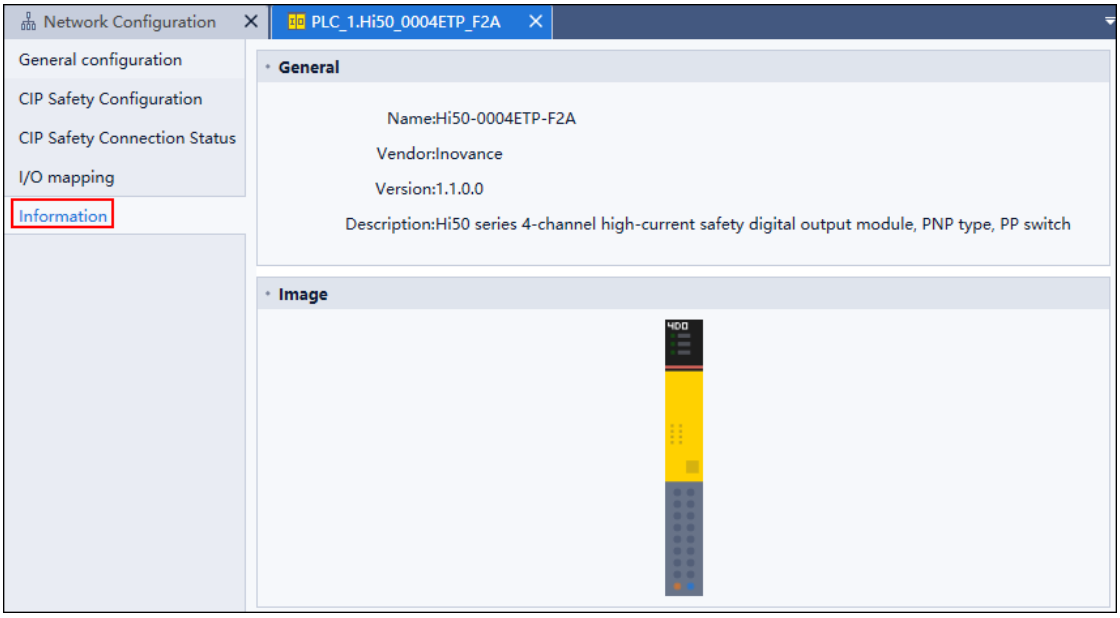
Parameter	Value Range	Note
FSoE connection ID	1 to 65535	The connection ID established in the safety PLC is automatically assigned and cannot be modified by the user.
FSoE slave address	1 to 65535	Entered manually by the user.
FSoE slave connection ID	1 to 65535	Generated by the iFA. It must be unique in the FSoE network and can be modified by the user.
FSoE slave watchdog time (ms)	1 to 65535	The default value is calculated by a formula. It can be modified by the user but cannot be less than the estimated value.

CIP Safety connection status / FSoE connection status



This tab displays the current connection status of the module, including status codes and descriptions.

I/O Mapping



This tab is used to view I/O mapping variable information for on-site signal acquisition. The information supports keyword search, condition-based filtering, and resetting. For detailed configuration parameter descriptions, see 10.6.3.3.9 I/O Mapping. A structure can be directly bound to failsafe I/O mappings for quick binding.

- Binding a structure is only supported when "Channel address follows variable address" is selected.
- For a successful binding, the member layout order of the defined structure must exactly match the variable order and data length of the I/O mapping.
- For safety variables, the variable property, variable type, and data length must be completely consistent.
- Cross-group matching between structures and I/O mappings is supported. For example, you can define a structure variable whose members have the same order and types as the variables in the I/O mapping area, allowing all I/O mappings to be bound in one step.
- After successful binding, the default address assigned to this I/O mapping becomes invalid.

Information

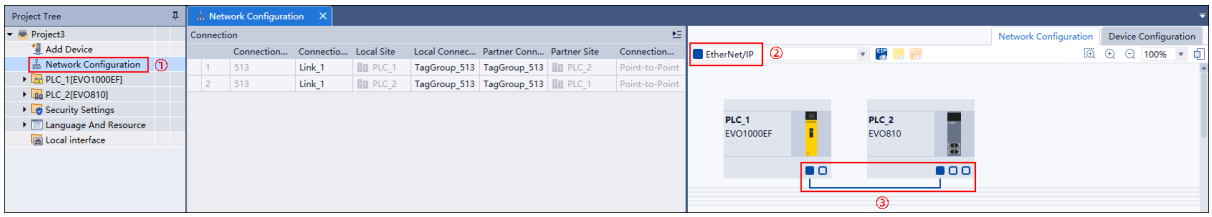
This tab displays general information and images of the I/O module.

11.4.3 EtherNet/IP Communication Configuration

11.4.3.1 Standard EtherNet/IP Communication Configuration

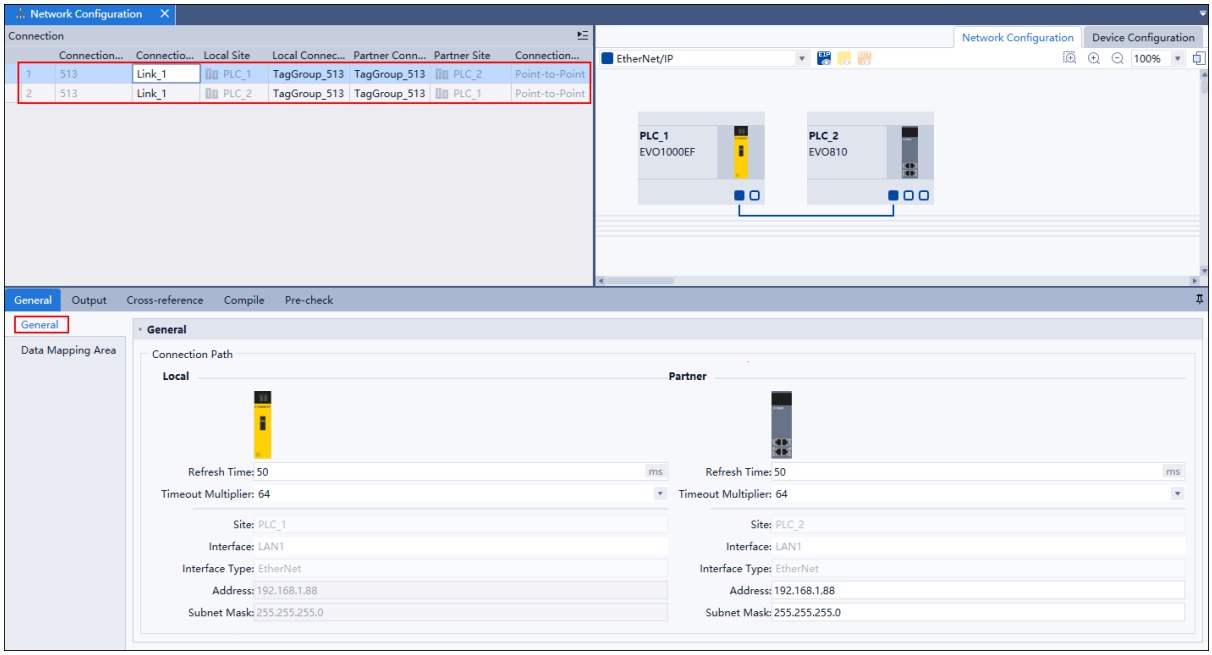
11.4.3.1.1 EtherNet/IP Communication Between PLCs

The EVO1000EF series safety PLC supports communication with standard PLCs via the EtherNet/IP protocol. Users can configure communication through network configuration. Communication configuration includes the following two scenarios:



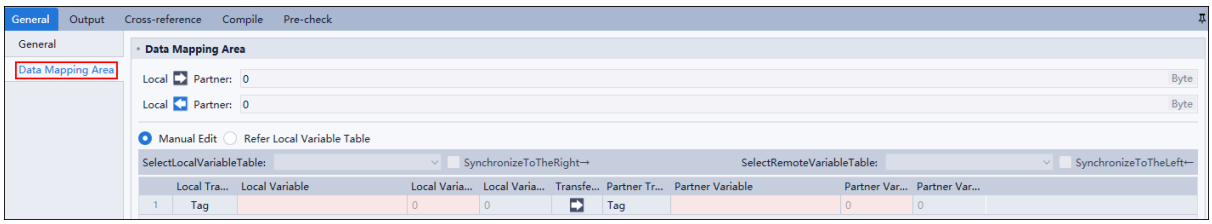
- The safety PLC and standard PLC devices are in the same project.
- The safety PLC and standard PLC devices are in different projects.

NOTE



- Only the LAN1 port of the safety PLC supports EtherNet/IP communication with standard PLCs.
- Data sent from the safety PLC to the standard PLC can be either of safety type or standard type.
- Data received by the safety PLC from the standard PLC can only be of standard type; otherwise, the safety PLC program will report a compilation fault.
- The LAN1 port of the safety PLC and the network port of the standard PLC are in the same network segment.
- The LAN1 port and the EIP2 network port of the safety PLC can be in the same network segment, but their IP addresses must not be the same.

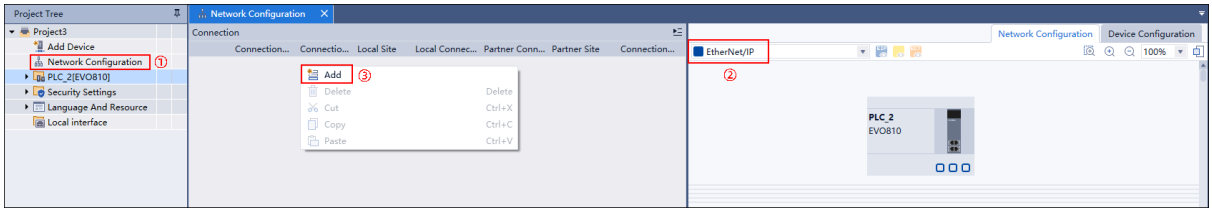
EtherNet/IP communication configuration for PLCs in the same project



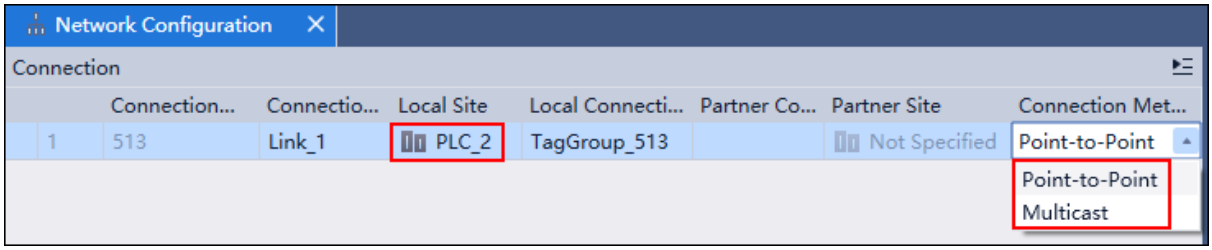
1. Create a project and add a safety PLC and standard PLC (using the EVO800 series large-scale PLC as an example).
2. Double-click "Network configuration" in the project tree, and select "EtherNet/IP" communication from the drop-down menu.
3. Select the LAN1 port of the safety PLC, drag and connect it to the network port of the large-scale PLC to establish an EtherNet/IP connection.

4. In the "Connection" area, the newly created EtherNet/IP connection information is displayed, including connection ID, connection name, local/partner site, local/partner connection ID, and connection method.
5. Select the connection, and in the "General" tab below, configure the EtherNet/IP communication refresh cycle and timeout multiplier, and verify the IP address and subnet mask information.

6. In the "Data mapping area" tab, configure the data mapping relationship between the communication parties by binding variables. Click the cell in the "Transfer direction" column to switch the data transfer direction.

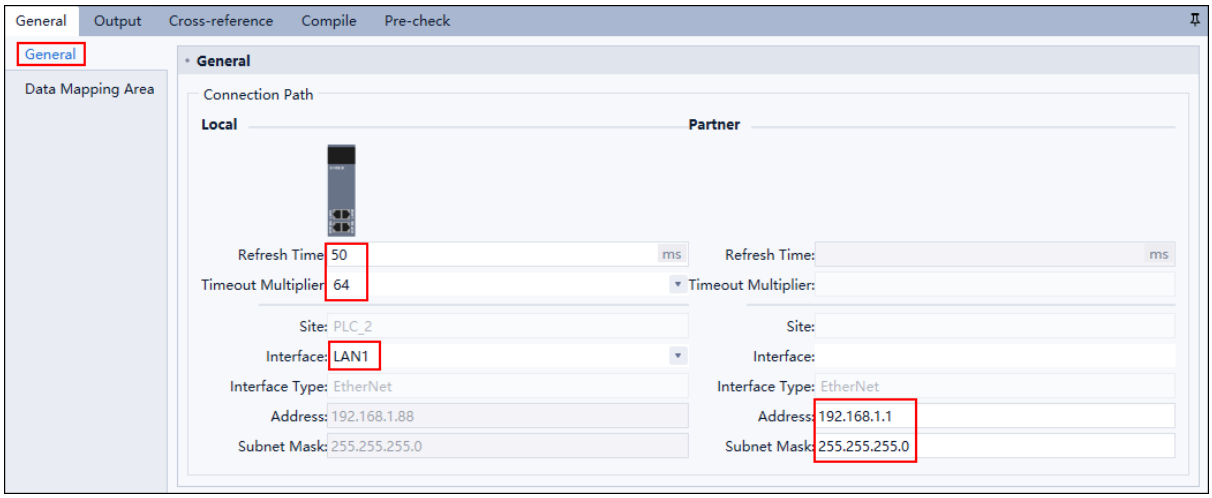


> **NOTE**
>
> The above drag-and-drop connection method only applies to "point-to-point" EtherNet/IP communication.



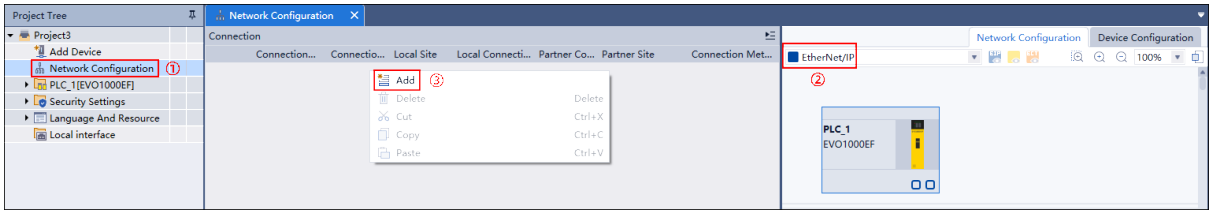
EtherNet/IP communication configuration for PLCs in different projects

- **Standard PLC configuration (using the EVO800 series large-scale PLC as an example)**

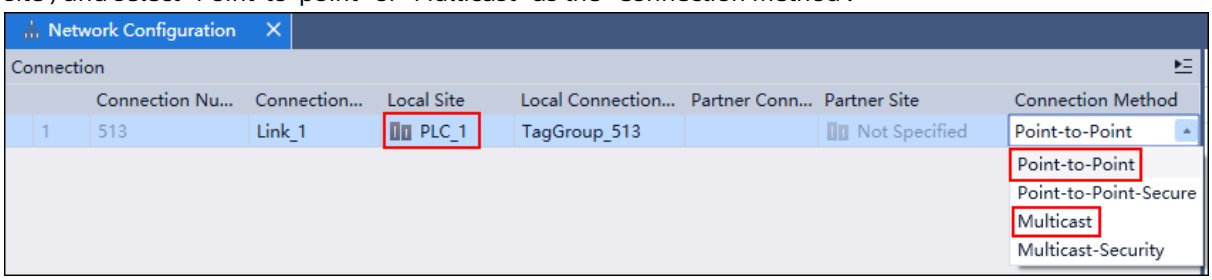


1. Create a project and add the EVO800 series large-scale PLC.
2. Double-click "Network configuration" in the project tree, and select "EtherNet/IP" communication from the drop-down menu.
3. Right-click a blank area in the "Connection" area, and select "Add" to create an EtherNet/IP connection.

4. In the newly created EtherNet/IP connection, select the large-scale PLC used for communication as the "Local site", and select "Point-to-point" or "Multicast" as the "Connection method".



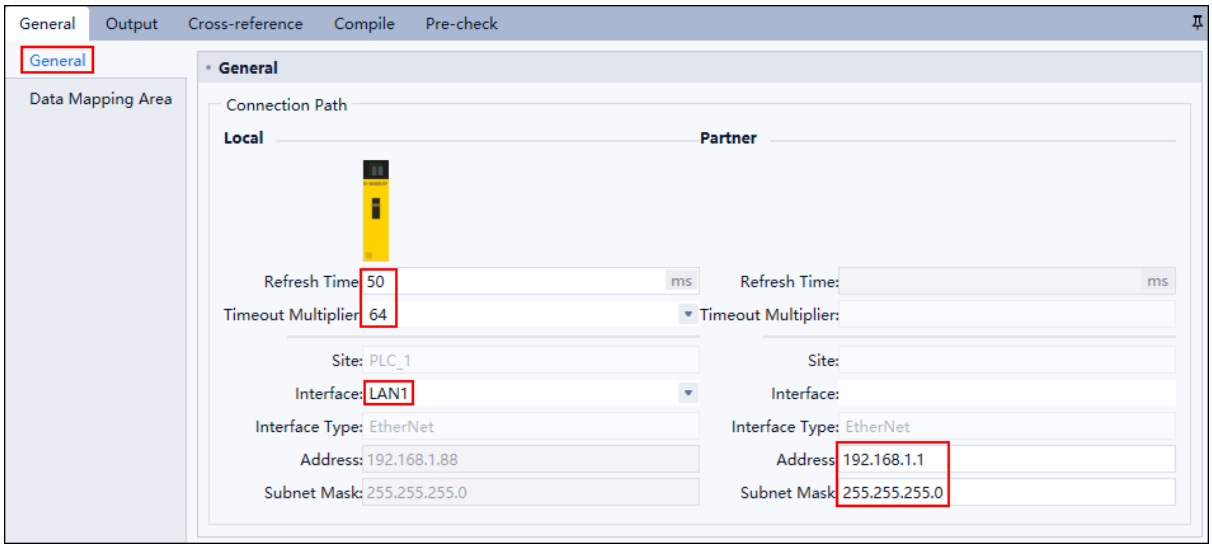
5. Select the connection, and in the "General" tab below, configure the EtherNet/IP communication refresh cycle and timeout multiplier.
6. In the "Interface" drop-down menu, select the network port for communication from "LAN1", "LAN2", or "EIP3".
7. Enter the IP address and subnet mask of the target safety PLC in the fields for partner address and subnet mask.



8. In the "Data mapping area" tab, configure the data mapping relationship between the communication parties by binding variables. Click the cell in the "Transfer direction" column to switch the data transfer direction.

- **EVO1000EF series safety PLC configuration**

1. Create a project and add a safety PLC device.
2. Double-click "Network configuration" in the project tree, and select "EtherNet/IP" communication from the drop-down menu.
3. Right-click a blank area in the "Connection" area, and select "Add" to create an EtherNet/IP connection.



4. In the newly created EtherNet/IP connection, select the safety PLC used for communication as the "Local site", and select "Point-to-point" or "Multicast" as the "Connection method".

NOTE

The "Point-to-point-safety" and "Multicast-safety" connection methods indicate communication based on the CIP Safety protocol. The CIP Safety protocol is supported only by safety PLCs. For details, see 11.4.3.2.2 Safety CIP Safety Communication.

5. Select the connection, and in the "General" tab below, configure the EtherNet/IP communication refresh cycle and timeout multiplier.
6. In the "Interface" drop-down menu, only "LAN1" can be selected.
7. Enter the IP address and subnet mask of the target large-scale PLC in the fields for partner address and subnet mask.

8. In the "Data mapping area" tab, configure the data mapping relationship between the communication parties by binding variables. Click the cell in the "Transfer direction" column to switch the data transfer direction.

11.4.3.1.2 EtherNet/IP Communication with HMI

The safety PLC only supports connecting to HMI via the LAN1 port of the EIP or ECT communication unit. When the safety PLC communicates with HMI via EtherNet/IP, an EIP Adapter service node is generated under the LAN1 port of the safety PLC. The configuration method for EtherNet/IP communication between the safety PLC and HMI is the same as those for the standard PLC. Only the functional differences are described here. For other common functions, see 10.6.4.2.7 Communication with HMI in the "PLC Programming" chapter.

NOTE

- The HMI supports reading and writing standard data type variables in the safety PLC, but only supports reading safety data type variables.
- When the HMI attempts to write to a safety variable, the safety PLC runtime rejects the operation and returns a failure.
- For the first download, the safety PLC project configured with the EtherNet/IP Adapter must be downloaded before the HMI can be downloaded.

11.4.3.2 Safety CIP Safety Communication Configuration

11.4.3.2.1 Overview

CIP Safety

CIP Safety is a safety communication extension based on CIP (Common Industrial Protocol), primarily used for secure data transmission between safety devices in industrial automation. It is especially suitable for communication scenarios between safety PLCs and other safety devices (including but not limited to safety PLCs), with transmitted data limited to safety types (such as emergency stop signals, safety door status, and safety interlock commands). It is designed to enable reliable interaction of safety data over standard CIP networks (such as EtherNet/IP) without requiring a dedicated safety network, while strictly ensuring communication security.

Core features

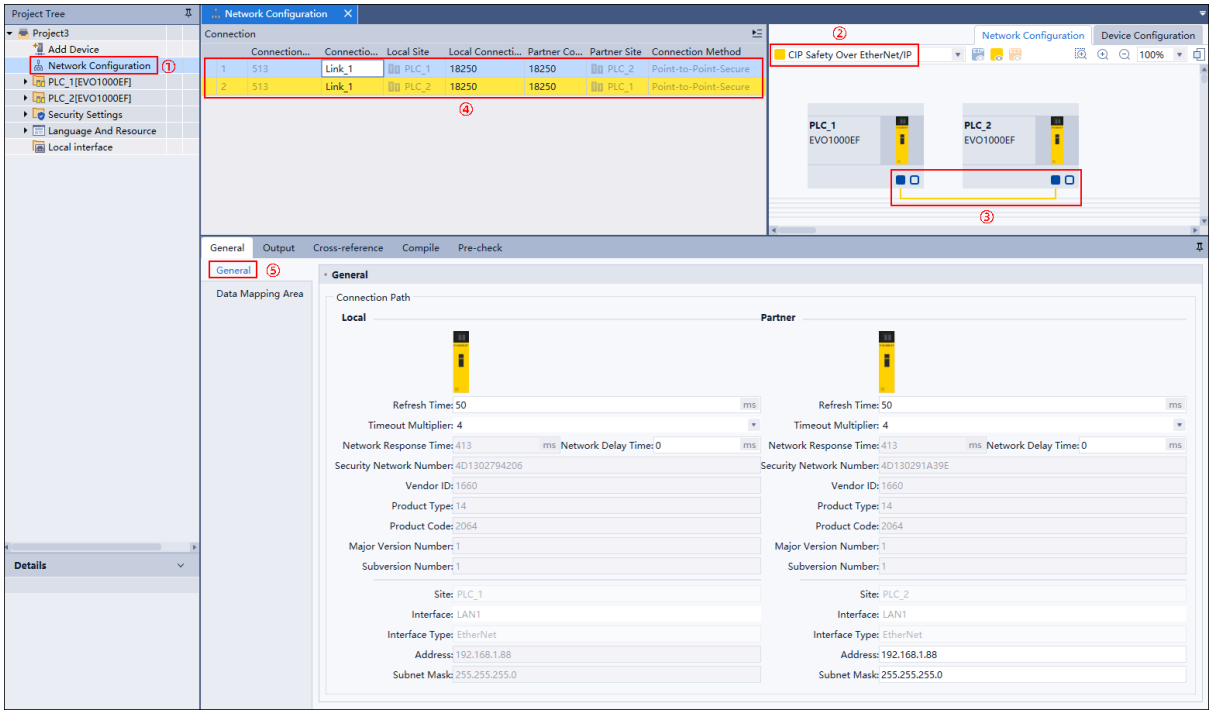
- Communication objects and data types
  CIP Safety is specifically designed for interaction between safety devices (such as safety PLCs and safety I/O modules). It only transmits safety-related data (non-safety data is transmitted via standard CIP channels), ensuring logical independence of safety data.
- Safety mechanisms
  Based on the characteristics of safety data, CIP Safety applies CRC check, device identity authentication, timestamp anti-replay, and timeout detection to ensure data integrity, authenticity, and timeliness, eliminating safety risks caused by communication anomalies (such as data tampering, delay, or forgery).
- Core roles in safety PLCs
  CIP Safety serves as a critical channel for transmitting safety commands and statuses between the safety PLC and upstream/downstream safety devices (such as another safety PLC or safety I/O modules), ensuring the reliable implementation of core safety functions such as emergency stop and safety interlock. By limiting the scope of safety data transmission and enhancing the safety interaction mechanism between devices, CIP Safety provides efficient and compliant communication assurance for safety PLCs within safety control systems, serving as a key technology for industrial functional safety systems.

CIP Safety Scanner

CIP Safety Scanner is a core component responsible for managing and controlling safety device networks in industrial automation safety communications. Integrated in safety PLCs, it acts as the "master device" in the CIP Safety communication architecture. It is primarily used to configure and monitor safety slave devices (such as Hi50 couplers and remote safety I/O modules) in the network, establish and maintain safety communication connections with these devices. Through standardized safety communication logic, it coordinates data interaction between safety devices and ensures the functional safety of industrial control systems.

11.4.3.2.2 CIP Safety Communication Between PLCs

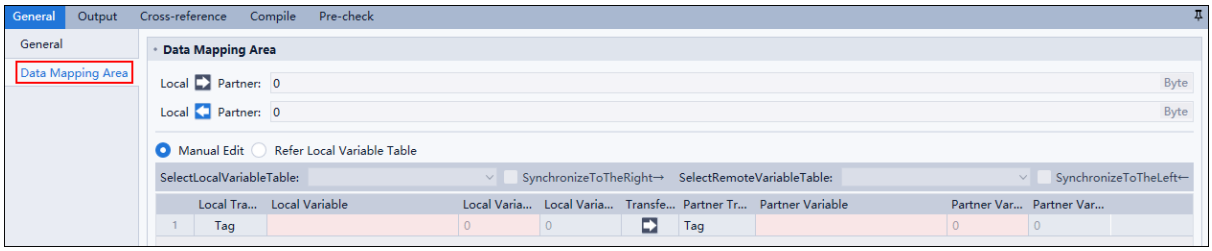
CIP Safety communication is supported among multiple safety PLCs. Users can configure communication via network configuration. Communication configuration includes the following two scenarios:



- Multiple safety PLCs are in the same project.

- Multiple safety PLCs are in different projects.

> **NOTE**
>
> - When safety PLC devices communicate via CIP Safety, only safety-type data can be transmitted.
> - Both the LAN1 and EIP2 ports of the safety PLC support CIP Safety communication, with each port supporting up to 16 safety connections.

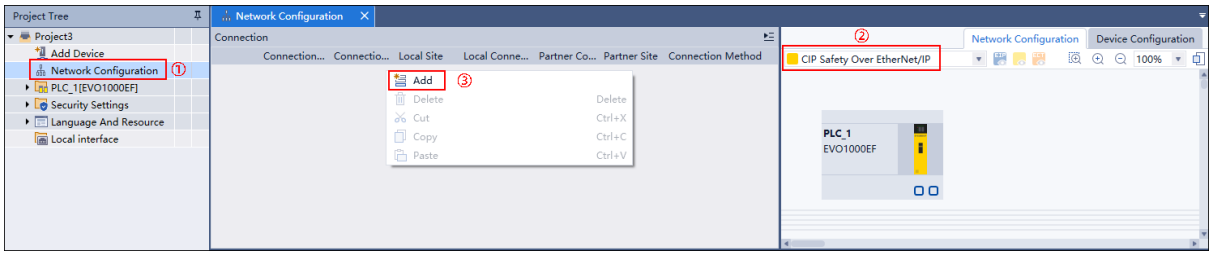


CIP Safety communication configuration for safety PLCs in the same project

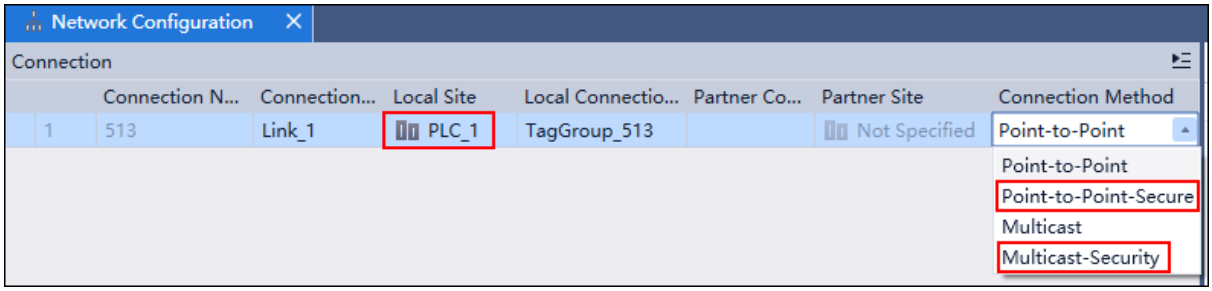
1. Create a project and add two safety PLC devices.
2. Double-click "Network configuration" in the project tree, and select "CIP Safety Over EtherNet/IP" communication from the drop-down menu.
3. Connect the LAN1 or EIP2 ports of the two safety PLCs by dragging to establish CIP Safety communication between the two safety PLCs. The following takes the LAN1 port as an example.
4. In the "Connection" area, the newly created CIP Safety connection information is displayed, including connection ID, connection name, local/partner site, local/partner connection ID, and connection method.
5. Select the connection, and in the "General" tab below, configure the CIP Safety communication parameters, including refresh time, timeout multiplier, network latency time, IP address, and subnet mask.

> **CAUTION**
>
> The "Refresh time" must be a common multiple of the task cycles of both safety PLCs; otherwise, communication timeout may occur.

6. In the "Data mapping area" tab, configure the data mapping relationship between the communication parties by binding variables. Click the cell in the "Transfer direction" column to switch the data transfer direction.

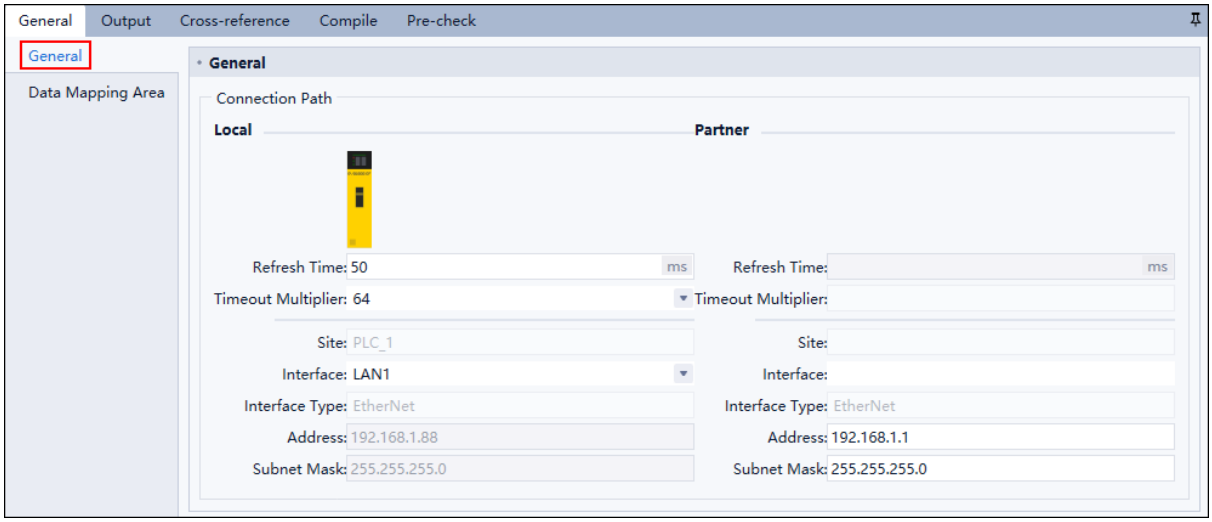


NOTE

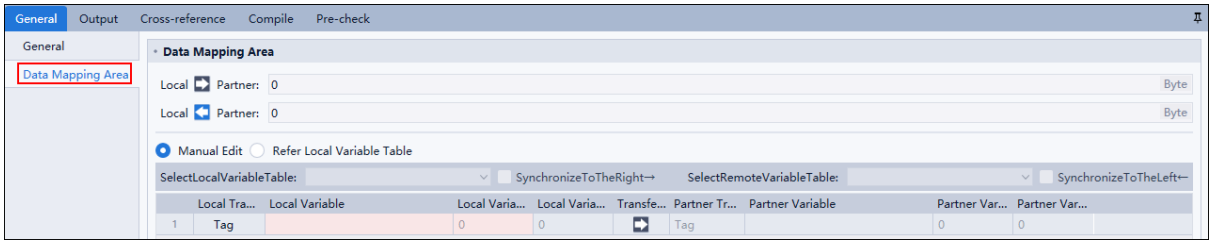


The above drag-and-drop connection method only applies to "Point-to-point-safety" CIP Safety communication.

CIP Safety communication configuration for safety PLCs in different projects



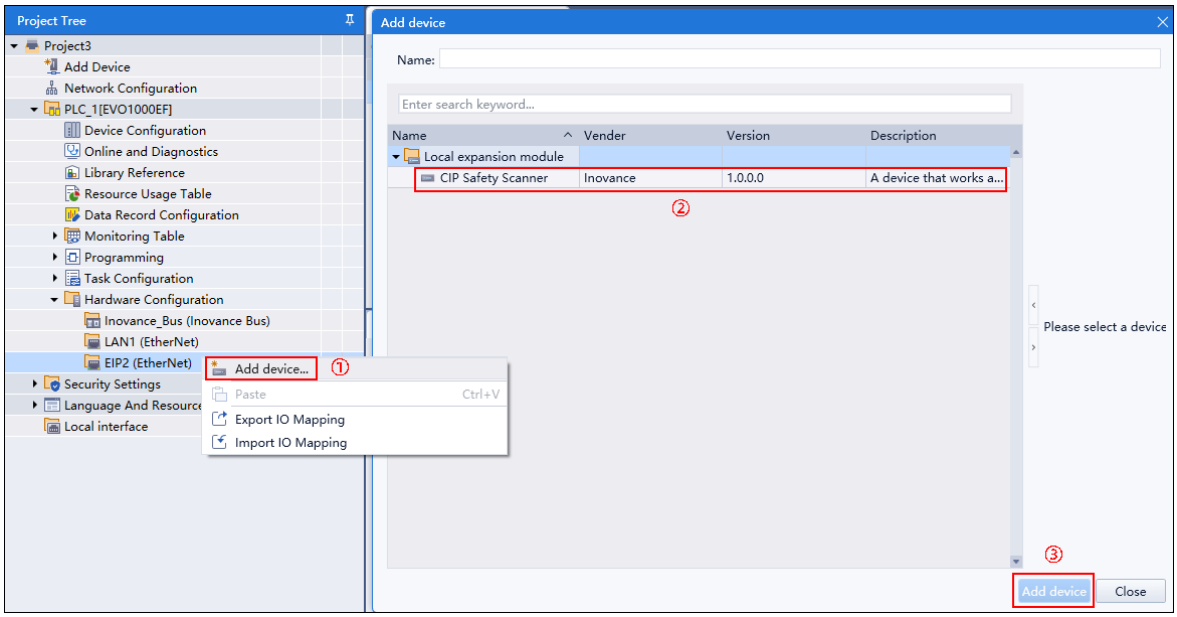
1. Create a project and add a safety PLC device.
2. Double-click "Network configuration" in the project tree, and select "CIP Safety Over EtherNet/IP" communication from the drop-down menu.
3. Right-click a blank area in the "Connection" area, and select "Add" to create a CIP Safety connection.



4. In the newly created connection, select the safety PLC used for communication as the "Local site," and select "Point-to-point-safety" or "Multicast-safety" as the "Connection method".

5. Select the connection, and in the "General" tab below, configure the communication parameters for the local and partner PLCs.
   The communication parameters for the local PLC include refresh time, timeout multiplier, network delay time, and interface. The device parameters for the partner PLC include safety network number, vendor ID, product type, IP address and subnet mask.

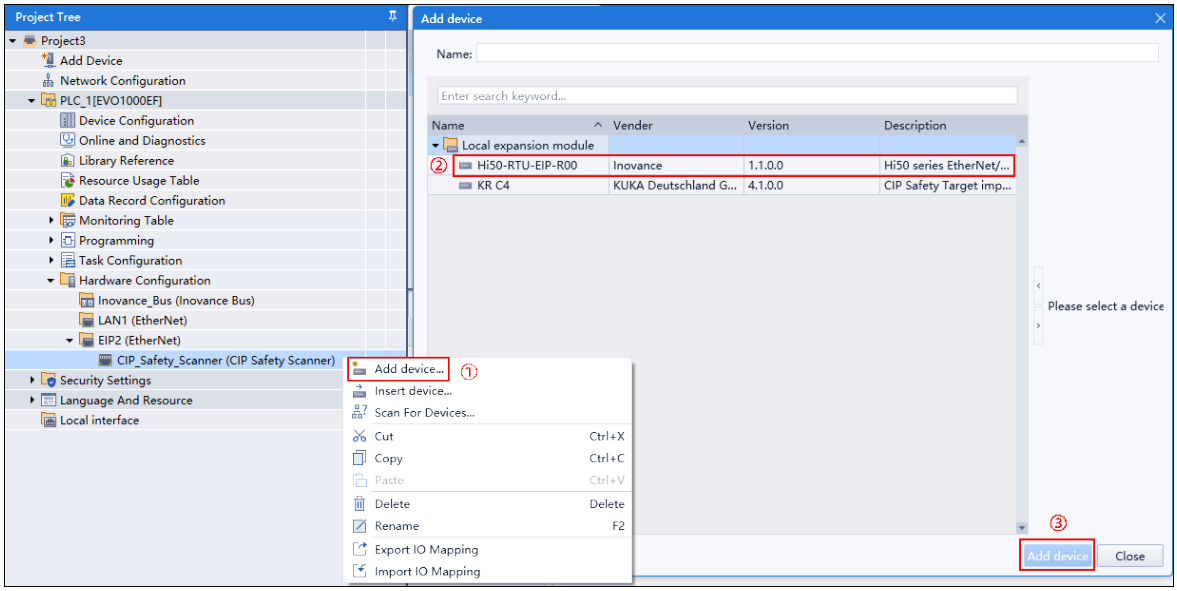
6. In the "Data mapping area" tab, configure parameters such as local variables and transfer direction.



11.4.3.2.3 Adding a Remote CIP Safety Device

The Hi50-RTU-EIP-R00 module is a Hi50 series EIP coupler, used to add and manage remote safety I/O modules. The addition methods for the coupler include manual addition in the project tree and device scanning. Besides these two methods, remote safety I/O modules can also be added via the device configuration view.

Manual addition



1. Add a "CIP_Safety_Scanner" node.
   a. Right-click the "EIP2 (EtherNet)" node under "Hardware configuration" node in the project tree, and select "Add device".
   b. In the pop-up window, select "CIP_Safety_Scanner", and click "Add device".

2. Add the Hi50-RTU-EIP-R00 coupler.

   a. Right-click the "CIP_Safety_Scanner" node, and select "Add device".

   b. In the pop-up window, select "Hi50-RTU-EIP-R00", and click "Add device".

3. Add a remote safety I/O module.

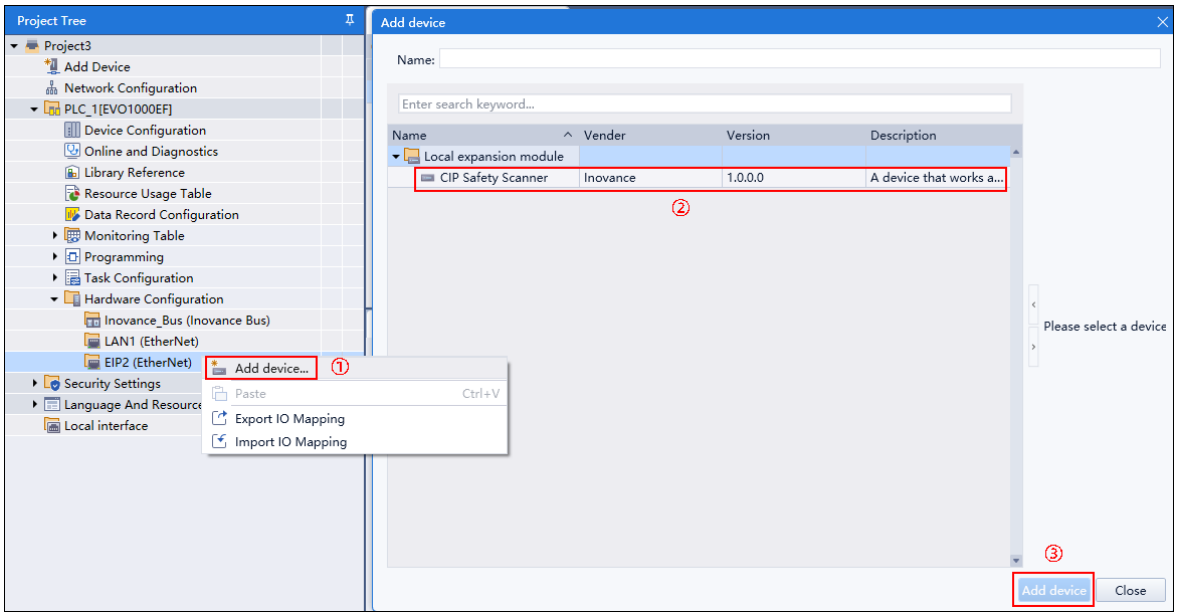
   a. Right-click the "Hi50-RTU-EIP-R00" node, and select "Add device".

   b. In the pop-up window, select the required safety I/O module, and click "Add device".

Addition via device scanning

The iFA Evolution software provides an automatic scanning function for safety I/O modules, allowing users to directly add modules by scanning.

Prerequisites



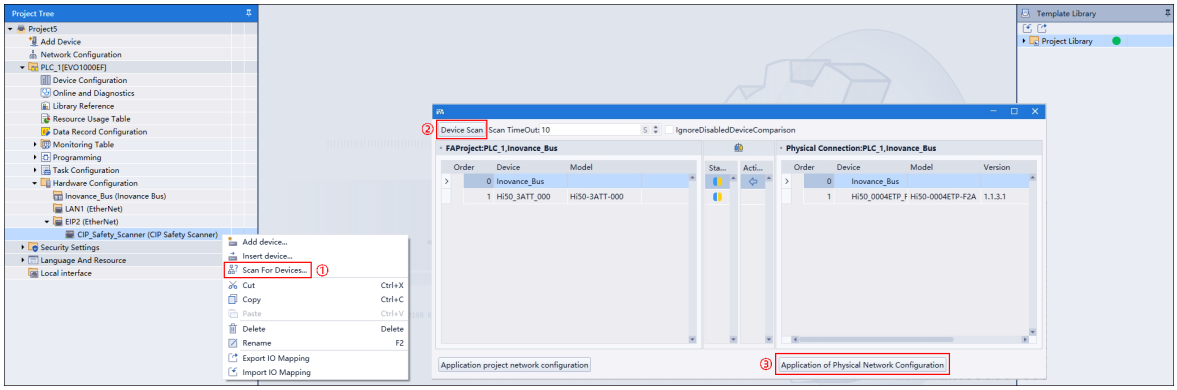
- A blank project containing the "CIP_Safety_Scanner" node has been deployed to the target safety PLC.
- The user program of the safety PLC is in the stopped state.

Procedure

1. Add a "CIP_Safety_Scanner" node.

   a. Right-click the "EIP2 (EtherNet)" node under "Hardware configuration" node in the project tree, and select "Add device".

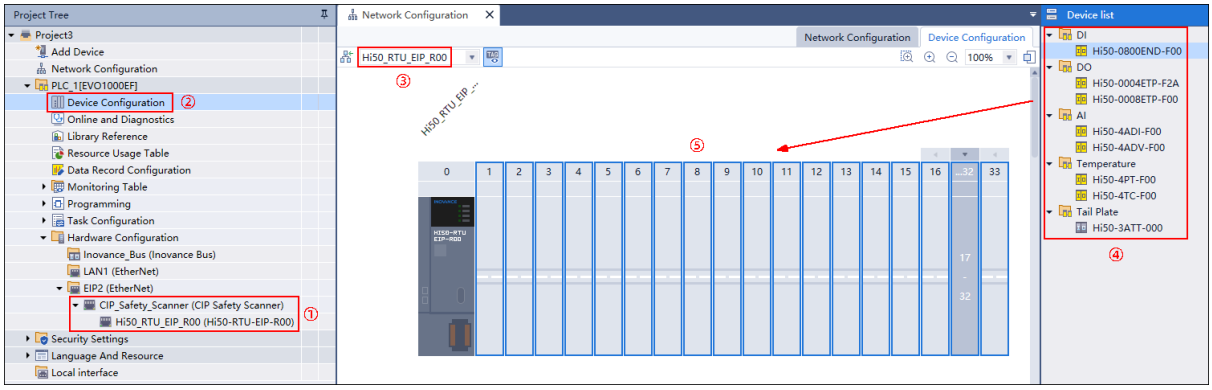
b. In the pop-up window, select "CIP_Safety_Scanner", and click "Add device".



2. Add a remote safety I/O module via device scanning.

a. Right-click the "CIP_Safety_Scanner" node, and select "Scan for devices".

b. In the pop-up window, click "Device scanning" and synchronize all scanned I/O modules into the current project.

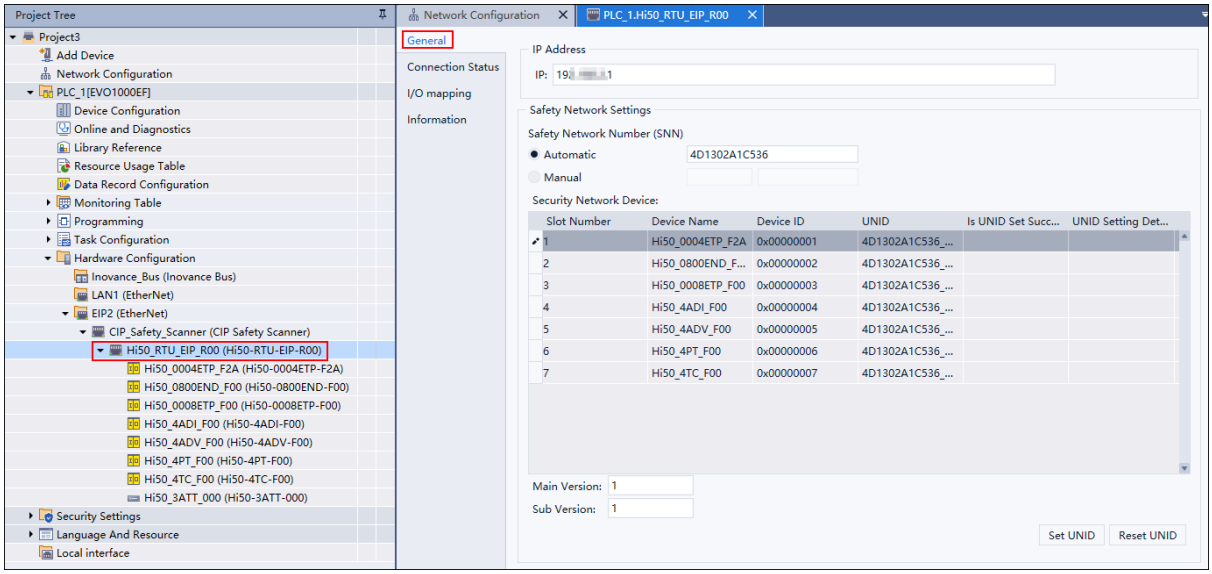


c. In the pop-up confirmation window, click "Yes" to restore the synchronized device configuration to default.

d. Click "OK" to add the safety I/O module to the project.

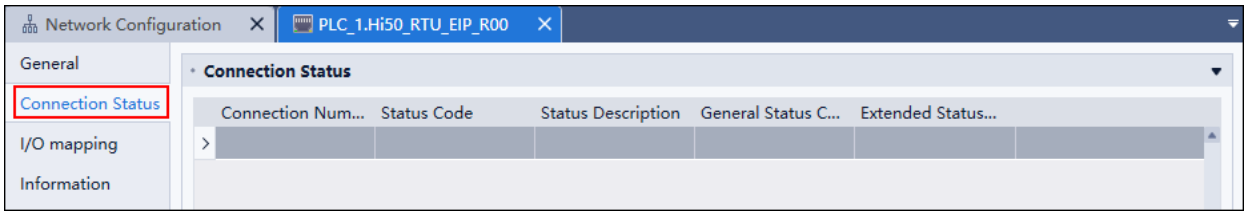
Addition via device configuration view

1. Add the "CIP_Safety_Scanner" node and the "Hi50-RTU-EIP-R00" coupler under "Hardware configuration > EIP2 (EtherNet)" of the corresponding device in the project tree.
2. Double-click the "Device configuration" node in the project tree.
3. In the device configuration view, select the "Hi50-RTU-EIP-R00" coupler device.
4. In the right device list, select the module. When a module is selected, the insertable slots for the module are highlighted in the configuration diagram.
5. In the device list, double-click a module to add it to the nearest available slot adjacent to the PLC. You can also drag the module from the device list to an available slot in the device configuration view.



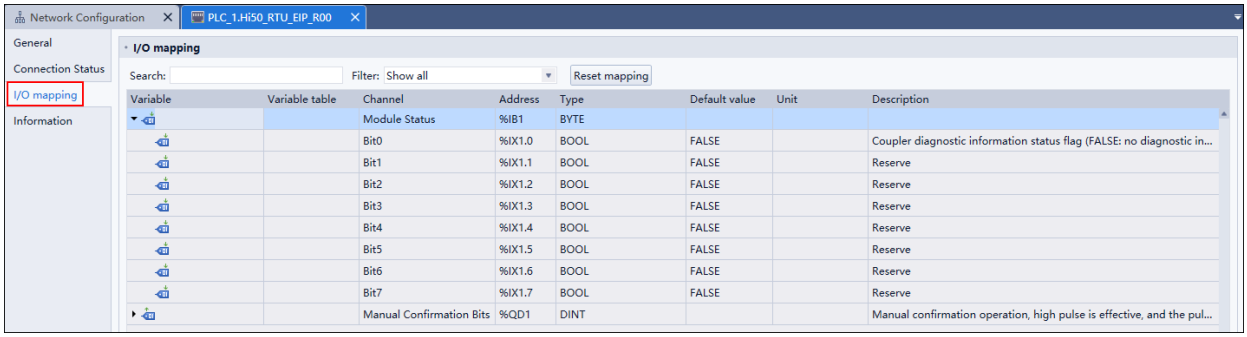
11.4.3.2.4 Configuring a Remote CIP Safety Device

The "CIP_Safety_Scanner" node is used to add safety Hi50 couplers (such as Hi50-RTU-EIP-R00) and configure remote safety I/O modules. The safety Hi50 coupler supports configuration of IP address, safety network number (SNN), and setting UNID for remote safety I/O modules. Configuration of remote safety I/O modules is the same as for local safety I/O modules. See 11.4.2.7 Safety I/O Module Configuration for details. The following describes the configuration related to the safety Hi50 coupler.



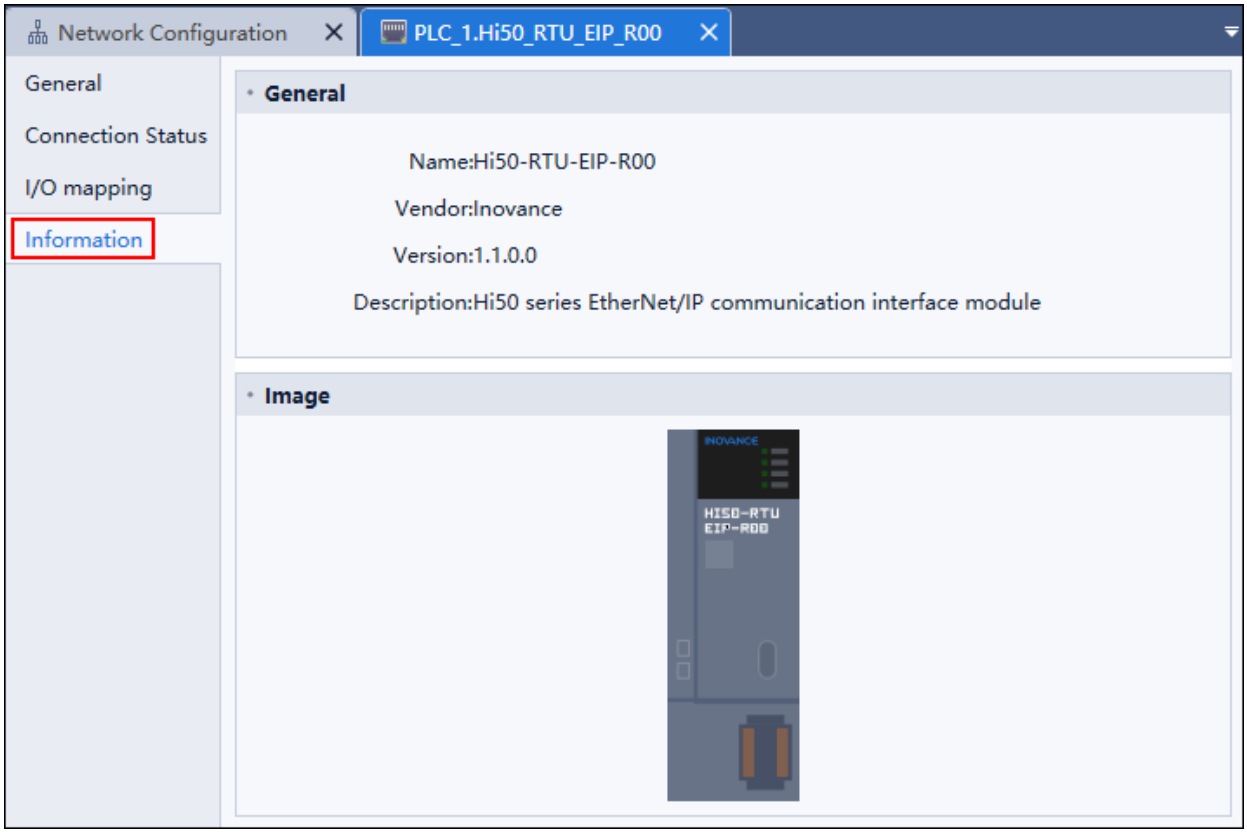
General settings

1. Double-click the "Hi50-RTU-EIP-R00" node under "Hardware configuration > EIP2" in the project tree.
2. In the pop-up coupler configuration page, select the "General" tab.
3. IP address: The coupler's IP address must be in the same subnet as the safety PLC device.
4. Safety network number (SNN): Supports automatic and manual assignment methods.
   - Automatic assignment: SNN is automatically generated based on the current system time.
   - Manual assignment: The first input box is fixed at 1, and the second allows values from 1 to 9999.
5. The safety network device list below displays slot numbers, device names, device IDs, UNIDs, and other information for each remote safety I/O module.
   When adding remote safety I/O modules, UNIDs are automatically assigned. After modifying the SNN, the UNID must be reset before configuration so that the new UNID can be successfully assigned to each module.
6. Click the "Reset UNID" button and confirm that the UNIDs of all remote safety I/O modules have been successfully reset.
7. Click the "Set UNID" button and confirm that the UNIDs of all remote safety I/O modules have been successfully set.



Connection status

This tab displays the coupler's connection status, including status codes and descriptions.

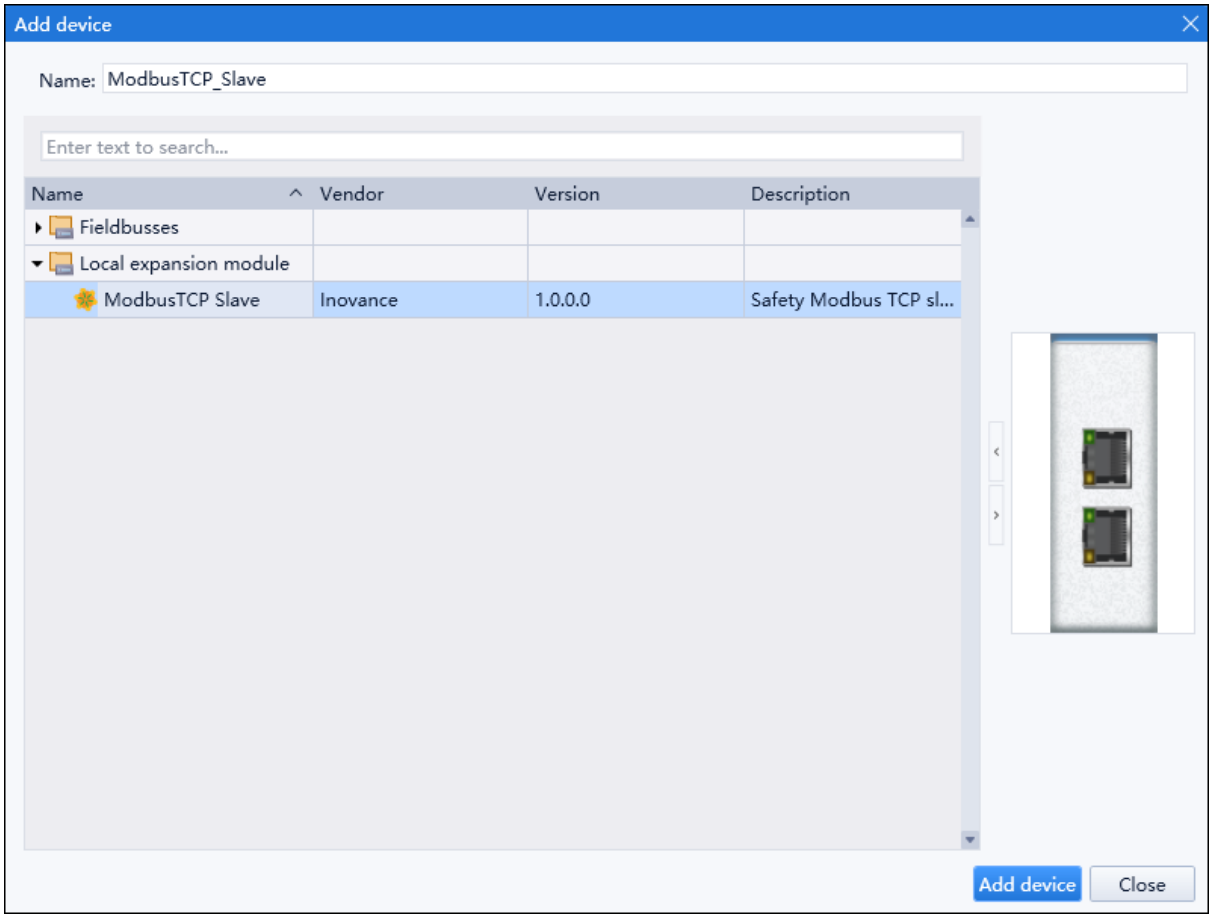


I/O Mapping

This tab is used to view I/O mapping variable information for on-site signal acquisition. The information supports keyword search, condition-based filtering, and resetting. For detailed configuration parameter descriptions, see 10.6.3.2.8 I/O Mapping.

Information

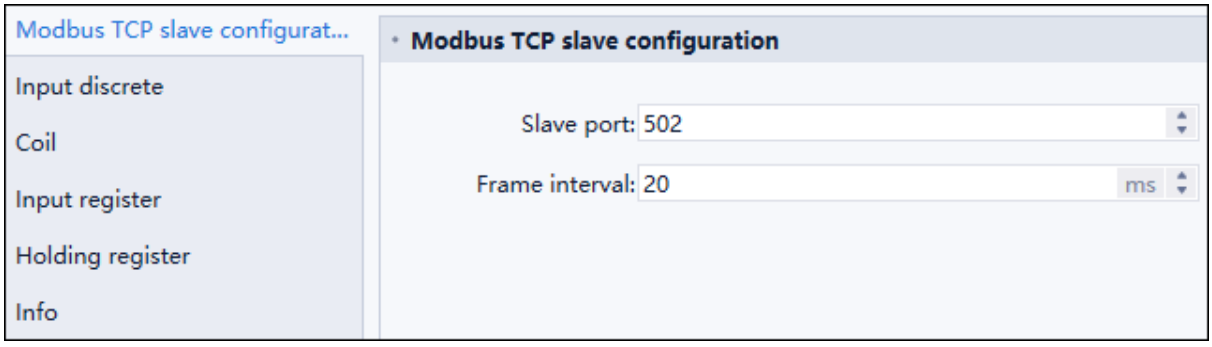
This tab displays the coupler's general information and image.



11.4.3.3 Modbus TCP Communication Configuration

The Modbus TCP communication configuration method for a safety PLC is the same as that of a standard PLC. Only the functional differences are introduced here. For other common functions, see 10.6.4.1 Modbus-TCP Communication Configuration in the "PLC Programming" chapter.

- The Modbus TCP Slave only supports configuration-based operation and does not support instruction-based operation.
- The maximum number of variables that the Modbus TCP Master can access is the number of public variables of the safety PLC.



Adding Modbus TCP Slave

1. In the project tree on the left, select "Hardware configuration > Inovance_Bus > LAN1 (EtherNet)" of a safety PLC, and select "Add device".
2. Double-click "ModbusTCP slave" or select it and click "Add device".

Configuring Modbus TCP Slave

1. Double-click the added "Modbus TCP Slave" node to open the "Modbus TCP slave configuration" page by default.

2. Configure the related parameters as needed.

Variables	Requirements
Starting Address	◦ Input discrete values: The input range is 0 to 65535, which is automatically converted to 1x0 to 1x65535. ◦ Coils: The input range is 0 to 65535, which is automatically converted to 0x0 to 0x65535. ◦ Input registers: The input range is 0 to 65535, which is automatically converted to 3x0 to 3x65535. ◦ Holding registers: The input range is 0 to 65535, which is automatically converted to 4x0 to 4x65535.

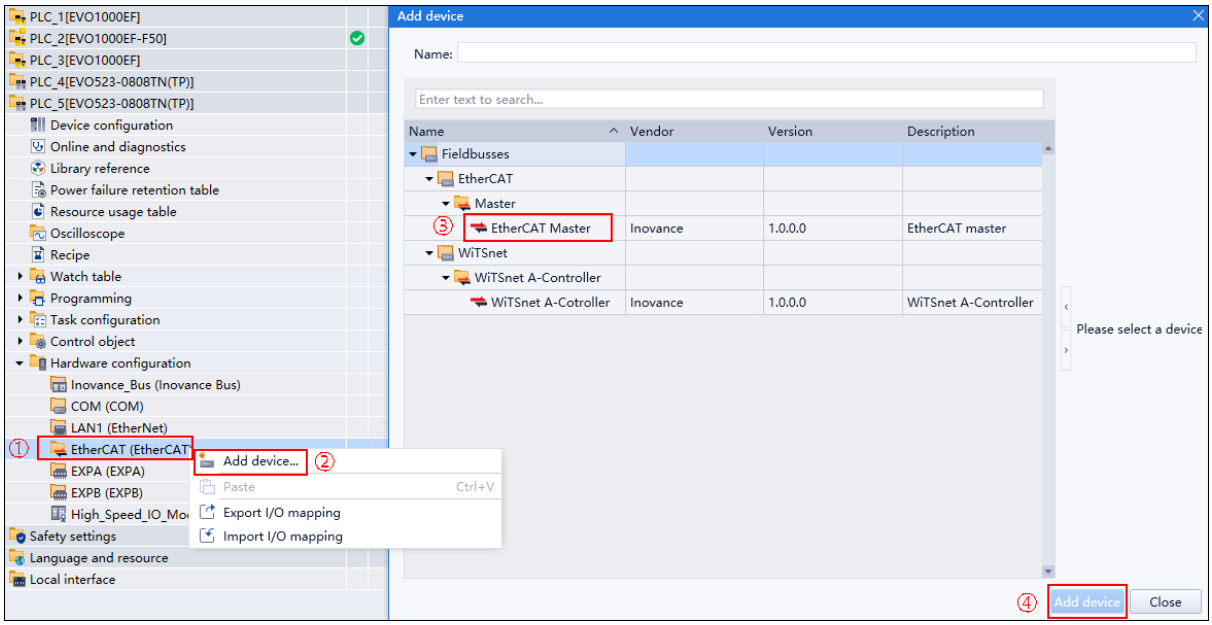
Variables	Requirements
Modbus address	Automatically generated and can be modified.
Variable	◦ Input discrete values: Select BOOL and SAFEBOOL variables with public property of "Read-Only" or "Read/Write". ▪ Binding method: Drop-down selection, drag-and-drop from the detail view, copy-paste from the variable table. ▪ Exception: If the public property of the current variable does not meet the requirements, or if the selected type is not BOOL or SAFEBOOL, a fault will occur. ◦ Coils: Select BOOL variables with public property of "Write-Only" or "Read/Write". If the public property of the current variable does not meet the requirements, or if the selected type is not BOOL, a fault will occur. ◦ Input registers: Select WORD and INT variables with public property of "Write-Only" or "Read/Write". If the public property of the current variable does not meet the requirements, or if the selected type is not WORD or INT, a fault will occur. ◦ Holding registers: Select WORD and INT variables with public property of "Write-Only" or "Read/Write". If the public property of the current variable does not meet the requirements, or if the selected type is not WORD or INT, a fault will occur.
Data Type	Automatically filled based on the selected variable name, and cannot be modified.
Comment	Automatically filled based on the selected variable name, and cannot be modified.
Variable table	Automatically filled based on the selected variable name, and cannot be modified.
Data read/ write requirements	◦ Modbus Master can perform read and write operations on standard data type variables within the safety PLC. ◦ Modbus Master can only perform read operations on safety data type variables within the safety PLC.

11.4.4 EtherCAT Communication Configuration

Based on the relationship between FSoE and the EtherCAT protocol, and the fact that an EtherCAT network has only one master, the EVO1000EF must be connected to a standard PLC that supports the EtherCAT protocol. In a safety PLC project, the standard PLC serves as the EtherCAT master, while the safety PLC, Hi50 coupler, GL20, GL10, and other standard I/O couplers serve as EtherCAT slaves. The safety PLC also serves as the FSoE master, with failsafe I/O modules or safety servo modules serving as FSoE slaves.

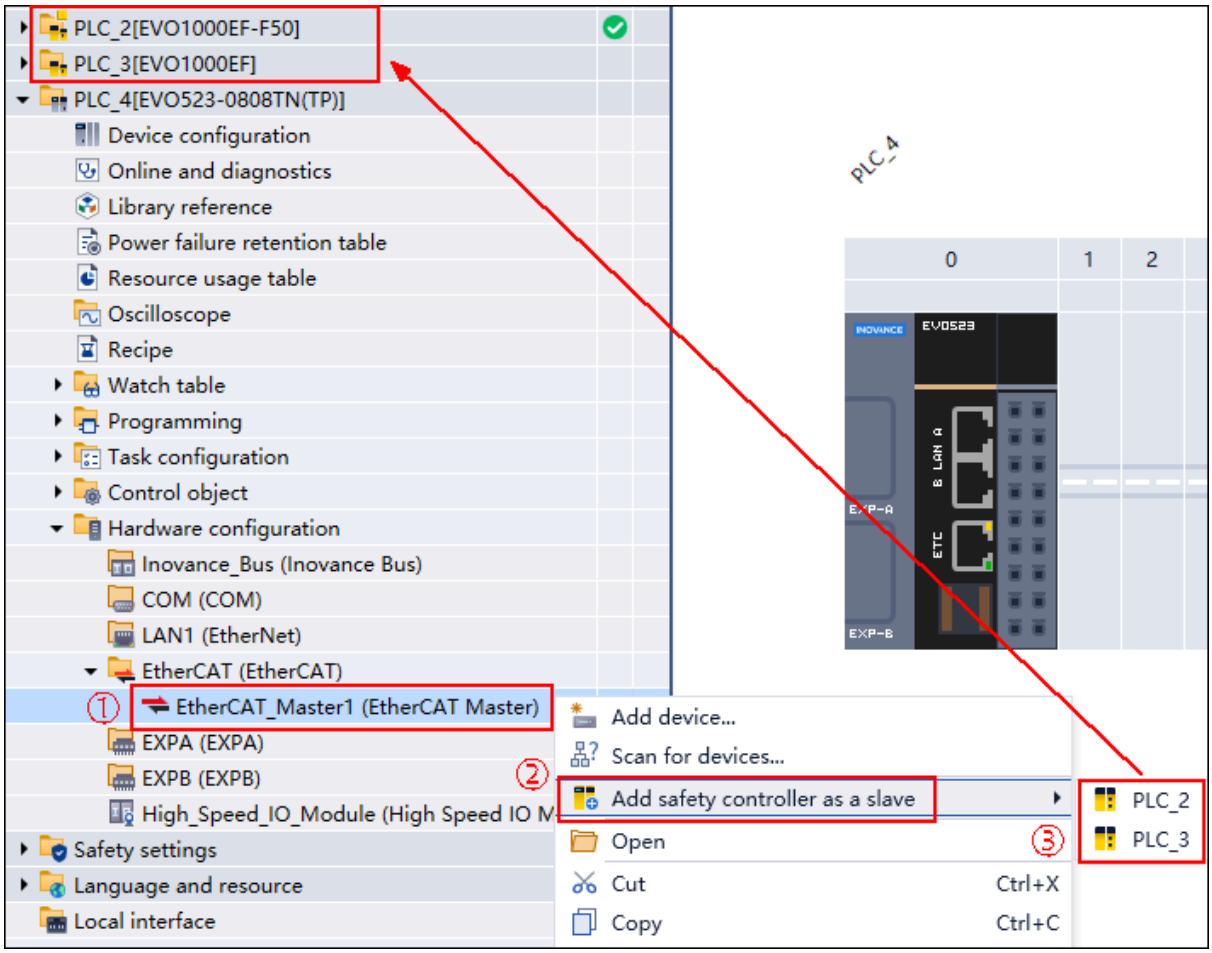
11.4.4.1 Configuring a Safety PLC as an EtherCAT Slave of a Standard PLC

A standard PLC and up to 8 safety PLCs form a control system. The supported standard PLC series are: EVO500, EVO700, EVO700C, and APC. The EtherCAT ports of the standard PLCs listed above that can act as the



EtherCAT master must support configuring multiple models of the EVO1000EF series safety PLCs as EtherCAT slaves.

- After an independent safety PLC is configured as an EtherCAT slave under a standard PLC, the name of the slave and the name of the safety PLC in the project tree are automatically synchronized when either is modified.
- If the safety PLC node of the EtherCAT slave under the standard PLC is deleted, the slave relationship will be terminated, but the hardware and software of the independent safety PLC in the project tree will remain unchanged.
- If the independent safety PLC in the project tree is deleted, the safety PLC node of the EtherCAT slave under the standard PLC will be automatically deleted.
- Under an independent safety PLC in the project tree, the following devices cannot be added, deleted, or renamed: communication units, local I/O, remote couplers, and remote I/O. Independent safety PLCs that are not configured as EtherCAT slaves of a standard PLC can freely add local and remote slaves (servos, couplers, I/O).
- The EtherCAT slave node of a safety PLC under a standard PLC does not support copy and paste. An independent safety PLC not configured as an EtherCAT slave under a standard PLC supports copy and paste.
- Device changes to the independent safety PLC in the project tree will be automatically reflected in its slave node under the standard PLC.

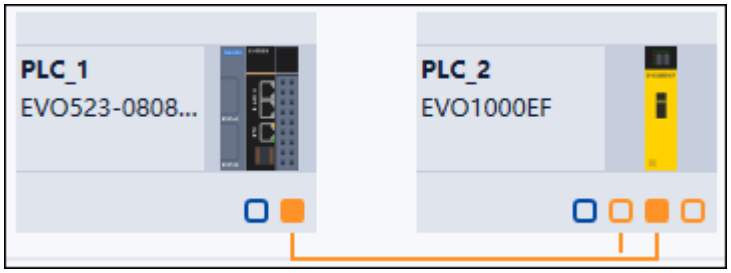


11.4.4.1.1 Configuring an Independent Safety PLC as an EtherCAT Slave

Method 1: Configuring via the project tree

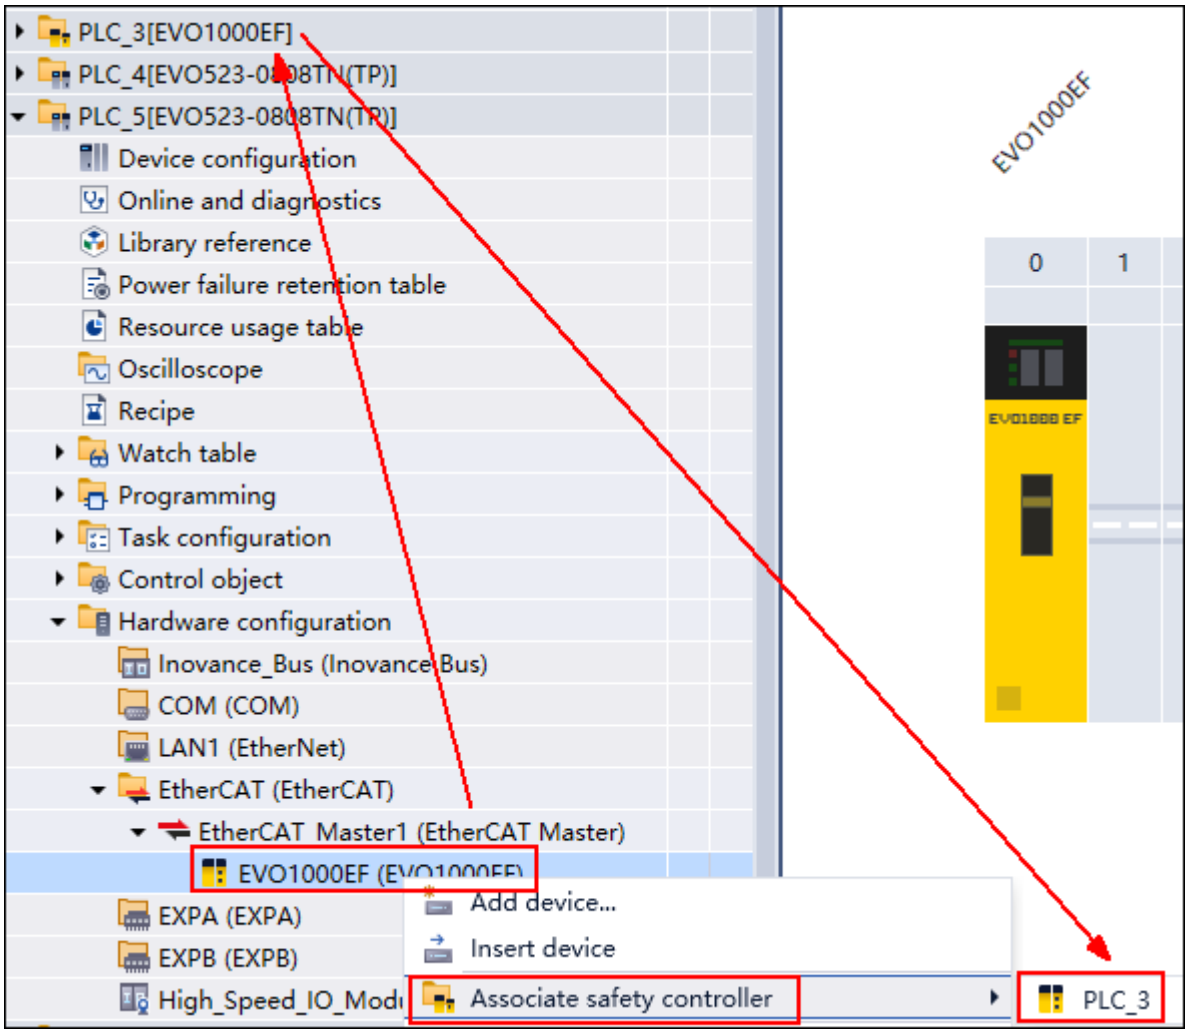
1. Create a project and add a safety PLC device and a standard PLC device.
2. Right-click "EtherCAT" under "Hardware configuration" of the standard PLC in the project tree, and select "Add device".
3. Select "EtherCAT Master" and click "Add device".

4. Right-click the added "EtherCAT Master" and select "Add safety controller as a slave".



5. Select the independent safety PLC created in the project, with the following specific requirements:
   - The safety PLC has not been associated any EtherCAT master.
   - The safety PLC has been configured with an ECT communication unit.
   - The model of the safety PLC is the same as the EVO1000EF slave model.

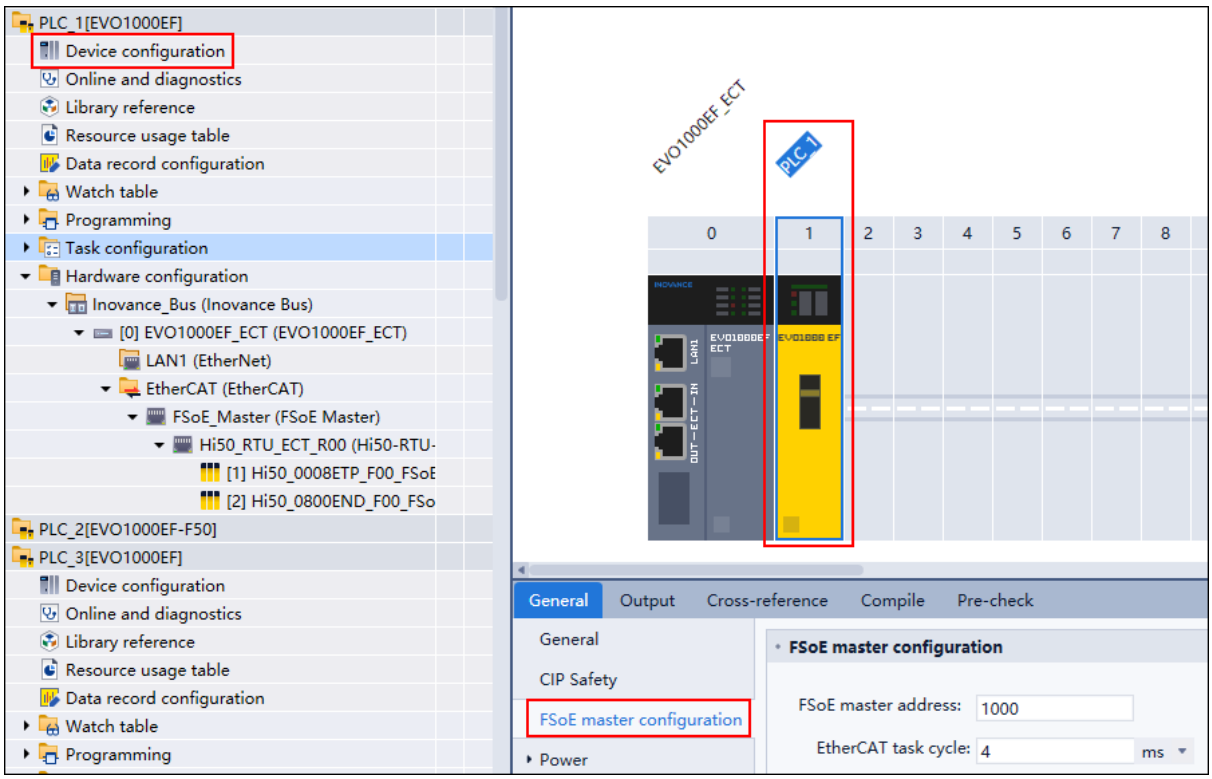
> **NOTE**
>
> If the current safety PLC has been configured with local or remote I/O modules, when you add the safety PLC as slave, a prompt message will appear, indicating that the I/O devices of PLC_2 will be deleted. After the user confirms, the association will be established.



Method 2: Configuring via network view

1. Create a project and add a safety PLC device and a standard PLC device.
2. Double-click "Network configuration" in the project tree to connect the EtherCAT ports of the standard PLC and the safety PLC.

11.4.4.1.2 Directly Creating a Safety PLC as an EtherCAT Slave



1. Create a project and add a safety PLC device and a standard PLC device.
2. Right-click "EtherCAT" under "Hardware configuration" of the standard PLC in the project tree, and select "Add device".
3. Select "EtherCAT Master" and click "Add device".
4. Right-click "EtherCAT Master" and select "Add device".
5. Select the safety PLC to be added, such as "EVO1000EF", and click "Add device". The specific requirements are as follows:
   - There is an independent safety PLC in the project that is not associated.
   - The independent safety PLC has been configured with an ECT communication unit.
   - The added safety PLC has the same model as the independent safety PLC in the project.
6. Right-click the added safety PLC under "EtherCAT Master", select "Associate safety controller", and select the independent safety PLC created in the project.

11.4.4.1.3 Configuring Communication Parameters of Safety PLC

1. Double-click "Device configuration" under the safety PLC in the project tree, click the safety PLC to open the monitoring area.
2. Configure parameters in "General > FSoE master configuration".

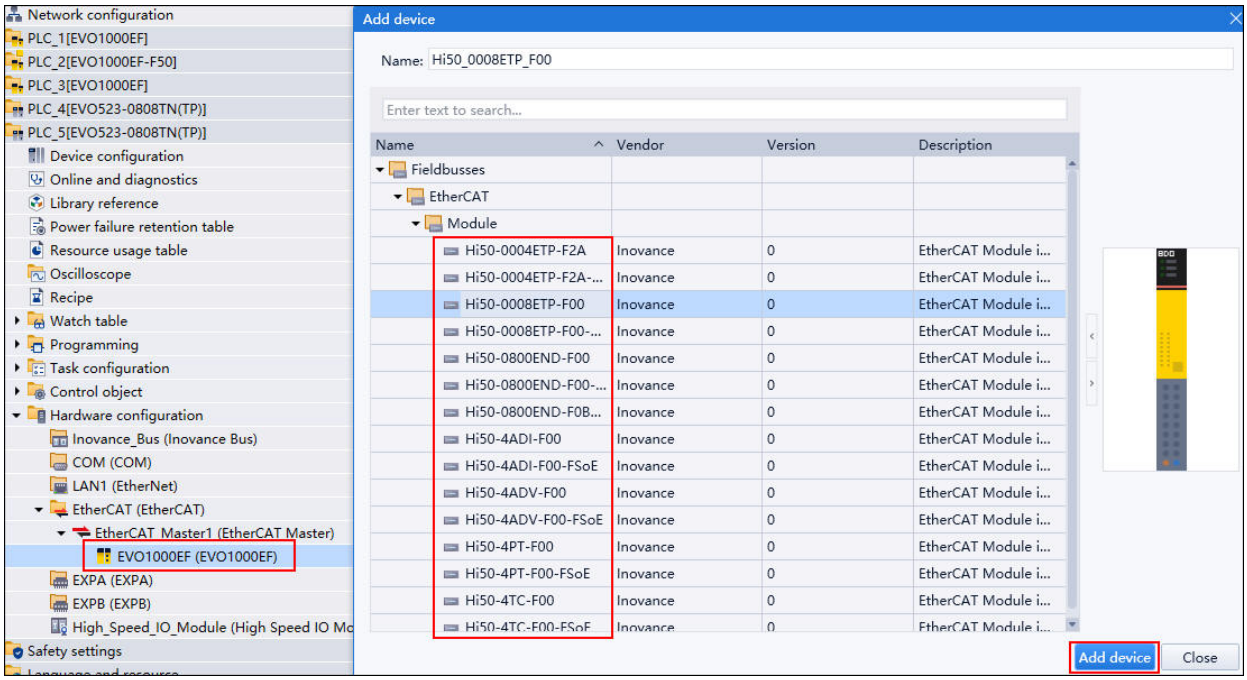
Parameter	Value Range	Default Value	Note
FSoE master address	1 to 65535	1000	◦ As the FSoE master address, it must be unique within the EtherCAT network. ◦ The iFA provides an automatically assigned address, which can be modified manually. ◦ It ensures the uniqueness of the FSoE master/slave address across the entire EtherCAT network to avoid master-master conflicts, slave-slave conflicts, and master-slave conflicts. ◦ During safety PLC compilation, the uniqueness of the master address and the FSoE addresses of its assigned slaves is checked.
EtherCAT task cycle	◦ For EIP communication unit, the FSoE option is grayed out. ◦ For ECT communication unit, both CIP Safety and FSoE need to be configured.	4 millisconds	◦ The task cycle can be defined by users. It must be consistent with the EtherCAT task cycle of the safety PLC's EtherCAT master. ◦ For standard PLCs, the EtherCAT task cycle can be selected in ms or us. ◦ The safety PLC must have the same EtherCAT task cycle value and unit as the standard PLC; otherwise, a fault level message will be displayed during the safety PLC compilation. ◦ Double-click "Device configuration" under the safety PLC in the project tree, click the safety PLC to open the monitoring area.

11.4.4.2 Configuring I/O Modules

I/O modules include local failsafe I/O modules and remote I/O modules, which can only be created under a standard PLC.

> **NOTE**
>
> During EtherCAT communication, local failsafe I/O and remote failsafe I/O (including couplers) can only be created, deleted, and renamed under a standard PLC. Whether it is local or remote I/O for the safety PLC, its slot number must be displayed in the project tree.

11.4.4.2.1 Adding a Local Failsafe I/O Module



Introduction

After adding a local failsafe I/O module, the local failsafe I/O module under the standard PLC must be synchronized to the independent safety PLC rack in the project tree.

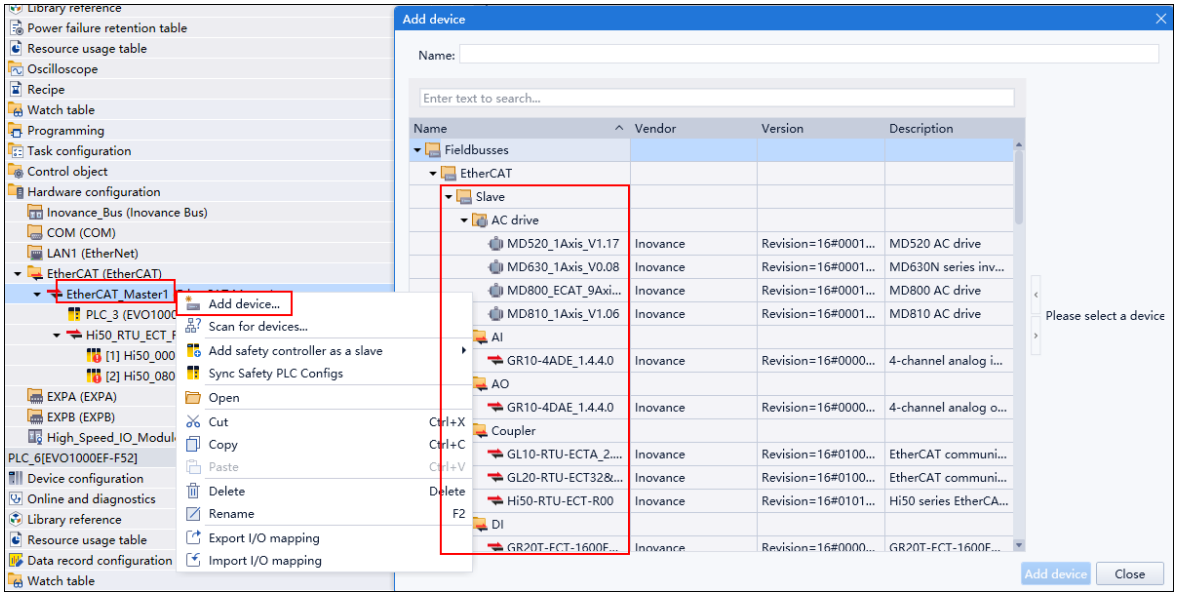
- Local failsafe I/O can only belong to this safety PLC.
- In the project tree, under the standard PLC and safety PLC, the I/O modules need to display the slot number.

Procedure

1. Right-click the safety PLC under "Hardware configuration > EtherCAT > EtherCAT Master" of the standard PLC and select "Add device".
2. Select the failsafe I/O module to be added and click "Add device".

11.4.4.2.2 Adding a Remote Failsafe I/O Module

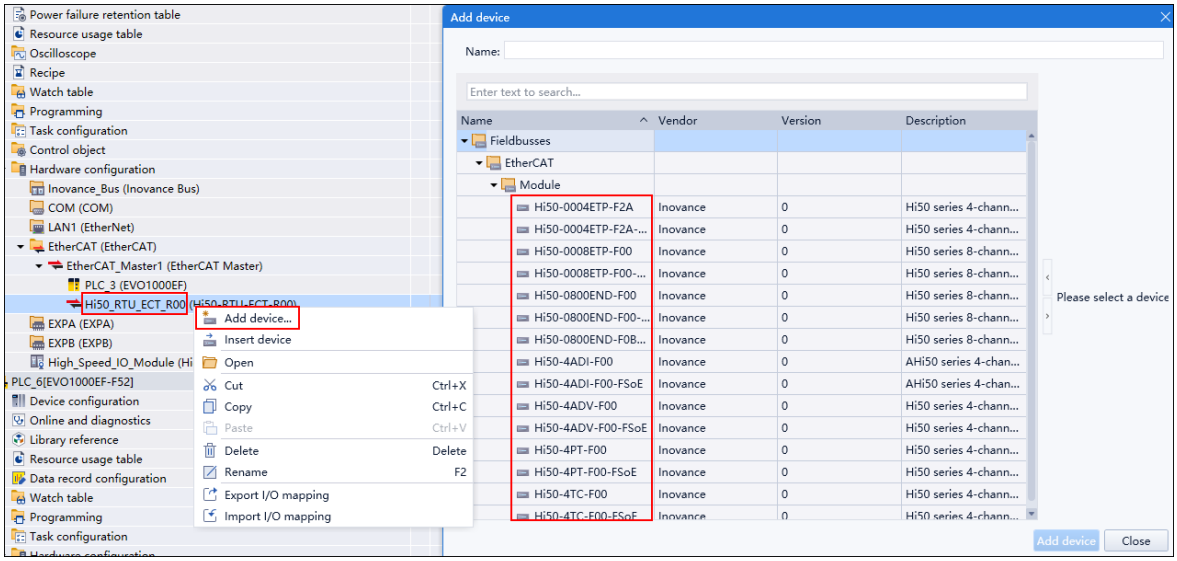
Introduction



Under the EtherCAT Master of a standard PLC, you can add standard I/O couplers such as GL10, GL20, and Hi50. You can also add standard I/O modules to the couplers. Standard couplers and standard I/O modules are automatically and exclusively subordinate to the standard PLC. In the EtherCAT network, the standard PLC is presented as the EtherCAT master, under which the safety PLC, failsafe I/O couplers, standard I/Os, and other EtherCAT slaves are connected.

When there are multiple safety PLCs under a standard PLC, the newly created remote failsafe I/O module defaults to be the first safety PLC. If there is currently no safety PLC, the failsafe I/O module is in an unassigned state.

Procedure



1. Add "Hi50-RTU-ECT-R00".
   a. Right-click "EtherCAT Master" under "Hardware configuration > EtherCAT" of the standard PLC and select "Add device".

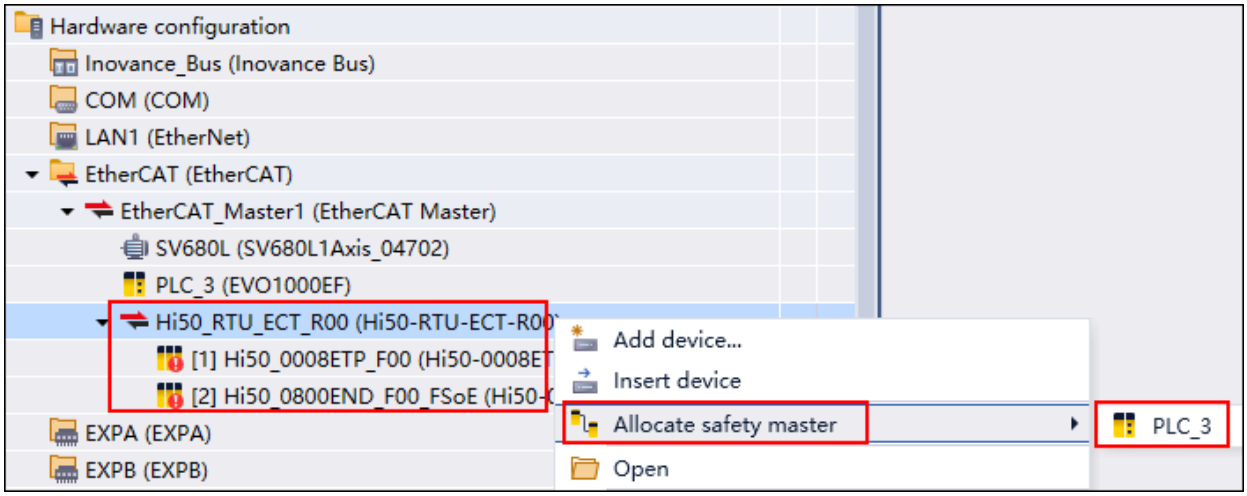
   b. Select "Hi50-RTU-ECT-R00" and click "Add device".

2. Add a remote failsafe I/O module.
   a. Right-click "Hi50-RTU-ECT-R00" and select "Add device".

   b. Select the failsafe I/O module to be added and click "Add device".

11.4.4.2.3 Assigning FSoE Master to Failsafe I/O Modules

Introduction

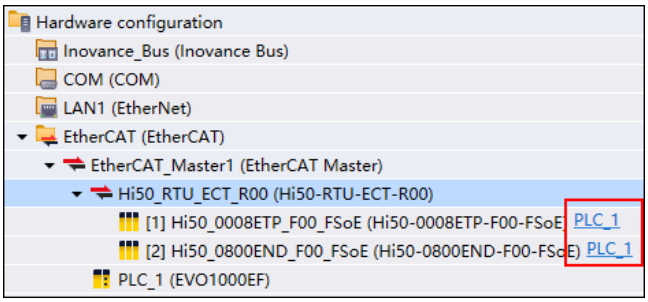


In EtherCAT and FSoE networks, there are multiple safety PLCs and multiple remote failsafe I/Os, so it is necessary to assign an FSoE master to the failsafe I/O modules on the coupler. Newly added I/O modules belong to the first safety PLC by default, which is the safety PLC closest to the standard PLC in the EtherCAT network.

- Hi50-RTU-ECT-R00 is a non-safety module, and its master is fixed as the standard PLC, requiring no master assignment.
- Failsafe I/O modules on the local rack of the safety PLC automatically and are permanently associated with the safety PLC on the same rack, requiring no master assignment.
- For servo modules with safety signals, it is necessary to support assigning a safety FSoE master to them.

Procedure

Right-click the added failsafe I/O module or coupler, select "Allocate safety master" to assign an FSoE master to the remote failsafe I/O.



- If an associated safety PLC (FSoE master) is renamed or its device model is changed, the master-slave relationship displayed for the I/O modules in the project tree shall be updated accordingly.
- When a safety PLC is deleted, the failsafe I/Os previously assigned to that PLC are automatically assigned to the default safety PLC.
- If there are no safety PLCs, the I/O modules are in an unassigned master state.
- When a failsafe I/O module is deleted, it shall also be synchronously updated (deleted) under the safety PLC to which it belongs.

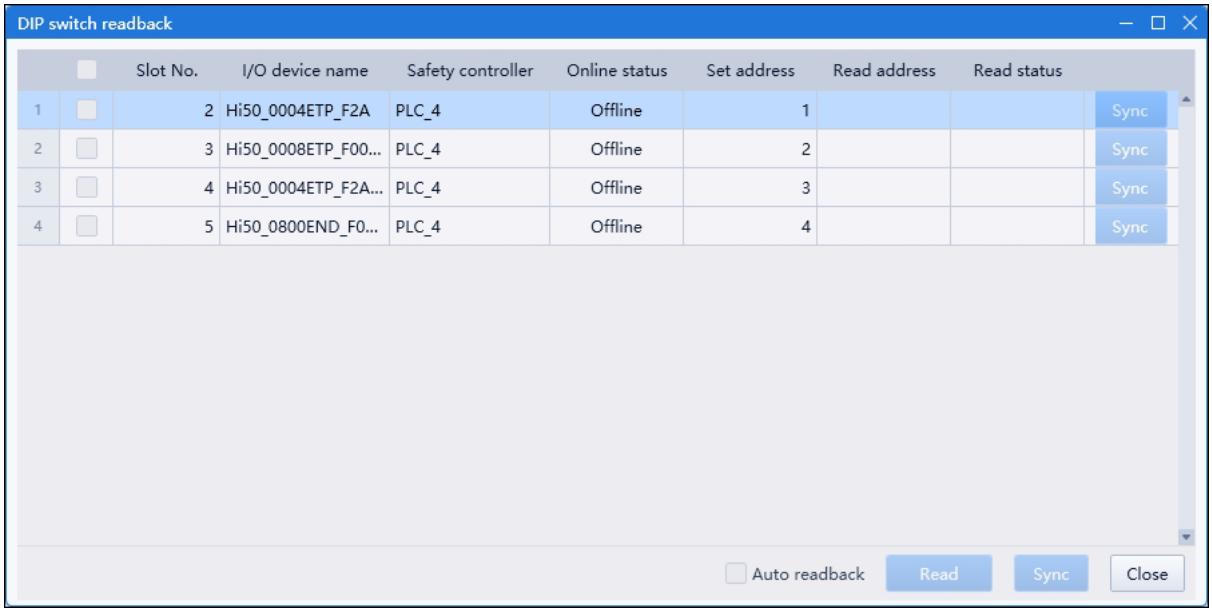
Result

Remote failsafe I/O modules display the name of the safety PLC (FSoE master) to which they belong.

- If at least one failsafe I/O module on a given coupler belongs to that safety PLC, then the coupler and that failsafe I/O module shall be displayed under the safety PLC.
- If none of the failsafe I/O modules on a given coupler belongs to that safety PLC, then neither the coupler nor its failsafe I/O modules shall be displayed under that safety PLC.

11.4.4.2.4 Reading FSoE DIP Switch Addresses of Failsafe I/O Modules

Introduction



The DIP switch readback function is designed for configuration verification and synchronization of slave failsafe I/O modules. It is primarily used to read the DIP switch address from the FSoE configuration of the failsafe I/O module and update the address to the "FSoE configuration > FSoE slave address" of the corresponding I/O module, either individually or in batch.

Prerequisites

The standard PLC must be in an online running state.

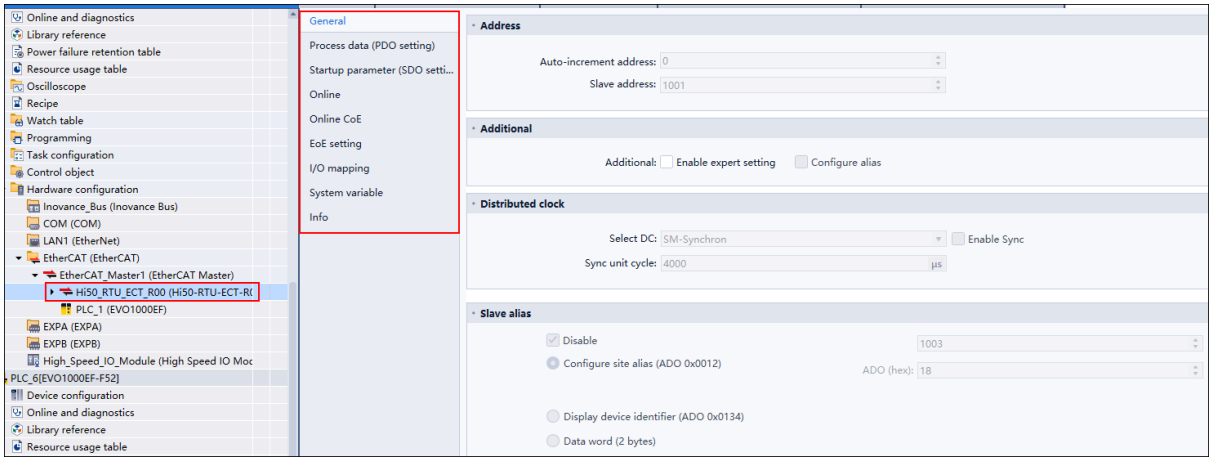
Procedure

1. With the standard PLC online, right-click the target I/O module under "Hardware configuration > EtherCAT > EtherCAT Master" of the standard PLC and select "DIP switch readback".

2. The DIP switch readback information list is dynamically adapted for display. It automatically reads the current I/O modules and generates corresponding information entries. If no I/O modules are present, the DIP switch readback function will not be displayed.
   - Slot number: The installation slot number corresponding to the I/O module.
   - IO device name: The currently mounted I/O device.
   - Safety controller: The associated safety PLC device.
   - Online status: The running status of the corresponding safety PLC, including online and offline.
   - Set address: The "FSoE configuration > FSoE slave address" of the slave I/O module.
   - Readback address: The actual DIP switch address of the I/O module read via the DIP switch readback function.
   - Readback status: The result of the DIP switch address readback for the current I/O module (Success/Failure).
3. Execute DIP switch readback and synchronization as needed.
   - Automatic readback: The system will automatically and cyclically execute DIP switch address readback for all I/O modules in the list order, continuously refreshing the readback addresses and statuses of the I/O modules until the automatic readback task is manually canceled.
   - DIP switch readback: The system will perform a single round of DIP switch address readback for all I/O modules in the list. After reading the addresses for all modules and refreshing the list data, it automatically stops without looping.
   - Synchronization: Synchronizes the successfully read-back DIP switch addresses to "FSoE configuration > FSoE slave address" of the corresponding I/O modules. Two modes are available:
     - Single synchronization: Each I/O module entry in the list has an independent "Synchronize" button for address synchronization of that single module.
     - Batch synchronization: A global "Synchronize" button is provided at the bottom right, allowing batch synchronization of the selected modules in the list.
4. Diagnosis of abnormal readback results.
   - When the device readback status is failed, or when the readback address completely matches the set address, the synchronization button for the I/O module is grayed out and disabled, the corresponding checkbox in the list is disabled, and synchronization cannot be performed.

- Synchronization permissions are restricted based on the online status of the safety controller:
  - Online status is "Online": The synchronization function for all I/O modules is disabled; checkboxes in the list cannot be operated; address synchronization is not allowed.
  - Online status is "Offline": When the readback address of the I/O module does not match the set address, address synchronization is allowed.
- During the system's DIP switch readback process, the list checkboxes and synchronization-related functions are globally locked, and all operations are temporarily unavailable. The lock is automatically released after the readback task is completed.

11.4.4.2.5 Configuring Failsafe I/O Module Parameters

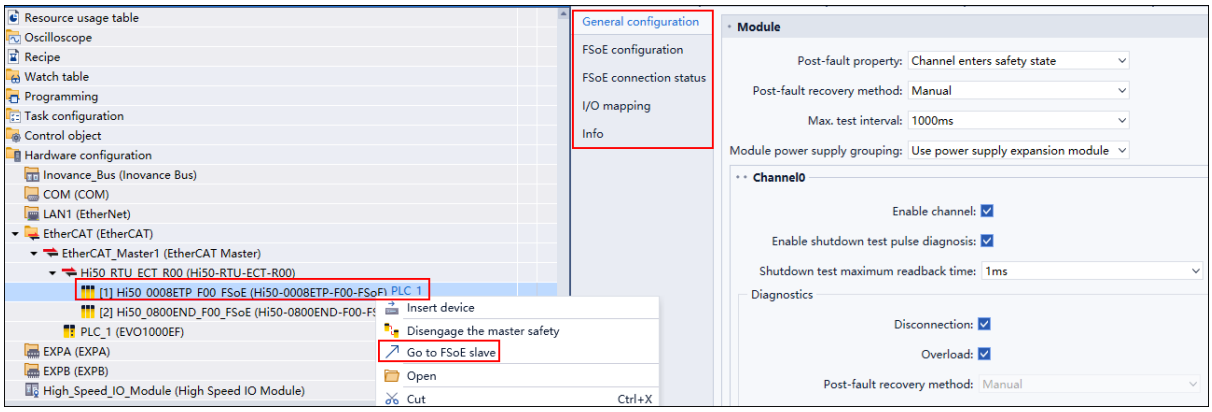


Local failsafe I/O modules on the safety PLC rack and remote failsafe I/O modules on the coupler both have EtherCAT and FSoE parameters. For failsafe I/O modules supporting CIP Safety and FSoE, if an ECT communication unit or coupler is configured, the configuration page displays FSoE information; if an EIP communication unit or coupler is configured, the configuration page displays CIP Safety information. Automatic adaptation is supported. Failsafe I/O modules that support FSoE only can only be used with an ECT communication unit or coupler.

When the iFA project file downloaded to the safety PLC remains unchanged, I/O modules that support both CIP Safety and FSoE in the EtherCAT/FSoE network can be directly interchanged with pure FSoE protocol failsafe I/O modules. For example, if the configured module in the project is Hi50-0800END-F00, it can be replaced with Hi50-0800END-F00-FSoE. All other failsafe I/O modules of the same type follow this rule.

> NOTE
>
> Module replacement must follow the firmware forward compatibility principle. If the project configuration firmware version is Hi50-0800END-F00 V2.0, it can be replaced with Hi50-0800END-F00-FSoE of V1.1, but not of V1.0.

Configuring EtherCAT parameters for failsafe I/O modules



1. Double-click the target coupler under the standard PLC to open the "General configuration" page by default.

2. For EtherCAT parameter configuration of failsafe I/O modules, see the 10.6.3.3 Configuring Slave Parameters.

Configuring FSoE parameters for I/O modules

1. Double-click the target failsafe I/O module under a safety PLC, or right-click the target I/O module under a standard PLC and select "Go to FSoE slave" to open the "General configuration" page.

2. For FSoE parameter configuration of failsafe I/O modules, see 11.4.2.7 Safety I/O Module Configuration.
3. After completing parameter configuration, right-click "EtherCAT Master" under the standard PLC in the project tree and select "Sync safety PLC variable mappings".

11.4.4.3 Configuring Safety Servo Modules

Introduction

Inovance servo devices with FSoE function: SV670NS and SV680-INT.

- Servo modules with FSoE function (SV670NS and SV680-INT) can be added to a safety PLC EtherCAT communication unit.
- The safety servo parameters are downloaded to the servo device by the standard PLC via EoE.
- Safety parameters of the servo with safety functions can be configured in the detailed view. For details, see 17.3.15 Safety Parameter.

Prerequisites

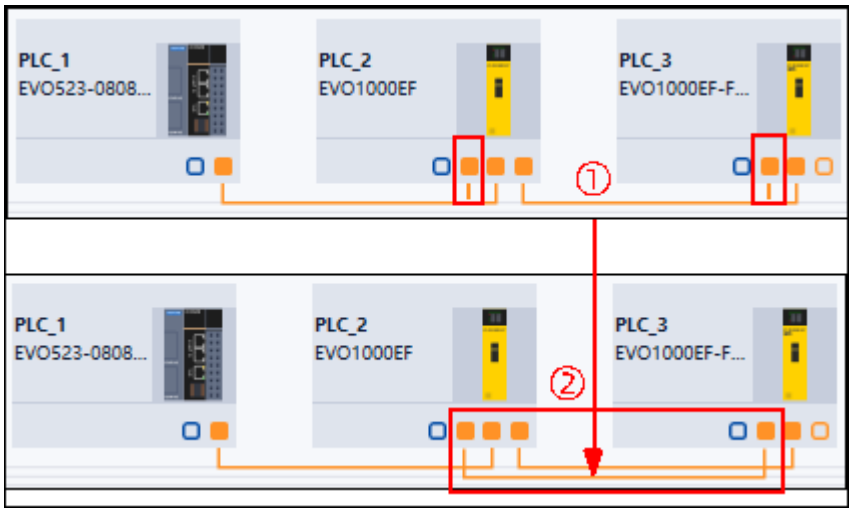
The iFA Evolution software supports automatic scanning for servo drives, which requires the following conditions to be met:

- The safety PLC project has be downloaded.
- The safety PLC device is in a stopped state.
- When the current PLC needs to connect to devices such as PLCs, HMIs, PACs, PCs, and drives, this function can scan all compatible devices within the same subnet, allowing users to select the target device. For IP address modification, see the "PLC Programming > Online Controller Operations > Network Settings" in the iFA Information System Guide.

Procedure

1. Manually add a safety servo module.
   a. Right-click "EtherCAT Master" under "Hardware configuration > EtherCAT" of the standard PLC and select "Add device".
   b. Select the servo drive to be added and click "Add device".

2. Scan to add a safety servo module.
   a. Right-click "EtherCAT Master" under "Hardware configuration > EtherCAT" of the standard PLC and select "Scan for devices".
   b. In the "Device scanning" window, click "Scan for devices". The scanned devices will be displayed in the "Physical connection" list.
   c. Select the servo drive to be added, and click "Apply physical network configuration".
3. Right-click the added safety servo module, select "Allocate safety master", and assign an FSoE master to the safety servo.
4. Double-click the servo drive under "Standard PLC > Hardware configuration > EtherCAT > EtherCAT Master". For parameter configuration, see 10.6.3.3 Configuring Slave Parameters.
5. For EoE configuration of the safety servo module, see 17.1 EtherCAT Configuration.
6. After completing parameter configuration, right-click "EtherCAT Master" under the standard PLC in the project tree and select "Sync safety PLC variable mappings".

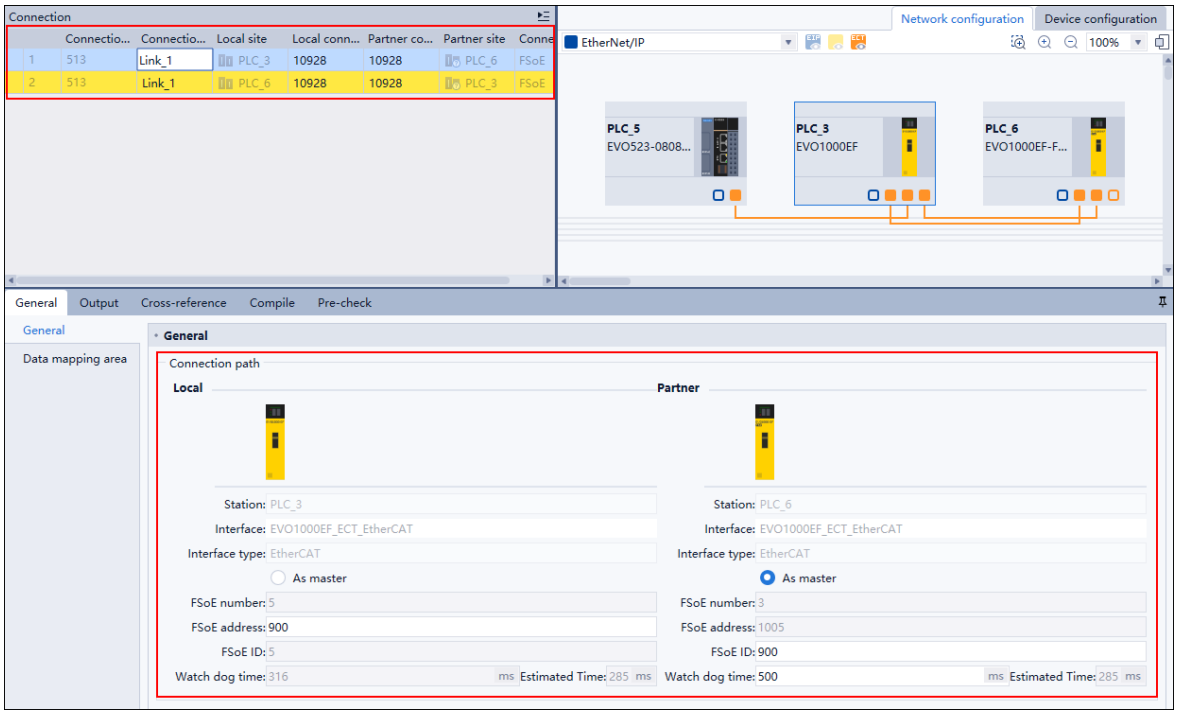


11.4.4.4 FSoE Communication Between Safety PLCs

EVO1000EF series safety PLCs support communication via FSoE, configurable through network configuration. Two communication configuration methods are supported:

- Multiple safety PLCs deployed in the same project.
- Multiple safety PLCs deployed in different projects.

FSoE communication between safety PLCs in the same project



1. Create a project and add two safety PLCs and a standard PLC.
2. Double-click "Network configuration" in the project tree to open the network configuration page.
3. In the same EtherCAT network, press and hold the left mouse button to connect the EtherCAT ports of the two safety PLCs to create an FSoE connection.

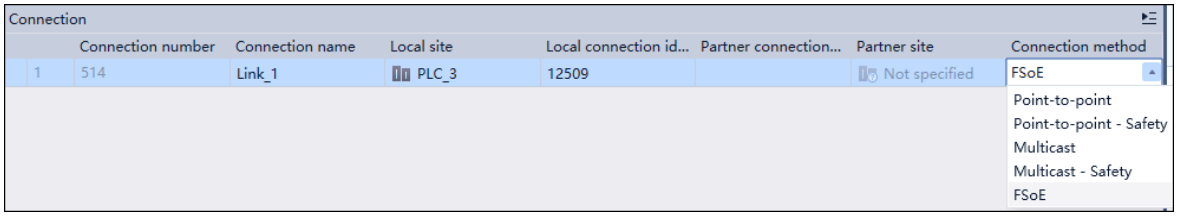
4. Configure parameters for the local PLC and partner PLC.
   a. Select the generated connection. On the "General" tab in the monitoring area, configure the connection parameters for the local PLC and partner PLC.

Parameter	Value Range	Default Value	Note
As master	Yes or No	Yes	-

Parameter	Value Range	Default Value	Note
FSoE connection ID	1 to 65535	-	Cannot be changed. The connection IDs of the two safety PLCs can be different.
FSoE address	1 to 65535	1	▪ If acting as a master, the "FSoE master address" (unmodifiable) can be viewed under "General > FSoE master configuration" of the safety PLC. ▪ If acting as a slave, the "FSoE master address" must be entered manually.
FSoE connection ID	1 to 65535	-	Must be unique within the FSoE network.
Watchdog time	1 to 65535	-	Must not be less than the estimated watchdog time.

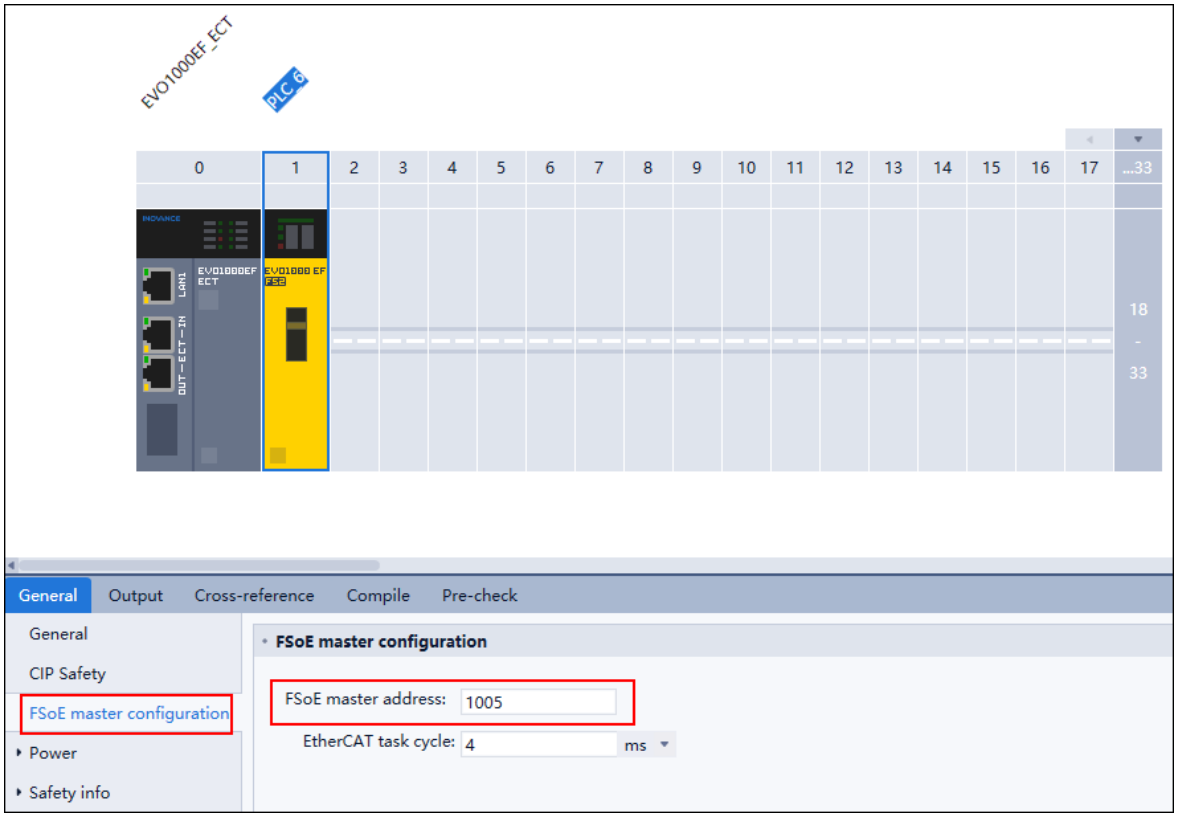
b. Switch to the "Data mapping area" tab to configure the related parameters for the connection.

> **NOTE**
>
> The length of data mapping area in each direction cannot exceed 240 bytes; otherwise, a fault level message will be displayed during compilation.



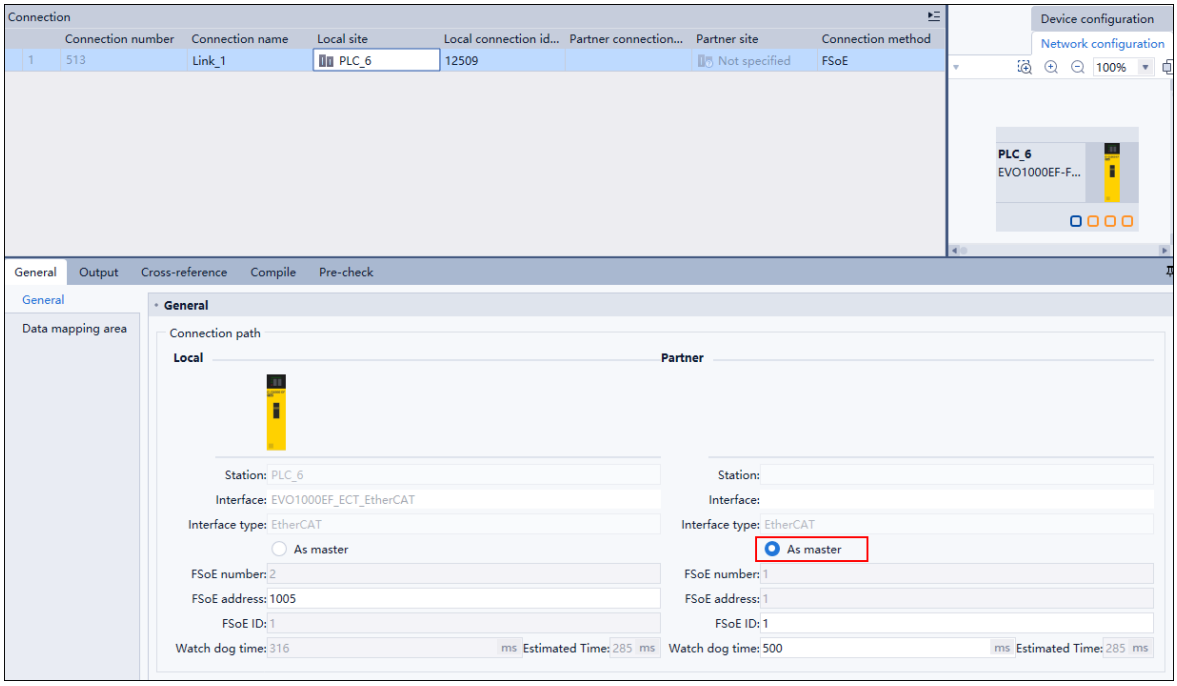
c. Configure the "Local variable", "Transfer direction", and "Partner variable" to send and receive communication data.

5. After completing parameter configuration, right-click "EtherCAT Master" under the standard PLC in the project tree and select "Sync safety C2C configuration".



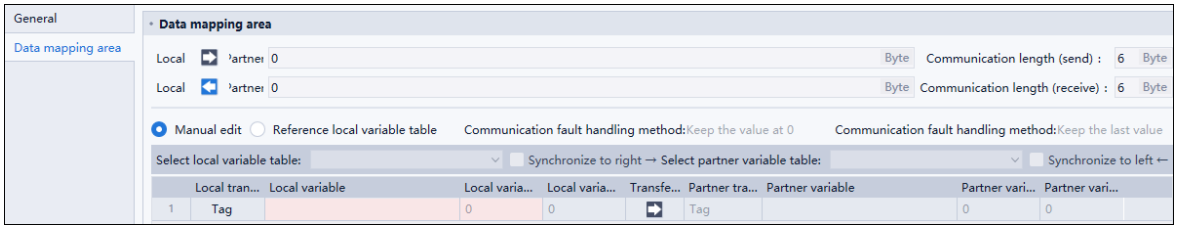
FSoE communication between safety PLCs in different projects

The configuration for the two safety PLCs are the same as above.



1. Create a project and add a safety PLC device and a standard PLC device.
2. Double-click "Network configuration" in the project tree to open the network configuration page.
3. Right-click the blank area in the "Connection" interface and select "Add" to add a connection.
4. Configure the connection parameters.
   - Select the configured safety PLC for "Local site".
   - Select "FSoE" for "Connection method".
   - Keep the "Local connection identifier" of the two PLCs in different projects consistent.

5. View the FSoE master address.
   a. Double-click "Device configuration" of the safety PLC in the project tree.
   b. Click the safety PLC in the "Device configuration" interface to open the "General" tab in the monitoring area.
   c. Select "FSoE master configuration" to view the "FSoE master address".



6. Select the generated connection. On the "General" tab in the monitoring area, configure the parameters for the local PLC and partner PLC.
   - Check "As master" for the partner PLC.
   - When the partner PLC is an FSoE master, ensure that the "FSoE address" of the local PLC is different from all master and slave addresses in the FSoE network.

7. Switch to the "Data mapping area" and configure the related parameters for the local PLC and partner PLC.

   a. On the "Data mapping area" tab, right-click the blank area and select "Add" to add a local transmission area.

   b. Configure the "Local variable" and "Transfer direction" to send and receive communication data.

8. After completing parameter configuration, right-click "EtherCAT Master" under the standard PLC in the project tree and select "Sync safety C2C configuration".

11.4.4.5 EtherCAT Communication Between Safety PLC and Standard PLC

1. Double-click "Device configuration" under the safety PLC in the project tree, click the communication unit to open the monitoring area.
2. Configure the "I/O mapping" parameters under "General > EtherCAT > Communication with the master".
   - Variables: Users can manually add mappings and bind them to safety variables or standard variables defined in the safety PLC.
     - Up to 512 variables can be configured. If exceeded, a compilation fault will be output.
     - When the total length of PDOs exceeds the limit, it needs to be checked during compilation in the standard PLC.
   - Data type and variable table: Automatically displayed based on the variable name, and cannot be modified.
   - Transmission direction: The standard PLC master can read both safety and standard data types, and can write only the standard data types.

3. After completing parameter configuration, right-click "EtherCAT Master" under the standard PLC in the project tree and select "Sync safety PLC variable mappings".

