</table>

- **Precautions**
  - In[ ] can be a higher-level structure member, for example: In[0] = str0.str1[0].
  - The data types of Member and Out must be consistent; otherwise, a compilation fault will occur.
  - When Member is a real number, different values may introduce errors and may not produce the expected results.
  - If an element from an array is passed to In[ ], all elements from that element onward will be processed.
  - In OMUtils library versions 1.2.0.1 and earlier, when Size is 0, Out and Num are 0, InOutPos[ ] remains unchanged, and the return value is TRUE.
    In OMUtils library versions 1.3.0.0 and later, when Size is 0, Out and Num are 0, InOutPos[ ] remains unchanged, and the return value is FALSE.
  - The dimension of In[ ] must be less than or equal to 3; otherwise, the function returns FALSE, Out and InOutPos[ ] remain unchanged, and Num is 0.
  - InOutPos[ ] must be a one-dimensional array; otherwise, a compilation fault will occur.
  - If Size exceeds the array region of In[ ], the function returns FALSE, Out and InOutPos[ ] remain unchanged, and Num is 0.
  - If Member is not a member of the element specified in In[ ], the function returns FALSE, Out and InOutPos[ ] remain unchanged, and Num is 0.

- If Member is of STRING type and is not NULL-terminated, the result may be abnormal.
- In[ ] can also be an array with two or more dimensions. For a 2D array, the first-dimension index of the matching element is stored in InOutPos[0], and the second-dimension index is stored in InOutPos[1].
- For a 3D array, the first-dimension index is stored in InOutPos[0], the second in InOutPos[1], and the third in InOutPos[2].
- When In[ ] is a multi-dimensional array, the number of elements in InOutPos[ ] must not be less than the dimension of In[ ]; otherwise, the function returns FALSE, Out and InOutPos[ ] remain unchanged, and Num is 0.

18.2.10.3 RecMin

Gets the minimum value of a specified member from a structure array.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
RecMin	Get the minimum record	FC		:= RecMin(In := , Size := , Member := , Out := , InOutPos := , Num =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In[ ] array	Structure array to search	Follows data type	-	Array of structures to search
	Size	Number of elements to search	Follows data type	1	Number of array elements to search
	Member	Member to search	Follows data type	-	Member of In[ ] structure array to search
	Out	Search result	Follows data type	-	Search result
Input/Output	InOutPos[ ] array	Index array of search results	Follows data type	-	Array storing the indices of the searched elements

Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	Num	Number of searched elements	Follows data type	-	Number of searched elements

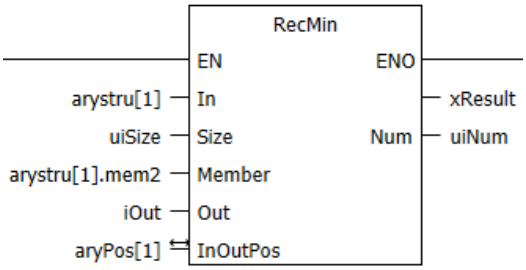
Variable types

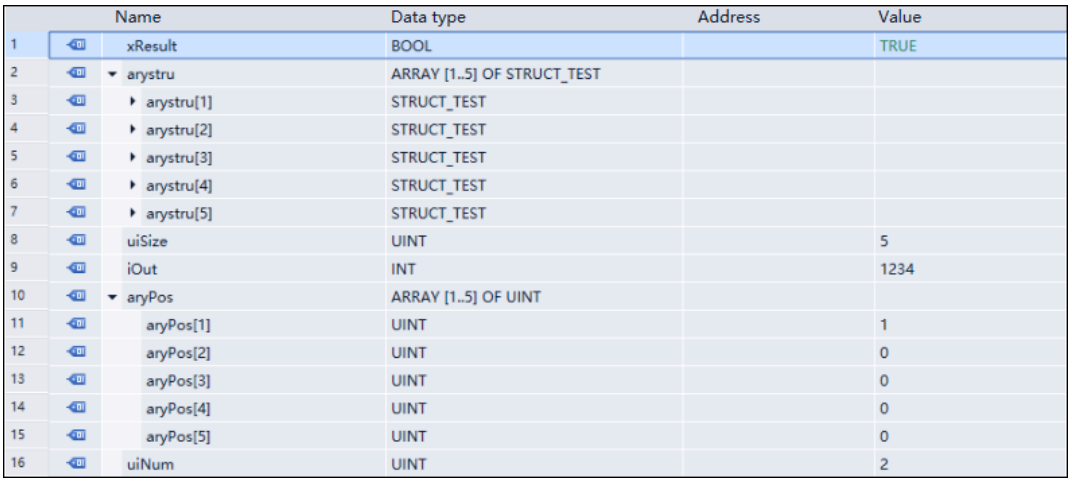
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In[ ] array	Specify an array of structures.																			
Size	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
Member	–	–	–	–	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
	Data with the same data type as the search member of In[ ]																			
Out	–	–	–	–	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
InOutPos[ ] array	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
Num	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - This instruction searches the Size elements of the structure array In[ ] (from In[0] to In[Size-1]) to get the value of the specified structure member Member. The member to search from any element of In[ ] is passed to the Member parameter. The indices of the searched elements are assigned to InOutPos[0] and the number of searched elements is assigned to Num. If there are more than two searched elements, the index of the lowest-order searched element is stored in InOutPos[0].
  - Input parameters passed to In[ ] shall be specified along with the element index, such as array[3]. The relationships between values with data types that are not integers or real numbers are determined as follows.

Data Type	Relationship
TIME	The numerically smaller value is considered to be smaller.
DATA, TOD, DT	Earlier dates or TOD are considered to be larger.

Data Type	Relationship
STRING	Character encoding is used for size comparison. Then there are the following possibilities: 1. Compare the character encodings of the first character of each string. If the encodings are different, the size of string is determined by the corresponding encoding values. 2. If the encodings are the same, compare the encodings of the second, third, and subsequent characters until a difference is found. 3. If the lengths of the strings are different, NULL characters (16#00) are added to the shorter string to complete the comparison.





RecMin retrieves the minimum value. The minimum value of the member to search is assigned to search result Out.

- **Program example**

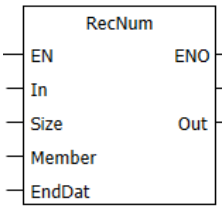
  The following example sets Size to UINT#5.

Item	LD	ST

Define variables	VAR
	xResult: BOOL;
	arystru: ARRAY [1..5] OF STRUCT_TEST := [(mem2 := 1234), (mem2 := 2345), (mem2 := 3456), (mem2 := 1234), (mem2 := 3456)];
	uiSize: UINT := 5;
	iOut: INT;
	aryPos: ARRAY [1..5] OF UINT;
	uiNum: UINT;
	END_VAR	

Program		xResult := RecMin(In := arystru[1], Size := uiSize, Member := arystru[1].mem2, Out := iOut, InOutPos := aryPos[1], Num => uiNum);
Operation result		

	Name	Data type	Address	Value
1	xResult	BOOL		TRUE
2	arystru	ARRAY [1..5] OF STRUCT_TEST		
3	arystru[1]	STRUCT_TEST		
4	arystru[2]	STRUCT_TEST		
5	arystru[3]	STRUCT_TEST		
6	arystru[4]	STRUCT_TEST		
7	arystru[5]	STRUCT_TEST		
8	uiSize	UINT		5
9	iOut	INT		1234
10	aryPos	ARRAY [1..5] OF UINT		
11	aryPos[1]	UINT		1
12	aryPos[2]	UINT		0
13	aryPos[3]	UINT		0
14	aryPos[4]	UINT		0
15	aryPos[5]	UINT		0
16	uiNum	UINT		2



- **Precautions**
  - In[ ] can be a higher-level structure member, for example: In[0] = str0.str1[0].
  - The data types of Member and Out must be consistent; otherwise, a compilation fault will occur.

- When Member is a real number, different values may introduce errors and may not produce the expected results.
- If an element from an array is passed to In[ ], all elements from that element onward will be processed.
- In OMUtils library versions 1.2.0.1 and earlier, when Size is 0, Out and Num are 0, InOutPos[ ] remains unchanged, and the return value is TRUE.
  In OMUtils library versions 1.3.0.0 and later, when Size is 0, Out and Num are 0, InOutPos[ ] remains unchanged, and the return value is FALSE.
- The dimension of In[ ] must be less than or equal to 3; otherwise, the function returns FALSE, Out and InOutPos[ ] remain unchanged, and Num is 0.
- InOutPos[ ] must be a one-dimensional array; otherwise, a compilation fault will occur.
- If Size exceeds the array region of In[ ], the function returns FALSE, Out and InOutPos[ ] remain unchanged, and Num is 0.
- If Member is not a member of the element specified in In[ ], the function returns FALSE, Out and InOutPos[ ] remain unchanged, and Num is 0.
- If Member is of STRING type and is not NULL-terminated, the result may be abnormal.
- In[ ] can also be an array with two or more dimensions. For a 2D array, the first-dimension index of the matching element is stored in InOutPos[0], and the second-dimension index is stored in InOutPos[1].
- For a 3D array, the first-dimension index is stored in InOutPos[0], the second in InOutPos[1], and the third in InOutPos[2].
- When In[ ] is a multi-dimensional array, the number of elements in InOutPos[ ] must not be less than the dimension of In[ ]; otherwise, the function returns FALSE, Out and InOutPos[ ] remain unchanged, and Num is 0.

18.2.10.4 RecNum

Gets the number records in an array of structures to the end data.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
RecNum	Get number of records	FC		:= RecNum(In := , Size := , Member := , EndDat := , Out =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In[ ] array	Structure array to search	Follows data type	-	Array of structures to search

Input/Output	Variable	Name	Valid Range	Default Value	Description
	Size	Number of elements to search	Follows data type	1	Number of array elements to search
	Member	Member to search	Follows data type	-	Member of In[ ] structure array to search
	EndDat	End data	Follows data type	-	End data
Output	Out	Number of records	Follows data type	-	Number of records

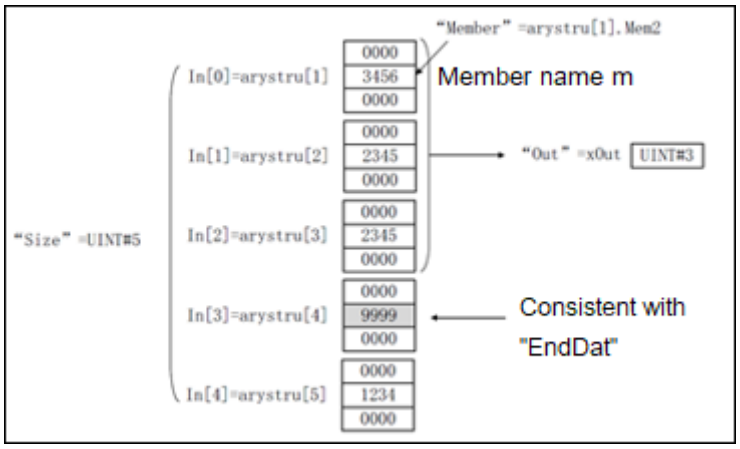
Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In[ ] array	Specify an array of structures.																			
Size	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
Member	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
	Data with the same data type as the search member of In[ ]																			
End Dat	Array with the same data type as the elements of Member																			
Out	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - This instruction searches an array of structures In[ ] for Size elements ranging from In[0] to In[Size–1] where the value of Member matches the end data EndDat. Then the number of elements (records) matching EndDat is assigned to Out.
  - The member to search from any element of In[ ] is passed to the Member parameter.
  - Input parameters passed to In[ ] shall be specified along with the element index, such as array[3].
- **Program example**

  The following example sets EndDat to INT#9999.

<table>
<tr><th>Item</th><th>LD</th><th>ST</th></tr>
<tr><td>Define variables</td><td colspan="2">



```
VAR
    xResult: BOOL;
    arystru: ARRAY [1..5] OF STRUCT_TEST := [(mem2 := 3456), 2((mem2 := 2345)), (mem2 := 9999), (mem2 := 1234)];
    uiSize: UINT := 5;
    iEndDat: INT := 9999;
    uiOut: UINT;
END_VAR
```

</td></tr>
<tr><td>Program</td><td>
</td><td>

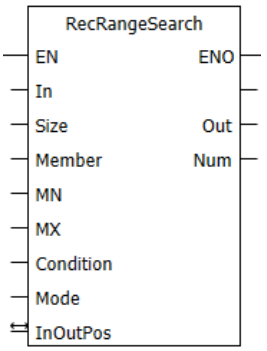
```
xResult := RecNum(In := arystru[1],
                  Size := uiSize,
                  Member := arystru[1].mem2,
                  EndDat := iEndDat,
                  Out => uiOut);
```

</td></tr>
<tr><td>Operation result</td><td colspan="2">

	Name	Data type	Address	Value
1	xResult	BOOL		TRUE
2	arystru	ARRAY [1..5] OF STRUCT_TEST		
3	arystru[1]	STRUCT_TEST		
4	arystru[2]	STRUCT_TEST		
5	arystru[3]	STRUCT_TEST		
6	arystru[4]	STRUCT_TEST		
7	arystru[5]	STRUCT_TEST		
8	uiSize	UINT		5
9	iEndDat	INT		9999
10	uiNum	UINT		3

</td></tr>
<tr><td>Principle analysis</td><td colspan="2">
</td></tr>
</table>

- **Precautions**
  - In[ ] must be an array of structure members, otherwise, a fault occurs during compilation.
  - The data types of Member and EndDat must be consistent; otherwise, an exception will occur during compilation.
  - If no element in Size members of In[ ] matches EndDat, the value of Out is Size.
  - When Member is a real number, different values may introduce errors and may not produce the expected results.
  - When EndDat is a real number, do not specify a non-numeric value for EndDat.
  - If an element from an array is passed to In[ ], all elements from that element onward will be processed.
  - If In[ ] exceeds 3 dimensions, the function returns FALSE, and Out is initialized to 0.
  - In OMUtils library versions 1.2.0.1 and earlier, when the value of Size is 0, Out is initialized to 0, and the function returns TRUE.



In OMUtils library versions 1.3.0.0 and later, when the value of Size is 0, Out is initialized to 0, and the function returns FALSE.

- When the value of Size exceeds the In[ ] array, the return value is FALSE and the value of Out is initialized to 0.
- When the value of Member is not a member of In[ ], the return value is FALSE and the value of Out is initialized to 0.
- If Member is of STRING type and is not NULL-terminated, the result may be abnormal.

18.2.10.5 RecRangeSearch

Searches an array of structures for elements that match the search condition range with the specified method.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
RecRange Search	Get records within specified range	FC		:= RecRangeSearch(In := , Size := , Member := , MN := , MX := , Condition := , Mode := , InOutPos := , Out => , Num =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In[ ] array	Array to search	Follows data type	-	Array of structures to search
	Size	Number of elements to search	Follows data type	0	Number of array elements to search
	Member	Member to search	Follows data type	-	Member of In[ ] structure array to search
	MN	Search condition lower limit	Follows data type	-	Search condition lower limit
	MX	Search condition upper limit	Follows data type	-	Search condition upper limit

Input/Output	Variable	Name	Valid Range	Default Value	Description
	Condition	Search condition	_eSEARCH_CONDITION	1(_EQ_BOTH)	Search condition
	Mode	Search method	_eSEARCH_MODE	1(_LINEAR)	Search method
Input/Output	InOutPos[ ] array	Element indices of matching elements	Follows data type	-	Element indices of matching elements
Output	Out	Search result	Follows data type	-	Search result
	Num	Number of matching elements	Follows data type	-	Number of matching elements

Variable types

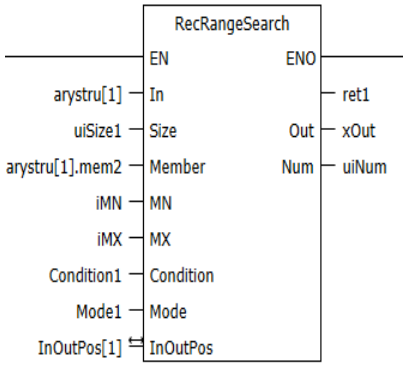
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In[ ] array	Specify an array of structures.																			
Size	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
Member	–	–	–	–	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
	Data with the same data type as the search member of In[ ]																			
MN	Array with the same data type as the elements of Member																			
MX	Array with the same data type as the elements of Member																			
Condition	Refer to "Function description" for the enumerators of _eSEARCH_CONDITION.																			
Mode	Refer to "Function description" for enumerators of _eSEARCH_MODE.																			

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
InOutPos[ ] array	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Num	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - This instruction searches an array of structures In[ ] for Size elements ranging from In[0] to In[Size–1] where the value of Member matches the search conditions.
  - Condition specifies the search condition. Mode specifies the search method. The member to search from any element of In[ ] is passed to the Member parameter. If any elements matching the conditions are found, the value of search result Out changes to TRUE. The indices of the matching elements are assigned to InOutPos[0] and the number of matching elements is assigned to Num. If there are more than two matching elements, the index of the lowest-order matching element is stored in InOutPos[0].
  - If there are no matching elements, the value of Out is FALSE and InOutPos[0] and Num are 0. Input parameters passed to In[ ] shall be specified along with the element index, such as array[3].
  - The data type of the search condition Condition is enumerated type _eSEARCH_CONDITION. The meanings of the enumerators are as follows:

Enumerator	Definition
1 (EQ_BOTH)	"MN" ≤ "Member" ≤ "MX"
2 (_EQ_MIN)	"MN" ≤ "Member" < "MX"
3 (_EQ_MAX)	"MN" < "Member" ≤ "MX"
4 (_NE_BOTH)	"MN" < "Member" < "MX"

  - The data type of search method Mode is enumerated type _eSEARCH_MODE. The meanings of the enumerators are as follows:

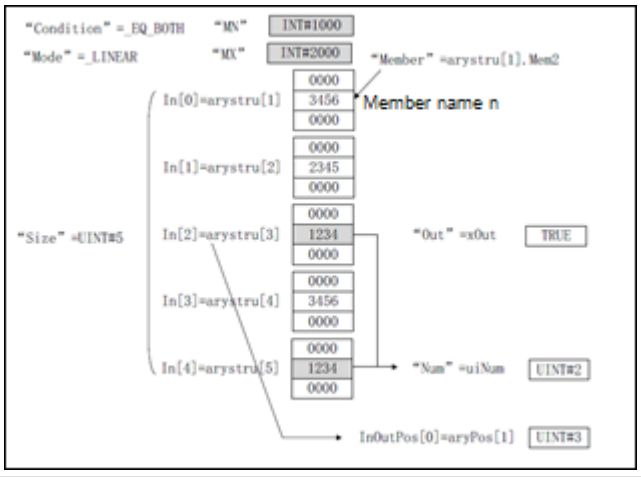


Enumerator	Definition
1 (_LINEAR)	Linear search
2 (_BIN_ASC)	Ascending binary search
3 (_BIN_DESC)	Descending binary search

- **Program example**

In the following example, "Size" is UINT#5, "MN" is INT#1000, "MX" is INT#2000, "Condition" is _EQ_BOTH, and "Mode" is _LINEAR.

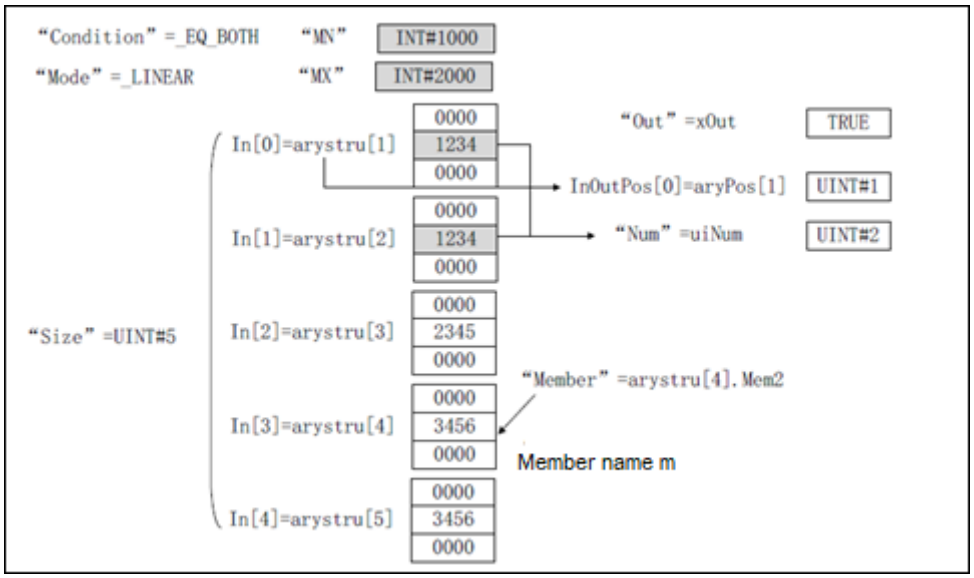
<table>
<tr><th>Item</th><th colspan="2">LD</th><th>ST</th></tr>
<tr><td>Define variables</td><td colspan="3">



```
VAR
    ret1: BOOL;
    arystru: ARRAY [1..5] OF STRUCT_TEST := [(mem2 := 3456), (mem2 := 2345), (mem2 := 1234), (mem2 := 3456), (mem2 := 1234)];
    uiSize1: UINT := 5;
    iMN: INT := 1000;
    iMX: INT := 2000;
    Condition1: _eSEARCH_CONDITION := _ESEARCH_CONDITION._EQ_BOTH;
    Mode1: _eSEARCH_MODE := _ESEARCH_MODE._LINEAR;
    InOutPos: ARRAY [1..3] OF UINT;
    xOut: BOOL;
    uiNum: UINT;
END_VAR
```

</td></tr>
<tr><td>Program</td><td colspan="2">
</td><td>

```
ret1 := RecRangeSearch(In := arystru[1],
Size := uiSize1,
Member := arystru[1].mem2,
MN := iMN,
MX := iMX,
Condition := Condition1,
Mode := Mode1,
InOutPos := InOutPos[1],
Out => xOut,
Num => uiNum);
```



</td></tr>
<tr><td>Operation result</td><td colspan="3">

Name	Data type	Address	Value
ret1	BOOL		TRUE
arystru	ARRAY [1..5] OF STRUCT_TEST		
arystru[1]	STRUCT_TEST

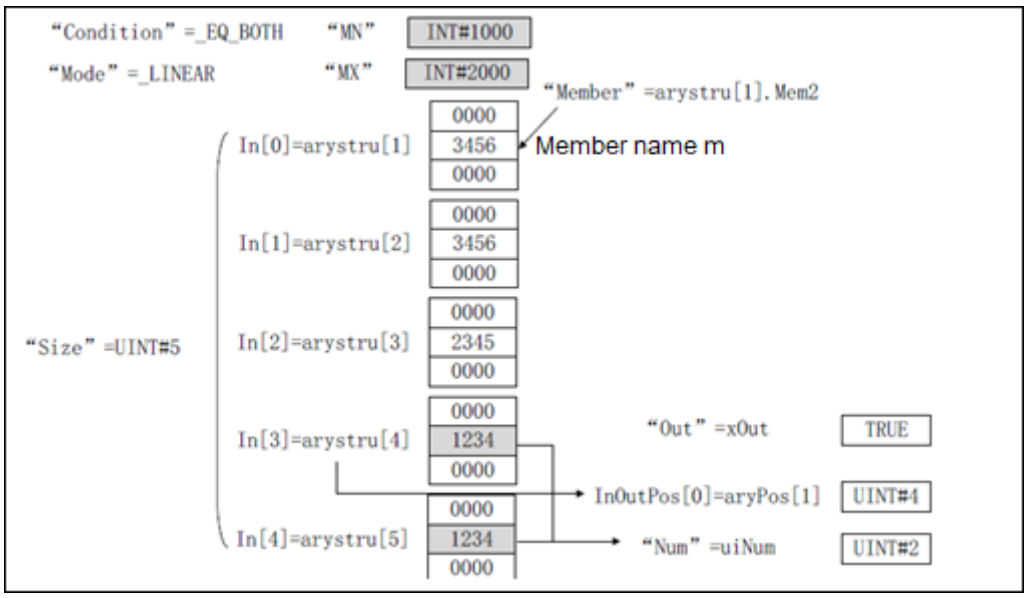
InOutPos	ARRAY [1..3] OF UINT		
InOutPos[1]	UINT		3
InOutPos[2]	UINT		0
InOutPos[3]	UINT		0
xOut	BOOL		TRUE
uiNum	UINT		2

</td></tr>
<tr><td>Principle analysis</td><td colspan="3">
</td></tr>
</table>

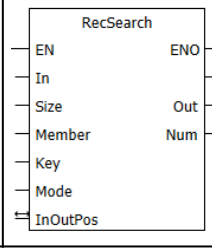


When performing an ascending binary search, the array elements passed to In[ ] must be converted into an ascending array. Then execute this instruction and perform a binary search.

The figure below shows order of the array elements and the processing results for the an ascending binary search based on the above example.

When performing a descending binary search, the array elements passed to In[ ] must be converted into a descending array. Then execute this instruction and perform a binary search.

The figure below shows order of the array elements and the processing results for the a descending binary search based on the above example.



- **Precautions**
  - In[ ] can be a higher-level structure member, for example: In[0] = str0.str1[0].
  - In[ ] must be an array of structure members, otherwise, a fault occurs during compilation.
  - The data types of "Member", "MN", and "MX" shall be the same as that of the members searched in In[ ], otherwise, a fault occurs during compilation.
  - If an element from an array is passed to In[ ], all elements from that element onward will be processed.
  - When Member is a real number, different values may introduce errors and may not produce the expected results.

- When "MN" or "MX" is a real number, do not specify a non-numeric value.
- When the value of Size is 0, Out changes to FALSE. When the value of Num is 0, InOutPos[ ] remains unchanged.
- When the value of Mode is _BIN_ASC or _BIN_DESC and the elements of In[ ] are not in ascending or descending order, the correct result is not obtained. Sort the elements in ascending or descending order before executing this instruction.
- If "MN" > "MX", a fault occurs in the program, the function returns FALSE, "Out" is FALSE, "Num" is 0, and InOutPos[ ] remains unchanged.
- When the value of Condition exceeds the valid range, a fault occurs during compilation.
- When the value of Mode exceeds the valid range, an error occurs during compilation.
- When the value of "Size" exceeds the array range of In[ ] or when the input array dimension is greater than 3, the function returns FALSE, and InOutPos[ ] remains unchanged.
- When Member is not a member of In[ ], the return value is FALSE and InOutPos[ ] remains unchanged.
- InOutPos[ ] must be an one-dimensional array.
- In[ ] can also be an array with two or more dimensions. For a 2D array, the first-dimension index of the matching element is stored in InOutPos[0], and the second-dimension index is stored in InOutPos[1].
- For a 3D array, the first-dimension index is stored in InOutPos[0], the second in InOutPos[1], and the third in InOutPos[2].
- When In[ ] is a multi-dimensional array, the number of elements in InOutPos[ ] must not be less than the dimension of In[ ]; otherwise, the function returns FALSE, Out is FALSE, Num is 0, and InOutPos[ ] remains unchanged.

18.2.10.6 RecSearch

Searches an array of structures for elements that match the search keyword with the specified method.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
RecSearch	Get specified record	FC		:= RecSearch(In := , Size := , Member := , Key := , Mode := , InOutPos := , Out => , Num =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In[ ] array	Array to search	Follows data type	-	Array of structures to search

Input/Output	Variable	Name	Valid Range	Default Value	Description
	Size	Number of elements to search	Follows data type	0	Number of array elements to search

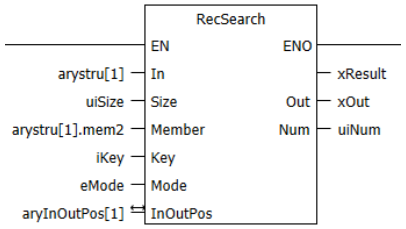
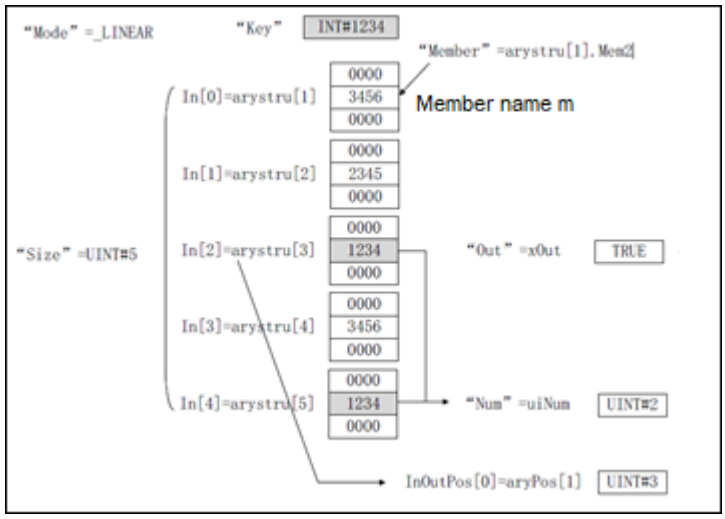
Num	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - This instruction searches an array of structures In[ ] for Size elements ranging from In[0] to In[Size–1] where the value of Member matches Key.
  - The member to search from any element of In[ ] is passed to the Member parameter. If any matching elements are found, the value of search result Out changes to TRUE. The indices of the matching elements are assigned to InOutPos[0] and the number of matching elements is assigned to Num. If there are more than two matching elements, the index of the lowest-order matching element is stored in InOutPos[0].
  - If there are no matching elements, the value of Out is FALSE and InOutPos[0] and Num are 0. Input parameters passed to In[ ] shall be specified along with the element index, such as array[3].
  - The data type of search method Mode is enumerated type _eSEARCH_MODE. The meanings of the enumerators are as follows:

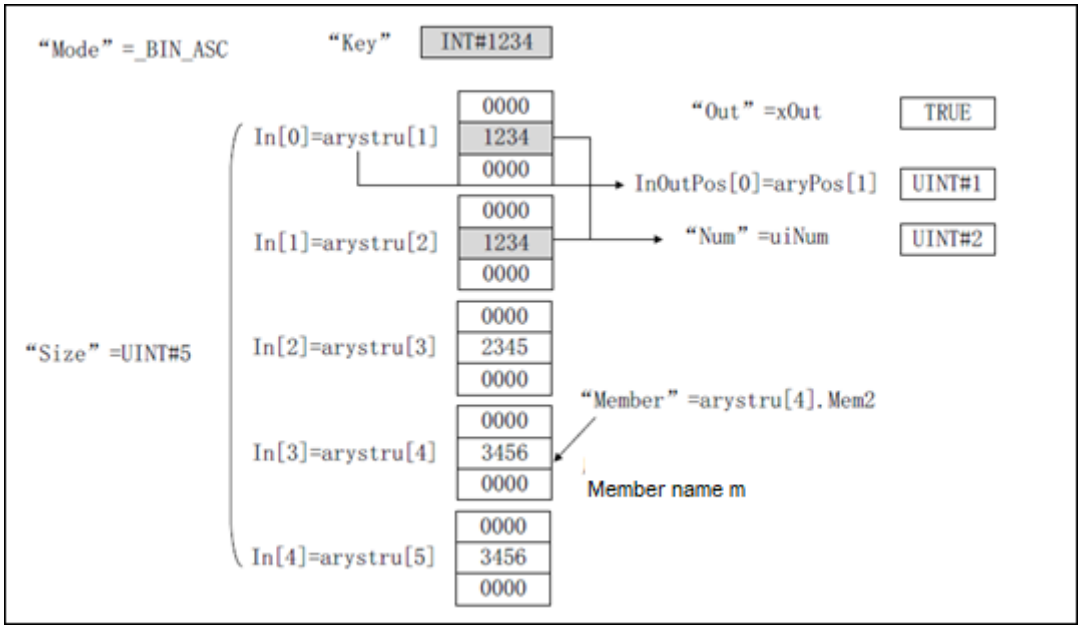




Enumerator	Definition
1 (_LINEAR)	Linear search
2 (_BIN_ASC)	Ascending binary search
3 (_BIN_DESC)	Descending binary search

- **Program example**

  For a linear search, the search is performed from the first element of In[ ]. In the following example, Size is UINT#5, Key is INT#1234, and Mode is _LINEAR.



Item	LD	ST
Define variables		

```
VAR
    xResult: BOOL;
    arystru: ARRAY [1..5] OF STRUCT_TEST := [(mem2 := 3456), (mem2 := 2345), (mem2 := 1234), (mem2 := 3456), (mem2 := 1234)];
    uiSize: UINT := 5;
    iKey: INT := 1234;
    eMode: _eSEARCH_MODE := _eSEARCH_MODE._LINEAR;
    aryInOutPos: ARRAY [1..5] OF UINT;
    xOut: BOOL;
    uiNum: UINT;
END_VAR
```

<table>
<tr><th>Item</th><th>LD</th><th>ST</th></tr>
<tr><td>Program</td><td>
</td><td><pre>
xResult := RecSearch(In := arystru[1],
Size := uiSize,
Member := arystru[1].mem2,

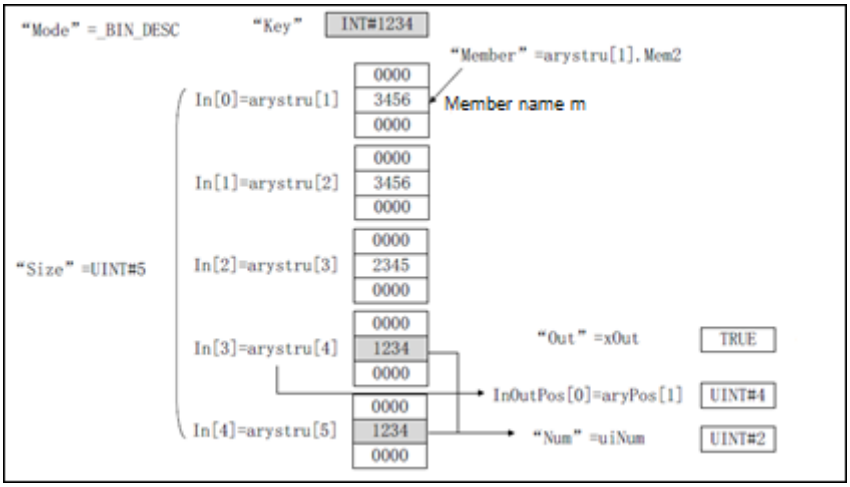
<tr><td>Cause Analysis</td><td colspan="2">
</td></tr>
</table>

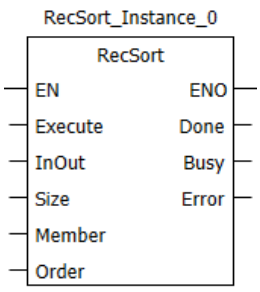


When performing an ascending binary search, the array elements passed to In[ ] must be converted into an ascending array. Then execute this instruction and perform a binary search.

The figure below shows order of the array elements and the processing results for the an ascending binary search based on the above example.

When performing a descending binary search, the array elements passed to In[ ] must be converted into a descending array. Then execute this instruction and perform a binary search.

The figure below shows order of the array elements and the processing results for the a descending binary search based on the above example.



- **Precautions**
  - In[ ] must be an array of structure members, otherwise, a fault occurs during compilation.
  - In[ ] can be a higher-level structure member, for example: In[0] = str0.str1[0].
  - If an element from an array is passed to In[ ], all elements from that element onward will be processed.
  - When Member is a real number, different values may introduce errors and may not produce the expected results.
  - When Key is a real number, do not specify a non-numeric value for Key, otherwise, the program may be faulty.
  - Use the same data type for Key and Member; otherwise, a fault occurs during compilation.
  - When the value of Size is 0, Out is 0 and the return value is TRUE. When the value of Num is 0, InOutPos[ ] remains unchanged.
  - When the value of Mode is _BIN_ASC or _BIN_DESC and the elements of In[ ] are not in ascending or descending order, the correct result is not obtained. Sort the elements in ascending or descending order before executing this instruction.

- When the value of Mode exceeds the valid range, an error occurs during compilation.
- When the value of Size exceeds the In[ ] array, the return value is FALSE and InOutPos[ ] remains unchanged.
- When Member is not a member of In[ ], the return value is FALSE and InOutPos[ ] remains unchanged.
- If Member is of STRING type and is not NULL-terminated, the result may be abnormal.
- InOutPos[ ] must be a one-dimensional array.
- In[ ] can also be an array with two or more dimensions. For a 2D array, the first-dimension index of the matching element is stored in InOutPos[0], and the second-dimension index is stored in InOutPos[1].
- For a 3D array, the first-dimension index is stored in InOutPos[0], the second in InOutPos[1], and the third in InOutPos[2].
- When In[ ] is a multi-dimensional array, the number of elements in InOutPos[ ] must not be less than the dimension of In[ ]; otherwise, the function returns FALSE, Out is FALSE, Num is 0, and InOutPos[ ] remains unchanged.

18.2.10.7 RecSort

Sorts the elements of an array of structures.

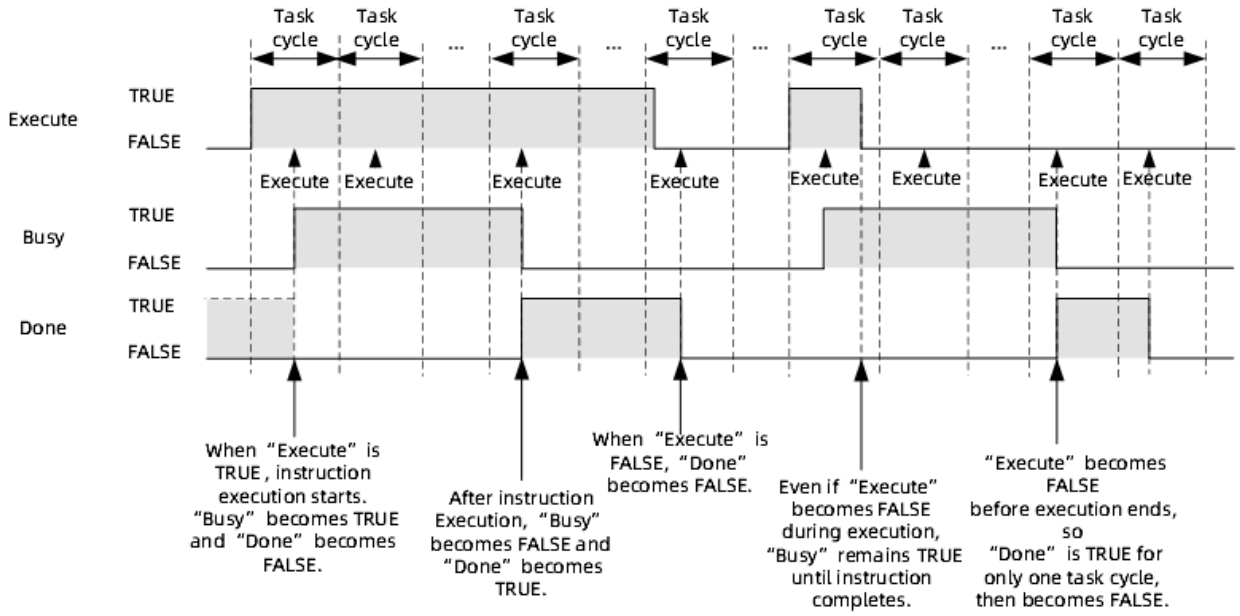
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
RecSort	Sort records	FB		RecSort_Instance_0(Execute := , InOut := , Size := , Member := , Order := , Done => , Busy => , Error =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Execute	Start	Follows data type	FALSE	FALSE: The instruction is not enabled. TRUE: The instruction is enabled.



Input/Output	Variable	Name	Valid Range	Default Value	Description
	Size	Number of elements to search	Follows data type	1	Number of array elements to search
	Member	Member to search	Follows data type	-	Member of InOut[ ] structure to sort
	Order	Array order	1(_ASC), 2(_DESC)	1 (_ASC)	1: Ascending order 2: Descending order
	InOut[ ] array	Array to sort	Follows data type	-	Array of structures to sort
Output	Done	Completion flag	Follows data type	FALSE	FALSE: Abnormal termination, execution in progress, or execution condition not met TRUE: Normal termination
	Busy	Operation flag	Follows data type	FALSE	FALSE: Not running TRUE: Running
	Error	Error flag	Follows data type	FALSE	FALSE: No error TRUE: An error exists.

Variable types

	Boolean	Bit String					
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	
Execute	√	–	–	–	–	–	–

	Boolean	Bit String					
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	
Size	–	–	–	–	–	–	√
Member	–	–	–	–	–	√	√
	Data with the same data type as the search member of InOut[ ]						
Order	Refer to Function for the enumerators of the enumerated type _eSORT_ORDER.						
InOut[ ] array	Specify an array of structures.						
Done	√	–	–	–	–	–	–
Busy	√	–	–	–	–	–	–
Error	√	–	–	–	–	–	–

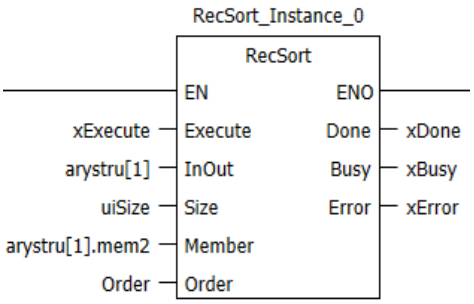
- **Function**
  - When Execute is TRUE, Size elements of InOut[ ] are sorted (from InOut[0] to InOut[Size–1]) based on the value of Member for the structure. Order specifies the sort order.
  - The member to search from any element of InOut[ ] is passed to the Member parameter. Input/Output parameters passed to InOut[ ] shall be specified along with the element index, such as array[3].
  - The sequence diagram for startup, execution, and termination is shown in the figure below.

◦ The data for the sort order Order is enumerated type _eSORT_ORDER. The meanings of the enumerators are as shown in the table below.

Enumerator	Definition
1 (_ASC)	Ascending
2 (_DESC)	Descending

◦ The relationships between values with data types that are not integers or real numbers are determined as follows.

Data Type	Relationship
TIME	The numerically larger value is considered to be larger.
DATA, TOD, DT	Later dates or TOD are considered to be larger.
STRING	Character encoding is used for size comparison. The comparison steps are as follows: 1. Compare the character encodings of the first character of each string. If the encodings are different, the size of string is determined by the corresponding encoding values. 2. If the encodings are the same, compare the encodings of the second, third, and subsequent characters until a difference is found. 3. If the lengths of the strings are different, NULL characters (16#00) are added to the shorter string to complete the comparison.



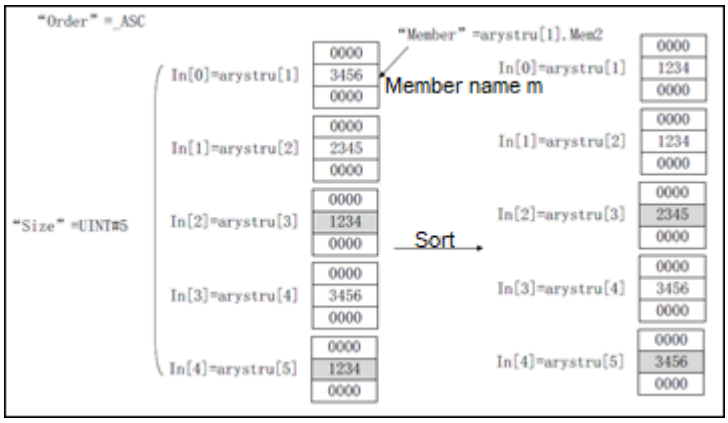
- **Program example**

  The following example sets Size to UINT#5 and Order to _ASC.

<table>
<tr><th>Item</th><th>LD</th><th>ST</th></tr>
<tr><td>Define variables</td><td colspan="2">

```
VAR
    RecSort_Instance_0: RecSort;
    xExecute: BOOL;
    arystru: ARRAY [1..5] OF STRUCT_TEST := [(mem2 := 3456), (mem2 := 2345), (mem2 := 1234), (mem2 := 3456), (mem2 := 1234)];
    uiSize: UINT := 5;
    Order: _eSORT_ORDER := _ESORT_ORDER._ASC;
    xDone: BOOL;
    xBusy: BOOL;
    xError: BOOL;
END_VAR
```

</td></tr>
<tr><td>Program</td><td>



</td><td>

```
RecSort_Instance_0(
Execute := xExecute,
InOut := arystru[1],
Size := uiSize,
Member := arystru[1].mem2,

mem2	INT		3456
mem3	INT		0
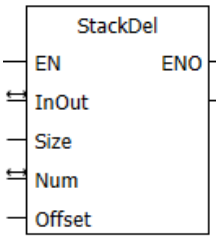
uiSize	UINT		5
Order	_ESORT_ORDER		_ASC
xDone	BOOL		TRUE
xBusy	BOOL		FALSE
xError	BOOL		FALSE

</td></tr>
</table>



Item	LD	ST
Principle analysis		

- **Precautions**
  - InOut[ ] must be an array of structure members, otherwise, a fault occurs during compilation.
  - Execution of this instruction is continued until processing is completed even if the value of Execute changes to FALSE or the execution time exceeds the task period. The value of Done changes to TRUE when processing is completed. Use this to confirm normal completion of processing.
  - When Member is a real number, different values may introduce errors and may not produce the expected results.
  - If an element from an array is passed to InOut[ ], all elements from that element onward will be processed.
  - The dimension of InOut[ ] cannot exceed 3; otherwise, InOut[ ] remains unchanged, and the value of Error is TRUE.
  - When the value of Size is 0, the value of Done is TRUE and InOut[ ] remains unchanged.
  - When the value of Order exceeds the valid range, a fault occurs during compilation.
  - When the value of Size exceeds the InOut[ ] array range, Error is TRUE and InOut[ ] remains unchanged.
  - When Member is not a member of InOut[ ], the value of Error is TRUE, and InOut[ ] remains unchanged.
  - If Member is of STRING type and is not NULL-terminated, the result may be abnormal.

18.2.10.8 StackDel

Deletes a value from any position in a stack.

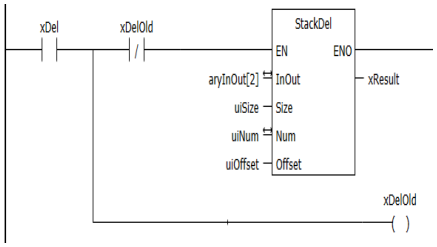
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
StackDel	Delete a value from a specified position in a stack	FC		:= StackDel(InOut := , Size := , Num := , Offset :=);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Size	Number of elements in stack	Follows data type	1	Number of array elements in stack
	Offset	Offset	Follows data type	0	Offset of an element to delete from stack
Input/Output	InOut[ ] array	Stack array	Follows data type	-	Array that functions as stack
	Num	Number of elements stored in stack	Follows data type	-	Number of elements stored in stack



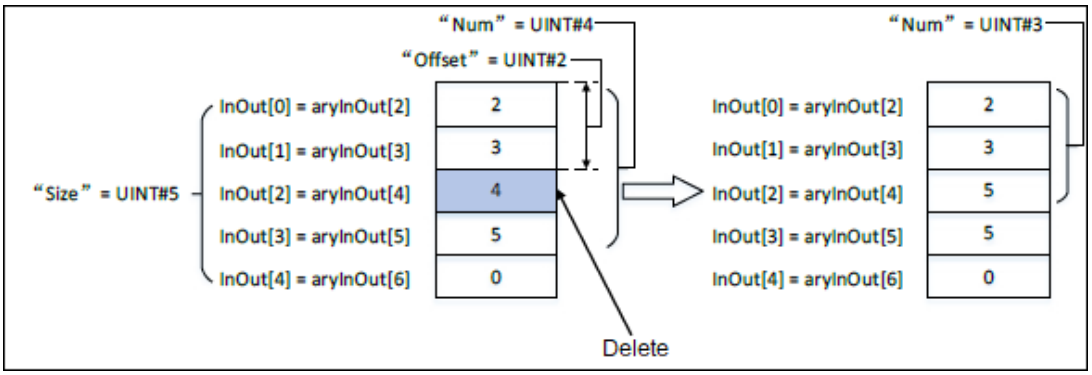
Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
InOut[ ] array	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
	Arrays of enumerations or structures can also be specified.																			
Size	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
Num	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
Offset	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - This instruction assumes that the InOut[ ] array containing Num elements is the stack array. It deletes the value at the position specified by InOut[Offset].
  - All higher elements (InOut[Offset + 1] to InOut[Num - 1]) are moved to the next lower element in the stack array.
  - If the value of (Offset + 1) is greater than (Num - 1), InOut[ ] remains unchanged.
  - Size specifies the number of elements to be used as a stack in InOut[ ].
- **Program example**

<table>
<tr><th>Item</th><th>LD</th><th>ST</th></tr>
<tr><td>Define variables</td><td colspan="2">

```
VAR
    xResult: BOOL;
    aryInOut: ARRAY [1..10] OF UINT := [1, 2, 3, 4, 5, 5(0)];
    uiSize: UINT:= 5;
    uiNum: UINT:= 4;
    uiOffset: UINT:= 2;
END_VAR
```



</td></tr>
<tr><td>Program</td><td>
</td><td>

```
IF xDel AND NOT xDelOld THEN
   xResult := StackDel(InOut := aryInOut[2], Size := uiSize, Num := uiNum, Offset := uiOffset);
END_IF

xDelOld:= xDel;
```

</td></tr>
<tr><td>Operation result</td><td colspan="2">

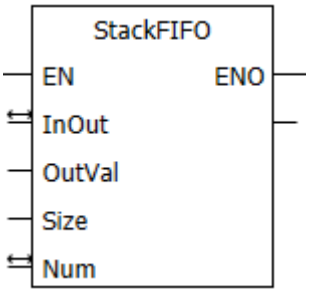
aryInOut[1]	INT		1
aryInOut[2]	INT		2
aryInOut[3]	INT		3
aryInOut[4]	INT		5
aryInOut[5]	INT		5
aryInOut[6]	INT		0
aryInOut[7]	INT		0
aryInOut[8]	INT		0
aryInOut[9]	INT		0
aryInOut[10]	INT		0
uiSize	UINT		5
uiNum	UINT		3
uiOffset	UINT		2
xDel	BOOL		TRUE
xDelOld	BOOL		TRUE

</td></tr>
<tr><td>Principle analysis</td><td colspan="2">
</td></tr>
</table>



- **Precautions**
  - In OMUtils library versions 1.2.0.1 and earlier, when the value of Size or Num is 0, the function returns TRUE, and InOut[ ] and Num remain unchanged.
    In OMUtils library versions 1.3.0.0 and later, when the value of Size is 0, the function returns TRUE; when the value of Num is 0, the function returns FALSE, and InOut[ ] and Num remain unchanged.
  - If the value of Size exceeds the InOut[ ] array range or when the InOut[ ] dimension exceeds 3, the function returns FALSE, and InOut[ ] and Num remain unchanged.
  - If Size and Num are both non-zero and the condition Size ≥ Num > Offset is not satisfied, the function returns FALSE, and InOut[ ] and Num remain unchanged.

◦ If an element from an array is passed to InOut[ ], all elements from that element onward will be processed.

18.2.10.9 StackFIFO

Retrieves the bottom value from a stack.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
StackFIFO	Retrieve the bottom value from a stack	FC		:= StackFIFO(InOut := , OutVal := , Size := , Num :=);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	OutVal	Output value	Follows data type	-	Value output from stack
	Size	Number of elements in stack	Follows data type	1	Number of array elements in stack
Input/Output	InOut[ ] array	Stack array	Follows data type	-	Array that functions as stack
	Num	Number of elements stored in stack	Follows data type	-	Number of elements stored in stack

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
InOut[ ] array	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
	An enumerator, a structure, or a structure member can also be specified.																			

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
OutVal	Array with the same data type as the elements of InOut[ ]																			
Size	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
Num	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - This instruction assumes that the InOut[ ] array containing Num elements is the stack array. It retrieves the value of the least-significant bit InOut[0] from the stack and assigns it to OutVal.
  - Then, all (Num - 1) elements that begin with InOut[1] are shifted to the next lower element in the stack array.
  - Size specifies the number of elements to be used as a stack in InOut[ ].
- **Program example**

Item	LD	ST

Define variables	VAR
	xResult: BOOL;

</table>
</td></tr>
<tr><td>Principle analysis</td><td colspan="2">
</td></tr>
</table>

- **Precautions**
  - If the value of Size exceeds the InOut[ ] array range or when the InOut[ ] dimension exceeds 3, the function returns FALSE, and the values of InOut[ ], Num, and OutVal remain unchanged.
  - When OutVal and InOut[ ] are of STRING type and the number of bytes in InOut[ ] exceeds the value of OutVal, the function returns FALSE, and the values of InOut[ ], Num, and OutVal remain unchanged.
  - The data type of OutVal shall be the same as that of the InOut[ ] elements; otherwise, a compilation fault will occur.
  - In OMUtils library versions 1.2.0.1 and earlier, when the value of Size or Num is 0, the function returns TRUE, and the values of InOut[ ], Num, and OutVal remain unchanged.
    In OMUtils library versions 1.3.0.0 and later, when the value of Size is 0, the function returns TRUE; when the value of Num is 0, the function returns FALSE, the values of InOut[ ], Num, and OutVal remain unchanged.
  - When the value of Size and Num are non-zero and Num is greater than Size, the function returns FALSE, the values of InOut[ ], Num, and OutVal remain unchanged
  - If an element from an array is passed to InOut[ ], all elements from that element onward will be processed.

18.2.10.10 StackIns

Inserts a value at any position in a stack.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
StackIns	Insert into stack	FC		:= StackIns(In := , InOut := , Size := , Num := , Offset :=);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Input	Follows data type	-	Value to input to the stack
	Size	Number of elements in stack	Follows data type	1	Number of array elements in stack
	Offset	Offset	Follows data type	0	Offset position in stack at which to insert In
Input/Output	InOut[ ] array	Stack array	Follows data type	-	Array that functions as stack
	Num	Number of elements stored in stack	Follows data type	-	Number of elements stored in stack

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
	An enumerator, a structure, or a structure member can also be specified.																			
InOut[ ] array	Array with the same data type as the elements of InOut[ ]																			

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Size	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
Num	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
Offset	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - This instruction assumes that the InOut[ ] array containing Num elements is the stack array. The input value In is inserted at the position specified by InOut[Offset] in the stack.
  - All higher elements (InOut[Offset] to InOut[Num - 1]) are moved to the next higher element in the stack array.
  - Size specifies the number of elements to be used as a stack in InOut[ ].
- **Program example**

Item	LD	ST

Define variables	VAR
	xResult: BOOL;
	iIn: INT := 10;
	aryInOut: ARRAY [1..10] OF INT := [1, 2, 3, 4, 5, 5(0)];
	uiSize: UINT := 5;
	uiNum: UINT := 4;

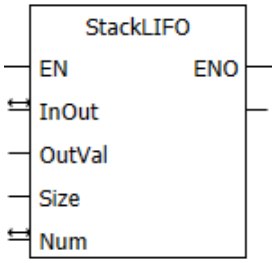
aryInOut[9]	INT		0
aryInOut[10]	INT		0
uiSize	UINT		5
uiNum	UINT		5
uiOffset	UINT		2
xIns	BOOL		TRUE
xInsOld	BOOL		TRUE

Principle analysis



- **Precautions**
  - If the value of Size exceeds the InOut[ ] array range or when the InOut[ ] dimension exceeds 3, the function returns FALSE, and InOut[ ] and Num remain unchanged.
  - If In and InOut[ ] are of STRING type and the number of bytes in In exceeds the value of InOut[ ], the function returns FALSE, and InOut[ ] and Num remain unchanged.
  - A compilation exception occurs when the data types of In and InOut differ.
  - When the value of Size is 0, the function returns TRUE, and InOut[ ] and Num remain unchanged.
  - When the value of Size is not 0 and the condition Size > Num ≥ Offset is not satisfied, the program fails to run, the function returns FALSE, and InOut[ ] and Num remain unchanged.
  - If an element from an array is passed to InOut[ ], all elements from that element onward will be processed.
  - The input parameter transmitted to In must be a variable. If a constant is transmitted, a fault occurs during compilation.
  - When In is an enumeration, no enumerator can be directly transmitted. If an enumerator is directly transmitted, a fault occurs during compilation.
  - When the values of Num and Offset are both 0, the input value is passed to InOut[Offset], and the value of Num is incremented by 1.

18.2.10.11 StackLIFO

Retrieves the top value from a stack.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
StackLIFO	Retrieve the top value from a stack	FC		:= StackLIFO(InOut := , OutVal := , Size := , Num :=);

- **Related variables**

Variable

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
InOut[ ] array	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
	An enumerator, a structure, or a structure member can also be specified.																			
OutVal	Array with the same data type as the elements of InOut[ ]																			

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Size	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
Num	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - This instruction assumes that the InOut[ ] array containing Num elements is the stack array. It retrieves the value of the most-significant bit InOut[Num - 1] from the stack and assigns it to OutVal.
  - Num is decremented by 1.
  - Size specifies the number of elements to be used as a stack in InOut[ ].
- **Program example**

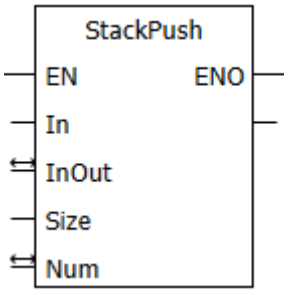
	xLIFOOld	BOOL		TRUE



Item	LD	ST
Principle analysis		

- **Precautions**
  - If the value of Size exceeds the InOut[ ] array range or when the InOut[ ] dimension exceeds 3, the function returns FALSE, and the values of InOut[ ], Num, and OutVal remain unchanged.
  - When OutVal and InOut[ ] are of STRING type and the number of bytes in InOut[ ] exceeds the value of OutVal, the function returns FALSE, and the values of InOut[ ], Num, and OutVal remain unchanged.
  - The data type of OutVal shall be the same as that of the InOut[ ] elements; otherwise, a compilation fault will occur.
  - In OMUtils library versions 1.2.0.1 and earlier, when the value of Size or Num is 0, the function returns TRUE, and the values of InOut[ ], Num, and OutVal remain unchanged.
    In OMUtils library versions 1.3.0.0 and later, when the value of Size is 0, the function returns TRUE; when the value of Num is 0, the function returns FALSE, the values of InOut[ ], Num, and OutVal remain unchanged.
  - When the value of Size and Num are non-zero and Num is greater than Size, the function returns FALSE, the values of InOut[ ], Num, and OutVal remain unchanged
  - If an element from an array is passed to InOut[ ], all elements from that element onward will be processed.

18.2.10.12 StackPush

Stores a value in a stack.

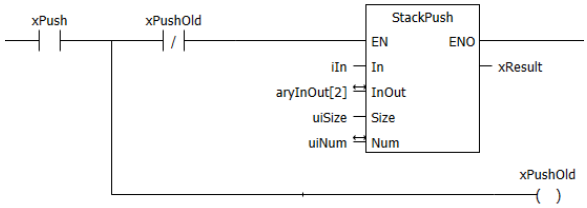
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
StackPush	Push a value into a stack	FC		:= StackPush(In := , InOut := , Size := , Num :=);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Input	Follows data type	-	Value to input to the stack
	Size	Number of elements in stack	Follows data type	1	Number of array elements in stack
Input/Output	InOut[ ] array	Stack array	Follows data type	-	Array that functions as stack
	Num	Number of elements stored in stack	Follows data type	-	Number of elements stored in stack



Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
	An enumerator, a structure, or a structure member can also be specified.																			
InOut[ ] array	Array with the same data type as elements of In																			
Size	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
Num	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - This instruction assumes that the InOut[ ] array containing Num elements is the stack array.
  - The input value In overwrites the next element InOut[Num]. Num is incremented by 1.
  - Size specifies the number of elements to be used as a stack in InOut[ ].
- **Program example**

<table>
<tr><th>Item</th><th>LD</th><th>ST</th></tr>

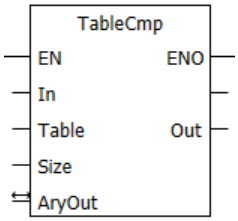
	uiNum	UINT		2
	xPush	BOOL		TRUE
	xPushOld	BOOL		TRUE

</td></tr>
<tr><td>Principle analysis</td><td colspan="2">
</td></tr>
</table>



- **Precautions**
  - If the value of Size exceeds the InOut[ ] array range or when the InOut[ ] dimension exceeds 3, the function returns FALSE, and InOut[ ] remains unchanged.
  - If In and InOut[ ] are of STRING type and the number of bytes in In exceeds the value of InOut[ ], the function returns FALSE, and InOut[ ] remains unchanged.
  - A compilation exception occurs when the data types of In and InOut differ.
  - When the value of Size is 0, InOut[ ] and Num remain unchanged, and the function returns TRUE.
  - When the value of Size is 0 and Num is greater than or equal to Size, the program cannot run and the function returns FALSE.

- If the value of Num is 0, the input value is assigned to InOut[Num] and the value of Num is incremented by 1.
- If an element from an array is passed to InOut[ ], all elements from that element onward will be processed.
- The input parameter transmitted to In must be a variable. If a constant is transmitted, a fault occurs during compilation.
- When In is an enumeration, no enumerator can be directly transmitted. If an enumerator is directly transmitted, a fault occurs during compilation.

18.2.10.13 TableCmp

Compares the comparison data with multiple defined ranges in a comparison table.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
TableCmp	Table comparison	FC		:= TableCmp(In := , Table := , Size := , AryOut := , Out =>);

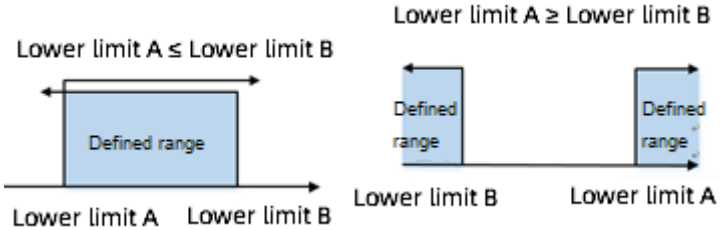
- **Related variables**

Variable

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Comparison data	Follows data type	-	Value to compare
	Table[ ] (two-dimensional array)	Comparison table	Follows data type	-	Two-dimensional array that contains the elements for the defined ranges
	Size	Number of elements to compare	Follows data type	1	Number of elements in Table[ ] to be compared with In
Input/ Output	AryOut[ ] array	Individual comparison result array	Follows data type	-	Comparison results for each element in Table[ ]: TRUE: Consistent. FALSE: Inconsistent.
Output	Out	Comparison result	Follows data type	FALSE	TRUE if all elements are consistent, otherwise FALSE.

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–
Table[ ] (two-dimensional array)	A two-dimensional array with elements that have the same data type as In																			
Size	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
AryOut[ ] array	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–



- **Function**

  This instruction compares the comparison data In with defined ranges of Size in the comparison table Table[ ].

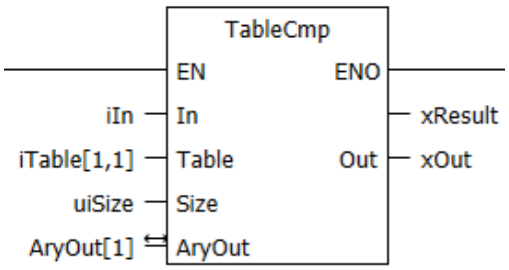
  Table[ ] is a two-dimensional array. The first dimension contains the indices of the defined ranges. In the second dimension, element 0 is the minimum value A of the defined range, and element 1 is the maximum value B of the range.

Defined Range	Minimum Value A	Maximum Value B
Range 0	Table[0,0]	Table[0,1]
Range 1	Table[1,0]	Table[1,1]
…	…	…
Interval Size - 1	Table[Size - 1, 0]	Table[Size - 1, 1]

  Use the minimum value A and maximum value B to specify the defined range. Both values are included in the defined range.

The results are stored in the individual comparison result array AryOut[ ]. If In is within the defined range for element i, AryOut[i] is TRUE. If it is not within the range, AryOut[i] is FALSE. If all Size elements of AryOut[ ] are TRUE, the comparison result Out is TRUE; otherwise, it is FALSE.

- **Program example**



<table>
<tr><th></th><th>LD</th><th>ST</th></tr>
<tr><td>Define variables</td><td colspan="2">

```
VAR
    xResult: BOOL;
    iIn: INT := 5;

    iTable: ARRAY [1..3,1..2] OF INT := [0,2,0,10,10,2];

    uiSize: UINT := 3;
    AryOut: ARRAY [1..3] OF BOOL;
    xOut: BOOL;
END_VAR
```

</td></tr>
<tr><td>Program</td><td>

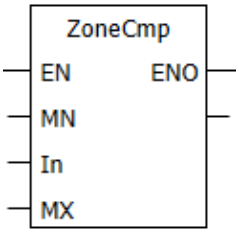
</td><td>

```
xResult := TableCmp(In := iIn,
Table := iTable[1,1],
Size := uiSize,
AryOut := AryOut[1],
Out => xOut);
```

</td></tr>
<tr><td>Operation result</td><td colspan="2">

Name	Data type	Address	Value
xResult	BOOL		TRUE
iIn	INT		5
iTable	ARRAY [1..3, 1..2] OF INT		
iTable[1, 1]	INT		0
iTable[1, 2]	INT		2
iTable[2, 1]	INT		0
iTable[2, 2]	INT		10
iTable[3, 1]	INT		10
iTable[3, 2]	INT		2
uiSize	UINT		3
AryOut	ARRAY [1..3] OF BOOL		
AryOut[1]	BOOL		FALSE
AryOut[2]	BOOL		TRUE
AryOut[3]	BOOL		FALSE
xOut	BOOL		FALSE

</td></tr>
</table>



- **Precautions**
  - The data types of In and Table[ ] elements must be consistent; otherwise, a compilation fault will occur.
  - Table[ ] must be a 2D array; otherwise, a compilation fault will occur. Additionally, the size of the second dimension array must be 2; otherwise, the output result may not match expectations.
  - If the size of AryOut[ ] is greater than the value of Size, the comparison results are stored in AryOut[0] to AryOut[Size - 1]. Other array elements remain unchanged.
  - If real numbers that contain non-terminating decimal numbers are compared, a rounding error may occur, causing unexpected processing results.
  - When the value of Size is 0, the function returns TRUE, the value of Out is FALSE, and AryOut[ ] remains unchanged.
  - When the value of Size exceeds the size of AryOut[ ] or exceeds the size of the first dimension of Table[ ], Out is FALSE, and AryOut[ ] remains unchanged.

◦ When the size of the second dimension of Table[ ] is less than 2, the function returns FALSE, Out is FALSE, and AryOut[ ] remains unchanged.

18.2.10.14 ZoneCmp

Determines whether the comparison data is within the specified range.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ZoneCmp	Zone comparison	FC		:= ZoneCmp(MN := , In := , MX :=);

- **Related variables**

Variable

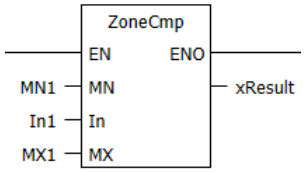
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	MN	Lower limit	Follows data type	-	Lower limit
	In	Comparison data	Follows data type	-	Value to compare
	Mexico	Upper limit	Follows data type	-	Upper limit
Output	Out	Return value	Follows data type	-	Comparison result.

Variable types

	Bool ean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
MN	–	–	–	–	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	–
In	Same data type as MN																			

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Mexico	Same data type as MN																			
Out	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - This instruction determines whether the comparison data "In" is between maximum value "MX" and minimum value "MN".
  - If "MX" ≥ "In" ≥ "MN", "Out" is TRUE; otherwise, "Out" is FALSE.
  - The relationships between values with data types that are not integers or real numbers are determined as follows.



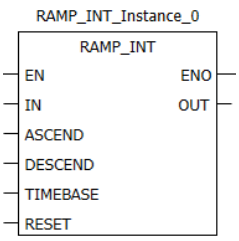
Data Type	Relationship
TIME	The numerically larger value is considered to be larger.
DATA, TOD, DT	Later dates or TOD are considered to be larger.

- **Sequence diagram**

- **Program example**

The following example sets "MN" to INT#10, "In" to INT#20, and "MX" to INT#30.

	LD	ST
Define variables	VAR xResult: BOOL; MN1: INT := 10; In1: INT := 20; MX1: INT := 30; END_VAR	
Program		xResult := ZoneCmp(MN := MN1, In := In1, MX := MX1);
Operation result		



Name	Data type	Address	Value
xResult	BOOL		TRUE
MN1	INT		10
In1	INT		20
MX1	INT		30

- **Precautions**
  - When the data types of In, "MX", and "MN" are different, a fault occurs during compilation.
  - If "In", "MX", and "MN" are real numbers that contain non-terminating decimal numbers, a rounding error may occur, causing unexpected processing results.
  - Two values that are positive infinity or negative infinity are considered equivalent.
  - When the value of In is non-numeric, the value of Out is FALSE.
  - When the value of "MN" is greater than "MX", a fault occurs and the return value is FALSE.
  - If either "MX" or "MN" is non-numeric, a fault occurs and the return value is FALSE.

18.2.10.15 RAMP_INT

Ramps the output to the input setpoint at a defined rate.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
RAMP_INT	Ramp function (integer type)	FB		RAMP_INT_Instance_0(IN := , ASCEND := , DESCEND := , TIMEBASE := , RESET := , OUT =>);

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Input	Follows data type	-	Input
	ASCEND	Ascending limit	Follows data type	-	Ascending limit within the specified time. For example, if TIMEBASE = 1s and ASCEND = 20, the output ascends by at most 20 every 1s.
	DESCEND	Descending limit	Follows data type	-	Descending limit within the specified time. For example, if TIMEBASE = 500 ms and DESCEND = 10, the output descends by at most 10 every 500 ms.
	TIMEBASE	Set time	Follows data type	-	Set time
	RESET	Reset a bit	Follows data type	-	Reset
Output	OUT	Output	Follows data type	-	Output

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
IN	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–

	Boolean	Bit String				Integer							Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
ASCEND	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–
DESCEND	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–
TIMEBASE	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–
RESET	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
OUT	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–

- **Function**

  When the input undergoes a step change, the output gradually ramps to the new value within the specified time.

- **Program example**

  Example: Set IN = 0, ASCEND = 4, DESCEND = 8, TIMEBASE = T#2s, assuming the cycle operation period CYC is 1s.

Input	Judgment	Output
IN = 50	$\text{IN change} > \frac{CYC * ASCEND}{TIMEBASE}$ $50 > \frac{1 * 4}{2}$	$\text{OUT} = \text{Last cycle output} + \frac{CYC * ASCEND}{TIMEBASE}$ $\text{OUT} = \text{Last cycle output} + \frac{1 * 4}{2}$ The output will gradually ascend to 50.
IN = 20	$\text{IN Variation} < -\frac{CYC * \text{DESCEND}}{TIMEBASE}$ $-30 < \frac{1 * 8}{2}$	$\text{OUT} = \text{Rising-edge output} - \frac{CYC * \text{DESCEND}}{TIMEBASE}$ $\text{OUT} = \text{Rising-edge output} - \frac{1 * 8}{2}$ The output will gradually descend to 20.

Output	OUT	Output value	Follows data type	-	-
	ERR	Fault message	0, 1, 2, 4	-	0: No fault. 1: Points in P are not in ascending order. 2: Input is outside the limits of P. 4: Number of valid points N is out of range.

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
IN	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–
N	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
P	ARRAY [0..10] OF POINT																			
OUT	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–
ERR	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

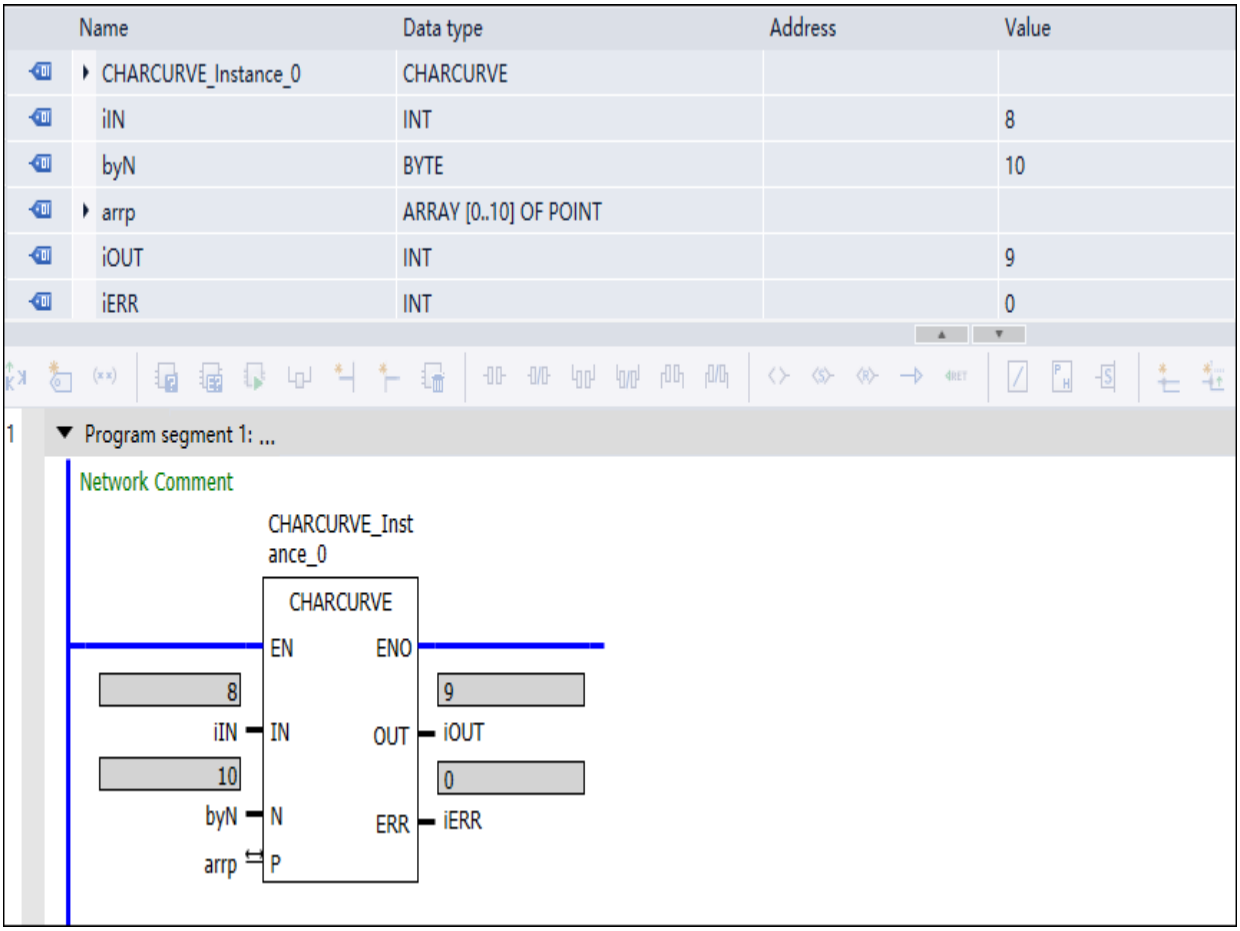
- **Function**

  Maps the input "IN" (X-value) to the output "OUT" (Y-value) based on the characteristic curve defined by 10 points specified by the array P.

- **Program example**

  Set "IN" to 8, the number of valid points N to 10, and the array of points P is shown in the table below.

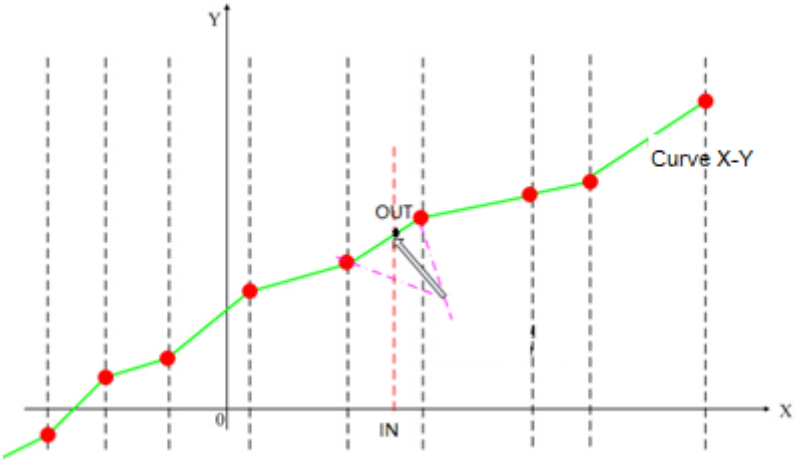
Array Index	X	Y
0	-6	-1
1	-4	1
2	-2	2
3	1	4
4	5	5
5	9	10
6	14	12
7	16	15
8	20	20
9	22	24



ST:

	Name	Data type	Address	Value
	CHARCURVE_Instance_0	CHARCURVE		
	iIN	INT		8
	byN	BYTE		10
	arrp	ARRAY [0..10] OF POINT		
	iOUT	INT		9
	iERR	INT		0

```
CHARCURVE_Instance_0(
IN  8   := iIN  8  ,
N  10  := byN  10  ,
P := arrp,
OUT  9   => iOUT  9  ,
ERR  0   => iERR  0  );RETURN
```



LD:

	Name	Data type	Address	Value
	CHARCURVE_Instance_0	CHARCURVE		
	iIN	INT		8
	byN	BYTE		10
	arrp	ARRAY [0..10] OF POINT		
	iOUT	INT		9
	iERR	INT		0

- **Precautions**
  - The X coordinates of the points in array P must be in ascending order for correct operation.
  - When "IN" > P[N].X, the output is outside the point boundary, "OUT" outputs P[N].Y, and "ERR" is 2.
  - When "IN" < P[0].X, the output is outside the point boundary, "OUT" outputs P[0].Y, and "ERR" is 2.
  - When "IN" is between the X coordinates of two points, the corresponding "OUT" is calculated by linear interpolation between the two points.

    The diagram below shows an example with N = 9:

18.2.10.18 BZAND_TAB

Controls an output value based on whether the input value is within the specified dead zone range. The dead zone range is defined by fLimitLow and fLimitHigh so that the input value fDataSrc is output to fDataOut outside the dead zone range.

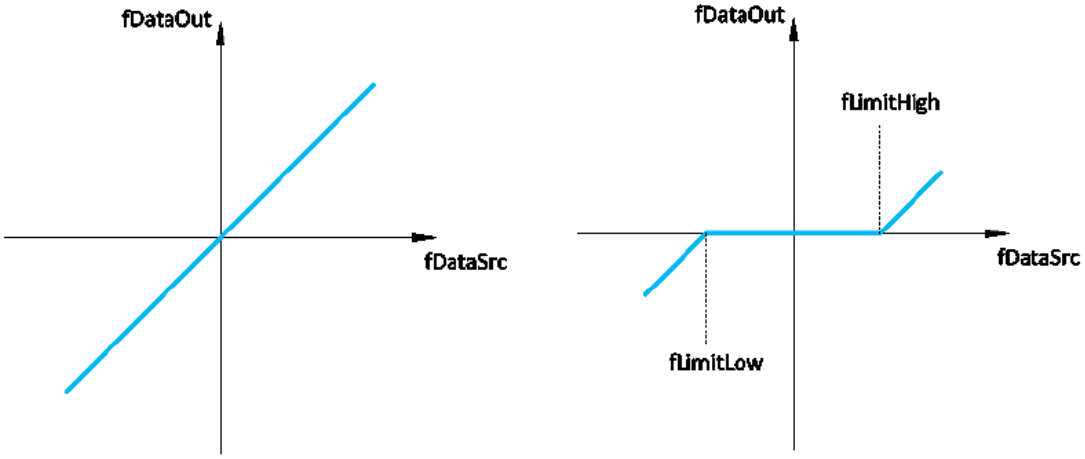
- Instruction format

Instruction	Name	FB/FC	LD Representation	ST Representation
BZAND_TAB	Dead zone control	FC	BZAND_TAB EN ENO fLimitHigh fLimitLow fDataOut fDataSrc	:= BZAND_TAB(fLimitHigh := , fLimitLow := , fDataSrc := , fDataOut =>);

- **Related variables**

Variable

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	fLimitHigh	Dead zone upper limit	Follows data type	0	Dead zone upper limit
	fLimitLow	Dead zone lower limit	Follows data type	0	Dead zone lower limit
	fDataSrc	Source data	Follows data type	0	Input value subject to dead zone control
Output	fDataOut	Source data	Follows data type	-	Output value from the dead zone



Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
fLimitHigh	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
fLimitLow	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
fDataSrc	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
fDataOut	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–

- **Function**

  Controls an output value based on whether the input value is within the specified dead zone range. The dead zone range is defined by fLimitLow and fLimitHigh so that the input value fDataSrc is output to fDataOut outside the dead zone range.

  When fLimitLow > fDataSrc, fDataSrc - fLimitLow => fDataOut;
  when fLimitHigh < fDataSrc, fDataSrc - fLimitHigh => fDataOut;
  when fLimitLow ≤ fDataSrc ≤ fLimitHigh, 0 => fDataOut.

- **Program example**

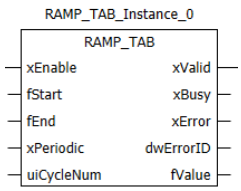
  ST:

	Name	Data type	Address	Value	Prepare value	Comment
1	fLimitHigh	REAL		9		
2	fLimitLow	REAL		1		
3	fDataSrc1	REAL		1		
4	fDataSrc2	REAL		9		
5	fDataSrc3	REAL		11		
6	fDataSrc4	REAL		-1		
7	fDataOut1	REAL		0		
8	fDataOut2	REAL		0		
9	fDataOut3	REAL		2		
10	fDataOut4	REAL		-2		
11	xResult1	BOOL		TRUE		
12	xResult2	BOOL		TRUE		
13	xResult3	BOOL		TRUE		
14	xResult4	BOOL		TRUE		

```
xResult1 TRUE := BZAND_TAB(fLimitHigh := fLimitHigh 9 , fLimitLow := fLimitLow 1 ,
fDataSrc := fDataSrc1 1 , fDataOut => fDataOut1 0 );
xResult2 TRUE := BZAND_TAB(fLimitHigh := fLimitHigh 9 , fLimitLow := fLimitLow 1 ,
fDataSrc := fDataSrc2 9 , fDataOut => fDataOut2 0 );
xResult3 TRUE := BZAND_TAB(fLimitHigh := fLimitHigh 9 , fLimitLow := fLimitLow 1 ,
fDataSrc := fDataSrc3 11 , fDataOut => fDataOut3 2 );
xResult4 TRUE := BZAND_TAB(fLimitHigh := fLimitHigh 9 , fLimitLow := fLimitLow 1 ,
fDataSrc := fDataSrc4 -1 , fDataOut => fDataOut4 -2 );RETURN
```

LD:

	Name	Data type	Address	Value	Prepare value	Comment
1	fLimitHigh	REAL		9		
2	fLimitLow	REAL		1		
3	fDataSrc1	REAL		1		
4	fDataSrc2	REAL		9		
5	fDataSrc3	REAL		11		
6	fDataSrc4	REAL		-1		
7	fDataOut1	REAL		0		
8	fDataOut2	REAL		0		
9	fDataOut3	REAL		2		
10	fDataOut4	REAL		-2		
11	xResult1	BOOL		TRUE		
12	xResult2	BOOL		TRUE		



- **Precautions**
  - If fLimitHigh is less than fLimitLow, the instruction execution fails and returns FALSE, and the output variable remains at its initial value. .
  - The instruction returns TRUE upon successful execution, otherwise returns FALSE.

18.2.10.19 RAMP_TAB

Changes the output value from the minimum to maximum at a specified interval, and vice versa. This instruction aims to perform linear interpolation between two given data entries at a specified time interval, to output intermediate values sequentially based on the scanning time, until the end value is reached.

- Instruction format

Instruction	Name	FB/FC	LD Representation	ST Representation
RAMP_TAB	Ramp instruction	FB		RAMP_TAB_Instance_0(xEnable := , fStart := , fEnd := , xPeriodic := , uiCycleNum := , xValid => , xBusy => , xError => , dwErrorID => , fValue =>);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description

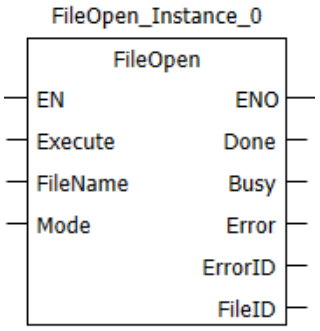
18.2.11.2 Overview

- File operations support the PLC user directory and the SD card, with the following rules:
  - The absolute path of the SD card can be obtained via the SysHC_UDiskPath instruction. When this absolute path is input, the SD card will be operated; otherwise, the user directory of the PLC will be operated by default.
  - "/PLCprogram/" in the SD card is a system directory and is prohibited for user operations. Any attempt to access it will return error code 255.
  - OMUtils library version 1.3.0.0 and above supports PLC path operations. The path in version 1.3.0.0 is not retained after power failure. Therefore, it is recommended to use file operation instructions from OMUtils library version 1.4.0.0 and above.
- Currently, SD-related instructions are triggered by rising edge and executed according to the task cycle schedule. Therefore, to use file read/write, copy, rename, and other operations, it is necessary to set an appropriate task cycle based on the current controller model and file read/write speed; otherwise, the PLC may be abnormal.
- The current SD card does not support hot-swapping. Ensure the SD card is properly inserted and mounted before performing operations.
- If Execute becomes FALSE or the instruction execution time exceeds the task cycle, the instruction continues executing until completion. The value of Done changes to TRUE when processing is completed. Use this to confirm normal completion of processing.
- The PLC program runs under the Linux system; therefore, illegal characters follow Linux rules, which differ from Windows rules.
- All filenames mentioned in this section include absolute paths and are subject to total length restrictions.
- In SD card file operation instructions, file contents are stored as binary streams. To view or modify them on other platforms, use a binary-aware editor (e.g., UltraEdit, hex editor) to prevent unintended content alteration.
- The PLC built-in user directory capacity is 15 MB for EVO400/EVO500 and 1 GB for EVO700.
- The maximum number of opened files is 300. Exceeding this limit when executing the FileOpen instruction returns fault code 1536.
- In simulation mode, please enter the absolute path (case-sensitive): c:\mnt\sdcard\filename.



File operations on the PLC's user directory are supported only when the OMUtils library version is 1.3.0.0 or later.

18.2.11.3 FileOpen

Opens the specified file.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
FileOpen	Open file	FB		FileOpen_Instance_0(Execute := , FileName :=, Mode := , Done => , Busy =>, Error =>, ErrorID => , FileID =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Execute	Enable	Follows data type	FALSE	(Triggered by edges) Execution of the function block switch
	FileName	Specified file name	Max. 200 characters	''	Name of the file to open
	Mode	Open mode	Follows data type	AM_READ	Mode in which to open file
Output	Done	Function block completed state	Follows data type	-	Function block completed state
	Busy	Function block execution flag	Follows data type	-	Function block execution flag
	Error	Function block fault flag	Follows data type	-	Function block fault flag
	ErrorID	Function block fault ID	Follows data type	-	Function block fault ID
	FileID	File ID	Follows data type	-	ID of the opened file

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Execute	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
FileName	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
Mode	See "Function description" for the enumerators for ACCESS_MODE.																			
Done	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Busy	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Error	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
ErrorID	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
FileID	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - Opens the file specified by FileName in the mode specified by Mode.
  - The file ID (FileID) is output, which can be used in the FileRead and FileWrite instructions to specify the file.
  - The data type of Mode is enumerated type _eSEARCH_MODE. The meanings of the enumerators are as follows:

Enumeration Value	Definition
AM_READ	If the file exists in the target path, the file is opened in read-only mode. If the file does not exist, the fault ID 16 is returned.
AM_WRITE	If the file exists in the target path, the file is opened in re-write mode. If the file does not exist, a new file with the write permission is automatically created.
AM_APPEND	If the file exists in the target path, open the file in write-only mode and the content is appended to the end of the file. If the file does not exist, the fault ID 16 is returned.

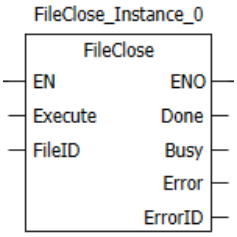
Enumeration Value	Definition
AM_READ_PLUS	If the file exists in the target path, the file is opened in read-write mode. If the file does not exist, the fault ID 16 is returned.
AM_WRITE_PLUS	If the file exists in the target path, the file is opened in re-read-write mode. If the file does not exist, a new file with the read/write permission is automatically created.
AM_APPEND_PLUS	If the file exists in the target path, the file is opened in read-write mode and the content is appended to the end of the file. If the file does not exist, a new file with the read/write permission is automatically created.

- **Program example**

Item	LD	ST
Define variables	VAR FileOpen_Instance_0: FileOpen; xExecute: BOOL; sFileName: STRING[200] := '/test_manual/fileopen.txt'; eMode: ACCESS_MODE := ACCESS_MODE.AM_WRITE_PLUS; xDone: BOOL; xBusy: BOOL; xError: BOOL; wErrorID: WORD; lwFileID: LWORD; END_VAR	
Program		

Item	LD	ST

Operation result



Name	Data type	Address	Value
FileOpen_Instance_0	FileOpen		
xExecute	BOOL		TRUE
sFileName	STRING[200]		'/test_manual/fileopen.txt'
eMode	ACCESS_MODE		AM_WRITE_PLUS
xDone	BOOL		TRUE
xBusy	BOOL		FALSE
xError	BOOL		FALSE
wErrorID	WORD		0
lwFileID	LWORD		3011511440

- **Precautions**
  - Before using this instruction, please read the 18.2.11.2 Overview to avoid improper operations.
  - To use instructions such as FileSeek, FileRead, FileWrite, FileGets, and FilePuts that require a FileID input, execute this instruction first to obtain the corresponding FileID.
  - After using the file opened by this instruction, execute the FileClose instruction to close the file.
  - After this instruction is completed, the file ID is output to FileID. The value of Done changes to TRUE.
  - If the SD card is removed while a file is open, the file remains in an open state. However, when the SD card is reinserted, the file cannot be read from or written to. To read and write the file, re-open the file.
  - An exception occurs and Error becomes TRUE in the following cases:
    - If the SD card is write-protected and the file is opened in a mode other than read-only (AM_READ), ErrorID is 16.
    - If the value of Mode is AM_READ, AM_APPEND, or AM_READ_PLUS, and the file specified by FileName does not exist, ErrorID is 16.
    - If FileName is invalid and the file is opened in a mode other than read-only (AM_READ), ErrorID is 16.
    - If the file is not closed, and the instruction is executed again to open a file with the same name, ErrorID is 1.
    - If the SD card is not successfully mounted, data stored on the card cannot be accessed, and ErrorID is 2.
    - If multiple threads execute the FileOpen instruction simultaneously, ErrorID is 1539.

18.2.11.4 FileClose

Closes the specified file.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
FileClose	Close file	FB		FileClose_Instance_0(Execute := , FileID := , Done => , Busy =>, Error =>, ErrorID =>);

- **Related variables**

- **Function**

  Closes the file specified by FileID

- **Program example**

  Note: The ID corresponding to the variable lwFileID is generated by the FileOpen instruction.

Item	LD	ST
Define variables	VAR FileOpen_Instance_0: FileOpen; xFileName: STRING[242] := '/test_manual/fileopen.txt'; eMode: ACCESS_MODE := ACCESS_MODE.AM_WRITE_PLUS; FileClose_Instance_0: FileClose; xExecute: BOOL; lwFileID: LWORD; xDone: BOOL; xBusy: BOOL; xError: BOOL; wErrorID: WORD; END_VAR	
Program		FileClose_Instance_0(Execute TRUE := xExecute TRUE, FileID 3008365680 := lwFileID 3008365680, Done TRUE => xDone TRUE, Busy FALSE => xBusy FALSE, Error FALSE => xError FALSE, ErrorID 0 => wErrorID 0);RETURN

Item	LD	ST

Operation result

	Name	Data type	Address	Value
1	FileOpen_Instance_0	FileOpen		
2	xFileName	STRING[242]		'/test_manual/fileopen.txt'
3	eMode	ACCESS_MODE		AM_WRITE_PLUS
4	FileClose_Instance_0	FileClose		
5	xExecute	BOOL		TRUE
6	lwFileID	LWORD		3008365680
7	xDone	BOOL		TRUE
8	xBusy	BOOL		FALSE
9	xError	BOOL		FALSE
10	wErrorID	WORD		0

- **Precautions**
  - Before using this instruction, please read the 18.2.11.2 Overview to avoid improper operations.
  - Do not execute this instruction on a file for multiple consecutive times; otherwise, the PLC may fail to run and even break down.
  - Execute the FileOpen instruction in advance to obtain the value for FileID.
  - After using the file opened by the FileOpen instruction, execute this instruction to close the file, otherwise, the result will be unexpected. If the SD card is removed while a file is open, the file remains in an open state. However, when the SD card is reinserted, the file cannot be read from or written to. To read and write the file, re-open the file.
  - An exception occurs and Error becomes TRUE in the following cases:
    - If the file specified by FileID does not exist, ErrorID is 1.
    - If a file opened by the FileOpen instruction is closed again by FileClose after already being closed, ErrorID is 1538.
    - If the input FileID is invalid (less than 0 or greater than 300), ErrorID is 1537.
    - If multiple threads execute the FileClose instruction simultaneously, ErrorID is 1539.

18.2.11.5 FileSeek

Sets a file position indicator in the specified file.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
FileSeek	Seek file	FB		FileSeek_Instance_0(Execute := , FileID := , Offset := , Origin := , Done => , Busy =>, Error =>, ErrorID =>);

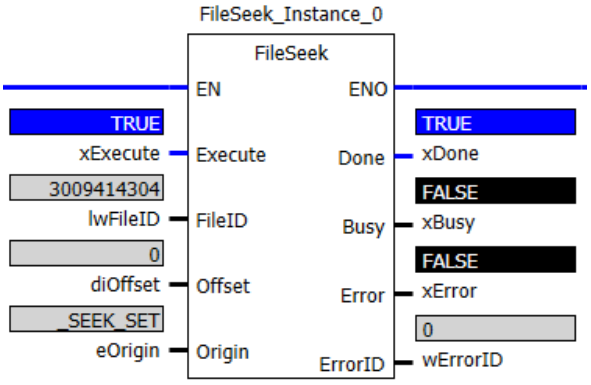
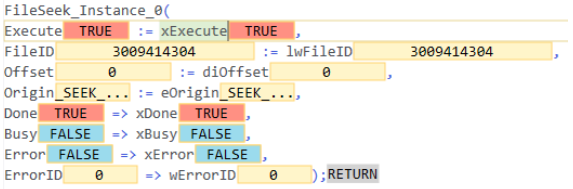
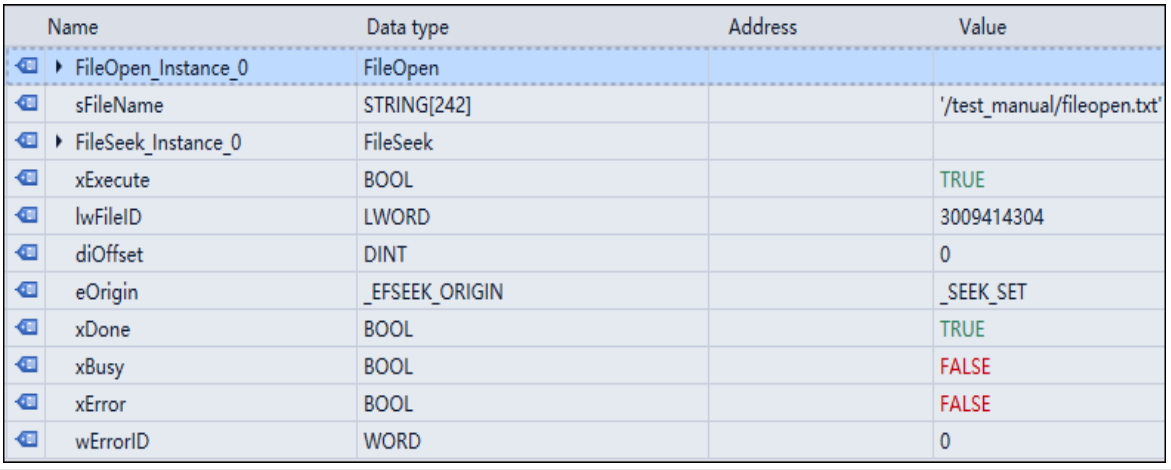
ErrorID	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - This instruction sets a file position indicator in the file specified by FileID. A file position indicator is the position in a file at which to start reading or writing when an instruction such as the FileRead or FileWrite instruction is executed. For example, to read from the beginning of a file, set a file position indicator at the beginning of the file with the FileSeek instruction, and then execute the FileRead instruction.
  - The file position indicator is set at offset Offset from reference position Origin. The data type of Origin is enumerated type _eFSEEK_ORIGIN. The meanings of the enumeration values are as follows in the table below.

Enumeration Value	Definition
_SEEK_SET	Beginning of the file
_SEEK_CUR	Current position of the file position indicator







Enumeration Value	Definition
_SEEK_END	End of the file

- **Program example**

  Note: The ID corresponding to the variable lwFileID is generated by the FileOpen instruction.

Item	LD	ST

Define variables	VAR
	FileOpen_Instance_0: FileOpen;
	sFileName: STRING[242] := '/test_manual/fileopen.txt';
	FileSeek_Instance_0: FileSeek;

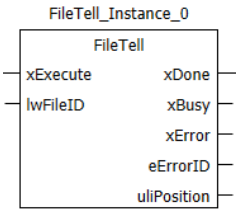
	wErrorID: WORD;
	END_VAR	

Program		
Operation result		

Name	Data type	Address	Value
FileOpen_Instance_0	FileOpen		
sFileName	STRING[242]		'/test_manual/fileopen.txt'
FileSeek_Instance_0	FileSeek		
xExecute	BOOL		TRUE
lwFileID	LWORD		3009414304
diOffset	DINT		0
eOrigin	_EFSEEK_ORIGIN		_SEEK_SET
xDone	BOOL		TRUE
xBusy	BOOL		FALSE
xError	BOOL		FALSE
wErrorID	WORD		0



- **Precautions**
  - Before using this instruction, please read the 18.2.11.2 Overview to avoid improper operations.
  - Execute the FileOpen instruction in advance to obtain the value for FileID.
  - An exception occurs and Error becomes TRUE in the following cases:
    - If the file specified by FileID does not exist, ErrorID is 1.

- If the file position indicator specified by Origin and Offset is located before the start of the file, ErrorID is 1.
- If the input FileID is invalid (less than 0 or greater than 300), ErrorID is 1537.
- If a file opened by the FileOpen instruction is used by FileSeek after already being closed by FileClose, ErrorID is 1538.

18.2.11.6 FileTell

Gets the file position indicator in the specified file.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
FileTell	Acquire position of file indicator	FB		FileTell_Instance_0(xExecute := , lwFileID := , xDone => , xBusy => , xError => , eErrorID => , uliPosition =>);

xBusy	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
xError	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
eErrorID	See "Function description" for the enumerators for HOU_ERROR.																			
uliPosition	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - This instruction gets the position of the file position indicator in the file specified by lwFileID. A file position indicator is the position in a file at which to start reading or writing when an instruction such as the FileRead or FileWrite instruction is executed.
  - The file ID lwFileID is obtained via the FileOpen instruction. The file position indicator is set in the specified file using the FileSeek instruction, and then obtained using FileTell. Then, use FileClose instruction to close the file.
- **Program example**

Note: The ID corresponding to the variable lwFileID is generated by the FileOpen instruction.

Item	LD	ST
Define variables	VAR FileOpen_Instance_0: FileOpen; sFileName: STRING[200] := '/test_manual/filetell.txt'; eMode: ACCESS_MODE := ACCESS_MODE.AM_WRITE_PLUS; FileTell_Instance_0: FileTell; xExecute: BOOL; lwFileID: LWORD; xDone: BOOL; xBusy: BOOL; xError: BOOL; eErrorID: HOU_ERROR; uliPosition: ULINT; END_VAR

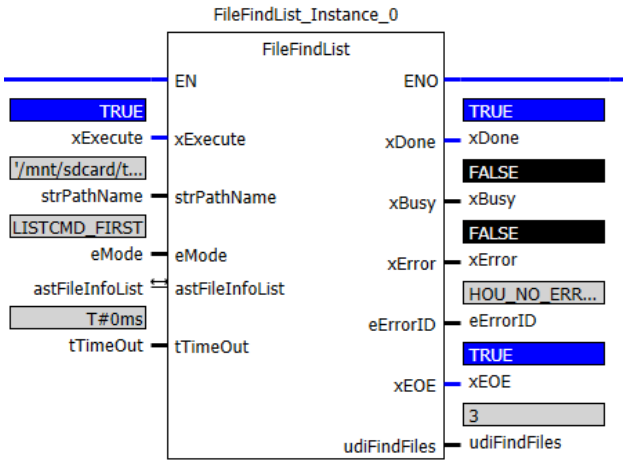
udiFindFiles	–	–	–	–	–	–	–	√	_	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - This instruction queries the files or subdirectories with names similar to the specified names in the directory.
  - The input parameter strPathName specifies the target directory and the name of the entry to be searched for. The file name to be searched for supports two types of wildcards (* and ?).
  - The input parameter eMode, whose data type is the FILELIST_MODE enumerator, specifies whether the search is conducted for the first time or in sequential mode. It is used to navigate in the entry list. The meanings of the enumerators are as follows.

Enumeration Value	Definition
LISTCMD_FIRST	It means to search for the first time. The number of files found is determined by the size of the astFileInfoList array and the number of similar files in the directory.
LISTCMD_NEXT	It means to search in sequential mode. After the first search is completed, it is called multiple times to find all similar files. The number of files found is determined by the size of the astFileInfoList array and the number of similar files in the directory.
LISTCMD ABORT	It means to abort the search and close the related directory handle.

  - The input/output parameter astFileInfoList (array of structures) stores the information of the files found. The meanings of the FILEINFO structure are as follows.



Structure Member	Data Type	Description
strFileName	STRING[255]	File or directory name
xDirectory	BOOL	File or directory

Structure Member	Data Type	Description
File size	ULINT	File size, in bytes
dtCreationTime	DATE_AND_TIME	Creation time of the file or directory
dtLastAccessTime	DATE_AND_TIME	Last access time of the file or directory
dtLastModificationTime	DATE_AND_TIME	Last write time of the file or directory

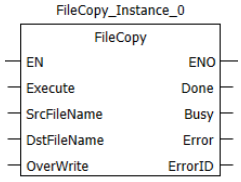
xEOE	BOOL		TRUE
udiFindFiles	UDINT		3

- **Precautions**
  - Execution of this instruction is continued until completion even if the value of xExecute changes to FALSE or the execution time exceeds the task cycle. Use the value of xDone to determine whether the instruction is completed, which becomes TRUE upon completion.
  - To search for the directory specified by strPathName, the user must have the access to the directory and its subdirectories.
  - The directory name strPathName must be in English and case-sensitive. Any character except wildcards (* and ?) is treated as valid data. Wildcards are only supported at the beginning or end of the filename, such as A*, *A, or *A*.

- When the found file name specified by strPathName is invalid, the value of xError is TRUE.
- The file name specified by strPathName contains the path separators (/), and each directory contains two entries "." and "..", respectively indicating the current directory and the parent directory.
- xEOE indicates whether all similar files in the specified directory are found. The function block may need to be triggered multiple times to find all similar files in the specified folder. The search is completed only when xEOE is TRUE or when the search is prematurely terminated by setting eMode to LISTCMD_ABORT. If the required file or directory is found in the program, xEOE is FALSE. In this case, the value of the input parameter eCmd must be changed to LISTCMD_ABORT and the function block must be triggered again to release all internal resources.
- bEOE turns to TRUE when the first attempt is made to read a non-existent entry.
- tTimeOut specifies the timeout period for execution of the function block. When it is set to T#0S, the timeout function is not enabled.
- A new search can begin only after the search completion signal xDone is set.

- **Fault ID**



eErrorID	Value	Note
HOU_NO_ERROR	0	No fault.

HOU_OVERBUFFERSIZE_ERROR	1030	Data area too small
HOU_SAMEFILENAME_ERROR	1403	File with the same name existing

18.2.11.8 FileCopy

Copies the specified file.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
FileCopy	Copy file	FB		FileCopy_Instance_0(Execute := , SrcFileName := , DstFileName := , OverWrite := , Done => , Busy =>, Error =>, ErrorID =>);

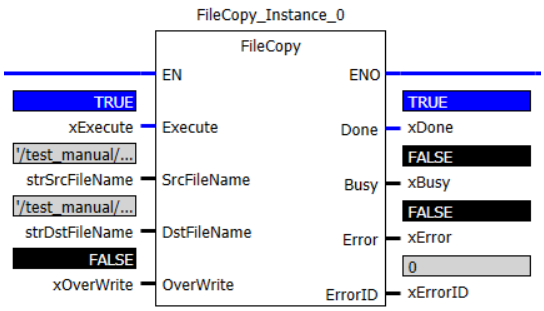
- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Execute	Enable	Follows data type	FALSE	Edge-triggered switch to execute the function block
	SrcFileName	Name of source file to copy	Max. 200 characters	''	Name of source file to copy
	DstFileName	Name of destination file to paste	Max. 200 characters	''	Name of destination file to paste
	OverWrite	Overwrite enable	Follows data type	FALSE	TRUE: Enable overwrite FALSE: Prohibit overwrite
Output	Done	Function block completed state	Follows data type	-	Function block completed state
	Busy	Function block execution flag	Follows data type	-	Function block execution flag
	Error	Function block fault flag	Follows data type	-	Function block fault flag
	ErrorID	Function block fault ID	Follows data type	-	Function block fault ID

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Execute	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
SrcFile Name	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
DstFile Name	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
OverWrite	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Done	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Busy	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Error	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
ErrorID	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–



- **Function**
  - This instruction copies the source file specified by SrcFileName to DstFileName.
  - If there is no file with the same name as DstFileName, a new file is created.
  - If a file with the same name as DstFileName already exists, the following is performed depending on the value of OverWrite, as shown below.

Value of OverWrite	Operation
TRUE	The existing file is overwritten
FALSE	The existing file is not overwritten and a fault error occurs

- **Program example**

<table>
<tr><th>Item</th><th>LD</th><th>ST</th></tr>
<tr><td>Define variables</td><td colspan="2">

```
VAR
    FileCopy_Instance_0: FileCopy;
    xExecute: BOOL;
    strSrcFileName: STRING[242] := '/test_manual/test1.txt';
    strDstFileName: STRING[242] := '/test_manual/test1_copy.txt';
    xOverWrite: BOOL := FALSE;
    xDone: BOOL;
    xBusy: BOOL;
    xError: BOOL;
    xErrorID: WORD;
END_VAR
```

</td></tr>
<tr><td>Program</td><td>

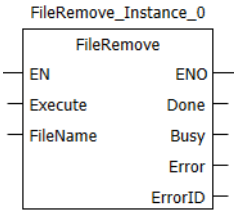
</td><td>

```
FileCopy_Instance_0(
Execute := xExecute,
SrcFileName := strSrcFileName,
DstFileName := strDstFileName,
OverWrite := xOverWrite,
Done => xDone,
Busy => xBusy,
Error => xError,
ErrorID => xErrorID);RETURN
```

</td></tr>
<tr><td>Operation result</td><td colspan="2">

	Name	Data type	Address	Value
1	FileCopy_Instance_0	FileCopy		
2	xExecute	BOOL		TRUE
3	strSrcFileName	STRING[242]		'/test_manual/test1.txt'
4	strDstFileName	STRING[242]		'/test_manual/test1_copy.txt'
5	xOverWrite	BOOL		FALSE
6	xDone	BOOL		TRUE
7	xBusy	BOOL		FALSE
8	xError	BOOL		FALSE
9	xErrorID	WORD		0

</td></tr>
</table>



- **Precautions**
  - Before using this instruction, please read the 18.2.11.2 Overview to avoid improper operations.
  - If the SD card is removed while a file is open, the file remains in an open state. However, when the SD card is reinserted, the file cannot be read from or written to. To read and write the file, re-open the file.
  - If there is insufficient space available on the SD card, a new file can be created, but the data in the copied file will be lost, compared to the original.
  - An exception occurs and Error becomes TRUE in the following cases:
    - If the SD card is write-protected, ErrorID is 1.
    - If DstFileName is empty and OverWrite is FALSE, ErrorID is 1403; if DstFileName is empty and OverWrite is TRUE, ErrorID is 1.
    - If SrcFileName is empty, ErrorID is 1.
    - If the file specified by SrcFileName does not exist, ErrorID is 1403.
    - If SrcFileName is an invalid file name, ErrorID is 1.

- If DstFileName is an invalid file name and OverWrite is FALSE, ErrorID is 1403; if DstFileName is an invalid file name and OverWrite is TRUE, ErrorID is 1.
- If a file with the name specified by DstFileName exits and OverWrite is FALSE, ErrorID is 1403.
- If the SD card is not successfully mounted, data stored on the card cannot be accessed, and ErrorID is 2.
- If multiple threads execute the FileCopy instruction simultaneously, execution is queued (threads themselves are not blocked). If the operation does not complete within 10 task cycles, ErrorID is 1540.
- If the FileCopy instruction is executed after user directory size initialization fails, ErrorID is 1543.

18.2.11.9 FileRemove

Deletes the specified file.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
FileRemove	Delete file	FB		FileRemove_Instance_0(Execute := , FileName :=, Done =>, Busy =>, Error =>, ErrorID =>);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Execute	Enable	Follows data type	FALSE	(Triggered by edges) Execution of the function block switch
	FileName	Specified file name	Max. 200 characters	''	Name of the file to delete
Output	Done	Function block completed state	Follows data type	-	Function block completed state
	Busy	Function block execution flag	Follows data type	-	Function block execution flag

Input/Output	Variable	Name	Valid Range	Default Value	Description
	Error	Function block fault flag	Follows data type	-	Function block fault flag
	ErrorID	Function block fault ID	Follows data type	-	Function block fault ID

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Execute	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
FileName	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
Done	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

<tr><td>5</td><td></td><td>xBusy</td><td>BOOL</td><td></td><td>FALSE</td></tr>
<tr><td>6</td><td></td><td>xError</td><td>BOOL</td><td></td><td>FALSE</td></tr>
<tr><td>7</td><td></td><td>xErrorID</td><td>WORD</td><td></td><td>0</td></tr>
</table>
</td></tr>
</table>

- **Precautions**
  - Before using this instruction, please read the 18.2.11.2 Overview to avoid improper operations.
  - If the SD card is removed while a file is open, the file remains in an open state. However, when the SD card is reinserted, the file cannot be read from or written to. To read and write the file, re-open the file.
  - An exception occurs and Error becomes TRUE in the following cases:
    - If the SD card is write-protected, ErrorID is 1.
    - If FileName is an empty name, ErrorID is 1.
    - If the file specified by FileName does not exist, ErrorID is 16.
    - If the SD card is not successfully mounted, data stored on the card cannot be accessed, and ErrorID is 2.

18.2.11.10 FileRename

Renames of the specified file or directory.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
FileRename	Change file name	FB		FileRename_Instance_0(Execute := , FileName :=, NewName := , OverWrite := , Done => , Busy =>, Error =>, ErrorID =>);

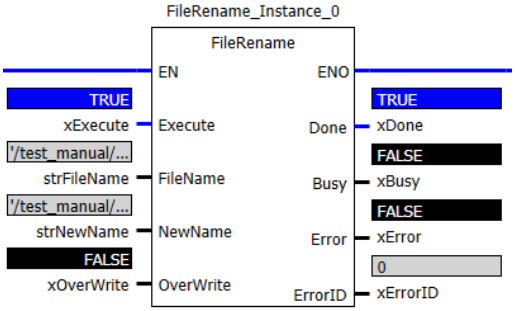
- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Execute	Enable	Follows data type	FALSE	(Triggered by edges) Execution of the function block switch
	FileName	Original file name	Max. 200 characters	''	Original file name
	NewName	New file name	Max. 200 characters	''	New file name
	OverWrite	Overwrite enable	Follows data type	FALSE	TRUE: Enable overwrite FALSE: Prohibit overwrite
Output	Done	Function block completed state	Follows data type	-	Function block completed state
	Busy	Function block execution flag	Follows data type	-	Function block execution flag
	Error	Function block fault flag	Follows data type	-	Function block fault flag
	ErrorID	Function block fault ID	Follows data type	-	Function block fault ID

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Execute	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
FileName	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
NewName	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
OverWrite	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Done	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Busy	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Error	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
ErrorID	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–



- **Function**
  - This instruction changes the original name of the file or directory specified by FileName to new file name specified by NewName.
  - If there is no file with the same name as NewName, a new file is created.
  - If a file with the same name as NewName already exists, the following is performed depending on the value of OverWrite, as shown below.

Value of OverWrite	Operation
TRUE	The file or directory is overwritten.
FALSE	The existing file is not overwritten and a fault error occurs.

- **Program example**

<table>
<tr><th>Item</th><th>LD</th><th>ST</th></tr>
<tr><td>Define variables</td><td colspan="2">

```
VAR
    FileRename_Instance_0: FileRename;
    xExecute: BOOL;
    strFileName: STRING[242] := '/test_manual/test1.txt';
    strNewName: STRING[242] := '/test_manual/test1_rename.txt';
    xOverWrite: BOOL;
    xDone: BOOL;
    xBusy: BOOL;
    xError: BOOL;
    xErrorID: WORD;
END_VAR
```

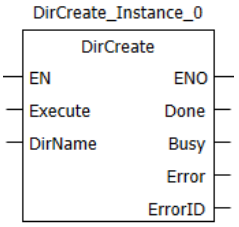
</td></tr>
<tr><td>Program</td><td>
</td><td>

```
FileRename_Instance_0(
Execute TRUE := xExecute TRUE,
FileName'/test_manual/test1.t... := strFileName'/test_manual/test1.t...,
NewName'/test_manual/test1_rename.t... := strNewName'/test_manual/test1_rename.t...,
OverWrite FALSE := xOverWrite FALSE,
Done TRUE => xDone TRUE,
Busy FALSE => xBusy FALSE,
Error FALSE => xError FALSE,
ErrorID 0 => xErrorID 0 );RETURN
```

</td></tr>
<tr><td>Operation result</td><td colspan="2">

	Name	Data type	Address	Value
1	FileRename_Instance_0	FileRename		
2	xExecute	BOOL		TRUE
3	strFileName	STRING[242]		'/test_manual/test1.txt'
4	strNewName	STRING[242]		'/test_manual/test1_rename.txt'
5	xOverWrite	BOOL		FALSE
6	xDone	BOOL		TRUE
7	xBusy	BOOL		FALSE
8	xError	BOOL		FALSE
9	xErrorID	WORD		0

</td></tr>
</table>



- **Precautions**
  - Before using this instruction, please read the 18.2.11.2 Overview to avoid improper operations.
  - If the directories are different for FileName and NewName, the file is moved to the directory specified by NewName. If the SD card is removed while a file is open, the file remains in an open state. However, when the SD card is reinserted, the file cannot be read from or written to. To read and write the file, re-open the file.
  - If a read-only file with the name NewName already exists and OverWrite is TRUE, it may cause a PLC exception.
  - An exception occurs and Error becomes TRUE in the following cases:
    - If the SD card is write-protected, ErrorID is 1.
    - If NewName is empty, ErrorID is 1403.
    - If FileName is empty or an invalid filename, ErrorID is 1.
    - If the file specified by FileName does not exist, ErrorID is 1403.

- If NewName is an invalid filename, ErrorID is 1403, which may cause a PLC exception.
- If a file with the name NewName already exits and OverWrite is FALSE, ErrorID is 1403.
- If NewName is the same as FileName and OverWrite is TRUE, ErrorID is 1403.
- If the directory or file specified by FileName and NewName both exist but are of different types, ErrorID is 1.
- If NewName contains both a different folder and a file compared to FileName, and the target folder does not exist, ErrorID is 1. For example, when FileName is "folder1/folder2/file01" and NewName is "folder1/folder3/file01_rename", but folder3 does not exist, the instruction fails to create a new folder and a new file simultaneously.
- If the SD card is not successfully mounted, data stored on the card cannot be accessed, and ErrorID is 2.

18.2.11.11 DirCreate

Creates a directory with the specified name.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
DirCreate	Create directory	FB		DirCreate_Instance_0(Execute := , DirName := , Done => , Busy =>, Error =>, ErrorID =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Execute	Enable	Follows data type	FALSE	(Triggered by edges) Execution of the function block switch
	DirName	Specified directory name	Max. 200 characters	''	Name of the directory to create
Output	Done	Function block completed state	Follows data type	-	Function block completed state

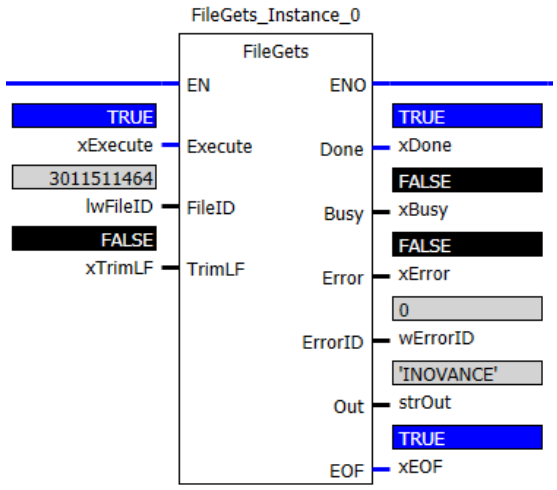
EOF	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - This instruction reads a string of one line from the file position indicator in the file specified by FileID.
  - The file position indicator is set at the desired location in advance with the FileSeek instruction.
  - Line endings are determined by a line feed code. The text string that is read is written to read the text string Out.

- Line endings are automatically identified from three types: CR (\r), LF (\n), and CR + LF (\r\n). If line feed designation TrimLF is TRUE, the line feed code is deleted from the text string before it is written to Out.
- If data is read to the end of the file, EOF (end of file) changes to TRUE.



- **Program example**

  Note: The ID corresponding to the variable lwFileID is generated by the FileOpen instruction.

- **Precautions**
  - Before using this instruction, please read the 18.2.11.2 Overview to avoid improper operations.
  - If the length of the one-line text string exceeds 1985 bytes, the first 1985 bytes of the text string and the NULL text string at the end are stored in Out. Execute the FileOpen instruction in advance to obtain the value for FileID.
  - An exception occurs under the following conditions. The value of Error is TRUE.
    - If the file specified by FileID does not exist, ErrorID is 1.
    - If the file specified by FileID is not opened in a reading mode, ErrorID is 1.
    - If the input FileID is invalid (less than 0 or greater than 300), ErrorID is 1537.
    - If a file opened by the FileOpen instruction is used by FileGets after already being closed by FileClose, ErrorID is 1538.

18.2.11.13.2 FilePuts

Writes a string to the specified file.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
FilePuts	Put text string	FB		FilePuts_Instance_0(Execute := , FileID := , In := , Done => , Busy =>, Error =>, ErrorID =>);

- **Related variables**

Variable

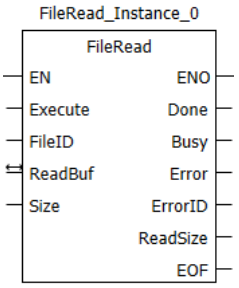
</table>



- **Precautions**
  - Before using this instruction, please read the 18.2.11.2 Overview to avoid improper operations.
  - Execute the FileOpen instruction in advance to obtain the value for FileID.
  - An exception occurs and Error becomes TRUE in the following cases:
    - If there is insufficient space available on the SD card, ErrorID is 41.
    - If the file specified by FileID does not exist, ErrorID is 1.
    - If In is empty, ErrorID is 2.
    - If the file specified by FileID is not opened in a writing mode, ErrorID is 1.

- If the input FileID is invalid (less than 0 or greater than 300), ErrorID is 1537.
- If a file opened by the FileOpen instruction is used by FilePuts after already being closed by FileClose, ErrorID is 1538.
- If multiple threads execute the DirRemove instruction simultaneously, execution is queued (threads themselves are not blocked). If the operation does not complete within 10 task cycles, ErrorID is 1540.
- If the FilePuts instruction is executed after user directory size initialization fails, ErrorID is 1543.

18.2.11.13.3 FileRead

Reads data from the specified file.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
FileRead	Read file	FB		FileRead_Instance_0(Execute := , FileID := , ReadBuf := , Size := , Done => , Busy =>, Error =>, ErrorID => , ReadSize => , EOF =>);

- **Related variables**

Variable

ErrorID	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Read Size	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
EOF	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - This instruction reads data from the file position indicator in the file specified by FileID, and then stores the data in read buffer ReadBuf[ ].
  - The file position indicator is set at the desired location in advance with the FileSeek instruction.
  - The amount of data that is read is the size of the data type of ReadBuf[ ] times Size.
  - The number of elements actually read is stored in ReadSize. In general, values of Size and ReadSize are the same. If the amount of data from the file position indicator to the end of the file is less than the value of Size, no error occurs and the data to the end of the file is stored in ReadBuf[ ]. If that occurs, the value of ReadSize is less than the value of Size.
  - When reading to the end of the file, EOF becomes TRUE; if not reading to the end, EOF is FALSE.
- **Program example**

  Note: The ID corresponding to the variable lwFileID is generated by the FileOpen instruction.

<table>
<tr><th>Item</th><th>LD</th><th>ST</th></tr>

</td></tr>
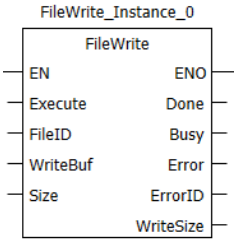
</table>



- **Precautions**
  - Before using this instruction, please read the 18.2.11.2 Overview to avoid improper operations.
  - If the data is read to the end of the file and the size of the data is not evenly divisible by the size of the data type of ReadBuf[ ], the data that is insufficient for the data size of ReadBuf[ ] is discarded. The file position indicator advances to the end of the file, and the value of EOF changes to TRUE.
  - If the value of Size exceeds the ReadBuf[ ] array, a program fault occurs, Error becomes TRUE, and ErrorID is 1030. The elements in ReadBuf[ ] retain their values from before executing this instruction.
  - Execute the FileOpen instruction in advance to obtain the value for FileID.

- If ReadBuf[ ] is an array of structures, adjustment areas between members may be inserted depending on the composition.
- An exception occurs and Error becomes TRUE in the following cases:
  - If the file specified by FileID does not exist, ErrorID is 1.
  - If Size is not 0 and the file specified by FileID is not opened in a reading mode, ErrorID is 1.
  - If the input FileID is invalid (less than 0 or greater than 300), ErrorID is 1537.
  - If a file opened by the FileOpen instruction is used by FileRead after already being closed by FileClose, ErrorID is 1538.

18.2.11.13.4 FileWrite

Writes the data to the specified file.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
FileWrite	Write file	FB		FileWrite_Instance_0(Execute := , FileID := , WriteBuf := , Size := , Done => , Busy =>, Error =>, ErrorID => , WriteSize =>);

- **Function**

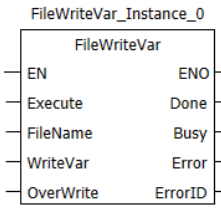
  This instruction reads variable data from the file specified by FileName in binary format and assigns the read data to the position variable specified by ReadVar.

- **Program example**

Item	LD	ST
Define variables	VAR FileReadVar_Instance_0: FileReadVar; xExecute: BOOL; strFileName: STRING[242] := '/test_manual/FileWriteVar.txt'; arrbyReadVar: ARRAY[1..5] OF BYTE; xDone: BOOL; xBusy: BOOL; xError: BOOL; wErrorID: WORD; END_VAR	

<table>
<tr><th>Item</th><th>LD</th><th>ST</th></tr>
<tr><td>Program</td><td>



</td></tr>
<tr><td>Operation result</td><td colspan="2">
</td></tr>
</table>

- **Precautions**
  - Before using this instruction, please read the 18.2.11.2 Overview to avoid improper operations.
  - If the size of the specified file is greater than that of ReadVar, no error occurs and only the data of the size of ReadVar is read. If the size of the specified file is less than that of ReadVar, no error occurs and only the data of the size of the specified file is read. The remaining area in ReadVar retains the values used before execution of this instruction. If ReadVar is a structure, adjustment areas between members may be inserted depending on the composition.
  - An exception occurs and Error becomes TRUE in the following cases:
    - If FileName is empty or an invalid filename, ErrorID is 1.
    - If the file specified by FileName does not exist, ErrorID is 16.
    - If the SD card is not successfully mounted, data stored on the card cannot be accessed, and ErrorID is 2.
    - If multiple threads execute the FileWriteVar instruction simultaneously, execution is queued (threads themselves are not blocked). If the operation does not complete within 10 task cycles, ErrorID is 1540.
    - If the FileWriteVar instruction is executed after user directory size initialization fails, ErrorID is 1543.

18.2.11.13.6 FileWriteVar

Writes the value of a variable to the specified file in binary format.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
FileWriteVar	File write variable	FB		FileWriteVar_Instance_0(Execute := , FileName :=, WriteVar := , OverWrite := , Done => , Busy =>, Error =>, ErrorID =>);

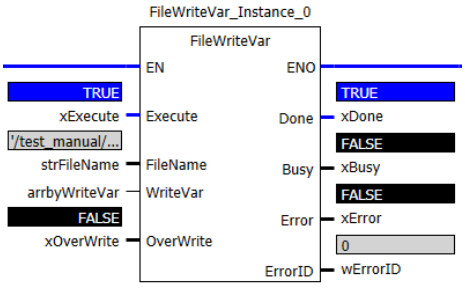
- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Execute	Enable	Follows data type	FALSE	(Triggered by edges) Execution of the function block switch
	FileName	Specified file name	Max. 200 characters	''	Name of the file to which to write variable data
	WriteVar	Specified variable	Follows data type	-	Variable to write
	OverWrite	Overwrite enable	Follows data type	FALSE	TRUE: Enable overwrite FALSE: Prohibit overwrite
Output	Done	Function block completed state	Follows data type	-	Function block completed state
	Busy	Function block execution flag	Follows data type	-	Function block execution flag
	Error	Function block fault flag	Follows data type	-	Function block fault flag
	ErrorID	Function block fault ID	Follows data type	-	Function block fault ID

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Execute	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
FileName	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
WriteVar	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
	An enumeration, an array, an array element, a structure, or a structure member can also be specified.																			
OverWrite	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Done	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Busy	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Error	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
ErrorID	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–



- **Function**
  - This instruction writes the value of variable WriteVar to the file specified by FileName in binary format.
  - If there is no file with the same name as FileName, a new file is created.
  - If a file with the same name as FileName already exists, the following is performed depending on the value of OverWrite, as shown below.

Value of OverWrite	Operation
TRUE	The file is overwritten.
FALSE	The file is not overwritten and an error occurs.

- **Program example**

<table>
<tr><th>Item</th><th>LD</th><th>ST</th></tr>

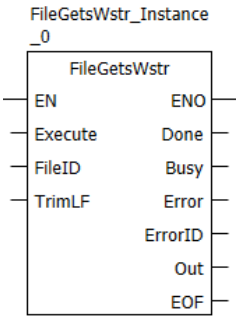
14	wErrorID	WORD		0

</td></tr>
</table>

- **Notes**
  - Before using this instruction, please read the 18.2.11.2 Overview to avoid improper operations.
  - If WriteVar is a structure, adjustment areas between members may be inserted depending on the composition.
  - An exception occurs under the following conditions. The value of Error is TRUE.
    - If the SD card is write-protected, ErrorID is 1.
    - If there is insufficient space available on the SD card, ErrorID is 41.
    - If FileName is empty and OverWrite is FALSE, ErrorID is 50; if FileName is empty and OverWrite is TRUE, ErrorID is 1.
    - If FileName is an invalid file name and OverWrite is FALSE, ErrorID is 50; if FileName is an invalid file name and OverWrite is TRUE, ErrorID is 1.
    - If a file with the name specified by FileName exits and OverWrite is FALSE, ErrorID is 50.



- If a file with the name FileName already exists and the file is read-only, ErrorID is 50.
- If the SD card is not successfully mounted, data stored on the card cannot be accessed, and ErrorID is 2.
- If multiple threads execute the FileWriteVar instruction simultaneously, execution is queued (threads themselves are not blocked). If the operation does not complete within 10 task cycles, ErrorID is 1540.
- If the FileWriteVar instruction is executed after user directory size initialization fails, ErrorID is 1543.

18.2.11.14 File Read/Write (Wstring Supported)

18.2.11.14.1 FileGetsWstr

Reads a string of one line from the specified file.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
FileGetsWstr	Get text string	FB		FileGetsWstr_Instance_0(Execute := , FileID := , TrimLF := , Done => , Busy =>, Error =>, ErrorID => , Out => , EOF =>);

- **Related variables**

Done	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Busy	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Error	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
ErrorID	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
EOF	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - This instruction reads a string of one line from the file position indicator in the file specified by FileID.
  - The file position indicator is set at the desired location in advance with the FileSeek instruction.
  - Line endings are determined by a line feed code. The text string that is read is written to read the text string Out.
  - Line endings are automatically identified from three types: CR (\r), LF (\n), and CR + LF (\r\n). If line feed designation TrimLF is TRUE, the line feed code is deleted from the text string before it is written to Out.
  - If data is read to the end of the file, EOF (end of file) changes to TRUE.
- **Program example**

  Note: The ID corresponding to the variable lwFileID is generated by the FileOpen instruction.

<table>
<tr><th>Item</th><th>LD</th><th>ST</th></tr>

</td></tr>
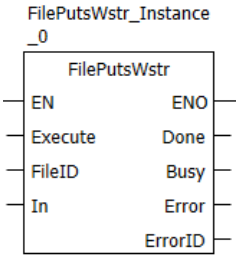
</table>



- **Precautions**
  - Before using this instruction, please read the 18.2.11.2 Overview to avoid improper operations.
  - If the length of the one-line text string exceeds 1985 bytes, the first 1985 bytes of the text string and the NULL text string at the end are stored in Out. Execute the FileOpen instruction in advance to obtain the value for FileID.
  - An exception occurs under the following conditions. The value of Error is TRUE.
    - If the file specified by FileID does not exist, ErrorID is 1.
    - If the file specified by FileID is not opened in a reading mode, ErrorID is 1.

- If the input FileID is invalid (less than 0 or greater than 300), ErrorID is 1537.
- If a file opened by the FileOpen instruction is used by FileGetsWstr after already being closed by FileClose, ErrorID is 1538.

18.2.11.14.2 FilePutsWstr

Writes a string to the specified file.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
FilePutsWstr	Input text string	FB		FilePutsWstr_Instance_0(Execute := , FileID := , In := , Done => , Busy =>, Error =>, ErrorID =>);

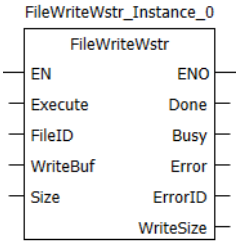
EOF	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - This instruction reads data from the file position indicator in the file specified by FileID, and then stores the data in read buffer ReadBuf[ ].
  - The file position indicator is set at the desired location in advance with the FileSeek instruction.
  - The amount of data that is read is the size of the data type of ReadBuf[ ] times Size.
  - The number of elements actually read is stored in ReadSize. In general, values of Size and ReadSize are the same. If the amount of data from the file position indicator to the end of the file is less than the value of Size, no error occurs and the data to the end of the file is stored in ReadBuf[ ]. If that occurs, the value of ReadSize is less than the value of Size.
  - When reading to the end of the file, EOF becomes TRUE; if not reading to the end, EOF is FALSE.
- **Program example**

  Note: The ID corresponding to the variable lwFileID is generated by the FileOpen instruction.

Item	LD	ST
Define variables	VAR FileOpen_Instance_0: FileOpen; FileWriteWstr_Instance_0: FileWriteWstr; FileSeek_Instance_0: FileSeek; FileReadWstr_Instance_0: FileReadWstr; FileClose_Instance_0: FileClose; xExecute: BOOL; lwFileID: LWORD; arrwstrReadBuf: ARRAY [1..4] OF WSTRING; uiSize: UINT := 4; xDone: BOOL; xBusy: BOOL; xError: BOOL; xErrorID: WORD; uiReadSize: UINT; xEOF: BOOL; END_VAR	

<table>
<tr><th>Item</th><th>LD</th><th>ST</th></tr>
<tr><td>Program</td><td>



</td><td>Operation result</td><td>
</td></tr>
</table>

- **Precautions**
  - Before using this instruction, please read the 18.2.11.2 Overview to avoid improper operations.
  - If the data is read to the end of the file and the size of the data is not evenly divisible by the size of the data type of ReadBuf[ ], the data that is insufficient for the data size of ReadBuf[ ] is discarded. The file position indicator advances to the end of the file, and the value of EOF changes to TRUE.
  - If the value of Size exceeds the ReadBuf[ ] array, a program fault occurs, Error becomes TRUE, and ErrorID is 1030. The elements in ReadBuf[ ] retain their values from before executing this instruction.
  - Execute the FileOpen instruction in advance to obtain the value for FileID.
  - If ReadBuf[ ] is an array of structures, adjustment areas between members may be inserted depending on the composition.
  - An exception occurs and Error becomes TRUE in the following cases:
    - If the file specified by FileID does not exist, ErrorID is 1.
    - If Size is not 0 and the file specified by FileID is not opened in a reading mode, ErrorID is 1.
    - If the input FileID is invalid (less than 0 or greater than 300), ErrorID is 1537.
    - If a file opened by the FileOpen instruction is used by FileReadWstr after already being closed by FileClose, ErrorID is 1538.

18.2.11.14.4 FileWriteWstr

Writes data to the specified file.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
FileWriteWstr	Write file	FB		FileWriteWstr_Instance_0(Execute := , FileID := , WriteBuf := , Size := , Done => , Busy =>, Error =>, ErrorID => , WriteSize =>);

Busy	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Error	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
ErrorID	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
WriteSize	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - This instruction writes the data written to WriteBuf[ ] to the file position indicator in the file specified by FileID.
  - The file position indicator is set at the desired location in advance with the FileSeek instruction.
  - The amount of data that is written is the size of the data type of WriteBuf[ ] times Size.
  - The number of elements actually written is saved to WriteSize. In general, values of Size and ReadSize are the same.
- **Program example**

  Note: The ID corresponding to the variable lwFileID is generated by the FileOpen instruction.

<table>

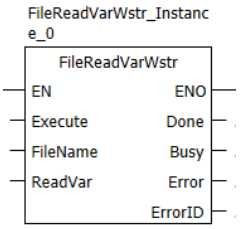
15		xBusy	BOOL		FALSE
16		xError	BOOL		FALSE
17		xErrorID	WORD		0
18		uiWriteSize	UINT		4

</td></tr>
</table>



- **Precautions**
  - Before using this instruction, please read the 18.2.11.2 Overview to avoid improper operations.
  - If the value of Size exceeds the WriteBuf[ ] array, a program fault occurs, Error becomes TRUE, and ErrorID is 1030.
  - Execute the FileOpen instruction in advance to obtain the value for FileID.
  - If WriteBuf[ ] is an array of structures, adjustment areas between members may be inserted depending on the composition.
  - An exception occurs under the following conditions. The value of Error is TRUE.
    - If the file specified by FileID does not exist, ErrorID is 1.
    - If the file specified by FileID is not opened in a writing mode, ErrorID is 1.
    - If there is insufficient space available on the SD card, ErrorID is 41.
    - If the input FileID is invalid (less than 0 or greater than 300), ErrorID is 1537.
    - If a file opened by the FileOpen instruction is used by FileWriteWstr after already being closed by FileClose, ErrorID is 1538.

- If multiple threads execute the FileWriteWstr instruction simultaneously, execution is queued (threads themselves are not blocked). If the operation does not complete within 10 task cycles, ErrorID is 1540.
- If the FileWriteWstr instruction is executed after user directory size initialization fails, ErrorID is 1543.

18.2.11.14.5 FileReadVarWstr

Reads the values of the specified file as binary data and writes the data to a variable.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
FileReadVarWstr	File read variable	FB		FileReadVarWstr_Instance_0(Execute := , FileName :=, ReadVar := , Done => , Busy =>, Error =>, ErrorID =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Execute	Enable	Follows data type	FALSE	(Triggered by edges) Execution of the function block switch
	FileName	Specified file name	Max. 200 characters	''	Name of the file to which to write variable data
	ReadVar	Position variable to read	Follows data type	-	Position variable from which to read variable data
Output	Done	Function block completed state	Follows data type	-	Function block completed state
	Busy	Function block execution flag	Follows data type	-	Function block execution flag

Input/Output	Variable	Name	Valid Range	Default Value	Description

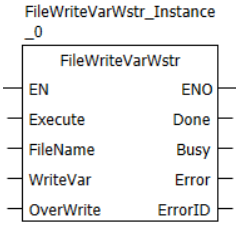
    strFileName: STRING;
    arrwstrReadVar: ARRAY [1..4] OF WSTRING;
    xOverWrite: BOOL;
    xDone: BOOL;
    xBusy: BOOL;
    xError: BOOL;
    xErrorID: WORD;
END_VAR
```

</td></tr>
<tr><td>Program</td><td>
</td><td>

```
FileReadVarWstr_Instance_0(
Execute  TRUE  := xExecute  TRUE ,
FileName   'FileVar'   := strFileName   'FileVar' ,
ReadVar := arrwstrReadVar,
Done  TRUE  => xDone  TRUE ,
Busy  FALSE  => xBusy  FALSE ,
Error  FALSE  => xError  FALSE ,
ErrorID   0   => xErrorID   0 );
```

</td></tr>
<tr><td>Operation result</td><td colspan="2">

		Name	Type	Address	Value
1		FileWriteVarWstr_Instance_0	FileWriteVarWstr		
2		FileReadVarWstr_Instance_0	FileReadVarWstr		
3		xExecute	BOOL		TRUE
4		strFileName	STRING		'FileVar'
5		arrwstrReadVar	ARRAY [1..4] OF WSTRING		
6		arrwstrReadVar[1]	WSTRING		"F"
7		arrwstrReadVar[2]	WSTRING		"I"
8		arrwstrReadVar[3]	WSTRING		"L"
9		arrwstrReadVar[4]	WSTRING		"E"
10		xOverWrite	BOOL		FALSE
11		xDone	BOOL		TRUE
12		xBusy	BOOL		FALSE
13		xError	BOOL		FALSE
14		xErrorID	WORD		0



</td></tr>
</table>

- **Precautions**
  - Before using this instruction, please read the 18.2.11.2 Overview to avoid improper operations.
  - If the size of the specified file is greater than that of ReadVar, no error occurs and only the data of the size of ReadVar is read. If the size of the specified file is less than that of ReadVar, no error occurs and only the data of the size of the specified file is read. The remaining area in ReadVar retains the values used before execution of this instruction. If ReadVar is a structure, adjustment areas between members may be inserted depending on the composition.
  - An exception occurs and Error becomes TRUE in the following cases:
    - If FileName is empty or an invalid filename, ErrorID is 1.
    - If the file specified by FileName does not exist, ErrorID is 16.

18.2.11.14.6 FileWriteVarWstr

Writes the value of a variable to the specified file in binary format.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
FileWriteVarWstr	File write variable	FB		FileWriteVarWstr_Instance_0(Execute := , FileName :=, WriteVar := , OverWrite := , Done => , Busy =>, Error =>, ErrorID =>);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Execute	Enable	Follows data type	FALSE	(Triggered by edges) Execution of the function block switch
	FileName	Specified file name	Max. 200 characters	''	Name of the file to which to write variable data
	WriteVar	Specified variable	Follows data type	-	Variable to write
	OverWrite	Overwrite enable	Follows data type	FALSE	TRUE: Enable overwrite FALSE: Prohibit overwrite
Output	Done	Function block completed state	Follows data type	-	Function block completed state
	Busy	Function block execution flag	Follows data type	-	Function block execution flag
	Error	Function block fault flag	Follows data type	-	Function block fault flag
	ErrorID	Function block fault ID	Follows data type	-	Function block fault ID

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String					
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING

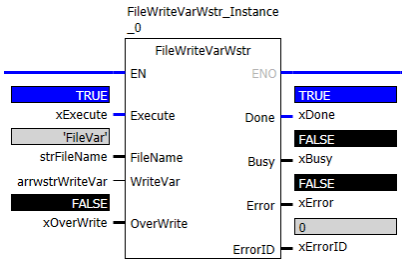
	An enumeration, an array, an array element, a structure, or a structure member can also be specified.																				
OverWrite	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Done	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Busy	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Error	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
ErrorID	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–



- **Function**
  - This instruction writes the value of variable WriteVar to the file specified by FileName in binary format.
  - If there is no file with the same name as FileName, a new file is created.
  - If a file with the same name as FileName already exists, the following is performed depending on the value of OverWrite, as shown below.

Value of OverWrite	Operation
TRUE	The file is overwritten.
FALSE	The file is not overwritten and an error occurs.

- **Program example**

<table>
<tr><th>Item</th><th>LD</th><th>ST</th></tr>
<tr><td>Define variables</td><td colspan="2">

```
VAR
    FileWriteVarWstr_Instance_0: FileWriteVarWstr;
    FileReadVarWstr_Instance_0: FileReadVarWstr;
    xExecute: BOOL;
    strFileName: STRING;
    arrwstrWriteVar: ARRAY [1..4] OF WSTRING := ["F","I","L","E"];
    xOverWrite: BOOL;
    xDone: BOOL;
    xBusy: BOOL;
    xError: BOOL;
    xErrorID: WORD;
END_VAR
```

</td></tr>
<tr><td>Program</td><td>

</td><td>

```
FileWriteVarWstr_Instance_0(
Execute  TRUE  := xExecute  TRUE ,
FileName  'FileVar'  := strFileName  'FileVar' ,
WriteVar := arrwstrWriteVar,
OverWrite  FALSE  := xOverWrite  FALSE ,
Done  TRUE  => xDone  TRUE ,
Busy  FALSE  => xBusy  FALSE ,
Error  FALSE  => xError  FALSE ,
ErrorID  0  => xErrorID  0 );
```

</td></tr>
<tr><td>Operation result</td><td colspan="2">

		Name	Type	Address	Value

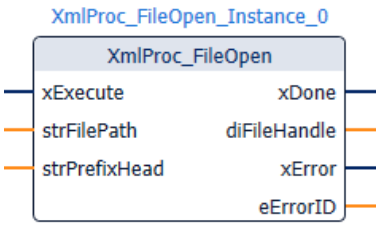
2		FileReadVarWstr_Instance_0	FileReadVarWstr		
3		xExecute	BOOL		TRUE
4		strFileName	STRING		'FileVar'
5		arrwstrWriteVar	ARRAY [1..4] OF WSTRING		
6		arrwstrWriteVar[1]	WSTRING		"F"
7		arrwstrWriteVar[2]	WSTRING		"I"
8		arrwstrWriteVar[3]	WSTRING		"L"
9		arrwstrWriteVar[4]	WSTRING		"E"
10		xOverWrite	BOOL		FALSE
11		xDone	BOOL		TRUE
12		xBusy	BOOL		FALSE
13		xError	BOOL		FALSE
14		xErrorID	WORD		0

</td></tr>
</table>

- **Notes**
  - Before using this instruction, please read the 18.2.11.2 Overview to avoid improper operations.
  - If WriteVar is a structure, adjustment areas between members may be inserted depending on the composition.
  - An exception occurs under the following conditions. The value of Error is TRUE.
    - If the SD card is write-protected, ErrorID is 1.
    - If there is insufficient space available on the SD card, ErrorID is 41.
    - If FileName is empty and OverWrite is FALSE, ErrorID is 50; if FileName is empty and OverWrite is TRUE, ErrorID is 1.
    - If FileName is an invalid file name and OverWrite is FALSE, ErrorID is 50; if FileName is an invalid file name and OverWrite is TRUE, ErrorID is 1.
    - If a file with the name specified by FileName exits and OverWrite is FALSE, ErrorID is 50.
    - If a file with the name FileName already exists and the file is read-only, ErrorID is 50.
    - If multiple threads execute the FileWriteVarWstr instruction simultaneously, execution is queued (threads themselves are not blocked). If the operation does not complete within 10 task cycles, ErrorID is 1540.
    - If the FileWriteVarWstr instruction is executed after user directory size initialization fails, ErrorID is 1543.

18.2.12 Special File Processing

18.2.12.1 XML File Processing



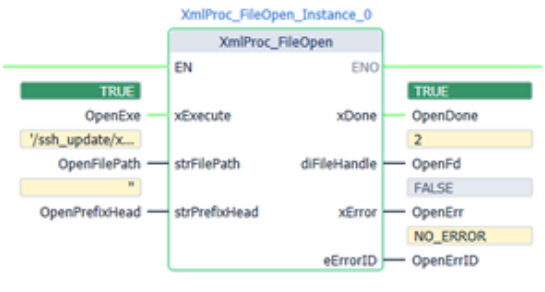
18.2.12.1.1 Instruction List

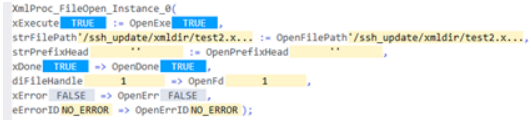
Instruction	FB/FC	Function	Library	Applicable Library Version
18.2.12.1.2 XmlProc_FileOpen	FB	Open the specified XML file	FileProc	Library version 1.0.0.0 and later
18.2.12.1.3 XmlProc_FileClose	FB	Close the specified XML file		Library version 1.0.0.0 and later
18.2.12.1.4 XmlProc_FileDelete	FB	Delete the specified XML file		Library version 1.0.0.0 and later
18.2.12.1.5 XmlProc_GetNameSpaceInfo	FB	Get namespace		Library version 1.0.0.0 and later
18.2.12.1.6 XmlProc_NodeEdit	FB	Edit nodes in the specified XML file		Library version 1.0.0.0 and later
18.2.12.1.7 XmlProc_AddJmfInfo	FB	Add information to a JMF file		Library version 1.0.0.0 and later

18.2.12.1.2 XmlProc_FileOpen

Opens the specified XML file and returns a file handle.

- **Instruction format**





Instruction	Name	FB/FC	LD Representation	ST Representation
XmlProc_FileOpen	Open the specified XML file	FB		XmlProc_FileOpen_Instance_0(xExecute := , strFilePath := , strPrefixHead := , xDone => , diFileHandle => , xError => , eErrorID =>);

- **Related variables**

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	xExecute	Trigger enable bit	BOOL	TRUE, FALSE	FALSE	Rising edge-triggered
	strFilePath	File path	STRING[128]	-	-	Path of the XML file.

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	strPrefixHead	Namespace prefix	STRING[8]	-	ns	Prefix of the namespace of the XML file. Default is ns.
Output	xDone	Completion flag	BOOL	TRUE, FALSE	FALSE	Completion flag.
	diFileHandle	File handle	DINT	[-1, 1000]	0	File handle returned after the file is opened.
	xError	Error flag	BOOL	TRUE, FALSE	FALSE	Error flag for file open failure.
	eErrorID	Fault ID	XML_PROC_ERROR_ID	-	NO_ERROR	Error code for file open failure. See 18.2.12.1.8 Fault Codes for details.

- **Function**
  - Before instruction execution, input the file path "strFilePath". This is a relative path, and the root directory is the PLC SFTP server path.
  - Before instruction execution, input the prefix of the namespace. If this item is empty, the default is ns. Taking ns as an example, the default namespaces of the XML file are ns0, ns1, etc. For details on XML file namespaces, use the 18.2.12.1.5 XmlProc_GetNameSpaceInfo instruction.
  - After instruction execution, the file handle "diFileHandle" is returned. A "diFileHandle" value of 0 or greater indicates that the file is opened successfully, allowing file operations via this handle.
- **Program example**

Item	LD	ST
Define variables	XmlProc_FileOpen_Instance_0: XmlProc_FileOpen; OpenExe : BOOL := FALSE; OpenFilePath : STRING[128] := '/ssh_update/xmldir/test1.xml'; OpenPrefixHead : STRING[8]; OpenDone : BOOL := FALSE; OpenFd : DINT := 0; OpenErr : BOOL := FALSE; OpenErrID : XML_PROC_ERROR_ID := XML_PROC_ERROR_ID.NO_ERROR;	
Program		

Item	LD	ST
Operation result	XmlProc_FileOpen_Instance_0 : XmlProc_FileOpen OpenExe : BOOL = TRUE OpenFilePath : STRING[128] = '/ssh_update/xmldir/test2.xml' OpenPrefixHead : STRING[8] = '' OpenDone : BOOL = TRUE OpenFd : DINT = 1 OpenErr : BOOL = FALSE OpenErrID : XML_PROC_ERROR_ID = NO_ERROR	

- **Precautions**
  - Open the XML file before use and close it after file operations are completed. Avoid frequent open/close actions during use.
  - After the file is opened successfully, "xDone" is set and "diFileHandle" is 0 or greater.
  - When opening a file, the system checks the number of XML files currently open. Supports up to 100 XML files opened simultaneously; otherwise, an error is reported indicating that the number of opened files exceeds the limit "OPENED_FILE_NUM_OVER_LIMIT".
  - When opening a file, the system checks the size of the XML file currently being opened. The file size must not exceed 1 MB; otherwise, an error is reported indicating that the opened file size exceeds the limit "FILE_SIZE_OVER_LIMIT".
  - When opening a file, the system checks the total size of all currently open files. The total size of all open XML files must not exceed 5% of the total memory of the PLC; otherwise, an error is reported indicating that the cumulative size of open files exceeds the limit "OPENED_FILE_SIZE_SUM_OVER_LIMIT".
  - The "diFileHandle" used here differs from file handles in other libraries and should not be mixed.

18.2.12.1.3 XmlProc_FileClose

Closes the XML file and determines how to save the file based on the close mode.

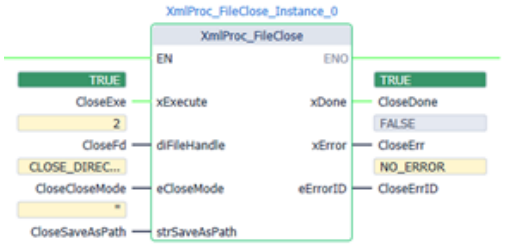
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
XmlProc_FileClose	Close the specified XML file	FB	XmlProc_FileClose_Instance_0 XmlProc_FileClose xExecute diFileHandle eCloseMode strSaveAsPath xDone xError eErrorID	XmlProc_FileClose_Instance_0(xExecute := , diFileHandle := , eCloseMode := , strSaveAsPath := , xDone => , xError => , eErrorID =>);

- **Related variables**

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	xExecute	Trigger enable bit	BOOL	TRUE, FALSE	FALSE	Rising edge-triggered
	diFileHandle	File handle	DINT	[-1, 1000]	0	Handle of the file.

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	eCloseMode	Close mode	XML_CLOSE_MODE	-	-	Close mode of the file.
	strSaveAsPath	Save Path	STRING[128]	-	-	Path for saving the file as a new file.
Output	xDone	Completion flag	BOOL	TRUE, FALSE	FALSE	Completion flag.
	xError	Error flag	BOOL	TRUE, FALSE	FALSE	Error flag.
	eErrorID	Fault code	XML_PROC_ERROR_ID	-	NO_ERROR	See 18.2.12.1.8 Fault Codes.



- **Function**
  - Before instruction execution, input the file handle "diFileHandle" and the file close mode "eCloseMode". The data type of "eCloseMode" is XML_CLOSE_MODE. The enumeration values are defined as follows:

Variable	Value	Description
CLOSE_DIRECTLY	16#0000	Close directly; changes will not be written back to the file.
CLOSE_AND_SAVE	16#0001	Close and save; changes will be written back to the original file.
CLOSE_AND_SAVE_AS	16#0002	Close and save the content to the specified file.

  - If the close mode is CLOSE_AND_SAVE_AS, the parameter "strSaveAsPath" must also be set.
  - After the instruction execution, the result is returned. If "xDone" is TRUE, the operation is successful.
- **Program example**

Item	LD	ST
Define variables		
Program		

```
XmlProc_FileClose_Instance_0: XmlProc_FileClose;
CloseExe        : BOOL := FALSE;
CloseFd         : DINT := 0;
CloseCloseMode  : XML_CLOSE_MODE;
CloseSaveAsPath : STRING[128];
CloseDone       : BOOL := FALSE;
CloseErr        : BOOL := FALSE;
CloseErrID      : XML_PROC_ERROR_ID := XML_PROC_ERROR_ID.NO_ERROR;
```

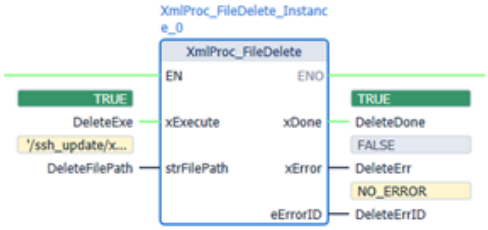
```
XmlProc_FileClose_Instance_0(
xExecute TRUE := CloseExe TRUE ,
diFileHandle 1 := CloseFd 1 ,
eCloseModeCLOSE_DIREC... := CloseCloseModeCLOSE_DIREC...,
strSaveAsPath '' := CloseSaveAsPath '' ,
xDone TRUE => CloseDone TRUE ,
xError FALSE => CloseErr FALSE ,
eErrorID NO_ERROR => CloseErrID NO_ERROR );
```

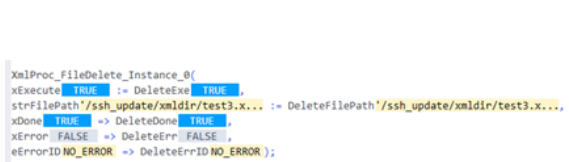
Item	LD	ST
Operation result	XmlProc_FileClose_Instance_0 / XmlProc_FileClose CloseExe / BOOL / TRUE CloseFd / DINT / 1 CloseCloseMode / XML_CLOSE_MODE / CLOSE_DIRECTLY CloseSaveAsPath / STRING[128] / '' CloseDone / BOOL / TRUE CloseErr / BOOL / FALSE CloseErrID / XML_PROC_ERROR_ID / NO_ERROR	

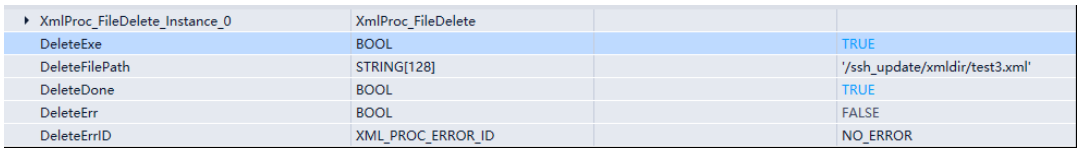
- **Precautions**
  - "strSaveAsPath" is valid only when the close mode is CLOSE_AND_SAVE_AS. In other modes, this parameter is empty.
  - When the close mode is CLOSE_AND_SAVE_AS, if the path specified by "strSaveAsPath" does not exist, the function block automatically creates the corresponding path.

18.2.12.1.4 XmlProc_FileDelete

Deletes the file at the specified path.







- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
XmlProc_FileDelete	Delete the specified XML file	FB	XmlProc_FileDelete_Instance_0 XmlProc_FileDelete xExecute / xDone strFilePath / xError eErrorID	XmlProc_FileDelete_Instance_0(xExecute := , strFilePath := , xDone => , xError => , eErrorID =>);

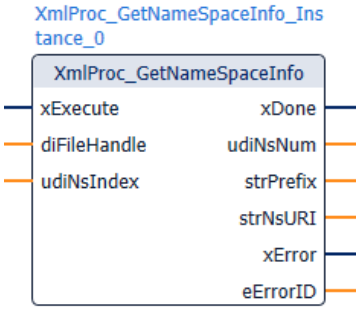
- **Related variables**

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	xExecute	Trigger enable bit	BOOL	TRUE, FALSE	FALSE	Rising edge-triggered
	strFilePath	File path	STRING[128]	-	-	File path.
Output	xDone	Completion flag	BOOL	TRUE, FALSE	FALSE	Completion flag.
	xError	Error flag	BOOL	TRUE, FALSE	FALSE	Error flag.
	eErrorID	Fault code	XML_PROC_ERROR_ID	-	NO_ERROR	See 18.2.12.1.8 Fault Codes.

- **Function**
  - Before instruction execution, input the file path "strFilePath". This path is relative to the SFTP server root directory.
  - After instruction execution, the corresponding file at the specified path will be deleted.
- **Program example**

Item	LD	ST
Define variables	XmlProc_FileDelete_Instance_0: XmlProc_FileDelete; DeleteExe : BOOL := FALSE; DeleteFilePath : STRING[128]:= '/ssh_update/xmldir/test3.xml'; DeleteDone : BOOL := FALSE; DeleteErr : BOOL := FALSE; DeleteErrID : XML_PROC_ERROR_ID := XML_PROC_ERROR_ID.NO_ERROR;	
Program		
Operation result		

XmlProc_FileDelete_Instance_0	XmlProc_FileDelete		
DeleteExe	BOOL		TRUE
DeleteFilePath	STRING[128]		'/ssh_update/xmldir/test3.xml'
DeleteDone	BOOL		TRUE
DeleteErr	BOOL		FALSE
DeleteErrID	XML_PROC_ERROR_ID		NO_ERROR



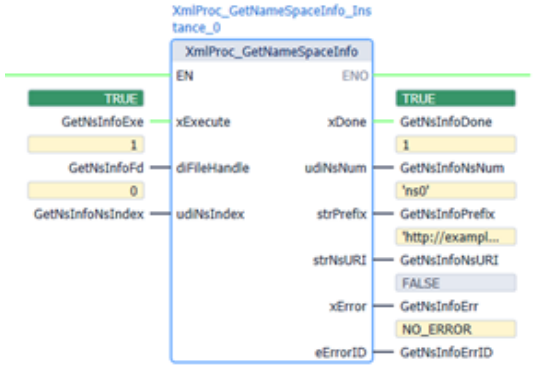
- **Precautions**

  This instruction deletes the file from the disk. Deletion is irreversible and cannot be recovered.

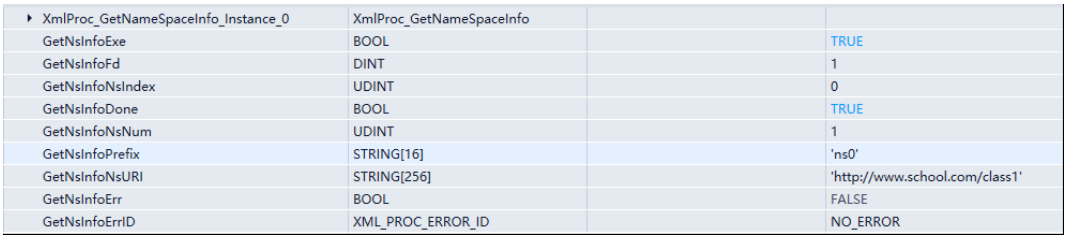
18.2.12.1.5 XmlProc_GetNameSpaceInfo

Gets the namespace information of the XML file.

- **Instruction format**



Instruction	Name	FB/FC	LD Representation	ST Representation
XmlProc_GetNameSpaceInfo	Get namespace	FB		XmlProc_GetNameSpaceInfo_Instance_0(xExecute := , diFileHandle := , udiNsIndex := , xDone => , udiNsNum => , strPrefix => , strNsURI => , xError => , eErrorID =>);



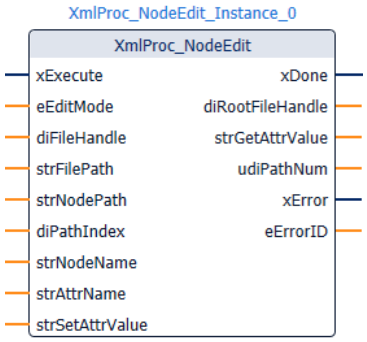
- **Related variables**

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	xExecute	Trigger enable bit	BOOL	TRUE, FALSE	FALSE	Rising edge-triggered
	diFileHandle	File handle	DINT	[-1, 1000]	0	Handle of the file.

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	udiNsIndex	Namespace index	UDINT	[0, udiNsNum-1]	0	Index of the namespace, starting from 0.
Output	xDone	Completion flag	BOOL	TRUE, FALSE	FALSE	Completion flag.
	udiNsNum	Number of namespaces	UDINT	-	0	Number of namespaces.
	strPrefix	Namespace prefix	STRING[16]	-	-	Namespace prefix.
	strNsURI	Namespace URI	STRING[256]	-	-	Namespace URI.
	xError	Error flag	BOOL	TRUE, FALSE	FALSE	Error flag.
	eErrorID	Fault code	XML_PROC_ERROR_ID	-	NO_ERROR	See 18.2.12.1.8 Fault Codes.

- **Function**
  - Before instruction execution, input the file handle "diFileHandle" and the namespace index "udiNsIndex".
  - After execution, the instruction returns the namespace prefix and namespace URI corresponding to the given index, as well as the total number of namespaces in the file referenced by "diFileHandle".
- **Program example**

Item	LD	ST
Define variables	XmlProc_GetNameSpaceInfo_Instance_0: XmlProc_GetNameSpaceInfo; GetNsInfoExe : BOOL := FALSE; GetNsInfoFd : DINT := 0; GetNsInfoNsIndex : UDINT := 0; GetNsInfoDone : BOOL := FALSE; GetNsInfoNsNum : UDINT := 0; GetNsInfoPrefix : STRING[16]; GetNsInfoNsURI : STRING[256]; GetNsInfoErr : BOOL := FALSE; GetNsInfoErrID : XML_PROC_ERROR_ID := XML_PROC_ERROR_ID.NO_ERROR;	
Program		



Item	LD	ST
Operation result		

- **Precautions**
  - The valid range for the namespace index "udiNsIndex" is [0, udiNsNum-1].
  - If a variable in the XML file belongs to a certain namespace, when accessing that variable, the corresponding namespace information should be added to the variable path.

18.2.12.1.6 XmlProc_NodeEdit

Edits nodes in specified XML file.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
XmlProc_NodeEdit	Edit nodes in the specified XML file	FB		XmlProc_NodeEdit_Instance_0(xExecute := , eEditMode := , diFileHandle := , strFilePath := , strNodePath := , diPathIndex := , strNodeName := , strAttrName := , strSetAttrValue := , xDone => , diRootFileHandle => , strGetAttrValue => , udiPathNum => , xError => , eErrorID =>);

- **Related variables**

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	xExecute	Trigger enable bit	BOOL	TRUE, FALSE	FALSE	Rising edge-triggered
	eEditMode	Edit mode	XML_NODE_EDIT_ACTION	-	NO_ACTION	Edit mode of the node.
	diFileHandle	File handle	DINT	[-1, 1000]	0	File handle.
	strFilePath	File path	STRING[128]	-	-	File path.

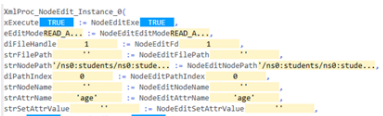
Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	strNodePath	Node path	STRING[256]	-	-	Node path.
	diPathIndex	Path index	DINT	[0, udiPathNum -1]	0	Index of the path, starting from 0.
	strNodeName	Node name	STRING[64]	-	-	Node name.
	strAttrName	Property	STRING[64]	-	-	Property name.
	strSetAttrValue	Set property value	STRING[256]	-	-	Set property value.
Output	xDone	Completion flag	BOOL	TRUE, FALSE	FALSE	Completion flag.
	diRootFileHandle	File handle of the root node	DINT	-	0	File handle of the root node.
	strGetAttrValue	Retrieved property value	STRING[256]	-	-	Retrieved property value.
	udiPathNum	Number of matching node paths	UDINT	-	0	Number of paths.
	xError	Error flag	BOOL	TRUE, FALSE	FALSE	Error flag.
	eErrorID	Fault code	XML_PROC_ERROR_ID	-	NO_ERROR	See 18.2.12.1.8 Fault Codes.

- **Function**
  - Before instruction execution, input the edit mode "eEditMode". The input/output parameters under different edit modes are as follows:

Key Parameter	Add Root Node	Delete Root Node	Add Child Node	Delete Child Node	Add Property	Delete Property	Read Property	Write Property
xExecute	Valid	Valid	Valid	Valid	Valid	Valid	Valid	Valid
eEditMode	1	2	3	4	5	6	7	8
diFileHandle	-	Valid	Valid	Valid	Valid	Valid	Valid	Valid
strFilePath	Valid	-	-	-	-	-	-	-
strNodePath	-	-	Valid	Valid	Valid	Valid	Valid	Valid
diPathIndex	-	-	Valid	Valid	Valid	Valid	Valid	Valid
strNodeName	Valid	-	Valid	Valid	-	-	-	-

Key Parameter	Add Root Node	Delete Root Node	Add Child Node	Delete Child Node	Add Property	Delete Property	Read Property	Write Property
strAttrName	-	-	-	-	Valid	Valid	Valid	Valid
strSetAttrValue	-	-	-	-	Valid	-	-	Valid
xDone	Valid	Valid	Valid	Valid	Valid	Valid	Valid	Valid
diRootFileHandle	Valid	-	-	-	-	-	-	-
strGetAttrValue	-	-	-	-	-	-	Valid	-
udiPathNum	-	-	Valid	Valid	Valid	Valid	Valid	Valid
xError	Valid	Valid	Valid	Valid	Valid	Valid	Valid	Valid
eErrorID	Valid	Valid	Valid	Valid	Valid	Valid	Valid	Valid

◦ After instruction execution, check "xDone", "xError", and "eErrorID" to view the result of the edit action.



◦ The data type of "eEditMode" is XML_NODE_EDIT_ACTION. The enumeration values are defined as follows:

Variable	Value	Description
NO_ACTION	16#0000	No action.
ADD_ROOT_NODE	16#0001	Add a root node.
DELETE_ROOT_NODE	16#0002	Delete a root node.
ADD_CHILD_NODE	16#0003	Add a child node.
DELETE_CHILD_NODE	16#0004	Delete a child node.
ADD_ATTR	16#0005	Add a property within the node.
DELETE_ATTR	16#0006	Delete a property within the node.
READ_ATTR	16#0007	Read a property within the node.
WRITE_ATTR	16#0008	Write a property within the node.

- **Program example**

<table>
<tr><th>Item</th><th>LD</th><th>ST</th></tr>
<tr><td>Define variables</td><td colspan="2">

```
XmlProc_NodeEdit_Instance_0: XmlProc_NodeEdit;
NodeEditExe          : BOOL := FALSE;

NodeEditErrID        : XML_PROC_ERROR_ID := XML_PROC_ERROR_ID.NO_ERROR;
```

</td></tr>
<tr><td>Program</td><td>
</td><td></td></tr>
</table>

<table>
<tr><th>Item</th><th>LD</th><th>ST</th></tr>
<tr><td>Operation result</td><td colspan="2">

The XML file does not contain a namespace.

File example

test1.xml

```
<?xml version="1.0" encoding="UTF-8"?>
<students>
    <student id="001" name="zhangsan" age="18" gender="male" ></student>
    <student id="002" name="lisi" age="17" gender="famale" ></student>
    <student id="003" name="lilei" age="18" gender="male" ></student>
</students>
```

Read property values

XmlProc_NodeEdit_Instance_0	XmlProc_NodeEdit		
NodeEditExe	BOOL		TRUE
NodeEditEditMode	XML_NODE_EDIT_ACTION		READ_ATTR
NodeEditFd	DINT		1
NodeEditFilePath	STRING[128]		''
NodeEditNodePath	STRING[256]		'/students/student'
NodeEditPathIndex	DINT		0
NodeEditNodeName	STRING[64]		''
NodeEditAttrName	STRING[64]		'age'
NodeEditSetAttrValue	STRING[256]		''
NodeEditDone	BOOL		TRUE
NodeEditRootFileHandle	DINT		-1
NodeEditGetAttrValue	STRING[256]		'18'
NodeEditPathNum	UDINT		3
NodeEditErr	BOOL		FALSE
NodeEditErrID	XML_PROC_ERROR_ID		NO_ERROR

The XML file contains a namespace.

File example

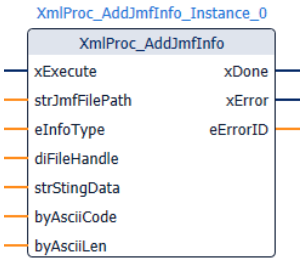
test2.xml

```
<?xml version="1.0" encoding="UTF-8"?>
<students xmlns="http://www.school.com/class1">
    <student id="001" name="zhangsan" age="18" gender="male" ></student>
    <student id="002" name="lisi" age="17" gender="famale" ></student>
    <student id="003" name="lilei" age="18" gender="male"></student>
</students>
```

Read property values

XmlProc_NodeEdit_Instance_0	XmlProc_NodeEdit		
NodeEditExe	BOOL		TRUE
NodeEditEditMode	XML_NODE_EDIT_ACTION		READ_ATTR
NodeEditFd	DINT		1
NodeEditFilePath	STRING[128]		''
NodeEditNodePath	STRING[256]		'/ns0:students/ns0:student'
NodeEditPathIndex	DINT		0
NodeEditNodeName	STRING[64]		''
NodeEditAttrName	STRING[64]		'age'
NodeEditSetAttrValue	STRING[256]		''
NodeEditDone	BOOL		TRUE
NodeEditRootFileHandle	DINT		-1
NodeEditGetAttrValue	STRING[256]		'18'
NodeEditPathNum	UDINT		3
NodeEditErr	BOOL		FALSE
NodeEditErrID	XML_PROC_ERROR_ID		NO_ERROR

</td></tr>
</table>



- **Precautions**
  - Different edit modes have different valid input and output parameters. Invalid parameters have no effect and may be set to 0 or empty.
  - If a node in the XML file belongs to a namespace, the node path should include the corresponding namespace information.

- In an XML file, "strNodePath" may match multiple paths. Different paths are distinguished by "diPathIndex".
- The value range of "diPathIndex" is [0, udiPathNum-1].

18.2.12.1.7 XmlProc_AddJmfInfo

Adds information to a JMF file.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
XmlProc_AddJmfInfo	Add information to a JMF file	FB		XmlProc_AddJmfInfo_Instance_0(xExecute := , strJmfFilePath := , eInfoType := , diFileHandle := , strStingData := , byAsciiCode := , byAsciiLen := , xDone => , xError => , eErrorID =>);

- **Related variables**

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	xExecute	Trigger enable bit	BOOL	TRUE, FALSE	FALSE	Rising edge-triggered
	strJmfFilePath	JMF file path	STRING[128]	-	-	Path to the JMF file.
	eInfoType	Information type to add	XML_ADD_INFO_TYPE	-	-	Information type to add.
	diFileHandle	File handle	DINT	-	0	Handle of the content to add.
	strStingData	String information to add	STRING[128]	-	-	String content to add.
	byAsciiCode	ASCII code value	ARRAY [0..15] OF BYTE	-	0	ASCII code value. For example, the ASCII code for a line feed is 10.
	byAsciiLen	Valid data length of ASCII code	BYTE	[0, 255]	0	Valid data length of ASCII code.

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Output	xDone	Completion flag	BOOL	TRUE, FALSE	FALSE	Completion flag.
	xError	Error flag	BOOL	TRUE, FALSE	FALSE	Error flag.
	eErrorID	Fault code	XML_PROC_ERROR_ID	-	NO_ERROR	See 18.2.12.1.8 Fault Codes.

- **Function**
  - Before instruction execution, input the JMF file path "strJmfFilePath" and the information type "eInfoType". The valid input parameters for different information type modes are shown in the following table:

Key Parameter	Handle Content to Add	String to Add	ASCII Code to Add
eInfoType	0	1	2
strJmfFilePath	Valid	Valid	Valid
diFileHandle	Valid	-	-
strStingData	-	Valid	-
byAsciiCode	-	-	Valid
byAsciiLen	-	-	Valid

  - After the instruction execution, the result is returned. If "xDone" is TRUE, the operation is successful.
  - The data type of "eInfoType" is XML_ADD_INFO_TYPE. The enumeration values are defined as follows:

Variable	Value	Description
HANDLE_INFO	16#0000	Add the content in the handle to the JMF file.
STRING_INFO	16#0001	Add the string information directly to the JMF file.
ASCII_INFO	16#0002	Add the character corresponding to the ASCII code to the JMF file.

- **Program example**

Item	LD	ST
Define variables		

```
XmlProc_AddJmfInfo_Instance_0: XmlProc_AddJmfInfo;
AddJmfExe           : BOOL := FALSE;
AddJmfFilePath      : STRING[128] := '/ssh_update/xmldir/jmf.txt';;
AddJmfInfoType      : XML_ADD_INFO_TYPE;
AddJmfFd            : DINT := 0;
AddJmfStingData     : STRING[128];
AddJmfAsciiCode     : ARRAY[0..15] OF BYTE;
AddJmfAsciiLen      : BYTE;
AddJmfDone          : BOOL := FALSE;
AddJmfErr           : BOOL := FALSE;
AddJmfErrID         : XML_PROC_ERROR_ID := XML_PROC_ERROR_ID.NO_ERROR;
```

Item	LD	ST
Program		
Operation result		

XmlProc_AddJmfInfo_Instance_0	XmlProc_AddJmfInfo		
AddJmfExe	BOOL		TRUE
AddJmfFilePath	STRING[128]		'/ssh_update/xmldir/jmf.txt'
AddJmfInfoType	XML_ADD_INFO_TYPE		STRING_INFO
AddJmfFd	DINT		0
AddJmfStingData	STRING[128]		'I love China'
AddJmfAsciiCode	ARRAY [0..15] OF BYTE		
AddJmfAsciiLen	BYTE		0
AddJmfDone	BOOL		TRUE
AddJmfErr	BOOL		FALSE
AddJmfErrID	XML_PROC_ERROR_ID		NO_ERROR

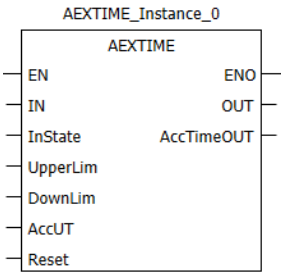
- **Precautions**
  - Different edit modes have different valid input and output parameters. Invalid parameters have no effect and may be set to 0 or empty.
  - When "eInfoType" is HANDLE_INFO, the content of the file corresponding to "diFileHandle" is added to the file at the path "strJmfFilePath".
  - When "eInfoType" is STRING_INFO, the specified string can be added to the file.
  - When "eInfoType" is ASCII_INFO, specific control characters can be added to the file at the path "strJmfFilePath".

18.2.12.1.8 Fault Codes

Variable	Value	Description
NO_ERROR	16#0000	No fault
FILE_NOT_EXIST	16#0001	File does not exist.
FILE_NAME_FORMAT_ERROR	16#0002	Filename format error.
NO_OPERATION_PERMISSION	16#0003	No operation permission for the file.
FILE_PARSE_FAILURE	16#0004	File parsing failed.
OPENED_FILE_NUM_OVER_LIMIT	16#0005	The number of open files exceeds the limit.
FILE_HANDLE_NOT_EXIST	16#0006	File handle does not exist.
FILE_CREATE_FAILURE	16#0007	File creation failed.
FILE_DELETE_FAILURE	16#0008	File deletion failed.
PARAMETER_FORMAT_ERROR	16#0009	Input parameter format error.
PARAMETER_OVER_LIMIT	16#000A	Input parameter exceeds the limit.
PARAMETER_ERROR	16#000B	Input parameter error.

Variable	Value	Description
OPENED_FILE_SIZE_SUM_OVER_LIMIT	16#000C	The total size of the cumulatively opened files exceeds the limit.
FILE_SIZE_EXCEEDS_LIMIT	16#000D	File size exceeds the limit.
PATH_INDEX_ERROR	16#0100	Path index error.
NODE_NO_FOUND	16#0101	The corresponding node not found in the file.
ATTR_NO_FOUND	16#0102	The corresponding property not found in the node.
PATH_INDEX_OVER_LIMIT	16#0103	Path index exceeds the limit.
VALUE_LEN_OVER_LIMIT	16#0104	Data length exceeds the limit.
ATTR_NAME_CONFLICT	16#0105	Property name conflict.
NAMESPACE_NO_FOUND	16#0106	Namespace not found in the file.
UNKNOWN	16#FFFF	Unknown error

18.2.13 Analog Signal



18.2.13.1 Instruction List

Instruction	FB/FC	Function	Library	Applicable Library Version
18.2.13.2 AEXTIME	FB	Analog over-limit time accumulation	SignalProcessing	Library version 1.0.0.0 and later
18.2.13.3 CHDETECT	FB	Value change detection		Library version 1.0.0.0 and later
18.2.13.4 CHDETECT_T	FB	Time-limited value change detection		Library version 1.0.0.0 and later
18.2.13.5 FILTER	FB	Analog filtering		Library version 1.0.0.0 and later
18.2.13.6 FLOWACC	FB	Flow accumulation		Library version 1.0.0.0 and later
18.2.13.7 INCRSUM	FB	Incremental summator		Library version 1.0.0.0 and later
18.2.13.8 SWND	FB	Bumpless switchover		Library version 1.0.0.0 and later
18.2.13.9 THRSEL	FB	Three-analog value selection		Library version 1.0.0.0 and later
18.2.13.10 TWOSEL	FB	Two-analog value selection		Library version 1.0.0.0 and later

18.2.13.2 AEXTIME

AEXTIME is used for analog over-limit time accumulation.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AEXTIME	Analog over-limit time accumulation	FB		AEXTIME_Instance_0(IN := , InState := , UpperLim := , DownLim := , AccUT := , Reset := , OUT => , AccTimeOUT =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Input	Follows data type	-	Input
	InState	Input state	Follows data type	TRUE	TRUR: Input is of good quality. FALSE: Input is of bad quality.
	UpperLim	Input upper limit	Follows data type	100.0	Input upper limit
	DownLim	Input lower limit	Follows data type	0.0	Input lower limit
	AccUT	Accumulation unit	Follows data type	-	0: Second 1: Minute 2: Hour 3: Day
	Reset	Reset a bit	Follows data type	-	Reset

Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	OUT	Accumulated time output (in specified unit)	Follows data type	-	Accumulated time output (in specified unit)
	AccTimeOUT	Total accumulated time output (in second)	Follows data type	-	Total accumulated time output (in second)

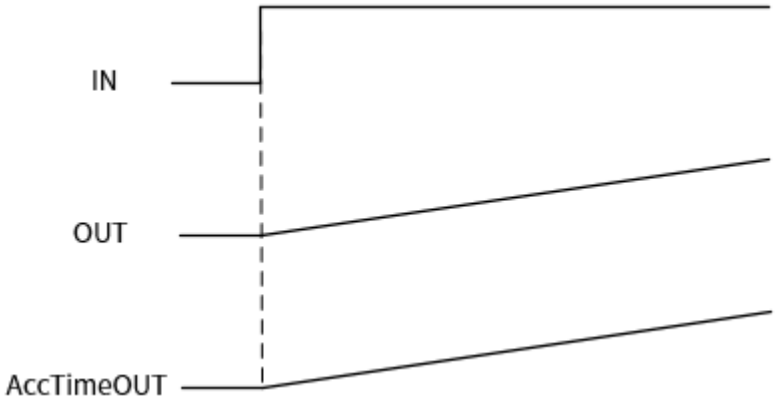
Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TOD	DT	STRING
IN	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
InState	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
UpperLim	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
DownLim	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
AccUT	Enumeration type: Acc_UT (0: Second; 1: Minute; 2: Hour; 3: Day)																			
Reset	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
OUT	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
AccTimeOUT	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–

- **Function**
  - Accumulates the time during which the analog input exceeds the upper or lower limit, or when the input signal is of bad quality.
  - When the input "IN" is of bad quality or exceeds upper/lower limits, time accumulation begins, and the result is output to "OUT" (in the unit specified by AccUT) and "AccTimeOUT" (in seconds).
- **Program example**

  The following example sets "IN" and UpperLim to REAL#11.0, the results after 14 executions are shown in the table below.

<table>
<tr><th>Item</th><th>LD</th><th>ST</th></tr>
<tr><td>Define variables</td><td colspan="2">



```
VAR
    AEXTIME_Instance_0: AEXTIME;
    rIN: REAL := 11;
    bInState: BOOL := FALSE;
    rUpperLim: REAL := 11;
    rDownLim: REAL := 0;
    mAccUT: ACC_UT := ACC_UT.Second;
    bRESET: BOOL := FALSE;
    rOUT: REAL;
    tAccTimeOUT: TIME;
END_VAR
```

</td></tr>
<tr><td>Program</td><td>
</td><td>

```
AEXTIME_Instance_0(

DownLim 0 := rDownLim 0,
AccUT Second := mAccUT Second,
Reset FALSE := bReset FALSE,
OUT 14 => rOUT 14,
AccTimeOUT T#14s => tAccTimeOUT T#14s);
```

</td></tr>
<tr><td>Operation result</td><td colspan="2">

		Name	Data type	Address	Value
1		AEXTIME_Instance_0	AEXTIME		
2		rIN	REAL		11
3		bInState	BOOL		FALSE
4		rUpperLim	REAL		11
5		rDownLim	REAL		0
6		mAccUT	ACC_UT		Second
7		bRESET	BOOL		FALSE
8		rOUT	REAL		14
9		tAccTimeOUT	TIME		T#14s

</td></tr>
<tr><td>Operation result</td><td colspan="2">
</td></tr>
</table>

18.2.13.3 CHDETECT

Detects changes in analog input values.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
CHDETECT	Value change detection	FB		CHDETECT_Instance_0(Input1 := , Input2 := , Input3 := , DeadZone := , OUT =>);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Input1	Input 1	Follows data type	0.0	Input 1
	Input2	Input 2	Follows data type	0.0	Input 2
	Input3	Input 3	Follows data type	0.0	Input 3
	DeadZone	Input dead zone width	Follows data type	0.0	Changes within the dead zone are not detected; DeadZone > 0.
Output	OUT	A flag indicating whether the input changes.	Follows data type	FALSE	A flag indicating whether the input changes.

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TOD	DT	STRING
Input1	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TOD	DT	STRING
Input2	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
Input3	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
DeadZone	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
OUT	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  Detects whether any of the three floating-point input values have changed. A dead zone can be specified, values within which are considered unchanged.

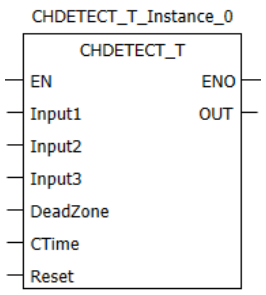
  Check method: $OUT = (|Input1 - lastInput1| \geq DeadZone)\ OR\ (|Input2 - lastInput2| \geq DeadZone)\ OR\ (|Input3 - lastInput3| \geq DeadZone)$

  Input - LastInput is the value from the previous cycle.

- **Program example**

  The following example sets the deadband width "DeadZone" to 10. When "Input1" increases from 5 to 15, the output "OUT" changes from FALSE to TRUE. Use variable "bFlag" to detect the change in "OUT".

Item	LD	ST



Define variables	VAR
	CHDETECT_Instance_0: CHDETECT;
	rInput1: REAL := 5;
	rInput2: REAL := 5;
	rInput3: REAL := 5;
	rDeadZone: REAL := 10;
	bOUT: BOOL;
	bFlag: BOOL := FALSE;
	END_VAR

</table>

18.2.13.4 CHDETECT_T

Detects whether the duration of analog value change exceeds the limit.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
CHDETECT_T	Time-limited value change detection	FB		CHDETECT_T_Instance_0(Input1 := , Input2 := , Input3 := , DeadZone := , CTime := , Reset := , OUT =>);

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Input1	Input 1	Follows data type	0.0	Input 1
	Input2	Input 2	Follows data type	0.0	Input 2
	Input3	Input 3	Follows data type	0.0	Input 3
	DeadZone	Input dead zone width	Follows data type	0.0	Changes within the dead zone are not detected; DeadZone > 0.
	CTime	Change duration limit	Follows data type	TIME#0ms	Change duration limit
	Reset	Timer reset	Follows data type	FALSE	Timer reset
Output	OUT	A flag indicating whether the input changes.	Follows data type	FALSE	A flag indicating whether the input changes.

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TOD	DT	STRING
Input1	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
Input2	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
Input3	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
DeadZone	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
CTime	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–
Reset	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
OUT	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  Detects whether the duration of change in any of the three inputs exceeds the set time; if so, the change flag is triggered. A dead zone can also be specified, values within which are considered unchanged.

  Supports timer reset function.

  Check method: $(|Input1 - lastInput1| \geq DeadZone)\ OR\ (|Input2 - lastInput2| \geq DeadZone)\ OR\ (|Input3 - lastInput3| \geq DeadZone)$

  If the duration of change in any input is greater than or equal to "CTime", output "OUT" becomes TRUE. Input - LastInput is the value from the previous cycle.

- **Program example**

  The following example sets the deadband width "DeadZone" to 10. When "Input1" increases from 5 to 15, the output "OUT" changes from FALSE to TRUE. Use variable "bFlag" to detect the change in "OUT".

18.2.13.5 FILTER

FILTER is used for analog value filtering.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
FILTER	Analog filtering	FB		FILTER_Instance_0(IN := , MODE := , FNum := , FOrdCoe := , Reset := , OUT =>);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Analog input	Follows data type	-	Analog input
	MODE	Filter mode	Follows data type	-	• average (0): Average filtering. • median (1): Median filtering. • first_order (2): First-order linear filtering.
	FNum	Filter cycle count	20 >= FNum >= 2	2	Filter cycle count
	FOrdCoe	Sampled value weight	Follows data type	1	Effective when MODE is set to first_order (2); 1 >= FOrdCoe >= 0; the closer to 1, the greater the weight of the new sampled value.
	Reset	Reset a bit	Follows data type	-	Reset
Output	OUT	Filter output	Follows data type	-	Filter output

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TOD	DT	STRING
IN	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
MODE	Enumeration type FILTER_MODE																			
FNum	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
FOrdCoe	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
Reset	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
OUT	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–

- **Function**

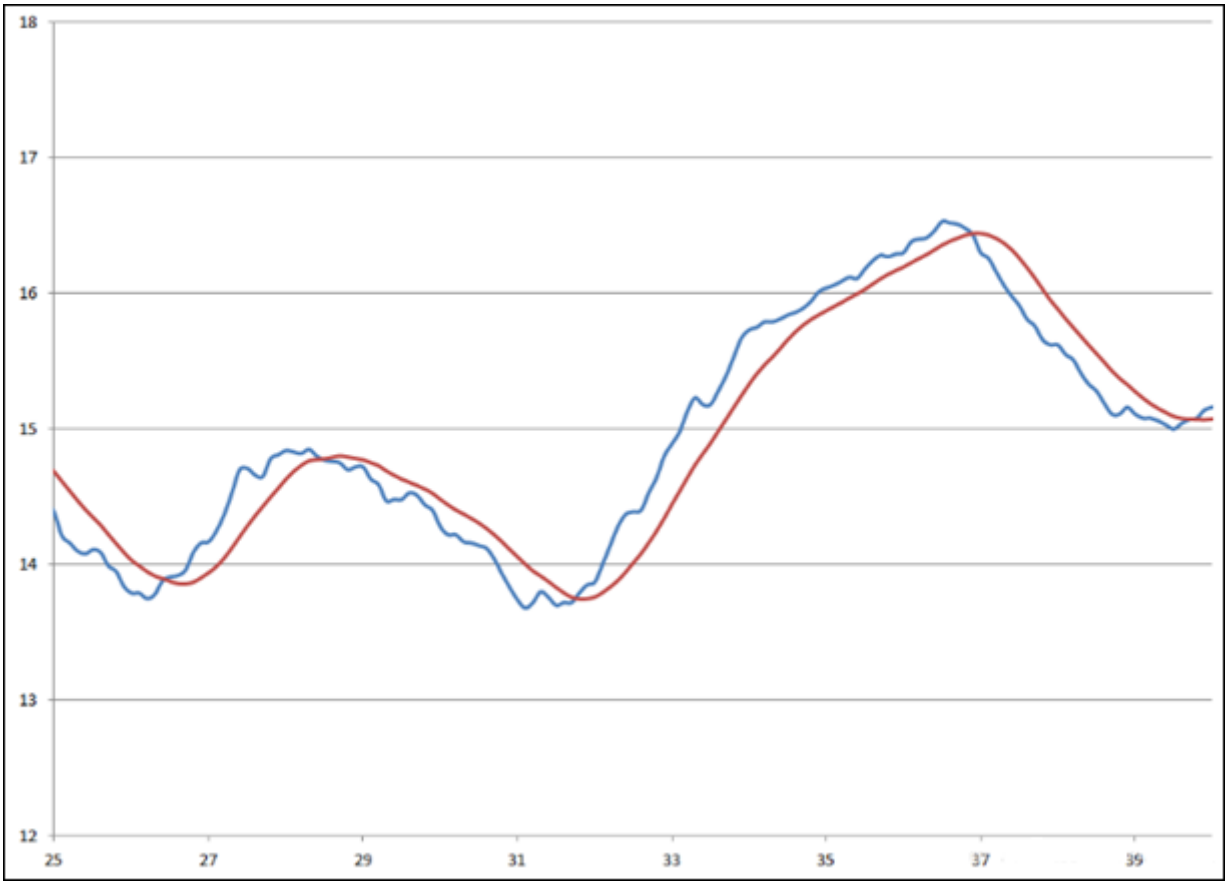
  Provides the following three filtering functions, which can be set via MODE.

  - **Average filtering (MODE = 0)**
    - This algorithm calculates the average of the sampled values over FNum cycles; the algorithm is relatively simple. When FNum is large, the filtered signal is smoother, but with poorer sensitivity; conversely, when FNum is small, the filtering is less smooth, but with greater sensitivity.
    - Due to software memory limitations, 20 cycles are recorded by default.
  - **Median filtering (MODE = 1)**
    - This algorithm collects data over FNum cycles, sorts the values, removes the top 1/3 and bottom 1/3 of the values, and averages the remaining data. This mode is suitable for systems where occasional abnormal values may occur.
    - The selected value range depends on FNum as follows:

      3n: Selected range is n-1 to 2n-1 (average of n values)

      3n+1: Selected range is n to 2n (average of n+1 values)

      3n+2: Selected range is n to 2n+1 (average of n+2 values)
  - **First-order filtering (MODE = 2)**

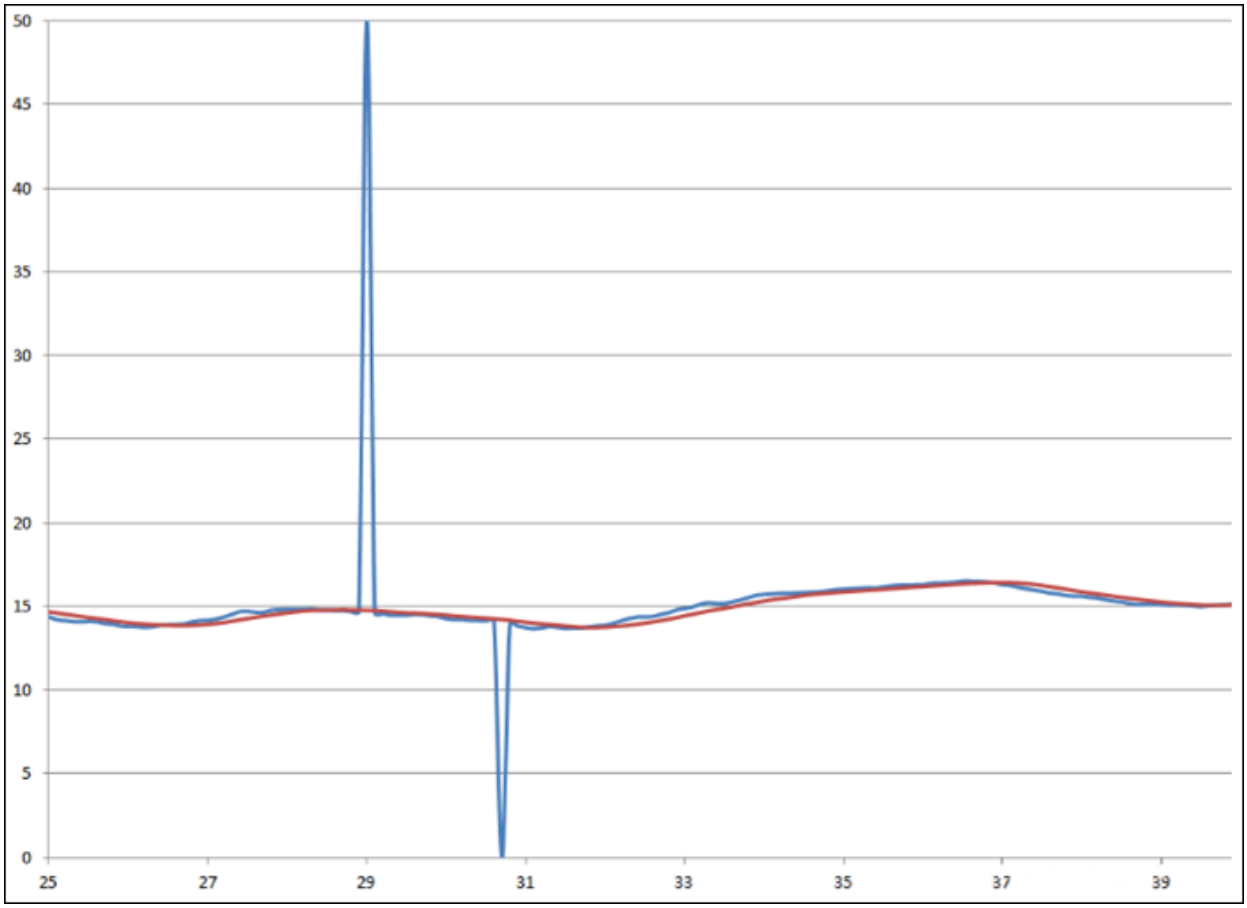


$$Y(n) = FOrdCoe * X(n) + (1 - FOrdCoe) * Y(n-1)$$

(Filter coefficient FOrdCoe ranges from 0 to 1)

- The first-order filter calculates a weighted average between the new sample and the previous filter output. The value of FOrdCoe determines the sensitivity of the algorithm. The larger the FOrdCoe, the greater the weight of the new sample, resulting in higher sensitivity but poorer smoothness; conversely, the smaller the FOrdCoe, the smaller the weight of the new sample, resulting in lower sensitivity but better smoothness.
- The filter also supports a reset function to restart filtering. Reset is level-triggered: when Reset transitions from TRUE to FALSE, the filter restarts.

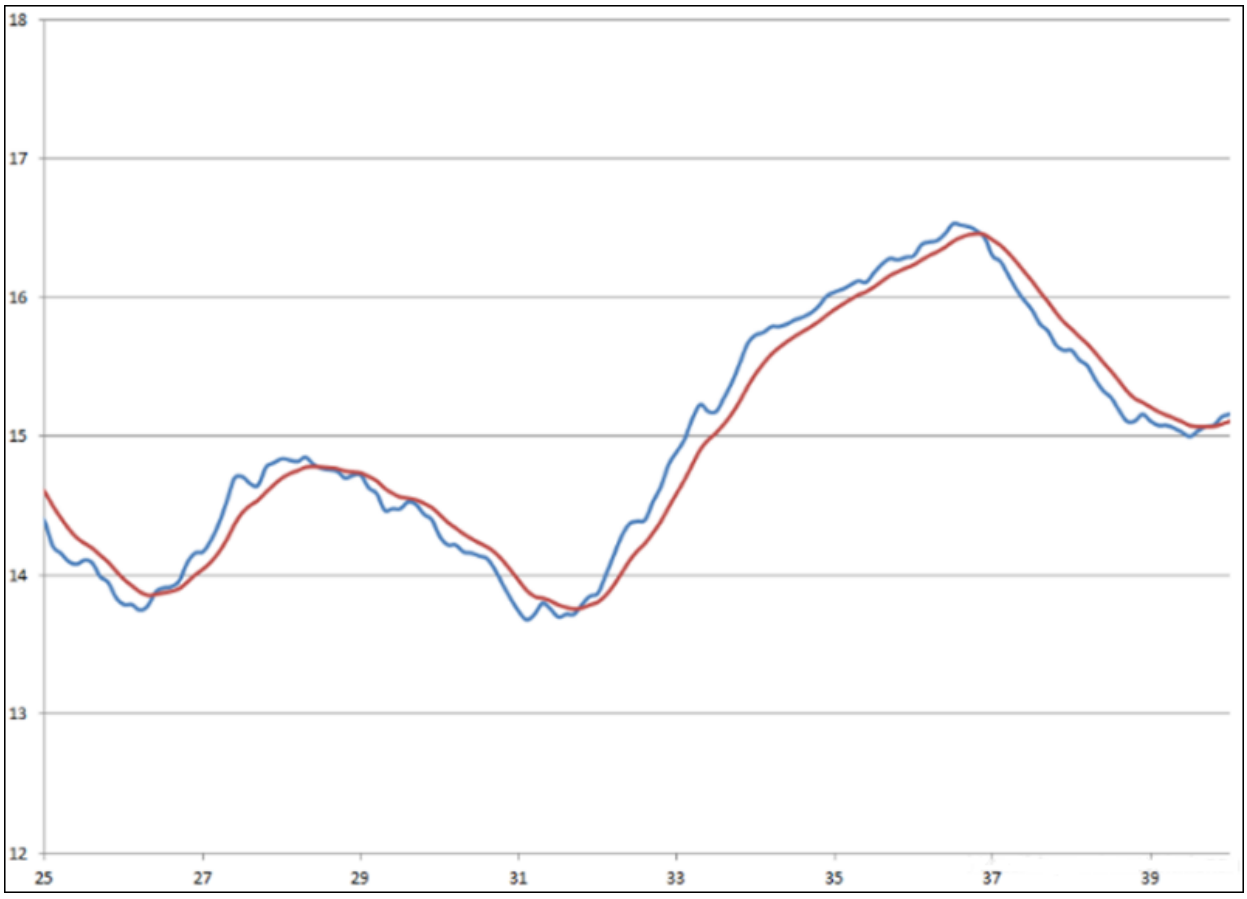
- Performance requirements: Performance specifications and requirements associated for this function.



◦ The average filter greatly smooths the data, but introduces data lag.

Blue - before filtering

Red - after filtering



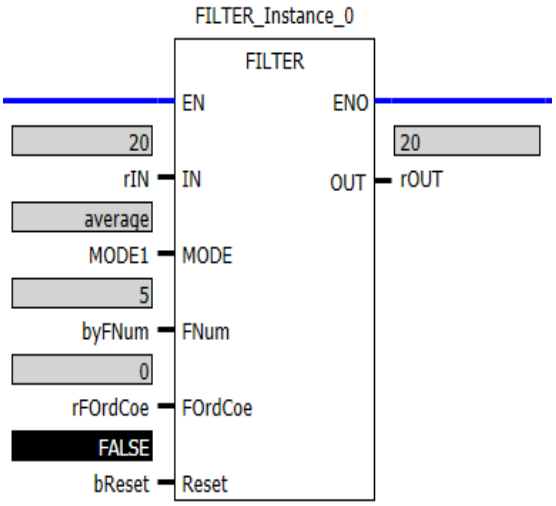
◦ When the original data contains two abnormal values, they may be caused by data interference during sampling or abnormal data processing. Median filtering can be used to effectively eliminate the impact caused by such abnormal values.

Blue - before filtering

Red - after filtering

◦ The first-order filtering smooths the original signal, but introduces lag.

Blue - before filtering



Red - after filtering

- **Program example**

  Taking average filtering as an example, the input signal rIN increases by 1 each scheduling, with the filtering period set to 5. The results are shown in the table below. It can be seen that the output signal of the average filtering exhibits a certain degree of lag.

<table>

ALARM_OUT	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  In many fields involving liquids or gases, it is necessary to obtain the instantaneous flow rate within the pipeline, and accurately measure the total flow volume over a specific period. This requirement can be met using the flow accumulation instruction.

  The specific functions are as follows:

  - The initial value of flow accumulation can be set. After reset, accumulation will start again from the set initial value.
  - Input limit alarm can be set. When the input exceeds the upper limit, ALARM_IN outputs 1, and the current output remains unchanged. When the input exceeds the lower limit, ALARM_IN outputs 2, and the current output remains unchanged.
  - Flow accumulation mode and accumulation time unit can be set:
    - AccMode = 0: Full accumulation. Accumulation occurs regardless of input value.
    - AccMode = 1: Positive accumulation. Accumulation occurs only when the input is positive.
  - Flow accumulation dead zone can be set. Inputs within the dead zone are not accumulated.
  - The integral limit function can be set via the mode parameter (AccLimOPT):
    - When AccLimOPT = 0, the system is in integral limit mode. When the output (OUT) reaches the accumulation completion value (FOUT), it is limited to FOUT, and ALARM_OUT becomes 1.
    - When AccLimOPT = 1, the system is in automatic reset mode. When the output (OUT) reaches the accumulation completion value (FOUT), it automatically resets. FullNum is incremented by 1 upon each completed accumulation.
    - When AccLimOPT = 2 (default mode), the system is in continuous accumulation mode. After the output (OUT) reaches the accumulation completion value (FOUT), accumulation continues without stopping until manually reset. If the output exceeds the floating-point limit, ALARM_OUT becomes 2.

- **Program example**

  When the accumulation mode is set to continuous accumulation, and the flow input is 1, the system output after seven task scheduling cycles is shown in the table below.

- **Function**

  Calculates output based on three analog input values, their quality status, and the operating mode (average, median, high select, low select, channel 1, channel 2, or channel 3).

  Supports manual and automatic modes.

  - In manual mode, output of channel 1/2/3 can be selected, and the output quality corresponds to the input quality.
  - In automatic mode, the following modes are supported: average, median, high select, low select, and channel 1/2/3. The deviation check function can be enabled or disabled.
    - Average: Outputs the average of the inputs, based on quality and deviation check.
    - Median: Outputs the median value when there are three inputs; Outputs the average value when there are two inputs.
  - When all three inputs are of good quality
    - Deviation check
      1. If all three input groups exceed the deviation limit, the output holds its previous value, and the output quality is set to bad.
      2. If two input groups exceed the deviation limit, the output is based on the configured mode using only the input group that is within the limit. The overall output quality is good, and the quality of the inputs used in the calculation is also good. The remaining input is marked as bad quality.
      3. If only one input group exceeds the deviation limit, the output is the median value – specifically, the input that is within the deviation limit relative to the other two. The overall output quality is good, and the two inputs that are within the limit are marked as good quality. The input that exceeded the limit is marked as bad quality.
      4. If no input exceeds the deviation limit, the output is determined by the configured mode.
    - No deviation check: The output is determined by the configured mode.
  - When two inputs are of good quality
    - Deviation check:
      1. If the two inputs exceed the deviation limit, the output holds its previous value, and the output quality is set to bad.
      2. If no input exceeds the deviation limit, the output is determined by the configured mode.
    - No deviation check: The output is determined by the configured mode.
  - When one input is of good quality

Regardless of deviation check, the input of good quality is selected. The overall output quality is also good.

◦ When all three inputs are of bad quality

Channel 1/2/3 is selected: if the selected path's input quality is good, that channel is directly output; if the selected channel's quality is bad, the output holds its previous value.

For example:

When all three inputs are of good quality (In1Qua = In2Qua = In3Qua = TRUE), and DEVOPT = TRUE, the deviation check is performed as follows:

◦ If all deviations are within limits, the output is determined by the selection mode; the overall output quality is good (QUA = TRUE), and the three inputs are also of good quality (QUA1 = QUA2 = QUA3 = TRUE).

◦ When one input group exceeds deviation limit

If In2 and In3 exceed limits: outputs the median value (In1). QUA = TRUE, QUA1 = TRUE, QUA2 = QUA3 = FALSE.

If In1 and In3 exceed limits: outputs the median value (In2). QUA = TRUE, QUA2 = TRUE, QUA1 = QUA3 = FALSE.

If In1 and In2 exceed limits: outputs the median value (In3). QUA = TRUE, QUA3 = TRUE, QUA1 = QUA2 = FALSE.

◦ When two input groups exceed deviation limit, the output is based on the configured mode using the input group that is within the limit.

If (In1, In2) and (In1, In3) exceed limits: the output is based on the group within the limit (In2, In3). QUA = TRUE, QUA2 = QUA3 = TRUE, QUA1 = FALSE.

If (In1, In2) and (In2, In3) exceed limits: the output is based on the group within the limit (In1, In3). QUA = TRUE, QUA1 = QUA3 = TRUE, QUA2 = FALSE.

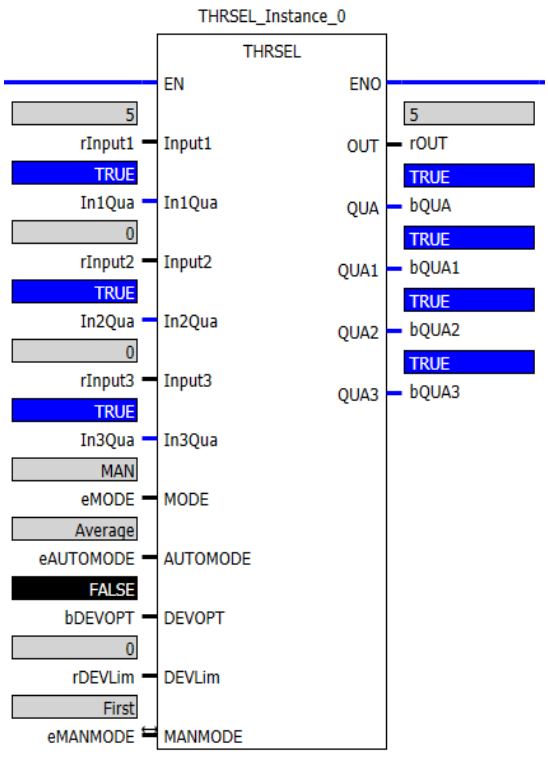
If (In1, In3) and (In2, In3) exceed limits: the output is based on the group within the limit (In1, In2). QUA = TRUE, QUA1 = QUA2 = TRUE, QUA3 = FALSE.

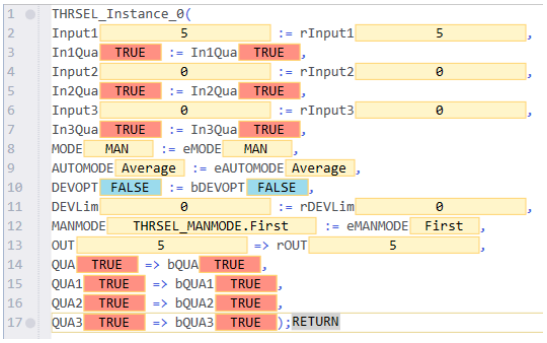
◦ When all three input groups exceed deviation limit, the output holds its previous value.

When two inputs are of good quality (In1Qua = In2Qua = TRUE; In3Qua = FALSE), and DEVOPT = TRUE, the deviation check is performed as follows:

Deviation within limits: The output follows the selected mode. For average or median mode, the output is the average of the two good inputs. QUA = TRUE, QUA1 = QUA2 = TRUE, QUA3 = FALSE.

Deviation exceeds limit: The output holds its previous value. All input qualities are bad and the overall output quality is also bad. QUA1 = QUA2 = QUA3 = FALSE, QUA = FALSE.





Bumpless switchover from automatic mode to manual mode

In automatic mode, manual mode tracks the automatic selection result to ensure bumpless switchover from automatic to manual mode. In automatic mode, if the input to track cannot be determined (e.g., in the case of averaging), the channel whose value is closest to the auto output is tracked.

- **Function**

Calculates output based on the two analog input values, their quality status, and the operating mode (high select, low select, redundant, channel 1, and channel 2).

- Supports manual and automatic modes.
  - In manual mode, output of channel 1/2 can be selected, and the output quality corresponds to the input quality.
  - In automatic mode, the following modes are supported: high select, low select, redundant, channel 1, and channel 2. The deviation check function can be enabled or disabled.

High select or low select:

- When both inputs are of good quality
  - Deviation check:
    1. If the deviation between the two inputs exceeds the limit, the output holds its previous value. The total output quality and the qualities of the both outputs are set to bad.
    2. If the deviation is within the limit, the output follows the selected mode. The total output quality and the qualities of the both outputs are set to good.
  - Deviation check disabled: The output follows the selected mode. The total output quality and the qualities of the both outputs are set to good.
- When only one input is of good quality:

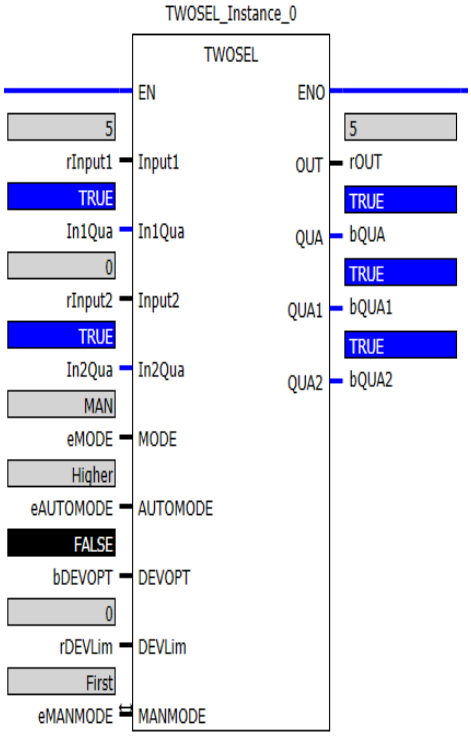
  This input is selected regardless of deviation check.

Redundancy mode:

- When only one input is of good quality, this input is selected. When both inputs are of good quality, the output holds its previous value.
- When both inputs are of bad quality, the output holds its previous value, and the total output quality and the qualities of the both outputs are set to bad.

Channel 1 or channel 2:

If the selected channel has good input quality, it is directly output; otherwise, the output holds its previous value, and the total output quality and the qualities of the both outputs are set to bad.



Bumpless switchover from automatic mode to manual mode

In automatic mode, manual mode tracks the automatic selection result to ensure bumpless switchover from automatic to manual mode.

- **Function**
  - Counts the number of rising edge transitions, falling edge transitions, or both rising and falling edge transitions for digital input signals. This instruction applies to scenarios requiring counting or accumulating the number of state transitions of equipment. It is commonly applied for valves, motors, and similar equipment.
  - The counted transition types include:
    - 0: Rising edge transition
    - 1: Falling edge transition
    - 2: Rising and falling edge transition
  - The statistics result can be reset via the "RESET" parameter.
- **Program example**

  The following example counts the number of both rising and falling edge transitions. Set input "IN" from FALSE to TRUE, and then from TRUE to FALSE; the output is as shown in the table below.

- **Function**

  Counts the number of digital inputs (up to 16 inputs supported) that are TRUE, compares the result with the set number NUM, and outputs the comparison result. In field applications, it is necessary to count how many devices are in TRUE (1) or FALSE (0) status. When the number of devices in certain status is greater than or equal to the set number, the output of BOOL type becomes ON; otherwise, it becomes OFF.

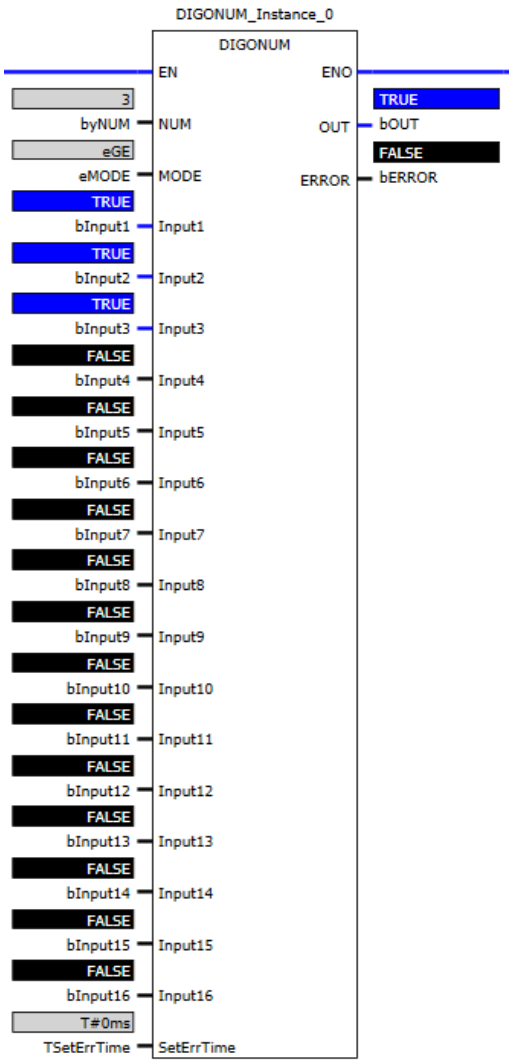
  ◦ Condition check

  Different comparison methods can be applied between the count result and the preset value. When the comparison condition is met, "OUT" outputs TRUE; otherwise, it outputs FALSE. Comparison methods include: greater than or equal, less than or equal, equal to, greater than, and less than.

  By setting the preset value NUM and comparison method MODE, the voting function for digital signals can be achieved. For example, to implement 2-out-of-3 voting for air-operated digital signals, set the comparison method MODE to 0 (Greater than or equal to) with a preset value of 2, set the comparison value to 2, and connect the three signals to be voted to the three inputs of the function block.

  ◦ Fault alarm

When the comparison output changes from TRUE to FALSE, the fault timer is started, counting the cumulative time during which the output remains FALSE. When the timer reaches the preset time limit for fault detection "SetErrTime", "ERR" outputs TRUE; otherwise, "ERR" outputs FALSE.



This function can be used to determine the duration of invalid field conditions. If this duration exceeds SetErrTime, the output ERROR is set to TRUE. If the fault alarm is not required, set SetErrTime to 0.

- **Program example**

  The following example sets the input NUM to 3. When three input signals are TRUE, the output result is as shown in the table below.

AccTime OUT	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–

- **Function**
  - This instruction accumulates the duration of the 0 (OFF) and 1 (ON) statuses of a digital input signal separately, and outputs the accumulated time for the selected status in the specified unit. It can be used to calculate the cumulative time of equipment in a specific status, such as pump operation or feeding timing.
  - The time units support seconds, minutes, hours, and days.
  - The selected status for accumulation AccOPT can be 0 or 1:
    - AccOPT = 0: accumulates only the time when the input signal is 0.
    - AccOPT = 1: accumulates only the time when the input signal is 1.
  - The accumulated time can be reset using the "RESET" parameter.
- **Program example**

  The following example calculates the accumulated time (in seconds) for input signal "IN". The calculation results for 10 scheduled cycles are shown in the table below.

<table>

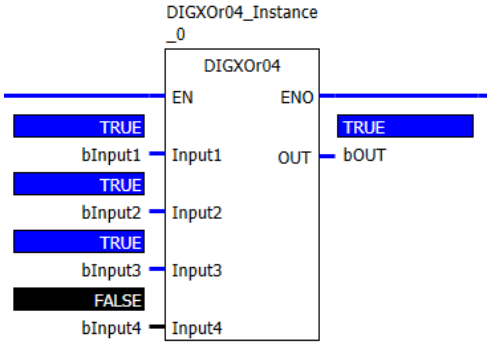
- **Function**

  Performs XOR logic operations on up to four digital inputs.

  This block can perform logical operations on up to four digital input parameters. If an odd number of inputs are 1 and the others are 0, the output "OUT" is 1.



No.	In1	In2	In3	In4	Out

CTimeOut	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–

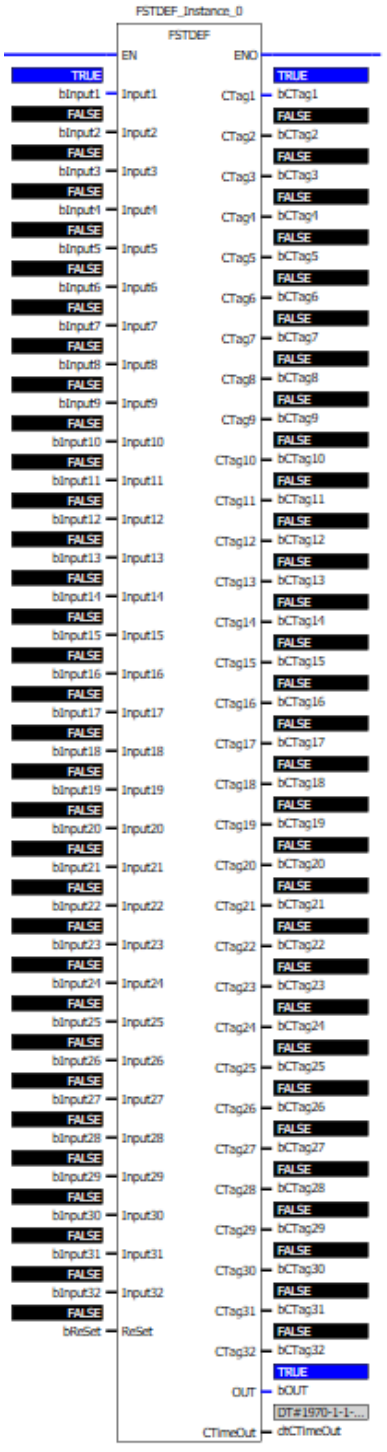
- **Function**

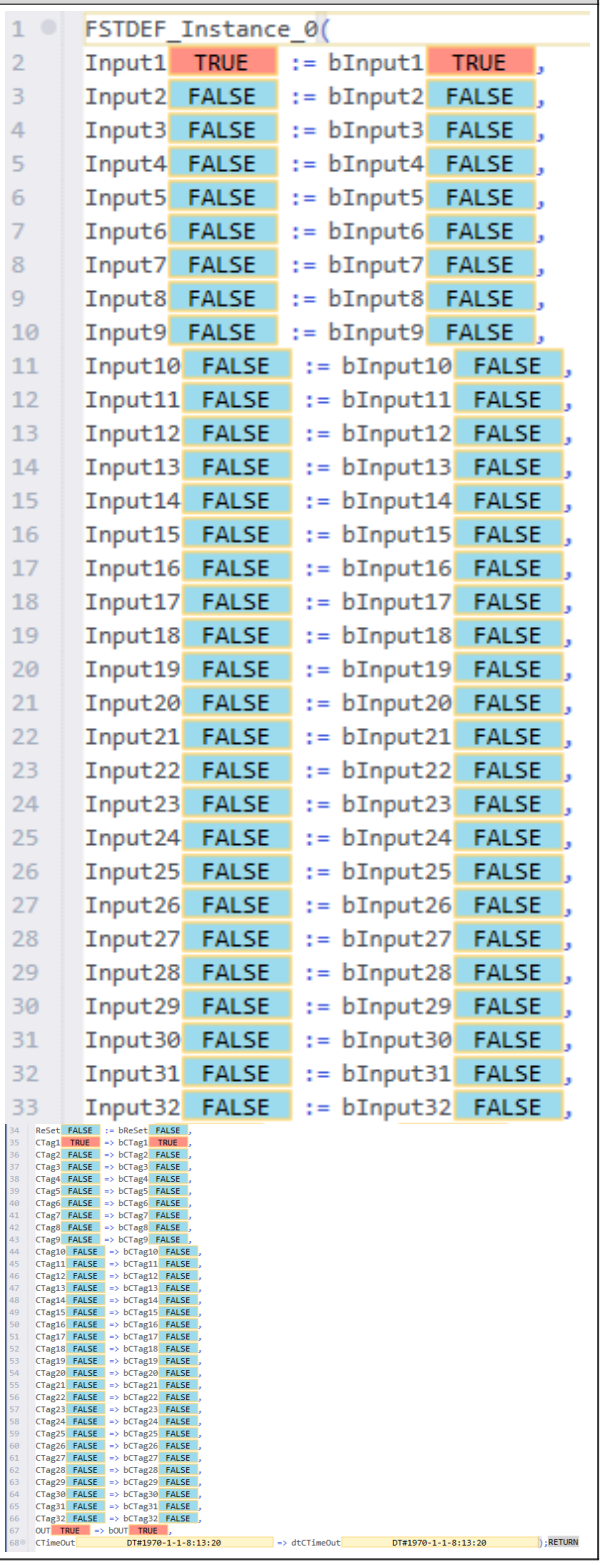
  This instruction monitors up to 32 digital signals for status transitions (rising edge-triggered). The transition mark corresponding to the first signal that transitions becomes TRUE until reset. It can be used for on-site accident analysis.

  - First transition function
    - If any one of the 32 input signals transitions, the total transition mark "OUT" becomes TRUE, and the transition mark of the corresponding input also becomes TRUE until reset.

- When multiple input signals transition in sequence, only the one occurs first is recorded; subsequent transitions are not recorded. This status is maintained until reset.
- When multiple input signals transition simultaneously, the function block defaults to recording the lowest-indexed input as the first transition.

◦ Time recording





- The moment the total transition mark "OUT" changes from FALSE to TRUE (i.e., when the first transition occurs) is output via the "CTimeOut" parameter.
- When no transition is triggered, CTimeOut continues to update to the current system time.

- **Program example**

  The following example sets "Input1" to TRUE and all other parameters to default. In this case, "CTag1" becomes TRUE, "OUT" becomes TRUE, and "CTimeOut" outputs the moment when "Input1" transitions from 0 to 1.

18.2.15.2 AryCmpEQ

Compares whether the elements of two arrays are equal.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AryCmpEQ	Array equality comparison	FC		:= AryCmpEQ(In1 := , In2 := , Size := , AryOut :=);

- **Related variables**

Variable

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	In1[ ] array	Comparison array 1	Follows data type	-	Array 1 to compare
	In2[ ] array	Comparison array 2	Follows data type	-	Array 2 to compare
	Size	Number of elements to compare	Follows data type	1	Number of elements to compare
Input/ Output	AryOut[ ] array	Comparison result array	Follows data type	-	Comparison result array
Output	AryCmpEQ	Function return value	Follows data type	-	TRUE: Normal execution completed. FALSE: The instruction was not executed due to an error.

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Array In1[ ]	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	-	-	-	-	-
In2[ ] array	Array with the same data type as In1[ ]																			
Size	-	-	-	-	-	-	-	-	-	-	-	√	-	-	-	-	-	-	-	-

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
AryOut[ ] array	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
AryCmpEQ	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

- **Function**
  - This instruction compares the elements with the same indices in two arrays (In1[0] to In1[Size-1] and In2[0] to In2[Size-1]) to determine whether they are equal. The comparison results are stored in elements with the corresponding indices in the array (AryOut[0] to AryOut[Size–1]).
  - When In1[i] = In2[i], AryOut[i] is TRUE; otherwise, it is FALSE.
- **Program example**

	LD	ST

Define variables	VAR
	ret1: BOOL;
	arr_int1: ARRAY[1..5] OF INT := [11,22,33,44,55];
	arr_int2: ARRAY[1..5] OF INT := [12,22,33,45,55];
	disize: DINT := 4;
	abArrout: ARRAY[1..5] OF BOOL;
	END_VAR	

Program		ret1 TRUE := AryCmpEQ(In1 := arr_int1[1] 11 , In2 := arr_int2[1] 12 , Size := diSize 4 , AryOut := abAryOut[1] FALSE);RETURN

	LD	ST
Operation result		

	Name	Data type	Address	Value
1	arr_int1	ARRAY [1..5] OF INT		
2	arr_int1[1]	INT		11
3	arr_int1[2]	INT		22
4	arr_int1[3]	INT		33
5	arr_int1[4]	INT		44
6	arr_int1[5]	INT		55
7	arr_int2	ARRAY [1..5] OF INT		
8	arr_int2[1]	INT		12
9	arr_int2[2]	INT		22
10	arr_int2[3]	INT		33
11	arr_int2[4]	INT		44
12	arr_int2[5]	INT		55
13	diSize	DINT		4
14	abAryOut	ARRAY [1..5] OF BOOL		
15	abAryOut[1]	BOOL		TRUE
16	abAryOut[2]	BOOL		FALSE
17	abAryOut[3]	BOOL		FALSE
18	abAryOut[4]	BOOL		FALSE
19	abAryOut[5]	BOOL		FALSE
20	ret1	BOOL		TRUE

- **Precautions**
  - Use the same data type for In1[ ] and In2[ ]; otherwise, a compilation fault will occur.
  - If In1[ ] and In2[ ] are real numbers that contain non-terminating decimal numbers, the processing results may be unexpected due to rounding errors.
  - When the value of Size is 0, the return value is TRUE and AryOut[ ] remains unchanged.
  - When the value of Size exceeds the In1[ ], In2[ ], or AryOut[ ] array, the return value is FALSE and AryOut[ ] remains unchanged.
  - When the value of Size is less than 0, the return value is TRUE and AryOut[ ] remains unchanged.
  - If the dimension of the input array exceeds 3, the return value is FALSE, and AryOut[ ] remains unchanged.
  - Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.15.3 AryCmpNE

Compares whether the elements of two arrays are unequal.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AryCmpNE	Array inequality comparison	FC		:= AryCmpNE(In1 := , In2 := , Size := , AryOut :=);

- **Related variables**

  Variable

</td></tr>
<tr><td>Operation result</td><td colspan="2">

</td></tr>
</table>

- **Precautions**
  - Use the same data type for In1[ ] and In2[ ]; otherwise, a compilation fault will occur.
  - If In1[ ] and In2[ ] are real numbers that contain non-terminating decimal numbers, the processing results may be unexpected due to rounding errors.
  - When the value of Size is 0, the return value is TRUE and AryOut[ ] remains unchanged.
  - When the value of Size exceeds the In1[ ] or AryOut[ ] array, the return value is FALSE and AryOut[ ] remains unchanged.
  - When the value of Size is less than 0, the return value is TRUE and AryOut[ ] remains unchanged.
  - If the dimension of the input array exceeds 3, the return value is FALSE, and AryOut[ ] remains unchanged.
  - Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.15.6 AryCmpLT

Performs a less-than comparison between the values of elements in two arrays.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AryCmpLT	Array comparison (less than)	FC		:= AryCmpLT(In1 := , In2 := , Size := , AryOut :=);

- **Related variables**

Variable

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	In1[ ] array	Comparison array 1	Follows data type	-	Array 1 to compare
	In2[ ] array	Comparison array 2	Follows data type	-	Array 2 to compare
	Size	Number of elements to compare	Follows data type	1	Number of elements to compare
Input/ Output	AryOut[ ] array	Comparison result array	Follows data type	-	Comparison result array
Output	AryCmpLT	Function return value	Follows data type	-	TRUE: Normal execution completed. FALSE: The instruction was not executed due to an error.

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1[ ] array	-	-	-	-	-	√	√	√	√	√	√	√	√	√	√	-	-	-	-	-
In2[ ] array	Array with the same data type as In1[ ]																			
Size	-	-	-	-	-	-	-	-	-	-	-	√	-	-	-	-	-	-	-	-

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING

	In2	Comparison variable	Follows data type	-	Variable to compare
	Size	Number of elements to compare	Follows data type	1	Number of elements to compare
Input/ Output	AryOut[ ] array	Comparison result array	Follows data type	-	Comparison result array
Output	AryCmpLEV	Function return value	Follows data type	-	TRUE: Normal execution completed. FALSE: The instruction was not executed due to an error.

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1[ ] array	-	-	-	-	-	√	√	√	√	√	√	√	√	√	√	-	-	-	-	-
In2	Same data type as the elements of In1[ ]																			
Size	-	-	-	-	-	-	-	-	-	-	-	√	-	-	-	-	-	-	-	-
AryOut[ ] array	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
AryCmpLEV	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

- **Function**
  - This instruction performs a less-than or equal-to comparison between the values of elements in the array (In1[0] to In1[Size-1]) and the value of In2. The comparison results are stored in elements with the corresponding indices in the array (AryOut[0] to AryOut[Size−1]).
  - When In1[i] <= In2, AryOut[i] is TRUE; otherwise, it is FALSE.
- **Program example**

<table>
<tr><th></th><th>LD</th><th>ST</th></tr>
<tr><td>Define variables</td><td colspan="2">

```
VAR
    ret1:BOOL;
    arr_int1:ARRAY[1..5] OF INT := [11,22,33,44,55];
    int2 :INT := 33;
    disize :DINT := 4;
    abArrout:Array[1..5] OF BOOL;
END_VAR
```

</td></tr>
<tr><td>Program</td><td>

</td><td>

```
ret1 TRUE := AryCmpLEV(
        In1 := arr_int1[1] 11 ,
        In2 := int2 33 ,
        Size := diSize 4 ,
        AryOut := abAryOut[1] TRUE );RETURN
```

</td></tr>
<tr><td>Operation result</td><td colspan="2">

	Name	Data type	Address	Value
1	arr_int1	ARRAY [1..5] OF INT		
2	arr_int1[1]	INT		11
3	arr_int1[2]	INT		22
4	arr_int1[3]	INT		33
5	arr_int1[4]	INT		44

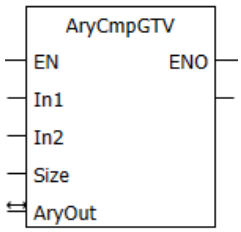
14	abAryOut[5]	BOOL		FALSE
15	ret1	BOOL		TRUE



</td></tr>
</table>

- **Precautions**
  - Use the same data type for In1[ ] and In2[ ]; otherwise, a compilation fault will occur.
  - If In1[ ] and In2[ ] are real numbers that contain non-terminating decimal numbers, the processing results may be unexpected due to rounding errors.
  - When the value of Size is 0, the return value is TRUE and AryOut[ ] remains unchanged.
  - When the value of Size exceeds the In1[ ] or AryOut[ ] array, the return value is FALSE and AryOut[ ] remains unchanged.
  - When the value of Size is less than 0, the return value is TRUE and AryOut[ ] remains unchanged.
  - If the dimension of the input array exceeds 3, the return value is FALSE, and AryOut[ ] remains unchanged.
  - Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.15.12 AryCmpGTV

Performs a greater-than comparison between the values of elements in an array and the value of a variable.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AryCmpGTV	Array and value comparison (greater than)	FC		:= AryCmpGTV(In1 := , In2 := , Size := , AryOut :=);

- **Related variables**

18.2.16.2 AryByteTo

Joins BYTE-type array elements and saves the result in a variable.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AryByteTo	Conversion from byte array	FC		:= AryByteTo(IN := , Size := , Order := , OutVal :=);

- **Related variables**

  Variable

Input Variable	Variable	Name	Valid Range	Default Value	Description
Input	In[ ] array	Array to convert	Follows data type	-	Array to convert
	Size	Number of elements to convert	Follows data type	1	Number of elements in In[ ] to convert
	Order	Conversion order	Follows data type	-	Conversion order
	OutVal	Conversion result	Follows data type	-	Conversion result

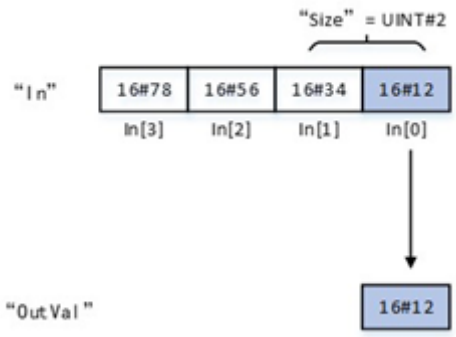
Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In[ ] array	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Size	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–
Order	See "Function description" for the enumerators for the enumerated type _eBYTE_ORDER.																			
OutVal	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
	An enumeration, an array, an array element, a structure, or a structure member can also be specified.																			

- **Function**
  - This instruction joins the first Size elements in In[ ] to match the size of the data type of the conversion result OutVal, and then saves the result to OutVal.
  - The order to join the elements of In[ ] is specified by Order. The data type of Order is enumerated type _eBYTE_ORDER. The meanings of the enumeration values are as follows.

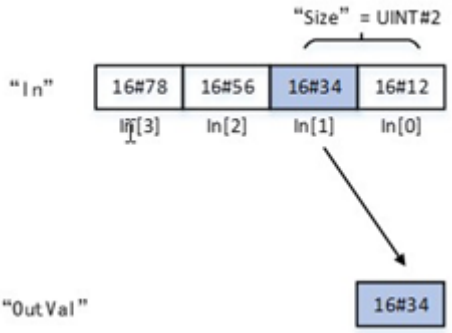
Enumeration Value	Definition
Low-High	Lower byte first, higher byte last

Enumeration Value	Definition
_HIGH_LOW	Higher byte first, lower byte last



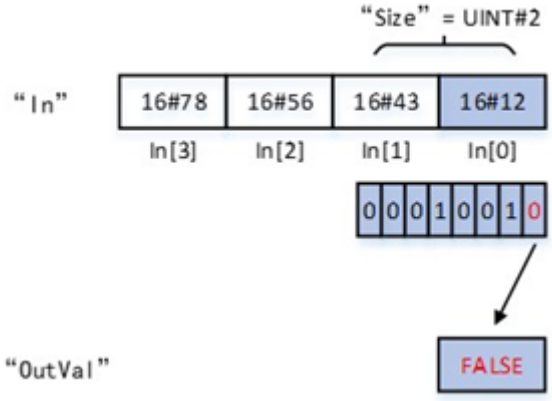
- The following describes the functions of AryByteTo in two situations.
  - If the data type of OutVal is one byte, In[ ] is stored in OutVal by one byte. The following data types have one byte.

Category	Data Type
Bit string	BYTE
Integer	USINT, SINT
Real number	/
Time, duration, date, and text string	/
Others	An enumeration with a size of one byte; an array for which the total for all elements is one byte; an array element that is one byte; a structure for which the total for all members is one byte; a structure member that is one byte

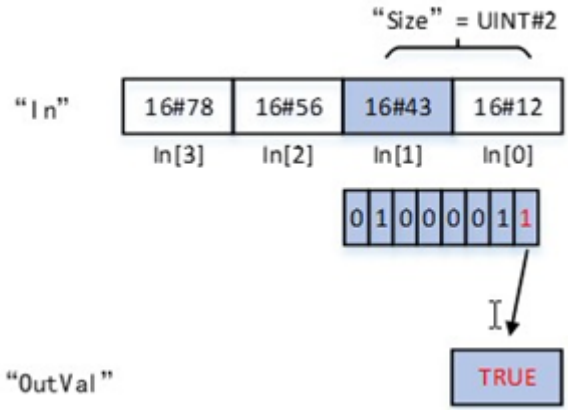


The storage method is as follows:

Value of Order	Data Type of OutVal	Storage Method
Low-High	BOOL	Bit 0 of In[0] is stored in OutVal.
	Non-BOOL	The value of In[0] is stored in OutVal.
_HIGH_LOW	BOOL	Bit 0 of In[1] is stored in OutVal.
	Non-BOOL	The value of In[1] is stored in OutVal.



The following example sets OutVal to a SINT variable, Size to UINT#2, and Order to _LOW_HIGH, as shown below.



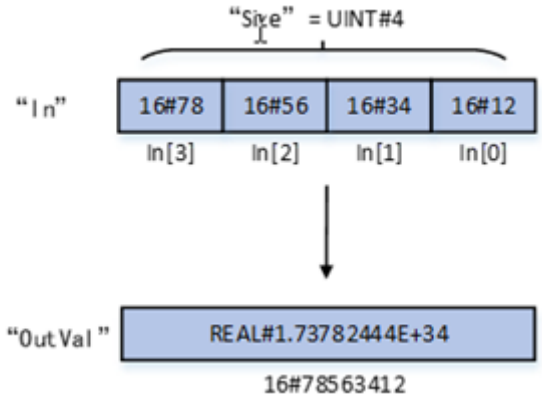
The following example sets OutVal to a SINT variable, Size to UINT#2, and Order to _HIGH_LOW, as shown below.

The following example sets OutVal to a BOOL variable, Size to UINT#2, and Order to _LOW_HIGH, as shown below.

The following example sets OutVal to a BOOL variable, Size to UINT#2, and Order to _HIGH_LOW, as shown below.

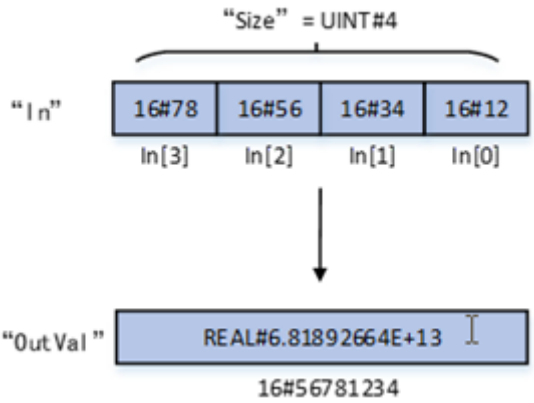
- If the data type of OutVal is two bytes or more, elements from In[ ] are joined to be equivalent to the data size of OutVal. The result is stored in OutVal. The following data types have two bytes or more.

Category	Data Type
Bit string	WORD, DWORD, LWORD
Integer	UINT, UDINT, ULINT, INT, DINT, LINT
Real number	REAL, LREAL
Time, duration, date, and text string	TIME, DATE, TOD, DT, and STRING types of two bytes or more



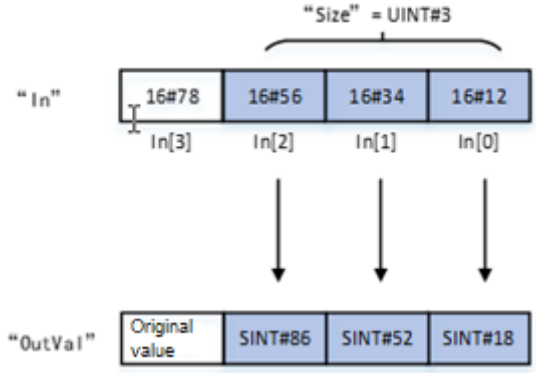
Category	Data Type
Others	An enumeration with two or more bytes; an array for which the total for all elements is two or more bytes; an array element that is two or more bytes; a structure for which the total for all members is two or more bytes; a structure member that is two or more bytes

The storage method is as follows:

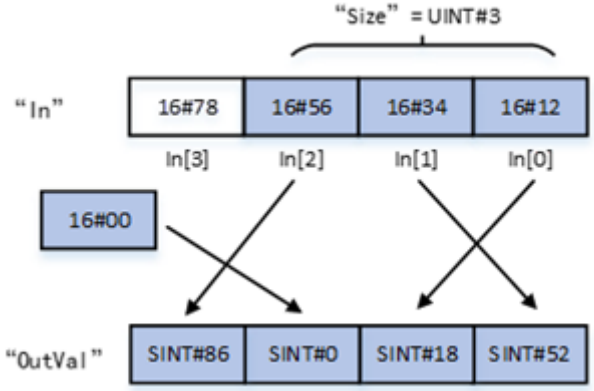


In[0] and In[1] are joined according to the value of Order to create one word (two bytes) of data. If Order is _LOW_HIGH, the higher byte is stored in In[1] and the lower byte is stored in In[0]. If Order is _HIGH_LOW, the higher byte is stored in In[0] and the lower byte is stored in In[1]. In the same way elements that start from In[2] and In[3] are joined to make more words of data. The words of data are joined to match the size of the data type of OutVal.

For example, if OutVal is DWORD data, four individual words of data are joined. If OutVal is an array, In[i] (i as an even number) is stored in OutVal[i+1]. In[i] (i as an odd number) is stored in OutVal[i-1]. If the value of "Size" is odd, data is stored till OutVal[Size], and 16#00 is stored in OutVal[Size-1]. The result data is stored in "OutVal".

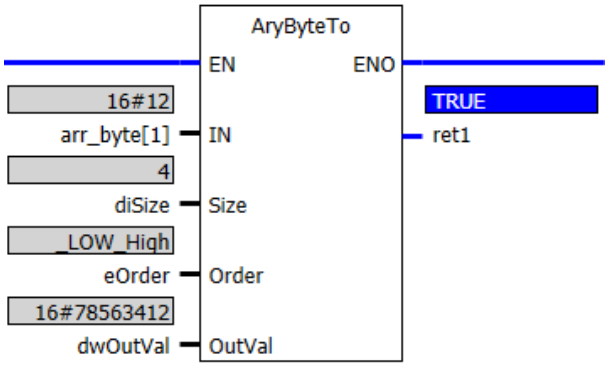


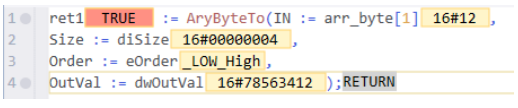
The following example sets OutVal to a REAL variable, Size to UINT#4, and Order to _LOW_HIGH, as shown below.



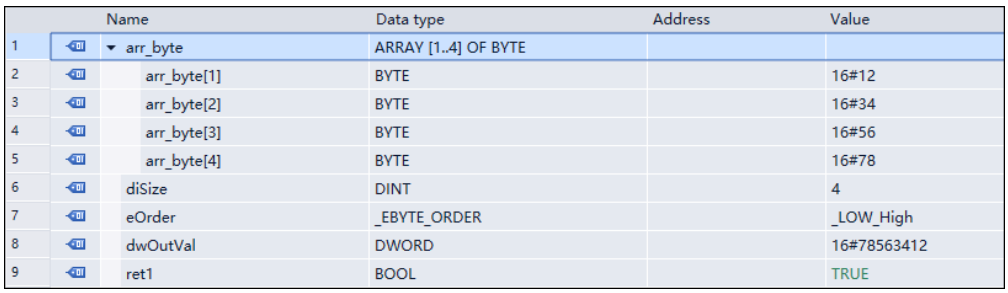
The following example sets OutVal to a REAL variable, Size to UINT#4, and Order to _HIGH_LOW, as shown below.

The following example sets OutVal to a SINT array with four elements, Size to UINT#3, and Order to _LOW_HIGH, as shown below.





The following example sets OutVal to a SINT array with four elements, Size to UINT#3, and Order to _HIGH_LOW, as shown below.



- **Program example**

	LD	ST

Define variables	VAR
	arr_byte: ARRAY[1..4] OF BYTE := [16#12,16#34,16#56,16#78];
	diSize: DINT := 4;
	eOrder: _eBYTE_ORDER := _EBYTE_ORDER._LOW_High;
	dwOutVal: DWORD;
	ret1: BOOL;
	END_VAR	

Program		

	LD	ST
Operation result		

	Name	Data type	Address	Value
1	arr_byte	ARRAY [1..4] OF BYTE		
2	arr_byte[1]	BYTE		16#12
3	arr_byte[2]	BYTE		16#34
4	arr_byte[3]	BYTE		16#56
5	arr_byte[4]	BYTE		16#78
6	diSize	DINT		4
7	eOrder	_EBYTE_ORDER		_LOW_High
8	dwOutVal	DWORD		16#78563412
9	ret1	BOOL		TRUE

- **Precautions**
  - When Size exceeds the array range of In[ ] or when Order exceeds the valid range of the enumeration _eBYTE_ORDER, the function returns FALSE, and OutVal remains unchanged.
  - OutVal cannot be a BOOL array; otherwise, the program operation fails.
  - When OutVal is a structure, some of the values of In[ ] may be inserted in areas between members depending on the composition.
  - When the value of Size is 0, the value of Out is TRUE and OutVal remains unchanged.
  - If the dimension of the input array exceeds 3, the return value is FALSE, and AryOut[ ] remains unchanged.
  - Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.
  - In[ ] must be an indexed array; otherwise, a compilation fault will occur.

18.2.16.3 AryExchange

Exchanges elements between two arrays.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AryExchange	Array element exchange	FC		:= AryExchange(InOut1 := , InOut2 := , Size :=);

- **Related variables**

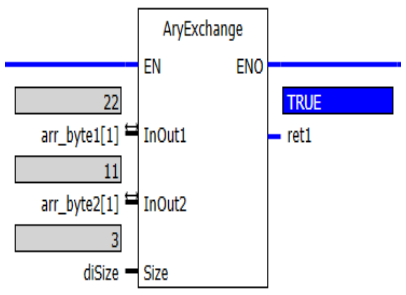
Input variables

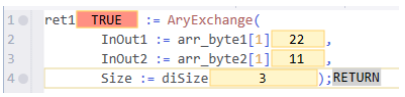
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Size	Number of elements to exchange	Follows data type	1	Number of elements to exchange
Input/Output	InOut1[ ] array	Array 1 to exchange	Follows data type	-	Array 1 to exchange

Input/Output	Variable	Name	Valid Range	Default Value	Description
	InOut2[ ] array	Array 2 to exchange	Follows data type	-	Array 2 to exchange

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Size	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–
InOut1[ ] array	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
	Arrays of enumerations or structures can also be specified.																			
InOut2[ ] array	Same data type as the elements of InOut1[ ].																			





- **Function**

  This instruction exchanges the values of InOut1[ ] and InOut2[ ]. This instruction exchanges Size elements from the specified position between arrays InOut1[ ] and InOut2[ ].

- **Program example**

	LD	ST

Define variables	VAR
	arr_byte1: ARRAY[1..4] OF BYTE := [4(11)];
	arr_byte2: ARRAY[1..4] OF BYTE := [4(22)];
	diSize: DINT := 3;
	ret1: BOOL;
	END_VAR	

Program		

	LD	ST
Operation result		

	Name	Data type	Address	Value
1	arr_byte1	ARRAY [1..4] OF BYTE		
2	arr_byte1[1]	BYTE		22
3	arr_byte1[2]	BYTE		22
4	arr_byte1[3]	BYTE		22
5	arr_byte1[4]	BYTE		11
6	arr_byte2	ARRAY [1..4] OF BYTE		
7	arr_byte2[1]	BYTE		11
8	arr_byte2[2]	BYTE		11
9	arr_byte2[3]	BYTE		11
10	arr_byte2[4]	BYTE		22
11	diSize	DINT		3
12	ret1	BOOL		TRUE

- **Precautions**
  - Use the same data type for InOut1[ ] and InOut2[ ]; otherwise, a compilation fault will occur.
  - When the value of Size is 0, the return value is TRUE, and InOut1[ ] and InOut2[ ] remain unchanged.
  - When both InOut1[ ] and InOut2[ ] are STRING-type arrays, and the length of a string element in one array exceeds that of the corresponding element in the other array, the return value is FALSE, and InOut1[ ] and InOut2[ ] remain unchanged.
  - When the value of Size exceeds the range of InOut1[ ] or InOut2[ ], the return value is FALSE, and InOut1[ ] and InOut2[ ] remain unchanged.
  - If the dimension of the input array exceeds 3, the return value is FALSE, and InOut1[ ] and InOut2[ ] remain unchanged.
  - Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.16.4 AryMove

Moves one or more array elements.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AryMove	Array move	FC		:= AryMove(In := , Size := , AryOut :=);

- **Related variables**

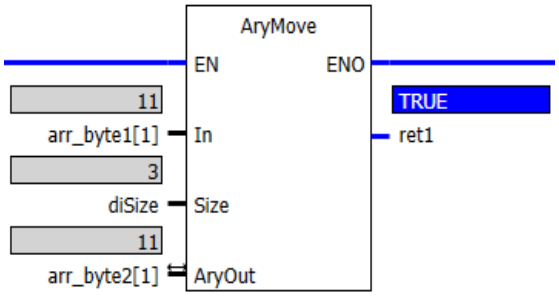
Variable

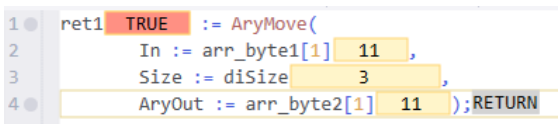
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In[ ] array	Move source array	Follows data type	-	Array to move
	Size	Number of elements to move	Follows data type	1	Number of elements to move

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input/Output	AryOut[ ] array	Move result array	Follows data type	-	Move result array

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In[ ] array	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
	Arrays of enumerations or structures can also be specified.																			
Size	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–
AryOut[ ] array	Same data type as the elements of In[ ]																			





- **Function**

  This instruction moves Size elements of In[ ] starting from In[0] to AryOut[ ] starting from AryOut[0].

- **Program example**

	LD	ST

Define variables	VAR
	arr_byte1 : ARRAY[1..4] OF BYTE := [4(11)];
	arr_byte2 : ARRAY[1..4] OF BYTE := [4(22)];
	diSize : DINT := 3;
	ret1 : BOOL;
	END_VAR	

Program		

	LD	ST

Operation result

	Name	Data type	Address	Value
1	arr_byte1	ARRAY [1..4] OF BYTE		
2	arr_byte1[1]	BYTE		11
3	arr_byte1[2]	BYTE		11
4	arr_byte1[3]	BYTE		11
5	arr_byte1[4]	BYTE		11
6	arr_byte2	ARRAY [1..4] OF BYTE		
7	arr_byte2[1]	BYTE		11
8	arr_byte2[2]	BYTE		11
9	arr_byte2[3]	BYTE		11
10	arr_byte2[4]	BYTE		22
11	diSize	DINT		3
12	ret1	BOOL		TRUE

- **Precautions**
  - Use the same data type for In[ ] and AryOut[ ]; otherwise, a compilation fault will occur.
  - When the value of Size is 0, the return value is TRUE and AryOut[ ] remains unchanged.
  - When both In[ ] and AryOut[ ] are STRING-type arrays and the length of a string in In[ ] exceeds the memory size of AryOut[ ], the return value is FALSE and AryOut[ ] remains unchanged.
  - When the value of Size exceeds the range of In[ ] or AryOut[ ], the return value is FALSE and AryOut[ ] remains unchanged.
  - If the dimension of the input array exceeds 3, the return value is FALSE, and AryOut[ ] remains unchanged.
  - Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.16.5 AryToBCD

Converts the elements of an unsigned integer array to BCD bit strings.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AryToBCD	Array-to-BCD conversion	FC		:= AryToBCD(In := , Size := , AryOut :=);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In[ ] array	Unsigned integer array	Follows data type	-	Unsigned integer array

Input/Output	Variable	Name	Valid Range	Default Value	Description
	Size	Number of elements to convert	Follows data type	1	Number of elements in In[ ] to convert
Input/Output	AryOut[ ] array	BCD array	Follows data type	-	BCD array

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In[ ] array	–	–	–	–	–	√	√	√	√	–	–	–	–	–	–	–	–	–	–	–
Size	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–
AryOut[ ] array	Same data type as the elements of In[ ]																			

- **Function**

  This instruction converts Size elements of the unsigned integer array In[ ] starting from In[0] to a BCD bit string, and outputs the result to the BCD array AryOut[ ]. The valid ranges for In[ ] and AryOut[ ] vary depending on the data types of their elements, as shown below.

Data Type of In[ ] Element	Valid Range of In[ ]	Valid Range of AryOut[ ]
USINT	0 to 99	16#00 to 16#99 (BCD)
UINT	0 to 9999	16#0000 to 16#9999 (BCD)
UDINT	0 to 99999999	16#0000_0000 to 16#9999_9999 (BCD)
ULINT	0 to 9999999999999999	16#0000_0000_0000_0000 to 16#9999_9999_9999_9999 (BCD)

- **Program example**

<table>
<tr><th></th><th>LD</th><th>ST</th></tr>
<tr><td>Define variables</td><td colspan="2">

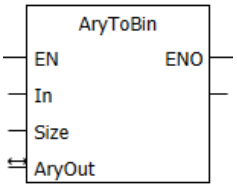
```
VAR
    arr_byte1: ARRAY[1..4] OF UINT := [12,34,567,89];
    arr_byte2: ARRAY[1..4] OF UINT;
    diSize: DINT := 3;
    ret1: BOOL;
END_VAR
```

</td></tr>
<tr><td>Program</td><td>
</td><td>

```
ret1 TRUE := AryToBCD(
        In := arr_byte1[1] 12 ,
        Size := diSize 3 ,
        AryOut := arr_byte2[1] 16#0012 );RETURN
```

</td></tr>
<tr><td>Operation result</td><td colspan="2">

	Name	Data type	Address	Value
1	arr_byte1	ARRAY [1..4] OF UINT		
2	arr_byte1[1]	UINT		12
3	arr_byte1[2]	UINT		34
4	arr_byte1[3]	UINT		567
5	arr_byte1[4]	UINT		89
6	arr_byte2	ARRAY [1..4] OF UINT		
7	arr_byte2[1]	UINT		16#0012
8	arr_byte2[2]	UINT		16#0034
9	arr_byte2[3]	UINT		16#0567
10	arr_byte2[4]	UINT		16#0000
11	diSize	DINT		3
12	ret1	BOOL		TRUE



</td></tr>
</table>

- **Precautions**
  - This instruction does not support conversion to signed BCD. Therefore, the data type of In[ ] must be unsigned integer (USINT, UINT, UDINT, or ULINT).
  - When the value of Size is 0, the return value is TRUE and AryOut[ ] remains unchanged.
  - When the value of In[ ] exceeds the valid range, the return value is FALSE and AryOut[ ] remains unchanged.
  - When the value of Size exceeds the range of In[ ] or AryOut[ ], the return value is FALSE and AryOut[ ] remains unchanged.
  - If the dimension of the input array exceeds 3, the return value is FALSE, and AryOut[ ] remains unchanged.
  - Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.16.6 AryToBin

Converts the elements of a BCD array into bit strings.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AryToBin	Array-to-bit string conversion	FC		:= AryToBin(In := , Size := , AryOut :=);

- **Related variables**

  Variable

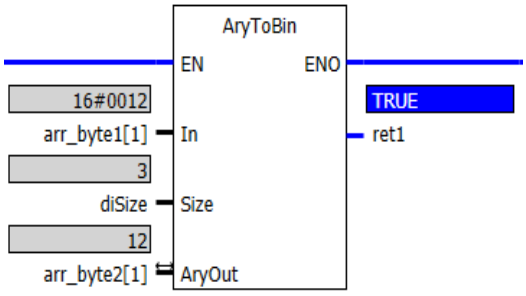
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In[ ] array	BCD array	Follows data type	-	BCD array
	Size	Number of elements to convert	Follows data type	1	Number of elements in In[ ] to convert
Input/Output	AryOut[ ] array	Bit string array	Follows data type	-	Bit string after conversion

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In[ ] array	–	√	√	√	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Size	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–
AryOut[ ] array	Same data type as the elements of In[ ]																			

- **Function**

  This instruction converts Size elements of the BCD array In[ ] starting from In[0] to bit strings, and outputs the result to the BCD array AryOut[ ]. The valid ranges for In[ ] and AryOut[ ] vary depending on the data types of their elements, as shown below.



Data Type of In[ ] Element	Valid Range of In[ ]	Valid Range of AryOut[ ]
BYTE	16#00 to 16#99 (BCD)	0 to 99
WORD	16#0000 to 16#9999 (BCD)	0 to 9999

Data Type of In[ ] Element	Valid Range of In[ ]	Valid Range of AryOut[ ]
DWORD	16#0000_0000 to 16#9999_9999 (BCD)	0 to 99999999
LWORD	16#0000_0000_0000_0000 to 16#9999_9999_9999_9999 (BCD)	0 to 9999999999999999

- **Program example**

	LD	ST

Define variables	VAR
	arr_byte1 : ARRAY[1..4] OF WORD := [16#12,16#34,16#567,16#89];
	arr_byte2 : ARRAY[1..4] OF WORD;
	diSize : DINT := 3;
	ret1 : BOOL;
	END_VAR	

Program		ret1 TRUE := AryToBin(In := arr_byte1[1] 16#0012 , Size := diSize 3 , AryOut := arr_byte2[1] 12);RETURN
Operation result		

	Name	Data type	Address	Value
1	arr_byte1	ARRAY [1..4] OF WORD		
2	arr_byte1[1]	WORD		16#0012
3	arr_byte1[2]	WORD		16#0034
4	arr_byte1[3]	WORD		16#0567
5	arr_byte1[4]	WORD		16#0089
6	arr_byte2	ARRAY [1..4] OF WORD		
7	arr_byte2[1]	WORD		12
8	arr_byte2[2]	WORD		34
9	arr_byte2[3]	WORD		567
10	arr_byte2[4]	WORD		0
11	diSize	DINT		3
12	ret1	BOOL		TRUE

- **Precautions**
  - This instruction does not support conversion to signed BCD. Therefore, use a bit string (BYTE, WORD, DWORD, or LWORD) as the data type of AryOut[ ].
  - When the value of Size is 0, the return value is TRUE and AryOut[ ] remains unchanged.
  - When the value of In[ ] exceeds the valid range, the return value is FALSE and AryOut[ ] remains unchanged.
  - When the value of Size exceeds the range of In[ ] or AryOut[ ], the return value is FALSE and AryOut[ ] remains unchanged.
  - If the dimension of the input array exceeds 3, the return value is FALSE, and AryOut[ ] remains unchanged.
  - Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.16.7 AryToString

Converts a BYTE-type array to a string.

- **Instruction format**

Instruction	Name	FB/FC	Ladder Diagram Representation	Structured Text Representation
AryToString	Array-to-string conversion	FC		:= AryToString(In := , Size := , Out =>);

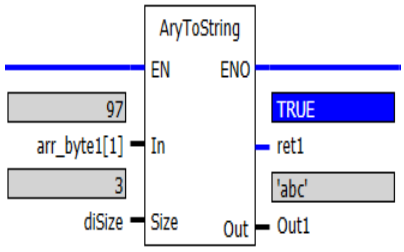
- **Related variables**

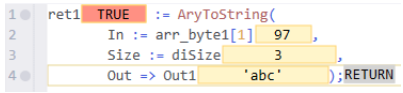
Variable

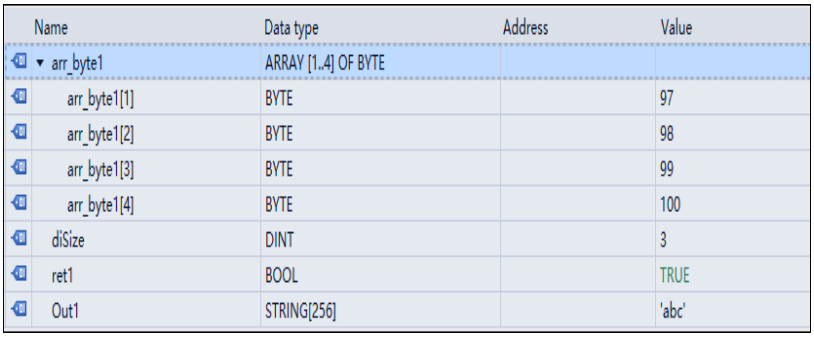
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In[ ] array	Byte array	Follows data type	-	Byte array
	Size	Number of elements to convert	Follows data type	1	Number of elements in In[ ] to convert
Output	Out	String	Follows data type	-	String

Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In[ ] array	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Size	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√







- **Function description**
  - This instruction processes the elements in the BYTE-type array In[ ] starting from In[0] as character codes, converts them into a string, and stores the result in Out. NULL is added to the end of Out.

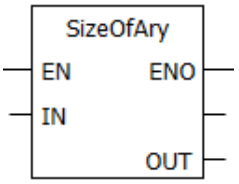
- Size specifies the number of elements in In[ ] to convert.
- If there is a NULL character between In[0] and In[Size–1], only the content before NULL is stored in Out.

- **Program example**

	LD	ST

Define variables	VAR
	arr_byte1 : ARRAY[1..4] OF BYTE := [97,98,99,100];
	diSize : DINT := 3;
	ret1 : BOOL;
	Out1 : STRING[256];
	END_VAR	

Program		
Operation result		



Name	Data type	Address	Value
arr_byte1	ARRAY [1..4] OF BYTE		
arr_byte1[1]	BYTE		97
arr_byte1[2]	BYTE		98
arr_byte1[3]	BYTE		99
arr_byte1[4]	BYTE		100
diSize	DINT		3
ret1	BOOL		TRUE
Out1	STRING[256]		'abc'

- **Precautions**
  - When Size exceeds the array range of In[ ] or exceeds the maximum string length of 1985, the function returns FALSE, and Out remains unchanged.
  - In[ ] must be of BYTE type; otherwise, a compilation fault will occur.
  - When the value of Size is 0, Out is a string containing only NULL characters.
  - If the dimension of the input array exceeds 3, the return value is FALSE, and "Out" remains unchanged.
  - Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.
  - If the size of the input elements exceeds the ASCII index range (0 to 127), the output result will be abnormal.

18.2.16.8 SizeOfAry

Gets the number of elements in an array.

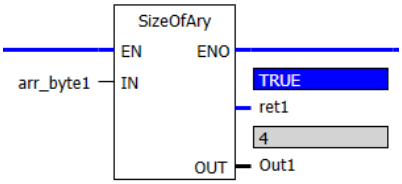
- **Instruction format**

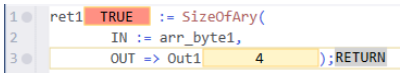
Instruction	Name	FB/FC	LD Representation	ST Representation
SizeOfAry	Get number of array elements	FC		:= SizeOfAry(IN := , OUT =>);

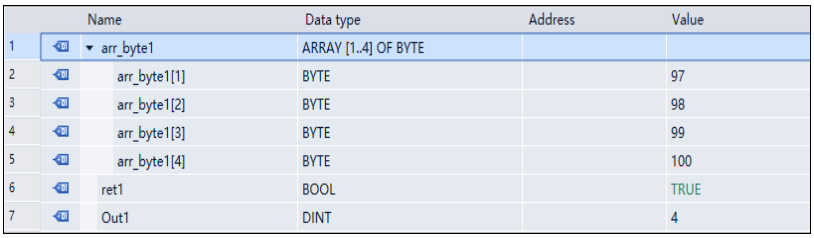
- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In[ ] array	Array	Follows data type	-	Array
Output	Out	Number of elements	Follows data type	-	Number of elements







Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In[ ] array	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
	Arrays of enumerations or structures can also be specified.																			
Out	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–

- **Function**

  This instruction gets the number of elements in array In[ ]. The input parameter can be an array or an array element.