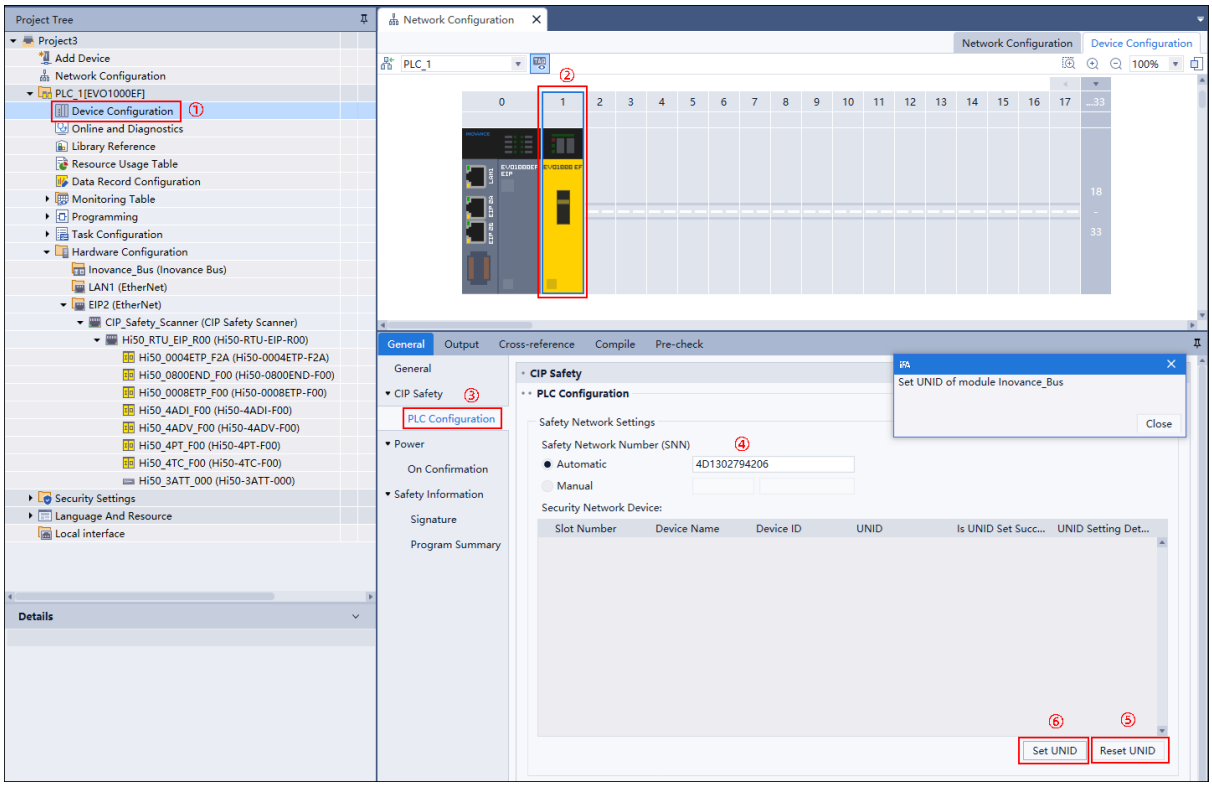
11.4.5 PLC Property Settings

11.4.5.1 PLC Configuration

Each device in the CIP Safety network has a unique node ID, known as the UNID (Unique Node Identifier), which uniquely identifies the device within the CIP Safety network during communication. The Safety Network Number (SNN) is a core component of the UNID. A complete UNID consists of the following two parts:

- SNN (6 bytes): Identifies the safety network domain to which the device belongs.
- UNID (4 bytes): Contains device type characteristics, such as slot address or port information.

The PLC configuration interface is used to set the UNID for local safety I/O modules, which are backplate modules, so the UNID is the module's slot address. Before the safety PLC starts running, the UNID assigned by the iFA Evolution software must be set to each safety I/O module.



Prerequisites

The safety PLC device is in offline status.

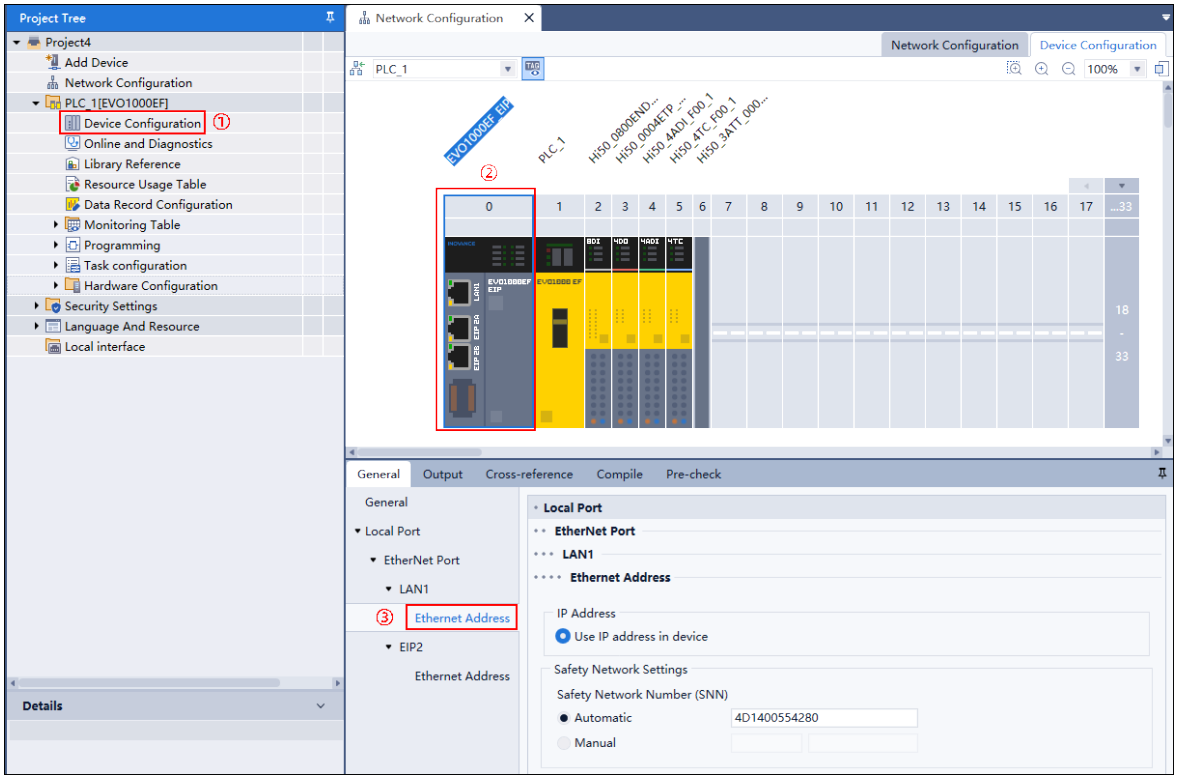
Procedure

1. In the project tree, double-click the "Device configuration" node under the safety PLC device.
2. In the device configuration interface, click the safety PLC device.
3. In the "General > CIP safety > PLC configuration" tab at the bottom of the interface, configure the SNN automatically or manually.
   - Automatic assignment: Generates the SNN automatically based on the current system time.
   - Manual assignment: The first input field is fixed at 1 and cannot be modified. The second input field accepts values from 1 to 9999.
4. The safety network device list below displays slot numbers, device names, device IDs, UNIDs, and other information for each safety I/O module.
   When adding safety I/O modules, UNIDs are automatically assigned. After modifying the SNN, the UNID must be reset before configuration so that the new UNID can be successfully assigned to each module.

5. Click the "Reset UNID" button and confirm that the UNIDs of all safety I/O modules have been successfully reset.
6. Click the "Set UNID" button and confirm that the UNIDs of all safety I/O modules have been successfully set.

CAUTION

- The UNID structure used by the Hi50 series safety I/O modules is: SNN (6 bytes) + physical slot address (4 bytes).
- Users are responsible for ensuring that all interconnected CIP Safety devices have globally unique UNIDs.



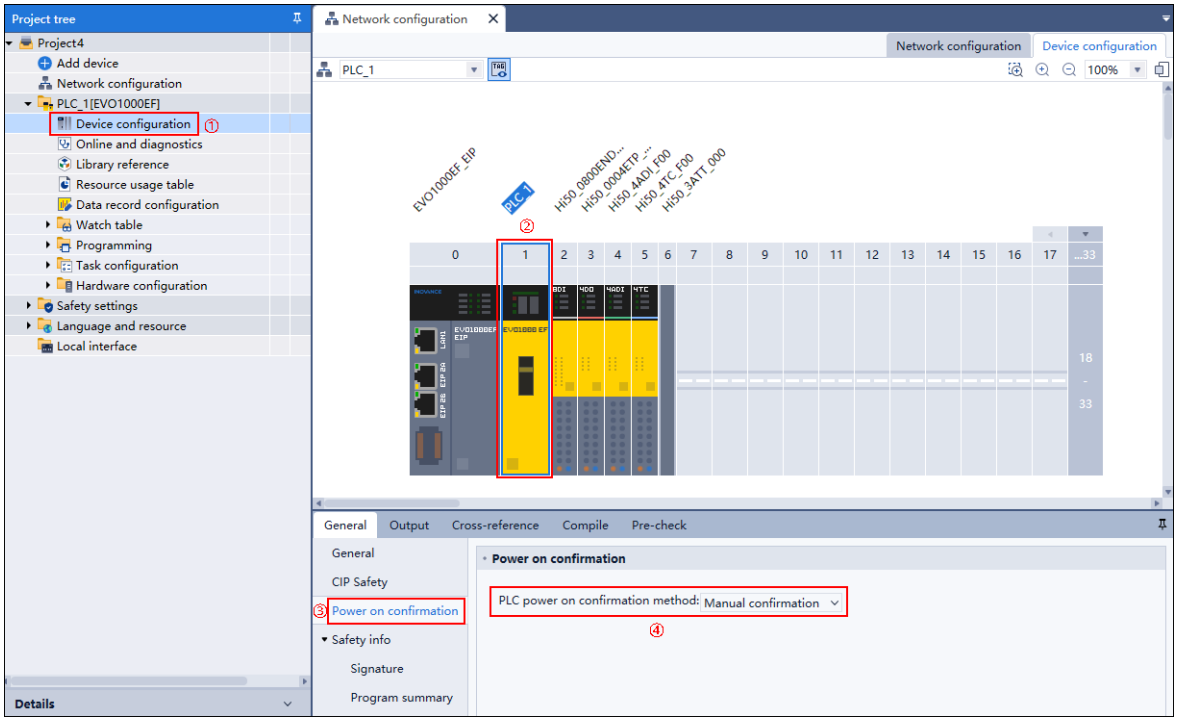
11.4.5.2 Ethernet Address and Safety Network Settings

The safety PLC device communicates via the communication unit with the safety I/O modules, safety gate system, and other safety PLCs on the Hi50 coupler using CIP Safety. Therefore, each network port of the communication unit must be configured with an SNN to assign a UNID to third-party CIP Safety devices connected to the LAN1 or EIP2 port. The UNID structure used is: SNN (6 bytes) + IP address of the device connected to the port (4 bytes).

Procedure

1. In the project tree, double-click the "Device configuration" node under the safety PLC device.
2. In the device configuration interface, click the safety PLC device.
3. Select the "General > Local ports > LAN1 > Ethernet address" tab at the bottom of the interface.
4. The IP address defaults to the device's IP address and cannot be modified.

5. The SNN can be assigned automatically and manually.
   - Automatic assignment: Generates the SNN automatically based on the current system time.
   - Manual assignment: When the first input box is set to 4, the allowable range for the second input box is 1 to 9999; when the first input box is set to 11688 to 65534, the allowable range for the second input box is 0 to 86399999.



6. The configuration method for EIP2 is the same as for LAN1.

11.4.5.3 Power-On Confirmation

The power-on confirmation mechanism of the safety PLC provides two methods: manual confirmation and automatic confirmation. After the safety confirmation of the safety PLC program, it meets the operating conditions each time it is powered on and passes self test to enter the safety status. At this point, users can choose either manual confirmation or automatic confirmation. If automatic confirmation is selected, the PLC will directly enter the operational mode; if manual confirmation is selected, the PLC enters the operational mode before manual confirmation by users. The system defaults to manual confirmation.

Procedure

1. In the project tree, double-click the "Device configuration" node under the safety PLC device.
2. In the device configuration interface, click the safety PLC device.
3. In the "General > Power-on confirmation" tab, configure the confirmation method.
   - Manual Confirmation: After the safety PLC is powered on, it enters the manual confirmation mode. At this time, the safety PLC is in a safe status, with all inputs and outputs at the safe value "0". The system will only enter the operational mode after users manually confirm that the safety conditions are met.
   - Automatic Confirmation: After the safety PLC is powered on, it automatically checks whether the safety conditions are met. If so, it automatically enters the operational mode without requiring manual confirmation.

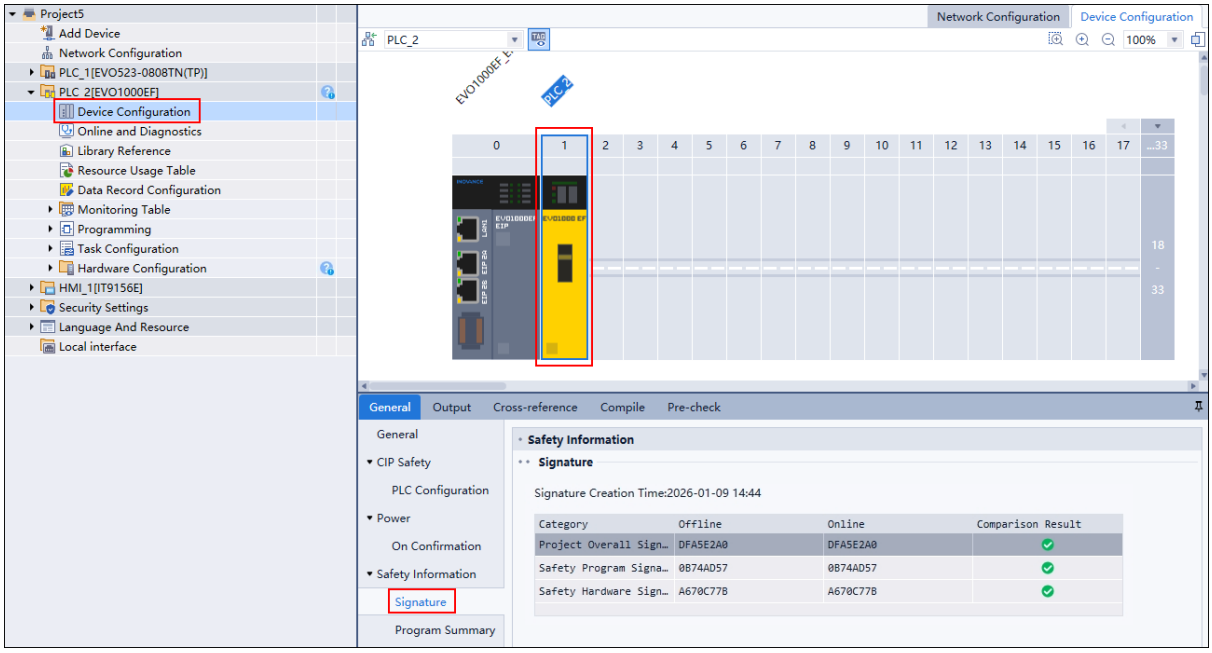
11.4.5.4 Safety Information

The safety program summary contains safety-related data (including project name, project signature, safety program signature, safety hardware signature) to support users during system acceptance. It supports generating the safety program summary in electronic format (such as in PDF format).

A safety signature is a unique identifier for project, hardware, and programs, divided into offline signatures and online signatures. An offline signature is generated after successful compilation, while an online signature is generated after successful online connection.

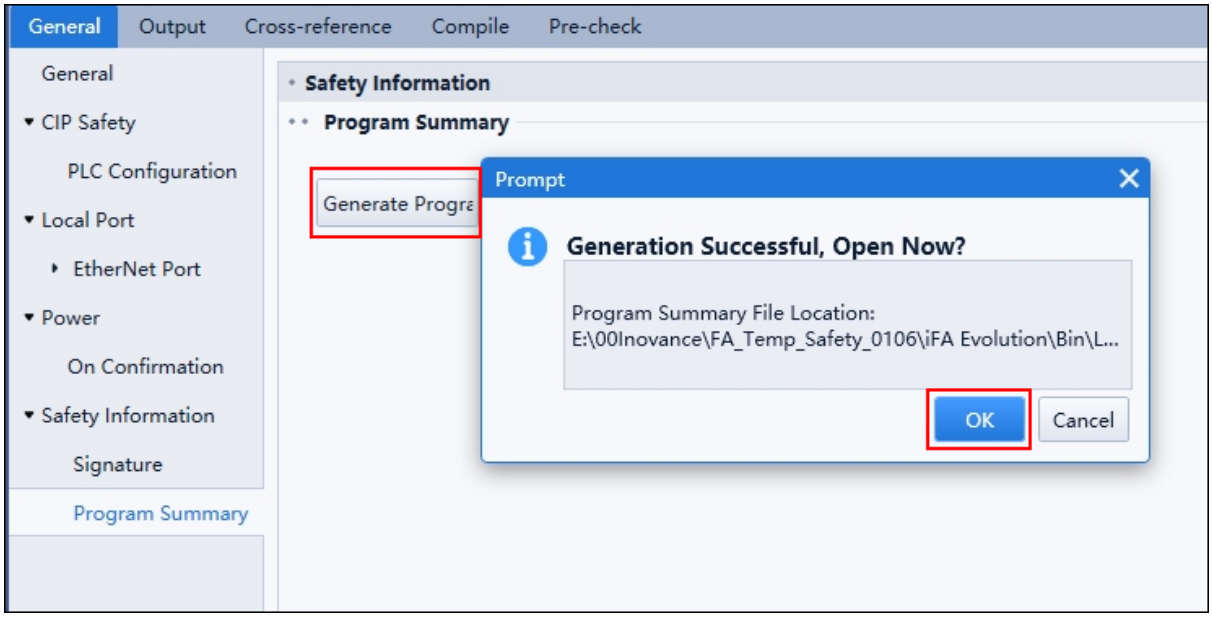
Before generating the safety program summary, confirm the safety project's signature generation time and verify that the comparison results for the project signature, safety program signature, and safety hardware signature are consistent.

Prerequisites



The safety PLC device is online.

Procedure



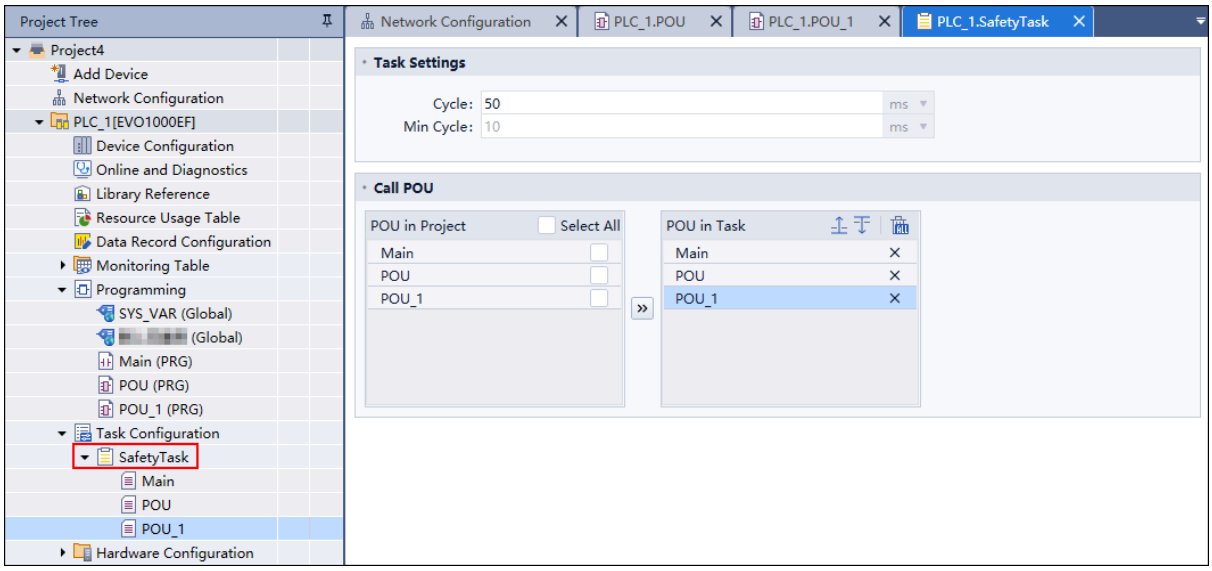
1. In the project tree, double-click the "Device configuration" node under the safety PLC device.
2. In the device configuration interface, click the safety PLC device.
3. In the "General > Safety information > Signature" tab, view signature information.

Item	Description
Signature creation time	Displays the date and time when the signature was generated.
Project overall signature	Displays online/offline signature information and comparison results. This signature is updated when the safety PLC program or hardware configuration changes and the compilation is successful.

Item	Description
Safety program signature	Displays online/offline signature information and comparison results. This signature is updated when the safety PLC program changes and compilation is successful. The scope of the safety program includes: SafeTask, program (PRG, FB), global variable table, and system variable table.
Safety hardware signature	Displays online/offline signature information and comparison results. This signature is updated when the hardware configuration of the safety PLC changes and the compilation is successful. The scope of safety hardware includes: hardware configuration (I/O modules added to local or coupling racks), I/O module parameters, and CIP Safety configuration information for I/O.

4. Confirm that the comparison results for the project overall signature, safety program signature, and safety hardware signature are correct.
5. Select the "Safety information > Program summary" tab.
6. Click "Generate program summary" to generate a PDF file of safety program summary.
7. Click "OK" in the pop-up window to open the summary file.

11.4.6 Task Configuration



Tasks are used to manage user program calls and are essential in PLC programming. When adding a safety PLC device, a default cycle task is automatically created. Users can configure the task cycle time and add a user program to be called. The device processes user programs under the task configuration; safety PLC devices do not support adding new tasks.

Prerequisites

A user program (PRG) has been created.

Procedure

1. In the left project tree, double-click "Task configuration > SafetyTask" under the safety PLC device.

2. Set the task cycle time.
   The default cycle time is 50 ms, with a configurable range of 10 ms to 100 ms. The minimum cycle is the minimum task cycle automatically calculated by the IDE; the actual task cycle must be greater than or equal to the minimum cycle.

3. Set user program calls.
   a. In the "POU in project" list, check the user programs to be called. Selecting all is supported.
   b. Click » to add them to the "POU in task" list, thereby adding the user programs to the task.

c. Click  to move up/down the selected item in the "POU in task" list. User programs in the list will be executed in order from top to bottom.

d. Click  to the right of a program to remove it from the task. Click  in the upper right corner of the list to remove all added programs.

> NOTE
>
> Considering future expansion of safety control systems or safety programs, it is recommended to set a safety task cycle time with some margin.

11.5 PLC Compilation

The compilation operations in safety PLCs are the same as those in standard PLCs. For details, see 10.7 PLC Compilation in the "PLC Programming" chapter.

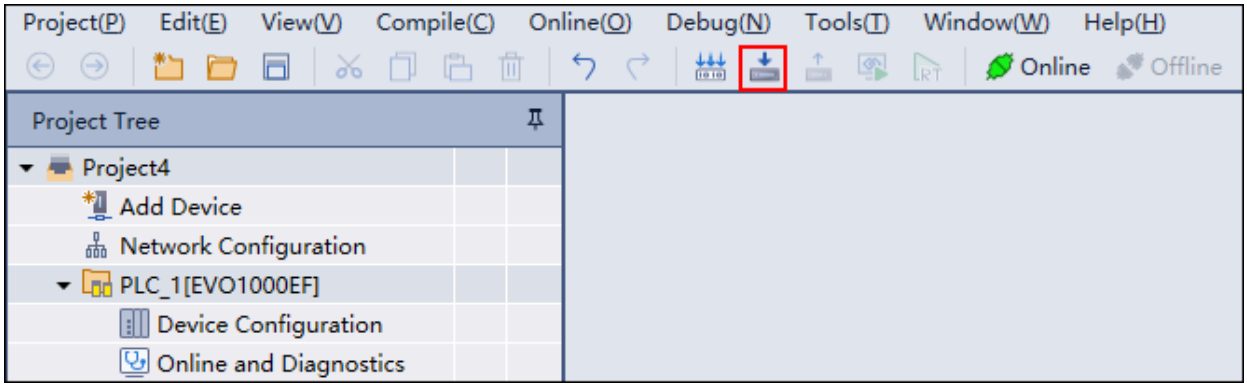
> NOTE
>
> The configuration items for safety PLC compilation differ from those in the standard PLC. For details, see the current software interface.

11.6 PLC Download

This section only covers the functional differences between the download of safety PLCs and standard PLCs; for other general functions, see 10.8 PLC Download in the "PLC Programming" chapter.

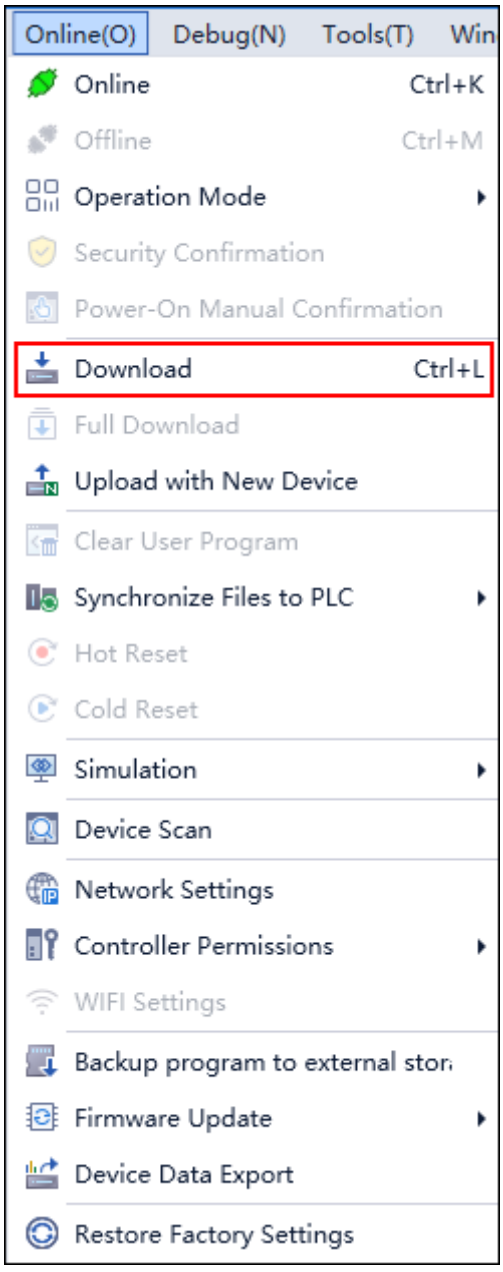
11.6.1 Full Download

Prerequisites



- A program or hardware configuration has changed.
- The project is in offline mode.

Procedure

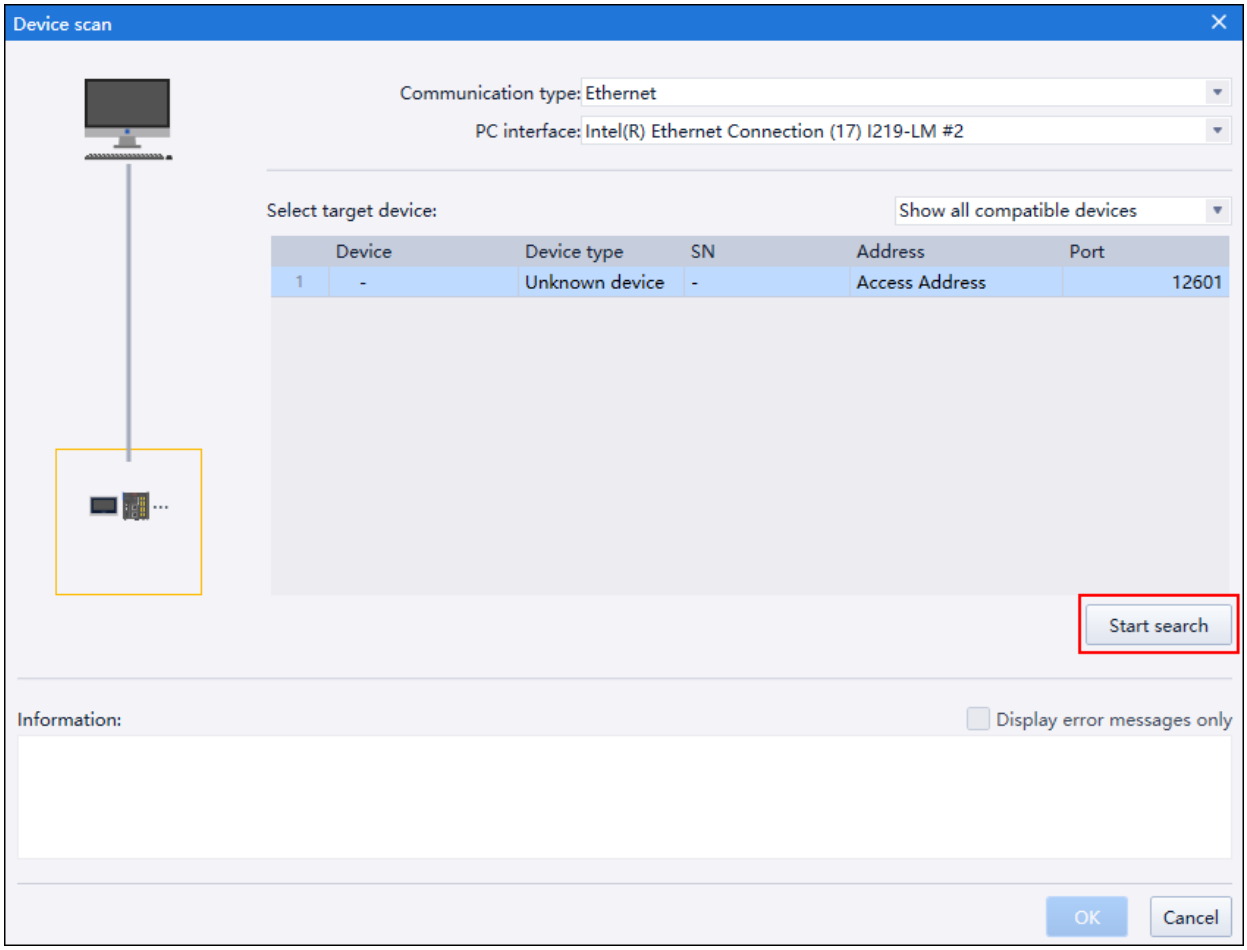


1. Open the download interface.

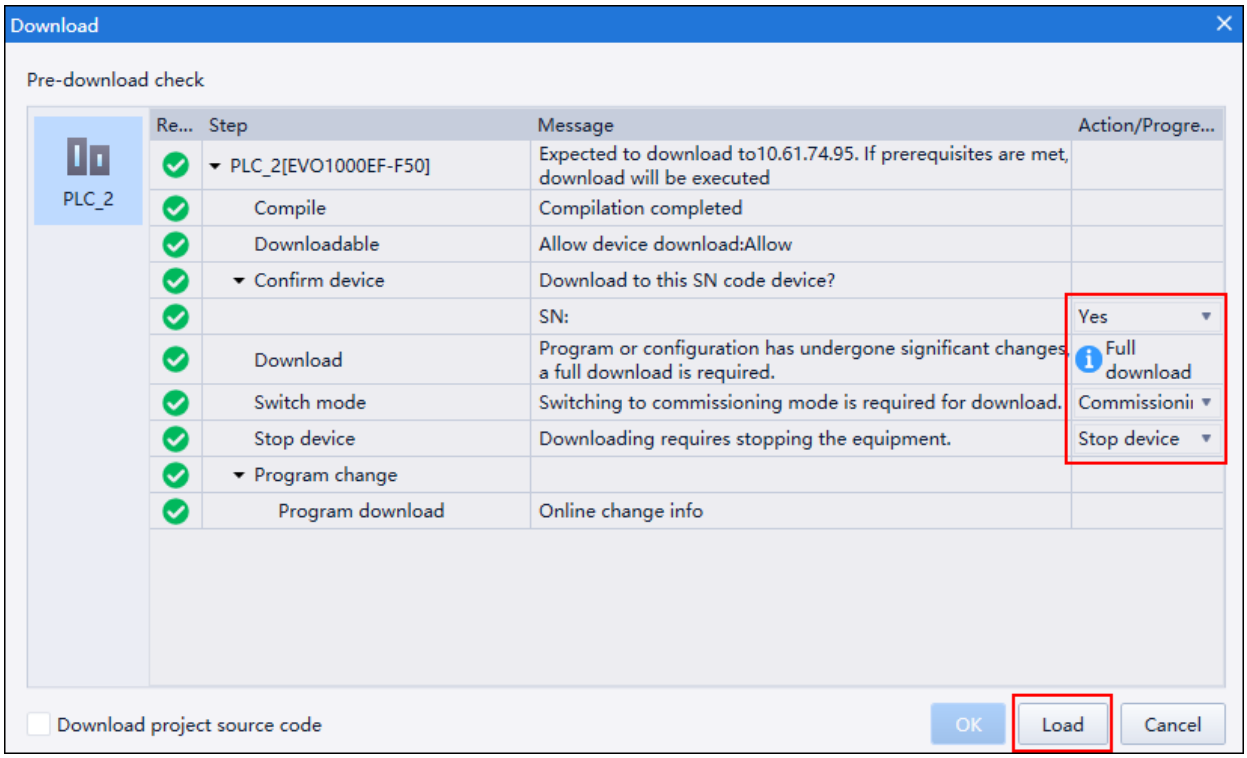
   There are three download entries: the toolbar, the menu bar, and the right-click menu of the PLC node in the project tree. The download button becomes enabled only when a PLC node or its child node is selected.

   - Toolbar: Select the corresponding PLC project in the project tree, then click the "Download" icon in the Toolbar, as shown in the figure below.

◦ Menu bar: Select the corresponding PLC project in the project tree, then click "Online > Download" in the menu bar, as shown in the figure below.



◦ Right-click menu: Right-click the corresponding PLC project in the project tree, then select "Download", as shown in the figure below.



2. Download the configuration.

In the pop-up device scanning window, click "Start search". Select the target device to download, then click "OK", as shown in the figure below.

3. Pre-download checks

A series of checks will be performed before downloading, and relevant information will be prompted. After configuration, click "Load", as shown in the figure below.

The main check items are as follows:

- Check for the device

  Before download, users must confirm that the SN code of the safety PLC matches the target safety PLC to be downloaded.

- Check if mode switching is required

  Before download, if the current PLC is in run mode, users must switch the device to commissioning mode before download.

- Check if shutdown is required

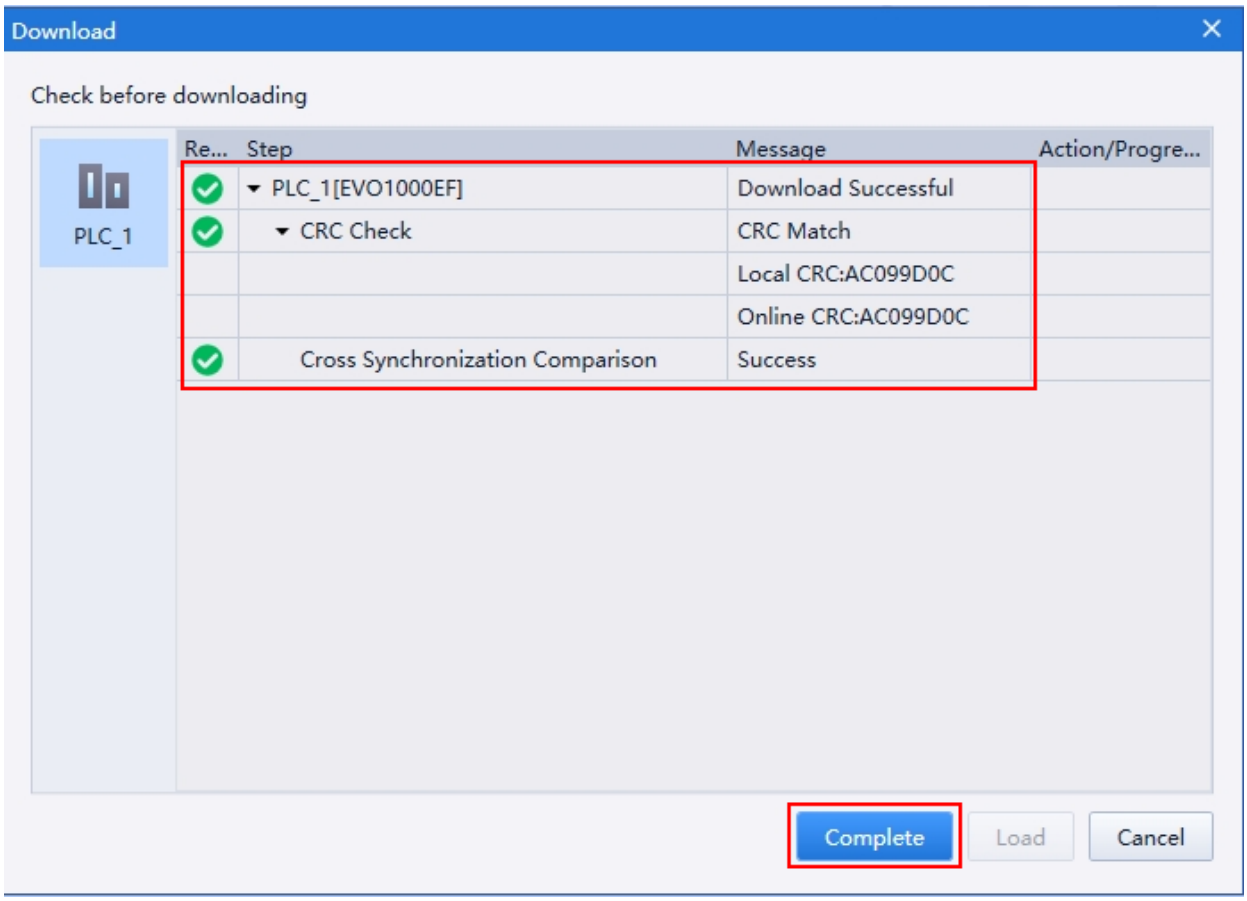
  For programs that must stop the PLC before downloading, users must select the "Stop device" action before downloading.

- Perform automatic compilation

  If compilation has not been performed before downloading, compilation will be automatically executed.

- Check for encryption permission downgrade

  A security prompt will be issued if the encryption permissions are downgraded before downloading.



- Check for password

  If a password has been set for the PLC, users must enter the password before downloading; otherwise, downloading is not allowed.

4. Post-download actions

   After the download is completed, the system will perform offline and online CRC checks and cross-synchronization verification. The download will only be considered successful if both verifications

succeed. If either fails, a download failure will be reported As shown in the figure below, confirm that all download results are correct to complete the download.

11.7 PLC Commissioning

11.7.1 PLC Start/Stop

The start/stop operations in safety PLCs are the same as those in standard PLCs. For details, see 10.10.1 PLC Start/Stop in the "PLC Programming" chapter.

11.7.2 PLC Online/Offline

The online/offline operations in safety PLCs are the same as those in standard PLCs. For details, see 10.10.2 PLC Online/Offline in the "PLC Programming" chapter.

11.7.3 Value Display and Calculation

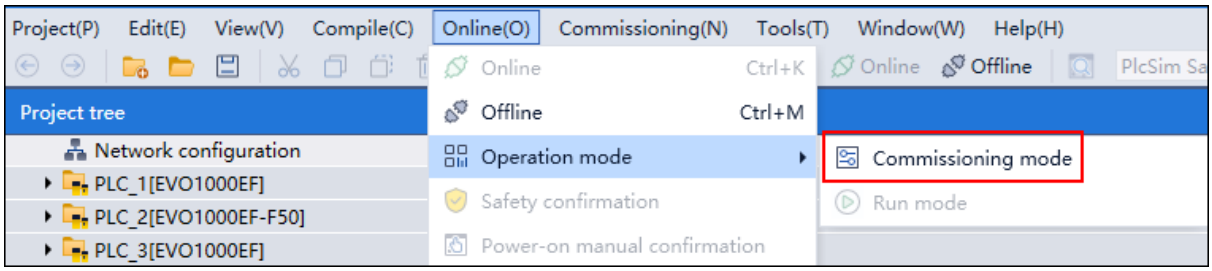
The methods for value display and calculation in safety PLCs are the same as those in standard PLCs. For details, see 10.10.3 Value Display and Calculation in the "PLC Programming" chapter.

11.8 PLC Online Operations

This section only covers the functional differences between the online operations of safety PLCs and standard PLCs; for other general functions, see 10.11 PLC Online Operation in the "PLC Programming" chapter.

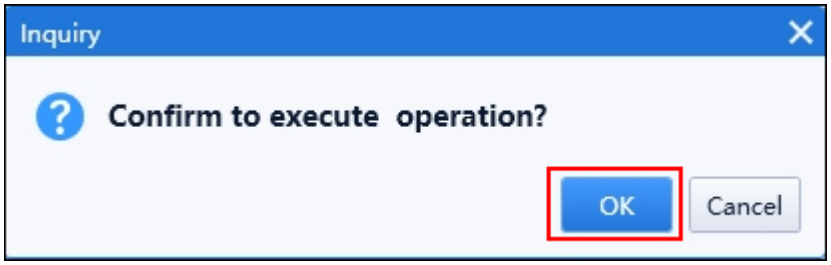
- The EIP2 port of the EIP communication unit supports DLR ring networking. For specific operations, see 10.11.16 DLR Ring Network Management of the standard PLC.
- The EIP2 port of the EIP communication unit in the safety PLC supports IP address configuration in the same subnet as the LAN1 port. The standard PLC maintains its original rules – different network ports must have IP addresses in different subnets.

11.8.1 Operation Modes



The operation modes of safety PLCs include startup mode, debug mode, run mode, recovery mode, and safety status mode. Manual switching is supported between debug mode and run mode. Startup mode, recovery mode, and safety mode are automatically determined and switched by the PLC based on the device status, and manual switching is not supported.

Prerequisites



The safety PLC has switched to online status.

Procedure

1. Select "Online > Operation mode" from the menu bar to view the current operation mode of the device.
2. If the current mode is operational mode, click "Commissioning mode" to switch.

3. Click "OK" in the pop-up window to switch the operation mode.

4. If the current operation mode is debug mode, 11.8.2 safety confirmation must be performed before manually switching to run mode.

> **WARNING**
>
> When switching the safety PLC operation mode to debug mode, ensure that all personnel on site have evacuated the hazardous area. Failure to do so may result in output activation, leading to personal injury.

Description of safety PLC operation modes

Operation Mode	Description
Startup mode	The safety PLC initializes hardware and software and performs a power-on self test.
Debug mode (stopped)	Users verify and debug the project in this mode. This mode supports project modification, download, online debugging, variable forcing, releasing and writing. Safety communication is not executed.
Debug mode (running)	Users verify and debug the project in this mode. This mode supports project modification, download, online debugging, variable forcing, releasing and writing. Safety communication is executed.
Run mode	Normal operation mode of the safety PLC. This mode does not support project download, variable forcing, or releasing.
Safety status mode (manual confirmation)	After project safety confirmation and power-on, the system enters this mode and waits for manual confirmation from users. In this mode, safety communication is executed, and input/output values are set to safety values.
Safety status mode (fault)	The system enters this mode after the safety PLC detects a fault in safety diagnostics. In this mode, input/output values are set to safety values.
Recovery mode	The safety PLC enters the recovery mode via the DIP switch. In this mode, backup data is restored to the safety PLC. After recovery, the system waits for power-off and restart.

When the safety PLC enters safety mode, the VAD indicator on the device's segment display maintains the status before entering safety mode.

Cycle communication status of the safety PLC under various operation modes

Operation Mode	Safety Input (CIP Safety)	Standard Input	Safety Output (CIP Safety)	Standard Output	Safety Status
Startup mode	Ignore	Ignore	Ignore	Ignore	Refresh
Debug mode (stopped)	Safety value	Ignore	Safety value	Ignore	Refresh
Debug mode (running)	Refresh	Refresh	Refresh	Refresh	Refresh
Run mode	Refresh	Refresh	Refresh	Refresh	Refresh
Safety status mode (manual confirmation)	Safety value	Refresh	Safety value	Refresh	Remain
Safety status mode (fault)	Safety value	Refresh	Safety value	Refresh	Remain

Operation Mode	Safety Input (CIP Safety)	Standard Input	Safety Output (CIP Safety)	Standard Output	Safety Status
Recovery mode	Ignore	Ignore	Ignore	Ignore	Ignore

Actions during safety PLC mode switching

Previous Operating Mode	New Operating Mode	Action
Startup Mode	Debug mode (stopped)	No project in safety PLC; no other actions
Startup Mode	Safety status mode (manual confirmation)	1. Starts safety communication; input/output values are set to safety values. 2. Starts scheduling and execution of user tasks.
Startup Mode	Safety status mode (fault)	Remains in safety mode; input/output values are set to safety values.
Startup Mode	Run mode	1. Starts safety communication; input/output values are set to real-time values. 2. Starts scheduling and execution of user tasks.
Startup Mode	Recovery mode	Starts restoring backup data from the SD card in the communication unit.
Debug mode (stopped)	Debug mode (running)	1. Starts safety communication; input/output values are set to real-time values. 2. Starts scheduling and execution of user projects.
Debug mode (running)	Debug mode (stopped)	1. Stops safety communication. 2. Stops scheduling and execution of user tasks.
Debug mode	Safety status mode (fault)	Input/output values are set to safety values.
Run mode	Safety status mode (fault)	Input/output values are set to safety values.
Debug mode (running)	Run mode	User project remains running.
Run mode	Debug mode (stopped)	1. Deletes safety confirmation file. 2. Stops safety communication. 3. Stops scheduling and execution of user tasks.

Functions supported by safety PLC in each operation mode

Description	Startup Mode	Debug Mode		Run Mode	Safety Status Mode	Recovery Mode
		Stop	Run			
User program execution	×	×	√	√	√	×
Safety communication	×	×	√	√	√	×
Backplate communication	√	√	√	√	√	√
Variable forcing	×	√	√	×	×	×
Variable releasing	×	√	√	×	×	×
Variable writing	×	√	√	×	×	×
Project download	×	√	√	×	×	×
Safety PLC status monitoring	×	√	√	√	√	√
Program monitoring	×	√	√	√	√	√
Safety data recovery	×	×	×	×	×	√
Restoring factory settings	×	√	√	×	×	×

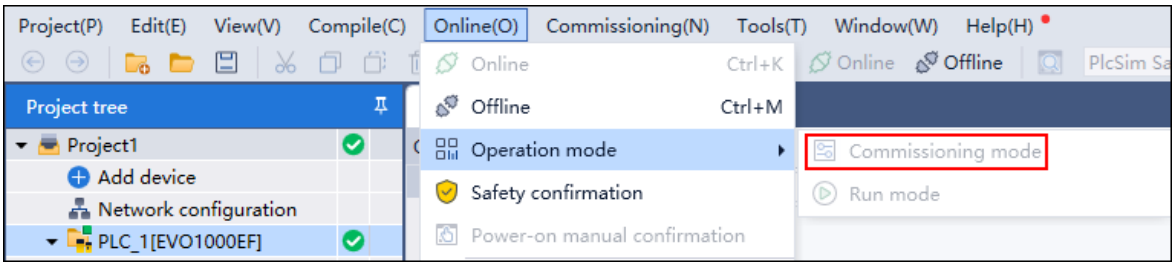
Time Settings	×	√	×	×	×	×
Safety confirmation	×	√	√	×	×	×
Device permissions	×	√	√	×	×	×
Power-On Manual Confirmation	×	×	×	×	√[1]	×

[1]: Power-on manual confirmation is only supported when the safety PLC enters the safety mode (manual confirmation) after power-on.

11.8.2 Safety Confirmation

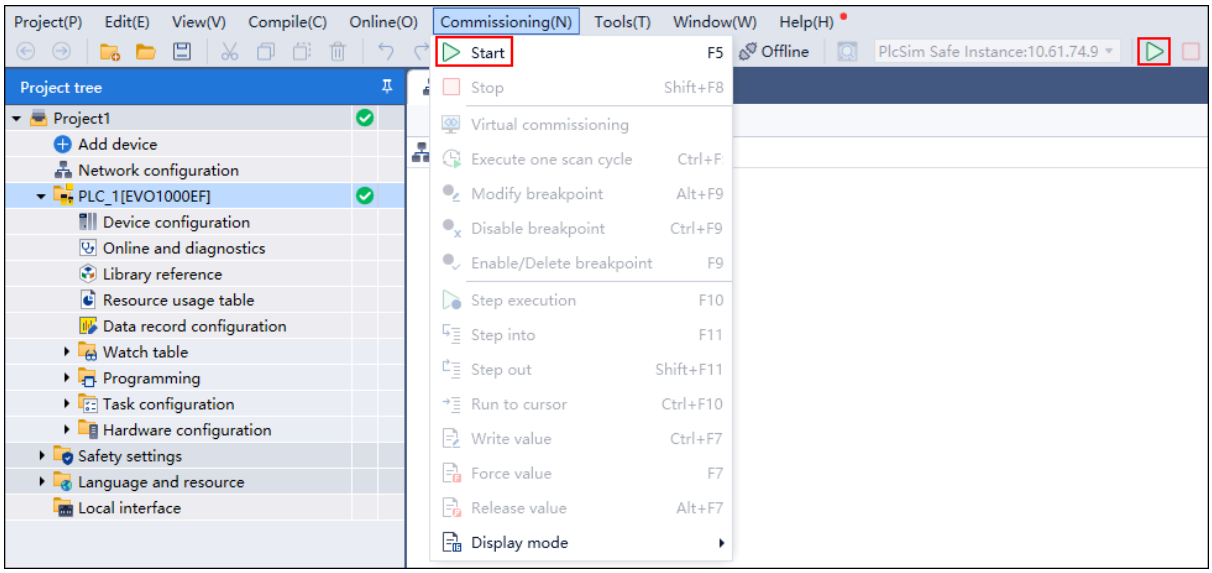
Users must perform a safety confirmation test to confirm that all safety functions, including safety sensors, safety I/O modules, safety PLCs, and safety actuators, meet the safety system requirements. After safety confirmation test, if all safety functions meet the requirements, users must attach the confirmation information to the safety program. This action is called safety confirmation.

After the user program has been debugged, safety confirmation can be performed on the user program. Only user programs that have undergone safety confirmation are allowed to be loaded and executed when the safety PLC is powered on again; otherwise, the user program will be lost.



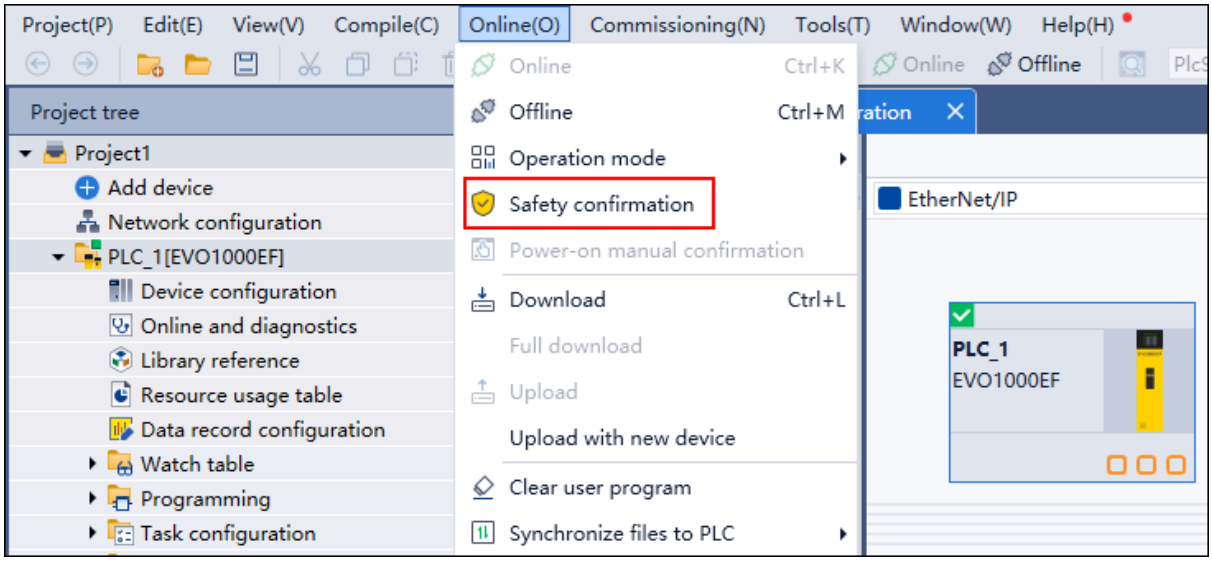
> **WARNING**
>
> For all safety connections, confirm that the calculated response time meets the requirements; otherwise, safety functions may be compromised, potentially resulting in personal injury.

Prerequisites



- The safety PLC has switched to online status.
- Before performing safety confirmation on the safety program, complete program debugging first.

Procedure



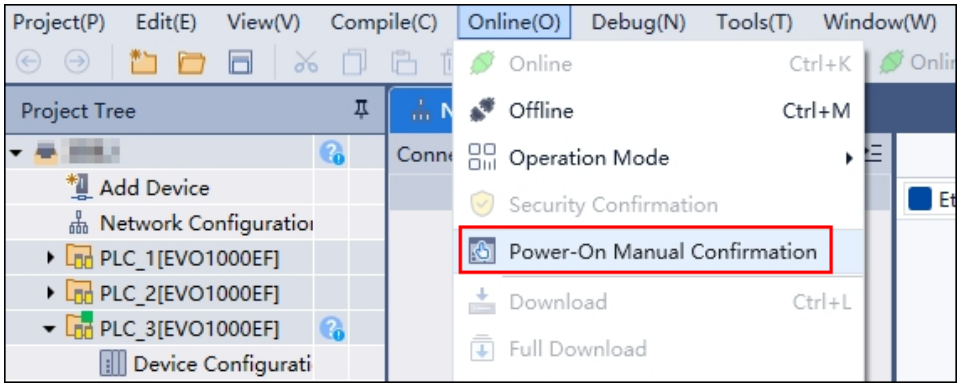
1. In the menu bar, select "Online > Operation mode" and confirm that the safety PLC is in "Commissioning mode".

2. In the menu bar, select "Commissioning > Start", or click , then click "OK" in the pop-up window to switch the device to run mode.

3. Click "Online > Safety confirmation" in the menu bar.

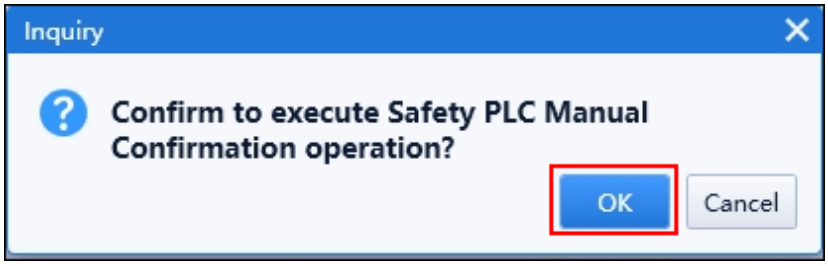
4. Click "OK" in the pop-up dialog box to complete the safety confirmation.

11.8.3 Power-On Manual Confirmation



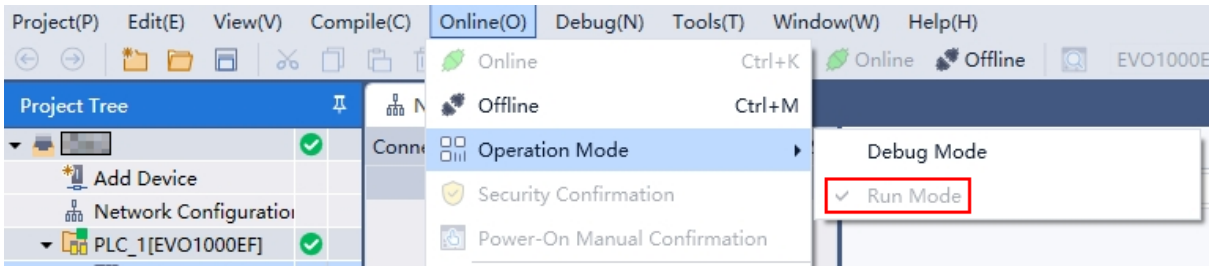
After safety confirmation of the safety program in the safety PLC, when the safety PLC is powered on and completes self test, it is ready to run. Users can choose either manual or automatic confirmation. If automatic confirmation is selected, the safety PLC will directly enter the run mode; if manual confirmation is selected, the PLC enters the run mode before manual confirmation by users. The system defaults to manual confirmation mode.

Prerequisites



- After the safety PLC clears faults and is powered on again, the device is in safety mode, waiting for manual confirmation.
- The safety PLC is switched to online status using the iFA Evolution software (the current projects in use must match the projects in the safety PLC).

Procedure



1. Click "Online > Power-on manual confirmation" in the menu bar.

2. Click "OK" in the pop-up window to complete the power-on manual confirmation of the safety PLC.

3. Select "Online > Operation mode" from the menu bar to check the current operation mode of the safety PLC. If the current mode is run mode, it indicates that the power-on manual confirmation is successful.

11.8.4 Operation Log

This section only covers the functional differences between operation logs in safety PLCs and standard PLCs; for other general functions, see 10.11.21 Operation Log in the "PLC Programming" chapter.

> NOTE
>
> Exporting and clearing logs require permission control. If the safety PLC has permission protection enabled, permission verification must be passed before execution.

11.9 Safety PLC Simulation Mode

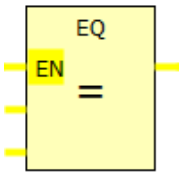
This section only covers the functional differences between the simulation mode in safety PLCs and standard PLCs; for other general functions, see 10.13 PLC Simulation Mode in the "PLC Programming" chapter.

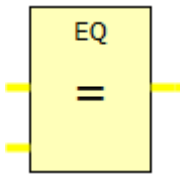
- Supports logic simulation.
- Supports online program commissioning.

11.10 Common Safety Instructions

11.10.1 Basic Instructions

11.10.1.1 Comparison Operations





11.10.1.1.1 Instruction List

Instruction	FB/FC	Function	Library	Applicable Library Version
11.10.1.1.2 EQ	FC	Equal to	SafetyInstructions	Applicable to library version 1.0.0.0/1.1.0.0
11.10.1.1.3 GE	FC	Greater than or equal to		
11.10.1.1.4 GT	FC	Greater than		
11.10.1.1.5 LE	FC	Smaller than or equal to		
11.10.1.1.6 LT	FC	Less than		
11.10.1.1.7 NE	FC	Not equal		

11.10.1.1.2 EQ

EQ determines whether the two input values are equal. If the first input value equals the second, the output is TRUE; otherwise, the output is FALSE.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
EQ	Equal to	FC		

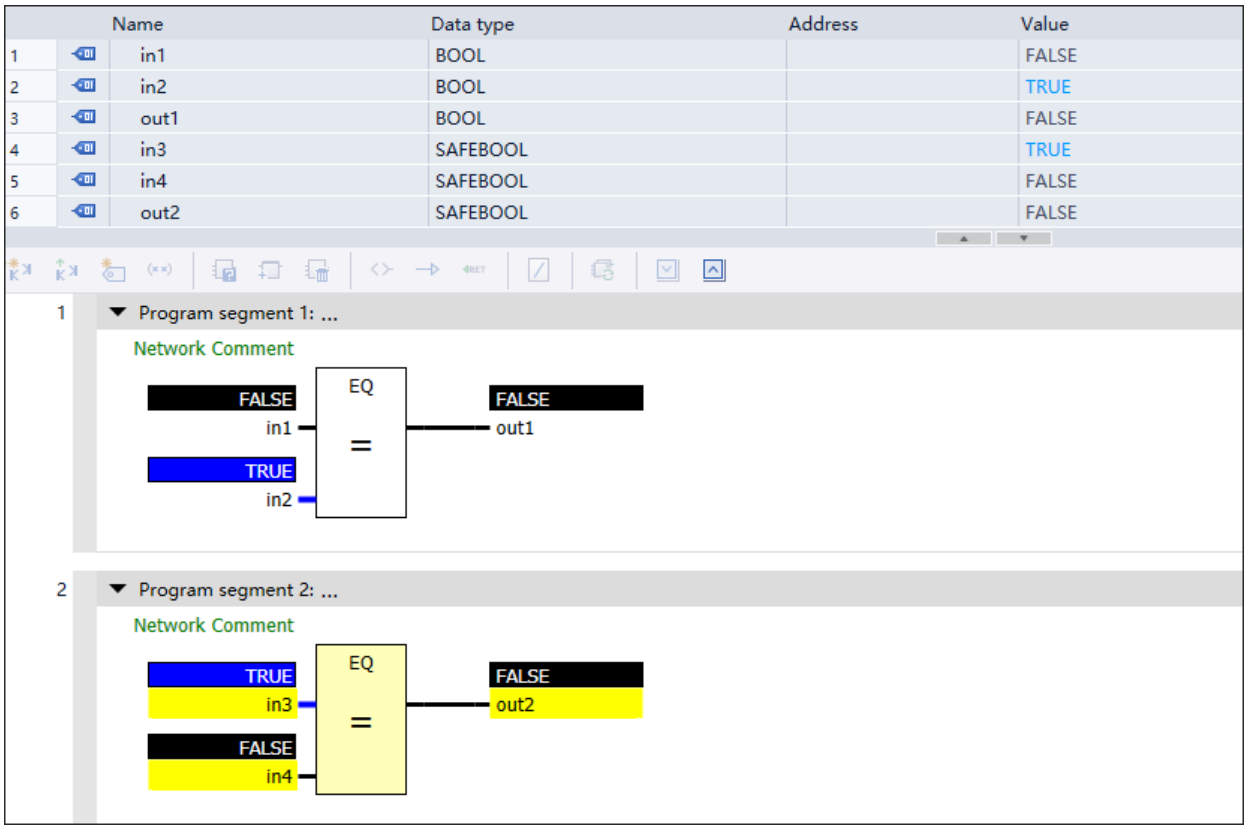
- **Related variables**

Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Comparison object	Follows data type	–	The value to be compared.
	In2	Comparison object	Follows data type	–	The value to be compared.
Output	Out	Comparison result	Follows data type	–	Comparison result

Data types

	Boolean		Bit String				Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In1	√	√	√	√	√	√	√	√	√	√	√	√
In2	√	√	√	√	√	√	√	√	√	√	√	√
Out	√	√	–	–	–	–	–	–	–	–	–	–



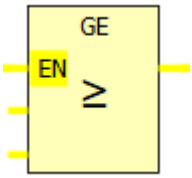
- **Function description**

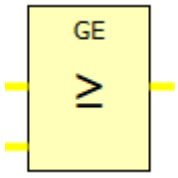
  Check whether the values of the two inputs, "In1" and "In2", are equal.

  If they are equal, the comparison result "Out" is TRUE. In all other cases, the value of "Out" is FALSE.

- **Program example**

  FBD:





- **Precautions**

  If the input/output parameter is omitted, a fault will occur during compilation. However, if the output terminal is unused or the input terminal for the next instruction is not connected, no fault will occur.

11.10.1.1.3 GE

GE compares the two input values. If the first input value is greater than or equal to the second, the output is TRUE; otherwise, the output is FALSE.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
GE	Greater than or equal to	FC		

- **Related variables**

  Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Comparison object	Follows data type	–	The value to be compared.
	In2	Comparison object	Follows data type	–	The value to be compared.
Output	Out	Comparison result	Follows data type	–	Comparison result

  Data types

	Boolean		Bit String				Integer				Time Format	
	BOOL	SAFE BOOL	BYTE	SAFE BYTE	WORD	SAFE WORD	INT	SAFEINT	DINT	SAFE DINT	TIME	SAFE TIME
In1	–	–	–	–	–	–	√	√	√	√	√	√
In2	–	–	–	–	–	–	√	√	√	√	√	√
Out	√	√	–	–	–	–	–	–	–	–	–	–

- **Function description**

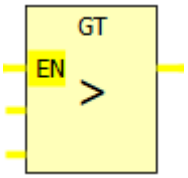
  Compare the values of the two inputs, "In1" and "In2".

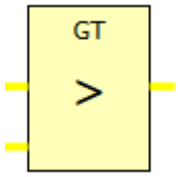
  If "In1" ≥ "In2", the output is TRUE; otherwise, the output is FALSE.

Input/Output Data Type	Comparison Basis
INT, SAFEINT, DINT, SAFEDINT	Compare signed values.
TIME, SAFETIME	Compare days, hours, minutes, seconds, and milliseconds.

- **Program example**

  FBD:





- **Precautions**
  - If the input/output parameter is omitted, a fault will occur during compilation. However, if the output terminal is unused or the input terminal for the next instruction is not connected, no fault will occur.
  - "In1" and "In2" follow the same comparison rule as safety and standard data types: they can be compared if they have the same format and size, but cannot be compared if they are of WORD and INT types. However, for integer types, comparisons between INT/DINT and SAFEINT are supported.
  - The input condition varies depending on whether the output is a safety or standard data type. If the condition is not met, a compilation fault will occur.
  - When assigning a safety data type variable to the output terminal, set both input terminals to safety data type variables; otherwise, a compilation fault will occur.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

11.10.1.1.4 GT

GT compares the two input values. When the first input value is greater than the second, the output is TRUE; otherwise, the output is FALSE.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
GT	Greater than	FC		

- **Related variables**

  Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Comparison object	Follows data type	–	The value to be compared.
	In2	Comparison object	Follows data type	–	The value to be compared.
Output	Out	Comparison result	Follows data type	–	Comparison result

  Data types

	Boolean		Bit String				Integer				Time Format	
	BOOL	SAFE BOOL	BYTE	SAFE BYTE	WORD	SAFE WORD	INT	SAFEINT	DINT	SAFE DINT	TIME	SAFE TIME
In1	–	–	–	–	–	–	√	√	√	√	√	√
In2	–	–	–	–	–	–	√	√	√	√	√	√
Out	√	√	–	–	–	–	–	–	–	–	–	–

- **Function description**

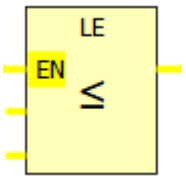
  Compare the values of the two inputs, "In1" and "In2".

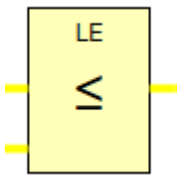
  If "In1" > "In2", the output is TRUE; otherwise, the output is FALSE.

Input/Output Data Type	Comparison Basis
INT, SAFEINT, DINT, SAFEDINT	Compare signed values.
TIME, SAFETIME	Compare days, hours, minutes, seconds, and milliseconds.

- **Program example**

  FBD:





- **Precautions**
  - If the input/output parameter is omitted, a fault will occur during compilation. However, if the output terminal is unused or the input terminal for the next instruction is not connected, no fault will occur.
  - "In1" and "In2" follow the same comparison rule as safety and standard data types: they can be compared if they have the same format and size, but cannot be compared if they are of WORD and INT types. However, for integer types, comparisons between INT/DINT and SAFEINT are supported.
  - The input condition varies depending on whether the output is a safety or standard data type. If the condition is not met, a compilation fault will occur.
  - When assigning a safety data type variable to the output terminal, set both input terminals to safety data type variables; otherwise, a compilation fault will occur.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

11.10.1.1.5 LE

LE compares the two input values. When the first input value is smaller than the second, the output is TRUE; otherwise, the output is FALSE.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
LE	Smaller than or equal to	FC		

- **Related variables**

  Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Comparison object	Follows data type	–	The value to be compared.
	In2	Comparison object	Follows data type	–	The value to be compared.
Output	Out	Comparison result	Follows data type	–	Comparison result

Data types

	Boolean		Bit String				Integer				Time Format	
	BOOL	SAFE BOOL	BYTE	SAFE BYTE	WORD	SAFE WORD	INT	SAFEINT	DINT	SAFE DINT	TIME	SAFE TIME
In1	–	–	–	–	–	–	√	√	√	√	√	√
In2	–	–	–	–	–	–	√	√	√	√	√	√
Out	√	√	–	–	–	–	–	–	–	–	–	–

- **Function description**

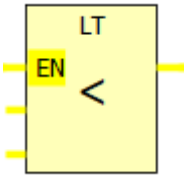
  Compare the values of the two inputs, "In1" and "In2".

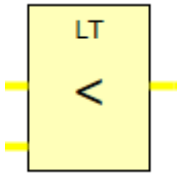
  If "In1" ≤ "In2", the output is TRUE; otherwise, the output is FALSE.

Input/Output Data Type	Comparison Basis
INT, SAFEINT, DINT, SAFEDINT	Compare signed values.
TIME, SAFETIME	Compare days, hours, minutes, seconds, and milliseconds.

- **Program example**

  FBD:





- **Precautions**
  - If the input/output parameter is omitted, a fault will occur during compilation. However, if the output terminal is unused or the input terminal for the next instruction is not connected, no fault will occur.
  - "In1" and "In2" follow the same comparison rule as safety and standard data types: they can be compared if they have the same format and size,

    but cannot be compared if they are of WORD and INT types. However, for integer types, comparisons between INT/DINT and SAFEINT are supported.
  - The input condition varies depending on whether the output is a safety or standard data type. If the condition is not met, a compilation fault will occur.
  - When assigning a safety data type variable to the output terminal, set both input terminals to safety data type variables; otherwise, a compilation fault will occur.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

11.10.1.1.6 LT

LT compares the two input values. When the first input value is smaller than the second, the output is TRUE; otherwise, the output is FALSE.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
LT	Less than	FC		

- **Related variables**

  Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Comparison object	Follows data type	–	The value to be compared.
	In2	Comparison object	Follows data type	–	The value to be compared.
Output	Out	Comparison result	Follows data type	–	Comparison result

  Data types

	Boolean		Bit String				Integer				Time Format	
	BOOL	SAFE BOOL	BYTE	SAFE BYTE	WORD	SAFE WORD	INT	SAFEINT	DINT	SAFE DINT	TIME	SAFE TIME
In1	–	–	–	–	–	–	√	√	√	√	√	√
In2	–	–	–	–	–	–	√	√	√	√	√	√
Out	√	√	–	–	–	–	–	–	–	–	–	–

- **Function description**

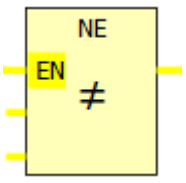
  Compare the values of the two inputs, "In1" and "In2".

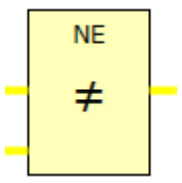
  If "In1" < "In2", the output is TRUE; otherwise, the output is FALSE.

Input/Output Data Type	Comparison Basis
INT, SAFEINT, DINT, SAFEDINT	Compare signed values.
TIME, SAFETIME	Compare days, hours, minutes, seconds, and milliseconds.

- **Program example**

  FBD:





- **Precautions**
  - If the input/output parameter is omitted, a fault will occur during compilation. However, if the output terminal is unused or the input terminal for the next instruction is not connected, no fault will occur.
  - "In1" and "In2" follow the same comparison rule as safety and standard data types: they can be compared if they have the same format and size, but cannot be compared if they are of WORD and INT types. However, for integer types, comparisons between INT/DINT and SAFEINT are supported.
  - The input condition varies depending on whether the output is a safety or standard data type. If the condition is not met, a compilation fault will occur.
  - When assigning a safety data type variable to the output terminal, set both input terminals to safety data type variables; otherwise, a compilation fault will occur.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

11.10.1.1.7 NE

NE compares the two input values. When the first input value is not equal to the second, the output is TRUE; otherwise, the output is FALSE.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
NE	Not equal	FC		

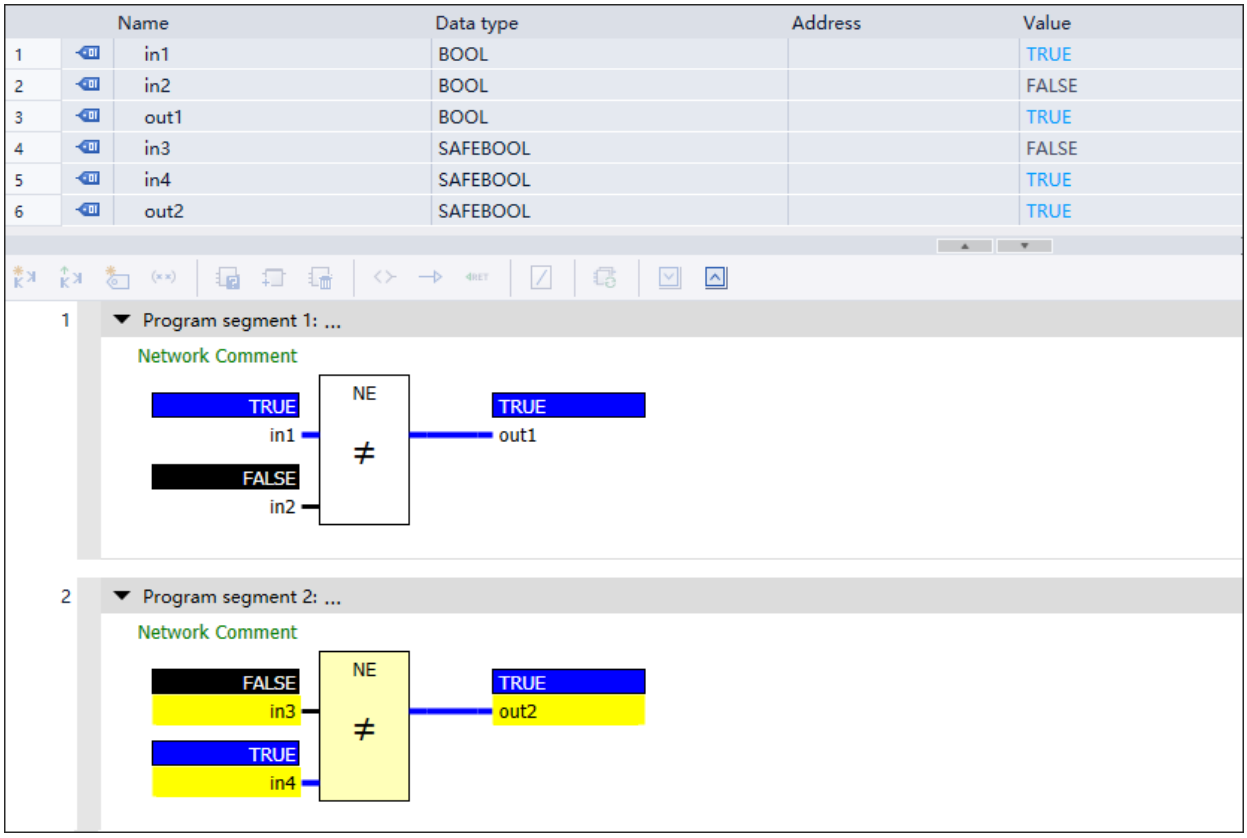
- **Related variables**

  Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Comparison object	Follows data type	–	The value to be compared.
	In2	Comparison object	Follows data type	–	The value to be compared.
Output	Out	Comparison result	Follows data type	–	Comparison result

Data types

	Boolean		Bit String				Integer				Time Format	
	BOOL	SAFE BOOL	BYTE	SAFE BYTE	WORD	SAFE WORD	INT	SAFEINT	DINT	SAFE DINT	TIME	SAFE TIME
In1	√	√	√	√	√	√	√	√	√	√	√	√
In2	√	√	√	√	√	√	√	√	√	√	√	√
Out	√	√	–	–	–	–	–	–	–	–	–	–



- **Function description**

  Check whether the values of the two inputs, "In1" and "In2", are not equal.

  If they are not equal, the comparison result "Out" is TRUE. If they are equal, the value of "Out" is FALSE.

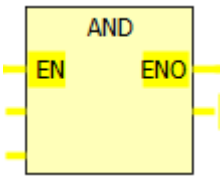
- **Program example**

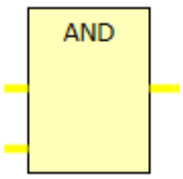
  FBD:

- **Precautions**
  - If the input/output parameter is omitted, a fault will occur during compilation. However, if the output terminal is unused or the input terminal for the next instruction is not connected, no fault will occur.

- "In1" and "In2" follow the same comparison rule as safety and standard data types: they can be compared if they have the same format and size, but cannot be compared if they are of WORD and INT types. However, for integer types, comparisons between INT/DINT and SAFEINT are supported.
- The input condition varies depending on whether the output is a safety or standard data type. If the condition is not met, a compilation fault will occur.
- When assigning a safety data type variable to the output terminal, set both input terminals to safety data type variables; otherwise, a compilation fault will occur.
- When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

11.10.1.2 Logic Operations





11.10.1.2.1 Instruction List

Instruction	FB/FC	Function	Library	Applicable Library Version
11.10.1.2.2 AND	FC	and	SafetyInstructions	Applicable to library version 1.0.0.0/1.1.0.0
11.10.1.2.3 NOT	FC	Not		
11.10.1.2.4 OR	FC	Or		
11.10.1.2.5 XOR	FC	Exclusive OR		

11.10.1.2.2 AND

Bitwise AND: When the same bit in all inputs is 1, the corresponding output bit is 1; if not, the output bit is 0.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
AND	and	FC		

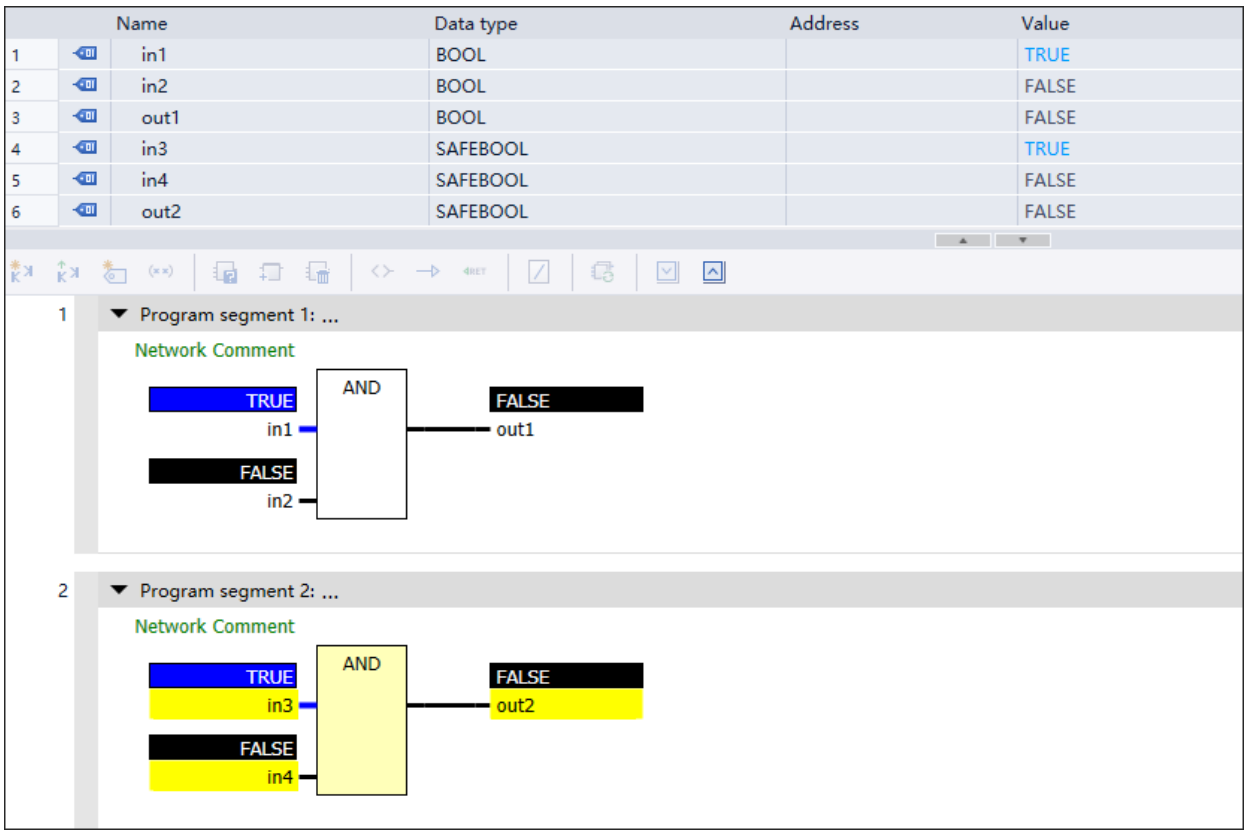
- **Related variables**

Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1 to InN	Operand	FALSE, TRUE	FALSE	Operand
Output	Out	Operation result	FALSE, TRUE	–	Operation result

Data types

	Boolean		Bit String				Integer				Time Format	
	BOOL	SAFE BOOL	BYTE	SAFE BYTE	WORD	SAFE WORD	INT	SAFEINT	DINT	SAFE DINT	TIME	SAFE TIME
In0 to InN	√	√	–	–	–	–	–	–	–	–	–	–
Out	√	√	–	–	–	–	–	–	–	–	–	–



- **Function description**

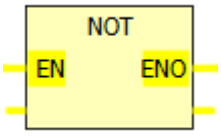
  AND operation is performed on multiple Boolean operands "In1 to InN".

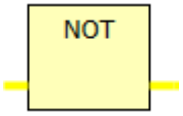
  The operation result is TRUE when all input operands are TRUE. Otherwise, the operation result is FALSE.

- **Program example**

  FBD:

  LD:





- **Precautions**
  - The data types of "In1" to "InN" and "Out" can only be set to Boolean.
  - The input condition varies depending on whether the output is a safety or standard data type. If the condition is not met, a compilation fault will occur.
  - When assigning a safety data type variable to the output terminal, set at least one safety data type variable for the input terminals.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

11.10.1.2.3 NOT

NOT inverts the bits of a Boolean value.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
NOT	Not	FC		

- **Related variables**

Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Operand	FALSE, TRUE	–	Operand

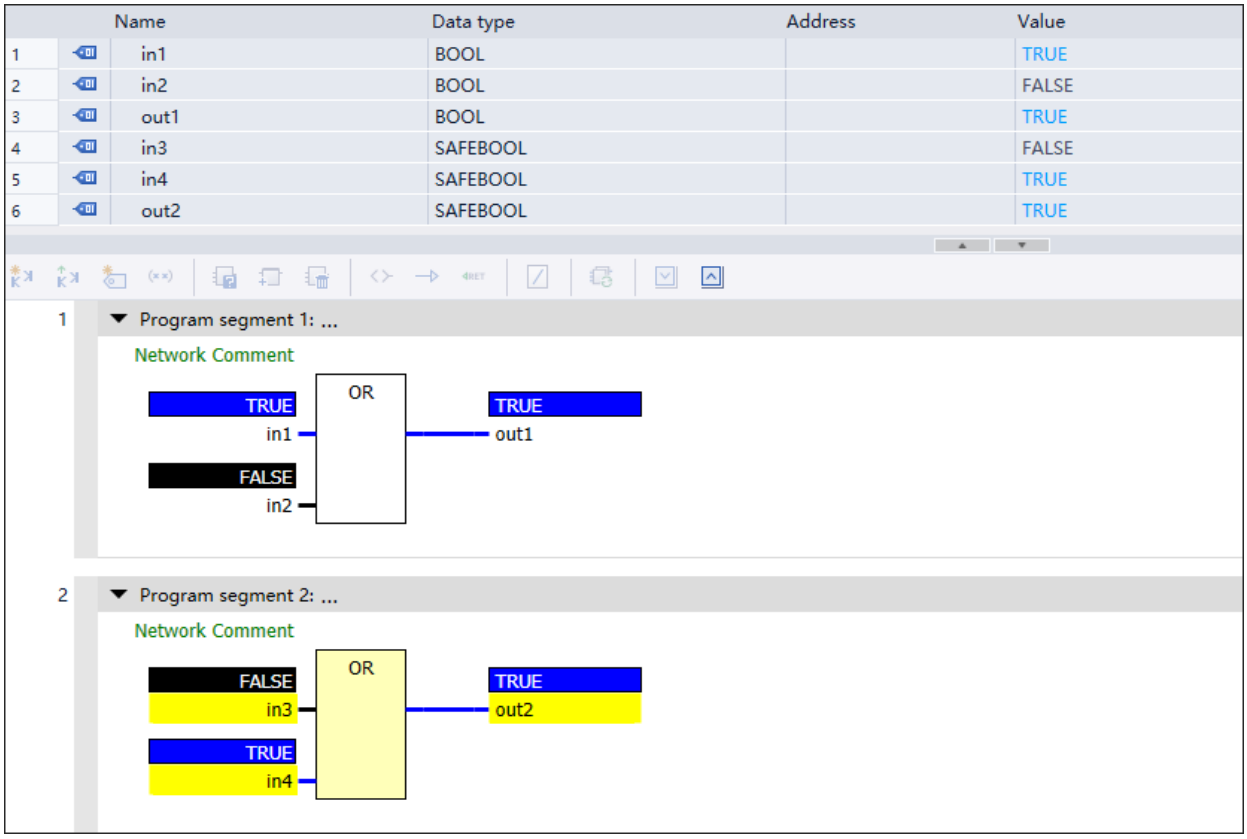
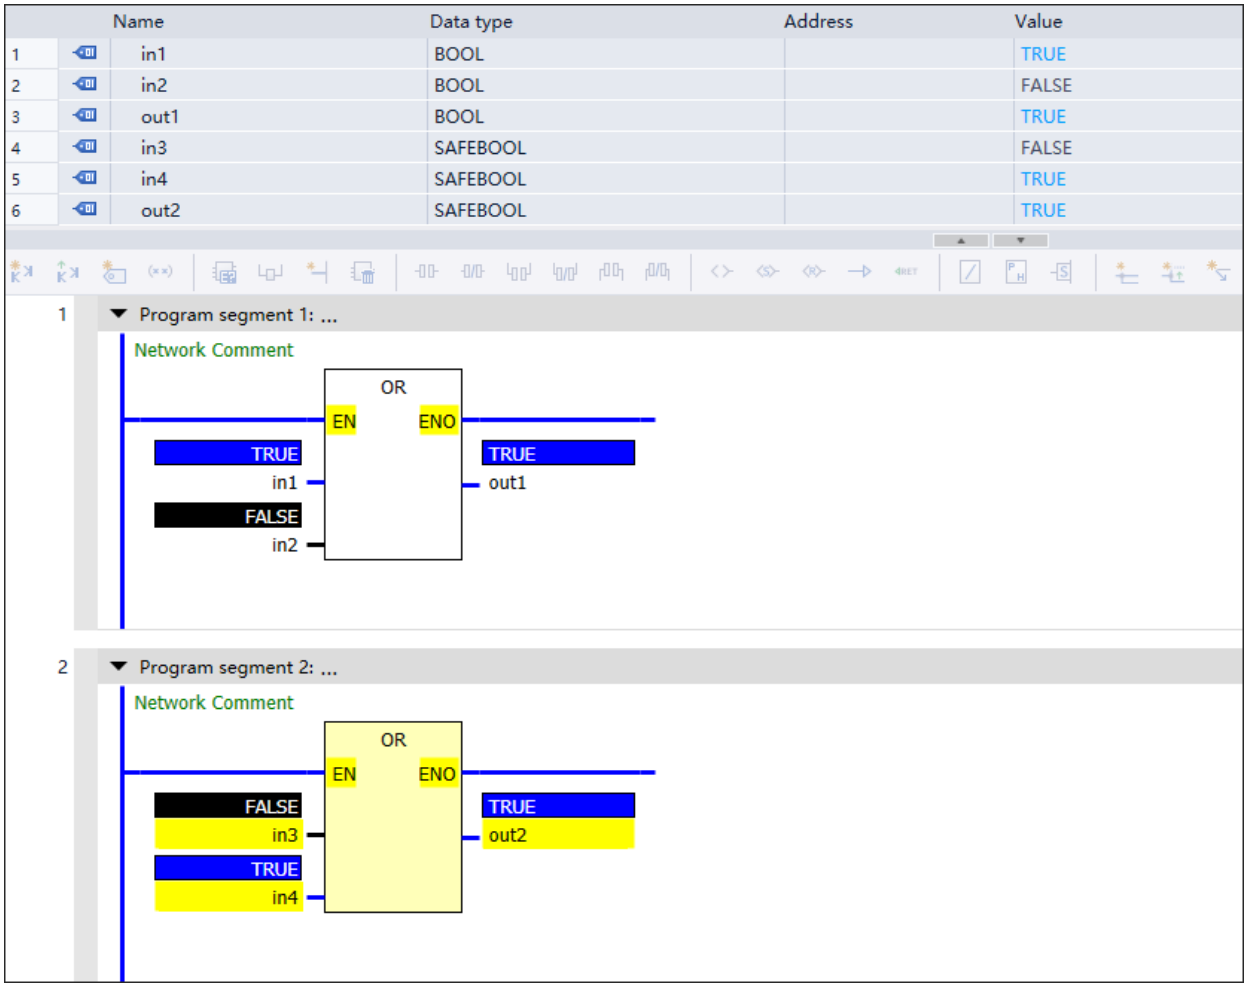
In1 to InN	√	√	–	–	–	–	–	–	–	–	–	–
Out	√	√	–	–	–	–	–	–	–	–	–	–



- **Function description**

AND operation is performed on multiple Boolean operands "In1 to InN".

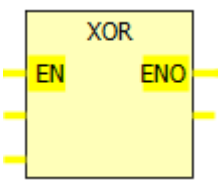


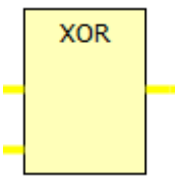
The operation result is FALSE when all input operands are FALSE. Otherwise, the operation result is TRUE.

- **Program example**

FBD:

LD:





- **Precautions**
  - The data types of "In1" to "InN" and "Out" can only be set to Boolean.
  - The input condition varies depending on whether the output is a safety or standard data type. If the condition is not met, a compilation fault will occur.
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

11.10.1.2.5 XOR

Bitwise XOR: When one input is 1 and the other is 0 for the same bit of the two inputs, the corresponding output bit is 1; otherwise, when the two input values are the same for the same bit, the output bit is 0.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
XOR	Exclusive OR	FC		

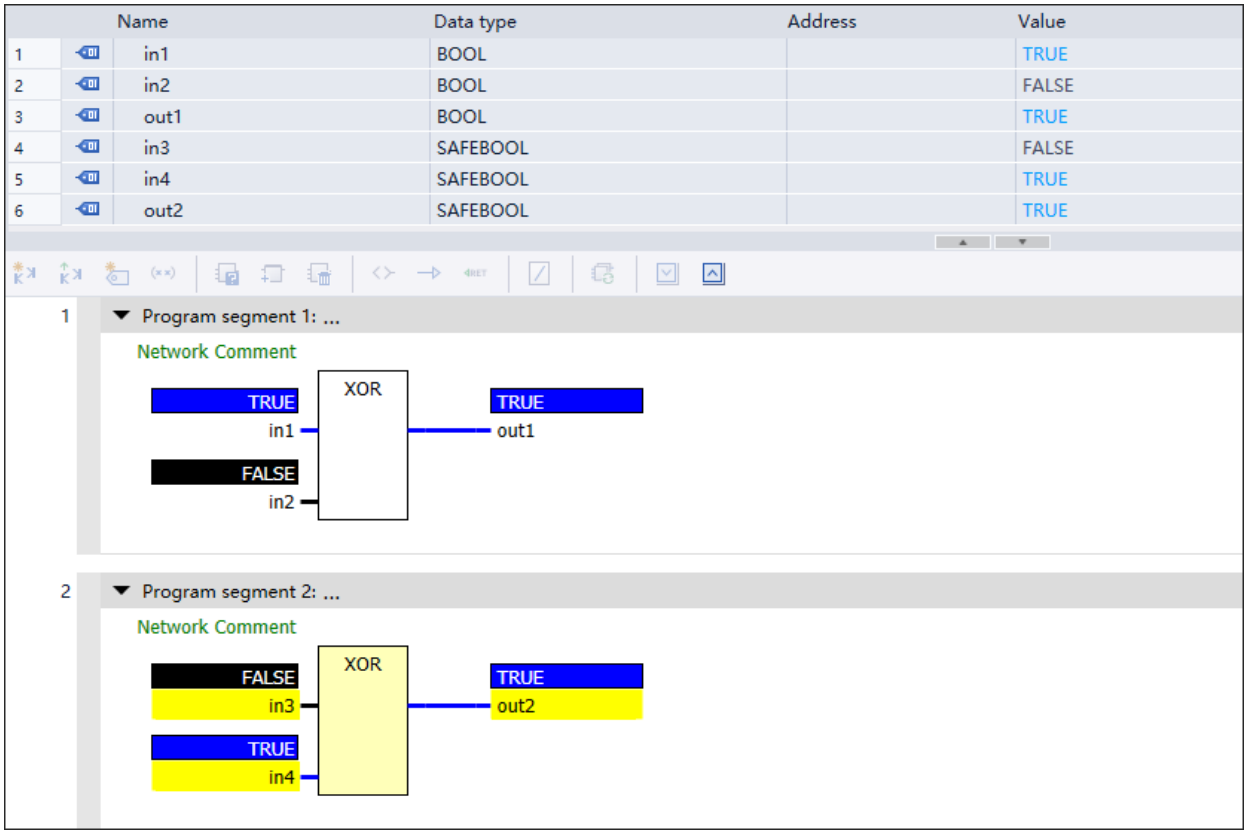
- **Related variables**

  Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1 to InN	Operand	FALSE, TRUE	FALSE	Operand
Output	Out	Operation result	FALSE, TRUE	–	Operation result

Data types

	Boolean		Bit String				Integer				Time Format	
	BOOL	SAFE BOOL	BYTE	SAFE BYTE	WORD	SAFE WORD	INT	SAFEINT	DINT	SAFE DINT	TIME	SAFE TIME
In1 to InN	√	√	–	–	–	–	–	–	–	–	–	–
Out	√	√	–	–	–	–	–	–	–	–	–	–



- **Function description**

  AND operation is performed on multiple Boolean operands "In1 to InN".

  The operation result is FALSE when the two input operands have the same value. The operation result is TRUE when they are different.

- **Program example**

  FBD:

  LD:

- **Precautions**
  - The data types of "In1" to "InN" and "Out" can only be set to Boolean.
  - The input condition varies depending on whether the output is a safety or standard data type. If the condition is not met, a compilation fault will occur.
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

Instruction	FB/FC	Function	Library	Applicable Library Version
11.10.1.3.5 DIV	FC	Divide		

11.10.1.3.2 ADD

ADD operation is performed on integers and durations.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
ADD	Add	FC		

- **Related variables**

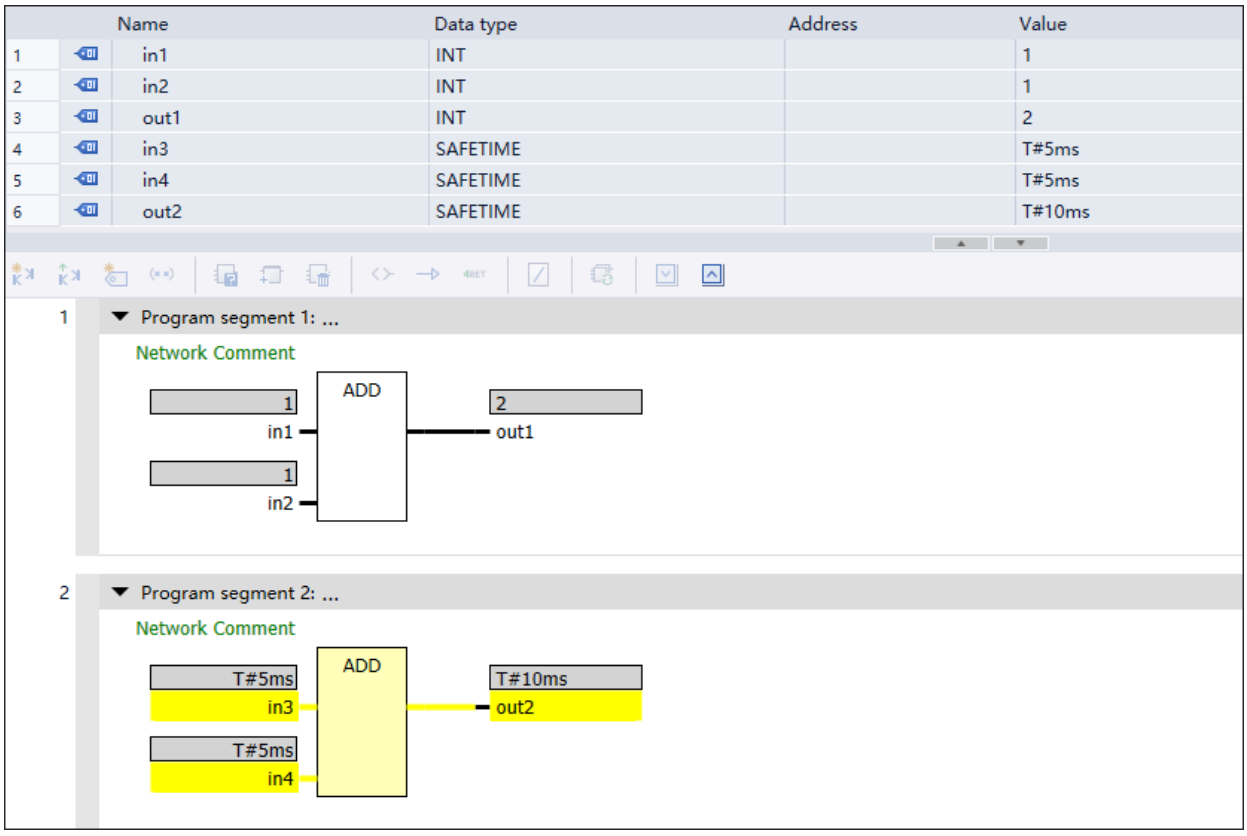
  Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1 to InN	Addend	Follows data type	-	Values to be added
Output	Out	Output value	Follows data type	-	Output value

  Data types

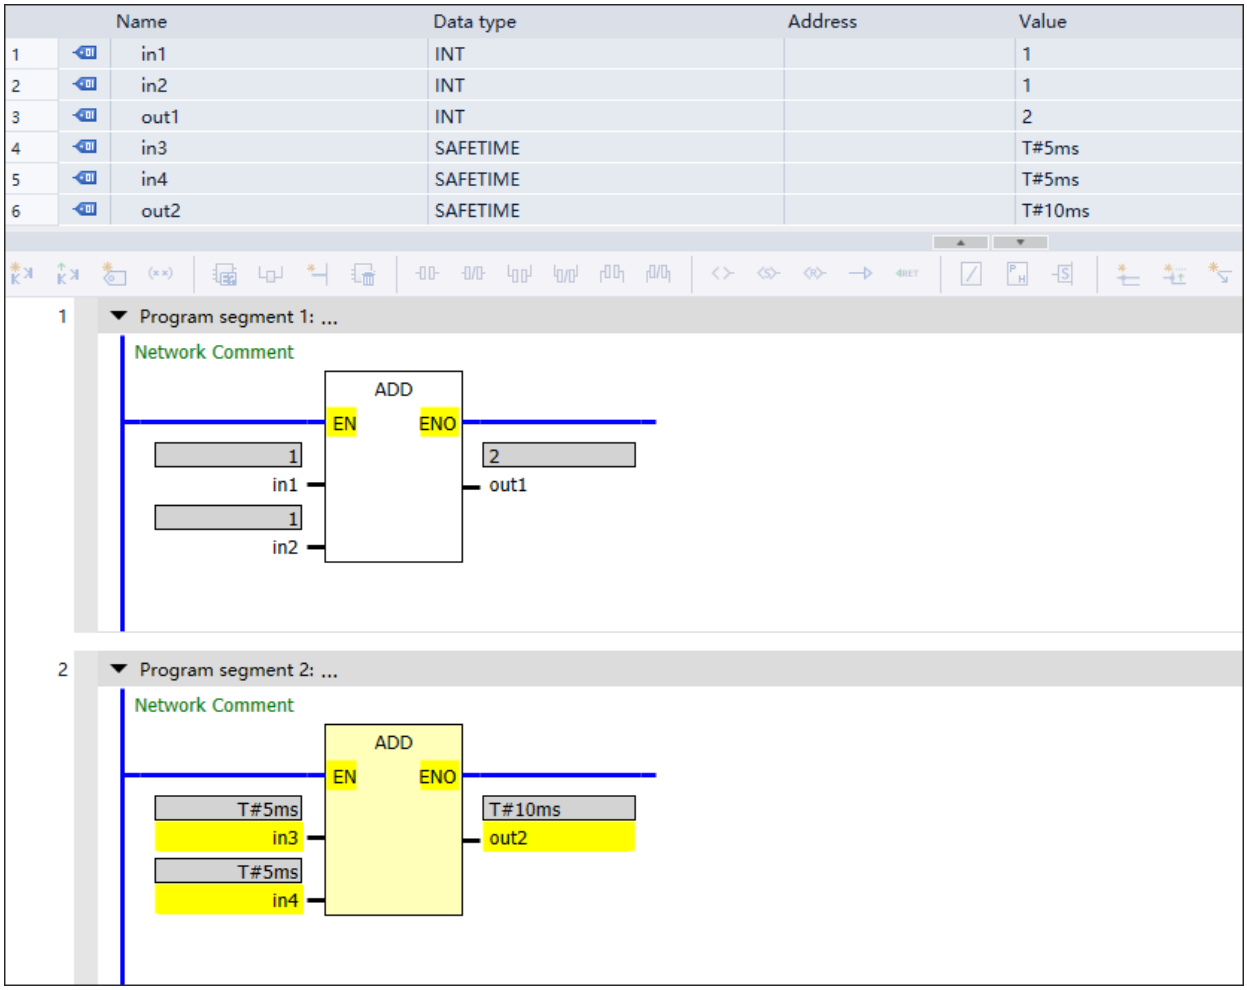
	Boolean		Bit String				Integer				Time Format	
	BOOL	SAFE BOOL	BYTE	SAFE BYTE	WORD	SAFE WORD	INT	SAFEINT	DINT	SAFE DINT	TIME	SAFE TIME
In1 to InN	–	–	–	–	–	–	√	√	√	√	√	√
Out	–	–	–	–	–	–	√	√	√	√	√	√

- **Function description**
  - Output the result of adding integers or durations.
  - Overflow occurs when the sum of "In1" to "InN" exceeds the valid range of the data type of the result. When overflow occurs, the relationship among the data types of "In1" to "InN", the data type of the result, and the value of the result is shown in the table below.



Input/Output Data Type	Addition Result
Integer	The sum of In1 to InN is represented by the data type of the addition result [1]. When both inputs are of the same type, the output must be of the same type, such as INT + INT = INT. When the two inputs are of different types, the output must be the type with the wider bit width, such as INT + DINT = DINT. The result of safety type input and standard type input is a standard type. The result of safety type inputs can be either a standard or safety data type. The result of standard type inputs is a standard type.
Time format	The sum of TIME type values is represented by DWORD. Overflow is truncated according to bit width [2].

[1]: For example, if the value of "In1" is INT#32767 and the value of "In2" is INT#3, the value of the addition result is 32770. When the output is set to INT type, the value of the addition result is -32766, which is the lower 16 bits of the sum 32770. When the output is set to DINT type, the result is DINT#32770.

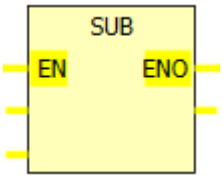


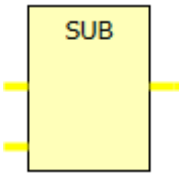
[2]: For example, if the value of "In1" is TIME#49d17h2m47s295ms and the value of "In2" is TIME#5ms, the sum is TIME#49d17h2m47s30ms. However, the maximum value of TIME type is the same as DWORD, which is 4294967295. Therefore, the value of the addition result is TIME#4ms, representable in 32 bits.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - If the input/output parameter is omitted, a fault will occur during compilation. However, if the output terminal is unused or the input terminal for the next instruction is not connected, no fault will occur.
  - "In0" to "InN", and "Out" can be of different data types. In this case, the operation is processed using the data type that includes all the above input parameters. For example, if "In0" is INT type and "In1" is DINT type, the operation is processed using DINT type. Therefore, the addition result "Out" is of DINT type.
  - The input condition varies depending on whether the output is a safety or standard data type. If the condition is not met, a compilation fault will occur.
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

11.10.1.3.3 SUB

SUB operation is performed on integers and durations.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SUB	Subtract	FC		

- **Related variables**

  Variables

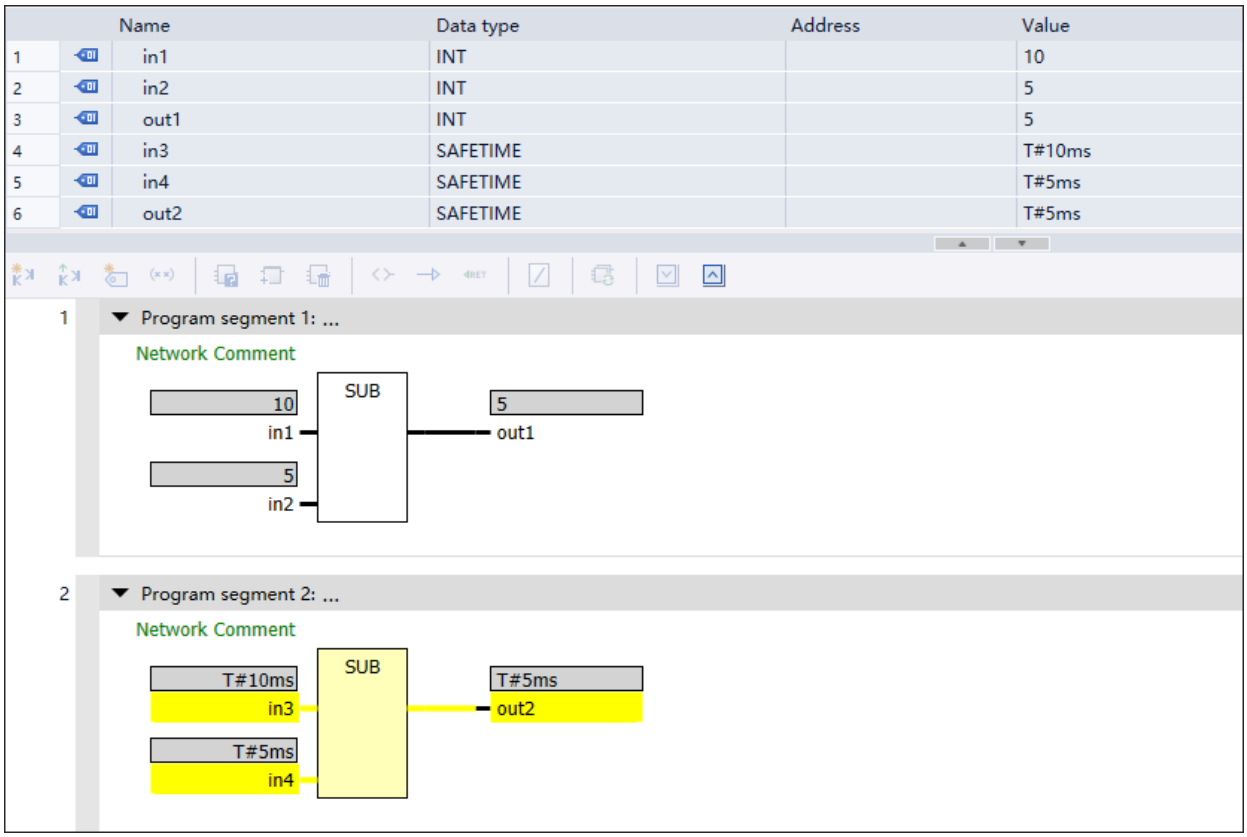
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Subtrahend	Follows data type	–	Subtrahend
	In2	Minuend	Follows data type	–	Minuend
Output	Out	Output value	Follows data type	–	Output value

  Data types

	Boolean		Bit String				Integer				Time Format	
	BOOL	SAFE BOOL	BYTE	SAFE BYTE	WORD	SAFE WORD	INT	SAFEINT	DINT	SAFE DINT	TIME	SAFE TIME
In1	–	–	–	–	–	–	√	√	√	√	√	√
In2	–	–	–	–	–	–	√	√	√	√	√	√
Out	–	–	–	–	–	–	√	√	√	√	√	√

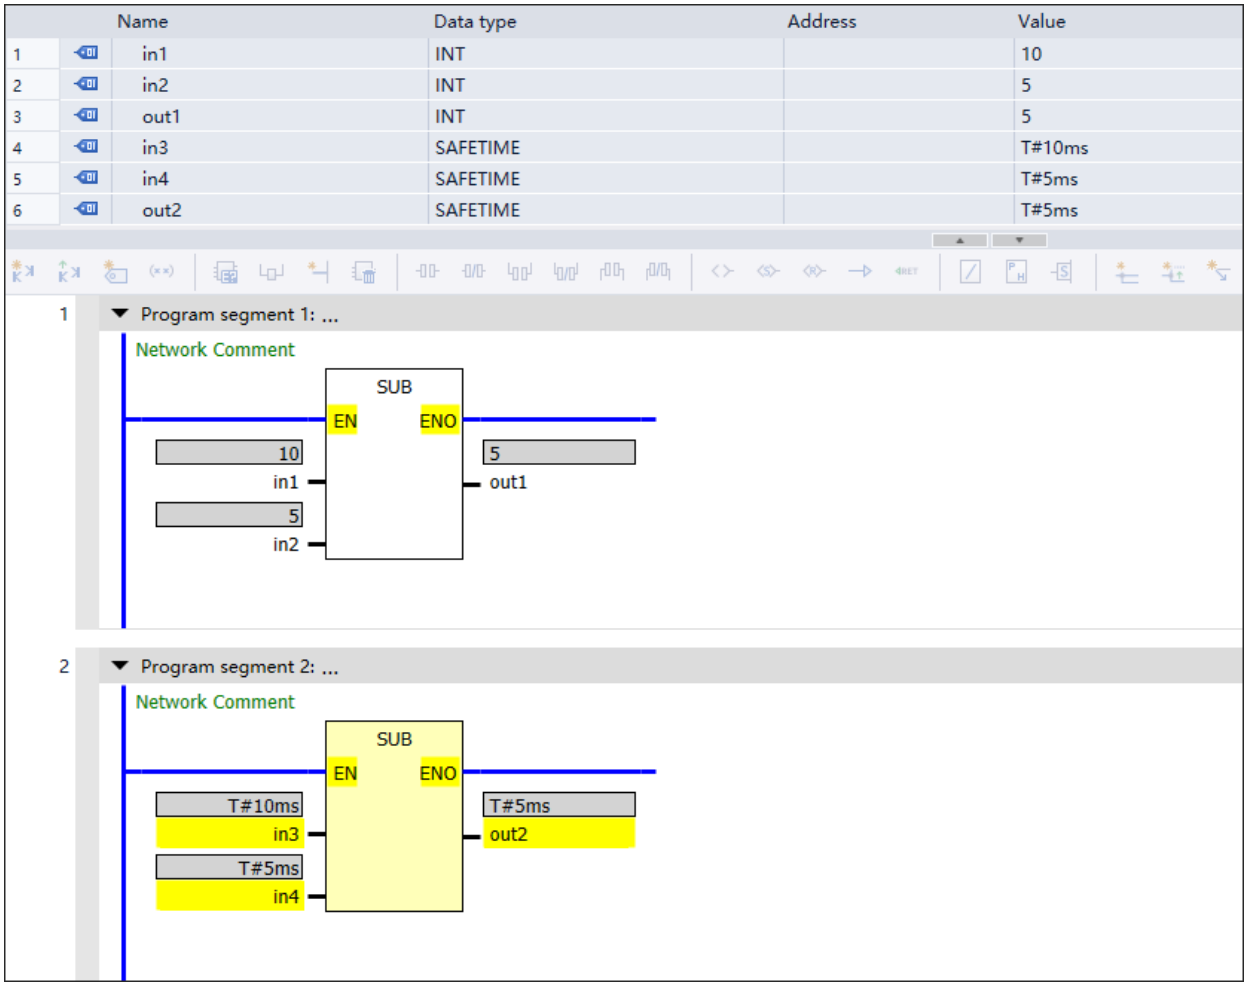
- **Function description**
  - Output the result of subtracting integers or durations.
  - Overflow occurs when the subtraction result of "In1" and "In2" exceeds the valid range of the data type of the result. When overflow occurs, the relationship among the data types of "In1" and "In2", the data type of the result, and the value of the result is shown in the table below.

Input/Output Data Type	Subtraction Result
Integer	The value difference between In1 and In2 is represented by the data type of the subtraction result [1]. When both inputs are of the same type, the output must be of the same type, such as INT - INT = INT. When the two inputs are of different types, the output must be the type with the wider bit width, such as INT - DINT = DINT. The result of safety type input and standard type input is a standard type. The result of safety type inputs can be either a standard or safety data type. The result of standard type inputs is a standard type.



Input/Output Data Type	Subtraction Result
Time Format	The subtraction of TIME type values is represented by DWORD. Overflow is truncated according to bit width [2].

[1]: For example, if the value of "In1" is INT#-5 and the value of "In2" is INT#32767, the value of the addition result is -32772. When the output is set to INT type, the value of the subtraction result is 32764, which is the lower 16 bits of -32772. When the output is set to DINT type, the result is DINT#-32772.

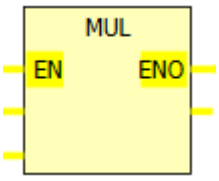


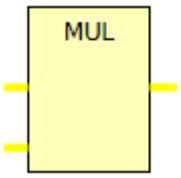
[2]: For example, when the value of "In1" is TIME#10ms and the value of "In2" is TIME#14ms, the value of the subtraction result is TIME#-4ms (although negative time does not exist, negative values are used for representation). However, since the maximum value of TIME is the same as DWORD, which is 4294967295, the subtraction result is T#49d17h2m47s292ms, representable within 32 bits.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - If the input/output parameter is omitted, a fault will occur during compilation. However, if the output terminal is unused or the input terminal for the next instruction is not connected, no fault will occur.
  - "In1", "In2", and "Out" can be of different data types. In this case, the operation is processed using the data type that includes all the above input parameters. For example, if "In0" is INT type and "In1" is DINT type, the operation is processed using DINT type. Therefore, the subtraction result "Out" is of DINT type.
  - The input condition varies depending on whether the output is a safety or standard data type. If the condition is not met, a compilation fault will occur.
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

11.10.1.3.4 MUL

MUL operation is performed on integers and durations.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
MUL	Multiply	FC		

- **Related variables**

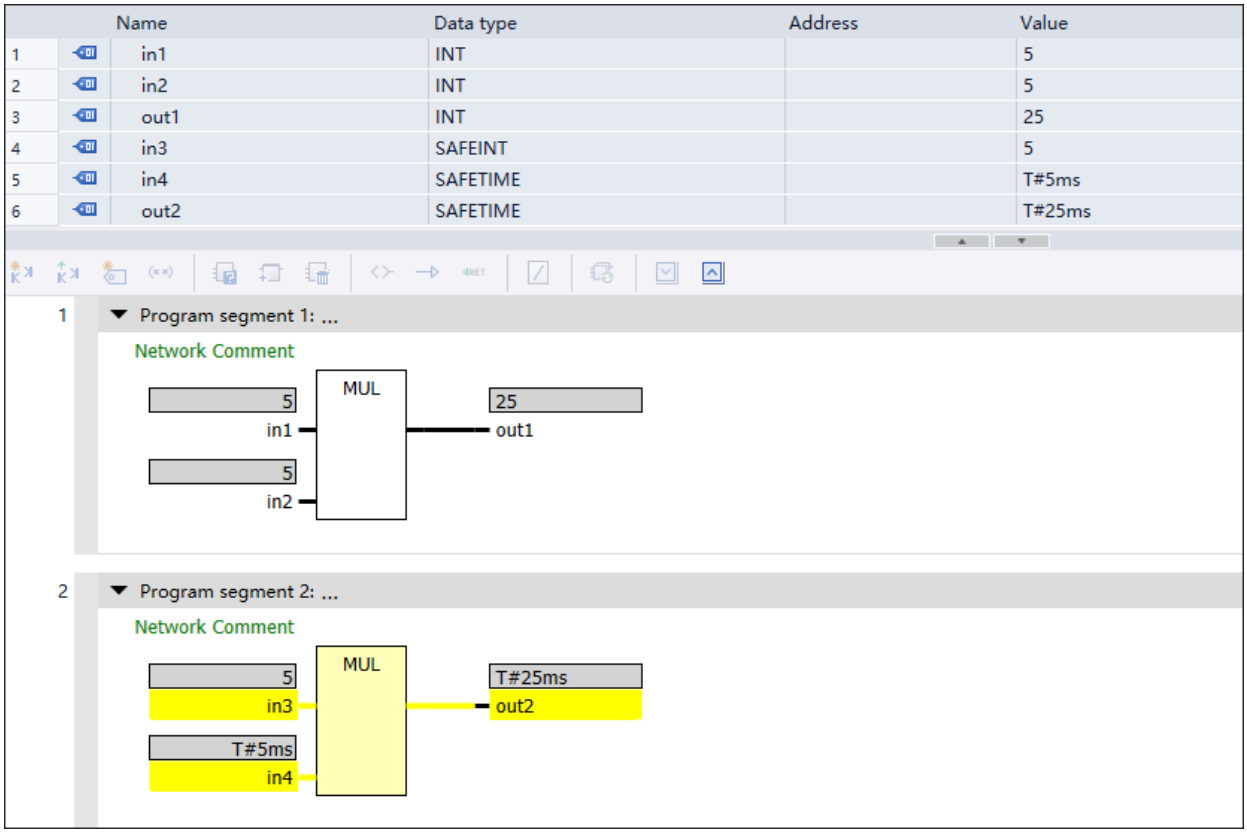
  Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1 to InN	Multiplier	Follows data type	–	Multiplier
Output	Out	Output value	Follows data type	–	Output value

  Data types

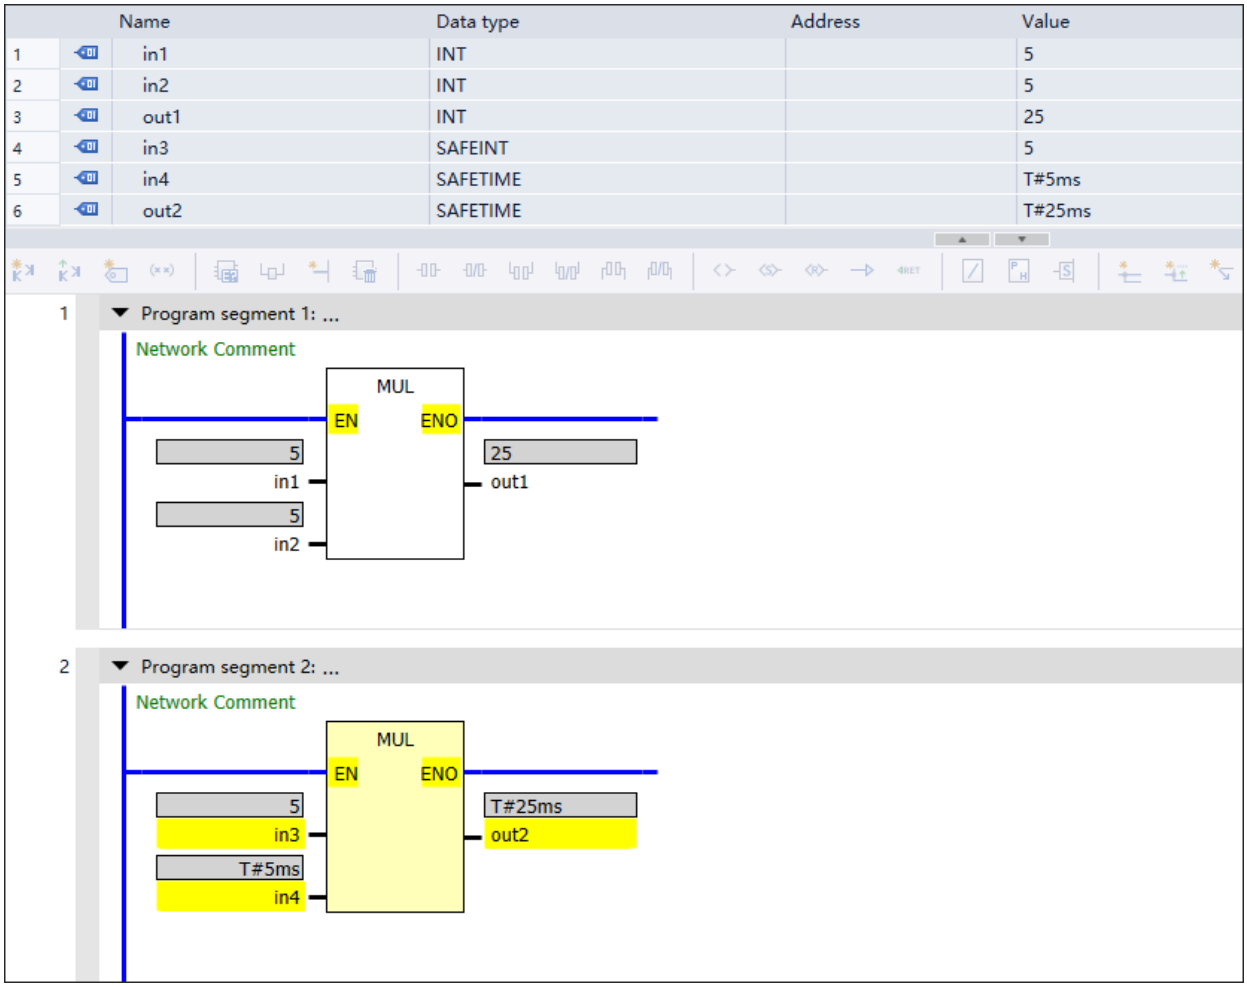
	Boolean		Bit String				Integer				Time Format	
	BOOL	SAFE BOOL	BYTE	SAFE BYTE	WORD	SAFE WORD	INT	SAFEINT	DINT	SAFE DINT	TIME	SAFE TIME
In1	–	–	–	–	–	–	√	√	√	√	√	√
In2 to InN	–	–	–	–	–	–	√	√	√	√	–	–
Out	–	–	–	–	–	–	√	√	√	√	√	√

- **Function description**
  - Output the result of multiplying integers or durations.
  - Overflow occurs when the product of "In1" to "InN" exceeds the valid range of the data type of the result. When overflow occurs, the relationship among the data types of "In1" to "InN", the data type of the result, and the value of the result is shown in the table below.



Input/Output Data Type	Product Result
Integer	The product of In1 to InN is represented by the data type of the product result [1]. When both inputs are of the same type, the output must be of the same type, such as INT × INT = INT. When the two inputs are of different types, the output must be the type with the wider bit width, such as INT × DINT = DINT. The result of safety type input and standard type input is a standard type. The result of safety type inputs can be either a standard or safety data type. The result of standard type inputs is a standard type.
Time Format	The product of TIME type values is represented by DWORD. Overflow is truncated according to bit width [2].

[1]: For example, if the value of "In1" is INT#16390 and the value of "In2" is INT#2, the product value is 32780. When the output is set to INT type, the product value is -32756, which is the lower 16 bits of 32780. When the output is set to DINT type, the result is DINT#32780.

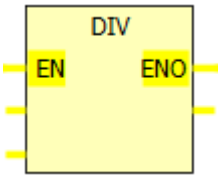


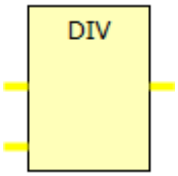
[2]: For example, if the value of "In1" is T#24d20h31m23s649ms and the value of "In2" is INT#2, the product result is T#49d17h2m47s298ms. However, the maximum value of TIME type is the same as DWORD, which is 4294967295. Therefore, the product result is T#2ms, representable in 32 bits.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - If the input/output parameter is omitted, a fault will occur during compilation. However, if the output terminal is unused or the input terminal for the next instruction is not connected, no fault will occur.
  - MUL operation cannot be performed on multiple time format data. When multiplying time format data, set the time format for "In1" and "Out", and set integer type for "In2" to "InN".
  - When multiplying integer types, "In1" to "InN" and "Out" can be of different data types. In this case, the operation is processed using the data type that includes all the above input parameters. For example, if "In1" is INT type and "In2" is DINT type, the operation is processed using DINT type. Therefore, the product result "Out" is of DINT type.
  - When using time format for the multiplier, set the time format for any one of "In1" to "InN" and for "Out".
  - The input condition varies depending on whether the output is a safety or standard data type. If the condition is not met, a compilation fault will occur.
  - When assigning a safety data type variable to the output terminal, set all input terminals to safety data type variables; otherwise, a compilation fault will occur.