- **Program example**

	LD	ST
Define variables	VAR arr_byte1 : ARRAY[1..4] OF BYTE := [97,98,99,100]; ret1 : BOOL; Out1 : DINT; END_VAR	
Program		
Operation result		

	Name	Data type	Address	Value
1	arr_byte1	ARRAY [1..4] OF BYTE		
2	arr_byte1[1]	BYTE		97
3	arr_byte1[2]	BYTE		98
4	arr_byte1[3]	BYTE		99
5	arr_byte1[4]	BYTE		100
6	ret1	BOOL		TRUE
7	Out1	DINT		4

- **Precautions**
  - If the dimension of the input array exceeds 3, the return value is FALSE, and Out remains unchanged.
  - Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.16.9 StringToAry

Converts a string to a BYTE-type array.

- **Instruction format**

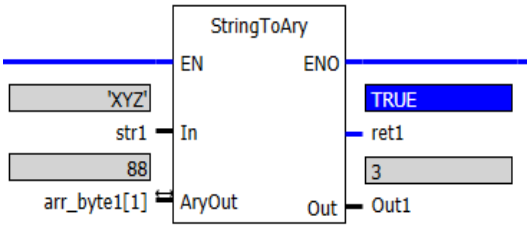
Instruction	Name	FB/FC	LD Representation	ST Representation
StringToAry	String-to-array conversion	FC		:= StringToAry(In := , AryOut := , Out =>);

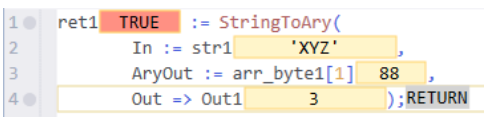
- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	String	Max. 1985 characters	-	String
Input/Output	AryOut[ ] array	Byte array	Follows data type	-	Byte array

Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	Out	Number of bytes after conversion	0 to 1985	-	Number of bytes after conversion





Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
AryOut[ ] array	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–

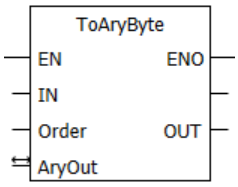
- **Function**

  This instruction processes the character codes in text string In as numeric values and stores each value to the corresponding element of the byte array AryOut[ ]. The number of bytes after conversion is stored in Out.

- **Program example**

	LD	ST
Define variables	VAR str1 : STRING[256] := 'XYZ'; arr_byte1 : ARRAY[1..4] OF BYTE; ret1 : BOOL; Out1 : DINT; END_VAR	
Program		

	LD	ST
Operation result		



Name	Data type	Address	Value
str1	STRING[256]		'XYZ'
arr_byte1	ARRAY [1..4] OF BYTE		
arr_byte1[1]	BYTE		88
arr_byte1[2]	BYTE		89
arr_byte1[3]	BYTE		90
arr_byte1[4]	BYTE		0
ret1	BOOL		TRUE
Out1	DINT		3

- **Precautions**
  - The NULL character at the end of In is not stored in AryOut[ ].
  - When In contains only NULL characters, the value of Out is 0 and AryOut[ ] remains unchanged.
  - When the number of bytes in In exceeds the number of elements in AryOut[ ], the return value is FALSE and AryOut[ ] remains unchanged.
  - When the number of bytes in In exceeds the upper limit 1985, excessive characters are truncated and only 1985 characters are converted.
  - If the dimension of the output array exceeds 3, the return value is FALSE, and AryOut[ ] remains unchanged.
  - Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.16.10 ToAryByte

Separates a variable into bytes and stores the result in a BYTE-type array.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ToAryByte	Conversion to byte array	FC		:= ToAryByte(IN := , Order := , AryOut := , OUT =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	Follows data type	-	Conversion object
	Order	Conversion order	Follows data type	_LOW_HIGH	Conversion order

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input/Output	AryOut[ ] array	Conversion result array	Follows data type	-	An array indicating the conversion result
Output	Out	Number of elements in the conversion result	Follows data type	-	Number of elements in the conversion result

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
	An enumeration, an array, an array element, a structure, or a structure member can also be specified.																			
Order	See "Function description" for the enumerators for the enumerated type _eBYTE_ORDER.																			
AryOut[ ] array	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–

- **Function**

  This instruction separates the input variable In into bytes and stores them in order in AryOut[ ] starting from AryOut[0]. The number of elements in AryOut[ ] is stored in Out. The conversion order Order specifies the order in which to convert the value of In to bytes. The data type of Order is enumerated type _eBYTE_ORDER. The meanings of the enumerators are as follows.

Enumerator	Definition
_LOW_HIGH	Lower byte first, higher byte last
_HIGH_LOW	Higher byte first, lower byte last

In is separated into bytes and stored in AryOut[ ]. The following data types have two bytes or more.

Category	Data Type
Bit string	WORD, DWORD, and LWORD

Category	Data Type
Integer	UINT, UDINT, ULINT, INT, DINT, LINT
Real number	REAL, LREAL
Time, duration, date, and text string	TIME, DATE, TOD, DT, and STRING types of two bytes or more
Others	An enumeration An array for which the total for all elements is two bytes or more An array element of two bytes or more A structure for which the total for all members is two bytes or more A structure member of two bytes or more

Processing steps:

1. Split the value of In by word (two bytes).
2. The lowest word is separated into bytes.
3. If the value of Order is _LOW_HIGH, save the lower byte into AryOut[0] and the higher byte into AryOut[1]; if the value of Order is _HIGH_LOW, save the higher byte into AryOut[0] and the lower byte into AryOut[1].
4. The next word is separated into bytes and stored in AryOut[2] and AryOut[3] in the same way.
5. This process is repeated to the end of the value of In, and the result is stored in the corresponding position. If In is an array, the same process is repeated to the last element of In.

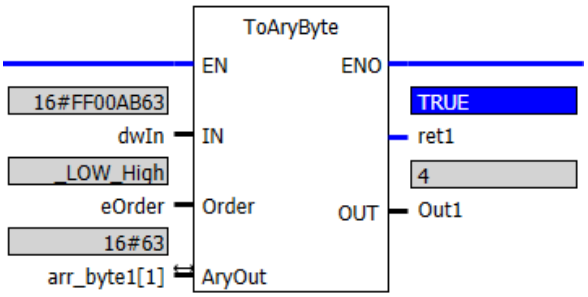
When the data type of In is one byte, In is stored in AryOut[ ] as one byte. The following data types have one byte.

Category	Data Type
Bit string	BYTE
Integer	USINT, SINT
Real number	/
Time, duration, date, and text string	String of one byte
Others	An array for which the total for all elements is one byte; An array element that is one byte; A structure for which the total for all members is one byte; A structure member that is one byte

The storage method is as follows:

Value of Order	In (Array or Not)	Storage Method
_LOW_HIGH	Not an integer	The value of In is stored in AryOut[0].
	Integer	The value of In[i] is stored in AryOut[i].
_HIGH_LOW	Not an array	The value of In is stored in AryOut[1]. 16#00 is stored in AryOut[0].
	Array	In[i] (where i is even) is stored in AryOut[i+1]. In[i] (where i is odd) is stored in AryOut[i-1]. If the number of elements in In[ ] is odd, 16#00 is stored in the last element of AryOut[n–1].

Data is stored in AryOut[ ] as described below.



Value of Order	In (Array or Not)	Storage Method
_LOW_HIGH	Not an array	The logical AND of the value of In and 16#00 is stored in AryOut[0].
	Array	The value of In[0] to In[7] is stored in AryOut[0]. The value of In[8] to In[15] is stored in AryOut[1]. The same process is repeated to store the rest of the data. When In[ ] contains fewer than eight elements, add FALSE to the higher bits. The value of Out is always even. Any insufficient bits are filled with FALSE.
_HIGH_LOW	Not an array	The logical AND of the value of In and 16#00 is stored in AryOut[1]. 16#00 is stored in AryOut[0].
	Array	The value of In[0] to In[7] is stored in AryOut[1]. The value of In[8] to In[15] is stored in AryOut[0]. The same process is repeated to store the rest of the data. The value of Out is always even. Any insufficient bits are filled with FALSE.

- **Program example**

<table>
<tr><th></th><th>LD</th><th>ST</th></tr>
<tr><td>Define variables</td><td colspan="2">

```
VAR
    dwIn: DWORD := 16#FF00AB63;
    eOrder: _eBYTE_ORDER := _EBYTE_ORDER._LOW_High;
    arr_byte1: ARRAY[1..4] OF BYTE;
    ret1: BOOL;
    Out1: DINT;
END_VAR
```

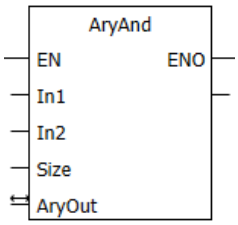
</td></tr>
<tr><td>Program</td><td>

</td><td>

```
ret1 := ToAryByte(
        IN := dwIn ,
        Order := eOrder ,
        AryOut := arr_byte1[1] ,
        OUT => Out1 );RETURN
```

</td></tr>
<tr><td>Operation result</td><td colspan="2">

	Name	Data type	Address	Value
1	dwIn	DWORD		16#FF00AB63
2	eOrder	_EBYTE_ORDER		_LOW_High
3	arr_byte1	ARRAY [1..4] OF BYTE		
4	arr_byte1[1]	BYTE		16#63
5	arr_byte1[2]	BYTE		16#AB
6	arr_byte1[3]	BYTE		16#00
7	arr_byte1[4]	BYTE		16#FF
8	ret1	BOOL		TRUE
9	Out1	DINT		4



</td></tr>
</table>

- **Precautions**
  - The input parameter In must be a variable. If it is a constant, a compilation fault will occur.
  - When In is an enumeration, you cannot directly pass an enumerator. Otherwise, a compilation fault will occur.
  - When In is of STRING type, the ASCII value of each character is converted into a byte array.
  - When In is a structure, adjustment areas between members may be inserted into AryOut[ ] depending on the composition.
  - When the value of Order is _HIGH_LOW and the total number of bytes in In is an odd number, 16#00 is added to the end of In to make an even number of bytes before the conversion is started.
  - When the value of Order exceeds the valid range, the return value is FALSE, and Out and AryOut[ ] remain unchanged.
  - When the conversion result exceeds the AryOut[ ] array, the return value is FALSE, and Out and AryOut[ ] remain unchanged.
  - If the dimension of the output array exceeds 3, the return value is FALSE, and AryOut[ ] remains unchanged.
  - Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.16.11 AryAnd

Performs a bit-wise logical AND operation on each Boolean or bit-string element in two arrays.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AryAnd	Array logic AND	FC		:= AryAnd(In1 := , In2 := , Size := , AryOut :=);

- **Related variables**

Variable

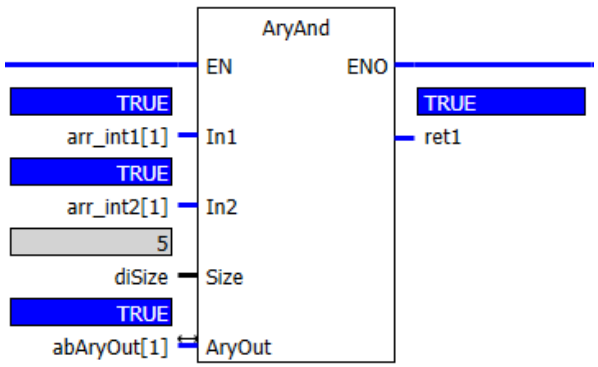
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Array In1[ ]	Array 1 to process	Follows data type	-	Array 1 to process
	Array In2[ ]	Array 2 to process	Follows data type	-	Array 2 to process
	Size	Number of elements to process	Follows data type	1	Number of elements to process
Input/Output	AryOut[ ] array	Processing result array	Follows data type	-	Processing result array

Variable types

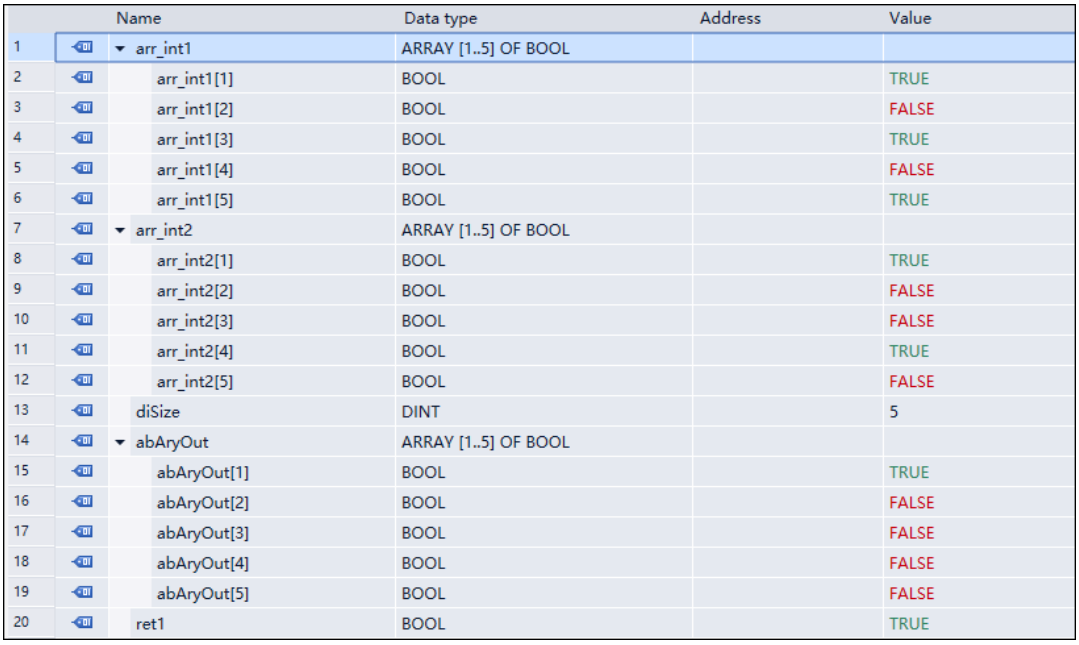
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Array In1[ ]	√	√	√	√	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Array In2[ ]	Same data type as In1[ ]																			
Size	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
AryOut[ ] array	Same data type as In1[ ]																			

- **Function**
  - This instruction performs a bit-wise logical AND operation on Size elements in arrays In1[ ] and In2[ ]. The operation result is stored in the corresponding element of AryOut[ ]. Therefore, In1[ ], In2[ ], and AryOut[ ] must be of the same data type. The relationships between input and output variables are described in the following tables.
  - When both bits are TRUE, the processing result is TRUE. Otherwise, the processing result is FALSE.



Bit of Element in In1[ ]	Bit of Element in In2[ ]	Bit of AryOut[ ]
FALSE	FALSE	FALSE
FALSE	TRUE	FALSE
TRUE	FALSE	FALSE
TRUE	TRUE	TRUE



- **Program example**

  The following example sets Size to DINT#5:

	LD	ST

Define variables	VAR
	arr_int1: ARRAY[1..5] OF BOOL := [TRUE,FALSE,TRUE,FALSE,TRUE];
	arr_int2: ARRAY[1..5] OF BOOL := [TRUE,FALSE,FALSE,TRUE,FALSE];
	diSize: DINT := 5;
	abAryOut: ARRAY[1..5] OF BOOL;
	ret1: BOOL;
	END_VAR	

Program		ret1 TRUE := AryAnd(In1 := arr_int1[1] TRUE , In2 := arr_int2[1] TRUE , Size := diSize 5 , AryOut := abAryOut[1] TRUE);RETURN

	LD	ST
Operation result		

	Name	Data type	Address	Value
1	arr_int1	ARRAY [1..5] OF BOOL		
2	arr_int1[1]	BOOL		TRUE
3	arr_int1[2]	BOOL		FALSE
4	arr_int1[3]	BOOL		TRUE
5	arr_int1[4]	BOOL		FALSE
6	arr_int1[5]	BOOL		TRUE
7	arr_int2	ARRAY [1..5] OF BOOL		
8	arr_int2[1]	BOOL		TRUE
9	arr_int2[2]	BOOL		FALSE
10	arr_int2[3]	BOOL		FALSE
11	arr_int2[4]	BOOL		TRUE
12	arr_int2[5]	BOOL		FALSE
13	diSize	DINT		5
14	abAryOut	ARRAY [1..5] OF BOOL		
15	abAryOut[1]	BOOL		TRUE
16	abAryOut[2]	BOOL		FALSE
17	abAryOut[3]	BOOL		FALSE
18	abAryOut[4]	BOOL		FALSE
19	abAryOut[5]	BOOL		FALSE
20	ret1	BOOL		TRUE

- **Precautions**
  - In1[ ], In2[ ], and AryOut[ ] must be of the same data type. Otherwise, a compilation fault will occur.
  - When the value of Size exceeds the In1[ ], In2[ ], or AryOut[ ] array, the return value is FALSE and AryOut[ ] remains unchanged.
  - When the value of Size is 0, AryOut[ ] remains unchanged and the return value is TRUE.
  - If the dimension of the input array exceeds 3, the return value is FALSE, and AryOut[ ] remains unchanged.
  - Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.16.12 AryOr

Performs a bit-wise logical OR operation on each Boolean or bit-string element in two arrays.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AryOr	Array logic OR	FC		:= AryOr(In1 := , In2 := , Size := , AryOut :=);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Array In1[ ]	Array 1 to process	Follows data type	-	Array 1 to process
	Array In2[ ]	Array 2 to process	Follows data type	-	Array 2 to process
	Size	Number of elements to process	Follows data type	1	Number of elements to process
Input/Output	AryOut[ ] array	Processing result array	Follows data type	-	Processing result array

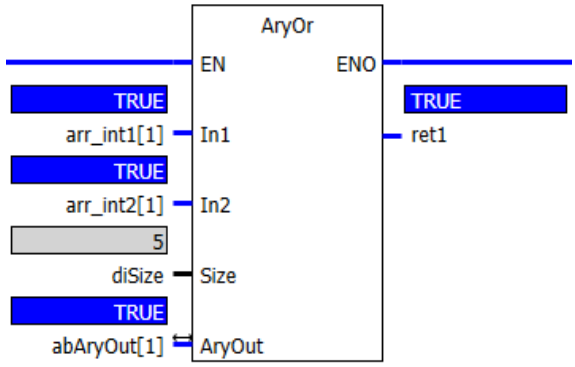
Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Array In1[ ]	√	√	√	√	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Array In2[ ]	Same data type as In1[ ]																			
Size	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–
AryOut[ ] array	Same data type as In1[ ]																			

- **Function**
  - This instruction performs a bit-wise logical XNOR operation on Size elements in arrays In1[ ] and In2[ ]. The operation result is stored in the corresponding element of AryOut[ ]. Therefore, In1[ ], In2[ ], and AryOut[ ] must be of the same data type. The relationships between input and output variables are described in the following tables.
  - When both bits are FALSE, the processing result is FALSE. Otherwise, the processing result is TRUE.

Bit of Element in In1[ ]	Bit of Element in In2[ ]	Bit of AryOut[ ]
FALSE	FALSE	FALSE
FALSE	TRUE	TRUE
TRUE	FALSE	TRUE

Bit of Element in In1[ ]	Bit of Element in In2[ ]	Bit of AryOut[ ]
TRUE	TRUE	TRUE



- **Program example**

  The following example sets Size to DINT#4:

<table>
<tr><th></th><th>LD</th><th>ST</th></tr>
<tr><td>Define variables</td><td colspan="2">

```
VAR
    arr_int1: ARRAY[1..5] OF BOOL := [TRUE,FALSE,TRUE,FALSE,TRUE];
    arr_int2: ARRAY[1..5] OF BOOL := [TRUE,FALSE,FALSE,TRUE,FALSE];
    diSize: DINT := 5;
    abAryOut: ARRAY[1..5] OF BOOL;
    ret1: BOOL;
END_VAR
```

</td></tr>
<tr><td>Program</td><td>

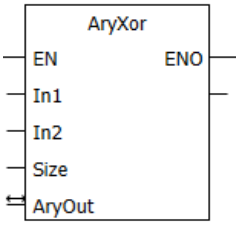
</td><td>

```
ret1 TRUE := AryOr(
        In1 := arr_int1[1] TRUE ,
        In2 := arr_int2[1] TRUE ,
        Size := diSize 5 ,
        AryOut := abAryOut[1] TRUE );RETURN
```

</td></tr>
<tr><td>Operation result</td><td colspan="2">

	Name	Data type	Address	Value
1	arr_int1	ARRAY [1..5] OF BOOL		
2	arr_int1[1]	BOOL		TRUE
3	arr_int1[2]	BOOL		FALSE
4	arr_int1[3]	BOOL		TRUE
5	arr_int1[4]	BOOL		FALSE
6	arr_int1[5]	BOOL		TRUE
7	arr_int2	ARRAY [1..5] OF BOOL		
8	arr_int2[1]	BOOL		TRUE
9	arr_int2[2]	BOOL		FALSE
10	arr_int2[3]	BOOL		FALSE
11	arr_int2[4]	BOOL		TRUE
12	arr_int2[5]	BOOL		FALSE
13	diSize	DINT		5
14	abAryOut	ARRAY [1..5] OF BOOL		
15	abAryOut[1]	BOOL		TRUE
16	abAryOut[2]	BOOL		FALSE
17	abAryOut[3]	BOOL		TRUE
18	abAryOut[4]	BOOL		TRUE
19	abAryOut[5]	BOOL		TRUE
20	ret1	BOOL		TRUE

</td></tr>
</table>



- **Precautions**
  - In1[ ], In2[ ], and AryOut[ ] must be of the same data type. Otherwise, a compilation fault will occur.
  - When the value of Size exceeds the In1[ ], In2[ ], or AryOut[ ] array, the return value is FALSE and AryOut[ ] remains unchanged.
  - When the value of Size is 0, AryOut[ ] remains unchanged and the return value is TRUE.
  - If the dimension of the input array exceeds 3, the return value is FALSE, and AryOut[ ] remains unchanged.

◦ Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.16.13 AryXor

Performs a bit-wise logical XOR operation on each Boolean or bit-string element in two arrays.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AryXor	Array logic XOR	FC		:= AryXor(In1 := , In2 := , Size := , AryOut :=);

- **Related variables**

Variable

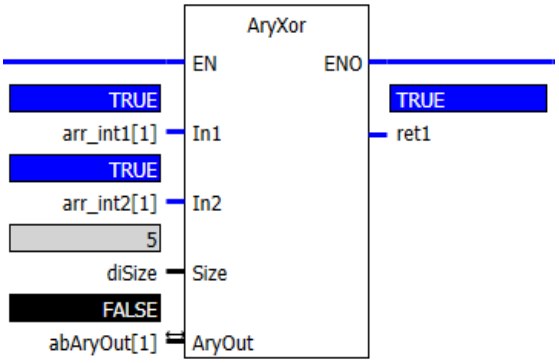
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Array In1[ ]	Array 1 to process	Follows data type	-	Array 1 to process
	Array In2[ ]	Array 2 to process	Follows data type	-	Array 2 to process
	Size	Number of elements to process	Follows data type	1	Number of elements to process
Input/Output	AryOut[ ] array	Processing result array	Follows data type	-	Processing result array

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Array In1[ ]	√	√	√	√	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Array In2[ ]	Same data type as In1[ ]																			
Size	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
AryOut[ ] array	Same data type as In1[ ]																			

- **Function**
  - This instruction performs a bit-wise logical XNOR operation on Size elements in arrays In1[ ] and In2[ ]. The operation result is stored in the corresponding element of AryOut[ ]. Therefore, In1[ ], In2[ ], and AryOut[ ] must be of the same data type. The relationships between input and output variables are described in the following tables.
  - When both bits are the same, the processing result is FALSE. The operation result is TRUE when they are different.



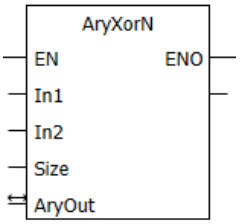
Bit of Element in In1[ ]	Bit of Element in In2[ ]	Bit of AryOut[ ]
FALSE	FALSE	FALSE
FALSE	TRUE	TRUE
TRUE	FALSE	TRUE
TRUE	TRUE	FALSE

- **Program example**

  The following example sets Size to DINT#5:

	LD	ST

Define variables	VAR
	arr_int1: ARRAY[1..5] OF BOOL := [TRUE,FALSE,TRUE,FALSE,TRUE];
	arr_int2: ARRAY[1..5] OF BOOL := [TRUE,FALSE,FALSE,TRUE,FALSE];
	diSize: DINT := 5;
	abAryOut: ARRAY[1..5] OF BOOL;
	ret1: BOOL;
	END_VAR	



<table>
<tr><th></th><th>LD</th><th>ST</th></tr>
<tr><td>Program</td><td>
</td><td>ret1 TRUE := AryXor(
In1 := arr_int1[1] TRUE ,
In2 := arr_int2[1] TRUE ,
Size := diSize 5 ,
AryOut := abAryOut[1] FALSE);RETURN</td></tr>
<tr><td>Operation result</td><td colspan="2">

</table>
</td></tr>
</table>

- **Precautions**
  - In1[ ], In2[ ], and AryOut[ ] must be of the same data type. Otherwise, a compilation fault will occur.
  - When the value of Size exceeds the In1[ ], In2[ ], or AryOut[ ] array, the return value is FALSE and AryOut[ ] remains unchanged.
  - When the value of Size is 0, AryOut[ ] remains unchanged and the return value is TRUE.
  - If the dimension of the input array exceeds 3, the return value is FALSE, and AryOut[ ] remains unchanged.
  - Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.16.14 AryXorN

Performs a bit-wise logical XNOR operation on each Boolean or bit-string element in two arrays.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AryXorN	Array logic XNOR	FC		:= AryXorN(In1 := , In2 := , Size := , AryOut :=);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Array In1[ ]	Array 1 to process	Follows data type	-	Array 1 to process
	Array In2[ ]	Array 2 to process	Follows data type	-	Array 2 to process
	Size	Number of elements to process	Follows data type	1	Number of elements to process
Input/Output	AryOut[ ] array	Processing result array	Follows data type	-	Processing result array

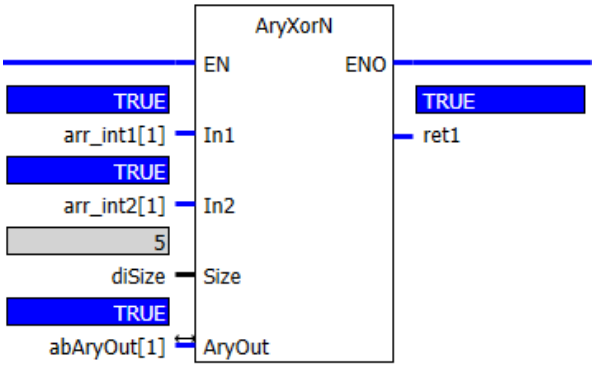
  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Array In1[ ]	√	√	√	√	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Array In2[ ]	Same data type as In1[ ]																			
Size	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–
AryOut[ ] array	Same data type as In1[ ]																			

- **Function**
  - This instruction performs a bit-wise logical XNOR operation on Size elements in arrays In1[ ] and In2[ ]. The operation result is stored in the corresponding element of AryOut[ ]. Therefore, In1[ ], In2[ ], and

AryOut[ ] must be of the same data type. The relationships between input and output variables are described in the following tables.

- When both bits are the same, the processing result is TRUE. The operation result is FALSE when they are different.



Bit of Element in In1[ ]	Bit of Element in In2[ ]	Bit of AryOut[ ]
FALSE	FALSE	TRUE
FALSE	TRUE	FALSE
TRUE	FALSE	FALSE
TRUE	TRUE	TRUE

- **Program example**

The following example sets Size to DINT#5:

	LD	ST

Define variables	VAR
	arr_int1: ARRAY[1..5] OF BOOL := [TRUE,FALSE,TRUE,FALSE,TRUE];
	arr_int2: ARRAY[1..5] OF BOOL := [TRUE,FALSE,FALSE,TRUE,FALSE];
	diSize: DINT := 5;
	abAryOut: ARRAY[1..5] OF BOOL;
	ret1: BOOL;
	END_VAR	

Program		ret1 TRUE := AryXorN(In1 := arr_int1[1] TRUE , In2 := arr_int2[1] TRUE , Size := diSize 5 , AryOut := abAryOut[1] TRUE);RETURN

	LD	ST

Operation result

	Name	Data type	Address	Value
1	arr_int1	ARRAY [1..5] OF BOOL		
2	arr_int1[1]	BOOL		TRUE
3	arr_int1[2]	BOOL		FALSE
4	arr_int1[3]	BOOL		TRUE
5	arr_int1[4]	BOOL		FALSE
6	arr_int1[5]	BOOL		TRUE
7	arr_int2	ARRAY [1..5] OF BOOL		
8	arr_int2[1]	BOOL		TRUE
9	arr_int2[2]	BOOL		FALSE
10	arr_int2[3]	BOOL		FALSE
11	arr_int2[4]	BOOL		TRUE
12	arr_int2[5]	BOOL		FALSE
13	diSize	DINT		5
14	abAryOut	ARRAY [1..5] OF BOOL		
15	abAryOut[1]	BOOL		TRUE
16	abAryOut[2]	BOOL		TRUE
17	abAryOut[3]	BOOL		FALSE
18	abAryOut[4]	BOOL		FALSE
19	abAryOut[5]	BOOL		FALSE
20	ret1	BOOL		TRUE

- **Precautions**
  - In1[ ], In2[ ], and AryOut[ ] must be of the same data type. Otherwise, a compilation fault will occur.
  - When the value of Size exceeds the In1[ ], In2[ ], or AryOut[ ] array, the return value is FALSE and AryOut[ ] remains unchanged.
  - When the value of Size is 0, AryOut[ ] remains unchanged and the return value is TRUE.
  - If the dimension of the input array exceeds 3, the return value is FALSE, and AryOut[ ] remains unchanged.
  - Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.16.15 AryAdd

Adds corresponding elements of two arrays.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AryAdd	Array Addition	FC		:= AryAdd(In1 := , In2 := , Size := , AryOut :=);

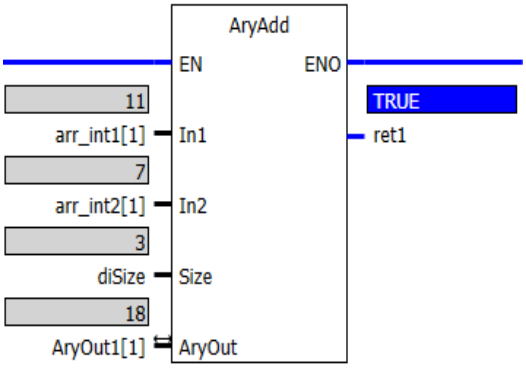
- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Array In1[ ]	Array 1 to process	Follows data type	-	Array 1 to process
	Array In2[ ]	Array 2 to process	Follows data type	-	Array 2 to process
	Size	Number of elements to process	Follows data type	1	Number of elements to process
Input/Output	AryOut[ ] array	Processing result array	Follows data type	-	Processing result array

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1[ ] array	–	–	–	–	–	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–
Array In2[ ]	Same data type as elements in In1[ ]																			
Size	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–
AryOut [ ] array	Same data type as elements in In1[ ]																			



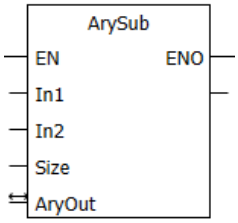
- **Function**

  This instruction adds Size elements starting from the calculation index of array In1[ ] to the corresponding elements of In2[ ]. The result is stored in AryOut[ ].

- **Program example**

	LD	ST
Define variables		

```
VAR
    arr_int1: ARRAY[1..3] OF INT := [11, 23, 35];
    arr_int2: ARRAY[1..3] OF INT := [7, 9, 18];
    diSize: DINT := 3;
    AryOut1: ARRAY[1..3] OF INT;
    ret1: BOOL;
END_VAR
```



<table>
<tr><th></th><th>LD</th><th>ST</th></tr>
<tr><td>Program</td><td>
</td><td>ret1 TRUE := AryAdd(
In1 := arr_int1[1] 11 ,
In2 := arr_int2[1] 7 ,
Size := diSize 3 ,
AryOut := AryOut1[1] 18);RETURN</td></tr>
<tr><td>Operation result</td><td colspan="2">
<table>
<tr><th></th><th></th><th>Name</th><th>Data type</th><th>Address</th><th>Value</th></tr>
<tr><td>1</td><td></td><td>arr_int1</td><td>ARRAY [1..3] OF INT</td><td></td><td></td></tr>
<tr><td>2</td><td></td><td>arr_int1[1]</td><td>INT</td><td></td><td>11</td></tr>
<tr><td>3</td><td></td><td>arr_int1[2]</td><td>INT</td><td></td><td>23</td></tr>
<tr><td>4</td><td></td><td>arr_int1[3]</td><td>INT</td><td></td><td>35</td></tr>
<tr><td>5</td><td></td><td>arr_int2</td><td>ARRAY [1..3] OF INT</td><td></td><td></td></tr>
<tr><td>6</td><td></td><td>arr_int2[1]</td><td>INT</td><td></td><td>7</td></tr>
<tr><td>7</td><td></td><td>arr_int2[2]</td><td>INT</td><td></td><td>9</td></tr>
<tr><td>8</td><td></td><td>arr_int2[3]</td><td>INT</td><td></td><td>18</td></tr>
<tr><td>9</td><td></td><td>diSize</td><td>DINT</td><td></td><td>3</td></tr>
<tr><td>10</td><td></td><td>AryOut1</td><td>ARRAY [1..3] OF INT</td><td></td><td></td></tr>
<tr><td>11</td><td></td><td>AryOut1[1]</td><td>INT</td><td></td><td>18</td></tr>
<tr><td>12</td><td></td><td>AryOut1[2]</td><td>INT</td><td></td><td>32</td></tr>
<tr><td>13</td><td></td><td>AryOut1[3]</td><td>INT</td><td></td><td>53</td></tr>
<tr><td>14</td><td></td><td>ret1</td><td>BOOL</td><td></td><td>TRUE</td></tr>
</table>
</td></tr>
<tr><td>Principle analysis</td><td colspan="2">Add arr_int1[1] and arr_int2[1], and save the result in ArrOut1[1]. The same operation is repeated for Size elements.</td></tr>
</table>

- **Precautions**
  - When the value of Size exceeds the range of In[ ] or AryOut[ ], the return value is FALSE and AryOut[ ] remains unchanged.
  - Elements in In1[ ], In2[ ], and AryOut[ ] must be of the same data type. Otherwise, a compilation fault will occur.
  - If the results exceed the valid range of AryOut[ ], AryOut[ ] will contain elements of illegal values. In this case, no fault will occur. Data in the memory area adjacent to those elements will not be corrupted.
  - When the value of Size is 0, AryOut[ ] remains unchanged and the return value is TRUE.
  - If the dimension of the input array exceeds 3, the return value is FALSE, and AryOut[ ] remains unchanged.
  - Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.16.16 ArySub

Subtracts corresponding elements of two arrays.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ArySub	Array subtraction	FC		:= ArySub(In1 := , In2 := , Size := , AryOut :=);

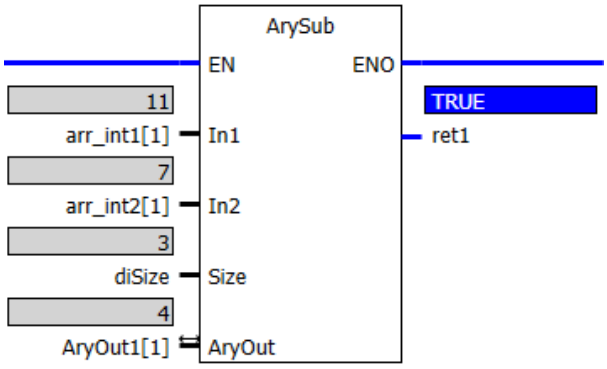
- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Array In1[ ]	Array 1 to process	Follows data type	-	Array 1 to process
	Array In2[ ]	Array 2 to process	Follows data type	-	Array 2 to process
	Size	Number of elements to process	Follows data type	1	Number of elements to process
Input/Output	AryOut[ ] array	Processing result array	Follows data type	-	Processing result array

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1[ ] array	–	–	–	–	–	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–
Array In2[ ]	Same data type as elements in In1[ ]																			
Size	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–
AryOut[ ] array	Same data type as elements in In1[ ]																			



- **Function**

This instruction subtracts Size elements starting from the calculation index of subtrahend array In2[ ] from the corresponding elements of minuend array In1[ ]. The result is stored in AryOut[ ].

- **Program example**

<table>
<tr><th></th><th>LD</th><th>ST</th></tr>
<tr><td>Define variables</td><td colspan="2">

```
VAR
    arr_int1: ARRAY[1..3] OF INT := [11, 23, 35];

    diSize: DINT := 3;
    AryOut1: ARRAY[1..3] OF INT;
    ret1: BOOL;
END_VAR
```

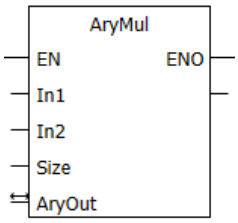
</td></tr>
<tr><td>Program</td><td>
</td><td>

```
ret1 TRUE := ArySub(
        In1 := arr_int1[1]  11 ,
        In2 := arr_int2[1]  7 ,
        Size := diSize  3 ,
        AryOut := AryOut1[1]  4 );RETURN
```

</td></tr>
<tr><td>Operation result</td><td colspan="2">

		Name	Data type	Address	Value
1		arr_int1	ARRAY [1..3] OF INT		
2		arr_int1[1]	INT		11
3		arr_int1[2]	INT		23
4		arr_int1[3]	INT		35
5		arr_int2	ARRAY [1..3] OF INT		
6		arr_int2[1]	INT		7
7		arr_int2[2]	INT		9
8		arr_int2[3]	INT		18
9		diSize	DINT		3
10		AryOut1	ARRAY [1..3] OF INT		
11		AryOut1[1]	INT		4
12		AryOut1[2]	INT		14
13		AryOut1[3]	INT		17
14		ret1	BOOL		TRUE

</td></tr>
<tr><td>Principle analysis</td><td colspan="2">Subtract arr_int2[1] from arr_int1[1], and save the result in ArrOut1[1]. The same operation is repeated for Size elements.</td></tr>
</table>



- **Precautions**
  - When the value of Size exceeds the range of In[ ] or AryOut[ ], the return value is FALSE and AryOut[ ] remains unchanged.
  - Elements in In1[ ], In2[ ], and AryOut[ ] must be of the same data type. Otherwise, a compilation fault will occur.
  - If the results exceed the valid range of AryOut[ ], AryOut[ ] will contain elements of illegal values. In this case, no fault will occur. Data in the memory area adjacent to those elements will not be corrupted.
  - When the value of Size is 0, AryOut[ ] remains unchanged and the return value is TRUE.
  - If the dimension of the input array exceeds 3, the return value is FALSE, and AryOut[ ] remains unchanged.

◦ Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.16.17 AryMul

Multiplies corresponding elements of two arrays.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AryMul	Array multiplication	FC		:= AryMul(In1 := , In2 := , Size := , AryOut :=);

- **Related variables**

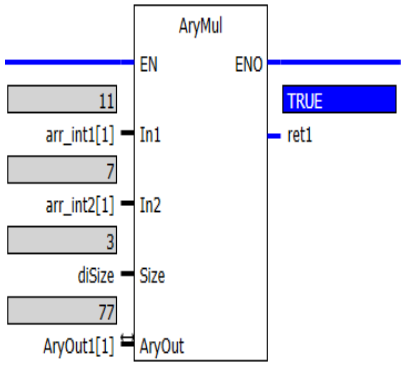
Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Array In1[ ]	Array 1 to process	Follows data type	-	Array 1 to process
	Array In2[ ]	Array 2 to process	Follows data type	-	Array 2 to process
	Size	Number of elements to process	Follows data type	1	Number of elements to process
Input/Output	AryOut[ ] array	Processing result array	Follows data type	-	Processing result array

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1[ ] array	–	–	–	–	–	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Array In2[ ]	Same data type as elements in In1[ ]																			
Size	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–
AryOut[ ] array	Same data type as elements in In1[ ]																			



- **Function**

  This instruction multiplies Size elements starting from the calculation index of the array In1[ ] by the corresponding elements of In2[ ]. The result is stored in AryOut[ ].

- **Program example**

	LD	ST

Define variables	VAR
	arr_int1: ARRAY[1..3] OF INT := [11, 23, 35];
	arr_int2: ARRAY[1..3] OF INT := [7, 9, 18];
	diSize: DINT := 3;
	AryOut1: ARRAY[1..3] OF INT;
	ret1: BOOL;
	END_VAR	

Program		ret1 TRUE := AryMul(In1 := arr_int1[1] 11 , In2 := arr_int2[1] 7 , Size := diSize 3 , AryOut := AryOut1[1] 77);RETURN

	LD	ST
Operation result		
Principle analysis	Multiply arr_int1[1] by arr_int2[1], and save the result in ArrOut1[1]. The same operation is repeated for Size elements.	

- **Precautions**
  - When the value of Size exceeds the range of In[ ] or AryOut[ ], the return value is FALSE and AryOut[ ] remains unchanged.
  - Elements in In1[ ], In2[ ], and AryOut[ ] must be of the same data type. Otherwise, a compilation fault will occur.
  - If the results exceed the valid range of AryOut[ ], AryOut[ ] will contain elements of illegal values. In this case, no fault will occur. Data in the memory area adjacent to those elements will not be corrupted.
  - When the value of Size is 0, AryOut[ ] remains unchanged and the return value is TRUE.
  - If the dimension of the input array exceeds 3, the return value is FALSE, and AryOut[ ] remains unchanged.
  - Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.16.18 AryDiv

Divides corresponding elements of two arrays.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AryDiv	Array division	FC		:= AryDiv(In1 := , In2 := , Size := , AryOut :=);

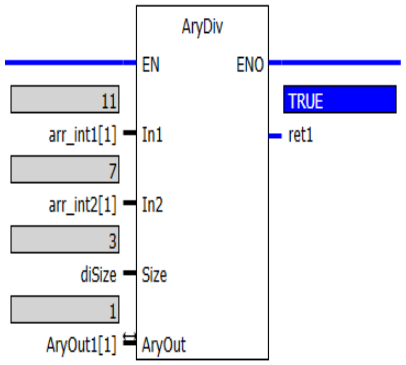
- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Array In1[ ]	Array 1 to process	Follows data type	-	Array 1 to process
	Array In2[ ]	Array 2 to process	Follows data type	-	Array 2 to process
	Size	Number of elements to process	Follows data type	1	Number of elements to process
Input/Output	AryOut[ ] array	Processing result array	Follows data type	-	Processing result array

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1[ ] array	–	–	–	–	–	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–
Array In2[ ]	Same data type as elements in In1[ ]																			
Size	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–
AryOut[ ] array	Same data type as elements in In1[ ]																			



- **Function**

  This instruction divides Size elements starting from the calculation index of the divisor array In2[ ] into the corresponding elements of the dividend array In1[ ]. The result is stored in AryOut[ ].

- **Program example**

<table>
<tr><th></th><th>LD</th><th>ST</th></tr>
<tr><td>Define variables</td><td colspan="2">

</td></tr>
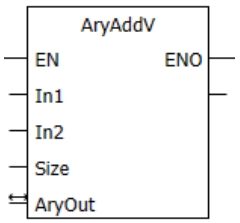
<tr><td>Principle analysis</td><td colspan="2">Divide arr_int2[1] into arr_int1[1], and save the result in ArrOut1[1]. The same operation is repeated for Size elements.</td></tr>
</table>



- **Precautions**
  - When the value of Size exceeds the range of In[ ] or AryOut[ ], the return value is FALSE and AryOut[ ] remains unchanged.
  - Elements in In1[ ], In2[ ], and AryOut[ ] must be of the same data type. Otherwise, a compilation fault will occur.
  - If the results exceed the valid range of AryOut[ ], AryOut[ ] will contain elements of illegal values. In this case, no fault will occur. Data in the memory area adjacent to those elements will not be corrupted.
  - When the value of Size is 0, AryOut[ ] remains unchanged and the return value is TRUE.
  - If the dimension of the input array exceeds 3, the return value is FALSE, and AryOut[ ] remains unchanged.
  - Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

◦ When the dividend is 0, the instruction follows the system's zero-division protection rule and returns FALSE.

18.2.16.19 AryAddV

Adds the same value to each element of an array.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AryAddV	Array and value addition	FC		:= AryAddV(In1 := , In2 := , Size := , AryOut :=);

- **Related variables**

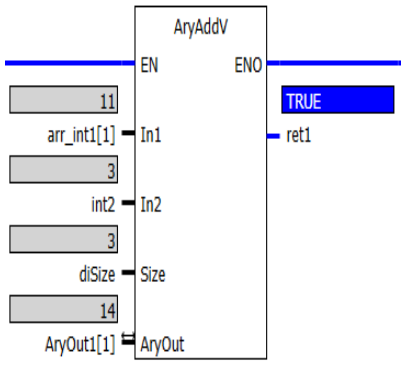
Variable

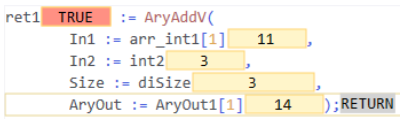
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1[ ] array	Array to process	Follows data type	-	Array to process
	In2	Divisor variable	Follows data type	-	Divisor variable
	Size	Number of elements to process	Follows data type	1	Number of elements to process
Input/Output	AryOut[ ] array	Processing result array	Follows data type	-	Processing result array

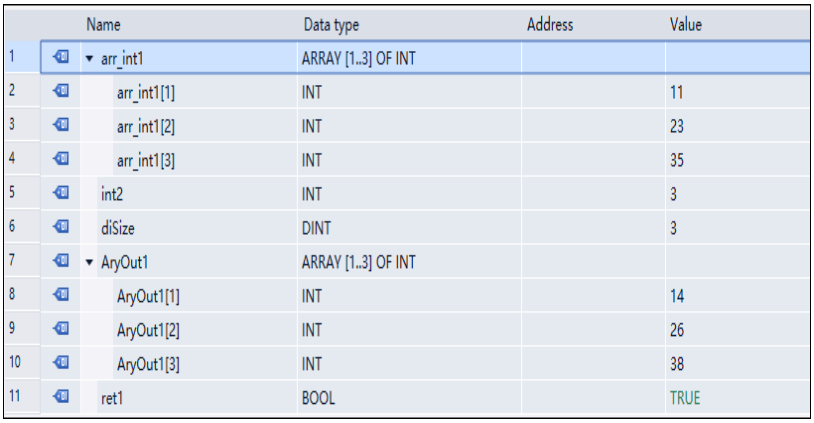
Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1[ ] array	–	–	–	–	–	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–
In2	Same data type as the elements of In1[ ]																			
Size	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
AryOut[ ] array	Same data type as elements in In1[ ]																			







- **Function**

  This instruction adds the value In2 to each of the Size elements of the array In1[ ] starting from In1[0]. The result is stored in AryOut[ ].

- **Program example**

	LD	ST

Define variables	VAR
	arr_int1: ARRAY[1..3] OF INT := [11, 23, 35];
	int2: INT := 3;
	diSize: DINT := 3;
	AryOut1: ARRAY[1..3] OF INT;
	ret1: BOOL;
	END_VAR	

Program		
Operation result		

	Name	Data type	Address	Value
1	arr_int1	ARRAY [1..3] OF INT		
2	arr_int1[1]	INT		11
3	arr_int1[2]	INT		23
4	arr_int1[3]	INT		35
5	int2	INT		3
6	diSize	DINT		3
7	AryOut1	ARRAY [1..3] OF INT

9	AryOut1[2]	INT		26
10	AryOut1[3]	INT		38
11	ret1	BOOL		TRUE

	LD	ST
Principle analysis	Add int2 to arr_int1[1 to 3] respectively, and store the results in ArrOut1[1 to 3].	

- **Precautions**
  - When the value of Size exceeds the range of In[ ] or AryOut[ ], the return value is FALSE and AryOut[ ] remains unchanged.
  - In1[ ], In2[ ], and AryOut[ ] must be of the same data type. Otherwise, a compilation fault will occur.
  - If the results exceed the valid range of AryOut[ ], AryOut[ ] will contain elements of illegal values. In this case, no fault will occur. Data in the memory area adjacent to those elements will not be corrupted.
  - When the value of Size is 0, AryOut[ ] remains unchanged and the return value is TRUE.
  - If the dimension of the input array exceeds 3, the return value is FALSE, and AryOut[ ] remains unchanged.
  - Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.16.20 ArySubV

Subtracts the same value from each element of an array.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ArySubV	Array and value subtraction	FC		:= ArySubV(In1 := , In2 := , Size := , AryOut :=);

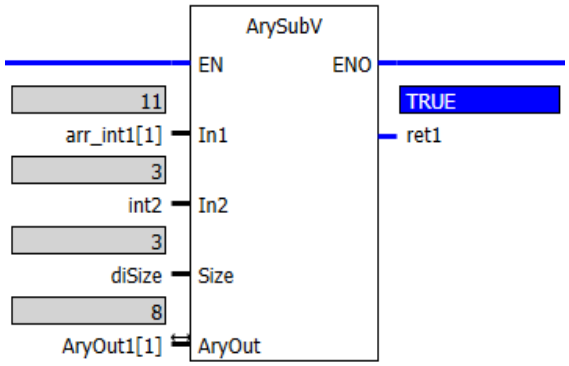
- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1[ ] array	Array to process	Follows data type	-	Array to process
	In2	Divisor variable	Follows data type	-	Divisor variable
	Size	Number of elements to process	Follows data type	1	Number of elements to process
Input/Output	AryOut[ ] array	Processing result array	Follows data type	-	Processing result array

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1[ ] array	–	–	–	–	–	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–
In2	Same data type as the elements of In1[ ]																			
Size	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–
AryOut[ ] array	Same data type as elements in In1[ ]																			



- **Function**

  This instruction subtracts In2 from each of the Size elements in the array In1[ ] starting from In1[0]. The result is stored in AryOut[ ].

- **Program example**

	LD	ST

Define variables	VAR

  - In1[ ], In2[ ], and AryOut[ ] must be of the same data type. Otherwise, a compilation fault will occur.
  - If the results exceed the valid range of AryOut[ ], AryOut[ ] will contain elements of illegal values. In this case, no fault will occur. Data in the memory area adjacent to those elements will not be corrupted.
  - When the value of Size is 0, AryOut[ ] remains unchanged and the return value is TRUE.
  - If the dimension of the input array exceeds 3, the return value is FALSE, and AryOut[ ] remains unchanged.
  - Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.16.22 AryDivV

Divides each element of an array by the same value.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AryDivV	Array and value division	FC		:= AryDivV(In1 := , In2 := , Size := , AryOut :=);

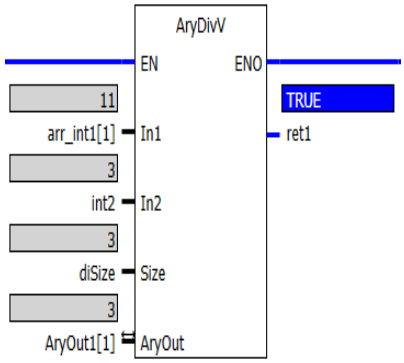
- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1[ ] array	Array to process	Follows data type	-	Array to process
	In2	Divisor variable	Follows data type	-	Divisor variable
	Size	Number of elements to process	Follows data type	1	Number of elements to process
Input/Output	AryOut[ ] array	Processing result array	Follows data type	-	Processing result array

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1[ ] array	–	–	–	–	–	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–
In2	Same data type as the elements of In1[ ]																			
Size	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–
AryOut[ ] array	Same data type as elements in In1[ ]																			



- **Function**

This instruction divides In2 into each of the Size elements in the dividend array In1[ ] starting from In1[0]. The result is stored in AryOut[ ].

- **Program example**

<table>
<tr><th></th><th>LD</th><th>ST</th></tr>
<tr><td>Define variables</td><td colspan="2">

```
VAR
    arr_int1: ARRAY[1..3] OF INT := [11, 23, 35];
    int2: INT := 3;
    diSize: DINT := 3;
    AryOut1: ARRAY[1..3] OF INT;
    ret1: BOOL;
END_VAR
```

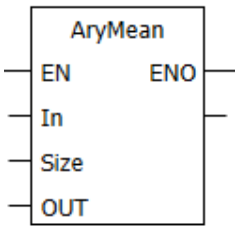
</td></tr>
<tr><td>Program</td><td>
</td><td>

```
ret1  TRUE  := AryDivV(
      In1 := arr_int1[1]   11  ,
      In2 := int2    3  ,
      Size := diSize    3  ,
      AryOut := AryOut1[1]   3  );RETURN
```

</td></tr>
<tr><td>Operation result</td><td colspan="2">

	Name	Data type	Address	Value
1	arr_int1	ARRAY [1..3] OF INT		
2	arr_int1[1]	INT		11
3	arr_int1[2]	INT		23
4	arr_int1[3]	INT		35
5	int2	INT		3
6	diSize	DINT		3
7	AryOut1	ARRAY [1..3] OF INT		
8	AryOut1[1]	INT		3
9	AryOut1[2]	INT		7
10	AryOut1[3]	INT		11
11	ret1	BOOL		TRUE

</td></tr>
<tr><td>Principle analysis</td><td colspan="2">Divide int2 into arr_int1[1 to 3] respectively, and store the results in ArrOut1[1 to 3].</td></tr>
</table>



- **Precautions**
  - When the value of Size exceeds the range of In[ ] or AryOut[ ], the return value is FALSE and AryOut[ ] remains unchanged.
  - In1[ ], In2[ ], and AryOut[ ] must be of the same data type. Otherwise, a compilation fault will occur.
  - If the results exceed the valid range of AryOut[ ], AryOut[ ] will contain elements of illegal values. In this case, no fault will occur. Data in the memory area adjacent to those elements will not be corrupted.
  - When the value of Size is 0, AryOut[ ] remains unchanged and the return value is TRUE.
  - If the dimension of the input array exceeds 3, the return value is FALSE, and AryOut[ ] remains unchanged.
  - Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

◦ When the dividend is 0, the instruction follows the system's zero-division protection rule and returns FALSE.

18.2.16.23 AryMean

Calculates the mean of the elements of an array.

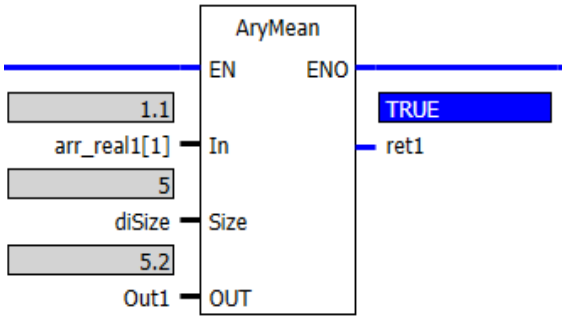
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AryMean	Array mean calculation	FC		:= AryMean(In := , Size := , OUT :=);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In[ ] array	Array to process	Follows data type	-	Array to process
	Size	Number of elements to process	Follows data type	1	Number of elements to process
	Out	Operation result	Follows data type	-	Mean value



Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In[ ] array	–	–	–	–	–	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–
Size	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–
Out	Same data type as elements in In1[ ]																			

- **Function**

This instruction calculates the mean of elements of the array In[ ].

- **Program example**

<table>
<tr><th></th><th>LD</th><th>ST</th></tr>

</table>

- **Precautions**
  - Arithmetic operations are not supported when the elements of In[ ] are positive infinity, negative infinity, or non-numeric data.
  - When the data types of In[ ] and Out are different, a fault occurs during compilation.
  - When the value of Size exceeds the array range of In[ ], the return value is FALSE, and Out remains unchanged.
  - When In[ ] or Out is an integer, the decimal portion of the mean is truncated.
  - When the value of Size is 0, Out is 0 and the return value is TRUE.
  - If the dimension of the input array exceeds 3, the return value is FALSE, and AryOut[ ] remains unchanged.
  - Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.16.24 ArySD

Calculates the standard deviation of the elements in an array.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ArySD	Array standard deviation calculation	FC		:= ArySD(In := , Size := , OUT :=);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In[ ] array	Array to process	Follows data type	-	Array to process
	Size	Number of elements to process	Follows data type	2	Number of elements to process
	Out	Operation result	Follows data type	-	Standard deviation

Variable types

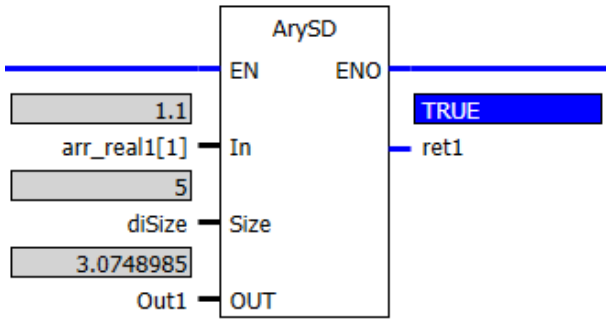
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In[ ] array	–	–	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–
Size	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–

- **Function**

This instruction calculates the standard deviation of Size elements of the array In[ ] starting from In[0].

Standard deviation calculation formula:

$$\frac{\sqrt{\sum_i (In[i]-InM)^2}}{Size-1}$$



i: Suffix of In[ ] (0 to Size-1).

InM: Mean value of In[0] to In[Size-1].

- **Program example**

<table>
<tr><th></th><th>LD</th><th>ST</th></tr>
<tr><td>Define variables</td><td colspan="2">

```
VAR
    arr_real1: ARRAY[1..5] OF REAL := [1.1, 3.4, 5.5, 7, 9];

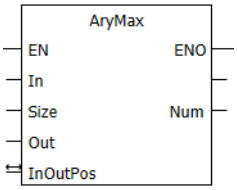
9	ret1	BOOL		TRUE



</td></tr>
<tr><td>Principle analysis</td><td colspan="2">Calculate the mean value of the elements to process, and then calculate the standard deviation based on the above formula.</td></tr>
</table>

- **Precautions**
  - In ArrayUtils library versions 1.2.0.1 and earlier, when the value of Size is 0 or 1, Out is set to 0 and TRUE is returned.
    In ArrayUtils library versions 1.3.0.0 and later, when the value of Size is less than 2, Out is set to 0 and FALSE is returned.
  - Elements in the input array In[ ] and Out must be of the same data type.
  - When an intermediate value in the calculation process exceeds the valid range of In[ ], the value of Out is an illegal value. In this case, no fault will occur.
  - When the value of Size exceeds the array range of In[ ], the return value is FALSE, and Out remains unchanged.
  - If the dimension of the input array exceeds 3, the return value is FALSE, and AryOut[ ] remains unchanged.
  - Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.16.25 AryMax

Gets the maximum value in a one-dimensional array.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AryMax	Maximum array value retrieval	FC		:= AryMax(In := , Size := , Out := , InOutPos := , Num =>);

- **Related variables**

Variable

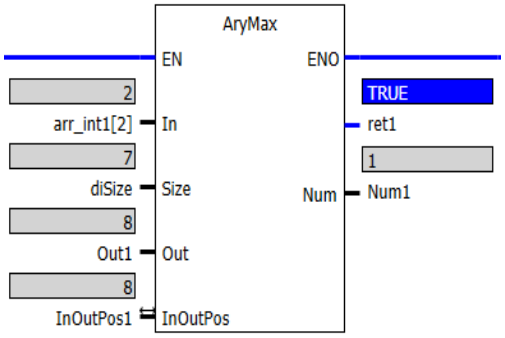
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In[ ] array	Array to search	Follows data type	-	Array to search
	Size	Number of elements to search	Follows data type	-	Number of elements in In[ ] to search
	Out	Search result	Follows data type	1	Search result
Input/Output	InOutPos	Index of the retrieved element	Follows data type	-	Index of the retrieved element
Output	Num	Number of times the key value is retrieved	Follows data type	-	Number of times the key value is retrieved

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In[ ] array	–	–	–	–	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
Size	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–
InOutPos	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–
Out	Data with the same data type as elements in In[ ]																			
Num	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–

- **Function**

  This instruction gets the minimum value of the Size elements in the array In[ ] starting from In[0]. The retrieval result is assigned to Out, the index of the retrieved element is assigned to InOutPos, and the number of times that the minimum value is retrieved is assigned to Num. If Num is greater than 1, the lowest index of the retrieved element is assigned to InOutPos. The relationship between values with data types that are not integers or real numbers is determined as given in the following table.



Data Type	Relationship
TIME	The numerically larger value is considered to be larger.
DATE, TOD, DT	The later date or time is considered to be larger.
STRING	First, the first character encodings in all strings are compared. If the encodings are different, the size of string is determined by the corresponding encoding values. If the encodings are the same, compare the encodings of the second, third, and subsequent characters until a difference is found. If the lengths of the strings are different, NULL characters (16#00) are added to the shorter string to complete the comparison.

- **Program example**

<table>
<tr><th></th><th>LD</th><th>ST</th></tr>
<tr><td>Define variables</td><td colspan="2">

```
VAR
    arr_int1: ARRAY[0..9] OF INT := [0, 1, 2, 3, 4, 5, 6, 7, 8, 9];
    diSize: DINT := 7;
    Out1: INT;
    InOutPos1: DINT;
    Num1: DINT;
    ret1: BOOL;

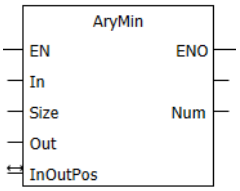
12	diSize	DINT		7
13	Out1	INT		8
14	InOutPos1	DINT		8
15	Num1	DINT		1
16	ret1	BOOL		TRUE

</td></tr>
</table>



- **Precautions**
  - When the value of Size exceeds the array range of In[ ], the return value is FALSE, and Out remains unchanged.
  - When In[ ] is not a one-dimensional array, a fault occurs during compilation.
  - Ensure that the data type of Out is the same as that of the In[ ] array; otherwise, a fault occurs during compilation.
  - The index of the retrieved element is assigned to InOutPos.
  - When In[ ] is a real number, the result may be unexpected due to operation errors.
  - When the value of Size is 0, the value of Num changes to 0, the values of InOutPos and Out remain unchanged, and the return value is TRUE.
  - When the data type of In[ ] is not supported, a fault occurs during compilation.
  - When the data type of In[ ] and Out is STRING, the size of In[ ] shall not exceed that of Out; otherwise, the return value is FALSE and Out remains unchanged.

- When the data type of In[ ] and "Out" is STRING, the value range supports a maximum of 256 characters. Characters beyond the range will be truncated.
- Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.16.26 AryMin

Gets the minimum value in a one-dimensional array.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AryMin	Minimum array value retrieval	FC		:= AryMin(In := , Size := , Out := , InOutPos := , Num =>);

- **Related variables**

Variable

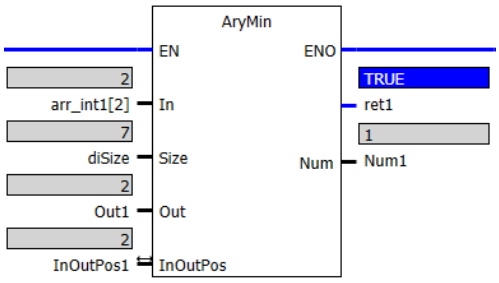
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In[ ] array	Array to search	Follows data type	-	Array to search
	Size	Number of elements to search	Follows data type	-	Number of elements in In[ ] to search
	Out	Search result	Follows data type	1	Search result
Input/Output	InOutPos	Index of the retrieved element	Follows data type	-	Index of the retrieved element
Output	Num	Number of times the key value is retrieved	Follows data type	-	Number of times the key value is retrieved

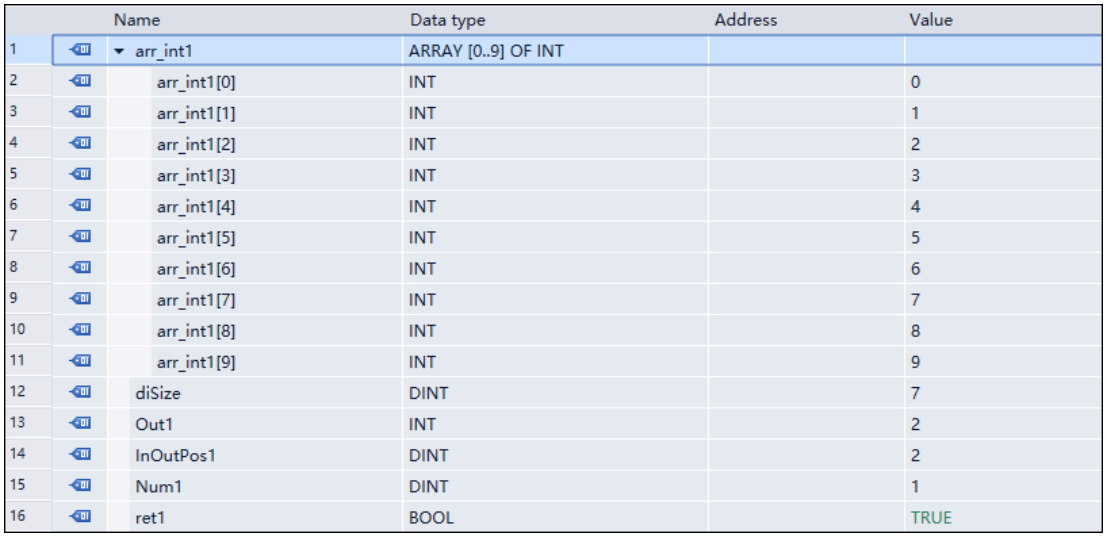
Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In[ ] array	–	–	–	–	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
Size	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–
InOutPos	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–
Out	Data with the same data type as elements in In[ ]																			
Num	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–

- **Function**

  This instruction gets the minimum value of the Size elements in the array In[ ] starting from In[0]. The retrieval result is assigned to Out, the index of the retrieved element is assigned to InOutPos, and the number of times that the minimum value is retrieved is assigned to Num. If Num is greater than 1, the lowest index of the retrieved element is assigned to InOutPos. The relationship between values with data types that are not integers or real numbers is determined as given in the following table.





Data Type	Relationship
TIME	The numerically larger value is considered to be larger.
DATE, TOD, DT	The later date or time is considered to be larger.

Data Type	Relationship
STRING	Compare the character encodings of the first character of each string. If the encodings are different, the size of string is determined by the corresponding encoding values. If the encodings are the same, compare the encodings of the second, third, and subsequent characters until a difference is found. If the lengths of the strings are different, NULL characters (16#00) are added to the shorter string to complete the comparison.

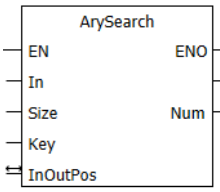
15	Num1	DINT		1
16	ret1	BOOL		TRUE



- **Precautions**
  - When the value of Size exceeds the array range of In[ ], the return value is FALSE, and Out remains unchanged.

- When In[ ] is not a one-dimensional array, a fault occurs during compilation.
- Ensure that the data type of Out is the same as that of the In[ ] array; otherwise, a fault occurs during compilation.
- The index of the retrieved element is assigned to InOutPos.
- When In[ ] is a real number, the result may be unexpected due to operation errors.
- When the value of Size is 0, the value of Num changes to 0, the values of InOutPos and Out remain unchanged, and the return value is TRUE.
- When the data type of In[ ] is not supported, a fault occurs during compilation.
- When the data type of In[ ] and Out is STRING, the size of In[ ] shall not exceed that of Out; otherwise, the return value is FALSE and Out remains unchanged.
- When the data type of In[ ] and "Out" is STRING, the value range supports a maximum of 256 characters. Characters beyond the range will be truncated.
- Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.16.27 ArySearch

Gets the specified value in a one-dimensional array.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ArySearch	Array search	FC		:= ArySearch(In := , Size := , Key := , InOutPos := , Num =>);

- **Related variables**

Variable

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	In[ ] array	Array to search	Follows data type	-	Array to search
	Size	Number of elements to search	Follows data type	1	Number of elements in In[ ] to search
	Key	Search keyword	Follows data type	-	Search keyword
Input/ Output	InOutPos	Index of the retrieved element	Follows data type	-	Index of the retrieved element in the target array In[ ]

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Output	Num	Number of times the key value is retrieved	Follows data type	-	Number of times the key value is retrieved

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In[ ] array	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
	Arrays of enumerations can also be specified.																			
Size	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–
Key	Data with the same data type as elements in In[ ]																			
InOutPos	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–
Num	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–

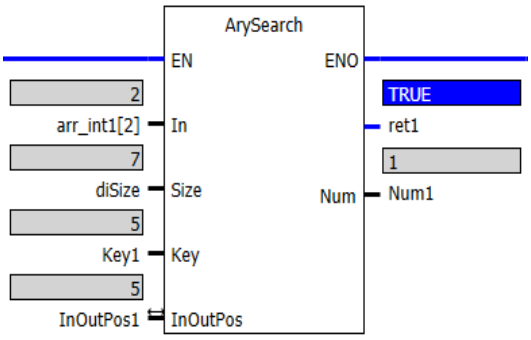
- **Function**

  This instruction searches Size elements in the one-dimensional array In[ ] starting from In[0] for elements with the same value as the search keyword Key.

  The values of the element index InOutPos and the number of times that the key value is retrieved Num are as shown in the table below.

Element with Same Value As Key	"InOutPos"	"Num"
Exists	Index of the lowest element among those with the same value as Key	Number of elements with the same value as Key
Does not exist	No change	0

The relationship between values with data types that are not integers or real numbers is determined as given in the following table.



Data Type	Relationship
TIME	The numerically larger value is considered to be larger.
DATE	The later date is considered to be larger.
STRING	First, the first character encodings in all strings are compared. If the encodings are different, the size of string is determined by the corresponding encoding values. If the encodings are the same, compare the encodings of the second, third, and subsequent characters until a difference is found. If the lengths of the strings are different, NULL characters (16#00) are added to the shorter string to complete the comparison.

	LD	ST
Principle analysis		

- **Precautions**
  - When the value of Size exceeds the AryOut[ ] array, the return value is FALSE and the value of Num is initialized to 0.
  - When In[ ] is not a one-dimensional array, a fault occurs during compilation.
  - Ensure that the data type of Key is the same as that of the In[ ] array; otherwise, a fault occurs during compilation.
  - The index of the retrieved element is assigned to InOutPos.
  - When the value of Size is 0, the value of Num is initialized to 0, InOutPos remains unchanged, and the return value is TRUE.
  - When the data type of In[ ] and Key is STRING, the value range supports a maximum of 256 characters. Characters beyond the range will be truncated. When the value exceeds the value range, the return value is FALSE and the value of Num is initialized to 0.
  - Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.16.28 ArySHL

Shifts multiple array elements to the left (toward the higher elements).

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ArySHL	Shift N-bits left with carry	FC		:= ArySHL(InOut := , Size := , Num :=);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Size	Number of elements in the shift register array	Follows data type	1	Number of elements in the shift register array

Input/Output	Variable	Name	Valid Range	Default Value	Description
	Num	Number of bits to shift	Follows data type	1	Number of bits to shift
Input/Output	InOut[ ] array	Array where the shift object is located	Follows data type	-	Array where the shift object is located

Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
InOut[ ] array	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
	Arrays of structures can also be specified.																			
Size	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–
Num	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–

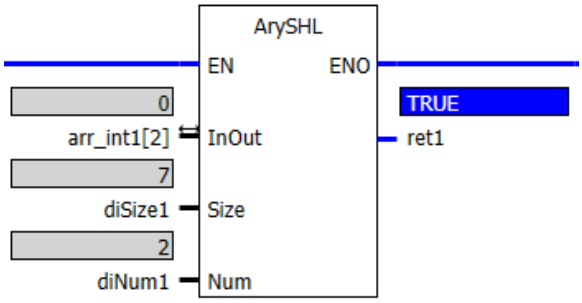
- **Function**

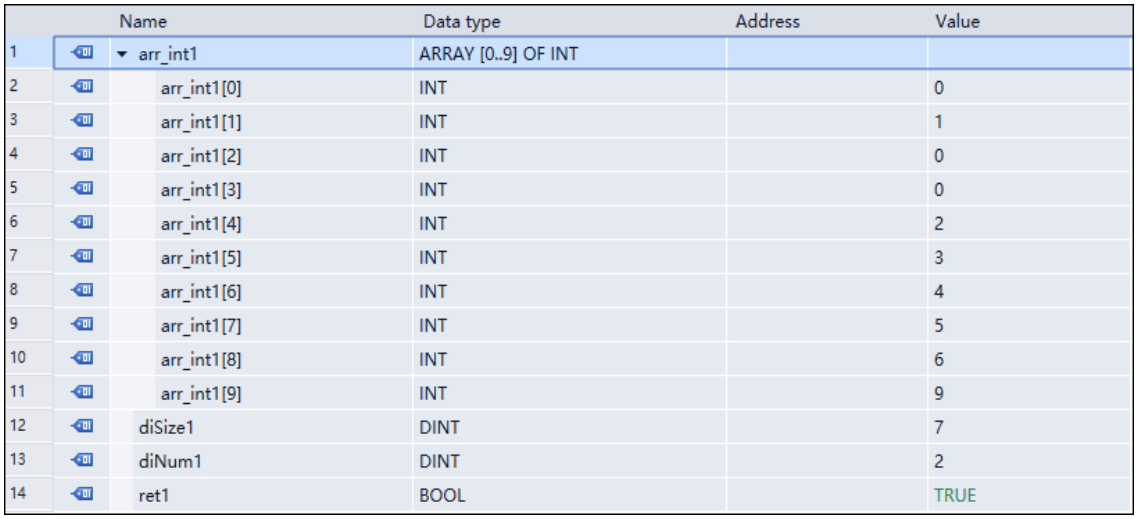
  This instruction shifts the lower Size elements in shift register array InOut[ ] to the left by Num elements.

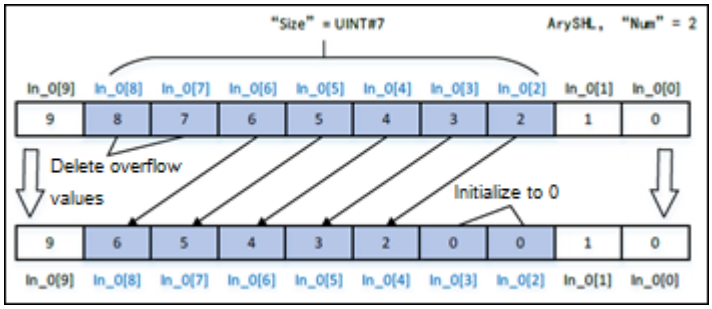
  Elements that are shifted out of the array are discarded.

  The empty elements in InOut[ ] after shifting are assigned with the initial values of the corresponding data types.

  The following table describes default values for various data types.







Data Type	Initial Value
BOOL	FALSE
BYTE, WORD, DWORD, LWORD	16#0
USINT, UINT, UDINT, ULINT, SINT, INT, DINT, LINT, REAL, LREAL	0
TIME	T#0ms
DATE	D#1970-1-1

Data Type	Initial Value
TOD	TOD#0:0:0
DT	DT#1970-1-1-0:0:0
STRING	''

- **Program example**

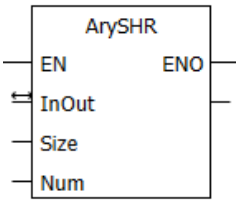
	LD	ST

Define variables	VAR
	arr_int1: ARRAY[0..9] OF INT := [0, 1, 2, 3, 4, 5, 6, 7, 8, 9];
	diSize1: DINT := 7;
	diNum1: DINT := 2;
	ret1: BOOL;
	END_VAR	

Program		ret1 TRUE := ArySHL(InOut := arr_int1[2] 0 , Size := diSize1 7 , Num := diNum1 2);RETURN
Operation result		
Principle analysis		

	Name	Data type	Address	Value
1	arr_int1	ARRAY [0..9] OF INT		
2	arr_int1[0]	INT		0
3	arr_int1[1]	INT		1
4	arr_int1[2]	INT		0
5	arr_int1[3]	INT		0
6	arr_int1[4]	INT		2
7	arr_int1[5]	INT		3
8	arr_int1[6]	INT		4
9	arr_int1[7]	INT		5
10	arr_int1[8]	INT		6
11	arr_int1[9]	INT		9
12	diSize1	DINT		7
13	diNum1	DINT		2
14	ret1	BOOL		TRUE

- **Precautions**
  - In ArrayUtils library versions 1.2.0.0 and earlier, when the value of Num is 0, no shifting is performed, and TRUE is returned (this condition has the highest priority).
    In ArrayUtils library versions 1.2.0.1 and later, when the value of Num is 0, no shifting is performed; in



this case, if the value of Size exceeds the array area of InOut[ ], FALSE is returned; otherwise, TRUE is returned.

- When the value of Size is 0, no shifting is performed, and TRUE is returned.
- When the value of Num is greater than Size, all values from InOut[0] to InOut[Size–1] are initialized to 0.
- If the value of "Size" exceeds the InOut[ ] array, the return value is FALSE and InOut[ ] does not change.
- If the dimension of the input array exceeds 3, the return value is FALSE, and InOut[ ] remains unchanged.
- Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.16.29 ArySHR

Shifts multiple array elements to the right (toward the lower elements).

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ArySHR	Shift N-bits right with carry	FC		:= ArySHR(InOut := , Size := , Num :=);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Size	Number of elements in the shift register array	Follows data type	1	Number of elements in the shift register array
	Num	Number of bits to shift	Follows data type	1	Number of bits to shift
Input/Output	InOut[ ] array	Array where the shift object is located	Follows data type	-	Array where the shift object is located

Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
InOut[ ] array	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
	Arrays of structures can also be specified.																			
Size	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–
Num	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–

- **Function**

  This instruction shifts the higher Size elements in shift register array InOut[ ] to the right by Num elements. Elements that are shifted out of the array are discarded. The empty elements in InOut[ ] after shifting are assigned with the initial values of the corresponding data types.

  The following table describes default values for various data types.

Data Type	Initial Value
BOOL	FALSE
BYTE, WORD, DWORD, LWORD	16#0
USINT, UINT, UDINT, ULINT, SINT, INT, DINT, LINT, REAL, LREAL	0
TIME	T#0ms
DATE	D#1970-1-1
TOD	TOD#0:0:0
DT	DT#1970-1-1-0:0:0
STRING	''

- **Program example**

	LD	ST

Define variables	VAR
	arr_int1: ARRAY[0..9] OF INT := [0, 1, 2, 3, 4, 5, 6, 7, 8, 9];
	diSize1: DINT := 7;
	diNum1: DINT := 2;
	ret1: BOOL;
	END_VAR

</table>
</td></tr>
</table>

- **Precautions**
  - In ArrayUtils library versions 1.2.0.0 and earlier, when the value of Num is 0, no shifting is performed, and TRUE is returned (this condition has the highest priority).
    In ArrayUtils library versions 1.2.0.1 and later, when the value of Num is 0, no shifting is performed; in this case, if the value of Size exceeds the array area of InOut[ ], FALSE is returned; otherwise, TRUE is returned.
  - When the value of Size is 0, no shifting is performed, and TRUE is returned.
  - When the value of Num is greater than Size, all values from InOut[0] to InOut[Size–1] are initialized to 0.
  - If the value of "Size" exceeds the InOut[ ] array, the return value is FALSE and InOut[ ] does not change.
  - If the dimension of the input array exceeds 3, the return value is FALSE, and InOut[ ] remains unchanged.
  - Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.16.30 AryShiftReg

Shifts an array to the left by one bit and inserts the input value to the least-significant bit.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AryShiftReg	Shift register	FB		AryShiftReg_Instance_0(Shift := , Reset := , IN := , Size := , InOut := , P_CY =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Shift	Shift	Follows data type	FALSE	Shift when the signal changes to TRUE
	Reset	Reset a bit	Follows data type	FALSE	Reset when the signal changes to TRUE
	In	Input Value	Follows data type	FALSE	Value to insert to the least-significant bit of InOut[ ]
	Size	Number of elements to process	Follows data type	1	Number of elements to use as a shift register in InOut[ ]
Input/Output	InOut[ ] array	Array where the shift object is located	Follows data type	-	Array where the shift object is located
Output	P_CY	Carry flag	Follows data type	-	Value stored in the carry flag

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Shift	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Reset	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
In	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
InOut[ ] array	√	√	√	√	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Size	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–
P_CY	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

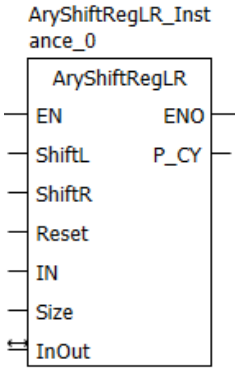
  This instruction shifts Size element in InOut[ ] starting from InOut[0] to the left (toward the most-significant bit) by one bit when Shift changes from FALSE to TRUE. The input value In is inserted into the least-significant bit. The most-significant bit shifted out of the array is output to the carry (CY) flag P_CY.

  When Reset is TRUE, CY and all bits of the Size elements starting from InOut[0] are set to FALSE.

- **Program example**

	LD	ST

Define variables	VAR
	AryShiftReg_0: AryShiftReg;
	xshift: BOOL;
	xReset: BOOL;
	disize1: DINT := 3;
	xIn: BOOL;
	xP_CY: BOOL;
	inout1:ARRAY[1..4] OF BYTE :=[2#10011001,2#10111001,2#11101101,2#10101101];
	END_VAR	



<table>
<tr><th></th><th>LD</th><th>ST</th></tr>
<tr><td>Program</td><td>
</td><td>
</td></tr>
<tr><td>Operation result</td><td>
</td><td></td></tr>
<tr><td>Principle analysis</td><td>
</td><td></td></tr>
</table>

- **Precautions**
  - When Reset is TRUE, no shift is performed even if Shift changes from FALSE to TRUE.
  - When the value of Size is 0, InOut[ ] remains unchanged.
  - When the value of Size exceeds the array area of InOut[ ], InOut[ ] remains unchanged.
  - If the dimension of the input array exceeds 3, AryOut[ ] remains unchanged.
  - Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.16.31 AryShiftRegLR

Shifts an array to the left or right by one bit and inserts the input value to the least-significant bit or most-significant bit.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AryShiftRegLR	Reversible shift register	FB		AryShiftRegLR_Instance_0(ShiftL := , ShiftR := , Reset := , IN := , Size := , InOut := , P_CY =>);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	ShiftL	Left shift	Follows data type	FALSE	Shift left when the signal changes to TRUE
	ShiftR	Right shift	Follows data type	FALSE	Shift right when the signal changes to TRUE
	Reset	Reset a bit	Follows data type	FALSE	Reset when the signal changes to TRUE
	In	Input Value	Follows data type	FALSE	Value to insert to the least-significant bit of InOut[ ]
	Size	Number of elements to process	Follows data type	1	Number of elements to use as a shift register in InOut[ ]
Input/Output	InOut[ ] array	Array where the shift object is located	Follows data type	-	Array where the shift object is located
Output	P_CY	Carry flag	Follows data type	-	Value stored in the carry flag

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
ShiftL	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
ShiftR	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Reset	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
In	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
InOut[ ] array	√	√	√	√	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Size	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–
P_CY	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  This instruction shifts Size element in InOut[ ] starting from InOut[0] to the left (toward the most-significant bit) by one bit when ShiftL changes from FALSE to TRUE. The input value In is inserted into the least-significant bit. The most-significant bit shifted out of the array is output to the carry (CY) flag P_CY.

  This instruction shifts Size element in InOut[ ] starting from InOut[0] to the right (toward the least-significant bit) by one bit when ShiftR changes from FALSE to TRUE. The input value In is inserted into the most-significant bit. The least-significant bit shifted out of the array is output to the carry (CY) flag P_CY.

  When Reset is TRUE, CY and all bits of the Size elements starting from InOut[0] are set to FALSE.

- **Program example**

	LD	ST

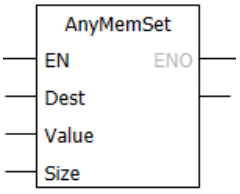
Define variables	VAR
	AryShiftRegLR_0: AryShiftRegLR;
	xShiftL: BOOL;
	xShiftR: BOOL := 1;
	xReset: BOOL;
	xIn: BOOL;
	xP_CY: BOOL;
	disizel: DINT := 3;
	inoutl:ARRAY[1..4] OF BYTE :=[2#10011001,2#10111001,2#11101101,2#10101101];
	END_VAR	

<table>
<tr><th></th><th>LD</th><th>ST</th></tr>
<tr><td>Program</td><td>
</td><td>
</td></tr>
<tr><td>Operation result</td><td colspan="2">
</td></tr>
</table>

- **Precautions**
  - When Reset is TRUE, no shift is performed even if ShiftL/ShiftR changes from FALSE to TRUE.
  - No shift is performed when both ShiftL and ShiftR change from FALSE to TRUE simultaneously.
  - When the value of Size is 0, InOut[ ] remains unchanged.
  - When the value of Size exceeds the array area of InOut[ ], InOut[ ] remains unchanged.
  - If the dimension of the input array exceeds 3, AryOut[ ] remains unchanged.
  - Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.17 Memory Copy

18.2.17.1 Instruction List



Instruction	FB/FC	Function	Library	Applicable Library Version
18.2.17.2 AnyMemSet	FC	Memory fill	Util	Library version 1.1.0.0 and later
18.2.17.3 AnyMemCpy	FC	Memory copy		Library version 1.1.0.0 and later

Instruction	FB/FC	Function	Library	Applicable Library Version
18.2.17.4 AnyMemMove	FC	Memory move		Library version 1.1.0.0 and later
18.2.17.5 AnyMemCmp	FC	Memory comparison		Library version 1.2.0.0 and later

18.2.17.2 AnyMemSet

Fills the specified memory.

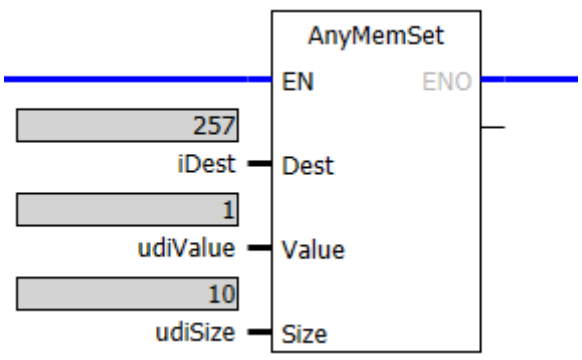
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AnyMemSet	Memory fill	FC		:= AnyMemSet(Dest := , Value := , Size :=);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Dest	Target variable	Follows data type	-	Target object for memory fill
	Value	Fill value	Follows data type	-	Value to be filled into the memory
	Size	Fill length	Follows data type	16#FFFFFFFF	Number of bytes to fill
Output	AnyMemSet	Execution result	Follows data type	FALSE	The result of the instruction.



Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String					
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
Dest	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
	An enumeration, an array, an array element, a structure, or a structure member can also be specified.																				
Value	-	-	-	-	-	-	-	√	-	-	-	-	-	-	-	-	-	-	-	-	-
Size	-	-	-	-	-	-	-	√	-	-	-	-	-	-	-	-	-	-	-	-	-
AnyMemSet	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

- **Function**

  This instruction fills data into Dest in bytes, with the number of bytes filled being the minimum of the byte size of Dest and the Size parameter.

- **Program example**

Item	LD	ST
Define variables	PROGRAM POU VAR iDest: INT; udiValue: UDINT; udiSize: UDINT; END_VAR	
Program		AnyMemSet(Dest := iDest 257 , Value := udivalue 1 , Size := udiSize 10);

Item	LD	ST
Operation result		

	Name	Data type	Address	Value
1	iDest	INT		257
2	udiValue	UDINT		1
3	udiSize	UDINT		10

- **Precautions**
  - When Dest is an array element, the fill calculates the byte length starting from that element to the end of the array, compares it with Size, and fills the smaller of the two.
  - Dest supports arrays with a maximum dimension of three. If the dimension exceeds three, the function immediately returns TRUE, and Dest remains unchanged.
  - Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.17.3 AnyMemCpy

Copies the specified memory.

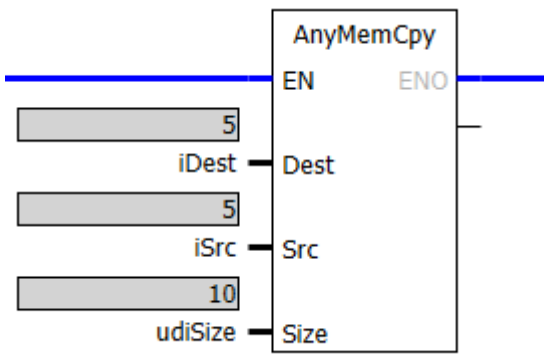
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AnyMemCpy	Memory copy	FC		:= AnyMemCpy(Dest := , Src := , Size :=);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Dest	Target variable	Follows data type	-	Target object for memory copy
	Src	Source variable	Follows data type	-	Source object to be copied
	Size	Copy length	Follows data type	16#FFFFFFFF	Number of bytes to copy
Output	AnyMemCpy	Execution result	Follows data type	FALSE	The result of the instruction.



Variable types

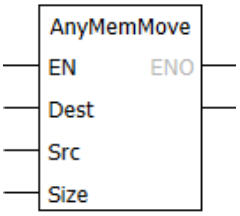
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String					
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
Dest	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
	An enumeration, an array, an array element, a structure, or a structure member can also be specified.																				
Src	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
	An enumeration, an array, an array element, a structure, or a structure member can also be specified.																				
Size	-	-	-	-	-	-	-	√	-	-	-	-	-	-	-	-	-	-	-	-	-
AnyMemCpy	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

- **Function**

  This instruction copies data from the starting position of Src to Dest in bytes. The number of bytes copied is the minimum of the byte count of Src, the byte count of Dest, and Size.

- **Program example**

Item	LD	ST
Define variables	VAR iDest: INT; iSrc: INT; udiSize: UDINT; END_VAR	
Program		AnyMemCpy(Dest := iDest 5 , Src := iSrc 5 , Size := udiSize 10);



Item	LD	ST
Operation result		

- **Precautions**
  - When Dest or Src is an array element, this instruction calculates the byte length starting from Dest or Src to the end of the array, compares it with Size, and the smaller value is used for copying.
  - The data types of Dest and Src can be different, but the copy result may be incorrect. For example, if Dest is INT and Src is DINT with a value of 65536, Dest will be assigned 0.
  - Dest or Src supports arrays with a maximum dimension of three. If the dimension exceeds three, the function immediately returns TRUE, and Dest remains unchanged.
  - Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.17.4 AnyMemMove

Moves the specified memory.

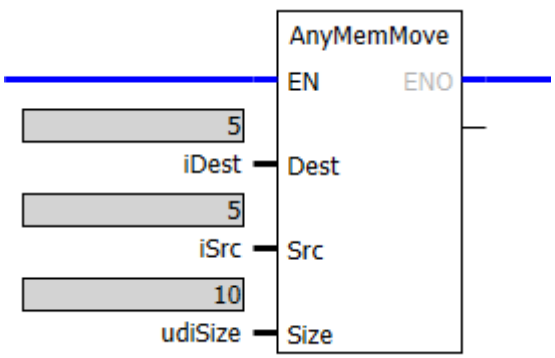
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AnyMemMove	Memory move	FC		:= AnyMemMove(Dest := , Src := , Size :=);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Dest	Target variable	Follows data type	-	Target object for memory move
	Src	Source variable	Follows data type	-	Source object for memory move
	Size	Move length	Follows data type	16#FFFFFFFF	Number of bytes to move
Output	AnyMemMove	Execution result	Follows data type	FALSE	The result of the instruction.



Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String					
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
Dest	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
	An enumeration, an array, an array element, a structure, or a structure member can also be specified.																				
Src	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
	An enumeration, an array, an array element, a structure, or a structure member can also be specified.																				
Size	-	-	-	-	-	-	-	√	-	-	-	-	-	-	-	-	-	-	-	-	-
AnyMemMove	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

- **Function**

  This instruction moves data from the starting position of Src to Dest in bytes. The number of bytes moved is the minimum of the byte count of Src, the byte count of Dest, and Size.

- **Program example**

Item	LD	ST
Define variables	VAR iDest: INT; iSrc: INT; udiSize: UDINT; END_VAR	
Program		AnyMemMove(Dest := iDest 5 , Src := iSrc 5 , Size := udiSize 10);

Item	LD	ST
Operation result		

	Name	Data type	Address	Value
1	iDest	INT		5
2	iSrc	INT		5
3	udiSize	UDINT		10

- **Precautions**
  - When Dest or Src is an array element, this instruction calculates the byte length starting from Dest or Src to the end of the array, compares it with Size, and the smaller value is used for moving.
  - The data types of Dest and Src can be different, but the result may be incorrect. For example, if Dest is INT and Src is DINT with a value of 65536, Dest will be assigned 0.
  - Dest or Src supports arrays with a maximum dimension of three. If the dimension exceeds three, the function immediately returns TRUE, and Dest remains unchanged.
  - Size is of fixed type DINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.17.5 AnyMemCmp

Compares the memory of two specified variables.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AnyMemCmp	Memory comparison	FC		:= AnyMemCmp(Buffer1 := , Buffer2 := , Count :=);

- **Related variables**

Variable

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	Buffer1	Comparison buffer 1	Follows data type	-	Variable to be compared
	Buffer2	Comparison buffer 2	Follows data type	-	Variable to be compared
	Count	Comparison length	Follows data type	0	Number of bytes to compare

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Output	AnyMemCmp	Comparison result	Follows data type	0	Comparison result. • A negative return value indicates that the first unequal byte in the two buffers has a smaller value in Buffer1 than in Buffer2. • A return value of 0 indicates that the values in the two buffers are completely equal within the comparison range. • A positive return value indicates that the first unequal byte in the two buffers has a greater value in Buffer1 than in Buffer2. Note: Only the sign of the return value is meaningful; the specific return value is meaningless.

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String					
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
Buffer1	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
	An enumeration, an array, an array element, a structure, or a structure member can also be specified.																				
Buffer2	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
	An enumeration, an array, an array element, a structure, or a structure member can also be specified.																				
Count	-	-	-	-	-	-	-	√	-	-	-	-	-	-	-	-	-	-	-	-	-

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String					
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
AnyMemCmp	-	-	-	-	-	-	-	-	-	-	-	√	-	-	-	-	-	-	-	-	-

- **Function**

  This instruction compares whether the memory of Count bytes starting from the addresses of Buffer1 and Buffer2 are identical.

- **Program example**

Item	LD	ST

Define variables	VAR
	aiBuf1 : ARRAY[0..3] OF INT := [1,2,3,4];
	aiBuf2 : ARRAY[0..3] OF INT := [1,2,3,5];
	Count : UDINT := 8;
	Ret1 : DINT;
	END_VAR	

Program	AnyMemCmp EN ENO aiBuf1 Buffer1 aiBuf2 Buffer2 8 Count -1 Ret1	Ret1 -1 := AnyMemCmp(Buffer1 := aiBuf1, Buffer2 := aiBuf2, Count := Count 8); RETURN
Operation result	Name / Type / Address / Value aiBuf1 / ARRAY [0..3] OF INT aiBuf2 / ARRAY [0..3] OF INT Count / UDINT / 8 Ret1 / DINT / -1	

- **Precautions**
  - When Buffer1 or Buffer2 is an array element, this instruction calculates the byte length starting from Buffer1 or Buffer2 to the end of the array, compares it with Size, and the smaller value is used for comparison.
  - The data types of Buffer1 and Buffer2 can be different. The comparison is performed byte-by-byte and is independent of data types.
  - Buffer1 or Buffer2 supports arrays with a maximum dimension of three. If the dimension exceeds three, the function performs a 0-byte comparison and returns 0 directly.
  - Count is of fixed type UDINT. If another data type is passed to the function block, it will be handled according to implicit type conversion rules.

18.2.18 Recipe Library

18.2.18.1 RecipeManager

18.2.18.1.1 Instruction List

Instruction	FB/FC	Function	Library	Applicable Library Version
18.2.18.1.3 CreateRecipe	Method	Create a recipe	RecipeManagement	Library version 1.0.0.0 and later
18.2.18.1.4 CreateRecipeNoSave	Method	Create a recipe without saving files		Library version 1.0.0.0 and later
18.2.18.1.5 DeleteAllRecipe	Method	Delete all recipes		Library version 1.2.0.0 and later
18.2.18.1.6 DeleteRecipe	Method	Delete a recipe		Library version 1.0.0.0 and later

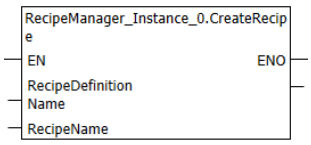
18.2.18.1.17 WriteRecipe	Method	Write a recipe		Library version 1.0.0.0 and later

Instruction	FB/FC	Function	Library	Applicable Library Version
18.2.18.1.18 ReloadRecipes	Method	Reload recipes		Library version 1.0.0.0 and later
18.2.18.1.19 GetRecipeCount	Method	Get the number of recipes associated to a specified recipe		Library version 1.0.0.0 and later
18.2.18.1.20 GetRecipeNames	Method	Get the recipe names associated to a specified recipe		Library version 1.0.0.0 and later
18.2.18.1.21 GetRecipeValues	Method	Get the variable values of a specified recipe		Library version 1.0.0.0 and later
18.2.18.1.22 GetRecipeVariableNames	Method	Get the variable names of a specified recipe		Library version 1.0.0.0 and later
18.2.18.1.23 SetRecipeValues	Method	Set the variable values of a specified recipe		Library version 1.0.0.0 and later
18.2.18.1.24 GetRecipeNamesV2	Method	Get the recipe names associated to a specified recipe		Library version 1.1.0.0 and later
18.2.18.1.25 GetRecipeValuesV2	Method	Get the variable values of a specified recipe		Library version 1.1.0.0 and later
18.2.18.1.26 GetRecipeVariableNames V2	Method	Get the variable names of a specified recipe		Library version 1.1.0.0 and later
18.2.18.1.27 SetRecipeValuesV2	Method	Set the variable values of a specified recipe		Library version 1.1.0.0 and later
18.2.18.1.28 GetLastError	Method	Get the latest fault code		Library version 1.0.0.0 and later
18.2.18.1.29 ResetLastError	Method	Reset fault codes		Library version 1.0.0.0 and later
18.2.18.1.30 SetStoragePath	Method	Set storage path		Library version 1.0.0.0 and later
18.2.18.1.31 CreateRecipeV3	FB	Create a recipe		Library version 2.0.0.0 and later
18.2.18.1.32 DeleteALLRecipeV3	FB	Deletes all recipes under a recipe definition		Library version 2.0.0.0 and later
18.2.18.1.33 DeleteRecipeV3	FB	Delete a specified recipe under a recipe definition		Library version 2.0.0.0 and later
18.2.18.1.34 GetRecipeDefinitionInfoV3	FB	Get recipe definition information		Library version 2.0.0.0 and later

Instruction	FB/FC	Function	Library	Applicable Library Version
18.2.18.1.35 GetRecipeInfoV3	FB	Get recipe information		Library version 2.0.0.0 and later
18.2.18.1.36 LoadRecipeV3	FB	Load a recipe		Library version 2.0.0.0 and later
18.2.18.1.37 ReadRecipeV3	FB	Read PLC values into a recipe		Library version 2.0.0.0 and later
18.2.18.1.38 RenameRecipeV3	FB	Rename a recipe		Library version 2.0.0.0 and later
18.2.18.1.39 SaveRecipeV3	FB	Save a recipe file		Library version 2.0.0.0 and later
18.2.18.1.40 SetRecipeValuesV3	FB	Set the variable values of a specified recipe		Library version 2.0.0.0 and later
18.2.18.1.41 WriteRecipeV3	FB	Write the recipe into the PLC		Library version 2.0.0.0 and later
18.2.18.1.42 SetStoragePathV3	FB	Set the path to store or load the recipe file		Library version 2.0.0.0 and later



18.2.18.1.2 Overview

1. The basic configuration of the recipe can be defined under the "Recipe" node in the project tree. For details, see the 10.3 Recipe chapter.
2. The storage location and format of the recipe can be defined in the RecipeManager object, under which one or more recipe definitions can be added. Each recipe definition includes multiple recipe names corresponding to all variables within it, with each recipe name containing specific variable values.
3. All instructions in the recipe management library are methods of the RecipeManager function bloc and must be used within the same RecipeManager instance to manage recipes programmatically.
4. It is recommended to use edge-triggered signals for the enable input EN. This can be achieved by inserting an edge detection contact at the connection point or using the 18.1.1.4 PLS or 18.1.1.2 R_TRIG rising edge output instruction in combination.

18.2.18.1.3 CreateRecipe

Creates a new recipe based on the specified recipe definition. The current PLC variable values are read into the new recipe and saved as a recipe file with the default name. The default recipe file name format is <recipe definition>.<recipe>.txtrecipe.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
CreateRecipe	Create a recipe	Method		:= RecipeManager_Instance_0.CreateRecipe(RecipeDefinitionName := , RecipeName :=);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	RecipeDefinitionName	Recipe definition name	Follows data type	-	Recipe definition name
	RecipeName	Recipe name	Follows data type	-	Recipe name
Output	CreateRecipe	Return value	Follows data type	-	Refer to Fault Code.

  Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TOD	DT	STRING
RecipeDefinitionName	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
RecipeName	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
CreateRecipe	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

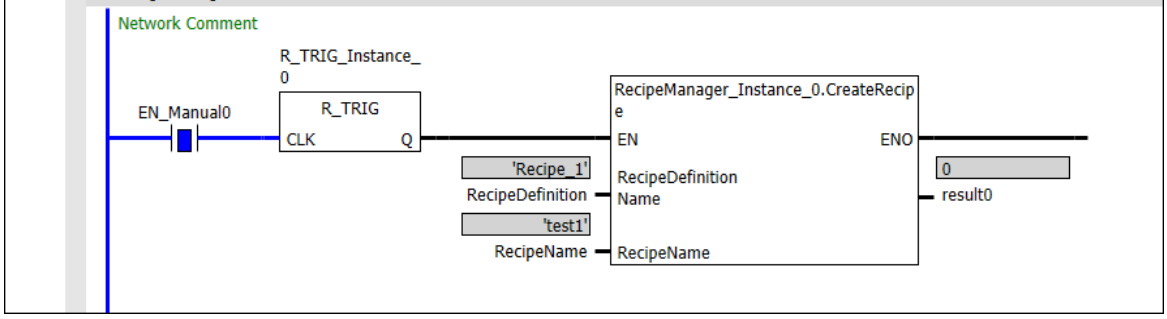
- **Function**

  This instruction creates a new recipe based on the specified recipe definition. The current PLC variable values are read into the new recipe and saved as a recipe file with the default name.

- **Program example**

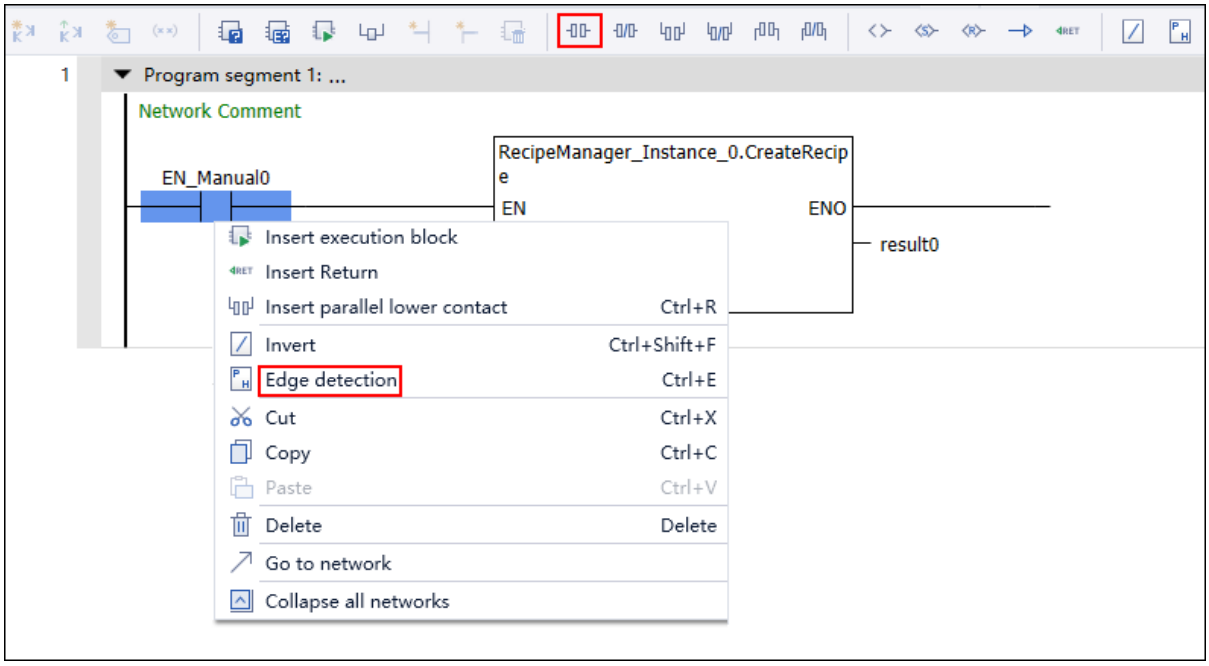
  ST:

	Name	Data type	Address	Value	Prepare value	Comment
1	RecipeManager_Instance_0	RecipeManager				
2	R_TRIG_Instance_0	R_TRIG				
3	EN_Manual0	BOOL		TRUE		
4	RecipeDefinition	STRING		'Recipe_1'		
5	RecipeName	STRING		'test1'		
6	result0	DWORD		0		



```
R_TRIG_Instance_0(
CLK := EN_Manual0,
Q => );

IF R_TRIG_Instance_0.Q THEN
    result0 := RecipeManager_Instance_0.CreateRecipe(
    RecipeDefinitionName := RecipeDefinition 'Recipe_1',
    RecipeName := RecipeName 'test1');
END_IF

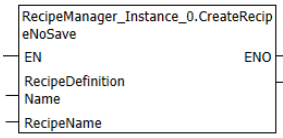


RETURN
```

LD:

	Name	Data type	Address	Value	Prepare value	Comment
1	RecipeManager_Instance_0	RecipeManager				
2	R_TRIG_Instance_0	R_TRIG				
3	EN_Manual0	BOOL		TRUE		
4	RecipeDefinition	STRING		'Recipe_1'		
5	RecipeName	STRING		'test1'		
6	result0	DWORD		0		

- **Precautions**
  - It is recommended to use edge-triggered signals for the enable input EN; otherwise, this method will return a fault code.
  - Take the following ladder logic (LD) diagram as an example:
    - Insert a contact at the connection point, and select "Edge detection" in the right-click menu.



- Use the 18.1.1.2 R_TRIGrising edge output instruction in combination.

18.2.18.1.4 CreateRecipeNoSave

Creates a new recipe based on the specified recipe definition, and reads the current PLC variable values into the new recipe.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
CreateRecipeNoSave	Create a recipe without saving files	Method		:= RecipeManager_Instance_0.CreateRecipeNoSave(RecipeDefinitionName := , RecipeName :=);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	RecipeDefinitionName	Recipe definition name	Follows data type	-	Recipe definition name
	RecipeName	Recipe name	Follows data type	-	Recipe name
Output	CreateRecipeNoSave	Return value	Follows data type	-	Refer to Fault Code.

Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TOD	DT	STRING
RecipeDefinitionName	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
RecipeName	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
CreateRecipeNoSave	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

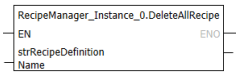
- **Function**

  This instruction creates a new recipe based on the specified recipe definition, and reads the current PLC variable values into the new recipe.

- **Program example**

  ST:

  LD:



- **Precautions**

  It is recommended to use edge-triggered signals for the enable input EN; otherwise, this method will return a fault code.

18.2.18.1.5 DeleteAllRecipe

Deletes all recipes from the specified recipe definition.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
DeleteAllRecipe	Delete all recipes	Method		:= RecipeManager_Instance_0.DeleteAllRecipe(strRecipeDefinitionName :=);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	strRecipeDefinitionName	Recipe definition name	Follows data type	-	Recipe definition name
Output	DeleteAllRecipe	Return value	Follows data type	-	Refer to Fault Code.

  Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TOD	DT	STRING
strRecipeDefinitionName	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
DeleteAllRecipe	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  This instruction deletes all recipes from the specified recipe definition.

- **Program example**

  Call the CreateRecipe instruction to create a new recipe. Then, call the GetRecipeCount and GetRecipeNamesV2 instructions to get the recipe count and recipe names. Finally, execute the DeleteAllRecipe instruction and compare the recipe count and recipe names before and after deletion.

  ST:

  Before executing the DeleteAllRecipe instruction, the recipe count is 3, and the recipe names associated with the recipe definition are 'recipe1', 'recipe2', and 'recipe3'.

	Name	Data type	Address	Value
1	RecipeManager_Instance_0	RecipeManager		
2	RecipeDefinitionName	STRING		'Recipe_1'
3	RecipeName	STRING		'recipe3'
4	result0	DWORD		0
5	result1	DWORD		0
6	result2	DWORD		3
7	result3	DWORD		0
8	EN_Manual0	BOOL		TRUE
9	EN_Manual1	BOOL		FALSE
10	EN_Manual2	BOOL		TRUE
11	R_TRIG_Instance_0	R_TRIG		
12	R_TRIG_Instance_1	R_TRIG		
13	aString	ARRAY [0..5] OF STRING		
14	aString[0]	STRING		'recipe1'
15	aString[1]	STRING		'recipe3'
16	aString[2]	STRING		'recipe2'
17	aString[3]	STRING		''
18	aString[4]	STRING		''
19	aString[5]	STRING		''

```
R_TRIG_Instance_0(
CLK TRUE := EN_Manual0 TRUE,
Q => );

IF R_TRIG_Instance_0.Q FALSE THEN
    result0 0 := RecipeManager_Instance_0.CreateRecipe(
    RecipeDefinitionName := RecipeDefinitionName 'Recipe_1' ,
    RecipeName := RecipeName 'recipe3' );
END_IF

R_TRIG_Instance_1(
CLK FALSE := EN_Manual1 FALSE,
Q => );

IF R_TRIG_Instance_1.Q FALSE THEN
    result1 0 := RecipeManager_Instance_0.DeleteAllRecipe(
    strRecipeDefinitionName := RecipeDefinitionName 'Recipe_1' );
END_IF

IF EN_Manual2 TRUE THEN
    result2 3 := RecipeManager_Instance_0.GetRecipeCount(
    RecipeDefinitionName := RecipeDefinitionName 'Recipe_1' );

    result3 0 := RecipeManager_Instance_0.GetRecipeNamesV2(
    RecipeDefinitionName := RecipeDefinitionName 'Recipe_1' ,
    aStrings := aString[0] 'recipe1' ,
    iSize := 3,
    iStartIndex := 0);
END_IFRETURN
```

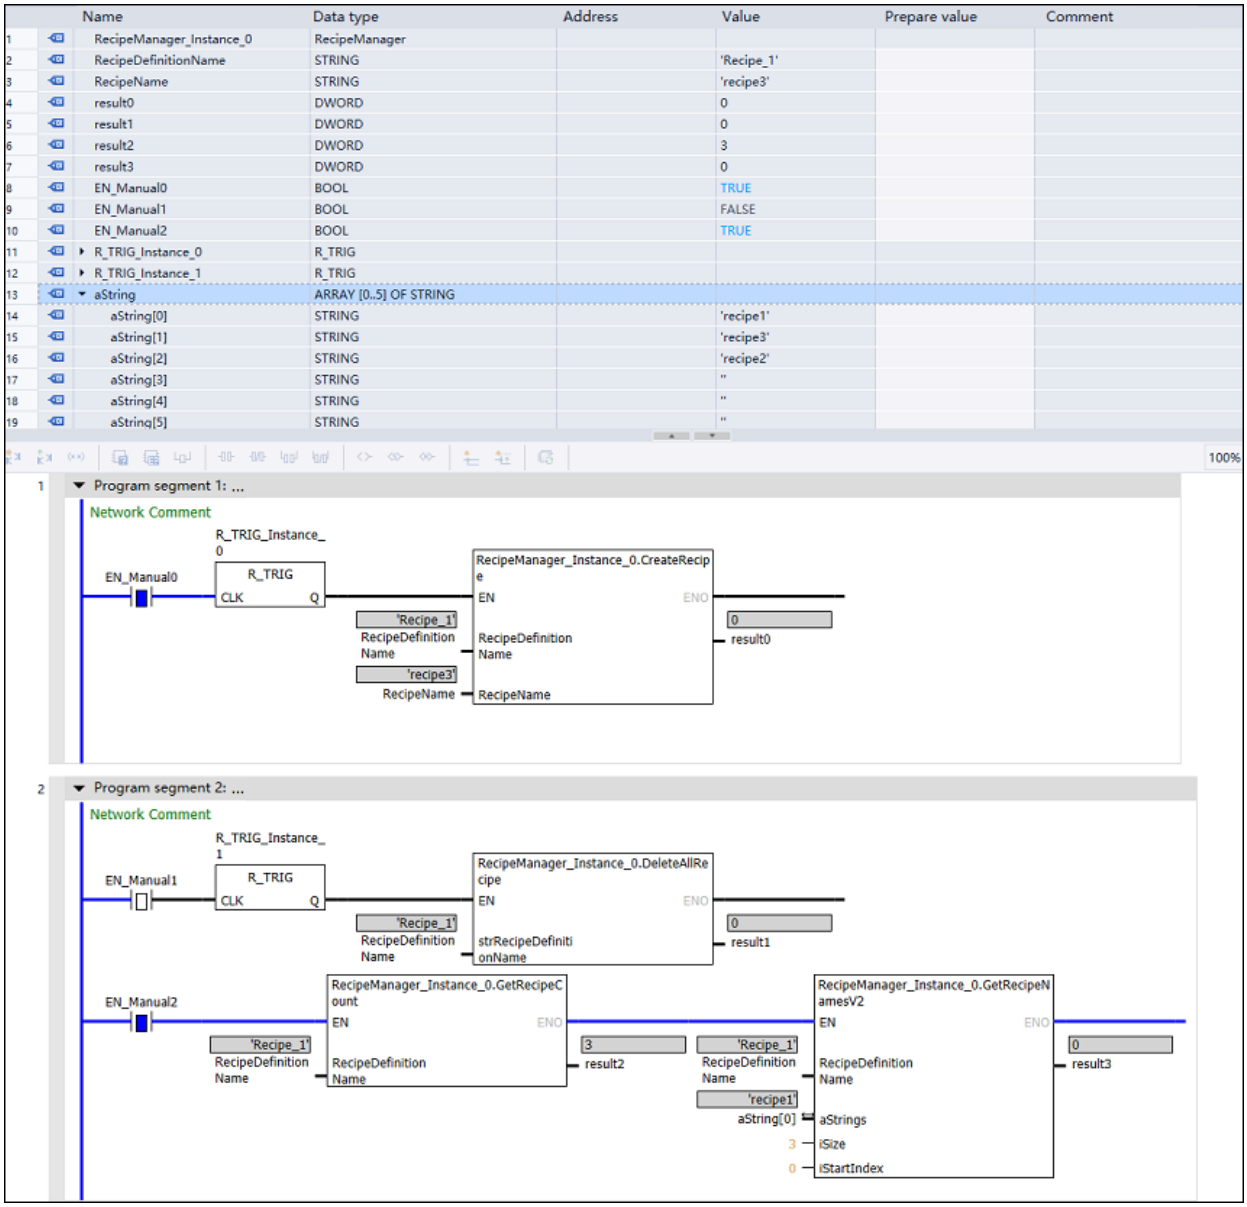
After executing the DeleteAllRecipe instruction, the recipe count is 0, and the recipe names associated with the recipe definition are empty.

	Name	Data type	Address	Value
1	RecipeManager_Instance_0	RecipeManager		
2	RecipeDefinitionName	STRING		'Recipe_1'
3	RecipeName	STRING		'recipe3'
4	result0	DWORD		0
5	result1	DWORD		0
6	result2	DWORD		0
7	result3	DWORD		0
8	EN_Manual0	BOOL		TRUE
9	EN_Manual1	BOOL		TRUE
10	EN_Manual2	BOOL		TRUE
11	R_TRIG_Instance_0	R_TRIG		
12	R_TRIG_Instance_1	R_TRIG		
13	aString	ARRAY [0..5] OF STRING		
14	aString[0]	STRING		''
15	aString[1]	STRING		''
16	aString[2]	STRING		''
17	aString[3]	STRING		''
18	aString[4]	STRING		''
19	aString[5]	STRING		''

```
R_TRIG_Instance_0(
CLK  TRUE  := EN_Manual0  TRUE ,
Q => );

IF R_TRIG_Instance_0.Q  FALSE  THEN
    result0      0       :=  RecipeManager_Instance_0.CreateRecipe(
    RecipeDefinitionName := RecipeDefinitionName    'Recipe_1'    ,
    RecipeName := RecipeName    'recipe3'    );
END_IF

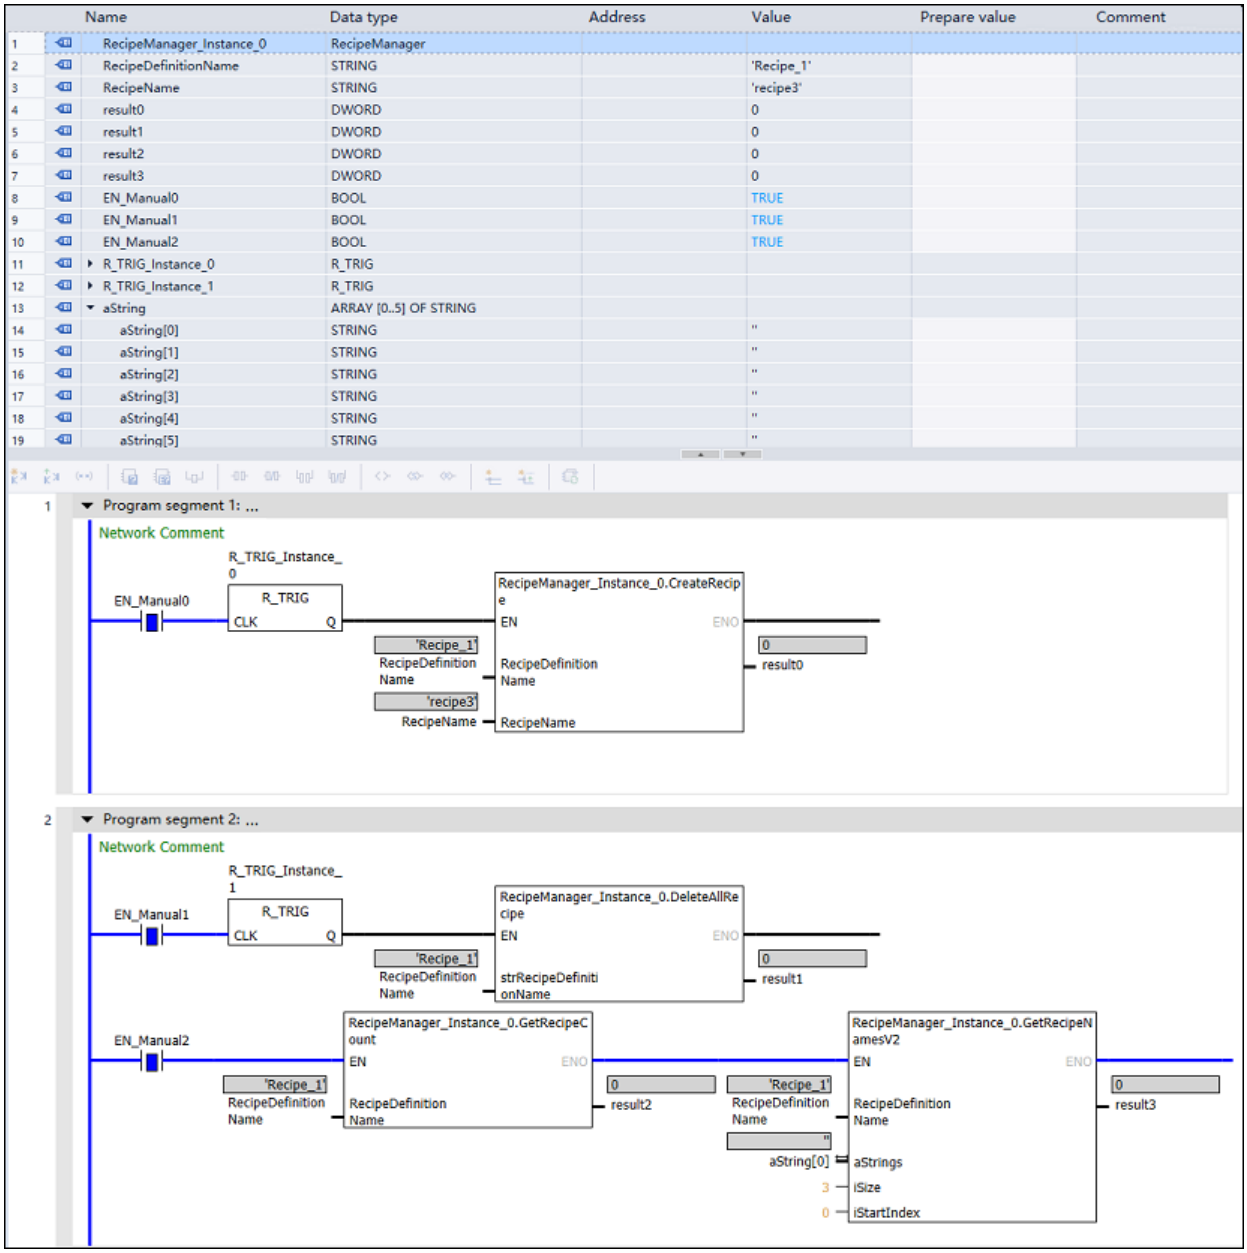
R_TRIG_Instance_1(
CLK  TRUE  := EN_Manual1  TRUE ,
Q => );



IF R_TRIG_Instance_1.Q  FALSE  THEN
    result1      0       :=  RecipeManager_Instance_0.DeleteAllRecipe(
    strRecipeDefinitionName := RecipeDefinitionName    'Recipe_1'    );
END_IF

IF EN_Manual2  TRUE  THEN
    result2      0       :=  RecipeManager_Instance_0.GetRecipeCount(
    RecipeDefinitionName := RecipeDefinitionName    'Recipe_1'    );

    result3      0       :=  RecipeManager_Instance_0.GetRecipeNamesV2(
    RecipeDefinitionName := RecipeDefinitionName    'Recipe_1'    ,
    aStrings := aString[0]       ''       ,
    iSize := 3,
    iStartIndex := 0);
END_IFRETURN
```

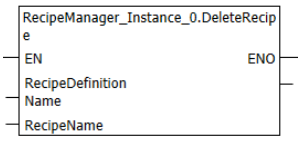


LD:

Before executing the DeleteAllRecipe instruction, the recipe count is 3, and the recipe names associated with the recipe definition are 'recipe1', 'recipe2', and 'recipe3'.

	Name	Data type	Address	Value	Prepare value	Comment
1	RecipeManager_Instance_0	RecipeManager				
2	RecipeDefinitionName	STRING		'Recipe_1'		
3	RecipeName	STRING		'recipe3'		
4	result0	DWORD		0		
5	result1	DWORD		0		
6	result2	DWORD		3		
7	result3	DWORD		0		
8	EN_Manual0	BOOL		TRUE		
9	EN_Manual1	BOOL		FALSE		
10	EN_Manual2	BOOL		TRUE		
11	R_TRIG_Instance_0	R_TRIG				
12	R_TRIG_Instance_1	R_TRIG				
13	aString	ARRAY [0..5] OF STRING				
14	aString[0]	STRING		'recipe1'		
15	aString[1]	STRING		'recipe3'		
16	aString[2]	STRING		'recipe2'		
17	aString[3]	STRING		''		
18	aString[4]	STRING		''		
19	aString[5]	STRING		''		

After executing the DeleteAllRecipe instruction, the recipe count is 0, and the recipe names associated with the recipe definition are empty.



- **Precautions**

  It is recommended to use edge-triggered signals for the enable input EN; otherwise, this method will return a fault code.

18.2.18.1.6 DeleteRecipe

Deletes a recipe from the specified recipe definition.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
DeleteRecipe	Delete a recipe	Method		:= RecipeManager_Instance_0.DeleteRecipe(RecipeDefinitionName := , RecipeName :=);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	RecipeDefinitionName	Recipe definition name	Follows data type	-	Recipe definition name
	RecipeName	Recipe name	Follows data type	-	Recipe name
Output	DeleteRecipe	Return value	Follows data type	-	Refer to Fault Code.

Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TOD	DT	STRING
RecipeDefinitionName	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
RecipeName	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
DeleteRecipe	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

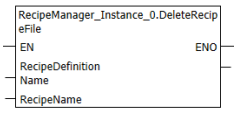
- **Function**

  This instruction deletes a recipe from the specified recipe definition.

- **Program example**

  ST:

  LD:



- **Precautions**

  It is recommended to use edge-triggered signals for the enable input EN; otherwise, this method will return a fault code.

18.2.18.1.7 DeleteRecipeFile

Deletes the recipe file corresponding to a recipe. The recipe file must be saved with the default filename format <recipe definition>.<recipe>.txtrecipe.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
DeleteRecipeFile	Delete a recipe file	Method		:= RecipeManager_Instance_0.DeleteRecipeFile(RecipeDefinitionName := , RecipeName :=);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	RecipeDefinitionName	Recipe definition name	Follows data type	-	Recipe definition name
	RecipeName	Recipe name	Follows data type	-	Recipe name

Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	DeleteRecipeFile	Return value	Follows data type	-	Refer to Fault Code.

Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TOD	DT	STRING
RecipeDefinitionName	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
RecipeName	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
DeleteRecipeFile	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

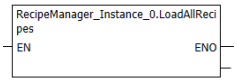
- **Function**

  This instruction deletes the recipe file corresponding to a recipe, which must be saved with the default filename format.

- **Program example**

  ST:

  LD:



- **Precautions**

  It is recommended to use edge-triggered signals for the enable input EN; otherwise, this method will return a fault code.

18.2.18.1.8 LoadAllRecipes

Loads the recipe files into a recipe. The recipe files must be saved with the default filename format <recipe definition>.<recipe>.txtrecipe.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
LoadAllRecipes	Load all recipe files	Method		:= RecipeManager_Instance_0.LoadAllRecipes();

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	LoadAllRecipes	Return value	Follows data type	-	Refer to Fault Code.

  Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TOD	DT	STRING
LoadAll Recipes	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

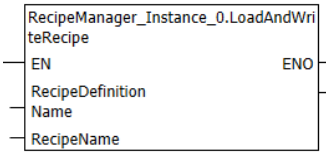
- **Function**

  This instruction loads all recipe files into a recipe.

- **Program example**

  ST:

  LD:



- **Precautions**

  It is recommended to use edge-triggered signals for the enable input EN.

18.2.18.1.9 LoadAndWriteRecipe

Loads a recipe file based on the specified recipe definition and recipe name, and writes the recipe values into the current PLC variables. The recipe file must be saved with the default filename format <recipe definition>.<recipe>.txtrecipe.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
LoadAndWriteRecipe	Load a recipe file and write it into a variable	Method		:= RecipeManager_Instance_0.LoadAndWriteRecipe(RecipeDefinitionName := , RecipeName :=);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	RecipeDefinitionName	Recipe definition name	Follows data type	-	Recipe definition name
	RecipeName	Recipe name	Follows data type	-	Recipe name
Output	LoadAndWriteRecipe	Return value	Follows data type	-	Refer to Fault Code.

  Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TOD	DT	STRING
RecipeDefinitionName	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
RecipeName	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
LoadAndWriteRecipe	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  This instruction loads the corresponding recipe file based on the specified recipe definition and recipe name.

- **Precautions**

  If entries in the recipe file are not included in the corresponding recipe, these entries will not be loaded and written to the current PLC variables.

- **Program example**

  ST:

	Name	Data type	Address	Value
1	RecipeManager_Instance_0	RecipeManager		
2	result	DWORD		0
3	var1	INT		0
4	RecipeDefinitionName	STRING		'Recipe_1'
5	RecipeName	STRING		'test1'

```
result := RecipeManager_Instance_0.LoadAndWriteRecipe(
RecipeDefinitionName := RecipeDefinitionName,
RecipeName := RecipeName);
```

LD:

	Name	Data type	Address	Value
1	RecipeManager_Instance_0	RecipeManager		
2	result	DWORD		0
3	var1	INT		0
4	RecipeDefinitionName	STRING		'Recipe_1'
5	RecipeName	STRING		'test1'

- **Precautions**

  It is recommended to use edge-triggered signals for the enable input EN.

18.2.18.1.10 LoadFromAndWriteRecipe

Loads a recipe file to the specified recipe and writes the recipe values to the current PLC variables. The default recipe file format is <recipe definition>.<recipe>.txtrecipe.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
LoadFromAndWriteRecipe	Load a recipe file from the specified file and write it into a variable	Method	RecipeManager_Instance_0.LoadFromAndWriteRecipe EN ENO RecipeDefinitionName RecipeName FileName	:= RecipeManager_Instance_0.LoadFromAndWriteRecipe(RecipeDefinitionName := , RecipeName := , FileName :=);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	RecipeDefinitionName	Recipe definition name	Follows data type	-	Recipe definition name
	RecipeName	Recipe name	Follows data type	-	Recipe name
	FileName	File name	Follows data type	-	File name
Output	LoadFromAndWriteRecipe	Return value	Follows data type	-	Refer to Fault Code.

Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TOD	DT	STRING
RecipeDefinitionName	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
RecipeName	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
FileName	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
LoadFromAndWriteRecipe	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

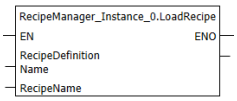
- **Function**

  This instruction loads a recipe file to the specified recipe and writes the recipe values to the current PLC variables.

- **Program example**

  ST:

LD:



- **Precautions**

  It is recommended to use edge-triggered signals for the enable input EN.

18.2.18.1.11 LoadRecipe

Loads a recipe from the specified recipe file. The recipe file must be saved with the default filename format <recipe definition>.<recipe>.txtrecipe.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
LoadRecipe	Load a recipe file	Method		:= RecipeManager_Instance_0.LoadRecipe(RecipeDefinitionName := , RecipeName :=);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	RecipeDefinitionName	Recipe definition name	Follows data type	-	Recipe definition name
	RecipeName	Recipe name	Follows data type	-	Recipe name
Output	LoadRecipe	Return value	Follows data type	-	Refer to Fault Code.

  Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TOD	DT	STRING
RecipeDefinitionName	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
RecipeName	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
LoadRecipe	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  This instruction loads a recipe from the specified recipe file.

- **Program example**

  ST:

LD:

- **Precautions**

  It is recommended to use edge-triggered signals for the enable input EN.

18.2.18.1.12 ReadAndSaveAs

Reads the current PLC values corresponding to the variables in the recipe definition, and saves these data sets as a recipe file.

The existing standard recipe file <recipe definition>.<recipe>.txtrecipe will not be modified.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ReadAndSaveAs	Read PLC variables and save as a recipe file	Method		:= RecipeManager_Instance_0.ReadAndSaveAs(RecipeDefinitionName := , FileName :=);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	RecipeDefinitionName	Recipe definition name	Follows data type	-	Recipe definition name

Input/Output	Variable	Name	Valid Range	Default Value	Description
	FileName	Recipe name	Follows data type	-	Recipe name
Output	ReadAndSaveAs	Return value	Follows data type	-	Refer to Fault Code.

Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TOD	DT	STRING
RecipeDefinitionName	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
RecipeName	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
ReadAndSaveAs	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  This instruction reads the current values of the variables in the recipe definition and saves them as a recipe file.

- **Program example**

  ST:

LD:

- **Precautions**

  It is recommended to use edge-triggered signals for the enable input EN.

18.2.18.1.13 ReadAndSaveRecipe

Reads the current PLC variable values into the recipe, then stores the recipe into a recipe file. The default recipe file name format is <recipe definition>.<recipe>.txtrecipe.

If the target recipe file already exists, it will be overwritten.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ReadAndSaveRecipe	Read PLC variables into a recipe and save the recipe file	Method	RecipeManager_Instance_0.ReadAndSaveRecipe EN ENO RecipeDefinition Name RecipeName	:= RecipeManager_Instance_0.ReadAndSaveRecipe(RecipeDefinitionName := , RecipeName :=);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	RecipeDefinitionName	Recipe definition name	Follows data type	-	Recipe definition name
	RecipeName	Recipe name	Follows data type	-	Recipe name

- **Program example**

  ST:

  LD:

- **Precautions**

  It is recommended to use edge-triggered signals for the enable input EN.

18.2.18.1.15 SaveRecipe

Saves the specified recipe as a recipe file. If a file with the same name exists, the existing file will be overwritten. The default format for recipe files is <recipe definition>.<recipe>.txtrecipe.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
SaveRecipe	Save a recipe file	Method		:= RecipeManager_Instance_0.SaveRecipe(RecipeDefinitionName := , RecipeName :=);

- **Related variables**

Variable

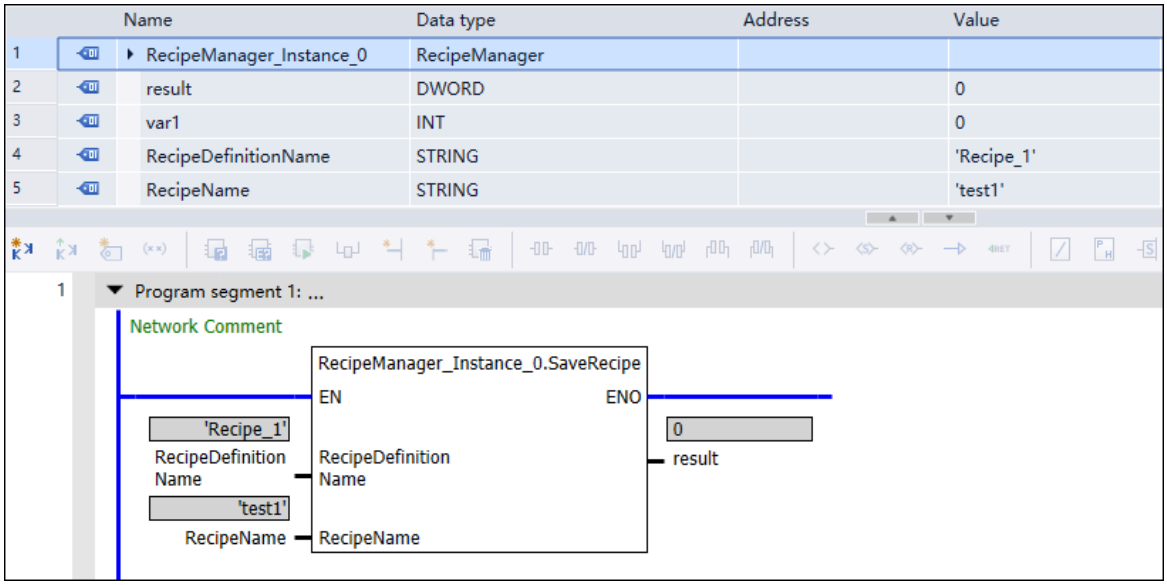
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	RecipeDefinitionName	Recipe definition name	Follows data type	-	Recipe definition name
	RecipeName	Recipe name	Follows data type	-	Recipe name
Output	SaveRecipe	Return value	Follows data type	-	Refer to Fault Code.

Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TOD	DT	STRING
RecipeDefinitionName	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
RecipeName	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
SaveRecipe	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

This instruction saves the specified recipe as a recipe file.



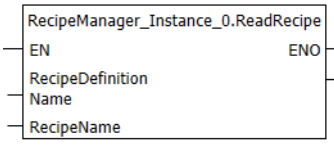
- **Program example**

ST:

	Name	Data type	Address	Value
1	RecipeManager_Instance_0	RecipeManager		
2	result	DWORD		0
3	var1	INT		0
4	RecipeDefinitionName	STRING		'Recipe_1'
5	RecipeName	STRING		'test1'

```
result := RecipeManager_Instance_0.SaveRecipe(
RecipeDefinitionName := RecipeDefinitionName 'Recipe_1',
RecipeName := RecipeName 'test1');
```

LD:



- **Precautions**

  It is recommended to use edge-triggered signals for the enable input EN.

18.2.18.1.16 ReadRecipe

Reads the current PLC variable values and saves it to the recipe.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ReadRecipe	Read PLC variables into a recipe	Method		:= RecipeManager_Instance_0.ReadRecipe(RecipeDefinitionName := , RecipeName :=);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	RecipeDefinitionName	Recipe definition name	Follows data type	-	Recipe definition name

Input/Output	Variable	Name	Valid Range	Default Value	Description
	RecipeName	Recipe name	Follows data type	-	Recipe name
Output	ReadRecipe	Return value	Follows data type	-	Refer to Fault Code.

Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TOD	DT	STRING
RecipeDefinitionName	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√

RecipeName	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
WriteRecipe	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  This instruction writes the variable values from a recipe into the current PLC variables.

- **Program example**

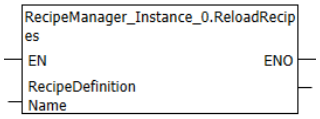
  ST:

	Name	Data type	Address	Value
1	RecipeManager_Instance_0	RecipeManager		
2	result	DWORD		0
3	var1	INT		0
4	RecipeDefinitionName	STRING		'Recipe_1'
5	RecipeName	STRING		'test1'

IF CAS FOR WHI REP RET EX //

```
result := RecipeManager_Instance_0.WriteRecipe(
RecipeDefinitionName := RecipeDefinitionName,
RecipeName := RecipeName);
```

LD:



- **Precautions**

  It is recommended to use edge-triggered signals for the enable input EN.

18.2.18.1.18 ReloadRecipes

Loads all recipe files under the storage path into the recipes, respectively. The recipe files must be saved with the default filename format <recipe definition>.<recipe>.txtrecipe.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ReloadRecipes	Reload recipes	Method		:= RecipeManager_Instance_0.ReloadRecipes(RecipeDefinitionName :=);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	RecipeDefinitionName	Recipe definition name	Follows data type	-	Recipe definition name
Output	ReloadRecipes	Return value	Follows data type	-	Refer to Fault Code.

  Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TOD	DT	STRING
RecipeDefinitionName	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
ReloadRecipes	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

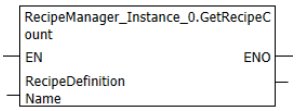
- **Function**

  This instruction loads all recipe files under the storage path into the recipes, respectively.

- **Program example**

  ST:

  LD:



- **Precautions**

  It is recommended to use edge-triggered signals for the enable input EN.

18.2.18.1.19 GetRecipeCount

Gets the number of recipes associated with the specified recipe definition.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
GetRecipeCount	Get the number of recipes associated to a specified recipe	Method		:= RecipeManager_Instance_0.GetRecipeCount(RecipeDefinitionName :=);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	RecipeDefinitionName	Recipe definition name	Follows data type	-	Recipe definition name
Output	GetRecipeCount	Recipe count	Follows data type	-	Recipe count

  Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TOD	DT	STRING

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
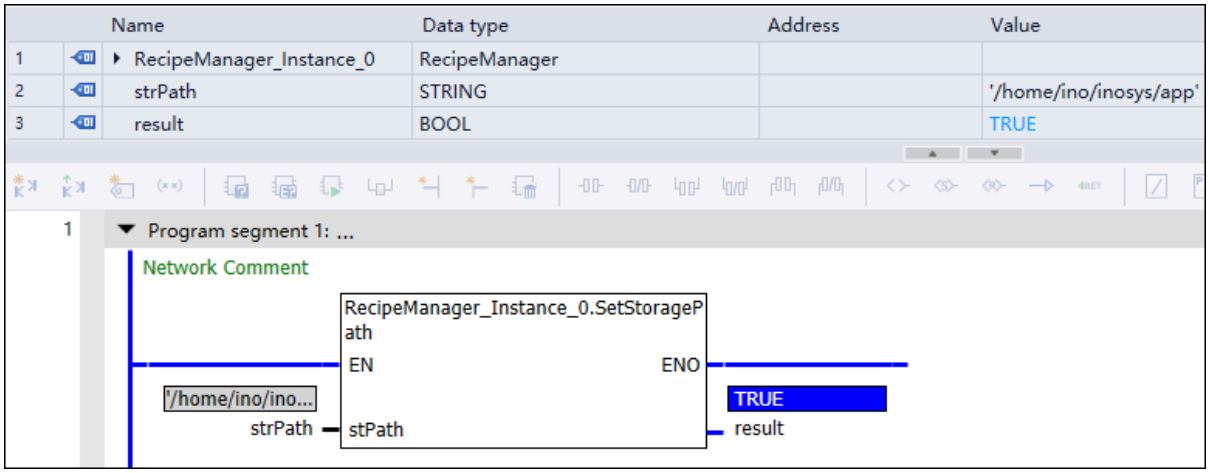
Input	stPath	Recipe storage path	Follows data type	-	Recipe storage path
Output	SetStoragePath	Return value	TRUE, FALSE	FALSE	Indicates whether the storage path is set successfully.

  Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TOD	DT	STRING
stPath	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	√
SetStoragePath	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

- **Function**

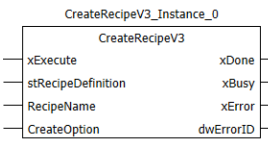


This instruction sets the storage path of the recipe file on the controller.

- **Program example**

ST:

LD:



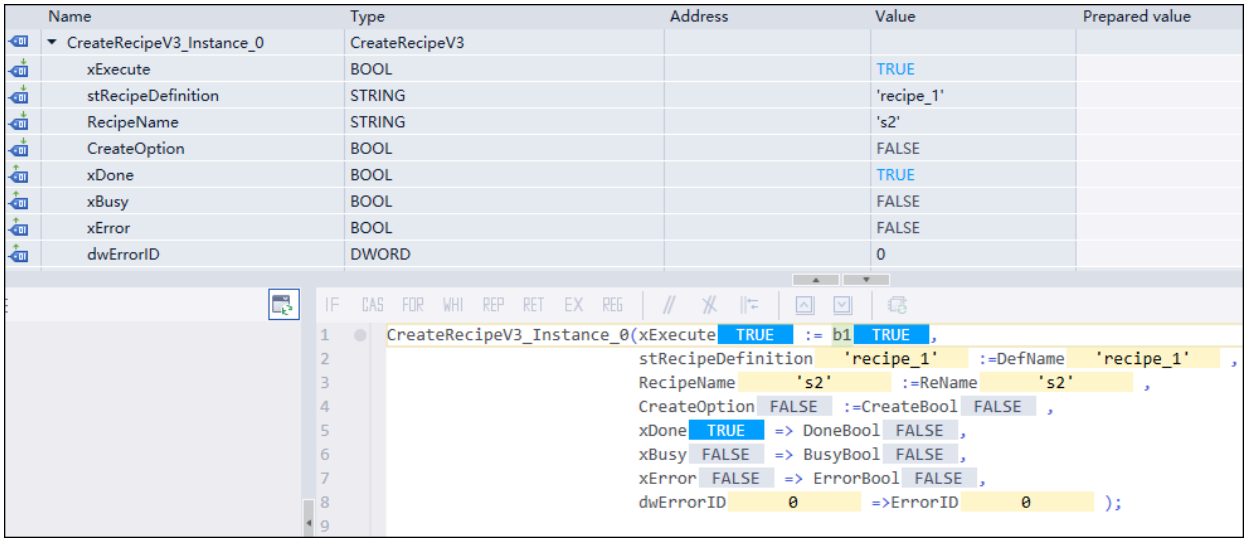
- **Precautions**

It is recommended to use edge-triggered signals for the enable input EN.

18.2.18.1.31 CreateRecipeV3

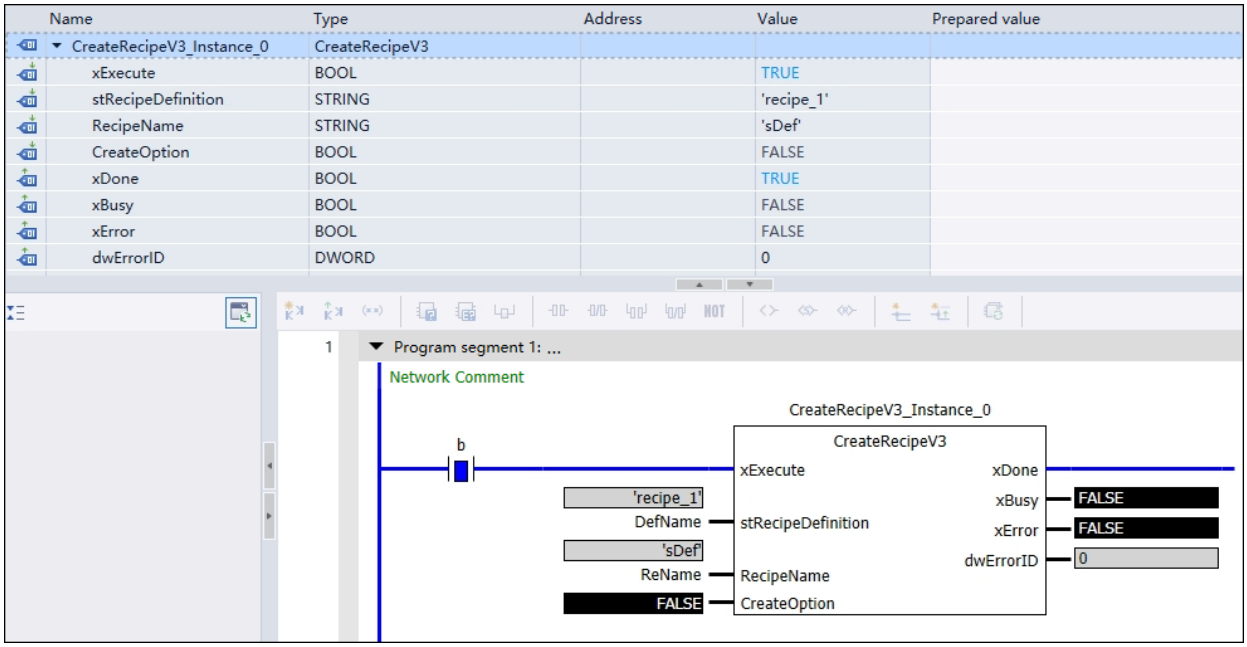
Creates recipe data and a file with the specified name based on the specified recipe definition.

- **Instruction format**



Instruction	Name	FB/FC	Ladder Diagram Representation	Structured Text Representation
CreateRecipeV3	Create a recipe	FB		CreateRecipeV3_Instance_0(xExecute := , stRecipeDefinition := , RecipeName := , CreateOption := , xDone => , xBusy => , xError => , dwErrorID =>);

- **Related variables**

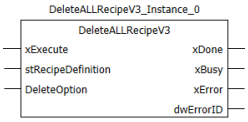


Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	xExecute	Enable	BOOL	TRUE, FALSE	FALSE	This instruction is triggered by the rising edge of xExecute.
	stRecipeDefinition	Recipe definition name	STRING	Follows data type	0	Specifies the recipe definition
	RecipeName	Recipe name	STRING	Follows data type	-	Specifies the recipe
	CreateOption	Creation mode	BOOL	TRUE, FALSE	FALSE	0: Creates recipe and file 1: Creates only temporary recipe
Output	xDone	Execution completion flag	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is completed.
	xBusy	Instruction in use	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is currently being executed.
	xError	Instruction fault flag	BOOL	TRUE, FALSE	FALSE	Indicates whether a fault occurred during instruction execution.
	dwErrorID	Instruction fault ID	DWORD	Depends on data type	0	Indicates the cause of the instruction faults. For details, see Fault Codes.

- **Function description**
  When the input parameter xExecute changes from FALSE to TRUE, the instruction is enabled and can be used to create a recipe after certain conditions are met.
- **Program example**
  Input the name of an existing recipe definition and the name of the recipe to be created, and change the value of CreateOption to determine whether to create a recipe file.

  ST:

LD:



- **Precautions**
  - If a temporary recipe with the same name already exists, it cannot be created again. The instruction will return a fault message indicating the recipe already exists.
  - A recipe cannot be created under a recipe definition that does not exist. The instruction will return a fault message indicating the recipe definition not found.
  - The created recipe file is saved to the path specified by the SetStoragePathV3 instruction. If an old recipe file with the same recipe definition and recipe name already exists at that path, the existing file will be overwritten.

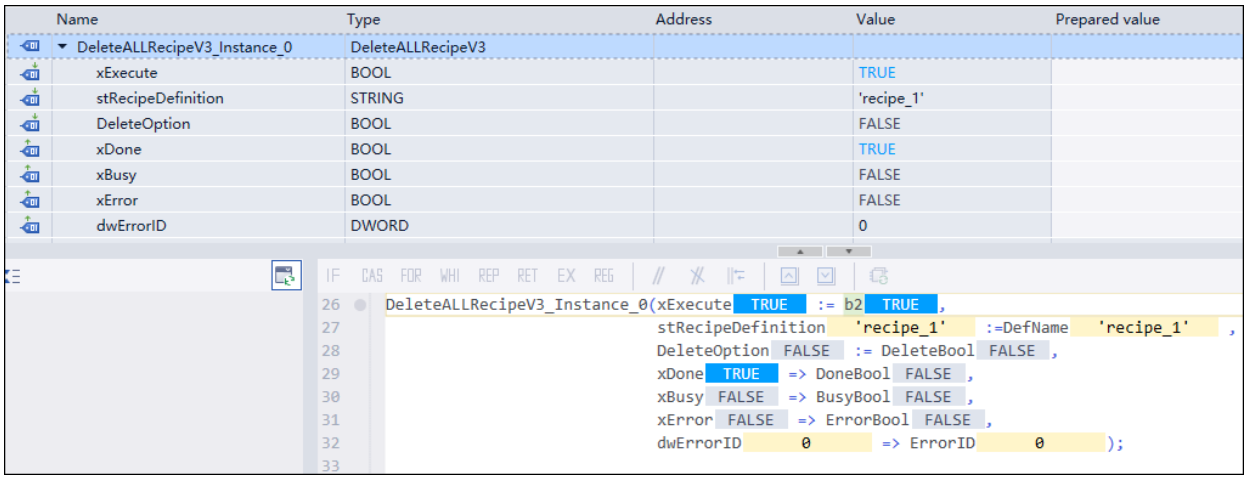
18.2.18.1.32 DeleteALLRecipeV3

Deletes all recipes under the specified recipe definition.

- **Instruction format**

Instruction	Name	FB/FC	Ladder Diagram Representation	Structured Text Representation
DeleteALLRecipeV3	Deletes all recipes under a recipe definition	FB		DeleteALLRecipeV3_Instance_0(xExecute := , stRecipeDefinition := , DeleteOption := , xDone => , xBusy => , xError => , dwErrorID =>);

- **Related variables**



Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	xExecute	Enable	BOOL	TRUE, FALSE	FALSE	This instruction is triggered by the rising edge of xExecute.
	stRecipeDefinition	Recipe definition name	STRING	Follows data type	0	Specifies the recipe definition
	DeleteOption	Deletion mode	BOOL	TRUE, FALSE	FALSE	0: Deletes recipe and file. 1: Deletes only temporary recipe in memory.
Output	xDone	Execution completion flag	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is completed.
	xBusy	Instruction in use	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is currently being executed.
	xError	Instruction fault flag	BOOL	TRUE, FALSE	FALSE	Indicates whether a fault occurred during instruction execution.
	dwErrorID	Instruction fault ID	DWORD	Depends on data type	0	Indicates the cause of the instruction faults. For details, see Fault Codes.

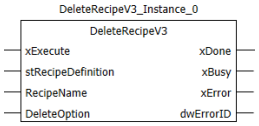
- **Function description**

  When the input parameter xExecute changes from FALSE to TRUE, the instruction is enabled and can be used to delete recipes after certain conditions are met.

- **Program example**
  Input the name of an existing recipe definition, and change the value of DeleteOption to determine whether to delete recipe files.

  ST:

  LD:



- **Precautions**
  To delete a file, the recipe file must be loaded as a temporary recipe. After the instruction is executed, the system searches for the recipe file under the path specified by the SetStoragePathV3 instruction. If the file is found, both the temporary recipe and the recipe file are deleted. If the file is not found, only the temporary recipe is deleted.

18.2.18.1.33 DeleteRecipeV3

Deletes recipe data and a file with the specified name based on the specified recipe definition.

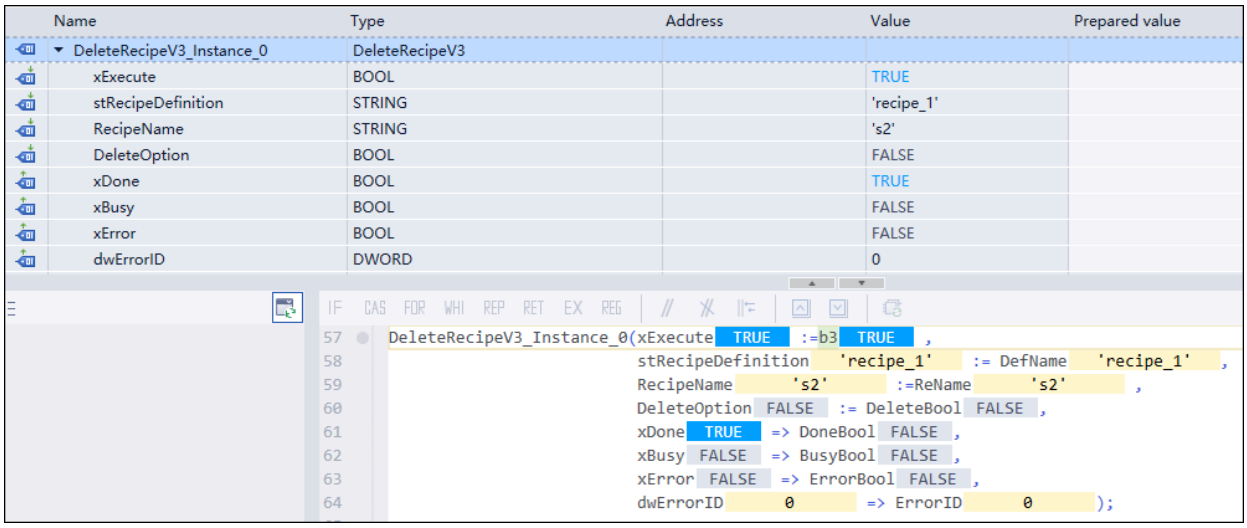
- **Instruction format**

Instruction	Name	FB/FC	Ladder Diagram Representation	Structured Text Representation
DeleteRecipeV3	Delete a specified recipe under a recipe definition	FB		DeleteRecipeV3_Instance_0(xExecute := , stRecipeDefinition := , RecipeName := , DeleteOption := , xDone => , xBusy => , xError => , dwErrorID =>);

- **Related variables**

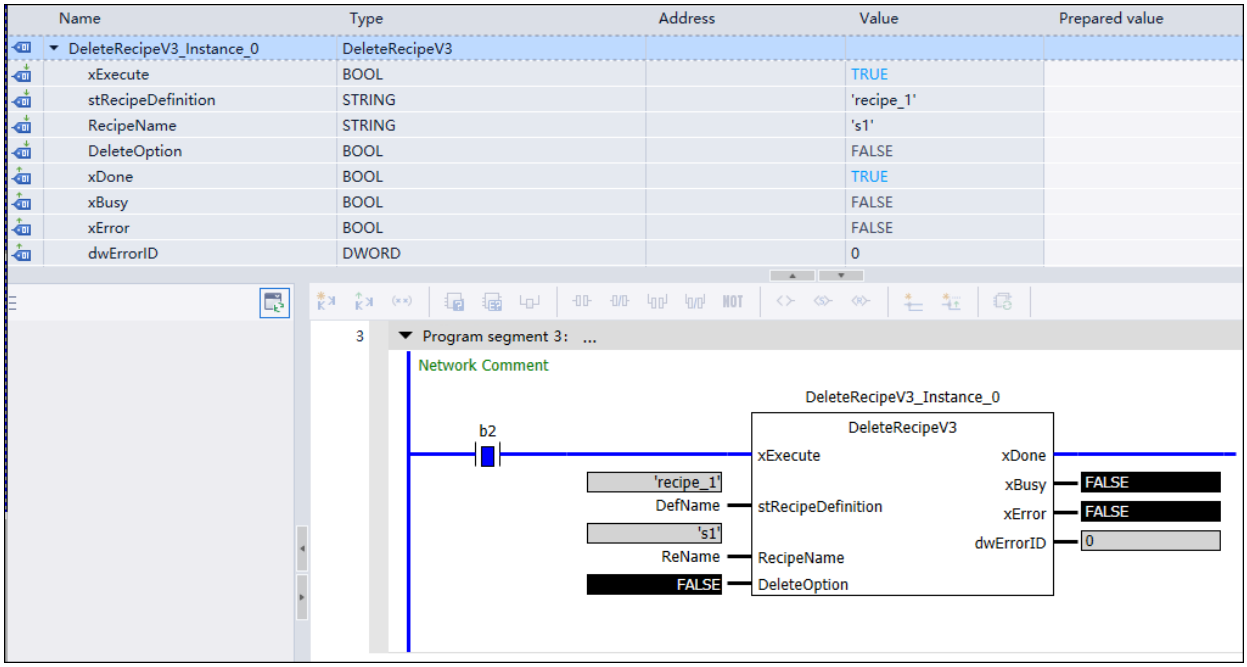
Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	xExecute	Enable	BOOL	TRUE, FALSE	FALSE	This instruction is triggered by the rising edge of xExecute.
	stRecipeDefinition	Recipe definition name	STRING	Follows data type	0	Specifies the recipe definition
	RecipeName	Recipe name	STRING	Follows data type	0	Specifies the recipe
	DeleteOption	Deletion mode	BOOL	TRUE, FALSE	FALSE	0: Deletes recipe and file. 1: Deletes only temporary recipe in memory.
Output	xDone	Execution completion flag	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is completed.
	xBusy	Instruction in use	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is currently being executed.
	xError	Instruction fault flag	BOOL	TRUE, FALSE	FALSE	Indicates whether a fault occurred during instruction execution.

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	dwErrorID	Instruction fault ID	DWORD	Depends on data type	0	Indicates the cause of the instruction faults. For details, see Fault Codes.



- **Function description**

  When the input parameter xExecute changes from FALSE to TRUE, the instruction is enabled and can be used to delete a recipe after certain conditions are met.



- **Program example**

  Input the name of an existing recipe definition and the name of a recipe that has been created under that recipe definition. Change the value of CreateOption to determine whether to delete the specified recipe file.

  ST:

  LD:

- **Precautions**

  If you determine to delete recipe and file, the system will search for recipe files under the path specified

by the SetStoragePathV3 instruction. If the recipe file is detected, both the temporary recipe and the recipe file will be deleted; if the file is not detected, only the temporary recipe will be deleted.

18.2.18.1.34 GetRecipeDefinitionInfoV3

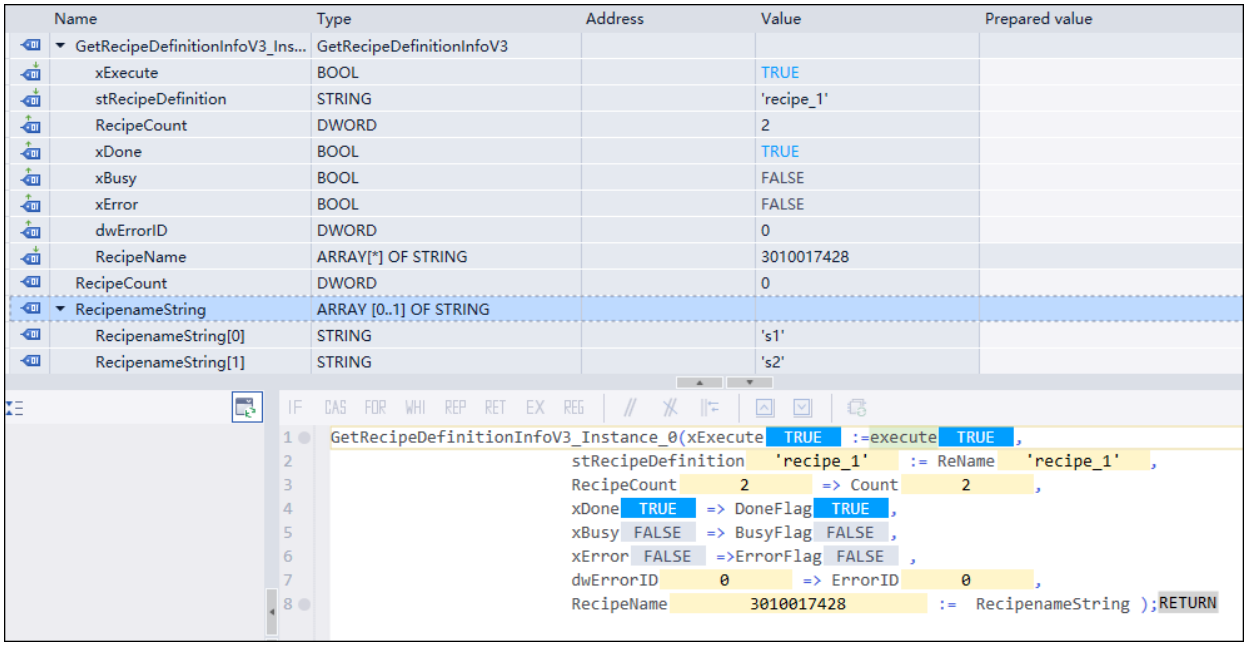
Gets the information about the specified recipe definition, including the number of recipes and recipe names.

- **Instruction format**

Instruction	Name	FB/FC	Ladder Diagram Representation	Structured Text Representation
GetRecipeDefinitionInfoV3	Get recipe definition information	FB		GetRecipeDefinitionInfoV3_Instance_0(xExecute := , stRecipeDefinition := , RecipeCount => , xDone => , xBusy => , xError => , dwErrorID => , RecipeName :=);

- **Related variables**

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	xExecute	Enable	BOOL	TRUE, FALSE	FALSE	This instruction is triggered by the rising edge of xExecute.
	stRecipeDefinition	Recipe definition name	STRING	Follows data type	0	Specifies the recipe definition
Output	RecipeCount	Recipe count	DWORD	Depends on data type	0	Indicates the number of recipes retrieved
	RecipeName	Recipe name	ARRAY [*] OF STRING	Follows data type	0	An array containing the names of all retrieved recipes
	xDone	Execution completion flag	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is completed.
	xBusy	Instruction in use	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is currently being executed.



Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	xError	Instruction fault flag	BOOL	TRUE, FALSE	FALSE	Indicates whether a fault occurred during instruction execution.
	dwErrorID	Instruction fault ID	DWORD	Depends on data type	0	Indicates the cause of the instruction faults. For details, see Fault Codes.

- **Function description**

  When the input parameter xExecute changes from FALSE to TRUE, the instruction is enabled and gets the information about the specified recipe definition after certain conditions are met, including the number of recipes under this recipe definition and their names.

- **Program example**

  ST:

  LD:

18.2.18.1.35 GetRecipeInfoV3

Gets the variable names and values of the specified recipe.

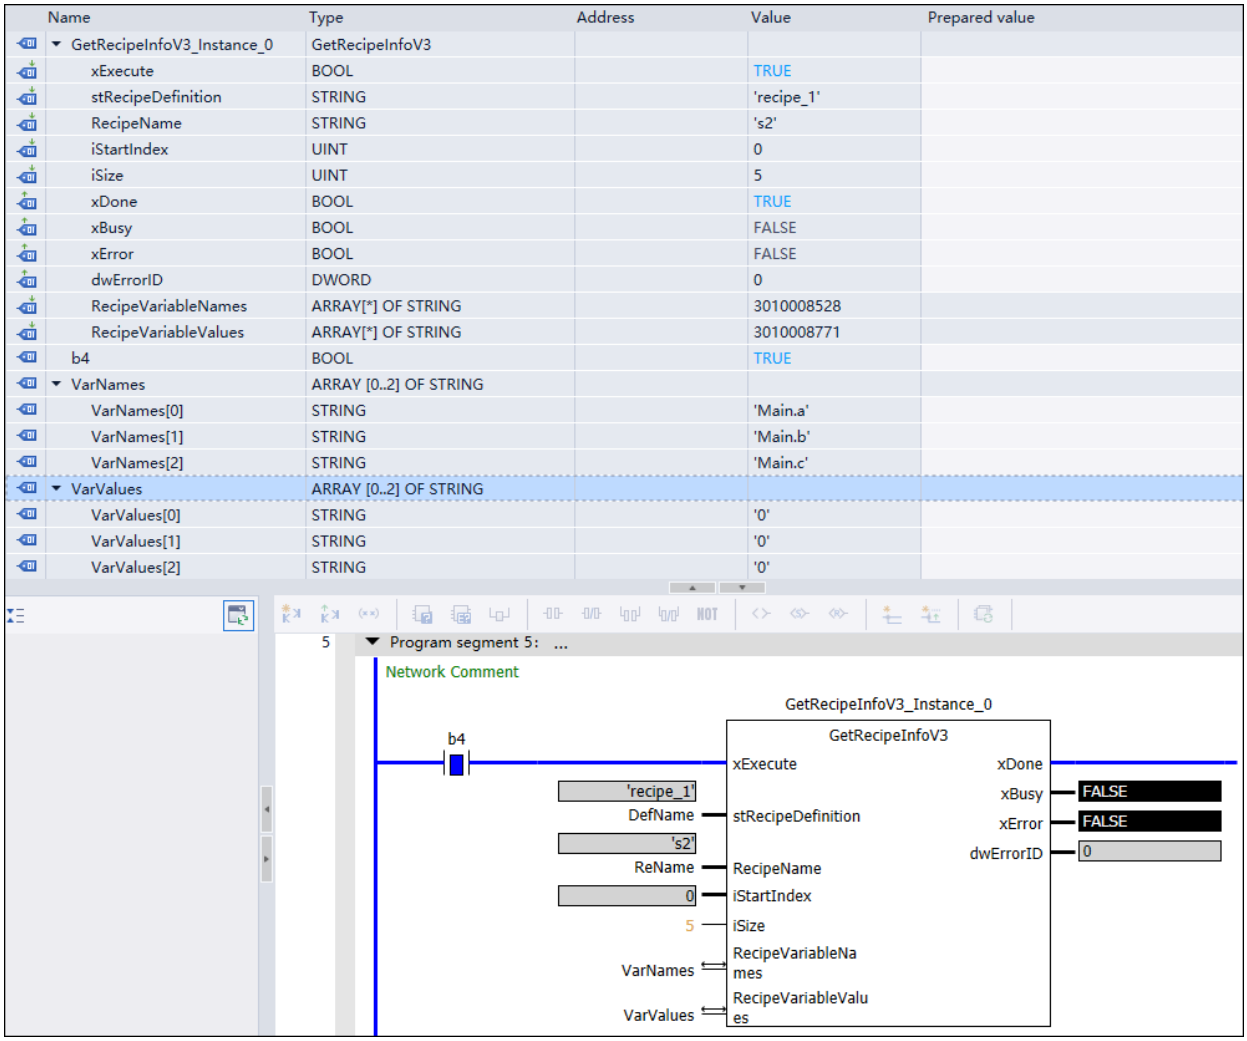
- **Instruction format**

Instruction	Name	FB/FC	Ladder Diagram Representation	Structured Text Representation
GetRecipeInfoV3	Get recipe information	FB		GetRecipeInfoV3_Instance_0(xExecute := , stRecipeDefinition := , RecipeName := , iStartIndex := , iSize := , xDone => , xBusy => , xError => , dwErrorID => , RecipeVariableNames := , RecipeVariableValues :=);

- **Related variables**

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	xExecute	Enable	BOOL	TRUE, FALSE	FALSE	This instruction is triggered by the rising edge of xExecute.
	stRecipeDefinition	Recipe definition name	STRING	Follows data type	0	Specifies the recipe definition

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	RecipeName	Recipe name	STRING	Follows data type	0	Specifies the recipe
	iSize	Size of the string array	UINT	Follows data type	0	Size of the string array that stores recipe variable names and values
	iStartIndex	Start index	UINT	Follows data type	0	Start index for retrieving recipe variables
Output	RecipeVariableNames	Recipe variable name	ARRAY [*] OF STRING	Follows data type	0	Outputs recipe variable names of the specified length
	RecipeVariableValues	Recipe variable value	ARRAY [*] OF STRING	Follows data type	0	Outputs recipe variable values of the specified length
	xDone	Execution completion flag	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is completed.
	xBusy	Instruction in use	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is currently being executed.
	xError	Instruction fault flag	BOOL	TRUE, FALSE	FALSE	Indicates whether a fault occurred during instruction execution.
	dwErrorID	Instruction fault ID	DWORD	Depends on data type	0	Indicates the cause of the instruction faults. For details, see Fault Codes.



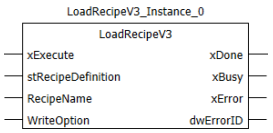
- **Function description**
  When the input parameter xExecute changes from FALSE to TRUE, the instruction is enabled. After certain conditions are met, the instruction gets the variable names and values for the specified recipe, based on the specified length (iSize) and start index (iStartIndex).
- **Program example**

  ST:

Name	Type	Address	Value	Prepared value
GetRecipeInfoV3_Instance_0	GetRecipeInfoV3			
xExecute	BOOL		TRUE	
stRecipeDefinition	STRING		'recipe_1'	
RecipeName	STRING		's1'	
iStartIndex	UINT		0	
iSize	UINT		3	
xDone	BOOL		TRUE	
xBusy	BOOL		FALSE	
xError	BOOL		FALSE	
dwErrorID	DWORD		0	
RecipeVariableNames	ARRAY[*] OF STRING		3010016560	
RecipeVariableValues	ARRAY[*] OF STRING		3010016803	
VarNameString	ARRAY [0..2] OF STRING			
VarNameString[0]	STRING		'Main.a'	
VarNameString[1]	STRING		'Main.b'	
VarNameString[2]	STRING		'Main.c'	
VarValueString	ARRAY [0..2] OF STRING			
VarValueString[0]	STRING		'0'	
VarValueString[1]	STRING		'0'	
VarValueString[2]	STRING		'0'	

```
1  GetRecipeInfoV3_Instance_0(xExecute  TRUE  := execute  TRUE ,
2                             stRecipeDefinition  'recipe_1'  :=ReDefName  'recipe_1'  ,
3                             RecipeName  's1'  := ReName  's1'  ,
4                             iStartIndex  0  := Index  0  ,
5                             iSize  3  :=Size  3  ,
6                             xDone  TRUE  => DoneFlag  TRUE ,
7                             xBusy  FALSE  => BusyFlag  FALSE ,
8                             xError  FALSE  => ErrorFlag  FALSE ,
9                             dwErrorID  0  => ErrorID  0  ,
10                            RecipeVariableNames  3010016560  := VarNameString,
11                            RecipeVariableValues  3010016803  := VarValueString);RETURN
```

LD:



- **Precautions**
  - The input index value specifies the starting position to read from the recipe. If the index exceeds the maximum number of recipe variables, the instruction returns a fault.
  - If the sum of the index value and the array size exceeds the maximum number of recipe variables, the instruction returns only the information about the variables from the start index to the last variable in the recipe.
  - Variable indices within a recipe start from 0.

18.2.18.1.36 LoadRecipeV3

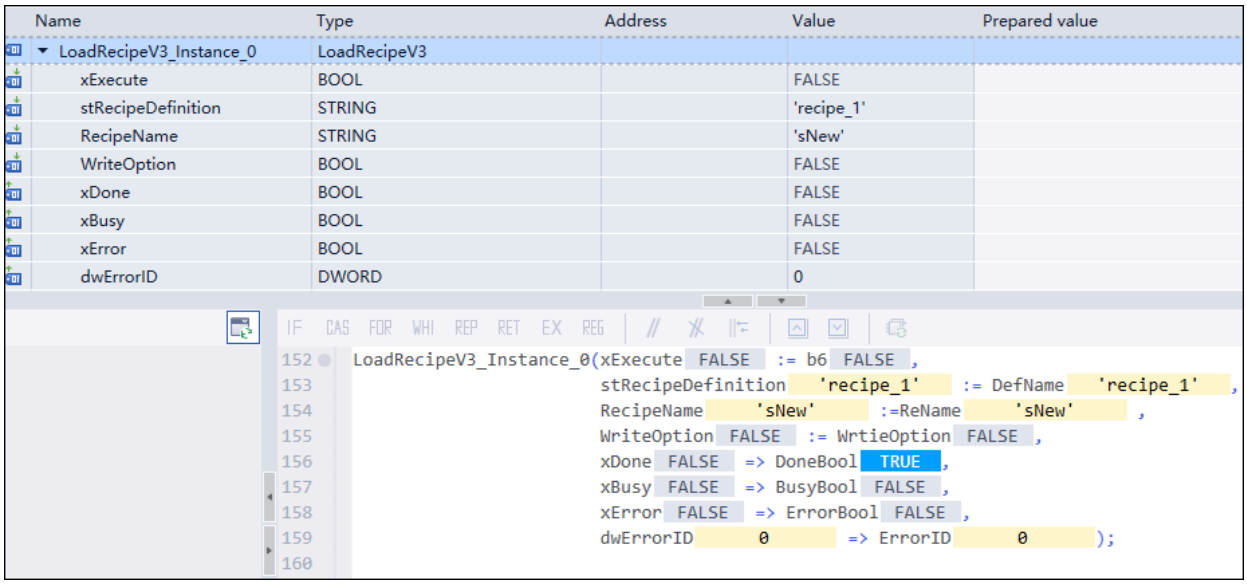
Loads the specified recipe into PLC memory and writes it to the PLC.

- **Instruction format**

Instruction	Name	FB/FC	Ladder Diagram Representation	Structured Text Representation
LoadRecipeV3	Load a recipe	FB		LoadRecipeV3_Instance_0(xExecute := , stRecipeDefinition := , RecipeName := , WriteOption := , xDone => , xBusy => , xError => , dwErrorID =>);

- **Related variables**

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	xExecute	Enable	BOOL	TRUE, FALSE	FALSE	This instruction is triggered by the rising edge of xExecute.
	stRecipeDefinition	Recipe definition name	STRING	Follows data type	0	Specifies the recipe definition
	RecipeName	Recipe name	STRING	Follows data type	0	Specifies the recipe
	WriteOption	Load mode	BOOL	TRUE, FALSE	FALSE	0: Loads without writing to PLC. 1: Loads and writes to PLC.
Output	xDone	Execution completion flag	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is completed.
	xBusy	Instruction in use	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is currently being executed.
	xError	Instruction fault flag	BOOL	TRUE, FALSE	FALSE	Indicates whether a fault occurred during instruction execution.



Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	dwErrorID	Instruction fault ID	DWORD	Depends on data type	0	Indicates the cause of the instruction faults. For details, see Fault Codes.

- **Function description**

  When the input parameter xExecute changes from FALSE to TRUE, the instruction is enabled. If WriteOption is set to 0 (load only), a temporary recipe with the specified recipe file name is created; if WriteOption is set to 1 (load and write), a temporary recipe is created, and the recipe variable values are written to PLC.

- **Program example**

  ST:

  LD:

- **Precautions**

  If a temporary recipe with the specified recipe name already exists, this instruction returns a fault

message indicating the recipe already exists. You can delete the existing temporary recipe and run the LoadRecipeV3 instruction to load again.

18.2.18.1.37 ReadRecipeV3

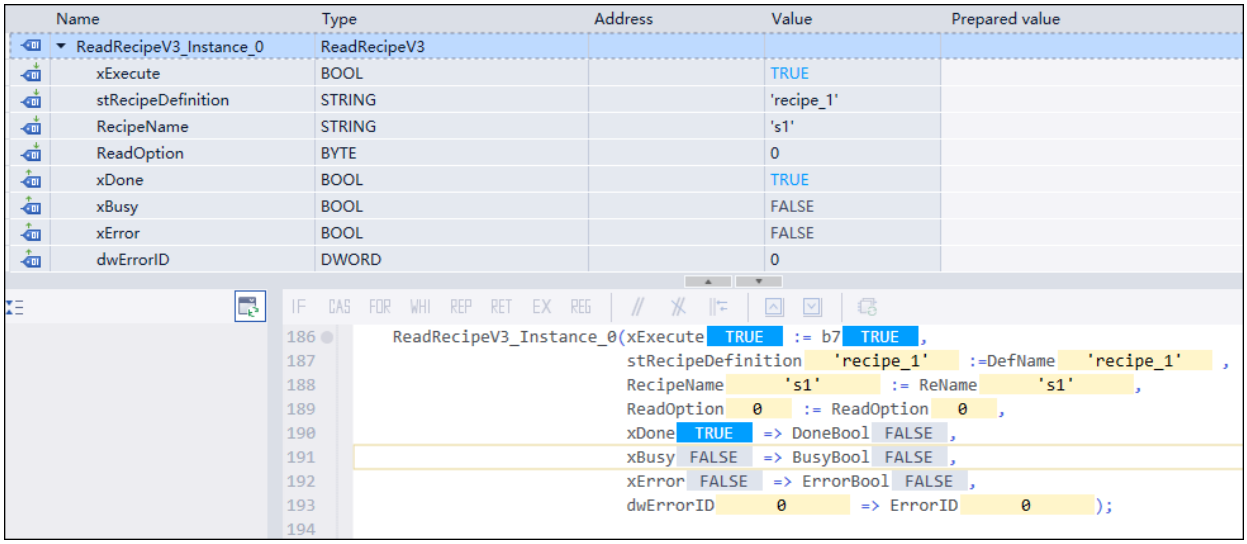
Writes the PLC variable values into the specified recipe or recipe file.

- **Instruction format**

Instruction	Name	FB/FC	Ladder Diagram Representation	Structured Text Representation
ReadRecipeV3	Read PLC values into a recipe	FB		ReadRecipeV3_Instance_0(xExecute := , stRecipeDefinition := , RecipeName := , ReadOption := , xDone => , xBusy => , xError => , dwErrorID =>);

- **Related variables**

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	xExecute	Enable	BOOL	TRUE, FALSE	FALSE	This instruction is triggered by the rising edge of xExecute.
	stRecipeDefinition	Recipe definition name	STRING	Follows data type	0	Specifies the recipe definition
	RecipeName	Recipe name	STRING	Follows data type	0	Specifies the recipe
	ReadOption	Write mode	BYTE	0 to 2	0	0: Writes only the recipe. 1: Writes both the recipe and the recipe file. 2: Writes only the recipe file.
Output	xDone	Execution completion flag	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is completed.
	xBusy	Instruction in use	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is currently being executed.



Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	xError	Instruction fault flag	BOOL	TRUE, FALSE	FALSE	Indicates whether a fault occurred during instruction execution.
	dwErrorID	Instruction fault ID	DWORD	Depends on data type	0	Indicates the cause of the instruction faults. For details, see Fault Codes.

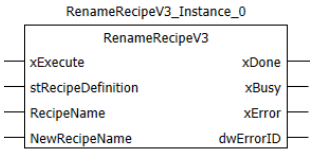
- **Function description**

  When the input parameter xExecute changes from FALSE to TRUE, the instruction is enabled. After certain conditions are met, the specified PLC variable values can be written into the recipe based on the write mode specified by ReadOption (write only recipe, write only recipe file, or write both).

- **Program example**

  ST:

  LD:



- **Precautions**

  If writing to a recipe file is selected, the instruction checks whether the file exists under the path set by the SetStoragePathV3 instruction. If the file does not exist, a fault message indicating file not found is returned. If the file exists, the recipe file is written normally.

18.2.18.1.38 RenameRecipeV3

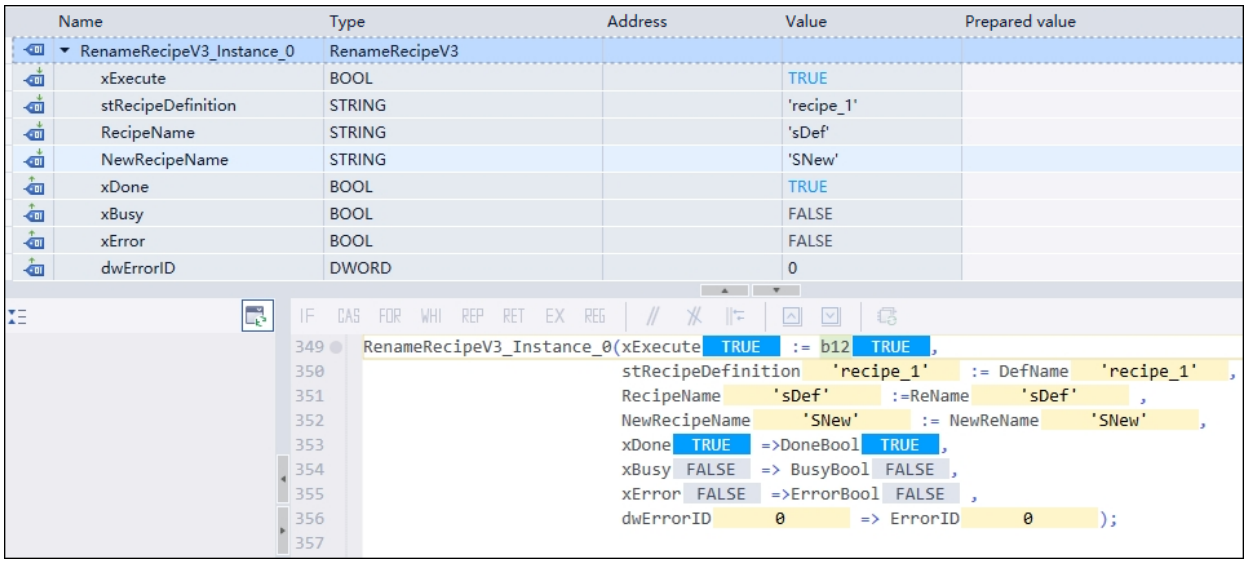
Renames the specified recipe and recipe file.

- **Instruction format**

Instruction	Name	FB/FC	Ladder Diagram Representation	Structured Text Representation
RenameRecipeV3	Rename a recipe	FB		RenameRecipeV3_Instance_0(xExecute := , stRecipeDefinition := , RecipeName := , NewRecipeName := , xDone => , xBusy => , xError => , dwErrorID =>);

- **Related variables**

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	xExecute	Enable	BOOL	TRUE, FALSE	FALSE	This instruction is triggered by the rising edge of xExecute.



Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	stRecipeDefinition	Recipe definition name	STRING	Follows data type	0	Specifies the recipe definition
	RecipeName	Recipe name	STRING	Follows data type	0	Specifies the recipe
	NewRecipeName	New recipe name	STRING	Follows data type	0	The new recipe name to be modified
Output	xDone	Execution completion flag	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is completed.
	xBusy	Instruction in use	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is currently being executed.
	xError	Instruction fault flag	BOOL	TRUE, FALSE	FALSE	Indicates whether a fault occurred during instruction execution.
	dwErrorID	Instruction fault ID	DWORD	Depends on data type	0	Indicates the cause of the instruction faults. For details, see Fault Codes.

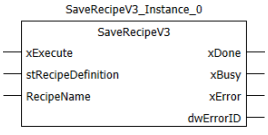
- **Function description**

  When the input parameter xExecute changes from FALSE to TRUE, the instruction is enabled and can be used to rename a recipe and recipe file after certain conditions are met.

- **Program example**

  ST:

  LD:



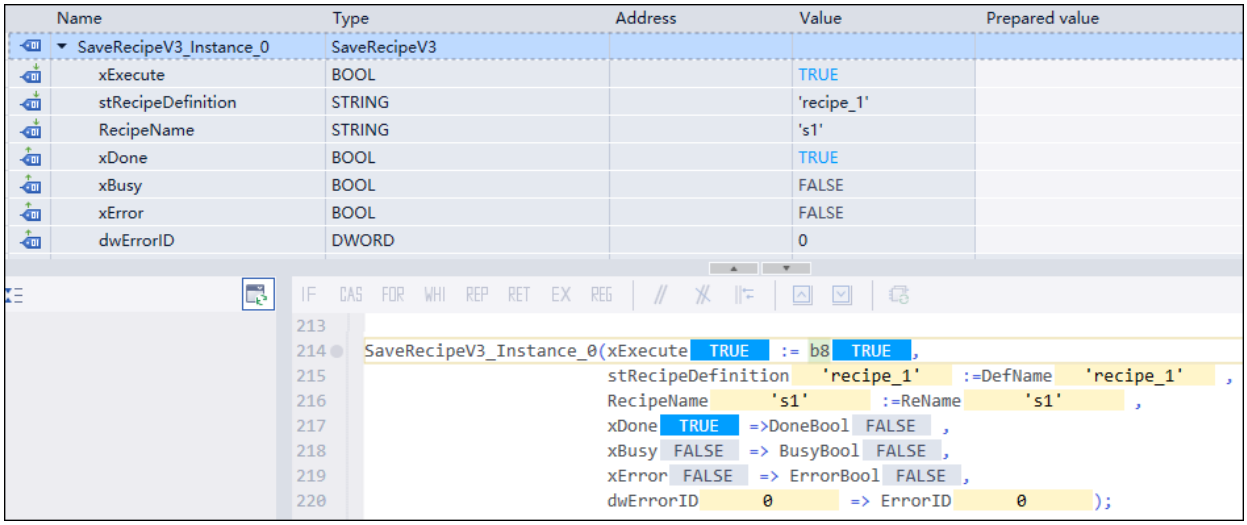
- **Precautions**
  - This instruction simultaneously renames both the temporary recipe and the recipe file. If the recipe file does not exist under the path set by SetStoragePathV3, the instruction returns a fault message indicating the file not found.
  - If a recipe file created by another project exists at the same path with the same recipe definition name and recipe name, the instruction returns a fault indicating the recipe and recipe file do not match.

18.2.18.1.39 SaveRecipeV3

Saves the recipe in memory as a recipe file.

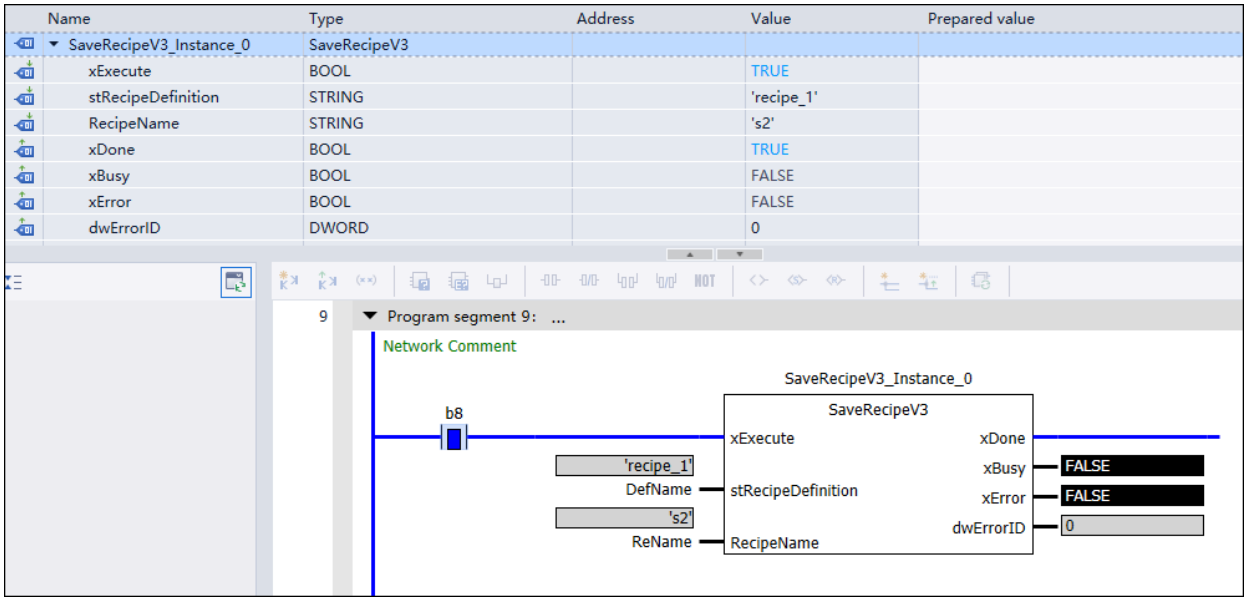
- **Instruction format**

Instruction	Name	FB/FC	Ladder Diagram Representation	Structured Text Representation
SaveRecipeV3	Save a recipe file	FB		SaveRecipeV3_Instance_0(xExecute := , stRecipeDefinition := , RecipeName := , xDone => , xBusy => , xError => , dwErrorID =>);



- **Related variables**

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	xExecute	Enable	BOOL	TRUE, FALSE	FALSE	This instruction is triggered by the rising edge of xExecute.

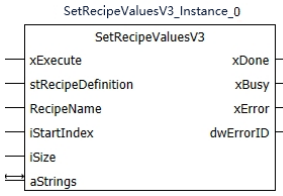


Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	stRecipeDefinition	Recipe definition name	STRING	Follows data type	0	Specifies the recipe definition
	RecipeName	Recipe name	STRING	Follows data type	0	Specifies the recipe
Output	xDone	Execution completion flag	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is completed.
	xBusy	Instruction in use	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is currently being executed.
	xError	Instruction fault flag	BOOL	TRUE, FALSE	FALSE	Indicates whether a fault occurred during instruction execution.
	dwErrorID	Instruction fault ID	DWORD	Depends on data type	0	Indicates the cause of the instruction faults. For details, see Fault Codes.

- **Function description**
  When the input parameter xExecute changes from FALSE to TRUE, the instruction is enabled and can be used to save the specified temporary recipe as a recipe file after certain conditions are met.
- **Program example**

  ST:

  LD:



- **Precautions**

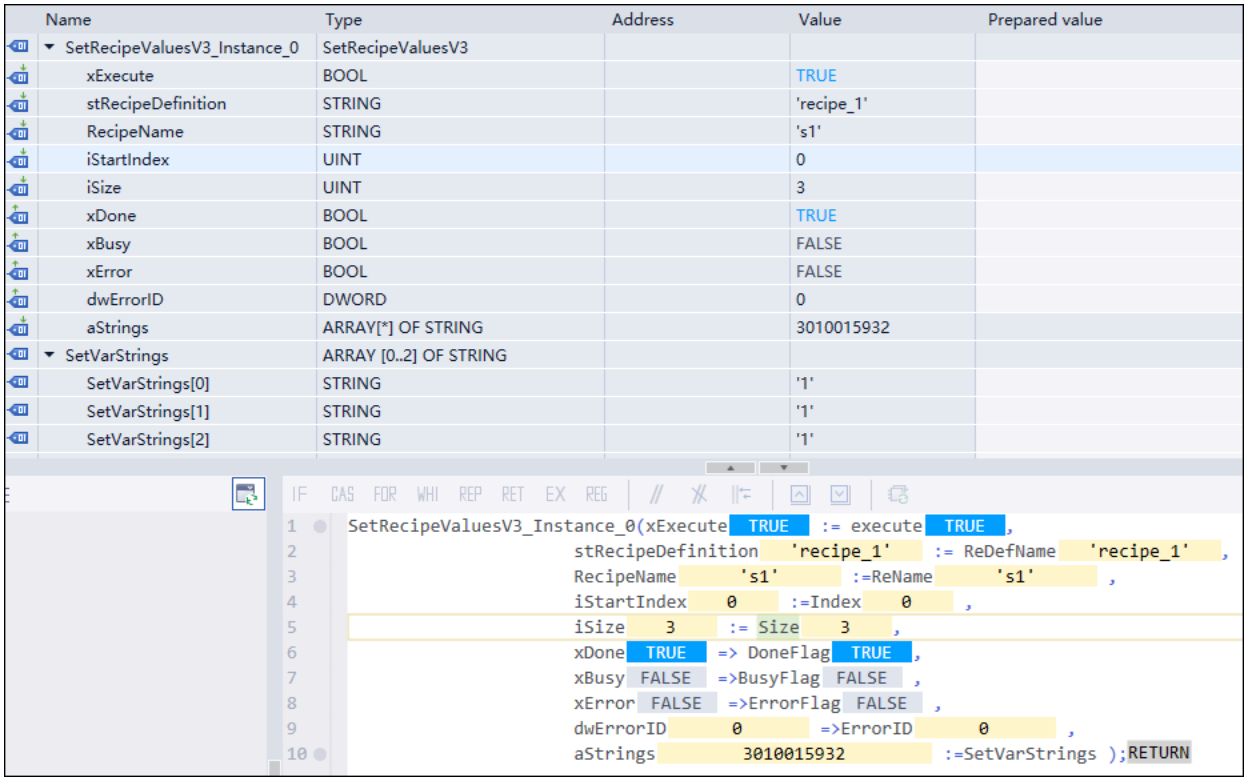
  This instruction saves the recipe file to the path set by SetStoragePathV3. If a recipe file with the same name already exists at this path, the instruction will execute normally and overwrite the existing recipe file.

18.2.18.1.40 SetRecipeValuesV3

Sets the recipe data in a recipe.

- **Instruction format**

Instruction	Name	FB/FC	Ladder Diagram Representation	Structured Text Representation
SetRecipeValuesV3	Set the variable values of a specified recipe	FB		SetRecipeValuesV3_Instance_0(xExecute := , stRecipeDefinition := , RecipeName := , iStartIndex := , iSize := , xDone => , xBusy => , xError => , dwErrorID => , aStrings :=);



- **Related variables**

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	xExecute	Enable	BOOL	TRUE, FALSE	FALSE	This instruction is triggered by the rising edge of xExecute.

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	stRecipeDefinition	Recipe definition name	STRING	Follows data type	0	Specifies the recipe definition
	RecipeName	Recipe name	STRING	Follows data type	0	Specifies the recipe
	iSize	Size of the string array	UINT	Follow data type	-	Number of recipe variables to write
	iStartIndex	Start index	UINT	Follow data type	-	Start index for writing recipe variables
	aStrings	String array of recipe values	ARRAY [*] OF STRING	Follows data type	-	Array of variable values to write into the recipe
Output	xDone	Execution completion flag	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is completed.
	xBusy	Instruction in use	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is currently being executed.
	xError	Instruction fault flag	BOOL	TRUE, FALSE	FALSE	Indicates whether a fault occurred during instruction execution.
	dwErrorID	Instruction fault ID	DWORD	Depends on data type	0	Indicates the cause of the instruction faults. For details, see Fault Codes.

- **Function description**
  When the input parameter xExecute changes from FALSE to TRUE, the instruction is enabled and can be used to write the variable values in the array aStrings to the recipe after certain conditions are met.
- **Program example**

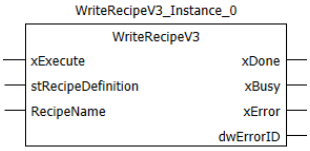
  ST:

Name	Type	Address	Value	Prepared value
SetRecipeValuesV3_Instance_0	SetRecipeValuesV3			
xExecute	BOOL		TRUE	
stRecipeDefinition	STRING		'recipe_1'	
RecipeName	STRING		's1'	
iStartIndex	UINT		0	
iSize	UINT		3	
xDone	BOOL		TRUE	
xBusy	BOOL		FALSE	
xError	BOOL		FALSE	
dwErrorID	DWORD		0	
aStrings	ARRAY[*] OF STRING		3010015932	
SetVarStrings	ARRAY [0..2] OF STRING			
SetVarStrings[0]	STRING		'1'	
SetVarStrings[1]	STRING		'1'	
SetVarStrings[2]	STRING		'1'	

```
1  SetRecipeValuesV3_Instance_0(xExecute TRUE := execute TRUE ,
2                               stRecipeDefinition 'recipe_1' := ReDefName 'recipe_1' ,
3                               RecipeName 's1' :=ReName 's1' ,
4                               iStartIndex 0 :=Index 0 ,
5                               iSize 3 := Size 3 ,
6                               xDone TRUE => DoneFlag TRUE ,
7                               xBusy FALSE =>BusyFlag FALSE ,
8                               xError FALSE =>ErrorFlag FALSE ,
9                               dwErrorID 0 =>ErrorID 0 ,
10                              aStrings 3010015932 :=SetVarStrings );RETURN
```

LD:

Name	Type	Address	Value	Prepared value
SetRecipeValuesV3_Instance_0	SetRecipeValuesV3			
xExecute	BOOL		TRUE	
stRecipeDefinition	STRING		'recipe_1'	
RecipeName	STRING		's2'	
iStartIndex	UINT		0	
iSize	UINT		5	
xDone	BOOL		TRUE	
xBusy	BOOL		FALSE	
xError	BOOL		FALSE	
dwErrorID	DWORD		0	
aStrings	ARRAY[*] OF STRING		3010010100	
b9	BOOL		TRUE	
SetValues	ARRAY [0..10] OF STRING			
SetValues[0]	STRING		'1'	
SetValues[1]	STRING		'2'	
SetValues[2]	STRING		'3'	



- **Precautions**
  - iStartIndex specifies which variable in the recipe to start writing from. Special attention shall be paid to this index to avoid execution faults. Variable indices within a recipe start from 0.
  - If the sum of the index value and the number of variables to write exceeds the maximum number of recipe variables, the instruction writes sequentially from the start index to the last variable in the recipe.

◦ If the index value is greater than the maximum number of recipe variables, the instruction returns an input fault.

18.2.18.1.41 WriteRecipeV3

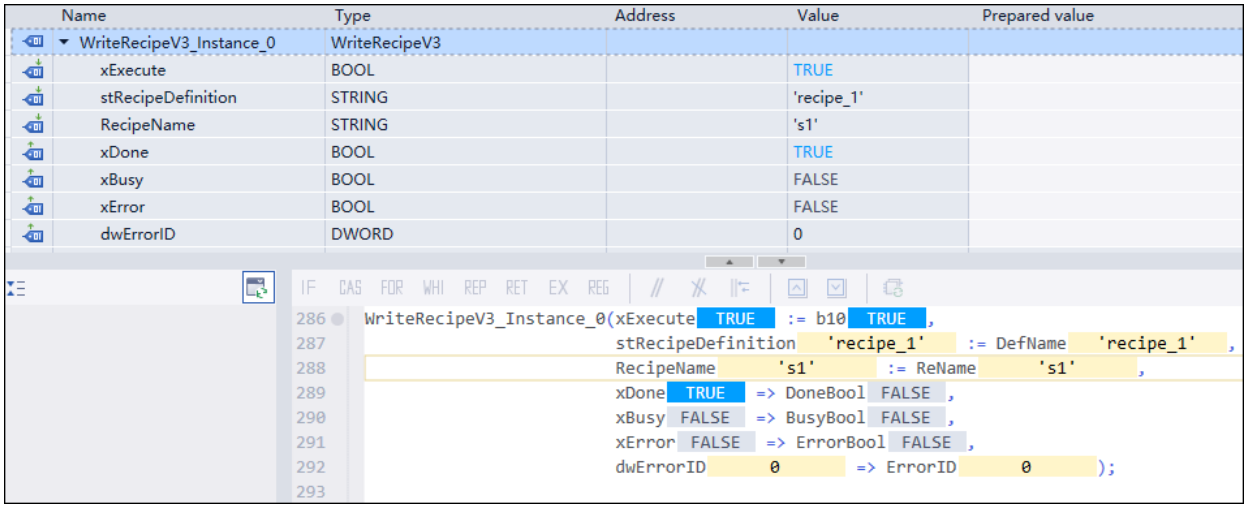
Writes the specified recipe data to the PLC.

- **Instruction format**

Instruction	Name	FB/FC	Ladder Diagram Representation	Structured Text Representation
WriteRecipeV3	Write the recipe into the PLC	FB		WriteRecipeV3_Instance_0(xExecute := , stRecipeDefinition := , RecipeName := , xDone => , xBusy => , xError => , dwErrorID =>);

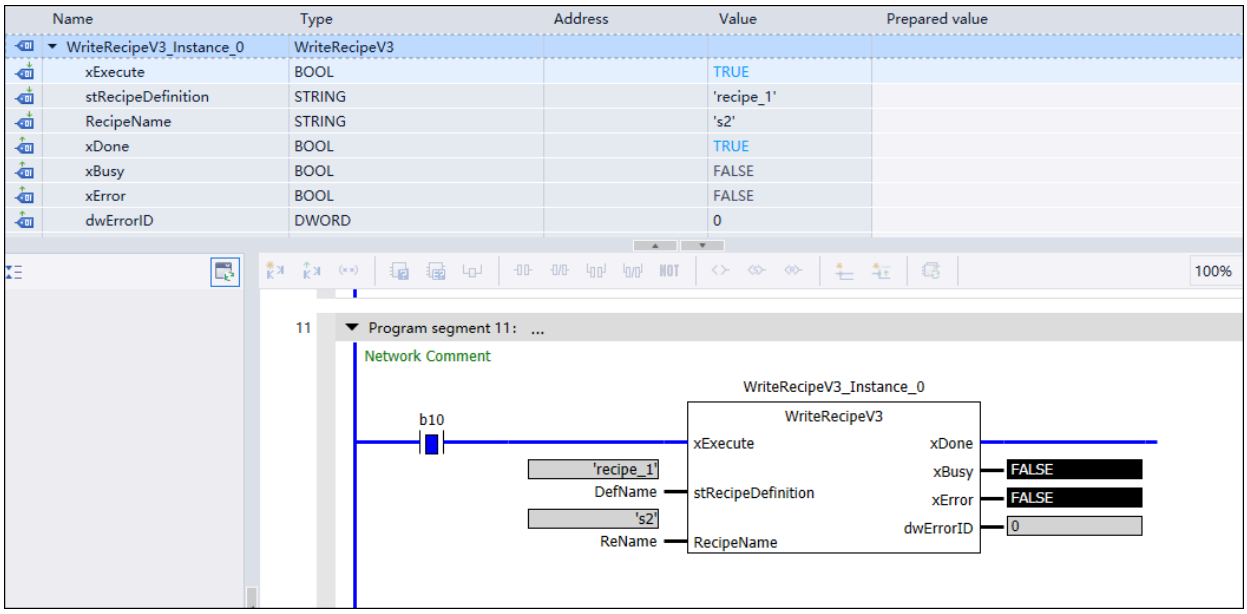
- **Related variables**

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	xExecute	Enable	BOOL	TRUE, FALSE	FALSE	This instruction is triggered by the rising edge of xExecute.
	stRecipeDefinition	Recipe definition name	STRING	Follows data type	0	Specifies the recipe definition
	RecipeName	Recipe name	STRING	Follows data type	0	Specifies the recipe
Output	xDone	Execution completion flag	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is completed.
	xBusy	Instruction in use	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is currently being executed.
	xError	Instruction fault flag	BOOL	TRUE, FALSE	FALSE	Indicates whether a fault occurred during instruction execution.
	dwErrorID	Instruction fault ID	DWORD	Depends on data type	0	Indicates the cause of the instruction faults. For details, see Fault Codes.



- **Function description**

  When the input parameter xExecute changes from FALSE to TRUE, the instruction is enabled and can be

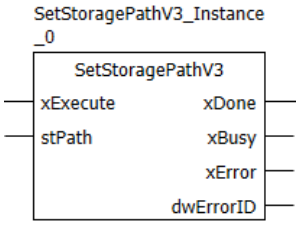


used to write the variables values in the specified temporary recipe into the PLC after certain conditions are met.

- **Program example**

  ST:

  LD:



- **Precautions**

  The temporary recipe to be written must already be created and exist in the running PLC.

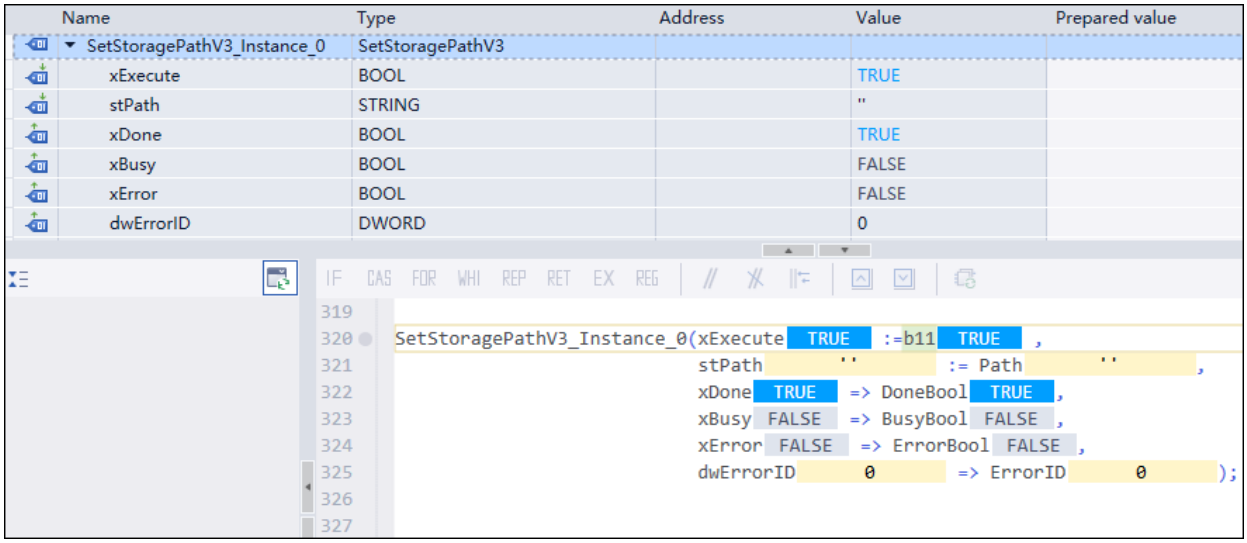
18.2.18.1.42 SetStoragePathV3

Modifies the recipe file storage path.

- **Instruction format**

Instruction	Name	FB/FC	Ladder Diagram Representation	Structured Text Representation
SetStoragePathV3	Set the path to store or load the recipe file	FB		SetStoragePathV3_Instance_0(xExecute := , stPath := , xDone => , xBusy => , xError => , dwErrorID =>);

- **Related variables**



Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	xExecute	Enable	BOOL	TRUE, FALSE	FALSE	This instruction is triggered by the rising edge of xExecute.
	stPath	Recipe file operation path	STRING	Follows data type	0	Recipe file operation path If empty, the default is the fixed PLC path.
Output	xDone	Execution completion flag	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is completed.
	xBusy	Instruction in use	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is currently being executed.
	xError	Instruction fault flag	BOOL	TRUE, FALSE	FALSE	Indicates whether a fault occurred during instruction execution.
	dwErrorID	Instruction fault ID	DWORD	Depends on data type	0	Indicates the cause of the instruction faults. For details, see Fault Codes.

- **Function description**

  When the input parameter xExecute changes from FALSE to TRUE, the instruction is enabled. This instruction affects the recipe file operation path of CreateRecipe, DeleteALLRecipe, DeleteRecipe, SaveRecipe, ReadRecipe, LoadRecipe, and RenameRecipe instructions.

- **Program example**

  ST:

LD:

- **Precautions**
  - The input path must start with "/". For example, "/home" indicates that the recipe files will be stored under /home. If only "home" is entered, the instruction will return a fault message indicating an invalid storage path.
  - The input path must be valid, such as "/home/ino/inodata/userspace". If an unexpected path separator such as "\" is entered, the recipe file may fail to be stored correctly.
  - This instruction affects the recipe file operation path of CreateRecipe, DeleteALLRecipe, DeleteRecipe, SaveRecipe, ReadRecipe, LoadRecipe, and RenameRecipe instructions.
  - If stPath is empty or the instruction is not triggered, the storage path is set to the default PLC path under the app directory.

18.2.18.1.43 Fault Codes

- Fault codes for library version 1.0.0.0/1.1.0.0/1.2.0.0

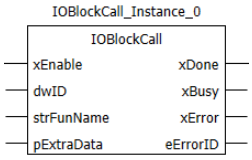
Name	Fault Code (Decimal)	Fault Code (Hexadecimal)	Description
ERR_OK	0	0	Operation succeeded.
ERR_FAILED	1	1	Operation failed.
ERR_PARAMETER	2	2	Parameter fault.
ERR_NOMEMORY	17	11	Insufficient memory.
ERR_RECIPE_FILE_NOT_FOUND	16384	4000	Recipe file not found.
ERR_RECIPE_MISMATCH	16385	4001	The recipe file does not match the current recipe.
ERR_RECIPE_SAVE_ERR	16386	4002	Failed to save the recipe file.
ERR_RECIPE_NOT_FOUND	16387	4003	Recipe not found.
ERR_RECIPE_DEFINITION_NOT_FOUND	16388	4004	Recipe definition not found.
ERR_RECIPE_ALREADY_EXIST	16389	4005	Recipe already exists.
ERR_NO_RECIPE_MANAGER_SET	16390	4006	Recipe manager not initialized.
ERR_RECIPE_NOT_ALL_VARIABLES_WERE_LOADED	16391	4007	The recipe definition contains more variables than the recipe file. Message: The recipe file will be loaded and written.
ERR_RELOAD_RECIPES_ALL_FAILED	16392	4008	Batch load of recipe files failed for all files.
ERR_RELOAD_RECIPES_PARTIAL_SUCCESS	16393	4009	Batch load of recipe files partially succeeded.

- Fault codes for library version 2.0.0.0

Name	Fault Code (decimal)	Fault Code (Hexadecimal)	Description
ERR_OK	0	0	Execution succeeded.
ERR_FAILED	1	1	Device fault (such as insufficient device memory or incorrect variable address in device).
OUT OF RANGE	7	7	Input index exceeds the maximum number of variables.

Name	Fault Code (decimal)	Fault Code (Hexadecimal)	Description
INPUT ERROR	8	8	Input value out of range (for example, the value of ReadOption in the ReadRecipe instruction is not from 0 to 2).
INPUT PATH ERROR	9	9	Input storage path is invalid.
ERR_RECIPE_FILE_NOT_FOUND	16384	4000	Recipe file not found.
RECIPE MISMATCH	16385	4001	Recipe does not match the recipe file.
ERR_RECIPE_SAVE_ERR	16386	4002	Device file read/write fault.
ERR_RECIPE_NOT_FOUND	16387	4003	Recipe not found.
ERR_RECIPE_DEFINITION_NOT_FOUND	16388	4004	Recipe definition not found.
ERR_RECIPE_ALREADY_EXIST	16389	4005	Recipe already exists.

18.2.19 C Function Support



18.2.19.1 Instruction List

Instruction	FB/FC	Function	Library	Applicable Library Version
18.2.19.2 IOBlockCall	FB	Call a C/C++ function	IOBlockHandle	Library version 1.2.0.0 and later
18.2.19.3 IOBlockProcess	FB	Call a C/C++ function with user-defined input and output parameters		Library version 1.2.0.0 and later
18.2.19.4 IOBlockLibCall	FB	Call a C/C++ function from a user-defined library		Library version 1.3.0.0 and later
18.2.19.5 IOBlockLibProcess	FB	Call a C/C++ function from a user-defined library with custom input and output parameters		Library version 1.3.0.0 and later

18.2.19.2 IOBlockCall

Calls a function with a specified format in the C/C++ dynamic library and passes IEC variables into the C/C++ program via pointers for processing.

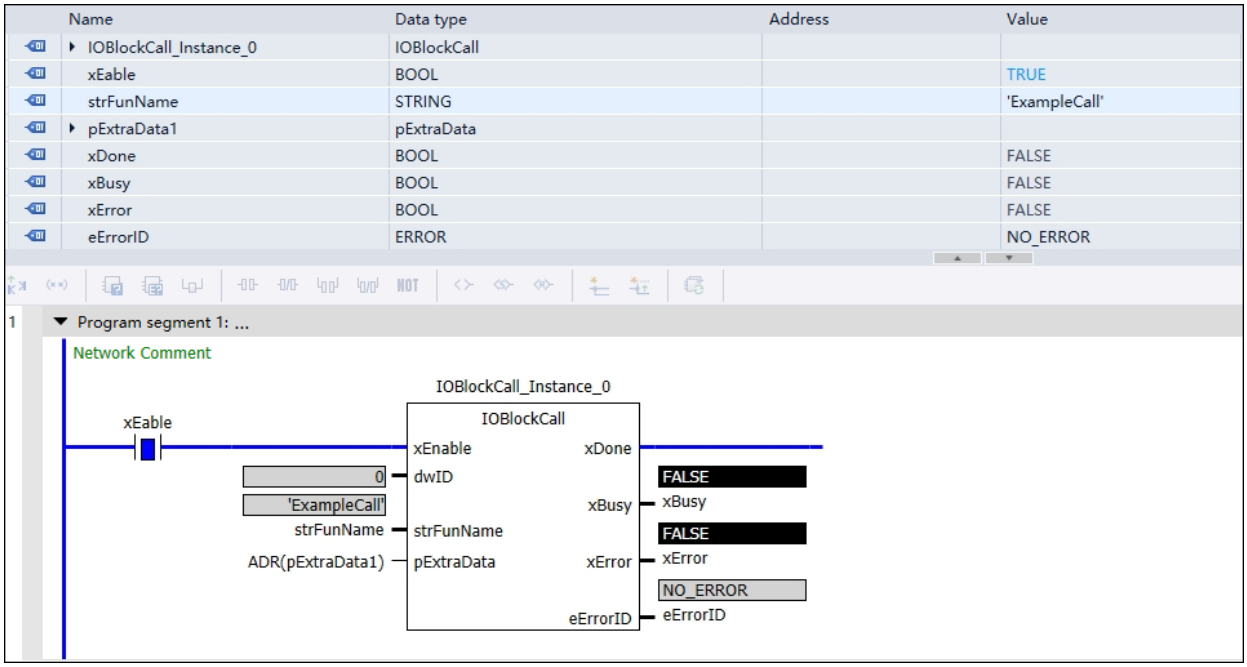
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
IOBlockCall	Call a C/C++ function	FB		IOBlockCall_Instance_0(xEnable := , dwID := , strFunName := , pExtraData := , xDone => , xBusy => , xError => , eErrorID =>);

- **Related variables**

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	xEnable	Enable instruction	BOOL	TRUE, FALSE	FALSE	TRUE: Enabled; FALSE: Disabled
	dwID	An ID specified by the user	DWORD	0 to 65535	0	An ID specified by the user to identify the call in C/C++ code
	strFunName	Function name in C/C++	STRING	Follows data type	Empty string	Function name in C/C++ (case-sensitive)
	pExtraData	Additional parameters	POINTER	Follows data type	NULL	Pointer to additional data to be passed to the C/C++ function
Output	xDone	Execution completion flag	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is completed.
	xBusy	Running status flag	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is running.
	xError	Error flag	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is faulty.

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	eErrorID	Fault code	ERROR	Follow data type	NO_ERROR	Fault code during C/C++ function call: NO_ERROR: No fault LIB_NOT_FOUND: Dynamic library not found FUN_NAME_ERROR: Incorrect function name FUN_NOT_FOUND: Function not found FUN_CALL_ERROR: Function call failed In addition to the above standard fault codes, eErrorID can also output a user-defined value returned by the C/C++ function.



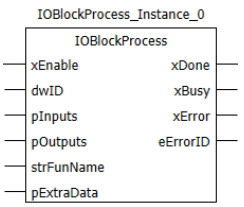
- **Function**
  - When the input parameter xEnable is TRUE, the instruction calls the user-written C/C++ dynamic library. After certain conditions are met, the pointer specified by pExtraData is passed into the C/C++ function context, allowing the user to process the data pointed to. When the input parameter xEnable is FALSE, the call to the C/C++ function is stopped.
  - If the user's dynamic library is not found, the user-defined function is not found, or a fault occurs during the call, the xError variable will be TRUE, and the relevant fault code will be displayed in eErrorID.
- **Program example**

  ST:

	Name	Data type	Address	Value
1	IOBlockCall_Instance_0	IOBlockCall		
2	xEable	BOOL		TRUE
3	dwID	DWORD		0
4	strFunName	STRING		'ExampleCall'
5	pExtraData1	pExtraData		
6	xDone	BOOL		TRUE
7	xBusy	BOOL		FALSE
8	xError	BOOL		FALSE
9	eErrorID	ERROR		NO_ERROR

```
IOBlockCall_Instance_0(
xEnable TRUE :=xEable TRUE ,
dwID 0 :=dwID 0 ,
strFunName 'ExampleCall' := strFunName 'ExampleCall' ,
pExtraData 3023960504 := ADR(pExtraData1),
xDone TRUE =>xDone TRUE ,
xBusy FALSE => xBusy FALSE ,
xError FALSE =>xError FALSE ,
eErrorID NO_ERROR =>eErrorID NO_ERROR );
```

LD:



- **Precautions**

  When replacing the dynamic library, it is recommended to place the PLC application in STOP mode. The C/C++ dynamic library will be reloaded when the PLC enters RUN mode, ensuring that the dynamic library in memory is the latest version.

18.2.19.3 IOBlockProcess

Calls a function with a specified format in the C/C++ dynamic library and passes IEC variables into the C/C++ program via pointers for processing.

- **Instruction format**

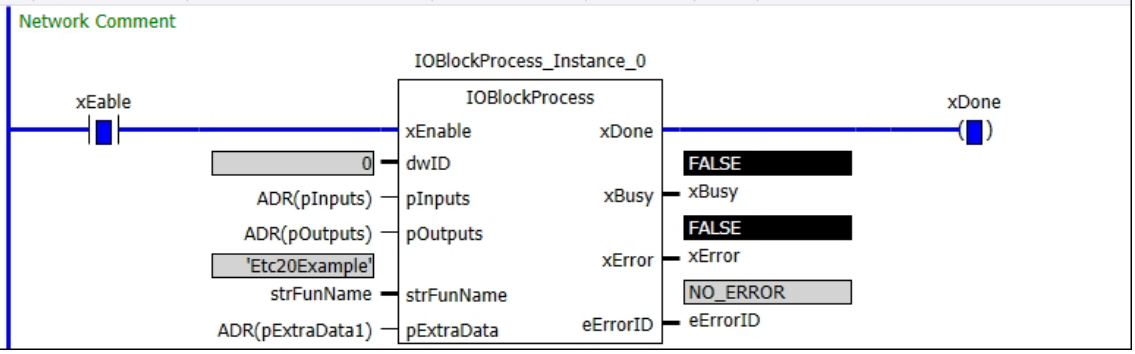
Instruction	Name	FB/FC	LD Representation	ST Representation
IOBlockProcess	Call a C/C++ function with user-defined input and output parameters	FB		IOBlockProcess_Instance_0(xEnable := , dwID := , pInputs := , pOutputs := , strFunName := , pExtraData := , xDone => , xBusy => , xError => , eErrorID =>);

- **Related variables**

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	xEnable	Enable instruction	BOOL	TRUE, FALSE	FALSE	TRUE: Enabled; FALSE: Disabled

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	dwID	An ID specified by the user	DWORD	0 to 65535	0	An ID specified by the user to identify the call in C/C++ code
	pInputs	POU of the input	POINTER	Follows data type	NULL	Typically a pointer to the mapped input structure
	pOutputs	POU of the output	POINTER	Follows data type	NULL	Typically a pointer to the mapped output structure
	strFunName	Function name in C/C++	STRING	Follows data type	Empty string	Function name in C/C++ (case-sensitive)
	pExtraData	Additional parameters	POINTER	Follows data type	NULL	Pointer to additional data to be passed to the C/C++ function
Output	xDone	Execution completion flag	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is completed.
	xBusy	Running status flag	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is running.
	xError	Error flag	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is faulty.

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	eErrorID	Fault code	ERROR	Follow data type	NO_ERROR	Fault code during C/C++ function call: NO_ERROR: No fault LIB_NOT_FOUND: Dynamic library not found FUN_NAME_ERROR: Incorrect function name FUN_NOT_FOUND: Function not found FUN_CALL_ERROR: Function call failed In addition to the above standard fault codes, eErrorID can also output a user-defined value returned by the C/C++ function.



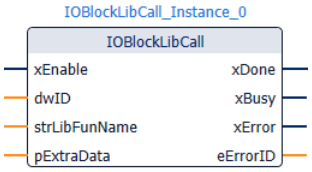
- **Function**
  - When the input parameter xEnable is TRUE, the instruction calls the user-written C/C++ dynamic library. After certain conditions are met, the pointer specified by pInput, pOutput, and pExtraData is passed into the C/C++ function context, allowing the user to process the data pointed to. When the input parameter xEnable is FALSE, the call to the C/C++ function is stopped.
  - If the user's dynamic library is not found, the user-defined function is not found, or a fault occurs during the call, the xError variable will be TRUE, and the relevant fault code will be displayed in eErrorID.
- **Program example**
  ST:

	Name	Data type	Address	Value
1	IOBlockProcess_Instance_0	IOBlockProcess		
2	xEable	BOOL		TRUE
3	dwID	DWORD		0
4	pInputs	pInputs		
5	pOutputs	pOutputs		
6	strFunName	STRING		'Etc20Example'
7	pExtraData1	pExtraData		
8	xDone	BOOL		TRUE
9	xBusy	BOOL		FALSE
10	xError	BOOL		FALSE
11	eErrorID	ERROR		NO_ERROR

```
IOBlockProcess_Instance_0(
xEnable TRUE := xEable TRUE ,
dwID 0 := dwID 0 ,
pInputs 3023960156 :=ADR(pInputs) ,
pOutputs 3023960288 := ADR(pOutputs),
strFunName 'Etc20Example' :=strFunName 'Etc20Example' ,
pExtraData 3023960504 :=ADR(pExtraData1) ,
xDone TRUE => xDone TRUE ,
xBusy FALSE => xBusy FALSE ,
xError FALSE => xError FALSE ,
eErrorID NO_ERROR => eErrorID NO_ERROR );
```

LD:

	Name	Data type	Address	Value
1	IOBlockProcess_Instance_0	IOBlockProcess		
2	xEable	BOOL		TRUE
3	pInputs	pInputs		
4	pOutputs	pOutputs		
5	strFunName	STRING		'Etc20Example'
6	pExtraData1	pExtraData		
7	xDone	BOOL		TRUE
8	xBusy	BOOL		FALSE
9	xError	BOOL		FALSE
10	eErrorID	ERROR		NO_ERROR



- **Precautions**

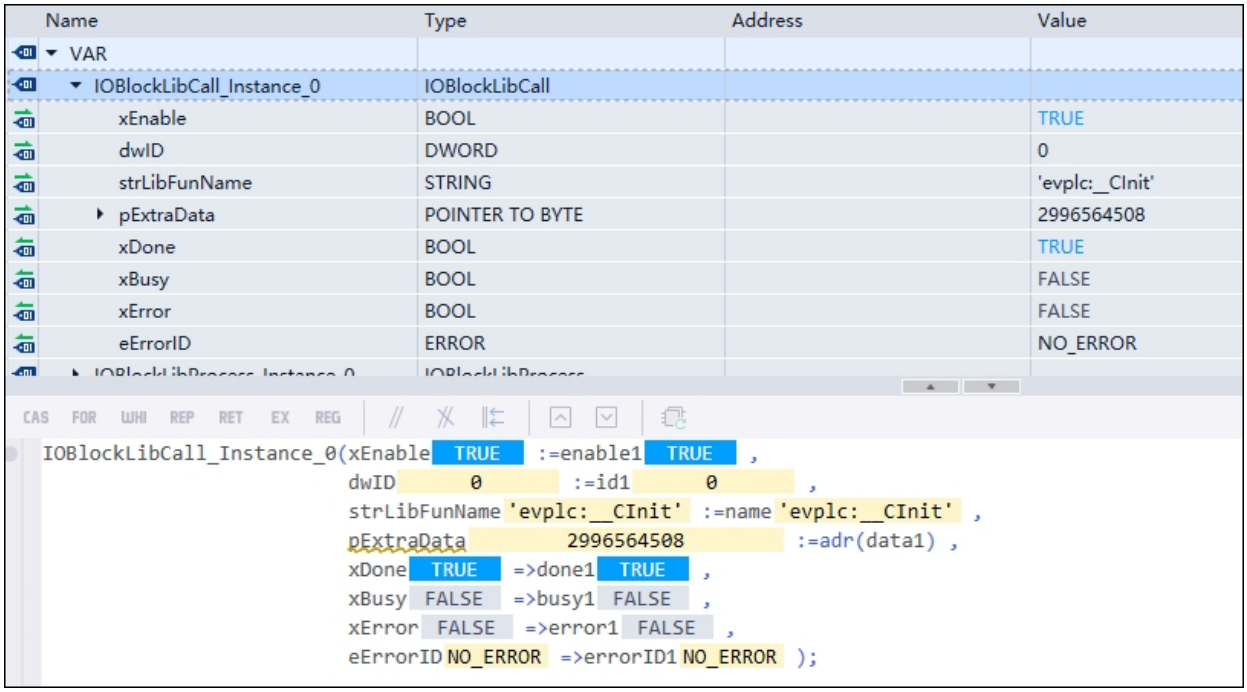
  When replacing the dynamic library, it is recommended to place the PLC application in STOP mode. The C/C++ dynamic library will be reloaded when the PLC enters RUN mode, ensuring that the dynamic library in memory is the latest version.

18.2.19.4 IOBlockLibCall

Calls a function with a specified format in the C/C++ dynamic library from a user-defined library and passes IEC variables into the C/C++ program via pointers for processing.

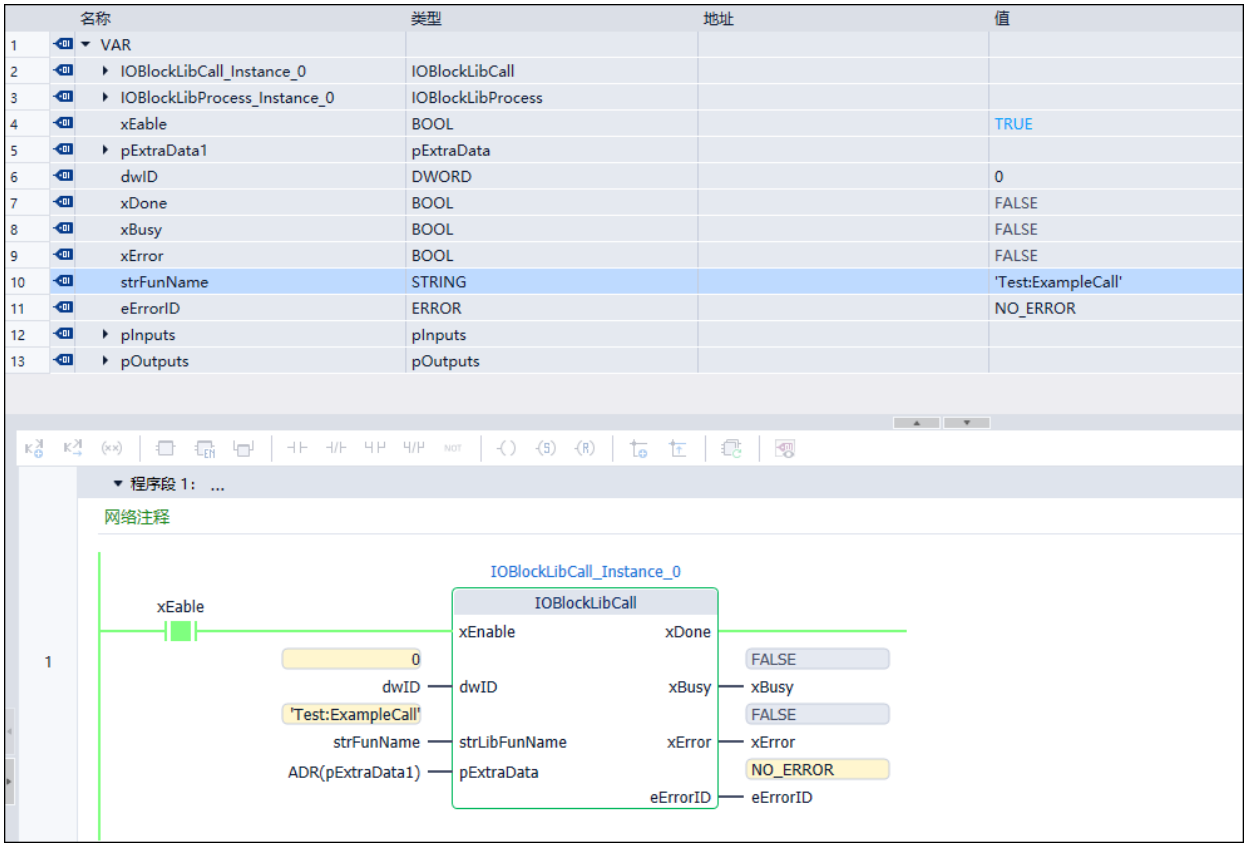
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
IOBlockLibCall	Call a C/C++ function from a user-defined library	FB		IOBlockLibCall_Instance_0(xEnable := , dwID := , strLibFunName := , pExtraData := , xDone => , xBusy => , xError => , eErrorID =>);



- **Related variables**

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	xEnable	Enable instruction	BOOL	TRUE, FALSE	FALSE	TRUE: Enabled; FALSE: Disabled
	dwID	An ID specified by the user	DWORD	0 to 65535	0	An ID specified by the user to identify the call in C/C++ code
	strLibFunName	Name of the library and function in C/C++	STRING	Follows data type	Empty string	Name of the library and function to be called, in the format "LibraryName:FunctionName". For example, if the library is libmylib.so and the function name is func, then this parameter is mylib:func.
	pExtraData	Additional parameters	POINTER	Follows data type	NULL	Pointer to additional data to be passed to the C/C++ function
Output	xDone	Execution completion flag	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is completed.
	xBusy	Running status flag	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is running.
	xError	Error flag	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is faulty.

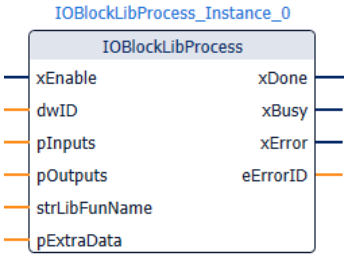


Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	eErrorID	Fault code	ERROR	Follow data type	NO_ERROR	Fault code during C/C++ function call: NO_ERROR: No error; LIB_NOT_FOUND: Dynamic library not found; FUN_NAME_ERROR: Function name error; FUN_NOT_FOUND: Function not found; FUN_CALL_ERROR: Function call failed In addition to the above standard fault codes, eErrorID can also output a user-defined value returned by the C/C++ function.

- **Function**
  - When the input parameter xEnable is TRUE, the instruction calls the user-defined C/C++ dynamic library. After certain conditions are met, the pointer specified by pExtraData is passed into the C/C++ function context, allowing the user to process the data pointed to. When the input parameter xEnable is FALSE, the call to the C/C++ function is stopped.
  - If the user's dynamic library is not found, the user-defined function is not found, or a fault occurs during the call, the xError variable will be TRUE, and the relevant fault code will be displayed in eErrorID.
- **Program example**

ST:

LD:



- **Precautions**

  When replacing the dynamic library, it is recommended to place the PLC application in STOP mode. The C/C++ dynamic library will be reloaded when the PLC enters RUN mode, ensuring that the dynamic library in memory is the latest version.

18.2.19.5 IOBlockLibProcess

Calls a function with a specified format in the user-defined C/C++ dynamic and passes IEC variables into the C/C++ program via pointers for processing.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
IOBlockLibProcess	Call a C/C++ function from a user-defined library with custom input and output parameters	FB		IOBlockLibProcess_Instance_0(xEnable := , dwID := , pInputs := , pOutputs := , strLibFunName := , pExtraData := , xDone => , xBusy => , xError => , eErrorID =>);

- **Related variables**

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	xEnable	Enable instruction	BOOL	TRUE, FALSE	FALSE	TRUE: Enabled; FALSE: Disabled
	dwID	An ID specified by the user	DWORD	0 to 65535	0	An ID specified by the user to identify the call in C/C++ code
	pInputs	POU of the input	POINTER	Follows data type	NULL	Typically a pointer to the mapped input structure
	pOutputs	POU of the output	POINTER	Follows data type	NULL	Typically a pointer to the mapped output structure
	strLibFunName	Function name in C/C++	STRING	Follows data type	Empty string	Name of the library and function to be called, in the format "LibraryName:FunctionName". For example, if the library is libmylib.so and the function name is func, then this parameter is mylib:func (case-sensitive).
	pExtraData	Additional parameters	POINTER	Follows data type	NULL	Pointer to additional data to be passed to the C/C++ function
Output	xDone	Execution completion flag	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is completed.
	xBusy	Running status flag	BOOL	TRUE, FALSE	FALSE	Indicates the instruction is running.
	xError	Error flag	BOOL	TRUE, FALSE	FALSE	Indicates whether the instruction is faulty.

Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	eErrorID	Fault code	ERROR	Follow data type	NO_ERROR	Fault code during C/C++ function call: NO_ERROR: No error; LIB_NOT_FOUND: Dynamic library not found; FUN_NAME_ERROR: Function name error; FUN_NOT_FOUND: Function not found; FUN_CALL_ERROR: Function call failed; In addition to the above standard error codes, eErrorID also returns the return value of the C/C++ function (user-defined).

- **Function**
  - When the input parameter xEnable is TRUE, the instruction calls the user-written C/C++ dynamic library. After certain conditions are met, the pointer specified by pInput, pOutput, and pExtraData is passed into the C/C++ function context, allowing the user to process the data pointed to. When the input parameter xEnable is FALSE, the call to the C/C++ function is stopped.
  - If the user's dynamic library is not found, the user-defined function is not found, or a fault occurs during the call, the xError variable will be TRUE, and the relevant fault code will be displayed in eErrorID.
- **Program example**

  ST:

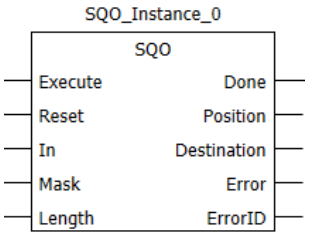
- **Precautions**

  When replacing the dynamic library, it is recommended to place the PLC application in STOP mode. The C/C++ dynamic library will be reloaded when the PLC enters RUN mode, ensuring that the dynamic library in memory is the latest version.

18.2.20 Sequencer



18.2.20.1 Instruction List

Instruction	FB/FC	Function	Library	Applicable Library Version
SQO	FB	Sequencer output	Util	Library version 1.3.0.1 and later

18.2.20.2 SQO

Outputs the set value for each step in sequence via a pre-filled data table. It is suitable for replacing complex self-locking and interlocking logic in controling processes such as assembly lines and packaging machines.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
SQO	Sequencer output	FB		SQO_Instance_0(Execute := , Reset := , In := , Mask := , Length := , Done => , Position => , Destination => , Error => , ErrorID =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Execute	Input signal	Follows data type.	FALSE	Rising edge-triggered
	Reset	Reset step	Follows data type	FALSE	"Position" becomes 0 when triggered.
	In	Sequence array	Follows data type	0	Specifies the first element of the sequence array.

Input/Output	Variable	Name	Valid Range	Default Value	Description
	Mask	Mask	Follows data type	0	Defines the enable/mask strategy for output data, taking effect during output assignment. 1: Output enabled. 0: Output disabled (masked).
	Length	Total steps	Follows data type	0	Total number of steps. Number of elements in the output sequence array.
Output	Done	Done	Follows data type	FALSE	Instruction is completed. Set to TRUE when "Length" equals "Position".
	Position	Current step	Follows data type	0	Current executing step. Current position in the array.
	Destination	Output value	Follows data type	0	Output value Array element value after mask operation.
	Error	Function block fault flag	Follows data type	FALSE	Function block fault flag
	ErrorID	Function block fault ID	Follows data type	0	Function block fault ID

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Execute	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Reset	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
In	-	-	-	-	-	-	-	-	-	-	-	√	-	-	-	-	-	-	-	-
Mask	-	-	-	-	-	-	-	-	-	√	√	√	-	-	-	-	-	-	-	-

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Length	-	-	-	-	-	-	-	-	-	-	-	√	-	-	-	-	-	-	-	-
Done	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Position	-	-	-	-	-	-	-	-	-	-	-	√	-	-	-	-	-	-	-	-
Destination	-	-	-	-	-	-	-	-	-	-	-	√	-	-	-	-	-	-	-	-
Error	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
ErrorID	-	-	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

- **Function**
  - Executes step advancement and outputs data only on the rising edge of Execute.
  - When Execute is first triggered on a rising edge, Position = 1, and the instruction outputs the value corresponding to the second element of the In array.
  - When the rising edge of Execute is triggered normally, the Position value increments; when Position equals Length, Done is set. On the next trigger, Position resets to 1 and a new cycle begins.
  - Each rising edge of Execute performs a bitwise AND between the array element at the current Position and the Mask, and a bitwise AND between Destination and the inverted Mask. The results are combined using a bitwise OR, and the final result is written to Destination.
    Output value calculation formula:

    $$\text{Destination} = (\text{In}[Position]\ AND\ Mask)\ OR\ \left(\text{Destination AND}\ \left(\text{NOT}(\text{Mask})\right)\right)$$

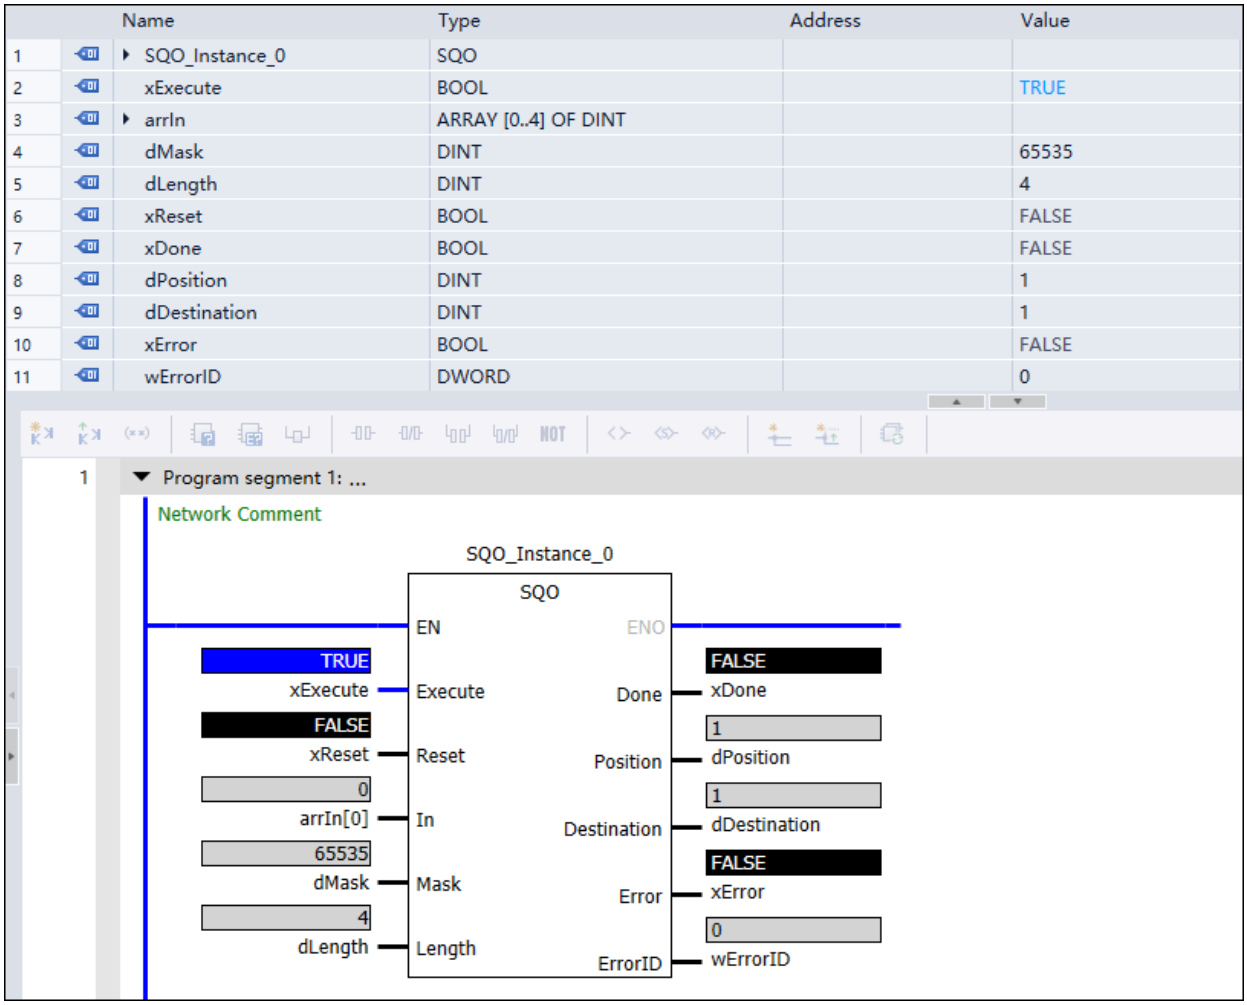
  - When Reset is TRUE, all output variables are cleared.
  - To modify the Position parameter, use the Set accessor of the ModifyPosition property to force-write the Position value into the function block.
- **Program example**

ST:

- When the input signal Execute changes from FALSE to TRUE, Destination outputs the calculated result. Position indicates the current execution position of the sequence array.

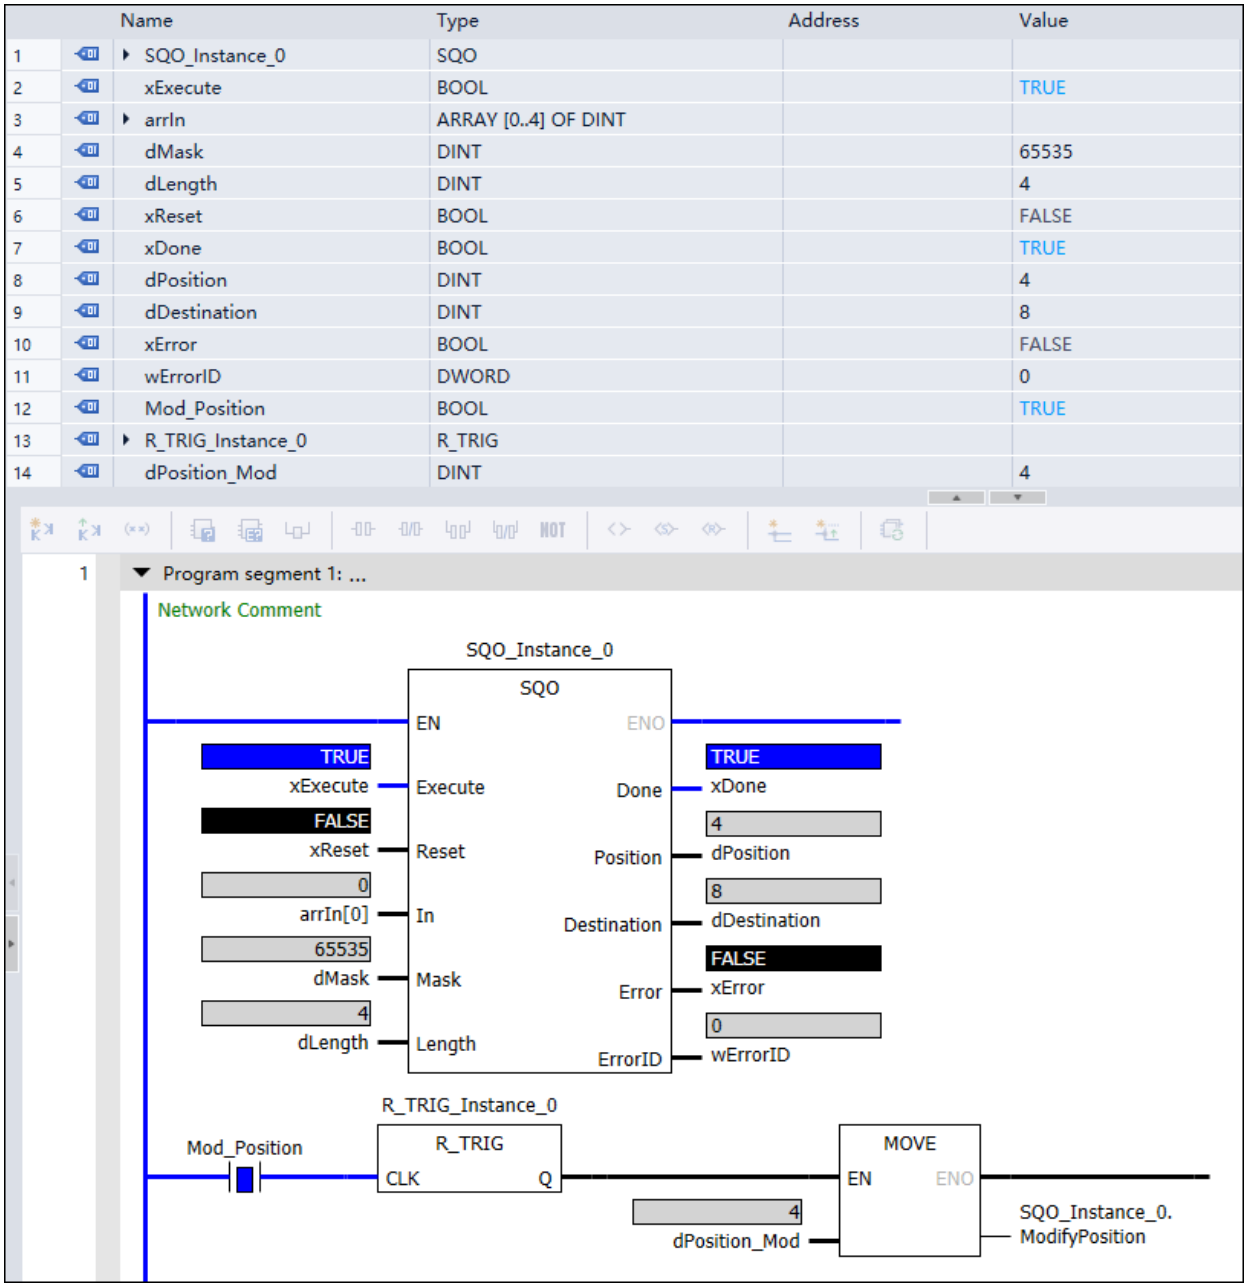
	Name	Type	Address	Value
1	SQO_Instance_0	SQO		
2	xExecute	BOOL		TRUE
3	arrIn	ARRAY [0..4] OF DINT		
4	dMask	DINT		65535
5	dLength	DINT		4
6	xReset	BOOL		FALSE
7	xDone	BOOL		FALSE
8	dPosition	DINT		1
9	dDestination	DINT		1
10	xError	BOOL		FALSE
11	wErrorID	DWORD		0

```
SQO_Instance_0(
Execute TRUE := xExecute TRUE,
Reset FALSE := xReset FALSE,
In := arrIn[0] 0,
Mask := dMask 65535,
Length 4 := dLength 4,
Done FALSE => xDone FALSE,
Position 1 => dPosition 1,
Destination 1 => dDestination 1,
Error FALSE => xError FALSE,
ErrorID 0 => wErrorID 0);RETURN
```



- When the input signal Execute is TRUE, the rising edge of Mod_Position serves as the modification trigger signal, and the set value dPosition_Mod is forced into Position through the Set accessor of the ModifyPosition property.

	Name	Type	Address	Value
1	SQO_Instance_0	SQO		
2	xExecute	BOOL		TRUE
3	arrIn	ARRAY [0..4] OF DINT		
4	dMask	DINT		65535
5	dLength	DINT		4
6	xReset	BOOL		FALSE
7	xDone	BOOL		FALSE
8	dPosition	DINT		1
9	dDestination	DINT		1
10	xError	BOOL		FALSE
11	wErrorID	DWORD		0



```
SQO_Instance_0(
Execute TRUE := xExecute TRUE,
Reset FALSE := xReset FALSE,
In := arrIn[0] 0,
Mask := dMask 65535,
Length 4 := dLength 4,
Done FALSE => xDone FALSE,
Position 1 => dPosition 1,
Destination 1 => dDestination 1,
Error FALSE => xError FALSE,
ErrorID 0 => wErrorID 0);RETURN
```

LD:

- When the input signal Execute changes from FALSE to TRUE, Destination outputs the calculated result. Position indicates the current execution position of the sequence array.

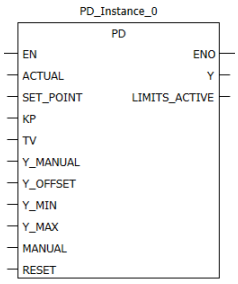
◦ When the input signal Execute is TRUE, the rising edge of Mod_Position serves as the modification trigger signal, and the set value dPosition_Mod is forced into Position through the Set accessor of the ModifyPosition property.

- **Precautions**
  - The In array supports input arrays and array index elements.
  - When Execute is TRUE and Position is modified, Destination outputs the corresponding calculated result of In[Position]; when Execute is FALSE and Position is modified, Destination does not change. When Execute transitions from FALSE to TRUE, Destination outputs the result corresponding to In[Position+1].
  - When Length is less than or equal to 0, Error is TRUE, and ErrorID is 1.
  - When the In array size is less than Length, Error is TRUE, and ErrorID is 2.
  - When Position is greater than Length, Error is TRUE, and ErrorID is 3.
  - When Position is less than 0, Error is TRUE, and ErrorID is 4.
  - When the dimension of the In array is greater than 3, Error is TRUE, and ErrorID is 5.
  - When the In array or Mask is not bound to a variable, Error is TRUE, and ErrorID is 6.

18.3 Process Instructions

18.3.1 PID Control

18.3.1.1 Instruction List



Instruction	FB/FC	Function	Library	Applicable Library Version
18.3.1.2 PD	FB	PD controller	Util	Library version 1.0.0.0 and later
18.3.1.3 PID	FB	PID controller		Library version 1.0.0.0 and later
18.3.1.4 PID_FIXCYCLE	FB	Universal PID control that can manually set the cycle time		Library version 1.0.0.0 and later
18.3.1.5 PID_AT	FB	Universal PID controller	LoopControl	Library version 1.0.0.0 and later
18.3.1.6 PID_ATC	FB	Bipolar temperature PID controller		Library version 1.0.0.0 and later
18.3.1.7.1 FPTLGSim	FB	Simulation of first-order lag plus pure dead time	Logic	Library version 1.0.0.0 and later
18.3.1.7.2 FSMITHSim	FB	First-order lag plus pure dead time compensation simulation		Library version 1.0.0.0 and later
18.3.1.7.3 SPTLGSim	FB	Simulation of second-order lag plus pure dead time		Library version 1.0.0.0 and later
18.3.1.7.4 SSMITHSim	FB	Second-order lag plus pure dead time compensation simulation		Library version 1.0.0.0 and later
18.3.1.7.5 LEAD_LAG	FB	Lead-lag compensator		Library version 1.0.0.0 and later
18.3.1.7.6 DELIM	FC	Deviation determination		Library version 1.0.0.0 and later
18.3.1.7.7 DZLIM	FB	Dead zone determination		Library version 1.0.0.0 and later
18.3.1.7.8 RALIM	FB	Rate determination		Library version 1.0.0.0 and later
18.3.1.7.9 MANCON	FB	Manual operator	ProcessControl	Library version 1.0.0.0 and later
18.3.1.7.10 ORSEL	FB	Override control		Library version 1.0.0.0 and later

Instruction	FB/FC	Function	Library	Applicable Library Version
18.3.1.7.11 PWMC	FB	Pulse modulation control		Library version 1.0.0.0 and later
18.3.1.7.12 RATIO	FB	Ratio control		Library version 1.0.0.0 and later
18.3.1.7.13 SPLRANGE	FB	Split-range control		Library version 1.0.0.0 and later
18.3.1.7.14 THPOSC	FB	Three-position control.		Library version 1.0.0.0 and later
18.3.1.7.15 TWPOSC	FB	Two-position control		Library version 1.0.0.0 and later

18.3.1.2 PD

This instruction performs proportional-derivative (PD) control.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
PD	PD controller	FB		PD_Instance_0(ACTUAL := , SET_POINT := , KP := , TV := , Y_MANUAL := , Y_OFFSET := , Y_MIN := , Y_MAX := , MANUAL := , RESET := , Y => , LIMITS_ACTIVE =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	ACTUAL	Current value of the control variable	Follows data type	-	Current value of the control variable.

Input/Output	Variable	Name	Valid Range	Default Value	Description
	SET_POINT	Set value	Follows data type	-	Set value.
	KP	Proportional coefficient	Follows data type	-	Proportional coefficient, the proportional gain of the P-part.
	TV	Derivative time	Follows data type	-	Derivative time, time of the D part in seconds. For example, 0.5 indicates 500 microseconds.
	Y_MANUAL	Manual output value	Follows data type	-	When the value of MANUAL is TRUE, the output value of Y is Y_MANUAL.
	Y_OFFSET	Offset output of Y	Follows data type	-	Offset output of Y.
	Y_MIN	Minimum output value of Y	Follows data type	-	Minimum output value of Y.
	Y_MAX	Maximum output value of Y	Follows data type	-	Maximum output value of Y.
	MANUAL	Manual output	Follows data type	-	Manual output control. If the value is TRUE, manual operation is activated and the output value of Y is Y_MANUAL.

Input/Output	Variable	Name	Valid Range	Default Value	Description
	RESET	Reset a bit	Follows data type	-	When the value is TRUE, the controller is reset, and the value of Y is Y_OFFSET during re-initialization.
Output	Y	Output value	Follows data type	-	Output value of the PD controller.
	LIMITS_ACTIVE	Set limit reached	Follows data type	FALSE	When the value is TRUE, Y has reached the given limit (Y_MIN, Y_MAX).

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String

LIMITS_ACTIVE	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Program example**

  This instruction performs incremental proportional-derivative (PD) control.

  ST:

	Name	Type	Address	Value	Prepared val
1	PD_Instance_0	PD			
2	ACTUAL	REAL		0	
3	SET_POINT	REAL		100	
4	KP	REAL		1	
5	TV	REAL		0.5	
6	Y_MANUAL	REAL		0	
7	Y_OFFSET	REAL		0	
8	Y_MIN	REAL		0	
9	Y_MAX	REAL		100	
10	MANUAL	BOOL		FALSE	
11	RESET	BOOL		FALSE	
12	Y	REAL		100	
13	LIMITS_ACTIVE	BOOL		FALSE	

```
IF  CAS  FOR  WHI  REP  RET  EX  //  //
1  PD_Instance_0(
2  ACTUAL 0 := fACTUAL 0 ,
3  SET_POINT 100 := fSET_POINT 100
4  KP 1 := fKP 1 ,
5  TV 0.5 := fTV 0.5 ,
6  Y_MANUAL 0 := fY_MANUAL 0
7  Y_OFFSET 0 := fY_OFFSET 0
8  Y_MIN 0 := fY_MIN 0 ,
9  Y_MAX 100 := fY_MAX 100 ,
10 MANUAL FALSE := xMANUAL FALSE ,
11 RESET FALSE := xRESET FALSE ,
12 Y 100 => xY 100 ,
13 LIMITS_ACTIVE FALSE => xLIMITS_ACTIVE FALSE );RETURN
```

LD:

	Name	Type	Address	Value
1	PD_Instance_0	PD		
2	ACTUAL	REAL		0
3	SET_POINT	REAL		100
4	KP	REAL		1
5	TV	REAL		0.5
6	Y_MANUAL	REAL		0
7	Y_OFFSET	REAL		0
8	Y_MIN	REAL		0
9	Y_MAX	REAL		100
10	MANUAL	BOOL		FALSE
11	RESET	BOOL		FALSE
12	Y	REAL		100
13	LIMITS_ACTIVE	BOOL		FALSE

- **Precautions**
  - The output value of Y is calculated as follows:

$$Y = KP \cdot (\Delta + 1/TN \int edt + TV\ \delta\Delta/\delta t) + Y_OFFSET$$

  - If there are no output limit values, the values of Y_MIN and Y_MAX must be set to 0.
  - These controls will only take effect if Y_MIN is less than Y_MAX.
  - If the value of the MANUAL is TRUE, and the value of KP is non-zero, Y_MANUAL will be written to the output value of Y.

◦ If RESET and MANUAL are set simultaneously, the value of Y will be Y_OFFSET during re-initialization.

18.3.1.3 PID

This is the instruction for proportional integral derivative control.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
PID	PID controller	FB		PID_Instance_0(ACTUAL := , SET_POINT := , KP := , TN := , TV := , Y_MANUAL := , Y_OFFSET := , Y_MIN := , Y_MAX := , MANUAL := , RESET := , Y => , LIMITS_ACTIVE => , OVERFLOW =>);

- **Related variables**

Variable

Input / Output	Variable	Name	Valid Range	Default Value	Description
Input	ACTUAL	Current value of the control variable	Follows data type	-	Current value of the control variable.
	SET_POINT	Set value	Follows data type	-	Set value of the control variable.
	KP	Proportional coefficient	Follows data type	-	Proportional coefficient, the proportional gain of the P-part.

Input / Output	Variable	Name	Valid Range	Default Value	Description
	TN	Integral time	Follows data type	-	Integral time, time of the I part in seconds. For example, 0.5 indicates 500 milliseconds. The value must be greater than 0. Otherwise, the function block does not perform any calculation.
	TV	Derivative time	Follows data type	-	Derivative time, time of the D part in seconds. For example, 0.5 indicates 500 milliseconds.
	Y_MANUAL	Manual output value	Follows data type	-	Manual output value. When the value of MANUAL is TRUE, the output value of Y is Y_MANUAL.
	Y_OFFSET	Offset output of Y	Follows data type	-	Offset output of Y.
	Y_MIN	Minimum output value of Y	Follows data type	-	Minimum output value of Y.
	Y_MAX	Maximum output value of Y	Follows data type	-	Maximum output value of Y.
	MANUAL	Manual output	Follows data type	-	Manual output control. If the value is TRUE, manual operation is activated and the output value of Y is Y_MANUAL.
	RESET	Reset a bit	Follows data type	-	When the value is TRUE, the controller is reset, and the value of Y is Y_OFFSET during re-initialization.
Output	Y	Output value	Follows data type	-	Output value of the PID controller.
	LIMITS_ACTIVE	Set limit reached	Follows data type	FALSE	When the value is TRUE, Y has reached the given limit (Y_MIN, Y_MAX).
	OVERFLOW	Overflow flag	Follows data type	FALSE	Overflow flag. If the integral part of e is larger, incorrect parameter settings for the controller may cause overflow. For the sake of security, the output of OVERFLOW is TRUE in this case.

Variable types

	GeneralConfig		PID_GENERALCONFIG	-	-	PID general configuration structure.
	GeneralConfig	SampleTime	DINT	1 to 1000000	100	Sampling time in ms. That is the PID calculation cycle.
		CycleTime	DINT	1 to 1000000	1000	PWM output cycle in ms. Takes effect when the output mode is set to PWM mode.
		PIDType	DINT	0, 1, 2, 3	0	PID type: 0: PID calculation. 1: PI calculation. 2: PD calculation. 3: ID calculation.

Input/Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	Variable	Name	Data Type	Valid Range	Default Value	Description
		ControlMode	DINT	0, 1	0	PID control mode: 0: Reverse (unipolar heating control). 1: Forward (unipolar cooling control). If other values are input, a parameter error will be triggered.
		ManualEnable	BOOL	TRUE, FALSE	FALSE	Manual mode enable. FALSE: Automatic mode is enabled. TRUE: Manual mode is enabled.
		ManualValue	REAL	OutMin~OutMax	0.0	Output percentage in manual mode, unit: %.
		ATCoefficient	REAL	0.0 to 1.0	0.5	Self-tuning adjustment coefficient, ranging from 0.1 to 1.0. A larger value results in faster adjustment, with a default setting of 0.5.

Input/Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	Variable	Name	Data Type	Valid Range	Default Value	Description
		DelayStartUp	DINT	0 to 1000000	0	Delay startup time in ms.
		DelayShutDown	DINT	0 to 1000000	0	Delay shutdown time in ms.
		PhysicalQuantity	INT	0 to 3	0	Physical object to control: 0: General. 1: Temperature and other parameters. For details, see object description. Default: General
		PhysicalUnit	DINT	Follows data type	-	Unit of the physical object.
		IsMaster	BOOL	TRUE, FALSE	FALSE	Master control: 0: No. 1: Yes. Value must be assigned during cascade configuration.