11.10.1.3.5 DIV

DIV operation is performed on integers and durations.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
DIV	Divide	FC		

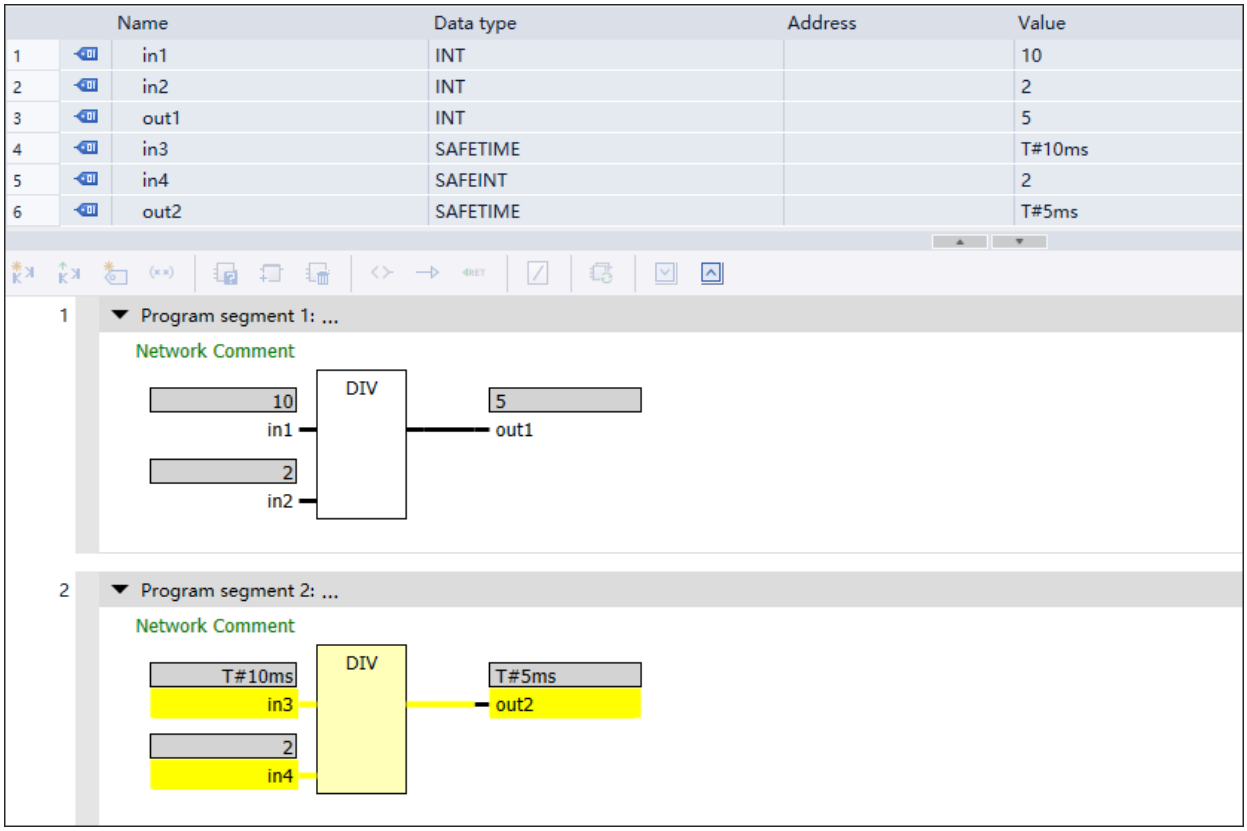
- **Related variables**

  Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Dividend	Follows data type	–	Dividend
	In2	Divider	Follows data type	–	Divider
Output	Out	Output value	Follows data type	–	Output value

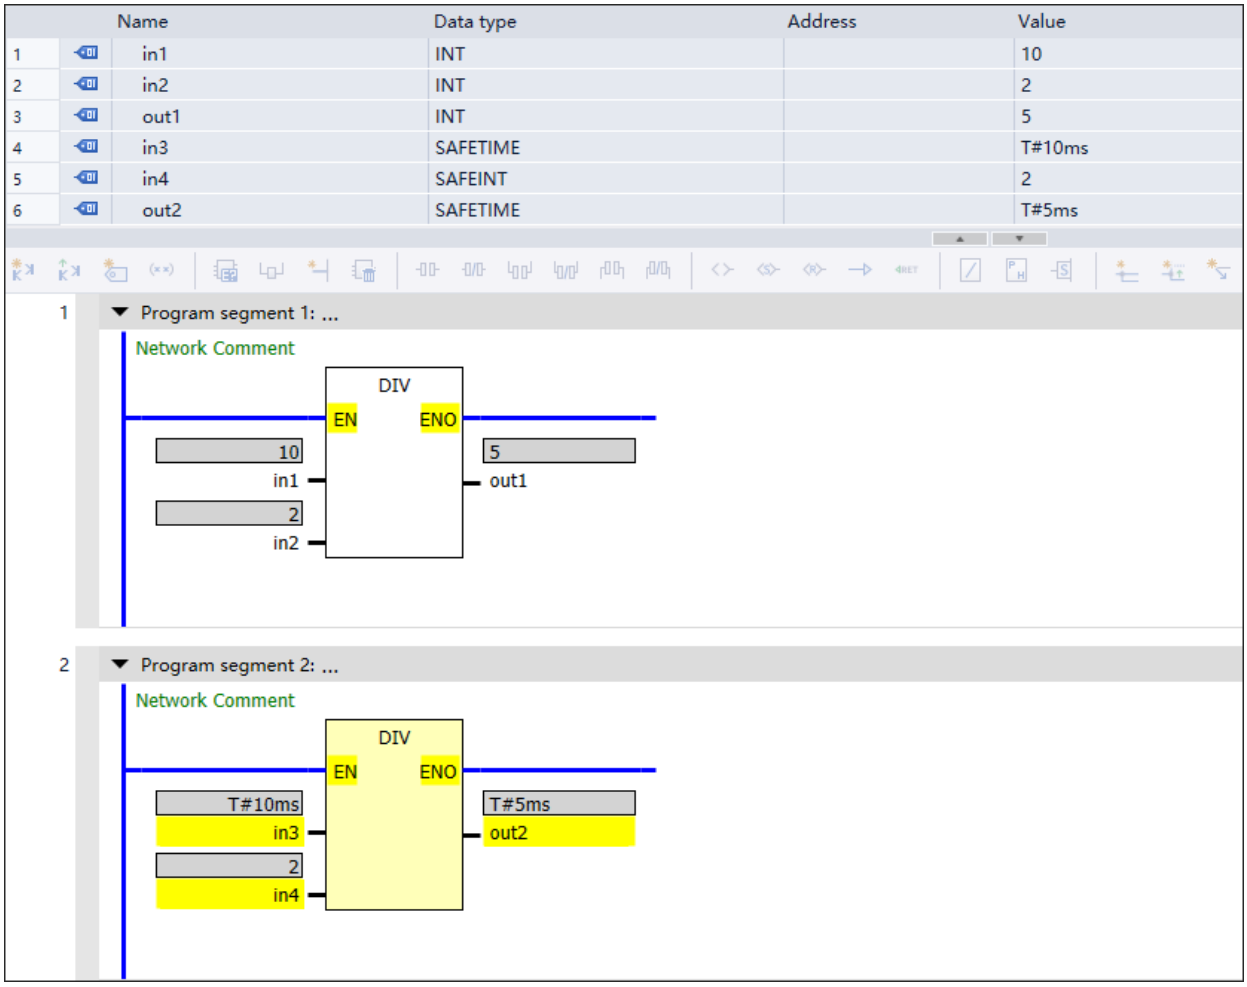
  Data types

	Boolean		Bit String				Integer				Time Format	
	BOOL	SAFE BOOL	BYTE	SAFE BYTE	WORD	SAFE WORD	INT	SAFEINT	DINT	SAFE DINT	TIME	SAFE TIME
In1	–	–	–	–	–	–	√	√	√	√	√	√
In2	–	–	–	–	–	–	√	√	√	√	–	–
Out	–	–	–	–	–	–	√	√	√	√	√	√



- **Function description**
  - Output the result of dividing integers or durations.
  - When division is not exact, the remainder is discarded.
  - Overflow occurs when the division result of "In1" and "In2" exceeds the valid range of the data type of the result. When overflow occurs, the relationship among the data types of "In1" and "In2", the data type of the result, and the value of the result is shown in the table below.

Input/Output Data Type	Division Result
Integer	The quotient of In1 and In2 is represented by the data type of the division result. When both inputs are of the same type, the output must be of the same type, such as INT ÷ INT = INT. When the two inputs are of different types, the output must be the type with the wider bit width, such as INT ÷ DINT = DINT. The result of safety type input and standard type input is a standard type. The result of safety type inputs can be either a standard or safety data type. The result of standard type inputs is a standard type.



Input/Output Data Type	Division Result
Time Format	The quotient of TIME type is represented by DWORD, and overflow is truncated according to bit width.

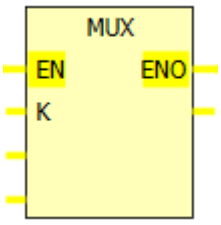
- **Program example**

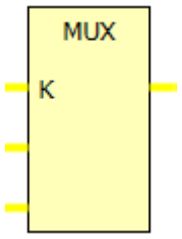
FBD:

LD:

- **Precautions**
  - If the input/output parameter is omitted, a fault will occur during compilation. However, if the output terminal is unused or the input terminal for the next instruction is not connected, no fault will occur.
  - MUL operation cannot be performed on multiple time format data. When dividing time format data, set the time format for "In1" and "Out", and set integer type for "In2" to "InN".
  - The divider must not be 0. Using 0 as the divider causes a "division by zero" exception, and the program will stop.
  - When dividing integer types, "In1" to "InN" and "Out" can be of different data types. In this case, the operation is processed using the data type that includes all the above input parameters. For example, if "In1" is INT type and "In2" is DINT type, the operation is processed using DINT type. Therefore, the division result "Out" is of DINT type.
  - The input condition varies depending on whether the output is a safety or standard data type. If the condition is not met, a compilation fault will occur.
  - When assigning a safety data type variable to the output terminal, set all input terminals to safety data type variables; otherwise, a compilation fault will occur.

11.10.1.4 Selection Operations





11.10.1.4.1 Instruction List

Instruction	FB/FC	Function	Library	Applicable Library Version
11.10.1.4.2 MUX	FC	Select one from multiple	SafetyInstructions	Applicable to library version 1.0.0.0/1.1.0.0
11.10.1.4.3 SEL	FC	One out of two		

11.10.1.4.2 MUX

MUX operation selects one from multiple options.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
MUX	Select one from multiple	FC		

- **Related variables**

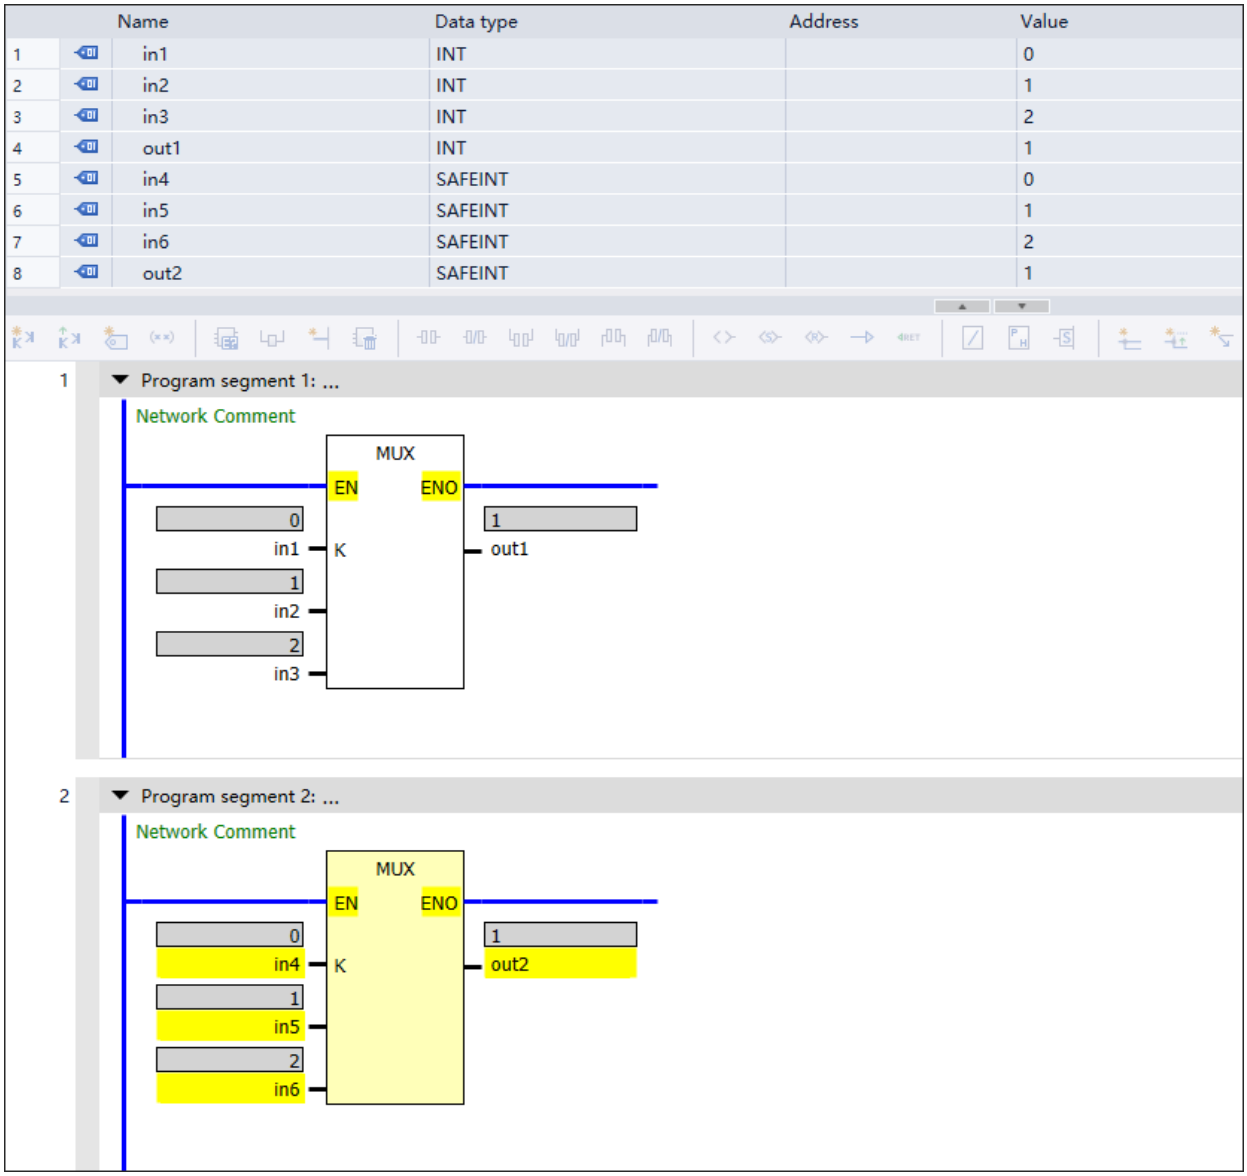
  Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	K	Selector	Follows data type	–	If K's value is N, select InN.
	In0 to InN	Options	Follows data type	–	Option
Output	Out	Selection result	Follows data type	–	Selection result

  Data types

	Boolean		Bit String				Integer				Time Format	
	BOOL	SAFE BOOL	BYTE	SAFE BYTE	WORD	SAFE WORD	INT	SAFEINT	DINT	SAFE DINT	TIME	SAFETIME
K	–	–	–	–	–	–	√	√	√	√	–	–
In0 to InN	√	√	√	√	√	√	√	√	√	√	√	√
Out	√	√	√	√	√	√	√	√	√	√	√	√

- **Function description**
  - Specify one from the two to N options ("In0" to "InN").

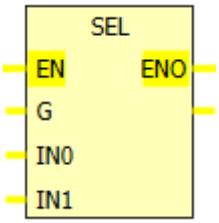


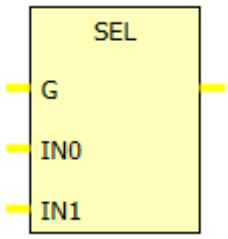
- When selecting one from "In0" to "InN", specify it using the selector "K".
- When the value of "K" is 0, assign "In0" to "Out"; when it is N, assign "InN" to "Out".

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - If the input/output parameter is omitted, a fault will occur during compilation. However, if the output terminal is unused or the input terminal for the next instruction is not connected, no fault will occur.
  - "In0", "In1", and "Out" can be of different data types, but note the following:
    - The valid range of "Out" must include the valid ranges of "In0" to "InN".
    - If the value of "K" is outside the valid range (less than 0 or greater than N), a "MUX exception" will occur and the program will stop.
    - If the output terminal of MUX is of safety type, all input parameters corresponding to the instruction must also be of safety type.

11.10.1.4.3 SEL

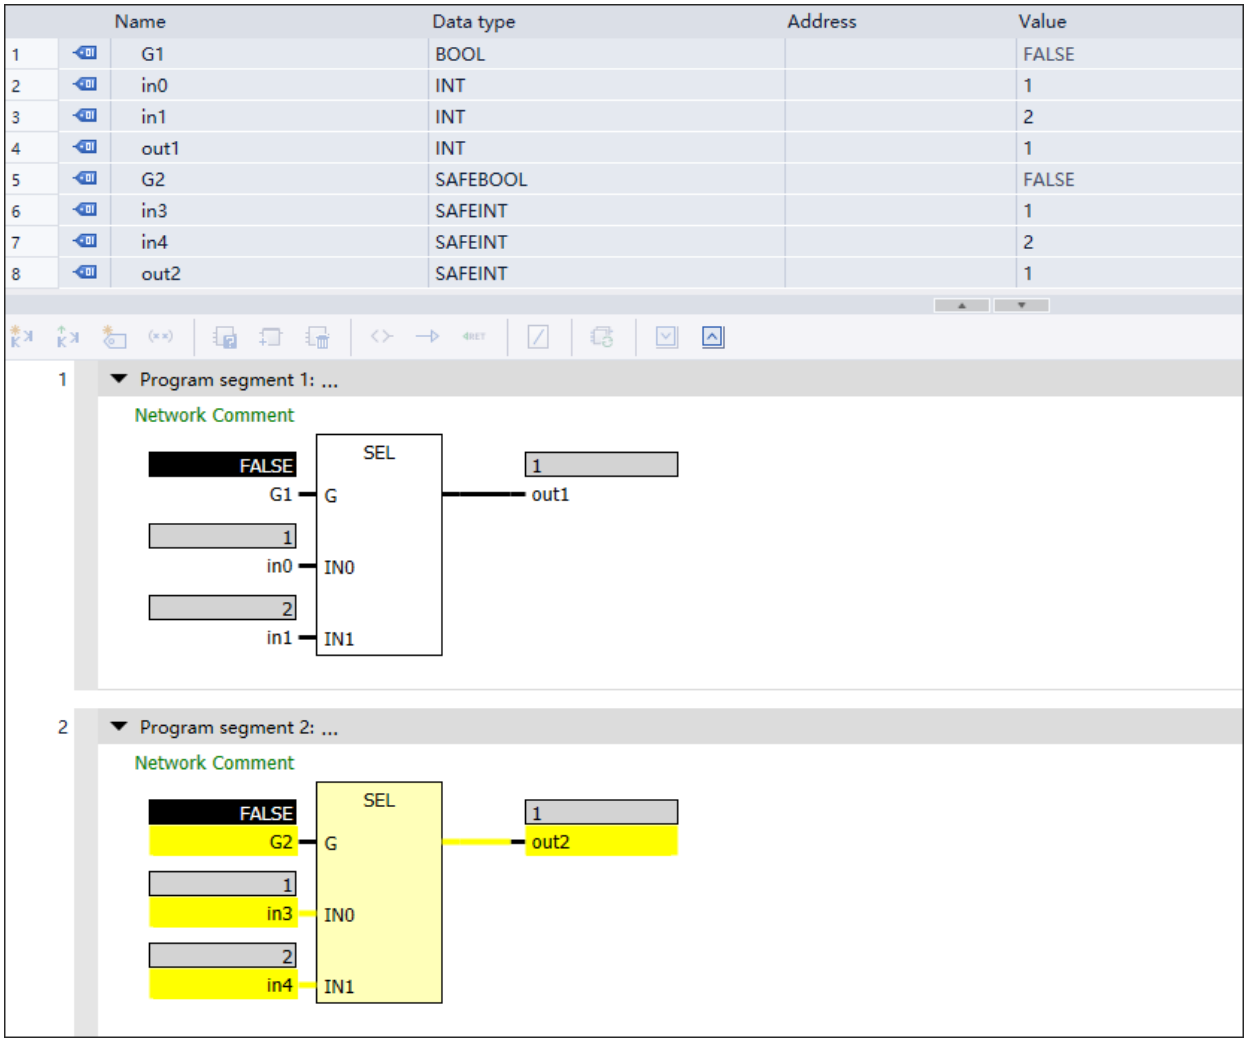
SEL operation selects one from two options.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SEL	One out of two	FC		

- **Related variables**

  Variables



Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	G	Selector gate	Follows data type	–	FALSE: Selects In0. TRUE: Selects In1.
	In0	Option	Follows data type	–	Option
	In1	Option	Follows data type	–	Option
Output	Out	Selection result	Follows data type	–	Selection result

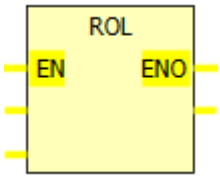
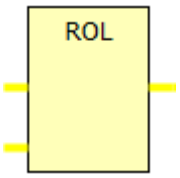
LD:

- **Precautions**
  - If the input/output parameter is omitted, a fault will occur during compilation. However, if the output terminal is unused or the input terminal for the next instruction is not connected, no fault will occur.
  - "In0", "In1", and "Out" can be of different data types. In this case, the operation is processed using the data type that includes all the above input parameters. For example, if "In0" is INT type and "In1" is DINT type, the operation is processed using DINT type. Therefore, the division result "Out" is of DINT type.
  - The input condition varies depending on whether the output is a safety or standard data type. If the condition is not met, a compilation fault will occur.
  - When input parameter "G" is of a safety data type, the output variable type can be either safety or standard data type; however, when "G" is of a standard data type, the output parameter can only be of standard data type.
  - If the output terminal of SEL is of safety type, all input parameters corresponding to the instruction must also be of safety type.

11.10.1.5 Shift Operations





11.10.1.5.1 Instruction List

IN1	–	–	√	√	√	√	–	–	–	–	–	–
NUM	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	–	√	√	√	√	–	–	–	–	–	–

- **Function**

  Rotates the input value to the left, with the bits shifted out from the left directly appended to the rightmost bit.

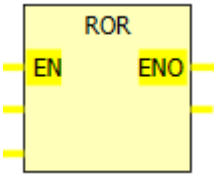
- **Program example**

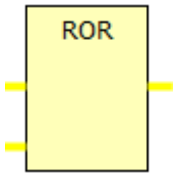
  When the source data is 2#11110000 and the number of shifted bits is 1, the output result is 2#11100001, with the valid data shifted left by one bit.

  When the source data is 2#11110000 and the number of shifted bits is 2, the output signal result is 2#11000011, with the valid data shifted left by two bits.

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.
  - NUM only supports immediate values.

11.10.1.5.3 ROR

ROR operation performs a bitwise cyclic right shift on the inputs.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
ROR	Cyclic right-shift	FC		

- **Related variables**

Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN1	Data Source	Follows data type	–	Data source

Input/Output	Variable	Name	Valid Range	Default Value	Description
	NUM	Number of shifted bits	Follows data type	–	Number of shifted bits
Output	Out	Return value	Follows data type	–	Shifted result

Data types

	Boolean		Bit String				Integer				Time Format	
	BOOL	SAFE BOOL	BYTE	SAFE BYTE	WORD	SAFE WORD	INT	SAFEI NT	DINT	SAFE DINT	TIME	SAFE TIME
IN1	–	–	√	√	√	√	–	–	–	–	–	–
NUM	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	–	√	√	√	√	–	–	–	–	–	–

- **Function description**

  Perform a bitwise cyclic right shift on the input value, with the bit shifted out from the right directly appended to the leftmost bit.

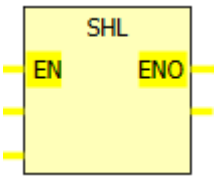
- **Program example**

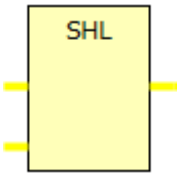
  When the source data is 2#11110000 and the number of shifted bits is 1, the output result is 2#01111000, with the valid data shifted right by one bit.

  When the source data is 2#11110000 and the number of shifted bits is 2, the output signal result is 2#00111100, with the valid data shifted right by two bits.

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.
  - NUM only supports immediate values.

11.10.1.5.4 SHL

Left shift instruction

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SHL	Left shift	FC		

- **Related variables**

Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN1	Data Source	Follows data type	–	Data source
	NUM	Number of shifted bits	Follows data type	–	Number of shifted bits

Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	Out	Return value	Follows data type	–	Shifted result

Data types

	Boolean		Bit String				Integer				Time Format	
	BOOL	SAFE BOOL	BYTE	SAFE BYTE	WORD	SAFE WORD	INT	SAFEINT	DINT	SAFE DINT	TIME	SAFE TIME
IN1	–	–	√	√	√	√	–	–	–	–	–	–
NUM	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	–	√	√	√	√	–	–	–	–	–	–

- **Function description**

  Perform a bitwise left shift on the input value. The bits shifted out from the left are discarded, and zeros are automatically filled in on the right.

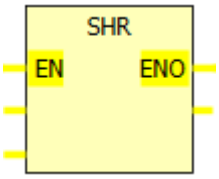
- **Program example**

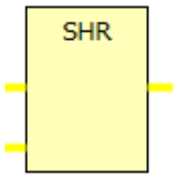
  When the source data is 2#11110000 and the number of shifted bits is 1, the output result is 2#11100000, with the valid data shifted left by one bit.

  When the source data is 2#11110000 and the number of shifted bits is 2, the output signal result is 2#11000000, with the valid data shifted left by two bits.

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.
  - NUM only supports immediate values.

11.10.1.5.5 SHR

Right shift instruction

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SHR	Right shift	FC		

- **Related variables**

Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN1	Data Source	Follows data type	–	Data source
	NUM	Number of shifted bits	Follows data type	–	Number of shifted bits

Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	Out	Return value	Follows data type	–	Shifted result

Data types

	Boolean		Bit String				Integer				Time Format	
	BOOL	SAFE BOOL	BYTE	SAFE BYTE	WORD	SAFE WORD	INT	SAFEINT	DINT	SAFE DINT	TIME	SAFE TIME
IN1	–	–	√	√	√	√	–	–	–	–	–	–
NUM	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	–	√	√	√	√	–	–	–	–	–	–

- **Function description**

  Perform a bitwise right shift on the input value. The bits shifted out from the right are discarded, and zeros are automatically filled in on the left.

- **Program example**

  When the source data is 2#11110000 and the number of shifted bits is 1, the output result is 2#01111000, with the valid data shifted right by one bit.

  When the source data is 2#11110000 and the number of shifted bits is 2, the output signal result is 2#00111100, with the valid data shifted right by two bits.

  FBD:

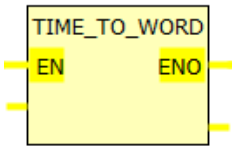
  LD:

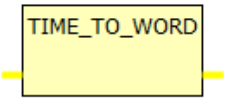
- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.
  - NUM only supports immediate values.

11.10.1.6 Conversion Operators

11.10.1.6.1 Instruction List

Instruction	FB/FC	Function	Library	Applicable Library Version
11.10.1.6.2 TIME_TO_WORD	FC	Convert data of TIME type to WORD type	SafetyInstructions	Applicable to library version 1.0.0.0/1.1.0.0
11.10.1.6.3 INT_TO_TIME	FC	Convert INT type to TIME type		
11.10.1.6.4 DINT_TO_WORD	FC	Convert DINT type to WORD type		
11.10.1.6.5 TIME_TO_DINT	FC	Convert TIME type to DINT type		
11.10.1.6.6 TIME_TO_BYTE	FC	Convert TIME type to BYTE type		
11.10.1.6.7 BOOL_TO_INT	FC	Convert BOOL type to INT type		





Instruction	FB/FC	Function	Library	Applicable Library Version
11.10.1.6.8 WORD_TO_INT	FC	Convert WORD type to INT type		
11.10.1.6.9 INT_TO_BYTE	FC	Convert INT type to BYTE type		
11.10.1.6.10 INT_TO_BOOL	FC	Convert INT type to BOOL type		
11.10.1.6.11 DINT_TO_TIME	FC	Convert DINT type to TIME type		
11.10.1.6.12 DINT_TO_BYTE	FC	Convert DINT type to BYTE type		
11.10.1.6.13 BOOL_TO_TIME	FC	Convert BOOL type to TIME type		
11.10.1.6.14 BYTE_TO_DINT	FC	Convert BYTE type to DINT type		
11.10.1.6.15 BOOL_TO_WORD	FC	Convert BOOL type to WORD type		
11.10.1.6.16 BYTE_TO_WORD	FC	Convert BYTE type to WORD type		
11.10.1.6.17 BYTE_TO_INT	FC	Convert BYTE type to INT type		
11.10.1.6.18 BOOL_TO_DINT	FC	Convert BOOL type to DINT type		
11.10.1.6.19 BYTE_TO_TIME	FC	Convert BYTE type to TIME type		
11.10.1.6.20 INT_TO_WORD	FC	Convert INT type to WORD type		
11.10.1.6.21 BOOL_TO_BYTE	FC	Convert BOOL type to BYTE type		
11.10.1.6.22 DINT_TO_BOOL	FC	Convert DINT type to BOOL type		
11.10.1.6.23 WORD_TO_BOOL	FC	Convert WORD type data to BOOL type		
11.10.1.6.24 BYTE_TO_BOOL	FC	Convert BYTE type data to BOOL type		
11.10.1.6.25 INT_TO_DINT	FC	Convert INT type data to DINT type		
11.10.1.6.26 WORD_TO_BYTE	FC	Convert WORD type data to BYTE type		

Instruction	FB/FC	Function	Library	Applicable Library Version
11.10.1.6.27 WORD_TO_TIME	FC	Convert WORD type data to TIME type		
11.10.1.6.28 WORD_TO_DINT	FC	Convert WORD type data to DINT type		
11.10.1.6.29 DINT_TO_INT	FC	Convert DINT type data to INT type		
11.10.1.6.30 TIME_TO_INT	FC	Convert TIME type data to INT type		
11.10.1.6.31 TIME_TO_BOOL	FC	Convert TIME type data to BOOL type		
11.10.1.6.32 BOOL_TO_DWORD	FC	Convert BOOL type data to DWORD type		Applicable to library version 1.1.0.0
11.10.1.6.33 BYTE_TO_DWORD	FC	Convert BYTE type data to DWORD type		
11.10.1.6.34 DINT_TO_DWORD	FC	Convert DINT type data to DWORD type		
11.10.1.6.35 DWORD_TO_BOOL	FC	Convert DWORD type data to BOOL type		
11.10.1.6.36 DWORD_TO_BYTE	FC	Convert DWORD type data to BYTE type		
11.10.1.6.37 DWORD_TO_DINT	FC	Convert DWORD type data to DINT type		
11.10.1.6.38 DWORD_TO_INT	FC	Convert DWORD type data to INT type		
11.10.1.6.39 DWORD_TO_TIME	FC	Convert DWORD type data to TIME type		
11.10.1.6.40 DWORD_TO_WORD	FC	Convert DWORD type data to WORD type		
11.10.1.6.41 INT_TO_DWORD	FC	Convert INT type data to DWORD type		
11.10.1.6.42 TIME_TO_DWORD	FC	Convert TIME type data to DWORD type		
11.10.1.6.43 WORD_TO_DWORD	FC	Convert WORD type data to DWORD type		

11.10.1.6.2 TIME_TO_WORD

Convert data of TIME type to WORD type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
TIME_TO_WORD	Convert data of TIME type to WORD type	FC		

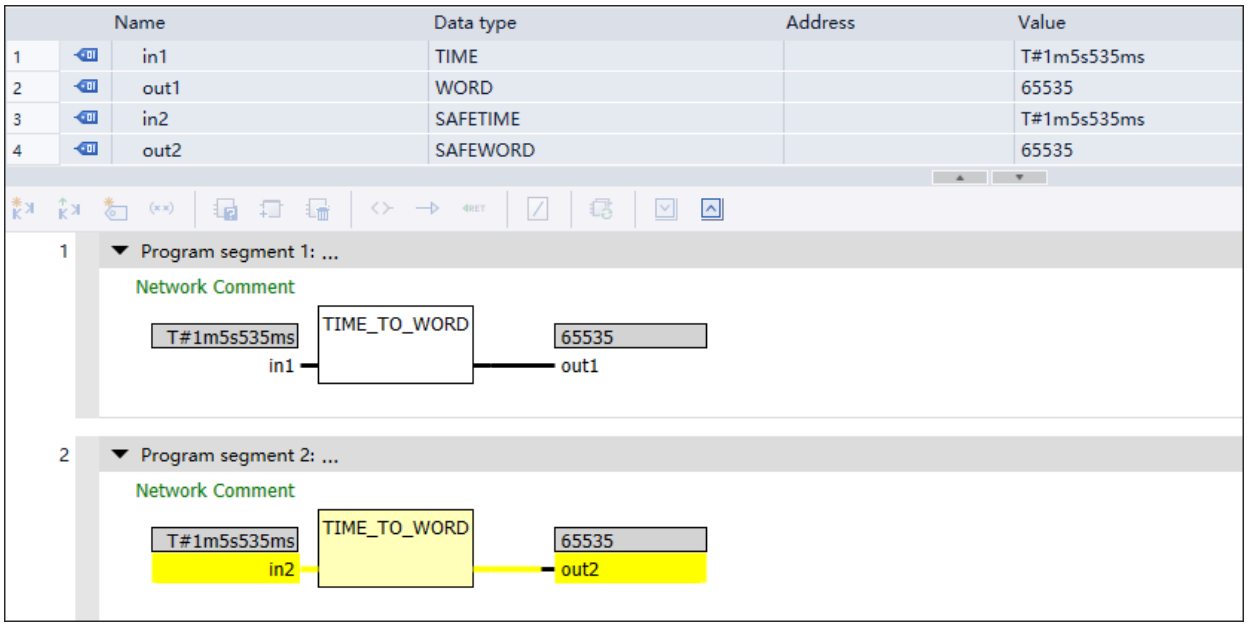
- **Related variables**

  Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	T#0ms to T#65s535ms	T#0ms	Conversion object
Output	Out	Conversion result	WORD#16#0000 to FFFF	WORD#16#0000	Conversion result

  Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	-	-	-	-	-	-	-	-	-	-	√	√
Out	-	-	-	-	√	√	-	-	-	-	-	-	-	-



- **Function description**

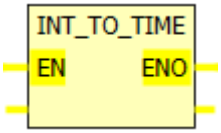
  Convert "In" of TIME type to the WORD-type bit string "Out".

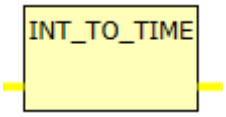
  Example: When the value of "In" is T#50s505ms, the value of "Out" is WORD#16#C549.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.
  - If a value outside the range of TIME#0ms to 66535ms is input, a "conversion exception" will occur and the program will stop.

11.10.1.6.3 INT_TO_TIME

Convert data of INT type to TIME type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
INT_TO_TIME	Convert INT type to TIME type	FC		

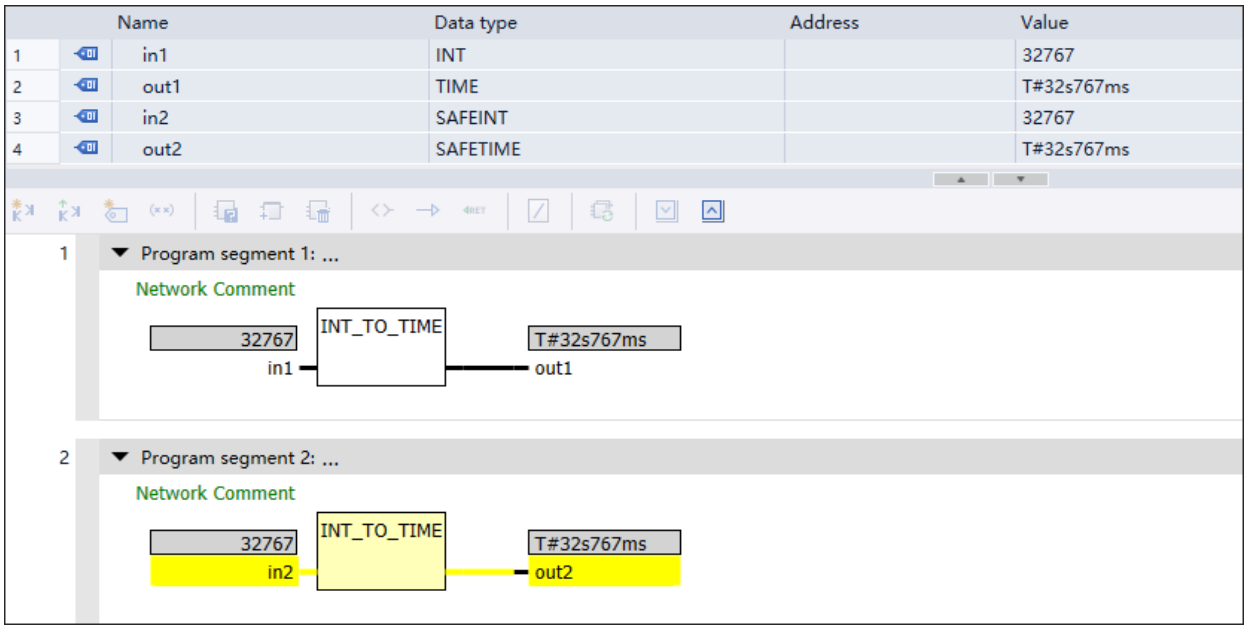
- **Related variables**

  Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	INT#0 to 32767	INT#0	Conversion object
Output	Out	Conversion result	T#0ms to T#32s767ms	T#0ms	Conversion result

  Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	-	-	-	-	-	-	√	√	-	-	-	-
Out	-	-	-	-	-	-	-	-	-	-	-	-	√	√



- **Function description**

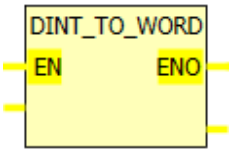
  Convert "In" of INT type to "Out" of TIME type.

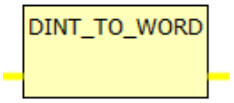
  Example: When the value of "In" is INT#10500, the value of "Out" is T#10s500ms.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.
  - If a value outside the range of INT#0 to 32767 is input, a "conversion exception" will occur and the program will stop.

11.10.1.6.4 DINT_TO_WORD

Convert data of DINT type to WORD type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
DINT_TO_WORD	Convert DINT type to WORD type	FC		

- **Related variables**

Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	DINT#0 to 65535	DINT#0	Conversion object
Output	Out	Conversion result	WORD#16#0000 to FFFF	WORD#16#0000	Conversion result

Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	-	-	-	-	-	-	-	-	√	√	-	-
Out	-	-	-	-	√	√	-	-	-	-	-	-	-	-

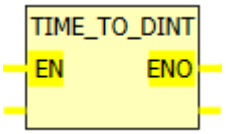
- **Function description**

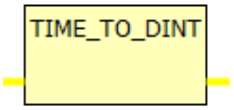
  Convert "In" of DINT type to the bit string "Out" of WORD type.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.
  - If a value outside the range of DINT#0 to 65535 is input, a "conversion exception" will occur and the program will stop.

11.10.1.6.5 TIME_TO_DINT

Convert data of TIME type to DINT type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
TIME_TO_DINT	Convert TIME type to DINT type	FC		

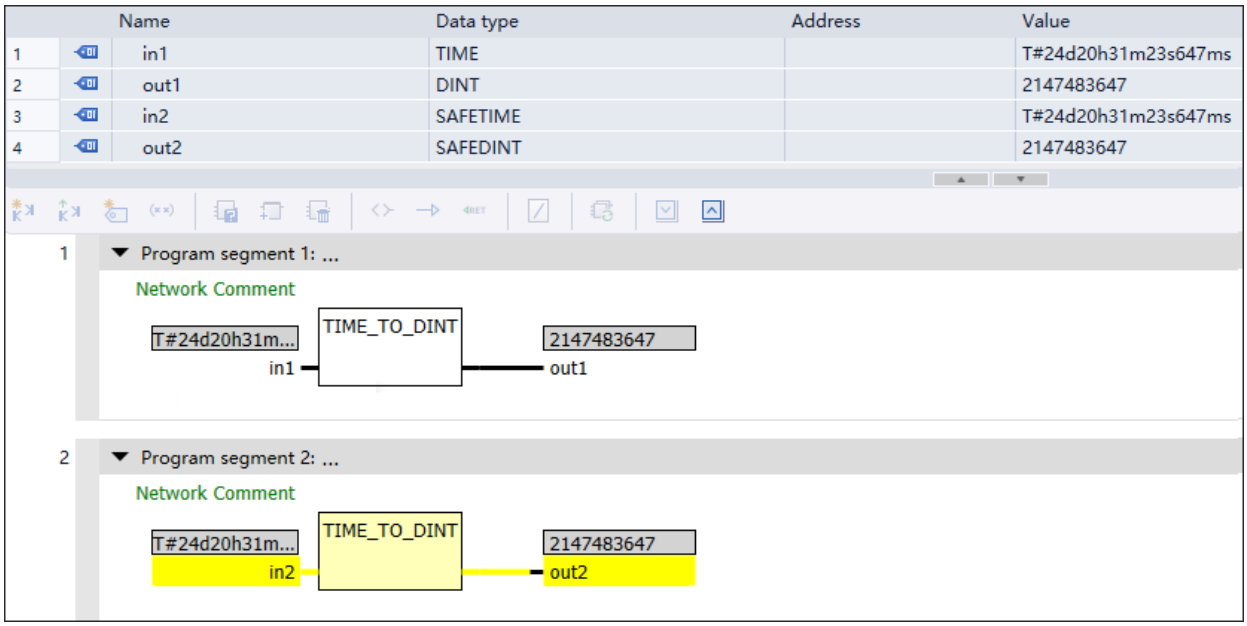
- **Related variables**

Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	T#0ms to T#49d17h2m47s295ms	T#0ms	Conversion object
Output	Out	Conversion result	DINT#0 to 2147483647	DINT#0	Conversion result

Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	-	-	-	-	-	-	-	-	-	-	√	√
Out	-	-	-	-	-	-	-	-	-	-	√	√	-	-



- **Function description**

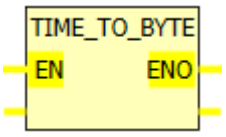
  Convert "In" of TIME type to "Out" of DINT type.

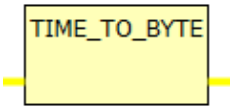
  Example: When the value of "In" is T#1d1h1m30s090ms, the value of "Out" is DINT#90090090.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.
  - If a value outside the range of TIME#0ms to 2147483647 ms is input, a "conversion exception" will occur and the program will stop.

11.10.1.6.6 TIME_TO_BYTE

Convert data of TIME type to BYTE type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
TIME_TO_BYTE	Convert TIME type to BYTE type	FC		

- **Related variables**

Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	T#0ms to T#255ms	T#0ms	Conversion object
Output	Out	Conversion result	BYTE16#00 to FF	BYTE16#00	Conversion result

Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	-	-	-	-	-	-	-	-	-	-	√	√
Out	-	-	√	√	-	-	-	-	-	-	-	-	-	-

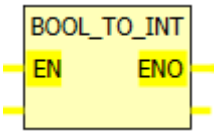
- **Function description**

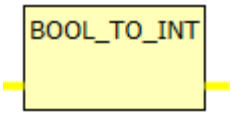
  Convert "In" of TIME type to the bit string "Out" of BYTE type.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.
  - If a value outside the range of TIME#0ms to 255 ms is input, a "conversion exception" will occur and the program will stop.

11.10.1.6.7 BOOL_TO_INT

Convert data of BOOL type to INT type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
BOOL_TO_INT	Convert BOOL type to INT type	FC		

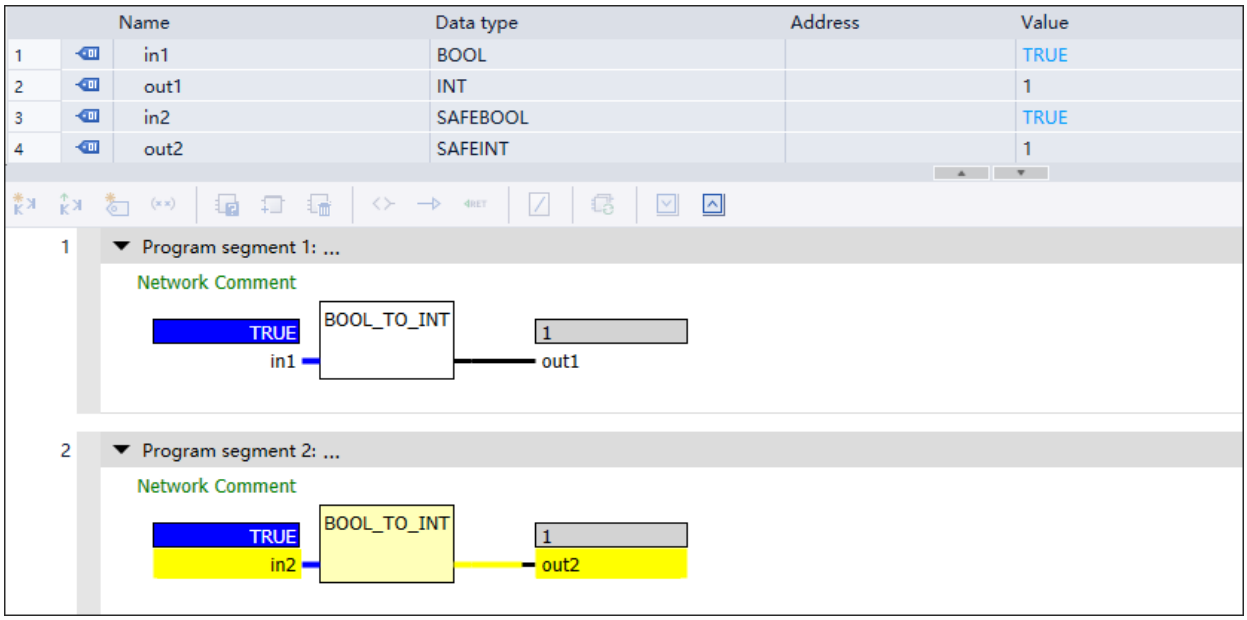
- **Related variables**

Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	FALSE, TRUE	FALSE	Conversion object
Output	Out	Conversion result	INT#0, INT#1	INT#0	Conversion result

Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	√	√	-	-	-	-	-	-	-	-	-	-	-	-
Out	-	-	-	-	-	-	-	-	√	√	-	-	-	-



- **Function description**

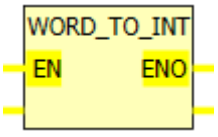
  Convert "In" of BOOL type to "Out" of INT type.

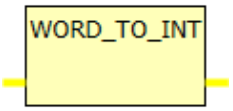
  - When the value of "In" is FALSE, the value of "Out" is INT#0.
  - When the value of "In" is TRUE, the value of "Out" is INT#1.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

11.10.1.6.8 WORD_TO_INT

Convert data of WORD type to INT type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
WORD_TO_INT	Convert WORD type to INT type	FC		

- **Related variables**

  Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	WORD#16#0000 to FFFF	WORD#16#0000	Conversion object
Output	Out	Conversion result	INT#-32768 to 32767	INT#0	Conversion result

  Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	-	-	√	√	-	-	-	-	-	-	-	-
Out	-	-	-	-	-	-	-	-	√	√	-	-	-	-

- **Function description**

  Convert the bit string "In" of WORD type to "Out" of INT type.

  - Example when the value of "Out" is positive (INT#0 to 32767):

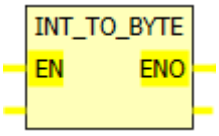
    When the value of "In" is WORD#16#0000 to 7FFF, the value of "Out" is INT#0 to 32767.

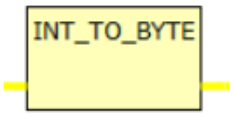
  - Example when the value of "Out" is negative (INT#-32768 to -1):
    - When the value of "In" is WORD#16#8000, which is 1000 0000 0000 0000 (BIN), the value of "Out" is INT#32768, represented as INT#-32768 using 2 bytes.
    - When the value of "In" is WORD#16#FFFF, which is 1111 1111 1111 1111 (BIN), the value of "Out" is INT#65535, represented as INT#-1 using 2 bytes.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

11.10.1.6.9 INT_TO_BYTE

Convert data of INT type to BYTE type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
INT_TO_BYTE	Convert INT type to BYTE type	FC		

- **Related variables**

  Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	INT#0 to 255	INT#0	Conversion object
Output	Out	Conversion result	BYTE#16#00 to FF	BYTE#16#00	Conversion result

  Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	-	-	-	-	-	-	√	√	-	-	-	-
Out	-	-	√	√	-	-	-	-	-	-	-	-	-	-

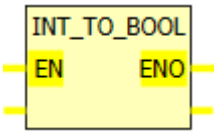
- **Function description**

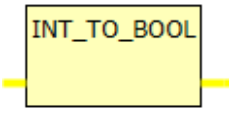
  Convert "In" of INT type to the bit string "Out" of BYTE type.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.
  - If a value outside the range of INT#0 to 255 is input, a "conversion exception" will occur and the program will stop.

11.10.1.6.10 INT_TO_BOOL

Convert data of INT type to BOOL type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
INT_TO_BOOL	Convert INT type to BOOL type	FC		

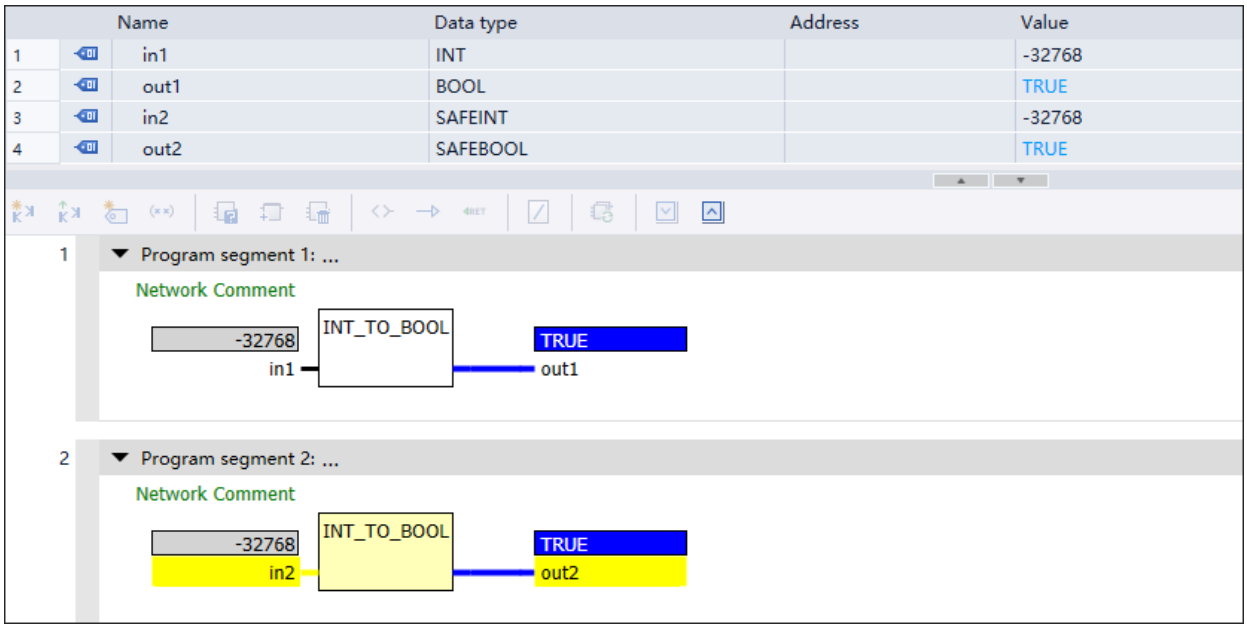
- **Related variables**

  Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	INT#-32768 to 32767	INT#0	Conversion object
Output	Out	Conversion result	FALSE, TRUE	FALSE	Conversion result

  Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	-	-	-	-	-	-	√	√	-	-	-	-
Out	√	√	-	-	-	-	-	-	-	-	-	-	-	-



- **Function description**

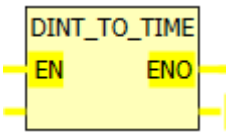
  Convert "In" of INT type to "Out" of BOOL type.

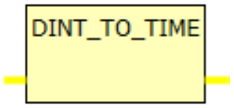
  When the value of "In" is INT#0, the value of "Out" is FALSE; when the value of "In" is INT#-32768 to -1 or INT#1 to 32767 (excluding INT#0), the value of "Out" is TRUE.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.
  - If a value outside the range of INT#-32768 to 32767 is input, a "conversion exception" will occur and the program will stop.

11.10.1.6.11 DINT_TO_TIME

Convert data of DINT type to TIME type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
DINT_TO_TIME	Convert DINT type to TIME type	FC		

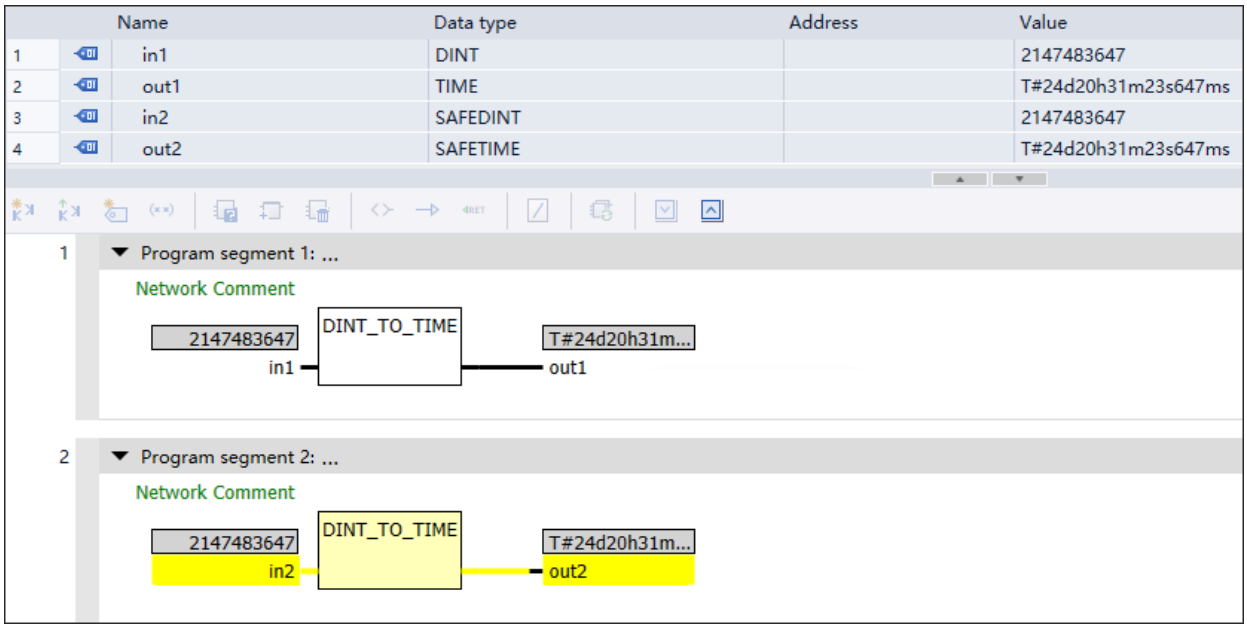
- **Related variables**

Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	DINT#0 to 2147483647	DINT#0	Conversion object
Output	Out	Conversion result	T#0ms to T#24d20h31m23s647ms	T#0ms	Conversion result

Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	-	-	-	-	-	-	-	-	√	√	-	-
Out	-	-	-	-	-	-	-	-	-	-	-	-	√	√



- **Function description**

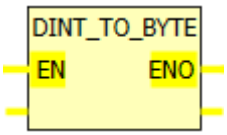
  Convert "In" of DINT type to "Out" of TIME type.

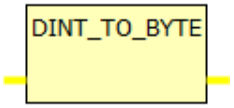
  Example: When the value of "In" is DINT#90090090, the value of "Out" is T#1d1h1m30s090ms.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.
  - If a value outside the range of DINT#0 to 2147483647 is input, a "conversion exception" will occur and the program will stop.

11.10.1.6.12 DINT_TO_BYTE

Convert data of DINT type to BYTE type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
DINT_TO_BYTE	Convert DINT type to BYTE type	FC		

- **Related variables**

Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	DINT#0 to 255	DINT#0	Conversion object
Output	Out	Conversion result	BYTE#16#00 to FF	BYTE#16#00	Conversion result

Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	-	-	-	-	-	-	-	-	√	√	-	-
Out	-	-	√	√	-	-	-	-	-	-	-	-	-	-

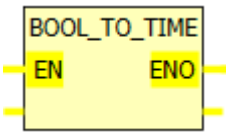
- **Function description**

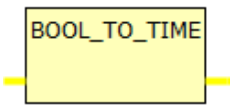
  Convert "In" of DINT type to the bit string "Out" of BYTE type.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.
  - If a value outside the range of DINT#0 to 255 is input, a "conversion exception" will occur and the program will stop.

11.10.1.6.13 BOOL_TO_TIME

Convert data of BOOL type to TIME type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
BOOL_TO_TIME	Convert BOOL type to TIME type	FC		

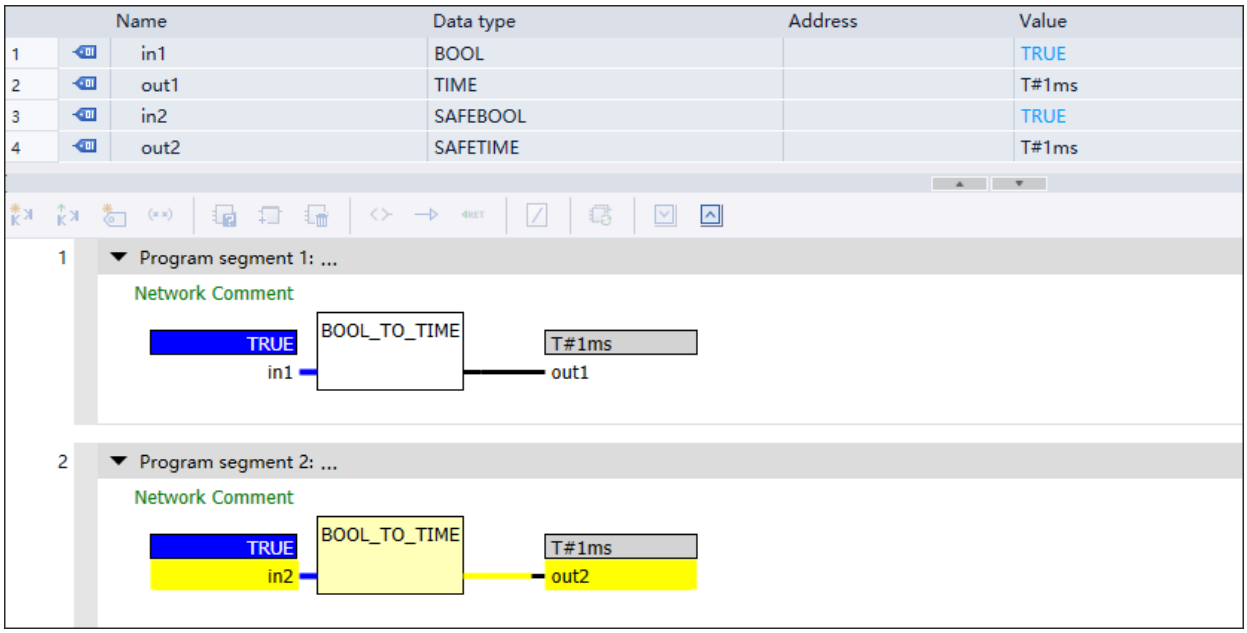
- **Related variables**

  Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	FALSE, TRUE	FALSE	Conversion object
Output	Out	Conversion result	T#0ms, T#1ms	T#0ms	Conversion result

  Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	√	√	-	-	-	-	-	-	-	-	-	-	-	-
Out	-	-	-	-	-	-	-	-	-	-	-	-	√	√



- **Function description**

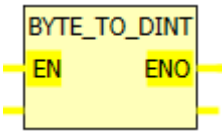
  Convert the bit string "In" of BOOL type to "Out" of TIME type.

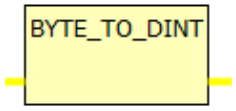
  - When the value of "In" is FALSE, the value of "Out" is T#0ms.
  - When the value of "In" is TRUE, the value of "Out" is T#1ms.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

11.10.1.6.14 BYTE_TO_DINT

Convert data of BYTE type to DINT type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
BYTE_TO_DINT	Convert BYTE type to DINT type	FC		

- **Related variables**

Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	BYTE#16#00 to FF	BYTE#16#00	Conversion object
Output	Out	Conversion result	DINT#0 to 255	DINT#0	Conversion result

Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	√	√	-	-	-	-	-	-	-	-	-	-
Out	-	-	-	-	-	-	-	-	-	-	√	√	-	-

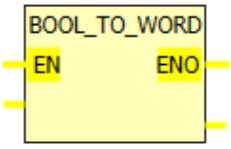
- **Function description**

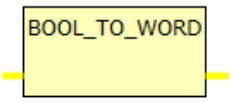
  Convert the bit string "In" of BYTE type to "Out" of DINT type.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

11.10.1.6.15 BOOL_TO_WORD

Convert data of BOOL type to WORD type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
BOOL_TO_WORD	Convert BOOL type to WORD type	FC		

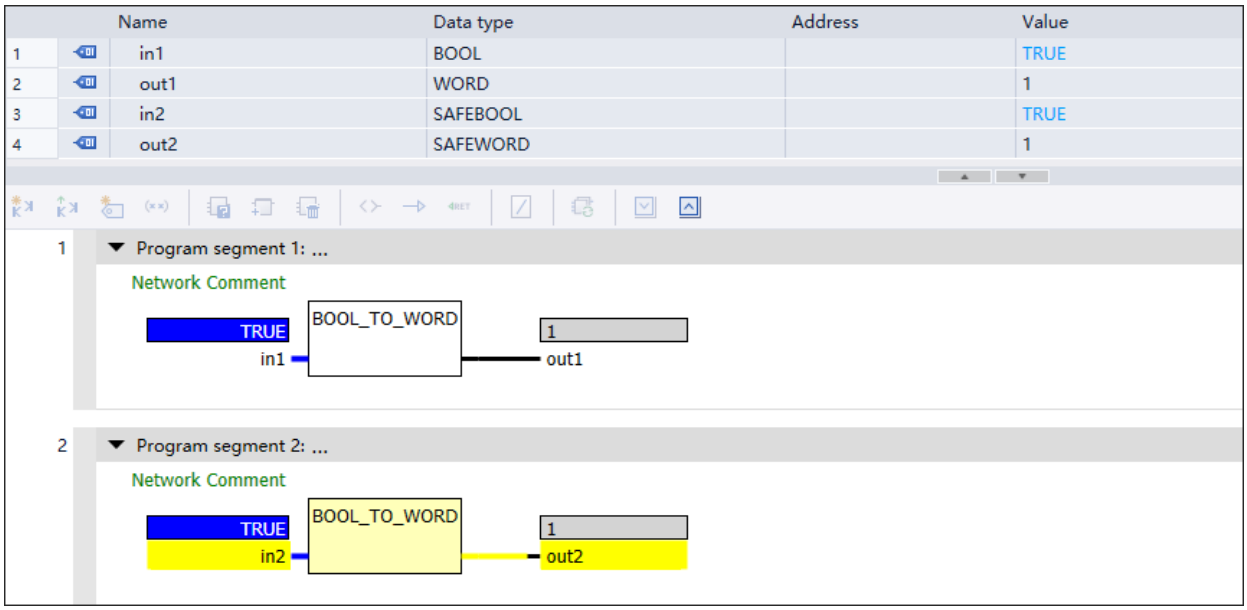
- **Related variables**

  Variables

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	FALSE, TRUE	FALSE	Conversion object
Output	Out	Conversion result	WORD#16#0000, WORD#16#0001	WORD#16#0000	Conversion result

  Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	√	√	-	-	-	-	-	-	-	-	-	-	-	-
Out	-	-	-	-	√	√	-	-	-	-	-	-	-	-



- **Function description**

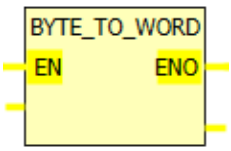
  Convert "In" of BOOL type to the bit string "Out" of WORD type.

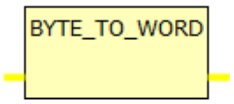
  - When the value of "In" is FALSE, the value of "Out" is WORD#16#0000.
  - When the value of "In" is TRUE, the value of "Out" is WORD#16#0001.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

11.10.1.6.16 BYTE_TO_WORD

Convert data of BYTE type to WORD type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
BYTE_TO_WORD	Convert BYTE type to WORD type	FC		

- **Related variables**

Variables

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	BYTE#16#00 to FF	BYTE#16#00	Conversion object
Output	Out	Conversion result	WORD#16#0000 and WORD#16#00FF	WORD#16#0000	Conversion result

Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	√	√	-	-	-	-	-	-	-	-	-	-
Out	-	-	-	-	√	√	-	-	-	-	-	-	-	-

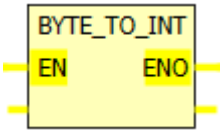
- **Function description**

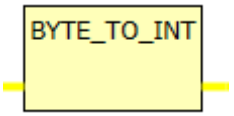
  Convert the bit string "In" of BYTE type to the bit string "Out" of WORD type.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

11.10.1.6.17 BYTE_TO_INT

Convert data of BYTE type to INT type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
BYTE_TO_INT	Convert BYTE type to INT type	FC		

- **Related variables**

  Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	BYTE#16#00 to FF	BYTE#16#00	Conversion object
Output	Out	Conversion result	INT#0 to 255	INT#0	Conversion result

  Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	√	√	-	-	-	-	-	-	-	-	-	-
Out	-	-	-	-	-	-	-	-	√	√	-	-	-	-

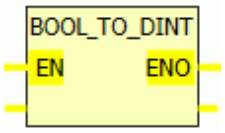
- **Function description**

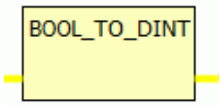
  Convert the bit string "In" of BYTE type to "Out" of INT type.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

11.10.1.6.18 BOOL_TO_DINT

Convert data of BOOL type to DINT type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
BOOL_TO_DINT	Convert BOOL type to DINT type	FC		

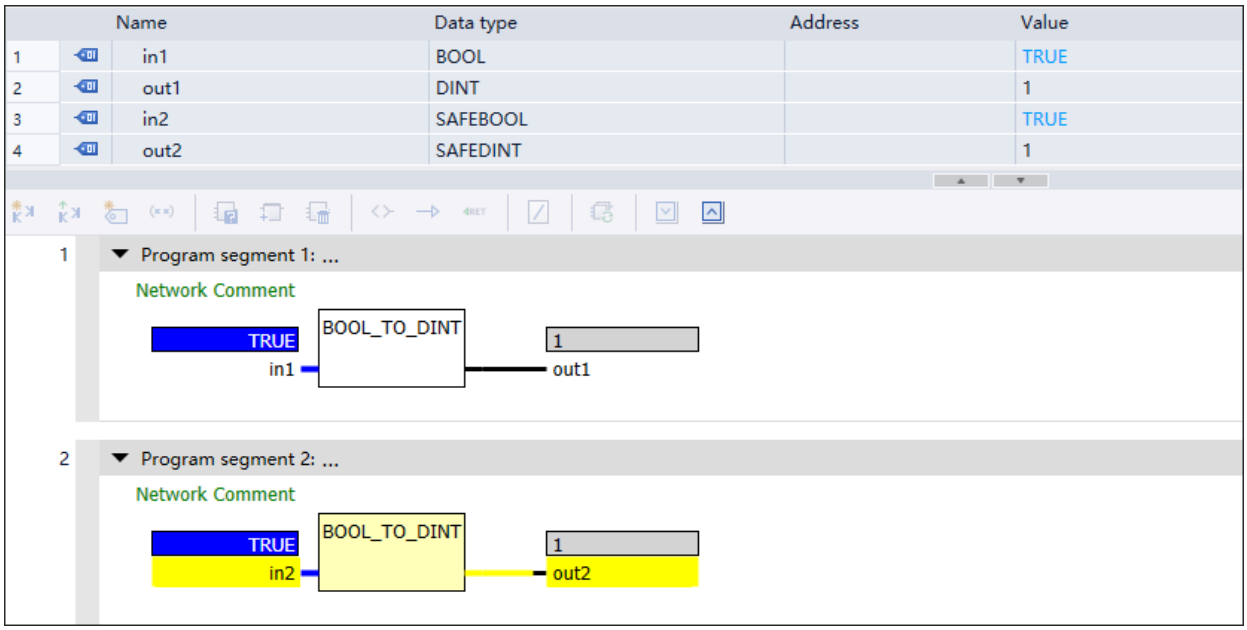
- **Related variables**

  Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	FALSE, TRUE	FALSE	Conversion object
Output	Out	Conversion result	DINT#0 and DINT#1	DINT#0	Conversion result

  Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	√	√	-	-	-	-	-	-	-	-	-	-	-	-
Out	-	-	-	-	-	-	-	-	-	-	√	√	-	-



- **Function description**

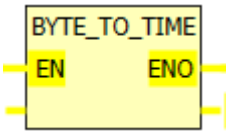
  Convert "In" of BOOL type to "Out" of DINT type.

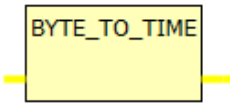
  - When the value of "In" is FALSE, the value of "Out" is DINT#0.
  - When the value of "In" is TRUE, the value of "Out" is DINT#1.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

11.10.1.6.19 BYTE_TO_TIME

Convert data of BYTE type to TIME type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
BYTE_TO_TIME	Convert BYTE type to TIME type	FC		

- **Related variables**

  Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	BYTE#16#00 to FF	BYTE#16#00	Conversion object
Output	Out	Conversion result	T#0ms to T#255ms	T#0ms	Conversion result

  Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	√	√	-	-	-	-	-	-	-	-	-	-
Out	-	-	-	-	-	-	-	-	-	-	-	-	√	√

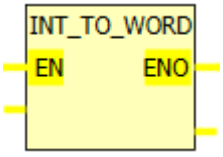
- **Function description**

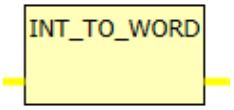
  Convert the bit string "In" of BYTE type to "Out" of TIME type.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

11.10.1.6.20 INT_TO_WORD

Convert data of INT type to WORD type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
INT_TO_WORD	Convert INT type to WORD type	FC		

- **Related variables**

  Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	INT#-32768 to 32767	INT#0	Conversion object
Output	Out	Conversion result	WORD#16#0000 to FFFF	WORD#16#0000	Conversion result

  Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	-	-	-	-	-	-	√	√	-	-	-	-
Out	-	-	-	-	√	√	-	-	-	-	-	-	-	-

- **Function description**

  Convert "In" of INT type to the bit string "Out" of WORD type.

  - Example when the value of "In" is positive (INT#0 to 32767):

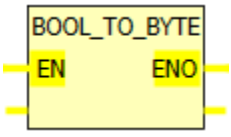
    When the value of "In" is INT#0 to 32767, the value of "Out" is WORD#16#0000 to 7FFF.

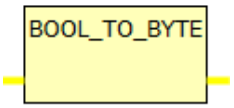
  - Example when the value of "In" is negative (INT#-32768 to -1):
    - When the value of "In" is INT#-32768, which is 1000 0000 0000 0000 (BIN), the value of "Out" is WORD#16#8000.
    - When the value of "In" is INT#-1, which is 1111 1111 1111 1111 (BIN), the value of "Out" is WORD#16#FFFF.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

11.10.1.6.21 BOOL_TO_BYTE

Convert data of BOOL type to BYTE type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
BOOL_TO_BYTE	Convert BOOL type to BYTE type	FC		

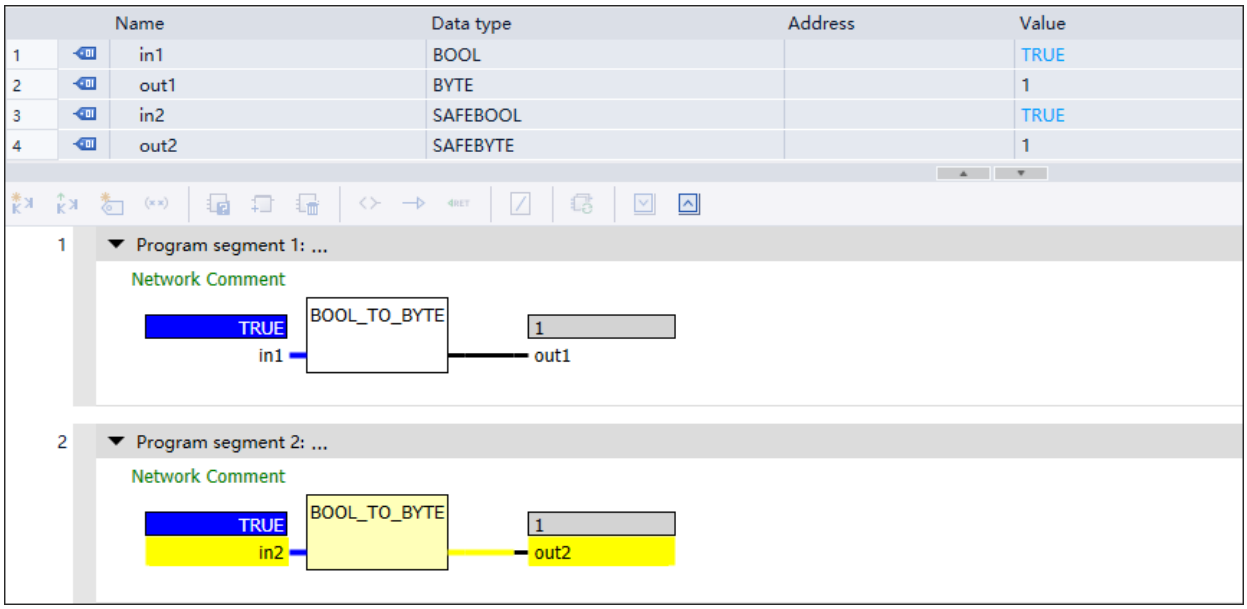
- **Related variables**

  Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	FALSE, TRUE	FALSE	Conversion object
Output	Out	Conversion result	BYTE#0 and BYTE#1	BYTE#0	Conversion result

  Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	√	√	-	-	-	-	-	-	-	-	-	-	-	-
Out	-	-	√	√	-	-	-	-	-	-	-	-	-	-



- **Function**

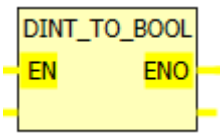
  Convert "In" of BOOL type to the bit string "Out" of BYTE type.

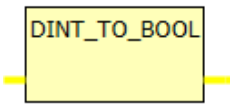
  - When the value of "In" is FALSE, the value of "Out" is BYTE#0.
  - When the value of "In" is TRUE, the value of "Out" is BYTE#1.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

11.10.1.6.22 DINT_TO_BOOL

Convert data of DINT type to BOOL type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
DINT_TO_BOOL	Convert DINT type to BOOL type	FC		

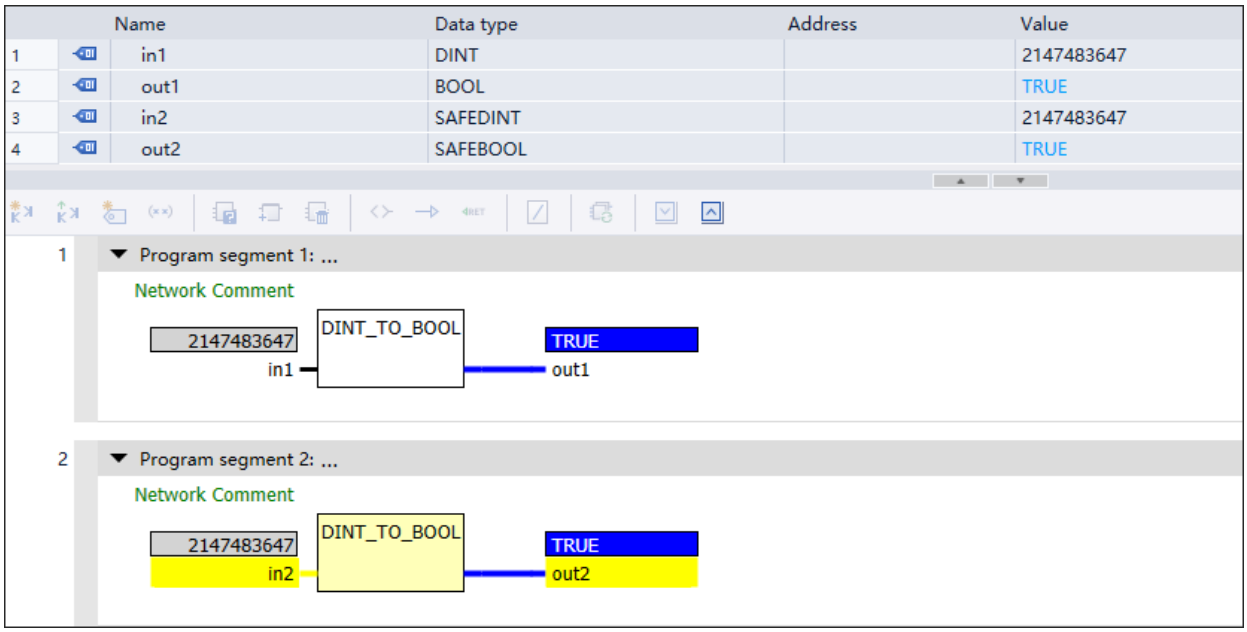
- **Related variables**

  Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	DINT#-2147483648 to 2147483647	DINT#0	Conversion object
Output	Out	Conversion result	FALSE, TRUE	FALSE	Conversion result

  Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	-	-	-	-	-	-	-	-	√	√	-	-
Out	√	√	-	-	-	-	-	-	-	-	-	-	-	-



- **Function description**

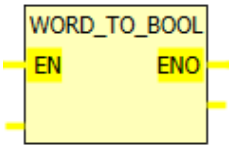
  Convert "In" of DINT type to "Out" of BOOL type.

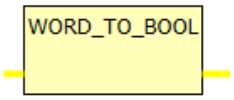
  - When the value of "In" is DINT#0, the value of "Out" is FALSE.
  - When the value of "In" is DINT#-2147483648 to -1 and DINT#1 to 2147483647 (excluding DINT#0), the value of "Out" is TRUE.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.
  - If a value outside the range of DINT#-2147483648 to 2147483647 is input, a "conversion exception" will occur and the program will stop.

11.10.1.6.23 WORD_TO_BOOL

Convert data of WORD type to BOOL type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
WORD_TO_BOOL	Convert WORD type data to BOOL type	FC		

- **Related variables**

Variables

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	WORD#16#0000 to FFFF	WORD#16#0000	Conversion object
Output	Out	Conversion result	FALSE, TRUE	FALSE	Conversion result

Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	-	-	√	√	-	-	-	-	-	-	-	-
Out	√	√	-	-	-	-	-	-	-	-	-	-	-	-

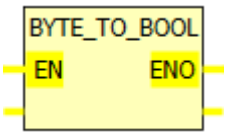
- **Function description**

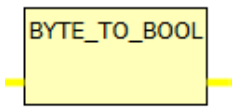
  Convert the bit string "In" of WORD type to "Out" of BOOL type.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.
  - If a value outside the range of WORD#0 to 1 is input, a "conversion exception" will occur and the program will stop.

11.10.1.6.24 BYTE_TO_BOOL

Convert data of BYTE type to BOOL type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
BYTE_TO_BOOL	Convert BYTE type data to BOOL type	FC		

- **Related variables**

  Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	BYTE#16#00 to FF	BYTE#16#00	Conversion object
Output	Out	Conversion result	FALSE, TRUE	FALSE	Conversion result

  Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	√	√	-	-	-	-	-	-	-	-	-	-
Out	√	√	-	-	-	-	-	-	-	-	-	-	-	-

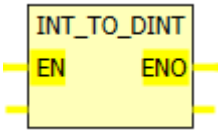
- **Function description**

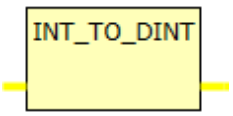
  Convert the bit string "In" of BYTE type to "Out" of BOOL type.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

11.10.1.6.25 INT_TO_DINT

Convert data of INT type to DINT type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
INT_TO_DINT	Convert INT type data to DINT type	FC		

- **Related variables**

  Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	INT#-32768 to 32767	INT#0	Conversion object
Output	Out	Conversion result	DINT#-32768 to 32767	DINT#0	Conversion result

  Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	-	-	-	-	-	-	√	√	-	-	-	-
Out	-	-	-	-	-	-	-	-	-	-	√	√	-	-

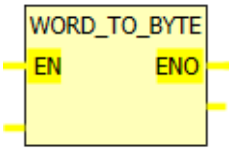
- **Function description**

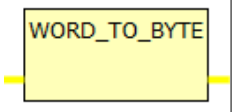
  Convert "In" of INT type to "Out" of DINT type.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

11.10.1.6.26 WORD_TO_BYTE

Convert data of WORD type to BYTE type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
WORD_TO_BYTE	Convert WORD type data to BYTE type	FC		

- **Related variables**

Variables

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	WORD#16#0000 to WORD#16#00FF	WORD#16#0000	Conversion object
Output	Out	Conversion result	BYTE#16#00 to FF	BYTE#16#00	Conversion result

Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	-	-	√	√	-	-	-	-	-	-	-	-
Out	-	-	√	√	-	-	-	-	-	-	-	-	-	-

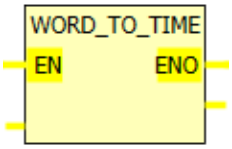
- **Function description**

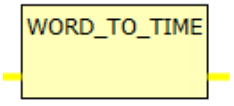
  Convert the bit string "In" of WORD type to the bit string "Out" of BYTE type.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.
  - If a value outside the range of WORD#16#0000 to 00FF is input, a "conversion exception" will occur and the program will stop.

11.10.1.6.27 WORD_TO_TIME

Convert data of WORD type to TIME type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
WORD_TO_TIME	Convert WORD type data to TIME type	FC		

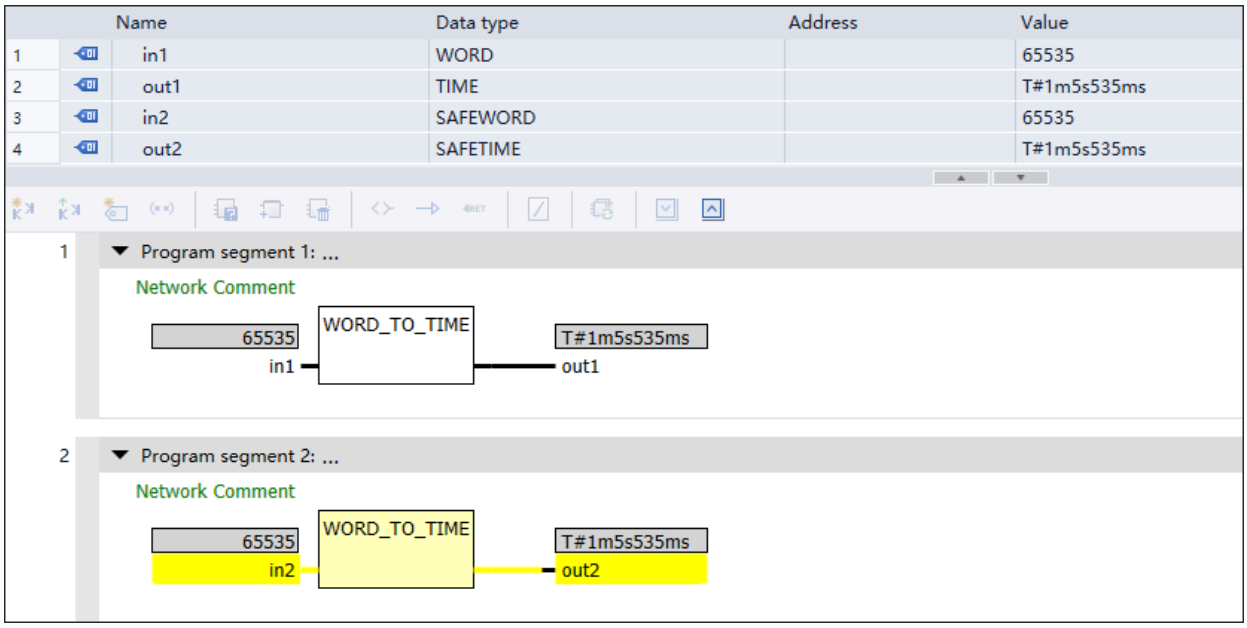
- **Related variables**

Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	WORD#16#0000 to FFFF	WORD#16#0000	Conversion object
Output	Out	Conversion result	T#0ms to T#1m5s535ms	T#0ms	Conversion result

Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	-	-	√	√	-	-	-	-	-	-	-	-
Out	-	-	-	-	-	-	-	-	-	-	-	-	√	√



- **Function description**

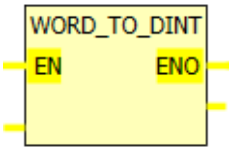
  Convert the bit string "In" of WORD type to "Out" of TIME type.

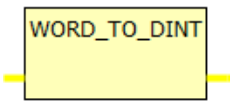
  Example: When the value of "In" is WORD#16#C549, the value of "Out" is T#50s505ms.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

11.10.1.6.28 WORD_TO_DINT

Convert data of WORD type to DINT type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
WORD_TO_DINT	Convert WORD type data to DINT type	FC		

- **Related variables**

  Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	WORD#16#0000 to FFFF	WORD#16#0000	Conversion object
Output	Out	Conversion result	DINT#0 to 65535	DINT#0	Conversion result

  Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	-	-	√	√	-	-	-	-	-	-	-	-
Out	-	-	-	-	-	-	-	-	-	-	√	√	-	-

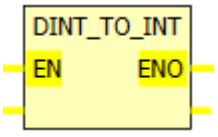
- **Function description**

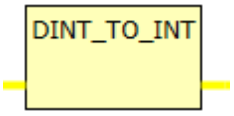
  Convert "In" of WORD type to "Out" of DINT type.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

11.10.1.6.29 DINT_TO_INT

Convert data of DINT type to INT type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
DINT_TO_INT	Convert DINT type data to INT type	FC		

- **Related variables**

Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	DINT#-32768 to 32767	DINT#0	Conversion object
Output	Out	Conversion result	INT#-32768 to 32767	INT#0	Conversion result

Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	-	-	-	-	-	-	-	-	√	√	-	-
Out	-	-	-	-	-	-	-	-	√	√	-	-	-	-

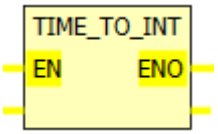
- **Function description**

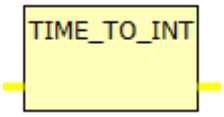
  Convert "In" of DINT type to "Out" of INT type.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.
  - If a value outside the range of DINT#-32768 to 32767 is input, a "conversion exception" will occur and the program will stop.

11.10.1.6.30 TIME_TO_INT

Convert data of TIME type to INT type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
TIME_TO_INT	Convert TIME type data to INT type	FC		

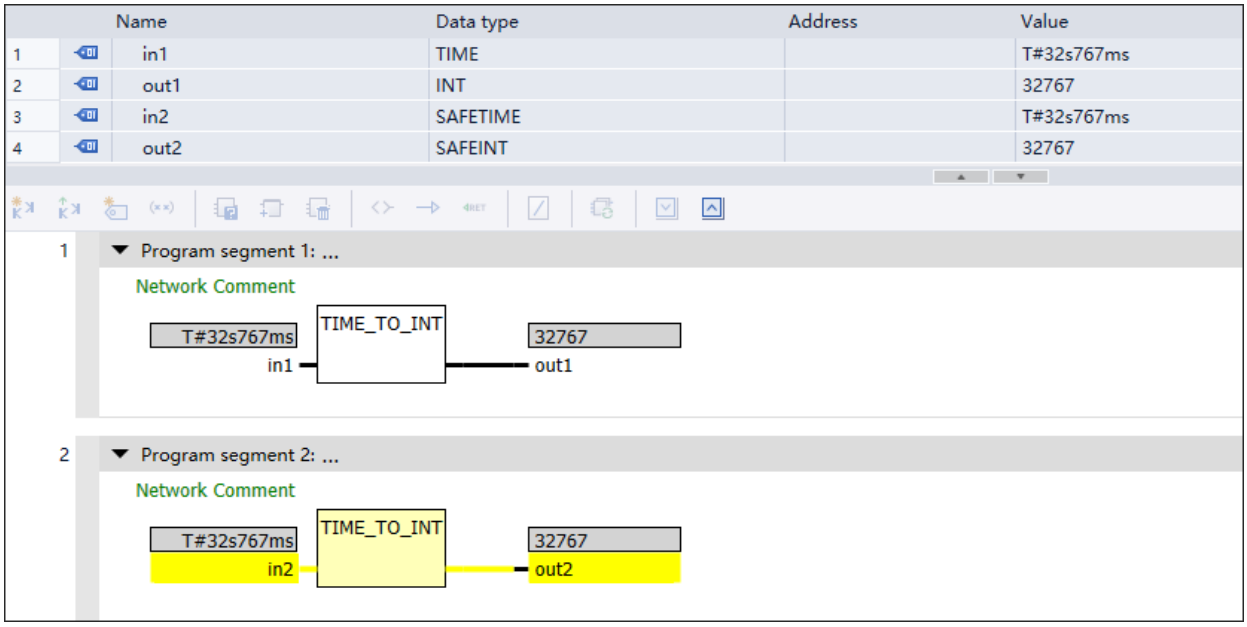
- **Related variables**

  Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	T#0ms to T#32s767ms	T#0ms	Conversion object
Output	Out	Conversion result	INT#0 to 32767	INT#0	Conversion result

  Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	-	-	-	-	-	-	-	-	-	-	√	√
Out	-	-	-	-	-	-	-	-	√	√	-	-	-	-



- **Function description**

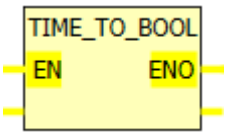
  Convert "In" of TIME type to "Out" of INT type.

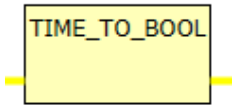
  Example: When the value of "In" is T#10s500ms, the value of "Out" is INT#10500.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.
  - If a value outside the range of TIME#0ms to 32s767ms is input, a "conversion exception" will occur and the program will stop.

11.10.1.6.31 TIME_TO_BOOL

Convert TIME type data to BOOL type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
TIME_TO_BOOL	Convert TIME type data to BOOL type	FC		

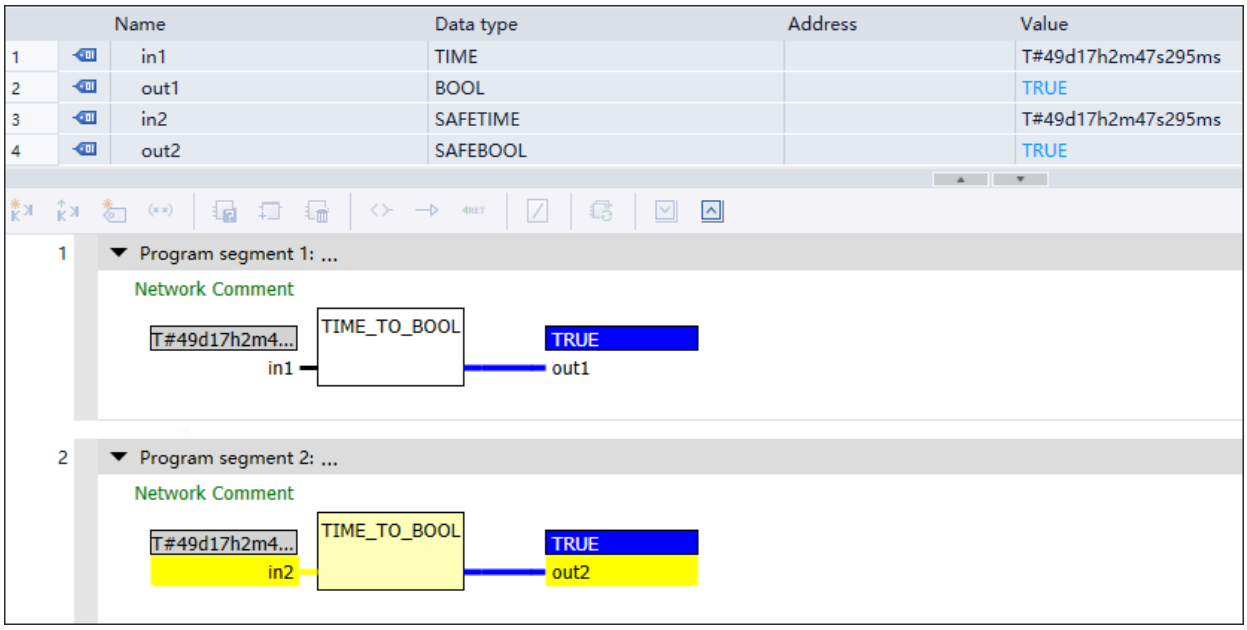
- **Related variables**

Variables

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	T#0ms to T#49d17h2m47s295ms	T#0ms	Conversion object
Output	Out	Conversion result	FALSE, TRUE	FALSE	Conversion result

Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	-	-	-	-	-	-	-	-	-	-	√	√
Out	√	√	-	-	-	-	-	-	-	-	-	-	-	-



- **Function description**

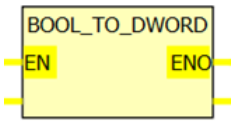
  Convert "In" of TIME type to "Out" of BOOL type.

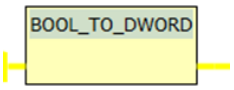
  - When the value of "In" is T#0ms, the value of "Out" is FALSE.
  - When the value of "In" is T#1ms to T#49d17h2m47s295ms (other than T#0ms), the value of "Out" is TRUE.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

11.10.1.6.32 BOOL_TO_DWORD

Convert BOOL type data to DWORD type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
BOOL_TO_DWORD	Convert BOOL type data to DWORD type	FC		

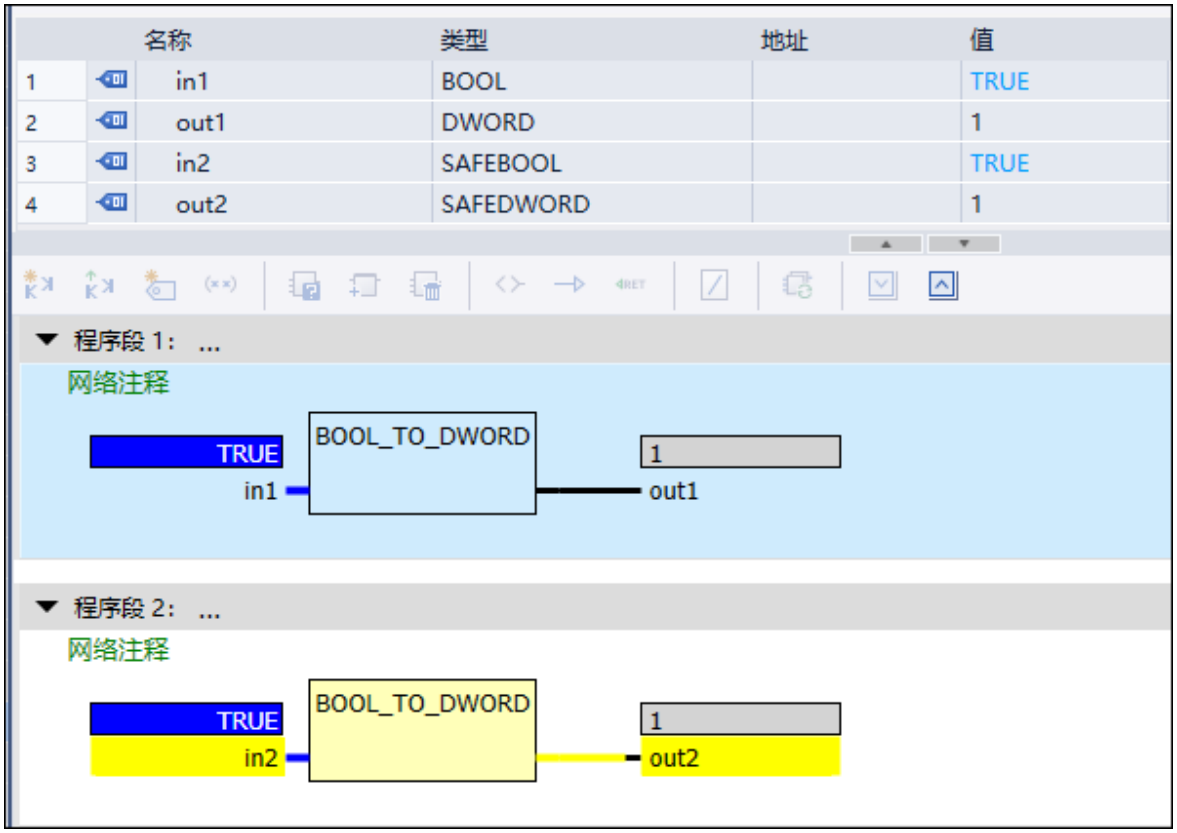
- **Related variables**

  Variables

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	FALSE, TRUE	FALSE	Conversion object
Output	Out	Conversion result	DWORD#0, DWORD #1	DWORD #0	Conversion result

  Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	√	√	-	-	-	-	-	-	-	-	-	-	-	-
Out	-	-	-	-	-	-	√	√	-	-	-	-	-	-



- **Function description**

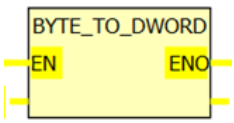
  Convert "In" of BOOL type to the bit string "Out" of WORD type.

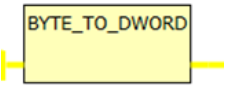
  - When the value of "In" is FALSE, the value of "Out" is DWORD#0.
  - When the value of "In" is TRUE, the value of "Out" is DWORD #1.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

11.10.1.6.33 BYTE_TO_DWORD

Convert BYTE type data to DWORD type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
BYTE_TO_DWORD	Convert BYTE type data to DWORD type	FC		

- **Related variables**

Variables

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	BYTE#16#00 to FF	BYTE#16#00	Conversion object

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Output	Out	Conversion result	DWORD#0 to DWORD#255	DWORD#0	Conversion result

Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	√	√	-	-	-	-	-	-	-	-	-	-
Out	-	-	-	-	-	-	√	√	-	-	-	-	-	-

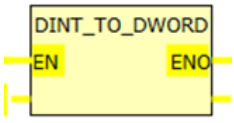
- **Function description**

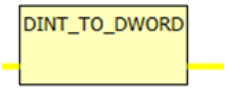
  Convert the bit string "In" of BYTE type to the bit string "Out" of DWORD type.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

11.10.1.6.34 DINT_TO_DWORD

Convert DINT type data to DWORD type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
DINT_TO_ DWORD	Convert DINT type data to DWORD type	FC		

- **Related variables**

Variables

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	DINT#0 to 2147483647	DINT#0	Conversion object

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Output	Out	Conversion result	DWORD#0 to 2147483647	DWORD#0	Conversion result

Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	-	-	-	-	-	-	-	-	√	√	-	-
Out	-	-	-	-	-	-	√	√	-	-	-	-	-	-

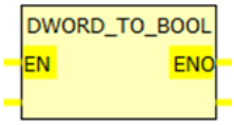
- **Function description**

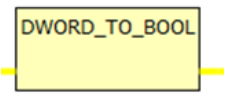
  Convert "In" of DINT type to the bit string "Out" of DWORD type.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.
  - If a value outside the range of DINT#0 to 2147483647 is input, a "conversion exception" will occur and the program will stop.

11.10.1.6.35 DWORD_TO_BOOL

Convert DWORD type data to BOOL type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
DWORD_TO_BOOL	Convert DWORD type data to BOOL type.	FC		

- **Related variables**

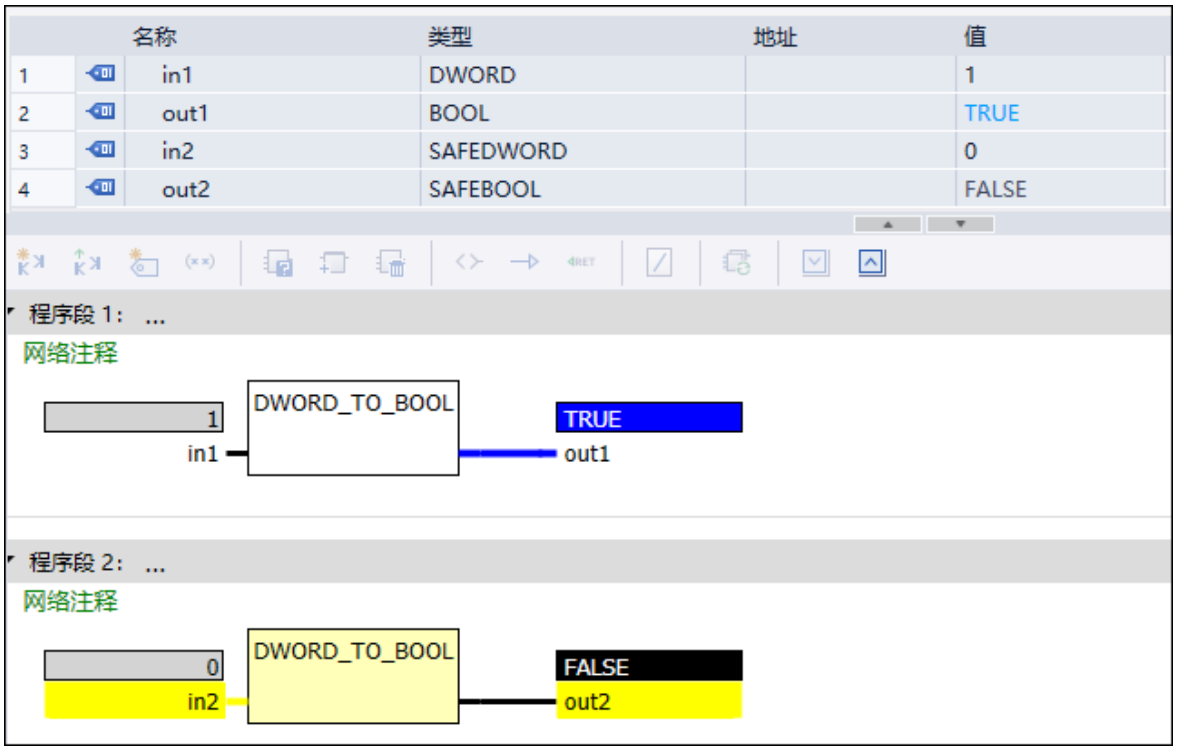
Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	DWORD#0 to 1	DWORD#0	Conversion object

Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	Out	Conversion result	FALSE, TRUE	FALSE	Conversion result

Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	-	-	-	-	√	√	-	-	-	-	-	-
Out	√	√	-	-	-	-	-	-	-	-	-	-	-	-



- **Function description**

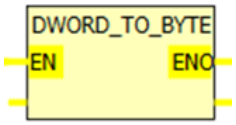
  Convert the bit string "In" of WORD type to "Out" of BOOL type.

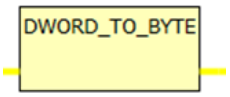
  - When the value of "In" is 0, the value of "Out" is FALSE.
  - When the value of "In" is 1, the value of "Out" is TRUE.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

11.10.1.6.36 DWORD_TO_BYTE

Convert DWORD type data to BYTE type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
DWORD_TO_BYTE	Convert DWORD type data to BYTE type	FC		

- **Related variables**

Variables

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	DWORD#0 to 255	DWORD#0	Conversion object
Output	Out	Conversion result	BYTE16#00 to FF	BYTE16#00	Conversion result

Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	-	-	-	-	√	√	-	-	-	-	-	-
Out	-	-	√	√	-	-	-	-	-	-	-	-	-	-

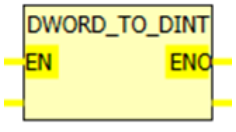
- **Function description**

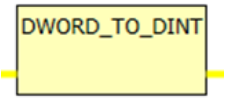
  Convert the bit string "In" of DWORD type to the bit string "Out" of BYTE type.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.
  - If a value outside the range of DWORD#0 to 255 is input, a "conversion exception" will occur and the program will stop.

11.10.1.6.37 DWORD_TO_DINT

Convert DWORD type data to DINT type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
DWORD_TO_DINT	Convert DWORD type data to DINT type	FC		

- **Related variables**

Variables

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	DWORD#0 to 2147483647	DWORD#0	Conversion object

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Output	Out	Conversion result	DINT#0 to 2147483647	DINT#0	Conversion result

Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	-	-	-	-	√	√	-	-	-	-	-	-
Out	-	-	-	-	-	-	-	-	-	-	√	√	-	-

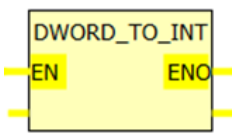
- **Function description**

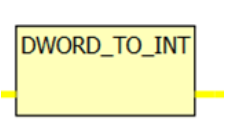
  Convert the bit string "In" of DWORD type to the integer "Out" of DINT type.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.
  - If a value outside the range of DWORD#0 to 2147483647 is input, a "conversion exception" will occur and the program will stop.

11.10.1.6.38 DWORD_TO_INT

Convert DWORD type data to INT type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
DWORD_TO_INT	Convert DWORD type data to INT type	FC		

- **Related variables**

Variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	DWORD#0 to 32767	DWORD#0	Conversion object

Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	Out	Conversion result	INT#0 to 32767	INT#0	Conversion result

Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	-	-	-	-	√	√	-	-	-	-	-	-
Out	-	-	-	-	-	-	-	-	√	√	-	-	-	-

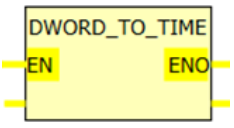
- **Function description**

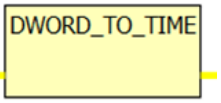
  Convert the bit string "In" of DWORD type to the integer "Out" of INT type.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.
  - If a value outside the range of DWORD#0 to 32767 is input, a "conversion exception" will occur and the program will stop.

11.10.1.6.39 DWORD_TO_TIME

Convert DWORD type data to TIME type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
DWORD_TO_TIME	Convert DWORD type data to TIME type	FC		

- **Related variables**

  Variables

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	DWORD#0 to 4294967295	DWORD#0	Conversion object
Output	Out	Conversion result	T#0ms to T#49d17h2m47s295ms	T#0ms	Conversion result

Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	-	-	-	-	√	√	-	-	-	-	-	-
Out	-	-	-	-	-	-	-	-	-	-	-	-	√	√

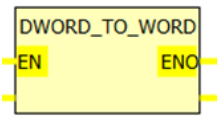
- **Function description**

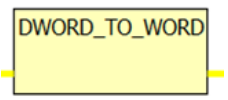
  Convert the bit string "In" of DWORD type to "Out" of TIME type.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

11.10.1.6.40 DWORD_TO_WORD

Convert DWORD type data to WORD type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
DWORD_TO_WORD	Convert DWORD type data to WORD type	FC		

- **Related variables**

Variables

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	DWORD#0 to T#65535	DWORD#0	Conversion object
Output	Out	Conversion result	WORD#16#0000 to FFFF	WORD#16#0000	Conversion result

Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	-	-	-	-	√	√	-	-	-	-	-	-
Out	-	-	-	-	√	√	-	-	-	-	-	-	-	-

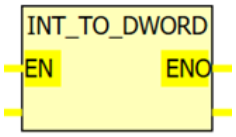
- **Function description**

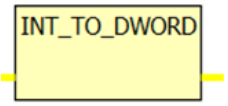
  Convert the bit string "In" of DWORD type to the bit string "Out" of WORD type.

- **Programming example**

  FBD:

  LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.
  - If a value outside the range of DWORD#0 to 66535 is input, a "conversion exception" will occur and the program will stop.

11.10.1.6.41 INT_TO_DWORD

Convert INT type data to DWORD type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
INT_TO_DWORD	Convert INT type data to DWORD type	FC		

- **Related variables**

Variables

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	INT#0 to 32767	INT#0	Conversion object
Output	Out	Conversion result	DWORD#0 to 32767	DWORD#0	Conversion result

Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	-	-	-	-	-	-	√	√	-	-	-	-
Out	-	-	-	-	-	-	√	√	-	-	-	-	-	-

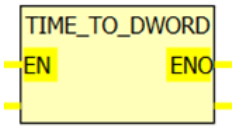
- **Function description**

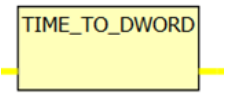
  Convert "In" of INT type to the bit string "Out" of DWORD type.

- **Programming example**

  FBD:

LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.
  - If a value outside the range of INT#0 to 32767 is input, a "conversion exception" will occur and the program will stop.

11.10.1.6.42 TIME_TO_DWORD

Convert TIME type data to DWORD type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
TIME_TO_DWORD	Convert TIME type data to DWORD type	FC		

- **Related variables**

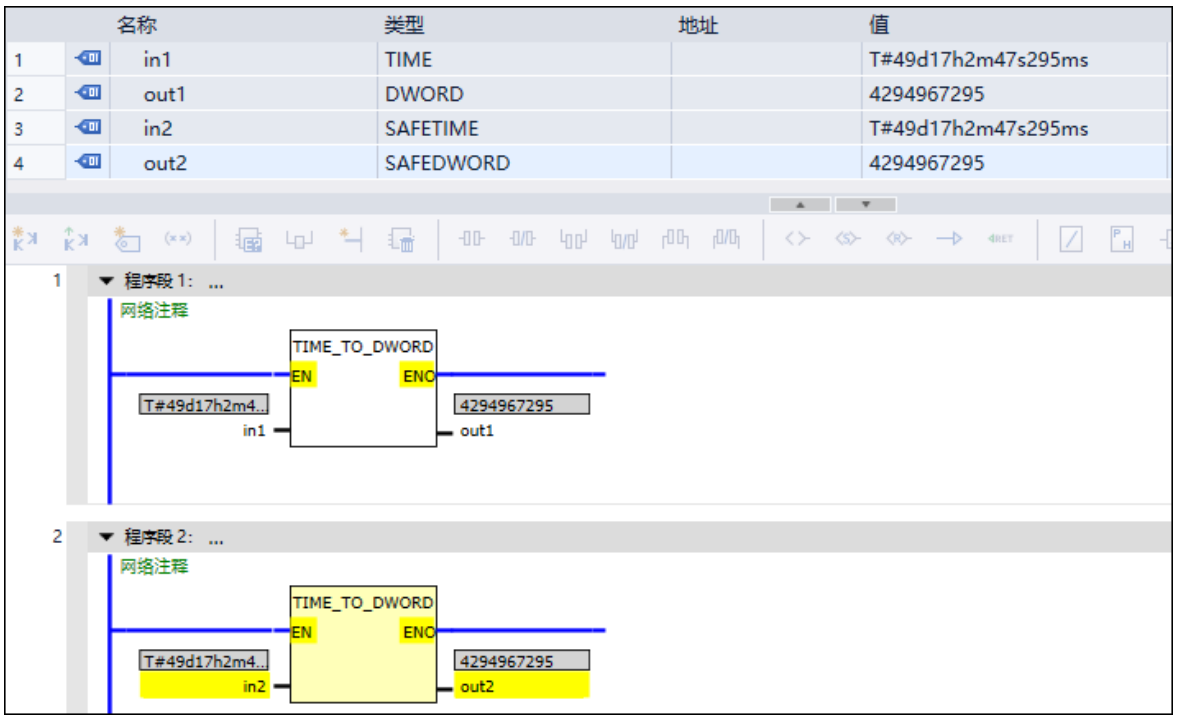
Variables

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	T#0ms to T#49d17h2m47s295ms	T#0ms	Conversion object
Output	Out	Conversion result	DWORD#0 to 4294967295	DWORD#0	Conversion result

Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	-	-	-	-	-	-	-	-	-	-	√	√
Out	-	-	-	-	-	-	√	√	-	-	-	-	-	-

- **Function description**

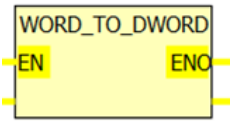


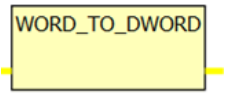
Convert "In" of TIME type to the bit string "Out" of DWORD type.

- **Programming example**

FBD:

LD:





- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

11.10.1.6.43 WORD_TO_DWORD

Convert WORD type data to DWORD type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
WORD_TO_DWORD	Convert WORD type data to DWORD type	FC		

- **Related variables**

  Variables

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	WORD#16#0000 to FFFF	WORD#16#0000	Conversion object
Output	Out	Conversion result	DWORD#0 to 65535	DWORD#0	Conversion result

  Data types

	Boolean		Bit String						Integer				Time Format	
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD	INT	SAFEINT	DINT	SAFEDINT	TIME	SAFETIME
In	-	-	-	-	√	√	-	-	-	-	-	-	-	-
Out	-	-	-	-	-	-	√	√	-	-	-	-	-	-

- **Function description**

  Convert the bit string "In" of WORD type to the bit string "Out" of DWORD type.

- **Programming example**

  FBD:

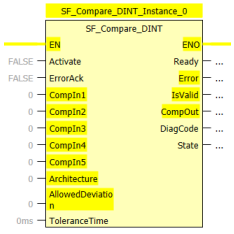
  LD:

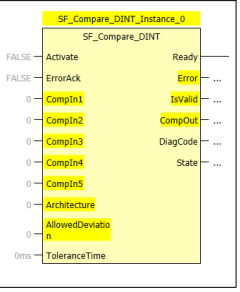
- **Precautions**
  - When assigning a safety data type variable to the output terminal, the input terminals must all be set to safety data type variables.
  - When assigning a standard data type variable to the output terminal, the input terminals can be set to either safety or standard data type variables.

11.10.2 Safety Instructions

11.10.2.1 Basic Safety Instruction

11.10.2.1.1 Instruction List





Instruction	FB/FC	Function	Library	Applicable Library Version
11.10.2.1.2 SF_Compare_DINT	FB	Comparison output instruction	SafetyInstructions	Applicable to library version 1.0.0.0/1.1.0.0
11.10.2.1.3 SF_Compare_INT	FB	Comparison output instruction		
11.10.2.1.4 SF_CTD	FB	Subtraction counter		
11.10.2.1.5 SF_CTU	FB	Addition counter		
11.10.2.1.6 SF_CTUD	FB	Addition/ subtraction counter		

Instruction	FB/FC	Function	Library	Applicable Library Version
11.10.2.1.7 SF_F_TRIG	FB	Falling edge triggered		
11.10.2.1.8 SF_Limit_DINT	FB	Limit		
11.10.2.1.9 SF_Limit_INT	FB	Limit		
11.10.2.1.10 SF_R_TRIG	FB	Rising edge-triggered		
11.10.2.1.11 SF_RS	FB	Prioritize the reset value		
11.10.2.1.12 SF_Scaling_DINT	FB	Proportional scaling		
11.10.2.1.13 SF_Scaling_INT	FB	Proportional scaling		
11.10.2.1.14 SF_SR	FB	Prioritize the set value		
11.10.2.1.15 SF_TON	FB	ON-delay timer		
11.10.2.1.16 SF_TOF	FB	OFF-delay timer		
11.10.2.1.17 SF_TP	FB	Time pulse		

11.10.2.1.2 SF_Compare_DINT

The SF_Compare_DINT instruction is used to check whether the two to five input parameters (of SAFEDINT type) are equal or differ by a specified allowable value within a set time range.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_Compare_DINT	Comparison output instruction	FB		

- **Related variables**

  Variables

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	Activate	Activate instruction	BOOL	TRUE, FALSE	FALSE	Determines whether to activate the instruction. FALSE: Instruction is not activated. TRUE: Instruction is activated.
	ErrorAck	Fault acknowledgment	BOOL	TRUE, FALSE	FALSE	Acknowledges faults. When a fault occurs, ErrorAck must be changed from FALSE to TRUE; otherwise, the instruction will remain in a faulty status.
	CompIn1	Comparative value 1	SAFEDINT	-2147483648 to 2147483647	0	The first value to be compared
	CompIn2	Comparative value 2	SAFEDINT	-2147483648 to 2147483647	0	The second value to be compared
	CompIn3	Comparative value 3	SAFEDINT	-2147483648 to 2147483647	0	The third value to be compared
	CompIn4	Comparative value 4	SAFEDINT	-2147483648 to 2147483647	0	The fourth value to be compared
	CompIn5	Comparative value 5	SAFEDINT	-2147483648 to 2147483647	0	The fifth value to be compared
	Architecture	Comparison output mode	SAFEDINT	0, 1, 2	0	Comparison output mode. Out-of-range values are corrected to mode 0.
	AllowedDeviation	Allowed deviation	SAFEDINT	-2147483648 to 2147483647	0	Allowed deviation. The comparison is based on the absolute value of the allowed deviation.
	Tolerance Time	Tolerance time	TIME	Follows data type	T#0ms	The maximum duration for which the input values remain unequal.
Output	Ready	Ready status	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is in ready status.
	Error	Faulty status	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is faulty.

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	IsValid	Input values are equal	SAFEBOOL	TRUE, FALSE	FALSE	Returns TRUE if the input values are equal (within tolerance range). Returns TRUE if no fault occurs within the allowed time.
	CompOut	Comparison output value	SAFEDINT	-2147483648 to 2147483647	0	Comparison output value. Displays the first value that meets the requirement.
	DiagCode	Instruction information code	16#WORD	Follows data type	0	Displays fault codes when an instruction fault occurs, to indicate the cause of the fault.
	State	Instruction operation status	WORD	Follows data type	0	Indicates the execution status of the instruction. The following statuses are available for the current instruction: 1: Run 2: Stop 4: Error 5: Reset 8: DelayOut

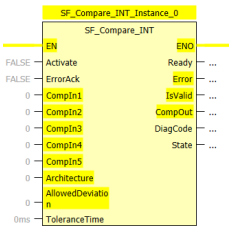
- **Function description**
  - The SF_Compare_DINT instruction is used to check whether the two to five input parameters are equal within a set time range.
  - The comparison mode "Architecture" determines how many input values are used for comparison.

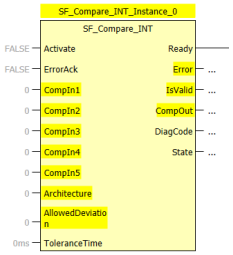
Architecture (Comparison Mode)	Comparison Mode
0: 1oo2	Checks whether the first two input values are equal (within the allowed range).
1: 2oo3	Checks whether two of the first three input values are equal (within the allowed range).
2: 3oo5	Checks whether three of the first five input values are equal (within the allowed range).

    The output parameter "CompOut" returns the first input value that meets the requirement under each comparison mode. If a valid output is found, the output parameter "IsValid" is set to TRUE; if a fault occurs, "IsValid" is reset to FALSE.
  - The instruction information code (DiagCode) is used to display fault codes to indicate the causes.

DiagCode (Instruction Information Code)	Description
0x4098	Input value exceeds the maximum value of the DINT type.
0x4099	Input value is less than the minimum value of the DINT type.
0x0217	Input values remain unequal (within the allowed range) for a time longer than "ToleranceTime".

◦ Status information (State) is used to indicate the execution status of the instruction. In the current instruction, the statuses are: 1 (Run), 2 (Stop), 4 (Error), 5 (Reset), and 8 (DelayOut).





State (Status Information)	Description
1 (Run)	The instruction enters the "Run" status if a sufficient number of input values are equal (within allowable range). Output values are as follows: Error = 0, IsValid = 1, CompOut = CompInX (the first value that meets the requirement)
2 (Stop)	In the "Stop" status, the instruction is not executed. Output values are as follows: Error = 0, IsValid = 0, CompOut = 0.
4 (Error)	In the "Error" status, a fault is detected during instruction execution. Output values are as follows: Error = 1, IsValid = 0, CompOut = 0.
5 (Reset)	In the "Reset" status, no further faults remain and "ErrorAck" changes from FALSE to TRUE. Output values are as follows: Error = 0, IsValid = 0, CompOut = 0.
8 (DelayOut)	If there are not enough input values that are equal (within allowable range), timing will start. If the set time is not exceeded, the instruction enters the "DelayOut" status. Output values are as follows: Error = 0, IsValid = 1, CompOut = retained value.

- **Note**
  : If the instruction execution fails, manual confirmation is required to restart the execution; if no manual confirmation is performed, the instruction status remains 4 (Error) and will not switch to 2 (Stop).

11.10.2.1.3 SF_Compare_INT

The SF_Compare_INT instruction is used to check whether the two to five input parameters (of SAFEINT type) are equal or differ by a specified allowable value within a set time range.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_Compare_INT	Comparison output instruction	FB		

- **Related variables**

  Variables

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	Activate	Activate instruction	BOOL	TRUE, FALSE	FALSE	Determines whether to activate the instruction. FALSE: Instruction is not activated. TRUE: Instruction is activated.
	ErrorAck	Fault acknowledgment	BOOL	TRUE, FALSE	FALSE	Acknowledges faults. When a fault occurs, ErrorAck must be changed from FALSE to TRUE; otherwise, the instruction will remain in a faulty status.
	CompIn1	Comparative value 1	SAFEINT	-32768 to 32767	0	The first value to be compared
	CompIn2	Comparative value 2	SAFEINT	-32768 to 32767	0	The second value to be compared
	CompIn3	Comparative value 3	SAFEINT	-32768 to 32767	0	The third value to be compared
	CompIn4	Comparative value 4	SAFEINT	-32768 to 32767	0	The fourth value to be compared
	CompIn5	Comparative value 5	SAFEINT	-32768 to 32767	0	The fifth value to be compared
	Architecture	Comparison output mode	SAFEINT	0, 1, 2	0	Comparison output mode. Out-of-range values are corrected to mode 0. 0: 1oo2 1: 2oo3 2: 3oo5

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	AllowedDeviation	Allowed deviation	SAFEINT	-32768 to 32767	0	Allowed deviation. The comparison is based on the absolute value of the allowed deviation.
	ToleranceTime	Tolerance time	TIME	Follows data type	T#0ms	The maximum duration for which the input values remain unequal.
Output	Ready	Ready status	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is in ready status.
	Error	Faulty status	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is faulty.
	IsValid	Input values are equal	SAFEBOOL	TRUE, FALSE	FALSE	Returns TRUE if the input values are equal (within tolerance range). Returns TRUE if no fault occurs within the allowed time.
	CompOut	Comparison output value	SAFEINT	-32768 to 32767	0	Comparison output value. Displays the first value that meets the requirement.
	DiagCode	Instruction information code	16#WORD	Follows data type	0	Displays fault codes when an instruction fault occurs, to indicate the cause of the fault.
	State	Instruction operation status	WORD	Follows data type	0	Indicates the execution status of the instruction. The following statuses are available for the current instruction: 1: Run 2: Stop 4: Error 5: Reset 8: DelayOut

- **Function description**
  - The SF_Compare_INT instruction is used to check whether the two to five input parameters are equal within a set time range.
  - The comparison mode "Architecture" determines how many input values are used for comparison.

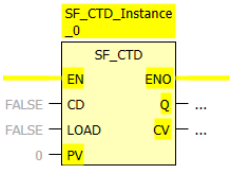
Architecture (Comparison Mode)	Comparison Mode
0: 1oo2	Checks whether the first two input values are equal (within the allowed range).
1: 2oo3	Checks whether two of the first three input values are equal (within the allowed range).
2: 3oo5	Checks whether three of the first five input values are equal (within the allowed range).

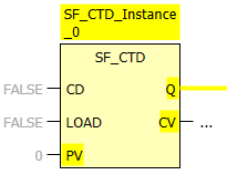
The output parameter "CompOut" returns the first input value that meets the requirement under each comparison mode. If a valid output is found, the output parameter "IsValid" is set to TRUE; if a fault occurs, "IsValid" is reset to FALSE.