Input/Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	Variable	Name	Data Type	Valid Range	Default Value	Description
		IsSlave	BOOL	TRUE, FALSE	FALSE	Slave control: 0: No. 1: Yes. Value must be assigned during cascade configuratio n.
		ATNum	DINT	0 to 20	2	Number of auto-tuning waveforms (applicable only to unipolar). 0: Reserved. 1-20: Number of oscillation waveforms.
		ATOut	DINT	OutMin~Out Max	100	Output percentage in auto-tuning (applicable only to unipolar, unit: %).
	InputConfig		PID_INPUTC ONFIG	-	-	PID input configuration structure.

Input/Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	Variable	Name	Data Type	Valid Range	Default Value	Description
	InputConfig	PVType	DINT	0, 1	0	PV type: 0: Use current PV as input. 1: Use peripheral analog signal as input, with conversion based on analog range.
		AIMin	DINT	Follows data type	0	Minimum value for analog conversion.
		AIMax	DINT	Follows data type	20000	Maximum value for analog conversion.
		PVMin	REAL	Follows data type	0.0	Minimum value of PV
		PVMax	REAL	Follows data type	100.0	Maximum value of PV.
		PVLowLimit	REAL	Follows data type	-100.0	Lower input limit.
		PVHighLimit	REAL	Follows data type	1000.0	Lower input limit.
		ErrorAction	BOOL	TRUE, FALSE	FALSE	Output on error alarm: FALSE: Maintain previous value. TRUE: Output substitute value.

Input/Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	Variable	Name	Data Type	Valid Range	Default Value	Description
		ErrorOut	REAL	OutMin~OutMax	0.0	Output of a predefined percentage value on error alarm.
		SPSel	BOOL	TRUE, FALSE	FALSE	Setpoint source selection: FALSE: External setpoint (SP configuration). TRUE: Internal setpoint (panel operation setpoint).
		SPRatio	REAL	Follows data type	0.0	SP setpoint change. If set to 0, no change judgment is performed. If set greater than 0, the final setpoint will approach the setpoint at the rate defined by SPRatio when the setpoint changes. Calculated once per task cycle.
		SPInt	REAL	Follows data type	-	Internal setpoint.

Input/Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	Variable	Name	Data Type	Valid Range	Default Value	Description
		SPTrack	BOOL	TRUE, FALSE	TRUE	The tracking switch of internal setpoint is on by default to ensure bumpless switchover when switching between external and internal setpoint sources. FALSE: Internal setpoint does not track external setpoint. TRUE: Internal setpoint tracks external setpoint.
	OutputConfig		PID_OUTPUT CONFIG	-	-	PID output configuration structure.
	OutputConfig	OutType	DINT	0, 1, 2	0	Output type: 0: PWM. 1: Analog output. 2: Percentage output.

Input/Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	Variable	Name	Data Type	Valid Range	Default Value	Description
		OutMin	REAL	-100.0~OutMax	0.0	Minimum value of output percentage. The upper limit of the PID calculation output, and also the lower limit of the analog output conversion range.
		OutMax	REAL	OutMin~100.0	100.0	Maximum value of output percentage. The upper limit of the PID calculation output, and also the upper limit of the analog output conversion range.
		AOMin	DINT	Follows data type	0	Minimum value of analog output.
		AOMax	DINT	Follows data type	20000	Maximum value of analog output.

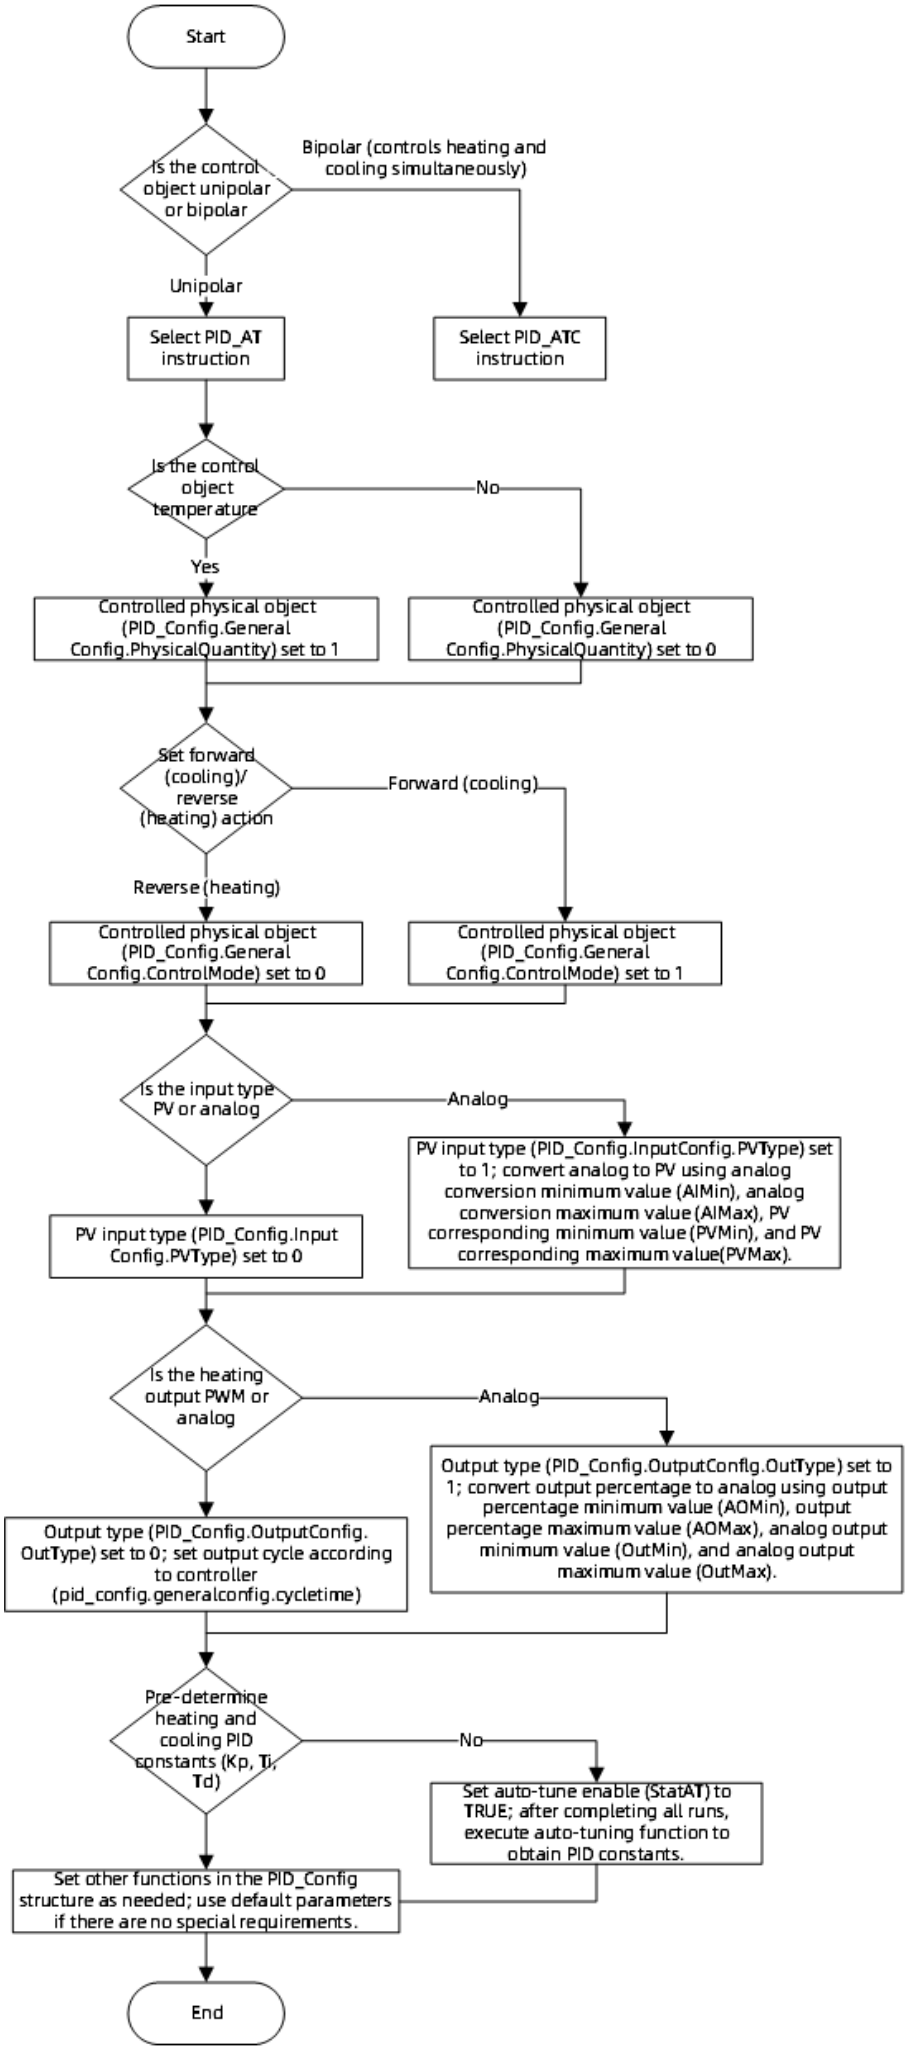
Input/Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	Variable	Name	Data Type	Valid Range	Default Value	Description
		OutputOffset	REAL	-100.0 to 100.0	0.0	Compensation value of the output offset. Directly added to the PID calculation output, limited by the output min and max values.
		MinPT	DINT	0 to 10000	0	Minimum on-off pulse time in ms. Active in PWM mode.
	SuperConfig		PID_SUPERCONFIG	-	-	Advanced PID configuration structure.
	SuperConfig	Fuzzy	BOOL	TRUE, FALSE	FALSE	Fuzzy control enable: 0: Disable fuzzy self-adaptation. 1: Enable fuzzy self-adaptation.
		ECMax	REAL	Follows data type	1.0	Fuzzy control, maximum heating rate, °C/s.
		IntegralSuspend	BOOL	TRUE, FALSE	FALSE	Integral pause: 0: Normal integral. 1: Integral paused.

Input/Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	Variable	Name	Data Type	Valid Range	Default Value	Description
		IntegralDivision	BOOL	TRUE, FALSE	TRUE	Integral separation for non-temperature objects: 0: No integral separation. 1: Integral separation.
		IntegralClear	BOOL	TRUE, FALSE	FALSE	Integral clearance: 0: Normal integral. 1: Integral cleared.
		IntegralMax	REAL	-100.0 to 100.0	100.0	Maximum integral value / the upper limit of the accumulated integral value.
		IntegralCut	REAL	0.0 to 1.0	0.75	Cut the integral coefficient when the setpoint changes.

Input/Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	Variable	Name	Data Type	Valid Range	Default Value	Description
		KdGain	REAL	0.0 to 1.0	0.65	Incomplete derivative coefficient (0.0 to 1.0). The larger the value, the smoother the differential effect. When set to 1, the differential action is disabled.
		IntegralDivLimit	REAL	0.0 to 100.0	50.0	Integral separation limit. When the value of IntegralDivision is TRUE for non-temperature objects, integral action is disabled if the deviation is greater than the integral separation limit.
		DeadBand	REAL	0.0 to 100.0	0.0	Deviation deadzone limit

Input/Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input/Output	StartAT	Auto-tuning switch	BOOL	TRUE, FALSE	FALSE	TRUE: Start tuning. After parameter tuning is completed, it will reset to FALSE and can be triggered multiple times.
	Kp	Proportional coefficient	REAL	0.01 ~ 1000.0	60.0	Proportional coefficient. Configuration error will report an error ID. The larger the Kp value, the stronger the proportional action.
	Ti	Integral time	REAL	0.0 to 10000.0	400.0	Integral time. Configuration error will report an error ID. 0 indicates no integral action. The larger the Ti value, the weaker the integral action.

Input/Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	Td	Derivative time	REAL	0.0 to 10000.0	50.0	Derivative time. Configuration error will report an error ID. 0 indicates no derivative action. The larger the Td value, the stronger the derivative action.
Output	OutPWM	PWM output	BOOL	TRUE, FALSE	FALSE	PWM output.
	OutPercent	Percentage output	REAL	-100.0%~100.0%	0.0	Percentage output in %.
	OutAO	Analog output	DINT	Follows data type	0	Analog output.
	PIDOutput	PID output variable structure	PID_Output	-	-	Other PID output variables.



Input/Output	Variable	Name	Data Type	Valid Range	Default Value	Description

Name	Data Type	Valid Range	Default Value	Description
PVOut	REAL	Follows data type	0.0	Actually calculated PV value.
ECMaxOut	REAL	Follows data type	0.0	Fuzzy control, maximum heating rate, ℃/s.
ATState	DINT	0, 1, 2	0	Auto-tuning state 0: Not tuned. 1: Tuning. 2: Tuned.
ErrorID	DINT	Follows data type	0	Parameter fault code.
SPOut	REAL	Follows data type	0.0	Actually calculated SP value.

State	Operation state	DINT	Follows data type	0	Operation state: 0: Not activated. 1: Manual. 2: Automatic. 3: Interlocked. 4: Tuning. 5: Last valid output on error. 6: Substitute value output on error. 7: Master tracking.

Input/Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	Error	Operation error	BOOL	TRUE, FALSE	FALSE	Operation error marking, see ErrorBits for details.
	ErrorBits	Fault code	WORD	-	-	Fault code, expressed by bits: bit0 = 1: PV overlimit. bit1 = 1: Parameter error (For detailed information about the parameter error, see PIDOutput.ErrorID.)
	SlaveState	Slave status	Slave_Data	-	-	In case of slave, the structure of the operation state must be connected back to CasSlaveState, the input of the master control.

- **Parameter initialization flow for PID_AT**

Start
Is the control object unipolar or bipolar
Bipolar (controls heating and cooling simultaneously)
Unipolar
Select PID_AT instruction
Select PID_ATC instruction
Is the control object temperature
No
Yes
Controlled physical object (PID_Config.General Config.PhysicalQuantity) set to 1
Controlled physical object (PID_Config.General Config.PhysicalQuantity) set to 0
Set forward (cooling)/ reverse (heating) action
Forward (cooling)
Reverse (heating)
Controlled physical object (PID_Config.General Config.ControlMode) set to 0
Controlled physical object (PID_Config.General Config.ControlMode) set to 1
Is the input type PV or analog
Analog
PV input type (PID_Config.InputConfig.PVType) set to 1; convert analog to PV using analog conversion minimum value (AIMin), analog conversion maximum value (AIMax), PV corresponding minimum value (PVMin), and PV corresponding maximum value(PVMax).
PV input type (PID_Config.Input Config.PVType) set to 0
Is the heating output PWM or analog
Analog
Output type (PID_Config.OutputConfig.OutType) set to 1; convert output percentage to analog using output percentage minimum value (AOMin), output percentage maximum value (AOMax), analog output minimum value (OutMin), and analog output maximum value (OutMax).
Output type (PID_Config.OutputConfig. OutType) set to 0; set output cycle according to controller (pid_config.generalconfig.cycletime)
Pre-determine heating and cooling PID constants (Kp, Ti, Td)
No
Set auto-tune enable (StatAT) to TRUE; after completing all runs, execute auto-tuning function to obtain PID constants.
Set other functions in the PID_Config structure as needed; use default parameters if there are no special requirements.
End

- **Parameter description**
  - StartAT auto-tuning

    This instruction has an auto-tuning function, which can automatically calculate the optimal values of the PID constants Kp, Ti, Td.

    Auto-tuning execution conditions for heating applications:

    1) The current value is less than the setpoint. Generally, the setpoint should be the common operating temperature of the equipment.

    2) When StartAT is set to TRUE: If Enable changes from FALSE to TRUE, auto-tuning will be executed at the start of operation. If Enable is TRUE and PID calculation is in progress, auto-tuning will start during operation when StartAT changes from FALSE to TRUE.

    After auto-tuning starts, the value of State.1 will be set to 1. When auto-tuning is completed, the value of State.1 will be set to 0 and the value of State.2 will be set to 1.

    In any of the above cases, if StartAT changes from TRUE to FALSE during auto-tuning, the auto-tuning process will be terminated, with State.1 = 0 and State.2 = 0.

    Note: After auto-tuning is completed, StartAT will automatically be set to FALSE.

    3) Auto-tuning output percentage ATOut: Used to set the heating/cooling output percentage during the auto-tuning phase, supports only unipolar mode.
    Number of auto-tuning waveforms ATNum: Auto-tuning is performed with multiple oscillation wavefroms based on the oscillation parameter ATNum.

  - When ATOut = 100 and ATNum = 1, the schematic diagram of the unipolar auto-tuning process is shown below.

  - When ATOut = 100 and ATNum = 3, the calculation is performed based on 3 oscillation parameters, and the schematic diagram of the unipolar auto-tuning process is shown below.

NOTE

LoopControl 1.1.0.0 and later versions supports multi-waveforms auto-tuning algorithm.

- **Function**

  A single circuit, also known as a simple control system, refers to a closed-circuit feedback control system composed of one controlled object, a sensor/transmitter, a controller, and an actuator. It applies to scenarios with low time lag, slight load/interference fluctuations and moderate control quality requirements.

  - **Calculation formula**

$$\mathbf{AV} = K_p * \left[(SP - PV) + \frac{1}{T_i * S}(SP - PV) + \frac{T_d}{S}(PV) \right]$$

  - **Discretization formula:**

$$\mathbf{AV(k)} = K_p * \mathbf{E}(k) + K_p * \frac{cycle}{T_i} \sum \mathbf{E}(k) + \frac{K_p * T_D}{cycle}(P(k) - \mathbf{P}(k-1))$$

  - **Operation mode**

Operation Mode	Action
Automatic	Calculate according to the proportional-integral-derivative (PID) principle and generate the output value of the PID module. The calculation result of the PID module is limited by "output amplitude".

Operation Mode	Action
Manual	Directly control the output (value written by the operator or online logic). The output in this mode is limited by "output amplitude".
Interlock	In this mode, the PID stops automatic calculation, and the output value of the PID module is a preset value "InlockVal", generally referred to as the interlock setpoint. The interlock function can also be used as a "tracking" function. When certain conditions are met (interlock "InlockSW" = TRUE), the PID module automatically switches to this mode. When the interlock conditions are not met, the PID module switches back to the previous mode.

1. Interlock mode has the highest priority, followed by manual mode, and then automatic mode.
2. Automatic mode: Primarily used for setpoint control. The setpoint can be configured via the interface.
3. The selection of external or internal setpoint can be configured by the parameter PIDConfig.InputConfig.SPSel:

   SPSel = FALSE: External setpoint (the setpoint configured in the logic configuration).

   SPSel = TRUE: Internal setpoint (the preset internal setpoint).

   Note: Enable "Internal setpoint tracks external setpoint" (PIDConfig.InputConfig.SPTrack = TRUE) to prevent loop fluctuations during setpoint switching. When external setpoint is selected, internal setpoint tracks it for bumpless switchover. Switching from internal to external setpoint directly adopts the real-time logic configuration value, which may cause bumpy switchover.

◦ **Bumpless switchover**

Operation Mode	Action
Interlock -> Manual	In interlock mode, the interlock value is output directly. The manual value tracks the output value to ensure bumpless switchover.
Interlock -> Automatic	In interlock mode, the interlock value is output directly. When switching to automatic mode, if the external setpoint is used, the logic calculation value will be adopted directly for PID calculation and output, which may cause disturbance.
Manual -> Interlock	The manual output is the manual value. Switching to interlock mode will output the interlock value directly, resulting in bumpy switchover.

Operation Mode	Action
Manual -> Automatic	The manual output is the operator-set value. When switching to automatic mode, if the external setpoint is used, the logic calculation value will be adopted directly for PID calculation and output, enabling bumpless switchover (disturbance is limited to the incremental part).
Automatic->Interlock	In automatic mode, the output is the normal calculation value. Switching to interlock mode will output the interlock value directly, resulting in bumpy switchover.
Automatic->Manual	In automatic mode, the output is the normal calculation value. The manual value tracks the output value to ensure bumpless switchover

- **Functional logic diagram (reverse-acting example)**

- **Supports direct/reverse action**

  Direct and reverse action: In automatic mode, direct action means output variation matches feedback variation; reverse action means the opposite. Simply put, direct action requires increasing output to eliminate deviation when feedback exceeds setpoint, while reverse action does the opposite. Configurable via parameter "PIDConfig.GeneralConfig.ControlMode":

  ControlMode = 0: Reverse action, such as heating control.

  ControlMode = 1: Direct action, such as cooling control.

- **Setpoint change limit function**

  In automatic mode, the change in setpoint (external and internal) is detected. If the change exceeds the predefined limit (PIDConfig.InputConfig.SPRatio), the actual setpoint used for calculation is limited to the change, and the setpoint will gradually approach the target value within the change limit range.

△SP > SPRatio (setpoint change): SP = LastSP + SPRatio

△SP < SPRatio (setpoint change): SP = LastSP - SPRatio

◦ **Input selection function**

Two modes of input signals can be selected.

PIDConfig.InputConfig.PVType	Input	Description
0	Current input "PV"	-
1	Analog input "AI"	Calibrate via linear conversion based on analog input limits and PV limits.  Analog upper limit - PIDConfig.InputConfig.AIMax Analog lower limit - PIDConfig.InputConfig.AIMin PV upper limit - PIDConfig.InputConfig.AIMax PV upper limit - PIDConfig.InputConfig.AIMin

◦ **Integral function**

Integral separation

Integral windup is mainly caused by the integral term. To overcome this issue, it is crucial to limit integral action and prevent excessive integral accumulation. The integral separation function can eliminate integral windup and enable the function block to resist integral windup.

For non-temperature-controlled quantities, the configuration of integral separation is described in the table below.

Integral separation enable PIDConfig.GeneralConfig.IntegralDivision	Integral separation limit PIDConfig.GeneralConfig.IntegralDivLimit
TRUE	|Deviation| >= Integral Separation Limit: Integral component calculation is disabled (control law operates as PD control).
	|Deviation| < Integral Separation Limit: Full integral calculation is enabled (control law operates as PID control).
FALSE	Full integral calculation is always enabled.

Integral pause

When integral suspend is triggered "PIDConfig.GeneralConfig.IntegralSuspend = TRUE", the integral action remains unchanged and stops accumulating.

Integral clearance

When integral clear is triggered "PIDConfig.GeneralConfig.IntegralClear = TRUE", integral action will be cleared to 0.

Integral cut coefficient

When the setpoint changes, the initial integral action can be reduced by setting the integral cut coefficient "PIDConfig.SuperConfig.IntegralCut". The setting range is [0,1], default is 0.75.

- **Incomplete derivative function**

  Incomplete derivative is equivalent to adding a first-order inertial element to the derivative action, which moderates the derivative effect and effectively improves the system's control performance.

Configuration parameter: PIDConfig.SuperConfig.KdGain	Derivative action
0	Derivative action is only active for the current cycle (default value).
(0,1)	The larger the value, the smoother the derivative action.
1	The derivative action is disabled.

- **Deadzone control**

  Supports width configuration of control dead zone via "PIDConfig.SuperConfig.DeadBand". Within the dead zone, the system is deemed stable with unchanged PID output; beyond it, PID operates normally.

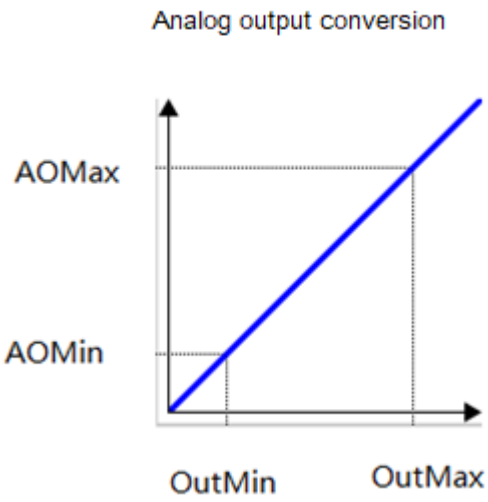
- **Delay start/delay shutdown function**

  For multi-channel device control, set different delayed startup/shutdown times to stagger on/off sequences. Prevent large current fluctuations caused by simultaneous multi-channel startup.

Delay start/shutdown time	Description
PIDConfig.GeneralConfig.DelayStartUp	After delaying the DelayStartUp time, the PID calculation starts.
PIDConfig.GeneralConfig.DelayShutdown	After delaying the DelayShutdown time, the PID calculation stops.

- **Output compensation function**

  The output compensation function directly adds the output compensation value to the result of the PID automatic calculation to form the output value. The output compensation function is active in automatic mode and inactive in manual mode.



- **Output amplitude limit function**

  If output > "PIDConfig.OutputConfig.OutMax" (Output Upper Limit), output = OutMax.

If output < "PIDConfig.OutputConfig.OutMin" (OutputLower Limit), output = OutMin.

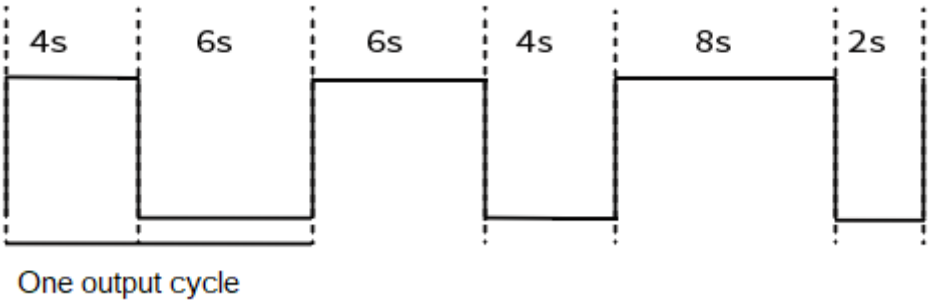
◦ **Output selection function**

Supports 3 modes of output control:

PIDConfig.OutputConfig.OutType	Output	Description
0	PWM output	Convert to switching output based on the PWM output cycle.
1	Analog output	Calibrate and output via linear conversion based on the analog output limits and PID output limits.  Analog output upper limit - PIDConfig.OutputConfig.AOMax Analog output lower limit - PIDConfig.OutputConfig.AOMin PID output upper limit - PIDConfig.OutputConfig.OutMax PID output lower limit - PIDConfig.OutputConfig.OutMin
2	Percentage output	Output within 0~100%

◦ **Fault detection**

If any bit of ErrorBits is triggered, Error is set to TRUE.



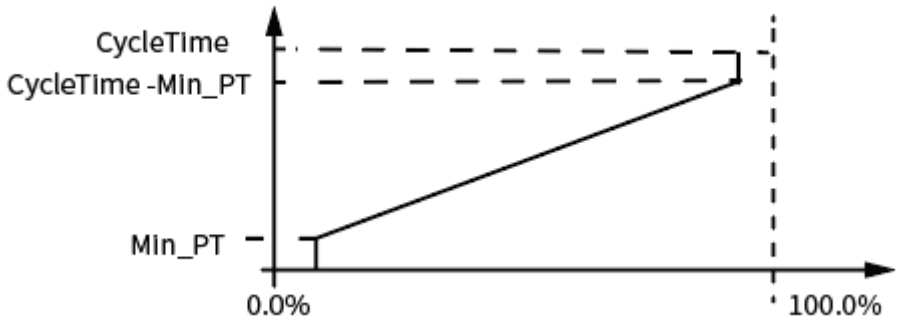
Bitwise description of ErrorBits		Error output configuration parameters PIDConfig.InputConfig.ErrorAction
Bit0 = 1	PV overlimit alarm	FALSE: Maintain previous output TRUE: Output the substitute value "PIDConfig.InputConfig.ErrorOut"
Bit1 = 1	Parameter configuration error alarm	

See ErrorID for detailed error information.

◦ **PWM output**

For PWM, the output is ON or OFF. The analog of PID output needs to be converted to digital output (ON/OFF) based on the duty cycle. The duty cycle is the percentage of the high-level pulse time to a whole pulse cycle.

For example: If the PID regulator output is 40% and the PWM output cycle "PIDConfig.GeneralConfig.CycleTime" is set to 10s, the ON duration is 10s × 40% = 4s, and the OFF duration is 10s – 4s = 6s. The duty cycle is 40%, meaning the signal stays ON for 4s and OFF for 6s per 10s cycle before repeating the calculation for the next cycle.



- Minimum On/Off pulse time

  To avoid frequent actuator operations, set the minimum on/off pulse time "PIDConfig.OutputConfig.Min_PT".

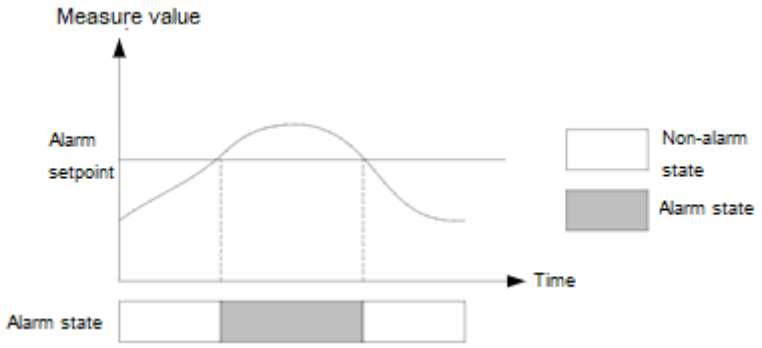
  If the calculated high-level pulse time < Min_PT, the output duty cycle is 0%.

  If the calculated high-level pulse time > PWM output cycle – Min_PT, the output duty cycle is 100%.

◦ **Cascade function**

Cascade control involves two or more cascaded PID controllers. The control variable of the master controller is interconnected with the setpoint of the slave controller, nesting the two control circuits. Cascade control has advantages that the slave circuit responds faster than the main circuit and can pre-compensate for interference in the inner circuit.

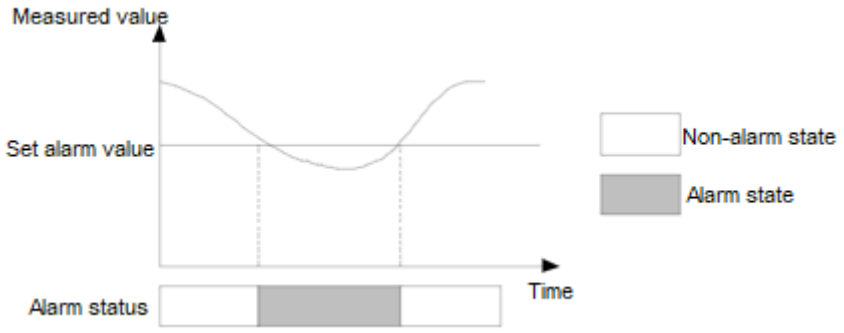
Note: Cascade control is only possible when there are other measurable variables in the process besides the main control variable, and the internal control circuit is much faster than the external circuit.



Bumpless switchover: If the slave circuit is not operating in cascade mode (automatic mode with external setpoint), the master circuit switches to tracking mode. The output value of the master circuit tracks the process value of the slave circuit to ensure a smooth transition to cascade mode.

Priority: Error response > Interlock > Manual > Master tracking mode (triggered by slave) > Automatic.

◦ **Upper and lower limit alarms**



- Upper limit alarm of the input PV value

An alarm is triggered when the measured PV value (or PV value after analog conversion) exceeds the upper limit alarm value.

- Lower limit alarm of the input PV value

  An alarm is triggered when the measured PV value (or PV value after analog conversion) falls below the lower limit alarm value.

- **Description**

  1. First, select the controlled physical object GeneralConfig.PhysicalQuantity, which includes General, Temperature, Pressure, and Flow options. For temperature control, select Temperature which features multiple optimizations; for non-temperature control, select the corresponding quantity, and configure Integral Separation via IntegralDivision and IntegralDivLimit in Advanced Settings.
  2. Enable the auto-tuning function at room temperature. Once the auto-tuning ends, xStartAT automatically sets to FALSE, and the tuned parameters Kp, Ti, Td are generated. Continue program operation to check if the controlled quantity reaches a steady state. If the usage needs are met after the controlled quantity reaches steady state, record the values of Kp, Ti, and Td, and write these values into the program as defaults. The Kp, Ti, and Td values can also be manually adjusted to meet the usage requirements.
  3. The larger the auto-tuning coefficient rATCoefficient, the faster the set temperature can be reached, but it may cause greater overshoot. The smaller the auto-tuning coefficient, the slower the set temperature can be reached. However, the temperature curve will be very smooth, without overshoot or with very small overshoot. If there is no requirement to use the default value of 0.5 and no customer needs to reach the set temperature faster, increase rATCoefficient and re-run auto-tuning. If the customer needs a smooth curve and small overshoot, decrease rATCoefficient and re-run auto-tuning.
  4. Interlock function: When the interlock switch InlockSW is triggered, the interlock safety value InlockVal is output.
  5. Output priority: Error output > Interlock output > Manual output > Automatic output.

  Note:

  1. Always verify parameter correctness before running the PID.

2. Auto-tuning is recommended to start at room temperature.
3. For common operating temperatures of 150 to 200 °C, tuning can be performed at 175 °C. Select the customer's typical operating temperature for tuning to ensure parameter accuracy.
4. Perform auto-tuning first to obtain initial PID parameters, then adjust them appropriately based on control performance.

- **Application instance**

  Control scheme configuration:

  Example:

No.	Instance	Type
1	LIC40201	Liquid level controller
2	LI40201	AI detection signal of liquid level
3	LV40201	Liquid level control valve

  Cascade control scheme configuration:

  LIC40201.PIDConfig.GeneralConfig.IsMaster = TRUE; // LIC40201 level control is master control.

  LIC40201.PIDConfig.GeneralConfig.PhysicalQuantity = Liquid Level; // The controlled quantity of LIC40201 is liquid level;

  FIC40201.PIDConfig.GeneralConfig. IsSlave = TRUE; // FIC40201 liquid level control is slave control.

FIC40201.PIDConfig.GeneralConfig.PhysicalQuantity = Flow; // The controlled quantity of LIC40201 is flow;

Example:

No.	Instance	Type
1	LIC40201	Liquid level controller
2	LI40201	AI detection signal of liquid level
3	FIC40201	Flow controller
4	LV40201	Flow control valve
5	FI40201	Flow AI detection signal

- **Fault codes (ErrorID)**

Grouping	Error No.	Fault Codes	Detailed Description
No error	0	NO_ERROR	No error
Wrong input interface parameters	1	KP_ERROR	Kp configuration error
	2	TI_ERROR	Ti configuration error
	3	TD_ERROR	Td configuration error
	4	KPCOOL_ERROR	Cooling Kp configuration error
	5	TICOOL_ERROR	Cooling Ti configuration error

Advanced	37	ECMAX_ERROR	Maximum heating speed - advanced configuration error
	38	KD_GAIN_ERROR	Incomplete derivative coefficient - advanced configuration error
	39	INTEGRAL_MAX_ERROR	Maximum integral value - advanced configuration error
	40	INTEGRAL_CUT_ERROR	Reduction of integral coefficient upon setpoint change - advanced configuration error
Cooling configuration (applicable to PID_ATC)	41	COOL_PID_TYPE_ERROR	Cooling PID type - cooling configuration error
	42	SAMPLE_COOL_TIME_ERROR	Cooling sampling period - cooling configuration error
	43	CYCLE_COOL_TIME_ERROR	Cooling output cycle - cooling configuration error
	44	COOL_OFFSET_ERROR	Cooling set deviation - cooling configuration error

Grouping	Error No.	Fault Codes	Detailed Description
PV limit alarm	45	PV_LOW_LIMIT_ALARM	PV low limit alarm. Check the PIDConfig.InputConfig.PVLowLimit and PIDConfig.InputConfig.PVHighLimit parameters to ensure the PV value is within the limits.
	46	PV_HIGH_LIMIT_ALARM	PV upper limit alarm. Check PIDConfig.InputConfig.PVLowLimit and PIDConfig.InputConfig.PVHighLimit parameters to ensure the PV value is within the limits.
Input interface configuration error	47	PV_AND_AI_NOINPUT	PV and AI are not configured for input simultaneously
Input configuration error	48	SP_RAT_ERROR	Setpoint change setting error
Advanced configuration fault	49	INTEGRAL_DIV_ERROR	Integral separation limit setting error
Advanced configuration fault	50	DEADBAND_ERROR	The control deadzone is incorrectly configured.
Cooling output configuration error (applicable to PID_ATC)	51	COOL_MINPT_ERROR	The minimum ON/OFF time for cooling is incorrectly configured.
Output configuration error	52	OUT_MINPT_ERROR	The minimum ON/OFF time is incorrectly configured.
Wrong Input interface parameters	53	INLOCKVAL_ERR	Interlock safety value configuration error
Wrong Input interface parameters	54	CASSLAVESTATE_PV_ERR	PV overlimit in slave data
Wrong input interface parameter	55	CASSLAVESTATE_OVE_ERR	OVE configuration error in slave data

Grouping	Error No.	Fault Codes	Detailed Description
Wrong input interface parameters	56	CASSLAVESTATE_CASSTATE_ERR	Slave status configuration error in slave data
General configuration fault	57	AT_NUM_ERROR	Number of Auto-tuning waveforms configuration error
General configuration fault	58	AT_OUT_ERROR	Auto-tuning output percentage configuration error

- **Error handling**

  Action on error alarm for PIDConfig.InputConfig.ErrorAction

  1. When PIDConfig.InputConfig.ErrorAction = FALSE, maintain previous output on error alarm. Recalculate current output upon error recovery.
  2. When PIDConfig.InputConfig.ErrorAction = TRUE, output ErrorOut substitute value on error alarm. Recalculate current output upon error recovery.

18.3.1.6 PID_ATC

Bipolar temperature PID controller.

	SuperConfig		PID_SUPERCONFIG	-	-	Advanced PID configuration structure.

Input/Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	Variable	Name	Data Type	Valid Range	Default Value	Description
	SuperConfig	Fuzzy	BOOL	TRUE, FALSE	FALSE	Fuzzy control enable: 0: Disable fuzzy self-adaptation. 1: Enable fuzzy self-adaptation.
		ECMax	REAL	Follows data type	1.0	Fuzzy control, maximum heating rate, °C/s.
		IntegralSuspend	BOOL	TRUE, FALSE	FALSE	Integral pause: 0: Normal integral. 1: Integral paused.
		IntegralDivision	BOOL	TRUE, FALSE	TRUE	Integral separation for non-temperature objects: 0: No integral separation. 1: Integral separation.
		IntegralClear	BOOL	TRUE, FALSE	FALSE	Integral clearance: 0: Normal integral. 1: Integral cleared.

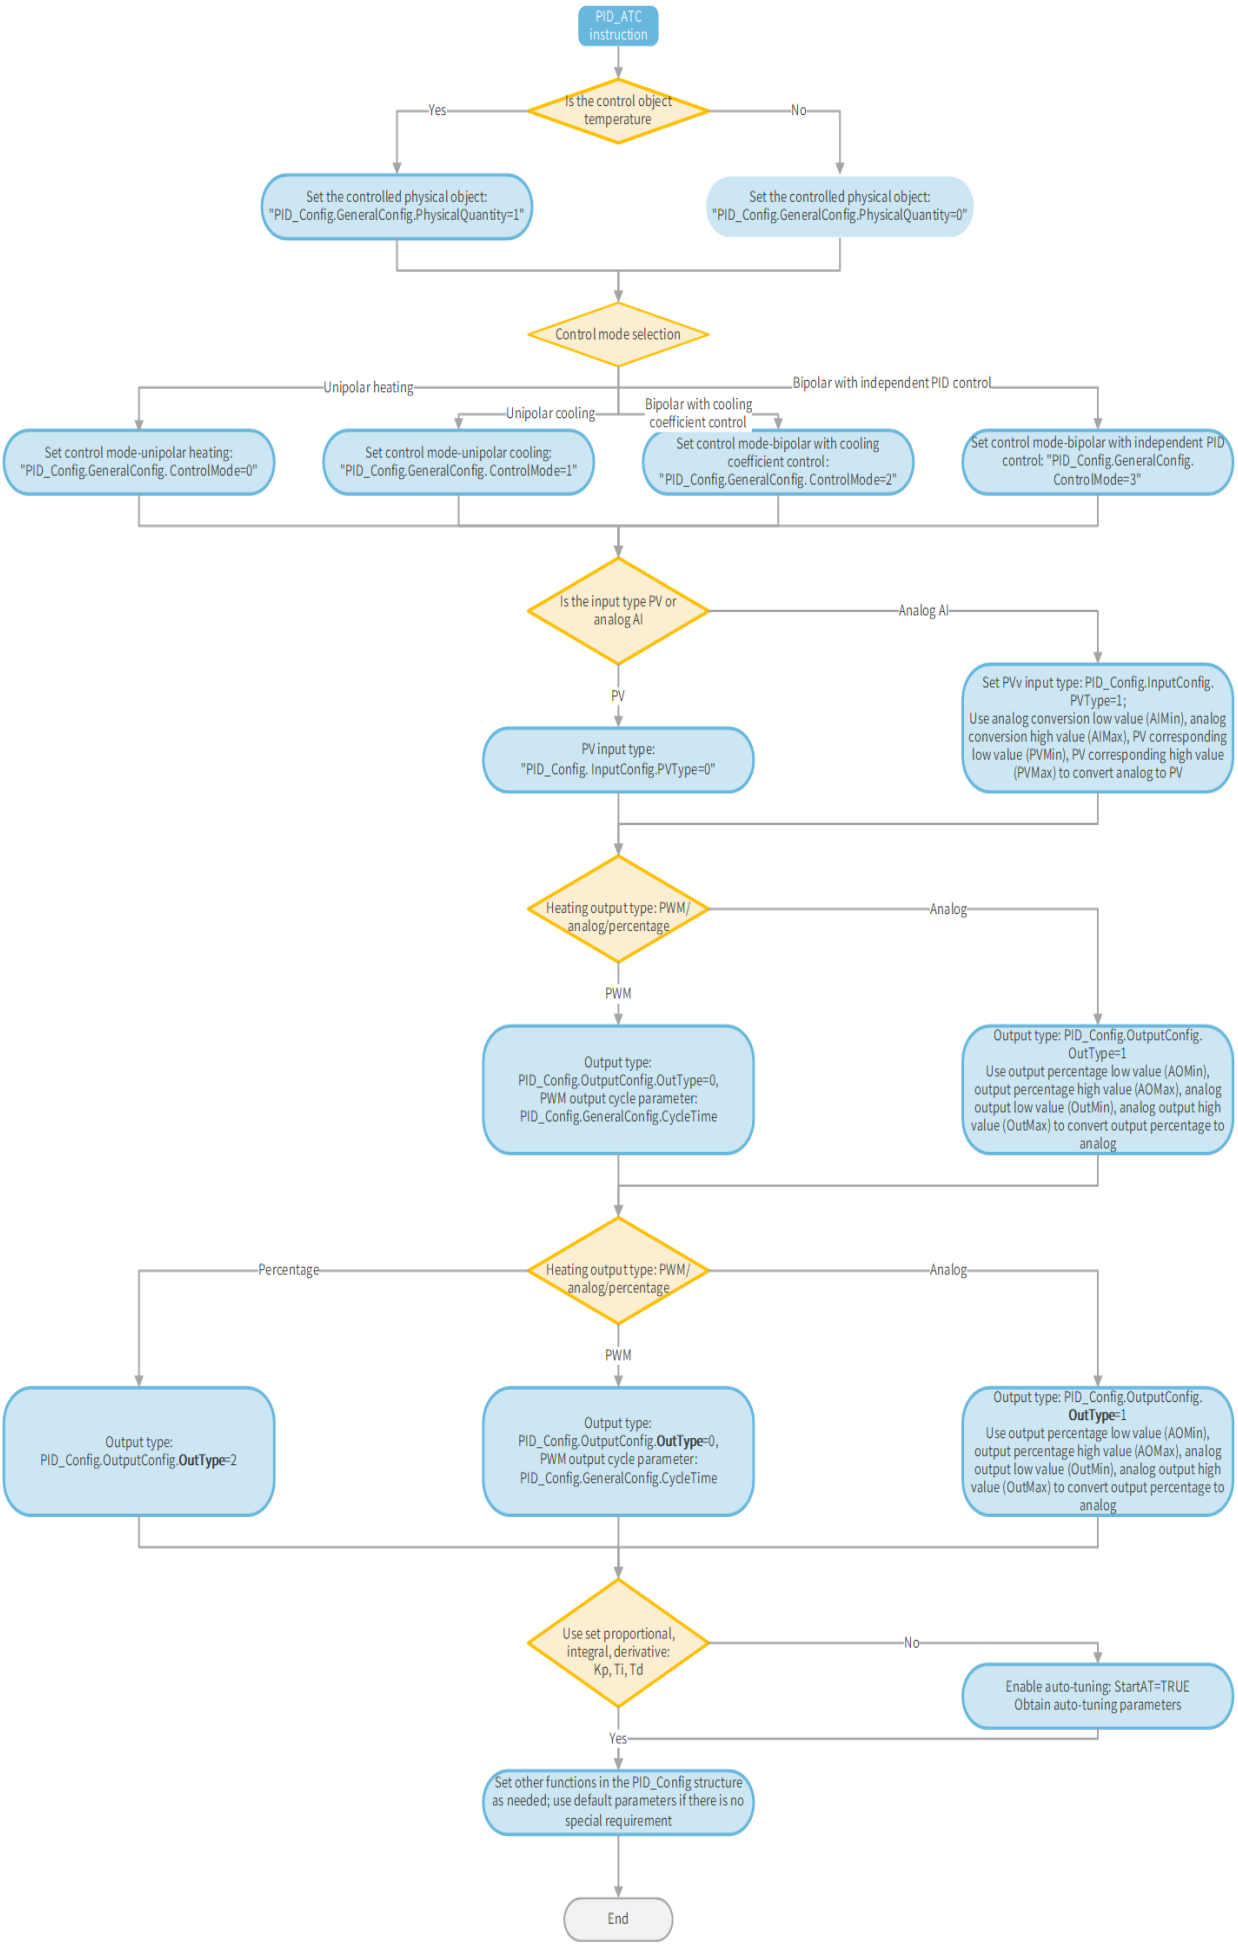
Input/Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	Variable	Name	Data Type	Valid Range	Default Value	Description
		IntegralMax	REAL	-100.0 to 100.0	100.0	Maximum integral value / the upper limit of the accumulated integral value.
		IntegralCut	REAL	0.0 to 1.0	0.75	Cut the integral coefficient when the setpoint changes.
		KdGain	REAL	0.0 ~ 1.0	0.65	Incomplete derivative coefficient. The larger the value, the smoother the differential effect. When set to 1, the differential action is disabled.

Input/Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	Variable	Name	Data Type	Valid Range	Default Value	Description
		IntegralDivLimit	REAL	0.0 to 100.0	50.0	Integral separation limit. When the value of IntegralDivision is TRUE for non-temperature objects, integral action is disabled if the deviation is greater than the integral separation limit.
		DeadBand	REAL	0.0 to 100.0	0.0	Deviation deadzone limit
Input/Output	StartAT	Auto-tuning switch	BOOL	TRUE, FALSE	FALSE	TRUE: Start tuning. After parameter tuning is completed, it will reset to FALSE and can be triggered multiple times.

Input/Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	Kp	Proportional coefficient	REAL	0.01 ~ 1000.0	60.0	Proportional coefficient. Configuration error will report an error ID. The larger the Kp value, the stronger the proportional action.
	Ti	Integral time	REAL	0.0 ~100000.	400.0	Integral time. Configuration error will report an error ID. 0 indicates no integral action. The larger the Ti value, the weaker the integral action.
	Td	Derivative time	REAL	0.0 ~ 10000.0	50.0	Derivative time. Configuration error will report an error ID. 0 indicates no derivative action. The larger the Td value, the stronger the derivative action.

Input/Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	KpCool	Cooling proportional coefficient	REAL	0.01 ~ 1000.0	0.0	Cooling proportional coefficient, an error ID will be reported if configured incorrectly. The larger the KpCool value, the stronger the proportional action.
	TiCool	Cooling integral time	REAL	0.0 ~ 10000.0	0.0	Cooling integral time, configuration error will report an error ID. 0 indicates no integral action. The larger the TiCool value, the weaker the integral action.
	TdCool	Cooling derivative time	REAL	0.0 ~ 10000.0	0.0	Cooling derivative time, configuration error will report an error ID. 0 indicates no derivative action. The larger the TdCool value, the stronger the derivative action.

Input/Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	CoolCoefficient	Cooling coefficient	REAL	0.0 to 100.0	0.1	Cooling coefficient, When mode GeneralConfig. ControlMode = 2, cooling output is calculated based on heating control coefficient and cooling coefficient. 0 indicates no cooling action.
Output	HeatPWM	Heating PWM output	BOOL	TRUE, FALSE	FALSE	PWM heating output. TRUE: On. FALSE: Off.
	HeatPercent	Heating percentage output	REAL	0.0 to 100.0 %	0.0	Heating output percentage (depends on output type selection).
	HeatAO	Heating analog output	DINT	Follows data type	0	Heating output analog value.
	CoolPWM	PWM cooling output	BOOL	TRUE, FALSE	FALSE	Cooling PWM output. TRUE: On. FALSE: Off.
	CoolPercent	Cooling percentage output	REAL	0.0 to 100.0 %	0.0	Cooling output percentage (depends on output type selection).



Input/Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	CoolAO	Cooling analog output	DINT	Follows data type	0	Cooling output analog value.
	PIDOutput	PID output variable structure	PID_OUTPUT	-	-	Output structure.

Name	Data Type	Valid Range	Default Value	Description
PVOut	REAL	Follows data type	0.0	Actually calculated PV value.
ECMaxOut	REAL	Follows data type	0.0	Fuzzy control, maximum heating rate, ℃/s.
ATState	DINT	0, 1, 2	0	Auto-tuning state 0: Untuned. 1: Tuning. 2: Tuned.
ErrorID	DINT	Follows data type	0	Parameter fault code.
SPOut	REAL	Follows data type	0.0	Actually calculated SP value.

Input/Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	State	Operation state	DINT	Follows data type	0	Operation state: 0: Not activated. 1: Manual. 2: Automatic. 3: Interlocked. 4: Tuning. 5: Last valid output on error. 6: Substitute value output on error. 7: Master tracking.
	Error	Operation error	BOOL	TRUE, FALSE	FALSE	Operation error marking, see ErrorBits for details.
	ErrorBits	Fault code	WORD	Follows data type	0	Fault code, expressed by bits: bit0 = 1: PV overlimit. bit1 = 1: Parameter error (For detailed information about the parameter error, see PIDOutput.ErrorID.)

Input/Output	Variable	Name	Data Type	Valid Range	Default Value	Description
	SlaveState	Slave status	Slave_Data	-	-	In case of slave, the structure of the operation state must be connected back to CasSlaveState, the input of the master control.

- **Parameter initialization flow for PID_ATC**

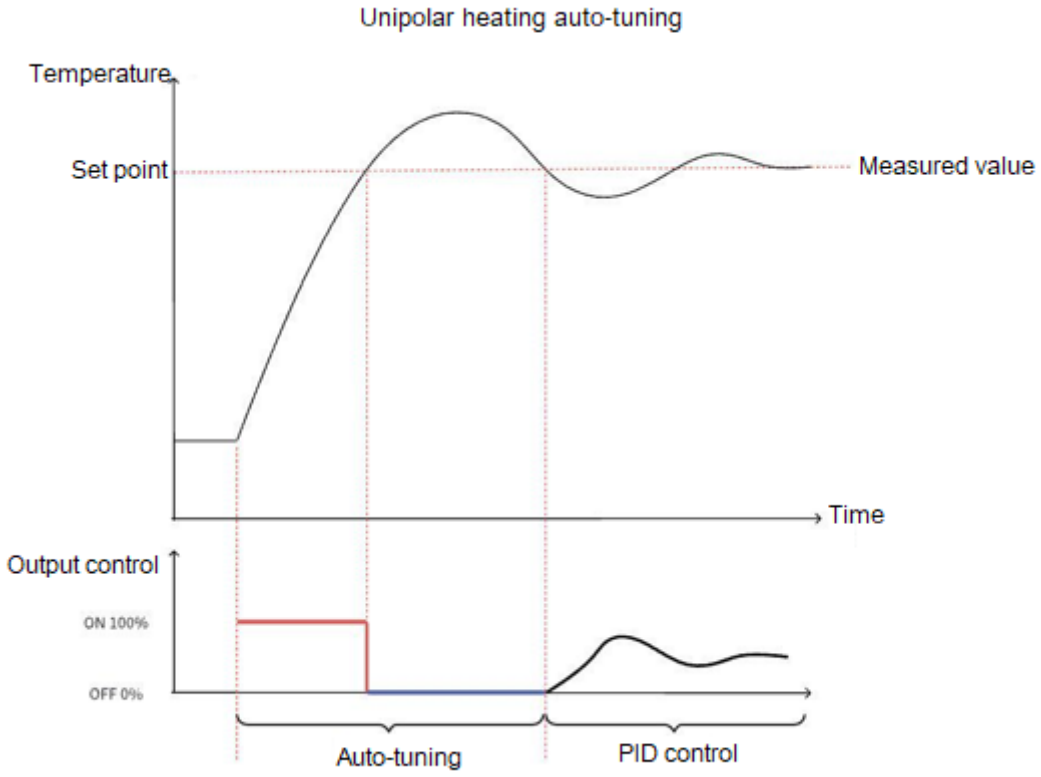
- **Parameter description**
  - StartAT auto-tuning

This instruction has an auto-tuning function, which can automatically calculate the optimal values of the PID constants Kp, Ti, Td.

Auto-tuning execution conditions for heating applications:

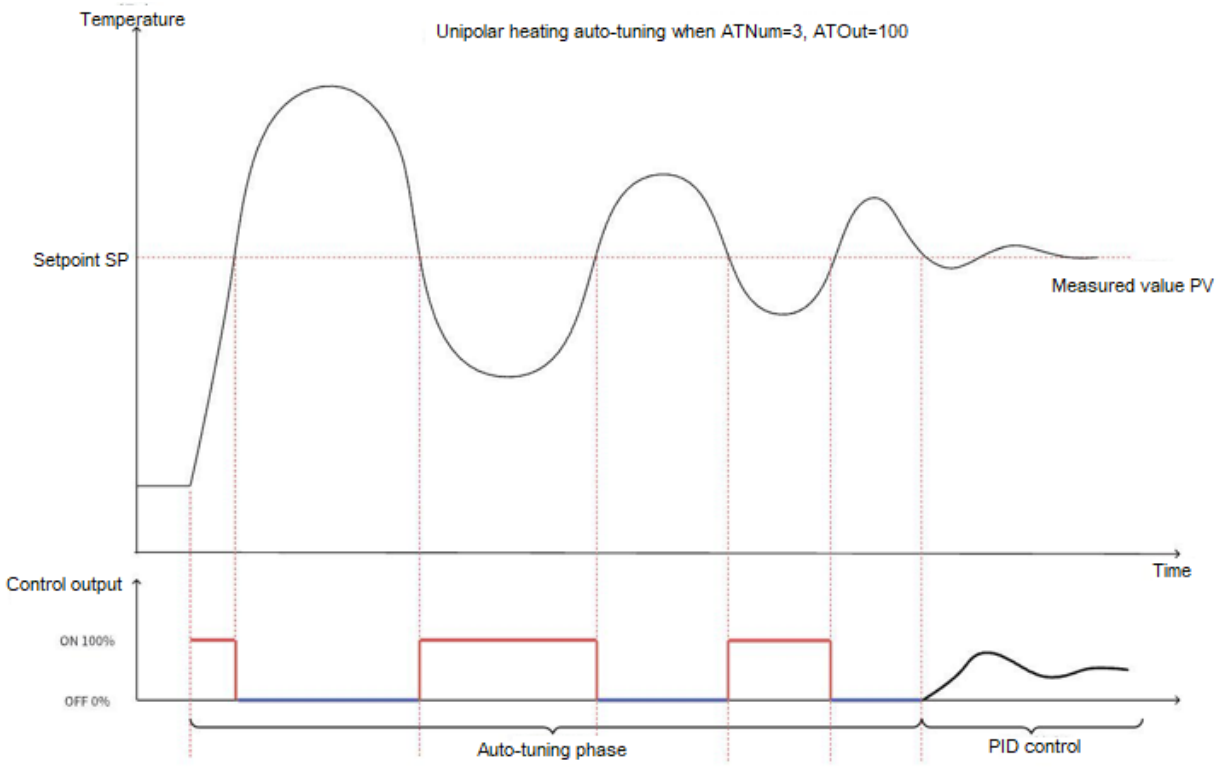
1) The current value is less than the setpoint. Generally, the setpoint should be the common operating temperature of the equipment.

2) When StartAT is set to TRUE: If Enable changes from FALSE to TRUE, auto-tuning will be executed at the start of operation. If Enable is TRUE and PID calculation is in progress, auto-tuning will start during operation when StartAT changes from FALSE to TRUE.



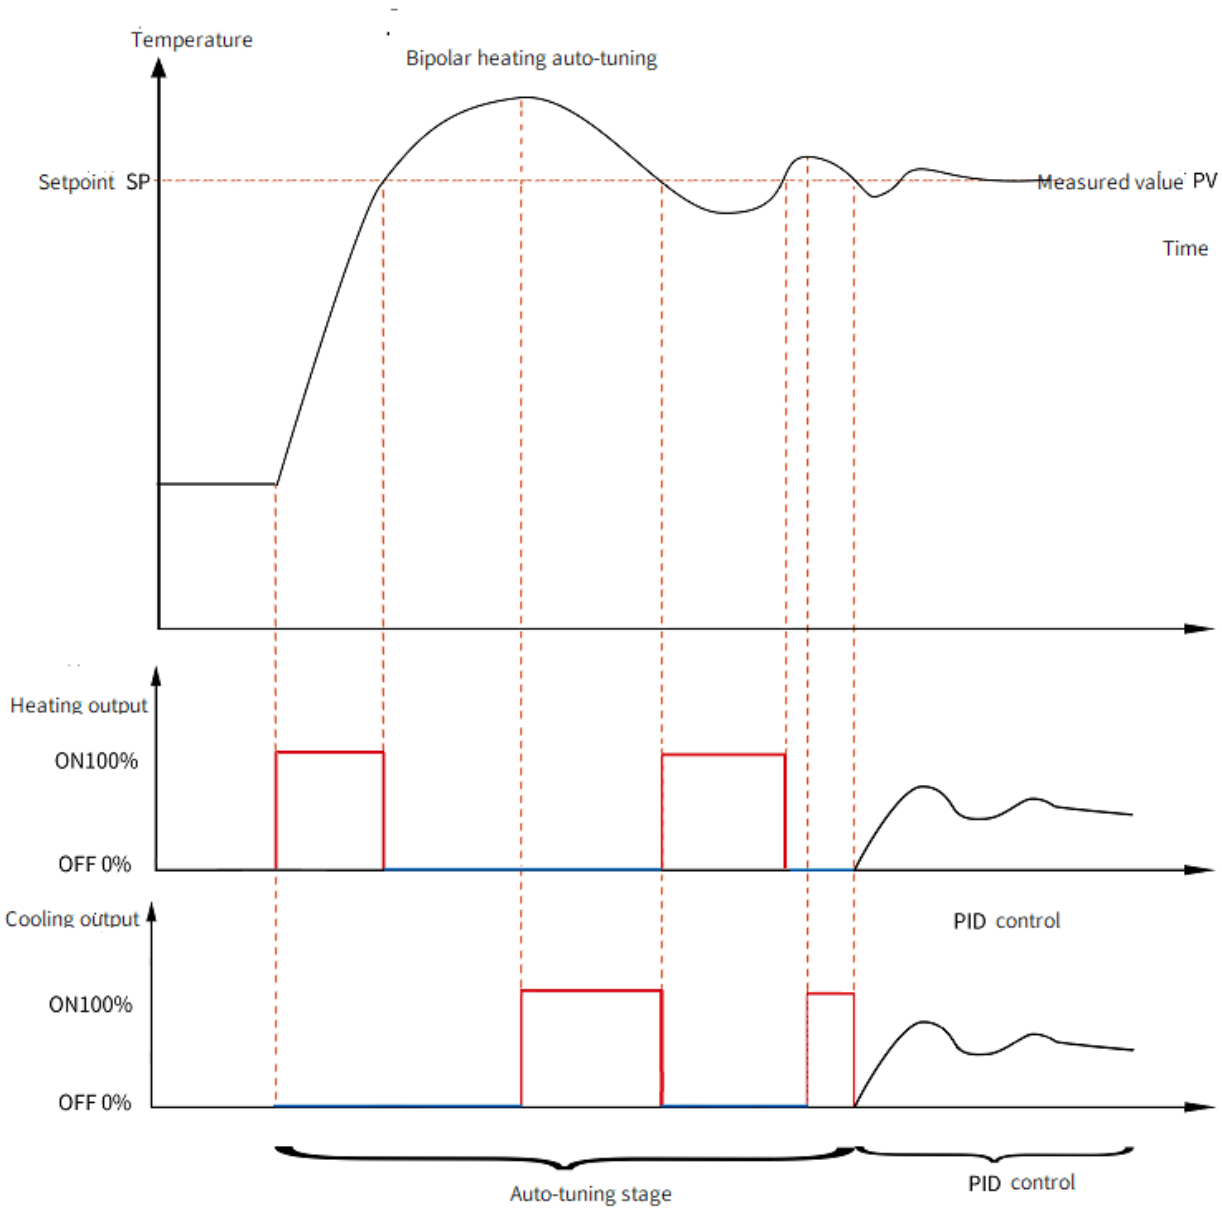
After auto-tuning starts, the value of State.1 will be set to 1. When auto-tuning is completed, the value of State.1 will be set to 0 and the value of State.2 will be set to 1.

In any of the above cases, if StartAT changes from TRUE to FALSE during auto-tuning, the auto-tuning process will be terminated, with State.1 = 0 and State.2 = 0.



Note: After auto-tuning is completed, StartAT will automatically be set to FALSE.

3) Auto-tuning output percentage ATOut: Used to set the heating/cooling output percentage during the auto-tuning phase, supports only unipolar mode.
Number of auto-tuning waveforms ATNum: Auto-tuning is performed with multiple oscillation wavefroms based on the oscillation parameter ATNum.



- When ATOut = 100 and ATNum = 1, the diagram of the unipolar auto-tuning process is shown below.

- When ATOut = 100 and ATNum = 3, the calculation is performed based on three oscillation parameters, and the diagram of the unipolar auto-tuning process is shown below.

- Bipolar auto-tuning will oscillate two waveforms around the setpoint. After auto-tuning is completed, StartAT will be set to FALSE;

Note: During the auto-tuning process, parameter configurations cannot be modified; otherwise, unreasonable parameters may be obtained.

NOTE

LoopControl 1.1.0.0 and later versions supports multi-waveforms auto-tuning algorithm.

- **Function**

  PID_ATC is a dedicated temperature controller for heating, cooling, and heating-cooling applications. It provides two independent outputs for heating and cooling respectively, and supports cascade configuration as well as auto-tuning.

  - **Calculation formula**

$$\mathbf{AV} = \boldsymbol{K_p} * \left[(\boldsymbol{SP} - \boldsymbol{PV}) + \frac{\mathbf{1}}{\boldsymbol{T_i} * \boldsymbol{S}} (\boldsymbol{SP} - \boldsymbol{PV}) + \frac{T_d}{\boldsymbol{S}} (\boldsymbol{SP} - \boldsymbol{PV}) \right]$$

  Discretization formula:

$$\mathbf{AV(k)} = K_p * \mathbf{E}(k) + K_p * \frac{cycle}{T_i} \sum \mathbf{E}(k) + \frac{K_p * T_D}{cycle} (\mathbf{E}(k) - \mathbf{E}(k-1))$$

◦ **Operation mode**

Operation Mode	Action
Automatic	Calculate according to the proportional-integral-derivative (PID) principle and generate the output value of the PID module. The calculation result of the PID module is limited by "output amplitude".
Manual	Directly control the output (value written by the operator or online logic). The output in this mode is limited by "output amplitude".
Interlock	In this mode, the PID stops automatic calculation, and the output value of the PID module is a preset value "InlockVal", generally referred to as the interlock setpoint. The interlock function can also be used as a "tracking" function. When certain conditions are met (interlock "InlockSW" = TRUE), the PID module automatically switches to this mode. When the interlock conditions are not met, the PID module switches back to the previous mode.

1. Interlock mode has the highest priority, followed by manual mode, and then automatic mode.
2. Automatic mode: Primarily used for setpoint control. The setpoint can be configured via the interface.
3. The selection of external or internal setpoint can be configured by the parameter PIDConfig.InputConfig.SPSel:

   SPSel = FALSE: External setpoint (the setpoint configured in the logic configuration).

   SPSel = TRUE: Internal setpoint (the preset internal setpoint).

   Note: Enable "Internal setpoint tracks external setpoint" (PIDConfig.InputConfig.SPTrack = TRUE) to prevent loop fluctuations during setpoint switching. When external setpoint is selected, internal setpoint tracks it for bumpless switchover. Switching from internal to external setpoint directly adopts the real-time logic configuration value, which may cause bumpy switchover.

◦ **Bumpless switchover**

Operation Mode	Action
Interlock -> Manual	In interlock mode, the interlock value is output directly. The manual value tracks the output value to ensure bumpless switchover.

Operation Mode	Action
Interlock -> Automatic	In interlock mode, the interlock value is output directly. When switching to automatic mode, if the external setpoint is used, the logic calculation value will be adopted directly for PID calculation and output, which may cause disturbance.
Manual -> Interlock	The manual output is the manual value. Switching to interlock mode will output the interlock value directly, resulting in bumpy switchover.
Manual -> Automatic	The manual output is the operator-set value. When switching to automatic mode, if the external setpoint is used, the logic calculation value will be adopted directly for PID calculation and output, enabling bumpless switchover (disturbance is limited to the incremental part).
Automatic->Interlock	In automatic mode, the output is the normal calculation value. Switching to interlock mode will output the interlock value directly, resulting in bumpy switchover.
Automatic->Manual	In automatic mode, the output is the normal calculation value. The manual value tracks the output value to ensure bumpless switchover

- **Functional logic diagram (reverse-acting example)**

◦ **Multiple control modes**

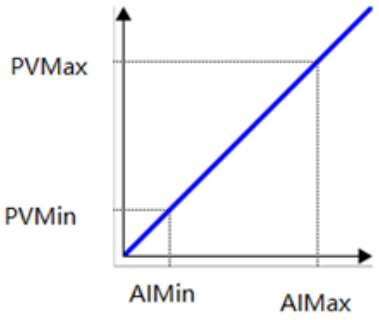
Supports selection of 4 control modes, which is configurable based on actual requirements:

Control Mode PIDConfig.GeneralConfig.Control Mode	Control mode	Note
0	Unipolar heating	For heating-only control scenarios
1	Unipolar cooling	For cooling-only control scenarios

Control Mode PIDConfig.GeneralConfig.Control Mode	Control mode	Note
2	Bipolar with cooling coefficient control	Applicable for scenarios where heating and cooling actuators have similar time responses but different gains. The cooling output is calculated based on the heating PID parameters and the cooling coefficient CoolCoefficient.
3	Bipolar with independent PID control	It applies to cases where heating and cooling actuators differ in time response and gain. Output calculation adopts independent PID parameters for heating and cooling.

◦ **Setpoint change limit function**

In automatic mode, the change in setpoint (external and internal) is detected. If the change exceeds the predefined limit (PIDConfig.InputConfig.SPRatio), the actual setpoint used for calculation is limited to the change, and the setpoint will gradually approach the target value within the change limit range.



△SP > SPRatio (setpoint change): SP = LastSP + SPRatio

△SP < SPRatio (setpoint change): SP = LastSP - SPRatio

◦ **Input selection function**

Two modes of input signals can be selected.

PIDConfig.InputConfig.PVType	Input	Description
0	Current input "PV"	-

PIDConfig.InputConfig.PVType	Input	Description
1	Analog input "AI"	Calibrate via linear conversion based on analog input limits and PV limits.  Analog upper limit - PIDConfig.InputConfig.AIMax Analog lower limit - PIDConfig.InputConfig.AIMin PV upper limit - PIDConfig.InputConfig.AIMax PV lower limit - PIDConfig.InputConfig.AIMin

- **Integral function**

  Integral separation

  Integral windup is mainly caused by the integral term. To overcome this issue, it is crucial to limit integral action and prevent excessive integral accumulation. The integral separation function can eliminate integral windup and enable the function block to resist integral windup.

  For non-temperature-controlled objects, the configuration instructions for integral separation are as follows:

Integral separation enable PIDConfig.GeneralConfig.IntegralDivision	Integral separation limit PIDConfig.GeneralConfig.IntegralDivLimit
TRUE	|Deviation| >= Integral Separation Limit: Integral component calculation is disabled (control law operates as PD control).
	|Deviation| < Integral Separation Limit: Full integral calculation is enabled (control law operates as PID control).
FALSE	Full integral calculation is always enabled.

  Integral pause

  When integral suspend is triggered "PIDConfig.GeneralConfig.IntegralSuspend = TRUE", the integral action remains unchanged and stops accumulating.

Integral clearance

When integral clear is triggered "PIDConfig.GeneralConfig.IntegralClear = TRUE", integral action will be cleared to 0.

Integral cut coefficient

When the setpoint changes, the initial integral action can be reduced by setting the integral cut coefficient "PIDConfig.SuperConfig.IntegralCut". The setting range is [0,1], default is 0.75.

- **Incomplete derivative function**

  Incomplete derivative is equivalent to adding a first-order inertial element to the derivative action, which moderates the derivative effect and effectively improves the system's control performance.

Configuration parameter: PIDConfig.SuperConfig.KdGain	Derivative action
0	Derivative action is only active for the current cycle (default value).
(0,1)	The larger the value, the smoother the derivative action.
1	The derivative action is disabled.

- **Deadzone control**

  Supports width configuration of control dead zone via "PIDConfig.SuperConfig.DeadBand". Within the dead zone, the system is deemed stable with unchanged PID output; beyond it, PID operates normally.

- **Delay start/delay shutdown function**

  For multi-channel device control, set different delayed startup/shutdown times to stagger on/off sequences. Prevent large current fluctuations caused by simultaneous multi-channel startup.

Delay start/shutdown time	Description
PIDConfig.GeneralConfig.DelayStartUp	After delaying the DelayStartUp time, the PID calculation starts.
PIDConfig.GeneralConfig.DelayShutdown	After delaying the DelayShutdown time, the PID calculation stops.

- **Output compensation function**

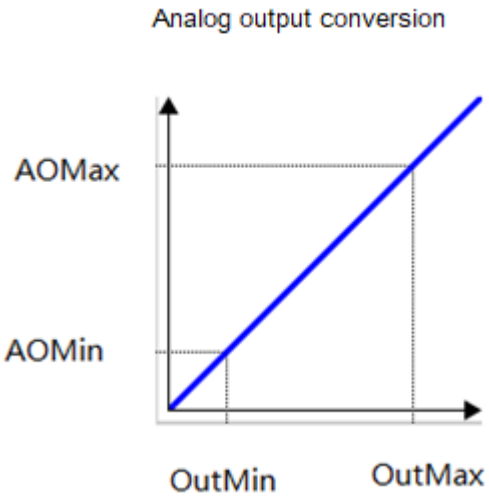
  The output compensation function directly adds the output compensation value to the result of the PID automatic calculation to form the output value. The output compensation function is active in automatic mode and inactive in manual mode.

  Heating output = Heating PID calculation output + Heating output compensation (PIDConfig.OutputConfigHeat.OutputOffset)

  Cooling output = Cooling PID calculation output + Cooling output compensation (PIDConfig.OutputConfigCool.OutputOffset)

- **Output amplitude limit function**

When the heating output value > Heating output upper limit "PIDConfig.OutputConfigHeat.OutMax", th e heating output value = Heating output upper limit.



When the heating output value < Heating output lower limit "PIDConfig.OutputConfigHeat.OutMin", the heating output value = Heating output lower limit.

When the cooling output value > the cooling output upper limit "PIDConfig.OutputConfigHeat.OutMax" , the cooling output value = the cooling output upper limit.

When the cooling output value < the cooling output lower limit "PIDConfig.OutputConfigHeat.OutMin", the cooling output value = the cooling output lower limit.

- **Output selection function**

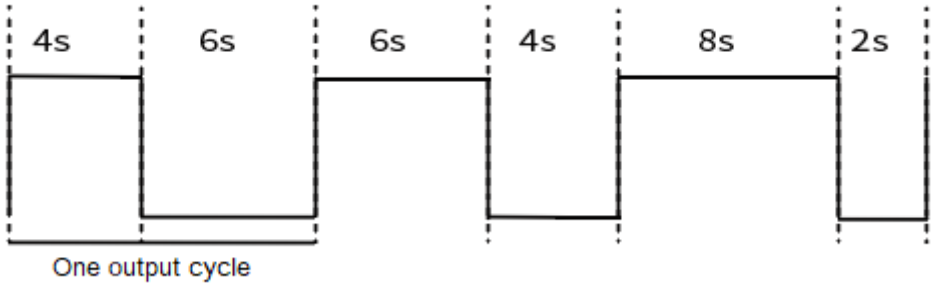
  Supports 3 modes of output control:

Heating output type - PIDConfig.OutputConfigHeat.OutType Cooling output type - PIDConfig.OutputConfigCool.OutType	Output	Description
0	PWM output	Convert to switching output based on the PWM output cycle.
1	Analog output	Calibrate and output via linear conversion based on the analog output limits and PID output limits.  Analog output upper limit - PIDConfig.OutputConfig.AOMax Analog output lower limit - PIDConfig.OutputConfig.AOMin PID output upper limit - PIDConfig.OutputConfig.OutMax PID output lower limit - PIDConfig.OutputConfig.OutMin

Heating output type - PIDConfig.OutputConfigHeat.OutType Cooling output type - PIDConfig.OutputConfigCool.OutType	Output	Description
2	Percentage output	Output within 0~100%

◦ **Fault detection**

If any bit of ErrorBits is triggered, Error is set to TRUE.



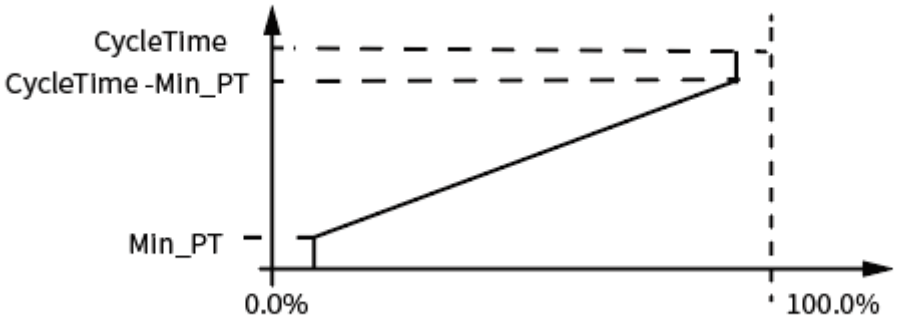
Bitwise description of ErrorBits		Error output configuration parameters PIDConfig.InputConfig.ErrorAction
Bit0 = 1	PV overlimit alarm	FALSE: Maintain previous output TRUE: Output the substitute value "PIDConfig.InputConfig.ErrorOut"
Bit1 = 1	Parameter configuration error alarm	

See ErrorID for detailed error information.

◦ **PWM output**

For PWM, the output is ON or OFF. The analog of PID output needs to be converted to digital output (ON/OFF) based on the duty cycle. The duty cycle is the percentage of the high-level pulse time to a whole pulse cycle.

For example: If the PID regulator output is 40% and the PWM output cycle "PIDConfig.GeneralConfig.CycleTime" is set to 10s, the ON duration is 10s × 40% = 4s, and the OFF duration is 10s – 4s = 6s. The duty cycle is 40%. The signal stays ON for 4s and OFF for 6s per 10s cycle before repeating the calculation for the next cycle.



▪ Minimum On/Off pulse time

To avoid frequent operation of the actuators, the minimum heating on/off pulse time PIDConfig.OutputConfigHeat.Min_PT and minimum cooling on/off pulse time PIDConfig.OutputConfigCool.Min_PT can be set separately.

If the calculated high-level pulse time < Min_PT, the output duty cycle is 0%.

If the calculated high-level pulse time > PWM output cycle – Min_PT, the output duty cycle is 100%.

- **Cascade function**

  Cascade control involves two or more cascaded PID controllers. The control variable of the master controller is interconnected with the setpoint of the slave controller, nesting the two control circuits. Cascade control has advantages that the slave circuit responds faster than the main circuit and can pre-compensate for interference in the inner circuit.
  Note: Cascade control is only possible when there are other measurable variables in the process besides the main control variable, and the internal control circuit is much faster than the external circuit.

  Bumpless switchover: If the slave circuit is not operating in cascade mode (automatic mode with external setpoint), the master circuit switches to tracking mode. The output value of the master circuit tracks the process value of the slave circuit to ensure a smooth transition to cascade mode.

  Priority: Error response > Interlock > Manual > Master tracking mode (triggered by slave) > Automatic.

- **Description**

1. First, select the controlled physical quantity GeneralConfig.PhysicalQuantity, which includes General and Temperature options.
   0: General, primarily for pressure, flow, and other control scenarios. For general control, integral separation can be configured via the IntegralDivision and IntegralDivLimit in Advanced Settings.

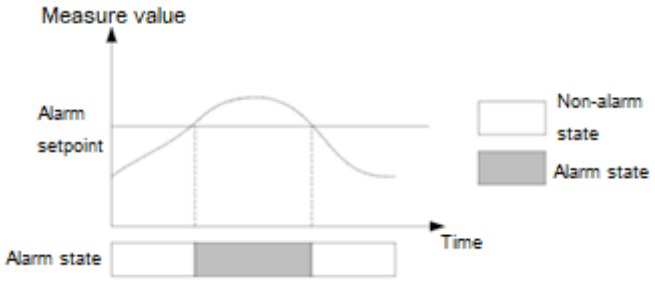
   1: Temperature, optimized for various temperature controls.

2. Enable the auto-tuning function at room temperature. Once the auto-tuning ends, xStartAT automatically sets to FALSE, and the tuned parameters Kp, Ti, Td are generated. Continue program operation to check if the controlled quantity reaches a steady state.

3. If the usage needs are met after the controlled quantity reaches steady state, record the values of Kp, Ti, and Td, and write these values into the program as defaults. The Kp, Ti, and Td values can also be manually adjusted to meet the usage requirements.

4. The larger the auto-tuning coefficient rATCoefficient, the faster the set temperature can be reached, but it may cause greater overshoot. The smaller the auto-tuning coefficient, the slower the set temperature can be reached. However, the temperature curve will be very smooth, without overshoot or with very small overshoot. If there is no requirement to use the default value of 0.5 and no customer needs to reach the set temperature faster, increase rATCoefficient and re-run auto-tuning. If the customer needs a smooth curve and small overshoot, decrease rATCoefficient and re-run auto-tuning.

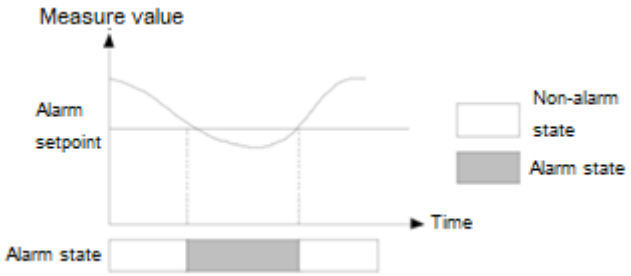
5. Interlock function: When the interlock switch InlockSW is triggered, the interlock safety value InlockVal is output.



6. Output priority: Error output > Interlock output > Manual output > Automatic output.

Note:

1. Always verify parameter correctness before running the PID.
2. Auto-tuning is recommended to start at room temperature.
3. For common operating temperatures of 150 to 200 °C, tuning can be performed at 175 °C. Select the customer's typical operating temperature for tuning to ensure parameter accuracy.
4. Perform auto-tuning first to obtain initial PID parameters, then adjust them appropriately based on control performance.



- **Upper and lower limit alarms**
  - Upper limit alarm of the input PV value

    An alarm is triggered when the measured PV value (or PV value after analog conversion) exceeds the upper limit alarm value.

  - Lower limit alarm of the input PV value

    An alarm is triggered when the measured PV value (or PV value after analog conversion) falls below the lower limit alarm value.

- **Application example**

  Control scheme configuration

Example

No.	Instance	Type
1	TIC40201	Temperature controller
2	TI40201	Temperature TC detection signal
3	FV40201	Hot water flow control valve
4	FV40202	Cold water flow control valve

Cascade control scheme configuration

Example

No.	Instance	Type
1	TIC40201	Temperature controller
2	TI40201	Temperature TC detection signal
3	FIC40201	Flow controller
4	LV40201	Liquid level control valve

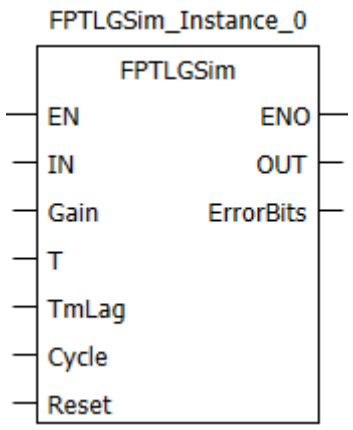
No.	Instance	Type
5	FI40201	Flow AI detection signal

- **Fault codes (ErrorID)**

  The fault codes (ErrorID) are the same as PID_AT. For details, see Fault codes (ErrorID).

- **Error handling**

  Action on error alarm for PIDConfig.InputConfig.ErrorAction



1. When PIDConfig.InputConfig.ErrorAction = FALSE, maintain previous output during error alarm, and recalculate current output upon error recovery.
2. When PIDConfig.InputConfig.ErrorAction = TRUE, output ErrorOut substitute value on error alarm, and recalculate current output upon error recovery.

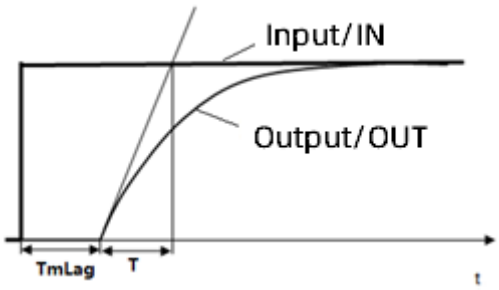
- **Function**

  This instruction can be used to simulate a plant/device object with first-order lag plus pure dead time.

  For systems with continuously varying parameters in industrial process control, such as temperature, pressure, and flow, the mathematical model can be simplified as a first-order lag plus pure dead time.

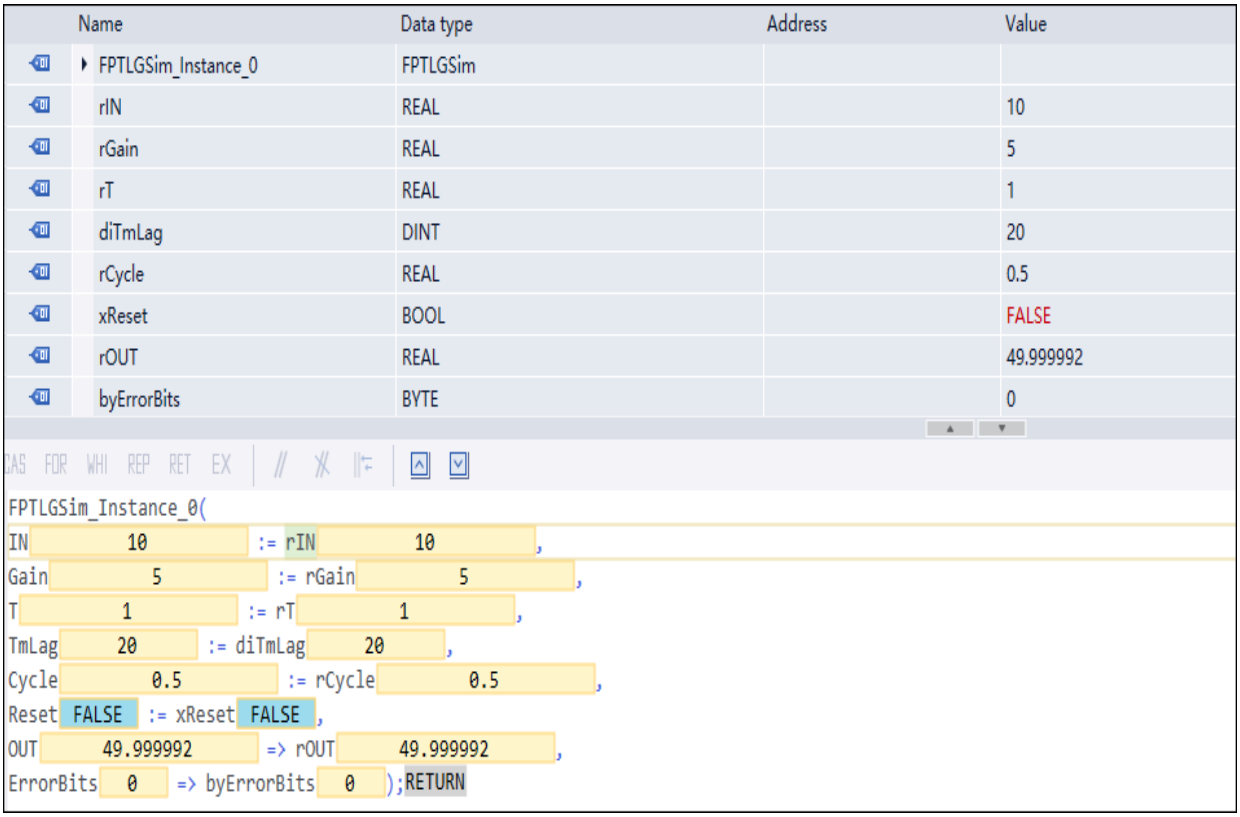
  Mathematical model:



$$G(s) = \frac{\mathrm{k}}{\mathrm{Ts}+1}\mathrm{e}^{-\tau s}$$

  K is the static gain of the object; T is the time constant of the object; τ is the pure dead time constant of the object.

  Difference equation:

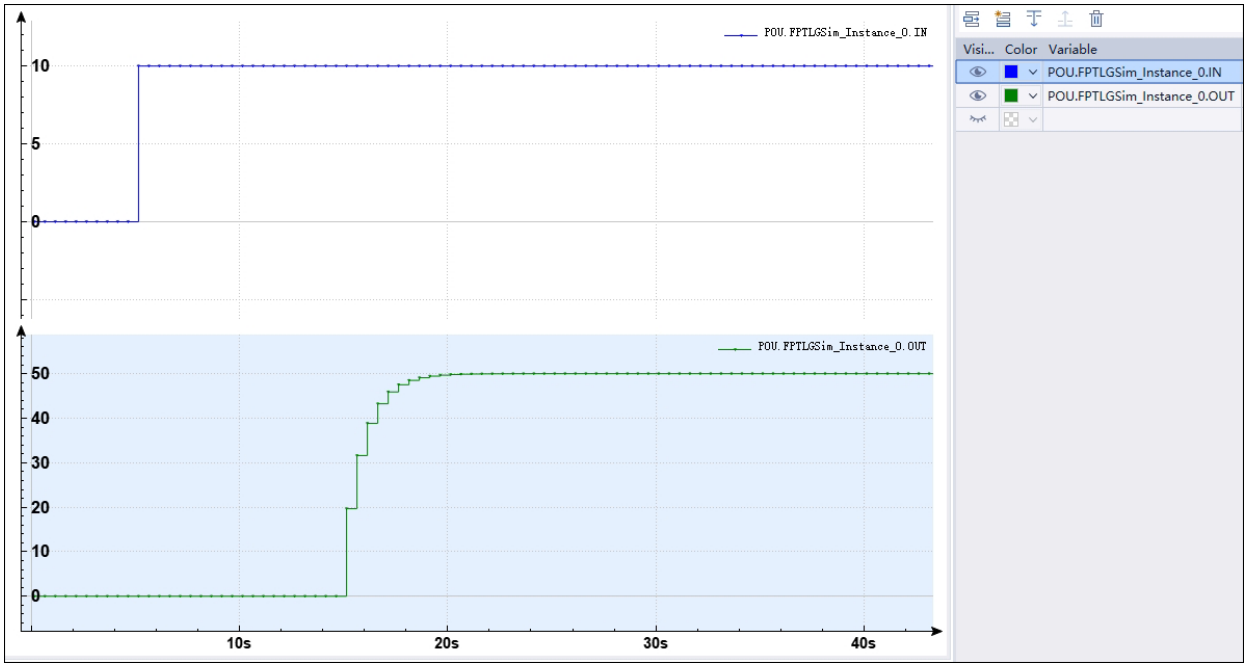


$$OUT(n) = \mathrm{e}^{-\frac{Cycle}{\mathrm{T}}} * OUT(n-1) + Gain * \left(1 - \mathrm{e}^{-\frac{Cycle}{\mathrm{T}}}\right) * IN(n - \mathrm{TmLag})$$

  The dynamic response diagram is shown in the figure below:

- **Program example**

  ST:



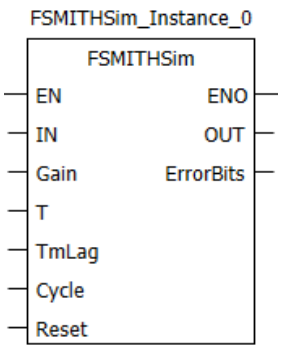
Name	Data type	Address	Value
FPTLGSim_Instance_0	FPTLGSim		
rIN	REAL		10
rGain	REAL		5
rT	REAL		1
diTmLag	DINT		20
rCycle	REAL		0.5
xReset	BOOL		FALSE
rOUT	REAL		49.999992
byErrorBits	BYTE		0

LD:

	Name	Data type	Address	Value
	FPTLGSim_Instance_0	FPTLGSim		
	rIN	REAL		10
	rGain	REAL		5
	rT	REAL		1
	diTmLag	DINT		20
	rCycle	REAL		0.5
	xReset	BOOL		FALSE
	rOUT	REAL		49.999992
	byErrorBits	BYTE		0

Operation result:

- **Precautions**
  - A larger pure dead time constant TmLag indicates a later curve response.
  - The actual dead time is the product of TmLag and cycle period.
  - Set the Cycle parameter to be consistent with the POU scheduling cycle when using the instruction.
  - A larger time constant T (the time for the output to reach 60% of the input) indicates a smoother curve response.
  - If the time constant T is negative, the result of the inverse Laplace transform is an exponentially increasing curve, which diverges over time. However, a divergent first-order system does not conform to practical application scenarios.
  - Affected by the cycle period, the OUT value may not accurately reach the theoretical value. The calculation result can be considered correct if it falls within the interval of one program cycle before or after.
  - Model verification can be performed using a step input or by comparison with MATLAB. Under a unit step input signal, a first-order inertial system (non-dead-time model) has two important performance indicators:
    - Time constant Ta (the time for the system output to reach approximately 63% of its final value $(1-\frac{1}{e})*100\%$): $T_a=\frac{1}{a}$.
    - Settling time Ts (the time required for the system output to stay within a 2% tolerance of the final value): $T_s=\frac{4}{a}$.
    - Considering the dead time of the system, the actual time constant and settling time of the output response are the sum of the dead time and the theoretical calculated time. For example, if the pure dead time constant is 5, the Cycle is set to 1 s, and the theoretical calculated T is 10 s, the actual time is 10 + 5 × 1 = 15 s.
  - Due to model accuracy limitations, the accuracy of OUT is 1.0E-7.
  - If system input parameters (other than the input IN) need to be modified, go offline, reconfigure, download, and then perform the simulation operation.
  - This instruction requires a significant amount of calculation. When using it, pay attention to designing the system task scheduling cycle appropriately. When calling a single instruction block, the minimum recommended task scheduling cycle is 5 ms. When multiple instructions of this type are called in the same task, the corresponding task scheduling cycle must be increased proportionally. Otherwise, PLC may malfunction.
  - It should be noted that when the value of ErrorBits is 4, it indicates that the system parameters are incorrectly set, and the output value will remain unchanged. In this case, one or more of the following conditions may exist. You must check the parameter settings before performing configuration simulation.



Error Report Result	Cause	Modification Suggestion
ErrorBits = 4	Input value IN overlimit	Modify the value of IN so that it is within the range of the REAL data type.

Error Report Result	Cause	Modification Suggestion
	Gain value GAIN overlimit	Modify the value of GAIN so that it is within the range [-1000000,1000000].
	Lag time Tmlag overlimit	Modify the dead time TmLag so that it is within the range of [0, 36000].
	Time constant T overlimit	Modify the time constant T so that it is within the range (-∞,10000].
	Cycle value Cycle overlimit	Modify the time constant T so that it is within the range (0,∞).

- **Function**

  Smith predictive control for first-order lag plus pure dead time objects, is used to compensate for the pure dead time in the control circuit and improve control performance.

  Smith predictive control is a widely used compensation method for dead time objects. It pre-estimates the dynamic characteristics of the system under a given signal, and then compensate through the predictor, allowing the delayed control variable to be reflected to the controller earlier, causing the controller to act in advance, thereby reducing overshoot and accelerating the regulation process. In practical applications, a Smith compensation block is typically connected in parallel with the PID controller.

  The transfer function of the compensation for the first-order lag plus pure dead time model is:

$$G(s) = \frac{\mathrm{k}}{\mathrm{Ts}+1}(1-\mathrm{e}^{-\tau \mathrm{s}})$$

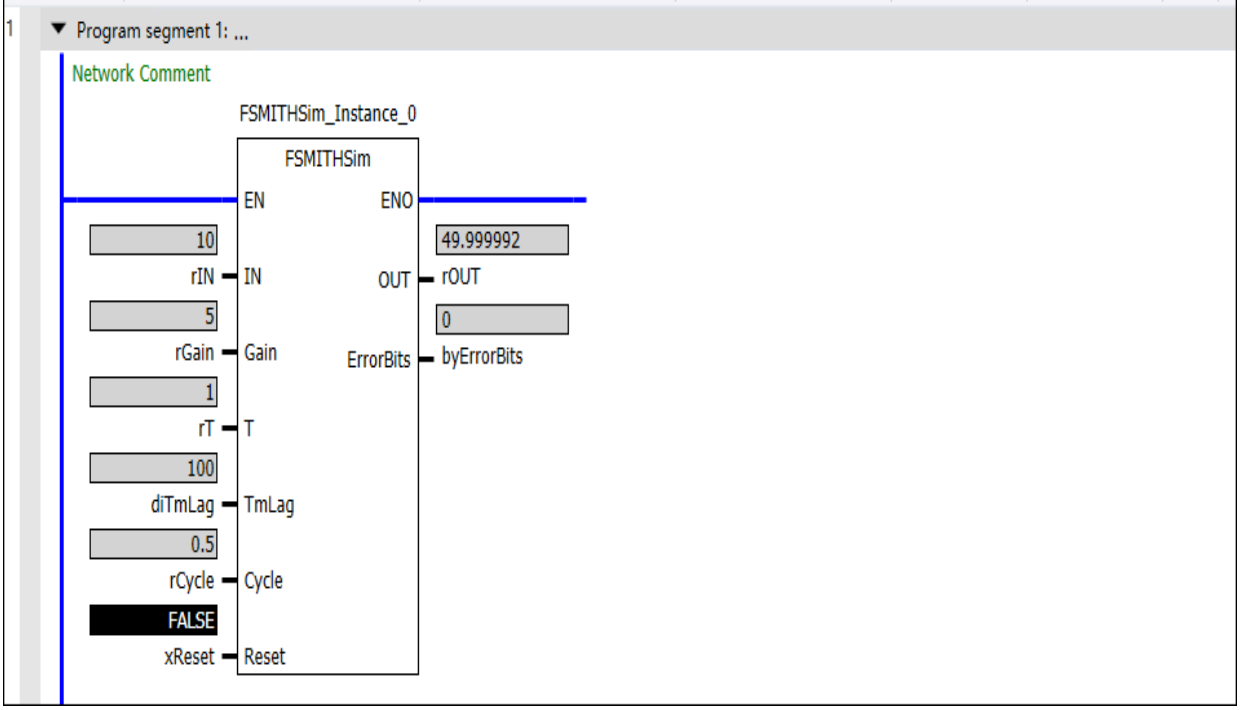
  K is the static gain of the object; T is the time constant of the object; τ is the pure dead time constant of the object.

  Converted difference equation:

$$OUT(n) = \mathrm{e}^{-\frac{Cycle}{\mathrm{T}}} * OUT(n-1) + Gain * \left(1-\mathrm{e}^{-\frac{Cycle}{\mathrm{T}}}\right) * (IN(n) - IN(n-\mathrm{TmLag}))$$

- **Program example**

  ST:



Name	Data type	Address	Value

rGain	REAL		5
rT	REAL		1
diTmLag	DINT		100
rCycle	REAL		0.5
xReset	BOOL		FALSE
rOUT	REAL		49.999992
byErrorBits	BYTE		0

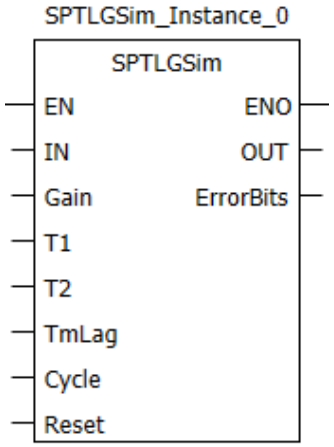
Operation result:

- **Precautions**
  - Set the Cycle parameter to be consistent with the POU scheduling cycle when using the instruction.
  - If the time constant T is negative, the original inertial system will diverge. However, a divergent first-order system does not conform to practical application scenarios.



- Affected by the cycle period, the OUT value may not accurately reach the theoretical value. The calculation result can be considered correct if it falls within the interval of one program cycle before or after.
- Model verification can be performed using a step input or by comparison with MATLAB. After completing the verification of the first-order lag plus dead time model, it can also be connected in parallel with the model to sum the outputs, thereby verifying the system under dead-time-free conditions. In this case, the system output will follow the theoretical value of the first-order system time-domain response.
  - Time constant Ta (the time for the system output to reach approximately 63% of its final value $(1-\frac{1}{e})*100\%$): $T_a=\frac{1}{a}$.
  - Settling time Ts (the time required for the system output to stay within a 2% tolerance of the final value): $T_s=\frac{4}{a}$.
- Due to model accuracy limitations, the accuracy of OUT is $1.0e^{-7}$.
- If system input parameters (other than the input IN) need to be modified, go offline, reconfigure, download, and then perform the simulation operation.
- This instruction requires a significant amount of calculation. When using it, pay attention to designing the system task scheduling cycle appropriately. When calling a single instruction block, the minimum recommended task scheduling cycle is 5 ms. When multiple instructions of this type are called in the same task, the corresponding task scheduling cycle must be increased proportionally. Otherwise, PLC may malfunction.
- It should be noted that when the value of ErrorBits is 4, it indicates that the system parameters are incorrectly set, and the output value will remain unchanged. In this case, one or more of the following conditions may exist. You must check the parameter settings before performing configuration simulation.

Error Report Result	Cause	Modification Suggestion
ErrorBits=4	Input value IN overlimit	Modify the value of IN so that it is within the range of the REAL data type.
	Gain value GAIN overlimit	Modify the value of GAIN so that it is within the range [-1000000,1000000].
	Lag time Tmlag overlimit	Modify the dead time TmLag so that it is within the range of [0, 36000].
	Time constant T overlimit	Modify the time constant T so that it is within the range (-∞,10000].
	Cycle value Cycle overlimit	Modify the time constant T so that it is within the range (0,∞).

- **Function**

  This instruction is used to simulate an object that exhibits second-order lag pure dead time.

  Transfer function:

$$G(s) = \frac{\mathrm{k}}{\mathrm{T2} * s^2 + \mathrm{T1} * \mathrm{s} + 1} \mathrm{e}^{-\tau \mathrm{s}}$$

  The model can be used with a step input. Under a unit step input signal, the performance indices of a second-order underdamped system are as follows:

  According to the standard form of a second-order system:

$$\Phi(\mathrm{s}) = \frac{\omega_{\mathrm{n}}^2}{\mathrm{s}^2 + 2\zeta\omega_{\mathrm{n}}\mathrm{s} + \omega_{\mathrm{n}}^2}$$

  By combining the transfer function of a second-order system, the damping ratio and natural frequency can be determined by the following equations:

$$\delta = \frac{T_{1} * \sqrt{T_2}}{2 * T_2}, \quad W_n = \frac{1}{\sqrt{T_2}}$$

  When 0 < δ < 1, the system is underdamped. The unit step response of an underdamped second-order system is stable and eventually approaches the unit step signal.

  When δ = 0, the system is undamped. In this case, the system exhibits constant-amplitude oscillations (the time-domain response is a sine function), with amplitude k and period $2*\pi/(W_n)$.

  When δ < 0, the system is negatively damped, and the system will diverge over time.

  When δ = 1, the system is critically damped. When δ > 1, the system is overdamped. In both cases, the response slowly rises to steady state without overshoot.

  As the damping ratio increases, the system's response speed gradually slows down, and the overshoot decreases accordingly.

1. Rise time t_r: The time required for the step response curve to rise from 10% to 90% of the steady-state value.

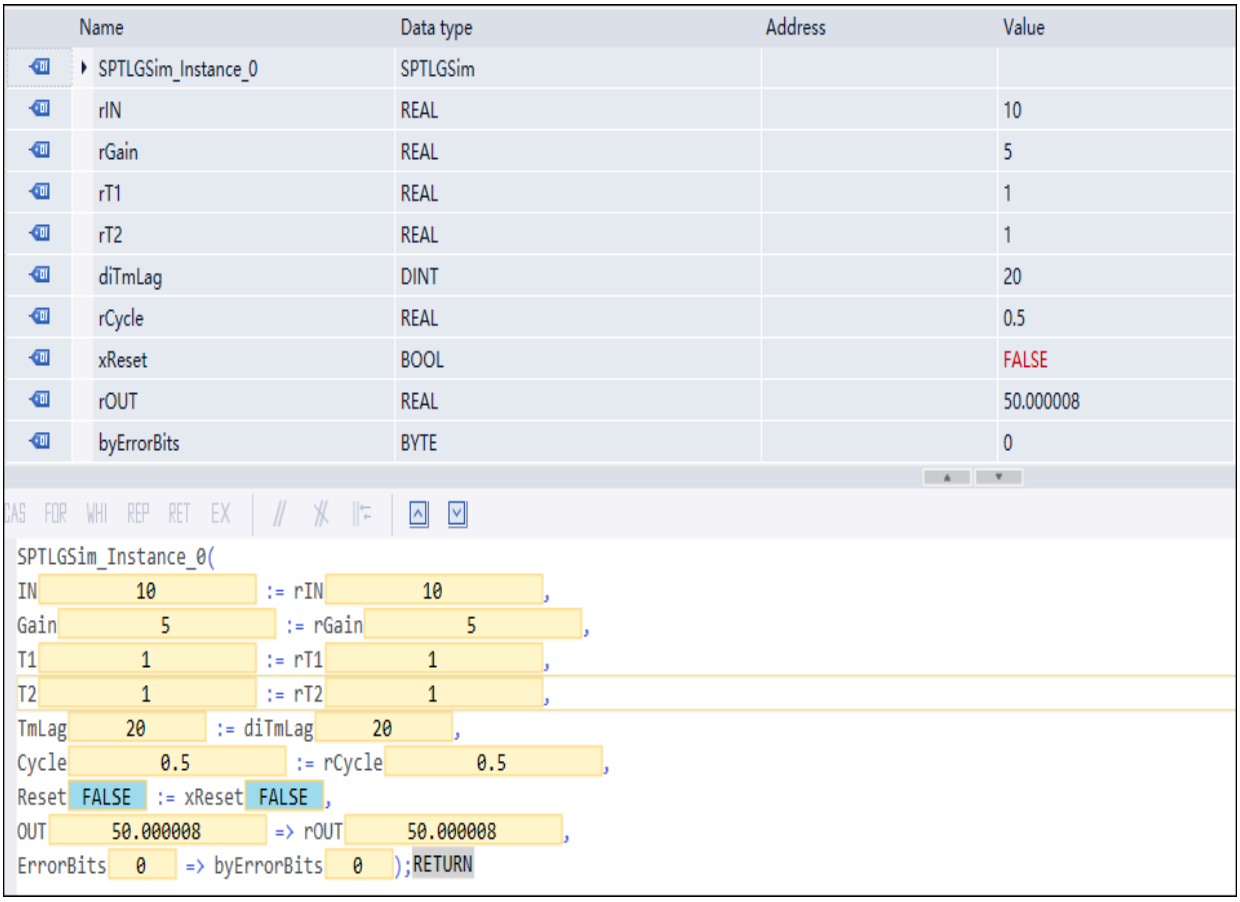
$$t_r = \frac{\pi - \beta}{W_n * \sqrt{1-\delta^2}}, \quad \beta = arctan\frac{\sqrt{1-\delta^2}}{\delta}$$

2. Peak time t_p: The time required for the step response curve to cross the steady-state value and reach the first peak.

$$t_p = \frac{\pi}{W_n * \sqrt{1-\delta^2}}$$

3. Settling time t_s: The shortest time required for the step response curve to reach and permanently remain within a specified tolerance (typically ±2%).

$$t_p = \frac{4}{W_n * \delta}$$

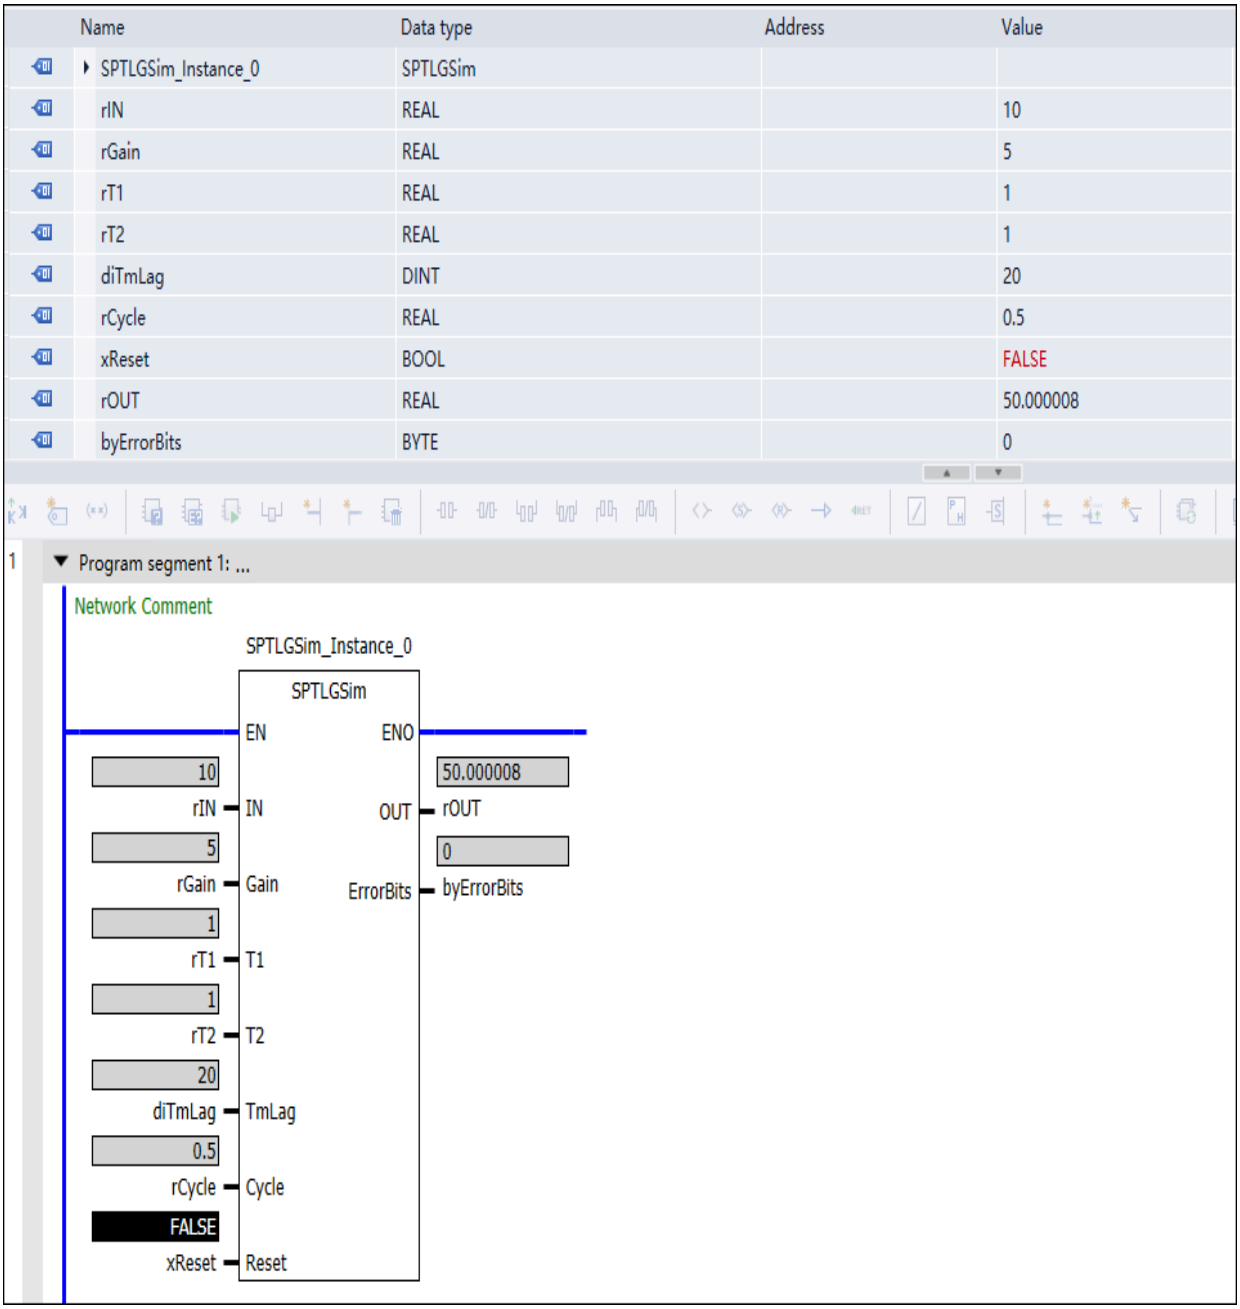


4. Overshoot σ_p: The percentage of the maximum deviation of the step response curve from the final value.

$$\sigma_p = e^{-\frac{\delta*\pi}{\sqrt{1-\delta^2}}}$$

TmLag is the number of dead time cycles of the system.

- **Program example**



ST:

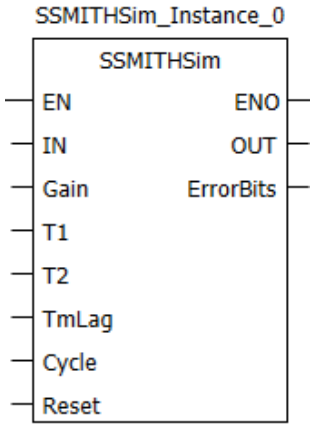
ErrorBits => byErrorBits);RETURN
```

LD:

Operation result:

- **Precautions**
  - A larger pure dead time constant TmLag indicates a later curve response.
  - The actual dead time is the product of TmLag and cycle period.
  - Set the Cycle parameter to be consistent with the POU scheduling cycle when using the instruction.
  - When IN exceeds the limit, the system will hold the output from the previous cycle and ErrorBits will be set to 4, indicating incorrect parameter settings.
  - If an input parameter value exceeds the specified range, the system holds the previous output and sets ErrorBits to 4, indicating incorrect parameter settings.
  - The second-order time constant T2 must be set to a non-negative value. Otherwise, ErrorBits will be set to 4. When T2 is 0, the system can be simplified to a first-order dead time system.
  - Due to model accuracy limitations, the accuracy of OUT is $1.0E^{-7}$.
  - If system input parameters (other than the input IN) need to be modified, go offline, reconfigure, download, and then perform the simulation operation.
  - This instruction requires a significant amount of calculation. When using it, pay attention to designing the system task scheduling cycle appropriately. When calling a single instruction block, the minimum recommended task scheduling cycle is 5 ms. When multiple instructions of this type are called in the same task, the corresponding task scheduling cycle must be increased proportionally. Otherwise, PLC may malfunction.
  - Affected by the cycle period, the OUT value may not accurately reach the theoretical value. The calculation result can be considered correct if it falls within the interval of one program cycle before or after.
  - It should be noted that when the value of ErrorBits is 4, it indicates that the system parameters are incorrectly set, and the output value will remain unchanged. In this case, one or more of the following conditions may exist. You must check the parameter settings before performing configuration simulation.



Error Report Result	Cause	Modification Suggestion
ErrorBits = 1	The calculated output value OUT exceeds the range of the data type.	Check whether the input parameter values are reasonable.

Error Report Result	Cause	Modification Suggestion
ErrorBits = 4	Input value IN overlimit	Modify the value of IN so that it is within the range of the REAL data type.
	Gain value GAIN overlimit	Modify the value of GAIN so that it is within the range [-1000000,1000000].
	Lag time Tmlag overlimit	Modify the dead time TmLag so that it is within the range of [0, 36000].
	First-order time constant T1overlimit	Modify the time constant T1 so that it is within the range (-∞, 10000].
	Second-order time constant T2 overlimit	Modify the time constant T2 so that it is within the range (0,10000].
	Cycle value Cycle overlimit	Modify the time constant T so that it is within the range (0,∞).

18.3.1.7.4 SSMITHSim

This is the instruction for second-order lag plus pure dead time compensation simulation.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
SSMITHSim	Second-order lag plus pure dead time compensation simulation	FB		SSMITHSim_Instance_0(IN := , Gain := , T1 := , T2 := , TmLag := , Cycle := , Reset := , OUT => , ErrorBits =>);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Input	Follows data type	0	Input
	Gain	Static gain	Follows data type	1	This parameter must be within the range [-1000000, 1000000].
	T1	First-order time constant	Follows data type	1	The maximum value of this parameter is 10000.
	T2	Second-order time constant	Follows data type	1	The maximum value of this parameter is 10000.
	TmLag	Pure delay time constant	Follows data type	20	Unit: calculation cycle. Range: 0 to 36000.
	Cycle	Calculation cycle	Follows data type	0.5	The logic calculation cycle must be set to a non-negative number.
	Reset	Reset flag	Follows data type	FALSE	If the reset flag is set to TRUE, the OUT is reset to 0.
Output	OUT	Output	Follows data type	0	Output.
	ErrorBits	Error report	Follows data type	-	0: No fault. 1: Calculation result overlimit. 4: Parameter setting error.

Data type

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String

Error Bits	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

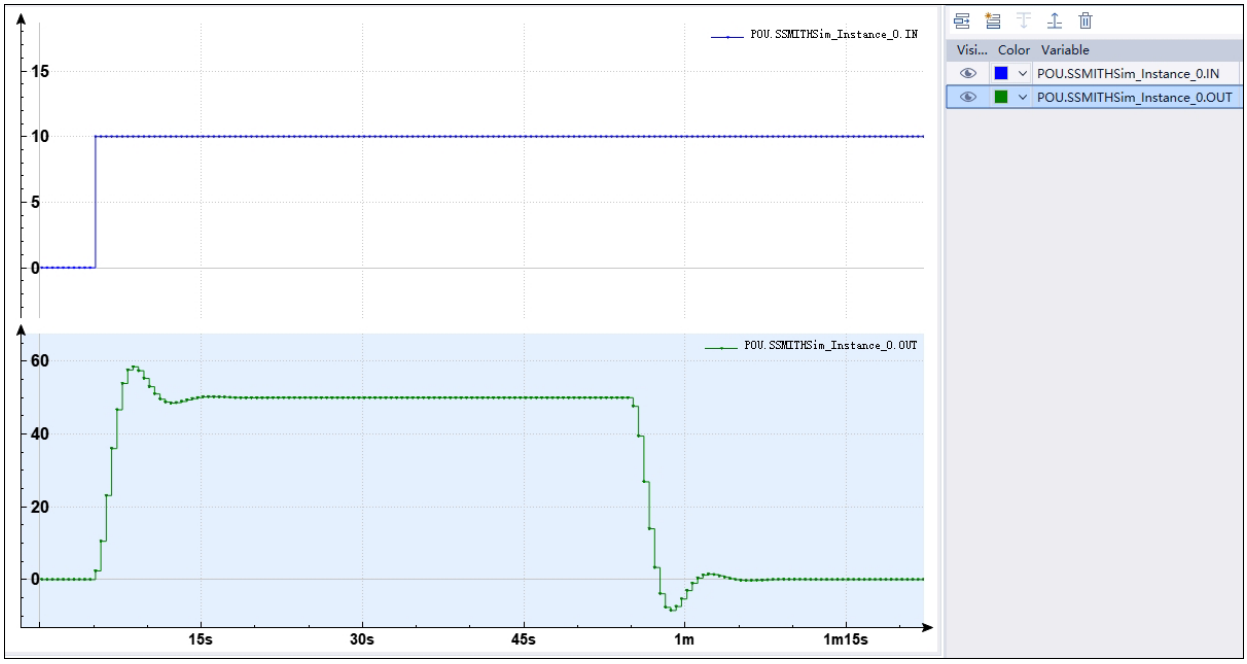
  Smith predictive control for second-order lag plus pure dead time objects, is used to compensate for the pure dead time in the control circuit and improve control performance.

  Transfer function:

$$G(s) = \frac{\mathrm{k}}{\mathrm{T2} * s^2 + \mathrm{T1} * \mathrm{s} + 1}(1 - \mathrm{e}^{-\tau \mathrm{s}})$$

- **Program example**

  ST:

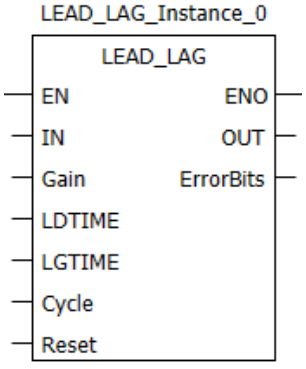


Name	Data type	Address	Value
SSMITHSim_Instance_0	SSMITHSim		
rIN	REAL		10
rGain	REAL		5
rT1	REAL		1
rT2	REAL		1
diTmLag	DINT		100
rCycle	REAL		0.5
xReset	BOOL		FALSE
rOUT	REAL		50.000004
byErrorBits	BYTE		0

```
SSMITHSim_Instance_0(
IN := rIN,
Gain := rGain,
T1 := rT1,
T2 := rT2,
TmLag := diTmLag,
Cycle := rCycle,
Reset := xReset,
OUT => rOUT,
ErrorBits => byErrorBits);RETURN
```

LD:

Operation result:



- **Precautions**
  - Set the Cycle parameter to be consistent with the POU scheduling cycle when using the instruction.
  - The second-order time constant T2 must be set to a non-negative value. Otherwise, ErrorBits will be set to 4. When T2 is 0, the system can be simplified to a first-order dead time system.
  - Within the allowed range, you can freely configure the system. Note, however, that if the system is designed as a negatively damped system (negative damping) or an undamped system (zero damping), sustained oscillations or even divergence may occur.
  - Affected by the cycle period, the OUT value may not accurately reach the theoretical value. The calculation result can be considered correct if it falls within the interval of one program cycle before or after.
  - This model is typically paired with the second-order lag plus dead time simulation model to compensate for dead time effects. After verifying the second-order dead time model, connect it in parallel with this model and sum the outputs to eliminate dead time. In this case, the output can be calculated theoretically according to the standard second-order model.
  - Due to model accuracy limitations, the accuracy of OUT is 1.0E-7.
  - If system input parameters (other than the input IN) need to be modified, go offline, reconfigure, download, and then perform the simulation operation.
  - This instruction requires a significant amount of calculation. When using it, pay attention to designing the system task scheduling cycle appropriately. When calling a single instruction block, the minimum recommended task scheduling cycle is 5 ms. When multiple instructions of this type are called in the same task, the corresponding task scheduling cycle must be increased proportionally. Otherwise, PLC may malfunction.
  - It should be noted that when the value of ErrorBits is 4, it indicates that the system parameters are incorrectly set, and the output value will remain unchanged. In this case, one or more of the following conditions may exist. You must check the parameter settings before performing configuration simulation.

Error Report Result	Cause	Modification Suggestion
ErrorBits = 1	The calculated output value OUT exceeds the range of the data type.	Check whether the input parameter values are reasonable.
ErrorBits = 4	Input value IN overlimit	Modify the value of IN so that it is within the range of the REAL data type.
	Gain value GAIN overlimit	Modify the value of GAIN so that it is within the range [-1000000,1000000].
	Lag time Tmlag overlimit	Modify the dead time TmLag so that it is within the range of [0, 36000].
	First-order time constant T1overlimit	Modify the time constant T1 so that it is within the range (-∞, 10000].
	Second-order time constant T2 overlimit	Modify the time constant T2 so that it is within the range [0,10000].
	Cycle value Cycle overlimit	Modify the time constant T so that it is within the range (0,∞).

18.3.1.7.5 LEAD_LAG

Lead-lag

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation

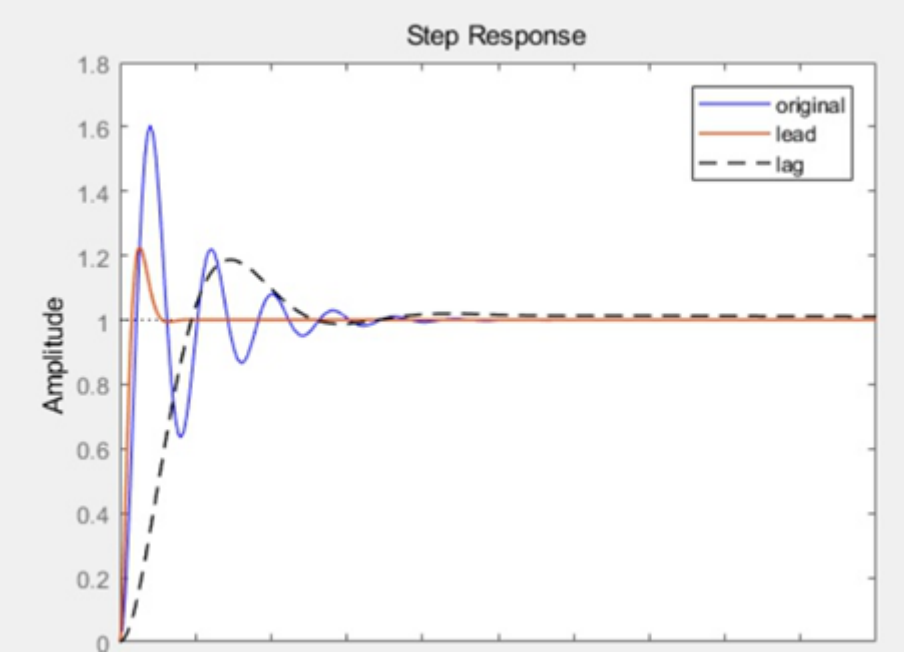
Error Bits	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  The LEAD_LAG controller is a frequency-domain correction method that improves phase margin, gain margin, and sensitivity to enhance stability and accuracy. It is primarily used for lead/lag compensation of disturbances in feedforward control.

  Transfer function:



$$G(s) = GAIN * \frac{1 + \mathrm{LDTIME} * \mathrm{S}}{1 + \mathrm{LGTIME} * \mathrm{S}}$$

  Converted difference form:

$$OUT(n) = e^{-\frac{\mathrm{Cycle}}{\mathrm{LGTIME}}} * OUT(n-1) + GAIN * \frac{\mathrm{LDTIME}}{\mathrm{LGTIME}} * \mathrm{IN}(n) + GAIN * (1 - e^{-\frac{\mathrm{Cycle}}{\mathrm{LGTIME}}} - \frac{\mathrm{LDTIME}}{\mathrm{LGTIME}}) * \mathrm{IN}(n-1)$$

  T1 > T2: Lead control.

  T1 < T2: Lag control.

Both lead compensation and lag compensation increase system damping and reduce overshoot. However, lead compensation significantly speeds up the system response, while lag compensation slows it down. Lead compensation improves system responsiveness and stability. Lag compensation improves steady-state accuracy and stability but reduces responsiveness. They can be combined as "lead-lag compensation". Generally, the lead correction coefficient is designed first, followed by the lag correction coefficient.

The "lead and lag algorithm" instruction can be used with loops as a compensator in dynamic feedforward control. This instruction consists of two operations. The "lead" operation shifts the phase of the output OUT, making the output lead the input. Conversely, the "lag" operation shifts the output, making the output lag behind the input. Since the "lag" operation is equivalent to integration, it can be used as a noise suppressor or low-pass filter. The "lead" operation is equivalent to differentiation, so it can be used as a high-pass filter. When both "lead" and "lag" are used together, the output phase lags the input at low frequencies and leads the input at high frequencies. This means the "lead and lag algorithm" instruction can be used as a bandpass filter.

- **Program example**

  ST:

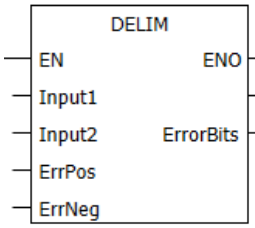
RETURN
```

LD:

- **Precautions**
  - Set the Cycle parameter to be consistent with the POU scheduling cycle when using the instruction.
  - Considering the actual application scenario, neither the lead time constant LDTIME nor the lag time constant LGTIME can be set to negative numbers, and the lag time constant cannot be 0. Otherwise, ErrorBits will be set to 4, indicating that the parameter settings are incorrect.
  - Affected by the cycle period, the OUT value may not accurately reach the theoretical value. The calculation result can be considered correct if it falls within the interval of one program cycle before or after.
  - Due to model accuracy limitations, the accuracy of OUT is 1.0E-7.



- If system input parameters (other than the input IN) need to be modified, go offline, reconfigure, download, and then perform the simulation operation.
- This instruction requires a significant amount of calculation. When using it, pay attention to designing the system task scheduling cycle appropriately. When calling a single instruction block, the minimum recommended task scheduling cycle is 5 ms. When multiple instructions of this type are called in the same task, the corresponding task scheduling cycle must be increased proportionally. Otherwise, PLC may malfunction.
- Model verification can be performed using a step input or by comparison with MATLAB.
- It should be noted that when the value of ErrorBits is 4, it indicates that the system parameters are incorrectly set, and the output value will remain unchanged. In this case, one or more of the following conditions may exist. You must check the parameter settings before performing configuration simulation.

Error Report Result	Cause	Modification Suggestion
ErrorBits = 4	Input value IN overlimit	Modify the value of IN so that it is within the range of the REAL data type.
	Gain value GAIN overlimit	Modify the value of GAIN so that it is within the range [-1000000,1000000].
	Lead time constant LDTIME overlimit	Modify the lead time constant LDTIME so that it is within the range [0,10000].
	Lag time constant LGTIME overlimit	Modify the lag time constant LGTIME so that it is within the range (0,10000].
	Cycle value Cycle overlimit	Modify the time constant T so that it is within the range (0,∞).

18.3.1.7.6 DELIM

This is the instruction for deviation determination.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
DELIM	Deviation determination	FC		:= DELIM(Input1 := , Input2 := , ErrPos := , ErrNeg := , ErrorBits =>);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Input1	Input Signal 1	Follows data type	-	Input Signal 1.
	Input2	Input Signal 2	Follows data type	-	Input Signal 2.
	ErrPos	Positive deviation	Follows data type	-	This value must be set to a non-negative number.
	ErrNeg	Negative deviation	Follows data type	-	This value must be set to a non-negative number.
Output	ErrorBits	Error report	Follows data type	-	0: No error. 4: Parameter setting error.

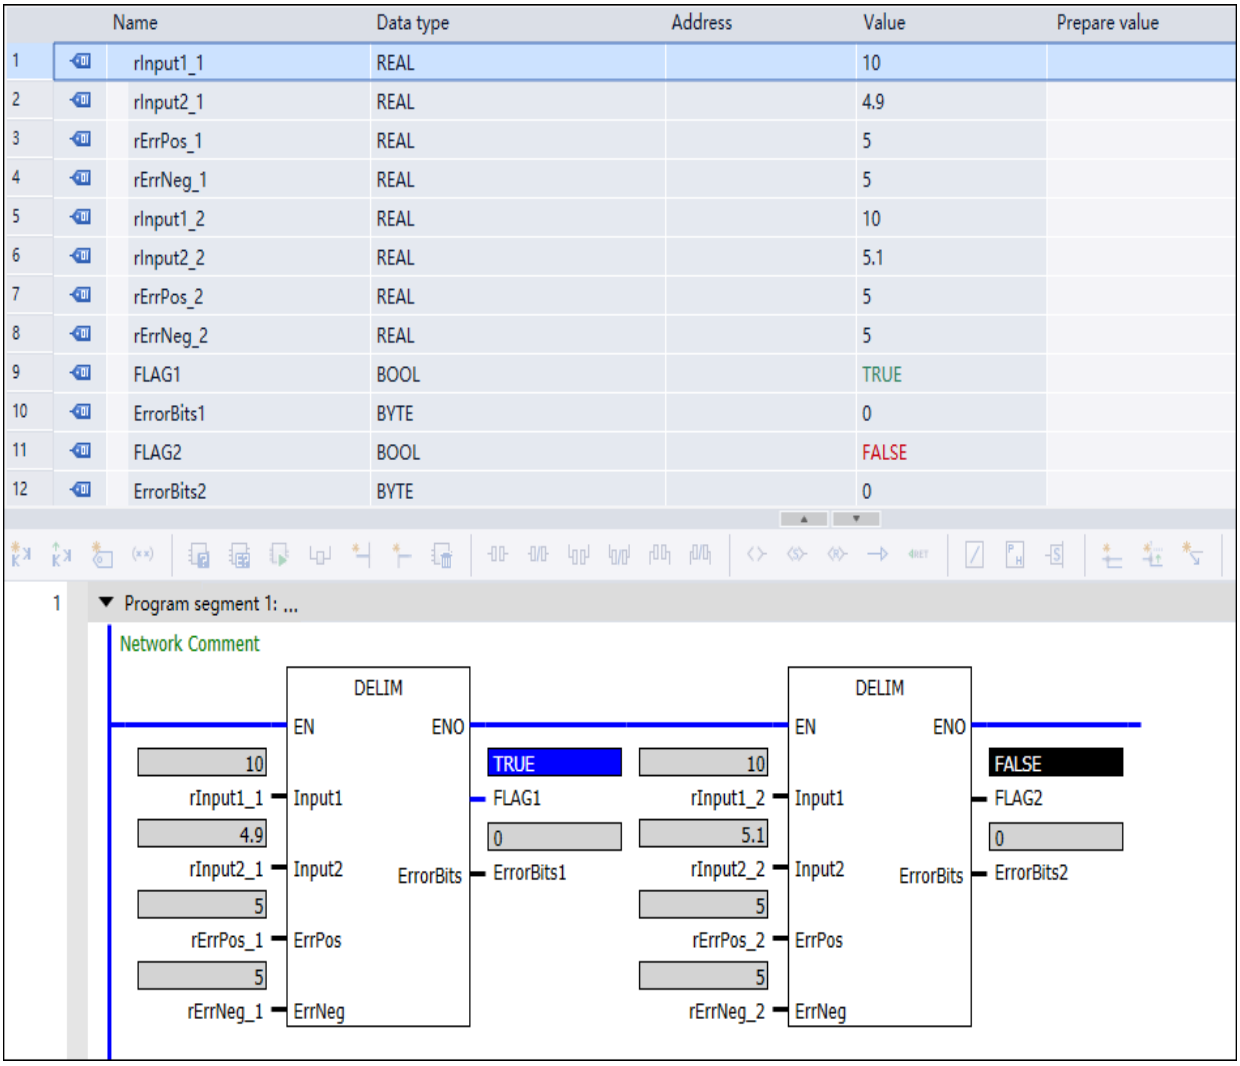
Data type

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TOD	DT	STRING
Input1	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
Input2	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
ErrPos	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
ErrNeg	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
ErrorBits	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  This instruction determines whether the deviation between two input analog values exceeds the limit based on the set positive or negative deviation, and outputs the overlimit flag.