◦ The instruction information code (DiagCode) is used to display fault codes to indicate the causes.

DiagCode (Instruction Information Code)	Description
0x4098	Input value exceeds the maximum value of the INT type.
0x4099	Input value is less than the minimum value of the INT type.
0x0217	Input values remain unequal (within the allowed range) for a time longer than "ToleranceTime".

◦ Status information (State) is used to indicate the execution status of the instruction. In the current instruction, the statuses are: 1 (Run), 2 (Stop), 4 (Error), 5 (Reset), and 8 (DelayOut).





State (Status Information)	Description
1 (Run)	The instruction enters the "Run" status if a sufficient number of input values are equal (within allowable range). Output values are as follows: Error = 0, IsValid = 1, CompOut = CompInX (the first value that meets the requirement).
2 (Stop)	In the "Stop" status, the instruction is not executed. Output values are as follows: Error = 0, IsValid = 0, CompOut = 0.
4 (Error)	In the "Error" status, a fault is detected during instruction execution. Output values are as follows: Error = 1, IsValid = 0, CompOut = 0.
5 (Reset)	In the "Reset" status, no further faults remain and "ErrorAck" changes from FALSE to TRUE. Output values are as follows: Error = 0, IsValid = 0, CompOut = 0.
8 (DelayOut)	If there are not enough input values that are equal (within allowable range), timing will start. If the set time is not exceeded, the instruction enters the "DelayOut" status. Output values are as follows: Error = 0, IsValid = 1, CompOut = retained value.

- **Note**
  : If the instruction execution fails, manual confirmation is required to restart the execution; if no manual confirmation is performed, the instruction status remains 4 (Error) and will not switch to 2 (Stop).

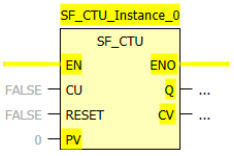
11.10.2.1.4 SF_CTD

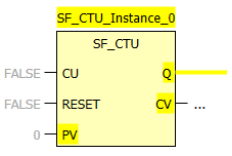
SF_CTD is a subtraction counter.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_CTD	Subtraction counter	FB		

- **Related variables**
  Variables





Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	CD	Counter input	BOOL	TRUE, FALSE	FALSE	Counter input
	LOAD	Load signal	BOOL	TRUE, FALSE	FALSE	TRUE: Loads "PV" into "CV".
	PV	Preset value	SAFEINT	0 to 32767	0	Preset value of the counter
Output	Q	Counter output	SAFEBOOL	TRUE, FALSE	FALSE	Counter output
	CV	Count value	SAFEINT	0 to 32767	0	The current value of the counter

- **Function description**
  - SF_CTD is a subtraction counter. The data type of preset value and count value is SAFEINT.
  - When the load signal "LOAD" is set to TRUE, the preset value "PV" is loaded into the count value "CV", and the counter output "Q" becomes FALSE. When the value of "CV" is less than or equal to 0, the value of "Q" becomes TRUE.
  - A subtraction operation is triggered for "CV" when the input signal "CU" is at the rising edge.
  - When the value of "CV" is less than or equal to 0, even if "CD" is at a rising edge, "CV" will not change.
  - When "LOAD" is TRUE, "CD" is ignored. "CV" does not perform a subtraction operation.

11.10.2.1.5 SF_CTU

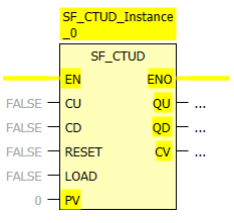
SF_CTU is an addition counter.

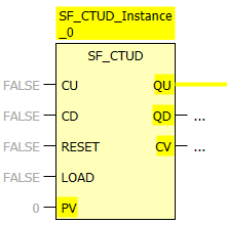
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_CTU	Addition counter	FB		

- **Related variables**

  Variables





Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	CU	Counter input	BOOL	TRUE, FALSE	FALSE	Counter input
	RESET	Reset signal	BOOL	TRUE, FALSE	FALSE	TRUE: Resets "CV" to 0.
	PV	Preset value	SAFEINT	0 to 32767	0	Preset value of the counter
Output	Q	Counter output	SAFEBOOL	TRUE, FALSE	FALSE	Counter output
	CV	Count value	SAFEINT	0 to 32767	0	The current value of the counter

- **Function description**
  - SF_CTU is an addition counter. The data type of preset value and count value is SAFEINT.
  - When the reset signal "RESET" is set to TRUE, the count value "CV" becomes 0, and the counter output "Q" becomes FALSE. When the value of "CV" is greater than or equal to the preset value "PV", the value of "Q" becomes TRUE.
  - An addition operation is triggered for "CV" when the input signal "CU" is at the rising edge.
  - When the value of "CV" exceeds the value of "PV", "CV" continues to perform addition operations at each rising edge of "CU" until it reaches the maximum value of 32767.
  - When "RESET" is TRUE, "CU" is ignored. "CV" does not perform an addition operation.

11.10.2.1.6 SF_CTUD

SF_CTUD is an addition/subtraction counter.

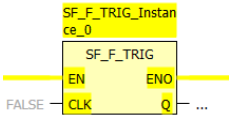
- **Instruction format**

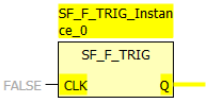
Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_CTUD	Addition/ subtraction counter	FB		

- **Related variables**

  Variables

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	CU	Addition counter input	BOOL	TRUE, FALSE	FALSE	Addition counter input
	CD	Subtraction counter input	BOOL	TRUE, FALSE	FALSE	Subtraction counter input
	RESET	Reset signal	BOOL	TRUE, FALSE	FALSE	TRUE: Resets "CV" to 0.
	LOAD	Load signal	BOOL	TRUE, FALSE	FALSE	TRUE: Loads "PV" into "CV".
	PV	Preset value	SAFEINT	0 to 32767	0	The positive count value of the addition counter and the default value of the subtraction counter.
Output	QU	Addition counter output	SAFEBOOL	TRUE, FALSE	FALSE	Addition counter output
	QD	Subtraction counter output	SAFEBOOL	TRUE, FALSE	FALSE	Subtraction counter output
	CV	Count value	SAFEINT	0 to 32767	0	The current value of the counter





- **Function description**
  - CTUD is a counter that performs addition and subtraction operations based on the input signals. It combines the functions of both the addition counter and the subtraction counter. The data type of preset value and count value is SAFEINT.
  - Addition counter function
    - When the reset signal "RESET" is set to TRUE, the count value "CV" becomes 0, and the addition counter output "QU" becomes FALSE. When the value of "CV" is greater than or equal to the preset value "PV", the value of "QU" becomes TRUE.
    - An addition operation is triggered for "CV" when the input signal "CU" is at the rising edge.
    - When the value of "CV" exceeds the value of "PV", "CV" continues to perform addition operations at each rising edge of "CU" until it reaches the maximum value of 32767.
  - Subtraction counter function
    - When the load signal "LOAD" is set to TRUE, the preset value "PV" is loaded into the count value "CV", and the subtraction counter output "QD" becomes FALSE. When the value of "CV" is less than or equal to 0, the value of "QD" becomes TRUE.
    - A subtraction operation is triggered for "CV" when the input signal "CD" is at the rising edge.
    - When the value of "CV" is less than or equal to 0, even if "CD" is at a rising edge, "CV" will not change.
  - Common functions of the addition/subtraction counter
    - When "LOAD" or "RESET" is TRUE, "CU" and "CD" are ignored, and "CV" does not perform addition or subtraction operations.
    - When "CU" and "CD" are both at the rising edge, "CV" does not change.
    - When both "RESET" and "LOAD" are TRUE, "RESET" takes priority, and the value of "CV" becomes 0.
    - When "RESET" is set to TRUE, the value of "CV" becomes 0, and the value of "QD" becomes TRUE.

- When "LOAD" is set to TRUE, the value of "CV" becomes equal to "PV", and the value of "QU" becomes TRUE.

11.10.2.1.7 SF_F_TRIG

SF_F_TRIG is a falling edge-triggered instruction.

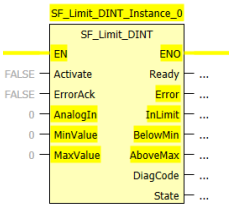
- **Instruction format**

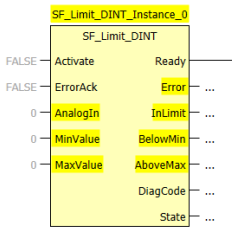
Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_F_TRIG	Falling edge triggered	FB		

- **Related variables**

  Variables

Input/Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	CLK	Input signal	SAFEBOOL	TRUE, FALSE	FALSE	Input signal
Output	Q	Output signal	SAFEBOOL	TRUE, FALSE	FALSE	Output signal





- **Function description**

  When the input signal "CLK" is at a falling edge (TRUE→FALSE), the output signal "Q" is set to TRUE for only one task cycle. In all other cases, the value of "Q" is FALSE.

11.10.2.1.8 SF_Limit_DINT

The SF_Limit_DINT instruction checks whether the input parameter AnalogIn (of SAFEDINT type) is within the range defined by the input parameters MinValue and MaxValue. If the value of AnalogIn is within the limits, the output parameter InLimit is set to TRUE. Otherwise, depending on the value of AnalogIn, the output parameter BelowMin or AboveMax is set to TRUE.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_Limit_DINT	Limit	FB		

- **Related variables**

  Variables

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	Activate	Activate instruction	BOOL	TRUE, FALSE	FALSE	Determines whether to activate the instruction. FALSE: Instruction is not activated. TRUE: Instruction is activated.
	ErrorAck	Fault acknowledgment	BOOL	TRUE, FALSE	FALSE	Acknowledges faults. When a fault occurs, ErrorAck must be changed from FALSE to TRUE; otherwise, the instruction will remain in a faulty status.
	AnalogIn	Input value	SAFEDINT	-2147483648 to 2147483647	0	The value for range check
	MinValue	Minimum value	SAFEDINT	-2147483648 to 2147483647	0	Minimum value
	MaxValue	Maximum value	SAFEDINT	-2147483648 to 2147483647	0	Maximum value
Output	Ready	Ready status	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is in ready status.
	Error	Faulty status	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is faulty.
	InLimit	Input range flag	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether the input value is within the set range.
	BelowMin	Input below the lower limit	SAFEBOOL	TRUE, FALSE	FALSE	The value of "AnalogIn" is less than the set minimum value.
	AboveMax	Input exceeding the upper limit	SAFEBOOL	TRUE, FALSE	FALSE	The value of "AnalogIn" exceeds the set maximum value.
	DiagCode	Instruction information code	16#WORD	Follows data type	0	Displays fault codes when an instruction fault occurs, to indicate the cause of the fault.

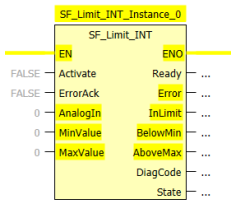
Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	State	Instruction operation status	WORD	Follows data type	0	Indicates the execution status of the instruction. The following statuses are available for the current instruction: 1: Run 2: Stop 3: Safe 4: Error 5: Reset

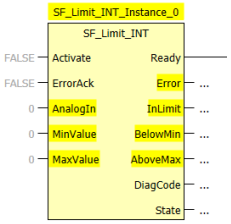
- **Function description**
  - The SF_Limit_DINT instruction checks whether the input parameter AnalogIn is within the range defined by the input parameters MinValue and MaxValue. If the value of AnalogIn is within the limits, the output parameter InLimit is set to TRUE. Otherwise, depending on the value of AnalogIn, the output parameter BelowMin or AboveMax is set to TRUE.
  - The instruction information code (DiagCode) is used to display fault codes to indicate the causes.

DiagCode (Instruction Information Code)	Description
0x4090	The input parameter MinValue is greater than MaxValue.

  - Status information (State) is used to indicate the execution status of the instruction. In the current instruction, the statuses are: 1 (Run), 2 (Stop), 3 (Safe), 4 (Error), and 5 (Reset).

State (Status Information)	Description
1 (Run)	If AnalogIn is greater than or equal to MinValue and less than or equal to MaxValue, the instruction enters the "Run" status. Output values are as follows: Error = 0; InLimit = 1; BelowMin = 0; AboveMax = 0
2 (Stop)	In the "Stop" status, the instruction is not executed. Output values are as follows: Error = 0, InLimit = 0, BelowMin = 0, AboveMax = 0.
3 (Safe)	In the "Safe" status, AnalogIn is less than MinValue or greater than MaxValue. Output values are as follows: Error = 0, InLimit = 0, BelowMin = (less than MinValue), AboveMax = (greater than MaxValue).
4 (Error)	In the "Error" status, a fault is detected during instruction execution. Output values are as follows: Error = 1, InLimit = 0, BelowMin = 0, AboveMax = 0





State (Status Information)	Description
5 (Reset)	In the "Reset" status, no further faults remain and "ErrorAck" changes from FALSE to TRUE. Output values are as follows: Error = 0, InLimit = 0, BelowMin = 0, AboveMax = 0.

- **Note**
  : If the instruction execution fails, manual confirmation is required to restart the execution; if no manual confirmation is performed, the instruction status remains 4 (Error) and will not switch to 2 (Stop).

11.10.2.1.9 SF_Limit_INT

The SF_Limit_INT instruction checks whether the input parameter AnalogIn (of SAFEINT type) is within the range defined by the input parameters MinValue and MaxValue. If the value of AnalogIn is within the limits, the output parameter InLimit is set to TRUE. Otherwise, depending on the value of AnalogIn, the output parameter BelowMin or AboveMax is set to TRUE.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_Limit_INT	Limit	FB		

- **Related variables**

Variables

Input / Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	Activate	Activate instruction	BOOL	TRUE, FALSE	FALSE	Determines whether to activate the instruction. FALSE: Instruction is not activated. TRUE: Instruction is activated.
	ErrorAck	Fault acknowledgment	BOOL	TRUE, FALSE	FALSE	Acknowledges faults. When a fault occurs, ErrorAck must be changed from FALSE to TRUE; otherwise, the instruction will remain in a faulty status.
	AnalogIn	Input value	SAFEINT	-32768 to 32767	0	The value for range check
	MinValue	Minimum value	SAFEINT	-32768 to 32767	0	Minimum value

Input / Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	MaxValue	Maximum value	SAFEINT	-32768 to 32767	0	Maximum value

11.10.2.1.10 SF_R_TRIG

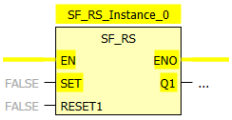
SF_R_TRIG is a rising edge-triggered instruction.

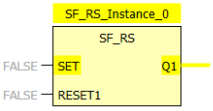
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_R_TRIG	Rising edge-triggered	FB		

- **Related variables**

  Variables





Input/Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	CLK	Input signal	SAFEBOOL	TRUE, FALSE	FALSE	Input signal
Output	Q	Output signal	SAFEBOOL	TRUE, FALSE	FALSE	Output signal

- **Function description**
  When the input signal "CLK" is at a rising edge (FALSE→TRUE), the output signal "Q" is set to TRUE for only one task cycle. In all other cases, the value of "Q" is FALSE.

11.10.2.1.11 SF_RS

SF_RS is a reset-priority self-holding instruction.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_RS	Prioritize the reset value	FB		

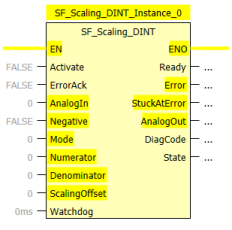
- **Related variables**

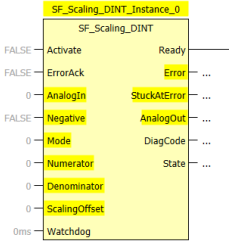
  Variables

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	SET	Set a bit	SAFEBOOL	TRUE, FALSE	FALSE	Set input
	RESET1	Reset a bit	BOOL	TRUE, FALSE	FALSE	Reset input (prioritized)
Output	Q1	Self-holding	SAFEBOOL	TRUE, FALSE	FALSE	Self-holding output

- **Function description**

  SF_RS is a reset-priority self-holding instruction. The input/output relationship is as follows.





"SET" Value	"RESET1" Value	"Q1" Value
TRUE	TRUE	FALSE
TRUE	FALSE	TRUE
FALSE	TRUE	FALSE
FALSE	FALSE	Remain

  - As long as the value of "RESET1" is TRUE, the value of "Q1" is FALSE.
  - When the value of "RESET1" is FALSE and the value of "SET" is TRUE, the value of "Q1" is TRUE.

11.10.2.1.12 SF_Scaling_DINT

The SF_Scaling_DINT function performs the calculation "AnalogIn * Numerator / Denominator + ScallingOffset" on the input value AnalogIn (of SAFEINTDINT type), and rounds the result according to the Mode (rounding method), outputting the final calculated value through AnalogOut.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_Scaling_DINT	Proportional scaling	FB		

- **Related variables**

  Variables

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	Activate	Activate instruction	BOOL	TRUE, FALSE	FALSE	Determines whether to activate the instruction. FALSE: Instruction is not activated. TRUE: Instruction is activated.
	ErrorAck	Fault acknowledgment	BOOL	TRUE, FALSE	FALSE	Acknowledges faults. When a fault occurs, ErrorAck must be changed from FALSE to TRUE; otherwise, the instruction will remain in a faulty status.
	AnalogIn	Value to be scaled	SAFEDINT	-2147483648 to 2147483647	0	The value that needs to be scaled proportionally
	Negative	Inversion flag	SAFEBOOL	TRUE, FALSE	FALSE	Inversion flag. FALSE: The input value is not inverted. TRUE: The input value is inverted first and then scaled proportionally.
	Mode	Rounding method	SAFEDINT	0, 1, 2	0	Rounding method 0: Round down 1: Round up 2: Round to nearest
	Numerator	Numerator of the scaling ratio	SAFEDINT	-2147483648 to 2147483647	1	Numerator of the scaling ratio
	Denominator	Denominator of the scaling ratio	SAFEDINT	-2147483648 to 2147483647	1	Denominator of the scaling ratio
	ScalingOffset	Scaling offset	SAFEDINT	-2147483648 to 2147483647	0	Scaling offset

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	Watchdog	Detection time	TIME	Follows data type	T#0ms	Detection time. Used to detect whether the input value has changed within the time range.
Output	Ready	Ready status	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is in ready status.
	Error	Faulty status	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is faulty.
	StuckAtError	Input stable flag	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether the input value has remained unchanged within the specified time range.
	AnalogOut	Output value	SAFEDINT	-2147483648 to 2147483647	0	Output value after scaling.
	DiagCode	Instruction information code	16#WORD	Follows data type	0	Displays fault codes when an instruction fault occurs, to indicate the cause of the fault.
	State	Instruction operation status	WORD	Follows data type	0	Indicates the execution status of the instruction. The following statuses are available for the current instruction: 1: Run 2: Stop 4: Error 5: Reset

- **Function description**
  - The SF_Scaling_DINT function performs the calculation "AnalogIn * Numerator / Denominator + ScallingOffset" on the input value AnalogIn, and rounds the result according to the Mode (rounding method), outputting the final calculated value through AnalogOut. The input parameter "Negative" can be used to invert "AnalogIn" before scaling.
  - The input parameter "Mode" can determine the rounding method after scaling. If set to a value greater than 2, it will take effect as 0.

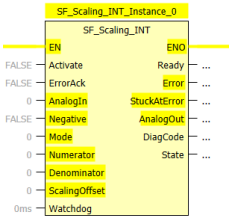
Mode (Rounding Mode)	Rounding Method
0: Round up	Returns the closest integer that is greater than or equal to the input. For example, returns 4 for 3.4 and -3 for -3.4.

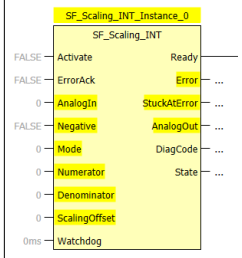
Mode (Rounding Mode)	Rounding Method
1: Round down	Returns the closest integer that is less than or equal to the input. For example, returns 3 for 3.4 and -4 for -3.4.
2: Round to nearest	Returns the closest integer. For example, returns 3 for 3.4, 4 for 3.5, -3 for -3.4, and -4 for -3.5.

◦ The instruction information code (DiagCode) is used to display fault codes to indicate the causes.

DiagCode (Instruction Information Code)	Description
0xC0B1	The output result exceeds the maximum value of the DINT type.
0xC0B2	The output result is less than the minimum value of the DINT type.

◦ Status information (State) is used to indicate the execution status of the instruction. In the current instruction, the statuses are: 1 (Run), 2 (Stop), 4 (Error), and 5 (Reset).





State (Status Information)	Description
1 (Run)	In the "Run" status, the scaling result is output to "AnalogOut". Output values are as follows: Error = 0; AnalogOut = Scaling result; StuckAtError = Detected StuckAtError
2 (Stop)	In the "Stop" status, the instruction is not executed. Output values are as follows: Error = 0; AnalogOut = 0; StuckAtError = 0
4 (Error)	In the "Error" status, a fault is detected during instruction execution. Output values are as follows: Error = 1; AnalogOut = 0; StuckAtError = 0
5 (Reset)	In the "Reset" status, no further faults remain and "ErrorAck" changes from FALSE to TRUE. Output values are as follows: Error = 0; AnalogOut = 0; StuckAtError = 0

- **Precautions**
  - ◦ If the instruction execution fails, manual confirmation is required to restart the execution; if no manual confirmation is performed, the instruction status remains 4 (Error) and will not switch to 2 (Stop).
  - ◦ If the denominator of the scaling ratio is bound to a variable or is an immediate value, the value will be automatically corrected to 1 when it is 0, but the corrected value will not be visible in the iFA interface.

11.10.2.1.13 SF_Scaling_INT

The SF_Scaling_INT function performs the calculation "AnalogIn * Numerator / Denominator + ScallingOffset" on the input value AnalogIn (of SAFEINT type), and rounds the result according to the Mode (rounding method), outputting the final calculated value through AnalogOut.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_Scaling_INT	Proportional scaling	FB

	ScalingOffset	Scaling offset	SAFEINT	-32768 to 32767	0	Scaling offset
	Watchdog	Detection time	TIME	Follows data type	T#0ms	Detection time. Used to detect whether the input value has changed within the time range.
Output	Ready	Ready status	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is in ready status.
	Error	Faulty status	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is faulty.
	StuckAtError	Input stable flag	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether the input value has remained unchanged within the specified time range.
	AnalogOut	Output value	SAFEINT	-32768 to 32767	0	Output value after scaling.
	DiagCode	Instruction information code	16#WORD	Follows data type	0	Displays fault codes when an instruction fault occurs, to indicate the cause of the fault.
	State	Instruction operation status	WORD	Follows data type	0	Indicates the execution status of the instruction. The following statuses are available for the current instruction: 1: Run 2: Stop 4: Error 5: Reset

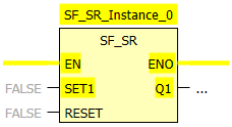
- **Function description**
  - The SF_Scaling_INT function performs the calculation "AnalogIn * Numerator / Denominator + ScallingOffset" on the input value AnalogIn, and rounds the result according to the Mode (rounding method), outputting the final calculated value through AnalogOut. The input parameter "Negative" can be used to invert "AnalogIn" before scaling.
  - The input parameter "Mode" can determine the rounding method after scaling. If set to a value greater than 2, it will take effect as 0.

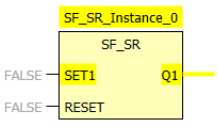
Mode (Rounding Mode)	Rounding Method
0: Round up	Returns the closest integer that is greater than or equal to the input. For example, returns 4 for 3.4 and -3 for -3.4.
1: Round down	Returns the closest integer that is less than or equal to the input. For example, returns 3 for 3.4 and -4 for -3.4.
2: Round to nearest	Returns the closest integer. For example, returns 3 for 3.4, 4 for 3.5, -3 for -3.4, and -4 for -3.5.

◦ The instruction information code (DiagCode) is used to display fault codes to indicate the causes.

DiagCode (Instruction Information Code)	Description
0xC0B1	Output result exceeds the maximum value of the INT type.
0xC0B2	Output result is less than the minimum value of the INT type.

◦ Status information (State) is used to indicate the execution status of the instruction. In the current instruction, the statuses are: 1 (Run), 2 (Stop), 4 (Error), and 5 (Reset).





State (Status Information)	Description
1 (Run)	In the "Run" status, the scaling result is output to "AnalogOut". Output values are as follows: Error = 0; AnalogOut = Scaling result; StuckAtError = Detected StuckAtError
2 (Stop)	In the "Stop" status, the instruction is not executed. Output values are as follows: Error = 0; AnalogOut = 0; StuckAtError = 0
4 (Error)	In the "Error" status, a fault is detected during instruction execution. Output values are as follows: Error = 1; AnalogOut = 0; StuckAtError = 0
5 (Reset)	In the "Reset" status, no further faults remain and "ErrorAck" changes from FALSE to TRUE. Output values are as follows: Error = 0; AnalogOut = 0; StuckAtError = 0

- **Precautions**
  - ◦ If the instruction execution fails, manual confirmation is required to restart the execution; if no manual confirmation is performed, the instruction status remains 4 (Error) and will not switch to 2 (Stop).
  - ◦ If the denominator of the scaling ratio is bound to a variable or is an immediate value, the value will be automatically corrected to 1 when it is 0, but the corrected value will not be visible in the iFA interface.

11.10.2.1.14 SF_SR

SF_SR is a set-priority self-holding instruction.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_SR	Prioritize the set value	FB		

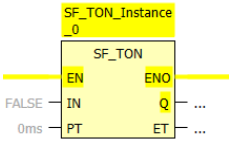
- **Related variables**

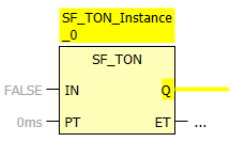
  Variables

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	SET1	Set a bit	SAFEBOOL	TRUE, FALSE	FALSE	Set input (prioritized)
	RESET	Reset a bit	BOOL	TRUE, FALSE	FALSE	Reset output
Output	Q1	Self-holding	SAFEBOOL	TRUE, FALSE	FALSE	Self-holding output

- **Function description**

  SF_SR is a set-priority self-holding instruction. The input/output relationship is as follows.





"SET1" Value	"RESET" Value	"Q1" Value
TRUE	TRUE	TRUE
TRUE	FALSE	TRUE
FALSE	TRUE	FALSE
FALSE	FALSE	Self-holding

  - As long as the value of "SET1" is "TRUE", the value of "Q1" is "TRUE".
  - When the value of "SET1" is "FALSE" and the value of "RESET" is "TRUE", the value of "Q1" is "FALSE".

11.10.2.1.15 SF_TON

SF_TON is a timer that outputs TRUE after a set time since startup.

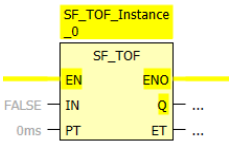
- **Instruction format**

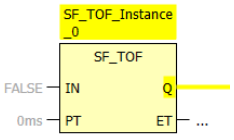
Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_TON	ON-delay timer	FB		

- **Related variables**

  Variables

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	IN	Timer input	BOOL	TRUE, FALSE	FALSE	TRUE: Starts timer. FALSE: Resets timer.





Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	PT	Set time	TIME	Follows data type	TIME#0ms	The time from when the timer starts to when "Q" becomes TRUE
Output	Q	Timer output	SAFEBOOL	TRUE, FALSE	FALSE	TRUE: "ET" reaches "PT". FALSE: "ET" is less than "PT" when "IN" is TRUE or after the timer starts.
	ET	Elapsed time	TIME	Follows data type	TIME#0ms	Elapsed time after timer starts

- **Function description**
  - SF_TON is a timer that outputs TRUE after a set time since startup. The set time unit is ms.
  - When the timer input "IN" changes from FALSE to TRUE, the timer starts and "ET" continuously increases until it reaches the preset time "PT".
  - When "ET" reaches the set time "PT", the timer output "Q" becomes TRUE, and at this point, "ET" stops increasing.
  - When "IN" becomes FALSE, the timer resets. "ET" becomes 0, and "Q" becomes FALSE. Even before "ET" reaches "PT", if "IN" becomes FALSE after the timer starts, the timer resets.

11.10.2.1.16 SF_TOF

SF_TOF is a timer that outputs FALSE after a set time since startup.

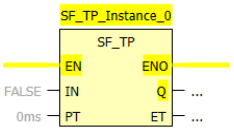
- **Instruction format**

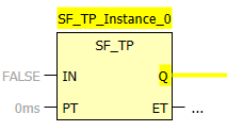
Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_TOF	OFF-delay timer	FB		

- **Related variables**

  Variables

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	IN	Timer input	BOOL	TRUE, FALSE	FALSE	TRUE: Resets timer. FALSE: Starts timer.
	PT	Set time	TIME	Follows data type	TIME#0ms	The time from when the timer starts to when "Q" becomes FALSE





Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Output	Q	Timer output	SAFEBOOL	TRUE, FALSE	FALSE	TRUE: "ET" is less than "PT" when "IN" is TRUE or after the timer starts. FALSE: "ET" reaches "PT".
	ET	Elapsed time	TIME	Follows data type	TIME#0ms	Elapsed time after timer starts

- **Function description**
  - SF_TOF is a timer that outputs FALSE after a set time since startup. The set time unit is ms.
  - When the timer input "IN" changes from TRUE to FALSE, the timer starts and "ET" continuously increases until it reaches the preset time "PT".
  - When "ET" reaches "PT", the timer output "Q" becomes FALSE. At this point, "ET" stops increasing.
  - When "IN" becomes TRUE, the timer resets. "ET" becomes 0, and "Q" becomes TRUE. Even before "ET" reaches "PT", if "IN" becomes TRUE after the timer starts, the timer resets.

11.10.2.1.17 SF_TP

SF_TP is a timer that outputs TRUE only for a set time after startup.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_TP	Time pulse	FB		

- **Related variables**

  Variables

Input / Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	IN	Timer input	BOOL	TRUE, FALSE	FALSE	TRUE: Starts timer. FALSE: Resets timer.
	PT	Set time	TIME	Follows data type	TIME#0ms	The time "Q" remains TRUE
Output	Q	Timer output	SAFEBOOL	TRUE, FALSE	FALSE	TRUE: "ET" is less than "PT" when "IN" is TRUE or after the timer starts. FALSE: "ET" reaches "PT".
	ET	Elapsed time	TIME	Follows data type	TIME#0ms	Elapsed time after timer starts

- **Function description**
  - SF_TP is a timer that outputs TRUE only for a set time after startup. The set time unit is ms.
  - When the timer input "IN" changes from FALSE to TRUE, the timer starts and timer output "Q" becomes TRUE. Elapsed time "ET" continuously increases until it reaches the set time "PT".
  - When "ET" reaches "PT", the timer output "Q" becomes FALSE. At this point, "ET" stops increasing.
  - When "IN" is FALSE, the timer resets and "ET" becomes 0. However, after the timer starts, if "IN" becomes FALSE before "ET" reaches "PT", the timer does not reset.

11.10.2.2 Safety Function Blocks

11.10.2.2.1 Instruction List

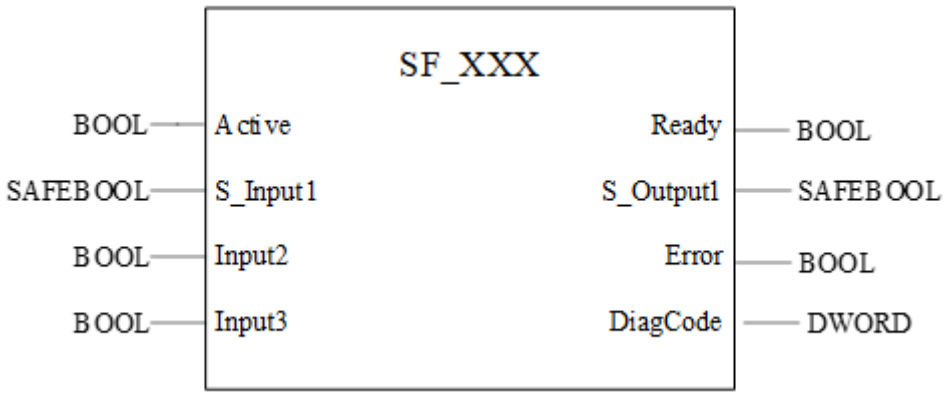
Instruction	FB/FC	Function	Library	Applicable Library Version
11.10.2.2.3 SF_Antivalent	FB	Inequivalent input	SafetyInstructions	Applicable to library version 1.0.0.0/1.1.0.0
11.10.2.2.4 SF_CamMonitoring	FB	Cam monitoring		
11.10.2.2.5 SF_CamshaftMonitor	FB	Cam shaft monitoring function		
11.10.2.2.6 SF_CycleControl	FB	Cycle control		
11.10.2.2.7 SF_EDM	FB	External monitoring		
11.10.2.2.8 SF_EmergencyStop	FB	Emergency stop.		
11.10.2.2.9 SF_EnableSwitch	FB	Enable switch		
11.10.2.2.10 SF_Equivalent	FB	Equivalent input		
11.10.2.2.11 SF_ESPE	FB	Electrically sensitive protective equipment		
11.10.2.2.12 SF_FootSwitch	FB	Foot switch		
11.10.2.2.13 SF_Guard	FB	Monitoring of safety-related protective devices		
11.10.2.2.14 SF_GuardLocking	FB	Safety door lock with interlock device		
11.10.2.2.15 SF_ModeSelector	FB	Mode selector		
11.10.2.2.16 SF_MutingPar	FB	Perform parallel muting with four muting sensors.		
11.10.2.2.17 SF_MutingPar_2Sensor	FB	Perform parallel muting with two muting sensors		
11.10.2.2.18 SF_MutingSeq	FB	Perform sequential muting with four muting sensors		

Instruction	FB/FC	Function	Library	Applicable Library Version
11.10.2.2.19 SF_OutControl	FB	Output control		
11.10.2.2.20 SF_Override	FB	Override muting function		
11.10.2.2.21 SF_PressControl	FB	Press control		
11.10.2.2.22 SF_PSE	FB	Pressure-sensitive equipment		
11.10.2.2.23 SF_ResetButton	FB	Reset button		
11.10.2.2.24 SF_SafetyRequest	FB	Safety request		
11.10.2.2.25 SF_ManualAck	FB	Safety confirmation		
11.10.2.2.26 SF_TempAlarm	FB	Temperature alarm		
11.10.2.2.27 SF_DataLog	FB	Safety logging function		
11.10.2.2.28 SF_TestableSafetySensor	FB	Testable safety sensors		
11.10.2.2.29 SF_TwoHandControlTypeII	FB	Type II two-hand control		
11.10.2.2.30 SF_TwoHandControlTypeIII	FB	Type III two-hand control		
11.10.2.2.31 SF_SafetyConnStatus	FB	Get safety C2C (CIP Safety) connection status		
11.10.2.2.32 SF_SafetyTaskInfo	FB	Get safety task information		
11.10.2.2.33 SF_GetSafetySignature	FB	Get safety signature		
11.10.2.2.34 SF_GetSystemMode	FB	Get safety PLC status		
11.10.2.2.35 SF_GetSafetyConfirmInfo	FB	Get safety confirmation information (including safety signature, safety confirmation time)		Applicable to library version 1.1.0.0
11.10.2.2.36 SF_GetCouplerState	FB	Get coupler status (EIP connection)		
11.10.2.2.37 SF_GetGlBusState	FB	Get local bus connection status (EIP device)		
11.10.2.2.38 SF_GetEtherNetIpStateCode	FB	Get EtherNet/IP (Scanner) connection status		
11.10.2.2.39 SF_GetFSoeStateCode	FB	Get FSoE connection status		
11.10.2.2.40 SF_GetCIPSafetyStateCode	FB	Get CIP Safety connection status code		

11.10.2.2.2 General Description of Safety Function Blocks

11.10.2.2.2.1 General Input Variables of Safety Function Blocks

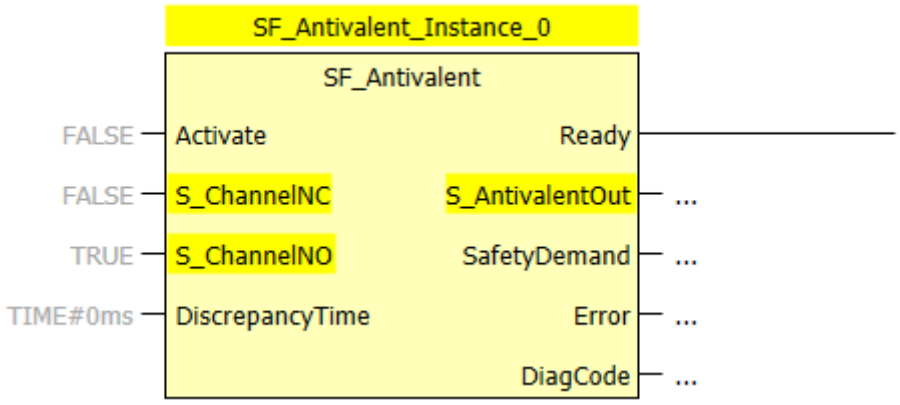
Input Parameter	Data Type	Description
Activate	BOOL	The "Activate" parameter is a Boolean (BOOL) variable or constant used to control the activation status of the function block (FB), with an initial value of FALSE. This parameter must be connected to a variable reflecting the status (activated/deactivated) of the associated safety device. Dynamic association with the device status prevents irrelevant diagnostic information when the device is disabled. When the parameter value is FALSE, all output variables of the function block are forced to reset to their initial values, thereby achieving output isolation in a safety status. If no physical device is connected in the system, a constant TRUE signal must be assigned to this parameter to ensure the function block remains enabled in scenarios without device connection.
S_StartReset	SAFEBOOL	FALSE (initial value): Manual reset is required when the programmable electronic system (PES) is started (either warm start or cold start). TRUE: Automatic reset is performed when the PES is started (either warm start or cold start). This function may only be enabled when it is ensured that no hazards will occur during PES startup. Therefore, if the automatic circuit reset feature of the function block is to be used, other system or application measures must be implemented to prevent accidental (or unintended) startup.
S_AutoReset	SAFEBOOL	The reset mode is determined by a variable or constant. When the initial value is set to FALSE, manual reset is required after the emergency stop button is released; if set to TRUE, automatic reset is triggered after the emergency stop button is released. Note that the automatic reset function shall only be activated on the premise that releasing the emergency stop button will not cause unintended device restart. Therefore, when using the automatic circuit reset feature of the function block, other system-level or application-level protective measures must be implemented to eliminate the risk of unintended (or unplanned) device restart.



Input Parameter	Data Type	Description
Reset	SAFEBOOL	The Reset parameter is controlled by a variable, with an initial value of FALSE. Depending on specific functional requirements, this parameter input can be used for various purposes, such as resetting the state machine and associated fault/status information (indicated by DiagCode), provided the fault cause has been eliminated. This type of reset behavior is designed as a confirmation of fault troubleshooting. The interlock can be restarted by manual reset (refer to EN 954-1 standard), which is considered a functional reset. Additional reset functions can also be implemented for specific function blocks. Note that this function responds only to signal transitions from FALSE to TRUE. A sustained TRUE signal will not initiate any operation and may be considered a fault in certain function blocks.

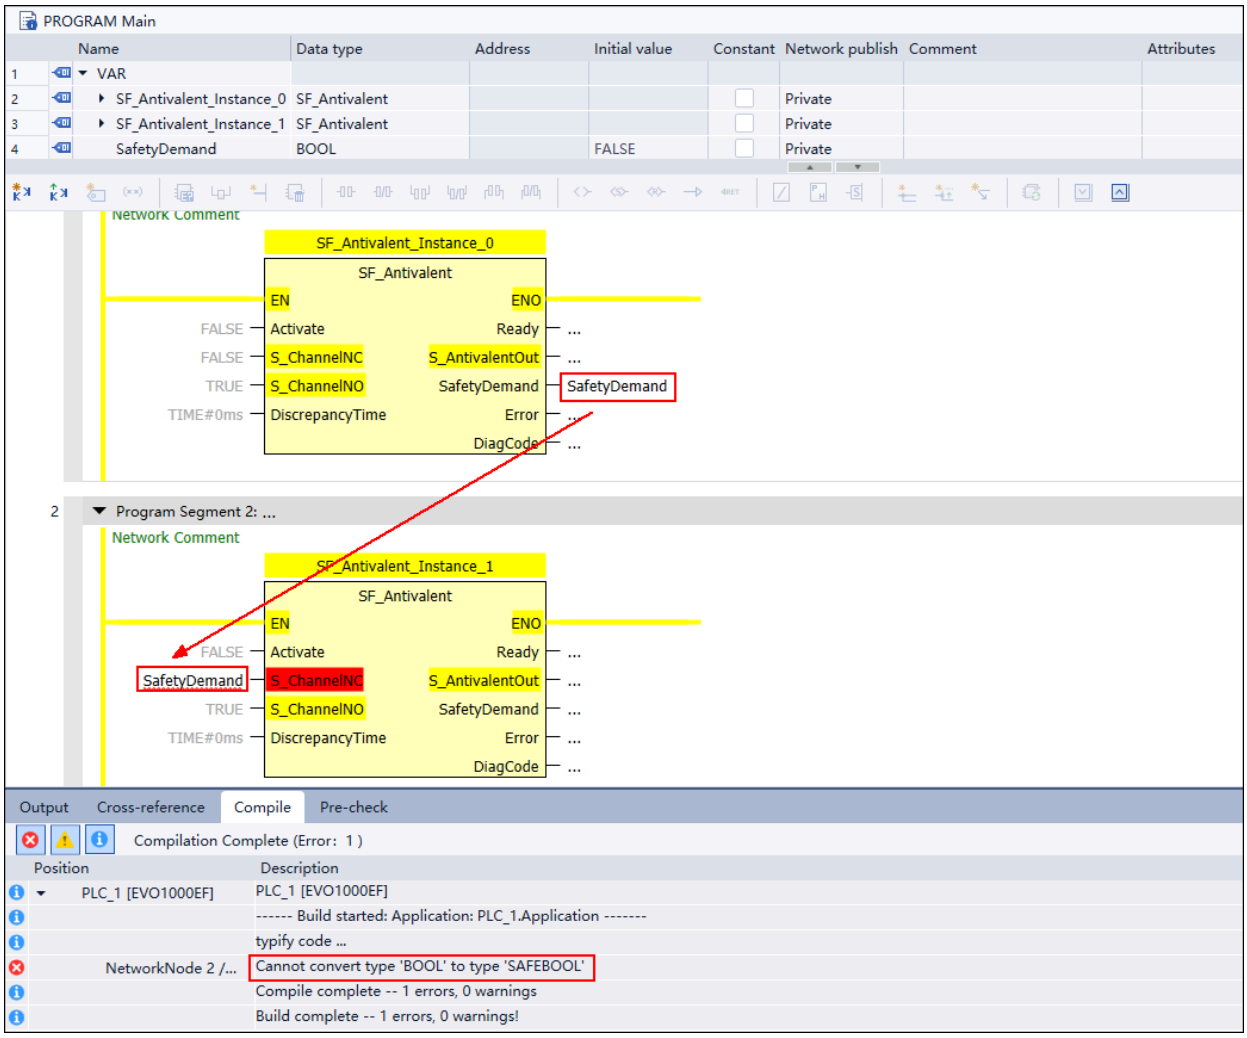
11.10.2.2.2.2 General Output Variables of Safety Function Blocks

Output Parameter	Data Type	Description
Ready	BOOL	When the input is TRUE, it indicates that the function block is activated and the output result is valid (equivalent to the "POWER" indicator logic of a safety relay). Under this condition, the function block enters normal operational mode, with its internal logic executed in compliance with the predefined Safety Integrity Level (SIL). The output signals shall satisfy the fail-safe principles specified in IEC 61508/ISO 13849 via a dual-channel validation scheme. When the input is FALSE, the function block is not activated, program logic execution is suspended, and all safety outputs are forced into a predefined fail-safety status (such as degraded mode or shutdown lock), preventing uncontrolled operation.
SafetyDemand	BOOL	This parameter indicates that the function block is activated and the primary safety function has been requested (e.g., associated with safety function logic). This signal only reflects the basic safety requests and does not include the results of other safety-related input parameters (such as SafetyActive and EDM). When the output is TRUE, it indicates that the safety circuit fails to form a closed-loop logic, forcing the associated safety outputs into a predefined safety status (such as power-off lock or torque limitation mode), with no fault record generated at this time. When the output is FALSE, it indicates no safety request is present, and the safety outputs can return to normal operational status.



Output Parameter	Data Type	Description
ResetRequest	BOOL	This output prompts the operator to press the reset button to proceed with subsequent operations. When the output is TRUE, it indicates a reset request is present. When the output is FALSE, it indicates no reset request is present.
Error	BOOL	This output is a fault flag (equivalent to the "K1/K2" fault indicator on a safety relay) used to indicate the operational status of the function block. When the flag is TRUE, it indicates a fault has been detected and the function block has entered a faulty status. The corresponding fault code will be mapped in real time via the DiagCode output interface (e.g., standard fault codes E01~E99). When the flag is FALSE, it indicates no fault is present, and the function block is in normal operational or standby status, with DiagCode updated synchronously to the corresponding status code at this time.
DiagCode	WORD	DiagCode fully maps all statuses of the function block (activated, inactivated, faulty). At runtime, the system reflects only a single valid code at any given moment; if multiple faults occur, the DiagCode output will prioritize displaying the first detected fault (following the fault priority mechanism of ISO 13849-1).

11.10.2.2.2.3 General Representation of Safety Function Blocks



The SF_XXX function block consists of a function name, input parameters, and output parameters. Different function blocks have different names, as well as different input and output parameters. Based on engineering requirements, users shall select the appropriate safety function blocks compliant with relevant standards.

The input and output parameters of safety function blocks support the simultaneous use of safety-related types (such as SAFEBOOL) and standard types (such as BOOL), which are clearly distinguished by whether the parameter name includes the "S_" prefix. For example, the SF_Antivalent function block is displayed entirely in yellow in the programming interface; if its input and output parameters include the "S_" prefix, they are also highlighted in yellow, contrasting with standard type parameters with no prefix.

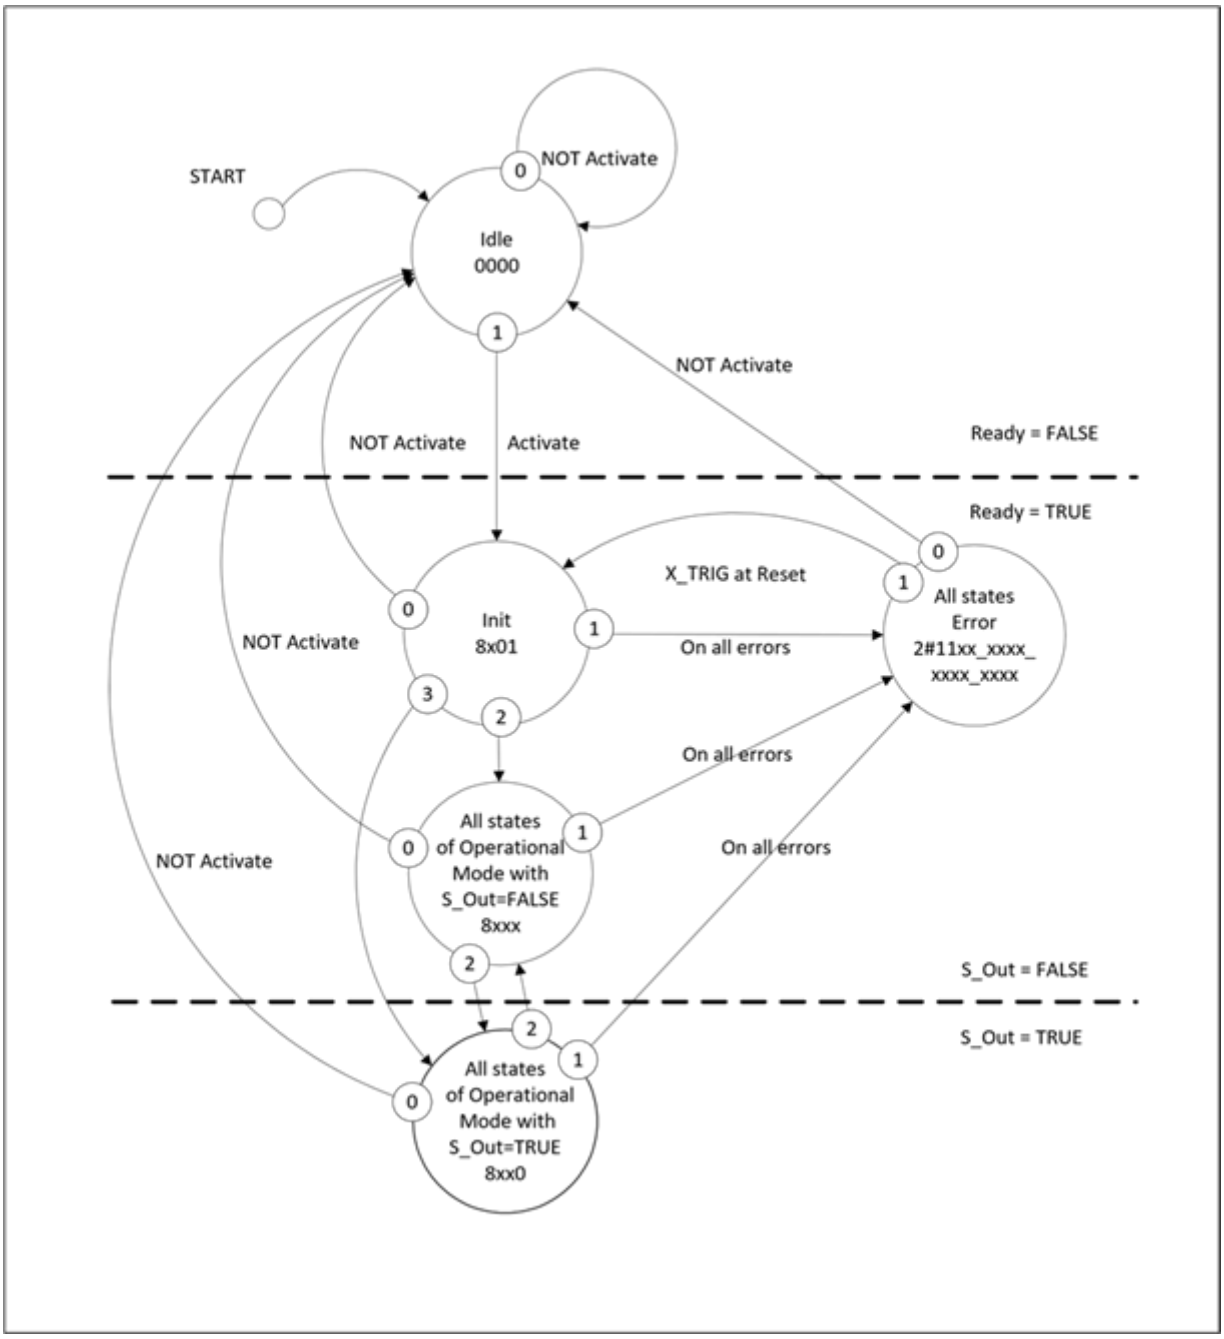
CAUTION

Although function blocks allow coexistence of safety-related parameters and standard parameters, a standard output of a function block cannot be directly connected to a safety input of another safety function block. If such an operation is attempted during programming, the compiler will report a fault, indicating that the operand 'SafetyDemand' expects a 'SAFEBOOL' input, and is unable to convert 'BOOL' to 'SAFEBOOL', as shown in the figure below.

11.10.2.2.2.4 Diagnostic Codes of Safety Function Blocks

A function block provides detailed diagnostic information regarding faults and statuses, including information about the conditions for status transition, and the output parameter values corresponding to each status.

Information Code	Description
0000(HEX)	The function block is not activated. This status code corresponds to the idle status. Taking a general-purpose function block as an example, its input/output (I/O) configuration can be set as: Activate = FALSE S_Input1 = FALSE or TRUE Input2 = FALSE Input3 = FALSE Ready = FALSE S_Output1 = FALSE Error = FALSE
8000(HEX)	When the function block is activated with no fault or condition triggering a safety output degradation, the system is in the default operational status. In this status, the safety output S_Output1 remains TRUE during normal operation. Taking a general-purpose function block as an example, its input/output (I/O) configuration can be set as: Activate = TRUE S_Input1 = TRUE Input2 = TRUE Input3 = TRUE Ready = TRUE S_Output1 = TRUE Error = FALSE



Information Code	Description
8401(HEX)	When the function block detects the activation signal and completes activation, but the safety output S_Out is still forced to FALSE, this status code indicates the system is in the initialization status of the operational mode. Taking a general-purpose safety function block as an example, its input/output (I/O) configuration can be set as: Activate = TRUE S_Input1 = TRUE Input2 = TRUE Input3 = TRUE Ready = TRUE S_Output1 = TRUE Error = FALSE

11.10.2.2.2.5 General Status Transition Diagram of Safety Function Blocks

The status transition diagram shows the conditions and corresponding diagnostic codes for the functional block as it transitions between different statuses.

Three areas in the diagram below: the top area represents the functional block in an inactivated status, the middle area represents the functional block in an activated status, and the bottom area represents the functional block in a normal status. The first horizontal line represents the transition from the inactivated status to the activated status, and the second horizontal line represents the transition from the non-safety status to the safety status. The priority of parallel transition conditions are indicated by numbers, with smaller numbers indicating higher priority. The status bubbles contain the status name and the hexadecimal

diagnostic code (DiagCode).

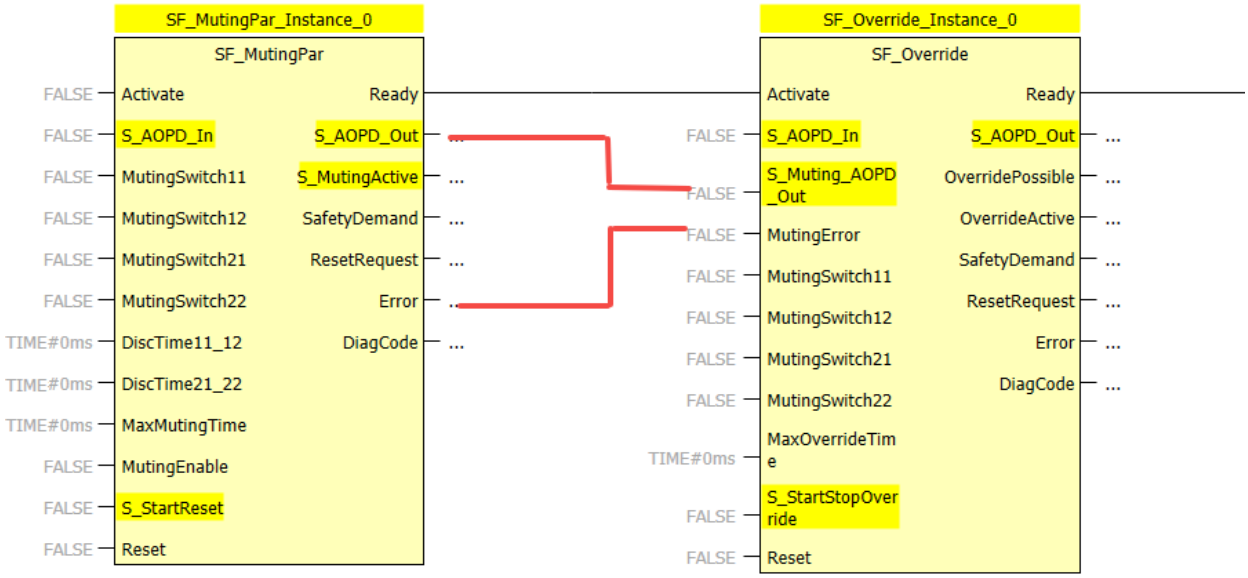
This diagram is referenced from the PLCopen specification, and the copyright belongs to the PLCopen organization.

11.10.2.2.2.6 Precautions of Safety Function Blocks

For safety function blocks, multiple safety function blocks are typically combined according to operating conditions. The following function blocks must not be used alone; they must be used together with other function blocks to accomplish a specific function.

- SF_Override: Used to override muting functions. The override function for manual operation may be required to remove obstructions generated during the muting process from the safety area. If the override function is activated, stop requests issued by safety devices will not take effect. The SF_Override function block can only be used in conjunction with muting function blocks (SF_MutingXXX).

  In the application, the muting function block must be processed first, followed by the override function block.



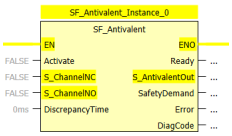
> **CAUTION**
>
> The output faults and DiagCode from the connected muting function block will not be transmitted to the output faults and DiagCode of the SF_Override function block.

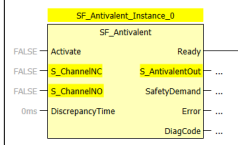
It may be required to release the safety zone lockout generated during the muting process via a manually operated override muting function. When the bypass is activated, stop requests from safety devices will be invalid.

The SF_Override function block must be used in conjunction with a muting function block. For example, it can be used in combination with an SF_MutingPar function block, whose safety output parameters serve as the safety input for the SF_Override function block.
In the application, the muting function block must be executed first, followed by the override function block.

> **CAUTION**
>
> The Error and DiagCode outputs from the preceding muting function block will not be passed to the corresponding output terminals of the SF_Override function block.

The following figure shows the combination of the SF_Override function block with the SF_MutingXXX function block in the programming interface.





- SF_PressControl: This function block provides three modes for press control and is used with the function blocks "SF_ModeSelector" and "SF_CamMonitor". This function block implements the single stroke function in manual and setting modes. Only one of the three modes can be selected through the function block "SF_ModeSelector".

11.10.2.2.3 SF_Antivalent

SF_Antivalent monitors the discrepancy time between two inequivalent safety input values.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_Antivalent	Inequivalent input	FB		

- **Related variables**

  Variables

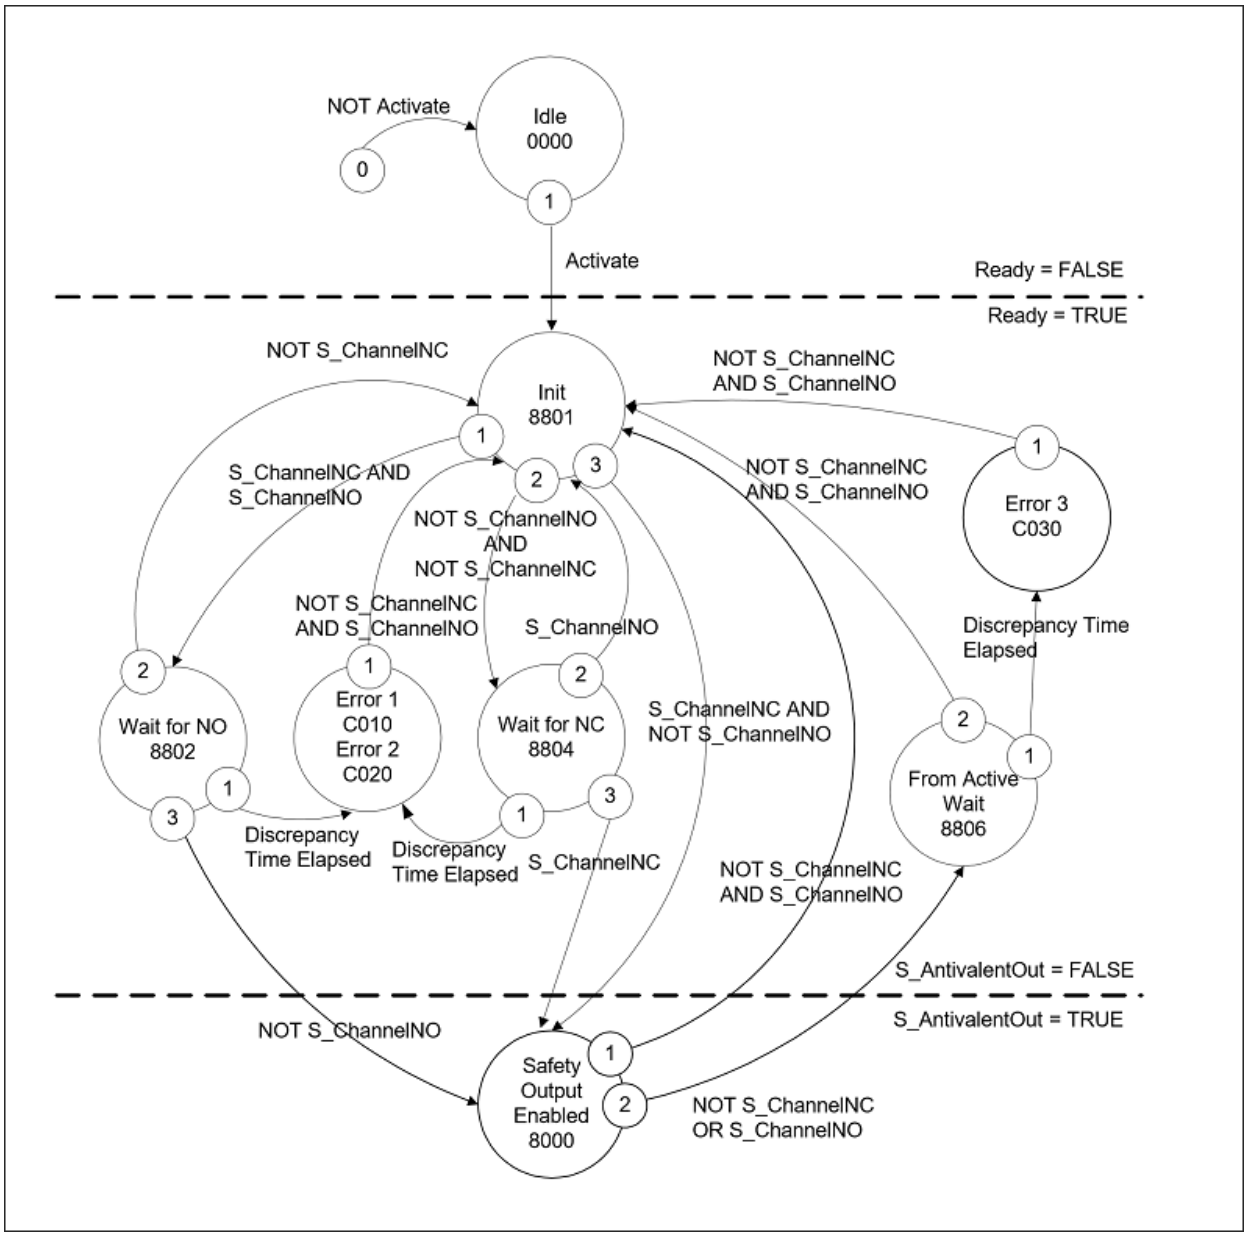
Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
Input	Activate	BOOL	TRUE, FALSE	FALSE	Activates the instruction.
	S_ChannelNC	SAFEBOOL	TRUE, FALSE	FALSE	Indicates the input for a normally closed (NC) contact. FALSE: NC contact is open. TRUE: NC contact is closed.
	S_ChannelNO	SAFEBOOL	TRUE, FALSE	TRUE	Indicates the input for a normally open (NO) contact. FALSE: NO contact is open. TRUE: NO contact is closed.
	DiscrepancyTime	TIME	Follows data type	T#0ms	Used to set the maximum discrepancy time between the two input statuses.
Output	Ready	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is in ready status.
	S_AntivalentOut	SAFEBOOL	TRUE, FALSE	FALSE	Safety-related output FALSE: At least one input signal is inactivated or the status change occurs outside the monitoring time. TRUE: Both input signals are activated and the status changes occurs within the monitoring time.
	SafetyDemand	BOOL	TRUE, FALSE	FALSE	Activates or maintains the status according to the instruction status.
	Error	BOOL	TRUE, FALSE	FALSE	Faulty status
	DiagCode	WORD	Follows data type	16#0000	Status code: Indicates fault code when instruction fails; indicates instruction status when instruction is running.

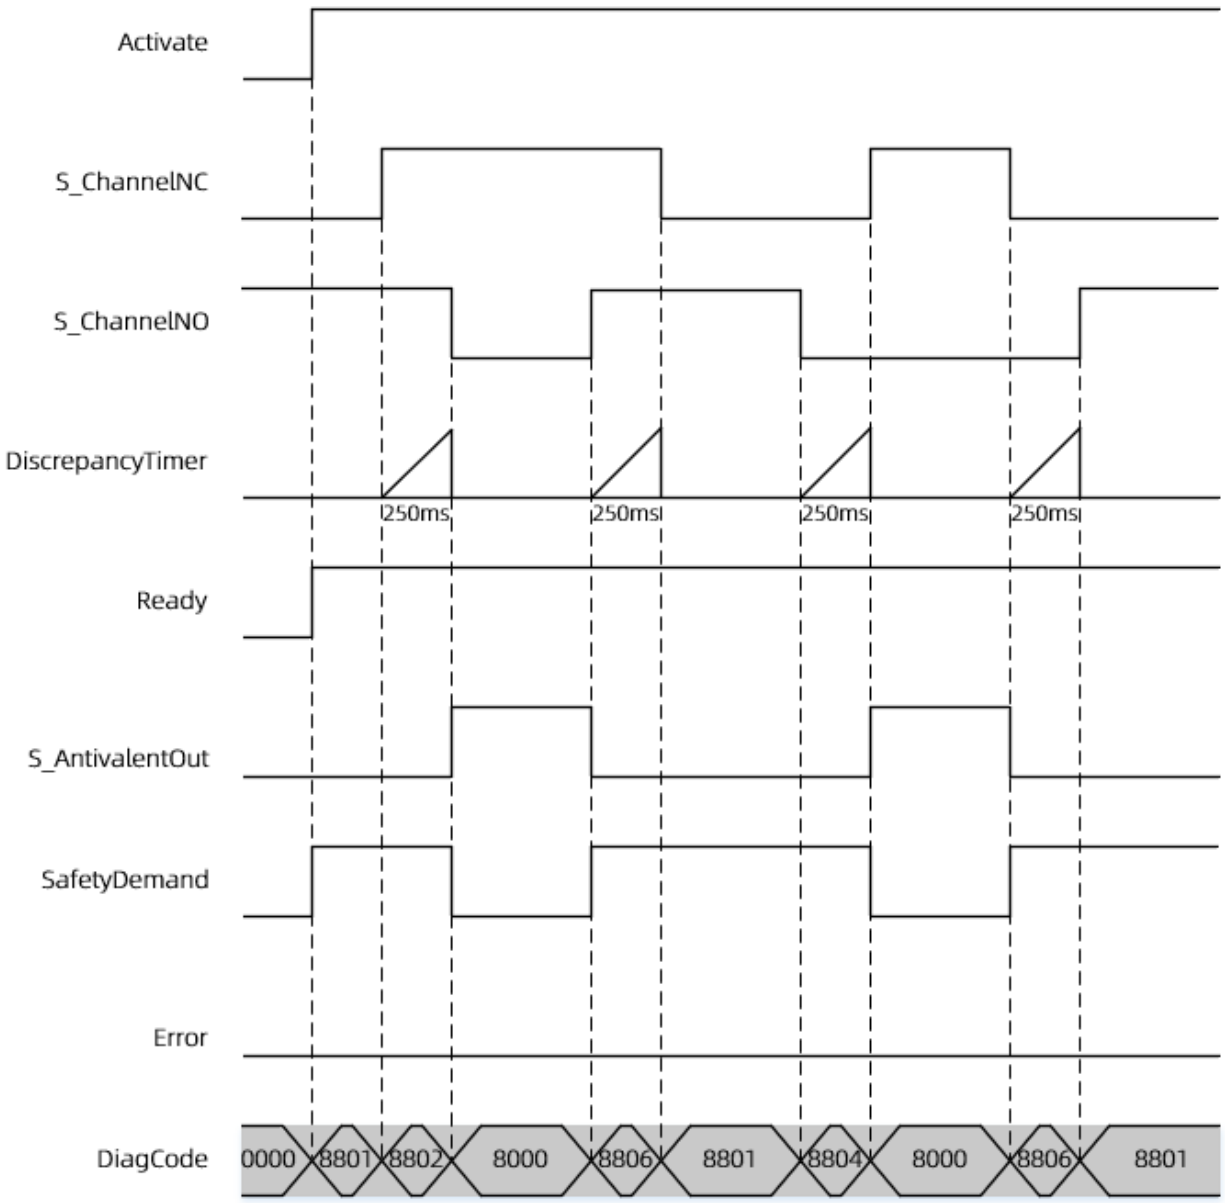
- **Function description**
  - This function block continuously monitors the logical exclusivity of two SAFEBOOL input signals (S_ChannelNC and S_ChannelNO), and outputs the evaluation result as a SAFEBOOL signal. The two input channels are interdependent. The function block output depends on the logical comparison

result between the two channels: the output is valid when the two channels are in inequivalent statuses; a safety response is triggered when the two channels are in equivalent statuses

- When a signal transition in either channel causes the two channels to enter an equivalent status (i.e., S_ChannelNC == S_ChannelNO), the function block immediately sets the safety output S_AntivalentOut to FALSE and starts the discrepancy timer. If the inequivalent statuses of the two channels are not restored within the time window predefined by DiscrepancyTime (which must be greater than the safety task cycle), a fault occurs.
- Set DiscrepancyTime to a value greater than the safety task cycle.

- **Status transition diagram**





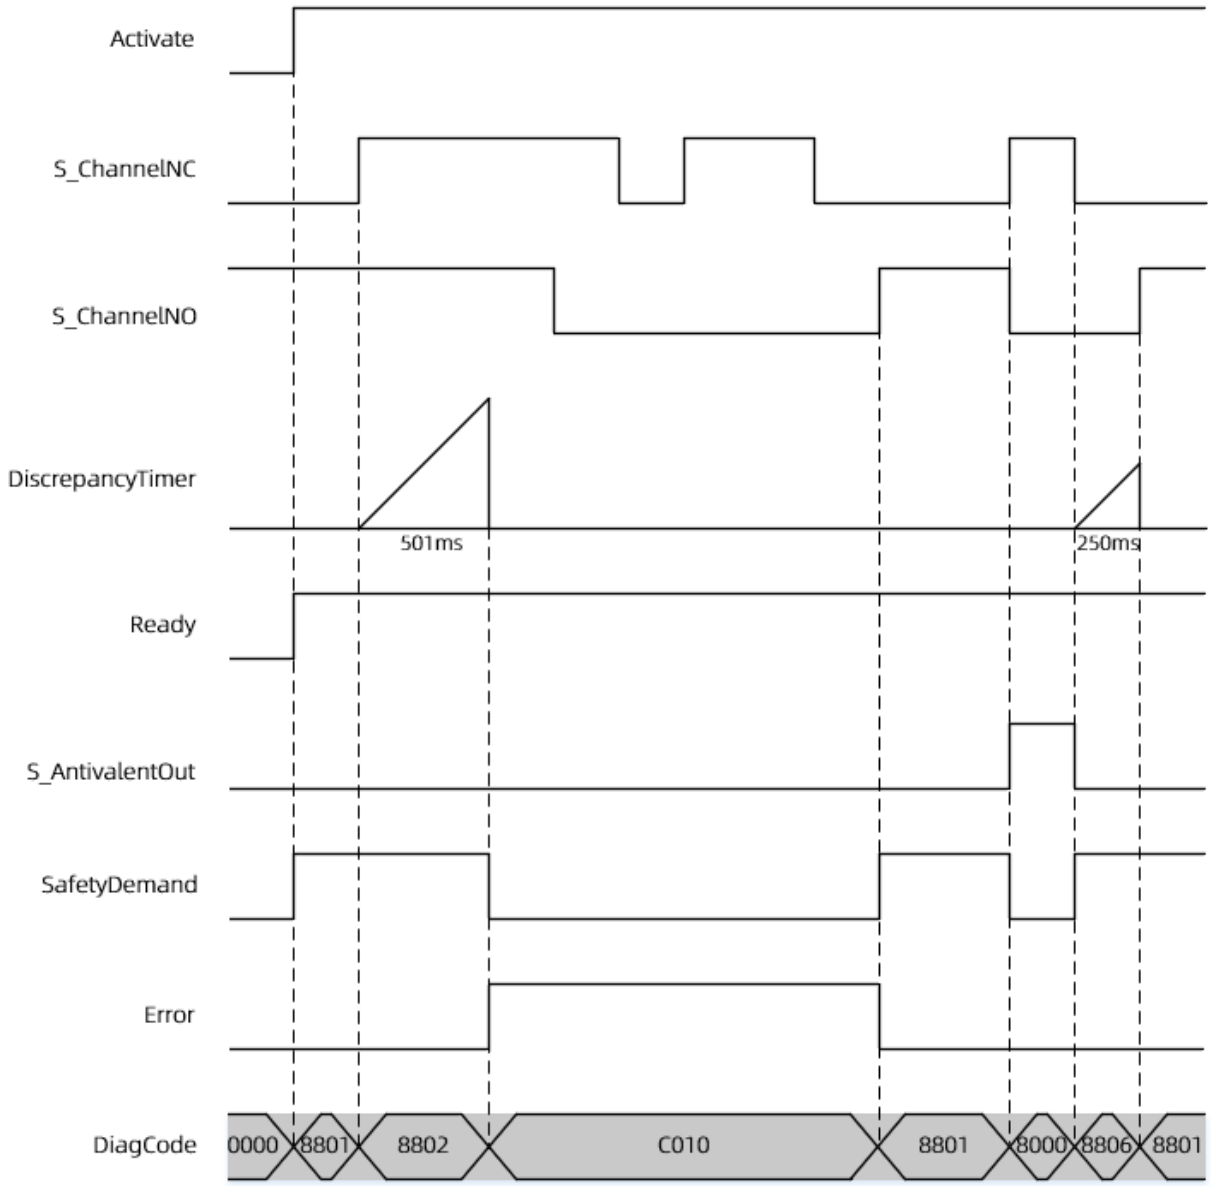


Figure 11-10-2-2-3-1 Status transition diagram for SF_Antivalent

- This diagram is referenced from the PLCopen specification, and the copyright belongs to the PLCopen organization.
- The transition from any status to the idle status when Activate = FALSE is not indicated, but the priority (0) for transitioning to the idle status is the highest.

- **Sequence diagram**

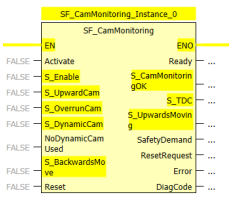
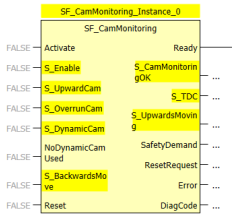
- **Fault detection**
  The function block monitors the discrepancy time between the NO channel and the NC channel.
- **Fault behavior**
  When a fault occurs, reset operation must be performed based on the fault code indicated by DiagCode, combined with the status transition diagram.
- **Function block-specific fault codes and status codes**
  - Fault code

DiagCode	Status Name	Description and Output
C010	Error 1	Discrepancy time timeout in status 8802. Ready = TRUE S_AntivalentOut = FALSE SafetyDemand = FALSE Error = TRUE

DiagCode	Status Name	Description and Output
C020	Error 2	Discrepancy time timeout in status 8804. Ready = TRUE S_AntivalentOut = FALSE SafetyDemand = FALSE Error = TRUE
C030	Error 3	Discrepancy time timeout in status 8806. Ready = TRUE S_AntivalentOut = FALSE SafetyDemand = FALSE Error = TRUE

◦ Status code





DiagCode	Status Name	Description and Output
0000	Idle	Function block is not activated (initial status). Ready = FALSE S_AntivalentOut = FALSE SafetyDemand = FALSE Error = FALSE
8801	Init (Initialization)	Function block is activated. Ready = TRUE S_AntivalentOut = FALSE SafetyDemand = TRUE Error = FALSE
8000	Safety Output Enabled	Input switches to TRUE in equivalent mode. Ready = TRUE S_AntivalentOut = TRUE SafetyDemand = FALSE Error = FALSE
8802	Wait for NO	NC channel has been switched to TRUE and is waiting for NO channel to switch to FALSE; the discrepancy timer has been started. Ready = TRUE S_AntivalentOut = FALSE SafetyDemand = TRUE Error = FALSE

DiagCode	Status Name	Description and Output
8804	Wait for NC	NO channel has been switched to FALSE and is waiting for NC channel to switch to TRUE; the discrepancy timer has been started. Ready = TRUE S_AntivalentOut = FALSE SafetyDemand = TRUE Error = FALSE
8806	From Active Wait	One channel has been switched to FALSE and is waiting for the other channel to switch to FALSE. Ready = TRUE S_AntivalentOut = FALSE SafetyDemand = TRUE Error = FALSE

11.10.2.2.4 SF_CamMonitoring

SF_CamMonitoring provides cam monitoring function. The cam signal must have a defined sequence.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_CamMonitoring	Cam monitoring	FB		

- **Related variables**

Variables

Input / Output	Variable	Data Type	Valid Range	Default Value	Description
Input	Activate	BOOL	TRUE, FALSE	FALSE	Activates the instruction.
	S_Enable	SAFEBOOL	TRUE, FALSE	FALSE	Control signal used to activate cam monitoring. FALSE: Cam monitoring is not activated. TRUE: Cam monitoring is activated.

Input / Output	Variable	Data Type	Valid Range	Default Value	Description
	S_UpwardCam	SAFEBOOL	TRUE, FALSE	FALSE	Input for upward cam. FALSE: Cam is activated. TRUE: Cam is not activated.
	S_OverrunCam	SAFEBOOL	TRUE, FALSE	FALSE	Input for overrun cam. FALSE: Cam is activated. TRUE: Cam is not activated.
	S_DynamicCam	SAFEBOOL	TRUE, FALSE	FALSE	Input for dynamic cam. FALSE: Cam is activated. TRUE: Cam is not activated.
	NoDynamicCamUsed	BOOL	TRUE, FALSE	FALSE	Input to disable the use of dynamic cam. FALSE: Enable dynamic cam. TRUE: Disable dynamic cam.
	S_BackwardsMove	SAFEBOOL	TRUE, FALSE	FALSE	Input to enable backward movement for the press. FALSE: Press moves forward. TRUE: Press moves backward.
	Reset	BOOL	TRUE, FALSE	FALSE	Manual reset
Output	Ready	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is in ready status.
	S_CamMonitoringOK	SAFEBOOL	TRUE, FALSE	FALSE	Output indicating the cam sequence. FALSE: Incorrect cam sequence or signal fault. TRUE: Correct cam sequence with no signal fault or deactivation.
	S_TDC	SAFEBOOL	TRUE, FALSE	FALSE	Output indicating whether the press is at top dead center (TDC). FALSE: The press is not at TDC. TRUE: The press is at TDC.

Input / Output	Variable	Data Type	Valid Range	Default Value	Description
	S_UpwardsMoving	SAFEBOOL	TRUE, FALSE	FALSE	Output indicating whether the press is moving upward (from BDC to TDC). FALSE: The press is not moving upward. TRUE: The press is moving upward.
	SafetyDemand	BOOL	TRUE, FALSE	FALSE	Activates or maintains the status according to the instruction status.
	ResetRequest	BOOL	TRUE, FALSE	FALSE	Flag indicating whether a reset is required.
	Error	BOOL	TRUE, FALSE	FALSE	Faulty status
	DiagCode	WORD	Follows data type	16#0000	Status code: Indicates fault code when instruction fails; indicates instruction status when instruction is running.

- **Function description**
  - This function block provides cam monitoring function. A defined cam signal sequence is required. The function block also provides information indicating whether the press is at top dead center (S_TDC) or whether it is moving upward (S_UpwardsMoving). Operation can be performed using two cams (upward and overrun) or three cams (upward, overrun, and dynamic).
  - The monitoring function of the function block can be enabled or disabled via the S_Enable input.

    Press movement sequence:

    1. Enable the monitoring function (activate function block).
    2. The press is in the TDC area (status code 8000)
       a. S_UpwardCam = FALSE
       b. S_OverrunCam = TRUE
       c. S_DynamicCam = FALSE
       d. S_TDC = TRUE
       e. S_UpwardsMoving = FALSE
    3. Overrun cam ends.
       a. The press is moving out of TDC area.
       b. F_TRIG at S_OverrunCam 8010
       c. S_UpwardCam = FALSE
       d. S_OverrunCam = FALSE
       e. S_DynamicCam = FALSE
       f. S_TDC = FALSE
       g. S_UpwardsMoving = FALSE

4. Upward cam starts.

   a. The press is in BDC area.

   b. R_TRIG at S_UpwardCam 8020

   c. S_UpwardCam = TRUE

   d. S_OverrunCam = FALSE

   e. S_DynamicCam = TRUE

   f. S_TDC = FALSE

   g. S_UpwardsMoving = TRUE

5. Overrun cam starts.

   a. R_TRIG at S_OverrunCam 8030

   b. S_UpwardCam = TRUE

   c. S_OverrunCam = TRUE

   d. S_DynamicCam = FALSE

   e. S_TDC = TRUE F_TRIG at S_DynamicCam

   f. S_UpwardsMoving = FALSE F_TRIG at S_DynamicCam

6. Upward cam ends.

   a. The press is in TDC area.

   b. F_TRIG at S_UpwardCam 8000

   c. S_UpwardCam = FALSE

   d. S_OverrunCam = TRUE

   e. S_DynamicCam = FALSE

   f. S_TDC = TRUE

   g. S_UpwardsMoving = FALSE

7. The press moves backwards.

   a. Signal to move backwards

   b. S_BackwardsMove = TRUE 8040

   c. S_Upwardcam = FALSE

   d. S_OverrunCam = FALSE

   e. S_DynamicCam = FALSE

   f. S_TDC = FALSE

   g. S_UpwardsMoving = FALSE

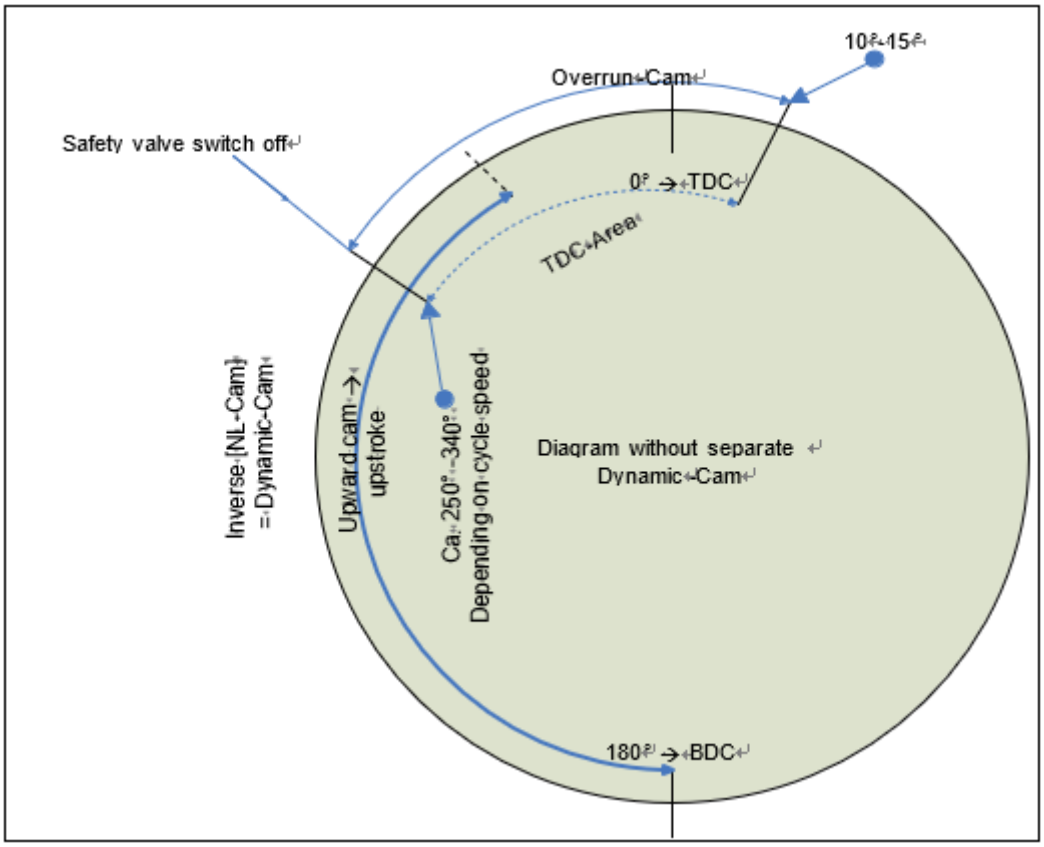

Figure 11-10-2-2-4-1 SF_CamMonitoring sequence diagram

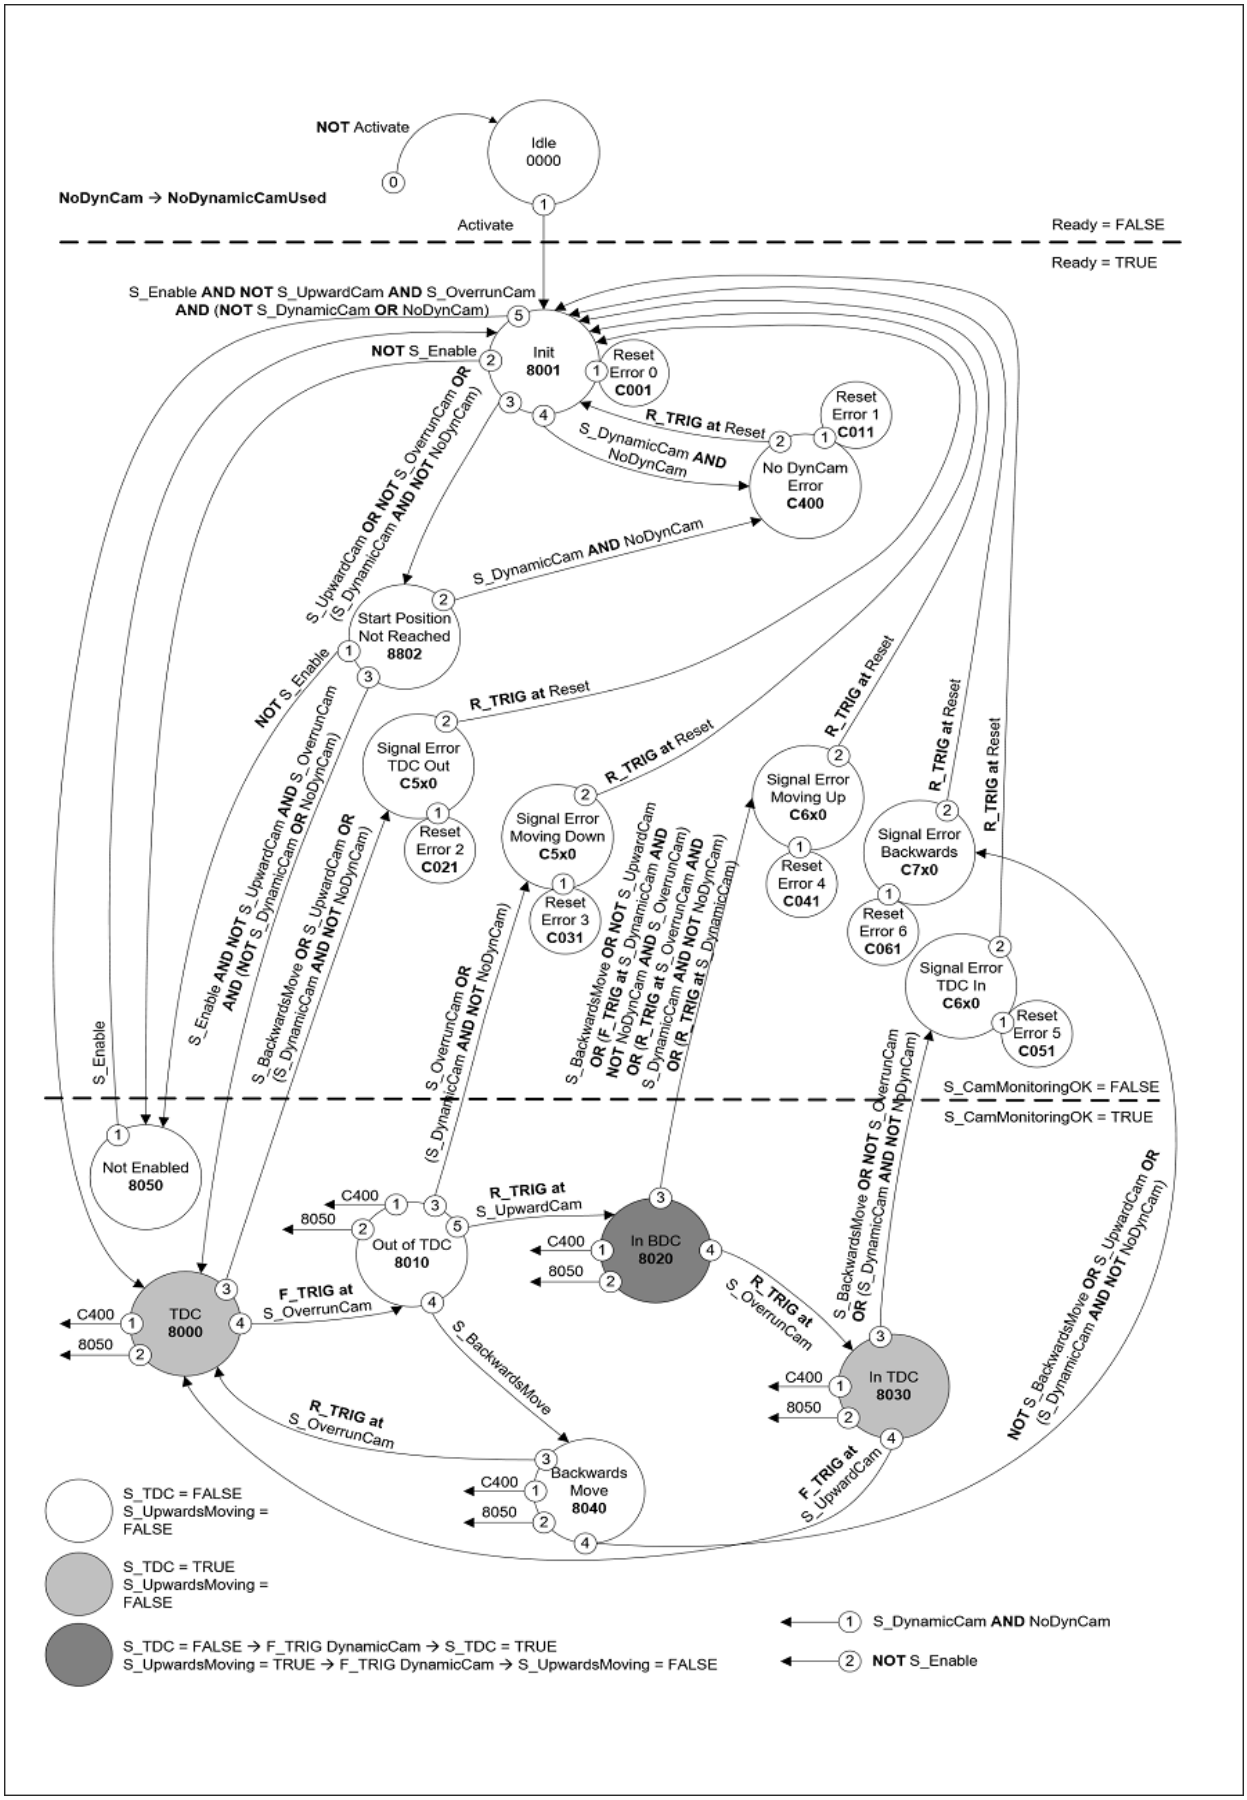
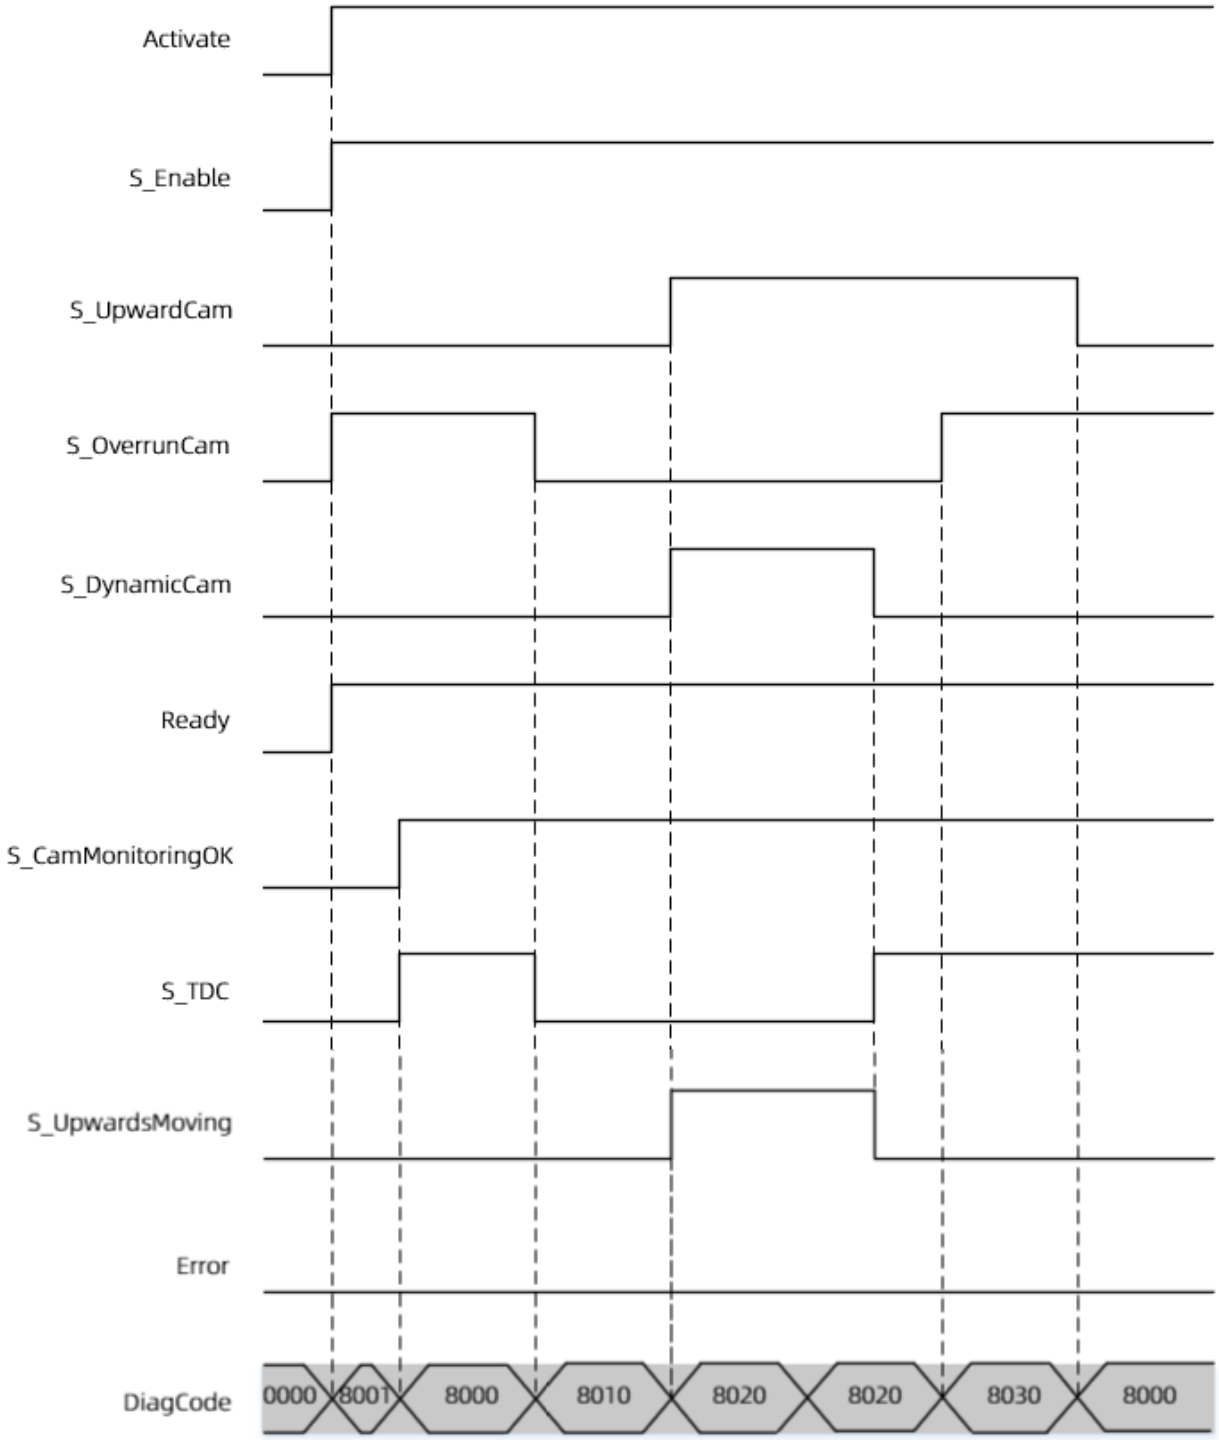
- **Status transition diagram**





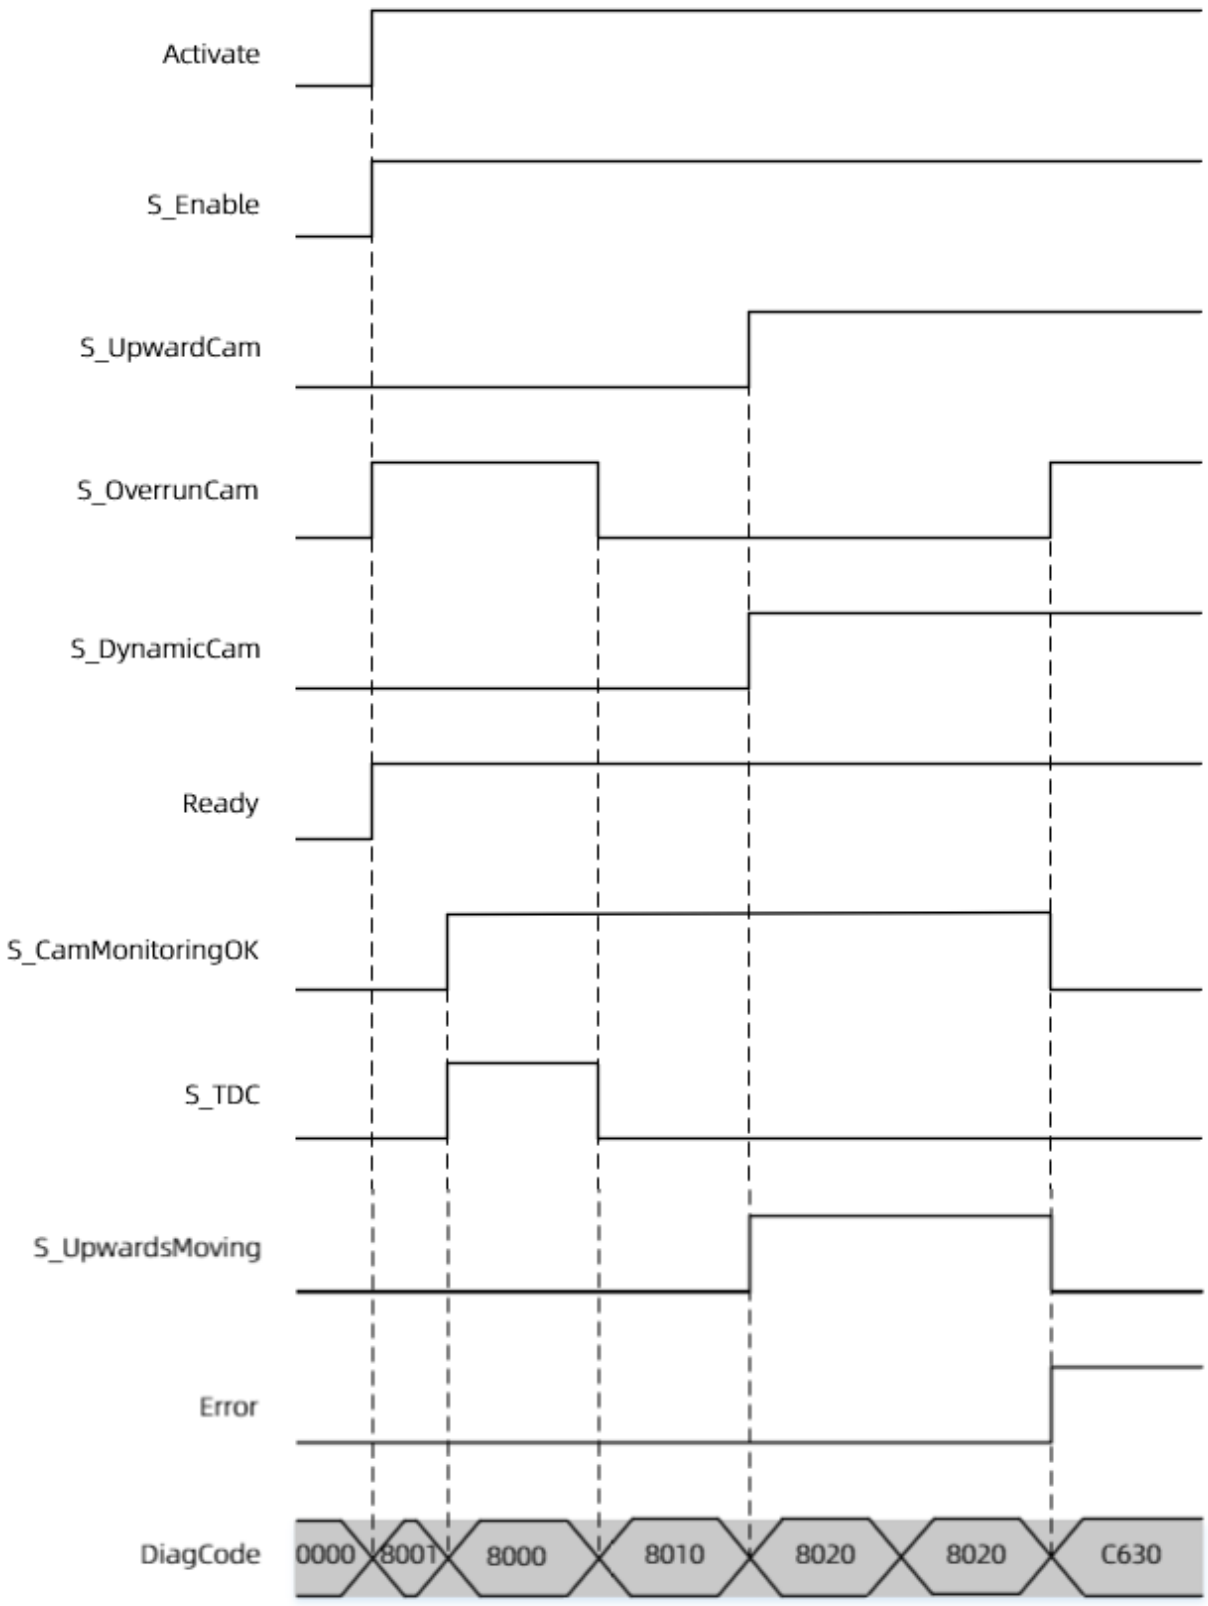


Figure 11-10-2-2-4-2 Status transition diagram for SF_CamMonitorin State Transition Diagram

◦ This diagram is referenced from the PLCopen specification, and the copyright belongs to the PLCopen organization.

◦ The transition from any status to the idle status when Activate = FALSE is not indicated, but the priority (0) for transitioning to the idle status is the highest.

- **Sequence diagram**

- **Fault detection**

  The faulty status is triggered when a static TRUE signal of the Reset input is detected.

- **Fault behavior**

  When a fault occurs, the S_CamMonitoringOK output is set to FALSE. The DiagCode output indicates the relevant fault code, and the Error output is set to TRUE.

  Restart is prohibited until the fault condition is cleared and the operator confirms the safety status via Reset.

11.10.2.2.5 SF_CamshaftMonitor

SF_CamshaftMonitor provides cam shaft monitoring function. A certain amount of signal changes must occur within the specified period.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_CamshaftMonitor	Cam shaft monitoring function	FB		

- **Related variables**

  Variables

Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
Input	Activate	BOOL	TRUE, FALSE	FALSE	Activates the instruction.

Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
	S_Enable	SAFEBOOL	TRUE, FALSE	FALSE	Control signal used to activate cam shaft monitoring. FALSE: Cam shaft monitoring is not activated. TRUE: Cam shaft monitoring is activated.
	S_SafeControl	SAFEBOOL	TRUE, FALSE	FALSE	Input used to indicate that the press is moving and monitoring needs to be performed. It is typically connected to a control signal or feedback signal of the press safety valve. FALSE: The press is not moving - monitoring is not activated. TRUE: The press is moving - monitoring is activated.
	S_CamSwitch	SAFEBOOL	TRUE, FALSE	FALSE	Input for the cam switch. FALSE: Cam is not activated. TRUE: Cam is activated.
	StartingTime	TIME	Follows data type	T#0ms	Ranges from 0 to X ms. This input indicates the device start time. The number of signal changes must reach CounterValueStarting within this time period.
	CounterValueStarting	INT	Follows data type	INT#0	Ranges from 0 to 40. Number of signal changes required to be reached during startup.
	MonitoringTime	TIME	Follows data type	T#0ms	Ranges from 0 to X ms. Monitoring time must be less than StartingTime. This input indicates the monitoring time during cycling operation. The number of signal changes must reach CounterValueMonitoring within this time period.
	CounterValueMonitoring	INT	Follows data type	INT#0	Ranges from 0 to 40. Number of signal changes required to be reached during cycling operation.
	Reset	BOOL	TRUE, FALSE	FALSE	Manual reset

Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
Output	Ready	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is in ready status.
	S_Cam shaft MonitoringOK	SAFEBOOL	TRUE, FALSE	FALSE	Output indicating cam shaft monitoring status. FALSE: Incorrect cam shaft sequence or signal fault. TRUE: Cam shaft monitoring sequence is correct or not activated.
	SafetyDemand	BOOL	TRUE, FALSE	FALSE	Activates or maintains the status according to the instruction status.
	ResetRequest	BOOL	TRUE, FALSE	FALSE	Flag indicating whether a reset is required.
	Error	BOOL	TRUE, FALSE	FALSE	Faulty status
	DiagCode	WORD	Follows data type	16#0000	Status code: Indicates fault code when instruction fails; indicates instruction status when instruction is running.
If multiple cam switches are used, multiple instances of this function must be used. This function block can handle up to 20 strokes (40 signal changes). A signal change is the rising/falling edge of S_CamSwitch.					

- **Function description**
  SF_CamshaftMonitor provides cam shaft monitoring function. A series of signal changes of S_CamSwitch must be input within the specified time period.
  The monitoring function of the function block can be enabled or disabled via the S_Enable input.
  Monitoring sequence:
  1. Enable the monitoring function.
  2. The press is moving (S_SafeControl input is TRUE).
  3. Start the StartingTime timer and check the number of signal changes.
  4. Start the MonitoringTime timer and check the number of signal changes.
  5. Repeat step 4.
- **Note:**
  If a dynamic cam is not used, the input NoDynamicCamUsed must be set to TRUE.

11.10.2.2.6 SF_CycleControl

SF_CycleControl is used to control the ESPE cycle mode (1 to n cycles).

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_CycleControl	Cycle control	FB		

- **Related variables**

  Variables

Input / Output	Variable	Data Type	Valid Range	Default Value	Description
Input	Activate	BOOL	TRUE, FALSE	FALSE	Activates the instruction.
	S_AOPD_In	SAFEBOOL	TRUE, FALSE	FALSE	OSSD signal from AOPD. FALSE: Protective field is interrupted. TRUE: Protective field is not interrupted.

Input / Output	Variable	Data Type	Valid Range	Default Value	Description
	S_UpwardsMoving	SAFEBOOL	TRUE, FALSE	FALSE	Signal from the press, indicating the return stroke (e.g., from a cam controller). If the press return stroke is not hazardous and it is not desired for light curtain interruption to cause shutdown during the return stroke, this parameter must be connected to the relevant variable. FALSE: The press is not in return mode. TRUE: The press is in return mode. If the press return stroke is hazardous and/or no intervention is permitted during the return stroke, this parameter must be connected to a constant value of FALSE.
	S_TDC	SAFEBOOL	TRUE, FALSE	FALSE	Machine status signal (e.g., from a cam controller) indicating whether the machine is in the normal position. FALSE: The machine is not in the normal position. TRUE: The machine is in the normal position.
	S_Start	SAFEBOOL	TRUE, FALSE	FALSE	Edge-triggered signal used to start hazardous movement.
	SwedenStart	BOOL	TRUE, FALSE	FALSE	Specifies the start behavior (initialization of the function). FALSE: Standard start. TRUE: SwedenStart.
	CycleNo	INT	Follows data type	INT#0	Indicates the number of cycles (1 to n) that cause the safety output to be set to TRUE in one operating cycle. A single cycle is defined as a signal transition on S_AOPD_In from FALSE to TRUE.
	S_StartReset	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether to start reset.
	S_AutoReset	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether to automatically reset.
	Reset	BOOL	TRUE, FALSE	FALSE	Manual reset

Input / Output	Variable	Data Type	Valid Range	Default Value	Description
Output	Ready	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is in ready status.
	S_CycleOut	SAFEBOOL	TRUE, FALSE	FALSE	Signal controlling the cycle movement.
	StartNecessary	BOOL	TRUE, FALSE	FALSE	Indicates whether it is necessary to start or maintain the cycle mode. For initialization or maintaining the cycle mode, S_AOPD_In must be set according to the value of CycleNo (TRUE -> FALSE -> TRUE).
	InsertMaterial	BOOL	TRUE, FALSE	FALSE	Indicates whether it is necessary to insert material to start or maintain the cycle mode. For initialization or maintaining the cycle mode, S_AOPD_In must be set according to the value of CycleNo (TRUE -> FALSE -> TRUE).
	SafetyDemand	BOOL	TRUE, FALSE	FALSE	Activates or maintains the status according to the instruction status.
	ResetRequest	BOOL	TRUE, FALSE	FALSE	Flag indicating whether a reset is required.
	Error	BOOL	TRUE, FALSE	FALSE	Faulty status
	DiagCode	WORD	Follows data type	16#0000	Status code: Indicates fault code when instruction fails; indicates instruction status when instruction is running.

- **Function description**

  This function block is used for applications where access to hazardous areas during cyclic processes needs to be controlled by safety devices.

  - Normal operation: Manually start/initialize the first cycle/machine cycle. Two operating modes are available for starting this function (cycling function initialization): SwedenStart and normal start. After the first cycle/machine cycle (leaving TDC and reaching TDC again), subsequent machine cycles can be controlled by safety devices as long as MaxOperatorTime is not exceeded. If MaxOperatorTime is exceeded, the cyclic mode must be re-initialized. To start the cyclic mode, the machine must be in the normal position (TDC) in safety status.

    - Cyclic mode initialization (normal start):
      - The machine is at TDC (normal position).
      - The safety output is FALSE.
      - Interrupt ESPE (workpiece insertion) while the machine is in the normal position.
      - Interrupt ESPE (workpiece insertion) according to the CycleNo specification.
      - The time between two interventions must not exceed 30 seconds.
      - The safety output remains set to FALSE.

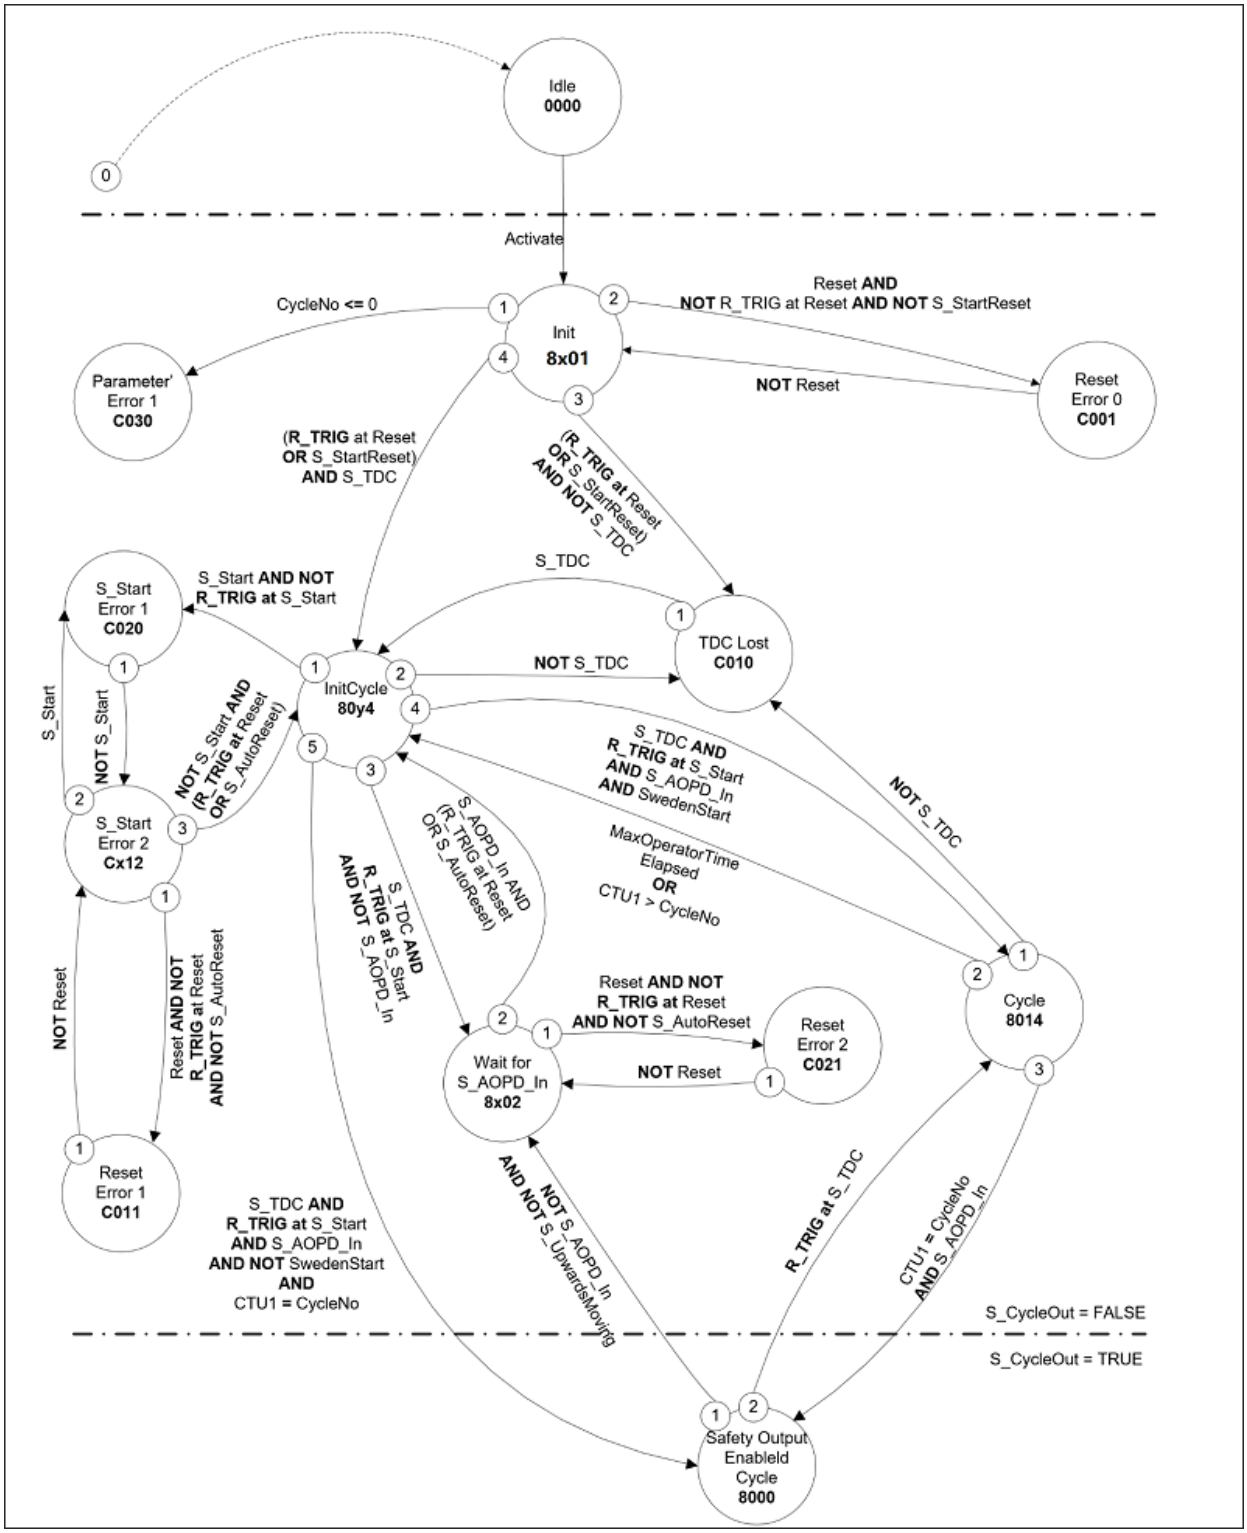
- The operator must switch S_Start from FALSE to TRUE within 30 seconds.

- Cyclic mode initialization (SwedenStart):
  - The machine is at TDC (normal position).
  - The safety output is FALSE.
  - The operator switches S_Start from FALSE to TRUE (starts 30-second timer).
  - The safety output remains set to FALSE.
  - Interrupt ESPE (workpiece insertion) according to the CycleNo specification. The time between two interventions must not exceed 30 seconds.
  - After reaching the number of cycles specified by CycleNo, the machine cycle is started.
- Cyclic mode operation/re-operation:
  - The machine is at TDC (normal position) or in return mode.
  - The time elapsed since the last initialization must not exceed 30 seconds.
    - TDC:
      - ESPE (workpiece insertion) must be interrupted.
      - Interrupt ESPE (workpiece insertion) according to the CycleNo specification.
      - The time between two interventions must not exceed 30 seconds.
    - Return stroke:
      - The number of interrupts on S_AOPD_In (from 1 to n) is counted by cycle counter.
      - Interrupt ESPE (workpiece insertion) according to the CycleNo specification.
      - The time between two interventions must not exceed 30 seconds.
  - After reaching the number of interrupts specified by CycleNo, the machine cycle is started.
  - Stop the time monitoring (T1) of material supply by MaxOperatorTime.
  - Set the safety output to TRUE. The machine moves away from TDC.
  - The machine reaches TDC (normal position) again. The safety output is set to FALSE again.

- Abnormal operation: If the safety output is TRUE and ESPE is interrupted, the safety output will be turned off and a fault message will be triggered under the following conditions:
  - The machine is moving downward.
  - Return stroke (S_UpwardsMoving) is dangerous for the operator.

  To exit the faulty status, a signal change from FALSE to TRUE on Reset may be required, and the cycle must be reinitialized.