  The deviations are defined as ErrPos and ErrNeg. If the analog value exceeds the positive deviation ErrPos or is less than –ErrNeg, the overlimit flag outputs TRUE; otherwise, it outputs FALSE.



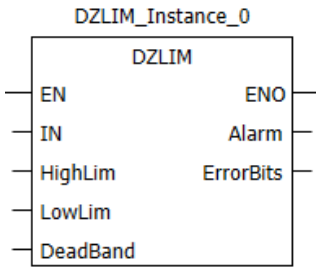
- **Program example**

  ST:

	Name	Data type	Address	Value
1	rInput1_1	REAL		10
2	rInput2_1	REAL		4.9
3	rErrPos_1	REAL		5
4	rErrNeg_1	REAL		5
5	rInput1_2	REAL		10
6	rInput2_2	REAL		5.1
7	rErrPos_2	REAL		5
8	rErrNeg_2	REAL		5
9	FLAG1	BOOL		TRUE
10	ErrorBits1	BYTE		0
11	FLAG2	BOOL		FALSE
12	ErrorBits2	BYTE		0

```
1  FLAG1 TRUE := DELIM(Input1 := rInput1_1 10 ,
2  Input2 := rInput2_1 4.9 ,
3  ErrPos := rErrPos_1 5 ,
4  ErrNeg := rErrNeg_1 5 ,
5  ErrorBits => ErrorBits1 0 );
6
7  FLAG2 FALSE := DELIM(Input1 := rInput1_2 10 ,
8  Input2 := rInput2_2 5.1 ,
9  ErrPos := rErrPos_2 5 ,
10 ErrNeg := rErrNeg_2 5 ,
11 ErrorBits => ErrorBits2 0 );RETURN
```

LD:



- **Precautions**
  - Due to the precision limitation of the REAL type, the measurement accuracy of this module is 10^-7.
  - Both the positive and negative deviation values must be set to non-negative numbers. Otherwise, ErrorBits will be set to 4, indicating a parameter configuration error, and the calculation result may be incorrect.
  - It should be noted that when the value of ErrorBits is 4, it indicates that the system parameters are incorrectly set. In this case, one or more of the following conditions may exist. You must check the parameter settings before performing configuration simulation.

Error Report Result	Cause	Modification Suggestion
ErrorBits = 4	Positive deviation ErrPos overlimit	Modify the positive deviation ErrPos and set it to a non-negative number
	Negative deviation ErrNeg overlimit	Modify the negative deviation ErrNeg and set it to a non-negative number

18.3.1.7.7 DZLIM

This is the instruction for dead zone check.

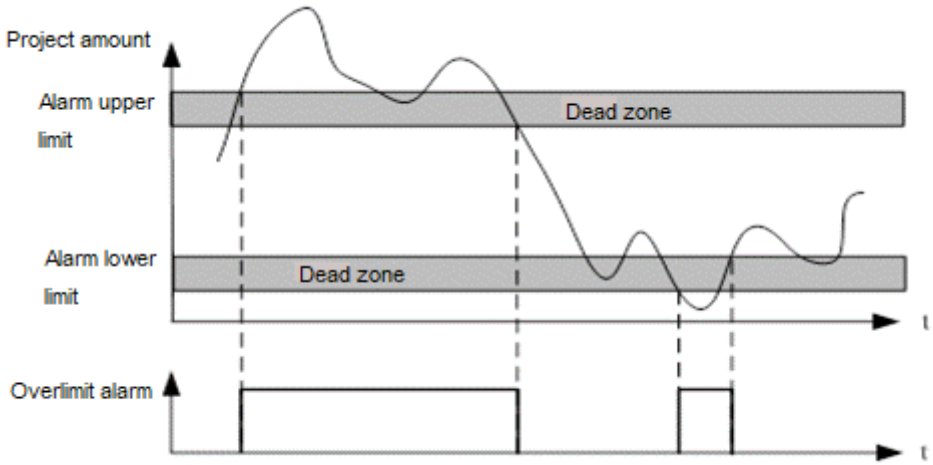
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
DZLIM	Dead zone check	FB		DZLIM_Instance_0(IN := , HighLim := , LowLim := , DeadBand := , Alarm => , ErrorBits =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Input Value	Follows data type	-	Input value.
	HighLim	Alarm high limit	Follows data type	-	Alarm high limit.
	LowLim	Alarm low limit	Follows data type	-	Low alarm limit.
	DeadBand	Alarm dead zone	Follows data type	-	Alarm dead zone
Output	Alarm	Alarm limit value	Follows data type	-	Alarm limit value.
	ErrorBits	Error report	Follows data type	-	0: No error. 4: Parameter setting error.



Data type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TOD	DT	STRING
IN	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
HighLim	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
LowLim	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
DeadBand	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
Alarm	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
ErrorBits	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  This instruction judges whether an analog input exceeds the high limit (or low limit) and incorporates a dead zone function. It can be used in industrial sites to determine if a signal exceeds the high or low limit value.

  When the input value first crosses the alarm high limit or alarm low limit, the Alarm is set to TRUE, and it remains TRUE until the input value crosses the dead zone, at which point the Alarm returns to FALSE.

- **Program example**

  ST:

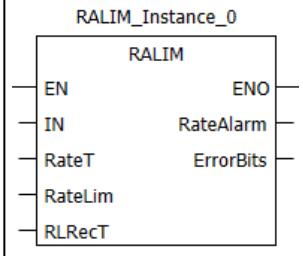
Name	Data type	Address	Value
DZLIM_Instance_0	DZLIM		
rIN	REAL		80
rHighLim	REAL		100
rLowLim	REAL		20
rDeadBand	REAL		0
xAlarm	BOOL		FALSE
byErrorBits	BYTE		0

```
DZLIM_Instance_0(
IN := 80,
HighLim := 100,
LowLim := 20,
DeadBand := 0,
Alarm => xAlarm,
ErrorBits => byErrorBits);RETURN
```

LD:

Name	Data type	Address	Value
DZLIM_Instance_0	DZLIM		
rIN	REAL		80
rHighLim	REAL		100
rLowLim	REAL		20
rDeadBand	REAL		0
xAlarm	BOOL		FALSE
byErrorBits	BYTE		0

- **Precautions**
  - Limited by the precision of the REAL type, the measurement accuracy of this module is 10^{-7}.
  - If the dead zone length is negative, the previous output is maintained and ErrorBits is set to 4, indicating incorrect parameter settings.



- If the input high limit is less than or equal to the input low limit, the previous output is maintained and ErrorBits is set to 4, indicating incorrect parameter settings.
- It must be noted that when the ErrorBits = 4, it indicates that the system's parameter are set incorrectly, and the system will maintain the previous output. In this case, one or more of the following situations may occur, and you need to check the parameter settings before performing configuration simulation:

Error Report Result	Cause	Modification Suggestion
ErrorBits = 4	In the input parameters, the input high limit HighLim is less than the input low limit LowLim.	Modify the setpoint so that the input high limit HighLim is greater than the input low limit LowLim.
	Dead zone length DeadBand overlimit	Set the dead zone length DeadBand to a non-negative value.

18.3.1.7.8 RALIM

This is the instruction for rate determination.

- **Instruction format**

- **Function**

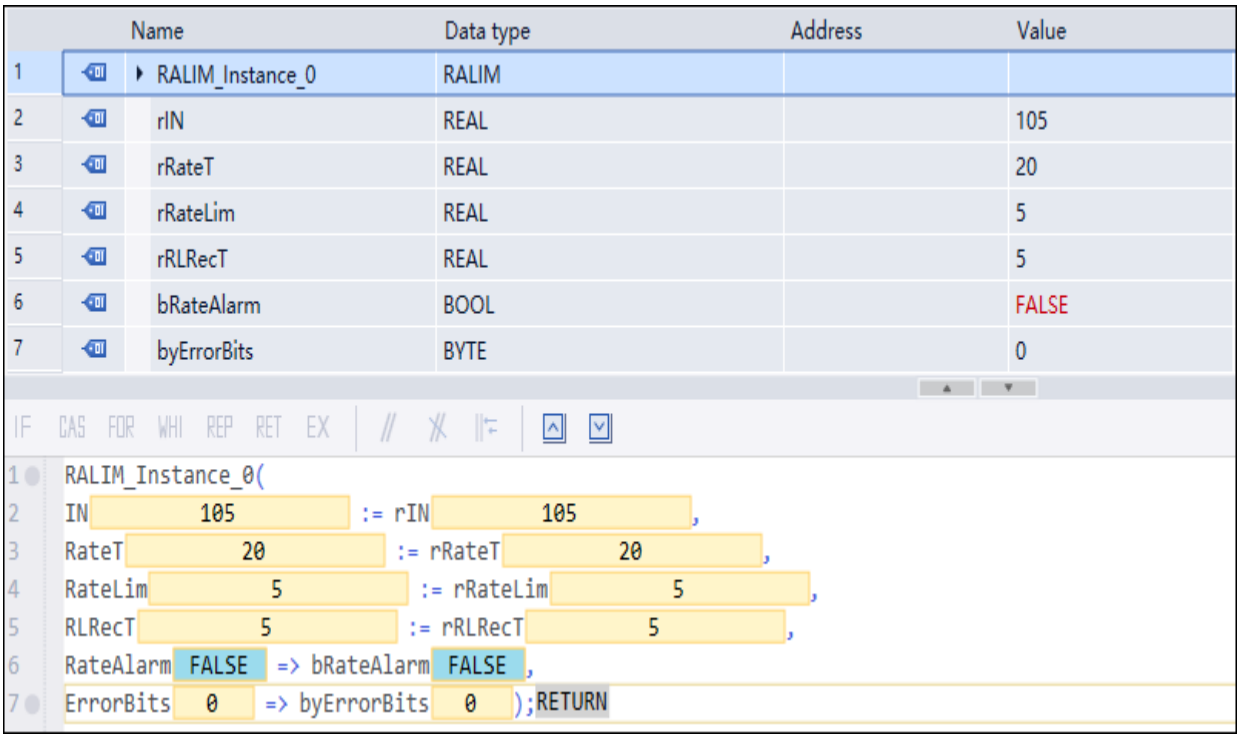
  This instruction determines whether the change rate of the input analog exceeds the limit within the set time.

  - **Rate alarm determination:**

    The time unit of rate change: seconds (internally converted to cycles). To determine whether the rate exceeds the limit, the current value is compared with the value from the set time ago. If the difference exceeds the configured rate limit, a rate alarm is triggered. The memory stores up to 20 historical data values. If the set time increases, the sampling interval also increases, reducing accuracy. For example, if the rate change time is set to 20s and the calculation cycle is 0.5s, data is recorded every two cycles.

  - **Rate alarm recovery:**

An alarm recovery time can be set. After a rate alarm occurs, if no new alarm is detected during the recovery period, the alarm automatically clears.



- **Program example**

  Set MainTask cycle to 1s, rate determination time RateT to 20s, rate alarm limit RateLim to 5, and rate alarm auto-recovery delay RLRecT to 5s.

  Set input IN to 0 first, and then change it to 105. Since (105 - 0) > 5, the input rate of change exceeds the rate alarm limit and the output is set high. An overlimit is detected within 20s.

  After 20s, as the stored values remain 105, the rate change is 0 and no overlimit condition exists. Alarm recovery timing then starts. Upon expiration of the rate alarm auto-recovery delay (5s), the system output is set low. The total high-level output duration is 25s. The operation result is shown in the figure below.

  ST:

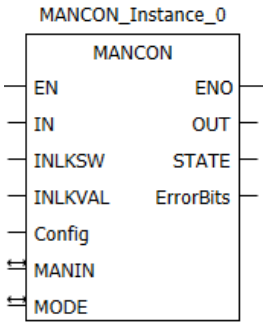
	Name	Data type	Address	Value
1	RALIM_Instance_0	RALIM		
2	rIN	REAL		105
3	rRateT	REAL		20
4	rRateLim	REAL		5
5	rRLRecT	REAL		5
6	bRateAlarm	BOOL		FALSE
7	byErrorBits	BYTE		0

```
RALIM_Instance_0(
IN := 105,
RateT := 20,
RateLim := 5,
RLRecT := 5,
RateAlarm => bRateAlarm,
ErrorBits => byErrorBits );RETURN
```

  LD:

Operation result:

- **Precautions**
  - The memory stores a maximum of 20 historical values. If the calculation cycle is 1s and the rate change time is 10s, data is recorded each cycle (10 records total). For a rate change time of 20s and 35s, data is recorded each cycle (20 records total) and every two cycles (18 records total, rounded up) respectively.
  - Limited by the precision of the REAL type, the measurement accuracy of this module is 10^{-7}.



- If parameters such as RateT or RLRecT are set to negative numbers, the calculation results are not affected but may deviate from your expectations. In this case, ErrorBits is set to 4, indicating a parameter configuration error.
- The rate determination time and recovery time must be greater than the POU scheduling cycle.
- When the rate alarm limit changes, there are two scenarios: If the rate previously exceeded the limit but no longer does, the alarm recovery function is triggered and the test is completed. If the rate previously did not exceed the limit but now does, a rate alarm is triggered.
- If time-related parameters (alarm time RateT, alarm recovery time RLRecT) are modified online during operation, the interval between data record cycles may become shorter. For example, originally the value of RateT is 40, calculation cycle is 1s, and data is collected every two cycles; now RateT is changed to 20, and data is collected every one cycle. After parameter modification, some sampled values may not have corresponding previous interval data. Therefore, when time-related parameters are modified in the algorithm block, the system reacquires signal values over the RateT alarm time period and the alarm output remains unchanged before determination and calculation.
- On first run of the block, overlimit determination is performed after the RateT alarm time has elapsed. Until then, the alarm output remains unchanged (default: FALSE).
- The rate alarm limit RateLim is an absolute value limit. For example, an actual rate of change of 5 or -5 will both trigger a slope alarm when the value of RateLim is 4.5.
- It should be noted that when the value of ErrorBits is 4, it indicates that the system parameters are incorrectly set, and the output value will remain unchanged. In this case, one or more of the following conditions may exist. You must check the parameter settings before performing configuration simulation.

Error Report Result	Cause	Modification Suggestion
ErrorBits = 4	Rate determination time RateT overlimit	Set RateT to a non-negative number
	Alarm recovery time RLRecT overlimit	Set RLRecT to a non-negative number
	Rate alarm limit RateLim overlimit	Set RateLim to a non-negative number

- **Function**

  MANCON manual operator refers to open-loop control of analog regulation objects. It is commonly used for manual control of valves, frequency converter speed references, and similar actuators.

The MANCON manual operator accepts a single input signal (e.g., the output from a PID function block) and provides a single output signal that is normally sent directly to an output module.

The specific functions of the MANCON manual operator are described as follows.

- **Operation mode**

Operation Mode	Action
Automatic	The output passes the processed input signal, which is limited by the output change rate and output limit.
Manual	The output is directly controlled (by writing a value from the upper layer or assigning a value online). The manual output is subject to the output limit.
Interlock	The output is set to a predefined interlock safety value. When the interlock is exited, the manual operator defaults to manual mode. The interlock output is subject to the output amplitude.

Interlock mode has the highest priority, followed by manual mode, and then automatic mode.

- **Bumpless switchover**

Operation Mode	Action
Automatic -> Manual Interlock -> Manual	In automatic or interlock mode, the internal manual value automatically tracks the current mode output value to ensure a bumpless switchover to manual.
Manual -> Interlock Automatic -> Interlock	In interlock mode, the interlock safety value is directly output, and there will be disturbances during switching.
Manual -> Automatic Interlock -> Automatic	In automatic mode, the input value is directly associated, and there will be disturbances during switching.

- **Output compensation**

  The output compensation directly adds the compensation value to the input. The output compensation is active in automatic mode and is subject to the output change rate and output limit. It is inactive in manual or interlock mode.

  Example: In automatic mode, the input value is 35 and the output bias is 10. Without considering output limit or output change rate, the output value is 35 + 10 = 45.

- **Output change limit**

In automatic mode, the output cycle change rate is monitored. If the change between adjacent cycles exceeds the set change limit, the current output change is limited to the change limit value.

Example: The output value range is 0 to 100, and the output change limit is 10. The output value of the previous cycle is 25, and the calculated value of the MANCON module in the current cycle is 45. Then, the output change = 45 - 25 = 20. Since 20 > 10, a change limit violation alarm is triggered (ErrorBits is set to 2). The actual output of the current cycle from the MANCON is 25 + 10 = 35.

The output change limit must be set to a value greater than 0. The default value is 10. If you want to disable this function, set the limit to a sufficiently large value.

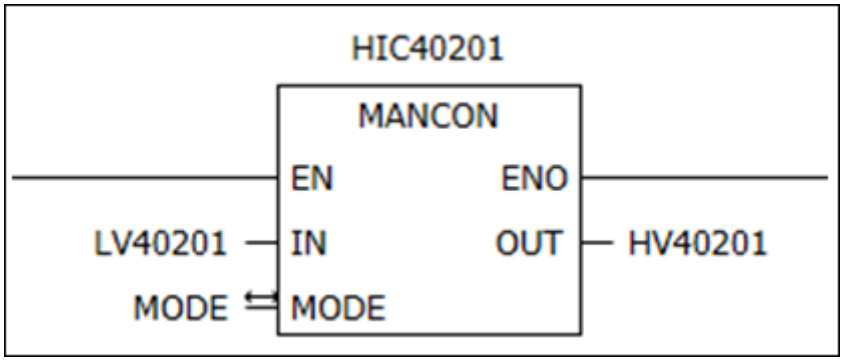
- **Output limit**

  Active in automatic, manual, and interlock modes:

  If the output value is greater than or equal to the upper limit of output range, the output is set to the upper limit.

  If the output value is less than or equal to the lower limit of output range, the output is set to the lower limit.

  Errorbits description

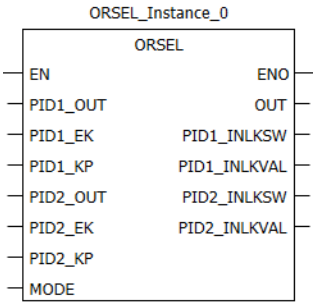


Errorbits	Note	Solution
16#0000	No error	/
16#0001	Output overlimit alarm. There are two possibilities: • OUT >= OUT_HLM (Output value greater than or equal to upper limit) • OUT <= OUT_LLM (Output value less than or equal to lower limit)	Output: Output is limited When the output restores to the normal range (OUT_LLM, OUT_HLM), the alarm is automatically cleared.
16#0002	Output rate-of-change alarm. Output change exceeds set limit in automatic mode	Output: Output change is limited The alarm is automatically cleared when the output change falls below the set limit or when switching to another mode.
16#0004	Parameter setting error alarm Includes: • The upper output limit (OUT_HLM) is less than or equal to the lower output limit (OUT_LLM). • In automatic mode, the output change limit (OUT_RAT) is less than or equal to 0.	Output: If parameters are invalid, they do not take effect and the output holds. • Check output limits to ensure OUT_HLM > OUT_LLM • Check output change limit to ensure OUT_RAT > 0

- **Application instance**

  Manual-automatic switching can be performed after the open-loop control of on-site manual control valve is completed.

Control scheme configuration:



Example:

No.	Instance	Type
1	HIC40201	Tag of manual operator function block
2	HV40201	Analog output
3	LV40201	Control input

18.3.1.7.10 ORSEL

- **Function**

  When the operation state is out of control, the system automatically switches to a new control system that takes over the control of the production process instead of initiating interlock or shutdown. When the state returns to normal, it automatically switches back to the original control system. It is necessary to determine whether the operating state is normal and to choose between the two control systems. Therefore, it is a selective control system, sometimes also referred to as substitution control or override control.

  In an override control system, the deviation of the override controller persists under normal operating conditions. If the override controller has integral action, integral windup will occur. Similarly, deviation of the normal controller persists under override conditions. If the normal controller is equipped with integral action, integral windup will also take place. In case of integral windup, timely controller switching cannot be realized.

  The key and difficulty of override control lies in fast and bumpless switchover between the normal controller and the override controller when process conditions exceed limits. The external feedback method is commonly adopted, which takes the selector output as the integral feedback signal and feeds it back to the controller in open-loop state.

  - **Calculation formula**

    Both low-select and high-select modes follow the rule:

    When Controller 1 is selected, the output of Controller 2 tracks the following value:
    OUT2=Override output+Kp2 EK2

    - Kp2: proportional gain of controller 2
    - EK2: deviation of controller 2

    When Controller 2 is selected, the output of Controller 1 tracks the following value:
    OUT1=Override output+Kp1 EK1

    - Kp1: proportional gain of controller 1
    - EK1: deviation of controller 1

- **Application instance**

  This is an example of a gas pipeline where pressure and flow are controlled by a single valve. The primary control is to maintain a specified flow rate, while pressure must be kept within a limited range for safety. Therefore, the pressure controller serves as the override controller.

Control scheme configuration:

Example

No.	Instance	Type
1	FIC101	Tag of PID1 function block
2	PIC102	Tag of PID2 function block
3	FY101	Tag of override function block
4	HV101	Tag of AO output

18.3.1.7.11 PWMC

This is the instruction for pulse modulation control.

<tr><td>ErrorBits</td><td>Error message list</td><td>BYTE</td><td>0</td><td>Bitwise analysis:
Bit0 = 1: Input overlimit
Bit1 = 1: Parameter setting error</td></tr>
</table>

- **Function**

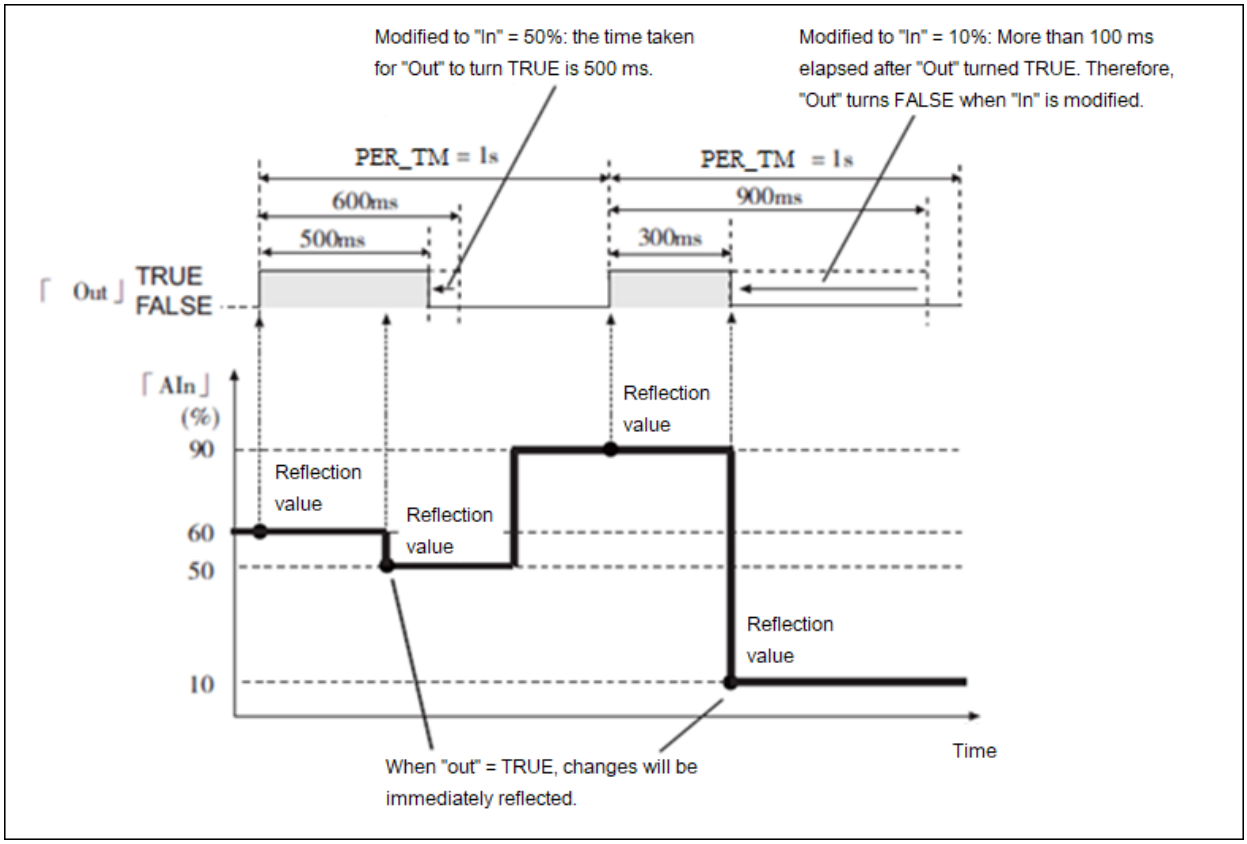
  For PWM, the output is ON or OFF. The analog of PID output needs to be converted to digital output (ON/OFF) based on the duty cycle. The duty cycle is the percentage of the high-level pulse time to a whole pulse cycle.

As shown above, the PID calculation cycle is identical to the pulse cycle (PerTM). Cycle_P is the PWMC call cycle, where PerTM = 10 Cycle_P. When the PID output is 30%, PWMC outputs ON in the first three cycles and OFF in the remaining seven cycles.

- **Position accuracy**

  The number of PWMC calls per PER_TM cycle determines the accuracy of pulse width, which improves as the call frequency increases.

  Control accuracy calculation formula:

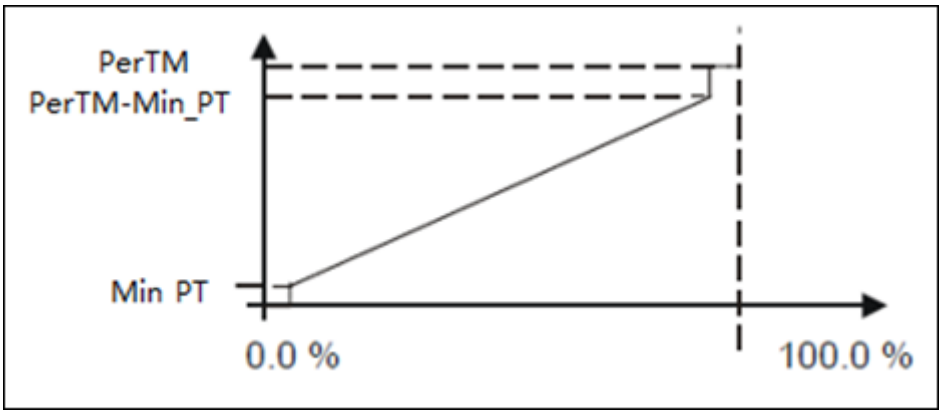


$$\text{Accuracy} = \frac{\text{Cycle}}{\text{PER TM}} * 100\%$$

  For example, if the task call cycle is 100ms and the PER_TM circle is 10s, the accuracy of the operation value range is 1%.

- **Response process**
  - When OUT is FALSE and IN changes, the change will be reflected in the next control cycle.

  - When OUT is TRUE and IN changes, the change is reflected immediately.



- **Minimum pulse interval**

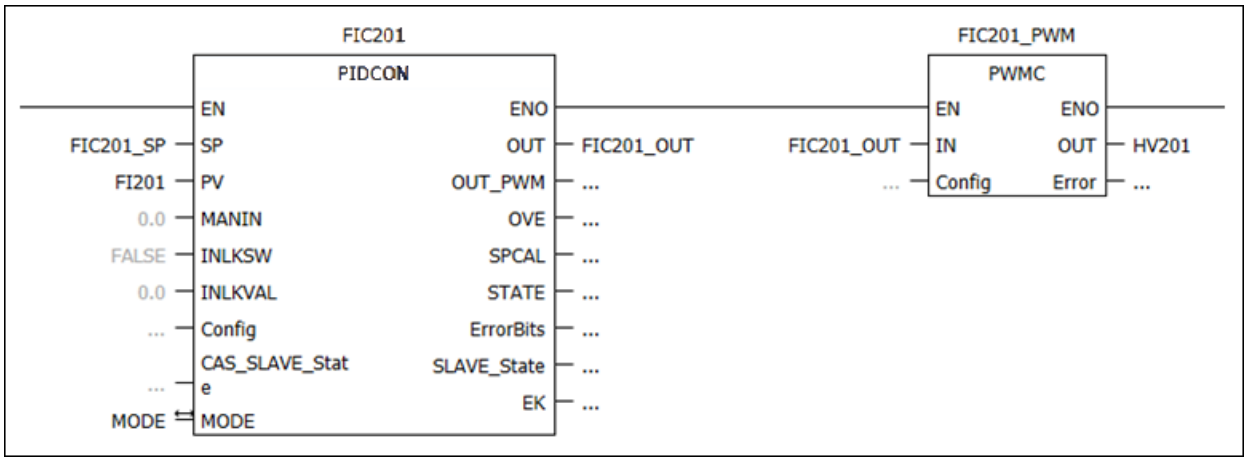
  To avoid frequent operation of the actuator, set the minimum pulse interval Min_PT.

  If the calculated high-level pulse time is less than the minimum pulse interval Min_PT, the output is always set to FALSE.

  If the calculated high-level pulse time is greater than the pulse cycle (PerTM) and the minimum pulse interval (Min_PT), the output is always set to TRUE.

- **Precautions**
  - Set the control cycle (PER_TM) to an integer multiple of the task cycle assigned to the program. When a value that is not an integer multiple of the task cycle is set, the actual control cycle spans from the end of control cycle (PER_TM) to the start of the next task execution. For example, when the task cycle is 3ms and the value of PER_TM is 1s, the actual control cycle of 1002ms is from the end of PER_TM to the next task execution.

  - Set the values of task cycle and control cycle (PER_TM) so that the output resolution is less than 0.1%. If the output resolution exceeds 0.1%, the error between the input value and the proportion at which the output switches to TRUE will rise, degrading control performance. For example, when the value of PER_TM is 10s, set the task cycle to less than 10ms.



◦ An error will occur if the parameter setting is incorrect. The value of OUT is FALSE, and ErrorBits will be set. After the error is cleared, the output will respond in the next cycle.

Errorbits description

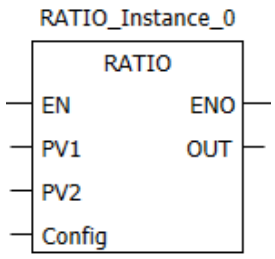
Errorbits	Note	Solution
16#0000	No error	/
16#0001	Two possible conditions trigger input limit alarm: • IN > IN_HLM (Input value greater than or equal to upper limit) • IN < IN _LLM (Input value less than or equal to lower limit)	Output OUT = FALSE
16#0002	Two possible conditions cause incorrect parameter setting: • IN_HLM <= IN_LLM • Min_PT > PerTM 0.5	Output OUT = FALSE

- **Application instance**

Control scheme configuration:

Config	PWMC_CONFIG					Private
PerTM	TIME		TIME#1s0ms			Private
Min_PT	TIME		TIME#10ms			Private
IN_HLM	REAL		100.0			Private
IN_LLM	REAL		0.0			Private

The task scheduling cycle can be set to 1ms and the sampling cycle of PIDCON (PIDCON. Config. ParamConfig. PIDSampleTime) can be set to 1s, achieving a control accuracy of 0.1%.



Example:

No.	Instance	Type
1	FIC201	Tag of PID1 function block
2	FI201	AI input

</table>

- **Function**

  A ratio control system associates two or more parameters in a certain proportional relationship for control. Ratio control is a widely adopted control method in process control, extensively used in industrial production processes such as chemical and pharmaceutical industries where raw material ratios need to be controlled. Undesired ratio fluctuation usually leads to degraded product quality, waste of energy and materials, and environmental pollution, and may even cause equipment damage and personal safety accidents.

  In industrial production processes, a control system maintains two or more parameters in a fixed proportional relationship. In a ratio control system, the dominant material is not regulated by the ratio controller and defined as the master parameter (active quantity) G1. Other subordinate

controlled materials are defined as slave parameters (dependent quantities) such as G2. The purpose of ratio control is to maintain a fixed ratio G2/G1 = K. The slave parameter is adjusted to match the master parameter and stabilize the set ratio.

Function block calculation formula:

Out = PV1 RatioCof + Offset

Where:

PV1: Acquisition value of master controller parameter

RatioCof: Ratio coefficient, which can be selected based on the configuration parameter RatioOpt

RatioOpt=0: RatioInt is selected as internal ratio setpoint with configurable parameters

RatioOpt=1: RatioExt (external ratio) is selected as the actual ratio. It is calculated automatically as RatioExt = (PV2 - Offset) / PV1. The output value of OUT is PV2. PV2: Acquisition value of the slave parameter

Offset: Offset value added to the output

- **Bumpless switchover between internal and external setpoints**

  When external ratio is selected, configuration depends on the bumpless ratio parameter RatTrk. If bumpless mode is enabled with RatTrk=TRUE, the internal ratio setpoint tracks the external ratio, that is, RatioInt = RatioExt, to ensure bumpless switchover.

- **Output limiting function**

  If the output exceeds OUT_HLM, the OUT is limited to OUT_HLM.

  If the output drops below OUT_LLM, the OUT is limited to OUT_LLM.

- **Application instance**

  When the lower-level PID is in automatic mode, the internal ratio is selected. The output is calculated as Out = PV1 RatioInt + Offset.

When the lower-level PID in non-automatic mode, the external ratio can be selected. The ratio block outputs PV2 and transmits it to the setpoint of the lower-level PID, keeping the setpoint consistent with the acquisition value to realize bumpless PID mode switchover. Meanwhile, set the value of ratio bumpless tracking parameter RatTrk to TRUE, ensuring bumpless switchover of ratio block parameters.

Control scheme configuration:

Example:

No.	Instance	Type
1	FFIC201	Tag of ratio control function block
2	FIC201	Tag of PID function block
3	FI101	Input of AI master variable
4	FI201	Input of AI slave variable

- **Function**

  Split-range control means that the output of a regulator drives two or more control valves at the same time, and each valve only operates within a specified range of the regulator output. It applies to scenarios where two or more control medium are adopted for regulation, or to meet control requirements under different process load conditions. The split-range control determines the split points and the action direction (direct/reverse acting) of each control valve, which needs to be configured based on actual process conditions.

  In split-range regulation, there are two types of opening/closing modes for control valves:

  ◦ Direct acting: same-direction split-range control. As the regulator output signal increases (or decreases), the valve opens wider (or closes tighter).

  ◦ Reverse acting: opposite-direction split-range control. As the regulator output signal increases (or decreases), the valve closes tighter (or opens wider).

  ◦ **Calculation formula**

  Positive action: OUTx = (IN - Sx_LLM) (OUTx_HLM - OUTx_LLM) / (Sx_HLM - Sx_LLM) + OUTx_LLM

  Reverse action: OUTx = (Sx_HLM – IN) (OUTx_HLM - OUTx_LLM) / (Sx_HLM - Sx_LLM) + OUTx_LLM

  Note: If the set upper limit is less than or equal to the lower limit (i.e., OUTx_LLM ≥ OUTx_HLM or Sx_LLM ≥ Sx_HLM), the parameter setting is invalid. In this case, Error is set to TRUE and the output holds. Normal calculation runs only when parameters are set correctly.

  The commonly used split forms are described as follows.

  Direct-direct split-range

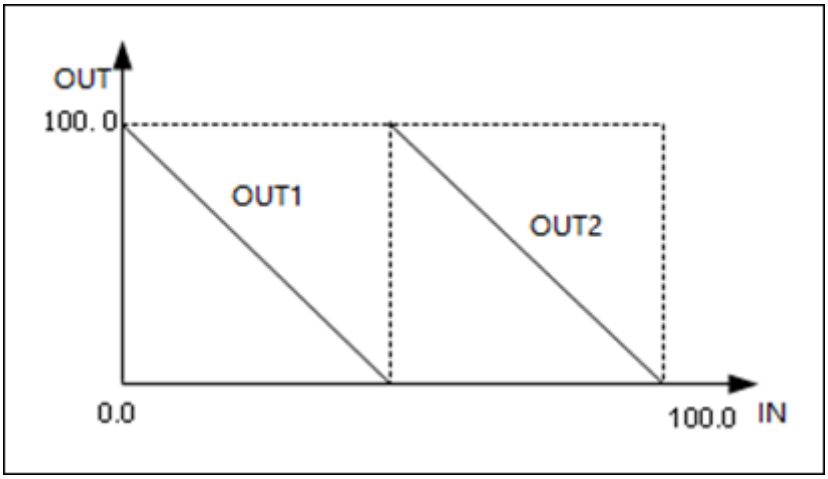
  ◦ Out1OPT = false, OUT1_HLM = 100, OUT1_LLM = 0, S1_HLM = 50, S1_LLM = 0

Direct acting: OUT1=(IN - S1_LLM) (OUT1_HLM - OUT1_LLM) / (S1_HLM - S1_LLM) + OUT1_LLM = (IN - 0) 100 / 50 + 0

- Out2OPT =false, OUT2_HLM = 100, OUT2_LLM = 0, S2_HLM = 100, S2_LLM = 50

  Direct acting: OUT2=(IN - S2_LLM) (OUT2_HLM - OUT2_LLM) / (S2_HLM - S2_LLM) + OUT2_LLM = (IN - 50) 100 / 50 + 0

Reverse-reverse split-range



Out1OPT = true, Out2OPT = true, S1_HLM = 50, S1_LLM = 0, S2_HLM = 100, S2_LLM = 50.

- Out1OPT = true, OUT1_HLM = 100, OUT1_LLM = 0, S1_HLM = 50, S1_LLM = 0

  Reverse acting: OUT1 = (S1_HLM - IN)(OUT1_HLM - OUT1_LLM) / (S1_HLM - S1_LLM) + OUT1_LLM= (50 - IN)100 / 50 + 0

- Out2OPT = true, OUT2_HLM =100, OUT2_LLM =0, S2_HLM =100, S2_LLM =50.

- **Application instance**

  A split-range control scheme is required for the pressure of a steam header. The control object is header pressure, and the actuators are two control valves: steam inlet valve (Valve A) and vent valve (Valve B). The action curve is shown in the figure below. When the output of the PID regulator ranges from 0% to 50%, Valve A moves from fully open to fully closed while Valve B remains fully closed. When the output ranges from 50% to 100%, Valve A stays fully closed, and Valve B opens gradually from fully closed to fully open.

Control scheme configuration:

The split-range configuration is shown in the figure below.

Config	SPLRANGE_CONFIG			☐	☐	Private
Out1OPT	BOOL		FALSE	☐	☐	Private
Out2OPT	BOOL		FALSE	☐	☐	Private
S1_HLM	REAL		50.0	☐	☐	Private
S1_LLM	REAL		0.0	☐	☐	Private
OUT1_HLM	REAL		100.0	☐	☐	Private
OUT1_LLM	REAL		0.0	☐	☐	Private
S2_HLM	REAL		100.0	☐	☐	Private
S2_LLM	REAL		50.0	☐	☐	Private
OUT2_HLM	REAL		100.0	☐	☐	Private
OUT2_LLM	REAL		0.0	☐	☐	Private

- **Function**

  Three-step control is a developed to overcome the contradiction between the heating rate and temperature overshoot that often occurs with two-step control. It has one additional output switch compared to a two-step controller. For example, when used to control an electric furnace, it can control two groups of heaters. When the furnace temperature is below the lower setpoint, both output switches are activated, and both groups of heaters heat simultaneously, causing the furnace temperature to rise quickly. When the furnace temperature is between the upper and lower setpoints, only one output switch is activated, and one group of heaters heats, causing the temperature to rise more slowly. When the furnace temperature exceeds the upper setpoint, both switches are disconnected, stopping the heating, and the furnace temperature decreases until it falls below the lower setpoint, at which point both groups of heaters are reactivated.

  Three-step control heats faster than two-step control, and after entering the constant temperature regulation status, the temperature fluctuation is smaller, with higher precision. A three-step controller provides better control performance than a two-step controller.

  - **Operation mode**

Operation Mode	Action
Automatic mode	The system will automatically output switch signals based on the comparison between the user-set setpoint and the process value of the controlled object.
Manual mode	In this mode, the system outputs manual values.
Interlock mode	In this mode, the system outputs interlock safety values.

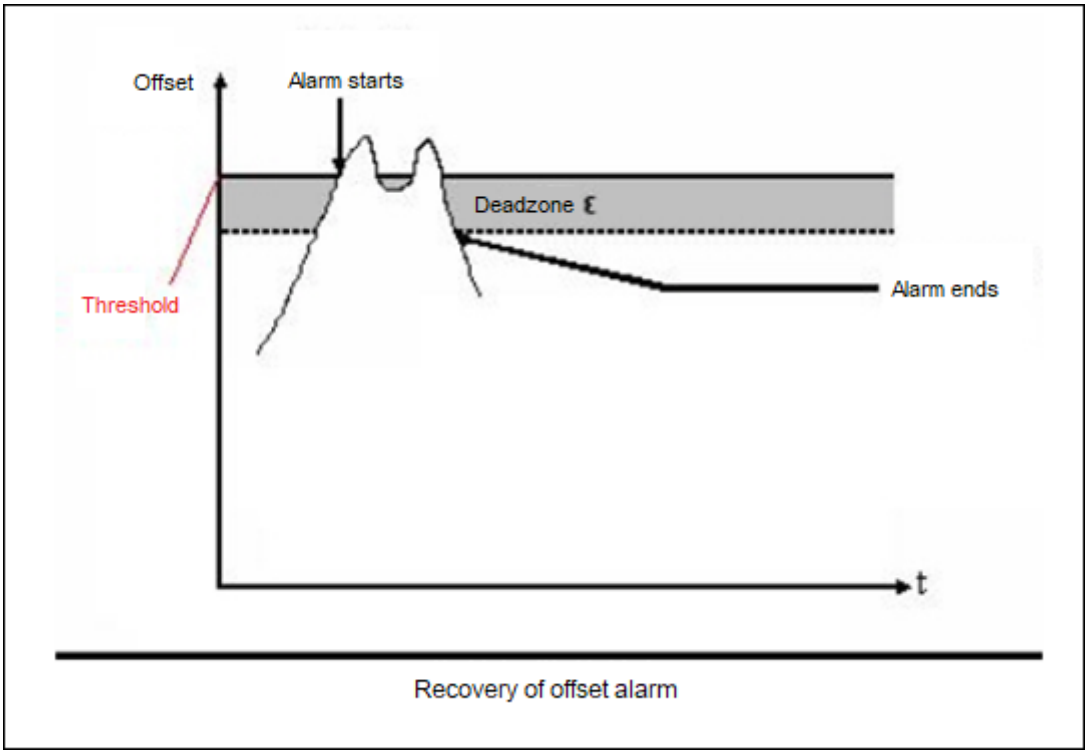
  Priority order: automatic mode < manual mode < interlock mode

  - **Action mode**

  There are two action modes: reverse action, where if the measured value PV is less than the setpoint SP, TWPOSC outputs positively (ON), and if PV is greater than SP, TWPOSC outputs negatively (OFF); direct action is the opposite, where if the measured value PV is less than the setpoint SP, TWPOSC outputs negatively (OFF), and if PV is greater than SP, TWPOSC outputs positively (ON).

  Compared to two-step control, three-step control has two output control signals, and the automatic mode works as follows:

Conditions	Output
PV > setpoint + control deadzone (SP + DeadZone)	Both OUT1 and OUT2 outputs are "OFF"
(SP - DeadZone) setpoint - control deadzone ≤ PV ≤ setpoint + control deadzone (SP + DeadZone)	OUT1 output is "ON" OUT2 output is "OFF"
PV < setpoint - control deadzone (SP - DeadZone)	Both OUT1 and OUT2 outputs are "ON"



- **Functional logic diagram (reverse-acting example)**

- **Deviation alarm (in automatic mode)**

  A deviation alarm refers to a situation in automatic control mode where the difference between the measured value and the setpoint (usually the absolute value) exceeds the preset deviation alarm limit, triggering a deviation alarm and switching the operating mode from automatic to manual.

- **Deviation alarm recovery**

  The deviation alarm recovery involves the concept of a deadzone. When the deviation value falls below the set threshold, the deviation alarm does not immediately disappear. This is because if it did, and the deviation value quickly rose above the threshold again, or fluctuated around the threshold, it would cause the system to repeatedly issue and end deviation alarms, leading to ping-pong alarms. Therefore, a deadzone is used to address this issue. If the deviation value falls below the set threshold, the deviation alarm does not immediately disappear. The alarm only disappears when the deviation value continues to decrease and falls outside the deadzone range, as shown in the figure below.

- **Deadzone control**

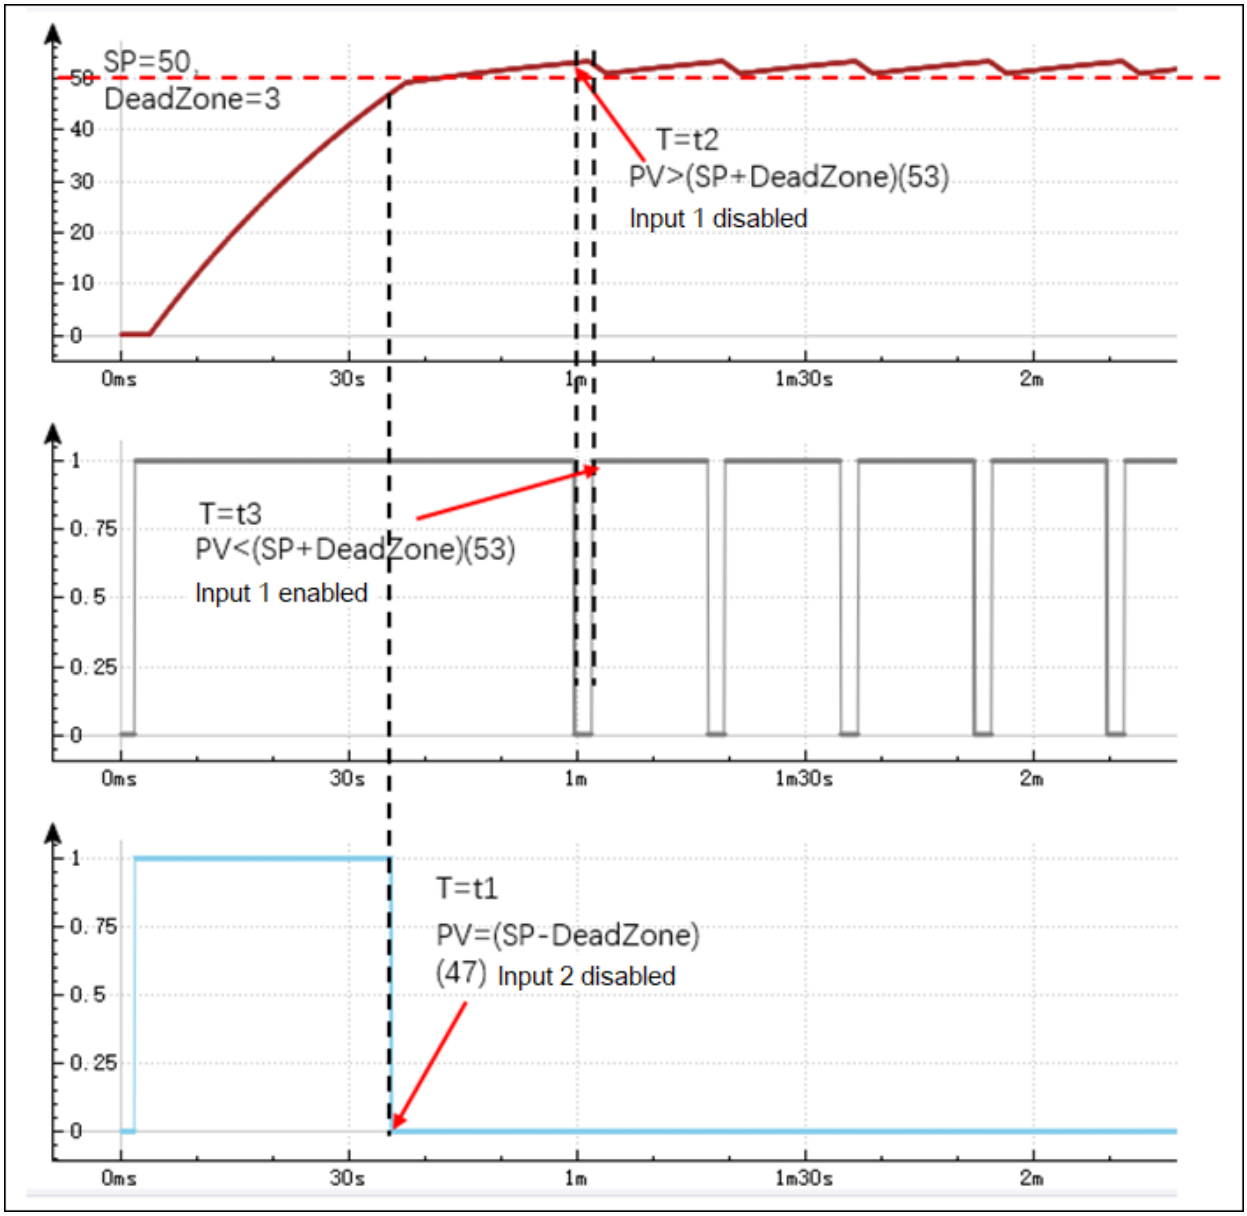
  It functions as a control interval, which affects the control mode of automatic mode. When the measured value PV fluctuates within the set range around the setpoint SP [SP-DeadZone, SP+DeadZone], THPOSC output value OUT1 is TRUE, and OUT2 is FALSE.

- **Bumpless switchover**

Bumpless switchover: When the module's operation mode changes, the module's output remains unchanged during the switching. After the switching is done, the module's output begins to calculate based on the previous output value, ensuring that there is no disturbance to the control of on-site equipment.

There are six operation modes for the THPOSC control module. Mode switching is generally bumpless, but disturbances may occur under certain conditions, as detailed below.

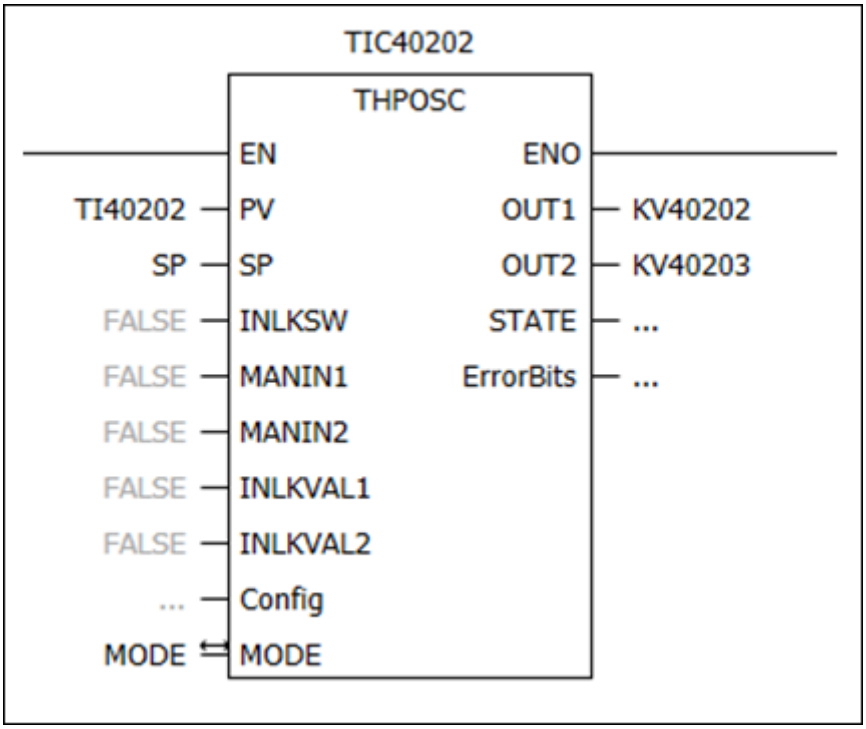
Automatic -> Manual Interlock -> Manual	Manual -> Interlock Automatic -> Interlock	Manual -> Automatic Interlock -> Automatic
In automatic or interlock mode, the internal manual value automatically tracks the current mode output value to ensure a bumpless switchover to manual.	In interlock mode, the interlock safety value is directly output, and the switch may cause disturbances.	In automatic mode, the input value is directly associated, and the switch may cause a disturbance.



Errorbits description

Errorbits	Note	Solution
16#0000	No error	/
16#0001	PV upper/lower limit alarm There are two possibilities: • PV > PV_HLM (Process value greater than upper limit). • PV < PV_LLM (Process value less than lower limit).	Output: Switch to manual mode, output current manual value (interlock mode does not switch) After checking and confirming, the user can switch to automatic mode to resume operation.
16#0002	Deviation overlimit alarm In automatic mode, the absolute value of the deviation between process value PV and setpoint SP is greater than the deviation alarm value.	Output: Switch to manual mode, output current manual value After checking and confirming, the user switches to automatic to continue running In automatic mode, if an alarm is triggered and switched to manual, the alarm remains until it is confirmed on-site, then switch back to automatic mode for deviation alarm recovery.

Errorbits	Note	Solution
16#0004	Parameter setting error alarm Includes: In all modes, the PV upper/lower limit setting is invalid if PV_LLM ≥ PV_HLM. In automatic mode: • EKDB >= EKLIM (Deviation deadzone greater than or equal to deviation alarm value) • DeadZone >= EKLIM (Control deadzone greater than or equal to deviation alarm value) • DeadZone >= EKLIM - EKDB (Deviation alarm reset within control deadzone) • Control deadzone (DeadZone) or deviation deadzone (EKDB) is less than 0, or the deviation alarm limit (EKLIM) is less than or equal to 0. • Setpoint rate limit SP_RAT≤0	Output: If parameters are invalid, they do not take effect and the output holds. • Reset the upper and lower limits of PV to ensure PV_HLM > PV_LLM • Reset the deviation alarm value (EKLIM), deviation deadzone (EKDB), and control deadzone (DeadZone). Ensure the following conditions are met: EKDB < EKLIM DeadZone < EKLIM; DeadZone < EKLIM - EKDB DeadZone, EKDB ≥ 0 EKLIM > 0 • Reset the setpoint rate limit (SP_RAT) to ensure that SP_RAT > 0.
16#0008	Setpoint overspeed alarm. In automatic mode, the setpoint change exceeds the rate limit (SP_RAT).	Output: Perform normal calculation based on the setpoint after rate limiting. The alarm automatically resets after the setpoint change is less than SP_RAT.



- **Application instance**

  For example, in a three-step temperature control system for an electric heating furnace, three-step regulation can be achieved using two relays to form three output statuses: heating up, temperature regulation, and stop heating. The control process is as follows:

1. Two groups of heaters, auxiliary heater A and main heater B, are adopted. When the measured value is below SP-DeadZone from time 0 to t1, both upper and lower limit relays are energized, and the system enters the "heating up" state. At this time, both heaters A and B heat simultaneously, so the heating rate is faster.
2. When the measured value reaches SP-DeadZone but is still below SP+DeadZone from time t1 to t2, the lower limit relay releases with the power supply to auxiliary heater A cutting off, and the heating rate decreases. The system enters the "temperature regulation" state.
3. When the measured value reaches SP+DeadZone from time t2 to t3, the lower limit relay remains open, and the upper limit relay begins to release, cutting off the power supply to main heater B. Since both the main and auxiliary heaters lose their power supply, the temperature gradually decreases until it falls within SP+DeadZone. From time t3 to t4, the upper limit relay re-energizes to reconnect the power supply to main heater B, and the temperature gradually rises again. The process repeats in cycles. Therefore, three-step regulation ensures low temperature fluctuation and high precision in constant-temperature mode.

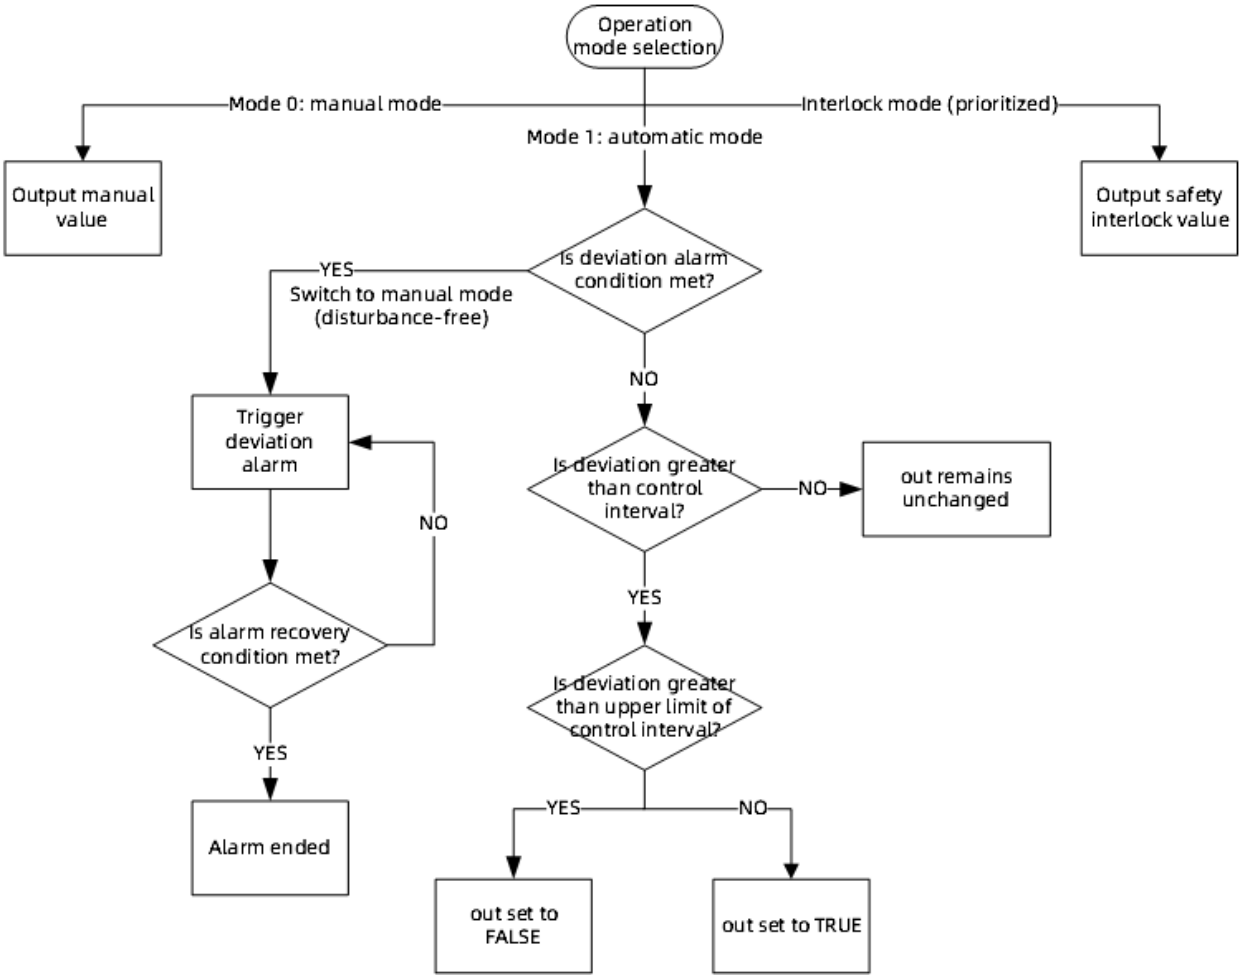
- **Function**

  Position control refers to an analog controller that outputs intermittent signals to drive actuators. Its output is typically on/off switching signals for power supply, so it is also known as on-off controller. The simplest position controller is two-position controller.

  Two-position control adopts two logic states (ON and OFF) of a single digital output to complete control of an analog, so that the controlled parameter is stabilized within a control range. That is, the controlled parameter is an analog. When it exceeds the setpoint, the controller outputs an OFF signal (the action can also be reversed); when it drops below the setpoint, the controller outputs an ON signal (the action can also be reversed). Repeated two-position regulation keeps the controlled parameter close to or at the setpoint. Two-position regulators are applicable to control systems with low precision requirements, such as thermostats, electric heating furnaces, air conditioners, air pumps and household appliances.

  - **Operation Mode**



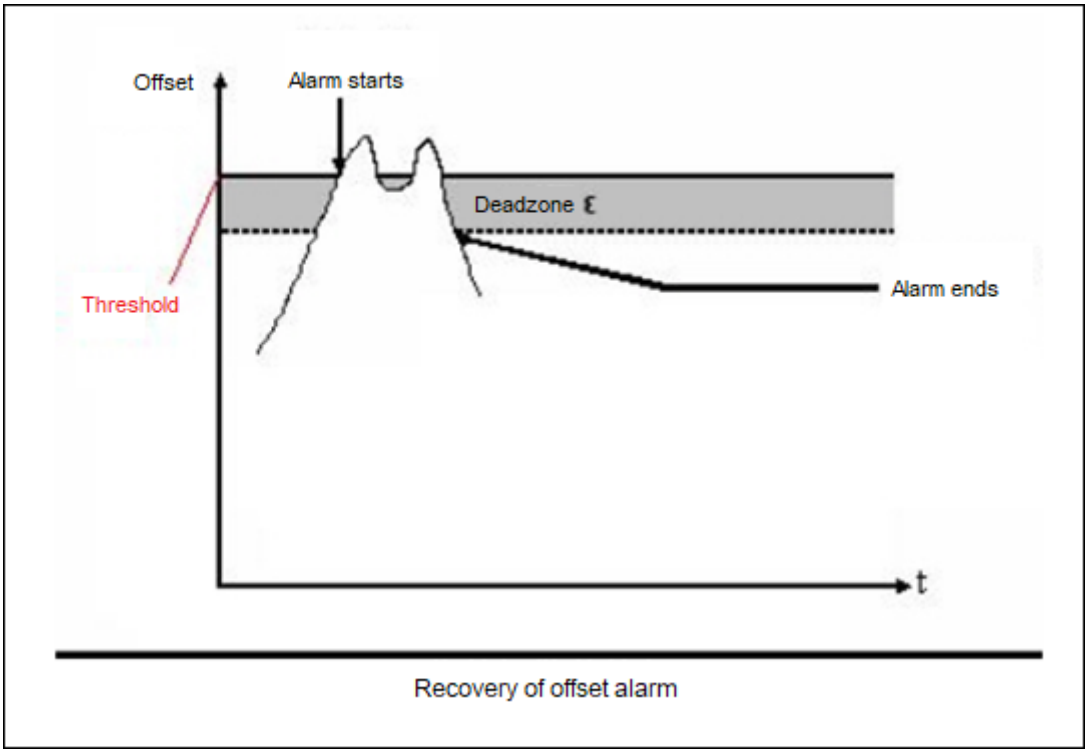
Operation Mode	Action
Automatic mode	The system will automatically output switch signals based on the comparison between the user-set setpoint and the process value of the controlled object.
Manual mode	In this mode, the system outputs manual values.
Interlock mode	In this mode, the system outputs the interlock safety value. It switches to manual mode by default when interlock is released.

  Priority order: automatic mode < manual mode < interlock mode

  - **Action mode**

There are two modes of action: reverse acting, where TWPOSC outputs positive (ON) when the process value (PV) is less than the setpoint (SP) and outputs negative (OFF) when PV is greater than SP; and direct acting, which is the opposite, where TWPOSC outputs negative (OFF) when PV is less than SP and outputs positive (ON) when PV is greater than SP.

- **Functional logic diagram (reverse-acting example)**



- **Deviation alarm (in automatic mode)**

  A deviation alarm refers to a situation in automatic control mode where the difference between the measured value and the setpoint (usually the absolute value) exceeds the preset deviation alarm limit, triggering a deviation alarm and switching the operating mode from automatic to manual.

- **Deviation alarm recovery**

  The deviation alarm recovery involves the concept of a deviation deadzone. When the deviation value falls below the set threshold, the deviation alarm does not immediately disappear. This is because if it did, and the deviation value quickly rose above the threshold again, or fluctuated around the threshold, it would cause the system to repeatedly issue and end deviation alarms, leading to ping-pong alarms. Therefore, a deadzone is used to address this issue. If the deviation value falls below the set threshold, the deviation alarm does not immediately disappear. The alarm only disappears when the deviation value continues to decrease and falls outside the deadzone range, as shown in the figure below.

- **Deadzone control**

  During the automatic control process, when the measured value fluctuates within a very small range around the setpoint, the output signal may frequently switch between ON and OFF. This is detrimental to on-site equipment and is ineffective. Therefore, an automatic control deadzone (DeadZone) is introduced. If the measured value PV fluctuates within the set range [SP-DeadZone, SP+DeadZone], TWPOSC considers the system to be stable and does not change the output.

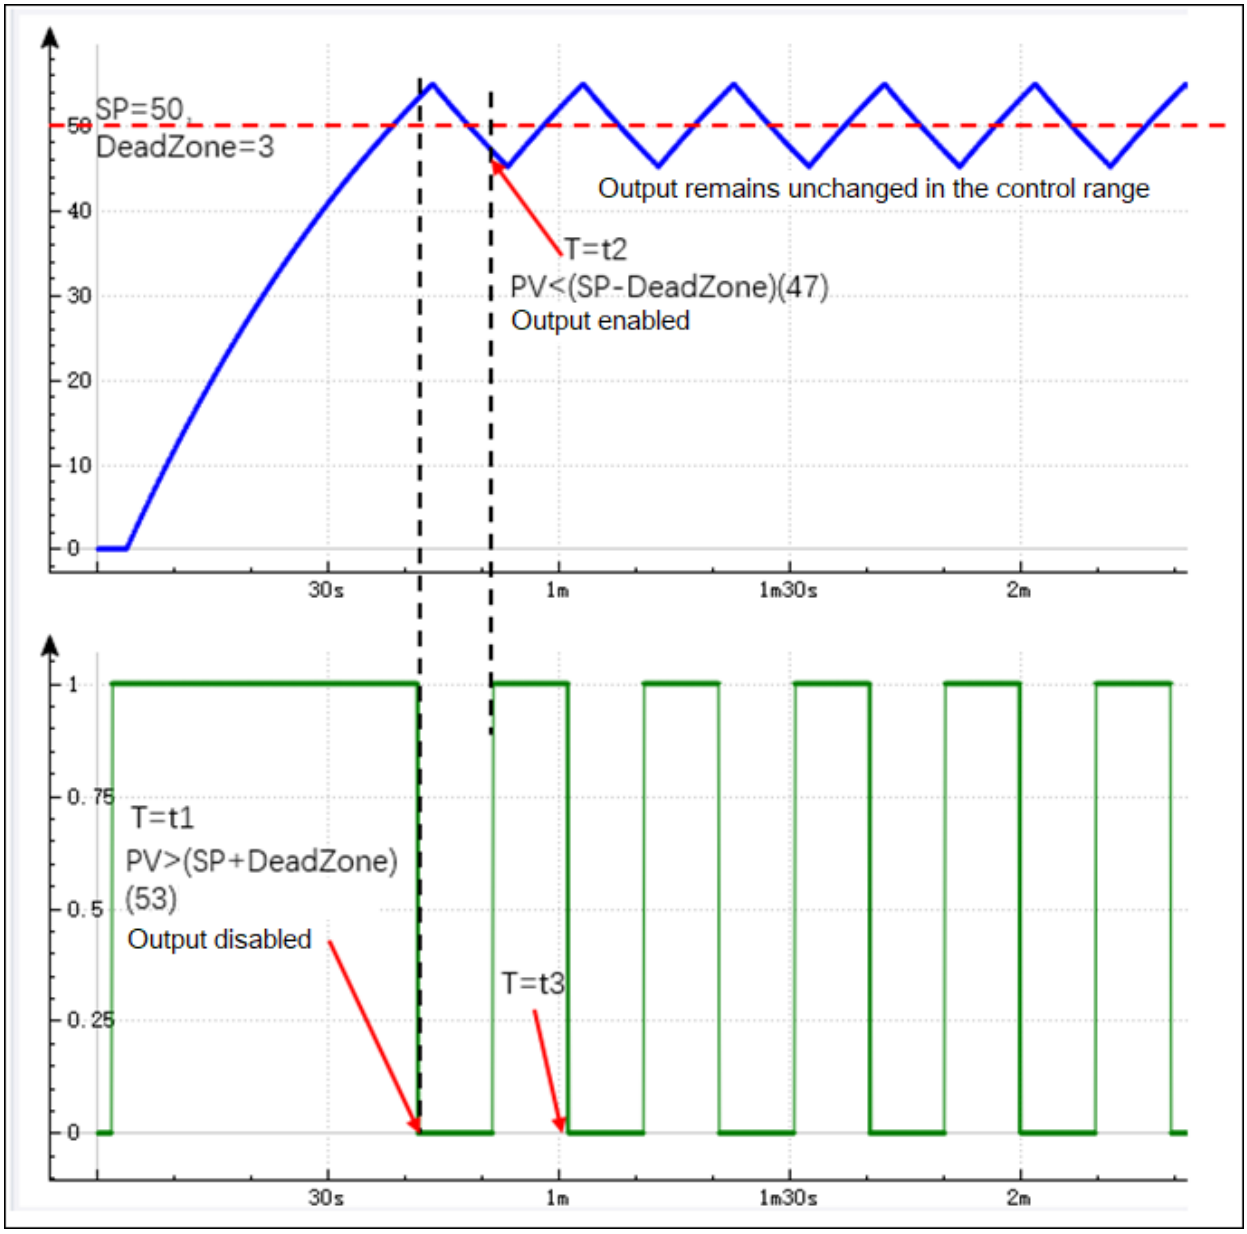
- **Bumpless switchover**

  Bumpless switchover: When the module's operation mode changes, the module's output remains unchanged during the switching. After the switching is completed, the module's output begins to calculate based on the previous output value, ensuring that there is no disturbance to the control of on-site equipment.

  There are six operation modes for the TWPOSC control module. Mode switching is generally bumpless, but disturbances may occur under certain conditions, as detailed below.

Automatic -> Manual Interlock -> Manual	Manual -> Interlock Automatic -> Interlock	Manual -> Automatic Interlock -> Automatic
In automatic or interlock mode, the internal manual value automatically tracks the current mode output value to ensure a bumpless switchover to manual.	In interlock mode, the interlock safety value is directly output, and the switch may cause disturbances.	In automatic mode, the input value is directly associated, and the switch may cause disturbances.

- **Corresponding faults to Errorbits**



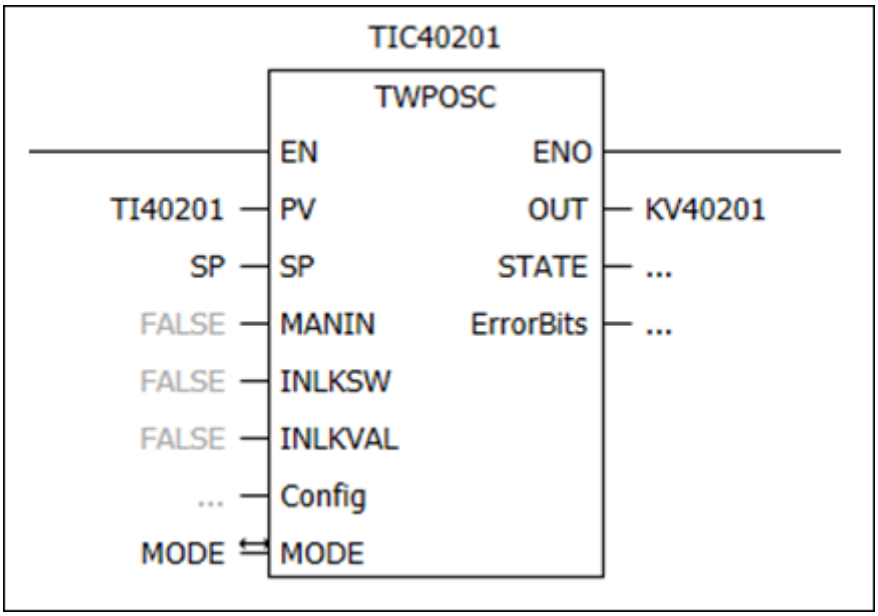
Errorbits	Note	Solution
16#0000	No error	/

Errorbits	Note	Solution
16#0001	PV upper/lower limit alarm There are two possibilities: • PV > PV_HLM (Process value greater than upper limit) • PV < PV_LLM (Process value less than lower limit)	Output: Switch to manual mode, output current manual value (interlock mode does not switch) After checking and confirming, the user can switch to automatic mode to resume operation.
16#0002	Deviation limit alarm In automatic mode, the absolute value of the deviation between process value PV and setpoint SP is greater than the deviation alarm value.	Output: Switch to manual mode, output current manual value After checking and confirming, the user switches to automatic to continue running In automatic mode, if an alarm is triggered and switched to manual, the alarm remains until it is confirmed on-site, then switch back to automatic mode for deviation alarm recovery.
16#0004	Parameter setting error alarm Includes: In all modes, the PV upper/lower limit setting is invalid if PV_LLM ≥ PV_HLM. In automatic mode: • EKDB >= EKLIM (Deviation deadzone greater than or equal to deviation alarm value) • DeadZone >= EKLIM (Control deadzone greater than or equal to deviation alarm value) • DeadZone >= EKLIM - EKDB (Deviation alarm reset within control deadzone) • Control deadzone (DeadZone) or deviation deadzone (EKDB) is less than 0, or the deviation alarm limit (EKLIM) is less than or equal to 0. • Setpoint rate limit (SP_RAT) ≤ 0	Output: If parameters are invalid, they do not take effect and the output holds. • Reset the upper and lower limits of PV to ensure PV_HLM > PV_LLM. • Reset the deviation alarm value (EKLIM), deviation deadzone (EKDB), and control deadzone (DeadZone). Ensure the following conditions are met: EKDB < EKLIM DeadZone < EKLIM DeadZone < EKLIM - EKDB DeadZone, EKDB ≥ 0 EKLIM > 0 • Reset the setpoint rate limit (SP_RAT) to ensure that SP_RAT > 0.

Errorbits	Note	Solution
16#0008	Setpoint overrate alarm In automatic mode, the setpoint change exceeds the rate limit (SP_RAT).	Output: Perform normal calculation based on the setpoint after rate limiting. The alarm automatically resets after the setpoint change is less than SP_RAT.

- **Application instance**

  Take the on-off temperature control system of an electric heating furnace as an example, the control process is shown in the figure below.



- At time 0-t1, since PV is less than SP + DeadZone, the heater remains powered and the temperature continues to rise. At time t = t1, since PV = SP + DeadZone, the power is turned off and heating stops, but the temperature does not immediately drop. On the contrary, it continues to rise for a period of time τ1, and only starts to gradually decrease from T' at t = t1 + τ1.

- At t = t2, since PV = SP - DeadZone, the heater power is turned on to start heating, but the temperature does not immediately rise. Instead, it continues to drop for a period of time τ2, and only begins to gradually increase from T'x at t = t2 + τ2.
- At t = t3, T equals SP + DeadZone again, and the temperature controller turns off the power to stop heating. The system and object then repeat the above process once again, and this cycle continues indefinitely. Since the control action alternates between two states, "on" and "off," the temperature of the controlled heating furnace will periodically fluctuate.

With on-off control, the deadzone (DeadZone) must be set appropriately based on the specific control object and the allowable fluctuation range. This method is mainly used for heating objects with small delay and large time constant.

Control scheme configuration:

SW	Operating switch	DINT	0, 1	0	0: Component off 1: Component on Ensure the component is in the on state when in use.
SP	Setpoint	LREAL	Follows data type	0	Setpoint for the controlled variable, which defines the control target of the controller. If properly configured, the actual control result (PV) must closely follow the SP.
PV	Measured value	LREAL	Follows data type	0	Input value for the measured value of the controlled variable, which must be provided via an external physical object or simulation object.

Variable	Name	Data Type	Valid Range	Default Value	Description
Km	Model gain	LREAL	Follows data type	1	An algorithm parameter that describes the response gain of the controlled object. It must be determined based on the influence of the output OP on the controlled object. The greater this influence, the larger the gain value.
Tm	Model time constant	LREAL	(0,1.7E 307]	1	An algorithm parameter that describes the response speed of the controlled object. The greater the inertia of the controlled object, the slower the response, and the larger this value.
Dm	Model hysteresis	LREAL	(0,10000]	0	An algorithm parameter that represents the response hysteresis of the controlled object. The greater the hysteresis of the object to input changes, the larger this value.
HP	Prediction horizon marker	ARRAY[0..199] OF DINT	The array contains values of 0 or 1.	-	0: Invalid 1: The predicted value for the current cycle is used in the prediction calculation. The HP sequence adjusts control performance. Ensure valid points are present in HP after the hysteresis period. The longer the valid length of the HP sequence, the further into the future the trend prediction extends.
DDVTrend	Future disturbance sequence	ARRAY[0..199] OF LREAL	Follows data type	-	Disturbance sequence generated by the PFCs_dv component. When using this variable, pass its "DDVTrend" output to this variable. It is used to predict future disturbances so that the controller can take proactive action to suppress them.

Variable	Name	Data Type	Valid Range	Default Value	Description
AuTuConfig	Auto-tuning parameter structure	AuTuConfig	Follows data type	-	Auto-tuning parameter configuration structure.
PFCsConfig	Input parameter structure	PFCsConfig	Follows data type	-	Input parameter configuration structure.

AuTuConfig structure configuration

Input Variable	Name	Data Type	Valid Range	Default Value	Description
AT_Start	Auto-tuning switch	DINT	0, 1	0	0: Inactive 1: On Set to 1 if auto-tuning function is required.
AT_Model	Model type	DINT	0, 1, 2	0	Model type for the controlled object. 0: Non-integral 1: Pseudo-integral 2: Pure integral Assign values based on actual conditions.
AT_SW	Operating switch	DINT	0, 1, 2	1	0: Off 1: Coarse tuning 2: Fine tuning If the auto-tuning function is enabled, assign values according to the conditions.
AT_OPInit	Initial OP value for tuning	LREAL	Follows data type	0	Initial output value that ensures a stable PV measurement of the object being tuned at the start of the tuning process. The object must remain essentially stable under the AT_OPInit output before tuning begins.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
AT_OPTarget	Tuning output step value	LREAL	Follows data type	100	Target output. After tuning starts, the OP output steps from AT_OPInit to AT_OPTarget, and returns to AT_OPInit when tuning is complete.
AT_PVTarget	PV value at tuning end.	LREAL	Follows data type	100	PV value at tuning end. After tuning starts, the PV of the controlled object will change from an initial steady state to AT_PVTarget under the influence of OP, completing the stepwise coarse tuning.
AT_PVDeltTar	Tuning target value range	LREAL	Follows data type	0	Required oscillation range of the controlled object during fine-tuning oscillation tuning When the PV measurement reaches the upper or lower limit of this range, the OP output switches. Set this value to 0 during coarse tuning.
AT_InitRate	Steady-state slope before tuning	LREAL	Follows data type	0	The initial steady-state slope range at the start of tuning. When the controlled object changes within this slope range, it is considered stable. The larger the AT_InitRate, the broader the range of slopes accepted as steady-state. If AT_InitRate equals 0, the steady-state slope of the system must be 0 for tuning to begin. Therefore, this value is generally not set to 0.

PFCsConfig structure configuration

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Ts	Sampling cycle	LREAL	(0,1.7E 307]	1	This value represents the control and tuning cycle. The value must be greater than 0. Ensure that this value is not set too low; otherwise it could exceed the operation cycle. If Ts is less than 0, the algorithm will automatically terminate, the switch will turn off, and the output will be held.
Model	Model type	DINT	0, 1, 2	1	Model types include: 0: Non-integral 1: Pseudo-integral 2: Pure integral Note that the algorithm internally distinguishes between non-integral and integral models. The logic for pseudo-integral models follows the same rules as those for integral models. When the model selection is not 0, 1, or 2, the algorithm terminates, the switch is turned off, and the output will be held.
COF	Filter coefficient	LREAL	[0,1]	0.9	An algorithm parameter that affects the performance of feedback correction. The feedback value balances the measurement for the current cycle with the model prediction. The magnitude of the COF determines whether the algorithm places greater weight on the measured value or the predicted value in the feedback loop. • When set to 0, the feedback value uses the model prediction, and no feedback correction is applied. • When set to 1, the feedback value uses the measured value. For other values, an average is calculated.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
COP	Performance coefficient	LREAL	(0,1.7E 307]	1	An algorithm parameter that affects the control performance. Decreasing the value speeds up the system response to some extent, while increasing it slows down the system response to some extent.
Tref	Closed-loop reference time	LREAL	(0,1.7E 307]	1	An algorithm parameter that affects the control performance. It is used to reduce the system response speed. Increasing this value slows down the system response to some extent, while decreasing it will speed up the system response to some extent. If the value exceeds the limit, it will be capped at 1e-6.
I_COF	Integral deviation correction coefficient	LREAL	[0,1]	0.1	Correction coefficient for integral speed. This value will take effect when the integral model is used. The larger the value, the faster the integral model speed operates in the algorithm, resulting in greater changes in future prediction, and thus causing output changes. Generally, fine-tuning this value after reaching steady state can reduce steady-state fluctuations.
DOPmax	Output increment limit	LREAL	>=0	100	Sets the upper limit of output increment.
OP_Low_Val	Output valid lower limit	LREAL	Follows data type	0	When the value falls below this output valid lower limit, the switch will be turned off and the control will be disabled.
OP_High_Val	Output valid upper limit	LREAL	Follows data type	100	When the value exceeds this output valid upper limit, the switch will be turned off and the control will be disabled.
OP_Low_Ope	Output operation lower limit	LREAL	Follows data type	0	When the value falls below this output operation lower limit, a warning is issued and the output is clamped to this limit.

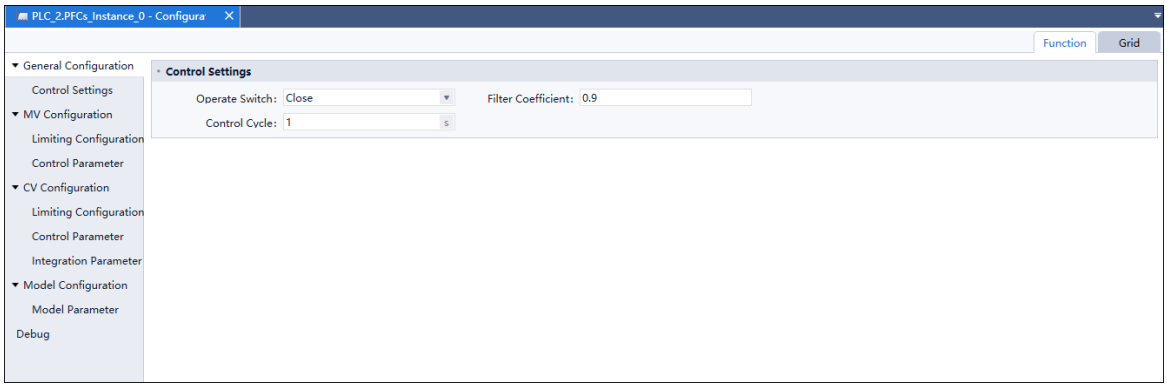
Input Variable	Name	Data Type	Valid Range	Default Value	Description
OP_High_Ope	Output operation upper limit	LREAL	Follows data type	100	When the value exceeds this output operation upper limit, a warning will be issued and the output is clamped to this limit.
SP_Low_Val	Setpoint valid lower limit	LREAL	Follows data type	0	Valid lower limit of the setpoint. When the value falls below this lower limit, the switch will be turned off and the control will be disabled.
SP_High_Val	Setpoint valid upper limit	LREAL	Follows data type	100	Valid upper limit of the setpoint. When the value exceeds this upper limit, the switch will be turned off and the control will be disabled.
SP_Low_Ope	Setpoint operation lower limit	LREAL	Follows data type	0	Operation lower limit of the setpoint. When the value falls below this lower limit, the system will display a warning and limit the value to the lower limit.
SP_High_Ope	Setpoint operation upper limit	LREAL	Follows data type	100	Operation upper limit of the setpoint. When the value exceeds this upper limit, the system will display a warning and limit the value to the upper limit.
SP_DMax	Setpoint increment upper range	LREAL	>=0	0.1	An algorithm parameter that affects the control performance. The system is considered stable if PV is within this range of SP + SP_DMax.
SP_DMin	Setpoint increment lower range	LREAL	<=0	-0.1	An algorithm parameter that affects the control performance. The system is considered stable if PV is within this range of SP - SP_DMin.

Output variable

Variable	Name	Data Type	Valid Range	Default Value	Description
State	Switch state	DINT	0, 1	-	Indicates the actual state of the controller.

Variable	Name	Data Type	Valid Range	Default Value	Description
ERR	Fault code	DINT	Follows data type	-	0 for normal operation; non-zero when an error occurs. See PFCs fault codes.
OP	Valve position output value	LREAL	Follows data type	-	Controller output value.
AT_ST	Tuning result	DINT	0, 1, 2, 3	-	Tuning state display. 0: Not tuned 1: Coarse tuning in progress 2: Fine tuning in progress 3: Tuning completed
PFCsOutput	Output parameter structure	PFCsOutput	Follows data type	-	Output parameter configuration structure.

PFCsOutput structure configuration



Output Variable	Name	Data Type	Valid Range	Default Value	Description
Version	Version information	ARRAY[0..3] OF DINT	Follows data type	-	Used to record internal version information.
DOP	Valve position increment output	LREAL	Follows data type	-	Increment of the output value OP.
PV_Pred_t	Estimated value	LREAL	Follows data type	-	Estimated value, that is, the response value of the controlled object, calculated by the internal model using historical data.
PV_Pred_tf	Predicted value	LREAL	Follows data type	-	Predicted value, that is, the estimated value corrected based on the actual measured value PV.
PV_Pred_e	Prediction error	LREAL	Follows data type	-	Difference between the actual measured value PV and the predicted value.
PV_Pred_eSum	Cumulative prediction error	LREAL	Follows data type	-	Cumulative sum of prediction errors.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
DCV_S	Integral speed	LREAL	Follows data type	-	Integral deviation speed.
PV_Pred	Open-loop prediction sequence	ARRAY[0..199] OF LREAL	Follows data type	-	Records the sequence of future measured values predicted when the current cycle is not applied.
Tref_Step	Reference trajectory sequence	ARRAY[0..199] OF LREAL	Follows data type	-	A trajectory sequence generated by the Tref parameter.
OP_Low_Ope_Past	Output lower limit history sequence	ARRAY[0..199] OF LREAL	Follows data type	-	Sequence of historical operation lower limits for the controller output OP.
OP_High_Ope_Past	Output upper limit history sequence	ARRAY[0..199] OF LREAL	Follows data type	-	Sequence of historical operation upper limits for the controller output OP.
OP_Low_Ope_Future	Output lower limit future sequence	ARRAY[0..199] OF LREAL	Follows data type	-	Records the sequence of predicted operation lower limits for the controller output at future sampling instants, computed after the current cycle has been applied.
OP_High_Ope_Future	Output upper limit future sequence	ARRAY[0..199] OF LREAL	Follows data type	-	Records the sequence of predicted operation upper limits for the controller output at future sampling instants, computed after the current cycle has been applied.
SP_Past	Setpoint history sequence	ARRAY[0..199] OF LREAL	Follows data type	-	Records the sequence of the historical setpoints.
SP_Future	Setpoint future sequence	ARRAY[0..199] OF LREAL	Follows data type	-	Records the sequence of future setpoints predicted by the algorithm after the current cycle has been applied.
SP_Low_Ope_Past	Setpoint lower limit history sequence	ARRAY[0..199] OF LREAL	Follows data type	-	Records the sequence of historical operation lower limits for the setpoint.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
SP_High_Ope_Past	Setpoint upper limit history sequence	ARRAY[0..199] OF LREAL	Follows data type	-	Records the sequence of historical operation upper limits for the setpoint.
SP_Low_Ope_Future	Setpoint lower limit future sequence	ARRAY[0..199] OF LREAL	Follows data type	-	Records the sequence of predicted operation lower limits for the setpoint at future sampling instants, computed after the current control cycle has been applied.
SP_High_Ope_Future	Setpoint upper limit future sequence	ARRAY[0..199] OF LREAL	Follows data type	-	Records the sequence of predicted operation upper limits for the setpoint at future sampling instants, computed after the current control action has been applied.
PV_Past	Measured value history sequence	ARRAY[0..199] OF LREAL	Follows data type	-	Records the sequence of historical measured values.
OP_Past	Output value history sequence	ARRAY[0..199] OF LREAL	Follows data type	-	Records the sequence of historical output values.
OP_Future	Output value future sequence	ARRAY[0..199] OF LREAL	Follows data type	-	Records the sequence of future output values predicted by the algorithm after the current cycle has been applied.
AT_Km	Tuning parameter Km	LREAL	Follows data type	-	Model gain result obtained from auto-tuning.
AT_Tm	Tuning parameter Tm	LREAL	> 0	-	Model time constant result obtained from auto-tuning.
AT_Dm	Tuning parameter Dm	LREAL	>=0	-	Model hysteresis parameter result obtained from auto-tuning.

- **Function**
  - PFCs is a simplified 1x1 single-input, single-output predictive function controllers. It includes one manipulated variable (output via OP) and one controlled variable (measured via PV), and support a feedforward input channel (for use with the PFC_DV function block). The PFCs component features a built-in auto-tuning function to obtain model parameters of the controlled object. This component is primarily used for rapid deployment in single-input single-output processes.
  - The PFCs function block includes an intuitive interface for parameter configuration and tuning. After adding the PFCs component, select "Control object > PFC" in the left project tree, and then double-click

the PFCs instance under the PFC node to open the configuration and tuning interface, as shown in the figure below.

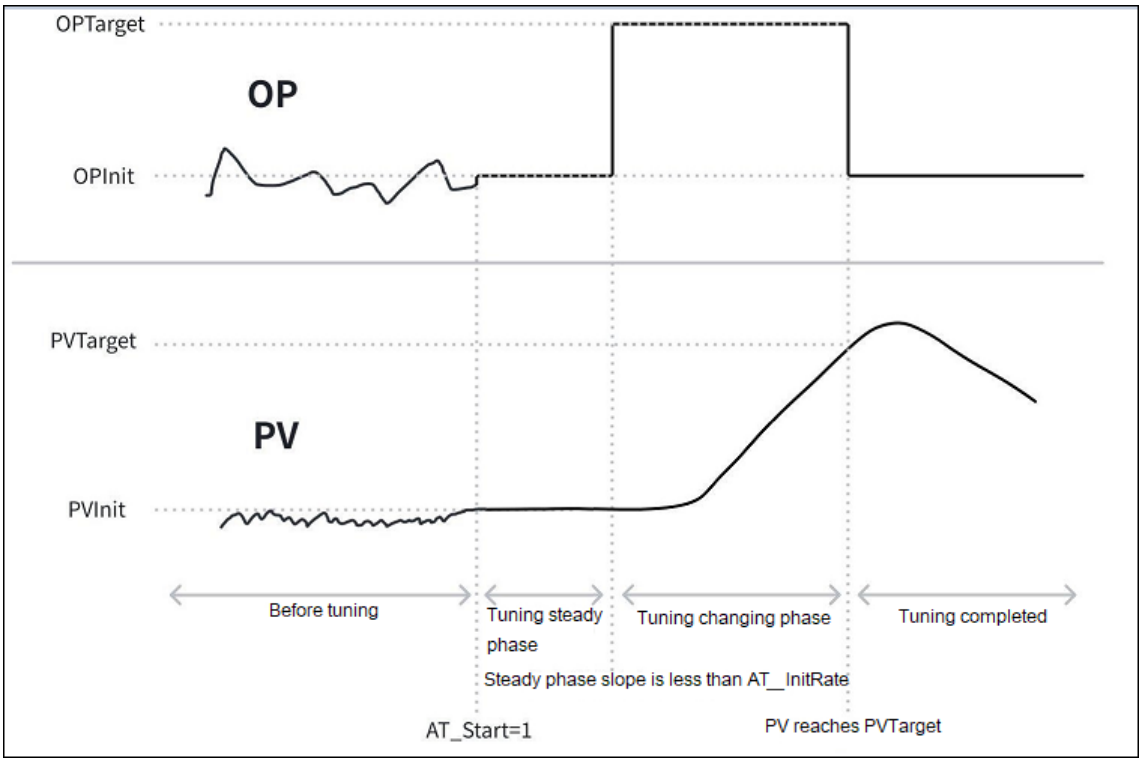
- Parameter configuration

  The parameter configuration of the PFCs instruction includes general configuration, MV configuration, CV configuration, and model configuration. For detailed parameter descriptions, see Relevant variables.

- Parameter auto-tuning

  The PFCs instruction includes a built-in parameter auto-tuning function, automatically obtaining the model parameters (Km, Tm, and Dm) of the controlled object.

  Click the "Tuning" button on the "Commissioning" page to start parameter tuning.



Because the controller internal variable array has a capacity of only 200, ensure that the duration from the OP output step to the completion of tuning stays within 200 control cycles. 100 to 150 cycles is recommended. Additionally, the tuning process does not require the system to reach final steady state after the step change.

The tuning process is as follows:

1. Use the auto-tuning switch AT_SW to select the model type for the tuning object.
2. Configure the tuning parameter "Initial OP value for tuning" (AT_OPInit). AT_OPInit is the OP output value at the initial steady state. Ensure that the controlled object reaches a basic stable state at this output. Open-loop control can be used before the tuning process to stabilize the controlled object at this output, then switch to auto-tuning. The initial steady state is critical for the tuning results. When it is difficult to achieve the initial steady state, the "Steady-state slope" (AT_InitRate) parameter can be used to appropriately relax the steady-state requirements.

3. Configure the tuning parameter "Tuning step value" (AT_OPTarget). This value is the step output value at the start of tuning. The controller will perform a step change from "AT_OPInit" to "AT_OPTarget" to excite the response of the controlled object.
4. Configure the tuning parameter "PV target value at the end of tuning" (AT_PVTarget). The tuning process completes when the measured value (PV) of the controlled object reaches this value after tuning begin. Pay special attention to the response polarity of the controlled object. Ensure that the measured value reaches AT_PVTarget after tuning starts, rather than the PV changing in the opposite direction after the OP step change.
5. Click the "Start tuning" button.
6. After tuning ends, click "Confirm" or "Cancel" to select parameters, and automatically switch to control mode.

- **Program example**

  This instruction is a control instruction and requires connection to the inputs and outputs of an external or simulated controlled object. Accordingly, the input PV of the PFCs instruction must be connected to the output of the controlled object, while the output OP of the instruction is connected to the input of the controlled object.

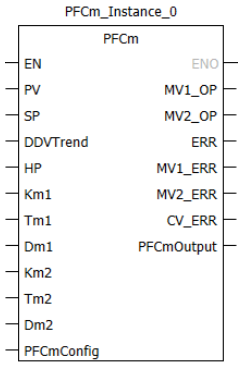
  Here, the collaborative simulation between the PFCs instruction and the first-order inertia plus pure delay simulation instruction (FPTLGsim) is used as an example. The parameter configuration and control process are as follows:

1. Parameter configuration
   Based on the characteristics of the control object, configure the relevant parameters of the PFCs instruction in the configuration interface.
2. Control process
   The PFCs instruction responds to the output (PV) of the FPTLGsim object, calculates the control output (OP), and applies it to the original controlled object, forming a closed control loop.

3. Control expectation

   If all parameters are configured properly, the controller will eventually keep the output value (PV) of the controlled object near the setpoint SP.

   LD language code example:



- **Precautions**
  - The module execution cycle must be consistent with the function block cycle parameter Ts.
  - Ensure the switch SW is in the open state (Value: 1) and the configuration is correct for use.
  - The execution time of the PFCs instruction is 8 ms. With 130 PFCs function blocks loaded, the total execution time is estimated to reach approximately 1 second. Loading 562 PFCs function blocks will reach the controller's resource limit. During operation, configure the scheduling task cycle properly. For example, if 10 PFCs are required to perform loop control simultaneously, with a block calculation time of 80 ms. The task cycle must be at least twice this value, that is, 160 ms, to ensure the CPU load does not become too high.

18.3.2.3 PFCm

This instruction is a single-input dual-output control instruction. It is primarily used in "2-to-1" control scenarios, such as regulating temperature via heating and cooling.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
PFCm	Multivariable advanced control	FB		PFCm_Instance_0(PV := , SP := , DDVTrend := , HP := , Km1 := , Tm1 := , Dm1 := , Km2 := , Tm2 := , Dm2 := , PFCmConfig := , MV1_OP => , MV2_OP => , ERR => , MV1_ERR => , MV2_ERR => , CV_ERR => , PFCmOutput =>);

- **Related variables**

  Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
PV	Measured value of the controlled variable	LREAL	Follows data type	0	Input value of the controlled variable measurement, which must be provided by an external physical object or simulation object.
SP	Controlled variable setpoint value	LREAL	Follows data type	50	Setpoint value of the controlled variable, which determines the control objective of the controller so that the final actual control result (PV) must closely follow the SP.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
DDVTrend	Disturbance sequence	ARRAY[0..199] OF LREAL	Follows data type	-	Disturbance sequence generated by the PFCs_dv component. When using this variable, pass its DDVTrend output to this variable. It is used to predict future disturbances so that the controller can take proactive action to suppress them.
HP	Prediction horizon marker	ARRAY[0..199] OF DINT	Follows data type	-	Note that if there are no valid values (that is, 1) in this array after M_Dm_CV_min, there will be no valid prediction. The internal logic will overwrite the values in this array to ensure a valid prediction horizon.
Km1	Model 1 gain	LREAL	Follows data type	1	An algorithm parameter that describes the response gain of the controlled object. It must be determined based on the influence of the output OP on the controlled object. The greater this influence, the larger the gain value.
Tm1	Model 1 time constant	LREAL	(0,1.7E 307]	1	An algorithm parameter that describes the response speed of the controlled object. The greater the inertia of the controlled object, the slower the response, and the larger this value. If the value exceeds the limit, it will be limited to 1e-6.
Dm1	Model 1 hysteresis	LREAL	[0,1.7E 307]	0	An algorithm parameter that represents the response hysteresis of the controlled object. The greater the hysteresis of the object to input changes, the larger this value. If the value exceeds the limit, it will be limited to 0.
Km2	Model 2 gain	LREAL	Follows data type	1	Same as Km1; this is the gain for model 2.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Tm2	Model 2 time constant	LREAL	(0,1.7E 307]	1	Same as Tm1, this is the time constant for model 2. If the value exceeds the limit, it will be limited to 1e-6.
Dm2	Model 2 hysteresis	LREAL	[0,1.7E 307]	0	Same as Dm2; this is the hysteresis for model 2. If the value exceeds the limit, it will be limited to 0.
PFCmConfig	Input parameter structure	PFCmConfig	Follows data type	-	Input parameter configuration structure.

PFCmConfig structure configuration

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Ts	Sampling cycle	LREAL	(0,1.7E 307]	1	This value determines the control cycle and must be greater than 0. Note that this value must not be too low; otherwise it can cause a time-out during computation, affecting control. When Ts is set to an invalid value (that is, less than 0), the algorithm will automatically terminate, the switch is turned off, and the output will remain unchanged.
Model	Model type	DINT	0, 1, 2	1	Model type: 0: Non-integral 1: Pseudo-integral 2: Pure integral Note that the algorithm internally distinguishes between non-integral and integral models. The logic for pseudo-integral models follows the same rules as those for integral models. When the model selection is not 0, 1, or 2, the algorithm terminates, the switch is turned off, and the output will be held.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
COF	Filter coefficient	LREAL	[0,1]	0.9	An algorithm parameter that affects the performance of feedback correction. The feedback value balances the measurement for the current cycle with the model prediction. When set to 0, the feedback value uses the model prediction, and no feedback correction is applied. When set to 1, the feedback value uses the measured value. For other values, an average is calculated. If this value exceeds the upper limit, it will be limited to the upper limit. If the value falls below the lower limit, it will be limited to the lower limit.
Tref	Closed-loop reference time	LREAL	(0,1.7E 307]	1	An algorithm parameter that affects the control performance. Increasing the value slows down the system response to some extent, while decreasing it speeds up the system response to some extent. If the value exceeds the limit, it will be limited to 1e-6.
I_COF	Integral deviation correction coefficient	LREAL	[0,1]	0.1	Correction coefficient for integral speed. This value will take effect when the integral model is used. The larger the value, the faster the integral model speed operates in the algorithm, resulting in greater changes in future prediction, and thus causing output changes. Generally, fine-tuning this value after reaching steady state can reduce steady-state fluctuations. If this value exceeds the upper limit, it will be limited to the upper limit. If the value falls below the lower limit, it will be limited to the lower limit.
MV1_Config	MV variable input parameter structure	MVConfig	Follows data type	-	MV1 variable input parameter configuration structure.
MV2_Config	MV variable input parameter structure	MVConfig	Follows data type	-	MV2 variable input parameter configuration structure.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
CV_SW	Controlled variable switch	DINT	0, 1	1	Controlled variable switch. When the switch is off, the control is disabled. When used, it must be set to 1. Invalid values are automatically set to 0.
CV_SP_Dmax	Upper deviation range	LREAL	[0,1.7E 307]	0.01	An algorithm parameter that affects the control performance. The system is considered stable if PV + CV_SP_Dmax is within this range. Invalid input values are limited to 0.
CV_SP_Dmin	Lower deviation range	LREAL	[-1.7E 307,0]	-0.01	An algorithm parameter that affects the control performance. The system is considered stable if PV + CV_SP_Dmax is within this range. Invalid input values are limited to 0.
DeltaCV	Maximum change rate of the controlled variable	LREAL	[0,1.7E 307]	100	This algorithm parameter defines the maximum change value of CV during prediction. Invalid values are limited to 100.
CV_Low_Val	Valid lower limit of the controlled variable	LREAL	Follows data type	0	Valid lower limit. When the value falls below the valid lower limit, the switch will be turned off and the control will be disabled.
CV_High_Val	Valid upper limit of the controlled variable	LREAL	Follows data type	100	Valid upper limit. When the value exceeds the valid upper limit, the switch will be turned off and the control will be disabled.
CV_Low_Ope	Operation lower limit of the controlled variable	LREAL	Follows data type	0	Operation lower limit. When the value falls below this operation lower limit, a warning will be issued and the value will be clamped to this operation lower limit.
CV_High_Ope	Operation upper limit of the controlled variable	LREAL	Follows data type	100	Operation upper limit. When the value exceeds this operation upper limit, a warning will be issued and the value will be clamped to this operation upper limit.

MVConfig structure configuration

Input Variable	Name	Data Type	Valid Range	Default Value	Description
MV_SW	Manipulated variable switch	DINT	0, 1	1	MV switch; when this switch is off, the control is disabled. Invalid values are automatically set to 0.
MV_High_Val	Manipulated variable valid upper limit	LREAL	Follows data type	200	Valid upper limit. When the value exceeds the valid upper limit, the switch will be turned off and the control will be disabled.
MV_Low_Val	Manipulated variable valid lower limit	LREAL	Follows data type	0	Valid lower limit. When the value falls below the valid lower limit, the switch will be turned off and the control will be disabled.
MV_High_Ope	Operation upper limit of the manipulated variable	LREAL	Follows data type	100	Operation upper limit. When the value exceeds this operation upper limit, a warning will be issued and the value will be clamped to this operation upper limit.
MV_Low_Ope	Operation lower limit of the manipulated variable	LREAL	Follows data type	0	Operation lower limit. When the value falls below this operation lower limit, a warning will be issued and the value will be clamped to this operation lower limit.
MV_DMax	Maximum positive increment for the manipulated variable	LREAL	[0,1.7E 307]	100	Defines the maximum allowable positive increment of the output. Invalid input values are limited to 100.
MV_DMin	Maximum negative increment for the manipulated variable	LREAL	[-1.7E 307, 0]	-100	Defines the maximum allowed negative increment of the output. Invalid input values are limited to -100.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
MV_COP	Manipulated variable performance coefficient	LREAL	[0,1.7E 307]	1	An algorithm parameter that affects the control performance. Decreasing the value speeds up the system response to some extent, while increasing it slows down the system response to some extent. If this value exceeds the upper limit, it will be limited to the upper limit. If the value falls below the lower limit, it will be limited to the lower limit.
MV_Irv	Ideal injection value for the manipulated variable	LREAL	Follows data type	1	The value that the corresponding MV output eventually converges to.
MV_Irv_C	Weight for manipulated variable ideal injection value	LREAL	Follows data type	1	Corresponding weight. The higher the weight, the closer the MV will converge to MV_Irv.
MV_Irv_SW	Ideal injection value switch	DINT	0, 1	0	When set to 0, the ideal injection value is inactive. When used, the value must be set to 1. Invalid values are automatically set to 0.

Output variable

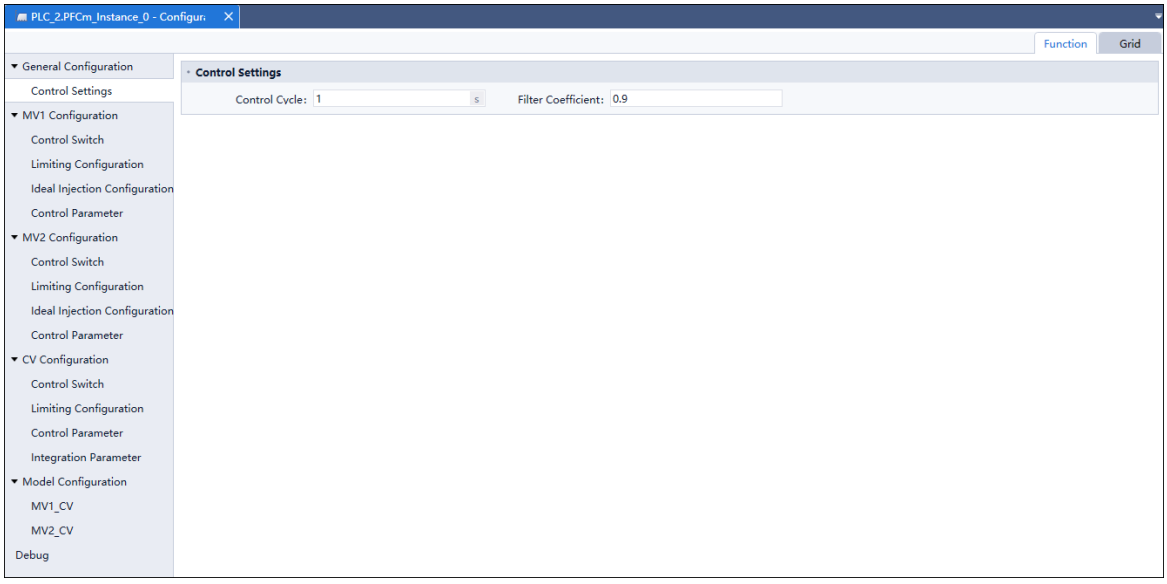
Output Variable	Name	Data Type	Valid Range	Default Value	Description
MV1_OP	Manipulated variable 1 output value	LREAL	Follows data type	-	Output value of manipulated variable 1. This value must be output to the simulation object or actual object.
MV2_OP	Manipulated variable 2 output value	LREAL	Follows data type	-	Output value of manipulated variable 2. This value must be output to the simulation object or actual object.
ERR	Fault code	DINT	Follows data type	-	For fault codes, see PFCm fault codes.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
MV1_ERR	Manipulated variable 1 fault code	DINT	Follows data type	-	Fault code of manipulated variable 1.
MV2_ERR	Manipulated variable 2 fault code	DINT	Follows data type	-	Fault code of manipulated variable 2.
CV_ERR	Controlled variable fault code	DINT	Follows data type	-	Fault code of controlled variable.
PFCmOutput	Output parameter structure	PFCmOutPut	Follows data type	-	Output parameter structure.

PFCmOutput structure configuration

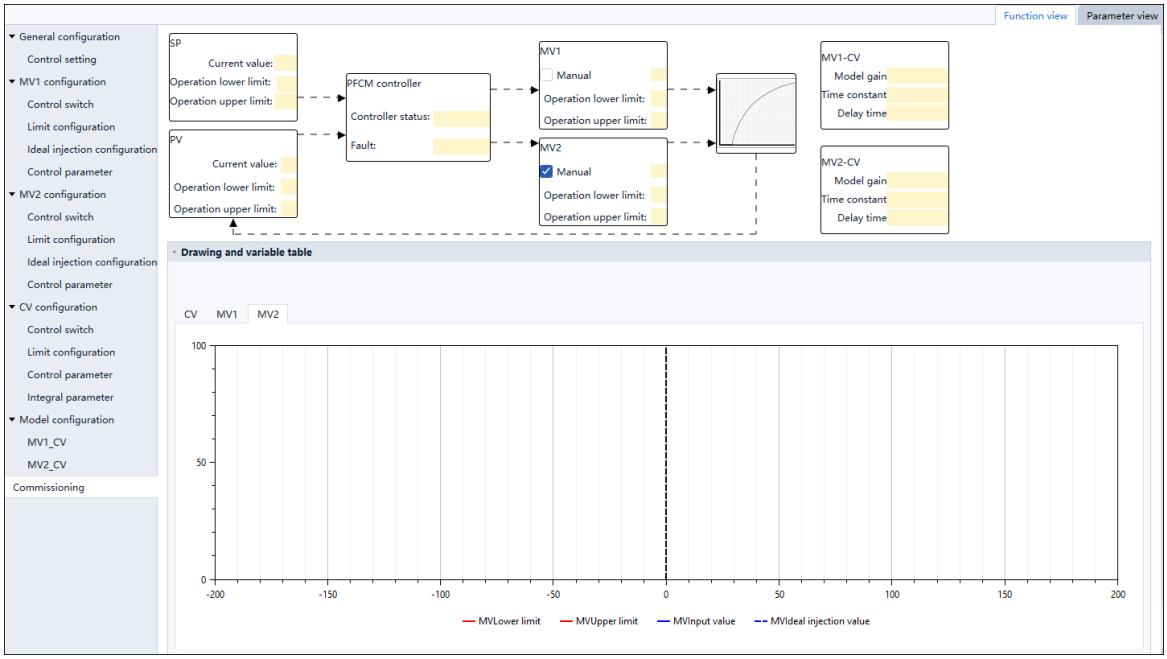
Output Variable	Name	Data Type	Valid Range	Default Value	Description
Version	Version information	ARRAY[0..3] OF DINT	Follows data type	-	Used to obtain the version information.
CV_Pred_t	Estimated value of controlled variable	LREAL	Follows data type	-	Estimated value, that is, the response value of the controlled object, calculated by the internal model using historical data.
CV_Pred_tf	Predicted value of controlled variable	LREAL	Follows data type	-	Predicted value, that is, the corrected predicted value based on the predicted value and the actual measured value PV.
DCV_S_i	Velocity after integral deviation correction	LREAL	Follows data type	-	Velocity after integral deviation correction.
CV_PV_e	Predicted error of the controlled variable	LREAL	Follows data type	-	Difference between the actual measured value and the predicted value.
CV_PV_eSum	Cumulative sum of predicted errors for the controlled variable	LREAL	Follows data type	-	The cumulative sum of errors (regardless of sign). Its magnitude indicates the degree of model mismatch.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
NFlag	Number of errors	DINT	[0, 10]	-	Counts the number of errors.
Flag	Error information	ARRAY[0..9] OF DINT	Follows data type	-	Records detailed information of each error.
MV1_OutConfig	Manipulated variable 1 output structure	MVOutConfig	Follows data type	-	Output structure of manipulated variable 1.
MV2_OutConfig	Manipulated variable 2 output structure	MVOutConfig	Follows data type	-	Output structure of manipulated variable 2.
CV_NFlag	Controlled variable error count	DINT	[0, 10]	-	Number of recorded errors for the controlled variable
CV_Flag	Controlled variable error information	ARRAY[0..9] OF DINT	Follows data type	-	Detailed information of recorded errors for the controlled variable
CV_ST	Controlled variable switch status	DINT	0, 1	-	Status of the controlled variable switch. Initially the value equals the switch input value. When an internal error occurs, this value is set to 1.
CV_Pred_t_Past	Sequence of historical estimated values for the controlled variable	ARRAY[0..199] OF LREAL	Follows data type	-	Records historical values.
CV_Pred	Open-loop prediction sequence of controlled variables	ARRAY[0..199] OF LREAL	Follows data type	-	Records the sequence of future values predicted when the current cycle is not applied.
CV_Future	Closed-loop prediction sequence of controlled variables	ARRAY[0..199] OF LREAL	Follows data type	-	Records the sequence of future values predicted after the current cycle has been applied.



Output Variable	Name	Data Type	Valid Range	Default Value	Description
CV_PV_Past	Sequence of historical measured values for the controlled variable	ARRAY[0..199] OF LREAL	Follows data type	-	Records historical measured values.
SP_Past	Setpoint history sequence	ARRAY[0..199] OF LREAL	Follows data type	-	Sequence of historical setpoint values, for plotting.
SP_Future	Setpoint future sequence	ARRAY[0..199] OF LREAL	Follows data type	-	Sequence of the future setpoint values, for plotting.
CV_SP_Href	Upper reference trajectory sequence	ARRAY[0..199] OF LREAL	Follows data type	-	The predicted upper trajectory that the controlled variable is expected to converge to.
CV_SP_Lref	Lower reference trajectory sequence	ARRAY[0..199] OF LREAL	Follows data type	-	The predicted lower trajectory that the controlled variable is expected to converge to.
CV_Low_Past	Controlled variable lower limit history sequence	ARRAY[0..199] OF LREAL	Follows data type	-	Sequence of historical operation lower limits for the controlled variable, for plotting.
CV_High_Past	Controlled variable upper limit history sequence	ARRAY[0..199] OF LREAL	Follows data type	-	Sequence of historical upper limits for the controlled variable, for plotting.
CV_Low_Future	Controlled variable lower limit future sequence	ARRAY[0..199] OF LREAL	Follows data type	-	Sequence of future operation lower limits for the controlled variable, for plotting.
CV_High_Future	Controlled variable upper limit future sequence	ARRAY[0..199] OF LREAL	Follows data type	-	Sequence of future operation upper limits for the controlled variable, for plotting.

MVOutConfig structure configuration



Input Variable	Name	Data Type	Valid Range	Default Value	Description
MV_NFlag	MV error count	DINT	[0, 10]	-	Number of errors counted for the manipulated variable.
MV_Flag	MV error message	ARRAY[0..9] OF DINT	Follows data type	-	Detailed information of recorded errors for the manipulated variable.
MV_Low_Past	Output lower limit history sequence	ARRAY[0..9] OF LREAL	Follows data type	-	Sequence of historical operation lower limits for the manipulated variable, for plotting.
MV_High_Past	Output upper limit history sequence	ARRAY[0..9] OF LREAL	Follows data type	-	Sequence of historical operation upper limits for the manipulated variable, for plotting.
MV_Low_Future	Output lower limit future sequence	ARRAY[0..9] OF LREAL	Follows data type	-	Sequence of future operation lower limits for the manipulated variable, for plotting.
MV_High_Future	Output upper limit future sequence	ARRAY[0..9] OF LREAL	Follows data type	-	Sequence of future operation upper limits for the manipulated variable, for plotting.
MV_Past	Output value history sequence	ARRAY[0..9] OF LREAL	Follows data type	-	Sequence of historical measured values for the manipulated variable, for plotting.
MV_Future	Output value future sequence	ARRAY[0..9] OF LREAL	Follows data type	-	Sequence of future measured values for the manipulated variable, for plotting.
MV_DOP_Past	Historical increment sequence of the valve position	ARRAY[0..9] OF LREAL	Follows data type	-	Sequence of historical increment values for the manipulated variable, for plotting.
MV_DOP	Manipulated variable action increment	LREAL	Follows data type	-	Increment value of the manipulated variable.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
MV_ST	Manipulated variable switch state	DINT	0, 1	-	Manipulated variable switch state. Initially, it equals the switch value. This value is set to 1 when an internal error occurs.
MV_Irv_Past	Ideal injection value history sequence	ARRAY[0..9] OF LREAL	Follows data type		Sequence of historical ideal injection values, for plotting.
MV_Irv_Future	Ideal injection value future sequence	ARRAY[0..9] OF LREAL	Follows data type		Sequence of future ideal injection values, for plotting.

- **Function**
  - PFCm is a 1×2 single-input, dual-output control instruction. The controlled object can support non-integrating, integrating, or pseudo-integrating responses. The instruction includes two manipulated variables (MV), one controlled variable (CV), and a feedforward input channel (for use with PFCs_dv). It does not rely on an external solver for optimization calculations. It is primarily intended for applications that require two manipulated variables but not high-end products. It is suitable for fast control application scenarios with millisecond-level control cycles.
  - The PFCm function block includes an intuitive interface for parameter configuration and commissioning. After adding the PFCm component, select "Control Objects -> PFC" in the left project tree, and then double-click the PFCm instance under the PFC node to open the configuration and tuning interface, as shown in the figure below.

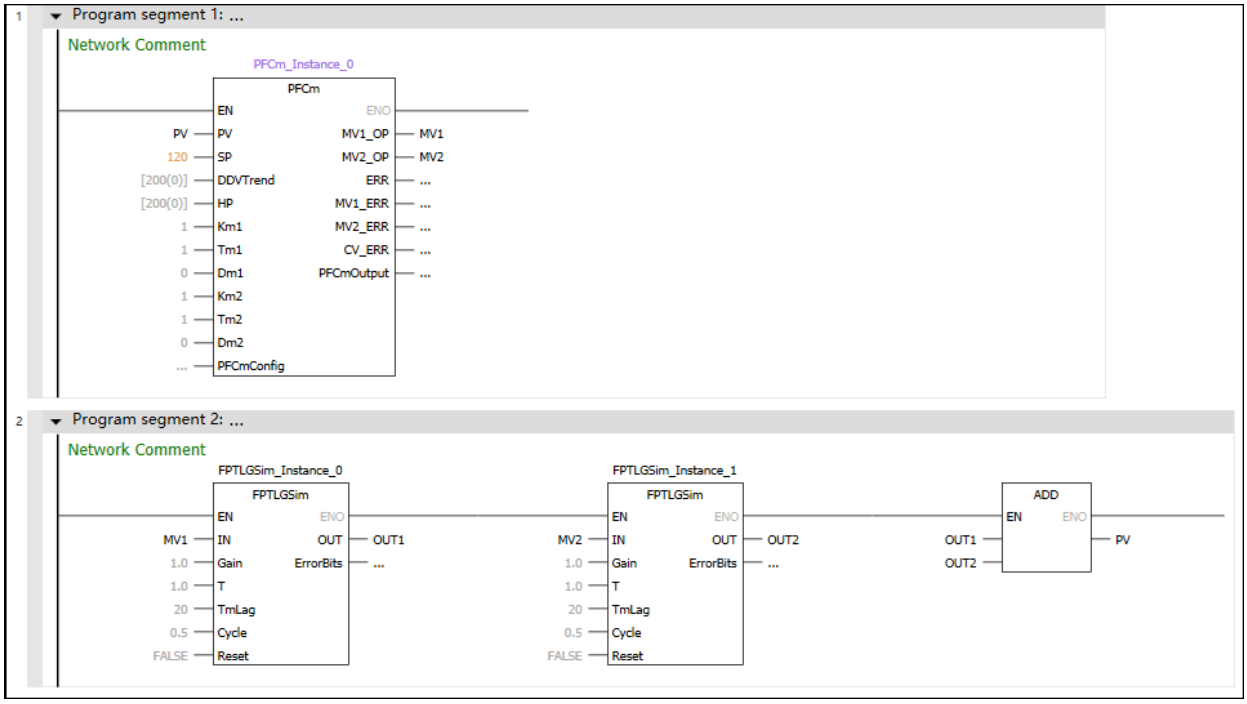
    - Parameter configuration
      The parameter configuration of the PFCm instruction includes general configuration, MV configuration, CV configuration, and model configuration. For detailed parameter descriptions, see Relevant variables.
    - Commissioning
      After the parameters are configured, the control effect can be viewed directly in the commissioning interface.

- **Program example**

  Here, the two-input, single-output control simulation between the PFCm instruction and two first-order inertia plus pure delay simulation instruction (FPTLGsim) is used as an example. The parameter configuration and control process are as follows:

1. Parameter configuration

   Configure the PFCm instruction parameters based on the characteristics of the control object (Model parameters: Km1, Km2, Dm1 and so on; controller parameters: COP, COF, etc.).



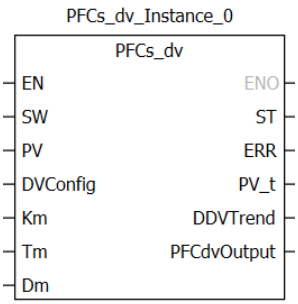
2. Control process

   The PFCm instruction responds to the output (PV) of the FPTLGsim object, obtains the control quantity (OP) output, and applies it to the original control object, forming a control loop.

3. Control expectation

   If all parameters are configured properly, the controller will eventually keep the output value (PV) of the controlled object near the setpoint SP.

   LD language code example:



- **Precautions**
  - During operation, ensure that the switch is on, and the configuration is correct.
  - The execution time of the PFCm instruction is 20 ms. With 50 PFCm function blocks loaded, the total execution time is estimated to reach approximately 1 second. Loading 364 PFCm function blocks will reach the controller's resource limit. During operation, configure the scheduling task cycle properly. For example, if 10 PFCm are required to perform loop control simultaneously, with a block calculation time of 200 ms. The task cycle must be at least twice this value, that is, 400 ms, to ensure the CPU load does not become too high.

18.3.2.4 PFCs_dv

The disturbance instruction outputs a predicted disturbance sequence and must be used in conjunction with a corresponding control instruction.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
PFCs_dv	Feedforward predictive control	FB		PFCs_dv_Instance_0(SW := , PV := , DVConfig := , Km := , Tm := , Dm := , ST => , ERR => , PV_t => , DDVTrend => , PFCdvOutput =>);

- **Related variables**

  Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
SW	Disturbance switch	DINT	0, 1	1	The disturbance switch disables the control when the switch is off. When used, it must be 1. Any invalid value is set to 0.
PV	Input value	LREAL	Follows data type	0	Disturbance input value provided externally. Based on this input value, a corresponding disturbance sequence is generated.
DVConfig	Input parameter structure	DVConfig	Follows data type	-	Input parameter configuration structure.
Km	Model gain	LREAL	Follows data type	1	An algorithm parameter that describes the response gain of the controlled object. It must be determined based on the influence of the output OP on the controlled object. The greater this influence, the larger the gain value.

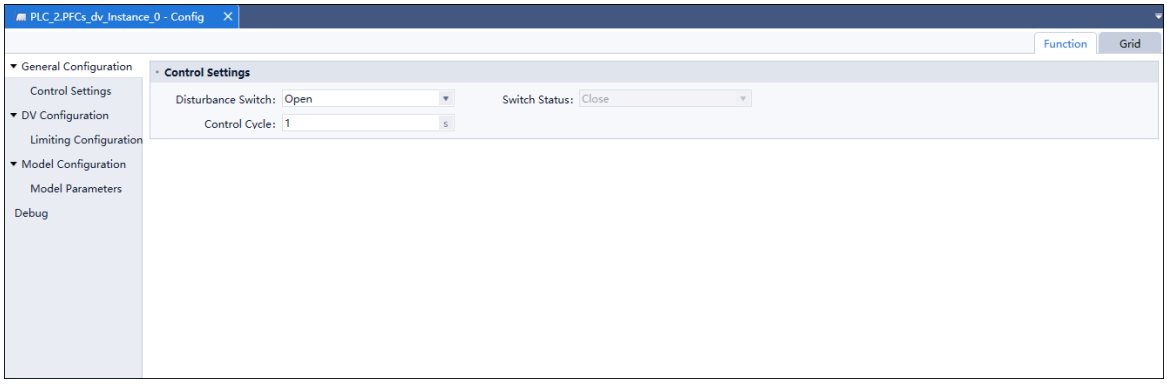
Input Variable	Name	Data Type	Valid Range	Default Value	Description
Tm	Model time constant	LREAL	(0,1.7E 307]	1	An algorithm parameter that describes the response speed of the controlled object. The greater the inertia of the controlled object, the slower the response, and the larger this value. If the value exceeds the limit, it will be limited to 1e-6.
Dm	Model hysteresis	LREAL	[0,1.7E 307]	0	An algorithm parameter that represents the response hysteresis of the controlled object. The greater the hysteresis of the object to input changes, the larger this value. If the value exceeds the limit, it will be limited to 0.

DVConfig structure configuration

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Ts	Sampling cycle	LREAL	(0,1.7E 307]	1	This value determines the control cycle and must be greater than 0. Note that this value must not be too low; otherwise it can cause a time-out during computation, affecting control. When Ts is set to an invalid value (that is, less than 0), the algorithm will automatically terminate, the switch is turned off, and the output will remain unchanged.
Model	Model type	DINT	0, 1, 2	1	Model type: 0: Non-integral 1: Pseudo-integral 2: Pure integral Currently, types 0 (Non-integral) and 1 (Pseudo-integral) are primarily used. Type 2 (Pure integral) is not implemented. In practice, integral models are typically handled as pseudo-integral. Note that this parameter only serves as display effect in DV. When used, it must match the model type of the control algorithm component. If the model selection does not follow 0, 1, 2, it is set to 0 by default.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Low	Lower limit of the disturbance variable	LREAL	Follows data type	0	Lower limit; if the value falls below the lower limit, it is clamped to the lower limit.
High	Upper limit of the disturbance variable	LREAL	Follows data type	100	Upper limit; if the value exceeds the upper limit, it is clamped to the upper limit.
DMax	Increment limit	LREAL	Follows data type	100	Increment limit; when exceeded, it will be clamped to the maximum increment value. Any invalid value is set to 0.

Output variable



Output Variable	Name	Data Type	Valid Range	Default Value	Description
ST	Switch state	DINT	0, 1	-	Switch status. Initially the value equals the switch input value. When an internal error occurs, this value is set to 1.
ERR	Fault code	DINT	Follows data type	-	For fault codes, see PFCs_dv fault codes.
PV_t	Feedforward correction value	LREAL	Follows data type	-	Feedforward value after limit.
DDVTrend	Disturbance sequence	ARRAY[0..199] OF LREAL	Follows data type	-	Disturbance sequence. After generating this sequence, it must be output to the input interface with the same name on the control instruction for feedforward correction.
PFCdvOutput	Output parameter structure	PFCdvOutput	Follows data type	-	Output parameter structure

PFCdvOutput structure configuration

Output Variable	Name	Data Type	Valid Range	Default Value	Description
PV_Past	Measured value history sequence	ARRAY[0..199] OF LREAL	Follows data type	-	Records historical values for the disturbance input.
PVt_Past	Feedforward value history sequence	ARRAY[0..199] OF LREAL	Follows data type	-	Records historical values of the feedforward signal.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
DV_Low_Past	Disturbance value lower limit history sequence	ARRAY[0..199] OF LREAL	Follows data type	-	Sequence of historical lower limits for the disturbance value, for plotting.
DV_High_Past	Disturbance value upper limit history sequence	ARRAY[0..199] OF LREAL	Follows data type	-	Sequence of historical upper limits for the disturbance value, for plotting.
DV_Low_Future	Disturbance value lower limit future sequence	ARRAY[0..199] OF LREAL	Follows data type	-	Sequence of future lower limits for the disturbance value, for plotting.
DV_High_Future	Disturbance value upper limit future sequence	ARRAY[0..199] OF LREAL	Follows data type	-	Sequence of future upper limits for the disturbance value, for plotting.
DV_PV_Future	Disturbance value future sequence	ARRAY[0..199] OF LREAL	Follows data type	-	Sequence of future disturbance values, for plotting.
DDV_Past	Feedforward value history increment sequence	ARRAY[0..199] OF LREAL	Follows data type	-	Sequence of historical increments for the feedforward value, for plotting.
Version	Version information	ARRAY[0..3] OF DINT	Follows data type	-	Records the version information.

- **Function**
  - PFCs_dv is a disturbance feedforward prediction module. Its primary function is to predict the future disturbance sequence of the controlled object based on the current disturbance input. The predicted disturbance sequence can be fed forward to the feedforward input channel of the PFCs/PFCm instruction, enabling proactive compensation of disturbances and improving disturbance rejection.
  - The PFCs_dv function block includes an intuitive interface for parameter configuration and commissioning. After adding the PFCs_dv component, select "Control object > PFC" in the left project tree, and then double-click the PFCs_dv instance under the PFC node to open the configuration and tuning interface, as shown in the figure below.

    - Parameter configuration

      The parameter configuration of the PFCs_dv instruction includes general configuration, CV

configuration, and model configuration. For detailed parameter descriptions, see Relevant variables.

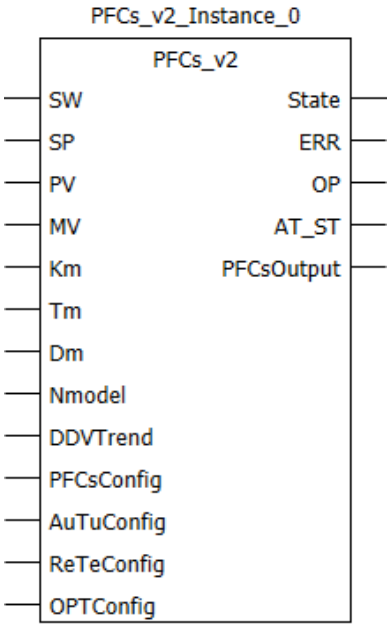
- Commissioning

  After the parameters are configured, the sequence of the predicted future disturbance values for the controlled variable can be viewed directly in the commissioning interface.

- **Program example**

  During operation, this instruction primarily feeds the sequence output by DDVTrend into the control component PFCm or PFCs. The generated sequence is determined by the model parameters Km, Tm, and Dm, as well as the input disturbance PV.

  LD:



- **Precautions**
  - During operation, ensure that the switch is on, and the configuration is correct.
  - When setting the model parameters, ensure they are consistent with the controller parameter type, either all integral or non-integral.
  - The execution time of the PFCs_dv instruction is 8 ms. With 140 PFCs_dv function blocks loaded, the total execution time is estimated to reach approximately 1 second. Loading 1154 PFCs_dv function

blocks will reach the controller's resource limit. During operation, configure the scheduling task cycle properly. For example, if 10 PFCs_dv are required to perform loop control simultaneously, with a block calculation time of 80 ms. The task cycle must be at least twice this value, that is, 160 ms, to ensure the CPU load does not become too high.

18.3.2.5 PFCs_v2

PFCs are simplified predictive function controller (PFCs_v2) components for single-input, single-output systems, primarily used in 1x1 control scenarios such as temperature heating control.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
PFCs_v2	Single-loop advanced control V2	FB		PFCs_v2_Instance_0(SW := , SP := , PV := , MV := , Km := , Tm := , Dm := , Nmodel := , DDVTrend := , PFCsConfig := , AuTuConfig := , ReTeConfig := , OPTConfig := , State => , ERR => , OP => , AT_ST => , PFCsOutput =>);

- **Related variables**

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
SW	Operating switch	DINT	0, 1	0	0: Component off. 1: Component on. Ensure the component is in the on state when in use.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
SP	Setpoint	REAL	Follows data type	0	Setpoint for the controlled variable, which defines the control target of the controller. If properly configured, the actual control result (PV) must closely follow the SP.
PV	Measured value	REAL	Follows data type	0	Input value of the controlled variable measurement, which must be provided by an external physical object or simulation object.
MV	Measured value of the valve position	REAL	Follows data type	0	Measured value of the manipulated variable. The actual output value must be written back to this variable.
Km	Model gain	REAL	Follows data type	1	An algorithm parameter that describes the response gain of the controlled object. It must be determined based on the influence of the output OP on the controlled object. The greater this influence, the larger the gain value.
Tm	Model time constant	REAL	[0, 10000]	1	An algorithm parameter that describes the response time of the controlled object. The greater the inertia of the controlled object, the slower the response, and the larger this value.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Dm	Model hysteresis	REAL	[0, 10000]	0	An algorithm parameter that represents the response hysteresis of the controlled object. The greater the hysteresis of the object to input changes, the larger this value.
Nmodel	Model length	DINT	[1, 200]	100	The model length is used to adjust the control effect. The larger this value, the longer the effective prediction horizon, and the further the future trends can be predicted.
DDVTrend	Future disturbance sequence	ARRAY [0..199] OF REAL	Follows data type	-	Disturbance sequence generated by the PFCs_dv_v2 component. When using this variable, pass its "DDVTrend" output to this variable. It is used to predict future disturbances so that the controller can take proactive action to suppress them.
PFCsConfig	Input parameter structure	PFCsConfig_v2	Follows data type	-	Input parameter configuration structure.
AuTuConfig	Auto-tuning parameter structure	AuTuConfig_v2	Follows data type	-	Auto-tuning parameter configuration structure.
ReTeConfig	Relay test structure	ReTeConfig_v2	Follows data type	-	Relay test structure.
OPTConfig	Closed-loop OP test structure	OPTConfig_v2	Follows data type	-	Closed-loop OP test structure.

PFCsConfig_v2 structure configuration

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Ts	Sampling cycle	REAL	(0, 10000]	1	This value represents the control and tuning cycle. The value must be greater than 0. Ensure that this value is not set too low (below the operation cycle). If Ts is less than 0, the algorithm will automatically terminate, the switch will turn off, and the output will be held.
Model	Model type	DINT	0, 1, 2	1	Model types include: 0: Non-integral. 1: Pseudo-integral. 2: Pure integral. **Note:** The algorithm internally distinguishes between non-integral and integral models. The logic for pseudo-integral models follows the same rules as those for integral models. When the model selection is not 0, 1, or 2, the algorithm terminates, the switch is turned off, and the output will be held.
COF	Filter coefficient	REAL	[0, 1]	0.9	An algorithm parameter that affects the performance of feedback correction. The feedback value balances the measurement for the current cycle with the model prediction. The magnitude of the COF determines whether the algorithm places greater weight on the measured value or the predicted value in the feedback loop. • When set to 0, the feedback value uses the model prediction, and no feedback correction is applied. • When set to 1, the feedback value uses the measured value. • For other values, an average is calculated.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
COP	Performance coefficient	REAL	(0, 10000]	1	An algorithm parameter that affects the control performance. Increasing the value speeds up the system response to some extent, while decreasing it slows down the system response to some extent.
Tref	Closed-loop reference time	REAL	(0, 10000]	1	An algorithm parameter that affects the control performance. It is used to reduce the system response speed. Increasing this value slows down the system response to some extent, while decreasing it will speed up the system response to some extent. If the value exceeds the limit, it will be capped at 1e-6.
I_COF	Integral deviation correction coefficient	REAL	[0, 1]	0.1	Correction coefficient for integral speed. This value will take effect when the integral model is used. The larger the value, the faster the integral model speed operates in the algorithm, resulting in greater changes in future prediction, and thus causing output changes. Generally, fine-tuning this value after reaching steady state can reduce steady-state fluctuations.
DOPmax	Output increment limit	REAL	>=0	100	Sets the upper limit of output increment.
OP_Low_Val	Output valid lower limit	REAL	Follows data type	0	When the value falls below this output valid lower limit, the switch will be turned off and the control will be disabled.
OP_High_Val	Output valid upper limit	REAL	Follows data type	100	When the value exceeds this output valid upper limit, the switch will be turned off and the control will be disabled.
OP_Low_Ope	Output operation lower limit	REAL	Follows data type	0	When the value falls below this output operation lower limit, a warning is issued and the output is clamped to this limit.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
OP_High_Ope	Output operation upper limit	REAL	Follows data type	100	When the value exceeds this output operation upper limit, a warning will be issued and the output is clamped to this limit.
SP_Low_Val	Setpoint valid lower limit	REAL	Follows data type	0	Valid lower limit of the setpoint. When the value falls below this lower limit, the switch will be turned off and the control will be disabled.
SP_High_Val	Setpoint valid upper limit	REAL	Follows data type	100	Valid upper limit of the setpoint. When the value exceeds this upper limit, the switch will be turned off and the control will be disabled.
SP_Low_Ope	Setpoint operation lower limit	REAL	Follows data type	0	Operation lower limit of the setpoint. When the value falls below this lower limit, the system will display a warning and limit the value to the lower limit.
SP_High_Ope	Setpoint operation upper limit	REAL	Follows data type	100	Operation upper limit of the setpoint. When the value exceeds this upper limit, the system will display a warning and limit the value to the upper limit.
SP_DMax	Setpoint increment upper range	REAL	>=0	0.1	Algorithm parameter that affects the control effect. The system is considered stable when PV is within the range SP + SP_DMax.
SP_DMin	Setpoint increment lower range	REAL	<=0	-0.1	Algorithm parameter that affects the control effect. The system is considered stable when PV is within the range SP + SP_DMin.
Cost_SS	Speed steady state weight	REAL	>=0	0	In an integral model, this weight determines how quickly the speed converges to steady state. A larger value slows down the convergence. If set too large, the output may remain unchanged.

AuTuConfig_v2 structure configuration

Input Variable	Name	Data Type	Valid Range	Default Value	Description
AT_Start	Auto-tuning switch	DINT	0, 1	0	Auto-tuning switch. If this function is used, set AT_Start to 1.
AT_Model	Tuning model type	DINT	Follows data type	0	Tuning model types include: 0: Non-integral. 1: Pseudo-integral. 2: Pure integral. The auto-tuning function outputs the corresponding model parameters according to the model type. It is recommended to select according to the actual characteristics of the controlled object.
AT_OPInit	Initial OP output for tuning	REAL	Follows data type	0	OP output value at initial steady state. The controlled object must reach a stable state at this output.
AT_OPTarget	Target OP output for tuning	REAL	Follows data type	100	This value is the step output value at the start of tuning. The controller will perform a step change from "AT_OPInit" to "AT_OPTarget" to excite the response of the controlled object.
AT_PVTarget	PV target value at the end of tuning	REAL	Follows data type	100	This value is the target PV value to be achieved during tuning. The tuning process completes when the measured value (PV) of the controlled object reaches this value after tuning begin. Then, the tuning result will be output.
AT_PVDeltTar	Advance end threshold	REAL	Follows data type	0	When the PV value reaches AT_PVTarget – AT_PVDeltTar, the tuning process terminates early and outputs the tuning result.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
AT_InitRate	Initial steady-state slope	REAL	Follows data type	0	PV measured value slope that allows the step response tuning to start.

ReTeConfig_v2 structure configuration

Input Variable	Name	Data Type	Valid Range	Default Value	Description
RT_Start	Relay test switch	DINT	0, 1	0	If this function is used, set RT _Start to 1.
RT_Direction	Input-output action direction	DINT	0, 1	0	0: Direct acting. When the output increases, the measured value increases. 1: Reverse acting. When the output increases, the measured value decreases.
RT_OP_Init	Initial value for the test	REAL	Follows data type	0	OP output at the start of the test.
RT_OP_DLow	Test output lower range	REAL	< 0	-1	Lower limit of the OP oscillation output at the start of the test = RT_OP_Init + RT_OP_DLow.
RT_OP_DHigh	Test output upper range	REAL	> 0	1	Upper limit of the OP oscillation output at the start of the test = RT_OP_Init + RT_OP_DHigh.
RT_PV_Target	Step measured value	REAL	Follows data type	100	Target PV measured value after the test starts.
RT_PV_DLow	Oscillation lower range	REAL	< 0	-1	Lower limit of PV oscillation switching after the test starts = RT_PV_Target + RT_PV_DLow.
RT_PV_DHigh	Oscillation upper range	REAL	> 0	1	Upper limit of PV oscillation switching after the test starts = RT_PV_Target + RT_PV_DHigh.
RT_Warn_Low	Warning lower range	REAL	Follows data type	0	Test protection lower range. If the value falls below this range, the test stops. Restart the test after reconfiguring the parameters.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
RT_Warn_High	Warning upper range	REAL	Follows data type	100	Test protection upper range. If the value exceeds this range, the test stops. Restart the test after reconfiguring the parameters.

OPTConfig_v2 structure configuration

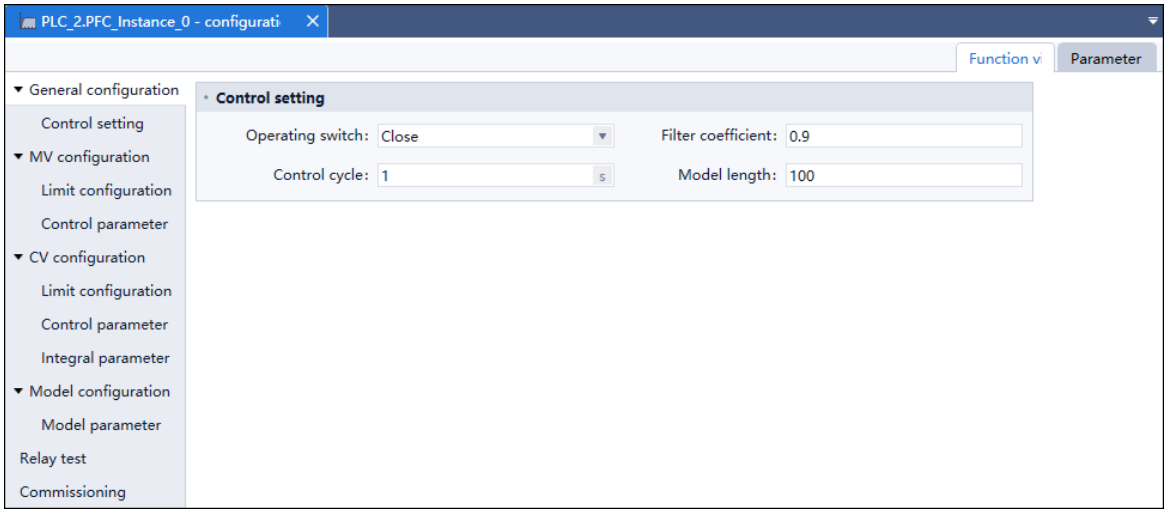
Input Variable	Name	Data Type	Valid Range	Default Value	Description
OPT_Start	Closed-loop OP test switch	DINT	0, 1	0	If this function is used, set OPT_Start to 1.
OPT_Type	PRBS type	DINT	0, 1, 2, 3	0	Type mode: 0: PRBS7 1: PRBS15 2: PRBS23 3: PRBS31
OPT_TS	PRBS cycle	DINT	>=1	1	Integer multiple of the task call cycle.
OPT_Amp	PRBS amplitude	REAL	>=0	0	Amplitude of the superimposed PRBS cycle during closed-loop testing.
OPT_Seed	PRBS initial seed	DINT	[1, 65535]	100	The seed value determines the initial value of the generated sequence.
OPT_Warn_Low	Warning lower range	REAL	Follows data type	0	Test protection lower range. If the value falls below this range, the test stops. Restart the test after reconfiguring the parameters.
OPT_Warn_High	Warning upper range	REAL	Follows data type	100	Test protection upper range. If the value exceeds this range, the test stops. Restart the test after reconfiguring the parameters.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
State	Switch state	DINT	0, 1	-	Indicates the actual state of the controller. 0: Normal control. 1: Switched to feedforward.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
ERR	Fault code	DINT	Follows data type	-	0 for normal operation; non-zero when an error occurs. See PFCs_v2 fault codes.
OP	Valve position output value	REAL	Follows data type	-	Controller output value.
AT_ST	Tuning result	DINT	0, 1, 2, 3	-	Tuning state display. 0: Not tuned 1: Coarse tuning in progress 2: Fine tuning in progress 3: Tuning completed
PFCsOutput	Output parameter structure	PFCsOutput_v2	Follows data type	-	Output parameter configuration structure.

PFCsOutput_v2 structure configuration



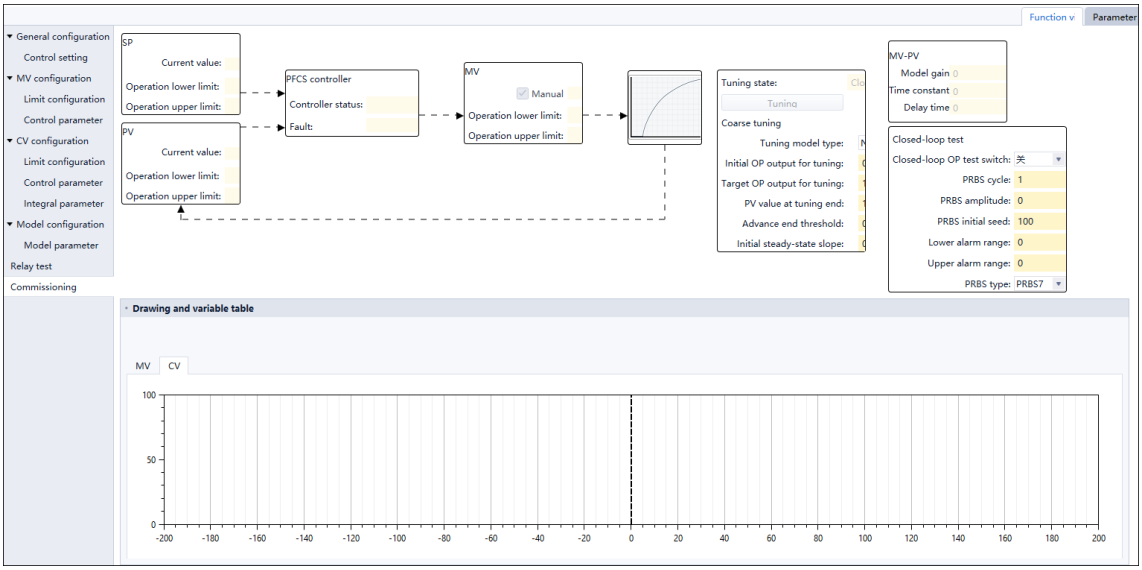
Output Variable	Name	Data Type	Valid Range	Default Value	Description
Version	Version information	ARRAY [0..3] OF DINT	Follows data type	-	Used to record internal version information.
DOP	Valve position output increment	REAL	Follows data type	-	Increment of the output value OP.
PV_Pred_t	Estimated value	REAL	Follows data type	-	Estimated value, that is, the response value of the controlled object, calculated by the internal model using historical data.
PV_Pred_tf	Predicted value	REAL	Follows data type	-	Predicted value, that is, the estimated value corrected based on the actual measured value PV.
PV_Pred_e	Prediction error	REAL	Follows data type	-	Difference between the actual measured value PV and the predicted value.
PV_Pred_eSum	Cumulative prediction error	REAL	Follows data type	-	Cumulative sum of prediction errors.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
DCV_S	Integral deviation speed.	REAL	Follows data type	-	Integral deviation speed.
PV_Pred	Open-loop prediction sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records the sequence of future measured values predicted when the current cycle is not applied.
Tref_Step	Reference trajectory sequence	ARRAY [0..199] OF REAL	Follows data type	-	A trajectory sequence generated by the Tref parameter.
OP_Low_Ope_Past	Output lower limit history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical operation lower limits for the controller output OP.
OP_High_Ope_Past	Output upper limit history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical operation upper limits for the controller output OP.
OP_Low_Ope_Future	Output lower limit future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records the sequence of predicted operation lower limits for the controller output at future sampling instants, computed after the current cycle has been applied.
OP_High_Ope_Future	Output upper limit future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records the sequence of predicted operation upper limits for the controller output at future sampling instants, computed after the current cycle has been applied.
SP_Past	Setpoint history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records the sequence of the historical setpoints.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
SP_Future	Setpoint future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records the sequence of future setpoints predicted by the algorithm after the current cycle has been applied.
SP_Low_Ope_Past	Setpoint lower limit history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records the sequence of historical operation lower limits for the setpoint.
SP_High_Ope_Past	Setpoint upper limit history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records the sequence of historical operation upper limits for the setpoint.
SP_Low_Ope_Future	Setpoint lower limit future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records the sequence of predicted operation lower limits for the setpoint at future sampling instants, computed after the current control cycle has been applied.
SP_High_Ope_Future	Setpoint upper limit future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records the sequence of predicted operation upper limits for the setpoint at future sampling instants, computed after the current control cycle has been applied.
SP_Href	Upper reference trajectory sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records the upper reference trajectory of the setpoint.
SP_Lref	Lower reference trajectory sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records the lower reference trajectory of the setpoint.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
PV_Past	Measured value history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records the sequence of the historical measured values.
OP_Past	Output value history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records the sequence of the historical output values.
OP_Future	Output value future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records the sequence of future output values predicted by the algorithm after the current cycle has been applied.
AT_Km	Tuning parameter Km	REAL	Follows data type	-	Model gain result obtained from auto-tuning.
AT_Tm	Tuning parameter Tm	REAL	> 0	-	Model time constant result obtained from auto-tuning.
AT_Dm	Tuning parameter Dm	REAL	>=0	-	Model hysteresis parameter result obtained from auto-tuning.

- **Function**
  - PFCs_v2 is a simplified 1x1 single-input, single-output predictive function controllers. It includes one manipulated variable (output via OP) and one controlled variable (measured via PV), and support a feedforward input channel (for use with the PFCs_dv function block). The PFCs_v2 component features a built-in auto-tuning function to obtain model parameters of the controlled object. This component is primarily used for rapid deployment in single-input single-output processes.
  - The PFCs_v2 function block provide easy-to-use interfaces for parameter configuration and tuning/commissioning. After adding the PFCs_v2 component, select "Control object > PFC" in the left project tree, and then double-click the PFCs_v2 instance under the PFC node to open the configuration and tuning interface, as shown in the figure below.

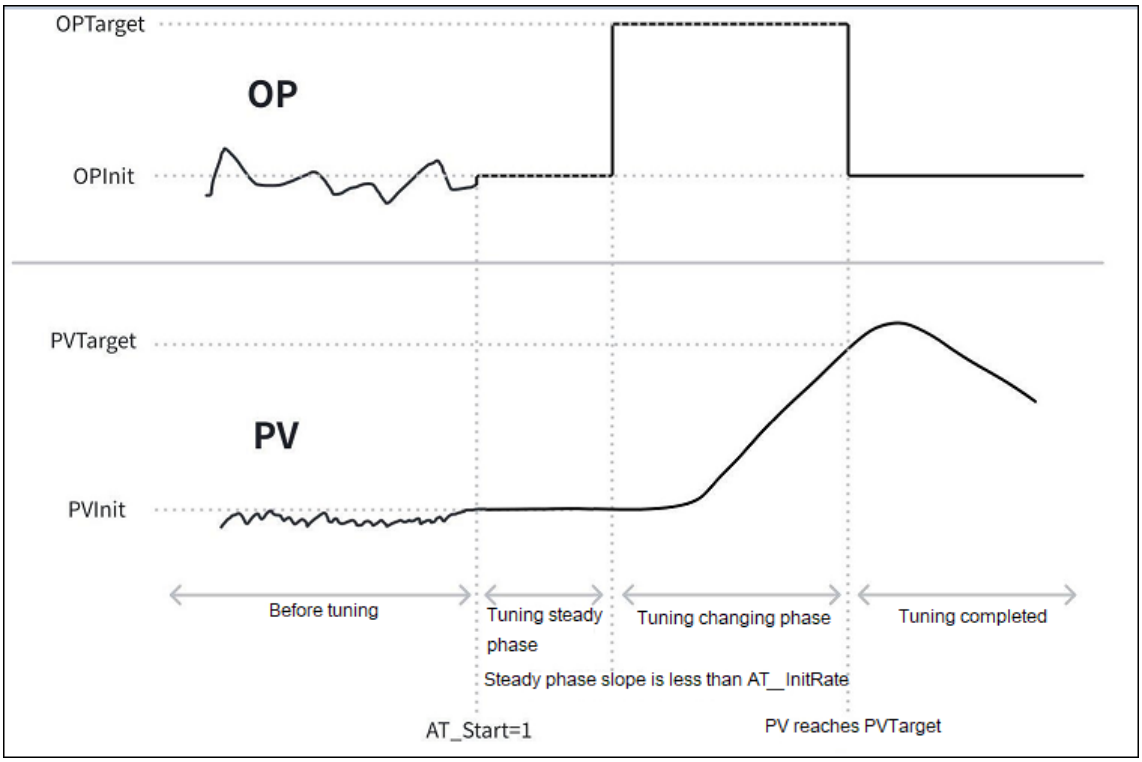


- Parameter configuration

  The parameter configuration of the PFCs_v2 instruction includes general configuration, MV configuration, CV configuration, model configuration and relay test. For detailed parameter descriptions, see Relevant variables.

- Parameter auto-tuning

  The PFCs_v2 instruction includes a built-in parameter auto-tuning function, automatically obtaining the model parameters (Km, Tm, and Dm) of the controlled object. Click the "Tuning" button on the "Commissioning" page to start parameter tuning.

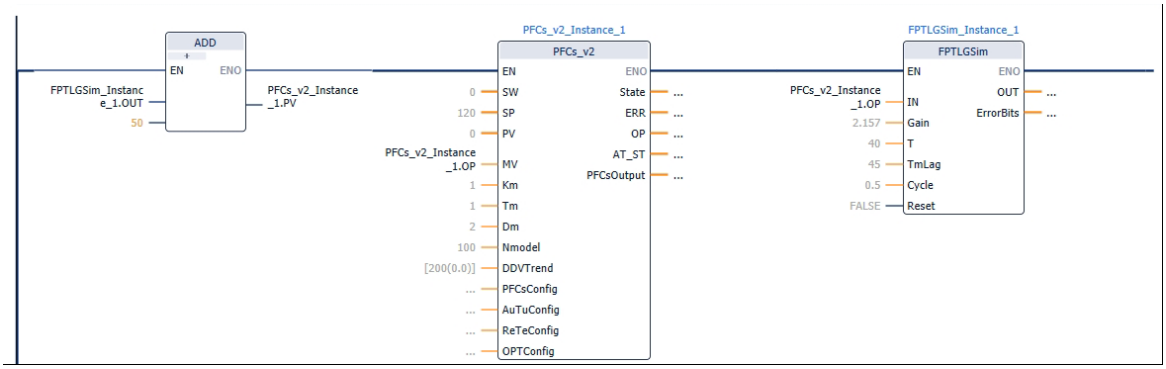


Because the controller internal variable array has a capacity of only 200, ensure that the duration from the OP output step to the completion of tuning stays within 200 control cycles. 100 to 150 cycles is recommended. An excessively long or short tuning process may lead to tuning failure. Furthermore, the tuning process does not require a complete steady state after the step. Generally, it only needs to capture the portion of the controlled object's response with the maximum slope.

The tuning process is as follows:

1. Select the model type of the tuning object.
2. Configure the tuning parameter "Initial OP output for tuning" (AT_OPInit). AT_OPInit is the OP output value at the initial steady state. Ensure that the controlled object reaches a basic stable state at this output. Open-loop control can be used before the tuning process to stabilize the controlled object at this output, then switch to auto-tuning. The initial steady state is critical for the tuning results. When it is difficult to achieve the initial steady state, the "Initial steady-state slope" (AT_InitRate) parameter can be used to appropriately relax the steady-state requirements.

3. Configure the tuning parameter "Target OP output for tuning" (AT_OPTarget). This value is the step output value at the start of tuning. The controller will perform a step change from "AT_OPInit" to "AT_OPTarget" to excite the response of the controlled object.
4. Configure the tuning parameter "PV value at tuning end" (AT_PVTarget) and "Advance end threshold" (AT_PVDeltTar). The tuning process completes when the measured value (PV) of the controlled object reaches this value after tuning begin. Pay special attention to the response polarity of the controlled object. Ensure that the measured value reaches AT_PVTarget after tuning starts, rather than the PV changing in the opposite direction after the OP step change.
5. Click the "Tuning" button.
6. After tuning ends, click "Confirm" or "Cancel" to select parameters, and automatically switch to control mode.

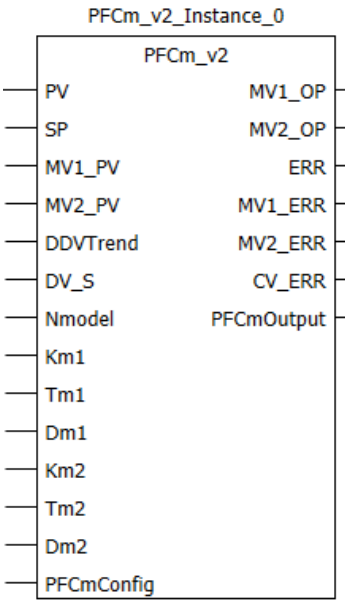


- Program example

  Here, the control simulation between the PFCs_v2 instruction and the first-order inertia plus pure delay simulation instruction (FPTLGsim) is used as an example. The parameter configuration and control process are as follows:

  1. Parameter configuration
     Configure the PFCs_v2 instruction parameters based on the characteristics of the control object (Model parameters: Km, Tm, Dm and so on; controller parameters: COP, COF, etc.).
  2. Control process
     The PFCs_v2 instruction responds to the output (PV) of the FPTLGsim object, obtains the control quantity (OP) output, and applies it to the original control object, forming a control loop.
  3. Control expectation
     If all parameters are configured properly, the controller will eventually keep the output value (PV) of the controlled object near the setpoint (SP).

  LD language code example:



- Precautions
  - The module execution cycle must be consistent with the function block cycle parameter Ts.
  - During operation, ensure that the switch is on, and the configuration is correct.
  - The execution time of the PFCs_v2 instruction is 10 ms. With 50 PFCs_v2 function blocks loaded, the total execution time is estimated to reach 500 ms. During operation, configure the scheduling task cycle properly to avoid high CPU load.

18.3.2.6 PFCm_v2

This instruction is a single-input dual-output control instruction. It is primarily used in 2x1 scenarios, such as regulating temperature via heating and cooling. This version is v2, with updates to several functions, including constrained solution handling, integral/non-integral decomposition, and speed steady state.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
PFCm_v2	Multivariable advanced control V2	FB		PFCm_v2_Instance_0(PV := , SP := , MV1_PV := , MV2_PV := , DDVTrend := , DV_S := , Nmodel := , Km1 := , Tm1 := , Dm1 := , Km2 := , Tm2 := , Dm2 := , PFCmConfig := , MV1_OP => , MV2_OP => , ERR => , MV1_ERR => , MV2_ERR => , CV_ERR => , PFCmOutput =>);

- **Related variables**

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
PV	Measured value of the controlled variable	REAL	Follows data type	0	Input value of the controlled variable measurement, which must be provided by an external physical object or simulation object.
SP	Controlled variable setpoint value	REAL	Follows data type	0	Setpoint value of the controlled variable, which determines the control objective of the controller so that the final actual control result (PV) must closely follow the SP.
MV1_PV	Measured value of the manipulated variable 1	REAL	Follows data type	0	Measured value of manipulated variable 1. The actual output value 1 must be written back to this variable. In a heating application: if only algorithmic control is active, write back the value of MV1_OP; if an external input is present, write back the actual value sent to the actuator.
MV2_PV	Measured value of the manipulated variable 2	REAL	Follows data type	0	Measured value of manipulated variable 2. The actual output value 2 must be written back to this variable. In a heating application: if only algorithmic control is active, write back the value of MV2_OP; if an external input is present, write back the actual value sent to the actuator.
DDVTrend	Disturbance sequence	ARRAY [0..199] OF REAL	Follows data type	-	Disturbance sequence generated by the dv series component. When using this variable, pass its output "DDVTrend" to this variable. It is used to predict future disturbances so that the controller can take proactive action to suppress them.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
DV_S	Disturbance velocity	REAL	Follows data type	0	Disturbance velocity generated by the PFCm_dv component. When using this variable, pass its output DV_S to this variable. It is used to predict future disturbances so that the controller can take proactive action to suppress them.
Nmodel	Model length	DINT	[1, 200]	100	The model length is used to adjust the control effect. The larger this value, the longer the effective prediction horizon, and the further the future trends can be predicted.
Km1	Model 1 gain	REAL	Follows data type	1	An algorithm parameter that affects the control performance. Increasing the value speeds up the system response to some extent, while decreasing it slows down the system response to some extent.
Tm1	Model 1 time constant	REAL	(0, 10000]	1	An algorithm parameter that affects the control performance. The smaller Tm is, the fewer control cycles needed to reach steady state. When Tm exceeds the allowable limit, it is limited to 1e-6.
Dm1	Model 1 hysteresis	REAL	[0, 10000]	0	An algorithm parameter that affects the control performance. The delay expressed in control cycles is Dm/Ts. If the value exceeds the limit, it will be limited to 0.
Km2	Model 2 gain	REAL	Follows data type	1	Same as Km1; this is the gain for model 2.
Tm2	Model 2 time constant	REAL	(0, 10000]	1	Same as Tm1, this is the time constant for model 2. If the value exceeds the limit, it will be limited to 1e-6.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Dm2	Model 2 hysteresis	REAL	[0, 10000]	0	Same as Dm1; this is the hysteresis for model 2. If the value exceeds the limit, it will be limited to 0.
PFCmConfig	Input parameter structure	PFCmConfig_v2	Follows data type	-	Input parameter configuration structure.

PFCmConfig_v2 structure configuration

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Ts	Sampling cycle	REAL	(0, 10000]	1	This value determines the control cycle. This value must be greater than 0, and can not be set too low. An excessively small value may cause a calculation timeout and degrade control performance. If Ts is less than 0, the algorithm will automatically terminate, the switch will turn off, and the output will be held.
Model1	Model type 1	DINT	0, 1, 2	1	Model for MV1-CV. Model type: 0: Non-integral 1: Pseudo-integral 2: Pure integral Currently, types 0 (Non-integral) and 1 (Pseudo-integral) are primarily used. Type 2 (Pure integral) is not implemented. In practice, integral models are typically handled as pseudo-integral. When the model selection is not 0, 1, or 2, the algorithm terminates, the switch is turned off, and the output will be held.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Model2	Model type 2	DINT	0, 1, 2	1	Model for MV2-CV. Model type: 0: Non-integral 1: Pseudo-integral 2: Pure integral Currently, types 0 (Non-integral) and 1 (Pseudo-integral) are primarily used. Type 2 (Pure integral) is not implemented. In practice, integral models are typically handled as pseudo-integral. When the model selection is not 0, 1, or 2, the algorithm terminates, the switch is turned off, and the output will be held.
Cost_SS	Speed steady state weight	REAL	[0, 10000]	0	In an integral model, this weight determines how quickly the speed converges to steady state. A larger value slows down the convergence. If set too large, the output may remain unchanged.
COF	Filter coefficient	REAL	[0, 1]	0.9	An algorithm parameter that affects the control performance. The smaller this value, the greater the confidence in the model prediction. When set to 0, no feedback correction is performed. Use a value greater than 0. If this value exceeds the upper limit, it will be limited to the upper limit. If the value falls below the lower limit, it will be limited to the lower limit.
Tref	Closed-loop reference time	REAL	(0, 10000]	1	An algorithm parameter that affects the control performance. Increasing the value slows down the system response to some extent, while decreasing it speeds up the system response to some extent. If the value exceeds the limit, it will be limited to 1e-6.
I_COF	Integral deviation correction coefficient	REAL	[0, 1]	0.1	An algorithm parameter that affects the control performance. The smaller the value, the greater the confidence in the model prediction. If this value exceeds the upper limit, it will be limited to the upper limit. If the value falls below the lower limit, it will be limited to the lower limit.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
MV1_Config	MV1 variable input parameter structure	MVConfig_v2	Follows data type	-	MV1 variable input parameter configuration structure.
MV2_Config	MV2 variable input parameter structure	MVConfig_v2	Follows data type	-	MV2 variable input parameter configuration structure.
Single_SW	Single output switch	DINT	0, 1	1	Single output switch. If this switch is set to ON, it ensures that when the two MV gains have opposite signs, only one output direction is active. This is typically used to save energy.
CV_SW	Controlled variable switch	DINT	0, 1	1	Controlled variable switch. When the switch is off, the control is disabled. When used, it must be set to 1. Invalid values are automatically set to 0.
CV_SP_DMax	Upper deviation range	REAL	[0, 10000]	0.1	An algorithm parameter that affects the control performance. The system is considered stable if CV_PV is within this range CV_SP + CV_SP_DMax. Invalid input values are limited to 0.
CV_SP_DMin	Lower deviation range	REAL	[-10000, 0]	-0.1	An algorithm parameter that affects the control performance. The system is considered stable if CV_PV is within the range CV_SP + CV_SP_Dmin. Invalid input values are limited to 0.
DeltaCV	Maximum change rate of the controlled variable	REAL	[0, 10000]	100	This algorithm parameter defines the maximum change value of CV during prediction. Invalid values are limited to 100.
CV_Low_Val	Valid lower limit of the controlled variable	REAL	Follows data type	0	Valid lower limit. When the value falls below the valid lower limit, the switch will be turned off and the control will be disabled.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
CV_High_Val	Valid upper limit of the controlled variable	REAL	Follows data type	100	Valid upper limit. When the value exceeds the valid upper limit, the switch will be turned off and the control will be disabled.
CV_Low_Ope	Operation lower limit of the controlled variable	REAL	Follows data type	0	Operation lower limit. When the value falls below this operation lower limit, a warning will be issued and the value will be clamped to this operation lower limit.
CV_High_Ope	Operation upper limit of the controlled variable	REAL	Follows data type	100	Operation upper limit. When the value exceeds this operation upper limit, a warning will be issued and the value will be clamped to this operation upper limit.

MVConfig_v2 structure configuration

Input Variable	Name	Data Type	Valid Range	Default Value	Description
MV_SW	Manipulated variable switch	DINT	0, 1	1	MV switch; when this switch is off, the control is disabled. Invalid values are automatically set to 0.
MV_High_Val	Manipulated variable valid upper limit	REAL	Follows data type	200	Valid upper limit. When the value exceeds the valid upper limit, the switch will be turned off and the control will be disabled.
MV_Low_Val	Manipulated variable valid lower limit	REAL	Follows data type	0	Valid lower limit. When the value falls below the valid lower limit, the switch will be turned off and the control will be disabled.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
MV_High_Ope	Operation upper limit of the manipulated variable	REAL	Follows data type	100	Operation upper limit. When the value exceeds this operation upper limit, a warning will be issued and the value will be clamped to this operation upper limit.
MV_Low_Ope	Operation lower limit of the manipulated variable	REAL	Follows data type	0	Operation lower limit. When the value falls below this operation lower limit, a warning will be issued and the value will be clamped to this operation lower limit.
MV_DMax	Maximum positive increment for the manipulated variable	REAL	[0, 10000]	100	Defines the maximum allowable positive increment of the output. Invalid input values are limited to 100.
MV_DMin	Maximum negative increment for the manipulated variable	REAL	[-10000, 0]	-100	Defines the maximum allowed negative increment of the output. Invalid input values are limited to -100.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
MV_COP	Manipulated variable performance coefficient	REAL	[0, 10000]	1	An algorithm parameter that affects the control performance. Decreasing the value speeds up the system response to some extent, while increasing it slows down the system response to some extent. If this value exceeds the upper limit, it will be limited to the upper limit. If the value falls below the lower limit, it will be limited to the lower limit.
MV_Irv	Ideal injection value for the manipulated variable	REAL	Follows data type	1	The value that the corresponding MV output eventually converges to.
MV_Irv_C	Weight for manipulated variable ideal injection value	REAL	[0, 10000]	1	The larger the value, the closer the MV will converge to MV_Irv.
MV_Irv_SW	Ideal injection value switch	DINT	0, 1	0	When set to 0, the ideal injection value is inactive. When used, the value must be set to 1. Invalid values are automatically set to 0.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
MV1_OP	Manipulated variable 1 output value	REAL	Follows data type	-	Output value of manipulated variable 1. This value must be output to the simulation object or actual object.

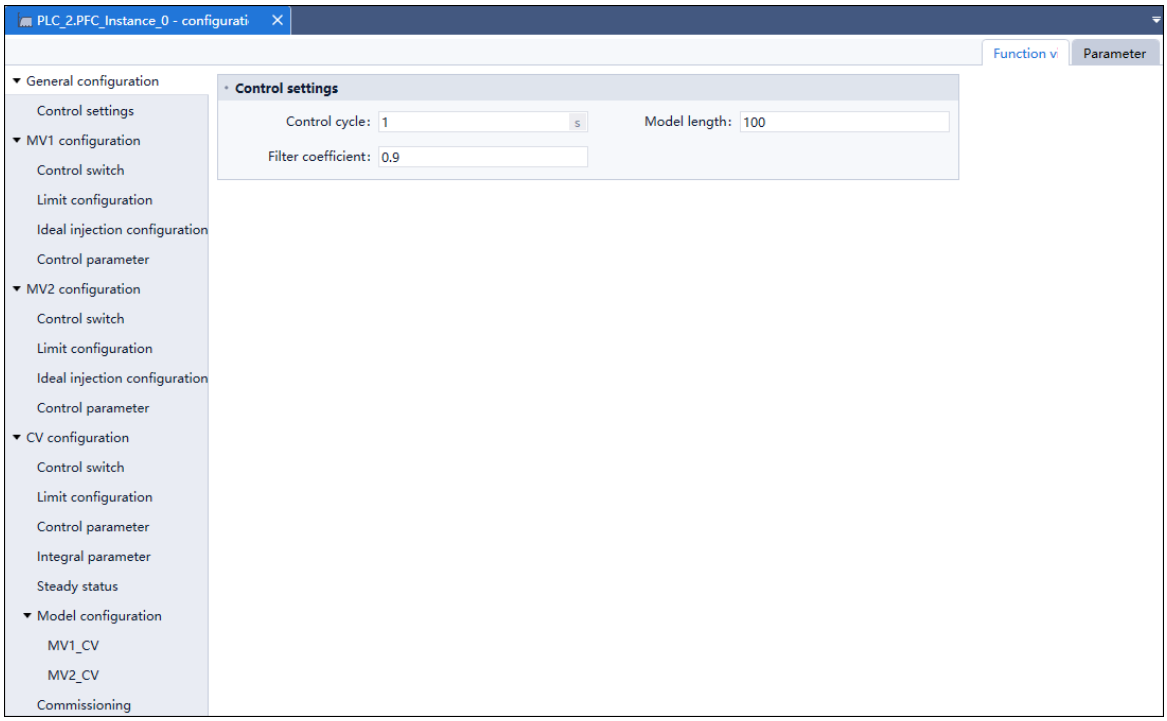
Output Variable	Name	Data Type	Valid Range	Default Value	Description
MV2_OP	Manipulated variable 2 output value	REAL	Follows data type	-	Output value of manipulated variable 2. This value must be output to the simulation object or actual object.
ERR	Fault code	DINT	Follows data type	-	For fault codes, see PFCm_v2 fault codes.
MV1_ERR	Manipulated variable 1 fault code	DINT	Follows data type	-	Fault code of manipulated variable 1.
MV2_ERR	Manipulated variable 2 fault code	DINT	Follows data type	-	Fault code of manipulated variable 2.
CV_ERR	Controlled variable fault code	DINT	Follows data type	-	Fault code of controlled variable.
PFCmOutput	Output parameter structure	PFCmOutput_v2	Follows data type	-	Output parameter structure.

PFCmOutput_v2 structure configuration

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Version	Version information	ARRAY [0..3] OF DINT	Follows data type	-	Used to obtain the version information.
CV_Pred_t	Estimated value of controlled variable	REAL	Follows data type	-	Estimated value, that is, the response value of the controlled object, calculated by the internal model using historical data.
CV_Pred_tf	Predicted value of controlled variable	REAL	Follows data type	-	Predicted value, that is, the corrected predicted value based on the predicted value and the actual measured value PV.
DCV_S_i	Velocity after integral deviation correction	REAL	Follows data type	-	Velocity after integral deviation correction.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
DCV_S_SS	Future speed steady state value	REAL	Follows data type	-	Steady-state speed value, which is the speed value predicted after 200 cycles.
CV_PV_e	Predicted error of the controlled variable	REAL	Follows data type	-	Difference between the actual measured value and the predicted value.
CV_PV_eSum	Cumulative sum of predicted errors for the controlled variable	REAL	Follows data type	-	The cumulative sum of errors (regardless of sign). Its magnitude indicates the degree of model mismatch.
NFlag	Number of errors	DINT	[0, 10]	-	Counts the number of errors.
Flag	Error information	ARRAY [0..9] OF DINT	Follows data type	-	Records detailed information of each error.
MV1_OutConfig	Manipulated variable 1 output structure	MVOutConfig_v2	Follows data type	-	Manipulated variable 1 output structure
MV2_OutConfig	Manipulated variable 2 output structure	MVOutConfig_v2	Follows data type	-	Manipulated variable 2 output structure
CV_NFlag	Controlled variable error count	DINT	[0, 10]	-	Number of recorded errors for the controlled variable
CV_Flag	Controlled variable error information	ARRAY [0..9] OF DINT	Follows data type	-	Detailed information of recorded errors for the controlled variable
CV_ST	Controlled variable switch status	DINT	0, 1	-	Controlled variable switch state. Initially the value equals CV_SW. When an internal error occurs, this value is set to 1.
CV_Pred_t_Past	Sequence of historical estimated values for the controlled variable	ARRAY [0..199] OF REAL	Follows data type	-	Records historical values.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
CV_Pred	Open-loop prediction sequence of controlled variables	ARRAY [0..199] OF REAL	Follows data type	-	Records the sequence of future values predicted when the current cycle is not applied.
CV_Future	Closed-loop prediction sequence of controlled variables	ARRAY [0..199] OF REAL	Follows data type	-	Records the sequence of future values predicted after the current cycle has been applied.
CV_PV_Past	Sequence of historical measured values for the controlled variable	ARRAY [0..199] OF REAL	Follows data type	-	Records historical measured values.
SP_Past	Setpoint history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical setpoint values, for plotting.
SP_Future	Setpoint future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of the future setpoint values, for plotting.
CV_SP_Href	Upper reference trajectory sequence	ARRAY [0..199] OF REAL	Follows data type	-	Predicted upper trajectory to be approached.
CV_SP_Lref	Lower reference trajectory sequence	ARRAY [0..199] OF REAL	Follows data type	-	Predicted lower trajectory to be approached.
CV_Low_Past	Controlled variable lower limit history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical operation lower limits for the controlled variable, for plotting.
CV_High_Past	Controlled variable upper limit history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical upper limits for the controlled variable, for plotting.
CV_Low_Future	Controlled variable lower limit future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of future operation lower limits for the controlled variable, for plotting.

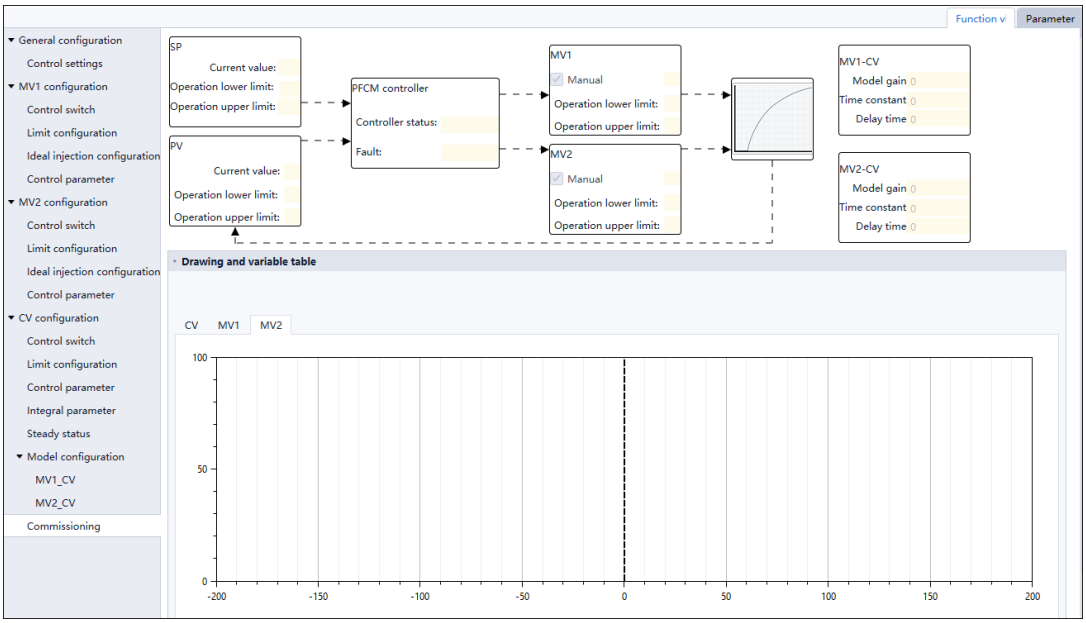


Output Variable	Name	Data Type	Valid Range	Default Value	Description
CV_High_Future	Controlled variable upper limit future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of future operation upper limits for the controlled variable, for plotting.

MVOutConfig_v2 structure configuration

Output Variable	Name	Data Type	Valid Range	Default Value	Description
MV_NFlag	MV error count	DINT	0, 1	-	Number of errors counted for the manipulated variable.
MV_Flag	MV error message	ARRAY [0..9] OF DINT	[0, 10]	-	Detailed information of recorded errors for the manipulated variable.
MV_Low_Past	Output lower limit history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical operation lower limits for the manipulated variable, for plotting.
MV_High_Past	Output upper limit history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical operation upper limits for the manipulated variable, for plotting.
MV_Low_Future	Output lower limit future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of future operation lower limits for the manipulated variable, for plotting.
MV_High_Future	Output upper limit future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of future operation upper limits for the manipulated variable, for plotting.
MV_Past	Output value history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical measured values for the manipulated variable, for plotting.
MV_Future	Output value future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of future measured values for the manipulated variable, for plotting.
MV_DOP_Past	Historical increment sequence of the valve position	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical increment values for the manipulated variable, for plotting.

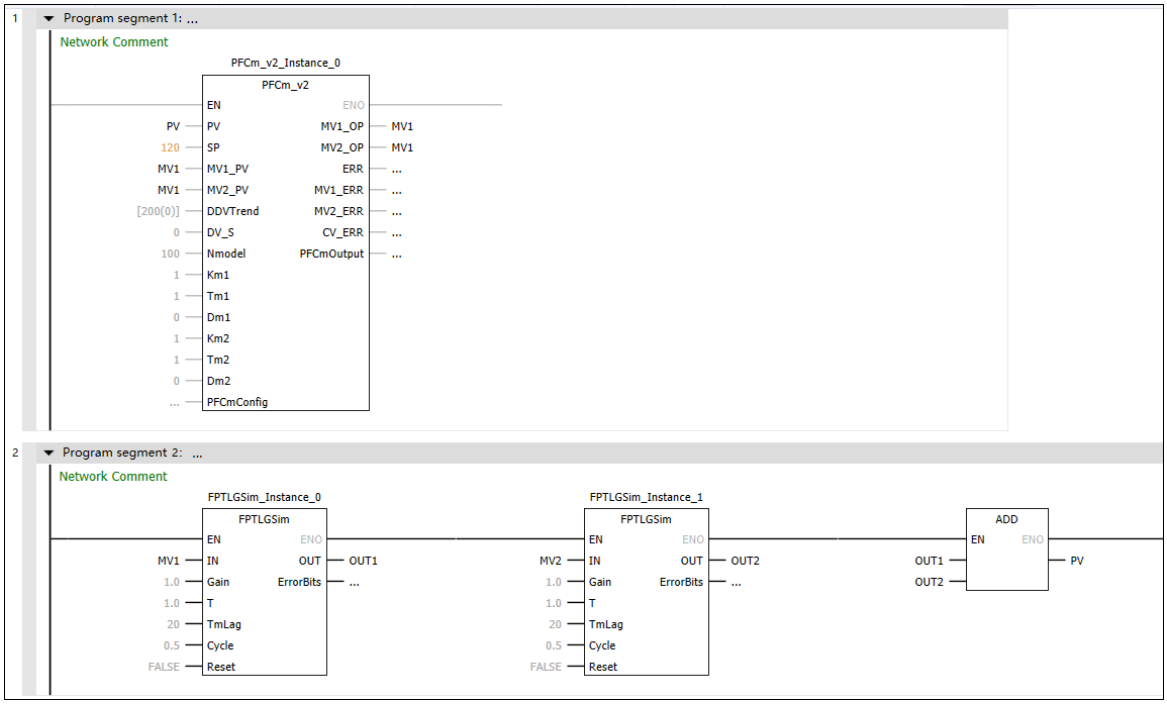
Output Variable	Name	Data Type	Valid Range	Default Value	Description
MV_DOP	Manipulated variable action increment	REAL	Follows data type	-	Increment value of the manipulated variable.
MV_ST	Manipulated variable switch state	DINT	0, 1	-	Manipulated variable switch state. Initially, it equals the switch value. This value is set to 1 when an internal error occurs.
MV_Irv_Past	Ideal injection value history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical ideal injection values, for plotting.
MV_Irv_Future	Ideal injection value future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of future ideal injection values, for plotting.



- **Function**
  - PFCm_v2 is a 1×2 single-input, dual-output control instruction. The controlled object can support non-integrating, integrating, or pseudo-integrating responses. The instruction includes two manipulated variables (MV), one controlled variable (CV), and a feedforward input channel (for use with PFCm_dv). It does not rely on an external solver for optimization calculations. It is primarily intended for applications that require two manipulated variables but not high-end products. It is suitable for fast control application scenarios with millisecond-level control cycles.
  - The PFCm_v2 function block includes an intuitive interface for parameter configuration and commissioning. After adding the PFCm_v2 component, select "Control object > PFC" in the left project tree, and then double-click the PFCm_v2 instance under the PFC node to open the configuration and tuning interface, as shown in the figure below.

    - Parameter configuration

The parameter configuration of the PFCm_v2 instruction includes general configuration, MV configuration, CV configuration, and model configuration. For detailed parameter descriptions, see Relevant variables.



- Commissioning
  After the parameters are configured, the control effect can be viewed directly in the commissioning interface.

- **Program example**
  Here, the two-input, single-output control simulation between the PFCm_v2 instruction and two first-order inertia plus pure delay simulation instruction (FPTLGsim) is used as an example. The parameter configuration and control process are as follows:

  1. Parameter configuration
     Configure the PFCm_v2 instruction parameters based on the characteristics of the control object (Model parameters: Km1, Km2, Dm1 and so on; controller parameters: COP, COF, etc.).
  2. Control process
     The PFCm_v2 instruction responds to the output (PV) of the FPTLGsim object, obtains the control quantity (OP) output, and applies it to the original control object, forming a control loop.
  3. Control expectation
     If all parameters are configured properly, the controller will eventually keep the output value (PV) of the controlled object near the setpoint SP.

     LD language code example:

- **Precautions**
  - During operation, ensure that the switch is on, and the configuration is correct.
  - The execution time of the PFCm_v2 instruction is 20 ms. With 50 PFCm_v2 function blocks loaded, the total execution time is estimated to reach approximately 1 second. Loading 364 PFCm_v2 function blocks will reach the controller's resource limit. During operation, configure the scheduling task cycle properly. For example, if 10 PFCm_v2 are required to perform loop control simultaneously, with a block calculation time of 200 ms. The task cycle must be at least twice this value, that is, 400 ms, to ensure the CPU load does not become too high.

18.3.2.7 PFCs_dv_v2

The disturbance instruction outputs a predicted disturbance sequence and must be used in conjunction with a corresponding control instruction.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
PFCs_dv_v2	Feedforward predictive control V2	FB	PFCs_dv_v2_Instance_0 PFCs_dv_v2 SW PV DVConfig Km Tm Dm ST ERR PV_t DDVTrend PFCdvOutput	PFCs_dv_v2_Instance_0(SW := , PV := , DVConfig := , Km := , Tm := , Dm := , ST => , ERR => , PV_t => , DDVTrend => , PFCdvOutput =>);

- **Related variables**

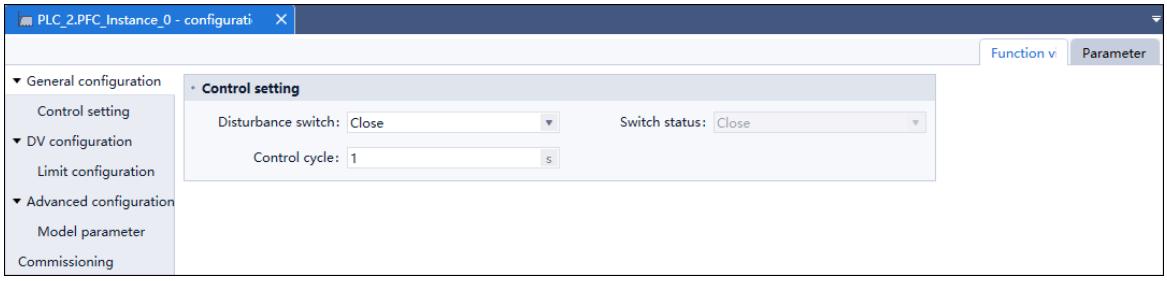
  Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
SW	Disturbance switch	DINT	0, 1	1	The disturbance switch disables the control when the switch is off. When used, it must be 1. Any invalid value is set to 0.
PV	Input value	REAL	Follows data type	0	Disturbance input value provided externally. Based on this input value, a corresponding disturbance sequence is generated.
DVConfig	Input parameter structure	DVConfig_v2	Follows data type	-	Input parameter configuration structure.
Km	Model gain	REAL	Follows data type	1	An algorithm parameter that affects the control performance. Increasing the value speeds up the system response to some extent, while decreasing it slows down the system response to some extent. It is used to predict the disturbance sequence.
Tm	Model time constant	REAL	(0, 10000]	1	An algorithm parameter that affects the control performance. The smaller the Tm value, the fewer cycles required to reach a steady state. It is used to predict the disturbance sequence. Any invalid value is set to 1e-6.
Dm	Model hysteresis	REAL	[0, 10000]	0	An algorithm parameter that affects the control performance. The delay expressed in control cycles is Dm/Ts. It is used to predict the disturbance sequence. Any invalid value is set to 0.

DVConfig_v2 structure configuration

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Ts	Sampling cycle	REAL	(0, 10000]	1	This value determines the control cycle. This value must be greater than 0, and can not be set too low. An excessively small value may cause a calculation timeout and degrade control performance. If Ts is less than 0, the algorithm will automatically terminate, the switch will turn off, and the output will be held.
Model	Model type	DINT	0, 1, 2	1	Model type: 0: Non-integral. 1: Pseudo-integral. 2: Pure integral. Currently, types 0 (Non-integral) and 1 (Pseudo-integral) are primarily used. Type 2 (Pure integral) is not implemented. In practice, integral models are typically handled as pseudo-integral. **Note:** This parameter only serves as display effect in DV. When used, it must match the model type of the control algorithm component. If the model selection does not follow 0, 1, 2, it is set to 0 by default.
Low	Lower limit of the disturbance variable	REAL	Follows data type	0	Lower limit; if the value falls below the lower limit, it is clamped to the lower limit.
High	Upper limit of the disturbance variable	REAL	Follows data type	100	Upper limit; if the value exceeds the upper limit, it is clamped to the upper limit.
DMax	Increment limit	REAL	Follows data type	100	Increment limit; when exceeded, it will be clamped to the maximum increment value. Any invalid value is set to 0.

Output variable



Output Variable	Name	Data Type	Valid Range	Default Value	Description
ST	Switch state	DINT	0, 1	-	Switch status. Initially the value equals the switch input value. When an internal error occurs, this value is set to 1.
ERR	Fault code	DINT	Follows data type	-	For fault codes, see PFCs_dv_v2 fault codes.
PV_t	Feedforward correction value	REAL	Follows data type	-	Feedforward value after limit.
DDVTrend	Disturbance sequence	ARRAY [0..199] OF REAL	Follows data type	-	Disturbance sequence. After generating this sequence, it must be output to the input interface with the same name on the control instruction for feedforward correction.
PFCdvOutput	Output parameter structure	PFCdvOutput_v2	Follows data type	-	Output parameter structure.

PFCdvOutput_v2 structure configuration

Output Variable	Name	Data Type	Valid Range	Default Value	Description
PV_Past	Measured value history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records historical values for the disturbance input.
PVt_Past	Feedforward value history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records historical values of the feedforward signal.
DV_Low_Past	Disturbance value lower limit history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical lower limits for the disturbance value, for plotting.
DV_High_Past	Disturbance value upper limit history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical upper limits for the disturbance value, for plotting.
DV_Low_Future	Disturbance value lower limit future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of future lower limits for the disturbance value, for plotting.
DV_High_Future	Disturbance value upper limit future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of future upper limits for the disturbance value, for plotting.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
DV_PV_Future	Disturbance value future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of future disturbance values, for plotting.
DDV_Past	Feedforward value history increment sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical increments for the feedforward value, for plotting.
Version	Version information	ARRAY [0..3] OF DINT	Follows data type	-	Records the version information.

- **Function**
  - PFCs_dv_v2 is a disturbance feedforward prediction module. The module is an upgrade from version v1. It has the same functions as v1 and differs only in data length. Its primary function is to predict the future disturbance sequence of the controlled object based on the current disturbance input. The predicted disturbance sequence can be fed forward to the feedforward input channel of the PFCs/PFCm instruction, enabling proactive compensation of disturbances and improving disturbance rejection.
  - The PFCs_dv_v2 function block includes an intuitive interface for parameter configuration and commissioning. After adding the PFCs_dv_v2 component, select "Control object > PFC" in the left project tree, and then double-click the PFCs_dv_v2 instance under the PFC node to open the configuration and tuning interface, as shown in the figure below.

    - Parameter description

      The parameter configuration of the PFCs_dv_v2 instruction includes general configuration, DV configuration, and model configuration. For detailed parameter descriptions, see Relevant variables.

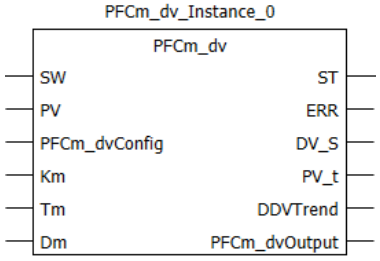
    - Commissioning

      After the parameters are configured, the historical and future disturbance value sequence can be viewed directly in the commissioning interface.

- **Program example**

  During operation, this instruction primarily feeds the sequence output by DDVTrend into the control component PFCm or PFCs. The generated sequence is determined by the model parameters Km, Tm, and Dm, as well as the input disturbance PV.

  LD:



- **Precautions**
  - During operation, ensure that the switch is on, and the configuration is correct.
  - When setting the model parameters, ensure they are consistent with the controller parameter type, either all integral or non-integral.
  - The execution time of the PFCs_dv_v2 instruction is 8 ms. With 140 PFCs_dv_v2 function blocks loaded, the total execution time is estimated to reach approximately 1 second. Loading 1154 PFCs_dv_v2 function blocks will reach the controller's resource limit. During operation, configure the scheduling task cycle properly. For example, if 10 PFCs_dv_v2 are required to perform loop control simultaneously,

with a block calculation time of 80 ms. The task cycle must be at least twice this value, that is, 160 ms, to ensure the CPU load does not become too high.

18.3.2.8 PFCm_dv

The disturbance instruction outputs a predicted disturbance sequence and must be used in conjunction with a corresponding control instruction.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
PFCm_dv	Feedforward predictive control M	FB		PFCm_dv_Instance_0(SW := , PV := , PFCm_dvConfig := , Km := , Tm := , Dm := , ST => , ERR => , DV_S => , PV_t => , DDVTrend => , PFCm_dvOutput =>);

- **Related variables**

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
SW	Disturbance switch	DINT	0, 1	1	The disturbance switch disables the control when the switch is off. When used, it must be 1. Any invalid value is set to 0.
PV	Input value	REAL	Follows data type	0	Disturbance input value provided externally. Based on this input value, a corresponding disturbance sequence is generated.
PFCm_dvConfig	Input parameter structure	PFCm_dvConfig	Follows data type	-	Input parameter configuration structure.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Km	Model gain	REAL	Follows data type	1	An algorithm parameter that affects the control performance. Increasing the value speeds up the system response to some extent, while decreasing it slows down the system response to some extent. It is used to predict the disturbance sequence.
Tm	Model time constant	REAL	(0, 10000]	1	An algorithm parameter that affects the control performance. The smaller the Tm value, the fewer cycles required to reach a steady state. It is used to predict the disturbance sequence. Any invalid value is set to 1e-6.
Dm	Model hysteresis	REAL	[0, 10000]	0	An algorithm parameter that affects the control performance. The delay expressed in control cycles is Dm/Ts. It is used to predict the disturbance sequence. Any invalid value is set to 0.

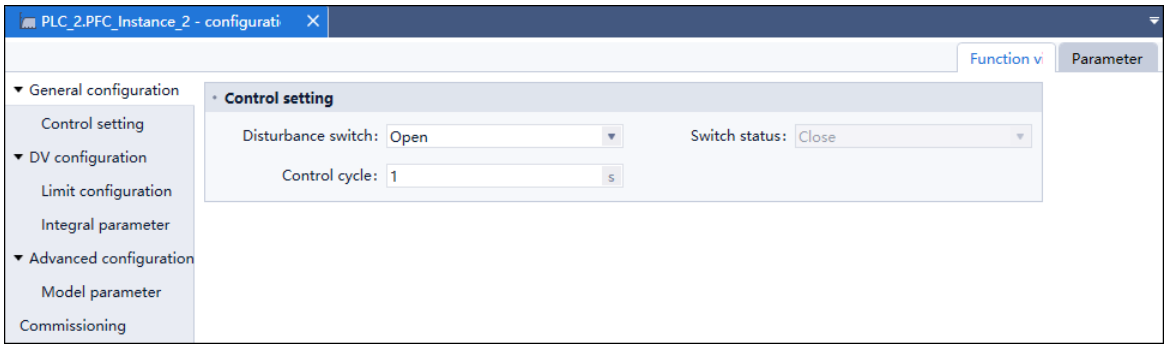
PFCm_dvConfig structure configuration

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Ts	Sampling cycle	REAL	(0, 10000]	1	This value determines the control cycle. This value must be greater than 0, and can not be set too low. An excessively small value may cause a calculation timeout and degrade control performance. If Ts is less than 0, the algorithm will automatically terminate, the switch will turn off, and the output will be held.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Model	Model type	DINT	0, 1, 2	1	Model type: 0: Non-integral. 1: Pseudo-integral. 2: Pure integral. Currently, types 0 (Non-integral) and 1 (Pseudo-integral) are primarily used. Type 2 (Pure integral) is not implemented. In practice, integral models are typically handled as pseudo-integral. If the model selection does not follow 0, 1, 2, it is set to 0 by default.
Low	Lower limit of the disturbance variable	REAL	Follows data type	0	Lower limit; if the value falls below the lower limit, it is clamped to the lower limit.
High	Upper limit of the disturbance variable	REAL	Follows data type	100	Upper limit; if the value exceeds the upper limit, it is clamped to the upper limit.
DMax	Increment limit	REAL	Follows data type	100	Increment limit; when exceeded, it will be clamped to the maximum increment value. Any invalid value is set to 0.

Output variable

Output Variable	Name	Data Type	Valid Range	Default Value	Description
ST	Switch state	DINT	0, 1	-	Switch status. Initially the value equals the switch input value. When an internal error occurs, this value is set to 1.
ERR	Fault code	DINT	Follows data type	-	For fault codes, see PFCm_dv fault codes.
DV_S	Disturbance velocity value	REAL	Follows data type	-	Disturbance velocity value calculated in integral mode and used by the PFCm component. Once generated, it must be output to the input interface with the same name on the control instruction for feedforward correction.



Output Variable	Name	Data Type	Valid Range	Default Value	Description
PV_t	Feedforward correction value	REAL	Follows data type	-	Feedforward value after limit.
DDVTrend	Disturbance sequence	ARRAY [0..199] OF REAL	Follows data type	-	Disturbance sequence. After generating this sequence, it must be output to the input interface with the same name on the control instruction for feedforward correction.
PFCm_dvOutput	Output parameter structure	PFCm_dvOutput	Follows data type	-	Output parameter structure.

PFCm_dvOutput structure configuration

with a block calculation time of 80 ms. The task cycle must be at least twice this value, that is, 160 ms, to ensure the CPU load does not become too high.

18.3.2.9 PIDR

The PIDR component is designed for 1×1 loop object control. It features fast computation and low memory usage, making it suitable for fast dynamic and resource-constrained systems. It includes built-in feedforward and auto-tuning functions, and can be deployed with simple configuration.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
PIDR	Robust PID	FB		PIDR_Instance_0(SW := , SP := , PV := , Km := , Tm := , Dm := , PIDRConfig := , PIDRAuToConfig := , PIDRDVConfig := , PIDROutput => , State => , ERR => , OP => , AT_ST =>);

- **Related variables**

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
SW	Operating switch	DINT	0, 1	0	0: Component off. 1: Component on. Ensure the component is in the on state when in use.
SP	Setpoint	REAL	Follows data type	0	Setpoint for the controlled variable, which defines the control target of the controller. If properly configured, the actual control result (PV) must closely follow the SP.
PV	Measured value	REAL	Follows data type	0	Input value of the controlled variable measurement, which must be provided by an external physical object or simulation object.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Km	Model gain	REAL	Follows data type	1	An algorithm parameter that describes the response gain of the controlled object. It must be determined based on the influence of the output OP on the controlled object. The greater this influence, the larger the gain value.
Tm	Model time constant	REAL	(0, 10000]	1	An algorithm parameter that describes the response speed of the controlled object. The greater the inertia of the controlled object, the slower the response, and the larger this value.
Dm	Model hysteresis	REAL	[0, 10000]	0	An algorithm parameter that represents the response hysteresis of the controlled object. The greater the hysteresis of the object to input changes, the larger this value.
PIDRConfig	Input parameter structure	PIDRConfig	Follows data type	-	Input parameter configuration structure.
PIDRAuToConfig	Auto-tuning parameter structure	PIDRAuToConfig	Follows data type	-	Auto-tuning parameter configuration structure.
PIDRDVConfig	Feedforward structure	PIDRDVConfig	Follows data type	-	Feedforward parameter configuration structure.

PIDRConfig structure configuration

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Ts	Control cycle	REAL	(0, 10000]	1	This value represents the control and tuning cycle. The value must be greater than 0. Ensure that this value is not set too low; otherwise it could exceed the operation cycle. If Ts is less than 0, the algorithm will automatically terminate, the switch will turn off, and the output will be held.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Model	Model type	DINT	0, 1, 2	1	Model type: 0: Non-integral. 1: Pseudo-integral. 2: Pure integral. **Note:** The algorithm internally distinguishes between non-integral and integral models. The logic for pseudo-integral models follows the same rules as those for integral models. When the model selection is not 0, 1, or 2, the algorithm terminates, the switch is turned off, and the output will be held.
Model_Feature	Control performance	DINT	0, 1, 2	1	Control performance: 0: Fast. 1: Medium. 2: Slow. Selecting "Fast" results in more aggressive control performance. Selecting "Slow" results in smoother control. Select the setting according to the actual control requirements.
COF	Filter coefficient	REAL	[0, 1]	0.9	An algorithm parameter that affects the performance of feedback correction. The feedback value balances the measurement for the current cycle with the model prediction. The magnitude of the COF determines whether the algorithm places greater weight on the measured value or the predicted value in the feedback loop. • When set to 0, the feedback value uses the model prediction, and no feedback correction is applied. • When set to 1, the feedback value uses the measured value. • For other values, an average is calculated.
COP	Performance coefficient	REAL	(0, 10000]	1	An algorithm parameter that affects the control performance. Increasing the value speeds up the system response to some extent, while decreasing it slows down the system response to some extent.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Tref	Closed-loop reference time	REAL	(0, 10000]	10	An algorithm parameter that affects the control performance. It is used to reduce the system response speed. Increasing this value slows down the system response to some extent, while decreasing it will speed up the system response to some extent. If the value exceeds the limit, it will be capped at 1e-6.
I_COF	Integral deviation correction coefficient	REAL	[0, 1]	0.1	Correction coefficient for integral speed. This value will take effect when the integral model is used. The larger the value, the faster the integral model speed operates in the algorithm, resulting in greater changes in future prediction, and thus causing output changes. Generally, fine-tuning this value after reaching steady state can reduce steady-state fluctuations.
DOPmax	Output increment limit	REAL	>=0	100	Sets the upper limit of output increment.
OP_Low_Val	Output valid lower limit	REAL	Follows data type	0	When the value falls below this output valid lower limit, the switch will be turned off and the control will be disabled.
OP_High_Val	Output valid upper limit	REAL	Follows data type	100	When the value exceeds this output valid upper limit, the switch will be turned off and the control will be disabled.
OP_Low_Ope	Output operation lower limit	REAL	Follows data type	0	When the value falls below this output operation lower limit, a warning is issued and the output is clamped to this limit.
OP_High_Ope	Output operation upper limit	REAL	Follows data type	100	When the value exceeds this output operation upper limit, a warning will be issued and the output is clamped to this limit.
SP_Low_Val	Setpoint valid lower limit	REAL	Follows data type	0	Valid lower limit of the setpoint. When the value falls below this lower limit, the switch will be turned off and the control will be disabled.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
SP_High_Val	Setpoint valid upper limit	REAL	Follows data type	100	Valid upper limit of the setpoint. When the value exceeds this upper limit, the switch will be turned off and the control will be disabled.
SP_Low_Ope	Setpoint operation lower limit	REAL	Follows data type	0	Operation lower limit of the setpoint. When the value falls below this lower limit, the system will display a warning and limit the value to the lower limit.
SP_High_Ope	Setpoint operation upper limit	REAL	Follows data type	100	Operation upper limit of the setpoint. When the value exceeds this upper limit, the system will display a warning and limit the value to the upper limit.
SP_DLimit	Setpoint increment range	REAL	>=0	0.1	Algorithm parameter that affects the control effect; the system is considered stable when PV is within the range SP ± SP_DLimit. When high steady-state accuracy is required, reduce the interval width.

PIDRAuToConfig structure configuration

Input Variable	Name	Data Type	Valid Range	Default Value	Description
AT_Start	Auto-tuning switch	DINT	0, 1	0	Auto-tuning switch. If this function is used, set AT_Start to 1.
AT_Model	Tuning model type	DINT	Follows data type	0	Tuning model type: 0: Non-integral 1: Pseudo-integral 2: Pure integral The auto-tuning function outputs the corresponding model parameters according to the selection. It is recommended to select according to the actual characteristics of the controlled object.
AT_OPInit	Initial OP output for tuning	REAL	Follows data type	0	OP output value at initial steady state. The controlled object must reach a stable state at this output.
AT_OPTarget	Target OP output for tuning	REAL	Follows data type	100	This value is the step output value at the start of tuning. The controller will perform a step change from "AT_OPInit" to "AT_OPTarget" to excite the response of the controlled object.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
AT_PVTarget	PV value at tuning end	REAL	Follows data type	100	This value is the target PV value to be achieved during tuning. The tuning process completes when the measured value (PV) of the controlled object reaches this value after tuning begin. Then, the tuning result will be output.
AT_PVDeltTar	Early termination threshold	REAL	Follows data type	0	When the PV value reaches AT_PV Target – AT_PVDeltTar, the tuning process terminates early and outputs the tuning result.
AT_InitRate	Initial steady-state slope	REAL	Follows data type	0	PV measured value slope that allows the step response tuning to start.

PIDRDVConfig structure configuration

Input Variable	Name	Data Type	Valid Range	Default Value	Description
DV_Start	Feedforward function switch	DINT	0, 1	0	Feedforward switch. If this function is used, set DV_Start to 1.
DV_Km	Disturbance model gain	REAL	Follows data type	1	Inputs the model gain of the measurable first-order disturbance model.
DV_Tm	Disturbance model time constant	REAL	(0, 10000]	1	Inputs the model time constant of the measurable first-order disturbance model.
DV_Dm	Disturbance model hysteresis	REAL	[0, 10000]	0	Inputs the model hysteresis of the measurable first-order disturbance model.
DV_PV	Measured disturbance value	REAL	Follows data type	0	Inputs the measured disturbance value.
DV_PVHigh	Disturbance input upper limit	REAL	Follows data type	100.0	When the measured disturbance input DV_PV exceeds this value, an alarm is triggered and the value is limited to this upper limit.
DV_PVLow	Disturbance input lower limit	REAL	Follows data type	-100.0	When the measured disturbance input DV_PV is below this value, an alarm is triggered and the value is limited to this lower limit.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
DDV_Pred_t	Current feedforward increment	REAL	Follows data type	0.0	Displays the feedforward increment calculated at the current moment. This value is superimposed on the prediction part.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
PIDROutput	Output parameter structure	PIDROutput	Follows data type	-	Output parameter configuration structure.
State	Switch state	DINT	0, 1	-	Indicates the actual state of the controller.
ERR	Fault code	DINT	Follows data type	-	0 for normal operation; non-zero when an error occurs. See PIDR fault codes.
OP	Valve position output value	REAL	Follows data type	-	Controller output value.
AT_ST	Tuning result	DINT	0, 1, 2, 3	-	Tuning state display. 0: Not tuned 1: Coarse tuning in progress 2: Fine tuning in progress 3: Tuning completed

PIDROutput structure configuration

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Version	Version information	ARRAY [0..3] OF DINT	Follows data type	-	Used to record internal version information.
DOP	Valve position increment output	REAL	Follows data type	-	Increment of the output value OP.
PV_Pred_t	Estimated value	REAL	Follows data type	-	Estimated value, that is, the response value of the controlled object, calculated by the internal model using historical data.
PV_Pred_tf	Predicted value	REAL	Follows data type	-	Predicted value, that is, the estimated value corrected based on the actual measured value PV.
PV_Pred_e	Prediction error	REAL	Follows data type	-	Difference between the actual measured value PV and the predicted value.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
PV_Pred_eSum	Cumulative prediction error	REAL	Follows data type	-	Cumulative sum of prediction errors.
DCV_S	Integral deviation accumulation rate	REAL	Follows data type	-	Used for integral deviation correction.
AT_Km	Tuning parameter Km	REAL	Follows data type	-	Model gain result obtained from auto-tuning.
AT_Tm	Tuning parameter Tm	REAL	> 0	-	Model time constant result obtained from auto-tuning.
AT_Dm	Tuning parameter Dm	REAL	>=0	-	Model hysteresis parameter result obtained from auto-tuning.

- **Function**
  PIDR includes one manipulated variable (output by OP), one controlled variable (measured by PV), and supports feedforward and auto-tuning functions. This component is primarily used for rapid deployment in single-input single-output processes.
- **Program example**
  1. Simulation example
     This example works with the FPTLGsim instruction, which simulates a first-order plus pure hysteresis process, to form a single-input single-output control simulation.
     Configure the PIDR instruction parameters (model parameters: Km, Tm, Dm; controller parameters: COP, COF, etc.) according to the characteristics of the controlled object.
     The PIDR instruction responds to the output (PV) of the FPTLGsim object, obtains the control quantity (OP) output, and applies it to the original control object, forming a control loop.
     Control expectation: If all parameters are configured properly, the controller will eventually keep the output value (PV) of the controlled object near the setpoint SP.
     ST language example is shown in the figure:

	Name	Data type	Address	Initial value
2	FPTLGSim_Instance_0	FPTLGSim		
3	PIDR_Instance_0	PIDR	First-order lag controlled object	
4	SP	REAL	PIDR controller	50
5	var1	REAL		

IF CAS FOR WHI REP RET EX REG

```
FPTLGSim_Instance_0(IN := ,
                    Gain := 20,
                    T := 13,
                    TmLag := 1,
                    Cycle := 1,
                    Reset := ,
                    OUT => ,
                    ErrorBits => );

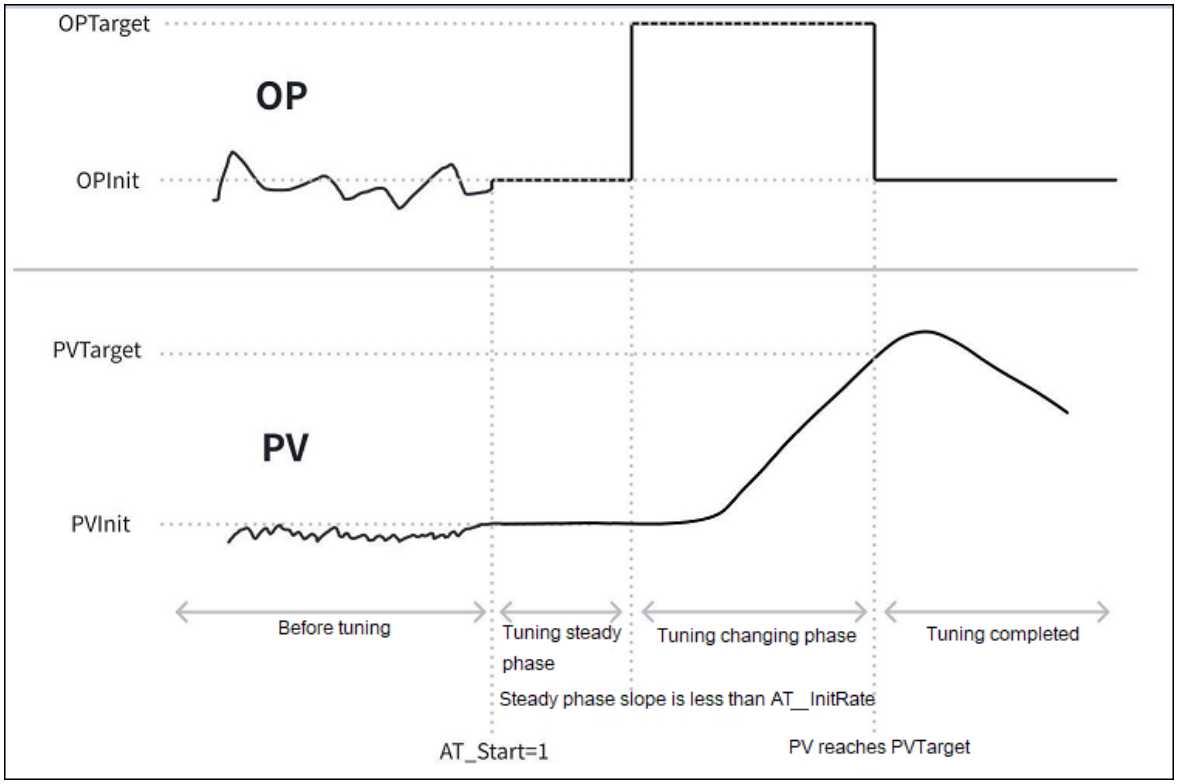
PIDR_Instance_0(SW := 1,
                SP := SP,
                PV := FPTLGSim_Instance_0.OUT,
                Km := 20,
                Tm := 13,
                Dm := 1,
                PIDRConfig := ,
                PIDRAuToConfig := ,
                PIDRDVConfig := ,
                PIDROutput => ,
                State => ,
                ERR => ,
                OP => FPTLGSim_Instance_0.IN,
                AT_ST => );
```

In the ST programming area, right-click the module name and select "Instruction configuration" to open the configuration interface. You can monitor the parameters on the "Commissioning" tab. After clicking "Start" in the "Drawing and variable table" area, the curves for the setpoint (SP), process value (PV), and controller output (OP) are displayed.

2. Auto-tuning function application

The PIDR instruction includes a built-in parameter auto-tuning function, automatically obtaining the model parameters (Km, Tm, and Dm) of the controlled object. Click the "Tuning" button on the "Commissioning" tab of the instruction configuration page. Configure the auto-tuning parameters according to the variable description to start parameter tuning.
Because the controller internal variable array has a capacity of only 200, ensure that the duration from the OP output step to the completion of tuning stays within 200 control cycles. 100 to 150 cycles is recommended. Furthermore, the tuning process does not require waiting for the response to reach a complete steady state after the step. Generally, it only needs to capture the portion of the controlled object's response with the maximum slope.

The tuning process is as follows:



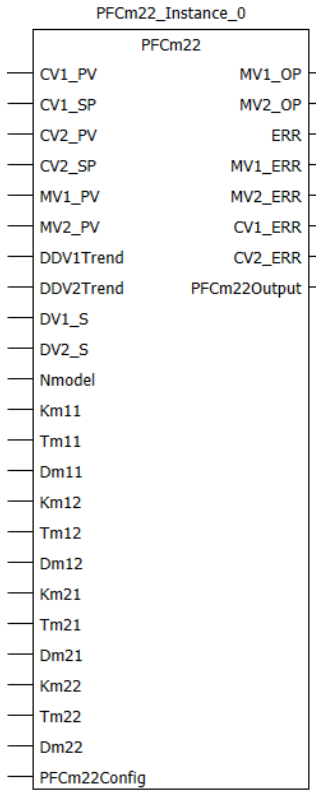
a. Set "AT_Start" to 1 to enable the auto-tuning switch.

b. Configure the tuning parameter "Initial OP output for tuning" (AT_OPInit). This value is the OP output value at the initial steady state. Ensure that the controlled object reaches a basic stable state at this output. Open-loop control can be used before the tuning process to stabilize the controlled object at this output. Then, use the auto-tuning function.

c. Configure the tuning parameter "Target OP output for tuning" (AT_OPTarget). This value is the step output value at the start of tuning. The controller will perform a step change from "AT_OPInit" to "AT_OPTarget" to excite the response of the controlled object.

d. Configure the tuning parameter "PV value at tuning end" (AT_PVTarget). This value is the target PV value to be achieved during tuning. The tuning process completes when the measured value (PV) of the controlled object has reached this value after tuning begin. Pay special attention to the response polarity of the controlled object. Ensure that the measured value reaches AT_PVTarget after tuning starts, rather than the PV changing in the opposite direction after the OP step change.

e. Click "Tuning" to run the auto-tuning, and the auto-tuning results can be obtained at AT_Km, AT_Tm, and AT_Dm.



- **Precautions**
  - During operation, ensure that the switch is on, and the configuration is correct.

◦ The execution time of a single PIDR instruction is 75 μs, and the memory usage is 1.6 KB. During operation, configure the scheduling task cycle properly. For example, if five PIDRs need to run simultaneously, the computation time is about 218 μs. It is recommended to set the task period to at least twice this value.

18.3.2.10 PFCm22

This instruction is a dual-input dual-output control instruction. It is primarily used in 2x2 scenarios, such as the coupled control of temperature 1 and temperature 2 by heater 1 and heater 2, involving mutual coupling between the two temperature zones.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
PFCm22	Multivariable input/output advanced control	FB		PFCm22_Instance_0(CV1_PV := , CV1_SP := , CV2_PV := , CV2_SP := , MV1_PV := , MV2_PV := , DDV1Trend := , DDV2Trend := , DV1_S := , DV2_S := , Nmodel := , Km11 := , Tm11 := , Dm11 := , Km12 := , Tm12 := , Dm12 := , Km21 := , Tm21 := , Dm21 := , Km22 := , Tm22 := , Dm22 := , PFCm22Config := , MV1_OP => , MV2_OP => , ERR => , MV1_ERR => , MV2_ERR => , CV1_ERR => , CV2_ERR => , PFCm22Output =>);

- **Related variables**

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
CV1_PV	Measured value of the controlled variable 1	REAL	Follows data type	0	Input value of the controlled variable 1 measurement, which must be provided by an external physical object or simulation object.
CV1_SP	Setpoint value of the controlled variable 1	REAL	Follows data type	0	Setpoint value of the controlled variable 1, which determines the control objective of the controller so that the final actual control result (PV) must closely follow CV1_SP.
CV2_PV	Measured value of the controlled variable 2	REAL	Follows data type	0	Input value of the controlled variable 2 measurement, which must be provided by an external physical object or simulation object.
CV2_SP	Setpoint value of the controlled variable 2	REAL	Follows data type	0	Setpoint value of the controlled variable 2, which determines the control objective of the controller so that the final actual control result (PV) must closely follow CV2_SP.
MV1_PV	Measured value of the manipulated variable 1	REAL	Follows data type	0	Measured value of manipulated variable 1. The actual output value 1 must be written back to this variable. In a heating application: if only algorithmic control is active, write back the value of MV1_OP; if an external input is present, write back the actual value sent to the actuator.
MV2_PV	Measured value of the manipulated variable 2	REAL	Follows data type	0	Measured value of manipulated variable 2. The actual output value 2 must be written back to this variable. In a heating application: if only algorithmic control is active, write back the value of MV2_OP; if an external input is present, write back the actual value sent to the actuator.
DDV1Trend	Disturbance sequence 1	ARRAY [0..199] OF REAL	Follows data type	-	Disturbance sequence 1 generated by the dv series component. When using this variable, pass its output "DDVTrend" to this variable. It is used to predict future disturbances so that the controller can take proactive action to suppress them. This variable corresponds to CV1 disturbance.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
DDV2Trend	Disturbance sequence 2	ARRAY [0..199] OF REAL	Follows data type	-	Disturbance sequence 2 generated by the dv series component. When using this variable, pass its output "DDVTrend" to this variable. It is used to predict future disturbances so that the controller can take proactive action to suppress them. This variable corresponds to CV2 disturbance.
DV1_S	Disturbance velocity 1	REAL	Follows data type	-	Disturbance velocity generated by the PFCm_dv component. When using this variable, pass its DV_S output to this variable. It is used to predict future disturbances so that the controller can take proactive action to suppress them. This variable corresponds to CV1 disturbance.
DV2_S	Disturbance velocity 2	REAL	Follows data type	-	Disturbance velocity generated by the PFCm_dv component. When using this variable, pass its DV_S output to this variable. It is used to predict future disturbances so that the controller can take proactive action to suppress them. This variable corresponds to CV2 disturbance.
Nmodel	Model length	DINT	[1, 200]	100	The model length is used to adjust the control effect. The larger this value, the longer the effective prediction horizon, and the further the future trends can be predicted.
Km11	Model MV1-CV1 gain	REAL	Follows data type	1	An algorithm parameter that affects the control performance. Increasing the value speeds up the system response to some extent, while decreasing it slows down the system response to some extent.
Tm11	Model MV1-CV1 time constant	REAL	(0, 10000]	1	An algorithm parameter that affects the control performance. The smaller the Tm value, the fewer cycles required to reach a steady state. If the value exceeds the limit, it will be limited to 1e-6.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Dm11	Model MV1-CV1 hysteresis	REAL	[0, 10000]	0	An algorithm parameter that affects the control performance. The delay expressed in control cycles is Dm/Ts. If the value exceeds the limit, it will be limited to 0.
Km12	Model MV2-CV1 gain	REAL	Follows data type	1	An algorithm parameter that affects the control performance. Increasing the value speeds up the system response to some extent, while decreasing it slows down the system response to some extent.
Tm12	Model MV2-CV1 time constant	REAL	(0, 10000]	1	An algorithm parameter that affects the control performance. The smaller the Tm value, the fewer cycles required to reach a steady state. If the value exceeds the limit, it will be limited to 1e-6.
Dm12	Model MV2-CV1 hysteresis	REAL	[0, 10000]	0	An algorithm parameter that affects the control performance. The delay expressed in control cycles is Dm/Ts. If the value exceeds the limit, it will be limited to 0.
Km21	Model MV1-CV2 gain	REAL	Follows data type	1	An algorithm parameter that affects the control performance. Increasing the value speeds up the system response to some extent, while decreasing it slows down the system response to some extent.
Tm21	Model MV1-CV2 time constant	REAL	(0, 10000]	1	An algorithm parameter that affects the control performance. The smaller the Tm value, the fewer cycles required to reach a steady state. If the value exceeds the limit, it will be limited to 1e-6.
Dm21	Model MV1-CV2 hysteresis	REAL	[0, 10000]	0	An algorithm parameter that affects the control performance. The delay expressed in control cycles is Dm/Ts. If the value exceeds the limit, it will be limited to 0.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Km22	Model MV2-CV2 gain	REAL	Follows data type	1	An algorithm parameter that affects the control performance. Increasing the value speeds up the system response to some extent, while decreasing it slows down the system response to some extent.
Tm22	Model MV2-CV2 time constant	REAL	(0, 10000]	1	An algorithm parameter that affects the control performance. The smaller the Tm value, the fewer cycles required to reach a steady state. If the value exceeds the limit, it will be limited to 1e-6.
Dm22	Model MV2-CV2 hysteresis	REAL	[0, 10000]	0	An algorithm parameter that affects the control performance. The delay expressed in control cycles is Dm/Ts. If the value exceeds the limit, it will be limited to 0.
PFCmConfig	Input parameter structure	PFCm22Config	Follows data type	-	Input parameter configuration structure.

PFCm22Config structure configuration

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Ts	Sampling cycle	REAL	(0, 10000]	1	This value determines the control cycle. This value must be greater than 0, and can not be set too low. An excessively small value may cause a calculation timeout and degrade control performance. If Ts is less than 0, the algorithm will automatically terminate, the switch will turn off, and the output will be held.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Model1	Model type 1	DINT	0, 1, 2	1	Model for MV1-CV1. Model type: 0: Non-integral. 1: Pseudo-integral. 2: Pure integral. Currently, types 0 (Non-integral) and 1 (Pseudo-integral) are primarily used. Type 2 (Pure integral) is not implemented. In practice, integral models are typically handled as pseudo-integral. When the model selection is not 0, 1, or 2, the algorithm terminates, the switch is turned off, and the output will be held.
Model2	Model type 2	DINT	0, 1, 2	1	Model for MV2-CV1. Model type: 0: Non-integral. 1: Pseudo-integral. 2: Pure integral. Currently, types 0 (Non-integral) and 1 (Pseudo-integral) are primarily used. Type 2 (Pure integral) is not implemented. In practice, integral models are typically handled as pseudo-integral. When the model selection is not 0, 1, or 2, the algorithm terminates, the switch is turned off, and the output will be held.
Model3	Model type 3	DINT	0, 1, 2	1	Model for MV1-CV2. Model type: 0: Non-integral. 1: Pseudo-integral. 2: Pure integral. Currently, types 0 (Non-integral) and 1 (Pseudo-integral) are primarily used. Type 2 (Pure integral) is not implemented. In practice, integral models are typically handled as pseudo-integral. When the model selection is not 0, 1, or 2, the algorithm terminates, the switch is turned off, and the output will be held.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Model4	Model type 4	DINT	0, 1, 2	1	Model for MV2-CV2. Model type: 0: Non-integral 1: Pseudo-integral 2: Pure integral Currently, types 0 (Non-integral) and 1 (Pseudo-integral) are primarily used. Type 2 (Pure integral) is not implemented. In practice, integral models are typically handled as pseudo-integral. When the model selection is not 0, 1, or 2, the algorithm terminates, the switch is turned off, and the output will be held.
MV1_Config	MV1 variable input parameter structure	PFCm22_MVConfig	Follows data type	-	MV1 variable input parameter configuration structure.
MV2_Config	MV2 variable input parameter structure	PFCm22_MVConfig	Follows data type	-	MV2 variable input parameter configuration structure.
CV1_Config	CV1 variable input parameter structure	PFCm22_CVConfig	Follows data type	-	CV1 variable input parameter configuration structure.
CV2_Config	CV2 variable input parameter structure	PFCm22_CVConfig	Follows data type	-	CV2 variable input parameter configuration structure.
Single_SW	Single output switch	DINT	0, 1	0	Single output switch. If this switch is set to ON, it ensures that when the two MV gains have opposite signs, only one output direction is active. This is typically used to save energy.

PFCm22_MVConfig structure configuration

Input Variable	Name	Data Type	Valid Range	Default Value	Description
MV_SW	Manipulated variable switch	DINT	0, 1	1	MV switch; when this switch is off, the control is disabled. Invalid values are automatically set to 0.
MV_High_Val	Manipulated variable valid upper limit	REAL	Follows data type	200	Valid upper limit. When the value exceeds the valid upper limit, the switch will be turned off and the control will be disabled.
MV_Low_Val	Manipulated variable valid lower limit	REAL	Follows data type	0	Valid lower limit. When the value falls below the valid lower limit, the switch will be turned off and the control will be disabled.
MV_High_Ope	Operation upper limit of the manipulated variable	REAL	Follows data type	100	Operation upper limit. When the value exceeds this operation upper limit, a warning will be issued and the value will be clamped to this operation upper limit.
MV_Low_Ope	Operation lower limit of the manipulated variable	REAL	Follows data type	0	Operation lower limit. When the value falls below this operation lower limit, a warning will be issued and the value will be clamped to this operation lower limit.
MV_DMax	Maximum positive increment for the manipulated variable	REAL	[0, 10000]	100	Defines the maximum allowable positive increment of the output. Invalid input values are limited to 100.
MV_DMin	Maximum negative increment for the manipulated variable	REAL	[-10000, 0]	-100	Defines the maximum allowed negative increment of the output. Invalid input values are limited to -100.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
MV_COP	Manipulated variable performance coefficient	REAL	[0, 10000]	1	An algorithm parameter that affects the control performance. Decreasing the value speeds up the system response to some extent, while increasing it slows down the system response to some extent. If this value exceeds the upper limit, it will be limited to the upper limit. If the value falls below the lower limit, it will be limited to the lower limit.
MV_Irv	Ideal injection value for the manipulated variable	REAL	Follows data type	1	The value that the corresponding MV output eventually converges to.
MV_Irv_C	Weight for manipulated variable ideal injection value	REAL	[0, 10000]	1	The larger the value, the closer the MV will converge to MV_Irv.
MV_Irv_SW	Ideal injection value switch	DINT	0, 1	0	When set to 0, the ideal injection value is inactive. When used, the value must be set to 1. Invalid values are automatically set to 0.

PFCm22_CVConfig structure configuration

Input Variable	Name	Data Type	Valid Range	Default Value	Description
CV_SW	Controlled variable switch	INT	0, 1	1	Controlled variable switch. When the switch is off, the control is disabled. When used, it must be set to 1. Invalid values are automatically set to 0.
Cost_SS	Speed steady state weight	REAL	[0, 10000]	0	Speed steady state weight. In an integral model, this weight determines how quickly the speed converges to steady state. A larger value slows down the convergence. If set too large, the output may remain unchanged.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
CV_ECE	Equivalent deviation	REAL	[0, 10000]	1	Determines the weight of the corresponding CV variable. A larger value gives higher priority to controlling that CV.
CV_COF	Filter coefficient	REAL	[0, 1]	0.9	An algorithm parameter that affects the control performance. The smaller this value, the greater the confidence in the model prediction. When set to 0, no feedback correction is performed. Use a value greater than 0. If this value exceeds the upper limit, it will be limited to the upper limit. If the value falls below the lower limit, it will be limited to the lower limit.
CV_Tref	Closed-loop reference time	REAL	(0, 10000]	1	An algorithm parameter that affects the control performance. Increasing the value slows down the system response to some extent, while decreasing it speeds up the system response to some extent. If the value exceeds the limit, it will be limited to 1e-6.
I_COF	Integral deviation correction coefficient	REAL	[0, 1]	0.1	An algorithm parameter that affects the control performance. The smaller the value, the greater the confidence in the model prediction. If this value exceeds the upper limit, it will be limited to the upper limit. If the value falls below the lower limit, it will be limited to the lower limit.
CV_SP_DMax	Upper deviation range	REAL	[0, 10000]	0.1	An algorithm parameter that affects the control performance. The system is considered stable if CV_PV is within this range CV_SP + CV_SP_DMax. Invalid input values are limited to 0.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
CV_SP_DMin	Lower deviation range	REAL	[-10000, 0]	-0.1	An algorithm parameter that affects the control performance. The system is considered stable if CV_PV is within this range CV_SP + CV_SP_DMin. Invalid input values are limited to 0.
DeltaCV	Maximum change rate of the controlled variable	REAL	[0, 10000]	100	This algorithm parameter defines the maximum change value of CV during prediction. Invalid values are limited to 100.
CV_Low_Val	Valid lower limit of the controlled variable	REAL	Follows data type	0	Valid lower limit. When the value falls below the valid lower limit, the switch will be tu rned off and the control will be disabled.
CV_High_Val	Valid upper limit of the controlled variable	REAL	Follows data type	100	Valid upper limit. When the value exceeds the valid upper limit, the switch will be turned off and the control will be disabled.
CV_Low_Ope	Operation lower limit of the controlled variable	REAL	Follows data type	0	Operation lower limit. When the value falls below this operation lower limit, a warning will be issued and the value will be clamped to this operation lower limit.
CV_High_Ope	Operation upper limit of the controlled variable	REAL	Follows data type	100	Operation upper limit. When the value exceeds this operation upper limit, a warning will be issued and the value will be clamped to this operation upper limit.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
MV1_OP	Manipulated variable 1 output value	REAL	Follows data type	-	Output value of manipulated variable 1. This value must be output to the simulation object or actual object.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
MV2_OP	Manipulated variable 2 output value	REAL	Follows data type	-	Output value of manipulated variable 2. This value must be output to the simulation object or actual object.
ERR	Fault code	DINT	Follows data type	-	For fault codes, see PFCm 22 fault codes.
MV1_ERR	Manipulated variable 1 fault code	DINT	Follows data type	-	Fault code of manipulated variable 1.
MV2_ERR	Manipulated variable 2 fault code	DINT	Follows data type	-	Fault code of manipulated variable 2.
CV1_ERR	Controlled variable 1 fault code	DINT	Follows data type	-	Fault code of controlled variable 1.
CV2_ERR	Controlled variable 2 fault code	DINT	Follows data type	-	Fault code of controlled variable 2.
PFCm22Output	Output parameter structure	PFCm22Output	Follows data type	-	Output parameter structure.

PFCm22Output structure configuration

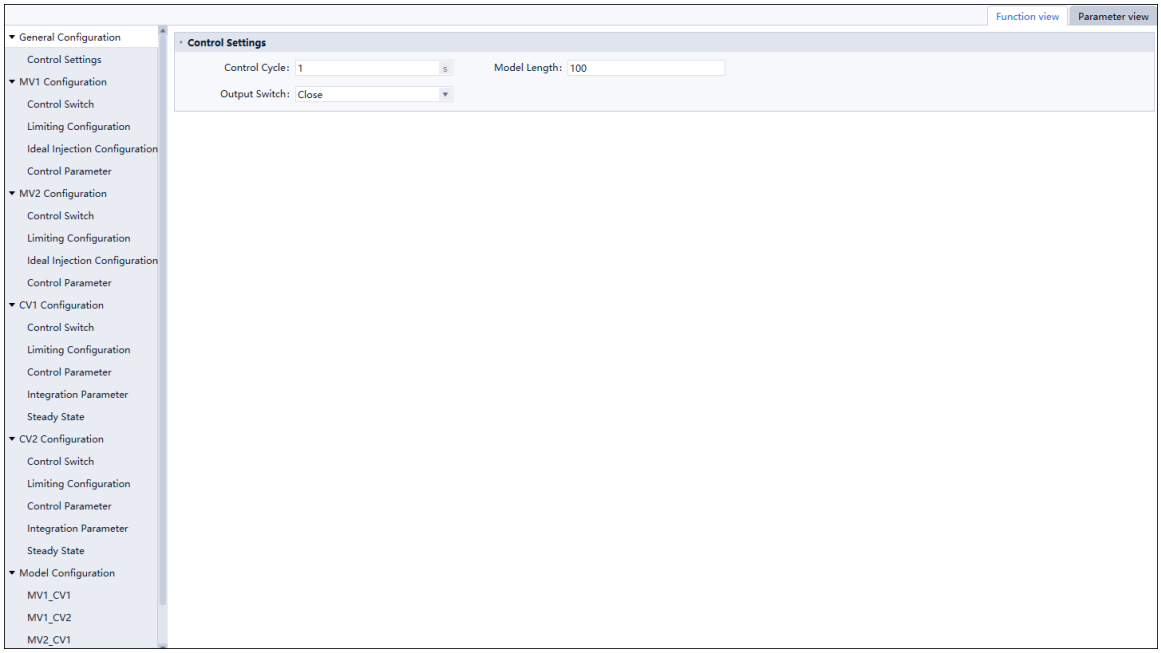
Output Variable	Name	Data Type	Valid Range	Default Value	Description
Version	Version information	ARRAY [0..3] OF REAL	Follows data type	-	Used to obtain the version information.
NFlag	Number of errors	DINT	[0, 10]	-	Counts the number of errors.
Flag	Error information	ARRAY [0..9] OF DINT	Follows data type	-	Records detailed information of each error.
CV1_OutConfig	Controlled variable 1 output structure	PFCm22_CVOutConfig	Follows data type	-	Output structure of controlled variable 1.
CV2_OutConfig	Controlled variable 2 output structure	PFCm22_CVOutConfig	Follows data type	-	Output structure of controlled variable 2.
MV1_OutConfig	Manipulated variable 1 output structure	PFCm22_MVOutConfig	Follows data type	-	Output structure of manipulated variable 1.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
MV2_OutConfig	Manipulated variable 2 output structure	PFCm22_MVOutConfig	Follows data type	-	Output structure of manipulated variable 2.

PFCm22_CVOutConfig structure configuration

Output Variable	Name	Data Type	Valid Range	Default Value	Description
CV_NFlag	Controlled variable error count	DINT	[0, 10]	-	Number of recorded errors for the controlled variable
CV_Flag	Controlled variable error information	ARRAY [0..9] OF DINT	Follows data type	-	Detailed information of recorded errors for the controlled variable
CV_ST	Controlled variable switch status	DINT	0, 1	-	Status of the controlled variable switch. Initially the value equals the switch input value. When an internal error occurs, this value is set to 1.
CV_Pred_t	Estimated value of controlled variable	REAL	Follows data type	-	Estimated value, that is, the response value of the controlled object, calculated by the internal model using historical data.
CV_Pred_tf	Predicted value of controlled variable	REAL	Follows data type	-	Predicted value, that is, the corrected predicted value based on the predicted value and the actual measured value PV.
DCV_S_i	Velocity after integral deviation correction	REAL	Follows data type	-	Velocity after integral deviation correction.
DCV_S_SS	Future speed steady state value	REAL	Follows data type	-	Steady-state speed value, which is the speed value predicted after 200 cycles.
CV_PV_e	Predicted error of the controlled variable	REAL	Follows data type	-	Difference between the actual measured value and the predicted value.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
CV_PV_eSum	Cumulative sum of predicted errors for the controlled variable	REAL	Follows data type	-	The cumulative sum of errors (regardless of sign). Its magnitude indicates the degree of model mismatch.
CV_Pred_t_Past	Sequence of historical estimated values for the controlled variable	ARRAY [0..199] OF REAL	Follows data type	-	Records historical values.
CV_Pred	Open-loop prediction sequence of controlled variables	ARRAY [0..199] OF REAL	Follows data type	-	Records the sequence of future values predicted when the current cycle is not applied.
CV_Future	Closed-loop prediction sequence of controlled variables	ARRAY [0..199] OF REAL	Follows data type	-	Records the sequence of future values predicted after the current cycle has been applied.
CV_PV_Past	Sequence of historical measured values for the controlled variable	ARRAY [0..199] OF REAL	Follows data type	-	Records historical measured values.
SP_Past	Setpoint history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical setpoint values, for plotting.
SP_Future	Setpoint future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of the future setpoint values, for plotting.
CV_SP_Href	Upper reference trajectory sequence	ARRAY [0..199] OF REAL	Follows data type	-	Predicted upper trajectory to be approached.
CV_SP_Lref	Lower reference trajectory sequence	ARRAY [0..199] OF REAL	Follows data type	-	Predicted lower trajectory to be approached.
CV_Low_Past	Controlled variable lower limit history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical operation lower limits for the controlled variable, for plotting.



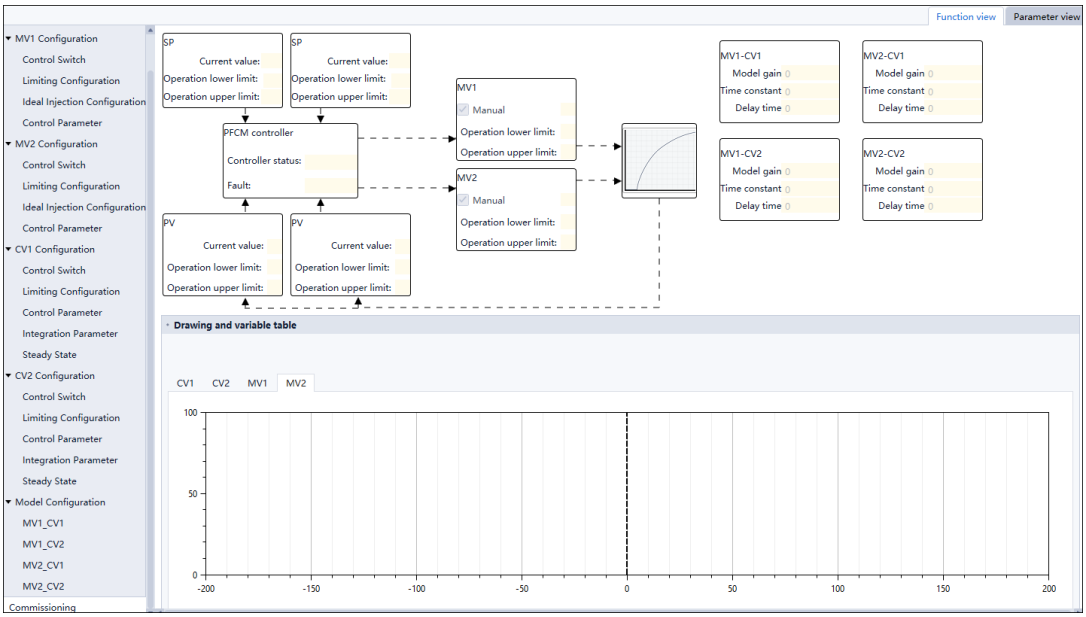
Output Variable	Name	Data Type	Valid Range	Default Value	Description
CV_High_Past	Controlled variable upper limit history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical upper limits for the controlled variable, for plotting.
CV_Low_Future	Controlled variable lower limit future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of future operation lower limits for the controlled variable, for plotting.
CV_High_Future	Controlled variable upper limit future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of future operation upper limits for the controlled variable, for plotting.

PFCm22_MVOutConfig structure configuration

Output Variable	Name	Data Type	Valid Range	Default Value	Description
MV_NFlag	MV error count	DINT	0, 1	-	Number of errors counted for the manipulated variable.
MV_Flag	MV error message	ARRAY [0..9] OF DINT	[0, 10]	-	Detailed information of recorded errors for the manipulated variable.
MV_Low_Past	Output lower limit history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical operation lower limits for the manipulated variable, for plotting.
MV_High_Past	Output upper limit history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical operation upper limits for the manipulated variable, for plotting.
MV_Low_Future	Output lower limit future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of future operation lower limits for the manipulated variable, for plotting.
MV_High_Future	Output upper limit future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of future operation upper limits for the manipulated variable, for plotting.
MV_Past	Output value history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical measured values for the manipulated variable, for plotting.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
MV_Future	Output value future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of future measured values for the manipulated variable, for plotting.
MV_DOP_Past	Historical increment sequence of the valve position	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical increment values for the manipulated variable, for plotting.
MV_DOP	Manipulated variable action increment	REAL	Follows data type	-	Increment value of the manipulated variable.
MV_ST	Manipulated variable switch state	DINT	0, 1	-	Manipulated variable switch state. Initially, it equals the switch value. This value is set to 1 when an internal error occurs.
MV_Irv_Past	Ideal injection value history sequence	ARRAY [0..199] OF REAL	Follows data type		Sequence of historical ideal injection values, for plotting.
MV_Irv_Future	Ideal injection value future sequence	ARRAY [0..199] OF REAL	Follows data type		Sequence of future ideal injection values, for plotting.

- **Function**
  - PFCm22 is a 2x2 dual-input, dual-output control instruction. The controlled object can support non-integrating, integrating, or pseudo-integrating responses. The instruction includes two manipulated variables (MV), two controlled variables (CV), and a feedforward input channel (for use with PFCm_dv). The instruction does not rely on an external solver for optimization calculations. It is mainly intended for applications with simple coupling and does not require high-end products. It is suitable for fast control application scenarios with millisecond-level control cycles.
  - The PFCm22 function block includes an intuitive interface for parameter configuration and commissioning. After adding the PFCm22 component, select "Control object > PFC" in the left project tree, and then double-click the PFCm22 instance under the PFC node to open the configuration and tuning interface, as shown in the figure below.



- Parameter description

  The parameter configuration of the PFCm22 instruction includes general configuration, MV configuration, CV configuration, and model configuration. For detailed parameter descriptions, see Relevant variables.

- Commissioning

  After the parameters are configured, the control effect can be viewed directly in the commissioning interface.

- **Program example**

  Here, the two-input, two-output control simulation between the PFCm22 instruction and four first-order inertia plus pure delay simulation instruction (FPTLGsim) is used as an example. The parameter configuration and control process are as follows:

  - Parameter configuration

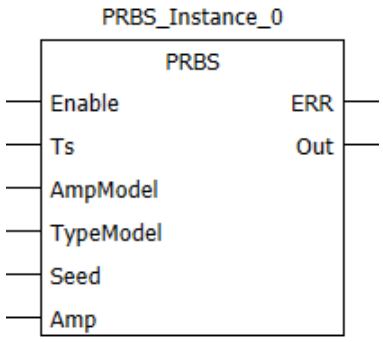
    Configure the PFCm22 instruction parameters based on the characteristics of the control object (Model parameters: Km11, Tm11, Dm11 and so on; controller parameters: COP, COF, etc.).

  - Control process

The PFCm22 instruction responds to the output (PV) of the FPTLGsim object, obtains the control quantity (OP) output, and applies it to the original control object, forming a control loop.

- Control expectation
  If all parameters are configured properly, the controller will eventually keep the output value (CV_PV) of the controlled object near the setpoint CV_SP.

LD language code example:



- **Precautions**
  - During operation, ensure that the switch is on, and the configuration is correct.
  - The execution time of the PFCm22 instruction is 20 ms. With 50 PFCm22 function blocks loaded, the total execution time is estimated to reach approximately 1 second. Loading 364 PFCm22 function blocks will reach the controller's resource limit. During operation, configure the scheduling task cycle properly. For example, if 10 PFCm22 are required to perform loop control simultaneously, with a block calculation time of 200 ms. The task cycle must be at least twice this value, that is, 400 ms, to ensure the CPU load does not become too high.

18.3.2.11 PRBS

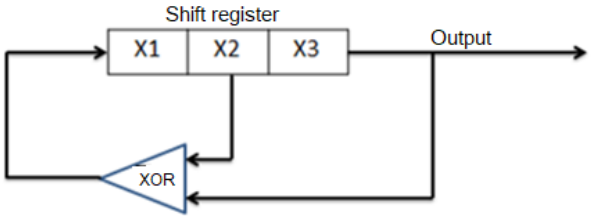
A pseudo-random binary sequence (PRBS) is a reproducible binary sequence generated according to certain rules.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
PRBS	Pseudo-Random Binary Sequence	FB		PRBS_Instance_0(Enable := , Ts := , AmpModel := , TypeModel := , Seed := , Amp := , ERR => , Out =>);

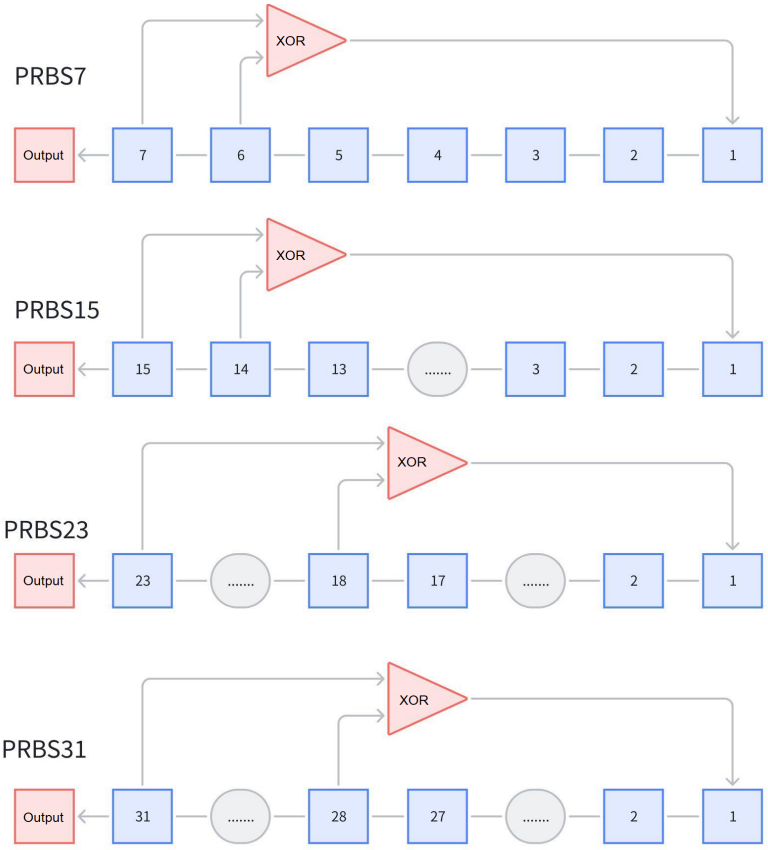
- **Related variables**

Input variables



Input Variable	Name	Data Type	Valid Range	Default Value	Description
Enable	Enable switch	BOOL	0, 1	0	Enable switch. 0: Off (disabled) 1: On (enabled) The switch must be On when in use.
Ts	Periodic	UINT	>=1	1	Generation period of the pulse signal, that is, a multiple of the task cycle.
AmpModel	Amplitude type	UINT	0, 1	0	0: Unipolar (positive-zero). The output pulses can be switched between 0 and a positive amplitude. 1: Bipolar (positive-negative). The output pulses can be switched between a positive and a negative amplitude.
TypeModel	PRBS type	UINT	0, 1, 2, 3	1	Type mode. 0: PRBS7 1: PRBS15 2: PRBS23 3: PRBS31
Seed	Initial seed	UDINT	1 to 65535	1	Initial seed. It must not be 0.
Amp	Amplitude	REAL	Follows data type	1	Amplitude.

Output variables



Output Variable	Name	Data Type	Valid Range	Default Value	Description
Out	PRBS output	REAL	Follows data type	0	PRBS output.
ERR	Fault code	DINT	Follows data type	0	0 indicates normal operation. A non-zero value indicates an error.

- **Function**

  PRBS patterns are generated by a PRBS pattern generator. A simplified schematic of a typical generator is shown below. It mainly consists of shift registers and XOR gates.

  PRBS signals can be classified into several types, such as PRBS7, PRBS15, PRBS23, and PRBS31. The algorithm primarily implements these four types. The key difference between these types lies in the XOR bit indices, and there are also some variations in the implementation methods.

- **Program example**

  The PRBS component can generate specific pulse waveforms through proper parameter configuration, as shown below:

18.3.2.12 PFC11

PFCs are simplified predictive function controller (PFC11) components for single-input, single-output systems, primarily used in 1x1 control scenarios such as temperature heating control.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation

  Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
SW	Operating switch	DINT	0, 1	0	0: Component off. 1: Component on. Ensure the component is in the on state when in use.
SP	Setpoint	REAL	Follows data type	0	Setpoint for the controlled variable, which defines the control target of the controller. If properly configured, the actual control result (PV) must closely follow the SP.
PV	Measured value	REAL	Follows data type	0	Input value of the controlled variable measurement, which must be provided by an external physical object or simulation object.
MV	Measured value of the valve position	REAL	Follows data type	0	Measured value of the manipulated variable. The actual output value must be written back to this variable.
Km	Model gain	REAL	Follows data type	1	An algorithm parameter that describes the response gain of the controlled object. It must be determined based on the influence of the output OP on the controlled object. The greater this influence, the larger the gain value.
Tm	Model time constant	REAL	[0, 10000]	1	An algorithm parameter that describes the response time of the controlled object. The greater the inertia of the controlled object, the slower the response, and the larger this value.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Dm	Model hysteresis	REAL	[0, 10000]	0	An algorithm parameter that represents the response hysteresis of the controlled object. The greater the hysteresis of the object to input changes, the larger this value.
Nmodel	Model length	DINT	[1, 200]	100	The model length is used to adjust the control effect. The larger this value, the longer the effective prediction horizon, and the further the future trends can be predicted.
DDVTrend	Future disturbance sequence	ARRAY [0..199] OF REAL	Follows data type	-	Disturbance sequence ge nerated by the PFC_DV component. When using this variable, pass its "DDVTrend" output to this variable. It is used to predict future disturbances so that the controller can take proactive action to suppress them.
DDV_T	Disturbance increment	REAL	Follows data type	-	Disturbance increment value, generated by the PFC_DV input interface of the same name and used for disturbance prediction and feedback correction.
PFC11_Config	Input parameter structure	PFC11_Config	Follows data type	-	Input parameter configuration structure.
PFC11_AuTu	Auto-tuning parameter structure	PFC11_AuTu	Follows data type	-	Auto-tuning parameter configuration structure.
PFC11_ReTe	Relay test structure	PFC11_ReTe	Follows data type	-	Relay test structure.
PFC11_OPT	Closed-loop OP test structure	PFC11_OPT	Follows data type	-	Closed-loop OP test structure.

PFC11_Config structure configuration

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Ts	Sampling cycle	REAL	(0, 10000]	1	This value represents the control and tuning cycle. The value must be greater than 0. Ensure that this value is not set too low (below the operation cycle). If Ts is less than 0, the algorithm will automatically terminate, the switch will turn off, and the output will be held.
Model	Model type	DINT	0, 1, 2	1	Model types include: 0: Non-integral. 1: Pseudo-integral. 2: Pure integral. **Note:** The algorithm internally distinguishes between non-integral and integral models. The logic for pseudo-integral models follows the same rules as those for integral models. When the model selection is not 0, 1, or 2, the algorithm terminates, the switch is turned off, and the output will be held.
COF	Filter coefficient	REAL	[0, 1]	0.9	An algorithm parameter that affects the performance of feedback correction. The feedback value balances the measurement for the current cycle with the model prediction. The magnitude of the COF determines whether the algorithm places greater weight on the measured value or the predicted value in the feedback loop. • When set to 0, the feedback value uses the model prediction, and no feedback correction is applied. • When set to 1, the feedback value uses the measured value. • For other values, an average is calculated.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
COP	Performance coefficient	REAL	(0, 10000]	1	An algorithm parameter that affects the control performance. Increasing the value speeds up the system response to some extent, while decreasing it slows down the system response to some extent.
Tref	Closed-loop reference time	REAL	(0, 10000]	1	An algorithm parameter that affects the control performance. It is used to reduce the system response speed. Increasing this value slows down the system response to some extent, while decreasing it will speed up the system response to some extent. If the value exceeds the limit, it will be capped at 1e-6.
I_COF	Integral deviation correction coefficient	REAL	[0, 1]	0.1	Correction coefficient for integral speed. This value will take effect when the integral model is used. The larger the value, the faster the integral model speed operates in the algorithm, resulting in greater changes in future prediction, and thus causing output changes. Generally, fine-tuning this value after reaching steady state can reduce steady-state fluctuations.
DOPmax	Output increment limit	REAL	>=0	100	Sets the upper limit of output increment.
OP_Low_Val	Output valid lower limit	REAL	Follows data type	0	When the value falls below this output valid lower limit, the switch will be turned off and the control will be disabled.
OP_High_Val	Output valid upper limit	REAL	Follows data type	100	When the value exceeds this output valid upper limit, the switch will be turned off and the control will be disabled.
OP_Low_Ope	Output operation lower limit	REAL	Follows data type	0	When the value falls below this output operation lower limit, a warning is issued and the output is clamped to this limit.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
OP_High_Ope	Output operation upper limit	REAL	Follows data type	100	When the value exceeds this output operation upper limit, a warning will be issued and the output is clamped to this limit.
SP_Low_Val	Setpoint valid lower limit	REAL	Follows data type	0	Valid lower limit of the setpoint. When the value falls below this lower limit, the switch will be turned off and the control will be disabled.
SP_High_Val	Setpoint valid upper limit	REAL	Follows data type	100	Valid upper limit of the setpoint. When the value exceeds this upper limit, the switch will be turned off and the control will be disabled.
SP_Low_Ope	Setpoint operation lower limit	REAL	Follows data type	0	Operation lower limit of the setpoint. When the value falls below this lower limit, the system will display a warning and limit the value to the lower limit.
SP_High_Ope	Setpoint operation upper limit	REAL	Follows data type	100	Operation upper limit of the setpoint. When the value exceeds this upper limit, the system will display a warning and limit the value to the upper limit.
SP_DMax	Setpoint increment upper range	REAL	>=0	0.1	Algorithm parameter that affects the control effect. The system is considered stable when PV is within the range SP + SP_DMax.
SP_DMin	Setpoint increment lower range	REAL	<=0	-0.1	Algorithm parameter that affects the control effect. The system is considered stable when PV is within the range SP + SP_DMin.
Cost_SS	Speed steady state weight	REAL	>=0	0	In an integral model, this weight determines how quickly the speed converges to steady state. A larger value slows down the convergence. If set too large, the output may remain unchanged.
TrefModel	Setpoint reference trajectory mode	DINT	0, 1, 2	0	Setpoint reference trajectory mode. 0: Normal control. 1: Slope control. 2: Range control.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
SPRatio	Setpoint filter coefficient	REAL	0~1	1	Setpoint filter coefficient.
DeltaCV	Maximum change rate of the controlled variable	REAL	[0, 10000]	100	This algorithm parameter defines the maximum change value of CV during prediction. Invalid values are limited to 100.

PFC11_AuTu structure configuration

Input Variable	Name	Data Type	Valid Range	Default Value	Description
AT_Start	Auto-tuning switch	DINT	0, 1	0	Auto-tuning switch. If this function is used, set AT_Start to 1.
AT_Model	Tuning model type	DINT	Follows data type	0	Tuning model types include: 0: Non-integral. 1: Pseudo-integral. 2: Pure integral. The auto-tuning function outputs the corresponding model parameters according to the model type. It is recommended to select according to the actual characteristics of the controlled object.
AT_OPInit	Initial OP output for tuning	REAL	Follows data type	0	OP output value at initial steady state. The controlled object must reach a stable state at this output.
AT_OPTarget	Target OP output for tuning	REAL	Follows data type	100	This value is the step output value at the start of tuning. The controller will perform a step change from "AT_OPInit" to "AT_OPTarget" to excite the response of the controlled object.
AT_PVTarget	PV value at tuning end	REAL	Follows data type	100	This value is the target PV value to be achieved during tuning. The tuning process completes when the measured value (PV) of the controlled object reaches this value after tuning begin. Then, the tuning result will be output.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
AT_PVDeltTar	Early termination threshold	REAL	Follows data type	0	When the PV value reaches AT_PVTarget – AT_PVDeltTar, the tuning process terminates early and outputs the tuning result.
AT_InitRate	Initial steady-state slope	REAL	Follows data type	0	PV measured value slope that allows the step response tuning to start.

PFC11_ReTe structure configuration

Input Variable	Name	Data Type	Valid Range	Default Value	Description
RT_Start	Relay test switch	DINT	0, 1	0	If this function is used, set RT_Start to 1.
RT_Direction	Input-output action direction	DINT	0, 1	0	0: Direct acting. When the output increases, the measured value increases. 1: Reverse acting. When the output increases, the measured value decreases.
RT_OP_Init	Initial value for the test	REAL	Follows data type	0	OP output at the start of the test.
RT_OP_DLow	Test output lower range	REAL	< 0	-1	Lower limit of the OP oscillation output at the start of the test = RT_OP_Init + RT_OP_DLow.
RT_OP_DHigh	Test output upper range	REAL	> 0	1	Upper limit of the OP oscillation output at the start of the test = RT_OP_Init + RT_OP_DHigh.
RT_PV_Target	Step measured value	REAL	Follows data type	100	Target PV measured value after the test starts.
RT_PV_DLow	Oscillation lower range	REAL	< 0	-1	Lower limit of PV oscillation switching after the test starts = RT_PV_Target + RT_PV_DLow.
RT_PV_DHigh	Oscillation upper range	REAL	> 0	1	Upper limit of PV oscillation switching after the test starts = RT_PV_Target + RT_PV_DHigh.
RT_Warn_Low	Warning lower range	REAL	Follows data type	0	Test protection lower range. If the value falls below this range, the test stops. Restart the test after reconfiguring the parameters.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
RT_Warn_High	Warning upper range	REAL	Follows data type	100	Test protection upper range. If the value exceeds this range, the test stops. Restart the test after reconfiguring the parameters.

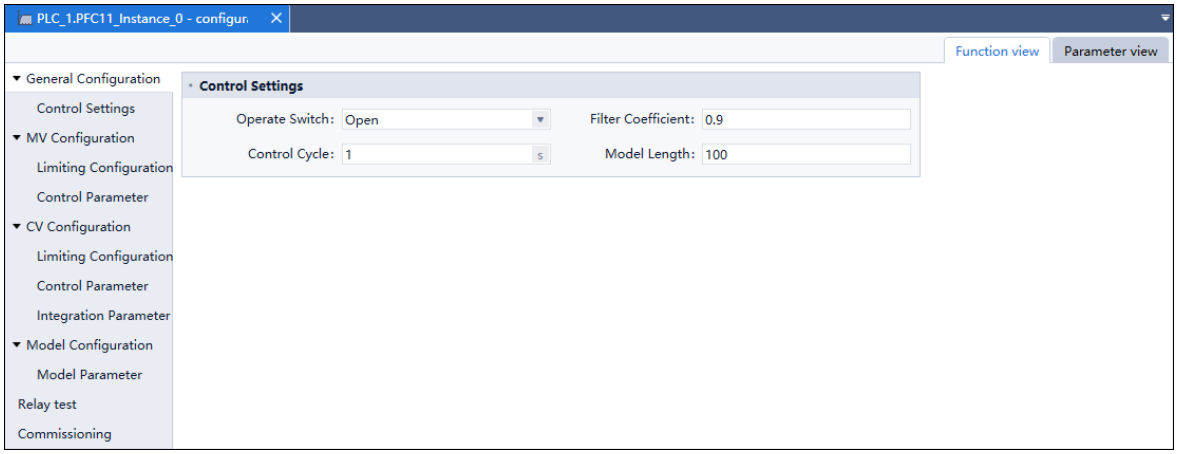
PFC11_OPT structure configuration

Input Variable	Name	Data Type	Valid Range	Default Value	Description
OPT_Start	Closed-loop OP test switch	DINT	0, 1	0	If this function is used, set OPT_Start to 1.
OPT_Type	PRBS type	DINT	0, 1, 2, 3	0	Type mode: 0: PRBS7 1: PRBS15 2: PRBS23 3: PRBS31
OPT_TS	PRBS cycle	DINT	>=1	1	Integer multiple of the task call cycle.
OPT_Amp	PRBS amplitude	REAL	>=0	0	Amplitude of the superimposed PRBS cycle during closed-loop testing.
OPT_Seed	PRBS initial seed	DINT	[1, 65535]	100	The seed value determines the initial value of the generated sequence.
OPT_Warn_Low	Warning lower range	REAL	Follows data type	0	Test protection lower range. If the value falls below this range, the test stops. Restart the test after reconfiguring the parameters.
OPT_Warn_High	Warning upper range	REAL	Follows data type	100	Test protection upper range. If the value exceeds this range, the test stops. Restart the test after reconfiguring the parameters.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
State	Switch state	DINT	0, 1	-	Indicates the actual state of the controller. 0: Normal control. 1: Switched to feedforward.
ERR	Fault code	DINT	Follows data type	-	0 for normal operation; non-zero when an error occurs. See PFC11 fault codes.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
OP	Valve position output value	REAL	Follows data type	-	Controller output value.
AT_ST	Tuning result	DINT	0, 1, 2, 3	-	Tuning state display. 0: Not tuned 1: Coarse tuning in progress 2: Fine tuning in progress 3: Tuning completed
PFC11_Output	Output parameter structure	PFC11_Output	Follows data type	-	Output parameter configuration structure.