- **Status transition diagram**



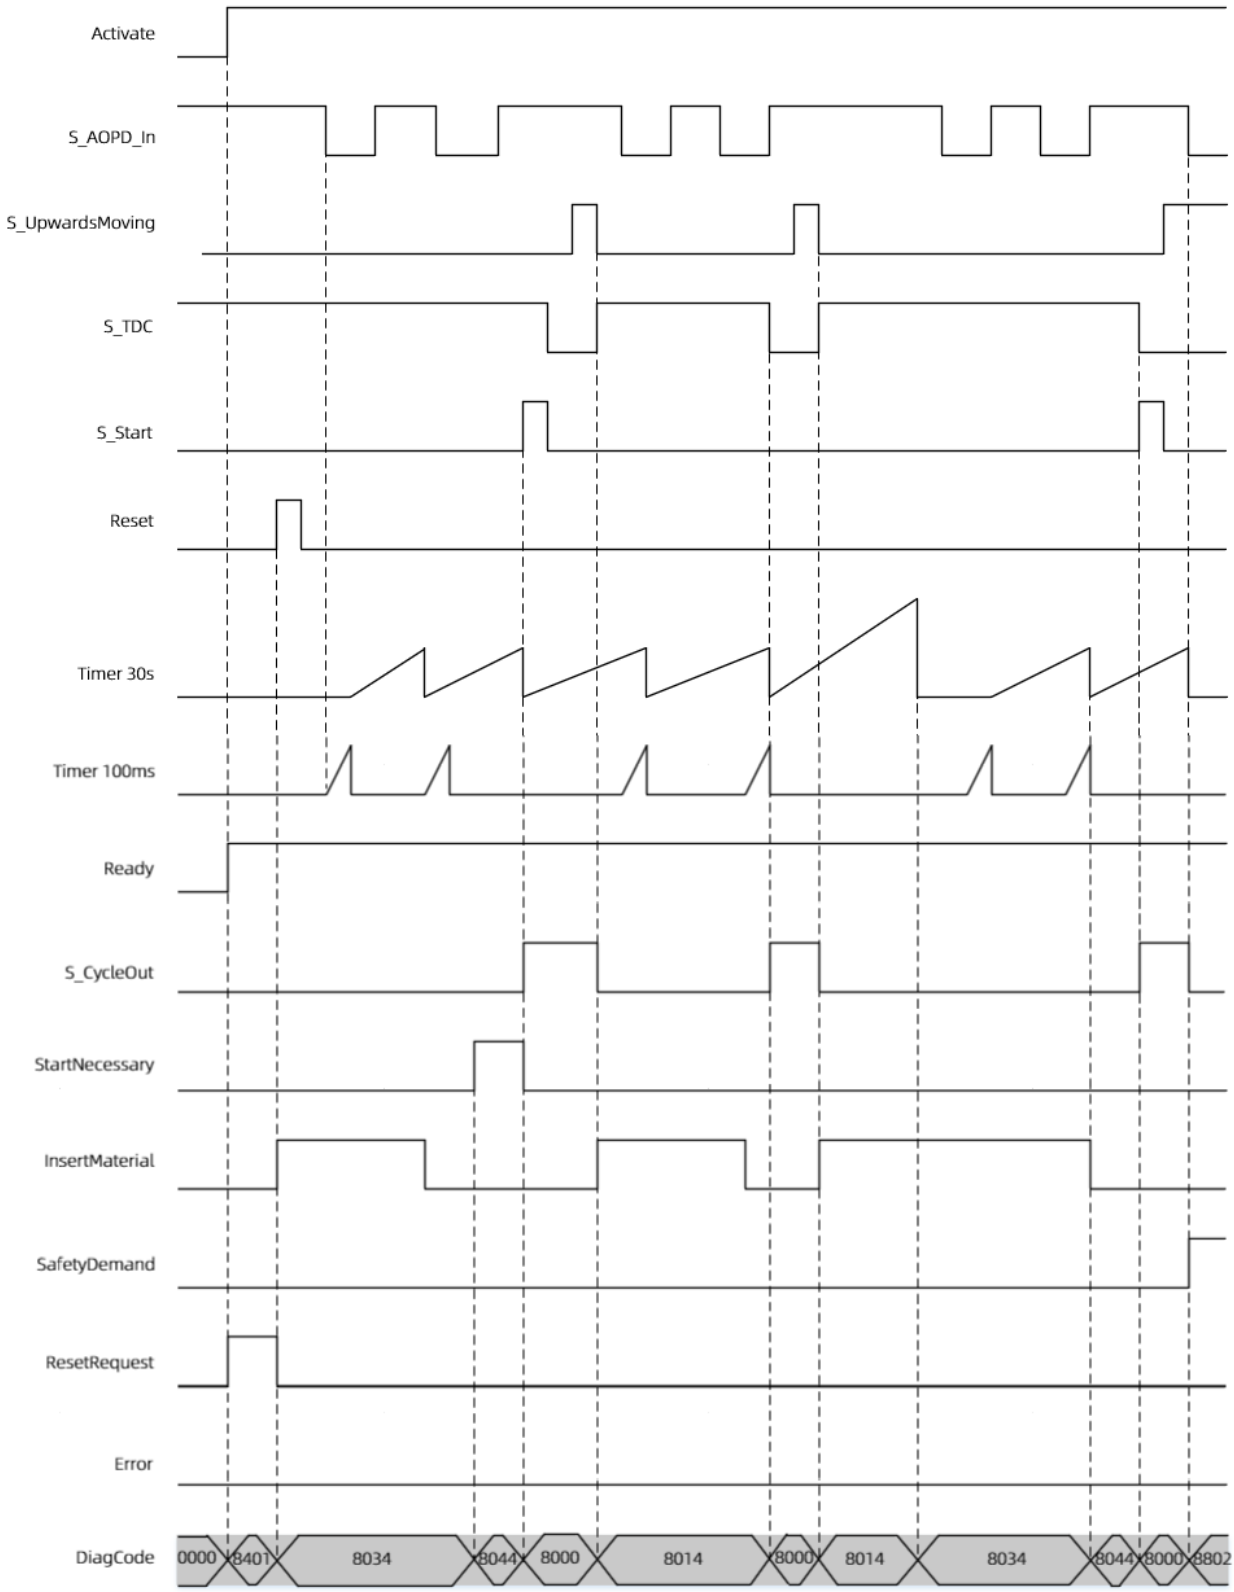


Figure 11-10-2-2-6-1 Status transition diagram for SF_CycleControl

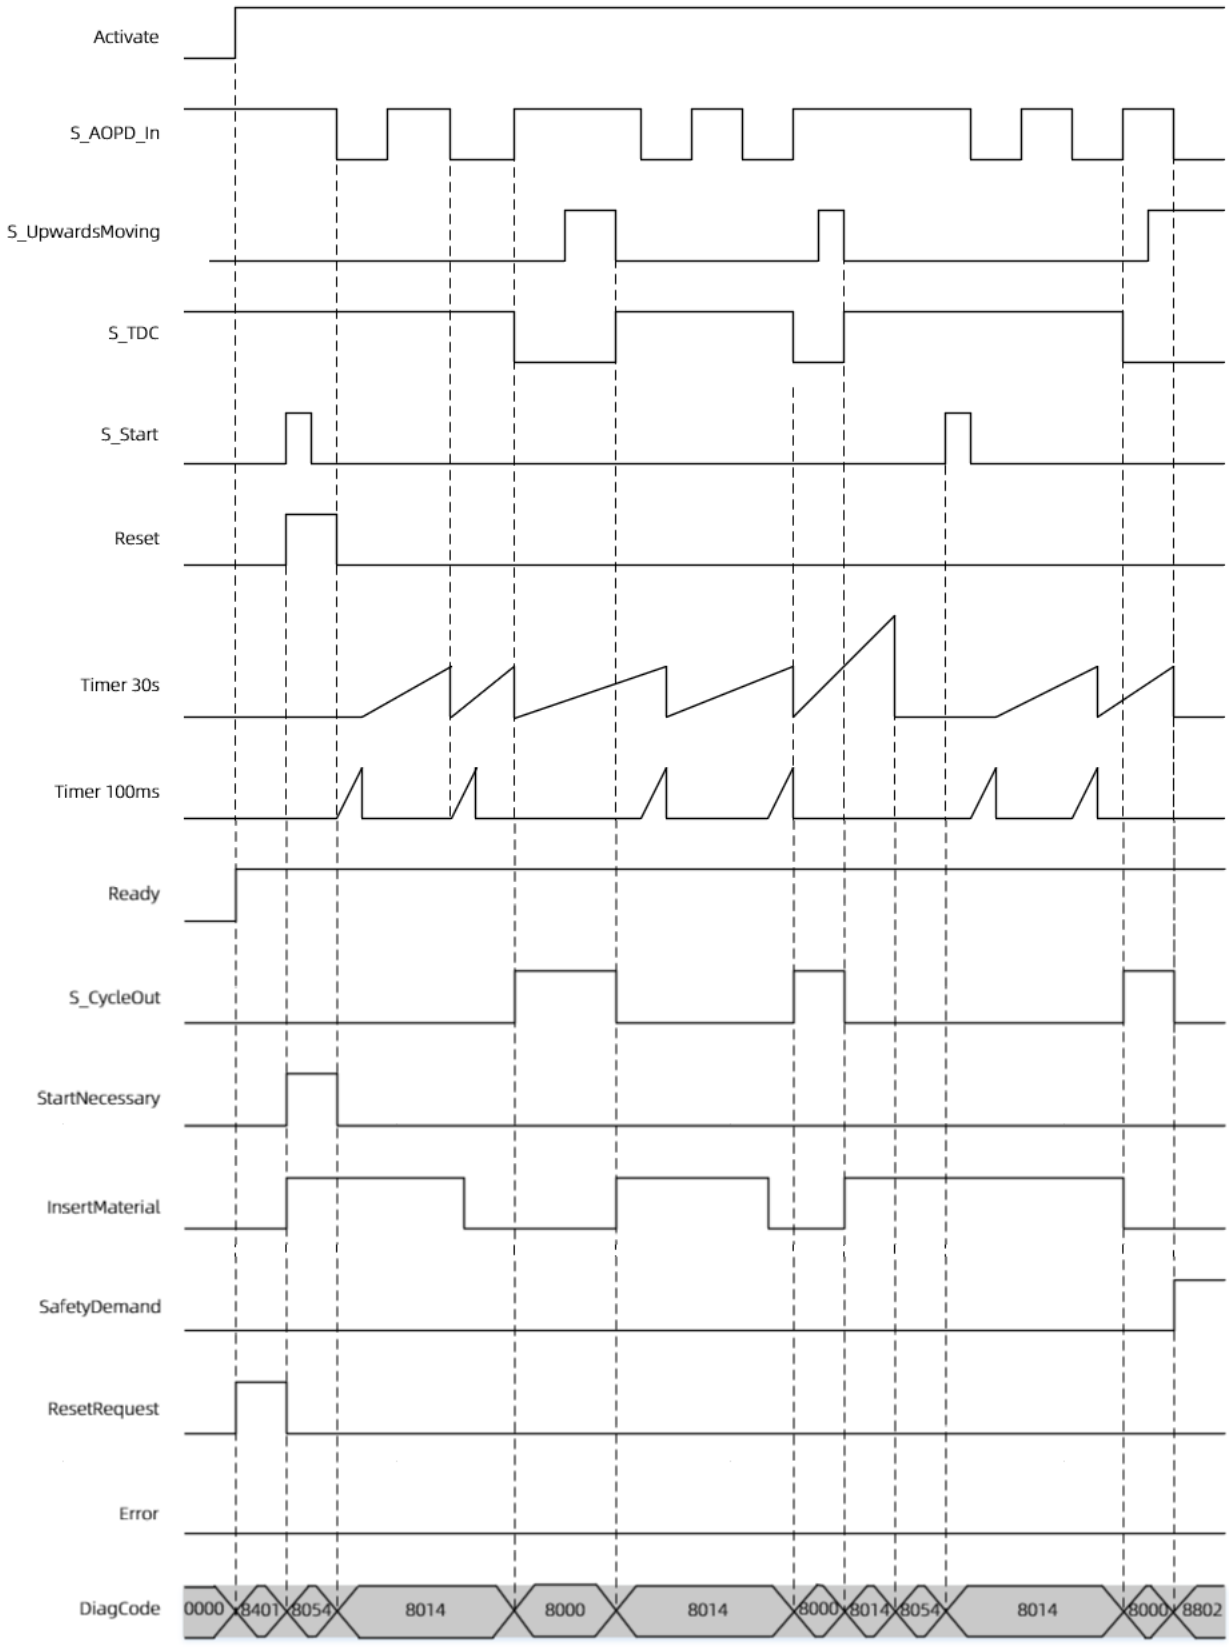
- This diagram is referenced from the PLCopen specification, and the copyright belongs to the PLCopen organization.
- The transition from any status to the idle status when Activate = FALSE is not indicated, but the priority (0) for transitioning to the idle status is the highest.



- **Sequence diagram**

  S_StartReset = FALSE, S_AutoReset = FALSE, SwedenStart = FALSE, CycleNo = INT#2

1. Initialize the function block.
2. Initialize the first cycle for standard start.
3. The machine operates normally.
4. The maximum operating time (30 seconds) has been reached; it is recommended to perform a new initialization cycle.
5. S_AOPD_In safety photoelectric device input signal is lost between stamping cycles.

S_StartReset = FALSE, S_AutoReset = FALSE, SwedenStart = TRUE, CycleNo = INT#2

1. Initialize the function block.
2. Initialize the first cycle for SwedenStart.
3. The machine operates normally.
4. The maximum operating time (30 seconds) has been reached; it is recommended to perform a new initialization cycle.

5. S_AOPD_In safety photoelectric device input signal is lost between stamping cycles.

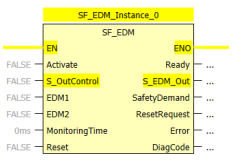
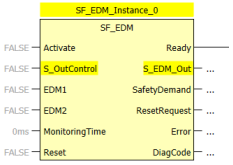
◦ Status code

DiagCode	Status Name	Description and Output
0000	Idle	Function block is not activated (initial status). Ready = FALSE S_CycleOut = FALSE SafetyDemand = FALSE InsertMaterial = FALSE StartNecessary = FALSE ResetRequest = FALSE Error = FALSE
8000	Safety Output Enable Cycle	Function block accepts cycle control. Ready = TRUE S_CycleOut = TRUE SafetyDemand = FALSE InsertMaterial = FALSE StartNecessary = FALSE ResetRequest = FALSE Error = FALSE • When S_UpwardMoving = FALSE: The cycle counter (CTU1) will be reset. S_AOPD_In = FALSE is considered an invalid interrupt. • When S_UpwardMoving = TRUE: Each signal transition of S_AOPD_In(FALSE) from FALSE to TRUE will be counted as a valid cycle (CTU1 count). The S_AOPD_In low-level signal for each interrupt must last for ≥ 100 ms (short-duration low-level signals that do not meet the requirement are not counted as interrupts). The maximum allowed interval between two interrupts/between cycle initialization and the next interrupt request is 30 seconds (T1). When the interval between two interrupts exceeds 30 seconds, the counter (CTU1) will be automatically reset to zero.

DiagCode	Status Name	Description and Output
8x01	Init (Initialization)	The function block is activated and initialized. A rising edge trigger is required on Reset. The counter (CTU1) and timer (T1) will be reset. If S_AutoReset = FALSE, the status code is 8401; otherwise, it is 8001. • When the status code is 8001: Ready = TRUE S_CycleOut = FALSE SafetyDemand = FALSE InsertMaterial = FALSE StartNecessary = FALSE ResetRequest = FALSE Error = FALSE • When the status code is 8401: Ready = TRUE S_CycleOut = FALSE SafetyDemand = FALSE InsertMaterial = FALSE StartNecessary = FALSE ResetRequest = TRUE Error = FALSE

DiagCode	Status Name	Description and Output
8x02	Wait for S_AOPD_In	The protective field is interrupted irregularly. The counter (CTU1) and timer (T1) will be reset. If S_AutoReset is FALSE and S_AOPD_In is TRUE, the status code is 8402; otherwise, it is 8802. • When the status code is 8802: Ready = TRUE S_CycleOut = FALSE SafetyDemand = TRUE InsertMaterial = FALSE StartNecessary = FALSE ResetRequest = FALSE Error = FALSE • When the status code is 8402: Ready = TRUE S_CycleOut = FALSE SafetyDemand = TRUE InsertMaterial = FALSE StartNecessary = FALSE ResetRequest = TRUE Error = FALSE





80y4	Init Cycle	Cycle control is enabled. When the first control cycle reaches status 8004, the cycle counter (CTU1) is automatically reset. • If SwedenStart is FALSE and CTU < CycleNo, the status code is 8034: Ready = TRUE S_CycleOut = FALSE SafetyDemand = FALSE InsertMaterial = TRUE StartNecessary = FALSE ResetRequest = FALSE Error = FALSE A signal transition of S_AOPD_In from FALSE to TRUE is counted as a valid cycle (CTU1 count). The low-level interrupt signal must last for ≥ 100 ms; short-duration low-level signals are not counted as valid interrupts. If the interval between two interrupts is ≤ 30s (T1), the counter will be reset to zero upon timeout. • If SwedenStart is FALSE and CTU = CycleNo, the status code is 8044: Ready = TRUE S_CycleOut = FALSE SafetyDemand = FALSE InsertMaterial = FALSE StartNecessary = TRUE ResetRequest = FALSE Error = FALSE The time interval between the last S_AOPD_In interrupt (used for standard initialization, CTU = CycleNo) and the signal transition of S_Start from FALSE to TRUE must not exceed 30 seconds. After timeout, the counter (CTU1) resets to 0 (diagnostic code 8034), and the full initialization procedure must be re-executed.

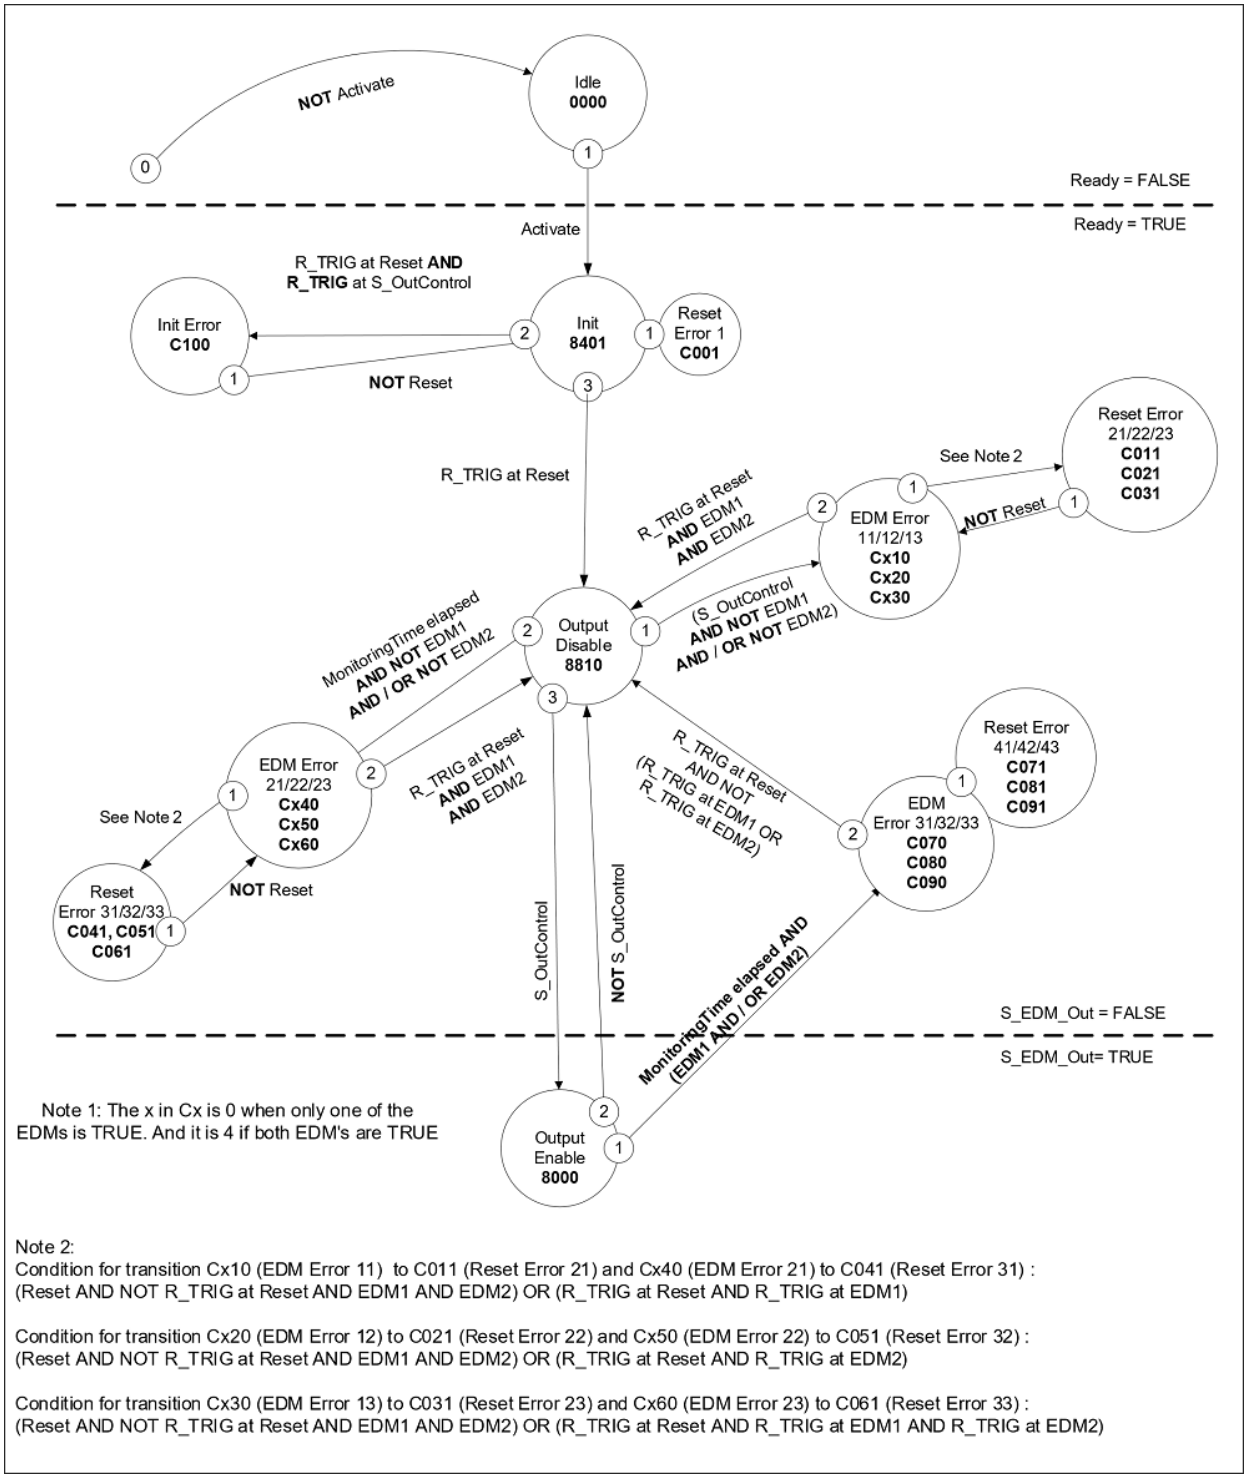
DiagCode	Status Name	Description and Output
		Each transition of S_AOPD_In from FALSE to TRUE (when S_AOPD_In = FALSE) is counted as a cycle (CTU1 count). The low-level interrupt signal must last for ≥ 100 ms; short-duration low-level signals are not counted as valid interrupts. If CTU > CycleNo, CTU is reset to zero and diagnostic code 8034 is triggered, requiring a complete re-initialization. • If SwedenStart is TRUE, the status code is 8054: Ready = TRUE S_CycleOut = FALSE SafetyDemand = FALSE InsertMaterial = FALSE StartNecessary = TRUE ResetRequest = FALSE Error = FALSE The time interval between the S_Start signal transition (FALSE→TRUE) and the first S_AOPD_In interrupt must be ≤ 30s.
8014	Cycle	Cycle control is activated. The device is in the start position. Material insertion must be performed. Ready = TRUE S_CycleOut = FALSE SafetyDemand = FALSE InsertMaterial = TRUE StartNecessary = FALSE ResetRequest = FALSE Error = FALSE A signal transition of S_AOPD_In from FALSE to TRUE is counted as a cycle (CTU1 count). The low-level interrupt signal must last for ≥ 100 ms; short-duration low-level signals are considered invalid. The interval between two interrupts must be ≤ 30 seconds (T1 timer monitoring); otherwise, the cycle control must be reinitialized.

11.10.2.2.7 SF_EDM

SF_EDM monitors inputs from external devices.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_EDM	External monitoring	FB		



- **Related variables**

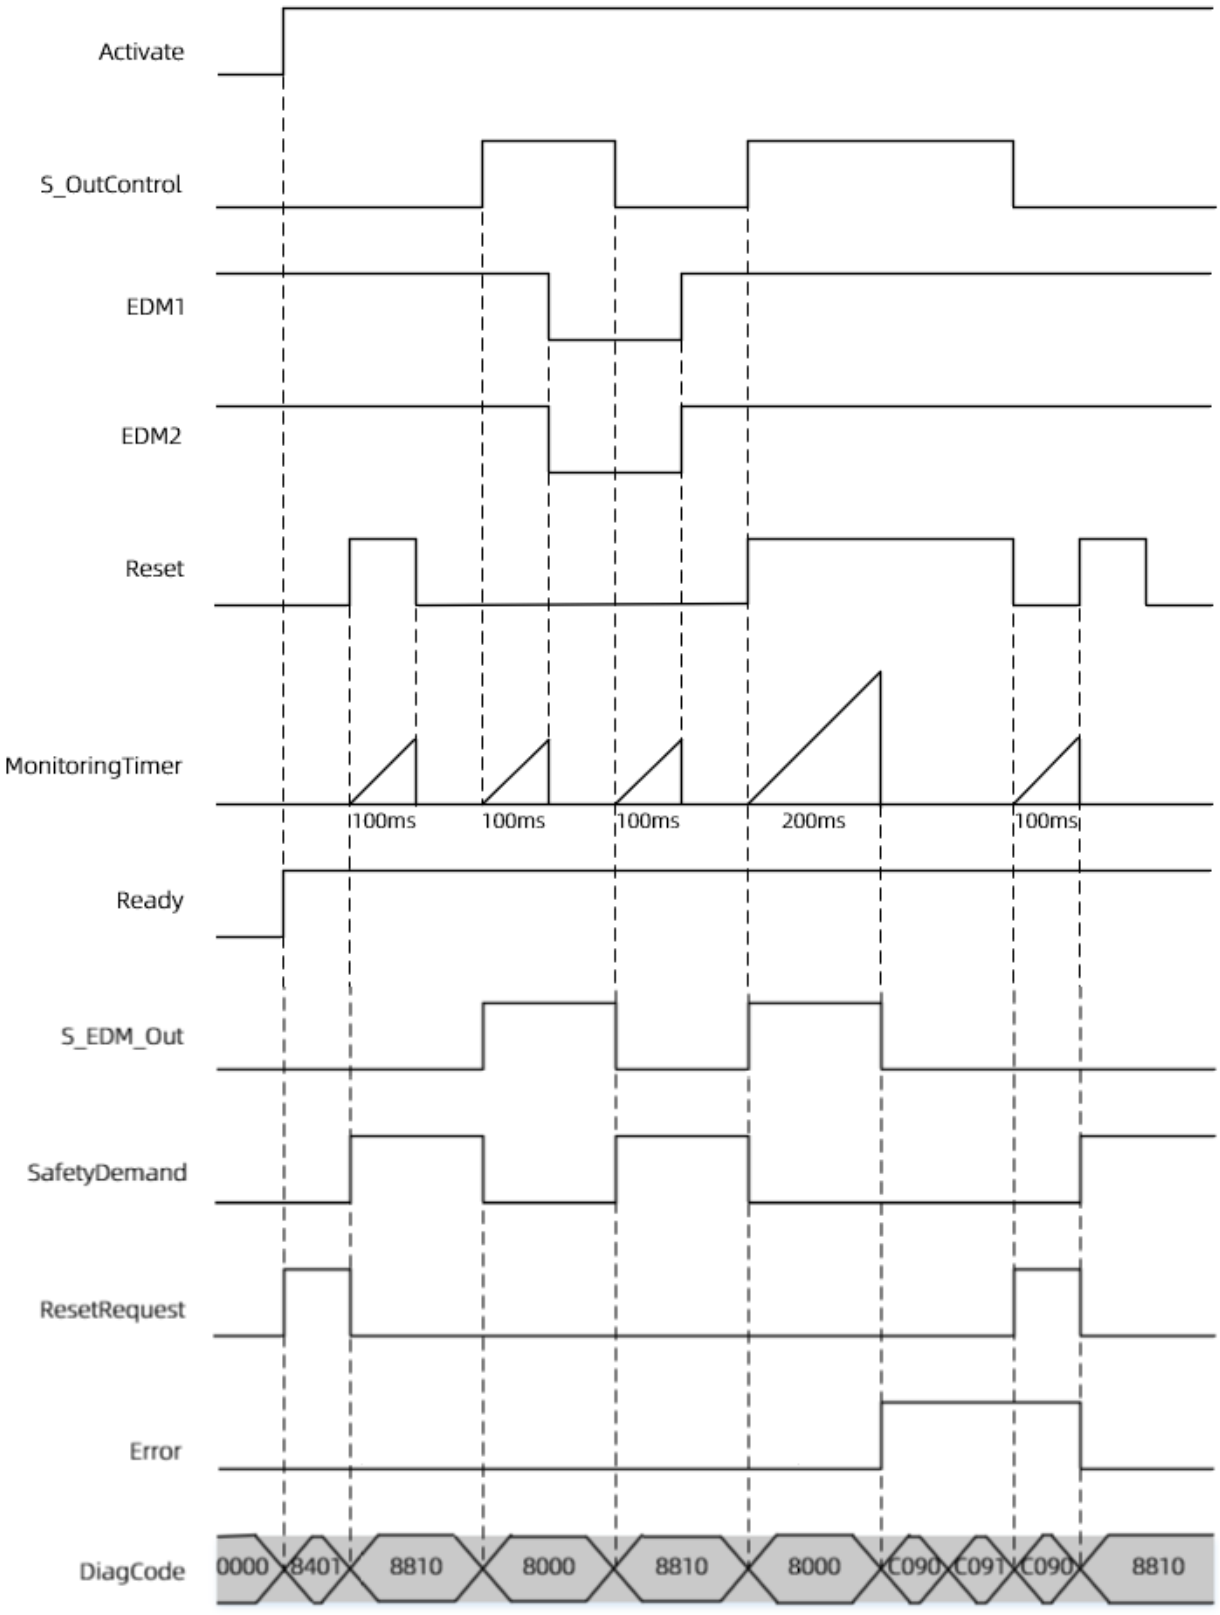
  Variables

Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
Input	Activate	BOOL	TRUE, FALSE	FALSE	Activates the instruction.
	S_OutControl	SAFEBOOL	TRUE, FALSE	FALSE	Control signal from other instructions. (such as SF_OutControl, SF_TwoHandControlTypeII, etc.). FALSE: Disable safety output (S_EDM_Out). TRUE: Enable safety output (S_EDM_Out).
	EDM1	BOOL	TRUE, FALSE	FALSE	Feedback signal from the first connected actuator. FALSE: The first connected actuator is in switch status. TRUE: The first connected actuator is in initial status.
	EDM2	BOOL	TRUE, FALSE	FALSE	Feedback signal from the second connected actuator. FALSE: The second connected actuator is in switch status. TRUE: The second connected actuator is in initial status.
	MonitoringTime	TIME	Follows data type	#0ms	Maximum response time for monitoring the actuator.
	Reset	BOOL	TRUE, FALSE	FALSE	Manual reset

Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
Output	Ready	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is in ready status.
	S_EDM_Out	SAFEBOOL	TRUE, FALSE	FALSE	Safety output. FALSE: Disable the connected actuator. TRUE: Enable the connected actuator.
	SafetyDemand	BOOL	TRUE, FALSE	FALSE	Activates or maintains the status according to the instruction status.
	ResetRequest	BOOL	TRUE, FALSE	FALSE	Flag indicating whether a reset is required.
	Error	BOOL	TRUE, FALSE	FALSE	Faulty status
	DiagCode	WORD	Follows data type	16#0000	Status code: Indicates fault code when instruction fails; indicates instruction status when instruction is running.

- **Function description**
  - The SF_EDM function block is used to control safety outputs and monitor the status of controlled actuators. This function block monitors the initial status of the actuator before it is enabled through feedback signals (EDM1 and EDM2), ensuring the actuator is in a predefined safe position (e.g., valve closed or motor braked). If the feedback signal does not match the expected status during this phase (e.g., EDM1 = TRUE and EDM2 = FALSE), a fault is triggered.
  - After the function block activates the actuator, it continuously monitors the actuator's switching status within the time window specified by the MonitoringTime parameter. If the expected transition (e.g., from FALSE->TRUE) of EDM1/EDM2 is not detected within this time window, the actuator is deemed to have a motion failure, and a fault is reported.
  - Feedback signal configuration rules: For precise diagnosis mode, two independent feedback signals (EDM1 and EDM2 connected to different detection points) must be configured for each actuator. For simplified diagnosis mode, two actuators can share one feedback signal, which must be connected to both EDM1 and EDM2 (i.e., EDM1=EDM2). In this mode, the system can only detect overall abnormalities of the actuator group but cannot identify the specific faulty unit.
  - Switching devices used for safety functions shall be selected from the categories specified in risk analysis (EN ISO 13849-1).
- **Status transition diagram**

Note 2:
Condition for transition Cx10 (EDM Error 11) to C011 (Reset Error 21) and Cx40 (EDM Error 21) to C041 (Reset Error 31) :
(Reset AND NOT R_TRIG at Reset AND EDM1 AND EDM2) OR (R_TRIG at Reset AND R_TRIG at EDM1)



Condition for transition Cx20 (EDM Error 12) to C021 (Reset Error 22) and Cx50 (EDM Error 22) to C051 (Reset Error 32) :
(Reset AND NOT R_TRIG at Reset AND EDM1 AND EDM2) OR (R_TRIG at Reset AND R_TRIG at EDM2)

Condition for transition Cx30 (EDM Error 13) to C031 (Reset Error 23) and Cx60 (EDM Error 23) to C061 (Reset Error 33) :
(Reset AND NOT R_TRIG at Reset AND EDM1 AND EDM2) OR (R_TRIG at Reset AND R_TRIG at EDM1 AND R_TRIG at EDM2)

Figure 11-10-2-2-7-1 Status transition diagram for SF_EDM

- This diagram is referenced from the PLCopen specification, and the copyright belongs to the PLCopen organization.
- The transition from any status to the idle status when Activate = FALSE is not indicated, but the priority (0) for transitioning to the idle status is the highest.
- The transition condition from status 8810 to status 8000 is S_OutControl being TRUE; this condition implicitly includes S_OutControl being TRUE, and both EDM1 and EDM2 being TRUE.

- **Sequence diagram**

- **Fault detection**
  - Detects that a TRUE value of Reset is triggered at the non-rising edge.
  - Detects invalid EDM signal during the process.
  - Due to a programming fault, S_OutControl and Reset are incorrectly connected to each other.
- **Fault behavior**
  When a fault occurs, reset operation must be performed based on the fault code indicated by DiagCode, combined with the status transition diagram.

- **Function block-specific fault codes and status codes**
  - Fault code

DiagCode	Status Name	Description and Output
C001	Reset Error 1	In the 8401 status, a TRUE value of Reset is triggered at the non-rising edge. Ready = TRUE S_EDM_Out = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE
C011	Reset Error 21	In the C010 status, a TRUE value of Reset is triggered at the non-rising edge or both EDM1 and Reset are triggered at the rising edge simultaneously. Ready = TRUE S_EDM_Out = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE
C021	Reset Error 22	In the C020 status, a TRUE value of Reset is triggered at the non-rising edge or both EDM2 and Reset are triggered at the rising edge simultaneously. Ready = TRUE S_EDM_Out = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE
C031	Reset Error 23	In the C030 status, a TRUE value of Reset is triggered at the non-rising edge, or EDM1, EDM2, and Reset are all triggered at the rising edge simultaneously. Ready = TRUE S_EDM_Out = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE

DiagCode	Status Name	Description and Output
C041	Reset Error 31	In the C040 status, a TRUE value of Reset is triggered at the non-rising edge or both EDM1 and Reset are triggered at the rising edge simultaneously. Ready = TRUE S_EDM_Out = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE

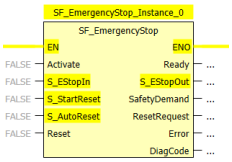
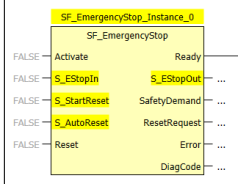
C010	EDM Error 11	EDM1 signal is invalid in the initial actuator status. In the 8810 status, when S_OutControl is enabled, EDM1 signal is FALSE and EDM2 signal is TRUE. Ready = TRUE S_EDM_Out = FALSE SafetyDemand = FALSE ResetRequest = R1 Error = TRUE
C020	EDM Error 12	EDM2 signal is invalid in the initial actuator status. In the 8810 status, when S_OutControl is enabled, EDM1 signal is TRUE and EDM2 signal is FALSE. Ready = TRUE S_EDM_Out = FALSE SafetyDemand = FALSE ResetRequest = R1 Error = TRUE

DiagCode	Status Name	Description and Output
C030	EDM Error 13	EDM1 and EDM2 signals are invalid in the initial actuator status. In the 8810 status, when S_OutControl is enabled, EDM1 and EDM2 signals are both FALSE. Ready = TRUE S_EDM_Out = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE
C040	EDM Error 21	EDM1 signal is invalid in the initial actuator status. In the 8810 status, the EDM1 signal is FALSE and exceeds the monitoring time. Ready = TRUE S_EDM_Out = FALSE SafetyDemand = FALSE ResetRequest = R1 Error = TRUE
C050	EDM Error 22	EDM2 signal is invalid in the initial actuator status. In the 8810 status, the EDM2 signal is FALSE and exceeds the monitoring time. Ready = TRUE S_EDM_Out = FALSE SafetyDemand = FALSE ResetRequest = R1 Error = TRUE
C060	EDM Error 23	EDM1 and EDM2 signals are invalid in the initial actuator status. In the 8810 status, the EDM1 and EDM2 signals are both FALSE and exceed the monitoring time. Ready = TRUE S_EDM_Out = FALSE SafetyDemand = FALSE ResetRequest = R1 Error = TRUE

DiagCode	Status Name	Description and Output
C070	EDM Error 31	EDM1 signal is invalid in the actuator switching status. In the 8000 status, the EDM1 signal is TRUE, the EDM2 signal is FALSE and exceeds the monitoring time. Ready = TRUE S_EDM_Out = FALSE SafetyDemand = FALSE ResetRequest = NOT RESET Error = TRUE
C080	EDM Error 32	EDM2 signal is invalid in the actuator switching status. In the 8000 status, the EDM2 signal is TRUE, the EDM1 signal is FALSE and exceeds the monitoring time. Ready = TRUE S_EDM_Out = FALSE SafetyDemand = FALSE ResetRequest = NOT RESET Error = TRUE
C090	EDM Error 33	EDM1 and EDM2 signals are invalid in the actuator switching status. In the 8000 status, the EDM1 and EDM2 signals are both TRUE and exceed the monitoring time. Ready = TRUE S_EDM_Out = FALSE SafetyDemand = FALSE ResetRequest = NOT RESET Error = TRUE
C100	Init Error	S_OutControl and Reset are both triggered at the rising edge at the same time. Ready = TRUE S_EDM_Out = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE





◦ Status code

DiagCode	Status Name	Description and Output
0000	Idle	Function block is not activated (initial status). Ready = FALSE S_EDM_Out = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = FALSE
8401	Init (Initialization)	When the function block is activated, start inhibit is in an activated status. Reset is required. Ready = TRUE S_EDM_Out = FALSE SafetyDemand = FALSE ResetRequest = TRUE Error = FALSE
8810	Output Disable	EDM control is not activated. Start timer upon entering the status. Ready = TRUE S_EDM_Out = FALSE SafetyDemand = TRUE ResetRequest = FALSE Error = FALSE
8000	Output Enable	EDM control is activated. Start timer upon entering the status. Ready = TRUE S_EDM_Out = TRUE SafetyDemand = FALSE ResetRequest = FALSE Error = FALSE

11.10.2.2.8 SF_EmergencyStop

SF_EmergencyStop monitors the input of the emergency stop button.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_EmergencyStop	Emergency stop.	FB		

- **Related variables**

  Variables

Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
Input	Activate	BOOL	TRUE, FALSE	FALSE	Activates the instruction.
	S_EStopIn	SAFEBOOL	TRUE, FALSE	FALSE	Safety requirement input. FALSE: Request for safety-related response (e.g., emergency stop button being pressed). TRUE: No request for safety-related response (e.g., emergency stop button not pressed).
	S_StartReset	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether to start reset.
	S_AutoReset	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether to automatically reset.
	Reset	BOOL	TRUE, FALSE	FALSE	Manual reset
Output	Ready	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is in ready status.
	S_EStopOut	SAFEBOOL	TRUE, FALSE	FALSE	Output for safety-related response. FALSE: Safety output is disabled. A safety-related response is requested (e.g., emergency stop button pressed, reset required, or internal fault is active). TRUE: Safety output is enabled. No safety-related response is requested (e.g., emergency stop button not pressed, no internal fault is active).
	SafetyDemand	BOOL	TRUE, FALSE	FALSE	Activates or maintains the status according to the instruction status.
	ResetRequest	BOOL	TRUE, FALSE	FALSE	Flag indicating whether a reset is required.
	Error	BOOL	TRUE, FALSE	FALSE	Faulty status
	DiagCode	WORD	Follows data type	16#0000	Status code: Indicates fault code when instruction fails; indicates instruction status when instruction is running.

- **Function description**
  - The S_EStopOut enabling signal is immediately reset to FALSE when the S_EStopIn input is set to FALSE. The S_EStopOut enabling signal only returns to TRUE when S_EStopIn input is set to TRUE and a reset operation occurs. The enabling of the reset logic depends on the defined inputs S_StartReset, S_AutoReset, and Reset.
    - If S_AutoReset = TRUE, reset is automatically executed.
    - If S_AutoReset = FALSE, reset is executed by a rising edge trigger of the Reset input.
    - If S_StartReset = TRUE, reset is automatically executed when the PES (Programmable Electronic System) starts for the first time.
    - If S_StartReset = FALSE, reset is executed by a rising edge trigger of the Reset input.
  - The S_StartReset and S_AutoReset inputs can only be activated when it is ensured that PES startup does not cause a hazardous status.
  - The SF_EmergencyStop function block can be used to monitor single-channel or dual-channel emergency stop buttons. For example, in dual-channel applications, the SF_Equivalent function block can be used to detect whether contact synchronization exceeds limits. The category classification according to EN ISO 13849-1 depends on the actual end components used.
  - SF_EmergencyStop automatically detects the static TRUE status of the Reset signal. Other fault detection (such as open circuit and short circuit) relies on the dedicated hardware used.
- **Status transition diagram**

11.10.2.2.9 SF_EnableSwitch

SF_EnableSwitch evaluates the signals of the enable switch with three positions.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_EnableSwitch	Enable switch	FB		

- **Related variables**

  Variables

Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
Input	Activate	BOOL	TRUE, FALSE	FALSE	Activates the instruction.
	S_SafetyActive	SAFEBOOL	TRUE, FALSE	FALSE	Confirm safety mode (limiting operating speed, power, or range). FALSE: Safety mode is not activated. TRUE: Safety mode is activated.
	S_EnableSwitchCh1	SAFEBOOL	TRUE, FALSE	FALSE	Signal connected to the E1 and E2 contacts of the enable switch. FALSE: The connected switch is open. TRUE: The connected switch is closed.
	S_EnableSwitchCh2	SAFEBOOL	TRUE, FALSE	FALSE	Signal connected to the E3 and E4 contacts of the enable switch. FALSE: The connected switch is open. TRUE: The connected switch is closed.
	S_AutoReset	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether to automatically reset.
	Reset	BOOL	TRUE, FALSE	FALSE	Manual reset
Output	Ready	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is in ready status.
	S_EnableSwitchOut	SAFEBOOL	TRUE, FALSE	FALSE	Safety-related output indicating whether the safety protection function is paused. FALSE: The safety protection function fails to be paused. TRUE: The safety protection function is paused.
	SafetyDemand	BOOL	TRUE, FALSE	FALSE	Activates or maintains the status according to the instruction status.
	ResetRequest	BOOL	TRUE, FALSE	FALSE	Flag indicating whether a reset is required.

Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
	Error	BOOL	TRUE, FALSE	FALSE	Faulty status
	DiagCode	WORD	Follows data type	16#0000	Status code: Indicates fault code when instruction fails; indicates instruction status when instruction is running.

- **Function description**
  - The SF_EnableSwitch function block supports pausing safety protective function (DIN EN 60204 section 9.2.4) via an enable switch (DIN EN 60204 section 9.2.5.8), provided that the relevant operating mode has been selected and activated. The relevant operating mode (limiting operating speed, power, or range) must be selected outside the SF_EnableSwitch function block.
  - The SF_EnableSwitch function block evaluates the signals of the three-position enable switch conforming to DIN EN 60204 section 9.2.5.8. Input parameters S_EnableSwitchCh1 and S_EnableSwitchCh2 are used to process signal levels from contacts E1 to E4, as shown below.

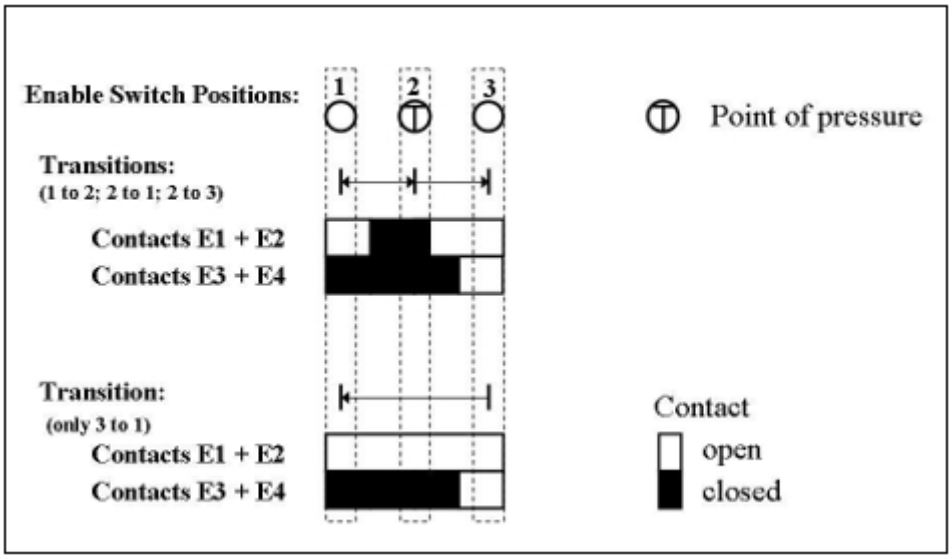

Figure 11-10-2-2-9-1 Switch position

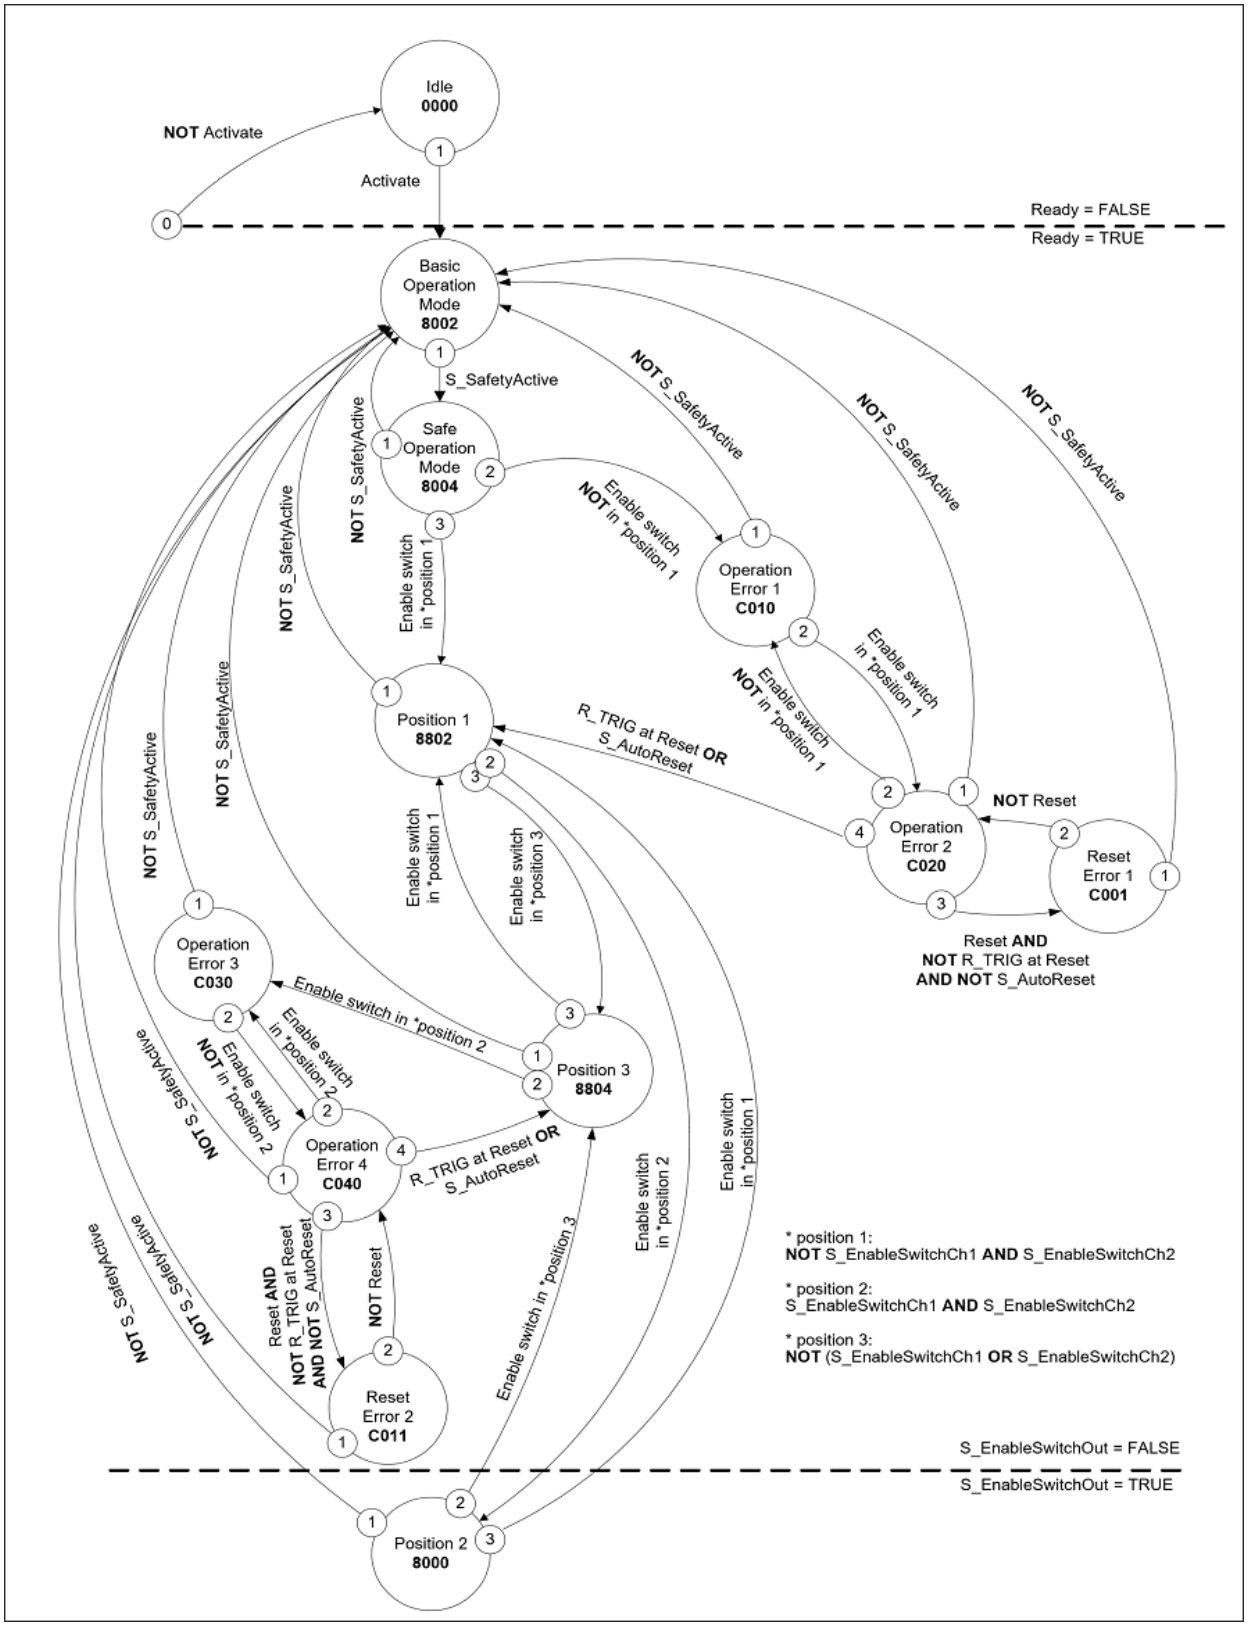
  - Signals E1 and E2 must be connected to parameter S_EnableSwitchCh1; signals E3 and E4 must be connected to parameter S_EnableSwitchCh2. The function block detects the enable switch position status through this signal sequence.
  - The transition from position 2 to position 3 may differ from the method described here. The function block can detect the switch direction (position 1 -> position 2/position 3 -> position 2) using predefined enable switch contact signal sequences. The safety protective function can be paused only when the enable switch transitions from position 1 to position 2; other transition directions or positions are invalid. This measure complies with requirement EN 60204 section 9.2.5.8.
  - To meet the requirements of DIN EN 60204 section 9.2.4, users must select a compliant switching device and ensure that the relevant operating mode is selected in the application (disable automatic operation in this mode by appropriate measures, which is in compliance with DIN EN 60204 section 9.2.3).
  - Operating modes are typically configured using the operating mode selector switch with the SF_ModeSelector function block and the SF_SafeRequest or SF_SafelyLimitedSpeed function blocks.

The SF_EnableSwitch function block confirms the safety mode status via the S_SafetyActive parameter. If the safety mode is not confirmed in the application, a static TRUE signal must be connected to the S_SafetyActive parameter.

- The S_AutoReset input can only be activated when it is ensured that the PES startup will not cause a hazardous status.

- **Status transition diagram**



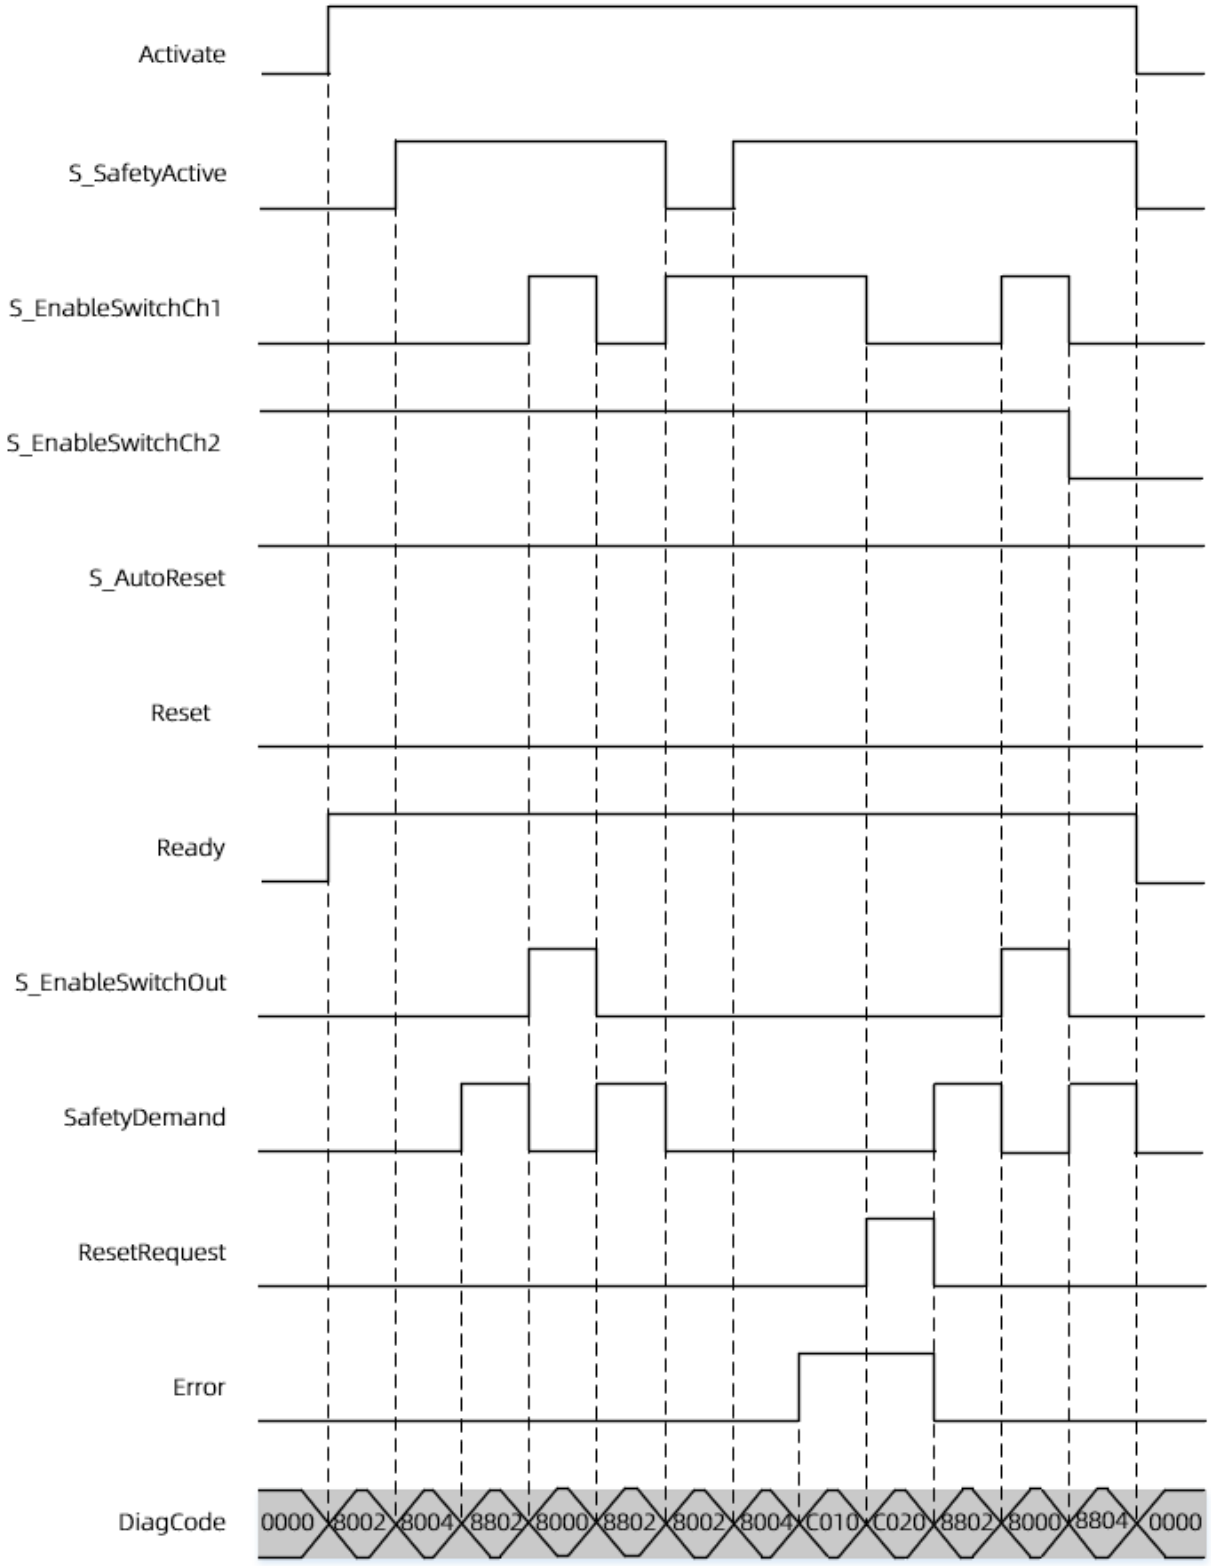


Figure 11-10-2-2-9-2 Status transition diagram for SF_EnableSwitch

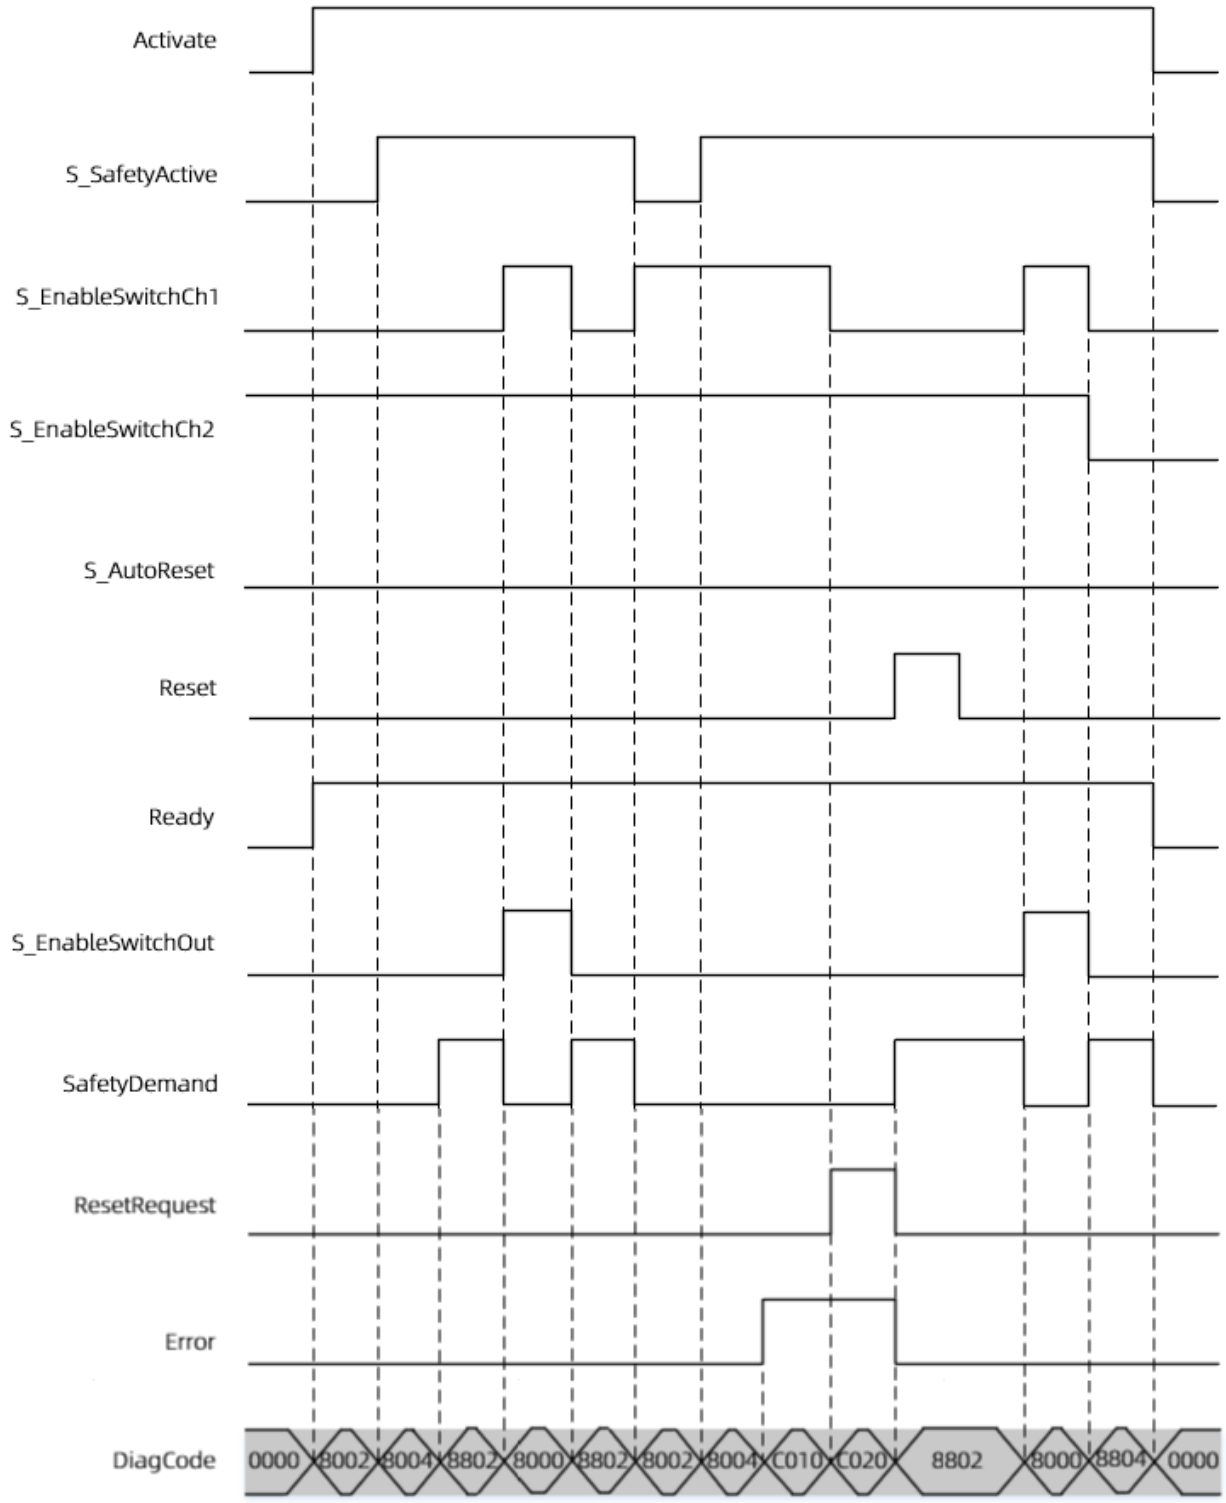

- This diagram is referenced from the PLCopen specification, and the copyright belongs to the PLCopen organization.
- The transition from any status to the idle status when Activate = FALSE is not indicated, but the priority (0) for transitioning to the idle status is the highest.

- **Sequence diagram**

  S_AutoReset = TRUE

S_AutoReset = FALSE

- **Fault detection**

  The faulty status is triggered by the following conditions:

  - Detects that a TRUE value of Reset is triggered at the non-rising edge.
  - The switch position is invalid.

- **Fault behavior**

  - When a fault occurs, the S_EnableSwitchOut safety output is set to FALSE and remains in this safety status. Unlike other function blocks, the faulty status can be cleared by setting Reset to FALSE, or on this basis, by setting S_SafetyActive to FALSE.

- After the fault is cleared, the enable switch must be in the initial position specified by the process flow before the S_EnableSwitchOut output can be set to TRUE via the enable switch. If S_AutoReset = FALSE, a TRUE value of Reset shall be triggered at the rising edge.

- **Function block-specific fault codes and status codes**
  - Fault code

DiagCode	Status Name	Description and Output

11.10.2.2.10 SF_Equivalent

SF_Equivalent monitors the discrepancy time between two equal safety input values.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_Equivalent	Equivalent input	FB		

- **Related variables**

  Variables

Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
Input	Activate	BOOL	TRUE, FALSE	FALSE	Activates the instruction.

Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
	S_ChannelA	SAFEBOOL	TRUE, FALSE	FALSE	Input A of the logical connection. FALSE: Contactor A is open. TRUE: Contactor A is closed.
	S_ChannelB	SAFEBOOL	TRUE, FALSE	FALSE	Input B of the logical connection. FALSE: Contactor B is open. TRUE: Contactor B is closed.
	DiscrepancyTime	TIME	Follows data type	T#0ms	Used to set the maximum discrepancy time between the two input statuses.
Output	Ready	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is in ready status.
	S_EquivalentOut	SAFEBOOL	TRUE, FALSE	FALSE	Safety-related output FALSE: At least one input signal is FALSE or the status change exceeds the monitoring time. TRUE: Both input signals are activated and the status change is within the monitoring time.
	SafetyDemand	BOOL	TRUE, FALSE	FALSE	Activates or maintains the status according to the instruction status.
	Error	BOOL	TRUE, FALSE	FALSE	Faulty status
	DiagCode	WORD	Follows data type	16#0000	Status code: Indicates fault code when instruction fails; indicates instruction status when instruction is running.

- **Function description**
  - This function block converts two equivalent SAFEBOOL inputs into a SAFEBOOL output with discrepancy time monitoring. Input channels A and B are interdependent. The function block output displays the evaluation result of both channels. If the signal of either channel changes from TRUE to FALSE, the output will be immediately shut down (FALSE) for safety reasons.
  - Discrepancy time monitoring: The discrepancy time is the maximum duration during which the two inputs are allowed to remain in different statuses without triggering the function block's fault detection. Discrepancy time monitoring starts immediately whenever the status of either input changes. If the two inputs have not reached the same status by the end of the monitoring, the function block detects a fault.

◦ Inputs must switch symmetrically. This means the monitoring process applies to both the turn-on (switching to TRUE) and turn-off (switching to FALSE) operations of the input signals.

8806	From Active Wait	A channel is switched to FALSE and is waiting for the second channel to be switched to FALSE. Discrepancy timer is started. Ready = TRUE S_EquivalentOut = FALSE SafetyDemand = TRUE Error = FALSE

11.10.2.2.11 SF_ESPE

SF_ESPE monitors the electrically sensitive protective equipment (ESPE).

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_ESPE	Electrically sensitive protective equipment	FB		

- **Related variables**

  Variables

Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
Input	Activate	BOOL	TRUE, FALSE	FALSE	Activates the instruction.
	S_ESPE_In	SAFEBOOL	TRUE, FALSE	FALSE	Safety request input. FALSE: Safety mode is not activated. TRUE: Safety mode is activated.

Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
	S_StartReset	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether to start reset.
	S_AutoReset	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether to automatically reset.
	Reset	BOOL	TRUE, FALSE	FALSE	Manual reset
Output	Ready	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is in ready status.
	S_ESPE_Out	SAFEBOOL	TRUE, FALSE	FALSE	Output for safety-related response. FALSE: Safety output is disabled. Safety-related response is required (e.g., reset is required or internal fault is active). TRUE: Safety output is enabled. No safety-related response is required.
	SafetyDemand	BOOL	TRUE, FALSE	FALSE	Activates or maintains the status according to the instruction status.
	ResetRequest	BOOL	TRUE, FALSE	FALSE	Flag indicating whether a reset is required.
	Error	BOOL	TRUE, FALSE	FALSE	Faulty status
	DiagCode	WORD	Follows data type	16#0000	Status code: Indicates fault code when instruction fails; indicates instruction status when instruction is running.

- **Function description**
  - This function block is used to monitor the electrical sensitive protective equipment (ESPE), and its function is identical to SF_EmergencyStop. When the S_ESPE_In input is set to FALSE, the S_ESPE_Out output signal is immediately set to FALSE. The S_ESPE_Out output signal is set to TRUE only when the S_ESPE_In input is set to TRUE and a reset is performed. The enabling of the reset depends on the defined inputs S_StartReset, S_AutoReset and Reset.
    - If S_AutoReset = TRUE, reset is automatically executed.
    - If S_AutoReset = FALSE, reset is executed by a rising edge trigger of the Reset input.
    - If S_StartReset = TRUE, reset is automatically executed when the PES (Programmable Electronic System) starts for the first time.
    - If S_StartReset = FALSE, reset is executed by a rising edge trigger of the Reset input.
  - The S_StartReset and S_AutoReset inputs can only be activated when it is ensured that PES startup does not cause a hazardous status.
  - ESPE selection must comply with EN IEC 61496-1, -2, and -3 standards, and the corresponding category must be determined according to EN 954-1 requirements.
- **Status transition diagram**

This diagram is referenced from the PLCopen specification, and the copyright belongs to the PLCopen organization.

- **Sequence diagram**

  S_StartReset=FALSE, S_AutoReset=FALSE

S_StartReset=TRUE, S_AutoReset=FALSE

S_StartReset=FALSE, S_AutoReset=TRUE

- **Fault detection**

  Detects that a TRUE value of Reset is triggered at the non-rising edge.

- **Fault behavior**

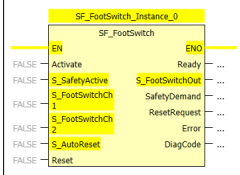
  S_ESPE_Out is set to FALSE. When the Reset input is a static TRUE signal, the DiagCode output indicates the corresponding fault code, and the Error output is set to TRUE.

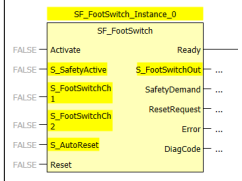
  To exit the faulty status, Reset must be set to FALSE.

- **Function block-specific fault codes and status codes**
  - Fault code

DiagCode	Status Name	Description and Output
C001	Reset Error 1	Reset is TRUE while waiting for S_ESPE_In = TRUE. Ready = TRUE S_ESPE_Out = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE
C011	Reset Error 2	Reset is TRUE while waiting for S_ESPE_In = TRUE. Ready = TRUE S_ESPE_Out = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE

  - Status code





DiagCode	Status Name	Description and Output
0000	Idle	Function block is not activated (initial status). Ready = FALSE S_ESPE_Out = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = FALSE
8001	Init (Initialization)	Function block is enabled, Check if S_StartReset is required. Ready = TRUE S_ESPE_Out = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = FALSE

DiagCode	Status Name	Description and Output
8802	Wait for S_ESPE_In 1	Check whether Reset is FALSE and wait for S_ESPE_In = TRUE. Ready = TRUE S_ESPE_Out = FALSE SafetyDemand = TRUE ResetRequest = FALSE Error = FALSE
8402	Wait for Reset 1	S_ESPE_In = TRUE. Wait for the rising edge of Reset. Ready = TRUE S_ESPE_Out = FALSE SafetyDemand = FALSE ResetRequest = NOT Reset Error = FALSE
8804	Wait for S_ESPE_In 2	The function block detected a safety request. Check whether Reset is FALSE and wait for S_ESPE_In = TRUE. Ready = TRUE S_ESPE_Out = FALSE SafetyDemand = TRUE ResetRequest = FALSE Error = FALSE
8404	Wait for Reset 2	S_ESPE_In = TRUE. Check S_AutoReset or wait for the rising edge trigger of Reset. Ready = TRUE S_ESPE_Out = FALSE SafetyDemand = FALSE ResetRequest = NOT Reset Error = FALSE
8000	Safety Output Enabled	S_ESPE_In = TRUE. In function mode, S_ESPE_Out = TRUE. Ready = TRUE S_ESPE_Out = TRUE SafetyDemand = FALSE ResetRequest = FALSE Error = FALSE

11.10.2.2.12 SF_FootSwitch

SF_FootSwitch evaluates the signals of a foot switch with three positions.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_FootSwitch	Foot switch	FB		

- **Related variables**

Variables

Input / Output	Variable	Data Type	Valid Range	Default Value	Description
Input	Activate	BOOL	TRUE, FALSE	FALSE	Activates the instruction.
	S_SafetyActive	SAFEBOOL	TRUE, FALSE	FALSE	Confirm safety mode (limiting operating speed, power, or range). FALSE: Safety mode is not activated. TRUE: Safety mode is activated.
	S_FootSwitchCh1	SAFEBOOL	TRUE, FALSE	FALSE	Signal connected to the E1 and E2 contacts of the foot switch. FALSE: The connected switch is open. TRUE: The connected switch is closed.
	S_FootSwitchCh2	SAFEBOOL	TRUE, FALSE	FALSE	Signal connected to the E3 and E4 contacts of the foot switch. FALSE: The connected switch is open. TRUE: The connected switch is closed.
	S_AutoReset	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether to automatically reset.
	Reset	BOOL	TRUE, FALSE	FALSE	Manual reset
Output	Ready	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is in ready status.
	S_FootSwitchOut	SAFEBOOL	TRUE, FALSE	FALSE	Safety-related output indicating whether the safety protection function is paused. FALSE: The safety protection function fails to be paused. TRUE: The safety protection function is paused.

Input / Output	Variable	Data Type	Valid Range	Default Value	Description
	SafetyDemand	BOOL	TRUE, FALSE	FALSE	Activates or maintains the status according to the instruction status.
	ResetRequest	BOOL	TRUE, FALSE	FALSE	Flag indicating whether a reset is required.
	Error	BOOL	TRUE, FALSE	FALSE	Faulty status
	DiagCode	WORD	Follows data type	16#0000	Status code: Indicates fault code when instruction fails; indicates instruction status when instruction is running.

- **Function description**
  - The SF_FootSwitch function block supports pausing safety protection (DIN EN 60204 section 9.2.4) via a foot switch (DIN EN 60204 section 9.2.5.8), provided that the relevant operating mode has been selected and activated. The relevant operating mode (limiting operating speed, power, or range) must be selected outside the SF_FootSwitch function block.
  - The SF_FootSwitch function block evaluates the signals of a foot switch with three positions (DIN EN 60204 section 9.2.5.8).

    Input parameters S_FootSwitchCh1 and S_FootSwitchCh2 are used to process signal levels from contacts E1 to E4, as shown below.

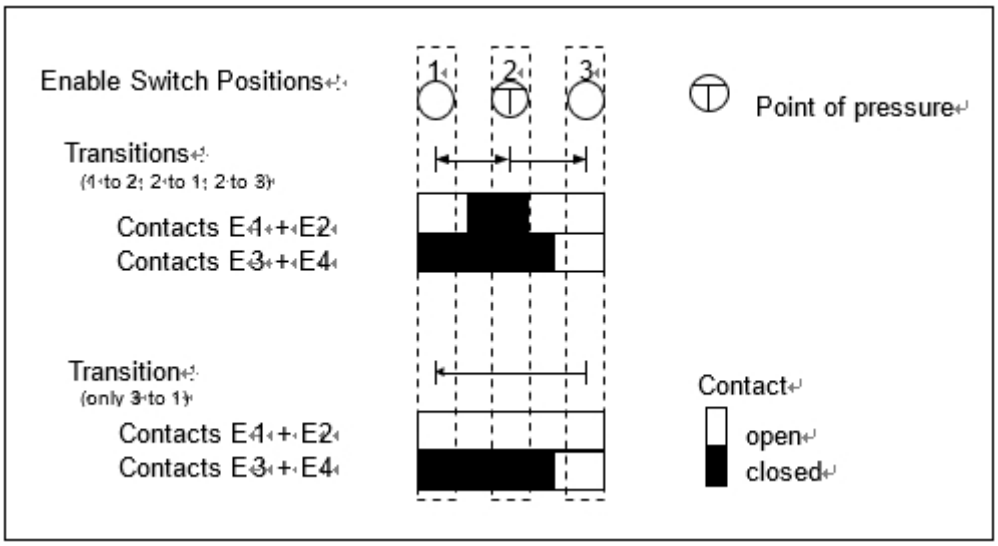


Figure 11-10-2-2-12-1 Switch position

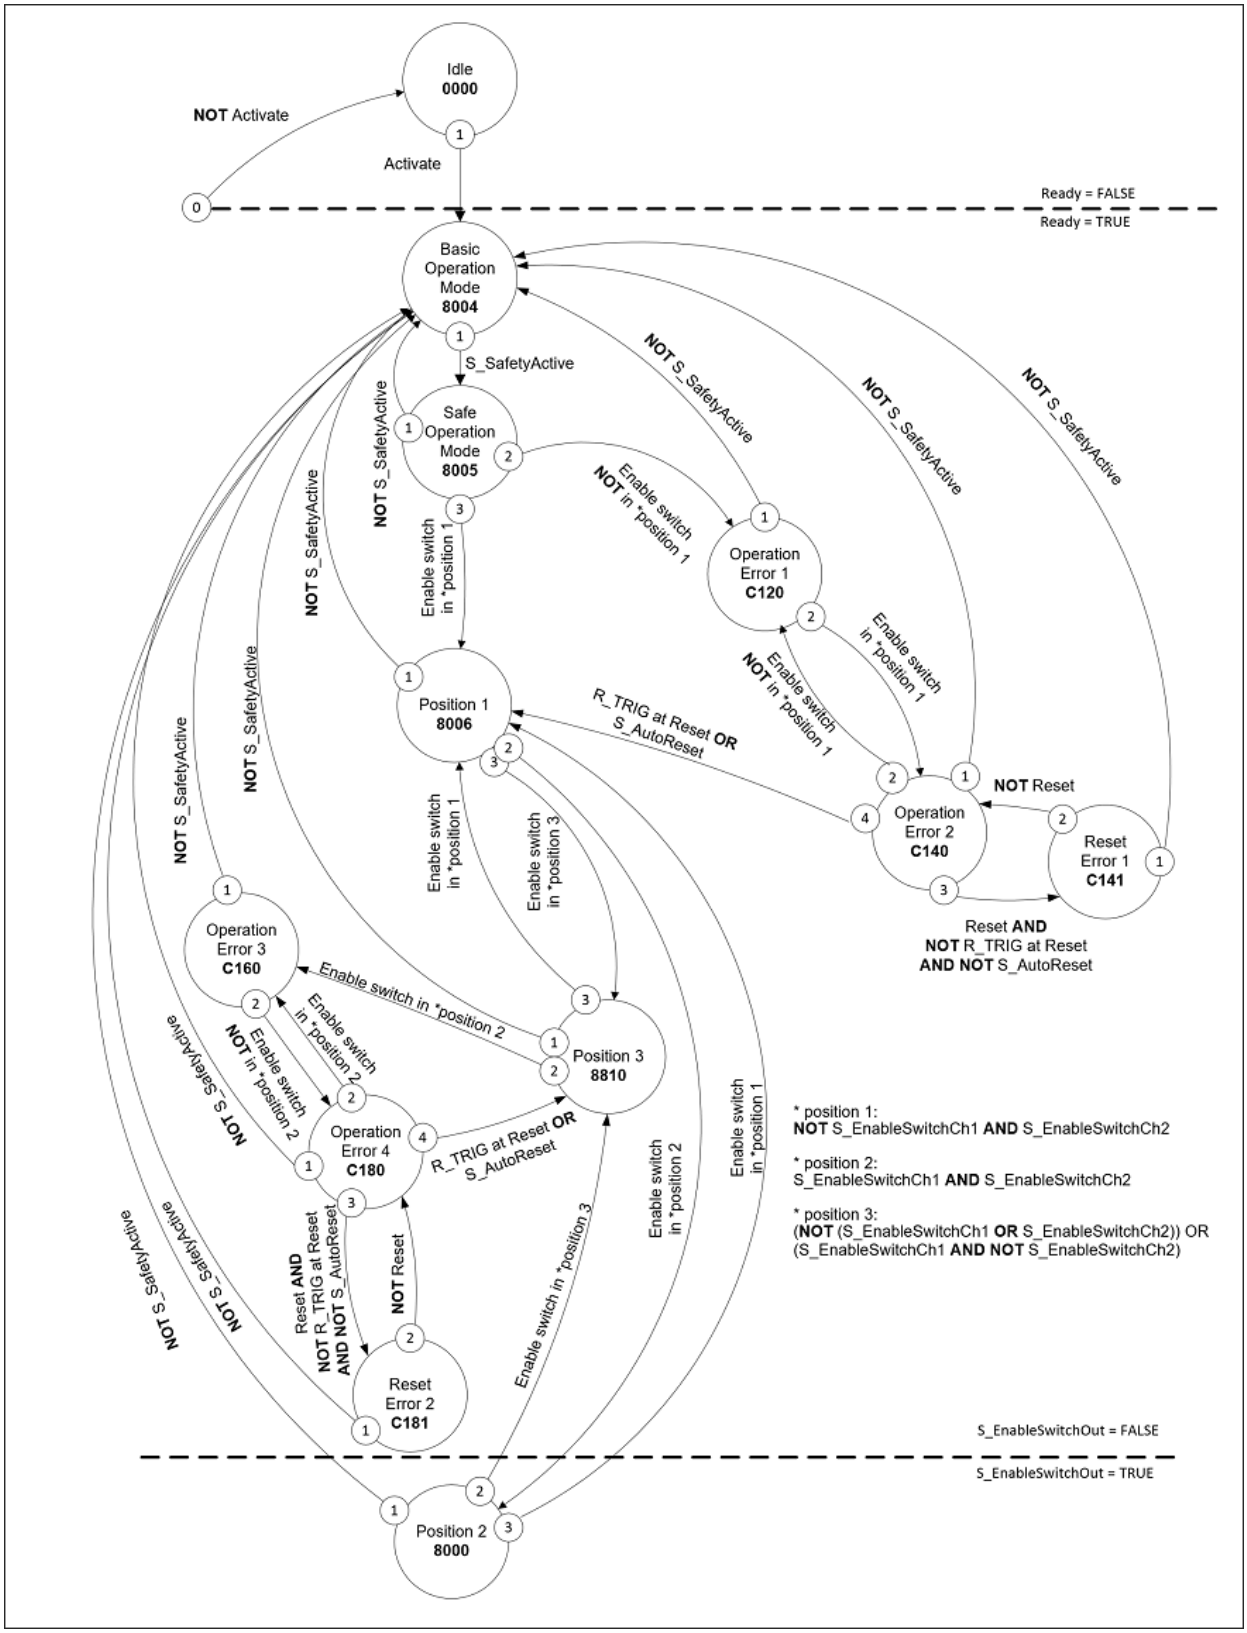
  - Signals E1 and E2 must be connected to parameter S_FootSwitchCh1. Signals E3 and E4 must be connected to parameter S_FootSwitchCh2. The foot switch position is detected by the function block based on the time sequence of signals. However, the transition from position 2 to 3 may differ from this diagram.
  - The function block can detect the switch transition (position 1 -> position 2/position 3 -> position 2) using predefined foot switch contact signal sequences. The safety protective function can only be paused when the foot switch transitions from position 1 to position 2. Other transition directions or switch positions cannot be used to pause the safety protective function. This measure complies with requirement 9.2.5.8 of EN 60204.

- To meet the requirements of section 9.2.4 of DIN EN 60204, users shall use appropriate switch devices. Additionally, users must ensure that the relevant operating mode is selected in the application (section 9.2.3 of DIN EN 60204) (in this operating mode, automatic operation must be disabled by appropriate measures).
- The operating mode is typically switched to a safety status using instructions such as SF_ModeSelector and SF_SafetyRequest.
- The SF_EnableSwitch function block confirms the safety mode through S_SafetyActive. If the safety mode is not confirmed before implementation, S_SafetyActive will be TRUE.
- Input S_AutoReset shall only be activated when it is ensured that no hazardous situation will occur during PES startup.

- **Status transition diagram**



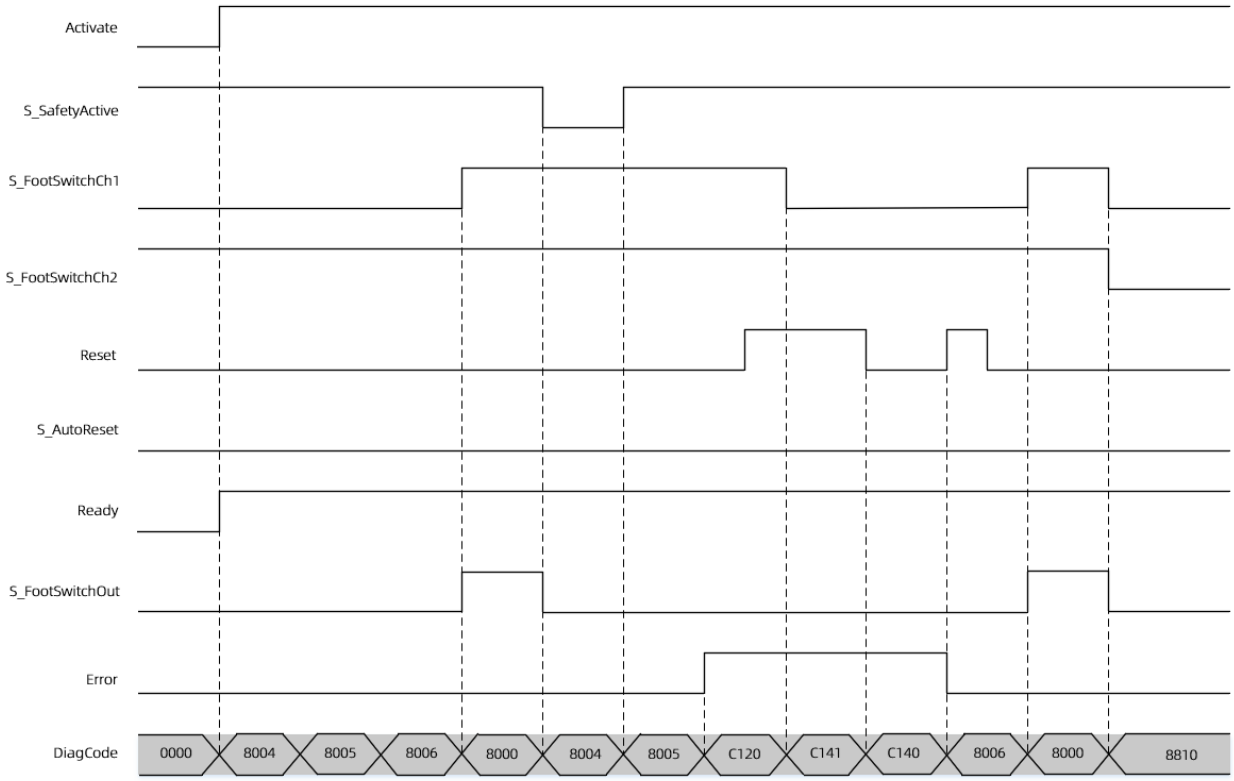


Figure 11-10-2-2-12-2 Status transition diagram for SF_FootSwitch

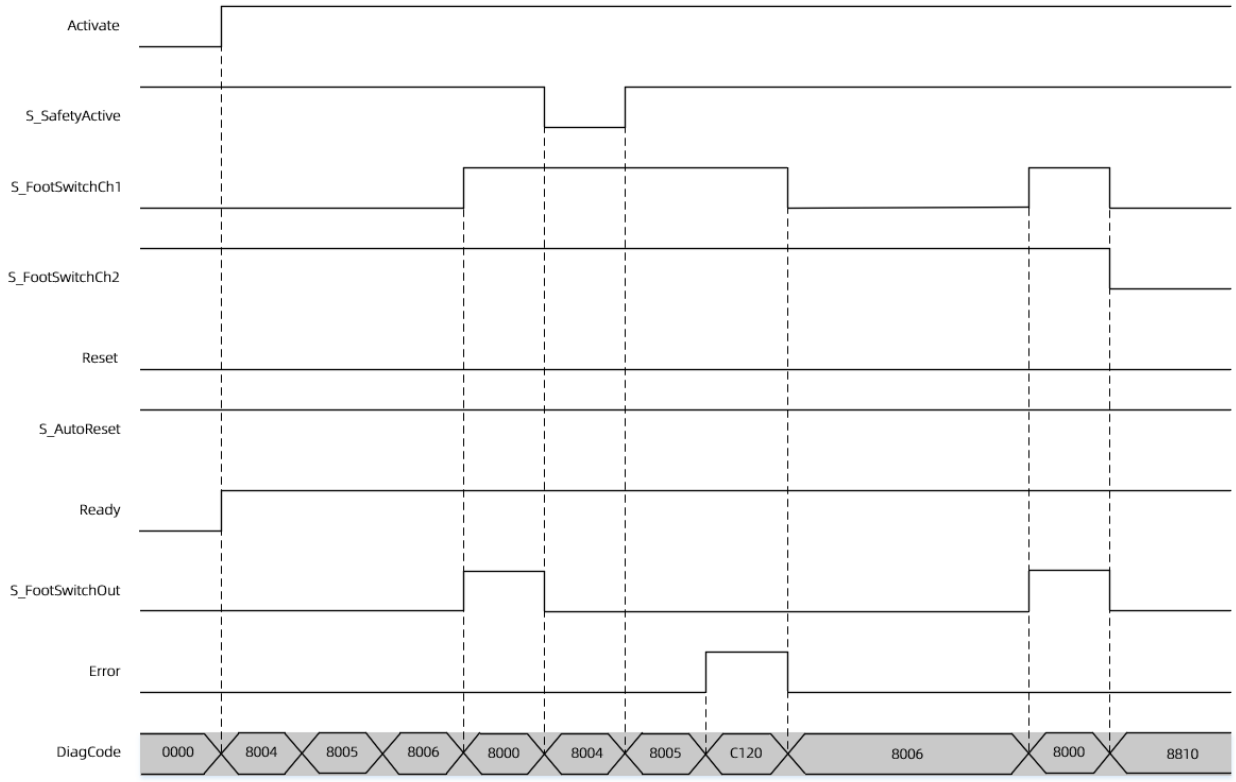

- This diagram is referenced from the PLCopen specification, and the copyright belongs to the PLCopen organization.
- The transition from any status to the idle status when Activate = FALSE is not indicated, but the priority (0) for transitioning to the idle status is the highest.

- **Sequence diagram**

  S_AutoReset = FALSE

S_AutoReset = TRUE

- **Fault detection**

  The faulty status is triggered by the following conditions:

  - Detects that a TRUE value of Reset is triggered at the non-rising edge.
  - The switch position is invalid.

- **Fault behavior**
  - When a fault occurs, the S_FootSwitchOut safety output is set to FALSE and remains in this status. Unlike other function blocks, the faulty status can be cleared by setting Reset to FALSE, or on this basis, by setting S_SafetyActive to FALSE.
  - After the fault is cleared, the valid switch must be set to the initial position defined in the process before the S_FootSwitchOut output can be set to TRUE via the foot switch.
  - If S_AutoReset = FALSE, a rising edge trigger on Reset is required.
- **Function block-specific fault codes and status codes**
  - Fault code

DiagCode	Status Name	Description and Output
C141	Reset Error 1	In the C140 status, a TRUE value of Reset is triggered at the non-rising edge. Ready = TRUE S_FootSwitchOut = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE
C181	Reset Error 2	In the C180 status, a TRUE value of Reset is triggered at the non-rising edge. Ready = TRUE S_FootSwitchOut = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE
C120	Operation Error 1	The foot switch is not in position 1 when S_SafetyActive is activated. Ready = TRUE S_FootSwitchOut = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE

DiagCode	Status Name	Description and Output
C140	Operation Error 2	The foot switch is in position 1 after status C120. Ready = TRUE S_FootSwitchOut = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE
C160	Operation Error 3	The foot switch is in position 2 after position 3. Ready = TRUE S_FootSwitchOut = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE

8000	Position 2	The safety operation mode is activated and the foot switch is in position 2. Ready = TRUE S_FootSwitchOut = TRUE SafetyDemand = TRUE ResetRequest = FALSE Error = FALSE

11.10.2.2.13 SF_Guard

SF_Guard monitors safety-related guard devices. It is equipped with two independent input parameters corresponding to the two switches on the guard device, and includes a discrepancy time (DiscrepancyTime) setting for disabling the guard device.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_Guard	Monitoring of safety-related protective devices	FB		

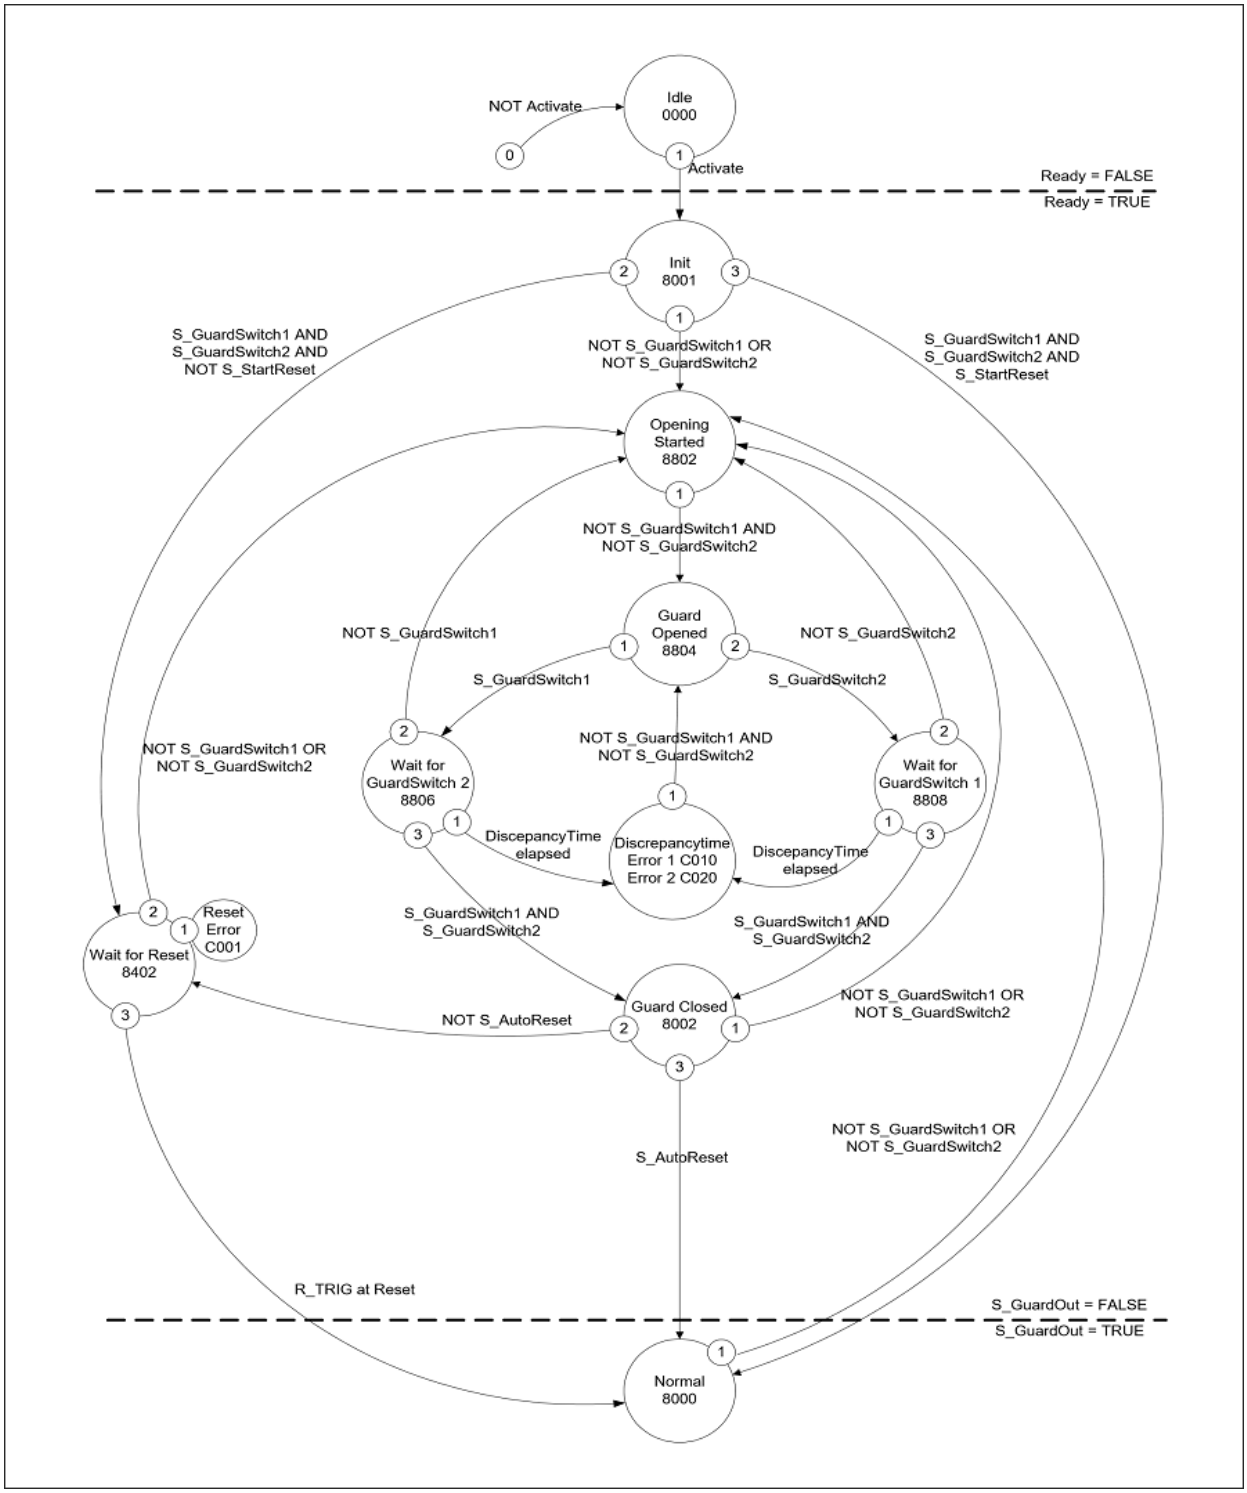
- **Related variables**

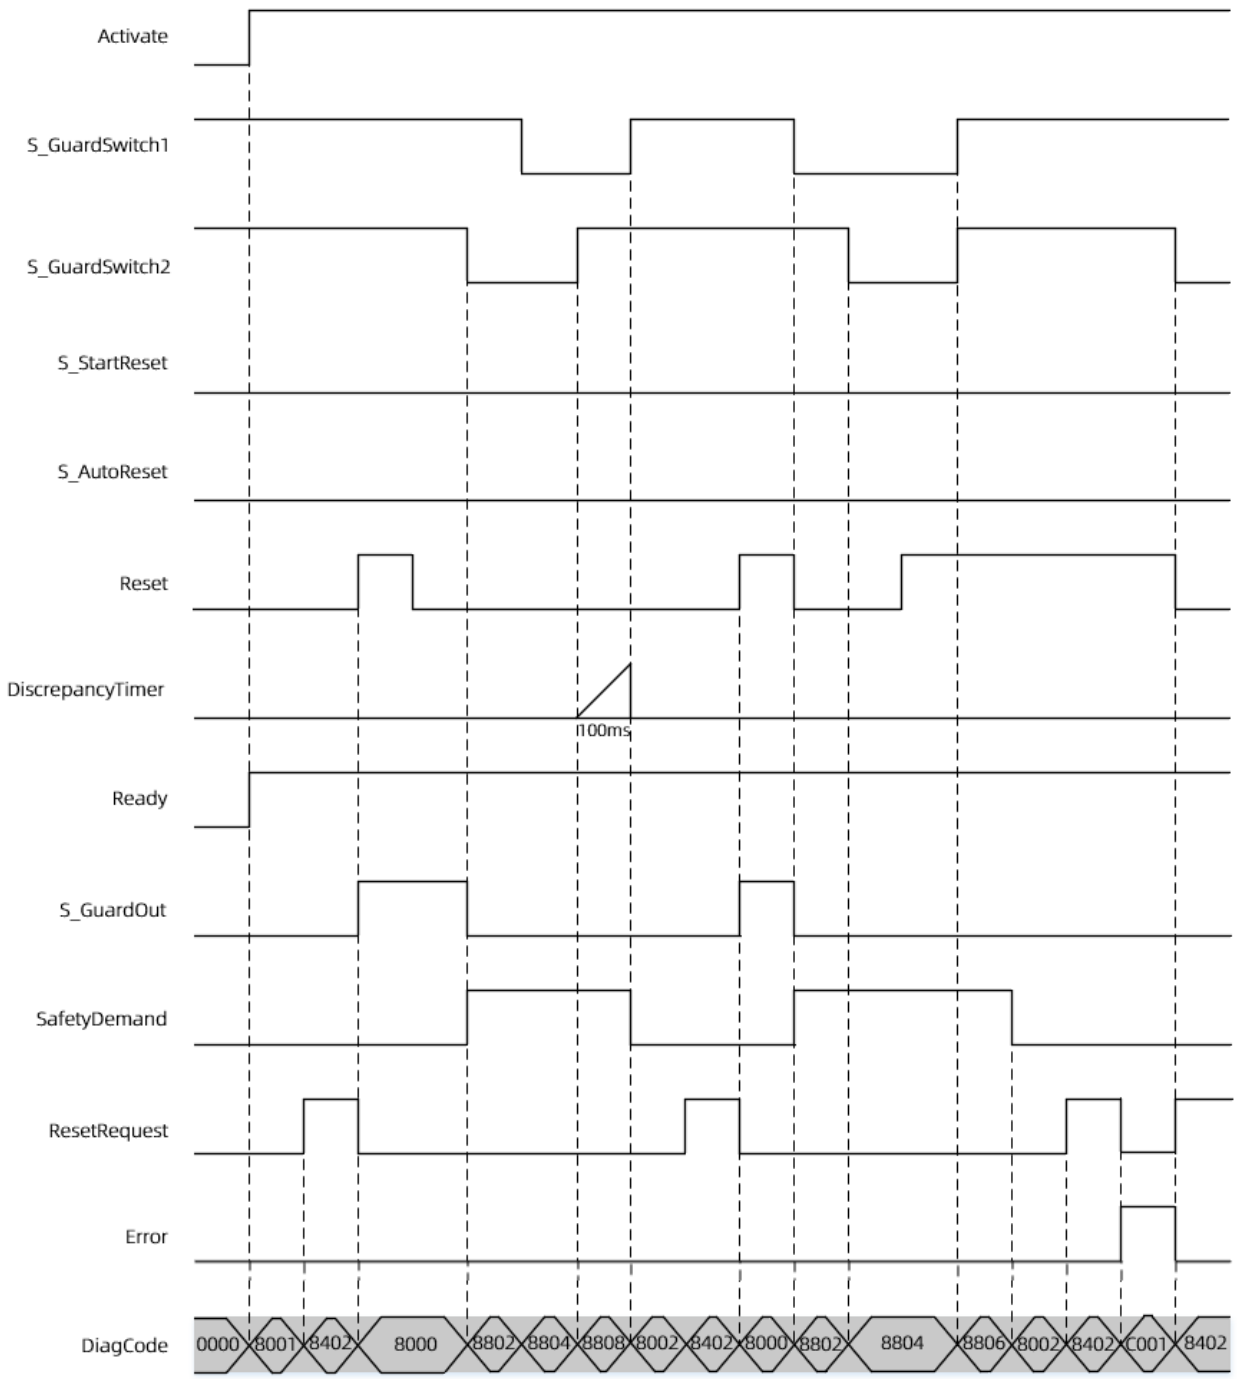
  Variables

Input / Output	Variable	Data Type	Valid Range	Default Value	Description
Input	Activate	BOOL	TRUE, FALSE	FALSE	Activates the instruction.
	S_GuardSwitch1	SAFEBOOL	TRUE, FALSE	FALSE	Protective switch 1 input. FALSE: The guard device is not disabled. TRUE: The guard device is disabled.
	S_GuardSwitch2	SAFEBOOL	TRUE, FALSE	FALSE	Protective switch 2 input. FALSE: The guard device is not disabled. TRUE: The guard device is disabled.
	DiscrepancyTime	TIME	Follows data type	T#0ms	Monitoring synchronization time between S_GuardSwitch1 and S_GuardSwitch2.
	S_StartReset	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether to start reset.
	S_AutoReset	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether to automatically reset.
	Reset	BOOL	TRUE, FALSE	FALSE	Manual reset
Output	Ready	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is in ready status.
	S_GuardOut	SAFEBOOL	TRUE, FALSE	FALSE	Output indicating that the guard device is disabled and the guarded area is safe. FALSE: The guard device is enabled. TRUE: Both S_GuardSwitch1 and S_GuardSwitch2 are TRUE, with no fault.
	SafetyDemand	BOOL	TRUE, FALSE	FALSE	Activates or maintains the status according to the instruction status.
	ResetRequest	BOOL	TRUE, FALSE	FALSE	Flag indicating whether a reset is required.

Input / Output	Variable	Data Type	Valid Range	Default Value	Description
	Error	BOOL	TRUE, FALSE	FALSE	Faulty status
	DiagCode	WORD	Follows data type	16#0000	Status code: Indicates fault code when instruction fails; indicates instruction status when instruction is running.

- **Function description**
  - This function block requires two input parameters to monitor the position of a safety guard device with two switches (in compliance with ISO 14119 standard), and includes a DiscrepancyTime input and a Reset input. If the safety guard device has only one switch, the S_GuardSwitch1 and S_GuardSwitch2 inputs can be bridged. Discrepancy time is the maximum time required for both switches to respond when disabling the safety guard device. Reset, S_StartReset, and S_AutoReset inputs are used to determine the reset method of the function block after the safety guard device is enabled.
    - When enabling the guard device: both S_GuardSwitch1 and S_GuardSwitch2 inputs should switch to FALSE. When either switch is set to FALSE, the S_GuardOut output immediately switches to FALSE.
    - When disabling the guard device: both S_GuardSwitch1 and S_GuardSwitch2 inputs should switch to TRUE.
  - This function block monitors the symmetry of the operations of the two switches: if only one contact completes the open/close process, the S_GuardOut output remains FALSE.
  - Relationship between the output behavior and discrepancy time:
    - When the input statuses of S_GuardSwitch1 and S_GuardSwitch2 input statuses are inconsistent, the discrepancy time monitoring is immediately initiated.
    - If the input remains inconsistent after the discrepancy time expires, the S_GuardOut output remains FALSE.
    - If the corresponding second input of S_GuardSwitch1/S_GuardSwitch2 switches to TRUE within the discrepancy time, the S_GuardOut output will be set to TRUE after verification.
  - Inputs S_StartReset and S_AutoReset can only be activated when it is ensured that the activation of the programmable electronic system (PES) will not cause hazardous conditions.
  - Set DiscrepancyTime to a value greater than the safety task cycle.
- **Status transition diagram**





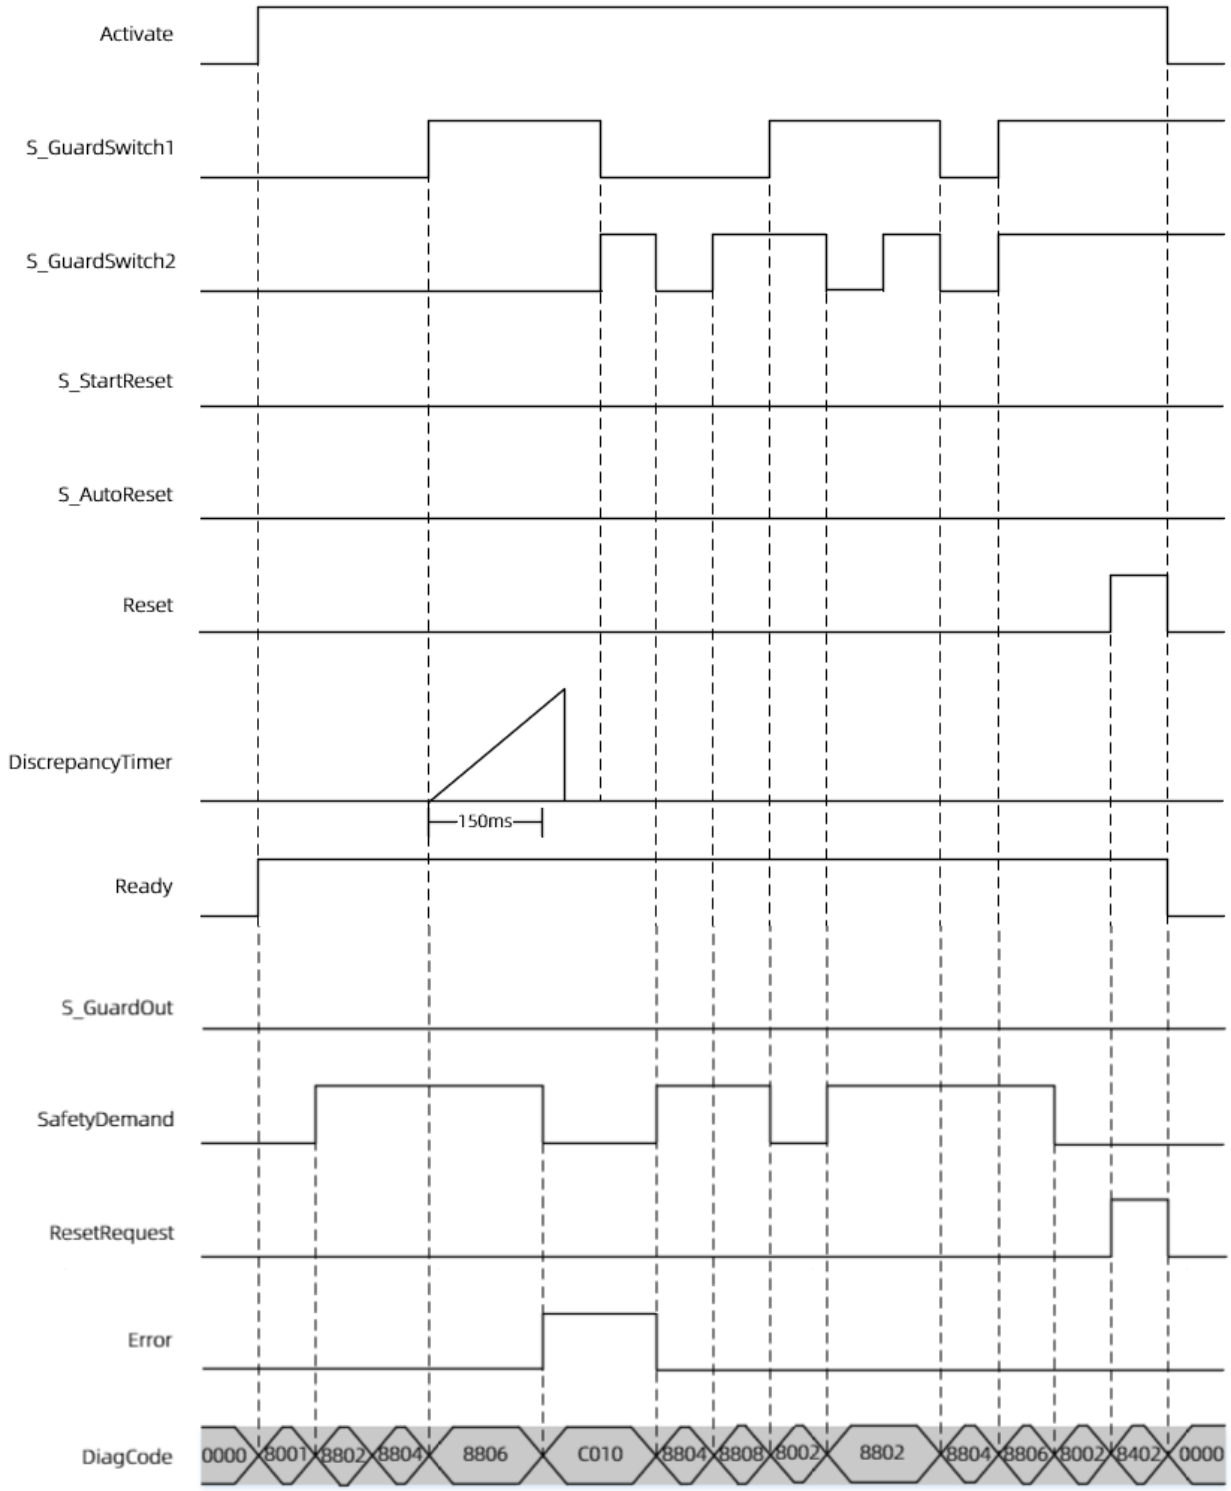


Figure 11-10-2-2-13-1 Status transition diagram for SF_Guard

- This diagram is referenced from the PLCopen specification, and the copyright belongs to the PLCopen organization.

- **Fault detection**
  - External signal characteristics: SAFEBOOL input possess inherent fault detection capability.
  - Mechanical configuration: Apply the mechanical combination of opening and closing switches according to EN 954 standard (safety guard devices with dual switches).
  - Discrepancy time monitoring: According to EN 954 standard, the time lag between the responses of two mechanical switches is monitored (considered as "application fault" detection, i.e., generated by the application). If the response time lag between the first S_GuardSwitch1/S_GuardSwitch2 input and the second input exceeds the value set by DiscrepancyTime, a fault is detected and the Error output is set to TRUE.
  - Static signal detection: The function block can detect a static TRUE signal at the RESET input.

- **Fault behavior**

  When a fault occurs, the S_GuardOut output is set to FALSE. If both S_GuardSwitch1 and S_GuardSwitch2 inputs are bridged, no fault will be detected.

  To exit the faulty status, Reset must be set to FALSE.

  To clear the discrepancy time fault, both S_GuardSwitch1 and S_GuardSwitch2 inputs must be set to FALSE.

- **Function block-specific fault codes and status codes**

  ◦ Fault code

DiagCode	Status Name	Description and Output
C001	Reset Error	In the 8402 status, a TRUE value of Reset is triggered at the non-rising edge. Ready = TRUE S_GuardOut = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE

11.10.2.2.14 SF_GuardLocking

SF_GuardLocking controls the access to the hazardous area using an interlocked guard device with a lock.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_GuardLocking	Safety door lock with interlock device	FB		

- **Related variables**

  Variables

Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
Input	Activate	BOOL	TRUE, FALSE	FALSE	Activates the instruction.
	S_Guard	SAFEBOOL	TRUE, FALSE	FALSE	Monitors the interlock of the guard device. FALSE: The guard device is enabled. TRUE: The guard device is disabled and the guarded area is safe.
	S_SafetyActive	SAFEBOOL	TRUE, FALSE	FALSE	Status of hazardous area (EDM), for example, based on speed monitoring or safety time delay. FALSE: Machine is in an unsafe status. TRUE: Machine is in a safety status.
	S_GuardLock	SAFEBOOL	TRUE, FALSE	FALSE	Status of the guard device lock. FALSE: The guard device is not locked. TRUE: The guard device is locked.
	UnlockRequest	BOOL	Follows data type	T#0ms	Operator intervention to request to unlock the guard device. FALSE: No request. TRUE: Unlock requested.
	S_StartReset	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether to start reset.
	S_AutoReset	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether to automatically reset.
	Reset	BOOL	TRUE, FALSE	FALSE	Manual reset
Output	Ready	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is in ready status.
	S_GuardLocked	SAFEBOOL	TRUE, FALSE	FALSE	Output for safety-related response. FALSE: Non-safety status. TRUE: Safety status.

Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
	S_UnlockGuard	SAFEBOOL	TRUE, FALSE	FALSE	Used to unlock the guard device. FALSE: Disable the guard device. TRUE: Unlock the guard device.
	SafetyDemand	BOOL	TRUE, FALSE	FALSE	Activates or maintains the status according to the instruction status.
	ResetRequest	BOOL	TRUE, FALSE	FALSE	Flag indicating whether a reset is required.
	Error	BOOL	TRUE, FALSE	FALSE	Faulty status
	DiagCode	WORD	Follows data type	16#0000	Status code: Indicates fault code when instruction fails; indicates instruction status when instruction is running.

- **Function description**
  - This function block controls the safety lock and monitors the guard device and lock position. It can also be used with mechanical lock switches.
  - When an operator requests access to a hazardous area, the safety device can only be unlocked when the hazardous area is in a safety status. The locking operation can be performed when the guard device is disabled. The machine can be started only when the guard device is disabled and locked. In safety-critical situations, a guard device that is not disabled or not locked will be detected.
  - Inputs S_StartReset and S_AutoReset can only be activated when it is ensured that the activation of the programmable electronic system (PES) will not cause hazardous conditions.

    Operation sequence:

1	Surface cleanness	Request to restore the hazardous area to a safety status – not performed within this function block.
2	Input	Feedback from the corresponding hazardous area in a safety status (via S_SafetyActive).
3	Input	Operator requests unlocking the protective device (via UnlockRequest).
4	Output	The protective device can be unlocked (via S_UnlockGuard).
5	Input	The protective device is unlocked (via S_GuardLock). The protective device can now be enabled (S_GuardLocked = FALSE).
6	Input	Monitor the guard device status via S_Guard signal when the guard device is disabled again.
7	Input	Restart the hazardous area (via Reset) according to the operator's feedback.
8	Output	Lock the protection (S_UnlockGuard).
9	Input	Check if protection is locked (S_GuardLock).
10	Output	Restore the hazardous area to operational status (S_GuardLocked = TRUE).

11	Surface cleanness	Restore operation in hazardous area.

- **Status transition diagram**

8010	Wait for Unlocked	S_UnlockGuard is TRUE, but the S_GuardLock input signal is still TRUE (waiting for S_GuardLock signal to become FALSE). Ready = TRUE S_GuardLocked = FALSE S_UnlockGuard = TRUE SafetyDemand = FALSE ResetRequest = FALSE Error = FALSE

11.10.2.2.15 SF_ModeSelector

SF_ModeSelector selects the system's operating mode (automatic, manual, semi-automatic, etc.).

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_ModeSelector	Mode selector	FB		

- **Related variables**

  Variables

Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
Input	Activate	BOOL	TRUE, FALSE	FALSE	Activates the instruction.
	S_Mode0	SAFEBOOL	TRUE, FALSE	FALSE	Input 0 of the mode selector switch. FALSE: Mode 0 is not requested. TRUE: Mode 0 is requested.
	S_Mode1	SAFEBOOL	TRUE, FALSE	FALSE	Input 1 of the mode selector switch. FALSE: Mode 1 is not requested. TRUE: Mode 1 is requested.

Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
	S_Mode2	SAFEBOOL	TRUE, FALSE	FALSE	Input 2 of mode selector switch. FALSE: Mode 2 is not requested. TRUE: Mode 2 is requested.
	S_Mode3	SAFEBOOL	TRUE, FALSE	FALSE	Input 3 of mode selector switch. FALSE: Mode 3 is not requested. TRUE: Mode 3 is requested.
	S_Mode4	SAFEBOOL	TRUE, FALSE	FALSE	Input 4 of mode selector switch. FALSE: Mode 4 is not requested. TRUE: Mode 4 is requested.
	S_Mode5	SAFEBOOL	TRUE, FALSE	FALSE	Input 5 of mode selector switch. FALSE: Mode 5 is not requested. TRUE: Mode 5 is requested.
	S_Mode6	SAFEBOOL	TRUE, FALSE	FALSE	Input 6 from mode selector switch. FALSE: Mode 6 is not requested. TRUE: Mode 6 is requested.
	S_Mode7	SAFEBOOL	TRUE, FALSE	FALSE	Input 7 from mode selector switch. FALSE: Mode 7 is not requested. TRUE: Mode 7 is requested.
	S_Unlock	SAFEBOOL	TRUE, FALSE	FALSE	Locks/unlocks the selected mode. FALSE: The actual "S_ModeXSel" output is locked, so even if the "S_ModeX" input changes due to a rising edge of "S_SetMode", the "S_ModeXSel" output will not change. TRUE: The selected "S_ModeXSel" output is not locked, and can be changed.

Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
	S_SetMode	SAFEBOOL	TRUE, FALSE	FALSE	When "AutoSetMode" is FALSE, S_SetMode changes the selected mode. TRUE: Select the mode by rising edge setting. FALSE: When "AutoSetMode" is TRUE, S_SetMode is set to FALSE. When the operator toggles the mode selector switch, "S_AnyModeSel" and "S_ModeXSel" become FALSE. Triggered by the rising edge of "S_SetMode", "S_ModeXSel" becomes TRUE, and the mode is changed accordingly.
	AutoSetMode	BOOL	TRUE, FALSE	FALSE	Setting for mode confirmation. FALSE: The mode can only be changed by the operator through "S_SetMode". TRUE: The operator does not need to confirm the change through "S_SetMode"; the "S_ModeXSel" output automatically changes according to the "S_ModeX" input. ("AutoSetMode" is equivalent to FALSE when the mode is locked using "S_Unlock")
	ModeMonitorTime	TIME	Follows data type	T#0ms	Maximum allowable time for changing the mode.
	Reset	BOOL	TRUE, FALSE	FALSE	Manual reset
Output	Ready	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is in ready status.
	S_Mode0Sel	SAFEBOOL	TRUE, FALSE	FALSE	Indicates mode 0 is selected and confirmed. FALSE: Mode 0 is not selected, or is not confirmed after selection. TRUE: Mode 0 is selected and confirmed.

Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
	S_Mode1Sel	SAFEBOOL	TRUE, FALSE	FALSE	Indicates mode 1 is selected and confirmed. FALSE: Mode 1 is not selected, or is not confirmed after selection. TRUE: Mode 1 is selected and confirmed.
	S_Mode2Sel	SAFEBOOL	TRUE, FALSE	FALSE	Indicates mode 2 is selected and confirmed. FALSE: Mode 2 is not selected, or is not confirmed after selection. TRUE: Mode 2 is selected and confirmed.
	S_Mode3Sel	SAFEBOOL	TRUE, FALSE	FALSE	Indicates mode 3 is selected and confirmed. FALSE: Mode 3 is not selected, or is not confirmed after selection. TRUE: Mode 3 is selected and confirmed.
	S_Mode4Sel	SAFEBOOL	TRUE, FALSE	FALSE	Indicates mode 4 is selected and confirmed. FALSE: Mode 4 is not selected, or is not confirmed after selection. TRUE: Mode 4 is selected and confirmed.
	S_Mode5Sel	SAFEBOOL	TRUE, FALSE	FALSE	Indicates mode 5 is selected and confirmed. FALSE: Mode 5 is not selected, or is not confirmed after selection. TRUE: Mode 5 is selected and confirmed.
	S_Mode6Sel	SAFEBOOL	TRUE, FALSE	FALSE	Indicates mode 6 is selected and confirmed. FALSE: Mode 6 is not selected, or is not confirmed after selection. TRUE: Mode 6 is selected and confirmed.

Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
	S_Mode7Sel	SAFEBOOL	TRUE, FALSE	FALSE	Indicates mode 7 is selected and confirmed. FALSE: Mode 7 is not selected, or is not confirmed after selection. TRUE: Mode 7 is selected and confirmed.
	S_AnyModeSel	SAFEBOOL	TRUE, FALSE	FALSE	Indicates one of the eight modes is selected and confirmed. FALSE: No mode is selected. TRUE: One of the eight modes is selected and confirmed.
	SafetyDemand	BOOL	TRUE, FALSE	FALSE	Activates or maintains the status according to the instruction status.
	ResetRequest	BOOL	TRUE, FALSE	FALSE	Flag indicating whether a reset is required.
	Error	BOOL	TRUE, FALSE	FALSE	Faulty status
	DiagCode	WORD	Follows data type	16#0000	Status code: Indicates fault code when instruction fails; indicates instruction status when instruction is running.

- **Function description**
  - Default status and safety status:
    The default status after the function block is activated is the mode changed status (ModeChanged), at which point all S_ModeXSel and S_AnyModeSel outputs are FALSE.
  - Mode changing logic:

    When the function block is in the ModeChanged status:

    - If AutoSetMode = FALSE: A rising edge on the S_SetMode input is required to confirm the new S_ModeX input, thereby generating the new S_ModeXSel output.
    - If AutoSetMode = TRUE: The new S_ModeX input directly generates the new S_ModeXSel output.

      Status transition condition: A transition from status 8802 to 8000 is only possible when at least one S_ModeX input is TRUE; if all S_ModeX inputs are FALSE, the function block remains in status 8802 even if S_SetMode is triggered.
  - Status transition monitoring:

    The transition from the ModeChanged status to ModeSelected (i.e., S_SetMode is triggered) is not monitored by a timer.

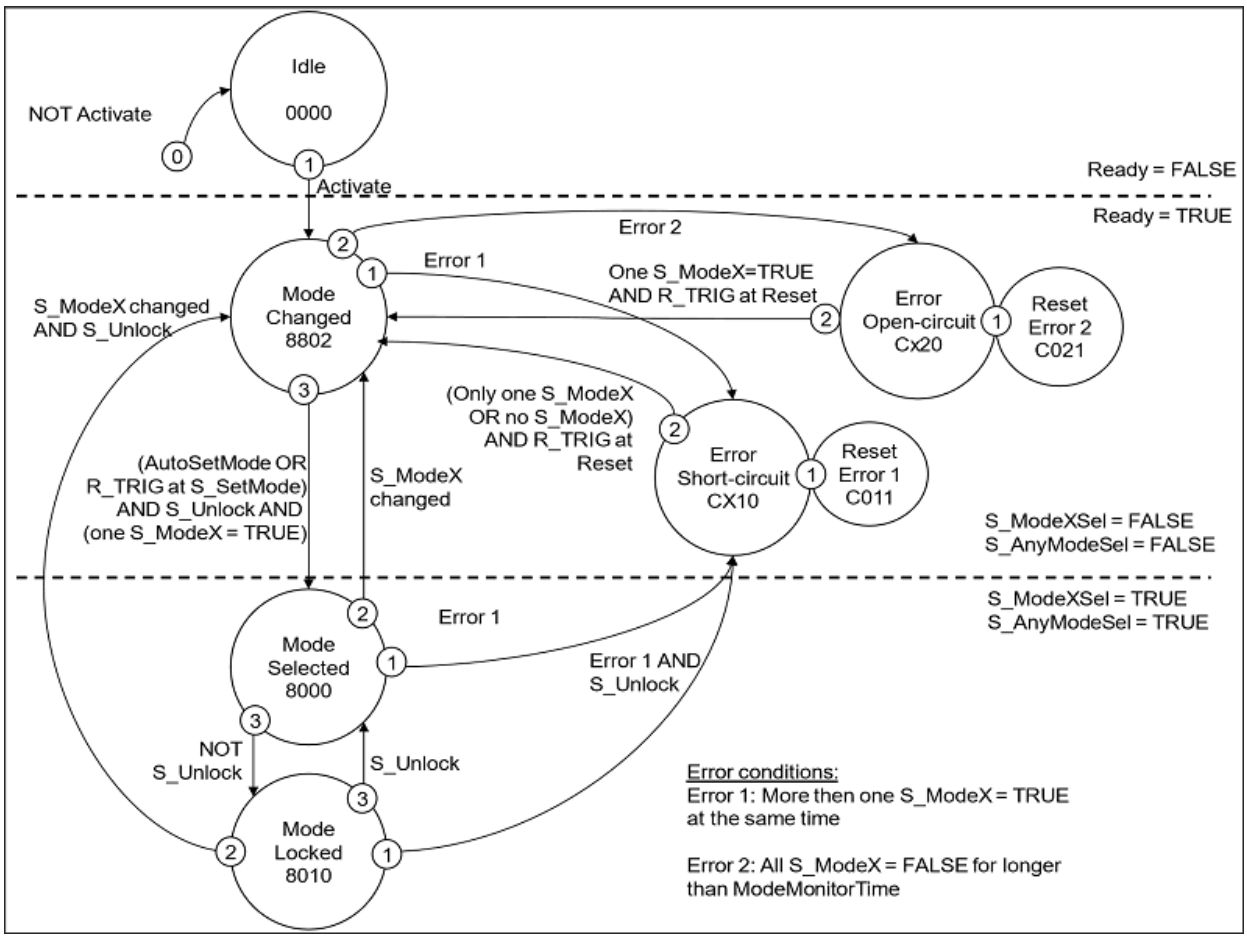
    If the function block is in the ModeSelected status: A transition back to the ModeChanged status occurs if a new S_ModeX input (with high priority) and a NOT S_Unlock signal (with low priority) occur simultaneously.

◦ Parameter configuration requirements:

S_ModeX inputs not used for mode selection shall be set to the default value FALSE to simplify program verification.

The AutoSetMode input can only be activated when it is ensured that the activation of the programmable electronic system (PES) will not cause hazardous conditions.

- **Status transition diagram**



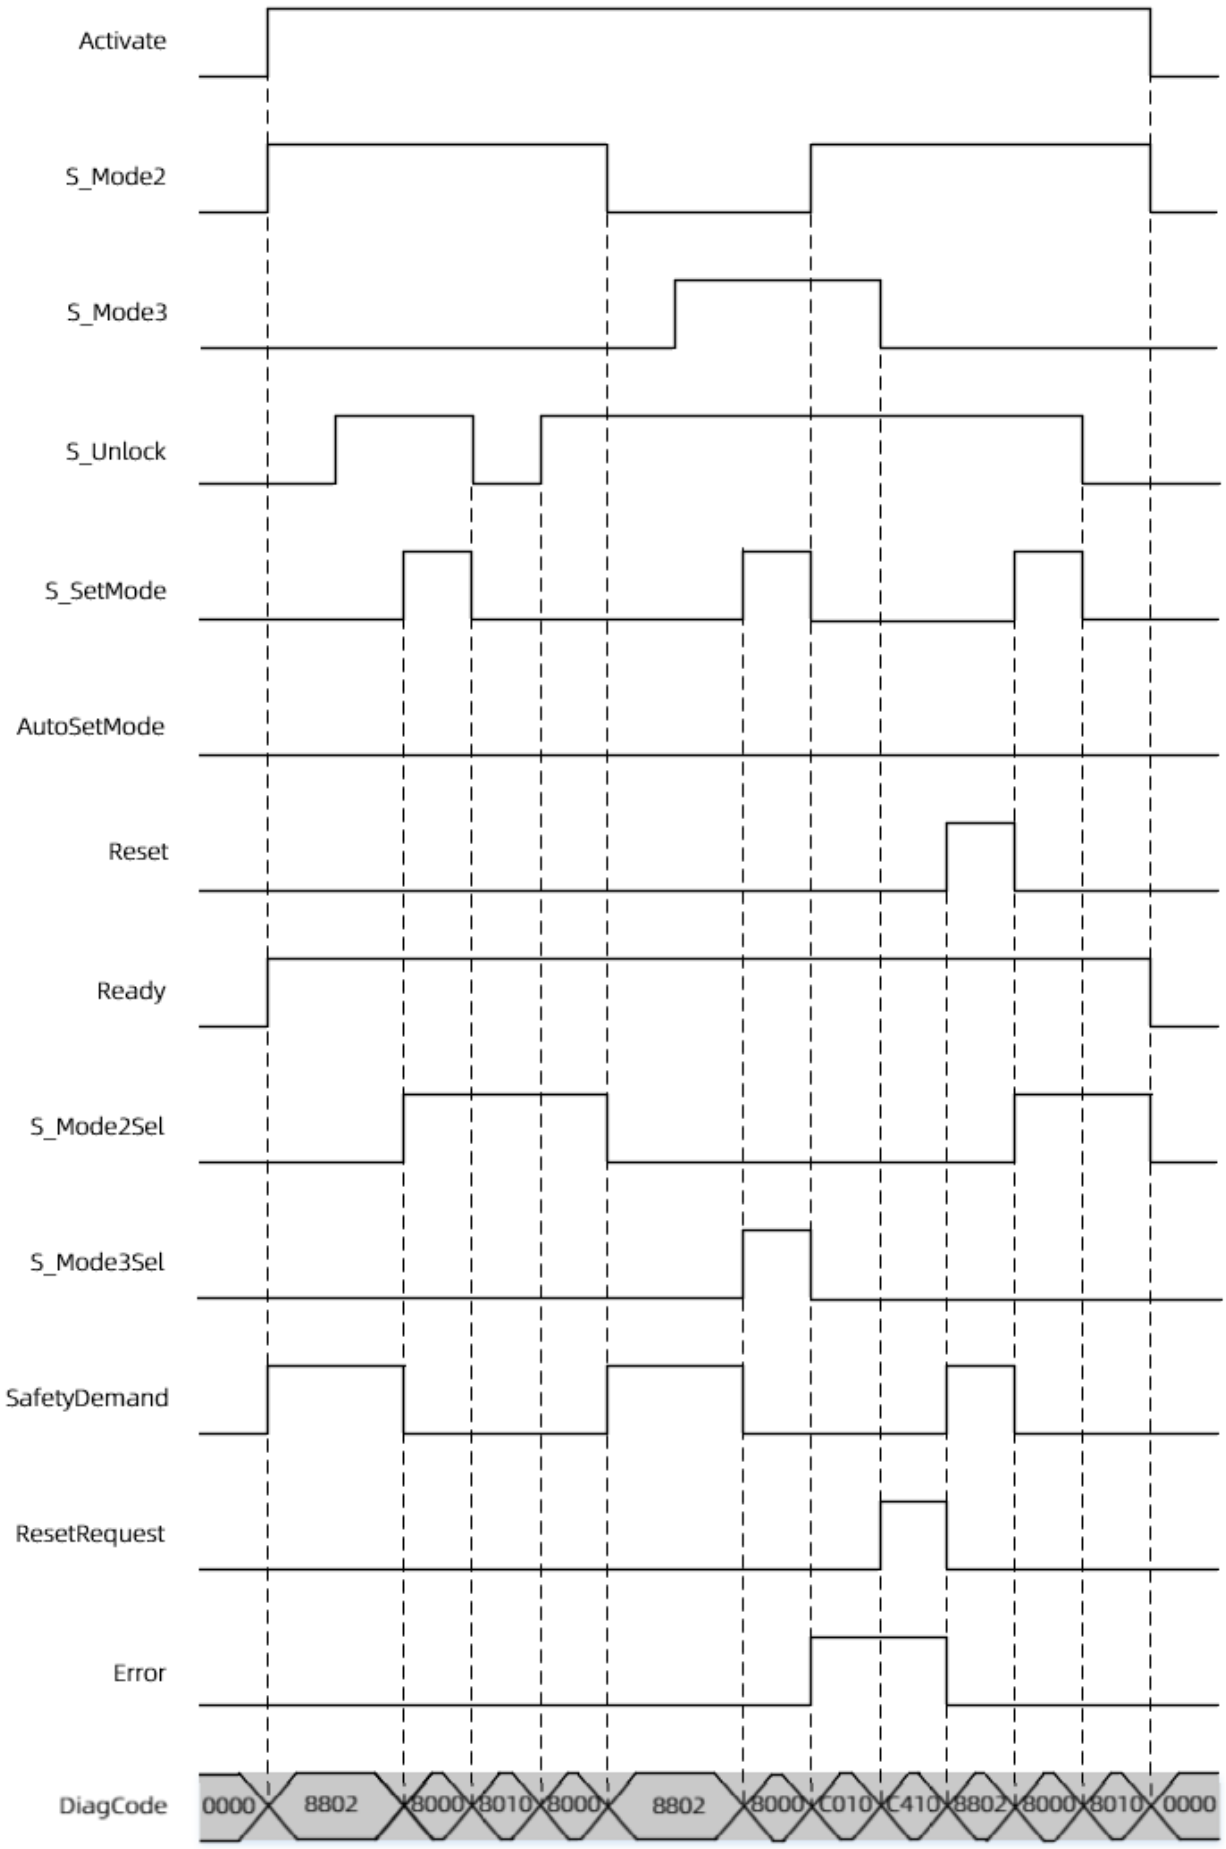


Figure 11-10-2-2-15-1 Status transition diagram for SF_ModeSelector

◦ This diagram is referenced from the PLCopen specification, and the copyright belongs to the PLCopen organization.

◦ The transition from any status to the idle status when Activate = FALSE is not indicated, but the priority (0) for transitioning to the idle status is the highest.

- **Sequence diagram**

- **Fault detection**

Detects whether no mode input is selected. If no mode is selected after the ModeMonitorTime timeout, the status is invalid. Each time an S_ModeX input is triggered at the falling edge, ModeMonitorTime is reset, and the function block transitions to the ModeChanged status after activation.

The function block also directly detects whether multiple S_ModeX inputs are selected simultaneously.

When the function block is in faulty status C011 or C021, a static reset condition is detected.

- **Fault behavior**

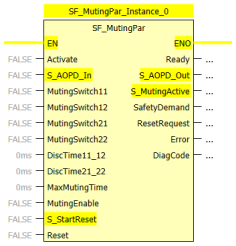
  Upon fault occurrence, the S_ModeXSel and S_AnyModeSel outputs are set to the safety status FALSE. The DiagCode output indicates the relevant fault code, and the Error output is set to TRUE. The fault must be reset by a rising edge trigger of the Reset input. The function block transitions from the faulty status to the ModeChanged status.

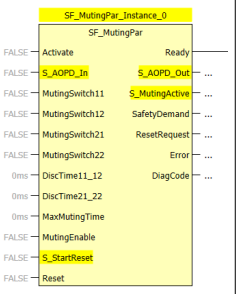
- **Function block-specific fault codes and status codes**

  ◦ Fault code

DiagCode	Status Name	Description and Output
Cx10	Error Short-circuit	Detects that two or more S_ModeX inputs are TRUE due to cable short circuit or other causes. If any S_ModeX (X = 0 to 7) is TRUE or all S_ModeX inputs are FALSE, the fault code is C410; otherwise, it is C010. • When the fault code is C410: Ready = TRUE SafetyDemand = FALSE ResetRequest = NOT Reset Error = TRUE S_AnyModeSel = FALSE All S_ModeXSel = FALSE • When the fault code is C010: Ready = TRUE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE S_AnyModeSel = FALSE All S_ModeXSel = FALSE

DiagCode	Status Name	Description and Output
Cx20	Error Open-circuit	Detects that all S_ModeX inputs are FALSE: The time period after S_ModeX is triggered has exceeded ModeMonitorTime due to cable open circuit or other causes. If any S_ModeX is TRUE, the fault code is C420; otherwise, it is C020. • When fault code is C420: Ready = TRUE SafetyDemand = FALSE ResetRequest = NOT Reset Error = TRUE S_AnyModeSel = FALSE All S_ModeXSel = FALSE • When the fault code is C020: Ready = TRUE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE S_AnyModeSel = FALSE All S_ModeXSel = FALSE
C011	Reset Error 1	A static reset signal was detected in status C410. Ready = TRUE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE S_AnyModeSel = FALSE All S_ModeXSel = FALSE
C021	Reset Error 2	A static reset signal was detected in status C420. Ready = TRUE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE S_AnyModeSel = FALSE All S_ModeXSel = FALSE





◦ Status code

DiagCode	Status Name	Description and Output

8802	ModeChanged	After function block activation, the mode selected by S_ModeX (unless locked) is reset or the faulty status is reset. Ready = TRUE SafetyDemand = TRUE ResetRequest = FALSE Error = FALSE S_AnyModeSel = FALSE All S_ModeXSel = FALSE
8000	ModeSelected	A valid mode is selected, but not yet locked. Ready = TRUE SafetyDemand = FALSE ResetRequest = FALSE Error = FALSE S_AnyModeSel = TRUE S_ModeXSel = TRUE (X is the selected S_ModeX, the inputs of other unselected modes are FALSE)
8010	ModeLocked	A valid mode is selected and locked. Ready = TRUE SafetyDemand = FALSE ResetRequest = FALSE Error = FALSE S_AnyModeSel = TRUE S_ModeXSel = TRUE (X is the selected S_ModeX, the inputs of other unselected modes are FALSE)

11.10.2.2.16 SF_MutingPar

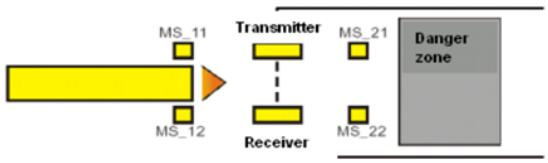
SF_MutingPar intentionally inhibits the safety function. In this function block, parallel muting with four muting sensors is specified.

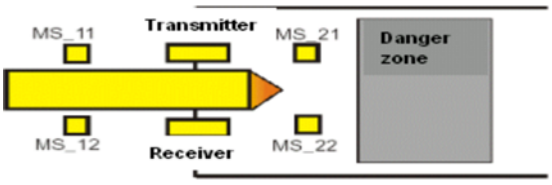
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_MutingPar	Perform parallel muting with four muting sensors.	FB		

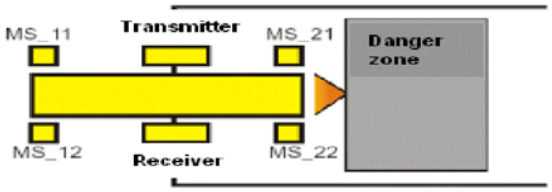
- **Related variables**

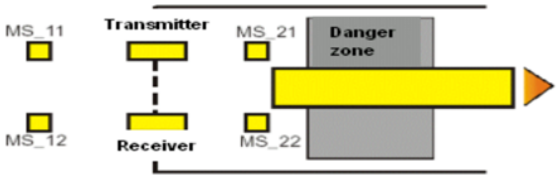
  Variables





Input / Output	Variable	Data Type	Valid Range	Default Value	Description
Input	Activate	BOOL	TRUE, FALSE	FALSE	Activates the instruction.
	S_AOPD_In	SAFEBOOL	TRUE, FALSE	FALSE	OSSD signal from AOPD. FALSE: The guarded area is invaded. TRUE: The guarded area is not invaded.
	MutingSwitch11	BOOL	TRUE, FALSE	FALSE	Status of muting sensor 11. FALSE: Muting sensor 11 is not activated. TRUE: Muting sensor 11 is activated.
	MutingSwitch12	BOOL	TRUE, FALSE	FALSE	Status of muting sensor 12. FALSE: Muting sensor 12 is not activated. TRUE: Muting sensor 12 is activated.
	MutingSwitch21	BOOL	TRUE, FALSE	FALSE	Status of muting sensor 21. FALSE: Muting sensor 21 is not activated. TRUE: Muting sensor 21 is activated.





Input / Output	Variable	Data Type	Valid Range	Default Value	Description
	MutingSwitch22	BOOL	TRUE, FALSE	FALSE	Status of muting sensor 22. FALSE: Muting sensor 22 is not activated. TRUE: Muting sensor 22 is activated.
	DiscTime11_12	TIME	Follows data type	T#0ms	Maximum discrepancy time between MutingSwitch11 and MutingSwitch12, with a range of 0 to 4s.
	DiscTime21_22	TIME	Follows data type	T#0ms	Maximum discrepancy time between MutingSwitch21 and MutingSwitch22, with a range of 0 to 4s.
	MaxMutingTime	TIME	Follows data type	T#0ms	Maximum time for the complete muting sequence, with a range of 0 to 120 minutes.
	MutingEnable	BOOL	TRUE, FALSE	FALSE	Control system command used to activate the muting function when required. FALSE: Muting is invalid. TRUE: Muting is valid.
	S_StartReset	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether to start reset.
	Reset	BOOL	TRUE, FALSE	FALSE	Manual reset
Output	Ready	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is in ready status.
	S_AOPD_Out	SAFEBOOL	TRUE, FALSE	FALSE	Safety-related output indicating the status of the muting guard device. FALSE: The AOPD guarded area is invaded and muting is invalid. TRUE: The AOPD guarded area is not invaded and muting is valid.
	S_MutingActive	SAFEBOOL	TRUE, FALSE	FALSE	Indicates the status of the muting process. FALSE: Muting is invalid. TRUE: Muting is valid.
	SafetyDemand	BOOL	TRUE, FALSE	FALSE	Activates or maintains the status according to the instruction status.
	ResetRequest	BOOL	TRUE, FALSE	FALSE	Flag indicating whether a reset is required.

Input / Output	Variable	Data Type	Valid Range	Default Value	Description
	Error	BOOL	TRUE, FALSE	FALSE	Faulty status
	DiagCode	WORD	Follows data type	16#0000	Status code: Indicates fault code when instruction fails; indicates instruction status when instruction is running.

- **Function description**
  - Muting refers to the intentional inhibition of the safety function. For example, SF_MutingPar can be used when feeding material into a hazardous area without causing the machine to stop. Muting is triggered by muting sensors and requires two or four muting sensors with proper integration into the production process to ensure no personnel enters the hazardous area during the muting period. Muting sensors may include non-safety proximity switches, photoelectric barriers, limit switches, and so on. The activation of muting must be indicated by an indicator.
  - The muting process is divided into sequential muting and parallel muting. This function block adopts parallel muting with four muting sensors and supports bidirectional use in both forward and backward directions. To prevent misoperation, muting shall be activated by the MutingEnable signal from the process.
  - Input parameters of this function block include:
    - Four muting sensor signals (MutingSwitch11...MutingSwitch22).
    - OSSD signal from the active photoelectric guard device (S_AOPD_In).
    - Three parameterizable times (DiscTime11_12, DiscTime21_22, and MaxMutingTime).
  - The S_StartReset input can only be activated when it is ensured that the activation of the programmable electronic system (PES) will not cause hazardous conditions.

Table11-10-2-2-16-1 Example of forward muting process with four muting sensors

No.	Figure	Explanation
1		During the time set by DiscTime11_12, when MutingSwitch11 (MS_11) and MutingSwitch12 (MS_12) are turned ON due to the workpiece passage, the muting mode becomes active (S_MutingActive = TRUE).
2		The muting mode remains active while MutingSwitch11 (MS_11) and MutingSwitch12 (MS_12) are turned ON due to the workpiece. The workpiece can pass through the light curtain without stopping the machine.

No.	Figure	Explanation
3		Before MutingSwitch11 (MS_11) and MutingSwitch12 (MS_12) are turned OFF, MutingSwitch21 (MS_21) and MutingSwitch22 (MS_22) must be turned ON. This ensures that the muting mode remains ON. The time discrepancy between MutingSwitch21 and MutingSwitch22 is monitored using the time set by DiscTime21_22.
4		The muting mode ends only when MutingSwitch22 (MS_22) is turned ON. The muting mode ends when either MutingSwitch21 (MS_21) or MutingSwitch22 (MS_22) is turned OFF due to the workpiece. The maximum time for which the muting mode remains active is set by MaxMutingTime.

- **Status transition diagram**

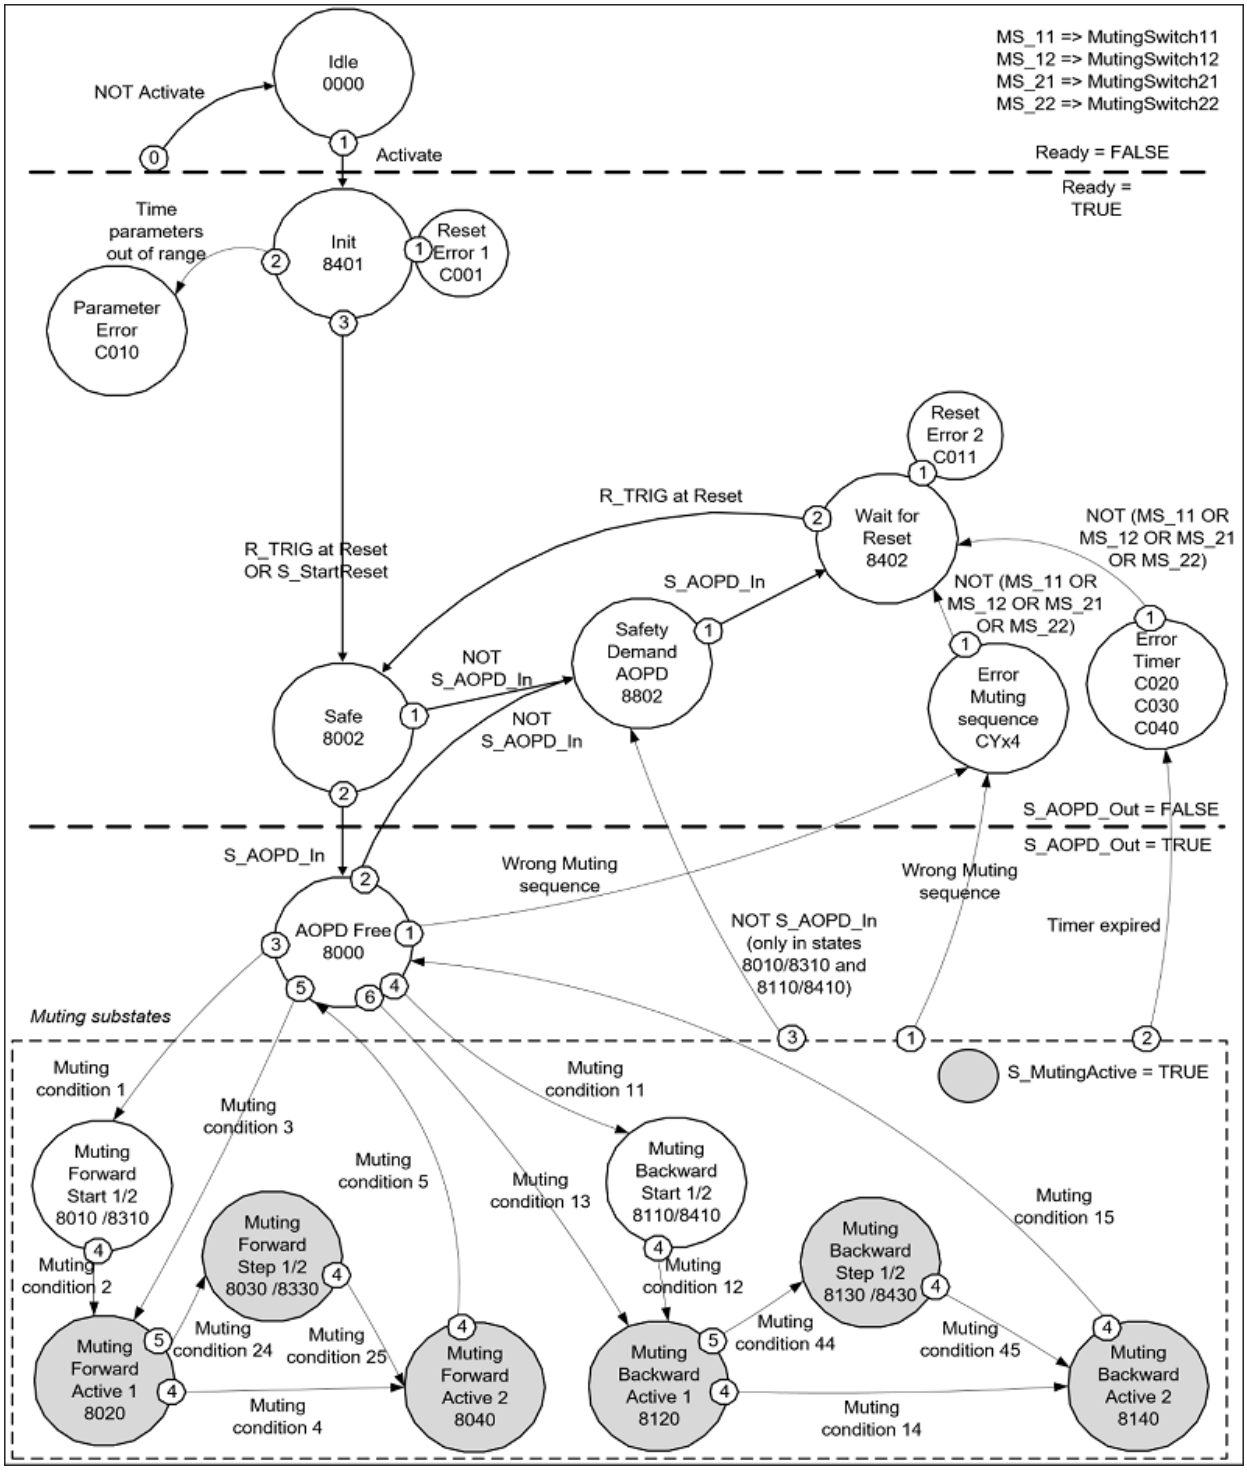


Figure 11-10-2-2-16-1 State transition diagram for SF_MutingPar

- This diagram is referenced from the PLCopen specification, and the copyright belongs to the PLCopen organization.
- The transition from any status to the idle status with Activate being FALSE is not shown. However, these transitions have the highest priority (0).
- In the muting status, AOPD transitions triggered by an incorrect muting sequence (priority 1), a faulty timer (priority 2), and a safety request (priority 3) have higher priority than transitions to the muting status (priority 4 or 5).
- The muting conditions are defined as follows.
  - Forward direction

Muting condition 1 (8000 → 8010, MS_11 as the first start switch): When timers MaxMutingTime and DiscTime11_12 start: MutingEnable AND (R_TRIG at MS_11 AND NOT MS_12 AND NOT MS_21 AND NOT MS_22)

Muting condition 1 (8000 → 8310, MS_12 as the first start switch): When timers MaxMutingTime and DiscTime11_12 start: MutingEnable AND (NOT MS_11 AND R_TRIG at MS_12 AND NOT MS_21 AND NOT MS_22)

Muting condition 2 (8010 → 8020, MS_12 as the second start switch): When timer DiscTime11_12 stops: MutingEnable AND (MS_11 AND R_TRIG at MS_12 AND NOT MS_21 AND NOT MS_22)

Muting condition 2 (8310 → 8020, MS_11 as the second start switch): When timer DiscTime11_12 stops: MutingEnable AND (R_TRIG at MS_11 AND MS_12 AND NOT MS_21 AND NOT MS_22)

Muting condition 3 (two switches simultaneously activated): When timer MaxMutingTime starts: MutingEnable AND (R_TRIG at MS_11 AND R_TRIG at MS_12 AND NOT MS_21 AND NOT MS_22)

Muting condition 4 (all switches activated): MS_11 AND MS_12 AND MS_21 AND MS_22

Muting condition 24 (8020 → 8030, MS_21 as the first start switch): When timer DiscTime21_22 starts: MS_11 AND MS_12 AND R_TRIG at MS_21 AND NOT MS_22

Muting condition 24 (8020 → 8330, MS_22 as the first start switch): When timer DiscTime21_22 starts: MS_11 AND MS_12 AND NOT MS_21 AND R_TRIG at MS_22

Muting condition 25 (8030→8040, MS_22 as the second start switch): When timer DiscTime21_22 stops: MS_11 AND MS_12 AND MS_21 AND R_TRIG at MS_22

Muting condition 25 (8330→8040, MS_21 as the second start switch): When timer DiscTime21_22 stops: MS_11 AND MS_12 AND R_TRIG at MS_21 AND MS_22

Muting condition 5 (a stop switch released): When timer MaxMutingTime stops: NOT MS_11 AND NOT MS_12 AND (F_TRIG at MS_21 OR F_TRIG at MS_22)

- Backward direction

  Muting condition 11 (8000 → 8110, MS_21 as the first start switch): When timers MaxMutingTime and DiscTime21_22 start: MutingEnable AND (NOT MS_22 AND R_TRIG at MS_21 AND NOT MS_11 AND NOT MS_12)

  Muting condition 11 (8000 → 8410, MS_22 as the first start switch): When timers MaxMutingTime and DiscTime21_22 start: MutingEnable AND (R_TRIG at MS_22 AND NOT MS_21 AND NOT MS_11 AND NOT MS_12)

  Muting condition 12 (8110 → 8120, MS_22 as the second start switch): When timer DiscTime21_22 stops: MutingEnable AND (MS_21 AND R_TRIG at MS_22 AND NOT MS_11 AND NOT MS_12)

  Muting condition 12 (8410 → 8120, MS_21 as the second start switch): When timer DiscTime21_22 stops: MutingEnable AND (R_TRIG at MS_21 AND MS_22 AND NOT MS_11 AND NOT MS_12)

  Muting condition 13 (two switches activated simultaneously): When timer MaxMutingTime starts: MutingEnable AND (R_TRIG at MS_21 AND R_TRIG at MS_22 AND NOT MS_11 AND NOT MS_12)

  Muting condition 14 (all switches activated): MS_11 AND MS_12 AND MS_21 AND MS_22

Muting condition 44 (8120→8130, MS_11 as the first start switch): When timer DiscTime11_12 starts: MS_21 AND MS_22 AND R_TRIG at MS_11 AND NOT MS_12

Muting condition 44 (8120→8430, MS_12 as the first start switch): When timer DiscTime11_12 starts: MS_21 AND MS_22 AND NOT MS_11 AND R_TRIG at MS_12

Muting condition 45 (8130 → 8140, MS_12 as the second start switch): When timer DiscTime11_12 stops: MS_21 AND MS_22 AND MS_11 AND R_TRIG at MS_12

Muting condition 45 (8430 → 8140, MS_11 as the second start switch): When timer DiscTime11_12 stops: MS_21 AND MS_22 AND R_TRIG at MS_11 AND MS_12

Muting condition 15 (a stop switch released): When timer MaxMutingTime stops: NOT MS_21 AND NOT MS_22 AND (F_TRIG at MS_11 OR F_TRIG at MS_12)

- Incorrect muting sequence

  OR ((MS_21 OR MS_22) AND (F_TRIG at MS_11 OR F_TRIG at MS_12))

  OR ((MS_21 OR MS_22) AND (F_TRIG at MS_11 OR F_TRIG at MS_12))

  OR (AND (F_TRIG at MS_21 OR F_TRIG at MS_22))

Status 8130: NOT MS_21 OR NOT MS_22 OR NOT MS_11

Status 8430: NOT MS_21 OR NOT MS_22 OR NOT MS_12

- **Sequence diagram**

- **Fault detection**

  This function block detects the following fault conditions:

  - DiscTime11_12 and DiscTime21_22 are set to values less than T#0s or greater than T#4s.
  - MaxMutingTime is set to a value less than T#0s or greater than T#120min.

- The discrepancy time for MutingSwitch11/MutingSwitch12 or MutingSwitch21/MutingSwitch22 sensor pairs exceeds the timeout setting.
- The muting function (S_MutingActive = TRUE) exceeds the maximum muting time MaxMutingTime.
- The muting sensors MutingSwitch11, MutingSwitch12, MutingSwitch21, and MutingSwitch22 are activated in an incorrect sequence.
- The muting sequence is started without being enabled by MutingEnable.
- A static Reset condition is detected in statuses 8401 and 8402.

- **Fault behavior**

  In case of a fault, the S_AOPD_Out and S_MutingActive outputs are set to FALSE. The DiagCode output indicates the relevant fault code, and the Error output is set to TRUE. Restart is prohibited until the fault condition is cleared and the safety status is confirmed by the operator via Reset.

- **Function block-specific fault codes and status codes**
  - Fault code

DiagCode	Status Name	Description and Output
C001	Reset Error 1	In the 8401 status, a TRUE value of Reset is triggered at the non-rising edge. Ready = TRUE S_AOPD_Out = FALSE S_MutingActive = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE
C011	Reset Error 2	In the 8402 status, a TRUE value of Reset is triggered at the non-rising edge. Ready = TRUE S_AOPD_Out = FALSE S_MutingActive = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE

CYx4	Error Muting sequence	Fault detected in muting sequence statuses 8000, 8010, 8310, 8020, 8040, 8030, 8330, 8110, 8410, 8120, 8140, 8130, or 8430. Ready = TRUE S_AOPD_Out = FALSE S_MutingActive = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE Y indicates the fault occurred under different status codes. Fault code C0x4 indicates the fault occurred in status 8000. Fault code C1x4 indicates the fault occurred in status 8010. Fault code C2x4 indicates the fault occurred in status 8310. Fault code C3x4 indicates the fault occurred in status 8020. Fault code C4x4 indicates the fault occurred in status 8030. Fault code C5x4 indicates the fault occurred in status 8330. Fault code C6x4 indicates the fault occurred in status 8040. Fault code C7x4 indicates the fault occurred in status 8110. Fault code C8x4 indicates the fault occurred in status 8410.   Variables

Input / Output	Variable	Data Type	Valid Range	Default Value	Description
Input	Activate	BOOL	TRUE, FALSE	FALSE	Activates the instruction.

Input / Output	Variable	Data Type	Valid Range	Default Value	Description
	S_AOPD_In	SAFEBOOL	TRUE, FALSE	FALSE	OSSD signal from AOPD. FALSE: The guarded area is invaded. TRUE: The guarded area is not invaded.
	MutingSwitch11	BOOL	TRUE, FALSE	FALSE	Status of muting sensor 11. FALSE: Muting sensor 11 is not activated. TRUE: Muting sensor 11 is activated.
	MutingSwitch12	BOOL	TRUE, FALSE	FALSE	Status of muting sensor 12. FALSE: Muting sensor 12 is not activated. TRUE: Muting sensor 12 is activated.
	DiscTimeEntry	TIME	Follows data type	T#0ms	Maximum discrepancy time between MutingSwitch11 and MutingSwitch12, with a range of 0 to 4s.
	MaxMutingTime	TIME	Follows data type	T#0ms	Maximum time for the complete muting sequence, with a range of 0 to 120 minutes.
	MutingEnable	BOOL	TRUE, FALSE	FALSE	Control system command used to activate the muting function when required. FALSE: Muting is invalid. TRUE: Muting is valid.
	S_StartReset	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether to start reset.
	Reset	BOOL	TRUE, FALSE	FALSE	Manual reset
Output	Ready	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is in ready status.
	S_AOPD_Out	SAFEBOOL	TRUE, FALSE	FALSE	Safety-related output indicating the status of the muting guard device. FALSE: The AOPD guarded area is invaded and muting is invalid. TRUE: The AOPD guarded area is not invaded and muting is valid.

Input / Output	Variable	Data Type	Valid Range	Default Value	Description
	S_MutingActive	SAFEBOOL	TRUE, FALSE	FALSE	Indicates the status of the muting process. FALSE: Muting is invalid. TRUE: Muting is valid.
	SafetyDemand	BOOL	TRUE, FALSE	FALSE	Activates or maintains the status according to the instruction status.
	ResetRequest	BOOL	TRUE, FALSE	FALSE	Flag indicating whether a reset is required.
	Error	BOOL	TRUE, FALSE	FALSE	Faulty status
	DiagCode	WORD	Follows data type	16#0000	Status code: Indicates fault code when instruction fails; indicates instruction status when instruction is running.

- **Function description**
  - Muting refers to the intentional inhibition of the safety function. For example, SF_MutingPar can be used when feeding material into a hazardous area without causing the machine to stop. Muting is triggered by muting sensors and requires two muting sensors with proper integration into the production process to ensure no personnel enters the hazardous area during the muting period. Muting sensors may include non-safety proximity switches, photoelectric barriers, limit switches, and so on. The activation of muting must be indicated by an indicator.
  - The muting process is divided into sequential muting and parallel muting. In this function block, parallel muting with two muting sensors is used. The positioning of the sensors shall comply with the requirements specified in Appendix F.7 of IEC 62046 (CD 2005 edition). The function block can be used in both forward and backward directions, but the actual direction cannot be identified. To prevent misoperation, muting shall be activated by the MutingEnable signal from the process.
  - Input parameters of this function block include:
    - Two muting sensor signals (MutingSwitch11 and MutingSwitch12).
    - OSSD signal from the active photoelectric guard device (S_AOPD_In).
    - Two parameterizable times (DiscTimeEntry and MaxMutingTime).
  - The S_StartReset input can only be activated when it is ensured that the activation of the programmable electronic system (PES) will not cause hazardous conditions.

Table11-10-2-2-17-1 Example of forward muting process with two muting sensors

No.	Figure	Explanation
1		When using retroreflective sensors as muting sensors, it is generally configured diagonally. Typically, this configuration requires two photoelectric sensors, and the assignment of S_MutingSwitch11 (MS_11) and S_MutingSwitch12 (MS_12).

- **Status transition diagram**

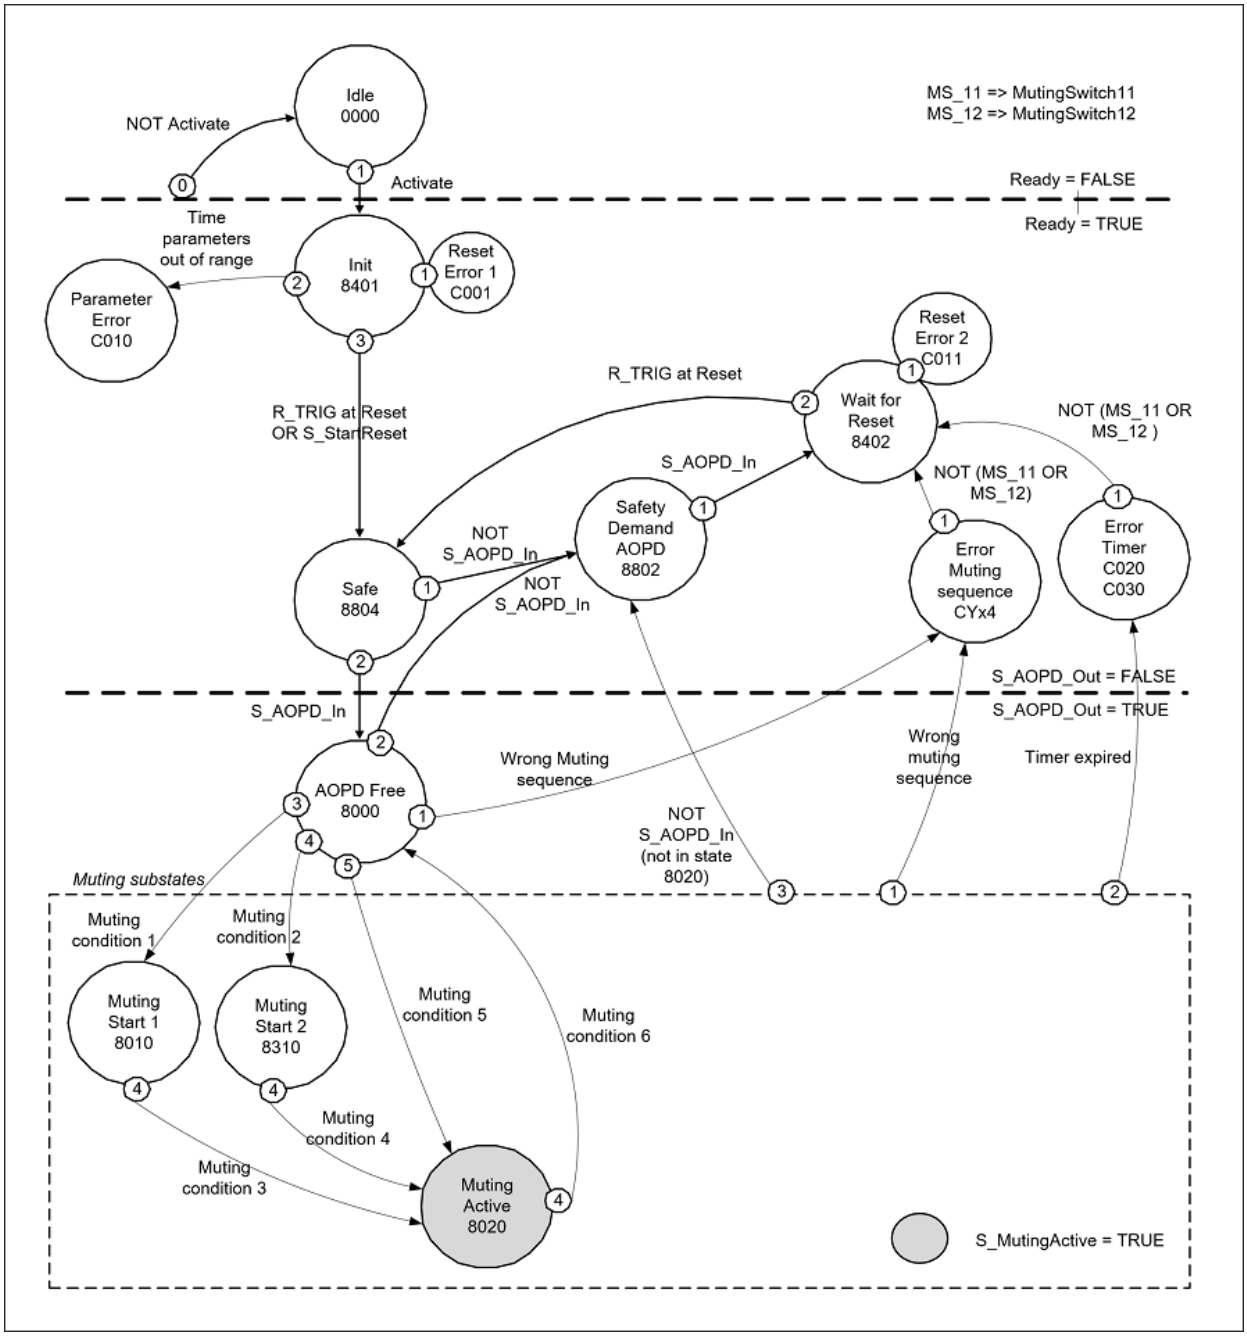

Figure 11-10-2-2-17-1 Status transition diagram SF_MutingPar_2Senso

◦ This diagram is referenced from the PLCopen specification, and the copyright belongs to the PLCopen organization.

- The transition from any status to the idle status with Activate being FALSE is not shown. However, these transitions have the highest priority (0).
- In the muting status, AOPD transitions triggered by an incorrect muting sequence (priority 1), a faulty timer (priority 2), and a safety request (priority 3) have higher priority than transitions to the muting status (priority 4 or 5).
- The muting conditions are defined as follows.
  - Muting conditions

    Muting condition 1 (8000 → 8010, MS_11 as the first start switch): When timers DiscTimeEntry and MaxMutingTime start: MutingEnable AND R_TRIG at MS_11 AND NOT MS_12

    Muting condition 2 (8000 → 8310, MS_12 as the first start switch): When timers DiscTimeEntry and MaxMutingTime start: MutingEnable AND NOT MS_11 AND R_TRIG at MS_12

    Muting condition 3 (8010 → 8020, MS_12 as the second start switch): When timer DiscTimeEntry stops: MutingEnable AND MS_11 AND R_TRIG at MS_12

    Muting condition 4 (8310 → 8020, MS_11 as the second start switch): When timer DiscTimeEntry stops: MutingEnable AND R_TRIG at MS_11 AND MS_12

    Muting condition 5 (8000 → 8020, both switches activated simultaneously): When timer MaxMutingTime starts: MutingEnable AND R_TRIG at MS_11 AND R_TRIG at MS_12

    Muting condition 6 (8020 → 8000, both switches are released simultaneously or MS_11 and MS_12 released consecutively): When timer MaxMutingTime stops: NOT MS_11 OR NOT MS_12
  - Incorrect muting sequence

    Status 8000:

    (R_TRIG at MS_11 AND MS_12 AND NOT R_TRIG at MS_12)

    OR (R_TRIG at MS_12 AND MS_11 AND NOT R_TRIG at MS_11)

    OR ((MS_11 AND NOT R_TRIG at MS_11) AND (MS_12 AND NOT R_TRIG at MS_12))

    OR (NOT MutingEnable AND R_TRIG at MS_11)

    OR (NOT MutingEnable AND R_TRIG at MS_12)

    Status 8010: NOT MutingEnable OR NOT MS_11

    Status 8310: NOT MutingEnable OR NOT MS_12

    Status 8020: No incorrect muting sequence

- **Fault detection**

  This function block detects the following fault conditions:

  - DiscTimeEntry is set to a value less than T#0s or greater than T#4s.
  - MaxMutingTime is set to a value less than T#0s or greater than T#120min.
  - The discrepancy time between the MutingSwitch11/MutingSwitch12 sensor pair exceeds the timeout.
  - The muting function (S_MutingActive = TRUE) exceeds the maximum muting time MaxMutingTime.
  - The muting sensors MutingSwitch11 and MutingSwitch12 are activated in the wrong order.
  - The muting sequence is started without being enabled by MutingEnable.
  - Static signals of the muting sensor exist.
  - A static Reset condition is detected in statuses 8401 and 8402.

- **Fault behavior**

  In case of a fault, the S_AOPD_Out and S_MutingActive outputs are set to FALSE. The DiagCode output indicates the relevant fault code, and the Error output is set to TRUE. Restart is prohibited until the fault condition is cleared and the safety status is confirmed by the operator via Reset.

- **Function block-specific fault codes and status codes**

  - Fault code

DiagCode	Status Name	Description and Output

- **Function description**
  - Muting refers to the intentional inhibition of the safety function. For example, SF_MutingPar can be used when feeding material into a hazardous area without causing the machine to stop. Muting is triggered by muting sensors and requires two or four muting sensors with proper integration into the production process to ensure no personnel enters the hazardous area during the muting period. Muting sensors may include non-safety proximity switches, photoelectric barriers, limit switches, and so on. The activation of muting must be indicated by an indicator.
  - The muting process is divided into sequential muting and parallel muting. In this function block, sequential muting with four muting sensors is used (the forward transport direction is used as an example). The function block can be used in both forward and backward directions. To prevent misoperation, muting shall be activated by the MutingEnable signal from the process. If the MutingEnable signal is not available, this input must be set to TRUE.
  - Input parameters of this function block include:
    - Four muting sensor signals (MutingSwitch11...MutingSwitch22).
    - OSSD signal from the active photoelectric guard device (S_AOPD_In).
  - The S_StartReset input can only be activated when it is ensured that the activation of the programmable electronic system (PES) will not cause hazardous conditions.

Table11-10-2-2-18-1 Example of forward muting process with four muting sensors

No.	Figure	Explanation
1		The muting mode remains active when MutingSwitch12 (MS_12) is turned ON due to the workpiece passage after MutingSwitch11 (MS_11).
2		The muting mode remains active while MutingSwitch11 (MS_11) and MutingSwitch12 (MS_12) are turned ON due to the workpiece. The workpiece can pass through the light curtain without stopping the machine.
3		Before MutingSwitch11 (MS_11) and MutingSwitch12 (MS_12) are turned OFF, MutingSwitch21 (MS_21) and MutingSwitch22 (MS_22) must be turned ON. This ensures that the muting mode remains ON.
4		The muting mode ends only when MutingSwitch22 (MS_22) is turned ON due to the workpiece.

- **Status transition diagram**

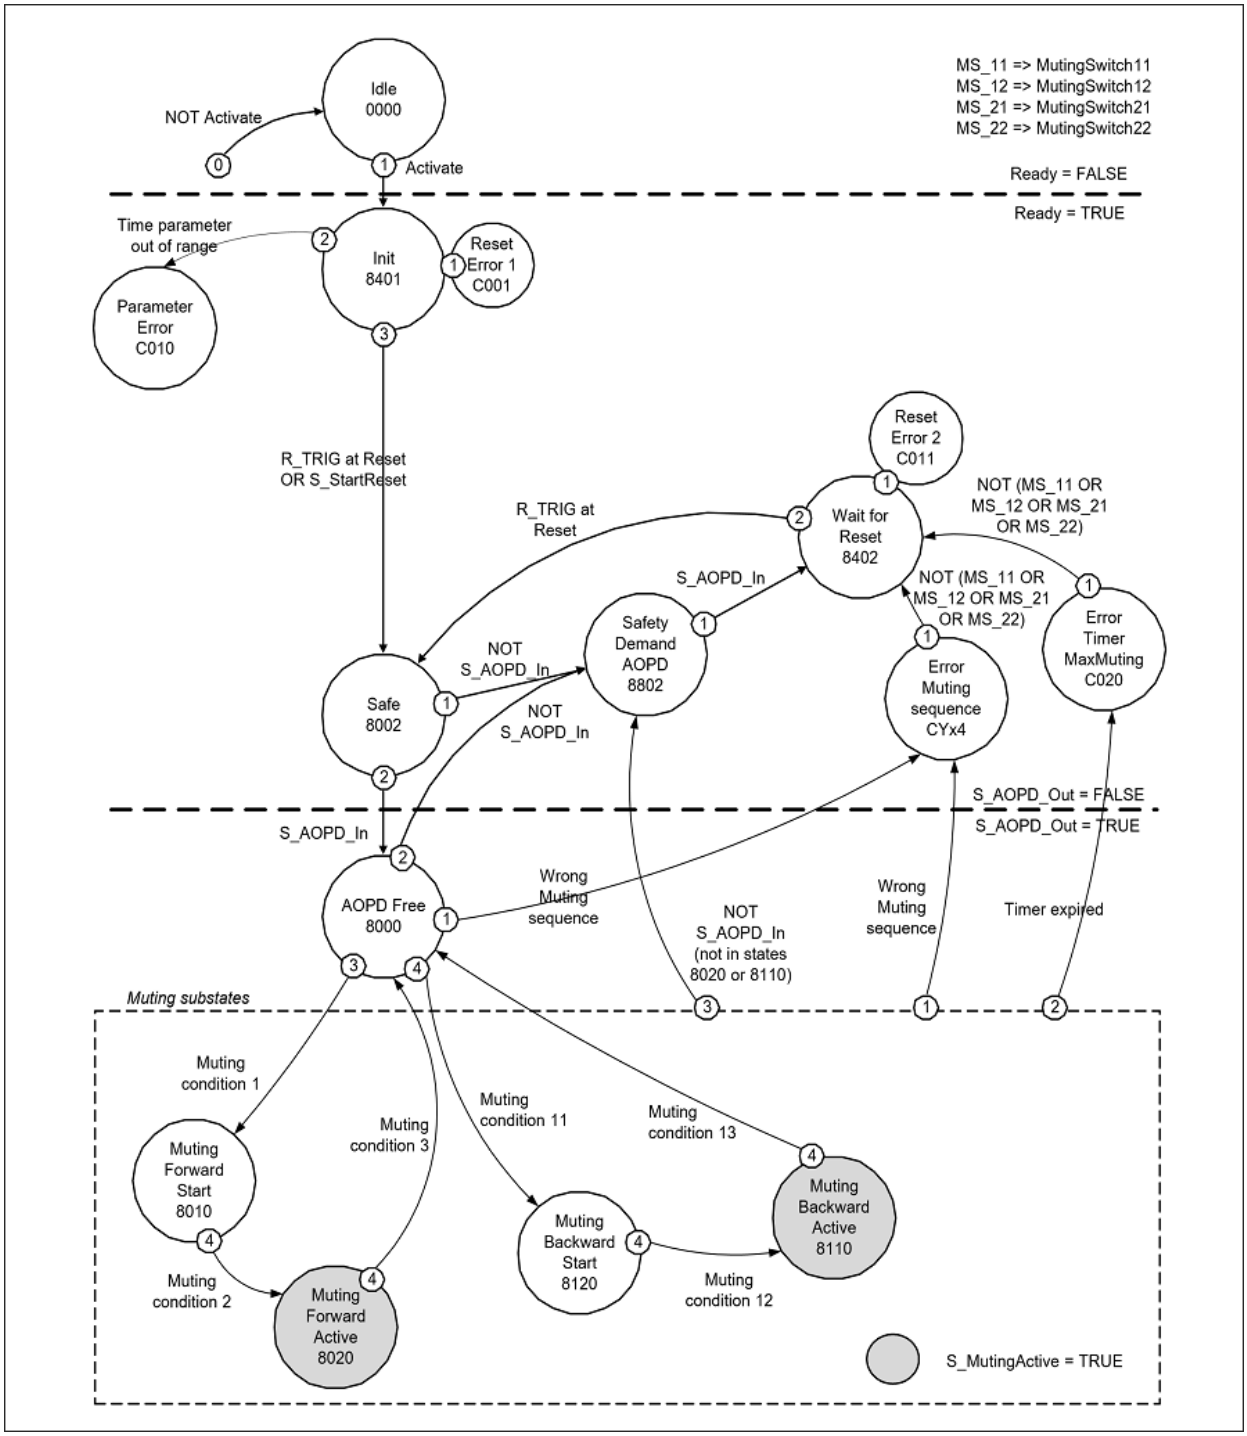

Figure 11-10-2-2-18-1 Status transition diagram for SF_MutingSeq

- This diagram is referenced from the PLCopen specification, and the copyright belongs to the PLCopen organization.
- The transition from any status to the idle status with Activate being FALSE is not shown. However, these transitions have the highest priority (0).
- In the muting status, AOPD transitions triggered by an incorrect muting sequence (priority 1), a faulty timer (priority 2), and a safety request (priority 3) have higher priority than transitions to the muting status (priority 4 or 5).
- The muting conditions are defined as follows.
  - Forward direction

    Muting condition 1 (8000 → 8010, MS_11 as the first start switch): When timer MaxMutingTime starts: MutingEnable AND (R_TRIG at MS_11 AND NOT MS_12 AND NOT MS_21 AND NOT MS_22)

Muting condition 2 (8010 → 8020, MS_12 as the second start switch): When timer MaxMutingTime starts: MutingEnable AND (MS_11 AND R_TRIG at MS_12 AND NOT MS_21 AND NOT MS_22)

8110	Muting Backward Start	The muting backward sequence is in the start phase, with no safety demand. Ready = TRUE S_AOPD_Out = TRUE S_MutingActive = TRUE SafetyDemand = FALSE ResetRequest = FALSE Error = FALSE
8120	Muting Backward Active	The muting backward sequence is activated. Ready = TRUE S_AOPD_Out = TRUE S_MutingActive = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = FALSE

11.10.2.2.19 SF_OutControl

SF_OutControl controls safety outputs based on control signals and safety signals issued according to functional applications.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_OutControl	Output control	FB		

- **Related variables**

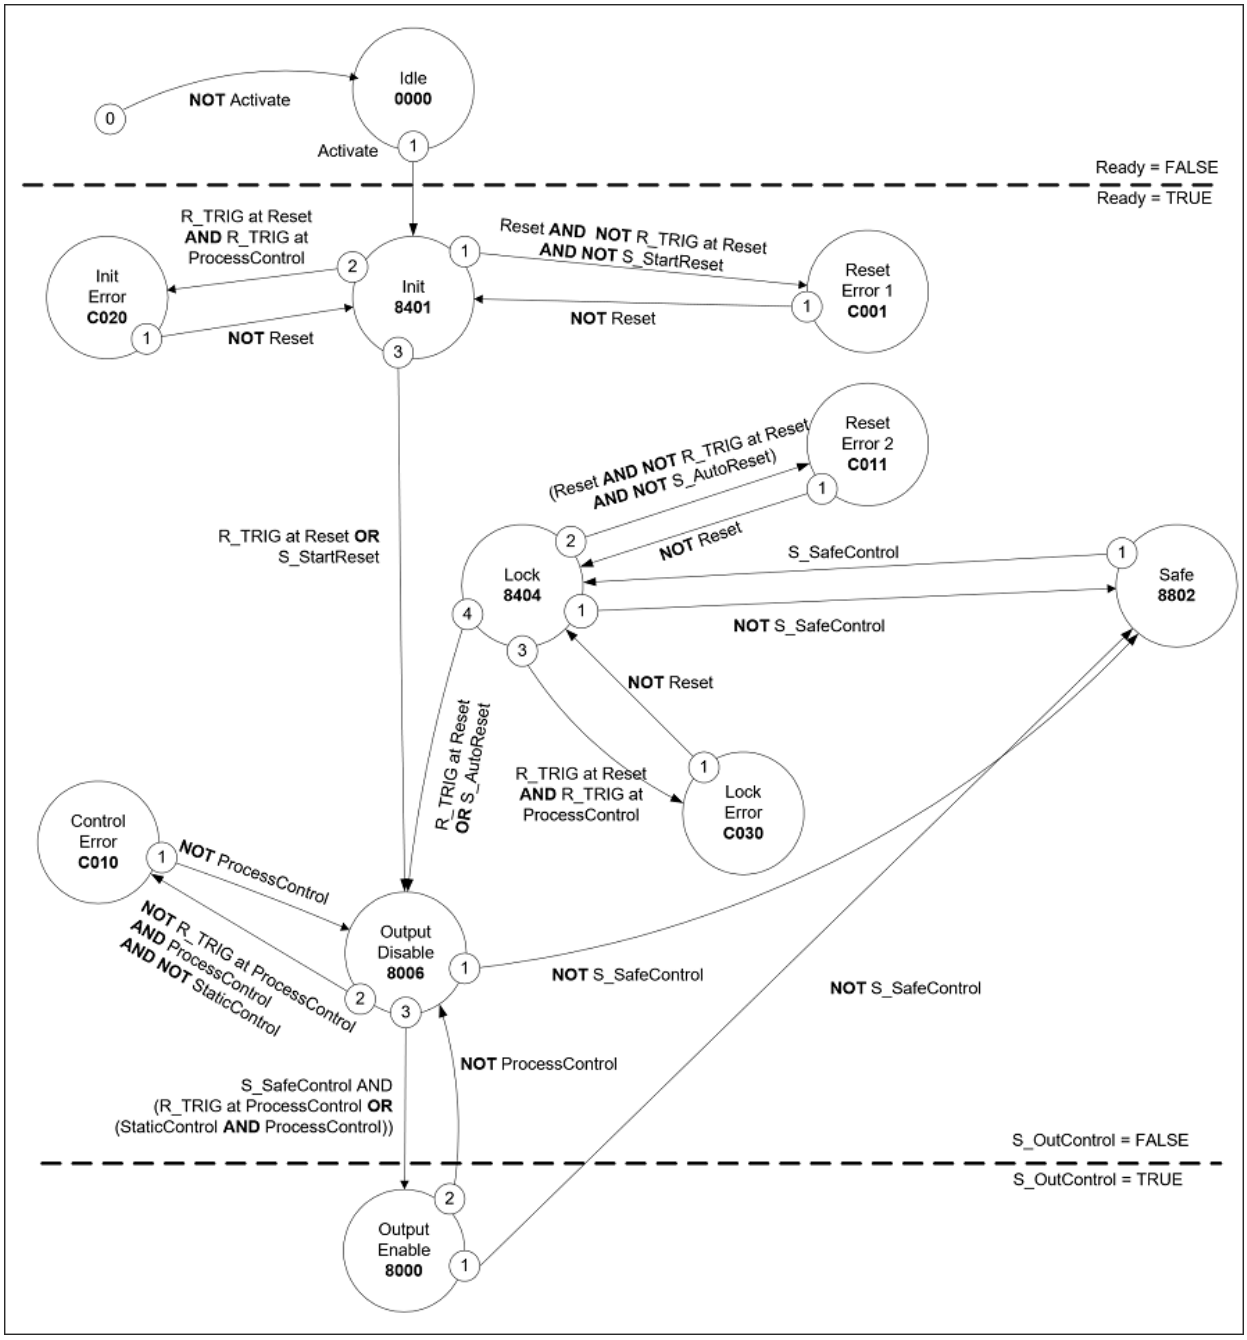
  Variables

Input / Output	Variable	Data Type	Valid Range	Default Value	Description
Input	Activate	BOOL	TRUE, FALSE	FALSE	Activates the instruction.
	S_SafeControl	SAFEBOOL	TRUE, FALSE	FALSE	Safety request input.
	ProcessControl	BOOL	TRUE, FALSE	FALSE	Control signal from functional application.
	StaticControl	BOOL	TRUE, FALSE	FALSE	Status of process control.
	S_StartReset	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether to start reset.
	S_AutoReset	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether to automatically reset.
	Reset	BOOL	TRUE, FALSE	FALSE	Manual reset
Output	Ready	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is in ready status.
	S_OutControl	SAFEBOOL	TRUE, FALSE	FALSE	Safety output.
	SafetyDemand	BOOL	TRUE, FALSE	FALSE	Activates or maintains the status according to the instruction status.
	ResetRequest	BOOL	TRUE, FALSE	FALSE	Flag indicating whether a reset is required.
	Error	BOOL	TRUE, FALSE	FALSE	Faulty status
	DiagCode	WORD	Follows data type	16#0000	Status code: Indicates fault code when instruction fails; indicates instruction status when instruction is running.

- **Function description**
  - The SF_OutControl function block serves as a drive for safety output control. Its input signals include:
    - Process application signal: ProcessControl/BOOL (used to control process flow).
    - Safety application signal: S_SafeControl/SAFEBOOL (used to control safety functions).
  - Optional conditions for ProcessControl:
    - Condition 1: After the function block is activated or the safety signal (S_SafeControl) is fed back, ProcessControl must transition from FALSE to TRUE to trigger the additional function; a static TRUE signal cannot set S_OutControl to TRUE.
    - Condition 2: After the function block is activated or the safety signal (S_SafeControl) is fed back, ProcessControl is not required to transition from FALSE to TRUE for the additional function; a static TRUE signal can set S_OutControl to TRUE if other conditions are met.
  - Optional start inhibit conditions:
    - Start inhibit after function block activation
    - Start inhibit after guard device interruption

◦ Inputs StaticControl, S_StartReset, and S_AutoReset can only be activated when no hazardous situation will occur during PES startup.

- **Status transition diagram**



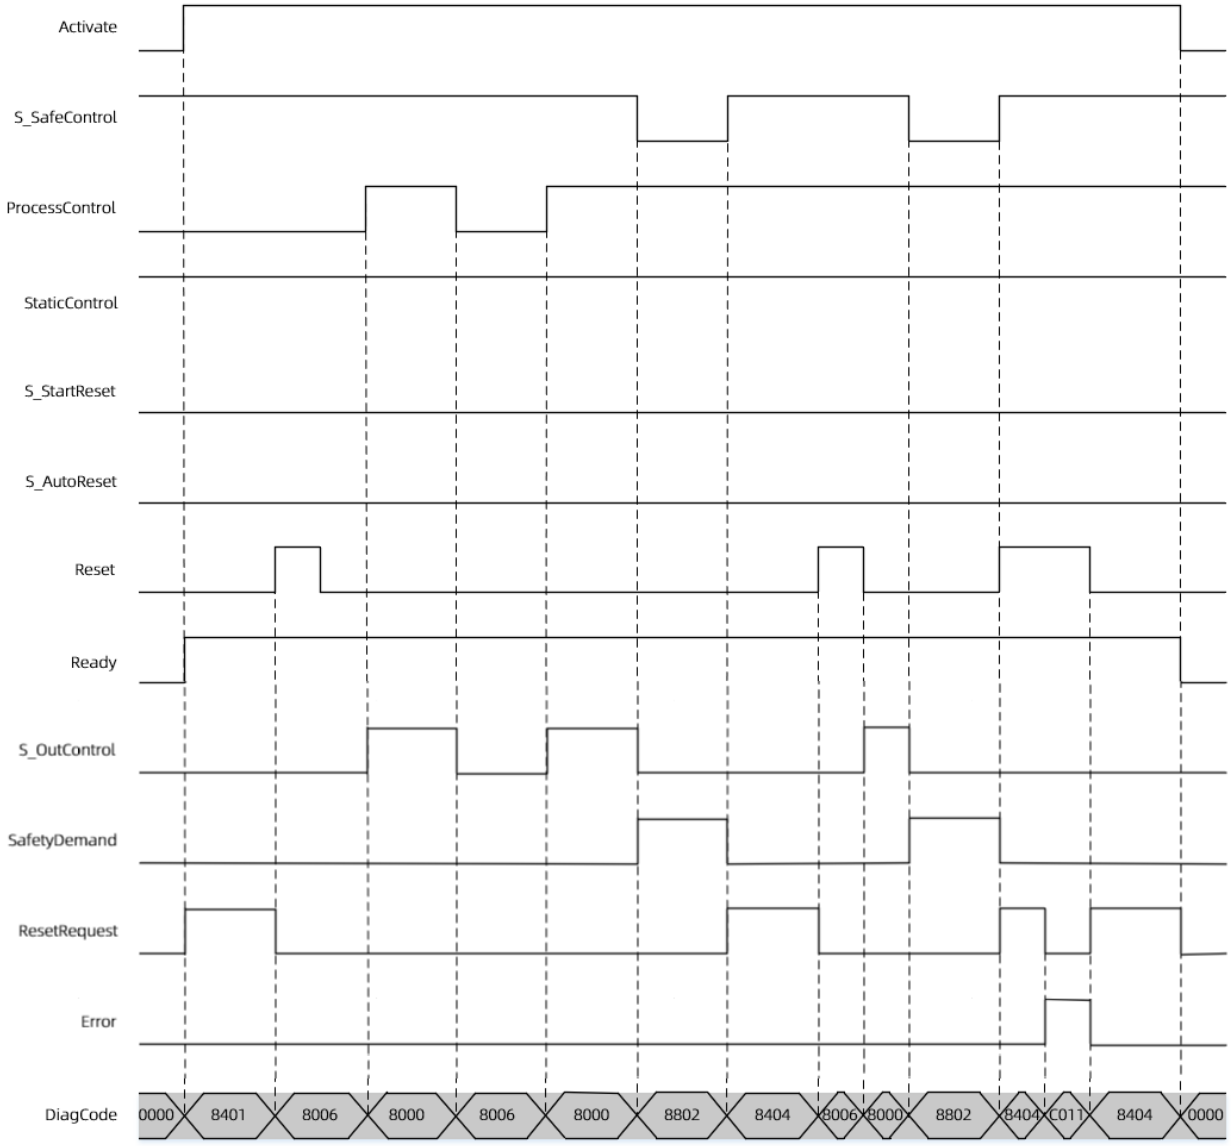


Figure 11-10-2-2-19-1 Status transition diagram for SF_OutControl

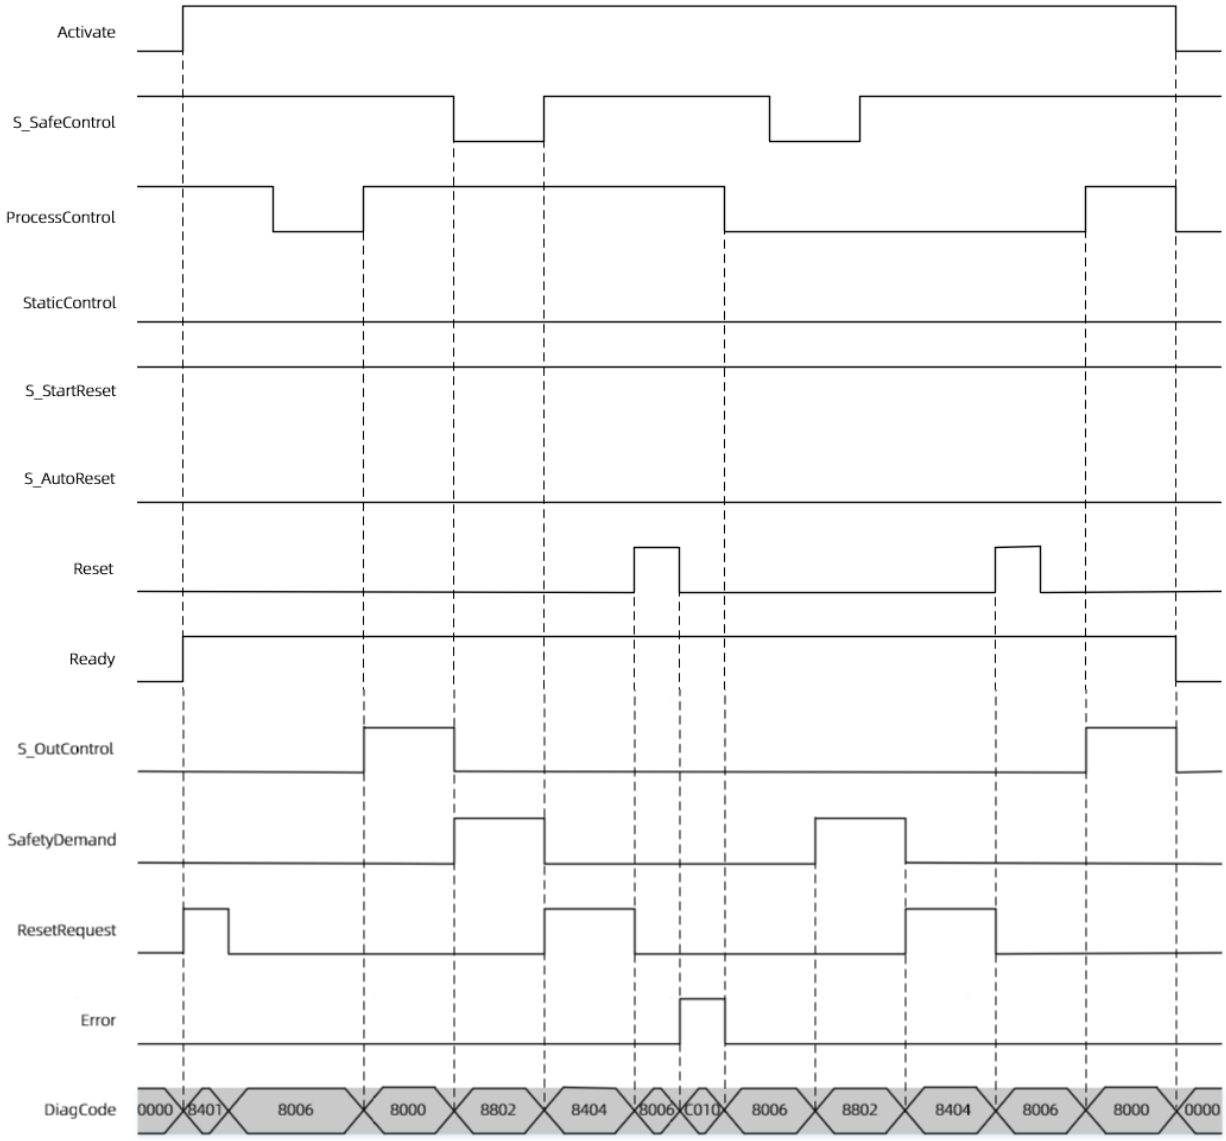
◦ This diagram is referenced from the PLCopen specification, and the copyright belongs to the PLCopen organization.



◦ The transition from any status to the idle status when Activate = FALSE is not indicated, but the priority (0) for transitioning to the idle status is the highest.

- **Sequence diagram**

S_StartReset = FALSE

S_StartReset = TRUE

- **Fault detection**

  The functional block forces a transition to the faulty status under the following conditions:

  - An invalid static Reset signal is detected.
  - An invalid static ProcessControl signal is detected.
  - ProcessControl and Reset are incorrectly interconnected due to a programming fault.

- **Fault behavior**

  When a fault occurs, S_OutControl is set to FALSE and remains in the safety status.

  - Fault clearance conditions:

    The Reset input must be set to FALSE to exit the Reset, Init, or Lock faulty status.

    The ProcessControl input must be set to FALSE to exit the Control faulty status.

  - Start inhibit reset method:

    After S_SafeControl switches to TRUE, the optional start inhibit can be reset by a rising edge at the Reset input.

    After the function block is activated, the optional start inhibit can be reset by a rising edge at the Reset input.

- **Function block-specific fault codes and status codes**
  - Fault code

DiagCode	Status Name	Description and Output
C001	Reset Error 1	In the 8401 status, a TRUE value of Reset is triggered at the non-rising edge. Ready = TRUE S_OutControl = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE
C011	Reset Error 2	In the 8404 status, a TRUE value of Reset is triggered at the non-rising edge. Ready = TRUE S_OutControl = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE
C010	Control Error	In the 8006 status, a TRUE value of ProcessControl is triggered at the non-rising edge. Ready = TRUE S_OutControl = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE
C020	Init Error	Reset and ProcessControl are triggered simultaneously in the 8401 status. Ready = TRUE S_OutControl = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE

DiagCode	Status Name	Description and Output
C030	Lock Error	Reset and ProcessControl are triggered simultaneously in the 8404 status. Ready = TRUE S_OutControl = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE

◦ Status code

11.10.2.2.20 SF_Override

SF_Override overrides the muting function. It allows product movement on the production line even if the muting function is aborted due to a fault. This function block is applicable only when used with the SF_MutingXXX instruction.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_Override	Override muting function	FB		

- **Related variables**

  Variables

Input / Output	Variable	Data Type	Valid Range	Default Value	Description
Input	Activate	BOOL	TRUE, FALSE	FALSE	Activates the instruction.
	S_AOPD_In	SAFEBOOL	TRUE, FALSE	FALSE	A OSSD signal from AOPD, indicating safety request input. FALSE: Protective field is interrupted. TRUE: Protective field is not interrupted.
	S_Muting_AOPD_Out	SAFEBOOL	TRUE, FALSE	FALSE	FALSE/TRUE: Depends on the status of the safety-related output S_AOPD_Out of the previous muting function block.
	MutingError	BOOL	TRUE, FALSE	FALSE	Fault output of the previous connected muting function block. FALSE: No fault occurs in the muting process. TRUE: A fault occurs in the muting process.
	MutingSwitch11	BOOL	TRUE, FALSE	FALSE	Status of the muting sensor signal at the MutingSwitch11 input of the previous muting function block. FALSE: Muting sensor 11 is not activated. TRUE: Muting sensor 11 is activated.
	MutingSwitch12	BOOL	TRUE, FALSE	FALSE	Status of the muting sensor signal at the MutingSwitch12 input of the previous muting function block. FALSE: Muting sensor 12 is not activated. TRUE: Muting sensor 12 is activated.
	MutingSwitch21	BOOL	TRUE, FALSE	FALSE	Status of the muting sensor signal at the MutingSwitch21 input of the previous muting function block. FALSE: Muting sensor 21 is not activated. TRUE: Muting sensor 21 is activated.

Input / Output	Variable	Data Type	Valid Range	Default Value	Description
	MutingSwitch22	BOOL	TRUE, FALSE	FALSE	Status of the muting sensor signal at the MutingSwitch22 input of the previous muting function block. FALSE: Muting sensor 22 is not activated. TRUE: Muting sensor 22 is activated.
	MaxOverrideTime	TIME	Follows data type	T#0ms	Ranges from 0 to 10 minutes. Indicates the total time of the override process. Timer starts when the override start condition becomes available. The timer continues running even after all muting sensors are no longer active, until the muting process ends.
	S_StartStopOverride	SAFEBOOL	TRUE, FALSE	FALSE	Signal to start and stop the override function. A rising edge is required to start the override function. TRUE: If all override conditions are met, the override process begins. At this point, the timer for MaxOverrideTime also starts. FALSE: The override process stops. The timer for MaxOverrideTime continues running until the muting process ends.
	Reset	BOOL	TRUE, FALSE	FALSE	Manual reset
Output	Ready	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is in ready status.
	S_AOPD_Out	SAFEBOOL	TRUE, FALSE	FALSE	Safety-related output Indicates the status of the muted protective device or override signal. FALSE: The AOPD protective field is interrupted and the muting function is not activated, or the override function is not activated. TRUE: The AOPD protective field is not interrupted or the muting function is activated, or the override function is activated.

Input / Output	Variable	Data Type	Valid Range	Default Value	Description
	OverridePossible	BOOL	TRUE, FALSE	FALSE	Status signal indicating whether the override function can be activated. FALSE: The override function cannot be activated. TRUE: The override function can be activated.
	OverrideActive	BOOL	TRUE, FALSE	FALSE	Indicates the status of the override process. FALSE: The override function is not activated. TRUE: The override function is activated.
	SafetyDemand	BOOL	TRUE, FALSE	FALSE	Activates or maintains the status according to the instruction status.
	ResetRequest	BOOL	TRUE, FALSE	FALSE	Flag indicating whether a reset is required.
	Error	BOOL	TRUE, FALSE	FALSE	Faulty status
	DiagCode	WORD	Follows data type	16#0000	Status code: Indicates fault code when instruction fails; indicates instruction status when instruction is running.

- **Function description**
  - The override function for manual operation may be required to remove obstructions generated during the muting process from the safety area. If the override function is activated, stop requests issued by safety devices will not take effect. The function block SF_Override can only be used in combination with SF_MutingXXX. In the application, the SF_MutingXXX function block must be processed first, followed by the SF_Override function block.

The output faults and DiagCode from the connected muting function block will not be transmitted to the output faults and DiagCode of the SF_Override function block.

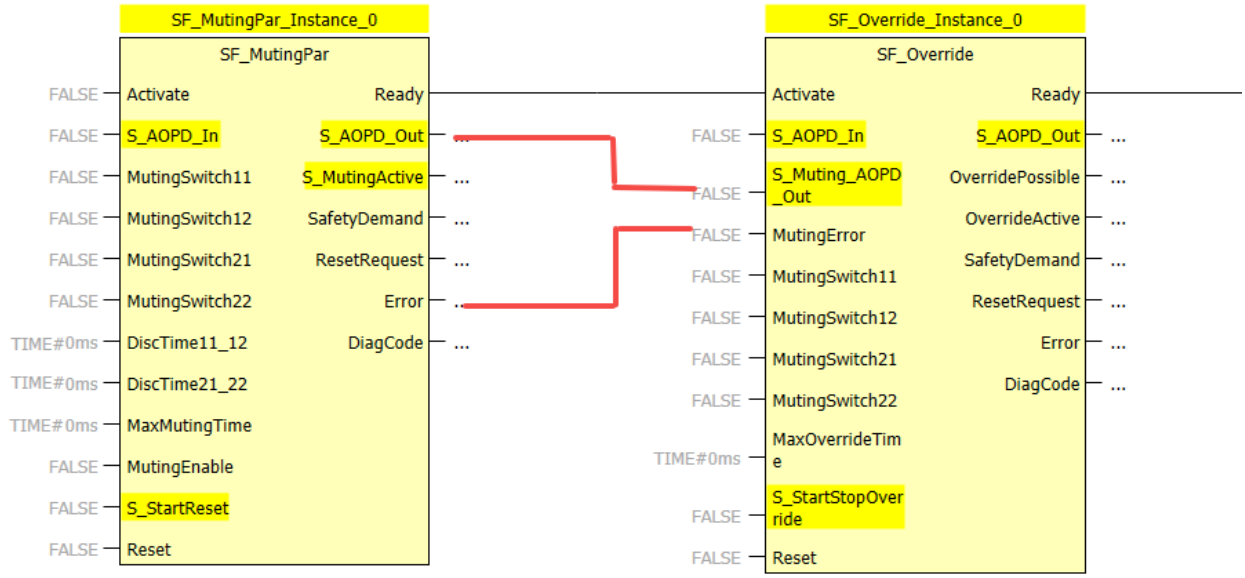

Figure 11-10-2-2-20-1 Combination of SF_Override and SF_Muting_Par with four sensors

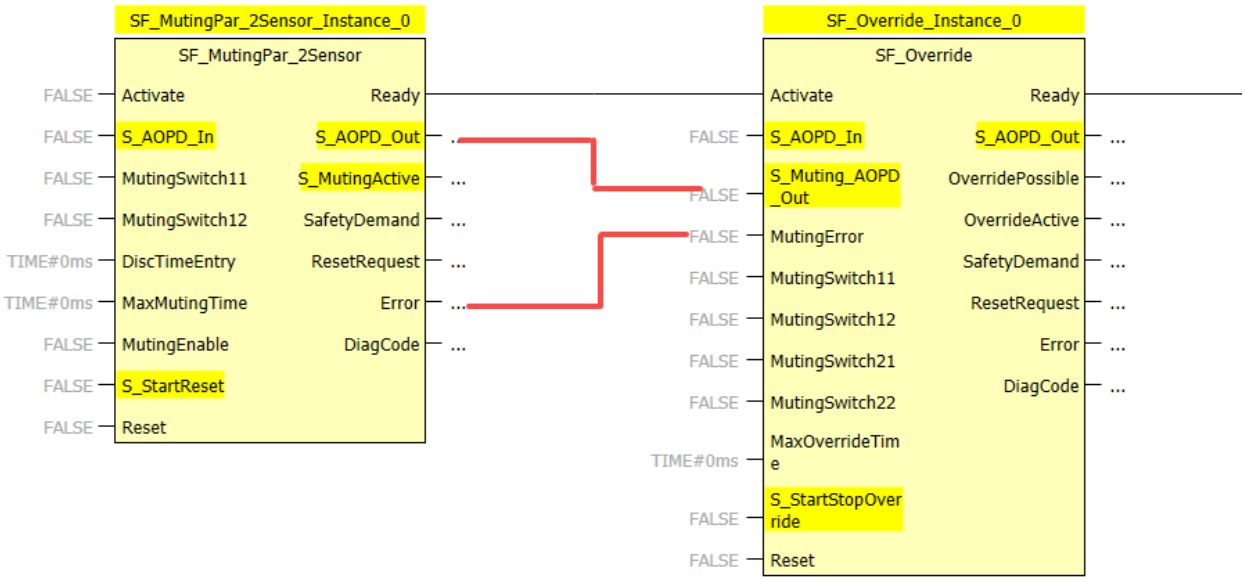

Figure 11-10-2-2-20-2 Combination of SF_Override and SF_Muting_Seq with two sensors

- The output parameter S_AOPD_Out of this function block will be set to TRUE under the following conditions:
  - The preceding muting function reports a fault.
  - A TRUE value of the input parameter S_StartStopOverride is triggered at the rising edge and remains TRUE.
  - The protective device (e.g., light curtain) is interrupted and/or at least one muting sensor is blocked.
- The output parameter S_AOPD_Out of this function block will be set to FALSE under the following conditions:
  - All muting sensors are "cleared" and the protective device (e.g., light curtain) is not interrupted.
  - The override time has exceeded the value set by MaxOverrideTime.
  - The signal of the input parameter S_StartStopOverride is FALSE.

11.10.2.2.21 SF_PressControl

SF_PressControl controls the press.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_PressControl	Press control	FB		

- **Related variables**

  Variables

Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
Input	Activate	BOOL	TRUE, FALSE	FALSE	Activates the instruction.

Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
	S_CycleStart	SAFEBOOL	TRUE, FALSE	FALSE	This parameter starts the cycle mode according to the operational mode. A transition from FALSE to TRUE starts the press cycle independently of the operational mode. Setting mode: A FALSE value sets the S_Enable signal to FALSE. Manual mode: A FALSE signal sets S_Enable to FALSE, as long as the slide is not moving upward (i.e., the S_UpwardMoving output of SF_CamMonitoring is FALSE). Automatic mode: A transition from FALSE to TRUE starts the cycle. Subsequent FALSE signal will not stop the process. To stop the process, set the input AutomaticModeEnable to FALSE. FALSE: No request to start the process. TRUE: Request to start the process.
	S_SafetyPrecondition	SAFEBOOL	TRUE, FALSE	FALSE	Signal from the previous safety function block (such as SF_EmergencyStop and SF_GuardMonitoring) FALSE: The safety-related prerequisite has not been met. TRUE: The safety-related prerequisite has been met.
	S_SetupMode	SAFEBOOL	TRUE, FALSE	FALSE	Setting mode is selected through the SF_ModeSelector function block. FALSE: Setting mode is not selected. TRUE: Setting mode is selected.
	S_ManualMode	SAFEBOOL	TRUE, FALSE	FALSE	Setting mode is selected through the SF_ModeSelector function block. FALSE: Manual mode is not selected. TRUE: Manual mode is selected.
	S_AutomaticMode	SAFEBOOL	TRUE, FALSE	FALSE	Automatic mode is selected through the SF_ModeSelector function block. FALSE: Automatic mode is not selected. TRUE: Automatic mode is selected.

Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
	S_TDC	SAFEBOOL	TRUE, FALSE	FALSE	Signal from the previous safety function block "SF_CamMonitor". FALSE: The press is not in the TDC area. TRUE: The press is in the TDC area.
	S_UpwardMoving	SAFEBOOL	TRUE, FALSE	FALSE	Signal from the previous safety function block "SF_CamMonitor". FALSE: The press is not moving upward. TRUE: The press is moving upward.
	S_BackwardMove	SAFEBOOL	TRUE, FALSE	FALSE	Allows the slide to move backward. It applies only in setting mode via individual switch input. FALSE: Backward movement is not requested. TRUE: Backward movement is requested.
	AutomaticModeEnable	BOOL	TRUE, FALSE	FALSE	Control signal from the functional application, used to enable/disable the process in automatic mode at the next TDC. FALSE: Automatic mode is not enabled, or the cycle is completed at TDC. TRUE: Automatic mode is enabled.
	ExternalProcessEnable	BOOL	TRUE, FALSE	FALSE	Control signal from the functional application, used as the prerequisite to enable the process in all modes. It is typically not safety-critical. Restart can only be performed via CycleStart. FALSE: Request to set S_Enable to FALSE. TRUE: Request to set S_Enable to TRUE.
	S_StartReset	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether to start reset.
	Reset	BOOL	TRUE, FALSE	FALSE	Manual reset
Output	Ready	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is in ready status.
	S_Enable	SAFEBOOL	TRUE, FALSE	FALSE	Safety-related output FALSE: Disable the connected valve. TRUE: Enable the connected valve.

Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
	PressUp	BOOL	TRUE, FALSE	FALSE	Output signal for diagnostics. FALSE: The press is not moving upward. TRUE: The press is moving upward.
	SafetyDemand	BOOL	TRUE, FALSE	FALSE	Activates or maintains the status according to the instruction status.
	ResetRequest	BOOL	TRUE, FALSE	FALSE	Flag indicating whether a reset is required.
	Error	BOOL	TRUE, FALSE	FALSE	Faulty status
	DiagCode	WORD	Follows data type	16#0000	Status code: Indicates fault code when instruction fails; indicates instruction status when instruction is running.

- **Function description**
  - This function block provides three modes for press control and is used with the function blocks "SF_ModeSelector" and "SF_CamMonitor".
  - This function block implements the single stroke function in manual and setting modes.
  - Only one of the three modes can be selected through the function block "SF_ModeSelector".
  - The optional modes include:
    - Manual mode

      In manual mode, the single stroke function is activated.

      - A stroke is initiated at the rising edge (0 -> 1) of S_CycleStart when inputs S_TDC, S_SafetyPrecondition, and ExternalProcessEnable are all TRUE.
      - After initiation, S_CycleStart must remain TRUE until the rising edge of UpwardMoving. Otherwise, S_Enable is set to FALSE.
      - If a stroke is initiated between the TDC area and BDC, and S_CycleStart is set to FALSE, the stroke can be re-initiated outside the TDC area.
        An overtravel fault prevents the initiation of a stroke.
      - When TDC zone is reached, the output S_Enable is set to FALSE. The stroke is fully completed, and the process can be restarted.
      - The cycle overtravel control performs monitoring, and only allows restarting from the TDC position after the rising edge of the TDC signal is detected.
      - Overtravel fault can only be reset in setting mode.

    - Setting mode
      - Setting mode (clockwise)
        - A stroke can be initiated from any position.
        - The single stroke function is activated.
          - For details, see "Manual mode".
          - Overtravel faults are for diagnostics only.

        - Muting (BDC signal changing from FALSE to TRUE) is not activated (S_CycleStart must be TRUE throughout the entire cycle).
    - Setting mode (counterclockwise)
        - A stroke can be initiated from any position.
        - The single stroke function is not activated.
        - The stroke automatically stops at the rising edge of S_TDC.
        - Movement can only be performed with the two-hand control device.
    - Automatic mode
        - A stroke can be initiated from any position.
        - The single stroke function is not activated.
        - Muting (BDC signal changing from FALSE to TRUE) is not activated.
        - If both S_SafetyPrecondition and AutomaticModeEnable are TRUE, the first stroke starts at the rising edge of S_CycleStart (S_CycleStart can be FALSE after the rising edge).
        - The stroke is stopped by setting S_SafetyPrecondition to FALSE or AutomaticModeEnable to FALSE.
        - If automatic mode is stopped while AutomaticModeEnable = FALSE, the cycle will continue until reaching TDC.
        - If S_SafetyPrecondition = FALSE, movement stops immediately.

    In all modes, if S_SafetyPrecondition = FALSE, movement stops immediately; if S_SafetyPrecondition is set to TRUE, a new press cycle can be triggered when Reset is triggered at the non-rising edge.

Automatic mode

- **Fault detection**

  The faulty status is triggered by the following conditions:

  - A static TRUE signal is detected at the Reset input.

- TDC is not activated after press cycle (overtravel fault).
- More than one mode has been selected.

- **Fault behavior**
  - When a fault occurs, the output S_Enable is set to FALSE. The DiagCode output indicates the relevant fault code, and the Error output is set to TRUE.
  - Restart is prohibited until the fault condition is cleared and the operator confirms the safety status via Reset.
- **Function block-specific fault codes and status codes**
  - Fault code

DiagCode	Status Name	Description and Output
8814	TDC Error for Diagnostic	This is not a fault in setting mode, used only for diagnostics. Ready = TRUE S_Enable = FALSE PressUp = FALSE SafetyDemand = TRUE ResetRequest = FALSE Error = FALSE
8100	Output Active Manual Mode	The press cycle is started in manual mode. Ready = TRUE S_Enable = TRUE PressUp = TRUE when the rising edge of S_UpwardMoving is detected. SafetyDemand = FALSE ResetRequest = FALSE Error = FALSE
8110	Output Active Setup Mode	The press cycle is started in setting mode. Ready = TRUE S_Enable = TRUE PressUp = TRUE when the rising edge of S_UpwardMoving is detected. SafetyDemand = FALSE ResetRequest = FALSE Error = FALSE
8120	Output Active Automatic Mode	The press cycle is started in automatic mode. Ready = TRUE S_Enable = TRUE PressUp = TRUE when the rising edge of S_UpwardMoving is detected. SafetyDemand = FALSE ResetRequest = FALSE Error = FALSE

DiagCode	Status Name	Description and Output
8130	Backwards Move	A press cycle is initiated in setting mode, and the press moves backwards. Ready = TRUE S_Enable = TRUE PressUp = TRUE when S_UpwardMoving is FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = FALSE

11.10.2.2.22 SF_PSE

SF_PSE monitors pressure-sensitive equipment (PSE), such as safety mats, buffers, etc.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_PSE	Pressure-sensitive equipment	FB		

- **Related variables**

  Variables

Input / Output	Variable	Data Type	Valid Range	Default Value	Description
Input	Activate	BOOL	TRUE, FALSE	FALSE	Activates the instruction.
	S_PSE_In	SAFEBOOL	TRUE, FALSE	FALSE	Safety requirement input. FALSE: PSE is activated, and a safety-related requirement is input. TRUE: PSE is not activated, and no safety-related requirement is input.
	S_StartReset	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether to start reset.
	S_AutoReset	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether to automatically reset.
	Reset	BOOL	TRUE, FALSE	FALSE	Manual reset
Output	Ready	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is in ready status.
	S_PSE_Out	SAFEBOOL	TRUE, FALSE	FALSE	Safety-related output FALSE: Safety output is disabled. TRUE: Safety output is enabled.

Input / Output	Variable	Data Type	Valid Range	Default Value	Description
	SafetyDemand	BOOL	TRUE, FALSE	FALSE	Activates or maintains the status according to the instruction status.
	ResetRequest	BOOL	TRUE, FALSE	FALSE	Flag indicating whether a reset is required.
	Error	BOOL	TRUE, FALSE	FALSE	Faulty status
	DiagCode	WORD	Follows data type	16#0000	Status code: Indicates fault code when instruction fails; indicates instruction status when instruction is running.

- **Function description**
  - This function block is used to monitor pressure-sensitive equipment (PSE), such as safety mats and buffers.

Table11-10-2-2-22-1 Different PSE configurations in practice

Short-circuit forming designs (energise to trip principle)		**Positive opening contact design (deenergise to trip principle)**
4-wire variant	Resistance variant	
		
A short circuit is formed when the protective device is activated. For the 4-wire variant, one circuit is shorted (with a resistance in the range of several ohms). For the resistance variant, a change in the set resistance (in the range of kiloohms) is detected.		This design is more universal and advantageous. When the protective device is activated, a switch contact on the safety switch is opened. By special wiring, short circuits are avoided.

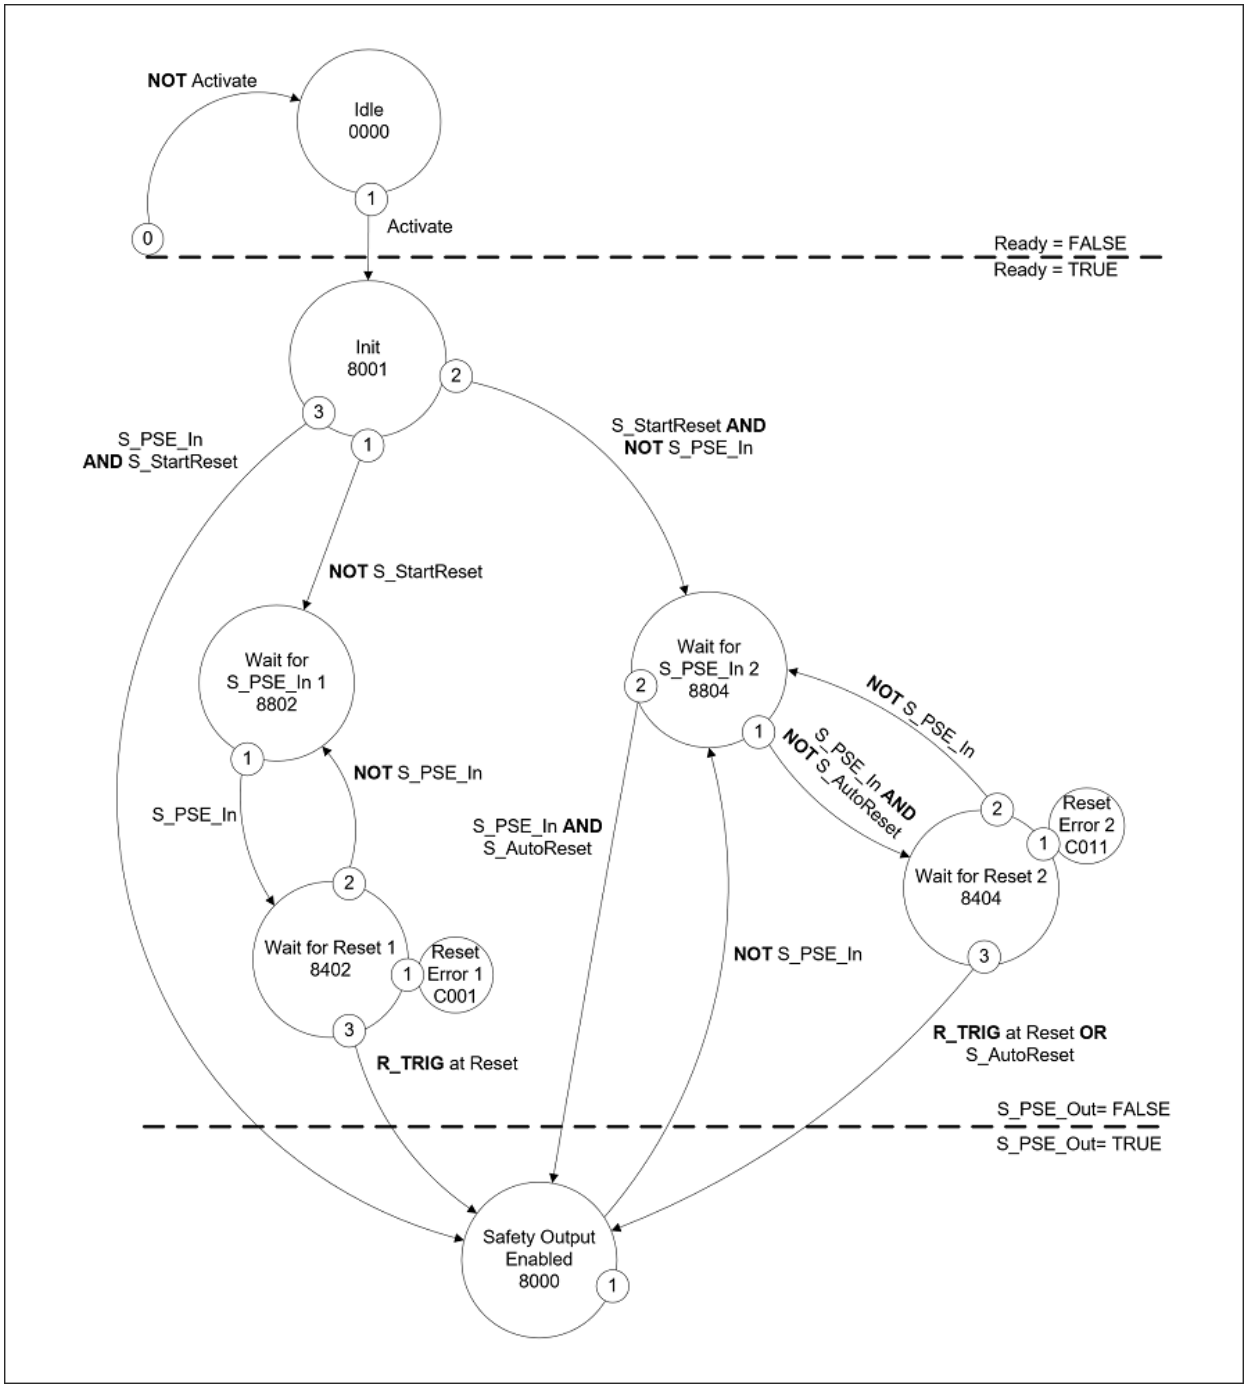
  - This function block requires a FALSE signal to activate the safety function. Therefore, as shown on the right of the figure above, PSE with positive opening contact design can be directly connected to a safety input device. However, the other two designs, as shown on the left of the figure above, require an evaluation unit to generate a suitable FALSE signal when the PSE is activated.
  - This function is identical to SF_EmergencyStop (except for two additional outputs: SafetyDemand and ResetRequest). Once the S_PSE_In input is set to FALSE, the S_PSE_Out is set to FALSE. The S_PSE_Out output signal is set to TRUE only when the S_PSE_In input is set to TRUE and a reset is performed. The enabling of the reset depends on the defined inputs S_StartReset, S_AutoReset and Reset.
    - If S_AutoReset = TRUE, reset is automatically confirmed.
    - If S_AutoReset = FALSE, reset is confirmed by a rising edge trigger of the Reset input.

- If S_StartReset = TRUE, reset is automatically confirmed upon the first startup of the PES.
- If S_StartReset = FALSE, reset is confirmed by a rising edge trigger of the Reset input.

S_StartReset and S_AutoReset inputs can only be activated when it is ensured that no hazardous conditions occur when the PES starts up.

◦ SF_PSE must be selected according to the product standards EN 1760-1, -2, and -3 and the performance level requirements of ISO 13849-1:2008.

- **Status transition diagram**



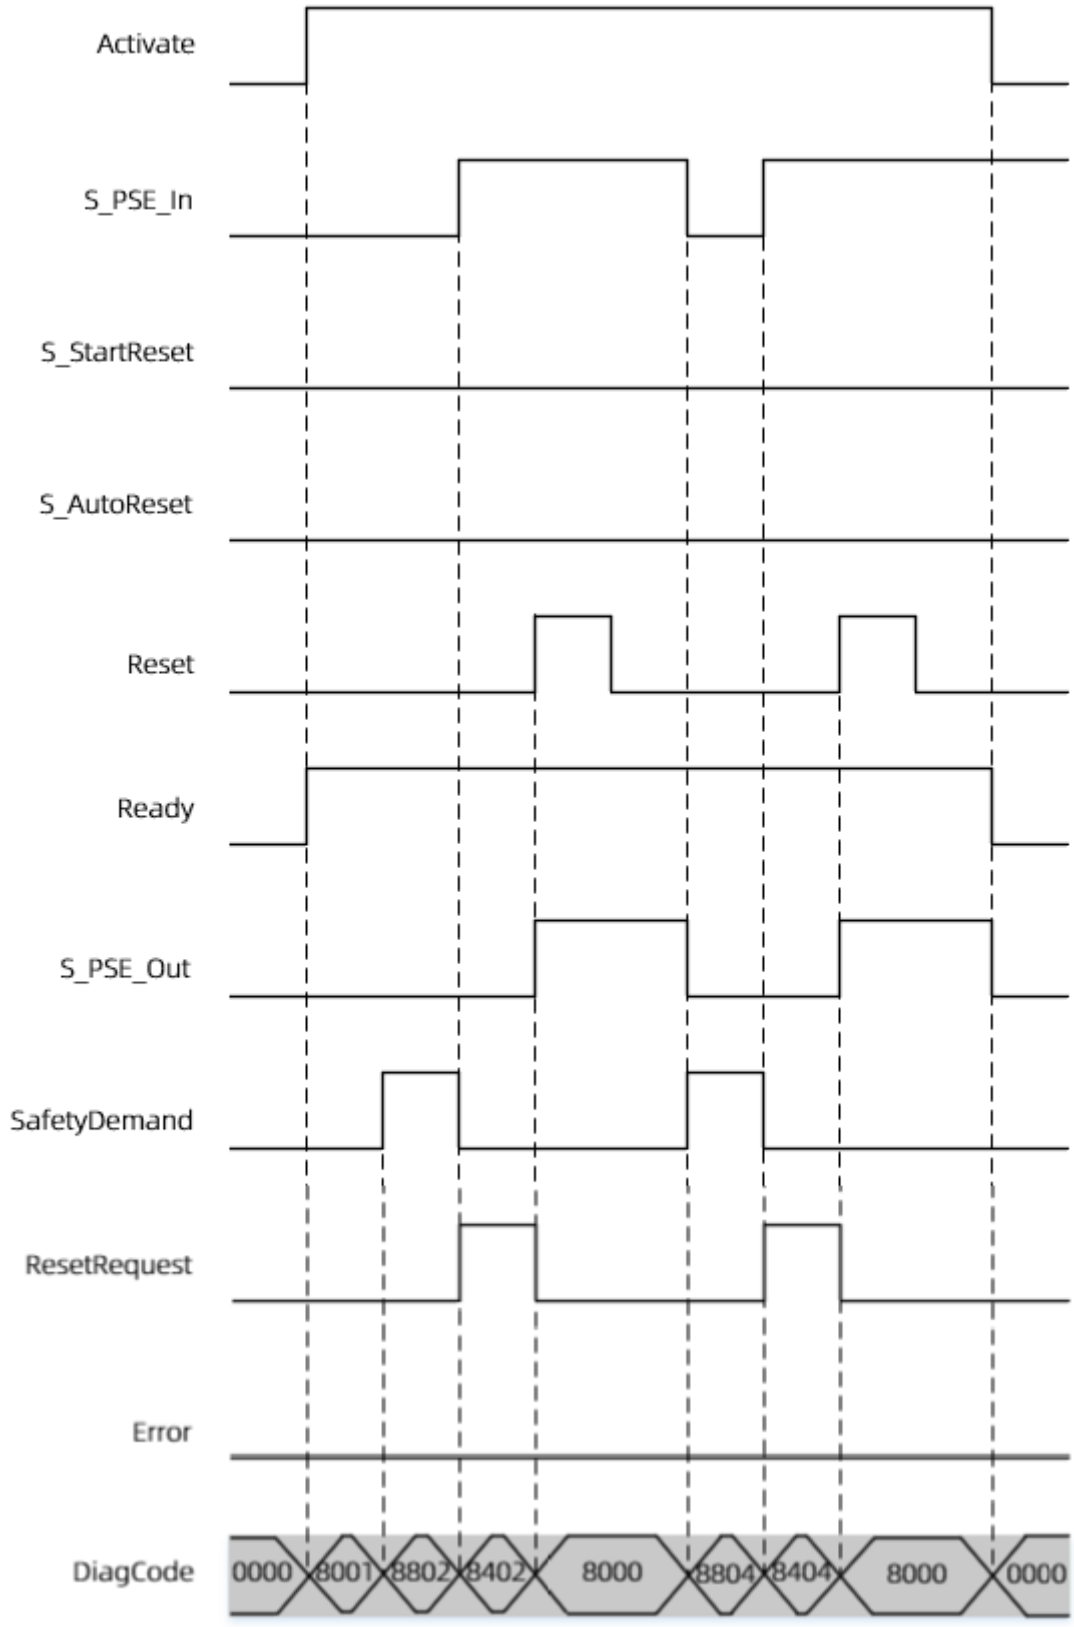


Figure 11-10-2-2-22-1 Status transition diagram for SF_PSE

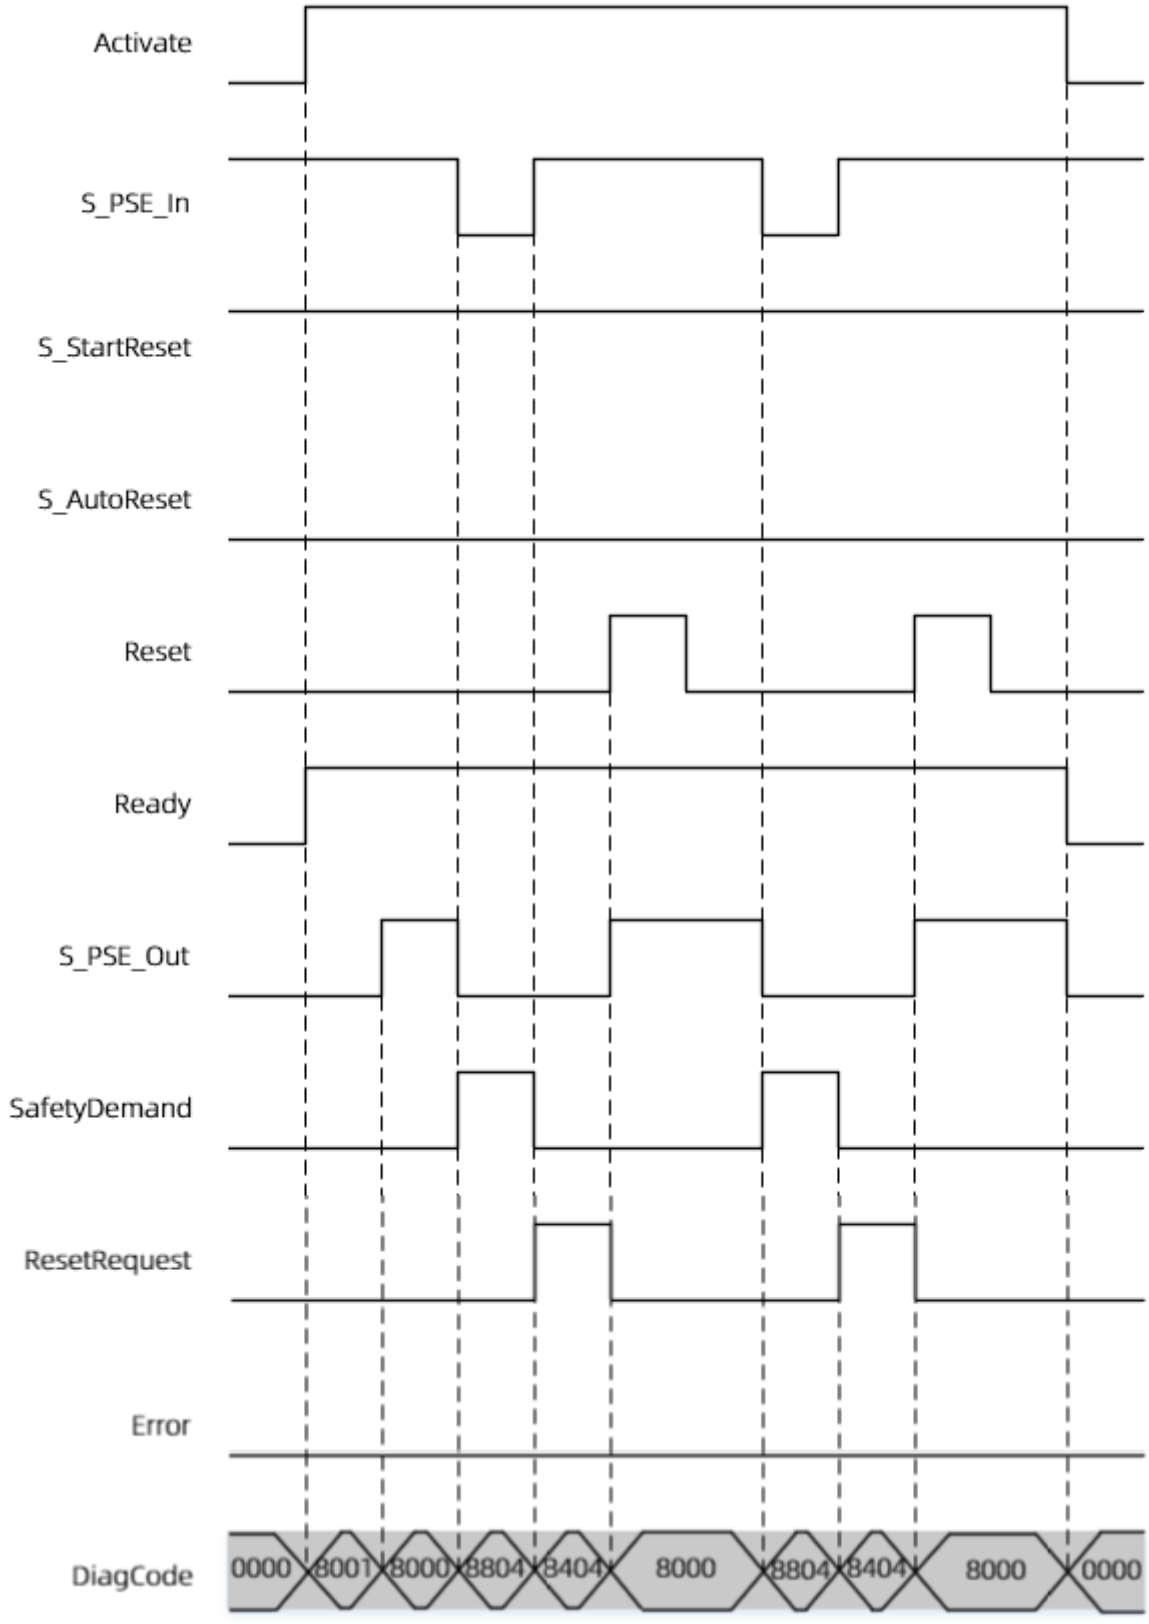
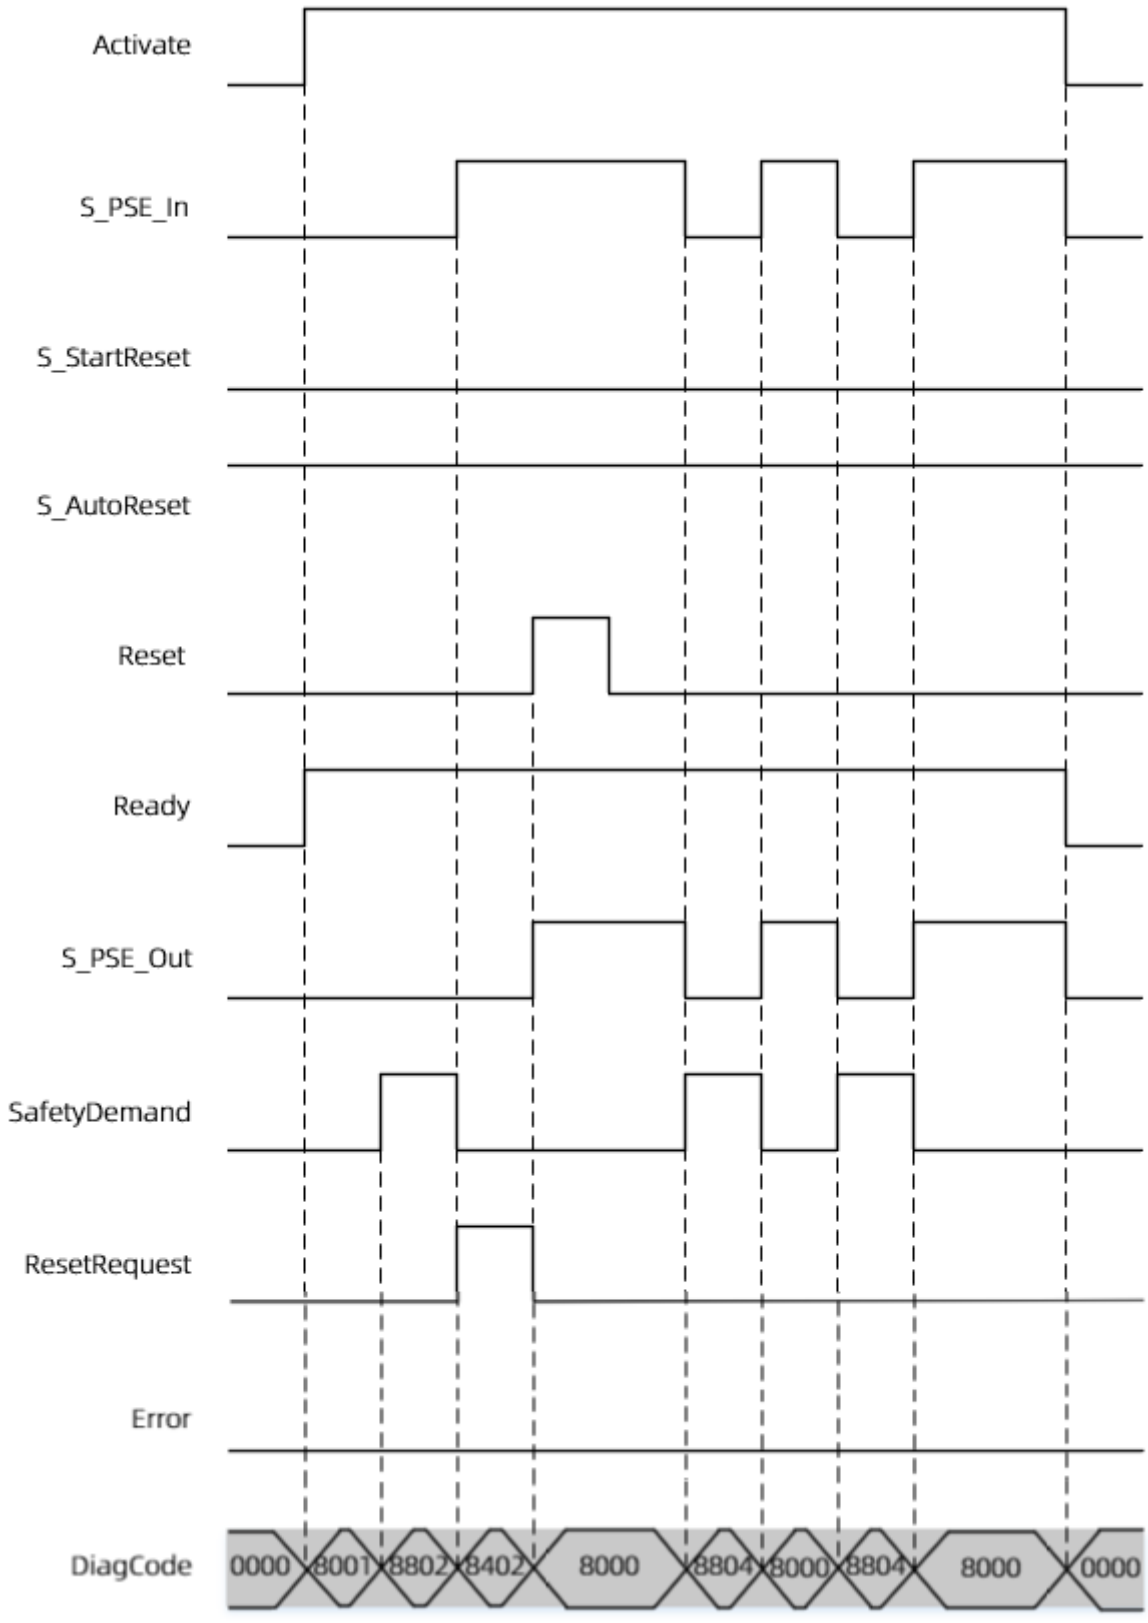
◦ This diagram is referenced from the PLCopen specification, and the copyright belongs to the PLCopen organization.



◦ The transition from any status to the idle status when Activate = FALSE is not indicated, but the priority (0) for transitioning to the idle status is the highest.

- **Sequence diagram**



S_StartReset = FALSE, S_AutoReset = FALSE

S_StartReset = TRUE, S_AutoReset = FALSE

S_StartReset = FALSE, S_AutoReset = TRUE

- **Fault detection**

  The faulty status is triggered when a TRUE value of Reset is detected at the non-rising edge.

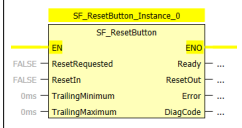
- **Fault behavior**

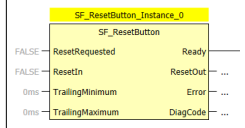
  S_PSE_Out is set to FALSE. If a static TRUE signal is detected at the Reset input, the DiagCode output displays the relevant fault code, and the Error output is set to TRUE. To exit the faulty status, Reset must be set to FALSE.

- **Function block-specific fault codes and status codes**
  - Fault code

DiagCode	Status Name	Description and Output
C001	Reset Error 1	Reset is set to TRUE while waiting for S_PSE_In = TRUE. Ready = TRUE S_PSE_Out = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE
C011	Reset Error 2	Reset is set to TRUE while waiting for S_PSE_In = TRUE. Ready = TRUE S_PSE_Out = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE

  - Status code





DiagCode	Status Name	Description and Output
0000	Idle	Function block is not activated (initial status). Ready = FALSE S_PSE_Out = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = FALSE
8001	Init (Initialization)	Function block is enabled, Check if S_StartReset is required. Ready = TRUE S_PSE_Out = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = FALSE

DiagCode	Status Name	Description and Output
8802	Wait for S_PSE_In (Wait for S_PSE 1)	Check if Reset is faulty, and wait for S_PSE_In = FALSE. Ready = TRUE S_PSE_Out = FALSE SafetyDemand = TRUE ResetRequest = FALSE Error = FALSE
8402	Wait for Reset 1	S_PSE_In = FALSE. Wait for the rising edge of Reset. Ready = TRUE S_PSE_Out = FALSE SafetyDemand = FALSE ResetRequest = NOT Reset Error = FALSE
8804	Wait for S_PSE_In (Wait for S_PSE 2)	The function block detected a safety request. Check if Reset is faulty, and wait for S_PSE_In = FALSE. Ready = TRUE S_PSE_Out = FALSE SafetyDemand = TRUE ResetRequest = FALSE Error = FALSE
8404	Wait for Reset 2	S_PSE_In = FALSE. Check S_AutoReset or wait for the rising edge of Reset. Ready = TRUE S_PSE_Out = FALSE SafetyDemand = FALSE ResetRequest = NOT Reset Error = FALSE
8000	Safety Output Enabled	S_PSE_In = FALSE. In function mode, S_PSE_Out = FALSE. Ready = TRUE S_PSE_Out = TRUE SafetyDemand = FALSE ResetRequest = FALSE Error = FALSE

11.10.2.2.23 SF_ResetButton

SF_ResetButton adds a falling edge function to function blocks that originally only detect rising-edge triggers for reset. This function is compliant with the EN ISO 13849-1:2015 standard.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_ResetButton	Reset button	FB		

- **Related variables**

  Variables

Input / Output	Variable	Data Type	Valid Range	Default Value	Description
Input	ResetRequested	BOOL	TRUE, FALSE	FALSE	Input connected to the ResetRequest output of the paired function block. TRUE: Reset requested. FALSE: No reset request / ResetIn not monitored.
	ResetIn	BOOL	TRUE, FALSE	FALSE	Input of the reset button. FALSE: Reset button released. TRUE: Reset button activated.
	TrailingMinimum	TIME	Follows data type	T#350ms	Valid at trailing edge. Minimum time the reset button must be activated. If the reset button is pressed for less than this time, the reset is ignored. Typical value is 350 ms. The absolute minimum is 100 ms, under which the task cycle time shall be less than or equal to TrailingMinimum / 2.
	TrailingMaximum	TIME	Follows data type	T#2s	Valid at trailing edge. Maximum time the reset button can be activated. Typical value is 2s. If the reset button is pressed for longer than this time, the reset is ignored.
Output	Ready	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is in ready status.

Input / Output	Variable	Data Type	Valid Range	Default Value	Description
	ResetOut	BOOL	TRUE, FALSE	FALSE	Pulse used to initiate the reset process. This pulse is generated after the falling edge. A rising-edge pulse output is generated first, which lasts for at least one cycle.
	Error	BOOL	TRUE, FALSE	FALSE	Faulty status
	DiagCode	WORD	Follows data type	16#0000	Status code: Indicates fault code when instruction fails; indicates instruction status when instruction is running.

- **Function description**

  This function block is used in automated control systems to provide a safety-compliant reset mechanism. It allows the system to safely resume operation after an emergency stop or safety event through intentional and explicit user operations. It detects the rising and falling edges of the reset button, ensuring that the reset action is executed only when specific safety conditions are met, thus preventing unintended operations and accidental startups, and safeguarding personnel and equipment.

Fault	No request	Request enabled	↓	↑↓
Switch jam		OK	OK	OK
Abnormal voltage-high-level latching			OK	OK

OK Module/signal in pre-operational status

↑ Rising-edge triggering

↓ Falling-edge triggering

↑↓ Reset on rising edge and fault detection on falling edge

  - This diagram is referenced from the PLCopen specification, and the copyright belongs to the PLCopen organization.
  - The transition from any status to the idle status when ResetRequested = FALSE is not indicated, but the priority (0) for transitioning to the idle status is the highest.

- **Sequence diagram**

- **Fault detection**

  The faulty status is triggered by the following conditions:

  - ResetIn is already TRUE when ResetRequested becomes TRUE.
  - ResetRequested and ResetIn are TRUE, and the reset button is pressed for a time less than TrailingMinimum or longer than TrailingMaximum.

- **Fault behavior**

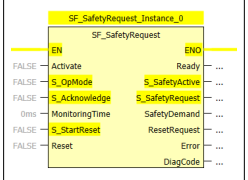
  When the ResetIn input is a static TRUE signal, the DiagCode output indicates the corresponding fault code, and the Error output is set to TRUE.

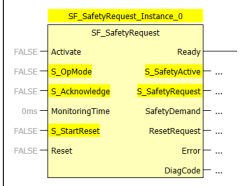
- **Function block-specific fault codes and status codes**

  - Fault code

DiagCode	Status Name	Description and Output
C000	Parameter Error	TrailingMinimum > TrailingMaximum or TrailingMinimum < 100 ms. Ready = TRUE ResetOut = FALSE Error = TRUE
C001	Reset Error	ResetIn is triggered at the non-rising edge. Ready = TRUE ResetOut = FALSE Error = TRUE
C3E0	Error Trailing Maximum	The maximum time for the trailing edge has been exceeded before the falling edge of ResetIn is detected. Ready = TRUE ResetOut = FALSE Error = TRUE
C3F0	Error Trailing Minimum	The minimum time for the trailing edge has not been exceeded before the falling edge of ResetIn is detected. Ready = TRUE ResetOut = FALSE Error = TRUE

◦ Status code





DiagCode	Status Name	Description and Output
0000	Idle	Function block is not activated (initial status). Ready = FALSE ResetOut = FALSE Error = FALSE
83E2	Wait for R_TRIG (Wait for rising edge)	Function block is enabled, and is waiting for rising edge of ResetIn. Ready = TRUE ResetOut = FALSE Error = FALSE

DiagCode	Status Name	Description and Output
83F2	Wait for F_TRIG (waiting for falling edge)	Function block is enabled, and is waiting for falling edge of ResetIn. Ready = TRUE ResetOut = FALSE Error = FALSE
8000	Reset Detected	Valid reset action is detected. This status is valid for at least one cycle and will automatically transition to the Wait for R_TRIG status. Ready = TRUE ResetOut = TRUE Error = FALSE

11.10.2.2.24 SF_SafetyRequest

SF_SafetyRequest targets safety-enabled actuators (such as drives and valves) to request and monitor their safety statuses.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_SafetyRequest	Safety request	FB		

- **Related variables**

  Variables

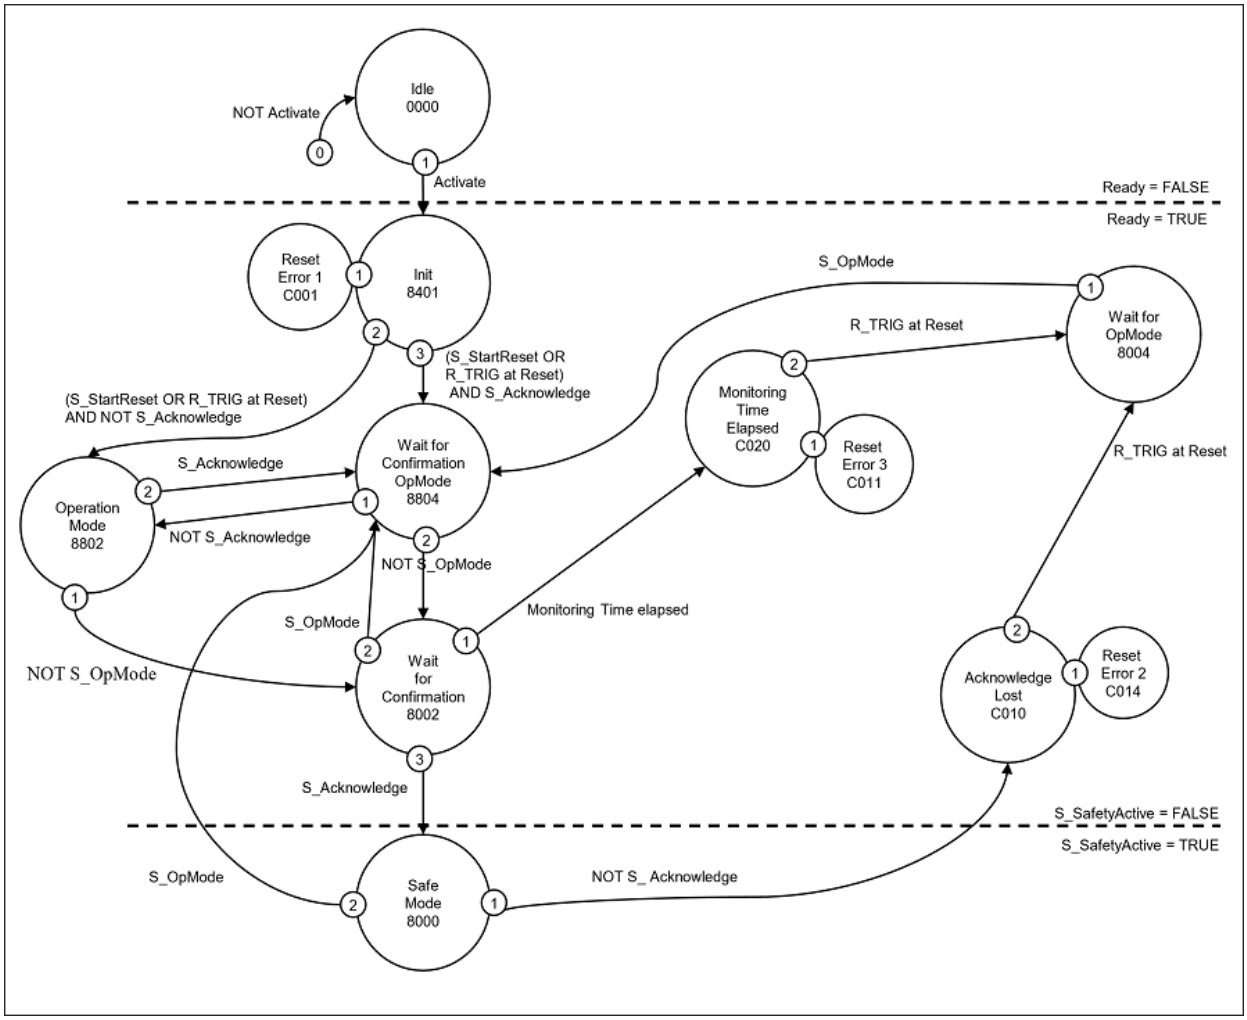
Input / Output	Variable	Data Type	Valid Range	Default Value	Description
Input	Activate	BOOL	TRUE, FALSE	FALSE	Activates the instruction.
	S_OpMode	SAFEBOOL	TRUE, FALSE	FALSE	Requested mode of the general-purpose safety actuator. FALSE: Request safety mode. TRUE: Request operational mode.
	S_Acknowledge	SAFEBOOL	TRUE, FALSE	FALSE	Confirm that the general-purpose actuator is in safety status. FALSE: Operational mode (non-safe). TRUE: Safe mode.

Input / Output	Variable	Data Type	Valid Range	Default Value	Description
	MonitoringTime	TIME	Follows data type	T#0ms	Response time between the safety function request (S_OpMode set to FALSE) and actuator confirmation (S_Acknowledge set to TRUE).
	S_StartReset	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether to start reset.
	Reset	BOOL	TRUE, FALSE	FALSE	Manual reset
Output	Ready	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is in ready status.
	S_SafetyActive	SAFEBOOL	TRUE, FALSE	FALSE	Confirmation of safety status. FALSE: Non-safety status. TRUE: Safety status.
	S_SafetyRequest	SAFEBOOL	TRUE, FALSE	FALSE	Request to set the actuator in safety status. FALSE: Request safety status. TRUE: Request operational mode.
	SafetyDemand	BOOL	TRUE, FALSE	FALSE	Activates or maintains the status according to the instruction status.
	ResetRequest	BOOL	TRUE, FALSE	FALSE	Flag indicating whether a reset is required.
	Error	BOOL	TRUE, FALSE	FALSE	Faulty status
	DiagCode	WORD	Follows data type	16#0000	Status code: Indicates fault code when instruction fails; indicates instruction status when instruction is running.

- **Function description**
  - This function block provides an interface between safety-related systems and general-purpose actuators, so that the safety-related functions of actuators can be called through the application. The actuator's safety status is controlled by only two binary signals: one for requesting and one for receiving confirmation.
    Safety functions are implemented by the actuators. Therefore, this function block is responsible only for initiating the request, monitoring the request, and setting the output when the actuator confirms the safety status (indicated by the S_SafetyActive output).
  - Parameter definition:
    This function block does not define parameters dedicated to general-purpose actuators; such parameters shall be defined within the actuators themselves.
    The function block is used to switch the general-purpose actuator from the operational mode to the safety status.
  - Additional input function:

    The S_StartReset input provides an automatic cold start function. Setting it to FALSE ensures compatibility with the original function.

- **Status transition diagram**



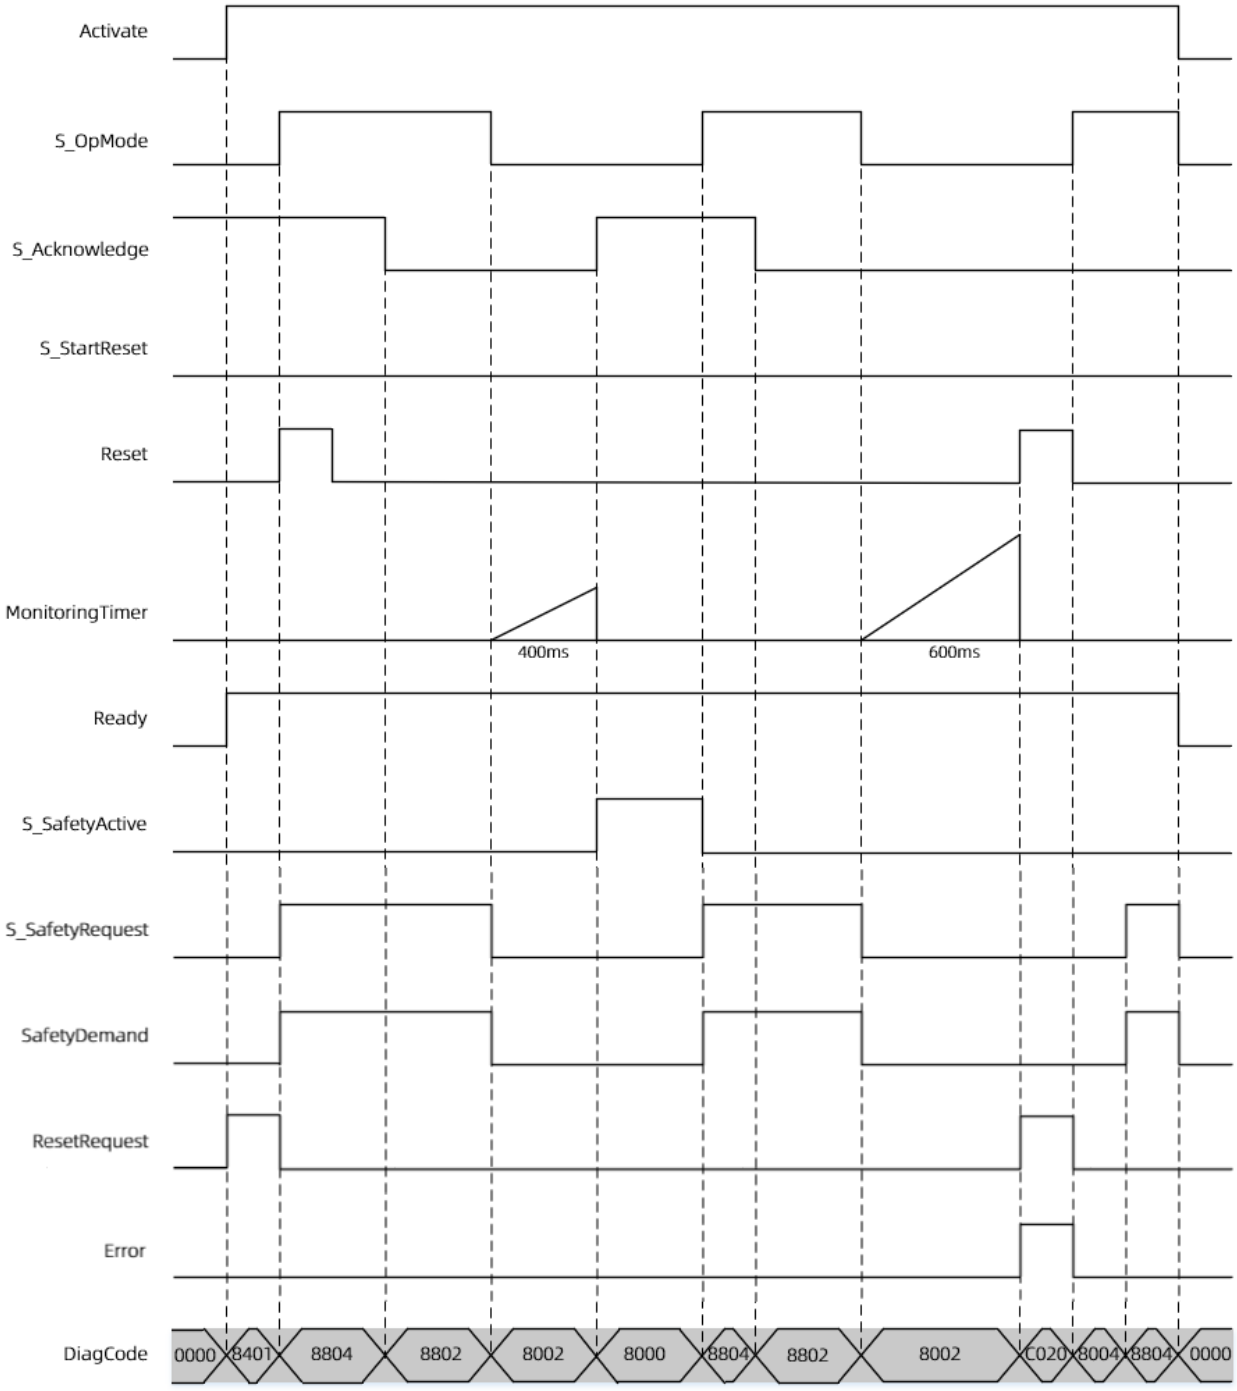


Figure 11-10-2-2-24-1 State transition diagram for SF_SafetyRequest

  - This diagram is referenced from the PLCopen specification, and the copyright belongs to the PLCopen organization.
  - The transition from any status to the idle status when Activate = FALSE is not indicated, but the priority (0) for transitioning to the idle status is the highest.

- **Sequence diagram**

- **Fault detection**
  - Detects that the actuator fails to enter the safety status within the monitoring time.
  - Detects that no confirmation signal is sent before the request becomes invalid.
  - Detects that a TRUE value of Reset is triggered at the non-rising edge.
- **Fault behavior**

  When a fault occurs, the S_SafetyActive output is set to FALSE.

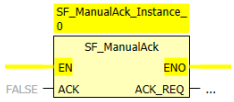
  The fault must be reset by a rising edge trigger of the Reset input. To continue operating the function block after this reset, set the S_OpMode request to TRUE or set S_Acknowledge to TRUE.
- **Function block-specific fault codes and status codes**
  - Fault code

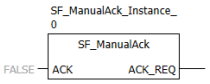
DiagCode	Status Name	Description and Output
C010	Acknowledge Lost	The confirmation signal is lost in the safety status. Ready = TRUE S_SafetyActive = FALSE S_SafetyRequest = FALSE SafetyDemand = FALSE ResetRequest = NOT Reset Error = TRUE
C020	MonitoringTime Elapsed	S_OpMode request cannot be completed within the monitoring time. Ready = TRUE S_SafetyActive = FALSE S_SafetyRequest = FALSE SafetyDemand = FALSE ResetRequest = NOT Reset Error = TRUE
C001	Reset Error 1	In the 8401 status, a TRUE value of Reset is detected at the non-rising edge. Ready = TRUE S_SafetyActive = FALSE S_SafetyRequest = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE
C014	Reset Error 2	In the C010 status, a TRUE value of Reset is detected at the non-rising edge. Ready = TRUE S_SafetyActive = FALSE S_SafetyRequest = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE

DiagCode	Status Name	Description and Output
C011	Reset Error 3	In the C020 status, a TRUE value of Reset is detected at the non-rising edge. Ready = TRUE S_SafetyActive = FALSE S_SafetyRequest = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE

◦ Status code

DiagCode	Status Name	Description and Output
0000	Idle	Function block is not activated (initial status). Ready = FALSE S_SafetyActive = FALSE S_SafetyRequest = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = FALSE
8000	Safe Mode	The actuator is in safe mode. Ready = TRUE S_SafetyActive = TRUE S_SafetyRequest = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = FALSE





DiagCode	Status Name	Description and Output
8401	Init (Initialization)	The function block enters the initialization status when it is activated or when a TRUE value of the Reset input is detected at the rising edge. Ready = TRUE S_SafetyActive = FALSE S_SafetyRequest = FALSE SafetyDemand = FALSE ResetRequest = NOT Reset Error = FALSE
8802	Operation Mode	Indicates the operational mode without safe mode confirmation. Ready = TRUE S_SafetyActive = FALSE S_SafetyRequest = TRUE SafetyDemand = TRUE ResetRequest = FALSE Error = FALSE
8804	Wait for Confirmation OpMode	Indicates the operational mode with safe mode confirmation. Ready = TRUE S_SafetyActive = FALSE S_SafetyRequest = TRUE SafetyDemand = TRUE ResetRequest = FALSE Error = FALSE
8002	Wait for Confirmation	The function block is waiting for confirmation from the actuator (system interface). Ready = TRUE S_SafetyActive = FALSE S_SafetyRequest = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = FALSE

DiagCode	Status Name	Description and Output
8004	Wait for OpMode	Faults have been removed. However, the function block can only be continued with S_OpMode or S_Acknowledge set to TRUE. Ready = TRUE S_SafetyActive = FALSE S_SafetyRequest = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = FALSE

11.10.2.2.25 SF_ManualAck

SF_ManualAck is a function block used for manual confirmation.

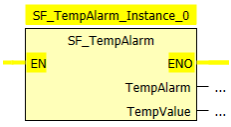
- **Instruction format**

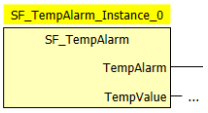
Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_ManualAck	Safety confirmation	FB		

- **Related variables**

  Variables

Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
Input	ACK	BOOL	TRUE, FALSE	FALSE	Manual confirmation operation. TRUE: Manual confirmation operation performed. FALSE: Manual confirmation operation not performed.
Output	ACK_REQ	BOOL	TRUE, FALSE	FALSE	Safety confirmation request. TRUE: Safety confirmation request exists. FALSE: No safety confirmation request.





- **Function description**

  This function block contains the input parameter "ACK" for confirmation operation and output parameter "ACK_REQ" for confirmation request. "ACK_REQ" being TRUE indicates a manual confirmation request is performed. It indicates that users confirm manually by writing TRUE to "ACK", with the TRUE status lasting for more than 1s and less than 10s. The safety PLC identifies the manual confirmation operation. When the confirmation is successful, ACK_REQ becomes FALSE.

11.10.2.2.26 SF_TempAlarm

SF_TempAlarm is a function block used for temperature alarm.

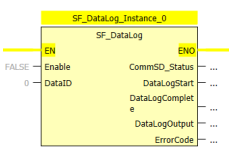
- **Instruction format**

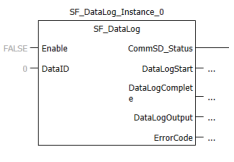
Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_TempAlarm	Temperature alarm	FB		

- **Related variables**

  Variables

Input/Output	Variable	Data Type	Valid Range	Default Value	Description
Output	TempAlarm	BOOL	TRUE, FALSE	FALSE	Temperature alarm. TRUE: Temperature exceeds the acceptable range. FALSE: Temperature is within the acceptable range.
	TempValue	DINT	Follows data type.	0	Indicates temperature display value. Displays device temperature.





- **Function description**

  This function block is used to monitor device temperature. The device temperature is displayed via the output parameter "TempValue", and an alarm is triggered via the output parameter "TempAlarm" when the temperature exceeds the acceptable range.

11.10.2.2.27 SF_DataLog

SF_DataLog is a function block used for safety data logging.

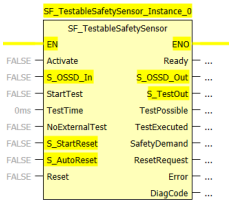
- **Instruction format**

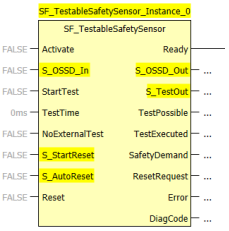
Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_DataLog	Safety logging function	FB		

- **Related variables**

  Variables

Input / Output	Variable	Data Type	Valid Range	Default Value	Description
Input	Enable	BOOL	TRUE, FALSE	FALSE	Rising edge: Start safety data logging function. Falling edge: Stop safety data logging function.
	DataID	DINT	1, 2	1	Safety data logging group number.
Output	CommSD_Status	BOOL	TRUE, FALSE	FALSE	SD card status. TRUE: SD card status is normal. FALSE: SD card status is faulty.
	DataLogStart	BOOL	TRUE, FALSE	FALSE	Safety data logging start flag. TRUE: Safety data logging is in progress. FALSE: Safety data logging has stopped.
	DataLogComplete	BOOL	TRUE, FALSE	FALSE	Safety data logging completion flag. TRUE: Safety data logging has been completed. FALSE: Safety data logging has not been completed.
	DataLogOutput	BOOL	TRUE, FALSE	FALSE	Safety data logging writing flag. TRUE: Safety data logging is written to file. FALSE: Safety data logging is not written to file.
	ErrorCode	INT	Follows data type	0	Fault code when safety data logging encounters a fault.





- **Function description**

  This function block is used to start/stop safety data logging. It displays the safety data logging status: SD card status, logging start status, logging completion status, output file status.

11.10.2.2.28 SF_TestableSafetySensor

SF_TestableSafetySensor is a function block used to detect faults such as sensing unit detection capability failure, excessive response time, and static ON signals in single-channel sensor systems. It is applicable to externally testable safety sensors, such as electro-sensitive protective equipment (ESPE, such as light curtains).

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_TestableSafetySensor	Testable safety sensors	FB		

- **Related variables**

  Variables

Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
Input	Activate	BOOL	TRUE, FALSE	FALSE	Activates the instruction.
	S_OSSD_In	SAFEBOOL	TRUE, FALSE	FALSE	Output status of the sensor (such as light curtains). FALSE: Safety sensor is in test status or requests a safety-related response. TRUE: Safety sensor is in normal operating status.
	StartTest	BOOL	TRUE, FALSE	FALSE	Input to start sensor test. Set "S_TestOut" and start internal time monitoring function. FALSE: No test request. TRUE: Test request.
	TestTime	TIME	Follows data type	T#0ms	Ranges from 0 to 150 ms. Test time for safety sensor.
	NoExternalTest	BOOL	TRUE, FALSE	FALSE	Indicates whether external manual sensor test is supported. FALSE: External manual sensor test is supported. Automatic sensor test cannot be performed again after test failure until the manual sensor switch sequence is completed. TRUE: External manual sensor test is not supported.
	S_StartReset	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether to start reset.
	S_AutoReset	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether to automatically reset.
	Reset	BOOL	TRUE, FALSE	FALSE	Manual reset
Output	Ready	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is in ready status.

Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
	S_OSSD_Out	SAFEBOOL	TRUE, FALSE	FALSE	Safety-related output indicating the ESPE status. FALSE: A safety-related action request or test fault is present in the sensor. TRUE: No safety-related action request and no test fault in the sensor.
	S_TestOut	SAFEBOOL	TRUE, FALSE	FALSE	Connected to the sensor's test input. Although specified as SAFEBOOL, this signal is typically connected to a BOOL output in practice. FALSE: A test request is issued. TRUE: No test request is issued.
	TestPossible	BOOL	TRUE, FALSE	FALSE	Feedback signal process. FALSE: Automatic sensor test cannot be executed. TRUE: Automatic sensor test can be executed.
	TestExecuted	BOOL	TRUE, FALSE	FALSE	Indicates the successful execution of automatic sensor test. FALSE: Automatic sensor test has not been executed, is in progress, or is faulty. TRUE: Automatic sensor test has been successfully executed.
	SafetyDemand	BOOL	TRUE, FALSE	FALSE	Activates or maintains the status according to the instruction status.
	ResetRequest	BOOL	TRUE, FALSE	FALSE	Flag indicating whether a reset is required.
	Error	BOOL	TRUE, FALSE	FALSE	Faulty status
	DiagCode	WORD	Follows data type	16#0000	Status code: Indicates fault code when instruction fails; indicates instruction status when instruction is running.

- **Function description**
  - This function block (Type 2 ESPE) must be equipped with cyclic test capability to detect dangerous faults (such as sensing unit detection capability failure, excessive response time, etc.).
  - Test signals shall simulate the operation of the sensing device, and the cyclic test must not last for longer than 150 ms. The test verifies that each beam operates as specified by the supplier. If the cyclic

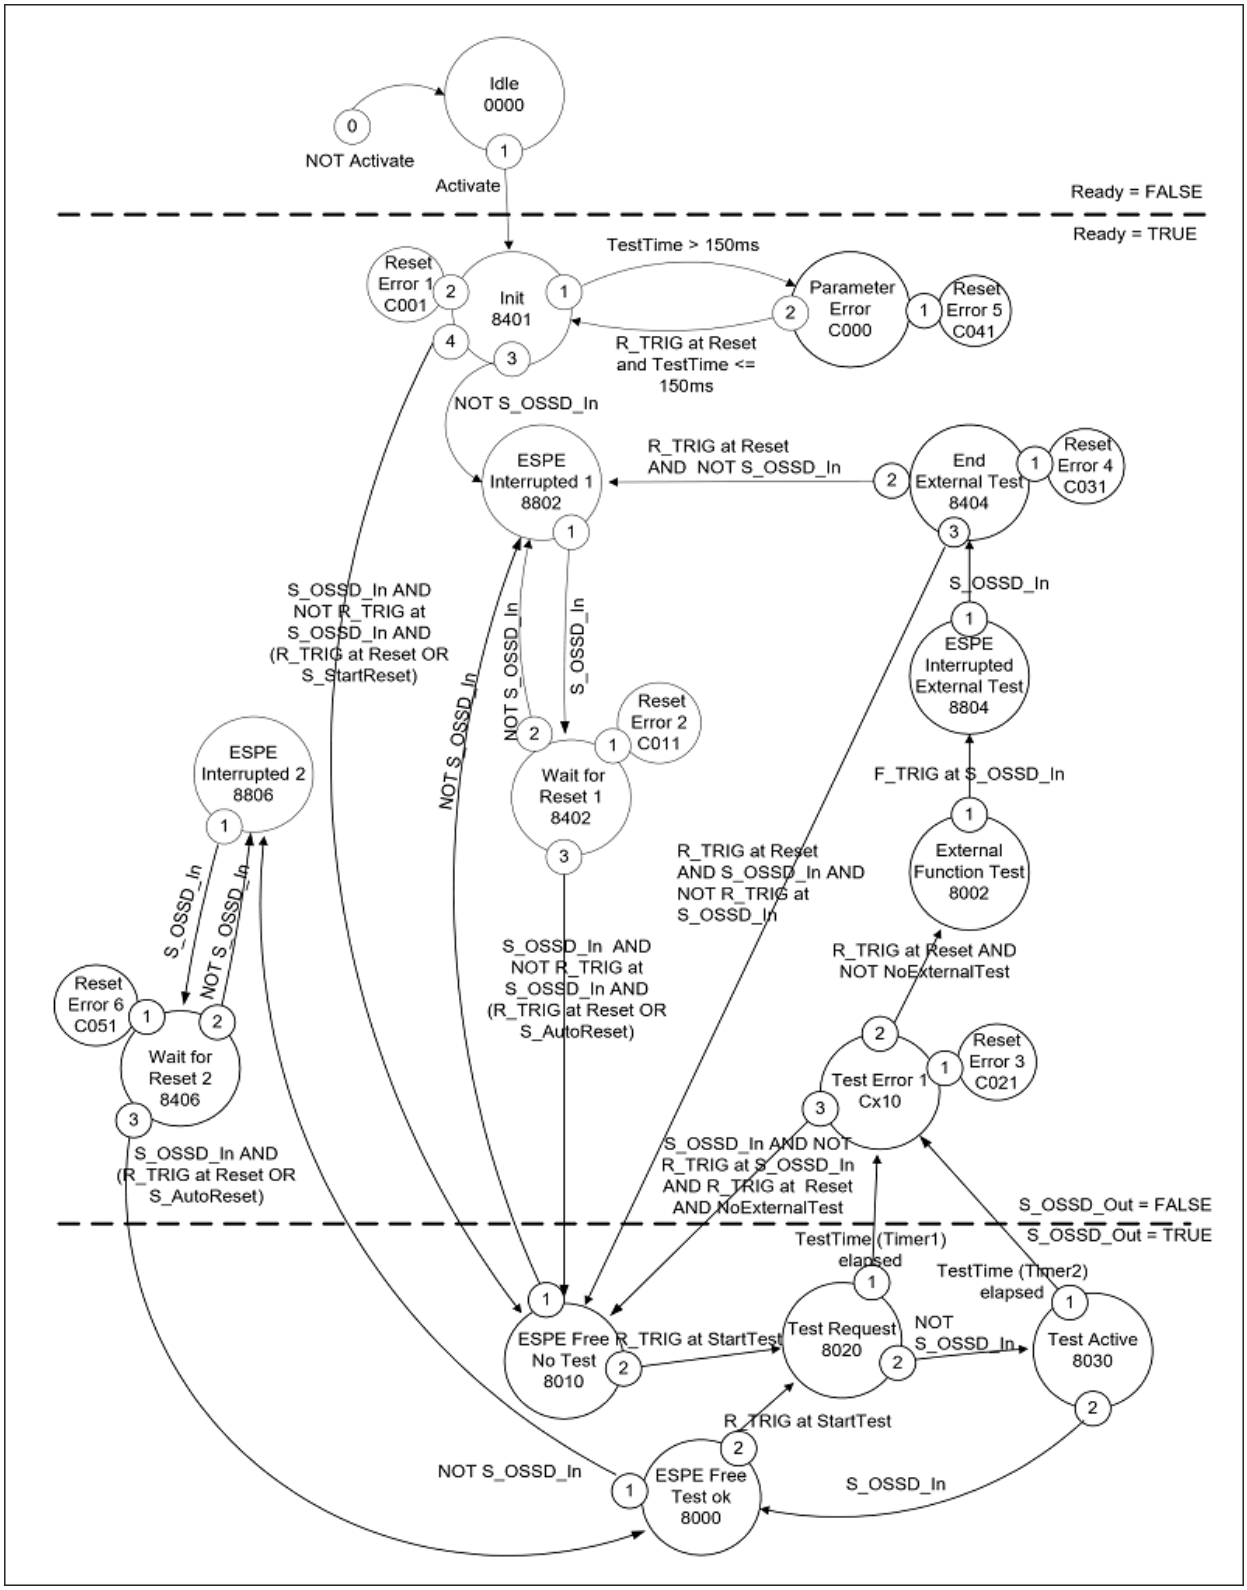
test needs to be triggered by an external safety-related control system (such as a machine equipment), the ESPE shall be equipped with appropriate input devices (such as terminals).

- The selection of the ESPE shall comply with the EN IEC 61496-1, -2, and -3 standards, and the test shall be monitored through independent functions to see if it is initiated at appropriate intervals
- Inputs S_StartReset and S_AutoReset can only be activated when it is ensured that the activation of the programmable electronic system (PES) will not cause hazardous conditions.

Power-on test of the ESPE is outside the scope of this function block and must be handled by users within the application.

- Test mode:
  1. StartTest = TRUE: S_TestOut is set to FALSE and monitoring timing is started.
  2. S_TestOut signal stops the transmitter (start TestTime monitoring for the first time).
  3. S_OSSD_In changes from TRUE to FALSE (start TestTime monitoring for the second time).
  4. S_TestOut changes from FALSE to TRUE.
  5. Start the transmitter.
  6. S_OSSD_In changes from FALSE to TRUE.
  7. Monitoring timing is stopped.
  8. During testing, S_OSSD_Out is set to TRUE.
- Optional start inhibit:
  - Startup is inhibited after the function block is activated.
  - Startup is inhibited after the protective device is interrupted.

- **Status transition diagram**



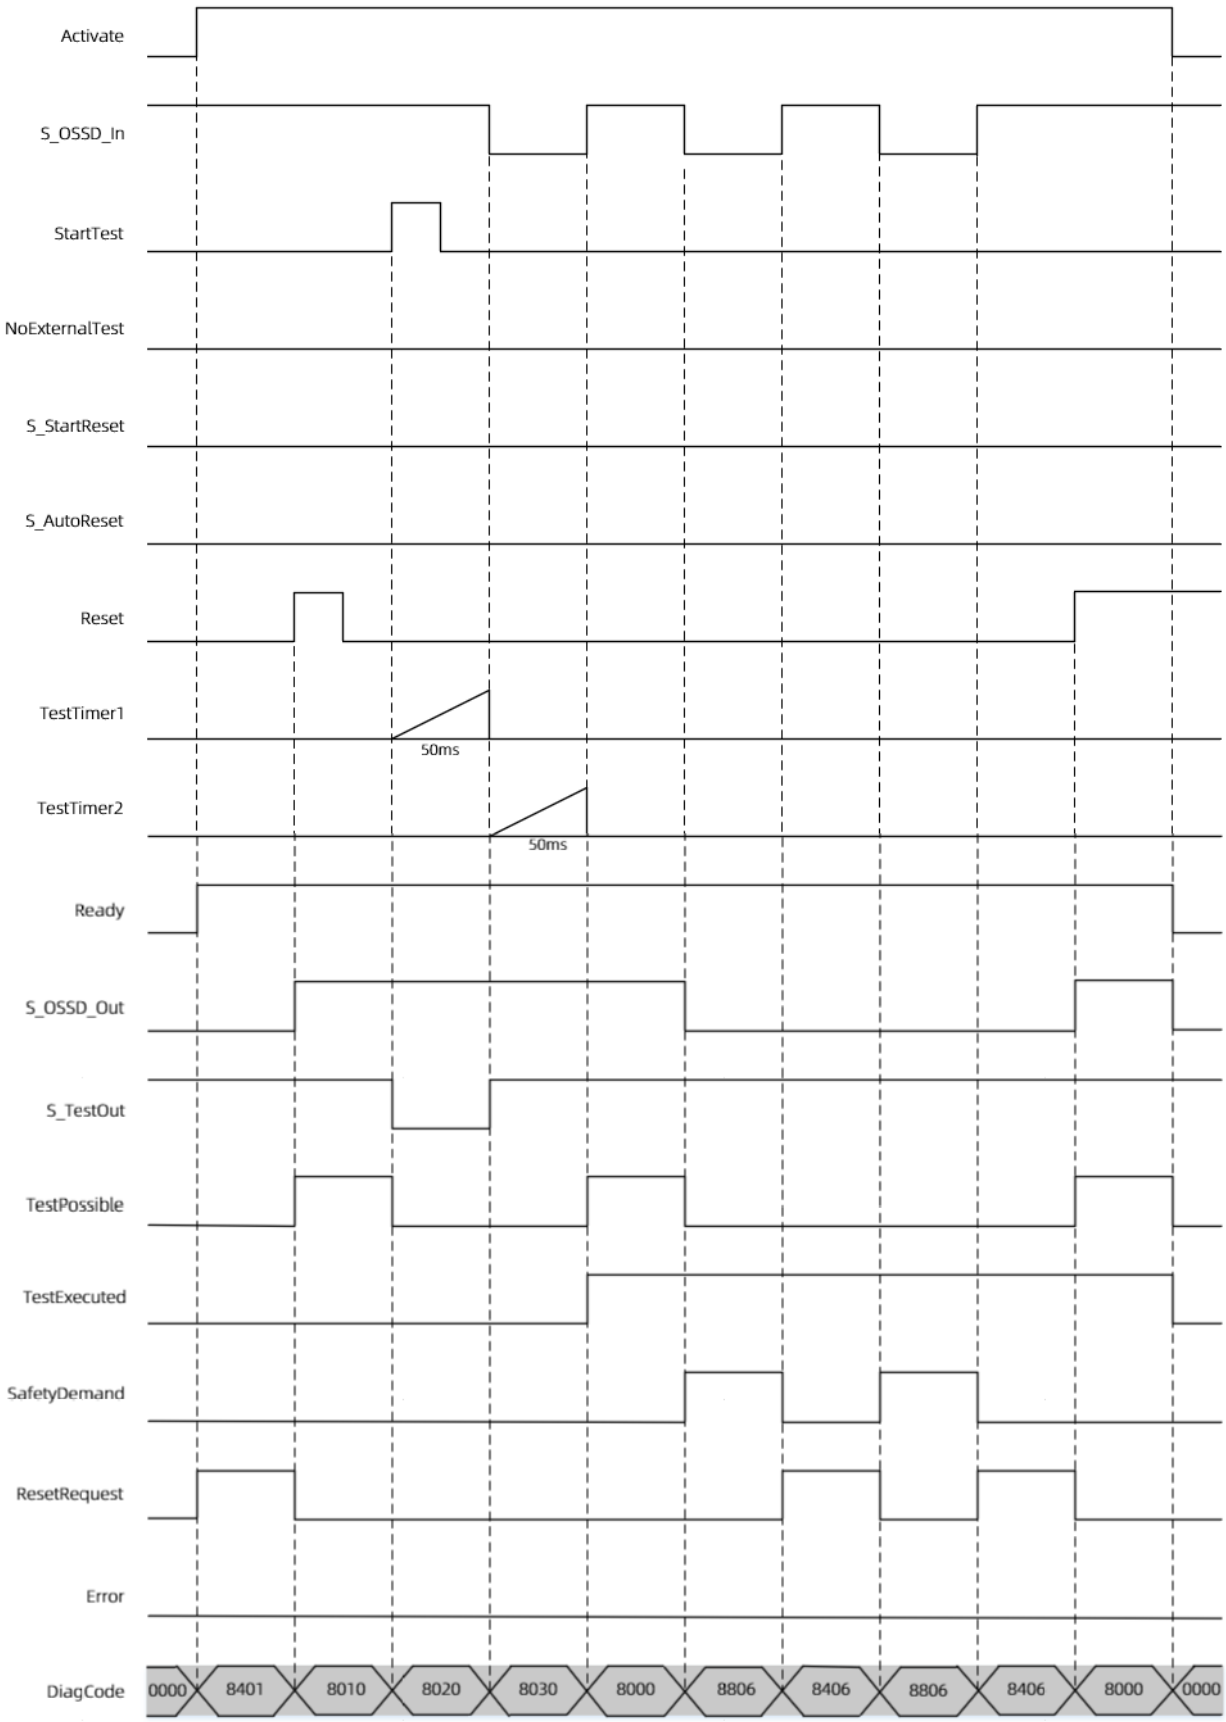


Figure 11-10-2-2-28-1 Status transition diagram for SF_TestableSafetySensor

- This diagram is referenced from the PLCopen specification, and the copyright belongs to the PLCopen organization.
- The transition from any status to the idle status when Activate = FALSE is not indicated, but the priority (0) for transitioning to the idle status is the highest.

- **Sequence diagram**

- **Fault detection**

  The functional block forces a transition to the faulty status under the following conditions:

  - Test timeout with no sensor feedback delay.
  - No sensor signal feedback during testing.
  - Invalid static reset signal present during testing.

- The validity check of the monitoring time setting fails.

- **Fault behavior**

  When a fault occurs, S_OSSD_Out is set to FALSE and remains in the safety status.

  - Troubleshooting and resetting conditions:

    After the fault is cleared and the sensor is enabled (S_OSSD_In = TRUE), the reset operation clears the faulty status and sets S_OSSD_Out to TRUE.

    If S_AutoReset = FALSE, a TRUE value of Reset shall be triggered at the rising edge.

  - Start inhibit reset method:

    After S_OSSD_In switches to TRUE, the optional start inhibit can be reset by a rising edge at the Reset input.

    After the function block is activated, the optional start inhibit can be reset by a rising edge at the Reset input.

- **Function block-specific fault codes and status codes**

  - Fault code

DiagCode	Status Name	Description and Output
C000	Parameter Error	Invalid value in the TestTime parameter. Valid values are between 0 ms and 150 ms. Ready = TRUE S_OSSD_Out = FALSE S_TestOut = TRUE TestPossible = FALSE TestExecuted = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE
C001	Reset Error 1	After the function block is activated, a TRUE value of Reset is triggered at the non-rising edge. Ready = TRUE S_OSSD_Out = FALSE S_TestOut = TRUE TestPossible = FALSE TestExecuted = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE

DiagCode	Status Name	Description and Output
Cx10	Test Error 1	Test timeout in status 8020 or 8030. If S_OSSD_IN is TRUE and NoExternalTest is TRUE, the fault code is C410; otherwise, it is C010. • When the fault code is C410: Ready = TRUE S_OSSD_Out = FALSE S_TestOut = TRUE TestPossible = FALSE TestExecuted = FALSE SafetyDemand = FALSE ResetRequest = NOT Reset Error = TRUE • When the fault code is C010: Ready = TRUE S_OSSD_Out = FALSE S_TestOut = TRUE TestPossible = FALSE TestExecuted = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = TRUE

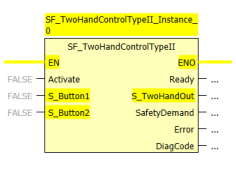
◦ Status code

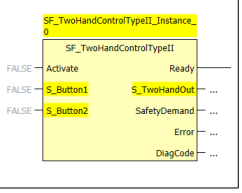
DiagCode	Status Name	Description and Output
0000	Idle	Function block is not activated (initial status). Ready = FALSE S_OSSD_Out = FALSE S_TestOut = TRUE TestPossible = FALSE TestExecuted = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = FALSE

DiagCode	Status Name	Description and Output
8401	Init (Initialization)	Function block is activated. Ready = TRUE S_OSSD_Out = FALSE S_TestOut = TRUE TestPossible = FALSE TestExecuted = FALSE SafetyDemand = FALSE ResetRequest = NOT Reset Error = FALSE
8802	ESPE Interrupted 1	The function block detected a safety request. Automatic testing of the switch has not yet been performed. Ready = TRUE S_OSSD_Out = FALSE S_TestOut = TRUE TestPossible = FALSE TestExecuted = FALSE SafetyDemand = TRUE ResetRequest = FALSE Error = FALSE
8402	Wait for Reset 1	Wait for a TRUE value of Reset to be triggered at the rising edge after entering status 8802 Ready = TRUE S_OSSD_Out = FALSE S_TestOut = TRUE TestPossible = FALSE TestExecuted = FALSE SafetyDemand = FALSE ResetRequest = NOT Reset Error = FALSE

DiagCode	Status Name	Description and Output
8002	External Function Test	Automatic sensor test is faulty. External manual sensor test is required. Necessary external manual sensor testing is supported in FB (NoExternalTest = FALSE). The sensor shall be triggered at the falling edge. Ready = TRUE S_OSSD_Out = FALSE S_TestOut = TRUE TestPossible = FALSE TestExecuted = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = FALSE
8804	ESPE Interrupted External Test	Automatic sensor test is faulty. External manual sensor test is required. Necessary external manual sensor testing is supported in FB (NoExternalTest = FALSE). TRUE signal is required at the sensor. Ready = TRUE S_OSSD_Out = FALSE S_TestOut = TRUE TestPossible = FALSE TestExecuted = FALSE SafetyDemand = TRUE ResetRequest = FALSE Error = FALSE

DiagCode	Status Name	Description and Output
8404	End External Test	Automatic sensor test is faulty. External manual sensor test is required. Necessary external manual sensor testing is supported in FB (NoExternalTest = FALSE). External manual test is completed. A complete sensor switching cycle (externally controlled) is detected. Ready = TRUE S_OSSD_Out = FALSE S_TestOut = TRUE TestPossible = FALSE TestExecuted = FALSE SafetyDemand = FALSE ResetRequest = NOT Reset Error = FALSE
8010	ESPE Free No Test	No safety request is detected by the function block. Automatic testing of the sensor has not yet been performed. Ready = TRUE S_OSSD_Out = TRUE S_TestOut = TRUE TestPossible = TRUE TestExecuted = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = FALSE





DiagCode	Status Name	Description and Output
8806	ESPE Interrupted 2	The function block detected a safety request. Automatic testing of the switch has been performed. Ready = TRUE S_OSSD_Out = FALSE S_TestOut = TRUE TestPossible = FALSE TestExecuted = TRUE SafetyDemand = TRUE ResetRequest = FALSE Error = FALSE
8406	Wait for Reset 2	Wait for a TRUE value of Reset to be triggered at the rising edge after entering status 8806 Ready = TRUE S_OSSD_Out = FALSE S_TestOut = TRUE TestPossible = FALSE TestExecuted = TRUE SafetyDemand = FALSE ResetRequest = NOT Reset Error = FALSE
8020	Test Request	The automatic sensor test is active. The test timer is started for the first time. The transmitter signal of the sensor is turned off by the function block. The receiver signal must follow the transmitter signal. Ready = TRUE S_OSSD_Out = TRUE S_TestOut = FALSE TestPossible = FALSE TestExecuted = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = FALSE

DiagCode	Status Name	Description and Output
8030	Test Active	The automatic sensor test is active. The test timer is started for the second time. Timer 1 has stopped. The transmitter signal of the sensor is activated by the function block, and the receiver signal must follow the transmitter signal. Ready = TRUE S_OSSD_Out = TRUE S_TestOut = TRUE TestPossible = FALSE TestExecuted = FALSE SafetyDemand = FALSE ResetRequest = FALSE Error = FALSE
8000	ESPE Free Test ok	No safety request is detected by the function block. Timer 2 has stopped. Automatic testing of the sensor has been performed. Ready = TRUE S_OSSD_Out = TRUE S_TestOut = TRUE TestPossible = TRUE TestExecuted = TRUE SafetyDemand = FALSE ResetRequest = FALSE Error = FALSE

11.10.2.2.29 SF_TwoHandControlTypeII

SF_TwoHandControlTypeII is a function block used for Type II two-hand control. It controls the safety output via signals from the function application and safety signals with optional start inhibit function.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_TwoHandControlTypeII	Type II two-hand control	FB		

- **Related variables**

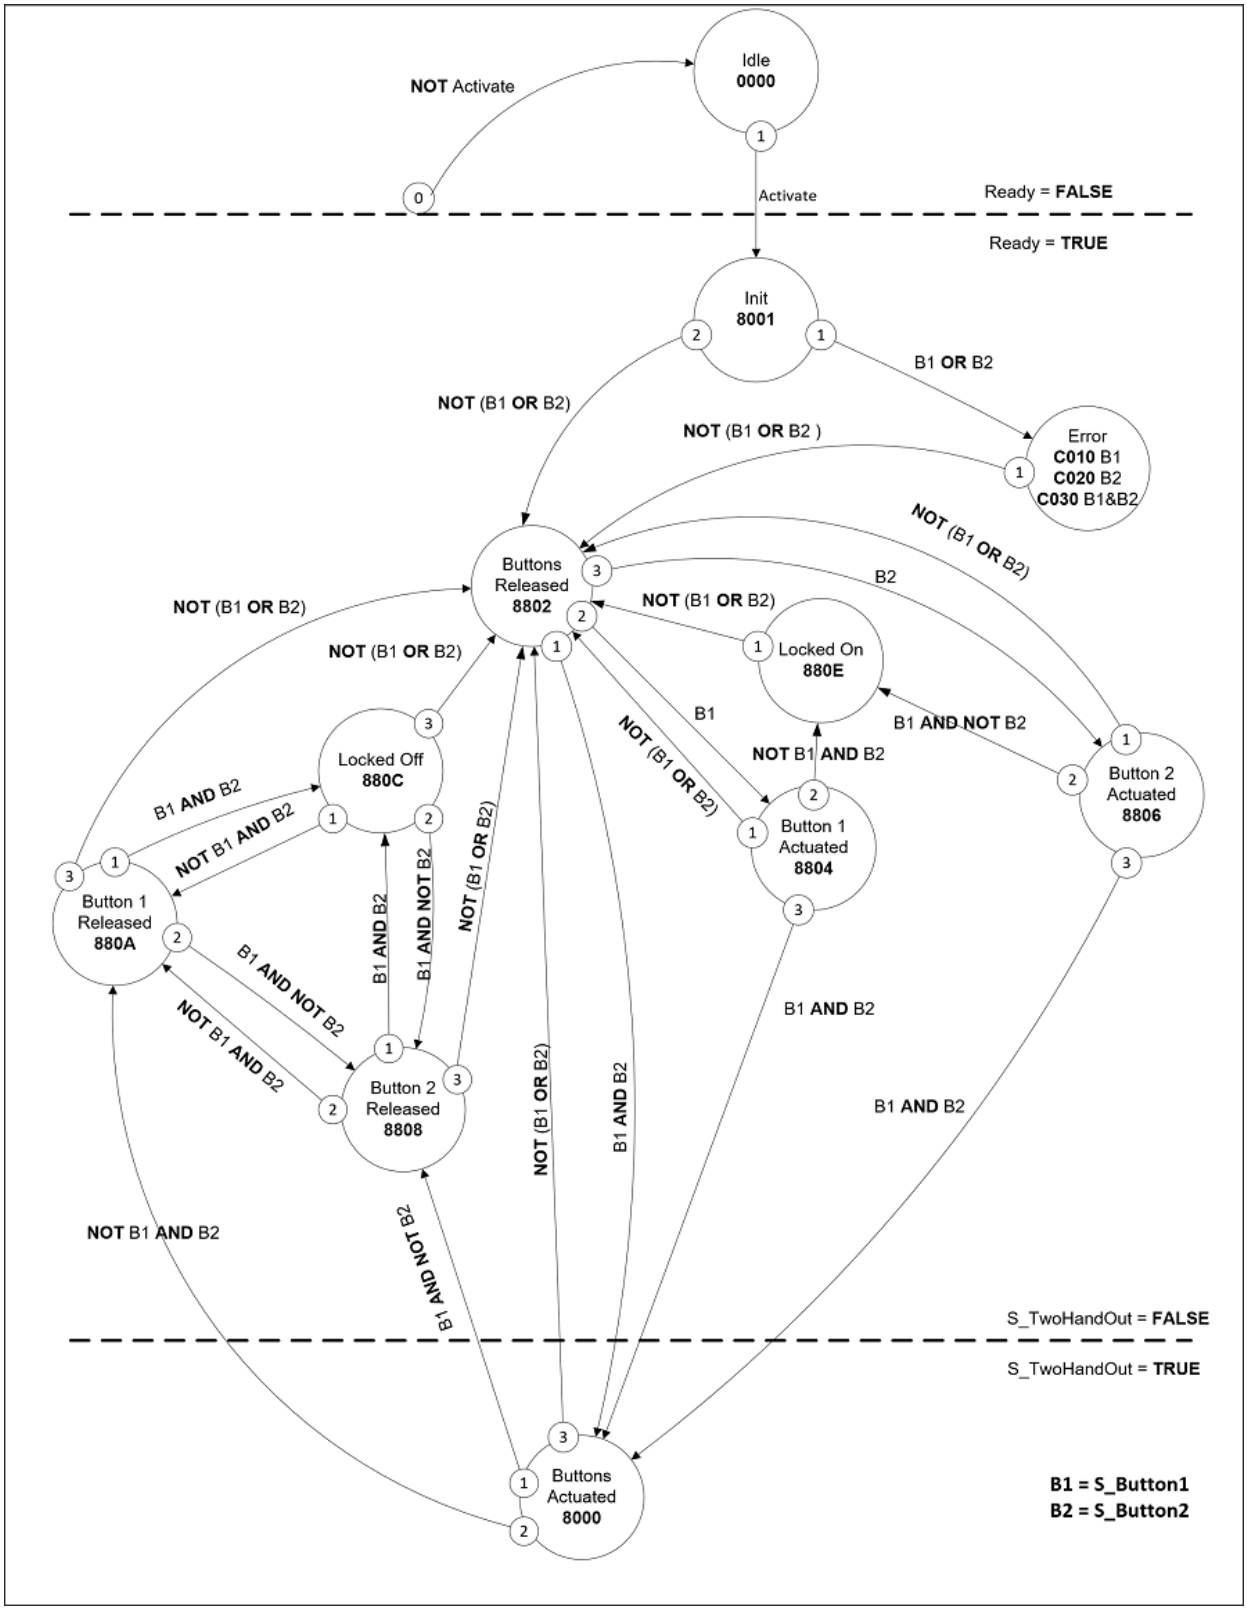
  Variables

Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
Input	Activate	BOOL	TRUE, FALSE	FALSE	Activates the instruction.
	S_Button1	SAFEBOOL	TRUE, FALSE	FALSE	Represents the input of button 1. FALSE: Button 1 is released. TRUE: Button 1 is activated.
	S_Button2	SAFEBOOL	TRUE, FALSE	FALSE	Input for button 2. FALSE: Button 2 is released. TRUE: Button 2 is activated.
Output	Ready	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is in ready status.
	S_TwoHandOut	SAFEBOOL	TRUE, FALSE	FALSE	Safety-related output FALSE: Correct two-hand operation is not performed. TRUE: S_Button1 and S_Button2 inputs are TRUE, with no fault. The two-hand operation is correct.
	SafetyDemand	BOOL	TRUE, FALSE	FALSE	Activates or maintains the status according to the instruction status.
	Error	BOOL	TRUE, FALSE	FALSE	Faulty status
	DiagCode	WORD	Follows data type	16#0000	Status code: Indicates fault code when instruction fails; indicates instruction status when instruction is running.

- **Function description**
  - The SF_OutControl function block is the driver for safety outputs, which are controlled via S_OutControl using signals from the functional application (ProcessControl/BOOL for process control) and signals from the safety application (S_SafeControl/SAFEBOOL for safety function control).
  - Optional conditions for ProcessControl:
    - After the function block is activated or the safety signal (S_SafeControl) is fed back, an additional function start is required (ProcessControl changes from FALSE to TRUE). A static TRUE signal at ProcessControl will not set S_OutControl to TRUE.
    - After the function block is activated or the safety signal (S_SafeControl) is fed back, no additional function start is required (ProcessControl changes from FALSE to TRUE). If other conditions are met, a static TRUE signal at ProcessControl will set S_OutControl to TRUE.

- Optional start inhibit:
  - Start inhibit after function block activation
  - Start inhibit after protective device interruption
- The StaticControl, S_StartReset, and S_AutoReset inputs should only be activated when no hazardous situation will occur during PES startup.

- **Status transition diagram**



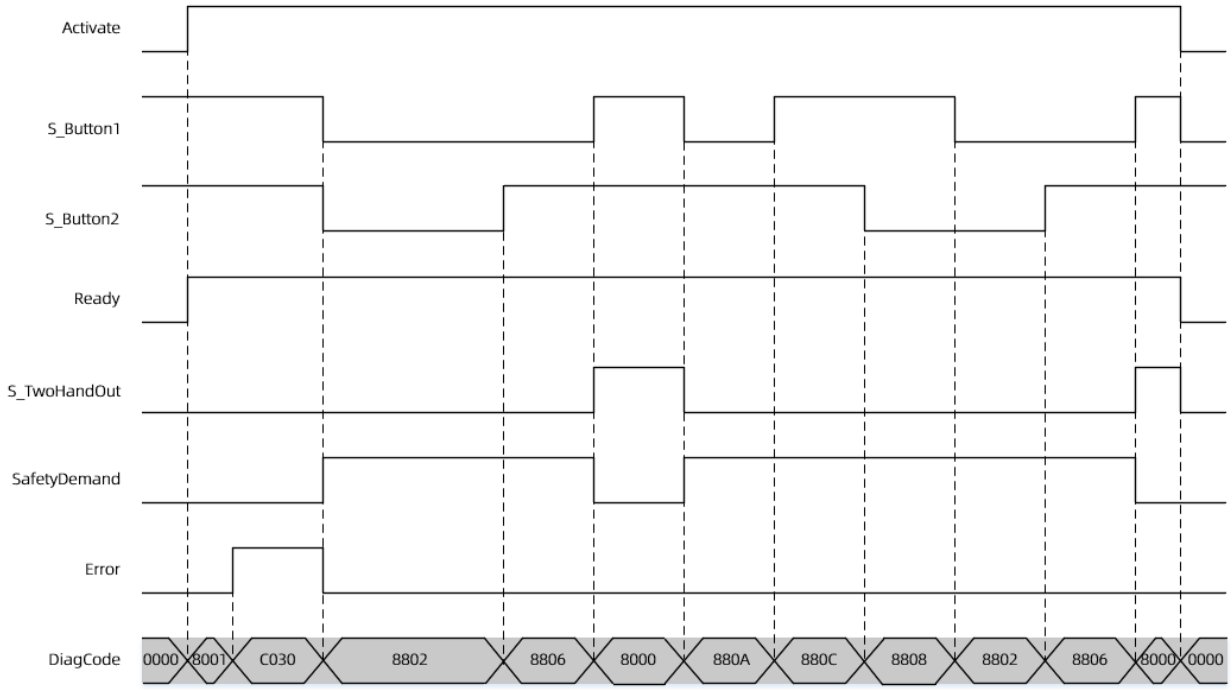


Figure 11-10-2-2-29-1 Status transition diagram for SF_TwoHandControlTypeII

- This diagram is referenced from the PLCopen specification, and the copyright belongs to the PLCopen organization.
- The transition from any status to the idle status when Activate = FALSE is not indicated, but the priority (0) for transitioning to the idle status is the highest.

- **Sequence diagram**

- **Fault detection**
  Detects if a TRUE signal is mistakenly sent to the input parameter after the function block is activated.
- **Fault behavior**

  When a fault occurs, the "S_TwoHandOut" output is set to FALSE and maintained in a safety status.

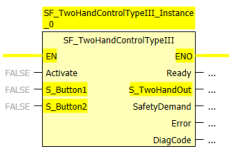
  After both buttons are released (set to FALSE), the faulty status is cleared.
- **Function block-specific fault codes and status codes**
  - Fault code

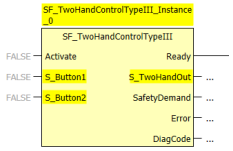
DiagCode	Status Name	Description and Output
C010	Error 1 B1	S_Button1 is TRUE when the function block is activated. Ready = TRUE S_TwoHandOut = FALSE SafetyDemand = FALSE Error = TRUE
C020	Error 1 B2	S_Button2 is TRUE when the function block is activated. Ready = TRUE S_TwoHandOut = FALSE SafetyDemand = FALSE Error = TRUE

DiagCode	Status Name	Description and Output
C030	Error 1 B1&B2	S_Button1 and S_Button2 are TRUE when the function block is activated. Ready = TRUE S_TwoHandOut = FALSE SafetyDemand = FALSE Error = TRUE

◦ Status code

DiagCode	Status Name	Description and Output
0000	Idle	Function block is not activated (initial status). Ready = FALSE S_TwoHandOut = FALSE SafetyDemand = FALSE Error = FALSE
8000	Buttons Actuated	Both buttons are actuated correctly. Safety-related output is valid. Ready = TRUE S_TwoHandOut = TRUE SafetyDemand = FALSE Error = FALSE
8001	Init	Function block is activated and is in initialization status. Ready = TRUE S_TwoHandOut = FALSE SafetyDemand = FALSE Error = FALSE
8802	Buttons Released	No buttons have been actuated. Ready = TRUE S_TwoHandOut = FALSE SafetyDemand = TRUE Error = FALSE





DiagCode	Status Name	Description and Output
8804	Button 1 Actuated	Only Button 1 has been actuated. Ready = TRUE S_TwoHandOut = FALSE SafetyDemand = TRUE Error = FALSE
8806	Button 2 Actuated	Only Button 2 has been actuated. Ready = TRUE S_TwoHandOut = FALSE SafetyDemand = TRUE Error = FALSE
8808	Button 2 Released	Safety output was set to valid, and then set to invalid. After setting the safety output to invalid, neither S_Button1 nor S_Button2 changes to FALSE. In this status, after setting the safety output to invalid, S_Button1 is TRUE and S_Button2 is FALSE. Ready = TRUE S_TwoHandOut = FALSE SafetyDemand = TRUE Error = FALSE
880 A	Button 1 Released	Safety output was set to valid, and then set to invalid. After setting the safety output to invalid, neither S_Button1 nor S_Button2 changes to FALSE. In this status, after setting the safety output to invalid, S_Button1 is FALSE and S_Button2 is TRUE. Ready = TRUE S_TwoHandOut = FALSE SafetyDemand = TRUE Error = FALSE

DiagCode	Status Name	Description and Output
880C	Locked Off	Safety output was set to valid, and then set to invalid. After setting the safety output to invalid, neither S_Button1 nor S_Button2 changes to FALSE. In this status, after setting the safety output to invalid, S_Button1 is TRUE and S_Button2 is TRUE. Ready = TRUE S_TwoHandOut = FALSE SafetyDemand = TRUE Error = FALSE
880E	Locked On	Incorrect button operation. Wait for both buttons to be released. Ready = TRUE S_TwoHandOut = FALSE SafetyDemand = TRUE Error = FALSE

11.10.2.2.30 SF_TwoHandControlTypeIII

SF_TwoHandControlTypeIII is a function block used for Type III two-hand control. It controls the safety output via signals from the function application and safety signals with optional start inhibit function.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_TwoHandControlTypeIII	Type III two-hand control	FB		

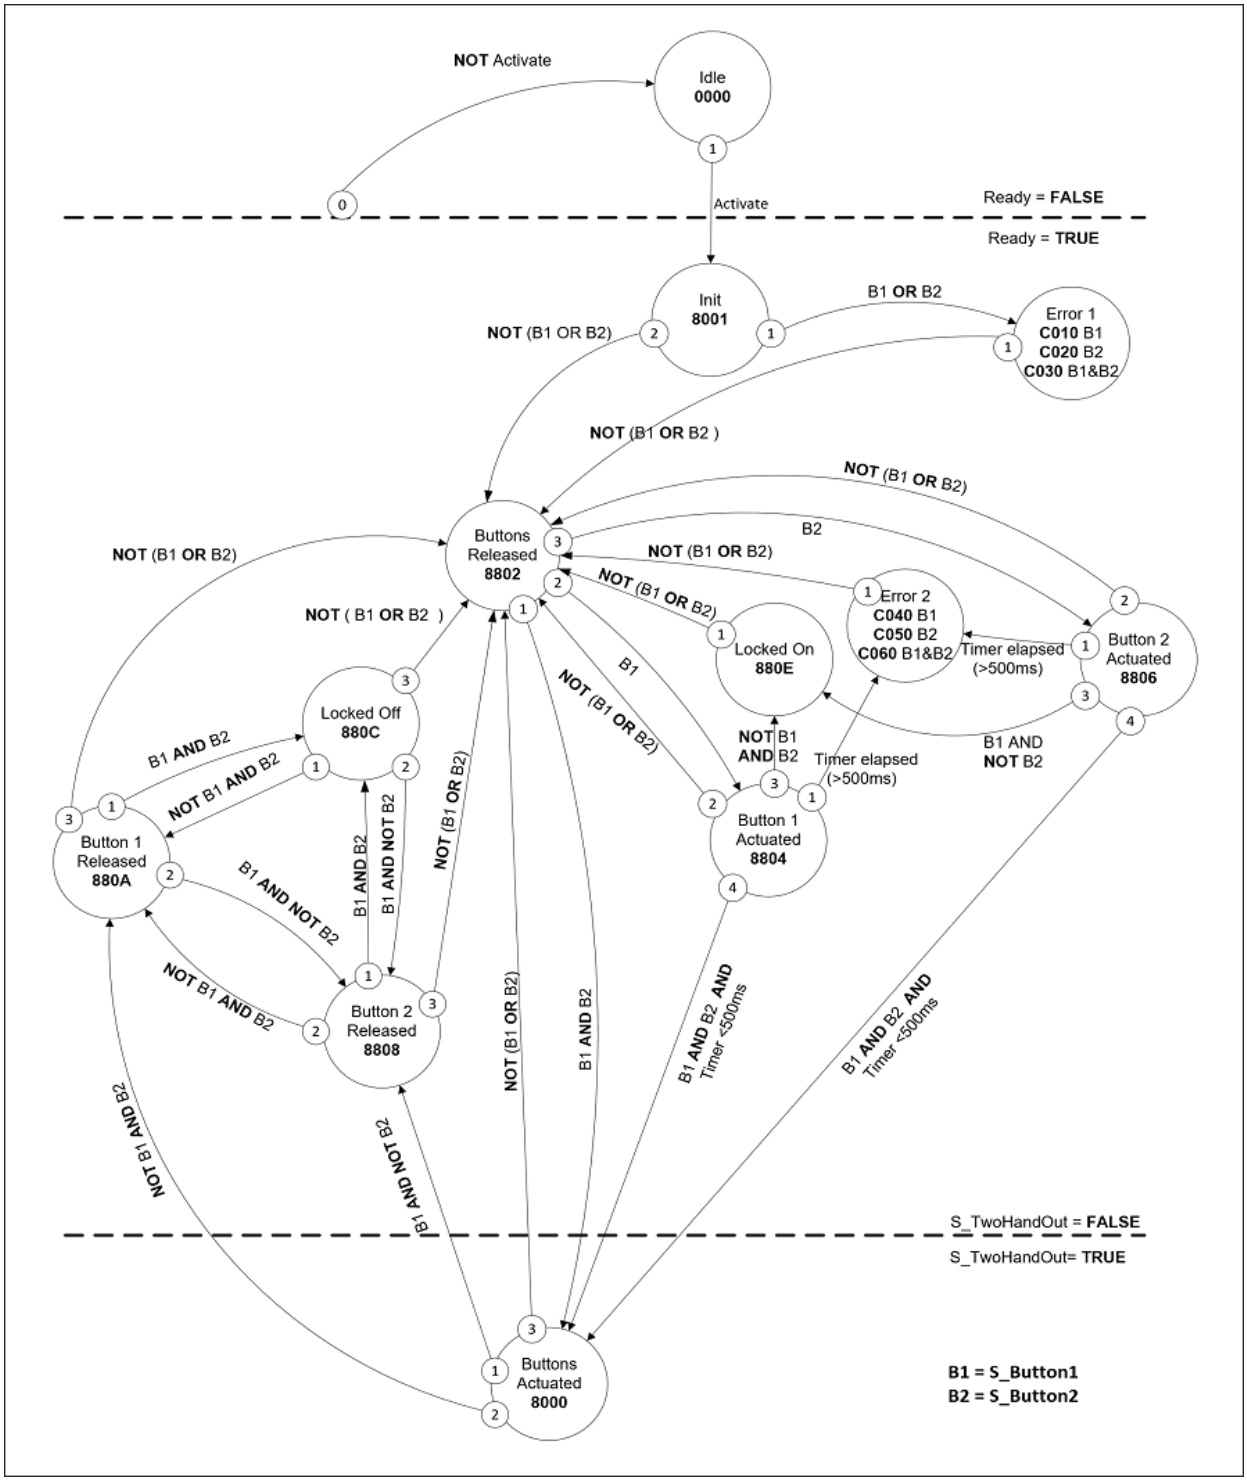
- **Related variables**

  Variables

Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
Input	Activate	BOOL	TRUE, FALSE	FALSE	Activates the instruction.
	S_Button1	SAFEBOOL	TRUE, FALSE	FALSE	Represents the input of button 1. FALSE: Button 1 is released. TRUE: Button 1 is activated.
	S_Button2	SAFEBOOL	TRUE, FALSE	FALSE	Input for button 2. FALSE: Button 2 is released. TRUE: Button 2 is activated.

Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
Output	Ready	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is in ready status.
	S_TwoHandOut	SAFEBOOL	TRUE, FALSE	FALSE	Safety-related output FALSE: Correct two-hand operation is not performed. TRUE: S_Button1 and S_Button2 inputs are TRUE, with no fault. The two-hand operation is correct.
	SafetyDemand	BOOL	TRUE, FALSE	FALSE	Activates or maintains the status according to the instruction status.
	Error	BOOL	TRUE, FALSE	FALSE	Faulty status
	DiagCode	WORD	Follows data type	16#0000	Status code: Indicates fault code when instruction fails; indicates instruction status when instruction is running.

- **Function description**
  - This function block supports two-hand control compliant with Type III of EN 574 Section 4.
  - If S_Button1 and S_Button2 are set to TRUE within 500 ms in the correct sequence, then S_TwoHandOut output is also set to TRUE.
  - The function block also controls the release of both buttons, and then allows the S_TwoHandOut output to be set to TRUE again after proper re-trigger operations.
- **Status transition diagram**



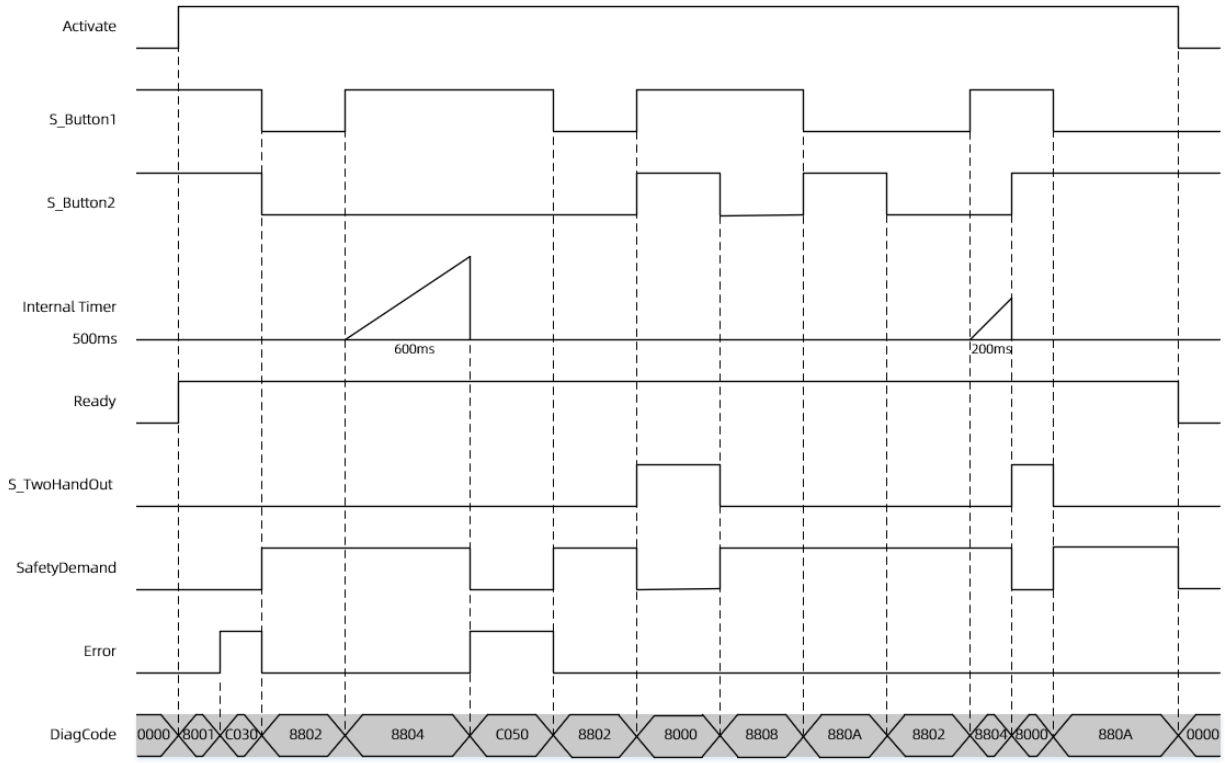


Figure 11-10-2-2-30-1 Status transition diagram for SF_TwoHandControlTypeIII

- This diagram is referenced from the PLCopen specification, and the copyright belongs to the PLCopen organization.
- The transition from any status to the idle status when Activate = FALSE is not indicated, but the priority (0) for transitioning to the idle status is the highest.

- **Sequence diagram**

- **Fault detection**
  Detects if a TRUE signal is mistakenly sent to the input parameter after the function block is activated.
  Detects if the discrepancy time between the two button inputs exceeds 500 ms.
- **Fault behavior**

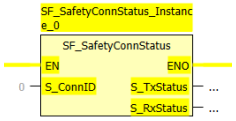
  When a fault occurs, the "S_TwoHandOut" output is set to FALSE and maintained in a safety status.

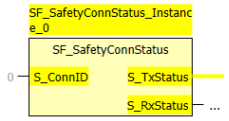
  After both buttons are released (set to FALSE), the faulty status is cleared.
- **Function block-specific fault codes and status codes**
  - Fault code

DiagCode	Status Name	Description and Output
C010	Error 1 B1	S_Button1 is TRUE when the function block is activated. Ready = TRUE S_TwoHandOut = FALSE SafetyDemand = FALSE Error = TRUE
C020	Error 1 B2	S_Button2 is TRUE when the function block is activated. Ready = TRUE S_TwoHandOut = FALSE SafetyDemand = FALSE Error = TRUE

DiagCode	Status Name	Description and Output
C030	Error 1 B1&B2	S_Button1 and S_Button2 are TRUE when the function block is activated. Ready = TRUE S_TwoHandOut = FALSE SafetyDemand = FALSE Error = TRUE
C040	Error 2 B1	After 500 ms in status 8804, S_Button1 becomes FALSE, and S_Button2 becomes TRUE. Ready = TRUE SafetyDemand = FALSE Error = TRUE S_TwoHandOut = FALSE
C050	Error 2 B2	After 500 ms in status 8806, S_Button1 becomes TRUE, and S_Button2 becomes FALSE. Ready = TRUE S_TwoHandOut = FALSE SafetyDemand = FALSE Error = TRUE
C060	Error 2 B1&B2	After 500 ms in status 8804 or 8806, S_Button1 becomes TRUE, and S_Button2 becomes TRUE. Condition to reach this status: Within the 500 ms timer cycle, the statuses of S_Button1 and S_Button2 change from different to same (both TRUE). Ready = TRUE S_TwoHandOut = FALSE SafetyDemand = FALSE Error = TRUE

◦ Status code





DiagCode	Status Name	Description and Output
0000	Idle	Function block is not activated (initial status). Ready = FALSE S_TwoHandOut = FALSE SafetyDemand = FALSE Error = FALSE
8000	Buttons Actuated	Both buttons are actuated correctly. Safety-related output is valid. Ready = TRUE S_TwoHandOut = TRUE SafetyDemand = FALSE Error = FALSE

8806	Button 2 Actuated	Only Button 2 has been actuated. Ready = TRUE S_TwoHandOut = FALSE SafetyDemand = TRUE Error = FALSE

DiagCode	Status Name	Description and Output
8808	Button 2 Released	Safety output was set to valid, and then set to invalid. After setting the safety output to invalid, neither S_Button1 nor S_Button2 changes to FALSE. In this status, after setting the safety output to invalid, S_Button1 is TRUE and S_Button2 is FALSE. Ready = TRUE S_TwoHandOut = FALSE SafetyDemand = TRUE Error = FALSE
880 A	Button 1 Released	Safety output was set to valid, and then set to invalid. After setting the safety output to invalid, neither S_Button1 nor S_Button2 changes to FALSE. In this status, after setting the safety output to invalid, S_Button1 is FALSE and S_Button2 is TRUE. Ready = TRUE S_TwoHandOut = FALSE SafetyDemand = TRUE Error = FALSE
880C	Locked Off	Safety output was set to valid, and then set to invalid. After setting the safety output to invalid, neither S_Button1 nor S_Button2 changes to FALSE. In this status, after setting the safety output to invalid, S_Button1 is TRUE and S_Button2 is TRUE. Ready = TRUE S_TwoHandOut = FALSE SafetyDemand = TRUE Error = FALSE
880E	Locked On	Incorrect button operation. Wait for both buttons to be released. Ready = TRUE S_TwoHandOut = FALSE SafetyDemand = TRUE Error = FALSE

11.10.2.2.31 SF_SafetyConnStatus

SF_SafetyConnStatus is a function block used to get the safety C2C (CIP Safety) connection status.

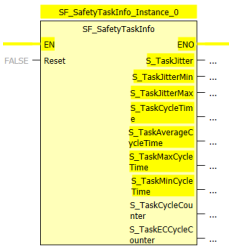
- **Instruction format**

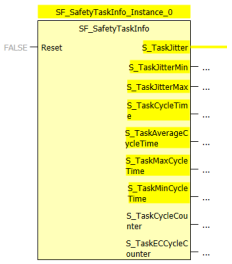
Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_SafetyConnStatus	Gets safety C2C (CIP Safety) connection status.	FB		

- **Related variables**

  Variables

Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
Input	S_ConnID	SAFEWORD	0 and positive numbers	0	Connection ID for safety C2C communication
Output	S_TxStatus	SAFEBOOL	TRUE, FALSE	FALSE	Transmission status of the connection TRUE: Connection status is normal. FALSE: Connection status is faulty.
	S_RxStatus	SAFEBOOL	TRUE, FALSE	FALSE	Receiving status of the connection TRUE: Connection status is normal. FALSE: Connection status is faulty.





- **Function description**

  This function block is used to obtain the safety C2C connection status. If the connection is only configured for one-direction communication (transmitting or receiving), the status of the other direction is fixed as FALSE.

11.10.2.2.32 SF_SafetyTaskInfo

SF_SafetyTaskInfo is a function block used to obtain safety task information.

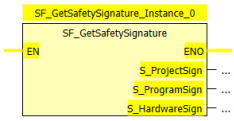
- **Instruction format**

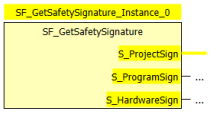
Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_SafetyTaskInfo	Obtains safety task information.	FB		

- **Related variables**

  Variables

Input/ Output	Variable	Data Type	Valid Range	Default Value	Description
Input	Reset	BOOL	TRUE, FALSE	FALSE	Resets task data.
Output	S_TaskJitter	SAFEDINT	Follows data type	0	Cycle jitter
	S_TaskJitterMin	SAFEDINT	Follows data type	0	Minimum cycle jitter
	S_TaskJitterMax	SAFEDINT	Follows data type	0	Maximum cycle jitter
	S_TaskCycleTime	SAFEWORD	Follows data type	0	Last execution time
	S_TaskAverageCycleTime	SAFEWORD	Follows data type	0	Average execution time
	S_TaskMaxCycleTime	SAFEDINT	Follows data type	0	Maximum execution time
	S_TaskMinCycleTime	SAFEWORD	Follows data type	0	Minimum execution time
	S_TaskCycleCounter	DWORD	Follows data type	0	System scheduling count
	S_TaskECCycleCounter	DWORD	Follows data type	0	User task execution count





- **Function description**

  This function block is used to obtain safety task information, which can be reset upon the rising edge (FALSE->TRUE) of the input parameter "Reset".

11.10.2.2.33 SF_GetSafetySignature

SF_GetSafetySignature is a function block used to obtain the safety signature.

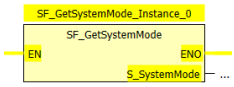
- **Instruction format**

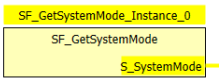
Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_GetSafetySignature	Obtains safety signature.	FB		

- **Related variables**

  Variables

Input/Output	Variable	Data Type	Valid Range	Default Value	Description
Output	S_ProjectSign	SAFEDINT	Follows data type	0	Represents the overall project signature.
	S_ProgramSign	SAFEDINT	Follows data type	0	Represents the safety program signature.
	S_HardwareSign	SAFEDINT	Follows data type	0	Represents the safety hardware signature.





- **Function description**

  This function block is used to obtain the overall project signature, safety program signature, and safety hardware signature.

11.10.2.2.34 SF_GetSystemMode

SF_GetSystemMode is a function block used to obtain the safety PLC status.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_GetSystemMode	Obtains safety PLC status.	FB		

- **Related variables**

  Variables

Input/Output	Variable	Data Type	Valid Range	Default Value	Description
Output	S_SystemMode	SAFEBYTE	Follows data type	0	Represents the system status of the safety PLC. 1: Commissioning mode 2: Run mode 3: Fault mode 4: Pending mode

- **Function description**

  This function block is used to obtain the system status of the safety PLC.

  - 1: Commissioning mode
  - 2: Run mode

- 3: Fault mode
- 4: Pending mode

11.10.2.2.35 SF_GetSafetyConfirmInfo

SF_GetSafetyConfirmInfo is a function block used to get safety confirmation information (including safety signature, safety confirmation time).

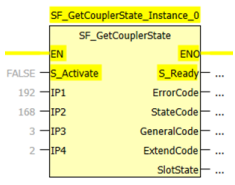
- **Instruction format**

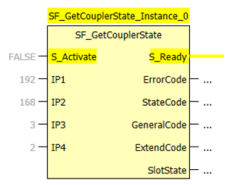
Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_GetSafetyConfirmInfo	Get safety confirmation information (including safety signature, safety confirmation time)	FB		

- **Related variables**

  Output variables

Output Variable	Variable	Data Type	Valid Range	Default Value	Description
S_ProjectSign	Project overall signature	SAFEDWORD	Follows data type	0	Project overall signature
S_ProgramSign	Safety program signature	SAFEDWORD	Follows data type	0	Safety program signature
S_HardwareSign	Safety hardware signature	SAFEDWORD	Follows data type	0	Safety hardware signature
S_SafetyConfirmTime	Safety confirmation time	SAFEDATE_AND_TIME	Follows data type	1970-01-01-0:0:0	Safety confirmation time





- **Function**

  This function block is used to get safety confirmation information (including safety signature, safety confirmation time).

11.10.2.2.36 SF_GetCouplerState

SF_GetCouplerState is a function block used to get the coupler status (EIP connection).

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_GetCouplerState	Get coupler status (EIP connection)	FB		

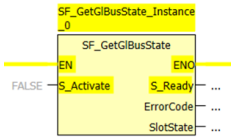
- **Related variables**

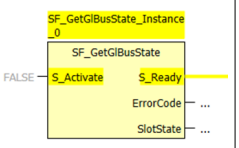
  Input variables

Input Variable	Variable	Data Type	Valid Range	Default Value	Description
S_Activate	Instruction activation status	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is activated.
IP1	IP field 1	BYTE	Follows data type	192	Coupler IP field 1
IP2	IP field 2	BYTE	Follows data type	168	Coupler IP field 2
IP3	IP field 3	BYTE	Follows data type	3	Coupler IP field 3
IP4	IP field 4	BYTE	Follows data type	2	Coupler IP field 4

  Output variables

Output Variable	Name	Data Type	Value Range	Default Value	Description
S_Ready	Instruction ready status	SAFEBOOL	TRUE, FALSE	FALSE	TRUE: Instruction is ready. FALSE: Instruction is not ready.
ErrorCode	Instruction status code	WORD	Follows data type	0	Status code: Indicates the instruction status. 0: Normal; 1: Abnormal
StateCode	Coupler EtherNet/IP communication status code	BYTE	Follows data type	0	Connection status code
GeneralCode		BYTE	Follows data type	0	General status code
ExtendCode		WORD	Follows data type	0	Extended status code
SlotState[32]	I/O module diagnostic status for each slot	SlotState	Follows data type	0	I/O module diagnostic status for each slot





- **Function**

This function block is used to get the coupler status under an EIP connection. Input the coupler IP address to query.

11.10.2.2.37 SF_GetGlBusState

SF_GetGlBusState is a function block used to obtain local bus connection status (EIP device).

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_GetGlBusState	Get local bus connection status (EIP device)	FB		

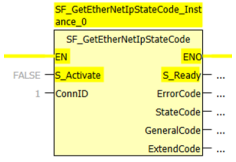
- **Related variables**

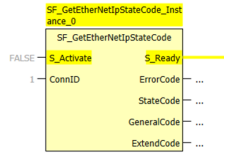
  Input variables

Input Variable	Variable	Data Type	Valid Range	Default Value	Description
S_Activate	Instruction activation status	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is activated.

  Output variables

Output Variable	Name	Data Type	Value Range	Default Value	Description
S_Ready	Instruction ready status	SAFEBOOL	TRUE, FALSE	FALSE	TRUE: Instruction is ready. FALSE: Instruction is not ready.
ErrorCode	Instruction status code	WORD	Follows data type	0	Status code: Indicates the instruction status. 0: Normal; 1: Abnormal
SlotState[32]	I/O module diagnostic status for each slot	SlotState	Follows data type	0	I/O module diagnostic status for each slot





- **Function**

  This function block is used to get the local bus connection status (local EIP device).

11.10.2.2.38 SF_GetEtherNetIpStateCode

SF_GetEtherNetIpStateCode is a function block used to get the EtherNet/IP (Scanner) connection status.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_GetEtherNetIpStateCode	Get EtherNet/IP (Scanner) connection status	FB		

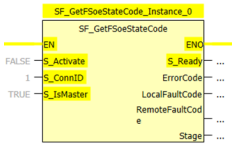
- **Related variables**

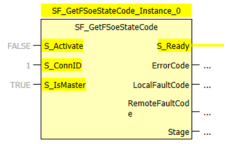
  Input variables

Input Variable	Variable	Data Type	Valid Range	Default Value	Description
S_Activate	Instruction activation status	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is activated.
ConnID	EtherNet/IP connection ID	WORD	Follows data type	1	EtherNet/IP connection ID

  Output variables

Output Variable	Name	Data Type	Value Range	Default Value	Description
S_Ready	Instruction ready status	SAFEBOOL	TRUE, FALSE	FALSE	TRUE: Instruction is ready. FALSE: Instruction is not ready.
ErrorCode	Instruction status code	WORD	Follows data type	0	Status code: Indicates the instruction status. 0: Normal; 1: Invalid connection ID
StateCode	EtherNet/IP connection status code	BYTE	Follows data type	0	Connection status code
GeneralCode		BYTE	Follows data type	0	General status code
ExtendCode		WORD	Follows data type	0	Extended status code





- **Function**

  This function block is used to get the EtherNet/IP (Scanner) connection status. Input the connection ID to query.

11.10.2.2.39 SF_GetFSoeStateCode

SF_GetFSoeStateCode is a function block used to get the FSoE connection status.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_GetFSoeStateCode	Get FSoE connection status	FB		

- **Related variables**

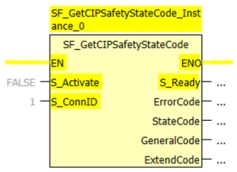
Input variables

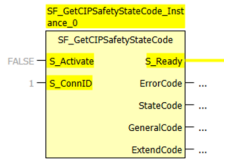
Input Variable	Variable	Data Type	Valid Range	Default Value	Description
S_Activate	Instruction activation status	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is activated.
S_ConnID	Connection ID	SAFEWORD	Follows data type	1	Connection ID for FSoE communication.
S_IsMaster	Specifies whether to query the device status as master or slave.	SAFEBOOL	TRUE, FALSE	TRUE	TRUE: Query the device status as master; FALSE: Query the device status as slave.

Output variables

Output Variable	Name	Data Type	Value Range	Default Value	Description
S_Ready	Instruction ready status	SAFEBOOL	TRUE, FALSE	FALSE	TRUE: Instruction is ready. FALSE: Instruction is not ready.
ErrorCode	Instruction status code	WORD	Follows data type	0	Status code: Indicates the instruction status. 0: Normal; 1: Incorrect connection ID; 2: Function block exception

LocalFaultCode	FSoE connection fault code (local)	WORD	Follows data type	0	FSoE connection fault code (local) 0: Normal; 1: Unexpected instruction error; 2: Unknown instruction; 3: Invalid connection ID; 4: CRC error; 5: Watchdog timeout; 6: Invalid slave address; 7: Invalid safety data; 8: Invalid communication parameter length; 9: Invalid communication parameter data; 10: Invalid application parameter length; 11: Invalid application parameter data
RemoteFaultCode	FSoE connection fault code (remote)	WORD	Follows data type	0	FSoE connection fault code (remote) 0: Normal; 1: Unexpected instruction error; 2: Unknown instruction; 3: Invalid connection ID; 4: CRC error; 5: Watchdog timeout; 6: Invalid slave address; 7: Invalid safety data; 8: Invalid communication parameter length; 9: Invalid communication parameter data; 10: Invalid application parameter length; 11: Invalid application parameter data
Stage	Current FSoE connection stage	WORD	Follows data type	0	Current FSoE connection stage 0: No state; 1: Reset stage; 2: Session stage; 3: Connection stage; 4: Parameter stage; 5: Data stage





- **Function**

  This function block is used to get the FSoE connection status. Input the connection ID to query.

11.10.2.2.40 SF_GetCIPSafetyStateCode

SF_GetCIPSafetyStateCode is a function block used to get the CIP Safety connection status code.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SF_GetCIPSafetyStateCode	Get CIP Safety connection status code	FB		

- **Related variables**

Input variables

Input Variable	Variable	Data Type	Valid Range	Default Value	Description
S_Activate	Instruction activation status	SAFEBOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is activated.
S_ConnID	CIP Safety connection ID	SAFEWORD	Follows data type	1	CIP Safety connection ID

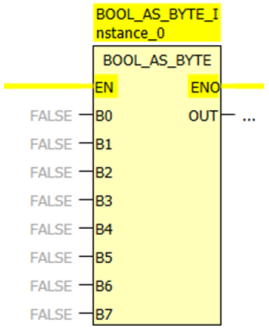
Output variables

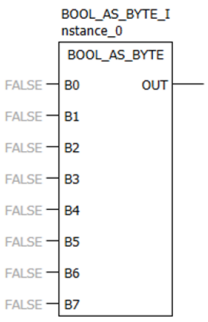
Output Variable	Name	Data Type	Value Range	Default Value	Description
S_Ready	Instruction ready status	SAFEBOOL	TRUE, FALSE	FALSE	TRUE: Instruction is ready. FALSE: Instruction is not ready.
ErrorCode	Instruction status code	WORD	Follows data type	0	Status code: Indicates the instruction status. 0: Normal; 1: Incorrect connection ID; 2: Function block exception
StateCode	CIP Safety connection status code	BYTE	Follows data type	0	Connection status code
GeneralCode		BYTE	Follows data type	0	General status code

ExtendCode		WORD	Follows data type	0	Extended status code

- **Function**
  This function block is used to get the CIP Safety connection status code. Input the connection ID to query.

11.10.2.3 Extended Function Blocks





11.10.2.3.1 Instruction List

Instruction	FB/FC	Function	Library	Applicable Library Version
11.10.2.3.2 BOOL_AS_BYTE	FB	Convert BOOL type data to BYTE type	SafetyInstructions	Applicable to library version 1.1.0.0
11.10.2.3.3 BOOL_AS_WORD	FB	Convert BOOL type data to WORD type		
11.10.2.3.4 BOOL_AS_DWORD	FB	Convert BOOL type data to DWORD type		
11.10.2.3.5 SAFEBOOL_AS_SAFEBYTE	FB	Convert SAFEBOOL type data to SAFEBYTE type		
11.10.2.3.5 SAFEBOOL_AS_SAFEBYTE	FB	Convert SAFEBOOL type data to SAFEWORD type		
11.10.2.3.7 SAFEBOOL_AS_SAFEDWORD	FB	Convert SAFEBOOL type data to SAFEDWORD type		
11.10.2.3.8 BYTE_AS_BOOL	FB	Convert BYTE type data to BOOL type		
11.10.2.3.9 WORD_AS_BOOL	FB	Convert WORD type data to BOOL type		
11.10.2.3.10 DWORD_AS_BOOL	FB	Convert DWORD type data to BOOL type		
11.10.2.3.11 SAFEBYTE_AS_SAFEBOOL	FB	Convert SAFEBYTE type data to SAFEBOOL type		
11.10.2.3.12 SAFEWORD_AS_SAFEBOOL	FB	Convert SAFEWORD type data to SAFEBOOL type		
11.10.2.3.13 SAFEDWORD_AS_SAFEBOOL	FB	Convert SAFEDWORD type data to SAFEBOOL type		

11.10.2.3.2 BOOL_AS_BYTE

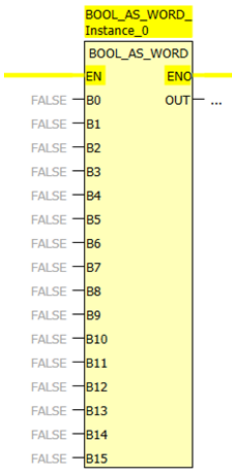
Converts eight input values of BOOL type into values of BYTE type, and outputs them from the right side.

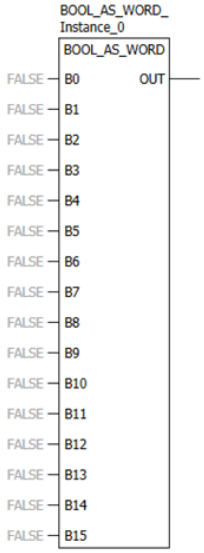
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
BOOL_AS_BYTE	Convert BOOL type data to BYTE type	FB		

- **Related variables**

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	B0 to B7	BOOL values to be converted	BOOL	Follows data type	FALSE	BOOL values to be converted, corresponding to each bit
Output	OUT	Converted BYTE value	BYTE	Follows data type	0	Conversion result





- **Data type range**

	Boolean		Bit String					
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD
IN	√	-	-	-	-	-	-	-
OUT	-	-	√	-	-	-	-	-

11.10.2.3.3 BOOL_AS_WORD

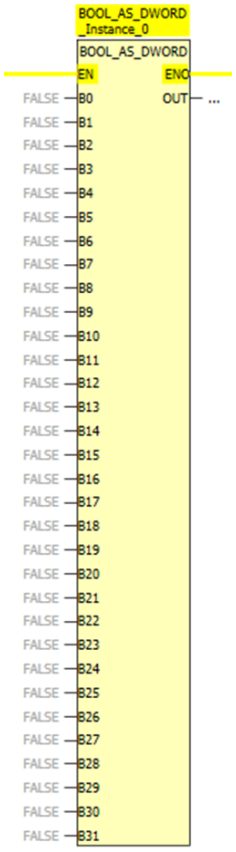
Converts 16 input values of BOOL type into values of WORD type, and outputs them from the right side.

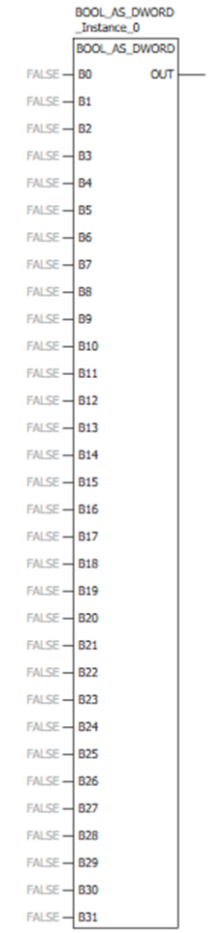
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
BOOL_AS_WORD	Convert BOOL type data to WORD type	FB		

- **Related variables**

Input/Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	B0 to B15	BOOL values to be converted	BOOL	Follows data type	FALSE	BOOL values to be converted, corresponding to each bit
Output	OUT	Converted WORD value	WORD	Follow data type	0	Conversion result





- **Data type range**

	Boolean		Bit String					
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD
IN	√	-	-	-	-	-	-	-
OUT	-	-	-	-	√	-	-	-

11.10.2.3.4 BOOL_AS_DWORD

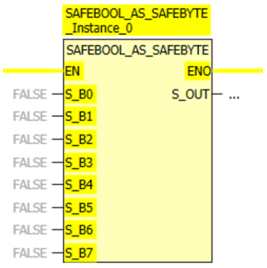
Converts 32 input values of BOOL type into values of DWORD type, and outputs them from the right side.

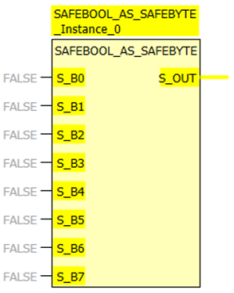
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
BOOL_AS_DWORD	Convert BOOL type data to DWORD type	FB		

- **Related variables**

Input/Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	B0 to B31	BOOL values to be converted	BOOL	Follows data type	FALSE	BOOL values to be converted, corresponding to each bit
Output	OUT	Converted DWORD value	DWORD	Depends on data type	0	Conversion result





- **Data type range**

	Boolean		Bit String					
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD
IN	√	-	-	-	-	-	-	-
OUT	-	-	-	-	-	-	√	-

11.10.2.3.5 SAFEBOOL_AS_SAFEBYTE

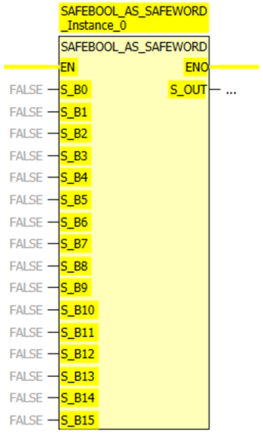
Converts eight input values of SAFEBOOL type into values of SAFEBYTE type, and outputs them from the right side.

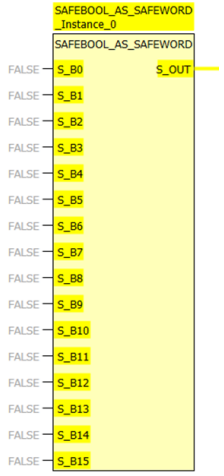
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SAFEBOOL_AS_SAFEBYTE	Convert SAFEBOOL type data to SAFEBYTE type	FB		

- **Related variables**

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	S_B0 to S_B7	SAFEBOOL value to be converted	SAFEBOOL	Follows data type	FALSE	SAFEBOOL values to be converted, corresponding to each bit
Output	S_OUT	Converted SAFEBYTE value	SAFEBYTE	Follows data type	0	Conversion result





- **Data type range**

	Boolean		Bit String					
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD
IN	-	√	-	-	-	-	-	-
OUT	-	-	-	√	-	-	-	-

11.10.2.3.6 SAFEBOOL_AS_SAFEWORD

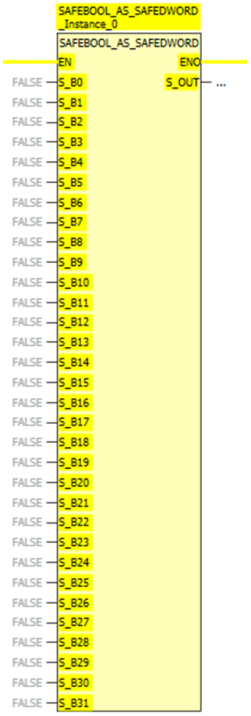
Converts 16 input values of SAFEBOOL type into values of SAFEWORD type, and outputs them from the right side.

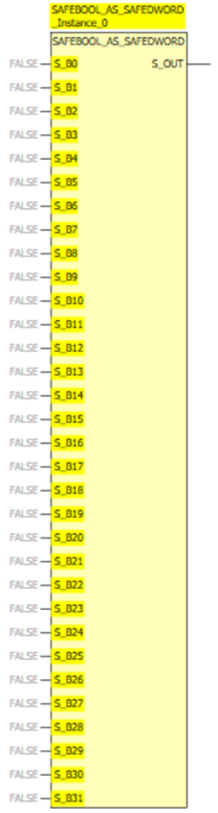
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SAFEBOOL_AS_SAFEWORD	Convert SAFEBOOL type data to SAFEWORD type	FB		

- **Related variables**

Input/Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	S_B0 to S_B15	SAFEBOOL value to be converted	SAFEBOOL	Follows data type	FALSE	SAFEBOOL values to be converted, corresponding to each bit
Output	S_OUT	Converted SAFEWORD value	SAFEWORD	Follows data type	0	Conversion result





- **Data type range**

	Boolean		Bit String					
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD
IN	-	√	-	-	-	-	-	-
OUT	-	-	-	-	-	√	-	-

11.10.2.3.7 SAFEBOOL_AS_SAFEDWORD

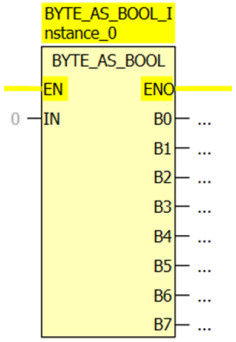
Converts 32 input values of SAFEBOOL type into values of SAFEWORD type, and outputs them from the right side.

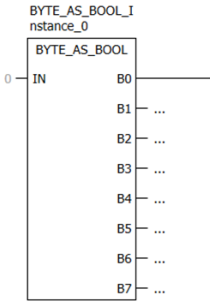
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SAFEBOOL_AS_SAFEDWORD	Convert SAFEBOOL type data to SAFEDWORD type	FB		

- **Related variables**

Input/Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	S_B0 to S_B31	SAFEBOOL value to be converted	SAFEBOOL	Follows data type	FALSE	SAFEBOOL values to be converted, corresponding to each bit
Output	S_OUT	Converted SAFEDWORD value	SAFEDWORD	Follows data type	0	Conversion result





- **Data type range**

	Boolean		Bit String					
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD
IN	-	√	-	-	-	-	-	-
OUT	-	-	-	-	-	-	-	√

11.10.2.3.8 BYTE_AS_BOOL

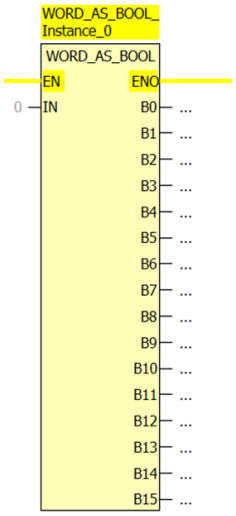
Converts the input value of BYTE type into eight values of BOOL type.

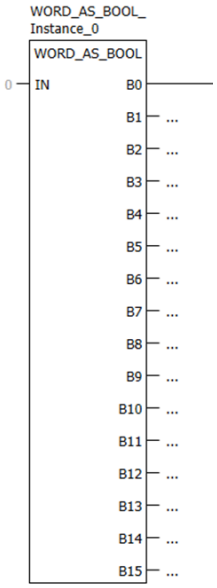
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
BYTE_AS_BOOL	Convert BYTE type data to BOOL type	FB		

- **Related variables**

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	IN	BYTE value to be converted	BYTE	Follows data type	0	BYTE value to be converted
Output	B0 to B7	Converted return value	BOOL	Follows data type	FALSE	Conversion result





- **Data type range**

	Boolean		Bit String					
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD
IN	-	-	√	-	-	-	-	-
OUT	√	-	-	-	-	-	-	-

11.10.2.3.9 WORD_AS_BOOL

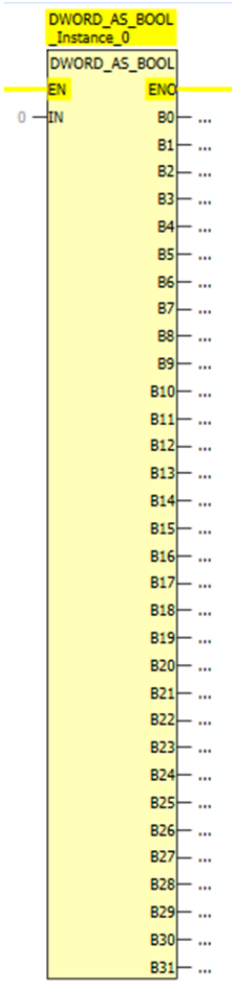
Converts the input value of WORD type into 16 values of BOOL type.

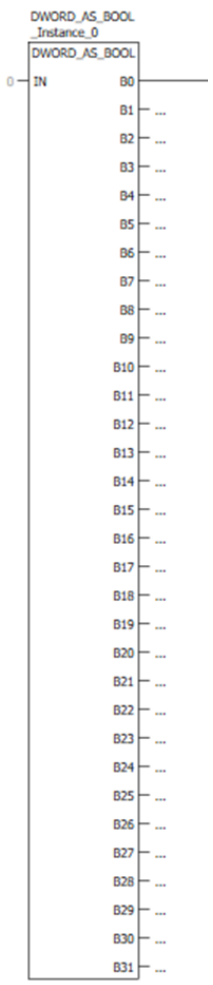
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
WORD_AS_BOOL	Convert WORD type data to BOOL type	FB		

- **Related variables**

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	IN	WORD value to be converted	WORD	Follow data type	0	WORD value to be converted
Output	B0 to B15	Converted return value	BOOL	Follows data type	FALSE	Conversion result





- **Data type range**

	Boolean		Bit String					
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD
IN	-	-	-	-	√	-	-	-
OUT	√	-	-	-	-	-	-	-

11.10.2.3.10 DWORD_AS_BOOL

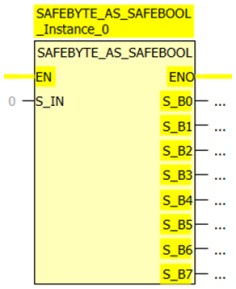
Converts the input value of DWORD type into 32 values of BOOL type.

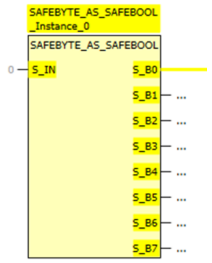
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
DWORD_AS_BOOL	Convert DWORD type data to BOOL type	FB		

- **Related variables**

Input/Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	IN	DWORD value to be converted	DWORD	Depends on data type	0	DWORD value to be converted
Output	B0 to B31	Converted return value	BOOL	Follows data type	FALSE	Conversion result





- **Data type range**

	Boolean		Bit String					
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD
IN	-	-	-	-	-	-	√	-
OUT	√	-	-	-	-	-	-	-

11.10.2.3.11 SAFEBYTE_AS_SAFEBOOL

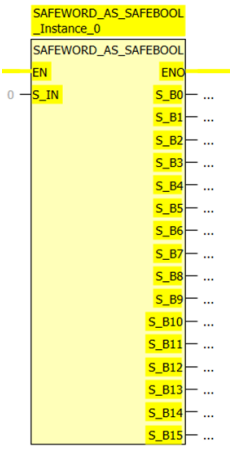
Converts the input value of SAFEBYTE type into eight values of SAFEBOOL type.

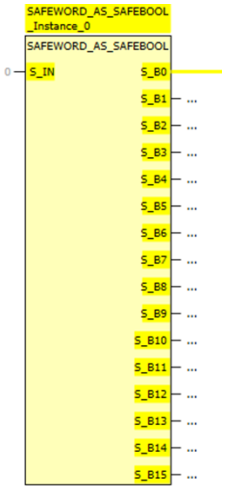
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SAFEBYTE_AS_SAFEBOOL	Convert SAFEBYTE type data to SAFEBOOL type	FB		

- **Related variables**

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	S_IN	SAFEBYTE value to be converted	SAFEBYTE	Follows data type	0	SAFEBYTE value to be converted
Output	S_B0 to S_B7	Converted return value	SAFEBOOL	Follows data type	FALSE	Conversion result





- **Data type range**

	Boolean		Bit String					
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD
IN	-	-	-	√	-	-	-	-
OUT	-	√	-	-	-	-	-	-

11.10.2.3.12 SAFEWORD_AS_SAFEBOOL

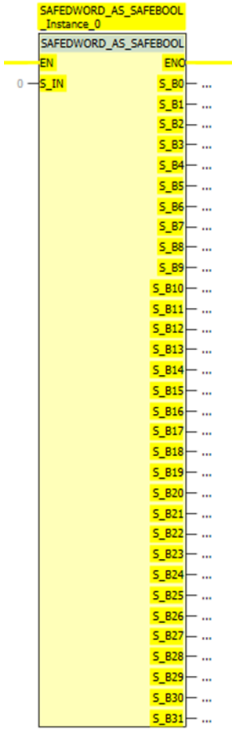
Converts the input value of SAFEWORD type into 16 values of SAFEBOOL type.

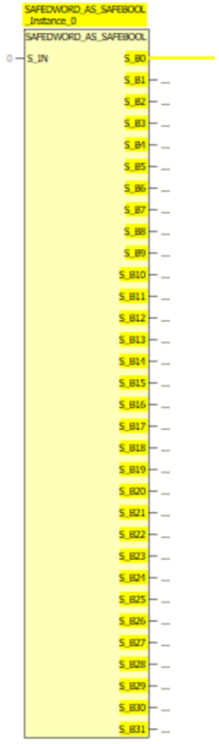
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SAFEWORD_AS_SAFEBOOL	Convert SAFEWORD type data to SAFEBOOL type	FB		

- **Related variables**

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	S_IN	SAFEWORD value to be converted	SAFEWORD	Follows data type	0	SAFEWORD value to be converted
Output	S_B0 to S_B15	Converted return value	SAFEBOOL	Follows data type	FALSE	Conversion result





- **Data type range**

	Boolean		Bit String					
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD
IN	-	-	-	-	-	√	-	-
OUT	-	√	-	-	-	-	-	-

11.10.2.3.13 SAFEDWORD_AS_SAFEBOOL

Converts the input value of SAFEWORD type into 32 values of SAFEBOOL type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	FBD Representation
SAFEDWORD_AS_SAFEBOOL	Convert SAFEDWORD type data to SAFEBOOL type	FB		

- **Related variables**

Input/Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	S_IN	SAFEDWORD value to be converted	SAFEDWORD	Follows data type	0	SAFEDWORD value to be converted
Output	S_B0 to S_B31	Converted return value	SAFEBOOL	Follows data type	FALSE	Conversion result

- **Data type range**

	Boolean		Bit String					
	BOOL	SAFEBOOL	BYTE	SAFEBYTE	WORD	SAFEWORD	DWORD	SAFEDWORD
IN	-	-	-	-	-	-	-	√
OUT	-	√	-	-	-	-	-	-

12 Library Management

12.1 Library Editing

12.1.1 Overview

Library editing refers to editing a library project, i.e., defining a library, specifically including:

- Adding, deleting, and modifying POU, customized types, global variable tables, parameter tables, and other elements in a library project, as well as configuration logic inside the POU.
- Modifying the library reference.
- Modifying the project information, including company name, library name, version, author, and description.
- Library projects support the project protection feature, which protects library project data through user management to prevent unauthorized access. For details, see 9.15 Library Project Safety Protection.

12.1.2 Library Update

Library update refers to editing or modifying the library project information based on an existing library to distinguish differences between versions before and after the changes.

Prerequisites

A saved library project is opened.

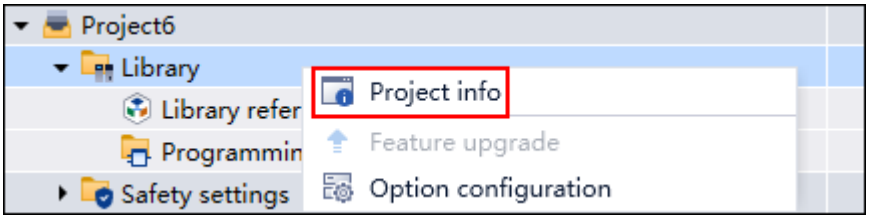
Procedure

1. Modify the library reference information or program configuration logic.
2. Modify the library project information (company name, library name, version, author, or description).
3. Save and load into library.

Result

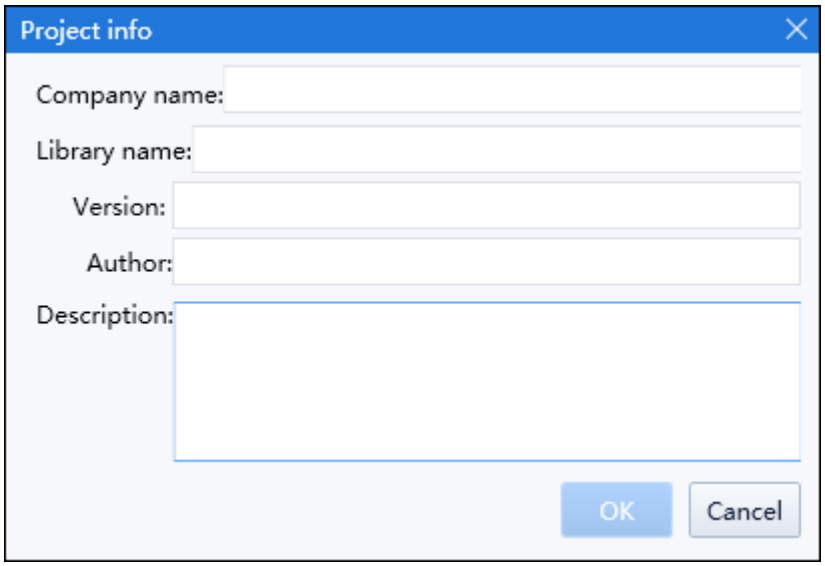
Through the Library Manager, you can view the information about multiple libraries, including the libraries before and after the upgrade.

12.1.3 Compiled Library



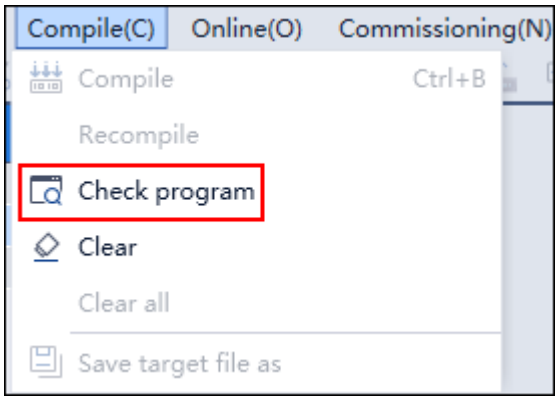
This is a compiled binary library, usually in .inoblib file format.

Prerequisites

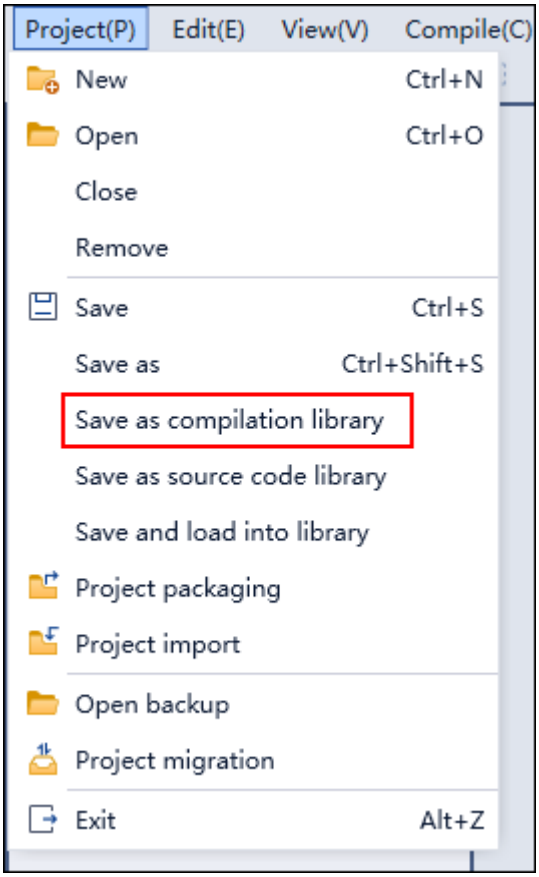


A library project has been created or opened.

Procedure



1. Add the program logic, such as program blocks and GV, and perform the logic configuration.
2. Right-click "Library" and then click "Project info".



3. On the opened "Project info" interface, enter the company name, library name, version (such as 1.0.0.1), author, and description. The library name serves as the unique identifier for the library, and a library may have multiple version numbers.

4. Choose "Compile > Check program" from the menu bar.

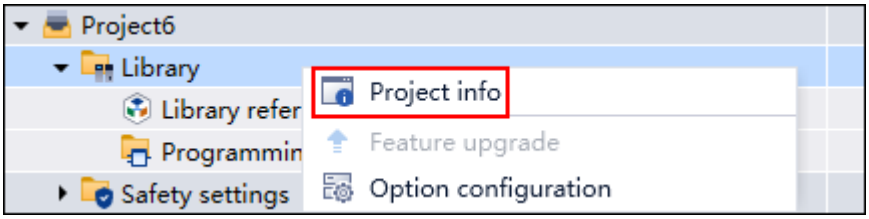
5. Choose "Project > Save as compilation library" from the menu bar after confirming no compilation errors.

6. Select a path, enter a filename, and then save it. The file format is .inoblib.

Result

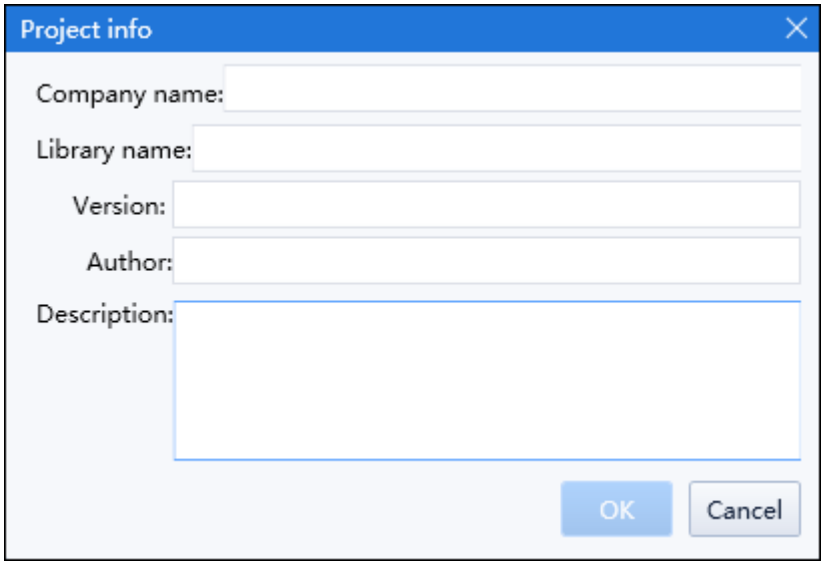
A file (xxx.inoblib) is generated in the specified folder.

12.1.4 Source Code Library



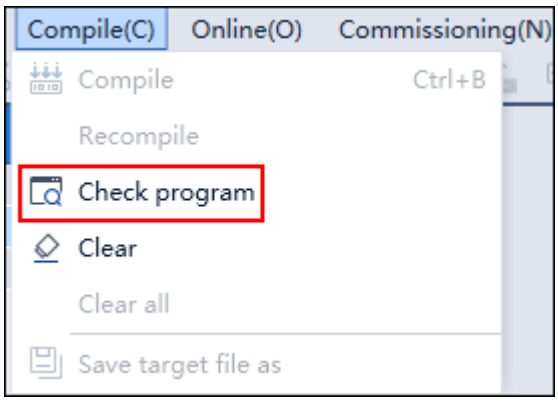
The source code library refers to uncompiled library files (typically in .inolib format) for a project, and can be used for project commissioning.

Prerequisites



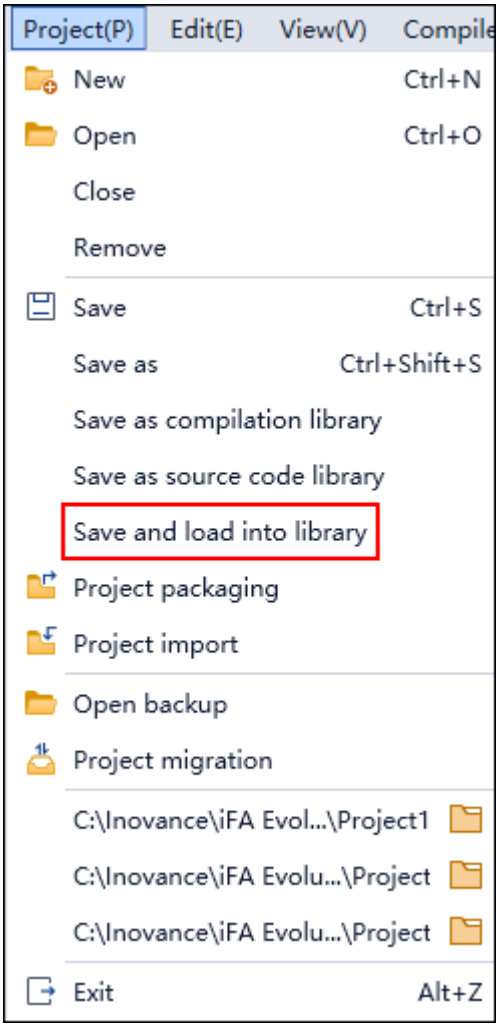
A library project has been created or opened.

Procedure

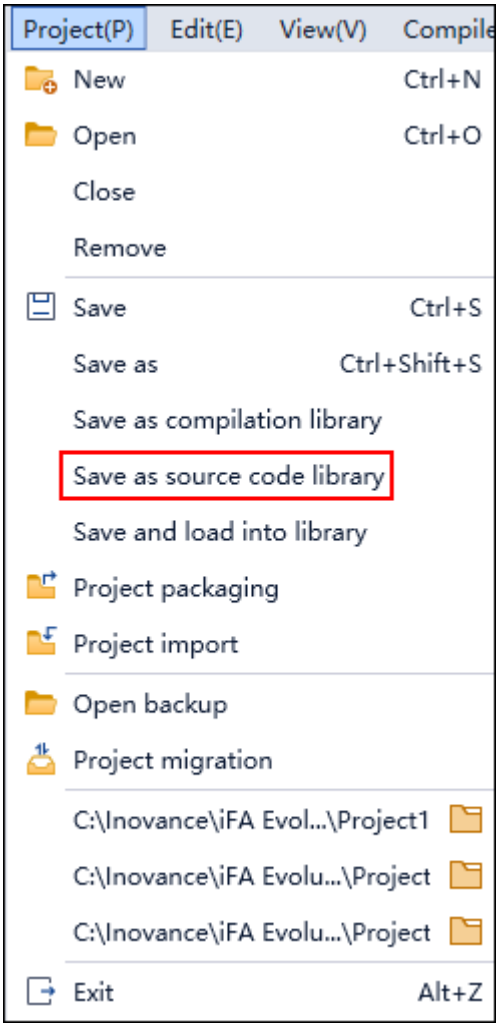


1. Add the program logic, such as program blocks and GV, and perform the logic configuration.
2. Right-click "Library" and then click "Project info".

3. On the opened "Project info" interface, enter the company name, library name, version (such as 1.0.0.1), author, and description. The library name serves as the unique identifier for the library, and a library may have multiple version numbers.



4. Choose "Compile > Check program" from the menu bar.



5. Save the source code library in two ways after confirming no compilation errors:

   - Method 1: Save and load into library
     Choose "Project > Save and load into library" from the menu bar. If a library with the same name and version number already exists, a prompt will appear asking whether to overwrite it. This method directly saves the source code library to the system directory, allowing users to view and use it through the "Reference manager".

- Method 2: Save as source code library
  Choose "Project > Save as source code library" from the menu bar, select a path, enter a filename, and then save it. The file format is .inolib. This method saves the source code library to a user-defined path, enabling flexible export and management of files.

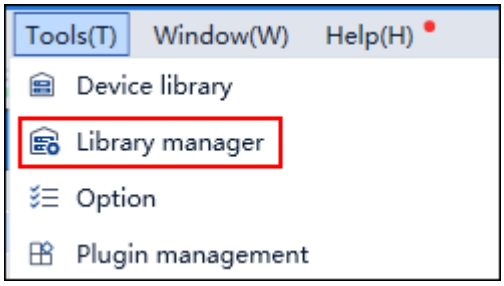
Results

- Method 1: Save and load into library
  - A file (.inolib) is generated in the project folder XXX\Repository\Libraries\XXX\.
  - The library information, including library name (entered in Step 3), version number, and author, can be viewed in the "Reference manager".
- Method 2: Save as source code library
  A file (xxx.inolib) is generated in the specified folder.

12.2 Library Manager

The Library Manager allows one-click installation/uninstallation and supports quick import of self-defined libraries into the current project, facilitating direct invocation of installed libraries and improving the development efficiency.

Installation



Installation refers to importing user-defined algorithm libraries into the current IDE environment for building user programs in a project.

Prerequisites

User-defined algorithm libraries (source code libraries or compiled libraries) are available in a computer, which means the .inolib file or .inoblib file is present.

Procedure

1. Choose "Tools > Library manager" from the menu bar to access the "Library manager" configuration interface.

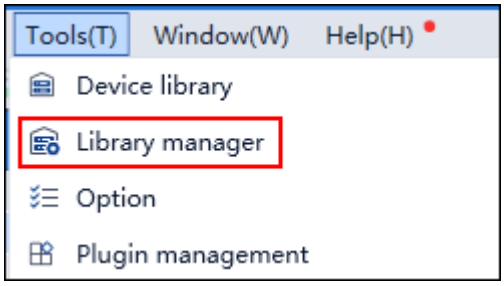
2. In the opened "Library manager" interface, click the "Install" button.
3. Select the path of the custom algorithm library.
4. Select .inolib or .inoblib file, and then click the "Open" button in the dialog box.

Result

The installed user-defined libraries are displayed under the "Users" node of the Library Manager.

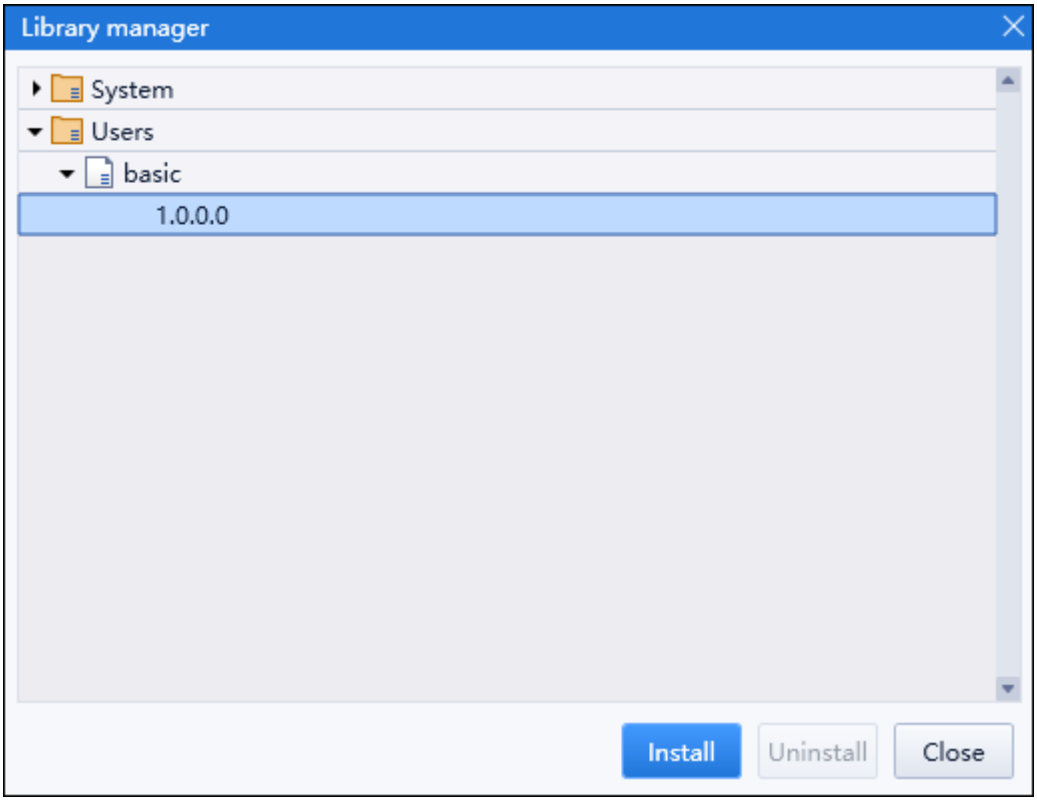
Uninstallation

Uninstallation refers to removing user-defined libraries from the current IDE environment, after which no information related to these libraries can be identified in the system. System libraries cannot be uninstalled.



> CAUTION
>
> Uninstalling a referenced library may cause a compilation error in the project program.

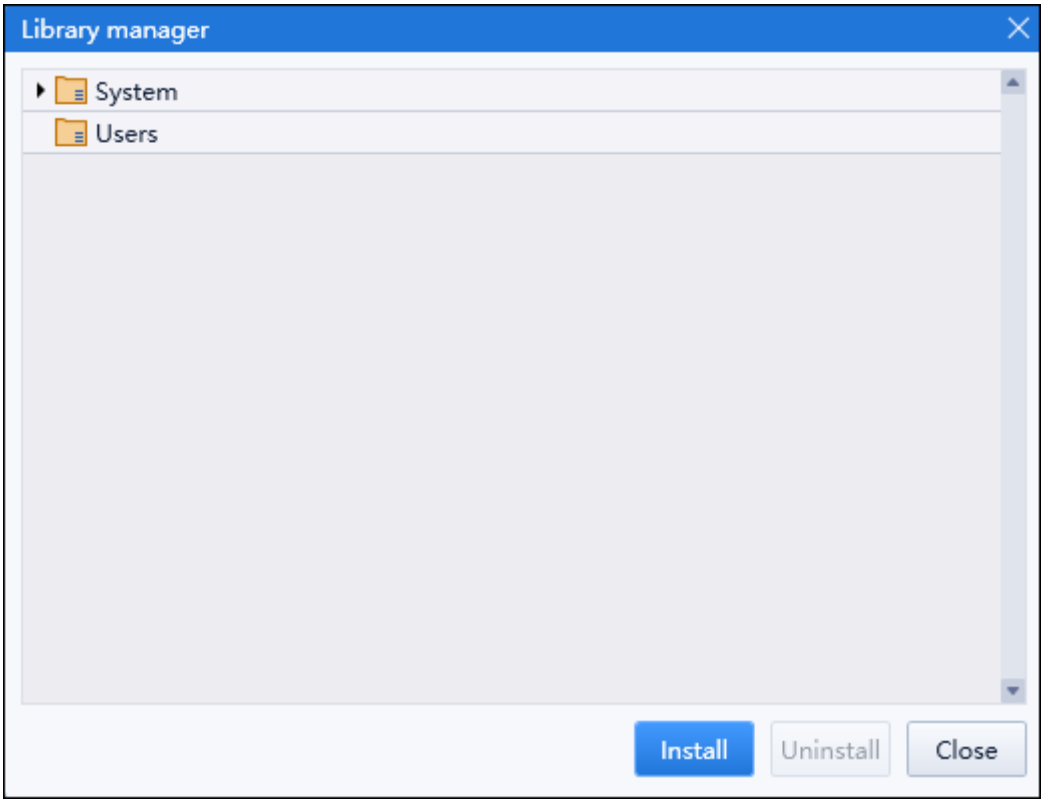
Prerequisites



User-defined algorithm libraries (source code libraries or compiled libraries) have been installed.

Procedure

1. Choose "Tools > Library manager" from the menu bar to access the "Library manager" configuration interface.



2. In the opened "Library manager" interface, select the version numbers of the libraries under the "Users" node.

3. Click the "Uninstall" button.

Result

- The uninstalled user-defined libraries are no longer displayed under the "Users" node of the Library Manager.
- The program cannot invoke any uninstalled libraries.

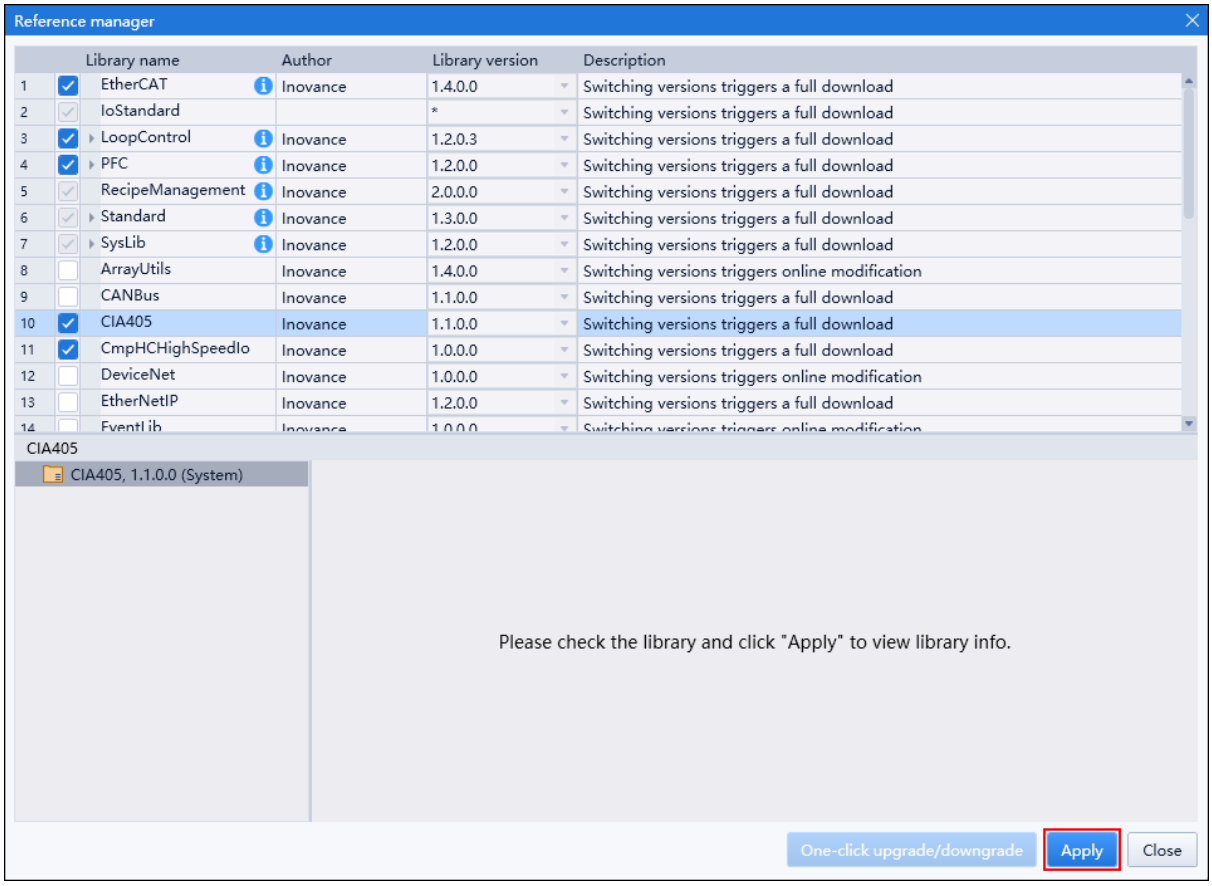
12.3 Library Reference

Library reference manages the libraries used in a project, supporting operations on system libraries or self-defined libraries, including referencing, dereferencing, one-click upgrade/downgrade, and library version switching. It applies to projects, including library projects and engineering projects. You can reference different libraries or different versions of the same library for different projects based on project requirements.

- Library referencing introduces the Lib symbols in the current IDE environment into the current project environment, facilitating the user configuration logic function. The referenced library information is saved in the project file to ensure recognition and loading next time when the project is opened.
- Dereferencing removes the referenced libraries from the current project, along with their symbols. If the symbol of a dereferenced library is being used, the system will send an error message.

Dereferencing may cause a software runtime exception or compilation error.

- One-click upgrade/downgrade automatically adjusts all library versions to the latest versions supported by the current device version after the device version switching, preventing conflicts caused by version incompatibility.
- Library version switching allows switching the library versions in a project as needed during development. Available library versions include all versions supported by the current device version, as well as the * version, where "*" indicates the latest version supported by the device version.

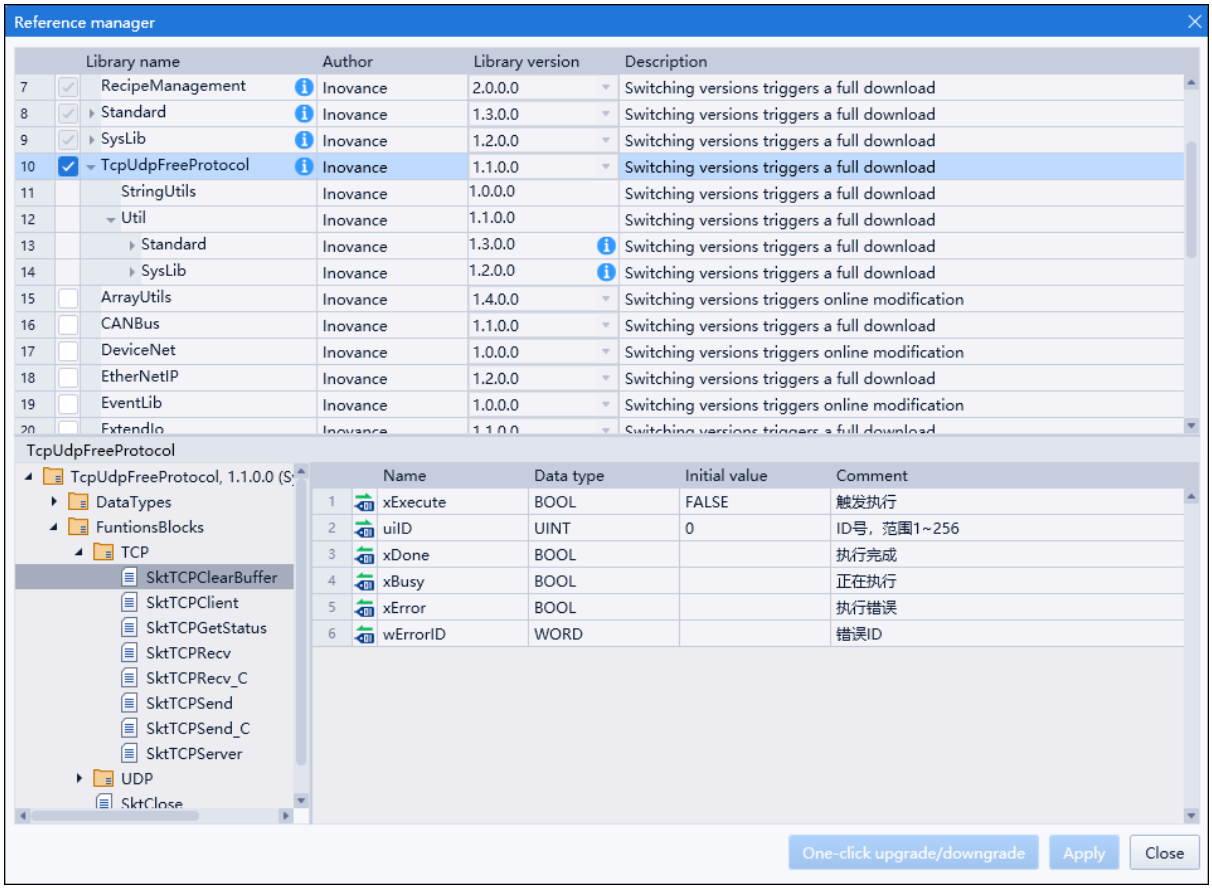


Library referencing and dereferencing

Prerequisites

- System libraries are available, or self-defined libraries have been installed.
- A library project has been opened, or a PLC has been added.

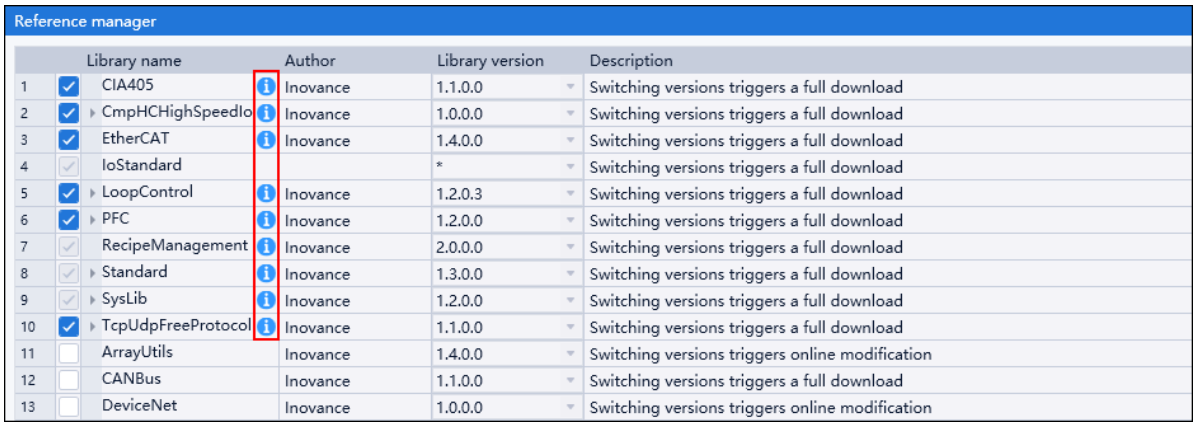
Procedure



1. Double-click "Library reference" in the left project tree to access the "Reference manager" configuration interface.
2. Check/Uncheck appropriate libraries for reference/dereference.

3. Click the "Apply" button.

Result

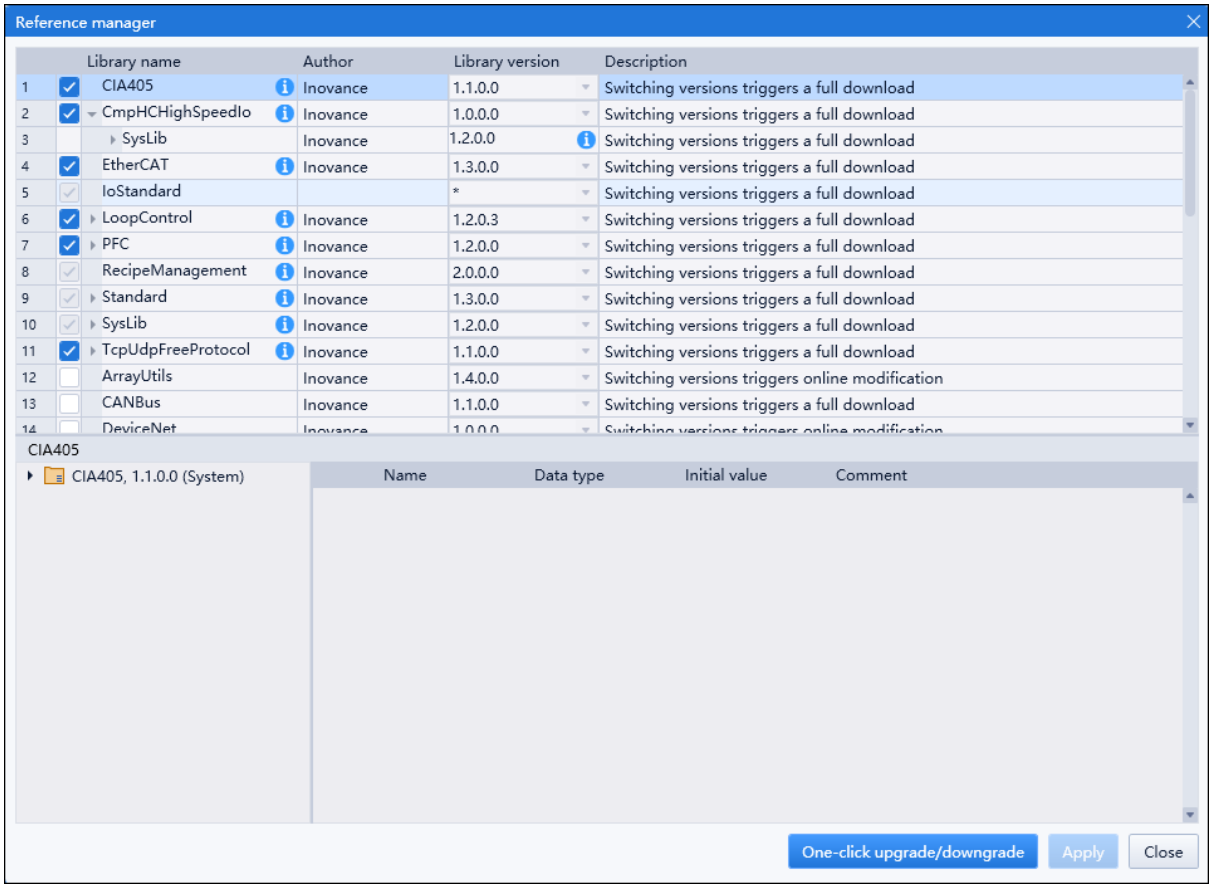


- Referencing: Introduces a selected library into the current project environment, and allows viewing details about supported instructions, variables, user-defined types, and dependent libraries.

- Dereferencing: Removes a referenced library from the current project, along with its symbols.

NOTE

- On the "Reference manager" interface, all installed system libraries and user-defined libraries are displayed, including those referenced for the project. The default library version is the latest, and the "*" in the drop-down list indicates that the latest library version is automatically applied when a new version is installed.
- When referencing system libraries in an engineering project, all versions except the "*" version are set as placeholder libraries by default.



One-click upgrade/downgrade

Prerequisites

A new device version is available.

Procedure

1. Double-click "Library reference" in the left project tree to access the "Reference manager" configuration interface.

2. Click the "One-click Upgrade/Downgrade" button, and then a dialog stating that "Do you want to perform one-click upgrade/downgrade? Click Apply after the upgrade/downgrade" appears. Click "Yes" and then click the "Apply" button.

Result

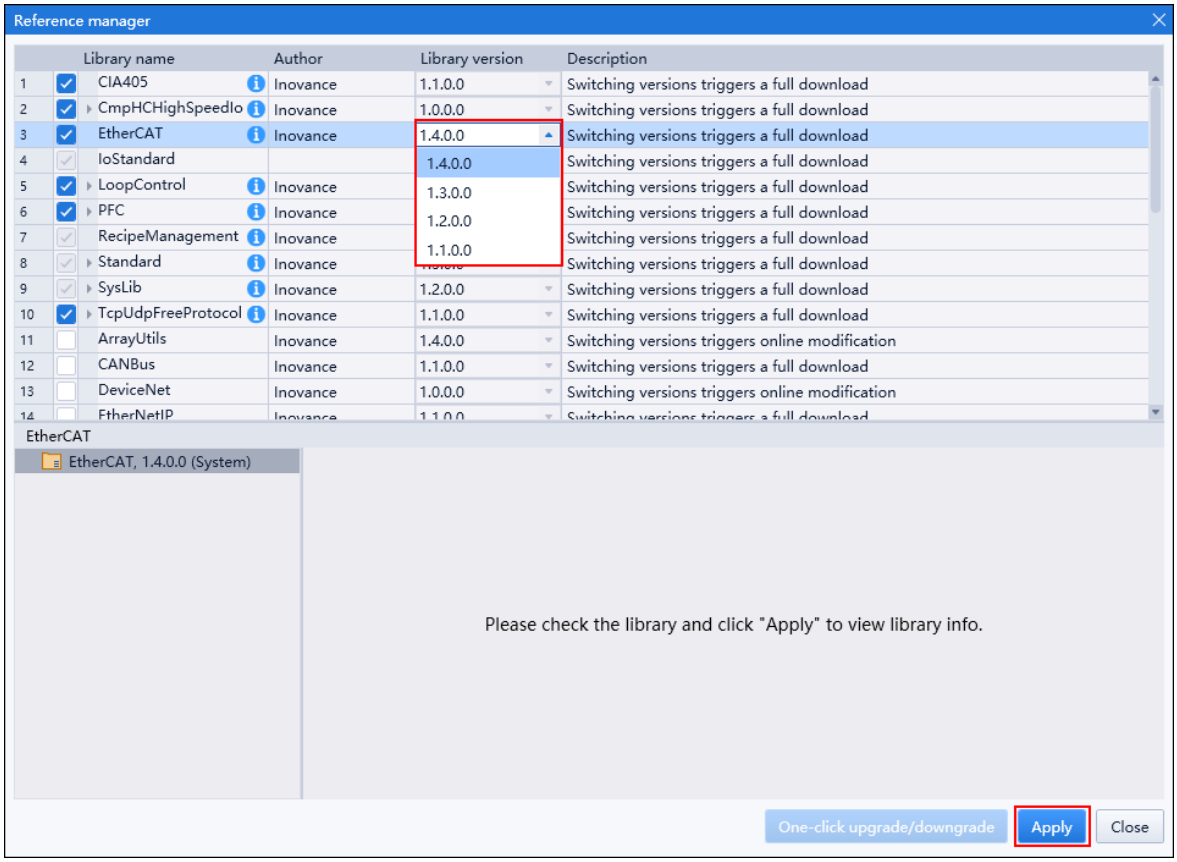
All libraries supported by this device (irrespective of the selection status) are upgraded to the latest versions (* version remains unchanged).

NOTE

- This feature only supports one-click upgrade/downgrade of system libraries; user-defined libraries are unaffected.
- If any library file is missing after the device version switching, the library version will remain unchanged after the upgrade/downgrade, and an error message will appear during compilation.

Library version switching

Prerequisites



- A library project has been opened, or a PLC has been added.
- System libraries or user-defined libraries have been installed.

Procedure

1. Double-click "Library reference" in the left project tree to access the "Reference manager" configuration interface.

2. You can switch the library version in two ways:

   - Method 1: Switch the library version directly via the drop-down list
     Check a library whose version you want to switch, then select the desired library version from the drop-down list under "Library Version" ("*" indicates using the latest version), and click the "Apply" button.

> **NOTE**
>
> This method only supports modifying the version of top-level libraries via the drop-down list; dependent library versions cannot be directly modified.

   - Method 2: Mark as placeholder library or unmark
     Selected a library, right-click "Mark as placeholder library" or "Unmark," and then a dialog stating that "Confirm that marking will adjust all library versions in the system to the same version" or "Confirm that umarking will restore the library versions in the system to the default version" appears. Follow the prompts to proceed.

> **NOTE**
>
> This method only supports system engineering projects.

Result

The library version in the project is switched to a specified version or the latest version.

Due to differences between library versions, changing the referenced library version may cause a software runtime exception or compilation error.

12.4 Library Properties

Library properties refer to library project information, including company name, library name, version, author, and description.

12.5 Library Permissions

Library permissions refer to read-write protection permissions managed by password for individual POU within a library project, following the read-write permissions of the POU. For details, see 10.1.2.5 Program Block Encryption.

13 Visual Design

13.1 Establishing a Connection

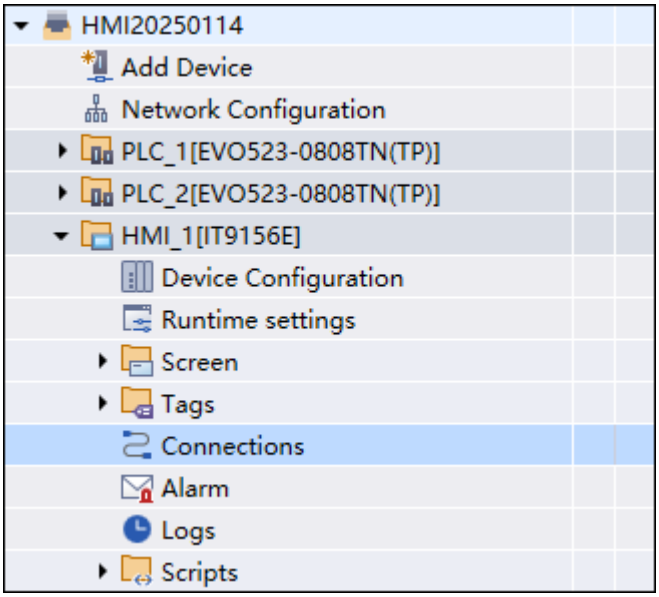
- 13.1.1 Connecting Devices
- 13.1.2 Connecting External Devices
- 13.1.4 Modifying a Connection
- 13.1.5 Copying a Connection
- 13.1.6 Supported Device Drivers

13.1.1 Connecting Devices

- 13.1.1.1 Establishing a Device Connection
- 13.1.1.2 Setting Device Connection Property
- 13.1.1.3 Deleting a Device Connection

13.1.1.1 Establishing a Device Connection

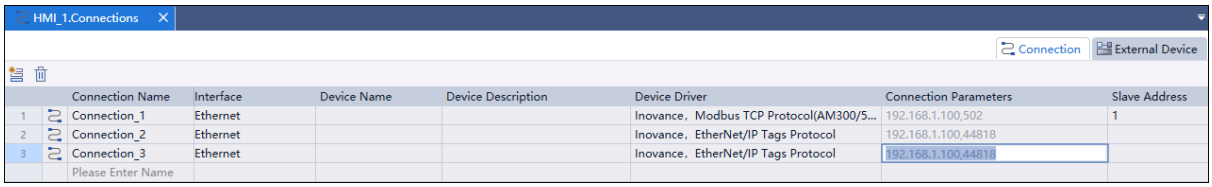
Connection is used to configure the communication link between monitoring devices and other devices (e.g., PLCs), supporting both serial and Ethernet link. A monitoring device can establish up to 32 such links.



Communication connections between monitoring devices and other devices (e.g., PLC) can be established in two ways: manual and automatic.

Manual: You can configure on the "Connections" page, supporting both serial and Ethernet link.

Automatic: When you configure relevant settings for other devices (e.g., PLCs) on the network view, screen or variable table (limited to default and user-defined variable tables) page, the system automatically triggers the connection. This method supports only Ethernet links.



Manually establishing a connection on the "Connections" page

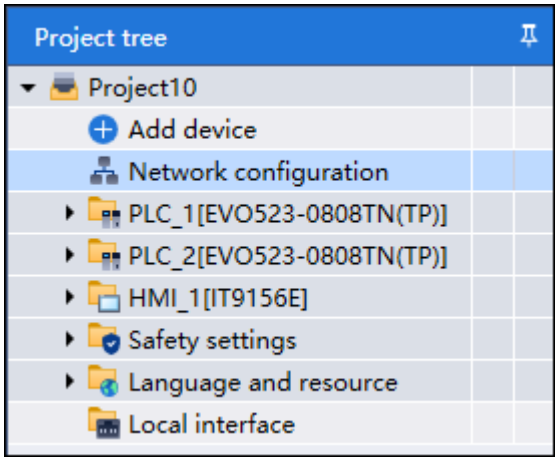
1. Open the "Connections" window.
   Double-click the **Connections** node in the project tree to open the corresponding window.

2. Add a connection.

   Click the icon  to add a connection row. Each added row indicates that the monitored device has established a communication link with a PLC, identified by .

3. Configure parameters.

   The communication properties vary depending on the device driver. For details on property settings, see 13.1.6 Supported Device Drivers.



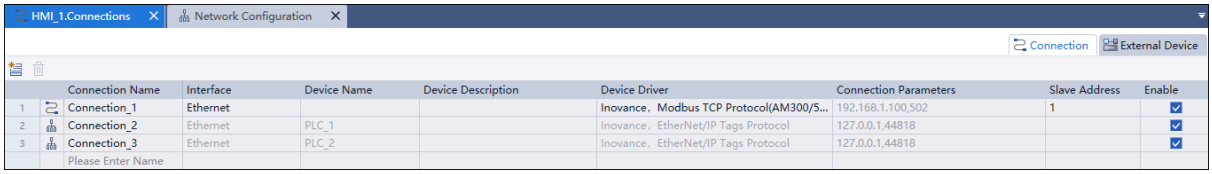
The Ethernet connection between the current monitoring device and a PLC has been successfully established.

Automatically establishing a connection via "Network configuration"

This method is applicable when the PLC and monitoring device belong to the same project and are connected via Ethernet.

1. Open the "Network configuration" window.

   Double-click the **device and network** node in the project tree to open the "Network configuration" window.



2. Connect devices.

   Manually connect the Ethernet ports of devices. As shown in the figure below, HMI_1 connects to PLC_1

and PLC_2 respectively.

The connection information will be synchronized to the connection window of the monitoring device (HMI_1) and will be identified with , e.g., Connection_2 and Connection_3.

For automatically established connections, the device driver defaults to the 13.1.6.1.7 EtherNet/IP Tags Protocol.

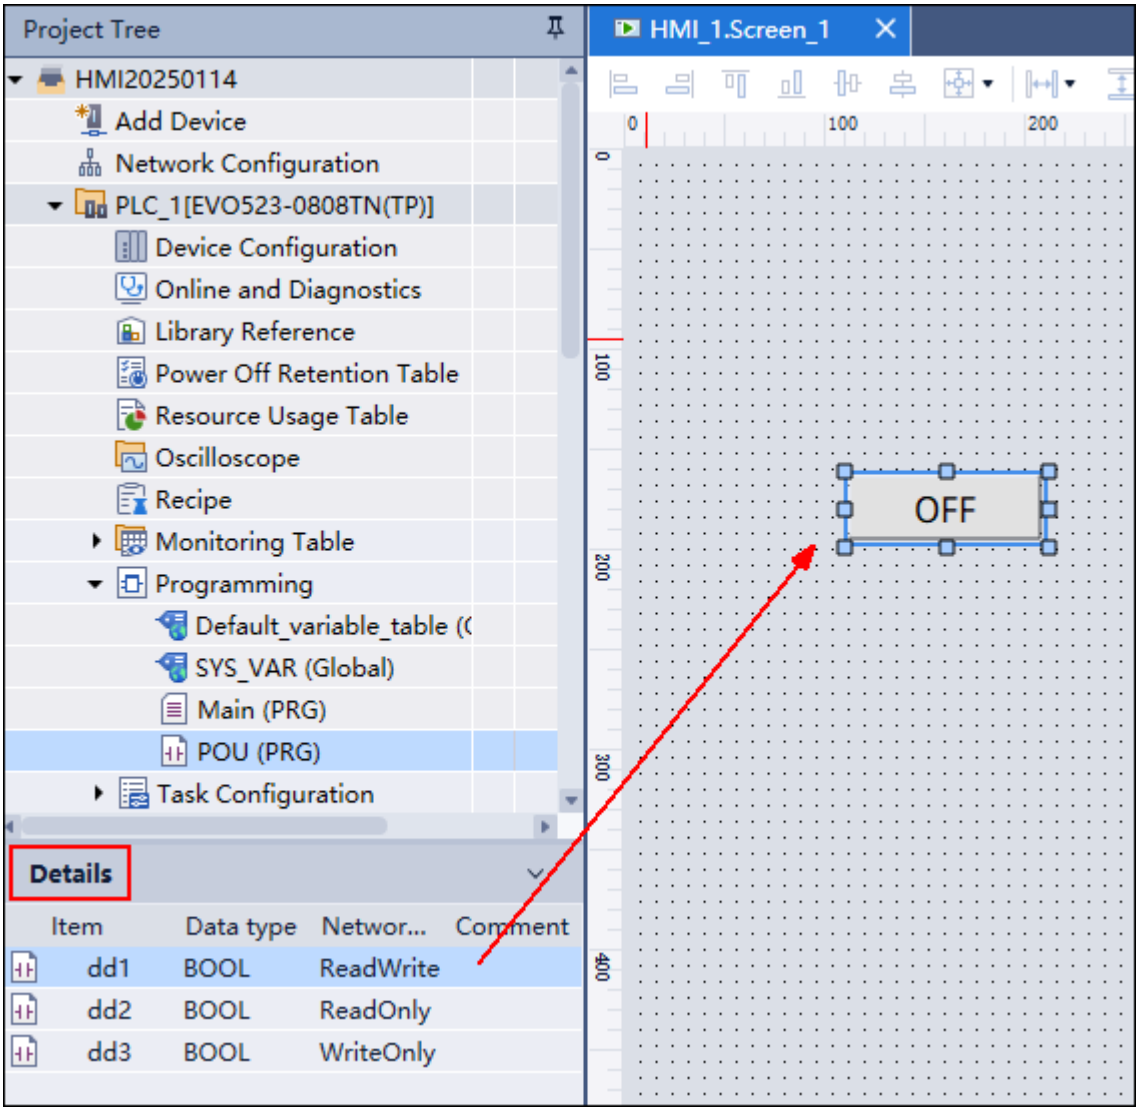
The Ethernet connection between the current monitoring device and a PLC has been successfully established.

Automatically establishing a connection via variable table

This method is applicable when the PLC and monitoring device belong to the same project and are connected via Ethernet.

1. Open the variable table of the monitoring device.
   Double-click the **default variable table** or user variable table node under the variable to open the corresponding window.
2. Add variables.
3. Configure reference variables.
   Double-click the reference variable cell, and select the public variable of the target PLC in the drop-down menu. A connection is established between the current monitoring device and the target PLC. Connection details will be synchronized to the project's "Network view" and the "Connection" window of the monitoring device.
4. Configure connection parameters.
   The connection information identifier is automatically created in the connection window. For parameter settings, see 13.1.6.1.7 EtherNet/IP Tags Protocol.

The Ethernet connection between the current monitoring device and a PLC has been successfully established.



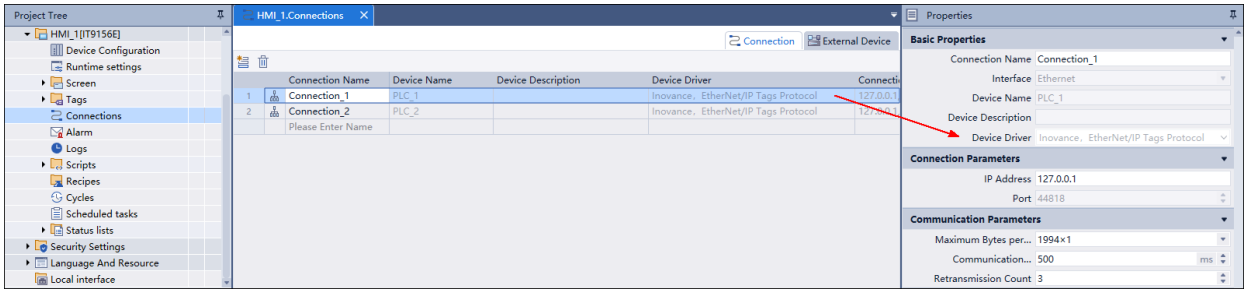
Automatically establishing a connection via screen

This method is applicable when the PLC and monitoring device belong to the same project and are connected via Ethernet.

1. Define variables in PLC_1.
   For the variable definition process, see 10.1.1.1 Global Variables or 10.1.1.2 Local Variables.
2. Set the variable as a public variable.
   Set the variable's "Network public" property to any value other than "Private." For details, see 10.1.1.9.3 Variable Declaration Property.

3. Add a screen to HMI_1.
   For operations, see 13.3.2 Adding a Screen.

4. Drag the variable from PLC_1 to the screen in HMI_1.
   For example, in the figure below, the local variable **dd1** of the POU is dragged from the detailed view to **Screen_1**. The connection between PLC_1 and HMI_1 is successfully established.

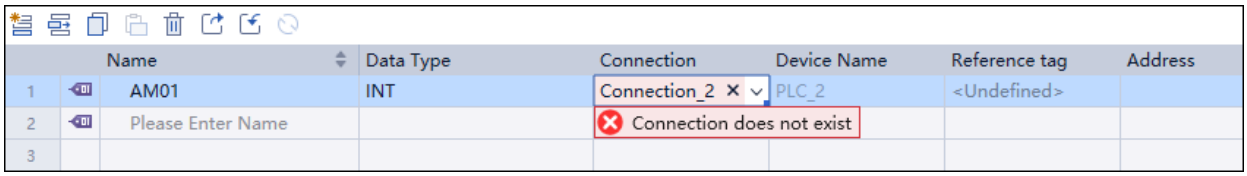


5. Configure connection parameters.
   The connection information identifier is automatically created in the connection window. For parameter settings, see 13.1.6.1.7 EtherNet/IP Tags Protocol.

6. The Ethernet connection between the current monitoring device and a PLC has been successfully established.

13.1.1.2 Setting Device Connection Property

When communication parameters for a monitoring device connected to another device (e.g., PLC) need to be adjusted, double-click the serial number of the target connection row to open the corresponding communication property window.



Different selections of device drive will result in differences in the number and content of the corresponding connection property. For details, see the respective sections.

Product	Device Driver	Reference Section
Inovance	TCP Monitoring Protocol (H5U/Easy Series)	For details, see the corresponding section according to the product series. 13.1.6.1.1 Easy Series PLCs and 13.1.6.1.2 H5U Series PLCs
	QLink TCP Protocol (H5U Series)	13.1.6.1.2 H5U Series PLCs
	QLink RTU Protocol (H5U Series)

	Modbus TCP Server	
	Modbus RTU Master	13.1.6.6.2 Modbus RTU Protocol
	Modbus RTU Slave	

13.1.1.3 Deleting a Device Connection

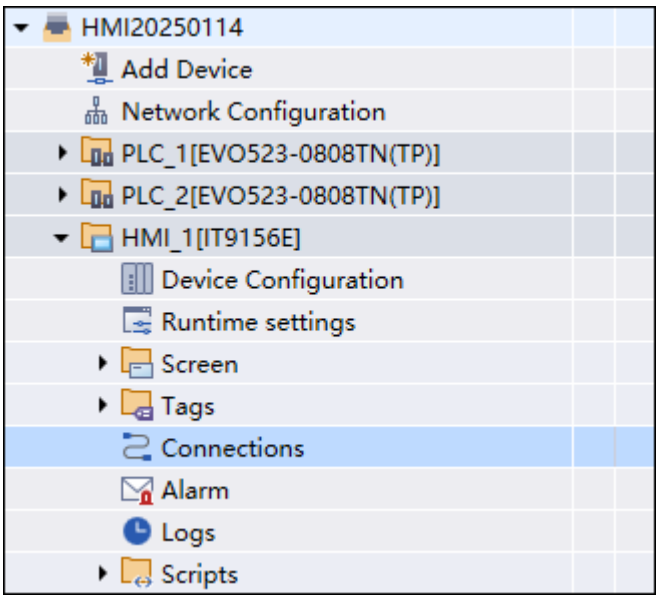
If variables for monitoring devices in the variable table are associated with connections to other devices (e.g., PLC), deleting such connections will cause the corresponding variable rows to display abnormally.

There are three ways to delete other device (e.g., PLC) connections:

1. Select the target row in the "Connections" window, and complete the operation via a command, icon , or the **Delete** key.
2. Delete the connections between devices in the network view to remove the connection to other devices (e.g., PLC).
3. Deleting the connected PLCs in the project tree can also remove the connection to other devices (e.g., PLC).

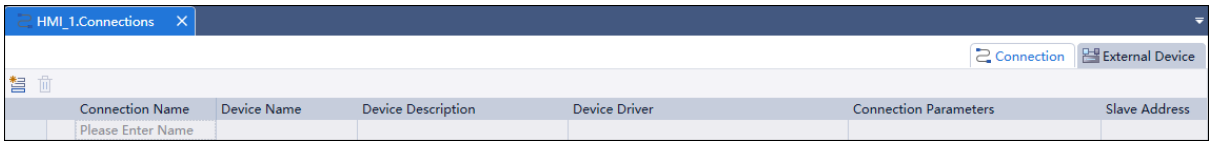
When a connection to another device (e.g., PLC) is deleted, its corresponding system variables will also be deleted automatically. If a connection with the same name is re-established later, the variable references must be re-established.

13.1.2 Connecting External Devices



- 13.1.2.1 Establishing an External Device Connection
- 13.1.2.2 Deleting an External Device Connection

13.1.2.1 Establishing an External Device Connection



The communication link between the monitoring device and the card reader or barcode scanner must be configured. The devices are connected via USB ports.

Establishing a connection

1. Open the "Connections" window.
   Double-click the **Connections** node in the project tree to open the corresponding window.

2. Switch to the "External device" tab.

3. Add a connection.

   Click the icon to add a connection row. Each added row indicates that a communication link has been established with an external device, identified by .

4. Configure connection parameters.

Property Category		Description
Basic property	Connection name	Connection identifier supports combinations of Chinese characters, English letters, numbers, `_`, and `-`, with a maximum length of 64 English characters. Connection name must be unique within the same monitoring device. Default name automatically increments based on the number of existing connections (including 13.1.1.1 Connecting Devices), ensuring no duplicates.
	Link type	USB supported
	Device name	Name of the connected object supports combinations of Chinese characters, English letters, numbers, `_`, and `-`, with a maximum length of 64 English characters. Device names do not support duplicates within the same monitoring device.
	Device description	Device description supports a maximum length of 128 characters.
	Device driver	Communication method
Link parameters	Communication port	Connection port selection.
Activate	Enable/Disable	Enable or disable the connection.

Connecting system variables

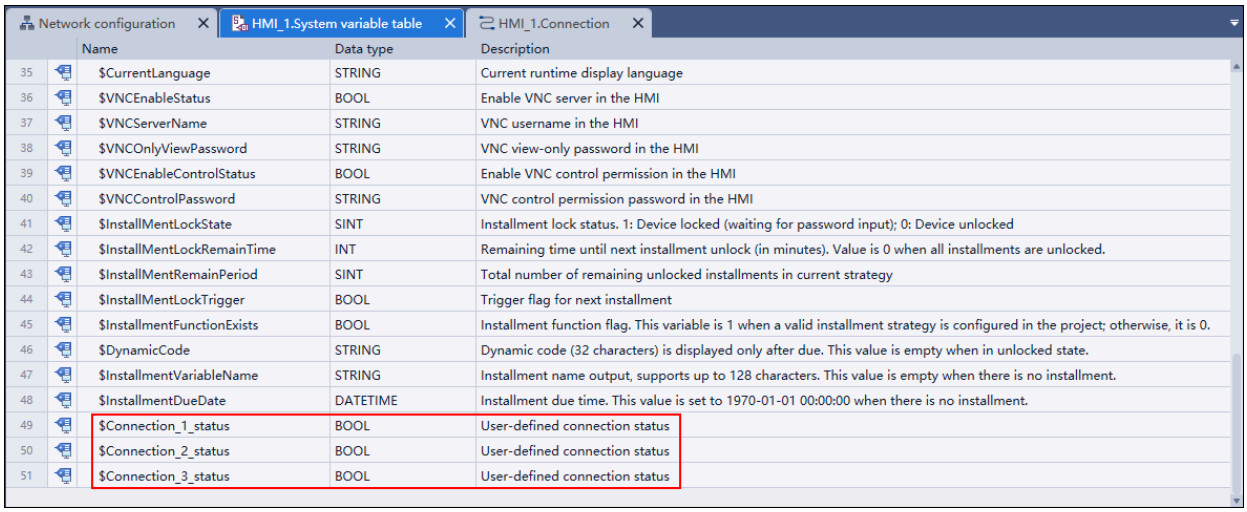
A corresponding system variable is automatically generated in the "System Variable Table" when an external device connection is established, named as "$Connection Name _status" to indicate the connection status.

	Name	Data type	Description
35	$CurrentLanguage	STRING	Current runtime display language
36	$VNCEnableStatus	BOOL	Enable VNC server in the HMI
37	$VNCServerName	STRING	VNC username in the HMI
38	$VNCOnlyViewPassword	STRING	VNC view-only password in the HMI
39	$VNCEnableControlStatus	BOOL	Enable VNC control permission in the HMI
40	$VNCControlPassword	STRING	VNC control permission password in the HMI
41	$InstallMentLockState	SINT	Installment lock status. 1: Device locked (waiting for password input); 0: Device unlocked
42	$InstallMentLockRemainTime	INT	Remaining time until next installment unlock (in minutes). Value is 0 when all installments are unlocked.
43	$InstallMentRemainPeriod	SINT	Total number of remaining unlocked installments in current strategy
44	$InstallMentLockTrigger	BOOL	Trigger flag for next installment
45	$InstallmentFunctionExists	BOOL	Installment function flag. This variable is 1 when a valid installment strategy is configured in the project; otherwise, it is 0.
46	$DynamicCode	STRING	Dynamic code (32 characters) is displayed only after due. This value is empty when in unlocked state.
47	$InstallmentVariableName	STRING	Installment name output, supports up to 128 characters. This value is empty when there is no installment.
48	$InstallmentDueDate	DATETIME	Installment due time. This value is set to 1970-01-01 00:00:00 when there is no installment.
49	$Connection_1_status	BOOL	User-defined connection status
50	$Connection_2_status	BOOL	User-defined connection status
51	$Connection_3_status	BOOL	User-defined connection status

For usage constraints, see 13.2.1 System Variable Table.

13.1.2.2 Deleting an External Device Connection

In the variable table, if variables of the monitoring device are associated with an external device connection, deleting the connection will cause the corresponding variable rows to display abnormally.



Select the target row in the "Connections" window, and complete the delete operation via a command, icon , or the **Delete** key.

When a connection to external device is deleted, its corresponding system variables will also be deleted automatically. If a connection with the same name is re-established later, the variable references must be re-established.

13.1.3 Adding a System Variable

A corresponding system variable is automatically generated in the "System variable table" when each connection is established, named as "$Connection Name_status" to indicate the connection status.

	Name	Data type	Description
35	$CurrentLanguage	STRING	Current runtime display language
36	$VNCEnableStatus	BOOL	Enable VNC server in the HMI
37	$VNCServerName	STRING	VNC username in the HMI
38	$VNCOnlyViewPassword	STRING	VNC view-only password in the HMI
39	$VNCEnableControlStatus	BOOL	Enable VNC control permission in the HMI
40	$VNCControlPassword	STRING	VNC control permission password in the HMI
41	$InstallMentLockState	SINT	Installment lock status. 1: Device locked (waiting for password input); 0: Device unlocked
42	$InstallMentLockRemainTime	INT	Remaining time until next installment unlock (in minutes). Value is 0 when all installments are unlocked.
43	$InstallMentRemainPeriod	SINT	Total number of remaining unlocked installments in current strategy
44	$InstallMentLockTrigger	BOOL	Trigger flag for next installment
45	$InstallmentFunctionExists	BOOL	Installment function flag. This variable is 1 when a valid installment strategy is configured in the project; otherwise, it is 0.
46	$DynamicCode	STRING	Dynamic code (32 characters) is displayed only after due. This value is empty when in unlocked state.
47	$InstallmentVariableName	STRING	Installment name output, supports up to 128 characters. This value is empty when there is no installment.
48	$InstallmentDueDate	DATETIME	Installment due time. This value is set to 1970-01-01 00:00:00 when there is no installment.
49	$Connection_1_status	BOOL	User-defined connection status
50	$Connection_2_status	BOOL	User-defined connection status
51	$Connection_3_status	BOOL	User-defined connection status

For usage constraints, see 13.2.1 System Variable Table.

13.1.4 Modifying a Connection

In the variable table, when variables of the monitoring device are associated with a connection, the impact of modifying connection parameters are as follows:

- Connection name change: The iFA software will automatically synchronize the change to the variable table (including the system variable table).
- Device driver change: The addresses in the variable table (excluding the system variable table) will revert to default values. For the address description, see variable Connection property.

13.1.5 Copying a Connection

Other devices (e.g., PLC) connected internally to the monitoring device do not support copy operations. For example, Connection_1 of HMI_1 device does not support copying.

When the entire device (HMI_1) is copied, the copied objects include identifiers  or connection information.

13.1.6 Supported Device Drivers

Different driver enable different device connections. You can choose a specific communication interface, configuration and transmission speed for an individual device. Supported protocol types in the visualization platform are shown in the table below:

Table13-1-6-1

Connection Type	Device Manufacturer/ Organization	Device Model	Supported Protocol	Visualization Device Type
Serial port	Inovance Technology	AM300, AM500 Series	Modbus-RTU	HMI
		AM400, AM600 Series	Modbus-RTU Protocol	HMI
		AC700, AC800 Series	Modbus-RTU Protocol	HMI
		EVO Series	Modbus-RTU Protocol	HMI
		H5U Series	QLink RTU Protocol	HMI
		MD Series	Modbus RTU Protocol	HMI
	Modbus IDA	/	Modbus RTU Master	HMI
		/	Modbus RTU Slave	HMI
	Mitsubishi	FX3U/FX3UC Series	FX485BD Protocol	HMI
Ethernet	Inovance Technology	AC700, AC800 Series	QLink TCP Protocol AC800 Tags Protocol Modbus TCP Protocol EtherNet/IP Tags Protocol	HMI

Connection Type	Device Manufacturer/ Organization	Device Model	Supported Protocol	Visualization Device Type
		AI800	AC800 Tags Protocol EtherNet/IP Tags Protocol	HMI
		AP700 Series	AC800 Tags Protocol EtherNet/IP Tags Protocol	HMI
		AM300, AM500 Series	QLink TCP Protocol AC800 Tags Protocol Modbus TCP Protocol EtherNet/IP Tags Protocol	HMI
		AM400, AM600 Series	QLink TCP Protocol AC800 Tags Protocol Modbus TCP Protocol EtherNet/IP Tags Protocol	HMI
		Easy series PLCs	TCP Monitoring Protocol EtherNet/IP Tags Protocol	HMI
		EVO Series	Modbus TCP Protocol EtherNet/IP Tags Protocol	HMI
		H5U Series	TCP Monitoring Protocol QLink TCP Protocol EtherNet/IP Tags Protocol	HMI
	Omron	NJ Series, NX Series, or XY Series	EtherNet/IP	HMI
	Siemens	S7-1200 or S7-1500	/	HMI
		S7-300	/	HMI
	Rockwell (AB)	/	EtherNet/IP	HMI
	Modbus IDA	/	Modbus TCP Client	HMI
		/	Modbus TCP Server	HMI
	OPC UA	/	OPC UA Client	HMI
	Mitsubishi	FX5U	FX5U (Binary) Protocol	HMI
		Q Series	MelSec-Q/L (Binary) Protocol	HMI
USB	/		Card reader	HMI
			Barcode scanner	HMI

13.1.6.1 Communicating with Inovance PLCs

13.1.6.1.1 Easy Series PLCs

When an HMI device communicates with an Easy series PLC, select the device driver labeled "Easy" to establish the connection. The connection link is Ethernet.

Communication link configuration

The Ethernet communication connection property of Easy series PLCs is the same as those of the AM300 series. For details, see Ethernet Connection Property of AM300 series.

Variable address configuration

To ensure correct data transmission across protocols, see the table below when configuring variable addresses.

Table13-1-6-1-1-1 Easy series PLCs – Modbus communication address lookup table

Access Type		Function Code			Address Range	Quantity	PLC Memory	
		Read	Single Write	Multiple Write			Type	Range
Bit access	Coil	0x01 or 0x02	0x05	0x0F	0x0000 to 0x1F3F	8000	M	M0 to M7999
					0x3000 to 0xAFFF	32768	B	B0 to B32767
					0xE000 to 0xEFFF	4096	S	S0 to S4095
					0xF800 to 0xFBFF	1024	X	X0 to X1777 (octal)
					0xFC00 to 0xFFFF	1024	Y	Y0 to Y1777 (octal)
Word access	Holding register	0x03 or 0x04	0x06	0x10	0x0000 to 0x1F3F	8000	D	D0 to D7999
					0x3000 to 0xAFFF	32768	R	R0 to R32767

13.1.6.1.2 H5U Series PLCs

When an HMI device communicates with an H5U series PLC, select the device driver labeled "H5U" to establish the connection. Connection links are divided into Ethernet and serial port, and the connection properties differ.

Communication link configuration

The Ethernet communication connection property of H5U series PLCs is the same as those of the AM300 series. For details, see Ethernet Connection Property of AM300 series.

The serial port communication connection property of H5U series PLCs is the same as those of the AM300 series. For details, see Serial Port Connection Property of the AM300 series.

Variable function code configuration

When an H5U series PLC communicates with an HMI using the Modbus protocol, the function codes are the same as those of the Easy series PLCs. For the correspondence between function codes and addresses, see Easy series PLCs – Modbus communication address lookup table .

13.1.6.1.3 EVO Series PLCs

When an HMI device communicates with an EVO series PLC, select the device drive labeled "EVO" to establish the connection. Connection links are divided into Ethernet and serial port, and the connection properties differ.

Communication link configuration

The Ethernet communication connection property of EVO series PLCs is the same as those of the AM300 series. For details, see Ethernet Connection Property of AM300 series.

The serial port communication connection property of EVO series PLCs is the same as those of the AM300 series. For details, see Serial Port Connection Property of AM300 series.

Variable address configuration

To ensure correct data transmission across protocols, see the table below when configuring variable addresses.

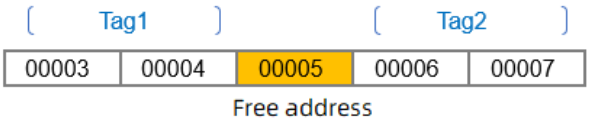
Table13-1-6-1-3-1 EVO series PLCs – Modbus communication address lookup table

Register Type	Function Code			Address Range	Quantity	PLC Memory	
	Read	Single Write	Multiple Write			Type	Range
Discrete input	0x02	/	/	0x0000 to 0xFFFF	65536	I[1]	IX0.0 to IX8191.7
Coil	0x01	0x05	0x0F	0x0000 to 0xFFFF	65536	Q[2]	QX0.0 to QX8191.7
Input register	0x04	/	/	0x0000 to 0xFFFF	65536	MW	MW0 to MW65535
Holding register	0x03	0x06	0x10	0x0000 to 0xFFFF	65536	MW	MW0 to MW65535

[1]: The I area supports two data access modes: bit access (IX) and word access (IW). The bit access address range is shown in the table above; the word access address ranges from IW0 to IW8192. Each word contains two bytes. For example, IW0 covers the range from IW0.0 to IW0.7, and from IW1.0 to IW1.7.

[2]: The Q area supports two data access modes: bit access (QX) and word access (QW). The bit access address range is shown in the table above; the word access address ranges from QW0 to QW8192. Each word contains two bytes. For example, QW0 covers the range from QW0.0 to QW0.7, and from QW1.0 to QW1.7.

13.1.6.1.4 AM300 and AM500 Series PLCs

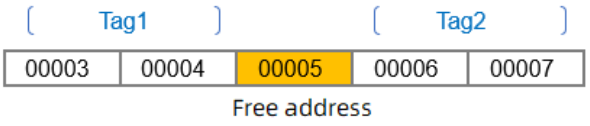


When an HMI device communicates with an AM300 or AM500 series PLC, select the device drive labeled "AM300/500" to establish the connection. Connection links are divided into Ethernet and serial port, and the connection properties differ.

Communication link configuration

Ethernet configuration

Table13-1-6-1-4-1 Description of Ethernet link connection property



Property Category		Description
Basic property	Connection name	Connection identifier supports combinations of Chinese characters, English letters, numbers, `_`, and `-`, with a maximum length of 64 English characters. Connection name must be unique within the same monitoring device. Default name automatically increments based on the number of existing connections (including 13.1.2.1 Connecting External Devices), ensuring no duplicates.
	Link type	Ethernet
	Device name	Name of the connected object supports combinations of Chinese characters, English letters, numbers, `_`, and `-`, with a maximum length of 64 English characters. Device names do not support duplicates within the same monitoring device.
	Device description	Device description supports a maximum length of 128 characters.
	Device driver	Modbus TCP protocol (AM300/500, AC700/800 series) or QLink TCP protocol (AM300/500, AC700/800 series)
Link parameters	IP address	The access address of the connected object.
	Port number	Setting range: 0 to 65535. Default: 502.
	Slave address	Unique number of a slave device. The master station communicates with a specific slave device via the station number. The setting range of station number is related with **Device Driver**. The default value is 1. For example, the station range for Modbus protocol is 1 to 255.

Property Category		Description
Communication parameter	Address interval	Applicable to both Modbus protocol and QLink protocol. This parameter refers to the number of idle addresses between adjacent data (addresses). When the number of idle addresses is less than or equal to the setting value, adjacent data will be merged into a single packet for transmission. The number of data packets affects the data transfer rate. More data packets result in a lower transfer rate. Setting range: 0 to 24, where 0 indicates each packet contains only one data. If set to 3, when reading two words of data Tag1 and Tag2 from address 0x00003 and 0x00006 respectively, with only one idle address 0x00005 in between, the packet merging condition is satisfied, meaning Tag1 and Tag2 can be sent in one combined packet. 
	Max. read (bytes)	The maximum number of bytes per data packet. The setting range is determined by **Device Driver**.
	Max. write (bytes)	
	Connection timeout	The client does not receive a response from the server within the specified time after sending a connection request during the establishment of a Modbus TCP/IP connection. Time unit: milliseconds (ms). Setting range: 1 to 3600000.
	Communication timeout	The master station does not receive a response from the slave within the specified time after sending a request. Time unit: milliseconds (ms). Setting range: 1 to 3600000.
	Retransmission count	Number of retries for resending commands when device response (e.g., PLC) data is abnormal. Up to 10 attempts are supported.
	Connection attempt interval	Reconnection interval after communication is disconnected. Time unit: seconds (s). Setting range: 1 to 3600000.
Activate	Enable/Disable	Enable or disable the connection.

Serial port configuration

Table13-1-6-1-4-2 Description of serial link connection property

Property Category		Description
Basic property	Connection name	Connection identifier supports combinations of Chinese characters, English letters, numbers, `_`, and `-`, with a maximum length of 64 English characters. Connection name must be unique within the same monitoring device. Default name automatically increments based on the number of existing connections (including 13.1.2.1 Connecting External Devices), ensuring no duplicates.
	Link type	Serial port
	Device name	Name of the connected object supports combinations of Chinese characters, English letters, numbers, `_`, and `-`, with a maximum length of 64 English characters. Device names do not support duplicates within the same monitoring device.
	Device description	Device description supports a maximum length of 128 characters.
	Device driver	Modbus RTU protocol (AM300/500, AC700/800 series)
Link parameters	Communication port	Supports COM1 to COM4.
	Type	Supports RS232, RS422 and RS485. The communication port is automatically adapted without manual configuration. COM1 in RS422 mode and COM4 in RS485 mode cannot be used simultaneously.
	Baud rate	Default: 9600 bps.
	Data bit	Supports 7 and 8. Defaults to 8.
	Stop bit	Supports 1 and 2. Defaults to 1.
	Parity check	Supports no parity, odd parity, and even parity. The default is no parity.
	Slave address	Unique number of a slave device. The master station communicates with a specific slave device via the station number. Station number range:1 to 255. Default: 1.

Property Category		Description
Communication parameter	Address interval	This parameter refers to the number of idle addresses between adjacent data (addresses). When the number of idle addresses is less than or equal to the setting value, adjacent data will be merged into a single packet for transmission. The number of data packets affects the data transfer rate. More data packets result in a lower transfer rate. Setting range: 0 to 24, where 0 indicates each packet contains only one data. If set to 3, when reading two words of data Tag1 and Tag2 from address 0x00003 and 0x00006 respectively, with only one idle address 0x00005 in between, the packet merging condition is satisfied, meaning Tag1 and Tag2 can be sent in one combined packet. 
	Max. read (bytes)	The maximum number of bytes per data packet. The setting range is determined by **Device Driver**.
	Max. write (bytes)	
	Max. bytes per packet	The maximum number of bytes per packet for EtherNet/IP Tags protocol.
	Communication timeout	The master station does not receive a response from the slave within the specified time after sending a request. Time unit: milliseconds (ms). Setting range: 1 to 3600000.
	Retransmission count	Number of retries for resending commands when PLC response data is abnormal. Up to 10 attempts are supported.
	Connection attempt interval	Reconnection interval after communication is disconnected. Time unit: seconds (s). Setting range: 1 to 36000.
	Device detection cycle	Device detection cycle after the device goes offline. Time unit: seconds (s). Setting range: 1 to 36000.
Activate	Enable/Disable	Enable or disable the connection.

Variable address configuration

To ensure correct data transmission across protocols, see the table below when configuring variable addresses.

Modbus communication address

Table13-1-6-1-4-3 AM 300 and AM 500 series PLCs – Modbus communication address lookup table

Access Type		Function Code			Address Range	Quantity	PLC Memory	
		Read	Single Write	Multiple Write			Type	Range
Bit Access	Discrete input	0x02	/	/	0x0000 to 0xFFFF	65536	IX	IX0.0 to IX8191.7
	Coil	0x01	0x05	0x0F	0x0000 to 0xFFFF	65536	QX	QX0.0 to QX8191.7
	Extension (coil)	0x21	0x25	0x2F	0x0000 to 0xFFFF	65536	MX	MX0.0 to MX8191.7
	Extension (coil)	0x51	0x55	0x5F	0x0000 to 0xFFFF	65536	MX	MX131072 to MX139263.7
Word access	Holding register	0x03	0x06	0x10	0x0000 to 0xFFFF	65536	MW	MW0 to MW65535
	Extension (holding register)	0x53	0x56	0x50	0x0000 to 0xFFFF	65536	MW	MW65536 to MW131071

QLink TCP communication address

Table13-1-6-1-4-4 AM 300 and AM 500 series PLCs – QLink TCP communication address lookup table

Access Type		Function Code			Address Range	Quantity	PLC Memory	
		Read	Single Write	Multiple Write			Type	Range
Bit Access	Discrete input	0x02	/	/	0x0000 to 0xFFFF	65536	IX	IX0.0 to IX8191.7
	Coil	0x01	0x05	0x0F	0x0000 to 0xFFFF	65536	QX	QX0.0 to QX8191.7
Word access	Holding register	0x03	0x06	0x10	0x0000 to 0xFFFF	65536	MW	MW0 to MW65535

13.1.6.1.5 AM400 and AM600 Series PLCs

When an HMI device communicates with an AM400 or AM600 series PLC, select the device drive labeled "AM400/600" to establish the connection. Connection links are divided into Ethernet and serial port, and the connection properties differ.

Communication link configuration

The Ethernet communication connection property of AM400/AM600 series PLCs is the same as those of the AM300 series. For details, see Ethernet Connection Property of AM300 series.

The serial port communication connection property of AM400/AM600 series PLCs is the same as those of the AM300 series. For details, see Serial Port Connection Property of AM300 series.

Variable address configuration

To ensure correct data transmission across protocols, see the table below when configuring variable addresses.

Modbus communication address

Table13-1-6-1-5-1 AM 400 and AM 600 series PLCs – Modbus communication address lookup table

Access Type		Function Code			Address Range	Quantity	PLC Memory	
		Read	Single Write	Multiple Write			Type	Range
Bit Access	Discrete input	0x02	/	/	0x0000 to 0xFFFF	65536	IX	IX0.0 to IX8191.7
	Coil	0x01	0x05	0x0F	0x0000 to 0xFFFF	65536	QX	QX0.0 to QX8191.7
	Extension (coil)	0x21	0x25	0x2F	0x0000 to 0xFFFF	65536	MX	MX0.0 to MX8191.7
	Extension (coil)	0x31	0x35	0x3F	0x0000 to 0x1F3F	8000	SM	SM0 to SM7999
Word access	Holding register	0x03	0x06	0x10	0x0000 to 0xFFFF	65536	MW	MW0 to MW65535
	Extension (holding register)	0x33	0x36	0x40	0x0000 to 0x1F3F	8000	SD	SD0 to SD7999

QLink TCP communication address

Table13-1-6-1-5-2 AM 400 and AM 600 series PLCs – QLink TCP communication address lookup table

Access Type		Function Code			Address Range	Quantity	PLC Memory	
		Read	Single Write	Multiple Write			Type	Range
Bit Access	Discrete input	0x02	/	/	0x0000 to 0xFFFF	65536	IX	IX0.0 to IX8191.7
	Coil	0x01	0x05	0x0F	0x0000 to 0xFFFF	65536	QX	QX0.0 to QX8191.7
Word access	Holding register	0x03	0x06	0x10	0x0000 to 0xFFFF	65536	MW	MW0 to MW65535

13.1.6.1.6 AC700 and AC800 Series PLCs

When an HMI device communicates with an AC700 or AC800 series PLC, select the device drive labeled "AC700/800" to establish the connection. Connection links are divided into Ethernet and serial port, and the connection properties differ.

Communication link configuration

The Ethernet communication connection property of AC700/800 series PLCs are the same as those of the AM300 series. For details, see Ethernet Connection Property of AM300 series.

The serial port communication connection property of AC700/AC800 series PLCs is the same as those of the AM300 series. For details, see Serial Port Connection Property of AM300 series.

Variable address configuration

To ensure correct data transmission across protocols, see the table below when configuring variable addresses.

Modbus communication address

Table13-1-6-1-6-1 AC 700 and AC 800 series PLCs – Modbus communication address lookup table

Access Type		Function Code			Address Range	Quantity	PLC Memory	
		Read	Single Write	Multiple Write			Type	Range
Bit Access	Discrete input	0x02	/	/	0x0000 to 0xFFFF	65536	IX	IX0.0 to IX8191.7
	Coil	0x01	0x05	0x0F	0x0000 to 0xFFFF	65536	QX	QX0.0 to QX8191.7
	Extension (coil)	0x21	0x25	0x2F	0x0000 to 0x0FFF	4096	MX	MX0.0 to MX8191.7
	Extension (coil)	0x51	0x55	0x5F	0x0000 to 0x0FFF	4096	MX	MX131072 to MX139263.7
Word access	Holding register	0x03	0x06	0x10	0x0000 to 0xFFFF	65536	MW	MW0 to MW65535
	Extension (holding register)	0x53	0x56	0x50	0x0000 to 0x0FFF	4096	MW	MW65536 to MW131071

QLink TCP communication address

Table13-1-6-1-6-2 AC 700 and AC 800 series PLCs – QLink TCP communication address lookup table

Access Type		Function Code			Address Range	Quantity	PLC Memory	
		Read	Single Write	Multiple Write			Type	Range
Bit Access	Discrete input	0x02	/	/	0x0000 to 0xFFFF	65536	IX	IX0.0 to IX8191.7
	Coil	0x01	0x05	0x0F	0x0000 to 0xFFFF	65536	QX	QX0.0 to QX8191.7
Word access	Holding register	0x03	0x06	0x10	0x0000 to 0xFFFF	65536	MW	MW0 to MW65535

13.1.6.1.7 EtherNet/IP Tags Protocol

The EtherNet/IP Tags protocol is applicable to all Inovance series PLCs, with Ethernet as the communication link. This protocol supports display messages in source/destination mode, with the message type being Class 3.

For the setting requirements of connection property, see the descriptions in the table.

Table13-1-6-1-7-1 Connection property description

Property Category		Description
Basic property	Connection name	Connection identifier supports combinations of Chinese characters, English letters, numbers, `_`, and `-`, with a maximum length of 64 English characters. Connection name must be unique within the same monitoring device. Default name automatically increments based on the number of existing connections (including 13.1.2.1 Connecting External Devices), ensuring no duplicates.
	Link type	Supports Ethernet
	Device name	Name of the connected object supports combinations of Chinese characters, English letters, numbers, `_`, and `-`, with a maximum length of 64 English characters. Device names do not support duplicates within the same monitoring device.
	Device description	Device description supports a maximum length of 128 characters.
	Device driver	Inovance Ethernet/IP Tags Protocol
Link parameters	IP address	The access address of the connected object.
	Port number	44818, and not editable.
Communication parameter	Max. bytes per packet	Multiple specifications are available for the max. bytes per packet. If the setting here exceeds the maximum specification of the PLCs, the software will automatically split and reassemble packets according to the PLC specifications to ensure normal data transmission. During the packet splitting process, the system will trigger a prompt and display it in the system alarm pop-up window.
	Communication timeout	The master station does not receive a response from the slave within the specified time after sending a request. Time unit: milliseconds (ms). Setting range: 1 to 3600000.
	Retransmission count	Number of retries for resending commands when PLC response data is abnormal. Up to 10 attempts are supported.
Tag	Import tags	Import XML file of tag variables.

Property Category		Description
	Target tag variable table	Displays the name of the connection to which the current tag belongs. For example: Connection_5. It will also be automatically updated when the tag variable table is renamed.
Activate	Enable/Disable	Enable or disable the connection.

13.1.6.1.8 AC, AI, AM, and AP Series Products

The AC, AI, AM, and AP series devices include the following models:

- AC Series: AC700 and AC800 Series
- AI Series: AI800 Series
- AM Series: AM300, AM500, AM400, and AM600 Series
- AP Series: AP700 Series

When an HMI device communicates with these series of devices select the device drive labeled "AC800 Tags" to establish the connection. The connection link is Ethernet.

For the setting requirements of connection property, see the descriptions in the table.

Table13-1-6-1-8-1 Connection property description

Property Category		Description
Basic property	Connection name	Connection identifier supports combinations of Chinese characters, English letters, numbers, `_`, and `-`, with a maximum length of 64 English characters. Connection name must be unique within the same monitoring device. Default name automatically increments based on the number of existing connections (including 13.1.2.1 Connecting External Devices), ensuring no duplicates.
	Link type	Supports Ethernet
	Device name	Name of the connected object supports combinations of Chinese characters, English letters, numbers, `_`, and `-`, with a maximum length of 64 English characters. Device names do not support duplicates within the same monitoring device.
	Device description	Device description supports a maximum length of 128 characters.
	Device driver	Inovance AC800 Tags Protocol (AC/AI/AM/AP Series Products)
Link parameters	IP address	Access address of the connected object

Property Category		Description
Authentication settings	Authentication method	Supports anonymous access and password authentication.
	Username	Password is displayed in ciphertext.
	Password	
Tag	Encoding format	Supports GB2312 and UTF-8.
	Import tags	Import XML file of tag variables.
	Target tag variable table	Displays the name of the connection to which the current tag belongs. For example: Connection_5. It will also be automatically updated when the tag variable table is renamed.
Activate	Enable/ Disable	Enable or disable the connection.

13.1.6.2 Communicating with Siemens S7 Series PLCs

13.1.6.2.1 S7-300 PLCs

When an HMI device communicates with an S7-300 PLC, select the "Siemens S7-300" device driver to establish the connection. For the setting requirements of connection property, see the descriptions in the table.

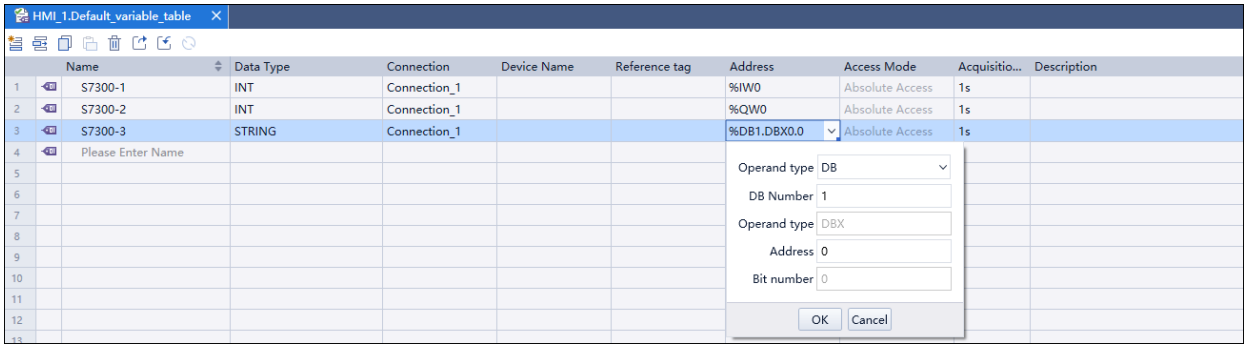
Connection property

Table13-1-6-2-1-1 Description of S7-300 connection property

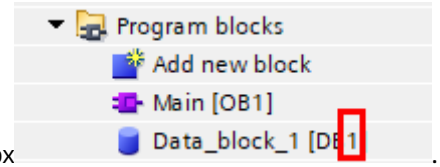
Property Category		Description
Basic property	Connection name	Connection identifier supports combinations of Chinese characters, English letters, numbers, `_`, and `-`, with a maximum length of 64 English characters. Connection name must be unique within the same monitoring device. Default name automatically increments based on the number of existing connections (including 13.1.2.1 Connecting External Devices), ensuring no duplicates.

Property Category		Description
	Connection type	Supports serial port and Ethernet.
	Device name	Name of the connected object supports combinations of Chinese characters, English letters, numbers, `_`, and `-`, with a maximum length of 64 English characters. Device names do not support duplicates within the same monitoring device.
	Device description	Device description supports a maximum length of 128 characters.
	Device driver	Communication protocol
Link parameters	IP address	The access address of the connected object.
	Port number	Setting range: 0 to 65535. Default: 102.
Communication parameter	Connection timeout	When establishing a connection, no response is received from the server within the specified time after the client sends a connection request. Time unit: milliseconds (ms). Setting range: 1 to 3600000.
	Communication timeout	The master station does not receive a response from the slave within the specified time after sending a request. Time unit: milliseconds (ms). Setting range: 1 to 3600000.
	Retransmission count	Number of retries for resending commands when PLC response data is abnormal. Up to 10 attempts are supported.
	Connection attempt interval	Reconnection interval after communication is disconnected. Time unit: seconds (s). Setting range: 1 to 3600000.
Activate	Enable/ Disable	Enable or disable the connection.

Setting variable address



When an HMI product communicates with an S7-300 PLC, the data types supported for communication between the PLC memory areas and the HMI are listed in the table below.



S7-300 Memory Area	Data Type	Remarks
I area	BOOL, SINT, USINT, INT, UINT, DINT, UDINT, LINT, ULINT, REAL, and LREAL	
Q area		
M area		
Zone DB	BOOL, SINT, USINT, INT, UINT, DINT, UDINT, LINT, ULINT, REAL, LREAL, and STRING	

CAUTION

The STRING type on the HMI side uses UTF-8 encoding, while the PLC side uses GBK encoding.

In the HMI-side variable table, the addresses of S7-300 PLC variables need to be configured. The configuration requirements for each parameter are as follows.

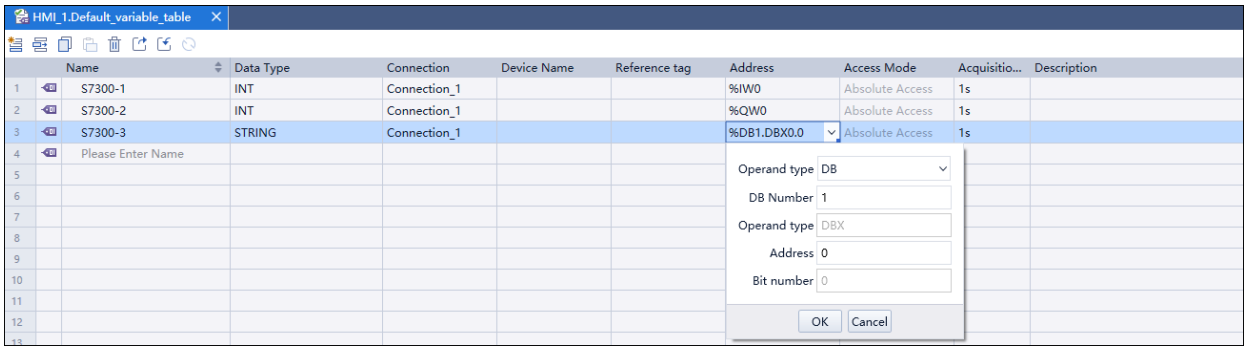
Parameter	Data Type
Area	PLC variable memory area
DB number	Data block (DB) number, e.g. the selected number in the box  .
Operand type	Software automatically matches.
Address	Absolute address
Bit	Bit number of the Boolean variable.

13.1.6.2.2 S7-1200 and S7-15001500 PLCs

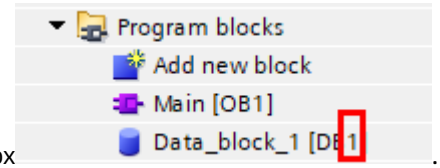
When an HMI device communicates with an S7-1200 or S7-1500 PLC, select the "Siemens S7-1200/1500" device driver to establish the connection.

Connection property

The connection properties of the "Siemens S7-1200/1500" device driver are the same as those of "Siemens S7-300". For details, see S7-300 Connection property.



Variable address



The data types supported by each PLC memory area for communication with the HMI are listed in the table below.

PLC Memory Area	Data Type	Remarks
I area	BOOL, SINT, USINT, INT, UINT, DINT, UDINT, LINT, ULINT, REAL, and LREAL	
Q area		
M area		

PLC Memory Area	Data Type	Remarks
Zone DB	BOOL, SINT, USINT, INT, UINT, DINT, UDINT, LINT, ULINT, REAL, LREAL, STRING, and WSTRING	For the STRING type, the maximum length is 256 bytes, with the first two bytes not storing text. For the WSTRING type, the maximum length is 256 bytes, with the first two characters not storing text.

In the HMI-side variable table, the addresses of S7-12/1500 PLC variables need to be configured. The configuration requirements for each parameter are as follows.

Parameter	Data Type
Area	PLC variable memory area
DB number	Data block (DB) number, e.g. the selected number in the box  .
Operand type	Software automatically matches.
Address	Absolute address
Bit	Bit number of the Boolean variable.

13.1.6.3 Communicating with Rockwell (AB) Devices

- 13.1.6.3.1 Configuring Connection Properties
- 13.1.6.3.2 Importing Tag Variables

13.1.6.3.1 Configuring Connection Properties

When an HMI device communicates with a Rockwell ControlLogix series 1756 PLC, select the "Rockwell (AB) EtherNet/IP" device driver to establish the connection. For the setting requirements of connection property, see the descriptions in the table.

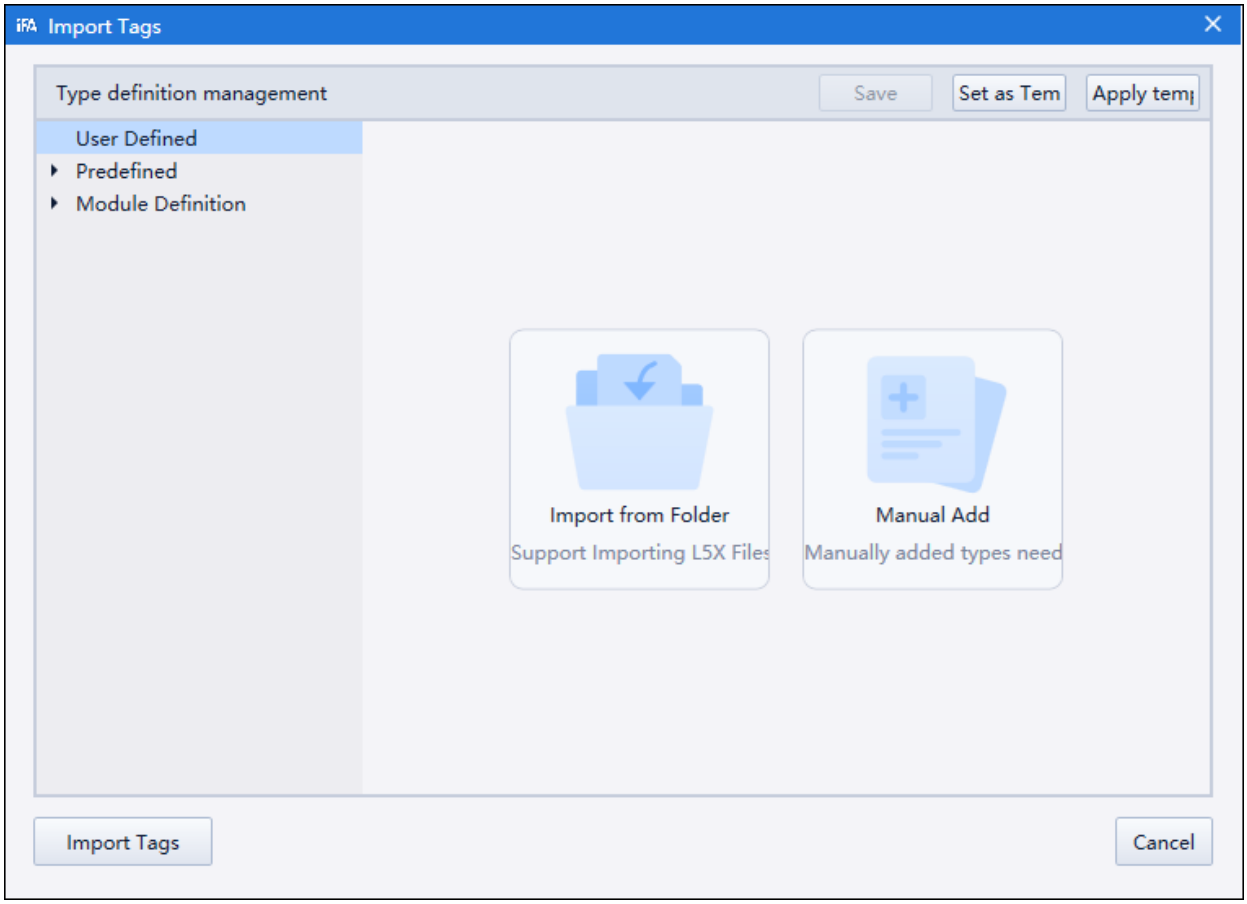


Table13-1-6-3-1-1 Connection property description

Property Category		Description
Basic property	Connection name	Connection identifier supports combinations of Chinese characters, English letters, numbers, `_`, and `-`, with a maximum length of 64 English characters. Connection name must be unique within the same monitoring device. Default name automatically increments based on the number of existing connections (including 13.1.2.1 Connecting External Devices), ensuring no duplicates.
	Connection type	Supports Ethernet
	Device name	Name of the connected object supports combinations of Chinese characters, English letters, numbers, `_`, and `-`, with a maximum length of 64 English characters. Device names do not support duplicates within the same monitoring device.
	Device description	Device description supports a maximum length of 128 characters.
	Device driver	Communication protocol
Link parameters	IP address	The access address of the connected object.
	Port number	Setting range: 0 to 65535. Default: 44818.
Communication parameter	Communication timeout	The master station does not receive a response from the slave within the specified time after sending a request. Time unit: milliseconds (ms). Setting range: 1 to 3600000.
	Retransmission count	Number of retries for resending commands when PLC response data is abnormal. Up to 10 attempts are supported.
Tag	Import tags	For related operations, see 13.1.6.3.2 Importing Tag Variables.
	Target tag variable table	Displays the name of the connection to which the current tag belongs. For example: Connection_5. It will also be automatically updated when the tag variable table is renamed.
Activate	Enable/Disable	Enable or disable the connection.

13.1.6.3.2 Importing Tag Variables

The tag variable import method for the Rockwell (AB) EtherNet/IP device driver differs from that for other EtherNet/IP device drivers. It imports structure definitions and structure variables separately.

Select the "Import tag" button in the property area to open the corresponding window.

Operations related to structure definitions

These operations are completed in the "Type definition management" area.

Three types of structure definitions:

User-defined: Struct types created by users according to control requirements, corresponding to the struct types under the “Data Types–User-defined” node in Studio 5000 software.

Predefined: Corresponds to the built-in types in Studio 5000 software, i.e., the structure types under the node Data Types – Predefined.

Module-defined: Structure types associated with specific hardware modules, corresponding to types compatible with Rockwell ControlLogix series 1756 PLC, excluding basic types.

Table13-1-6-3-2-1 Related operations and requirements

Operation	Applicable Objects	Requirements
Import	User-defined type	Scope: Definitions where the read/write flag is not "None". Method: Incremental import. Duplicates will be overwritten. File Format: L5X format.
Manual addition	Supported by all three types	Directly copy structure member definitions from Studio 5000 software and paste into the current window.

Operation	Applicable Objects	Requirements
New	Supported by all three types	Create a new structure definition in the current window. Naming requirements: Type name consists of letters, numbers, "_", and ":", and must not begin with a number or a ":". Name must be unique. Maximum name length is 100 characters. The member name consists of letters, digits, and "_", and must not begin with an underscore. Maximum name length is 100 characters. Up to 512 members supported.
Edit	Supported by all three types	Modify members of existing types.
Set as template	All types	Encapsulate all current types into a template, which will be updated into the current software. That is, recreate the project in the current software.
Apply template	Connection	"Apply template" operation automatically updates the current connection with the manually set template.

Importing structure variables

Click the "Import tag" button in the lower-left corner of the window to import. The file format is CSV. Batch import is supported.

Data type

Data type correspondence before and after import

Before Import		After Import
Integer	SINT	Unchanged
	INT	Unchanged
	DINT	Unchanged
	LINT	Unchanged
	USINT	Unchanged
	UINT	Unchanged
	UDINT	Unchanged
	ULINT	Unchanged
Decimal	REAL	Unchanged
	LREAL	Unchanged
Boolean	BOOL	Unchanged
Text	STRING	Fixed 82 characters
	STRING_16	Fixed 16 characters
	STRING_**32**	Fixed 32 characters

Before Import		After Import
Array	ARRAY	DINT[2,3,36] before import is converted to ARRAY OF format. All array sizes must not exceed 2M, with a maximum quantity of 65535.

13.1.6.4 Communicating with Omron Devices

When HMI devices communicate with Omron NJ, NX, and NY series PLCs, select the "Omron, EtherNet/IP (NJ/NX/NY series)" device drivers to establish the connection. For the setting requirements of connection property, see the descriptions in the table.

Table13-1-6-4-1 Connection property description

Property Category		Description
Basic property	Connection name	Connection identifier supports combinations of Chinese characters, English letters, numbers, `_`, and `-`, with a maximum length of 64 English characters. Connection name must be unique within the same monitoring device. Default name automatically increments based on the number of existing connections (including 13.1.2.1 Connecting External Devices), ensuring no duplicates.
	Link type	Supports Ethernet
	Device name	Name of the connected object supports combinations of Chinese characters, English letters, numbers, `_`, and `-`, with a maximum length of 64 English characters. Device names do not support duplicates within the same monitoring device.
	Device description	Device description supports a maximum length of 128 characters.
	Device driver	Communication protocol
Link parameters	IP address	The access address of the connected object.
	Port number	Setting range: 0 to 65535. Default: 44818.
Communication parameter	Communication rate	Standard rate: Data transmission is based on the standard EtherNet/IP protocol. High-speed rate: Under the same conditions, data transmission rate is higher than standard rate.
	Communication timeout	The master station does not receive a response from the slave within the specified time after sending a request. Time unit: milliseconds (ms). Setting range: 1 to 3600000.
	Retransmission count	Number of retries for resending commands when PLC response data is abnormal. Up to 10 attempts are supported.

Property Category		Description
Tag	Import tags	Import the text file (.txt) containing tag variable definitions. The file must be encoded in UTF-8.
	Target tag variable table	Displays the name of the connection to which the current tag belongs. For example: Connection_5. It will also be automatically updated when the tag variable table is renamed.
Activate	Enable/Disable	Enable or disable the connection.

When multiple EtherNet/IP (NJ/NX/NY series) protocol connections are established between the same HMI device and the same Omron PLC, ensure that the communication rate configuration is consistent across all connections. That is, set all to high-speed rate or all to standard rate. Do not mix two communication rates to avoid possible communication abnormalities.

13.1.6.5 OPC UA Client

OPC UA (OPC Unified Architecture) is a widely used communication protocol in industrial automation, enabling secure and reliable data exchange. When an HMI communicates with a PLC, the HMI acts as the client.

For the configuration requirements of OPC UA communication properties, see the descriptions in the table.

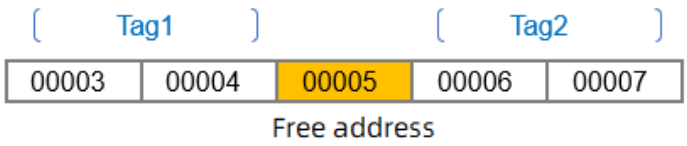
Table13-1-6-5-1 Communication property description

Property Category		Description
Basic property	Connection name	Connection identifier supports combinations of Chinese characters, English letters, numbers, `_`, and `-`, with a maximum length of 64 English characters. Connection name must be unique within the same monitoring device. Default name automatically increments based on the number of existing connections (including 13.1.2.1 Connecting External Devices), ensuring no duplicates.
	Link type	Supports serial port and Ethernet.
	Device name	Name of the connected object supports combinations of Chinese characters, English letters, numbers, `_`, and `-`, with a maximum length of 64 English characters. Device names do not support duplicates within the same monitoring device.
	Device description	Device description supports a maximum length of 128 characters.

Property Category		Description
	Device driver	The role of HMI device in communication. Select "OPC UA, OPC UA Client".
Link parameters	URL	OPC server address The address prefix is fixed as **opc.tcp://**, and the address length supports up to 256 bytes. Valid address example 1:: opc.tcp://192.168.1.99:48010 Valid address example 2: opc.tcp://test01:4840 URL
Security settings	Security policy	If either the security policy or security mode is set to "None", the other must also be set to "None". In other cases, the two parameters can be set to different options independently.
	Safety mode	
Authentication settings	Authentication method	Supports anonymous access and password authentication.
	Username	When authentication method is username/password, the password is displayed in ciphertext.
	Password	
Data access	Access mode	Supports subscription and active reading; subscription mode requires configuration of **publishing interval**.
	Publish interval	The subscription parameter is in milliseconds (ms). Setting range: 1 to 3600000.
Tag	Import tags	Import XML file of tag variables.
	Target tag variable table	Displays the name of the connection to which the current tag belongs. For example: Connection_5. It will also be automatically updated when the tag variable table is renamed.
Activate	Enable/Disable	Enable or disable the connection.

13.1.6.6 Modbus IDA

- 13.1.6.6.1 Modbus TCP Protocol
- 13.1.6.6.2 Modbus RTU Protocol



13.1.6.6.1 Modbus TCP Protocol

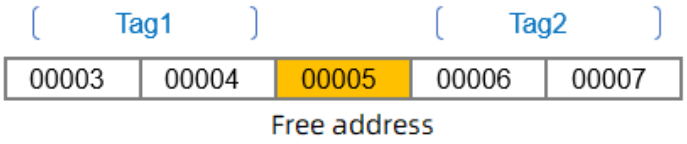
Modbus TCP protocol is an industry standard protocol widely used in the field of industrial automation. Modbus TCP protocol follows a unified communication specification, simplifying the configuration and maintenance processes when communicating with third-party devices or systems.

Modbus TCP protocol uses a Client-Server architecture, where the communication properties of the two parts differ. For details on respective settings, see the descriptions in the table.

Table13-1-6-6-1-1 Connection property description

Property Category		Description	Server	Client
Basic property	Connection name	Connection identifier supports combinations of Chinese characters, English letters, numbers, `_`, and `-`, with a maximum length of 64 English characters. Connection name must be unique within the same monitoring device. Default name automatically increments based on the number of existing connections (including 13.1.2.1 Connecting External Devices), ensuring no duplicates.	Applicable	Applicable
	Connection type	Ethernet	Applicable	Applicable
	Device name	Name of the connected object supports combinations of Chinese characters, English letters, numbers, `_`, and `-`, with a maximum length of 64 English characters. Device names do not support duplicates within the same monitoring device.	Applicable	Applicable
	Device description	Device description supports a maximum length of 128 characters.	Applicable	Applicable
	Device driver	The role of HMI device in communication. Modbus TCP Server indicates that the HMI device acts as the Server side. Modbus TCP Client indicates that the HMI device acts as the Client side.	Applicable	Applicable
Link parameters	IP address	The access address of the connected object.	Applicable	Applicable
	Port number	Setting range: 0 to 65535. Default: 502.	Applicable	Applicable
	Slave address	Unique number of a slave device. The master station communicates with a specific slave device via the station number. Station number range:1 to 255. Default: 1.	Not applicable	Applicable

Property Category		Description	Server	Client
Communication parameter	Address interval	This parameter refers to the number of idle addresses between adjacent data (addresses). When the number of idle addresses is less than or equal to the setting value, adjacent data will be merged into a single packet for transmission. The number of data packets affects the data transfer rate. More data packets result in a lower transfer rate. Setting range: 0 to 24, where 0 indicates each packet contains only one data. If set to 3, when reading two words of data Tag1 and Tag2 from address 0x00003 and 0x00006 respectively, with only one idle address 0x00005 in between, the packet merging condition is satisfied, meaning Tag1 and Tag2 can be sent in one combined packet. 	Not applicable	Applicable
	Max. read (bytes)	The maximum number of bytes per data packet. The setting range is determined by **device driver**.	Not applicable	Applicable
	Max. write (bytes)		Not applicable	Applicable
	Connection timeout	The client does not receive a response from the server within the specified time after sending a connection request during the establishment of a Modbus TCP/IP connection. Time unit: milliseconds (ms). Setting range: 1 to 3600000.	Not applicable	Applicable
	Communication timeout	The master station does not receive a response from the slave within the specified time after sending a request. Time unit: milliseconds (ms). Setting range: 1 to 3600000.	Not applicable	Applicable
	Retransmission count	Number of retries for resending commands when device response (e.g., PLC) data is abnormal. Up to 10 times are supported.	Not applicable	Applicable
	Connection attempt interval	Reconnection interval after communication is disconnected. Time unit: seconds (s). Setting range: 1 to 3600000.	Not applicable	Applicable
Activate	Enable/ Disable	Enable or disable the connection.	Applicable	Applicable



13.1.6.6.2 Modbus RTU Protocol

Modbus RTU protocol is an industry standard protocol widely used in industrial automation, especially in low-latency and high-precision applications. Modbus RTU protocol follows a unified communication specification, simplifying the configuration and maintenance processes when communicating with third-party devices or systems.

Modbus RTU protocol uses a Client-Server architecture, where the communication properties of the two parts differ. For details on respective settings, see the descriptions in the table.

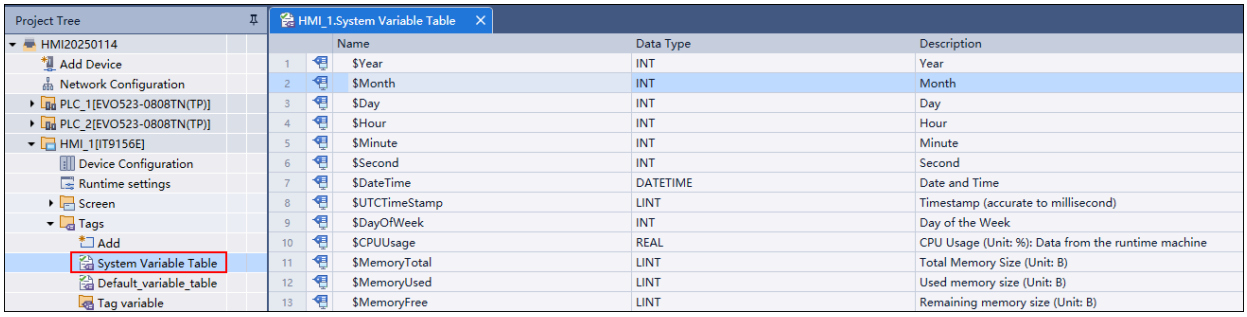
Table13-1-6-6-2-1 Connection property description

Property Category		Description	Server	Client
Basic property	Connection name	Connection identifier supports combinations of Chinese characters, English letters, numbers, `_`, and `-`, with a maximum length of 64 English characters. Connection name must be unique within the same monitoring device. Default name automatically increments based on the number of existing connections (including 13.1.2.1 Connecting External Devices), ensuring no duplicates.	Applicable	Applicable
	Link type	Serial port	Applicable	Applicable
	Device name	Name of the connected object supports combinations of Chinese characters, English letters, numbers, `_`, and `-`, with a maximum length of 64 English characters. Device names do not support duplicates within the same monitoring device.	Applicable	Applicable
	Device description	Device description supports a maximum length of 128 characters.	Applicable	Applicable
	Device driver	The role of HMI device in communication. Modbus RTU Server indicates that the HMI device acts as the Server side. Modbus RTU Client indicates that the HMI device acts as the Client side.	Applicable	Applicable
Link parameters	Communication port	The number of ports depends on the specific product model. For example, the IT9156E touch screen supports COM1 to COM5 ports.	Applicable	Applicable
	Type	Select the type according to on-site requirements.	Applicable	Applicable
	Baud rate	Default: 9600 bps.	Applicable	Applicable
	Data bit	Supports 6, 7 and 8. Defaults to 8.	Applicable	Applicable

Property Category		Description	Server	Client
	Stop bit	Supports 1 and 2. Defaults to 1.	Applicable	Applicable
	Parity check	Supports no parity, odd parity, and even parity. The default is odd parity.	Applicable	Applicable
	Slave address	Unique number of a slave device. The master station communicates with a specific slave device via the station number. The setting range of station number is related with **device driver**. The default value is 1. For example, the station number range for the Modbus protocol is 1 to 255.	Applicable	Applicable
Communication parameter	Address interval	This parameter refers to the number of idle addresses between adjacent data (addresses). When the number of idle addresses is less than or equal to the setting value, adjacent data will be merged into a single packet for transmission. The number of data packets affects the data transfer rate. More data packets result in a lower transfer rate. Setting range: 0 to 24, where 0 indicates each packet contains only one data. If set to 3, when reading two words of data Tag1 and Tag2 from address 0x00003 and 0x00006 respectively, with only one idle address 0x00005 in between, the packet merging condition is satisfied, meaning Tag1 and Tag2 can be sent in one combined packet. 	Applicable	Applicable
	Max. read (bytes)	The maximum number of bytes per data packet. The setting range is determined by **device driver**.	Applicable	Applicable
	Max. write (bytes)		Applicable	Applicable
	Communication timeout	The master station does not receive a response from the slave within the specified time after sending a request. Time unit: milliseconds (ms). Setting range: 1 to 3600000.	Applicable	Applicable
	Retransmission count	Number of retries for resending commands when device response (e.g., PLC) data is abnormal. Up to 10 attempts are supported.	Applicable	Applicable
	Connection attempt interval	Reconnection interval after communication is disconnected. Time unit: seconds (s). Setting range: 1 to 36000.	Applicable	Applicable

Property Category		Description	Server	Client
	Device detection cycle	Device detection cycle after the device goes offline. Time unit: seconds (s). Setting range: 1 to 36000.	Applicable	Applicable
Activate	Enable/ Disable	Enable or disable the connection.	Applicable	Applicable

13.2 Using Variables



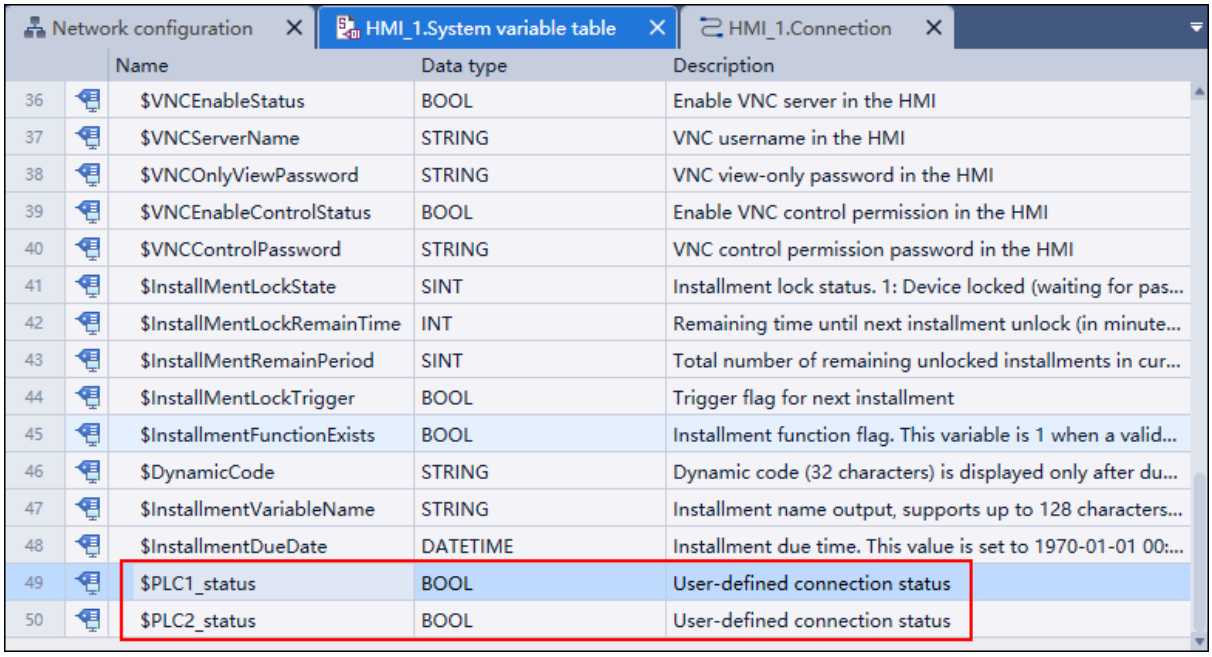
- 13.2.1 System Variable Table
- 13.2.2 Default Variable Table
- 13.2.3 Tag Variables
- 13.2.4 Using a Variable Table
- 13.2.5 Configuring Variables
- 13.2.6 Operating Variables

13.2.1 System Variable Table

The system variable table displays variables related to system operation, which can show real-time data of the current system while running on the screen, making it easier for you to monitor the system status.

The system variable table does not support editing or deletion. The variables in the table do not support writing values or recording historical data during runtime.

When adding a PC/HMI device to a project, a "System variable table" node is automatically created under the device, which can be opened by double-clicking.



System variables consist of two parts:

- Variables related to the hardware configuration and operation of monitoring device
  These variables are automatically generated when adding a device, typically distributed in the upper half of the variable table (e.g., rows 1 to 40), with the exact number varying depending on the hardware model. The IT9156E is used to demonstrate system variable distribution:
  Rows 1 to 9: variables related to system time;
  Rows 10 to 23: variables related to CPU operation;
  Rows 24 to 31: variables related to physical network ports;
  Rows 32 to 35: variables related to display and user permissions;
  Rows 36 to 40: variables related to VNC access permissions

No.	Category	Name	Data Type	Description		Applicable Device
1	System time	$Year	INT	Year		PC/HMI
2		$Month	INT	Month		PC/HMI
3		$Day	INT	Day		PC/HMI
4		$Hour	INT	Hour		PC/HMI
5		$Minute	INT	Minute		PC/HMI
6		$Second	INT	Second		PC/HMI
7		$DateTime	DATETIME	Date and time		PC/HMI
8		$UTCTimeStamp	LINT	Timestamp (millisecond)		PC/HMI
9		$DayOfWeek	INT	Week		PC/HMI
10	CPU running	$CPUUsage	REAL	CPU usage (unit: %)		PC/HMI
11		$MemoryTotal	LINT	Total memory size. Unit: byte		PC/HMI
12		$MemoryUsed	LINT	Used memory size (unit: byte)		PC/HMI
13		$MemoryFree	LINT	Free memory size. Unit: byte		PC/HMI
14		$MemoryUsage	REAL	Memory usage (unit: %)		PC/HMI
15		$LocalMachineName	STRING	Runtime machine name		PC/HMI
16		$OSVersion	STRING	Runtime machine operating system version		PC/HMI
17		$CPUTemperatureHigh	BOOL	CPU temperature exceeds 83°C		HMI
18		$CPUTemperatureTooHigh	BOOL	CPU temperature exceeds 115°C		HMI
19		$DiskTotal	LINT	Total disk size. Unit: byte	Disk of the touch screen refers to the inodata directory. Disk of a PC device refers to the disk where the runtime data storage path is located, such as Disk D.	PC/HMI
20		$DiskUsed	LINT	Used disk size. Unit: byte		PC/HMI
21		$DiskFree	LINT	Free disk size. Unit: byte		PC/HMI
22		$DiskUsage	REAL	Disk usage (unit: %)		PC/HMI
23		$RTCVoltage	INT	RTC battery voltage (unit: mV)		HMI
24	Physical network port	$IPAddress_1	STRING	IP address of physical network card 1		PC/HMI
25		$Netmask_1	STRING	Subnet mask of physical network card 1		PC/HMI

No.	Category	Name	Data Type	Description	Applicable Device
26		$Gateway_1	STRING	Gateway of physical network card 1	PC/HMI
27		$MACAddress_1	STRING	MAC address of physical network card 1	PC/HMI
28		$IPAddress_2	STRING	IP address of physical network card 2	PC/HMI
29		$Netmask_2	STRING	Subnet mask of physical network card 2	PC/HMI
30		$Gateway_2	STRING	Gateway of physical network card 2	PC/HMI
31		$MACAddress_2	STRING	MAC address of physical network card 2	PC/HMI
32	Other	$CurrentScreenId	LINT	Current screen ID	PC/HMI
33		$CurrentUserName	STRING	Current user name	PC/HMI
34		$CurrentRoleName	STRING	Current role name	PC/HMI
35		$CurrentLanguage	STRING	Current runtime display language	HMI
36	VNC	$VNCEnableStatus	BOOL	Enable VNC server in the HMI	HMI
37		$VNCServerName	STRING	VNC username for the HMI	HMI
38		VNCOnlyViewPassword	STRING	VNC monitoring password for the HMI	HMI
39		VNCEnableControlStatus	BOOL	Enable the VNC operation permission for the HMI	HMI
40		VNCControlPassword	STRING	VNC operation password for the HMI	HMI

- Connection variables
  These variables are generated when you create a connection. They are appended to the end of the table by default (e.g., after row 35). Connection variables are named in the format $ConnectionName_Status and are used to indicate the connection status.

	Name	Data type	Description
36	$VNCEnableStatus	BOOL	Enable VNC server in the HMI
37	$VNCServerName	STRING	VNC username in the HMI
38	$VNCOnlyViewPassword	STRING	VNC view-only password in the HMI
39	$VNCEnableControlStatus	BOOL	Enable VNC control permission in the HMI
40	$VNCControlPassword	STRING	VNC control permission password in the HMI

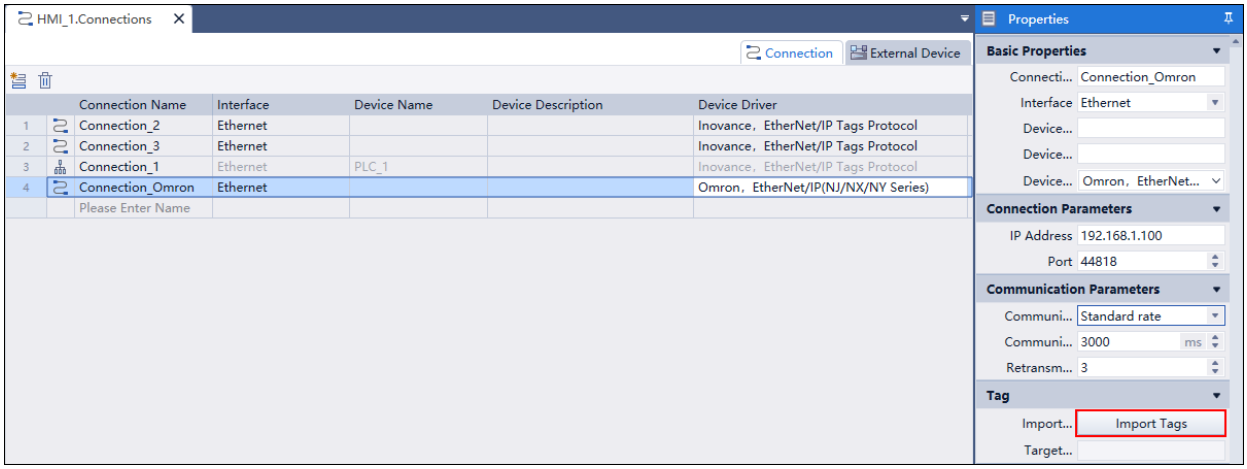
13.2.2 Default Variable Table

Each PC/HMI device in the project has a default variable table with a node ID , which does not support deletion or moving to a variable group.

The node name can be renamed. It consists of Chinese characters, English letters, digits, "_", and "-", with a maximum length of 128 characters.

The default variable table supports copy/paste operations. For details, see 13.2.4.4 Copying and Pasting a Variable Table. Variables support import/export operations. For details, see 13.2.6.2 Importing and Exporting Variables.



13.2.3 Tag Variables

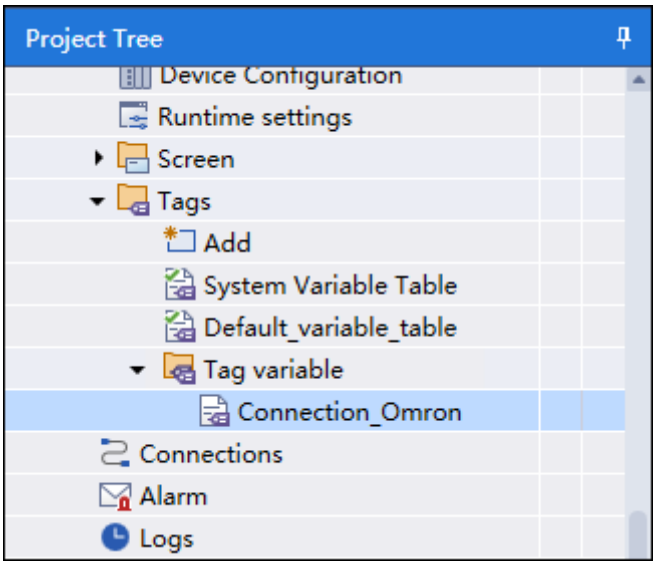
When monitoring devices communicate with other devices via the EtherNet/IP protocol, data transmission is achieved through tag variables.

Tag variables are imported into the iFA software in XML or TXT format. You can not edit the variable information.

Importing tag variables

Tag variables can be imported into the iFA software via the connection property panel (see figure below). For details on establishing a connection, see 13.1.1.1 Establishing a Device Connection.

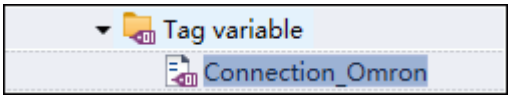
A single connection supports a maximum of 500,000 imported tags. If this limit is exceeded, the entire import will fail.



Variable count calculation: simple variables are counted as 1 each; complex variables (such as arrays or user-defined types) are counted based on their minimum number of sub-elements. For example, an array with 5 sub-elements is counted as 5.

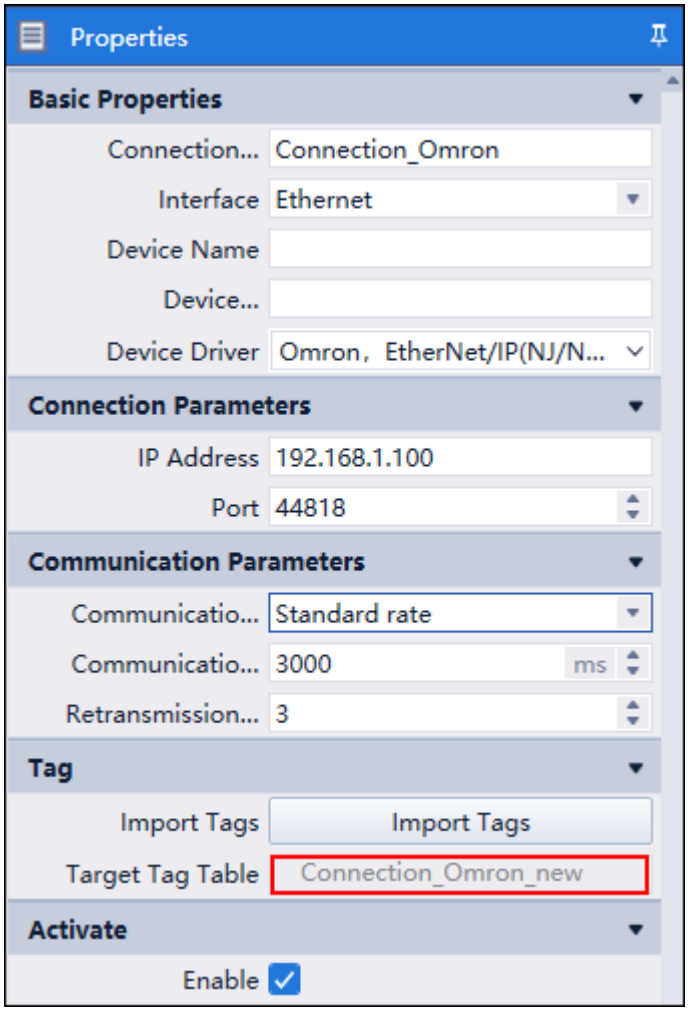
During the import of time and text variables into the iFA software, their data types are converted to match existing data types. The following table lists the data type mappings for the three protocols that require conversion.

Data Type Before Import	Data Type After Import via AC800 Tags Protocol	Data Type After Import via EtherNet/IP Tags Protocol	Data Type After Import via Omron EtherNet/IP Protocol
TIME	UDINT	32-bit. Range: 0 **ms** to 71582 **m** 47 **s** 295 **ms**	LINT
LTIME	ULINT	64-bit. Range: 0 **ms** to 213503 **d** 23 **h** 34 **m** 33 **s** 709 **ms** 551 **µs** 615 **ns**	N/A
TIME_OF_DAY(TOD)	UDINT	32-bit. Range: 00:00:00.000 to 23:59:59.999	UDINT
DATE	UDINT	32-bit. Range: 1970-01-01 to 2106-02-07	UDINT
DATE_AND_TIME(DT)	UDINT	32-bit. Range: 1970-01-01 00:00:00 to 2106-02-07 06:28:15	ULINT
STRING	Encoding format: ASCII (Chinese characters not supported). Default length: 80.	Encoding format: UTF-8. Default length: 80.	Encoding format: UTF-8. Default length: 80. Max. length:1986.
WSTRING	Unchanged	Encoding format: UTF-16. Default length: 80.	Not involved



Data Type Before Import	Data Type After Import via AC800 Tags Protocol	Data Type After Import via EtherNet/IP Tags Protocol	Data Type After Import via Omron EtherNet/IP Protocol
ARRAY	Unchanged	Supports one-dimensional and multi-dimensional arrays as well as nested arrays, with a maximum of 65,536 array elements.	Supports three-dimensional arrays but does not support nested arrays, with a maximum of 65,536 array elements.

Upon successful tag import, corresponding child nodes (variable tables) are generated under the **tag variable** node, and are named after the **connection name** by default.



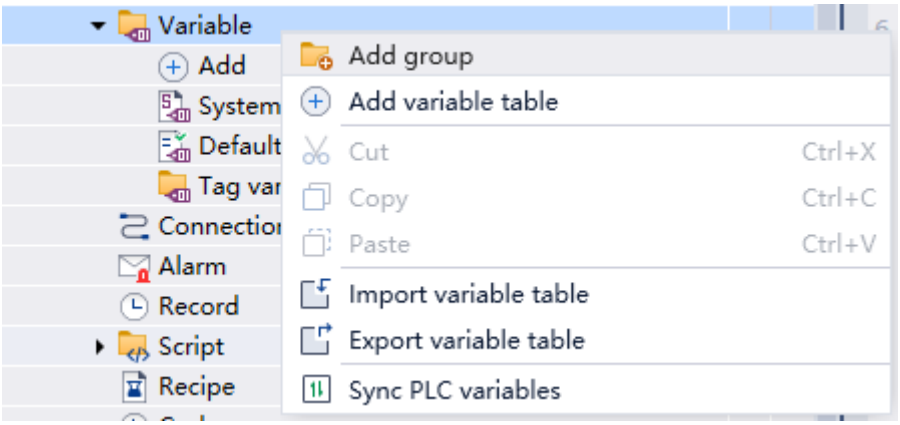
Operations related to tag variable table

- Rename a variable table
  Select the tag variable table node, and then select "Rename" from the right-click menu to put the name into edit mode.

  Enter the new name and press **Enter** to confirm. The new name will be automatically synchronized and updated in the connection property panel.

- Update tags
  Tag information in the tag variable table does not support editing.
  If a tag file with the same name is imported multiple times into the same connection, the tag content from the latest import takes precedence.
  The validity of tags referenced on the screen depends on the tag name. If the tag name remains unchanged, the reference remains valid; otherwise, it becomes invalid.
- Reference screens
  iFA software supports referencing tag variables through elements or graphic symbols on the screen.
- Delete a variable table
  Select the tag variable table node, and then choose "Delete" from the right-click menu to remove the variable table.
  After a tag is deleted, its references on the screen still exist and must be removed manually.

13.2.4 Using a Variable Table



- 13.2.4.1 Variable Table Groups
- 13.2.4.2 Adding a Variable Table
- 13.2.4.3 Importing and Exporting a Variable Table
- 13.2.4.4 Copying and Pasting a Variable Table
- 13.2.4.5 Deleting a Variable Table

13.2.4.1 Variable Table Groups

Regular variable tables are grouped and managed based on the properties of the variables.

A first-level group can be created under the "Variable" node, which supports expanding multiple levels of subgroups.

In the right-click menu of the "Variable" node, select "Add group" to add a variable group, with the node identifier .

Variable group names support combinations of Chinese, English, numbers, "_", and "-", with a maximum length of 64 characters. The default name is "Variable Group_n", with the sequence number incrementing automatically.

Variable group name must be unique within the same device.

13.2.4.2 Adding a Variable Table

The variable tables are used to store user-defined variables, and are divided into default variable table and regular variable table. The default variable table is automatically generated when adding a monitoring device, while the regular variable table is created by yourself.

Regular variable tables can be added under both the "Variable" node and the "Variable group" node. For details on creating variable groups, see 13.2.4.1 Variable Table Groups.

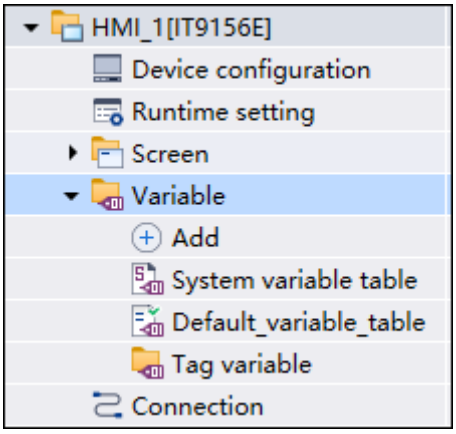


Figure 13-2-4-2-1 Add location - variable node

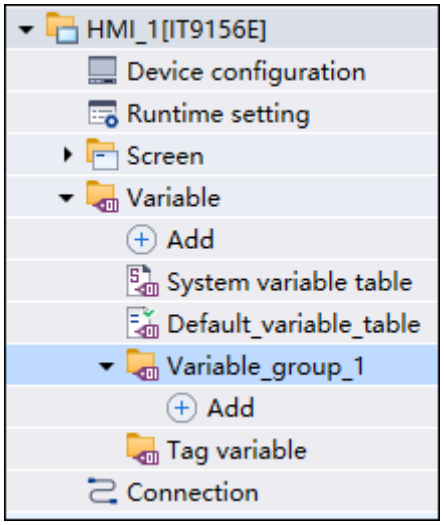

Figure 13-2-4-2-2 Add location - variable group

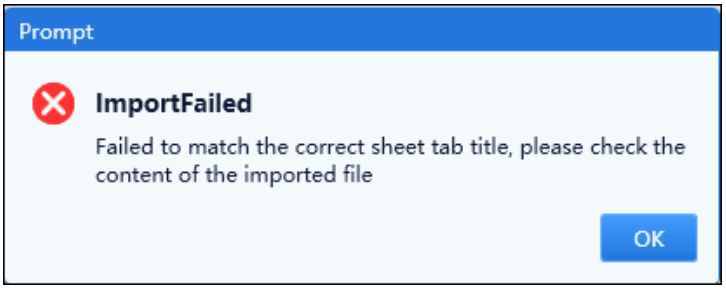
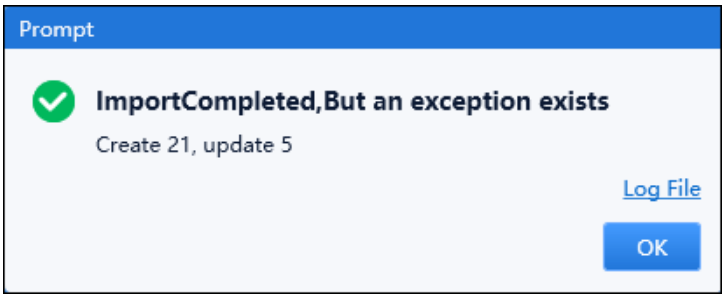
Add in the following three methods:

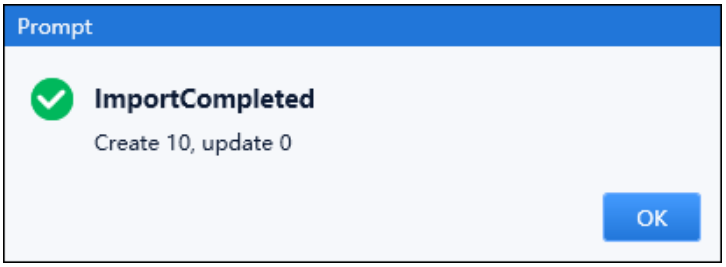
- Double-click the "Add" node.
- In the right-click menu of the parent node, select the "Add variable table" command.
- If the name of the imported variable table is different from existing variable tables in the project tree, corresponding node will be created automatically during import.

The name of variable table node identifier supports combinations of Chinese, English, numbers, "_", and "-", with a maximum length of 64 characters. The default name is "Variable Table_n", where n starts at 1 and increments automatically.

Variable table name must be unique within the same device.







13.2.4.3 Importing and Exporting a Variable Table

The import and export function of the variable table enables cross-device reuse of variable tables and reduces configuration time.

Importing a variable table

This section details the specifications and import procedure for variable table file. For import rules, see Importing variables.

<table>
<tr><th>Step</th><th>Operation</th><th>Description</th></tr>
<tr><td>1</td><td>Prepare variable table</td><td>Basic requirements for the variable table:
(1) File format must be xlsx.
(2) Sheet name length must be less than 64 characters and consist of Chinese, English, numbers, "_", and "-".
(3) The table must contain only one sheet page named "Variable".
(4) The content and order of the first row cannot be modified. The following table shows the property names for each column.
<table>
<tr><td>A</td><td>Name</td><td>G</td><td>Access mode</td><td>M</td><td>Range upper limit</td><td>S</td><td>PLC end value</td></tr>
<tr><td>B</td><td>Data type</td><td>H</td><td>Acquisition cycle</td><td>N</td><td>Range lower limit</td><td>T</td><td>HMI start value</td></tr>
<tr><td>C</td><td>Connection</td><td>I</td><td>Description</td><td>O</td><td>Constant range upper limit</td><td>U</td><td>HMI end value</td></tr>
<tr><td>D</td><td>Device name</td><td>J</td><td>Length</td><td>P</td><td>Constant range lower limit</td><td>V</td><td>Initial value</td></tr>
<tr><td>E</td><td>Referenced variable</td><td>K</td><td>Alarm group</td><td>Q</td><td>Enable linear conversion</td><td>W</td><td>Internal variable retention</td></tr>
<tr><td>F</td><td>Address</td><td>L</td><td>High-low byte swap</td><td>R</td><td>PLC start value</td><td></td><td></td></tr>
</table>
(5) The "name" column must contain variable names, with at least one entry.
(6) The content in the "Data type" column must match the format used in the software, for example, Bool is valid, but bool is invalid.
(7) For array-type variables, only the type name needs to be configured, such as <code>ARRAY[2..5] OF INT</code>. Individual data elements do not need to be listed.
If any of the first five conditions are not met, the table import will fail.</td></tr>
<tr><td>2</td><td>Select import command</td><td>Select the command based on the import location.
Select "Import variable table" in the right-click menu of the parent node or select "Import" in the right-click menu of the same-level variable table node.</td></tr>