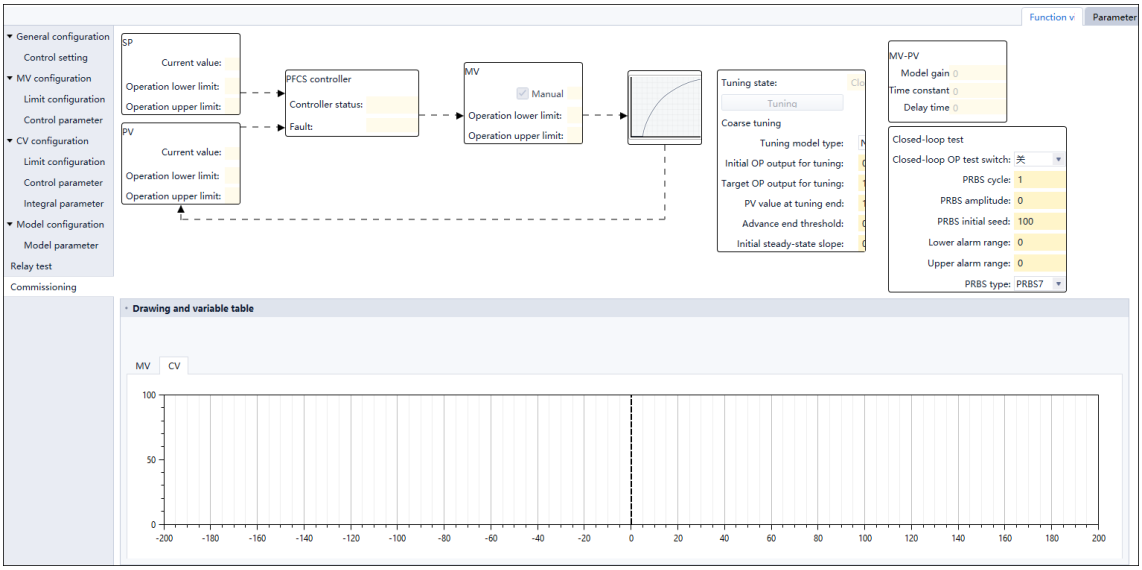
PFC11_Output structure configuration

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Version	Version information	ARRAY [0..3] OF DINT	Follows data type	-	Used to record internal version information.
DOP	Valve position output increment	REAL	Follows data type	-	Increment of the output value OP.
PV_Pred_t	Estimated value	REAL	Follows data type	-	Estimated value, that is, the response value of the controlled object, calculated by the internal model using historical data.
PV_Pred_tf	Predicted value	REAL	Follows data type	-	Predicted value, that is, the estimated value corrected based on the actual measured value PV.
PV_Pred_e	Prediction error	REAL	Follows data type	-	Difference between the actual measured value PV and the predicted value.
PV_Pred_eSum	Cumulative prediction error	REAL	Follows data type	-	Cumulative sum of prediction errors.
DCV_S	Integral deviation speed.	REAL	Follows data type	-	Integral deviation speed.
PV_Pred	Open-loop prediction sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records the sequence of future measured values predicted when the current cycle is not applied.
Tref_Step	Reference trajectory sequence	ARRAY [0..199] OF REAL	Follows data type	-	A trajectory sequence generated by the Tref parameter.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
OP_Low_Ope_Past	Output lower limit history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical operation lower limits for the controller output OP.
OP_High_Ope_Past	Output upper limit history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical operation upper limits for the controller output OP.
OP_Low_Ope_Future	Output lower limit future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records the sequence of predicted operation lower limits for the controller output at future sampling instants, computed after the current cycle has been applied.
OP_High_Ope_Future	Output upper limit future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records the sequence of predicted operation upper limits for the controller output at future sampling instants, computed after the current cycle has been applied.
SP_Past	Setpoint history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records the sequence of the historical setpoints.
SP_Future	Setpoint future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records the sequence of future setpoints predicted by the algorithm after the current cycle has been applied.
SP_Low_Ope_Past	Setpoint lower limit history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records the sequence of historical operation lower limits for the setpoint.
SP_High_Ope_Past	Setpoint upper limit history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records the sequence of historical operation upper limits for the setpoint.
SP_Low_Ope_Future	Setpoint lower limit future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records the sequence of predicted operation lower limits for the setpoint at future sampling instants, computed after the current control cycle has been applied.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
SP_High_Ope_Future	Setpoint upper limit future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records the sequence of predicted operation upper limits for the setpoint at future sampling instants, computed after the current control cycle has been applied.
SP_Href	Upper reference trajectory sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records the upper reference trajectory of the setpoint.
SP_Lref	Lower reference trajectory sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records the lower reference trajectory of the setpoint.
PV_Past	Measured value history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records the sequence of the historical measured values.
OP_Past	Output value history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records the sequence of the historical output values.
OP_Future	Output value future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records the sequence of future output values predicted by the algorithm after the current cycle has been applied.
AT_Km	Tuning parameter Km	REAL	Follows data type	-	Model gain result obtained from auto-tuning.
AT_Tm	Tuning parameter Tm	REAL	> 0	-	Model time constant result obtained from auto-tuning.
AT_Dm	Tuning parameter Dm	REAL	>=0	-	Model hysteresis parameter result obtained from auto-tuning.

- **Function**
  - PFC11 is a simplified 1x1 single-input, single-output predictive function controllers. It includes one manipulated variable (output via OP) and one controlled variable (measured via PV), and support a feedforward input channel (for use with the PFC_DV function block). The PFC11 component features a built-in auto-tuning function to obtain model parameters of the controlled object. This component is primarily used for rapid deployment in single-input single-output processes.
  - The PFC11 function block provide easy-to-use interfaces for parameter configuration and tuning/commissioning. After adding the PFC11 component, select "Control Objects -> PFC" in the left project tree, and then double-click the PFC11 instance under the PFC node to open the configuration and tuning interface, as shown in the figure below.

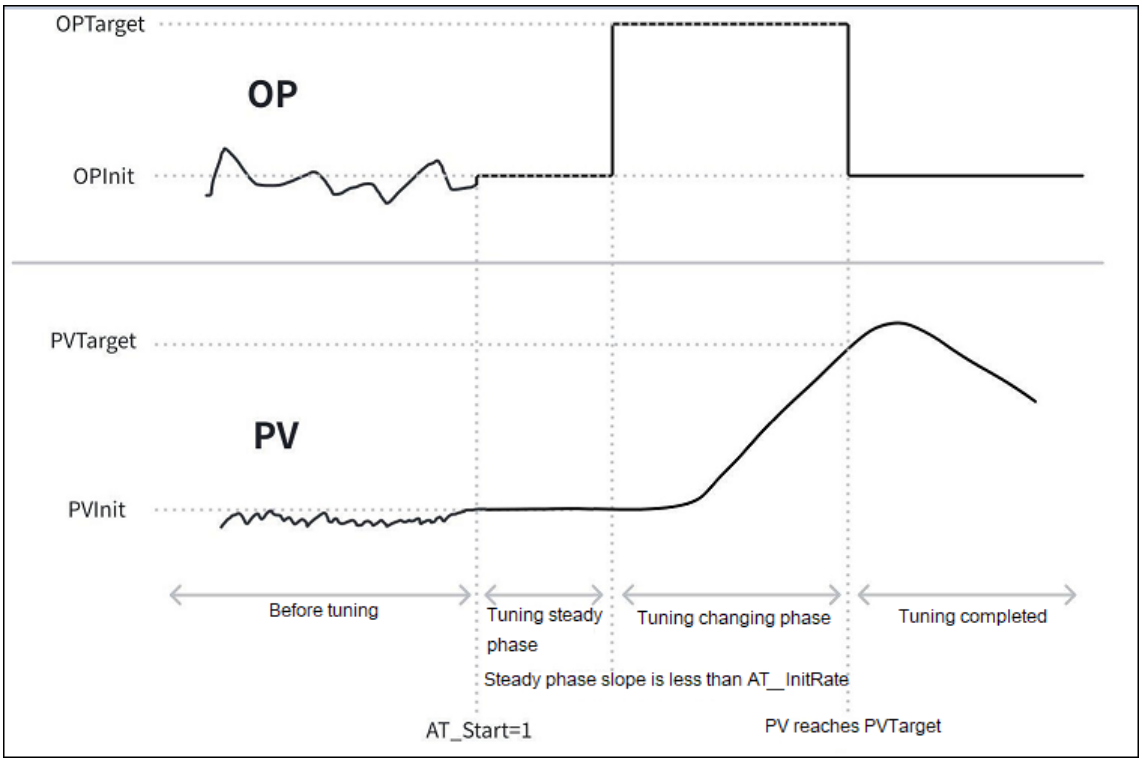


- Parameter configuration

  The parameter configuration of the PFC11 instruction includes general configuration, MV configuration, CV configuration, model configuration and relay test. For detailed parameter descriptions, see Relevant variables.

- Parameter auto-tuning

  The PFC11 instruction includes a built-in parameter auto-tuning function, automatically obtaining the model parameters (Km, Tm, and Dm) of the controlled object. Click the "Tuning" button on the "Commissioning" page to start parameter tuning.

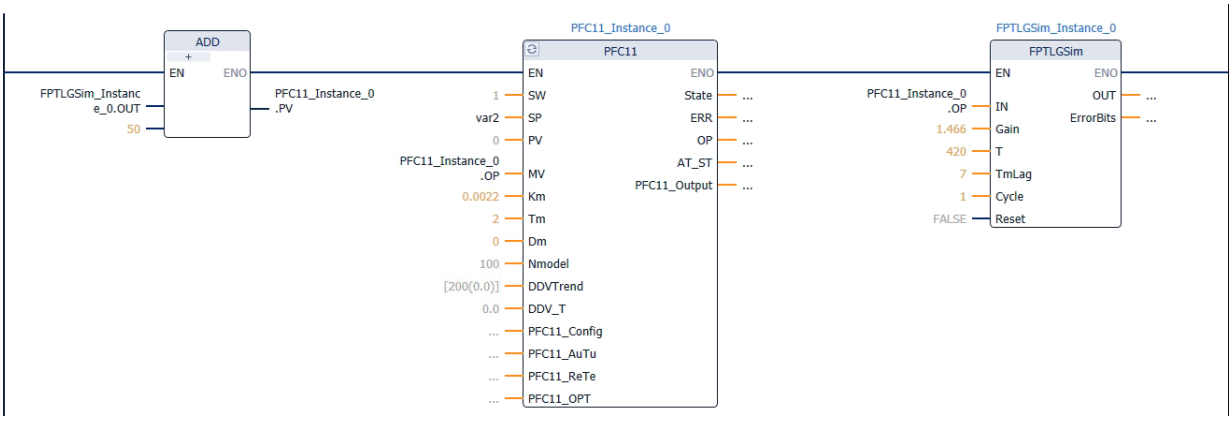


Because the controller internal variable array has a capacity of only 200, ensure that the duration from the OP output step to the completion of tuning stays within 200 control cycles. 100 to 150 cycles is recommended. An excessively long or short tuning process may lead to tuning failure. Furthermore, the tuning process does not require a complete steady state after the step. Generally, it only needs to capture the portion of the controlled object's response with the maximum slope.

The tuning process is as follows:

1. Select the model type of the tuning object.
2. Configure the tuning parameter "Initial OP output for tuning" (AT_OPInit). AT_OPInit is the OP output value at the initial steady state. Ensure that the controlled object reaches a basic stable state at this output. Open-loop control can be used before the tuning process to stabilize the controlled object at this output, then switch to auto-tuning. The initial steady state is critical for the tuning results. When it is difficult to achieve the initial steady state, the "Initial steady-state slope" (AT_InitRate) parameter can be used to appropriately relax the steady-state requirements.

3. Configure the tuning parameter "Target OP output for tuning" (AT_OPTarget). This value is the step output value at the start of tuning. The controller will perform a step change from "AT_OPInit" to "AT_OPTarget" to excite the response of the controlled object.
4. Configure the tuning parameter "PV value at tuning end" (AT_PVTarget) and "Advance end threshold" (AT_PVDeltTar). The tuning process completes when the measured value (PV) of the controlled object reaches this value after tuning begin. Pay special attention to the response polarity of the controlled object. Ensure that the measured value reaches AT_PVTarget after tuning starts, rather than the PV changing in the opposite direction after the OP step change.
5. Click the "Tuning" button.
6. After tuning ends, click "Confirm" or "Cancel" to select parameters, and automatically switch to control mode.

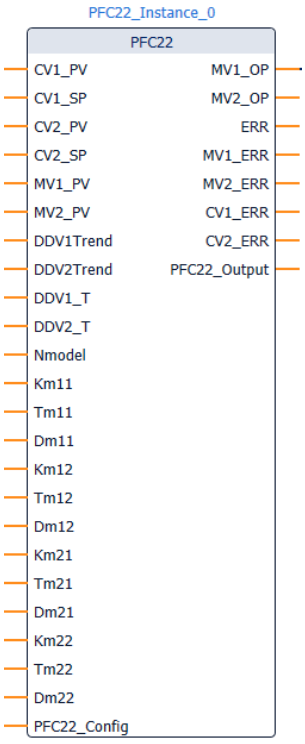


- Program example

  Here, the control simulation between the PFC11 instruction and the first-order inertia plus pure delay simulation instruction (FPTLGSim) is used as an example. The parameter configuration and control process are as follows:

1. Parameter configuration
   Configure the PFC11 instruction parameters based on the characteristics of the control object (Model parameters: Km, Tm, Dm and so on; controller parameters: COP, COF, etc.).
2. Control process
   The PFC11 instruction responds to the output (PV) of the FPTLGSim object, obtains the control quantity (OP) output, and applies it to the original control object, forming a control loop.
3. Control expectation
   If all parameters are configured properly, the controller will eventually keep the output value (PV) of the controlled object near the setpoint (SP).

   LD language code example:



- Precautions
  - The module execution cycle must be consistent with the function block cycle parameter Ts.
  - During operation, ensure that the switch is on, and the configuration is correct.
  - The execution time of the PFC11 instruction is 10 ms. With 50 PFC11 function blocks loaded, the total execution time is estimated to reach 500 ms. During operation, configure the scheduling task cycle properly to avoid high CPU load.

18.3.2.13 PFC22

This instruction is a dual-input dual-output control instruction. It is primarily used in 2x2 scenarios, such as the coupled control of temperature 1 and temperature 2 by heater 1 and heater 2, involving mutual coupling between the two temperature zones.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
PFC22	Multivariable input/ output advanced control	FB		PFC22_Instance_0(CV1_PV := , CV1_SP := , CV2_PV := , CV2_SP := , MV1_PV := , MV2_PV := , DDV1Trend := , DDV2Trend := , DDV1_T := , DDV2_T := , Nmodel := , Km11 := , Tm11 := , Dm11 := , Km12 := , Tm12 := , Dm12 := , Km21 := , Tm21 := , Dm21 := , Km22 := , Tm22 := , Dm22 := , PFC22_Config := , MV1_OP => , MV2_OP => , ERR => , MV1_ERR => , MV2_ERR => , CV1_ERR => , CV2_ERR => , PFC22_Output =>);

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
CV1_PV	Measured value of the controlled variable 1	REAL	Follows data type	0	Input value of the controlled variable 1 measurement, which must be provided by an external physical object or simulation object.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
CV1_SP	Setpoint value of the controlled variable 1	REAL	Follows data type	0	Setpoint value of the controlled variable 1, which determines the control objective of the controller so that the final actual control result (PV) must closely follow CV1_SP.
CV2_PV	Measured value of the controlled variable 2	REAL	Follows data type	0	Input value of the controlled variable 2 measurement, which must be provided by an external physical object or simulation object.
CV2_SP	Setpoint value of the controlled variable 2	REAL	Follows data type	0	Setpoint value of the controlled variable 2, which determines the control objective of the controller so that the final actual control result (PV) must closely follow CV2_SP.
MV1_PV	Measured value of the manipulated variable 1	REAL	Follows data type	0	Measured value of manipulated variable 1. The actual output value 1 must be written back to this variable. In a heating application: if only algorithmic control is active, write back the value of MV1_OP; if an external input is present, write back the actual value sent to the actuator.
MV2_PV	Measured value of the manipulated variable 2	REAL	Follows data type	0	Measured value of manipulated variable 2. The actual output value 2 must be written back to this variable. In a heating application: if only algorithmic control is active, write back the value of MV2_OP; if an external input is present, write back the actual value sent to the actuator.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
DDV1Trend	Disturbance sequence 1	ARRAY [0..199] OF REAL	Follows data type	-	Disturbance sequence 1 generated by the dv series component. When using this variable, pass its output "DDVTrend" to this variable. It is used to predict future disturbances so that the controller can take proactive action to suppress them. This variable corresponds to CV1 disturbance.
DDV2Trend	Disturbance sequence 2	ARRAY [0..199] OF REAL	Follows data type	-	Disturbance sequence 2 generated by the dv series component. When using this variable, pass its output "DDVTrend" to this variable. It is used to predict future disturbances so that the controller can take proactive action to suppress them. This variable corresponds to CV2 disturbance.
DDV1_T	Disturbance increment 1	REAL	Follows data type	0	Disturbance increment value, generated by the PFC_DV input interface of the same name and used for disturbance prediction and feedback correction.
DDV2_T	Disturbance Increment 2	REAL	Follows data type	0	Disturbance increment value, generated by the PFC_DV input interface of the same name and used for disturbance prediction and feedback correction.
Nmodel	Model length	DINT	[1, 200]	100	The model length is used to adjust the control effect. The larger this value, the longer the effective prediction horizon, and the further the future trends can be predicted.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Km11	Model MV1-CV1 gain	REAL	Follows data type	1	An algorithm parameter that affects the control performance. Increasing the value speeds up the system response to some extent, while decreasing it slows down the system response to some extent.
Tm11	Model MV1-CV1 time constant	REAL	(0, 10000]	1	An algorithm parameter that affects the control performance. The smaller the Tm value, the fewer cycles required to reach a steady state. If the value exceeds the limit, it will be limited to 1e-6.
Dm11	Model MV1-CV1 hysteresis	REAL	[0, 10000]	0	An algorithm parameter that affects the control performance. The delay expressed in control cycles is Dm/Ts. If the value exceeds the limit, it will be limited to 0.
Km12	Model MV2-CV1 gain	REAL	Follows data type	1	An algorithm parameter that affects the control performance. Increasing the value speeds up the system response to some extent, while decreasing it slows down the system response to some extent.
Tm12	Model MV2-CV1 time constant	REAL	(0, 10000]	1	An algorithm parameter that affects the control performance. The smaller the Tm value, the fewer cycles required to reach a steady state. If the value exceeds the limit, it will be limited to 1e-6.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Dm12	Model MV2-CV1 hysteresis	REAL	[0, 10000]	0	An algorithm parameter that affects the control performance. The delay expressed in control cycles is Dm/Ts. If the value exceeds the limit, it will be limited to 0.
Km21	Model MV1-CV2 gain	REAL	Follows data type	1	An algorithm parameter that affects the control performance. Increasing the value speeds up the system response to some extent, while decreasing it slows down the system response to some extent.
Tm21	Model MV1-CV2 time constant	REAL	(0, 10000]	1	An algorithm parameter that affects the control performance. The smaller the Tm value, the fewer cycles required to reach a steady state. If the value exceeds the limit, it will be limited to 1e-6.
Dm21	Model MV1-CV2 hysteresis	REAL	[0, 10000]	0	An algorithm parameter that affects the control performance. The delay expressed in control cycles is Dm/Ts. If the value exceeds the limit, it will be limited to 0.
Km22	Model MV2-CV2 gain	REAL	Follows data type	1	An algorithm parameter that affects the control performance. Increasing the value speeds up the system response to some extent, while decreasing it slows down the system response to some extent.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Tm22	Model MV2-CV2 time constant	REAL	(0, 10000]	1	An algorithm parameter that affects the control performance. The smaller the Tm value, the fewer cycles required to reach a steady state. If the value exceeds the limit, it will be limited to 1e-6.
Dm22	Model MV2-CV2 hysteresis	REAL	[0, 10000]	0	An algorithm parameter that affects the control performance. The delay expressed in control cycles is Dm/Ts. If the value exceeds the limit, it will be limited to 0.
PFC22_Config	Input parameter structure	PFC22_Config	Follows data type	-	Input parameter configuration structure.

PFC22_Config structure configuration

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Ts	Sampling cycle	REAL	(0, 10000]	1	This value determines the control cycle. This value must be greater than 0, and can not be set too low. An excessively small value may cause a calculation timeout and degrade control performance. If Ts is less than 0, the algorithm will automatically terminate, the switch will turn off, and the output will be held.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Model1	Model type 1	DINT	0, 1, 2	1	Model for MV1-CV1. Model type: 0: Non-integral. 1: Pseudo-integral. 2: Pure integral. Currently, types 0 (Non-integral) and 1 (Pseudo-integral) are primarily used. Type 2 (Pure integral) is not implemented. In practice, integral models are typically handled as pseudo-integral. When the model selection is not 0, 1, or 2, the algorithm terminates, the switch is turned off, and the output will be held.
Model2	Model type 2	DINT	0, 1, 2	1	Model for MV2-CV1. Model type: 0: Non-integral. 1: Pseudo-integral. 2: Pure integral. Currently, types 0 (Non-integral) and 1 (Pseudo-integral) are primarily used. Type 2 (Pure integral) is not implemented. In practice, integral models are typically handled as pseudo-integral. When the model selection is not 0, 1, or 2, the algorithm terminates, the switch is turned off, and the output will be held.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Model3	Model type 3	DINT	0, 1, 2	1	Model for MV1-CV2. Model type: 0: Non-integral. 1: Pseudo-integral. 2: Pure integral. Currently, types 0 (Non-integral) and 1 (Pseudo-integral) are primarily used. Type 2 (Pure integral) is not implemented. In practice, integral models are typically handled as pseudo-integral. When the model selection is not 0, 1, or 2, the algorithm terminates, the switch is turned off, and the output will be held.
Model4	Model type 4	DINT	0, 1, 2	1	Model for MV2-CV2. Model type: 0: Non-integral 1: Pseudo-integral 2: Pure integral Currently, types 0 (Non-integral) and 1 (Pseudo-integral) are primarily used. Type 2 (Pure integral) is not implemented. In practice, integral models are typically handled as pseudo-integral. When the model selection is not 0, 1, or 2, the algorithm terminates, the switch is turned off, and the output will be held.
MV1_Config	MV1 variable input parameter structure	PFC22_MVConfig	Follows data type	-	MV1 variable input parameter configuration structure.
MV2_Config	MV2 variable input parameter structure	PFC22_MVConfig	Follows data type	-	MV2 variable input parameter configuration structure.
CV1_Config	CV1 variable input parameter structure	PFC22_CVConfig	Follows data type	-	CV1 variable input parameter configuration structure.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
CV2_Config	CV2 variable input parameter structure	PFC22_CVConfig	Follows data type	-	CV2 variable input parameter configuration structure.
Single_SW	Single output switch	DINT	0, 1	0	Single output switch. If this switch is set to ON, it ensures that when the two MV gains have opposite signs, only one output direction is active. This is typically used to save energy.

PFC22_MVConfig structure configuration

Input Variable	Name	Data Type	Valid Range	Default Value	Description
MV_SW	Manipulated variable switch	DINT	0, 1	1	MV switch; when this switch is off, the control is disabled. Invalid values are automatically set to 0.
MV_High_Val	Manipulated variable valid upper limit	REAL	Follows data type	200	Valid upper limit. When the value exceeds the valid upper limit, the switch will be turned off and the control will be disabled.
MV_Low_Val	Manipulated variable valid lower limit	REAL	Follows data type	0	Valid lower limit. When the value falls below the valid lower limit, the switch will be turned off and the control will be disabled.
MV_High_Ope	Operation upper limit of the manipulated variable	REAL	Follows data type	100	Operation upper limit. When the value exceeds this operation upper limit, a warning will be issued and the value will be clamped to this operation upper limit.
MV_Low_Ope	Operation lower limit of the manipulated variable	REAL	Follows data type	0	Operation lower limit. When the value falls below this operation lower limit, a warning will be issued and the value will be clamped to this operation lower limit.
MV_DMax	Maximum positive increment for the manipulated variable	REAL	[0, 10000]	100	Defines the maximum allowable positive increment of the output. Invalid input values are limited to 100.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
MV_DMin	Maximum negative increment for the manipulated variable	REAL	[-10000, 0]	-100	Defines the maximum allowed negative increment of the output. Invalid input values are limited to -100.
MV_COP	Manipulated variable performance coefficient	REAL	[0, 10000]	1	An algorithm parameter that affects the control performance. Decreasing the value speeds up the system response to some extent, while increasing it slows down the system response to some extent. If this value exceeds the upper limit, it will be limited to the upper limit. If the value falls below the lower limit, it will be limited to the lower limit.
MV_Irv	Ideal injection value for the manipulated variable	REAL	Follows data type	1	The value that the corresponding MV output eventually converges to.
MV_Irv_C	Weight for manipulated variable ideal injection value	REAL	[0, 10000]	1	The larger the value, the closer the MV will converge to MV_Irv.
MV_Irv_SW	Ideal injection value switch	DINT	0, 1	0	When set to 0, the ideal injection value is inactive. When used, the value must be set to 1. Invalid values are automatically set to 0.

PFC22_CVConfig structure configuration

Input Variable	Name	Data Type	Valid Range	Default Value	Description
CV_SW	Controlled variable switch	DINT	0, 1	1	Controlled variable switch. When the switch is off, the control is disabled. When used, it must be set to 1. Invalid values are automatically set to 0.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Cost_SS	Speed steady state weight	REAL	[0, 10000]	0	Speed steady state weight. In an integral model, this weight determines how quickly the speed converges to steady state. A larger value slows down the convergence. If set too large, the output may remain unchanged.
TrefModel	Setpoint reference trajectory mode	DINT	0, 1, 2	0	Setpoint reference trajectory mode. 0: Normal control. 1: Slope control. 2: Range control.
SPRatio	Setpoint filter coefficient	REAL	0~1	1	Setpoint filter coefficient.
CV_ECE	Equivalent deviation	REAL	[0, 10000]	1	Determines the weight of the corresponding CV variable. A larger value gives higher priority to controlling that CV.
CV_COF	Filter coefficient	REAL	[0, 1]	0.9	An algorithm parameter that affects the control performance. The smaller this value, the greater the confidence in the model prediction. When set to 0, no feedback correction is performed. Use a value greater than 0. If this value exceeds the upper limit, it will be limited to the upper limit. If the value falls below the lower limit, it will be limited to the lower limit.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
CV_Tref	Closed-loop reference time	REAL	(0, 10000]	1	An algorithm parameter that affects the control performance. Increasing the value slows down the system response to some extent, while decreasing it speeds up the system response to some extent. If the value exceeds the limit, it will be limited to 1e-6.
I_COF	Integral deviation correction coefficient	REAL	[0, 1]	0.1	An algorithm parameter that affects the control performance. The smaller the value, the greater the confidence in the model prediction. If this value exceeds the upper limit, it will be limited to the upper limit. If the value falls below the lower limit, it will be limited to the lower limit.
CV_SP_DMax	Upper deviation range	REAL	[0, 10000]	0.1	An algorithm parameter that affects the control performance. The system is considered stable if CV_PV is within this range CV_SP + CV_SP_DMax. Invalid input values are limited to 0.
CV_SP_DMin	Lower deviation range	REAL	[-10000, 0]	-0.1	An algorithm parameter that affects the control performance. The system is considered stable if CV_PV is within this range CV_SP + CV_SP_DMin. Invalid input values are limited to 0.
DeltaCV	Maximum change rate of the controlled variable	REAL	[0, 10000]	100	This algorithm parameter defines the maximum change value of CV during prediction. Invalid values are limited to 100.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
CV_Low_Val	Valid lower limit of the controlled variable	REAL	Follows data type	0	Valid lower limit. When the value falls below the valid lower limit, the switch will be turned off and the control will be disabled.
CV_High_Val	Valid upper limit of the controlled variable	REAL	Follows data type	100	Valid upper limit. When the value exceeds the valid upper limit, the switch will be turned off and the control will be disabled.
CV_Low_Ope	Operation lower limit of the controlled variable	REAL	Follows data type	0	Operation lower limit. When the value falls below this operation lower limit, a warning will be issued and the value will be clamped to this operation lower limit.
CV_High_Ope	Operation upper limit of the controlled variable	REAL	Follows data type	100	Operation upper limit. When the value exceeds this operation upper limit, a warning will be issued and the value will be clamped to this operation upper limit.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
MV1_OP	Manipulated variable 1 output value	REAL	Follows data type	-	Output value of manipulated variable 1. This value must be output to the simulation object or actual object.
MV2_OP	Manipulated variable 2 output value	REAL	Follows data type	-	Output value of manipulated variable 2. This value must be output to the simulation object or actual object.
ERR	Fault code	DINT	Follows data type	-	For fault codes, see PFC22 fault codes.
MV1_ERR	Manipulated variable 1 fault code	DINT	Follows data type	-	Fault code of manipulated variable 1.
MV2_ERR	Manipulated variable 2 fault code	DINT	Follows data type	-	Fault code of manipulated variable 2.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
CV1_ERR	Controlled variable 1 fault code	DINT	Follows data type	-	Fault code of controlled variable 1.
CV2_ERR	Controlled variable 2 fault code	DINT	Follows data type	-	Fault code of controlled variable 2.
PFC22_Output	Output parameter structure	PFC22_Output	Follows data type	-	Output parameter structure.

PFC22_Output structure configuration

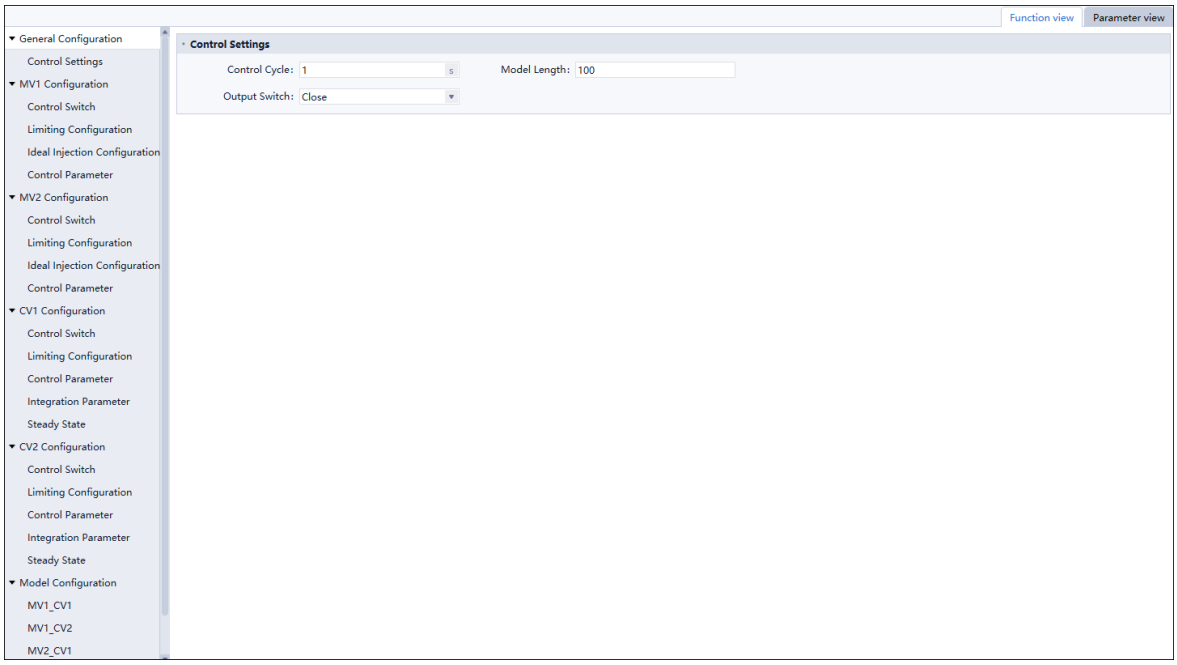
Output Variable	Name	Data Type	Valid Range	Default Value	Description
Version	Version information	ARRAY [0..3] OF DINT	Follows data type	-	Used to obtain the version information.
NFlag	Number of errors	DINT	[0, 10]	-	Counts the number of errors.
Flag	Error information	ARRAY [0..9] OF DINT	Follows data type	-	Records detailed information of each error.
MV1_OutConfig	Manipulated variable 1 output structure	PFC22_MVOutConfig	Follows data type	-	Output structure of manipulated variable 1.
MV2_OutConfig	Manipulated variable 2 output structure	PFC22_MVOutConfig	Follows data type	-	Output structure of manipulated variable 2.
CV1_OutConfig	Controlled variable 1 output structure	PFC22_CVOutConfig	Follows data type	-	Output structure of controlled variable 1.
CV2_OutConfig	Controlled variable 2 output structure	PFC22_CVOutConfig	Follows data type	-	Output structure of controlled variable 2.

PFC22_CVOutConfig structure configuration

Output Variable	Name	Data Type	Valid Range	Default Value	Description
CV_NFlag	Controlled variable error count	DINT	[0, 10]	-	Number of recorded errors for the controlled variable
CV_Flag	Controlled variable error information	ARRAY [0..9] OF DINT	Follows data type	-	Detailed information of recorded errors for the controlled variable

Output Variable	Name	Data Type	Valid Range	Default Value	Description
CV_ST	Controlled variable switch status	DINT	0, 1	-	Status of the controlled variable switch. Initially the value equals the switch input value. When an internal error occurs, this value is set to 1.
CV_Pred_t	Estimated value of controlled variable	REAL	Follows data type	-	Estimated value, that is, the response value of the controlled object, calculated by the internal model using historical data.
CV_Pred_tf	Predicted value of controlled variable	REAL	Follows data type	-	Predicted value, that is, the corrected predicted value based on the predicted value and the actual measured value PV.
DCV_S_i	Velocity after integral deviation correction	REAL	Follows data type	-	Velocity after integral deviation correction.
DCV_S_SS	Future speed steady state value	REAL	Follows data type	-	Steady-state speed value, which is the speed value predicted after 200 cycles.
CV_PV_e	Predicted error of the controlled variable	REAL	Follows data type	-	Difference between the actual measured value and the predicted value.
CV_PV_eSum	Cumulative sum of predicted errors for the controlled variable	REAL	Follows data type	-	The cumulative sum of errors (regardless of sign). Its magnitude indicates the degree of model mismatch.
CV_Pred_t_Past	Sequence of historical estimated values for the controlled variable	ARRAY [0..199] OF REAL	Follows data type	-	Records historical values.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
CV_Pred	Open-loop prediction sequence of controlled variables	ARRAY [0..199] OF REAL	Follows data type	-	Records the sequence of future values predicted when the current cycle is not applied.
CV_Future	Closed-loop prediction sequence of controlled variables	ARRAY [0..199] OF REAL	Follows data type	-	Records the sequence of future values predicted after the current cycle has been applied.
CV_PV_Past	Sequence of historical measured values for the controlled variable	ARRAY [0..199] OF REAL	Follows data type	-	Records historical measured values.
SP_Past	Setpoint history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical setpoint values, for plotting.
SP_Future	Setpoint future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of the future setpoint values, for plotting.
CV_SP_Href	Upper reference trajectory sequence	ARRAY [0..199] OF REAL	Follows data type	-	Predicted upper trajectory to be approached.
CV_SP_Lref	Lower reference trajectory sequence	ARRAY [0..199] OF REAL	Follows data type	-	Predicted lower trajectory to be approached.
CV_Low_Past	Controlled variable lower limit history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical operation lower limits for the controlled variable, for plotting.
CV_High_Past	Controlled variable upper limit history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical upper limits for the controlled variable, for plotting.
CV_Low_Future	Controlled variable lower limit future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of future operation lower limits for the controlled variable, for plotting.



Output Variable	Name	Data Type	Valid Range	Default Value	Description
CV_High_Future	Controlled variable upper limit future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of future operation upper limits for the controlled variable, for plotting.

PFCm22_MVOutConfig structure configuration

Output Variable	Name	Data Type	Valid Range	Default Value	Description
MV_NFlag	MV error count	DINT	0, 1	-	Number of errors counted for the manipulated variable.
MV_Flag	MV error message	ARRAY [0..9] OF DINT	[0, 10]	-	Detailed information of recorded errors for the manipulated variable.
MV_Low_Past	Output lower limit history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical operation lower limits for the manipulated variable, for plotting.
MV_High_Past	Output upper limit history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical operation upper limits for the manipulated variable, for plotting.
MV_Low_Future	Output lower limit future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of future operation lower limits for the manipulated variable, for plotting.
MV_High_Future	Output upper limit future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of future operation upper limits for the manipulated variable, for plotting.
MV_Past	Output value history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical measured values for the manipulated variable, for plotting.
MV_Future	Output value future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of future measured values for the manipulated variable, for plotting.
MV_DOP_Past	Historical increment sequence of the valve position	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical increment values for the manipulated variable, for plotting.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
MV_DOP	Manipulated variable action increment	REAL	Follows data type	-	Increment value of the manipulated variable.
MV_ST	Manipulated variable switch state	DINT	0, 1	-	Manipulated variable switch state. Initially, it equals the switch value. This value is set to 1 when an internal error occurs.
MV_Irv_Past	Ideal injection value history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical ideal injection values, for plotting.
MV_Irv_Future	Ideal injection value future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of future ideal injection values, for plotting.

- **Function**
  - PFC22 is a 2x2 dual-input, dual-output control instruction. The controlled object can support non-integrating, integrating, or pseudo-integrating responses. The instruction includes two manipulated variables (MV), two controlled variables (CV), and a feedforward input channel (for use with PFC_DV). The instruction does not rely on an external solver for optimization calculations. It is mainly intended for applications with simple coupling and does not require high-end products. It is suitable for fast control application scenarios with millisecond-level control cycles.
  - The PFC22 function block includes an intuitive interface for parameter configuration and commissioning. After adding the PFC22 component, select "Control Objects -> PFC" in the left project tree, and then double-click the PFC22 instance under the PFC node to open the configuration and tuning interface, as shown in the figure below.

    - Parameter description

      The parameter configuration of the PFC22 instruction includes general configuration, MV

configuration, CV configuration, and model configuration. For detailed parameter descriptions, see Relevant variables.

- Commissioning

  After the parameters are configured, the control effect can be viewed directly in the commissioning interface.

- **Program example**

  Here, the two-input, two-output control simulation between the PFC22 instruction and four first-order inertia plus pure delay simulation instruction (FPTLGSim) is used as an example. The parameter configuration and control process are as follows:

  - Parameter configuration

    Configure the PFC22 instruction parameters based on the characteristics of the control object (Model parameters: Km11, Tm11, Dm11 and so on; controller parameters: COP, COF, etc.).

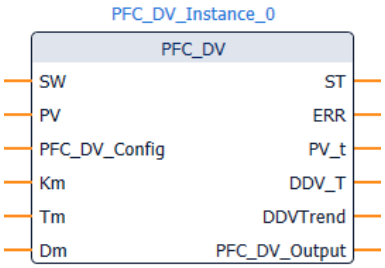
  - Control process

    The PFC22 instruction responds to the output (PV) of the FPTLGSim object, obtains the control quantity (OP) output, and applies it to the original control object, forming a control loop.

  - Control expectation

    If all parameters are configured properly, the controller will eventually keep the output value (CV_PV) of the controlled object near the setpoint CV_SP.

    LD language code example:



- **Precautions**
  - During operation, ensure that the switch is on, and the configuration is correct.
  - The execution time of the PFC22 instruction is 20 ms. With 50 PFC22 function blocks loaded, the total execution time is estimated to reach approximately 1 second. Loading 364 PFC22 function blocks will reach the controller's resource limit. During operation, configure the scheduling task cycle properly. For example, if 10 PFC22 are required to perform loop control simultaneously, with a block calculation time of 200 ms. The task cycle must be at least twice this value, that is, 400 ms, to ensure the CPU load does not become too high.

18.3.2.14 PFC_DV

The disturbance instruction outputs a predicted disturbance sequence and must be used in conjunction with a corresponding control instruction.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
PFC_DV	Feedforward predictive control	FB		PFC_DV_Instance_0(SW := , PV := , PFC_DV_Config := , Km := , Tm := , Dm := , ST => , ERR => , PV_t => , DDV_T => , DDVTrend => , PFC_DV_Output =>);

- **Related variables**

  Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
SW	Disturbance switch	DINT	0, 1	1	The disturbance switch disables the control when the switch is off. When used, it must be 1. Any invalid value is set to 0.
PV	Input value	REAL	Follows data type	0	Disturbance input value provided externally. Based on this input value, a corresponding disturbance sequence is generated.
PFC_DV_Config	Input parameter structure	PFC_DV_Config	Follows data type	-	Input parameter configuration structure.
Km	Model gain	REAL	Follows data type	1	An algorithm parameter that affects the control performance. Increasing the value speeds up the system response to some extent, while decreasing it slows down the system response to some extent. It is used to predict the disturbance sequence.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Tm	Model time constant	REAL	(0, 10000]	1	An algorithm parameter that affects the control performance. The smaller the Tm value, the fewer cycles required to reach a steady state. It is used to predict the disturbance sequence. Any invalid value is set to 1e-6.
Dm	Model hysteresis	REAL	[0, 10000]	0	An algorithm parameter that affects the control performance. The delay expressed in control cycles is Dm/Ts. It is used to predict the disturbance sequence. Any invalid value is set to 0.

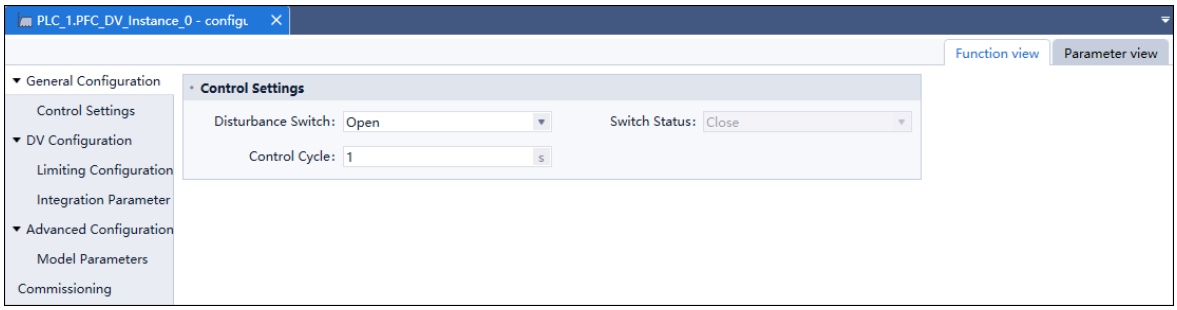
PFC_DV_Config structure configuration

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Ts	Sampling cycle	REAL	(0, 10000]	1	This value determines the control cycle. This value must be greater than 0, and can not be set too low. An excessively small value may cause a calculation timeout and degrade control performance. If Ts is less than 0, the algorithm will automatically terminate, the switch will turn off, and the output will be held.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Model	Model type	DINT	0, 1, 2	1	Model type: 0: Non-integral. 1: Pseudo-integral. 2: Pure integral. Currently, types 0 (Non-integral) and 1 (Pseudo-integral) are primarily used. Type 2 (Pure integral) is not implemented. In practice, integral models are typically handled as pseudo-integral. If the model selection does not follow 0, 1, 2, it is set to 0 by default.
Low	Lower limit of the disturbance variable	REAL	Follows data type	-100	Lower limit; if the value falls below the lower limit, it is clamped to the lower limit.
High	Upper limit of the disturbance variable	REAL	Follows data type	100	Upper limit; if the value exceeds the upper limit, it is clamped to the upper limit.
DMax	Increment limit	REAL	Follows data type	100	Increment limit; when exceeded, it will be clamped to the maximum increment value. Any invalid value is set to 0.

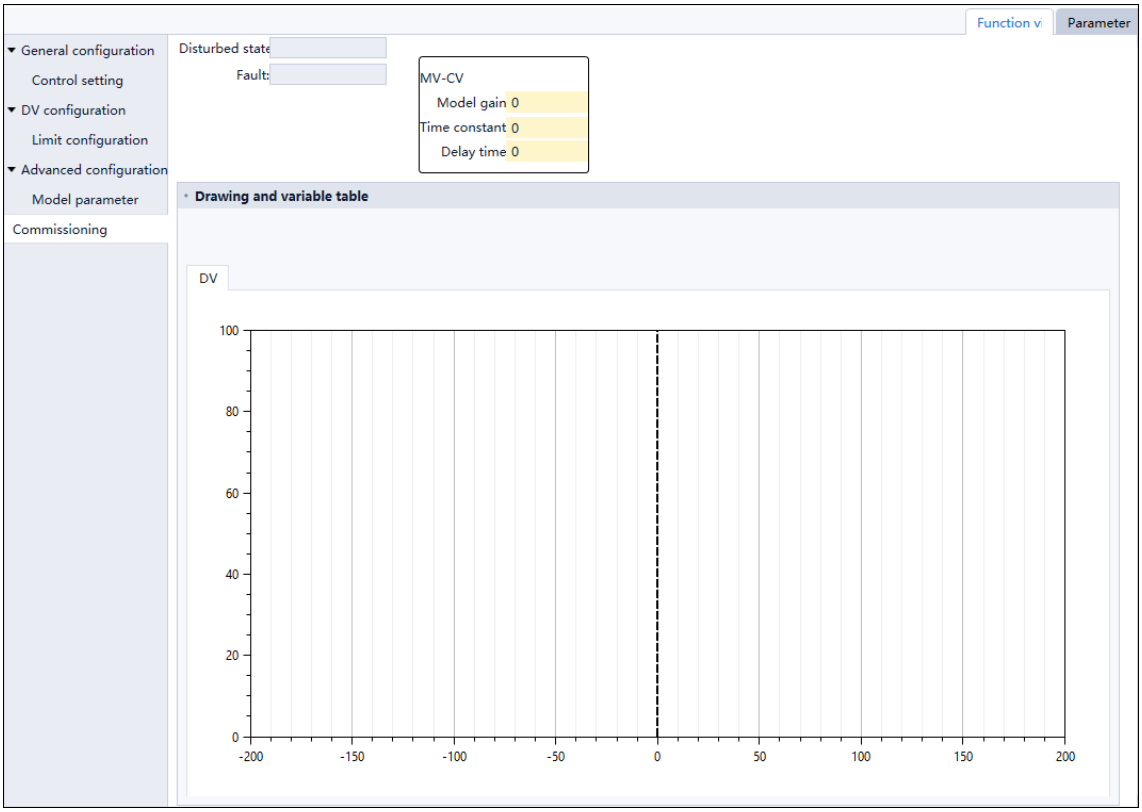
Output variable

Output Variable	Name	Data Type	Valid Range	Default Value	Description
ST	Switch state	DINT	0, 1	-	Switch status. Initially the value equals the switch input value. When an internal error occurs, this value is set to 1.
ERR	Fault code	DINT	Follows data type	-	For fault codes, see PFC_DV fault codes.
PV_t	Feedforward correction value	REAL	Follows data type	-	Feedforward value after limit.
DDV_T	Disturbance increment	REAL	Follows data type	-	Disturbance increment value for disturbance prediction and feedback correction.



Output Variable	Name	Data Type	Valid Range	Default Value	Description
DDVTrend	Disturbance sequence	ARRAY [0..199] OF REAL	Follows data type	-	Disturbance sequence. After generating this sequence, it must be output to the input interface with the same name on the control instruction for feedforward correction.
PFC_DV_Output	Output parameter structure	PFC_DV_Output	Follows data type	-	Output parameter structure.

PFC_DV_Output structure configuration



Output Variable	Name	Data Type	Valid Range	Default Value	Description
PV_Past	Measured value history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records historical values for the disturbance input.
PVt_Past	Feedforward value history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Records historical values of the feedforward signal.
DV_Low_Past	Disturbance value lower limit history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical lower limits for the disturbance value, for plotting.
DV_High_Past	Disturbance value upper limit history sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical upper limits for the disturbance value, for plotting.
DV_Low_Future	Disturbance value lower limit future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of future lower limits for the disturbance value, for plotting.
DV_High_Future	Disturbance value upper limit future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of future upper limits for the disturbance value, for plotting.
DV_PV_Future	Disturbance value future sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of future disturbance values, for plotting.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
DDV_Past	Feedforward value history increment sequence	ARRAY [0..199] OF REAL	Follows data type	-	Sequence of historical increments for the feedforward value, for plotting.
Version	Version information	ARRAY [0..3] OF DINT	Follows data type	-	Records the version information.

- **Function**
  - PFC_DV is a disturbance feedforward prediction module. Its primary function is to predict the future disturbance sequence of the controlled object based on the current disturbance input. The predicted disturbance sequence can be fed forward to the feedforward input channel of the PFC11/PFC22 instruction, enabling proactive compensation of disturbances and improving disturbance rejection.
  - The PFC_DV function block includes an intuitive interface for parameter configuration and commissioning. After adding the PFC_DV component, select "Control object > PFC" in the left project tree, and then double-click the PFC_DV instance under the PFC node to open the configuration and tuning interface, as shown in the figure below.

    - Parameter description
      The parameter configuration of the PFC_DV instruction includes general configuration, DV configuration, and model configuration. For detailed parameter descriptions, see Relevant variables.
    - Commissioning
      After the parameters are configured, the historical and future disturbance value sequence can be viewed directly in the commissioning interface.

- **Program example**

  During operation, this instruction primarily feeds the sequence output by DDVTrend into the control component PFC11/PFC22. The generated sequence is determined by the model parameters Km, Tm, and Dm, as well as the input disturbance PV.

  LD:

- **Precautions**
  - During operation, ensure that the switch is on, and the configuration is correct.
  - When setting the model parameters, ensure they are consistent with the controller parameter type, either all integral or non-integral.
  - The execution time of the PFC_DV instruction is 8 ms. With 140 PFC_DV function blocks loaded, the total execution time is estimated to reach approximately 1 second. Loading 1154 PFC_DV function blocks will reach the controller's resource limit. During operation, configure the scheduling task cycle properly. For example, if 10 PFC_DV are required to perform loop control simultaneously, with a block calculation time of 80 ms. The task cycle must be at least twice this value, that is, 160 ms, to ensure the CPU load does not become too high.

18.3.2.15 Fault Codes

PFCs fault codes

Fault code	Value	Description
APC_STATE_ERROR	-207	Tuning state error.
APC_NULL_POINT	-101	Null pointer.
APC_LENGTH_MISMATCH	-6	Length mismatch.
APC_OUT_OF_MEMORY	-5	Insufficient memory.
APC_FUNCTION_ERROR	-4	Component operation fault.
APC_PARAME_ID_NOT_FOUND	-2	ID not found.
APC_TS_OUT_OF_LIMIT	1	Ts is less than 0.
APC_SP_OUT_OF_LOW	100	The setpoint is below the lower limit.
APC_SP_OUT_OF_HIGH	101	The setpoint is above the upper limit.
APC_PARAM_OUT_OF_MAX	102	The parameter is above the upper limit of the range.
APC_PARAM_OUT_OF_MIN	103	The parameter is below the lower limit of the range.
APC_TM_OUT_OF_LIMIT	104	Tm is less than or equal to 0.
APC_TREF_OUT_OF_LIMIT	105	Tref is less than or equal to 0.
APC_DM_OUT_OF_LIMIT	106	Dm is less than 0.
APC_OP_LIMIT_ERROR	210	The OP output lower limit is greater than the upper limit.
APC_SP_LIMIT_ERROR	211	The SP lower limit is greater than the upper limit.
APC_SW_OUT_OF_LIMIT	212	SW is neither 0 nor 1.
APC_MODEL_OUT_OF_LIMIT	213	Model is not 0, 1, or 2.
APC_COF_OUT_OF_LIMIT	214	COF is neither 0 nor 1.
APC_COP_OUT_OF_LIMIT	215	COP is less than 0.
APC_I_COF_OUT_OF_LIMIT	216	I_COF is neither 0 nor 1.
APC_DOPMAX_OUT_OF_LIMIT	218	DOPMax is less than 0.
APC_SP_DMAX_OUT_OF_LIMIT	219	SP_DMax is less than 0.
APC_SP_DMIN_OUT_OF_LIMIT	220	SP_DMin is greater than 0.
APC_PARAM_DISABLE_CHANGE	1001	Parameter modification is prohibited.
APC_COMP_IS_NOT_RUNNING	1002	Tuning is not running.

PFCm/PFCm_v2/PFCm22/PFC22 fault code

Fault code	Value	Description
APC_OUT_NOTNULL_BEFORE_MEMORY	-7	The pointer is not null before memory allocation.
APC_OUT_OF_MEMORY	-5	Insufficient memory.
APC_TS_OUT_OF_LIMIT	1	Ts is less than 0.
APC_TM1_OUT_OF_LIMIT	101	Tm1 is less than or equal to 0.
APC_TM2_OUT_OF_LIMIT	102	Tm2 is less than or equal to 0.
APC_DM1_OUT_OF_LIMIT	103	Dm1 is less than 0.
APC_DM2_OUT_OF_LIMIT	104	Dm1 is less than 0.
APC_TREF_OUT_OF_LIMIT	105	Tref is less than or equal to 0.
APC_MODEL_OUT_OF_LIMIT	106	Model is not 0, 1 or 2.
APC_COF_OUT_OF_LIMIT	107	COF is neither 0 nor 1.
APC_I_COF_OUT_OF_LIMIT	108	I_COF is neither 0 nor 1.
APC_CONTROLLER_OPEN	110	The controller is in open-loop mode.
APC_MV_OUT_OF_CONTROL	201	MV variable has no target; no valid CV is available.
APC_MV_VAL_LIMIT_ERROR	202	The valid lower limit for MV exceeds the upper limit.
APC_MV_PV_OUT_OF_VAL_LOW	203	MV_PV quality is good, but the value below the valid lower limit.
APC_MV_PV_OUT_OF_VAL_HIGH	204	MV_PV quality is good, but the value exceeds the valid upper limit.
APC_MV_ST_OUT_OF_5	206	Five consecutive ON/ST anomalies trigger the alarm.
APC_MV_OPE_LIMIT_ERROR	210	The MV operation lower Limit exceeds the operation upper limit.
APC_MV_PV_OUT_OF_OPE_LOW	211	MV_PV quality is good, but the value below the operation lower limit.
APC_MV_PV_OUT_OF_OPE_HIGH	212	MV_PV quality is good, but the value exceeds the operation upper limit.
APC_MV_SW_OUT_OF_LIMIT	213	The MV switch signal is out of limit.
APC_MV_IRV_SW_OUT_OF_LIMIT	214	The MV_IRV switch signal is out of limit.
APC_MV_DMAX_OUT_OF_LIMIT	215	The MV maximum output limit is out of range.
APC_MV_OPE_OVER_VAL	215	The MV operation upper and lower limits exceed the valid upper and lower limits.
APC_MV_DMIN_OUT_OF_LIMIT	216	The MV minimum output limit is out of range.

Fault code	Value	Description
APC_MV_COP_OUT_OF_LIMIT	217	The MV_COP output is out of limit.
APC_CV_OUT_OF_CONTROL	401	The CV variable is out of control; no valid MV is available.
APC_CV_VAL_LIMIT_ERROR	402	The valid lower limit of CV exceeds the valid upper limit.
APC_SP_OUT_OF_VAL_LIMIT	403	The setpoint is outside the valid upper and lower limits.
APC_CV_OUT_OF_VAL_LOW	404	CV is below the valid lower limit.
APC_CV_OUT_OF_VAL_HIGH	405	CV exceeds the valid upper limit.
APC_CV_ST_OUT_OF_5	406	Five consecutive ON/ST anomalies trigger the alarm.
APC_CV_OPE_LIMIT_ERROR	410	CV operation upper and lower limit configuration error.
APC_SP_OUT_OF_OPE_LIMIT	411	The setpoint is outside the operation upper and lower limits.
APC_CV_SW_OUT_OF_LIMIT	413	The CV switch signal is out of limit.
APC_CV_SP_DMAX_OUT_OF_LIMIT	414	The CV maximum setpoint limit is out of range.
APC_CV_SP_DMIN_OUT_OF_LIMIT	415	The CV minimum setpoint limit is out of range.
APC_CV_DELTACV_OUT_OF_LIMIT	416	The CV increment limit is out of range.
APC_CV_OUT_OF_OPE_LOW	1415	CV is below the operation lower limit.
APC_CV_OUT_OF_OPE_HIGH	1416	CV exceeds the operational upper limit.

PFCs_dv/PFCs_dv_v2/PFCm_dv/PFC_DV fault code

Fault code	Value	Description
APC_TS_OUT_OF_LIMIT	1	Ts is less than 0.
APC_PV_LOW_GREATER_THAN_HIGH	2	The PV lower limit is greater than the upper limit.
APC_PV_OUT_OF_HIGH	100	PV exceeds the upper limit.
APC_PV_OUT_OF_LOW	101	PV is below the lower limit.
APC_PV_OUT_OF_DMAX	102	The disturbance value exceeds the increment upper limit.
APC_TM_OUT_OF_LIMIT	103	TM variable is out of limit.
APC_SW_OUT_OF_LIMIT	104	SW variable is out of limit.
APC_MODEL_OUT_OF_LIMIT	105	Model is not 0, 1 or 2.
APC_DMAX_OUT_OF_LIMIT	106	The maximum output limit is out of range.

PFCs_v2/PFC11 fault code

Fault code	Value	Description
APC_STATE_ERROR	-207	Tuning state error.
APC_NULL_POINT	-101	Null pointer.
APC_LENGTH_MISMATCH	-6	Length mismatch.
APC_OUT_OF_MEMORY	-5	Insufficient memory.
APC_FUNCTION_ERROR	-4	Component operation fault.
APC_PARAME_ID_NOT_FOUND	-2	ID not found.
APC_TS_OUT_OF_LIMIT	1	Ts is less than 0.
APC_SP_OUT_OF_LOW	100	The setpoint is below the lower limit.
APC_SP_OUT_OF_HIGH	101	The setpoint is above the upper limit.
APC_PARAM_OUT_OF_MAX	102	The parameter is above the upper limit of the range.
APC_PARAM_OUT_OF_MIN	103	The parameter is below the lower limit of the range.
APC_TM_OUT_OF_LIMIT	104	Tm is less than or equal to 0.
APC_TREF_OUT_OF_LIMIT	105	Tref is less than or equal to 0.
APC_DM_OUT_OF_LIMIT	106	Dm is less than 0.
APC_OP_LIMIT_ERROR	210	The OP output lower limit is greater than the upper limit.
APC_SP_LIMIT_ERROR	211	The SP lower limit is greater than the upper limit.
APC_SW_OUT_OF_LIMIT	212	SW is neither 0 nor 1.
APC_MODEL_OUT_OF_LIMIT	213	Model is not 0, 1 or 2.
APC_COF_OUT_OF_LIMIT	214	COF is neither 0 nor 1.
APC_COP_OUT_OF_LIMIT	215	COP is less than 0.
APC_I_COF_OUT_OF_LIMIT	216	I_COF is neither 0 nor 1.
APC_DOPMAX_OUT_OF_LIMIT	218	DOPMax is less than 0.
APC_SP_DMAX_OUT_OF_LIMIT	219	SP_DMax is less than 0.
APC_SP_DMIN_OUT_OF_LIMIT	220	SP_DMin is greater than 0.
APC_PV_OUT_OF_LOW	221	The PV value is below the alarm lower limit RT_Warn_Low.
APC_PV_OUT_OF_HIGH	222	The PV value exceeds the alarm upper limit RT_Warn_High.
APC_PARAM_DISABLE_CHANGE	1001	Parameter modification is prohibited.
APC_COMP_IS_NOT_RUNNING	1002	Tuning is not running.

PIDR fault codes

Fault code	Value	Description
APC_STATE_ERROR	-207	Tuning state error.
APC_NULL_POINT	-101	Null pointer.
APC_LENGTH_MISMATCH	-6	Length mismatch.
APC_OUT_OF_MEMORY	-5	Insufficient memory.
APC_FUNCTION_ERROR	-4	Component operation fault.
APC_PARAME_ID_NOT_FOUND	-2	ID not found.
APC_TS_OUT_OF_LIMIT	1	Ts is less than 0.
APC_SP_OUT_OF_LOW	100	The setpoint is below the lower limit.
APC_SP_OUT_OF_HIGH	101	The setpoint is above the upper limit.
APC_PARAM_OUT_OF_MAX	102	The parameter is above the upper limit of the range.
APC_PARAM_OUT_OF_MIN	103	The parameter is below the lower limit of the range.
APC_TM_OUT_OF_LIMIT	104	Tm is less than or equal to 0.
APC_TREF_OUT_OF_LIMIT	105	Tref is less than or equal to 0.
APC_DM_OUT_OF_LIMIT	106	Dm is less than 0.
APC_OP_LIMIT_ERROR	210	The OP output lower limit is greater than the upper limit.
APC_SP_LIMIT_ERROR	211	The SP lower limit is greater than the upper limit.
APC_SW_OUT_OF_LIMIT	212	SW is neither 0 nor 1.
APC_MODEL_OUT_OF_LIMIT	213	Model is not 0, 1 or 2.
APC_COF_OUT_OF_LIMIT	214	COF is neither 0 nor 1.
APC_COP_OUT_OF_LIMIT	215	COP is less than 0.
APC_I_COF_OUT_OF_LIMIT	216	I_COF is neither 0 nor 1.
APC_DOPMAX_OUT_OF_LIMIT	218	DOPMax is less than 0.
APC_SP_DMIN_OUT_OF_LIMIT	221	SP_DMin is greater than 0.
APC_DV_LIMIT_ERROR	223	Upper/lower limit error for measured disturbance values.
APC_DV_OUT_OF_LOW	224	The measured disturbance value is below the lower limit.
APC_DV_OUT_OF_HIGH	225	The measured disturbance value exceeds the upper limit.
APC_PARAM_DISABLE_CHANGE	1001	Parameter modification is prohibited.
APC_COMP_IS_NOT_RUNNING	1002	Tuning is not running.

18.3.3 Motion Control

18.3.3.1 Overview

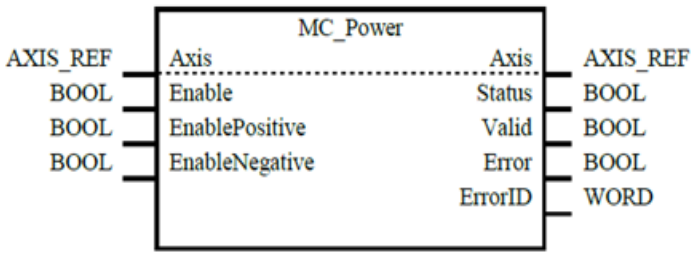
18.3.3.1.1 PLCopen Specifications

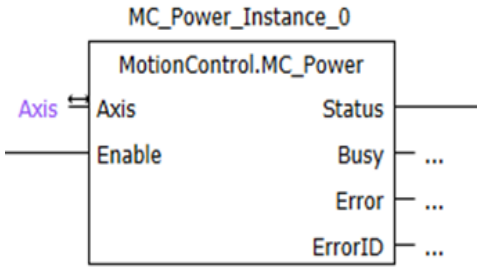
IEC 61131 is an international standard for general-purpose programmable logic controllers (PLCs). It was initially proposed as an industry standard by several leading European PLC companies. IEC 61131-3 is a section of the IEC 61131 standard for PLC programming, defining six programming language standards.

PLCopen, headquartered in Europe, is a global organization promoting the IEC 61131-3. Its members, several well-known PLC manufacturers, have refined technical details based on IEC 61131-3 to harmonize the programming across PLCs from different manufacturers, reducing technical differences and barriers. This allows users to switch between different PLC brands without needing to learn new programming methods.

In China, the corresponding national recommended standard GB/T 15969.3 was released in 1995 and upgraded in 2005. It serves as the recommended design standard for PLC manufacturers. PLCopen also has members in China. In addition to recommendations for common logic control instructions, program structures, and keywords in various languages, the PLCopen specifications contain the technical specifications for motion control (MC) function blocks, including the naming, functions, in-out variable definitions, and related temporal logic of MC function blocks, maximizing the interoperability of users' programming techniques.

The MC function blocks in iFA motion control are based on the PLCopen specifications for MC function blocks. The following table presents the differences between the MC function blocks in iFA motion control and in PLCopen specifications.





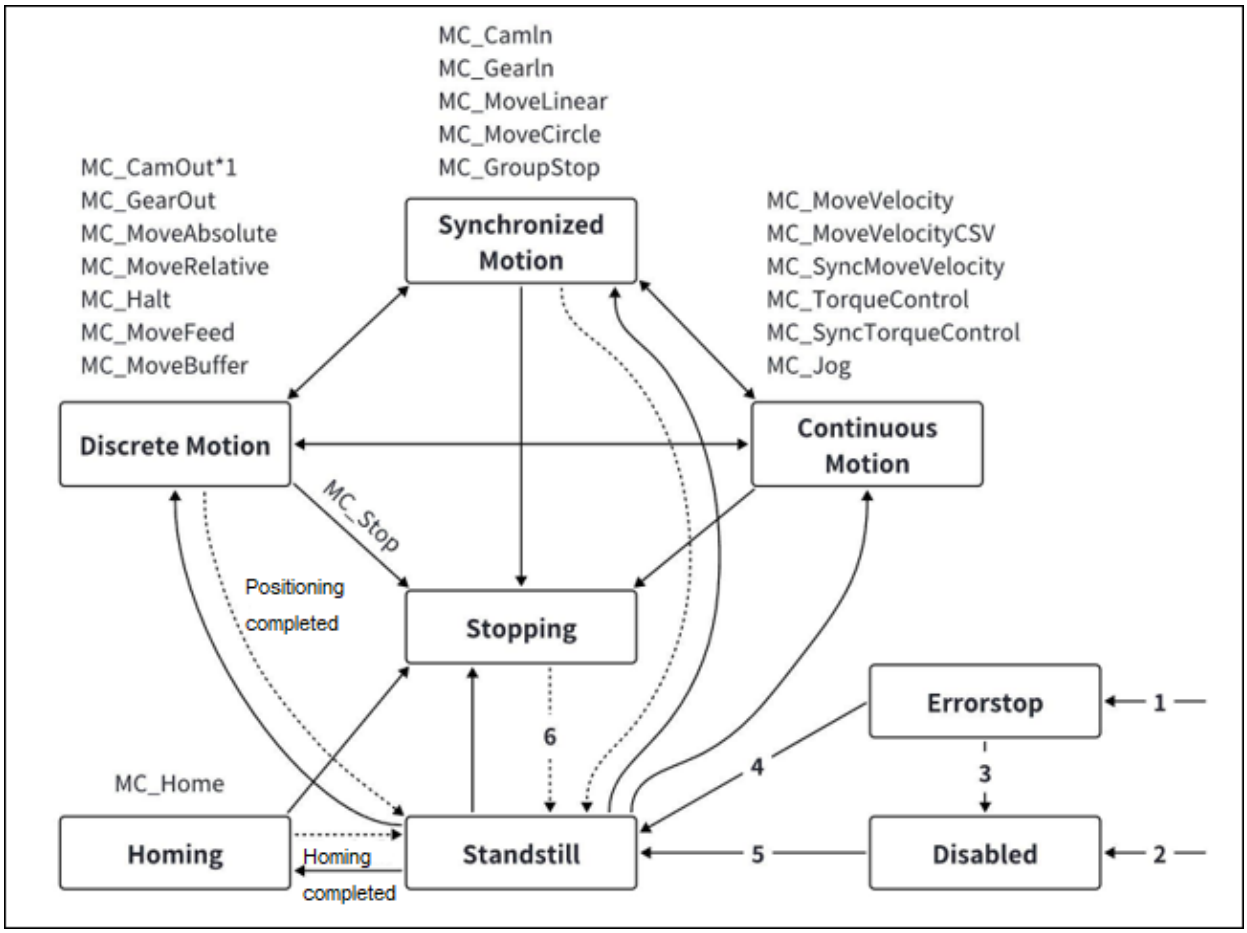
- **Differences in structure data**

Data Type		Description
PLCopen	iFA	
AXIS_REF	AXIS_REF	Single axis structure.
AXES_GROUP_REF	AXES_GROUP_REF	Axis group structure.
MC_TRIGGER_REF	Unused	Touch probe structure. The structure is split in the iFA to enhance usability.
MC_CAM_ID	Unused	Cam table ID structure. The MC_CAM_TABLE_REF structure is used in the iFA to simplify the cam function block calling in PLCopen specifications.

Data Type		Description
PLCopen	iFA	
MC_INPUT_REF	Unused	Input reference structure. The input parameter is axis instance in iFA.
MC_OUTPUT_REF	Unused	Output reference structure. The output parameter is axis instance in iFA.

- **Differences in FB forms**

  In PLCopen specifications, the input and output variables of FBs are represented by dashed lines; in iFA, the input and output variables of FBs are represented by double arrows. In PLCopen specifications, no instance names are shown in FBs, but other entity names, input variables, and output variables have the same forms.



PLCopen FB	iFA FB
	

- **Differences in general functions**

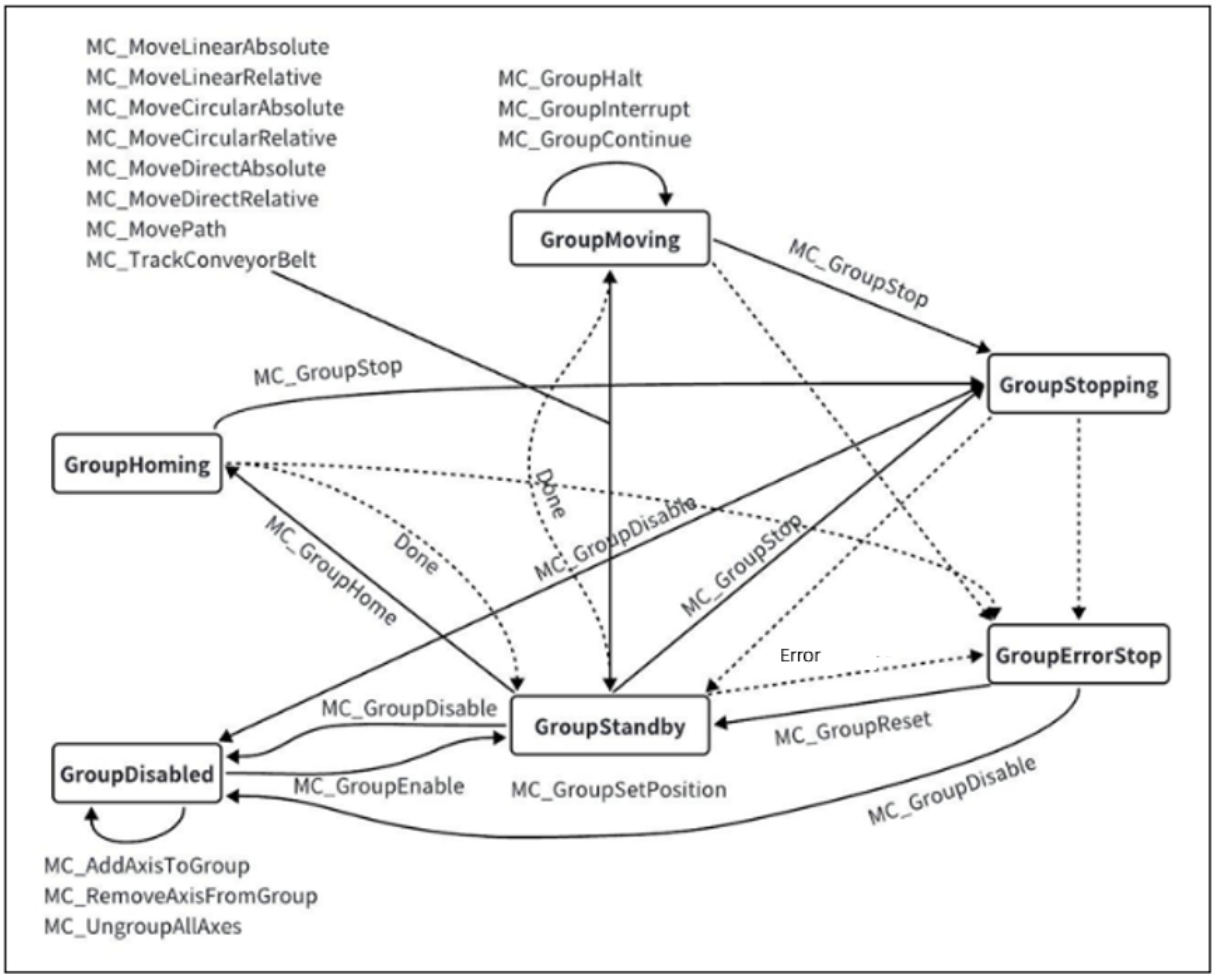
Function	PLCopen	iFA
Default behaviors of motion parameters	Instruction block fault reporting, compilation warning, specifying and selecting limits for motion parameters in the axis structure.	The instruction block automatically corrects improper input parameters. See specific instructions for correction details.
Positive and negative limits of motion parameters	Acceleration, deceleration, and jerk must be positive. Velocity, position, and distance can be either positive or negative.	Acceleration, deceleration, jerk, and velocity must be positive. The instruction block will automatically correct any abnormal values. Position and distance can be either positive or negative.
FB naming rules	MC_FBname_SupplierID	MC_FBname_InstanceID

- **Single axis state machine**

The axis state and motion are managed based on the state machines in PLCopen specifications.

The state machines are detailed in the following table:

Table18-3-3-1-1-1 State definitions



State	Description
Disabled	Disabled.
ErrorStop	Stop upon fault.
Standstill	Standstill.
Homing	Homing.
Stopping	Decelerating to stop.
Discrete Motion	Discrete motion.
Continuous Motion	Continuous motion.
Synchronized Motion	Synchronized motion.

Table18-3-3-1-1-2 State switching conditions

Switched to	Conditions
1	Immediately after a fault is detected by the fault detection logic of an axis.

Switched to	Conditions
2	When no fault occurs and the MC_Power.Enable is set to FALSE.
3	When the MC_Reset is called to reset an axis fault and the MC_Power.Status is set to FALSE.
4	When the MC_Reset is called to reset an axis fault and the MC_Power.Status is set to TRUE.
5	When the MC_Power.Enable is set to TRUE and the MC_Power.Status is set to TRUE.
6	When the MC_Stop.Done is set to TRUE and the MC_Stop.Execute is set to FALSE.

- **Axis group state machine**

The axis group state machines are used to describe the states of an axis group, including: GroupDisabled, GroupHoming, GroupMoving, GroupStopping, GroupErrorStop, and GroupStandby.

- **Precautions**
  - To switch the axis group state from GroupDisabled to GroupStandby, be sure that all axes in the axis group are connected and that there are no fault messages for any axes in the axis group.
  - If an axis in the axis group has a fault message while the axis group is in the GroupStandby state, the axis group state will be switched to GroupErrorStop.

- To switch the axis group state from GroupErrorStop to GroupStandby, call the MC_GroupReset to clear all errors of the axis group and the axes within the axis group. If any faults cannot be cleared, the axis group state will not be switched successfully.
- To switch the axis group state from GroupStandby to GroupMoving or GroupHoming, be sure that each axis in the axis group is in StandStill state. Otherwise, calling an axis group motion control instruction will result in a fault, but this will not affect the execution of the axis group state machine.
- To switch the axis group state from GroupStopping to GroupStandby, be sure that the output variable Done of the MC_GroupStop is set and the input variable Execute is reset.
- Do not execute a single axis instruction on a configured axis in the axis group.
- The MC_GroupSetPosition can be called only when the axis group is in the GroupStandby state.
- The MC_GroupDisable can switch the axis group state from GroupErrorStop to GroupDisabled.
- The GroupErrorStop state does not affect the states of individual axes within the axis group.

18.3.3.1.2 Single-Axis Instructions

- **Buffer**

  1. For buffered instructions with abnormal motion parameters, they will be executed normally if the abnormal parameters can be automatically corrected; otherwise, the instructions will immediately report a fault and abort the executing instructions.
  2. The MC_Jog instruction does not have a buffer, but it can be followed by buffered instructions. Since the MC_Jog instruction is always being executed without an end flag, the buffered instructions will never be executed. If the MC_Jog instruction stops executing, the buffered instructions can be executed. When the MC_Home instruction is being executed, no instructions can be buffered.
  3. An unsupported buffer mode will cause a fault.
  4. The motion is planned starting from the intermediate velocity. How to plan the motion in case of insufficient displacement depends on whether the axis is allowed to move in the reverse direction. If allowed, the axis will move in the reverse direction before reaching the target position. If not allowed, the jerk or acceleration/deceleration will be automatically corrected.
  5. When a buffered instruction is in Busy and not in Active state, its input parameters can be modified.
  6. Currently, only one instruction supports the buffer function.

- **Abort**

  1. If an instruction is aborted and the CommandAborted changes to TRUE, the instruction performing the abort will be executed with automatically corrected motion parameters.
  2. When the option No ErrorStop upon hitting the limit and triggering abnormal parameters is checked on the IDE interface, the axis state will not switch to ErrorStop. When this option is not checked, the axis state will switch to ErrorStop if the current velocity is not 0, and return to StandStill if the current velocity is 0.
  3. When the current motion control instruction and buffered instructions are aborted, the buffer will be cleared; the CommandAborted will change to TRUE for the current motion control instruction and buffered instructions; the instruction performing the abort will be executed normally.
  4. If the current motion state is not the state for executing an instruction, a fault will occur, without affecting the axis or the current motion control instruction. The priority of fault identification for

abnormal states is higher than that for abnormal parameters, with Stop and ImmediateStop having the highest priority.

5. The MC_Home instruction can be aborted by the MC_Stop and MC_ImmediateStop instructions only during execution.

- **Position limit**

1. Identification of hitting the limit/Handling rules for hitting the negative limit while moving in the positive direction: Limit check is performed only against the positive limit when the axis moves in the positive direction, and a fault occurs when the axis moves beyond the positive limit. Limit check is performed only against the negative limit when the axis moves in the negative direction, and a fault occurs when the axis moves beyond the negative limit.
2. Change rules for status bit, axis state, and instruction output flag upon hitting the limit: When the option No ErrorStop upon hitting the limit and triggering abnormal parameters is checked on the IDE interface, the axis state does not switch to ErrorStop upon hitting the limit, but a fault occurs. When this option is not checked, the axis state directly switches to ErrorStop with a fault message.
3. Handling rules for hitting the limit: The instruction identifies whether the axis will move beyond the limit during the execution. If the axis trajectory under the current instruction may exceed the limit, software limit-induced deceleration will be performed, and the axis will ultimately stop at the limit boundary with the deceleration parameters set in the software. Stopping at the limit boundary will cause the instruction to issue a fault message.
4. Stopping rules for hitting the software limit: If the software-restricted deceleration is less than the maximum deceleration for software limit, the axis will stop with the maximum deceleration. If the distance required to stop at the maximum deceleration is greater than the predicted maximum stopping distance based on the software limit, the axis will stop based on the maximum distance. The instruction identifies the current velocity and distance from the position limit and then selects one deceleration parameter that makes the axis to move the shortest deceleration distance from the maximum software-restricted deceleration, the deceleration for software limit, and the maximum deceleration distance for software limit. During the software limit-induced deceleration, the trajectory is the T-curve, which means that after the software limit-inducted deceleration is triggered, the acceleration immediately changes to the deceleration calculated based on the deceleration for software limit, the maximum software-restricted deceleration, and the maximum deceleration distance for software limit.
5. If the initial position is beyond the limit or on the limit and moving towards the limit direction, the axis will move normally. If the initial position is within the limit and moving outwards, the changes in axis processing logic and function block output flag are as follows: When the option No ErrorStop upon hitting the limit and triggering abnormal parameters is checked on the IDE interface, the axis state does not switch to ErrorStop upon hitting the limit, but a fault occurs. When this option is not checked, the axis state directly switches to ErrorStop with a fault message.

- **FB fault message display**

1. The name and path of the instruction causing a fault as well as the fault time stamp and ErrorID are recorded in the axis parameter fbeFBError. Up to 15 faults can be recorded in the fbeFBError.
2. When the axis structure parameter bDisableErrorLogging is set to TRUE, no fault message is recorded in the fbeFBError.
3. After the FB is reset, the fault state and fault code are cleared.

4. The MC_Reset instruction can clear the faults recorded by the fbeFBError.

- **Motion parameters**
  1. When a parameter value is greater than the maximum limit, it will be treated as the limit value.
  2. The decimal precision of floating-point motion parameters is within 10^{-6}.
  3. With an S-curve trajectory planning, if the parameter Jerk value is 0, it will be automatically corrected to 1e-5 by the instruction block. With a T-curve trajectory planning, the parameter Jerk will not be evaluated.
- **Axis pointer being null**

  Null pointer check is performed in all function blocks that receive axis variables, involving single axis instructions, synchronous axis instructions, and axis group instructions. If the axis pointer passed to the function block is null, a fault will occur after the instruction is executed, which will not cause project errors or a controller crash.

  During the execution of an instruction, it is prohibited to switch the axis object through REF=.
- **Instructions triggered within one cycle**

  The output Done of an instruction is used as the input for Execute in the instruction trigger logic. The supported instructions include MC_MoveAbsolute, MC_MoveRelative, MC_MoveSuperImposed, and MC_MoveFeed.
- **Servo terminal parameters**
  1. The specific number of supported touch probe channels depends on the servo drive. SV660N supports two probe channels, while SV670/SV680 supports one probe channel only.

Table18-3-3-1-2-1 SV660N DI/DO terminals

Signal		Default Function	Pin Number	Description
General	DI1	P-OT	10	Positive overtravel switch.
	DI2	N-OT	9	Negative overtravel switch.
	DI3	HomeSwitch	8	Home switch.
	DI4	TouchProbe2	7	Touch probe 2.
	DI5	TouchProbe1	11	Touch probe 1.
	+24V		15	Internal 24 V power supply; voltage range: 20 to 28 V; maximum output current: 200 mA.
	COM-		14	
	COM+		13	Common terminal of DI terminals.
	DO1+	S-RDY+	1	Servo ready.
	DO1-	S-RDY-	6	
	DO2+	ALM+	3	Alarm.
	DO2-	ALM-	2	
	DO1+	BK+	5	Brake.

Signal		Default Function	Pin Number	Description
	DO1-	BK-	4	

Table18-3-3-1-2-2 SV670N DI/DO terminals

Signal		Default Function	Pin Number	Description
General	DI1	P-OT	9	Positive overtravel switch.
	DI2	N-OT	7	Negative overtravel switch.
	DI3	HomeSwitch	8	Home switch.
	DI4	Emergence Stop	6	Emergency stop.
	DI5	TouchProbe1	10	Touch probe 1.
	COM+		5	Common terminal of DI terminals.
	+24V		3	Internal 24 V power supply; voltage range: 20 to 30 V; maximum output current: 200 mA.
	COM-		4	
	DO1+	S-RDY+	11	Servo ready.
	DO1-	S-RDY-	12	
	DO2+	BK+	13	Brake.
	DO2-	BK-	14	
	PZ-OUT	Phase-Z frequency-division output signal	1	Home pulse open-collector output signal.
	GND	Home pulse open-collector output signal ground	2	
	PE	Enclosure	15	-
	PE	Enclosure	16	-

2. Due to the differences in DI terminals of the servo, if you need to use the DI4 terminal of SV670 or SV680 as an emergency stop signal, you must obtain the terminal state from the 60FD object and add proper processing in the user program. The axis does not respond to the emergency stop signal from DI4.

3. PLC homing terminal binding: HomeSwitch, PositiveLimitSwitch, and NegativeLimitSwitch are bound to bit2, bit1, bit0 of the 60FD object by default. LatchInput must be manually mapped in the 60FD object.

Index 60FDh	Name	Digital Input			Setting Condition & Effective Time	-	Data Structure	VAR	Data Type	Int32
	Access	RO	Mapping	TPDO	Related Mode	PP HM CSP	Data Range	-	Factory Setting	0

Reflect the current DI terminal logic of the servo drive:

0: Logic invalid

1: Logic valid

Each bit represents the following DI signals:

bit	Signal
0	1: Negative overtravel active
1	1: Positive overtravel active
2	1: Home signal active
3-15	N/A
16	1: DI1 input active
17	1: DI2 input active
18	1: DI3 input active
19	1: DI4 input active
20	1: DI5 input active
21-26	N/A
27	1: STO1 signal input
28	1: STO2 signal input
29	1: EDM output active
30-31	N/A

- **Local pulse axis**

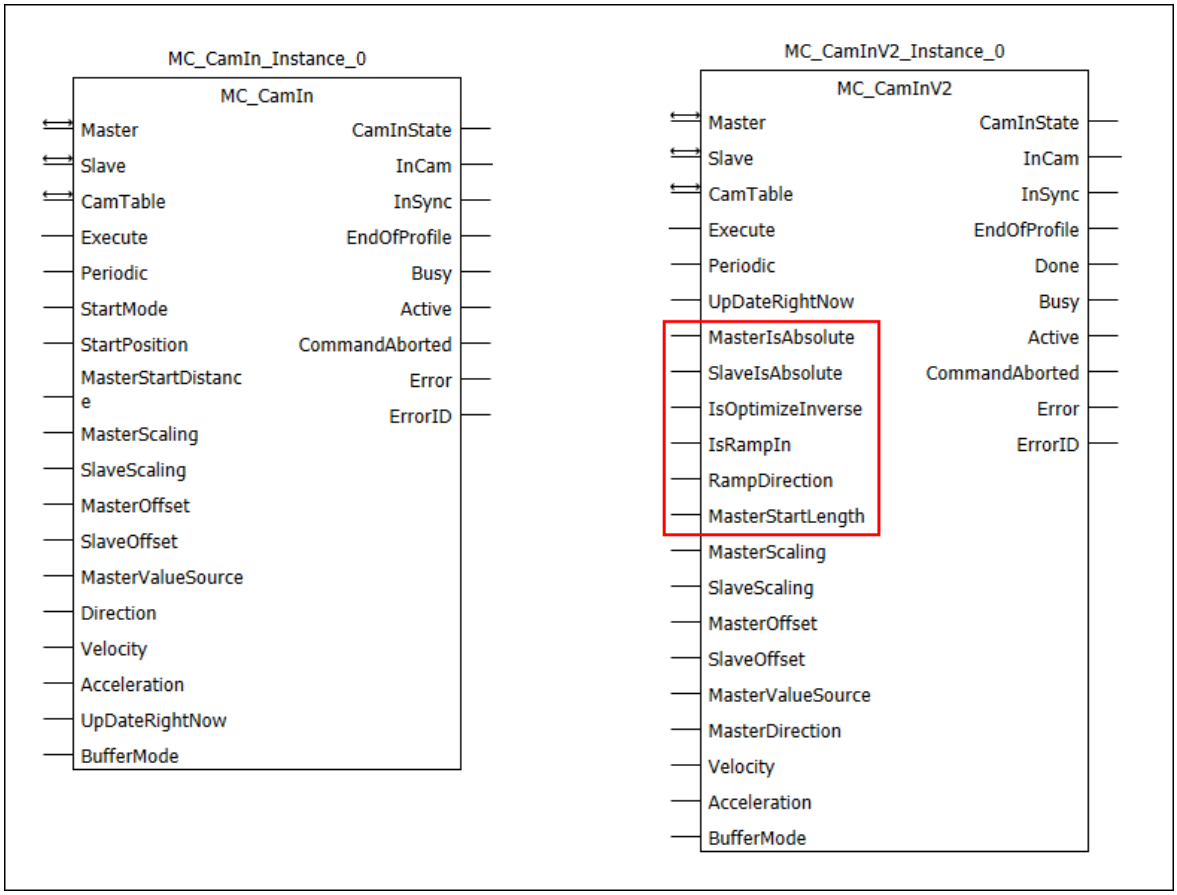
  Even if you select a single terminal such as Y0 or Y1, you can also use motion control instructions. In this case, the output signal is unclear. Therefore, it is not recommended to do so. When you select a single terminal, only the MC_SyncMoveVelocityCSV instruction can be executed.

18.3.3.1.3 Synchronous Axis Instructions

- **General specifications for cam**

  1. A fault will occur if the salve axis velocity exceeds the limit during synchronized motion.
  2. The start point (0,0) of the cam table cannot be modified, but the velocity ratio can be modified.
  3. A fault will occur if the master axis and the slave axis are specified as the same axis.
  4. For abnormal parameters, see the Parameter Correction section of respective instructions.
  5. Dense nodes are connected using the straight line.

6. The phase and displacement of the cam table are specified as relative quantities from the start point (0,0).



- **Operating specifications for cam table**

1. The velocity ratio of linear segments in the cam table cannot be modified.
2. The velocity ratios at the start and end points can be different.
3. The instruction MC_GenerateCamTable pre-checks the modified cam table parameters, and issues a fault message if any invalid parameter is identified. User-defined cam variables take effect only after passing the MC_CheckCamTable check. Precaution: Manually modifying checked cam data online may cause the slave axis to stall. It is recommended to recheck the data after modification.
4. When the node type in the cam table is dense node, the number of nodes cannot exceed 65535. When the node type is key node, the number of nodes cannot exceed 20000, and the minimum pitch between adjacent nodes is 0.0001.

- **Function differences between MC_CamInV2 and MC_CamIn**

1. Interface parameters

   Their interface parameters are different. For details, see the following function blocks.

2. Following modes of master and slave axes

   For MC_CamInV2, the scenario where the master axis in the cam table is in absolute mode and the slave axis is in absolute mode has been added, expanding the number of following modes from 1 to 4.

Following Mode	MC_CamInV2	MC_CamIn
Master axis in absolute mode and slave axis in absolute mode	√	×
Master axis in absolute mode and slave axis in relative mode	√	×

Following Mode	MC_CamInV2	MC_CamIn
Master axis in relative mode and slave axis in absolute mode	√	×
Master axis in relative mode and slave axis in relative mode	√	√

3. Coupling function

	MC_CamInV2	MC_CamIn
Enable selection	Selected through the parameter IsRampIn.	Cannot be selected; enabled by default.
Coupling method	Select positive or negative coupling through the parameter RampDirection.	×
Slave axis inverse optimization during coupling	Select whether to perform optimization or complete compensation as soon as possible through the parameter IsOptimizeInverse.	Cannot be selected; enabled by default.
Entry velocity	IsRampIn = FALSE: The slave axis velocity jumps (equal to the slave axis displacement increment in the current cycle/ task cycle); IsRampIn = TRUE: The slave axis moves without velocity jump and is smoothly coupled.	Controlled by acceleration input. Acceleration = 0: The slave axis velocity jumps directly (equal to cam velocity + coupling velocity); Acceleration ≠ 0: The slave axis moves without velocity jump and is smoothly coupled.
Entry direction	When the slave axis is a rotary axis, the slave axis increment can be switched between positive and negative based on the parameter RampDirection.	During entry, the slave axis displacement increment is calculated and compensated based on the master axis position. No direction parameter is available.

4. Master axis offset correction

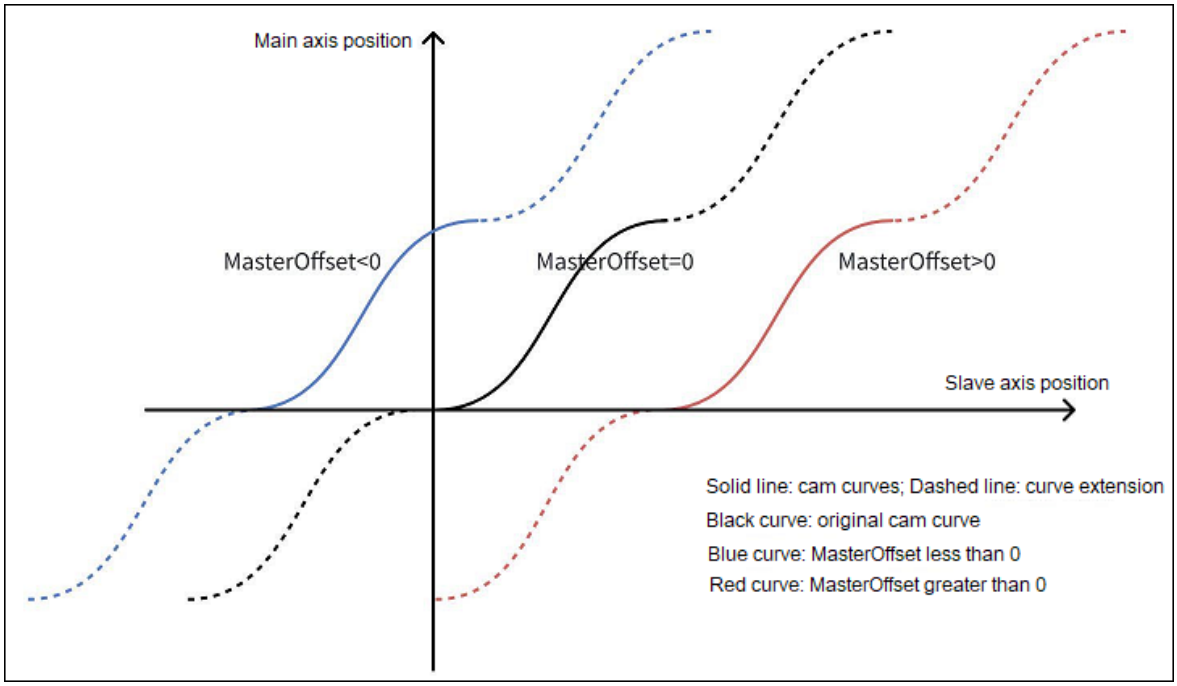


Figure 18-3-3-1-3-1 MC_CamInV2

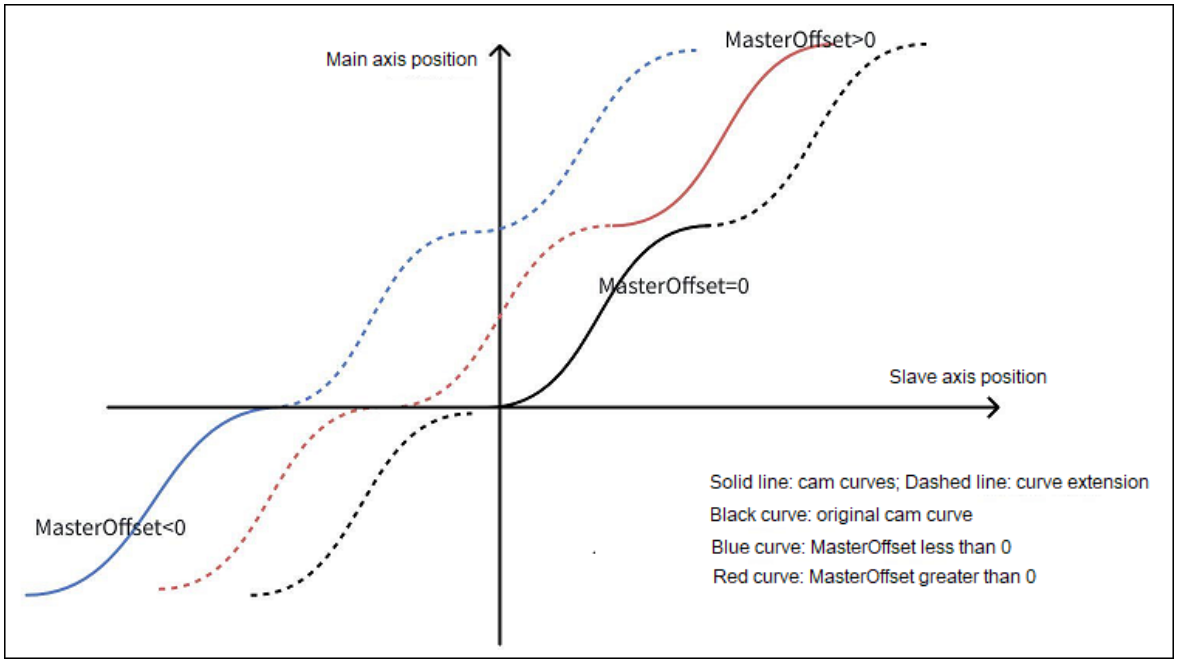

Figure 18-3-3-1-3-2 MC_CamIn

5. Cam table start point

   MC_CamIn: The cam table start point is (0,0).

   MC_CamInV2: The cam table start point can be specified arbitrarily.

6. Conditions for setting InSync and InCam

	MC_CamInV2	MC_CamIn
InCam	TRUE when the cumulative movement of the master axis reaches the input parameter MasterStartLength value after the instruction is executed.	TRUE when the master axis passes the start point of the cam table, which is specified by the input parameter StartPosition.

	MC_CamInV2	MC_CamIn
InSync	TRUE when the slave axis starts to follow the master axis and coupling is completed.	TRUE immediately after the slave axis starts to follow the master axis.

7. Conditions for the slave axis to start following

MC_CamInV2	MC_CamIn
The accumulative movement of the master axis reaches the MasterStartLength value (same sign as the direction of the master axis velocity).	The position of the master axis when the slave axis starts following the master axis is calculated based on the StartMode, MasterStartDistance, and StartPosition.

8. Re-execution

MC_CamInV2	MC_CamIn
It can be re-triggered after any parameters are modified. The modified parameters take effect immediately after the instruction is re-executed.	It can be re-executed after some parameters are modified. The modified parameters take effect in the next cycle.

9. Effective directions of the master axis

Master Axis Direction Parameter	MC_CamInV2	MC_CamIn
CAM_NO_DIRECTION	√	√
CAM_ABS_POSITIVE	√	√
CAM_REL_NEGATIVE	√	×
CAM_ABS_NEGATIVE	√	√
CAM_REL_NEGATIVE	√	×

10. Master axis offset

    MC_CamInV2: No modulo operation will be performed if the MasterOffset is greater than the master axis phase in corresponding camming cycle.

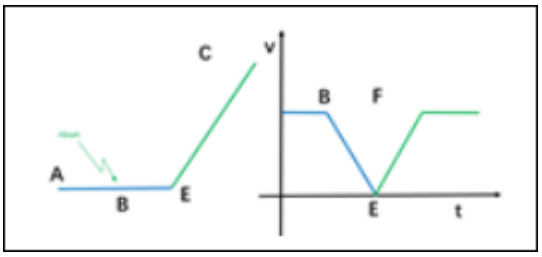
    MC_CamIn: Modulo operation will be performed if the MasterOffset is greater than the master axis phase in corresponding camming cycle.

	MC_CamInV2	MC_CamIn
MasterOffset greater than the master axis phase in corresponding camming cycle	No modulo operation.	Modulo operation of the MasterOffset will be performed based on the master axis phase in corresponding camming cycle.

18.3.3.1.4 Axis Group Instructions

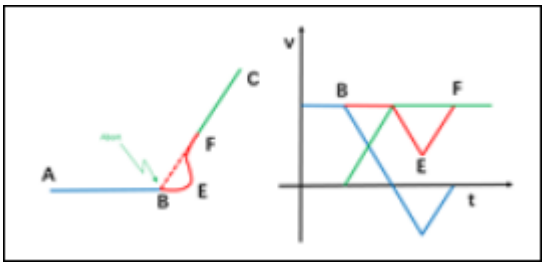
- **General specifications for axis group**
  - **Multiple execution of axis group instructions**

    Other instructions can be executed during the execution of an axis group instruction.



Axis group motion control instructions can be executed immediately or stored in a buffer for later execution, which is controlled by the parameter BufferMode. Up to eight instructions can be stored in each axis group.

The parameter BufferMode is defined as follows. mcAborting is executed immediately, while all others are buffered.



- **BufferMode**
  - mcAborting: Aborts the instruction being executed and switches to this instruction.
    New motion is re-planned starting from the current position and a transition trajectory is used to achieve smooth transition (velocity coordination) between the current trajectory and the new trajectory.

    This mode supports three transition modes, which are specified by the TransitionMode:

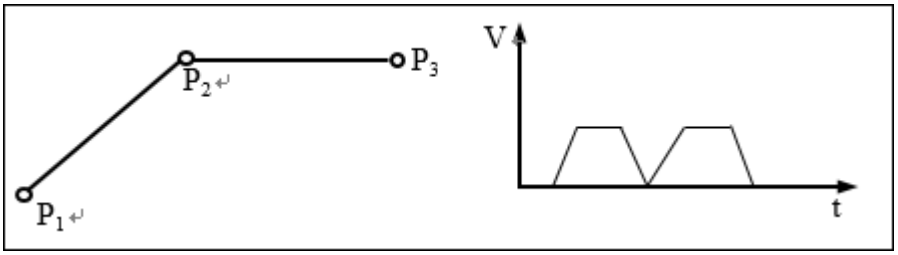
    (1) Transition disabled (equivalent to the effect of mcBuffered)
    TMNone: No transition curve.

    (2) Reset transition
    TM_RESET_ABORT: Deceleration is performed with the deceleration and jerk calculated based on the maximum values of the set motion parameters multiplied by the conversion factor.

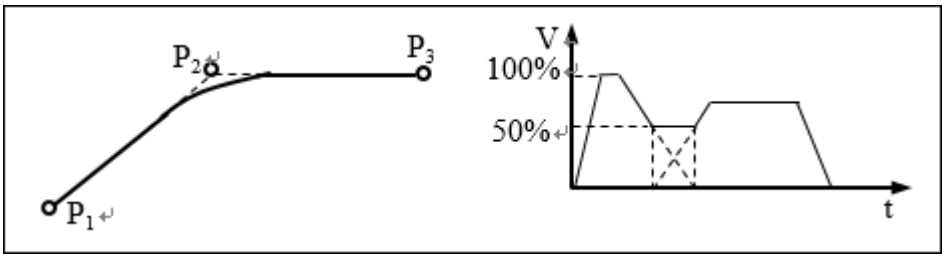
    (3) Deceleration transition
    TM_DEC_ABORT: Deceleration is performed with the deceleration and jerk set by the new aborting instruction.

  - mcBuffered: Buffers this instruction and executes it after the current instruction is completed.

  - Blending: mcBlendingHigh, mcBlendingLow, mcBlendingPrevious, mcBlendingNext: The velocities of the two adjacent instructions are blended in the specified manner in



TransitionMode.



- **TransitionMode**

  This variable specifies how to blend the velocities of two instructions when Blending is specified for the BufferMode.

  - TMNone: Insert no transition curve. If TMNone is selected in a blending mode, the result is consistent with the transition between the velocities of the two instructions in buffered mode.

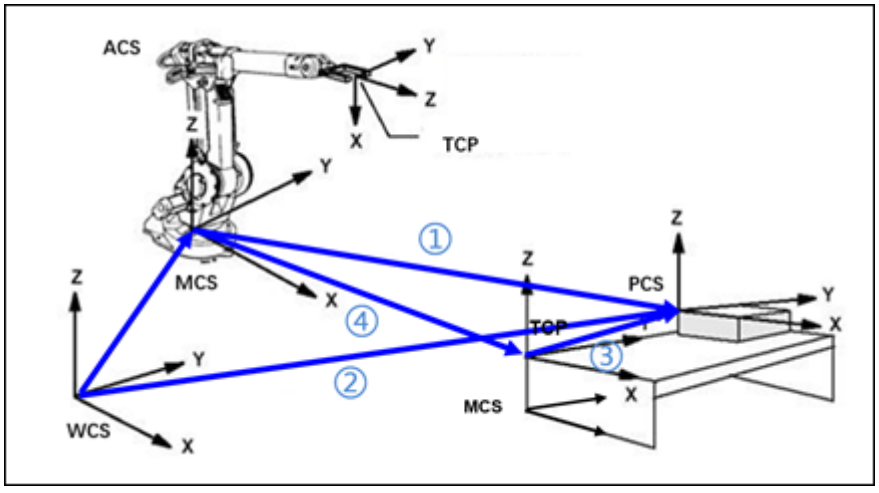
  - TMStartVelocity: Transition with given start velocity. Blending transition at a certain ratio (0, 1] of the actual maximum velocity of the current motion control instruction. Effective for transitions between any motion control instructions.

  - TMDefinedVelocity: Transition with defined velocity. Blending transition at a certain ratio (0, 1] of the actual maximum velocity of the instruction following the current motion control instruction. Effective for transitions between any motion control instructions.

  - TMCornerDistance: Transition with given corner distance. In Cartesian space, the distance to the end is specified by the preceding instruction in the main dimensional space, and the transition trajectory is initiated with this distance to connect the adjacent trajectory. The distance refers to a generalized distance, which depends on the main unit type setting for the axis group:
    - If the main unit is position, the parameter is the displacement from the start to the end of the transition.
    - If the main unit is orientation, the parameter is the orientation change from the start to the end of the transition.
    - If the main unit is a percent, the parameter is the percent (0, 1) of the path distance from the start to the end of the transition to the total path displacement.

Effective when both adjacent instructions are Cartesian space instructions (LIN/CIRC); otherwise, they are processed with transition disabled.

- TMMaxCornerDeviation: Transition with given maximum corner deviation. The maximum position deviation in the position subspace during the transition between adjacent instructions in Cartesian space. The adjacent trajectories are connected by constructing an appropriate transition trajectory to keep the maximum position deviation within a certain range. This is only the position deviation, independent of the main unit. Effective when both adjacent instructions are Cartesian space instructions (LIN/CIRC); otherwise, they are processed with transition disabled.



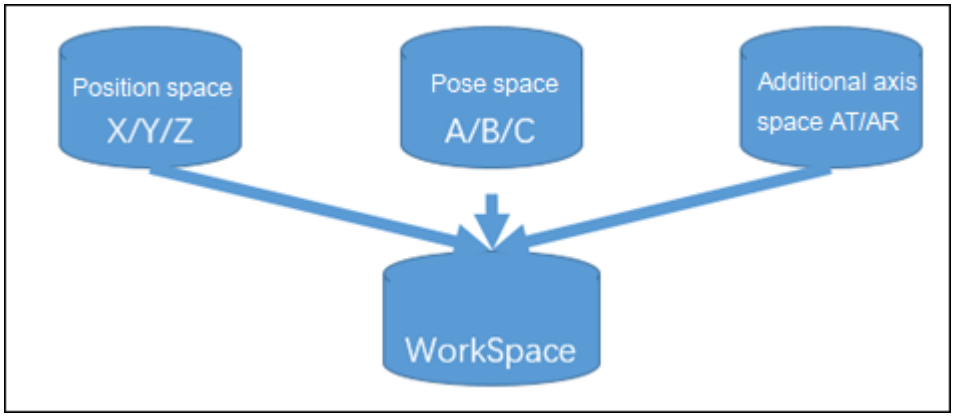
- **Axis group trajectory curve types**

  The trajectory curve types of the axes in the axis group do not affect the trajectory curve type of the axis group. The trajectory curve type eCurveType of the axis group supports three types of curves: trapezoidal curve, cubic S-curve, and seventh-order S-curve.

Curve Type	Curve Code	Enumeration Value	Continuity
Trapezoidal curve	TRAPEZOIDAL_CURVE	0	C1
Cubic S-curve	CUBIC_CURVE	1	C2
Seventh-order S-curve	SEVENTH_CURVE	2	C3

- **Definitions of coordinate system types related to axis groups**

  The core function of an axis group is coordinated motion. The coordinate system types (CoordSystem) involved in the axis group are shown in the following figure, and the corresponding names, definitions, and descriptions are shown in the following table.



Coordinate System	Definition	Description
Axis coordinate system	ACS	Axis related.
Motor axis coordinate system	MACS	Motor axis (actual physical axis).
Joint axis coordinate system	JACS	Joint axis (logical joint axis).
Machine coordinate system	MCS	Base coordinate system for the axis group, relative to the world coordinate system.
Part coordinate system	PCS	Work space.
MCS-based PCS	PART_BASE_MCS = 0	Static coordinate system ①: PCS defined based on the MCS for an axis group.
WCS-based PCS	PART_BASE_WCS = 1	Static coordinate system ②: PCS defined based on the WCS.
End dynamic coordinate system	DYN_PART_BASE_GROUP = 6	Dynamic coordinate system ③: Dynamically fixed PCS defined based on the TCP point at the end of another axis group.
Dynamic PCS based on the X axis	DYN_PART_BASE_AXIS_X = 7	Dynamic coordinate system ④: Dynamically fixed PCS based on the X direction of an axis.
Dynamic PCS based on the A rotary axis	DYN_PART_BASE_AXIS_A = 8	Dynamic coordinate system ④: Dynamically fixed PCS based on a rotation direction (around Z axis) of axis A.
World coordinate system	WCS	The reference space shared by all MCSs.

- **Axis group space composition and configuration**

  The axis group coordinate space can be divided into two spaces: Axis group work space (WorkSpace) and joint axis drive space (AxisSpace).

  - **Work space configuration**

    Axis group work space (WorkSpace): The operational space constituted by the Cartesian space where the TCP at the end of the axis group is located and its auxiliary axis. It is composed of position space, orientation space, and auxiliary axis space. According to the dimension of the axis group space, configure the position X/Y/Z subspaces the orientation A/B/C subspaces, and the auxiliary axis AR/AT subspaces to form the axis group work space.

- **Axis space configuration**
  The axis group AxisSpace is divided into two subspaces, the motor axis coordinate system (MACS) and the joint axis coordinate system (JACS). The AxisSpace describes the software limits of the joint space by configuring the positive limit (fPositiveLimit) and negative limit (fNegativeLimit).
- **Coordinate system transformation**
  Workpiece coordinate system transformation (PCS←→MCS).

  Kinematic model transformation (axis space, base coordinate system transformation ACS←→MCS).

  Axis coordinate system decoupling and anti-decoupling transformation (MACS←→JACS).

18.3.3.1.5 Position Retention upon Power Failure

When a motor with an absolute encoder is used, its actual position is retained and restored after a power cycle of the PLC or servo drive. When the motor is used with a supported servo drive of Inovance, position data can be saved on the servo drive or the PLC. When the motor is used with an unsupported servo drive of Inovance or a third party, position data can be saved on the PLC only. Additionally, if the servo drive is set to absolute rotary mode, position data can be saved on the PLC only, and Rotary Mode must be selected in the axis configuration interface.

Working principle

(1) Position data saved on the servo drive

With this option, when the servo drive is power-cycled, the PLC will obtain the motor position data saved in the servo drive and use it to restore the PLC position system, achieving position retention.

Note:

- In this mode, the servo drive must be set to absolute linear mode without encoder overflow alarm (i.e., H02.01 = 3); otherwise, this function cannot be used.
- This option does not restore the user-defined position offset in the PLC.
- Currently, this option supports the use of Inovance servo drives only. If another manufacturer's servo drive is used, position data can be saved on the PLC only.

(2) Position data saved on the PLC with the axis being set to linear mode

With this option, when the PLC is power-cycled, it will obtain the position data before power failure from the retentive memory area and combine it with the position data after power-on to restore the PLC position system, achieving position retention.

Note:

- For linear axes, this option does not support the use of the servo drive being set to incremental mode, absolute rotary mode, or single-turn absolute mode.
- For linear axes, this option can restore the user-defined position offset in the PLC.
- For linear axes, this option supports multi-turn position retention.

(3) Position data saved on the PLC with the axis being set to rotary mode and the servo drive being set to multi-turn mode

With this option, when the PLC is power-cycled, it will obtain the position data before power failure from the retentive memory area and combine it with the position data after power-on to restore the PLC position system, achieving position retention.

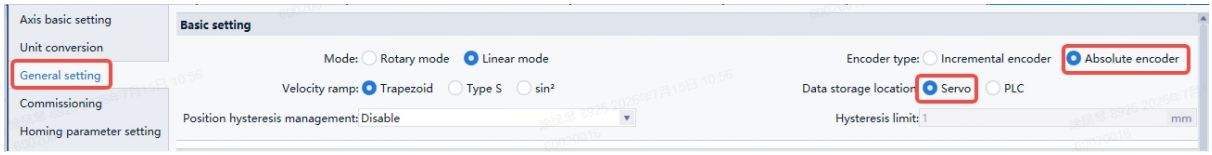
Note:

- For rotary axes, this option does not support the use of the servo drive being set to incremental mode, absolute rotary mode, or single-turn absolute mode.
- For rotary axes, this option can restore the user-defined position offset in the PLC.
- For rotary axes, this option supports multi-turn position retention.

(4) Position data saved on the PLC with the axis being set to rotary mode and the servo drive being set to single-turn mode

This option is designed to accommodate the absolute rotary mode of the servo drive. With this option and in the absolute rotary mode, the pulse position of the servo drive varies within the user-defined range.

Note:



- For rotary axes, this option supports the absolute rotary mode only.
- For rotary axes, this option does not restore the user-defined position offset in the PLC.
- For rotary axes, this option supports single-turn position retention only.

Examples

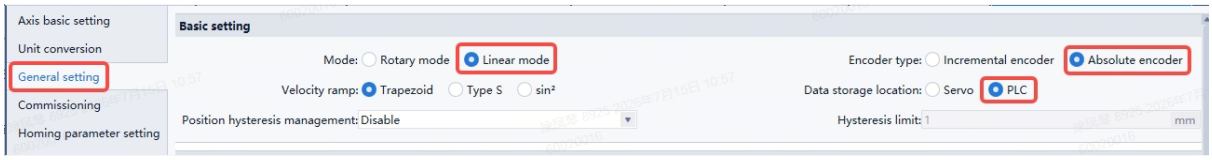
(1) Position data saved on the servo drive

1. Software interface settings
   In the "General setting" for the axis, select "Encoder Type" as "Absolute Encoder" and select "Data storage

location" as "Servo".

2. Servo drive settings

   Connect the encoder of the servo drive to a battery, and set the servo parameter H02.01 to 3 in the servo drive, and then power cycle the servo drive.



3. Servo drive power cycle

   After steps 1 and 2 are complete, compile and run the program. At this point, if the servo drive powers off, the position will be retained after a power cycle.

(2) Position data saved on the PLC with the axis being set to linear mode

1. Software interface settings

   In the "General setting" for the axis, select "Mode" as "Linear mode", select "Encoder type" as "Absolute encoder", and then select "Data storage location" as "PLC".

2. Servo drive settings

   Connect the encoder of the servo drive to a battery, and set the servo parameter H02.01 in the servo drive to 1 or 3, then power on the servo drive.

3. PLC power cycle

   After steps 1 and 2 are complete, compile and run the program. At this point, if the PLC powers off, the position will be retained after a power cycle.

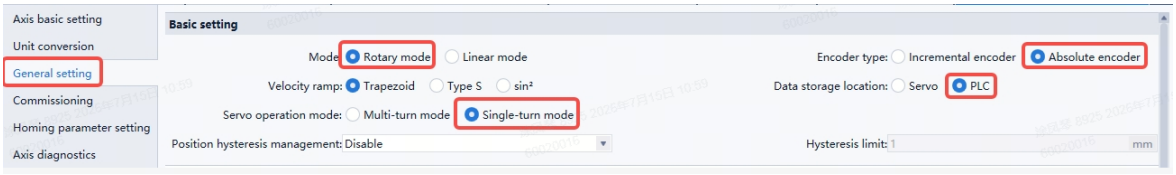
(3) Position data saved on the PLC with the axis being set to rotary mode and the servo drive being set to multi-turn mode

1. Software interface settings

   In the "General setting" for the axis, select "Mode" as "Rotary mode", select "Encoder type" as "Absolute encoder", select "Data storage location" as "PLC", and then select "Servo operation mode" as "Multi-turn mode".

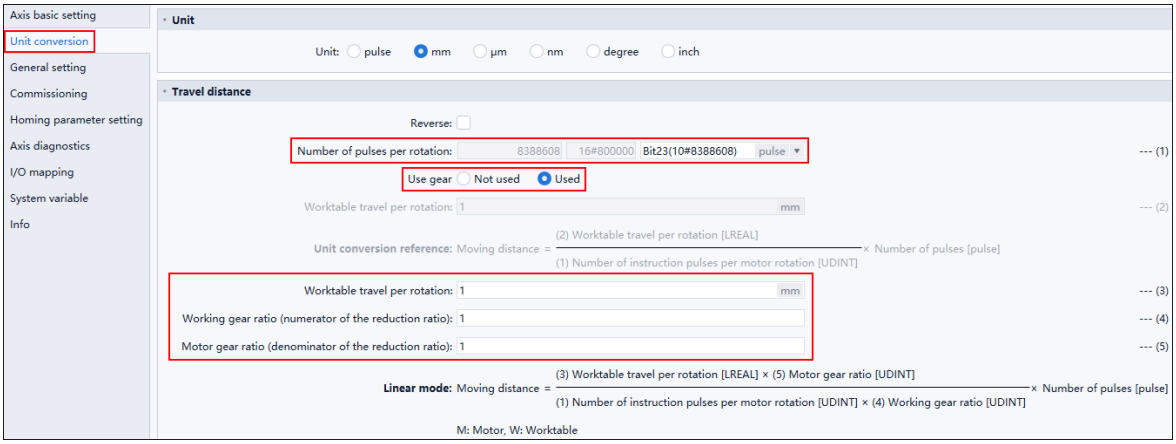
2. Servo drive settings

   Connect the encoder of the servo drive to a battery, and set the servo parameter H02.01 to 1 or 3 in the servo drive, and then power cycle the servo drive.



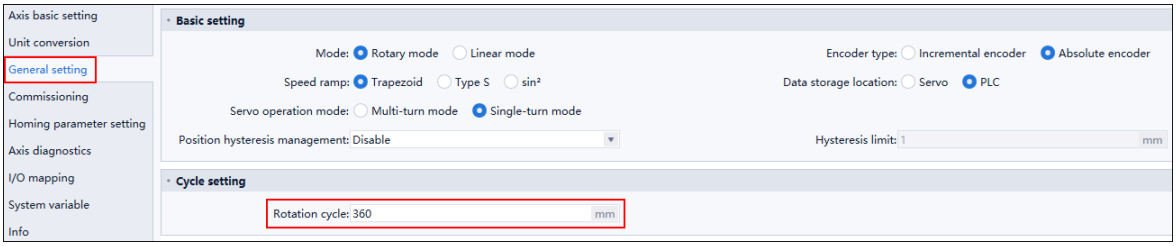
3. PLC power cycle

   After steps 1 and 2 are complete, compile and run the program. At this point, if the PLC powers off, the position will be retained after a power cycle.



(4) Position data saved on the PLC with the axis being set to rotary mode and the servo drive being set to single-turn mode

Under this option, to match the absolute rotary mode of the servo drive, some configurations must be made on both the iFA and the servo drive, and these configurations must be correlated.



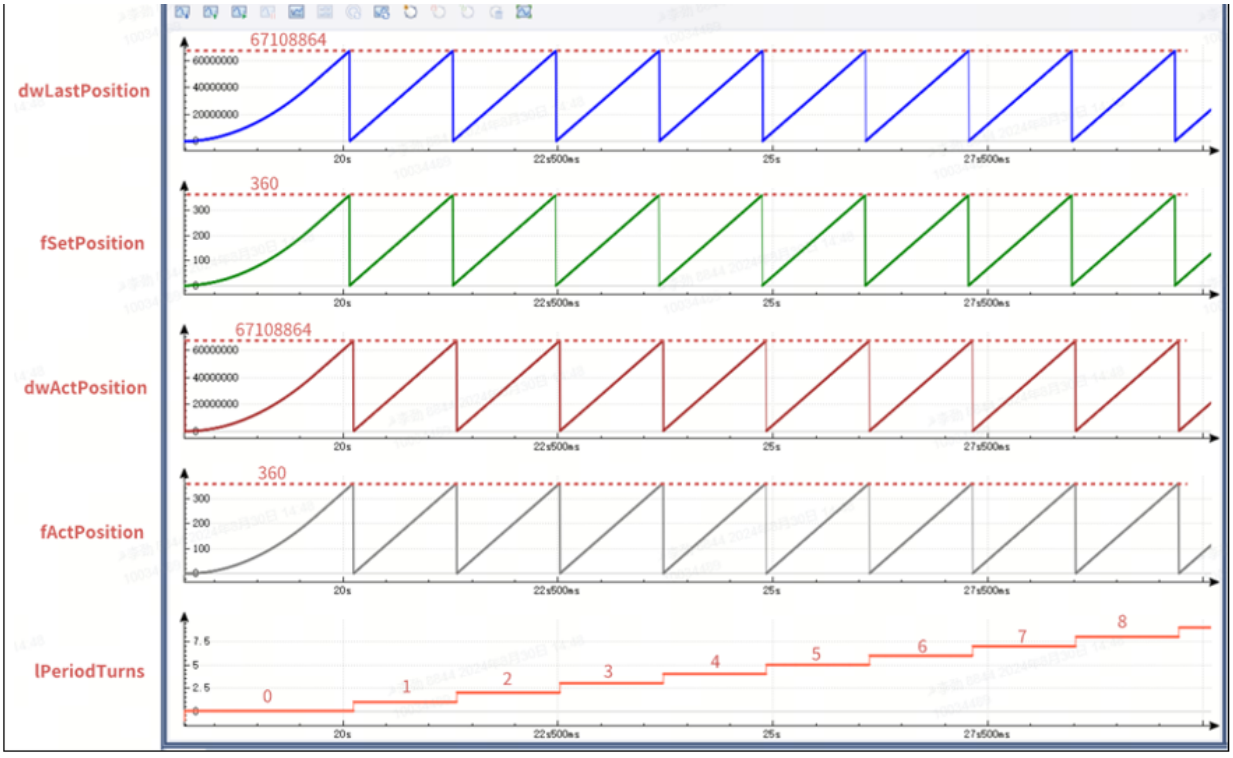
1. Servo drive settings
   - Set H02.01 to 2 (Rotary mode with absolute positioning);
   - Set the number of motor pulses corresponding to one full rotation of the axis by configuring H05.52 and H05.54;
   - If the number of motor pulses corresponding to one full rotation of the axis exceeds 2^31, set the gear ratio H05.07 and H05.09 to proportionally reduce the number of motor pulses, ensuring that the number of motor pulses does not exceed 2^31.
2. Software interface settings
   - In the "General setting" for the axis, select "Mode" as "Rotary mode", select "Encoder type" as "Absolute encoder", select "Data storage location" as "PLC", and then select "Servo operation mode" as "Single-turn mode".

   - In the "Unit conversion" for the axis, set the "Number of pulses per rotation", "Worktable travel per rotation," "Working gear ratio," and "Motor gear ratio."

   - In the "General setting" for the axis, set the "Rotation cycle" to 360°.

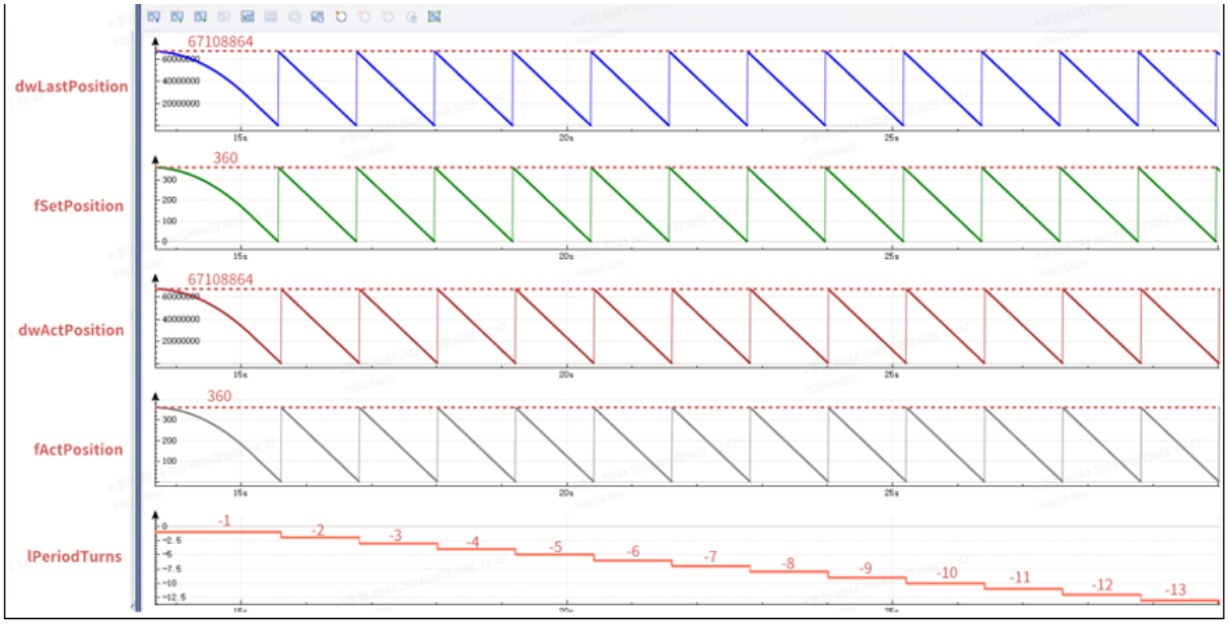
NOTE

The parameters set above have the following relationships with the parameters set in the servo drive:



(H05.52 + H05.54 * 2^32) * H05.09 / H05.07 = (Number of pulses per rotation * Working gear ratio / (Worktable travel per rotation* Motor gear ratio)) * Rotation cycle

3. Example:



The relevant settings on the servo drive and the iFA are as follows:

	Parameter	Value
Servo drive	H02.01	2 (Absolute rotary mode)
	H05.52	2^26 (67108864)
	H05.54	0
	H05.07	1
	H05.09	1
iFA	Rotation cycle	360°
	Number of pulses per rotation	2^23
	Worktable travel per rotation	360°
	Working gear ratio	8
	Motor gear ratio	1

When you set the pulse unit to 2^26 according to the parameters in the preceding table, the servo drive will be reset for another rotation. The diagram for the axis moving in the positive motion is as follows:

The diagram for the axis moving in the negative motion is as follows:

Correspondence between the controller mode and the servo drive's absolute system

The servo drive can be configured with different types of absolute systems, and iFA can be also used to set different axis types and modes for the PLC controller. However, the absolute system in the servo drive may not match the axis type and mode set in the PLC controller, so it is necessary to know their matching relationship to allow users to make different combinations during use. See the following table for details:

Controller Mode (Through iFA)		Servo Drive's Absolute System	Remarks
Rotary mode	Incremental encoder	0 (Incremental mode)	Position reset after power-on
		1 (Absolute linear mode)	After a power cycle, lTurn is reset, and single-turn position is retained.
		3 (Absolute linear mode without encoder overflow alarm)	After a power cycle, lTurn is reset, and single-turn position is retained.
	Absolute encoder + PLC + single-turn mode	2 (Absolute rotary mode)	Infinite rotation can be achieved, but the position offset recorded on the axis will not be restored.
	Absolute encoder + PLC + multi-turn mode	1 (Absolute linear mode)	Position system is restored after a power cycle.
		3 (Absolute linear mode without encoder overflow alarm)	Position system is restored after a power cycle.
	Absolute encoder + servo drive	3 (Absolute linear mode without encoder overflow alarm)	Position system is restored after a power cycle, but if the PLC powers off, the position offset recorded on the axis will not be restored.
Linear mode	Incremental encoder	0 (Incremental mode)	The position data is reset after a power cycle.

Controller Mode (Through iFA)		Servo Drive's Absolute System	Remarks
		1 (Absolute linear mode)	After a power cycle, lTurn is reset, and single-turn position is retained.
		3 (Absolute linear mode without encoder overflow alarm)	After a power cycle, lTurn is reset, and single-turn position is retained.
	Absolute encoder + PLC	1 (Absolute linear mode)	Position system is restored after a power cycle.
		3 (Absolute linear mode without encoder overflow alarm)	Position system is restored after a power cycle.
	Absolute encoder + servo drive	3 (Absolute linear mode without encoder overflow alarm)	Position system is restored after a power cycle, but if the PLC powers off, the position offset recorded on the axis will not be restored.

For incremental encoders, if the PLC powers off, the position offset will not be restored; if servo drive powers off, the position offset will be restored.

Special cases

In some special cases, after the position system is restored, homing must be performed for the servo drive before the axis operation; otherwise, the axis may move unexpectedly.

Position Retention Option	Special Cases
Position data saved on the servo drive	Switched the incremental encoder/absolute encoder.
	Switched the PLC/servo drive.
	Modified the axis parameters Linear Mode/Rotary Mode, Rotation Cycle, Unit Conversion, etc.
	Modified the servo parameters Gear Ratio (6091h), Rotation Direction, etc.
	The motor is not provided with an absolute encoder or has been replaced.
	The absolute encoder is used for the first time or the servo battery is depleted.
	The servo drive abnormality causes loss of absolute position information.
	Position offset is specified and the controller is replaced.
Position data saved on the PLC	Switched the incremental encoder/absolute encoder.

Position Retention Option	Special Cases
	Switched the PLC/servo drive.
	Modified the axis parameters Rotation Cycle, Unit Conversion, etc.
	The servo drive is not in absolute mode or the motor is not an absolute encoder motor.
	Modified the servo parameters Rotary/Linear Mode, Rotation Direction, and Gear Ratio (6091h).
	The absolute encoder is used for the first time or the servo battery is depleted.
	The PLC power-failure retention variable area experiences an exception or is cleared.
	After the PLC powers off, the motor has rotated multiple turns.
	The controller/motor has been replaced.

18.3.3.2 Object Definitions

18.3.3.2.1 Data Object Description

The following data structures are replaced with aliases to standardize the structure and enumeration definitions (PLCOpen standard) and ensure project compatibility. **The existing data type definitions are identical with the newly added data alias type definitions.**

Existing Data Type Definition	Newly Added Data Alias Type Definition	Type
ST_BUS_SERVO_AXIS	MC_BUS_SERVO_AXIS_REF	Structure
MC_HOMING_PARAMETER	MC_HOMING_PARAMETER_REF	Structure
MC_FBERROR	MC_FBERROR_REF	Structure
MC_CAM_TABLE	MC_CAM_TABLE_REF	Structure
MC_CAM_NODE_TYPE	MC_CAM_NODE_TYPE_REF	Structure
MC_CAM_KEY_NODE	MC_CAM_KEY_NODE_REF	Structure
MC_CAM_FITTING_NODE	MC_CAM_FITTING_NODE_REF	Structure
MC_CAM_IN_STATE	MC_CAM_IN_STATE_REF	Structure
S_AXIS_SPACE	MC_AXIS_SPACE_REF	Structure
S_WORK_SPACE	MC_WORK_SPACE_REF	Structure
S_GROUP_CFG	MC_GROUP_CFG_REF	Structure

Existing Data Type Definition	Newly Added Data Alias Type Definition	Type
E_AXES_GROUP_STATE	MC_AXES_GROUP_STATE	Enumeration
E_CIRCE_TYPE	MC_CIRCE_TYPE	Enumeration
E_COORD_TYPE	MC_COORD_TYPE	Enumeration
E_CURVE_TYPE	MC_CURVE_TYPE	Enumeration
E_ERROR_STOP	MC_ERROR_STOP	Enumeration
E_UNIT_SPACE	MC_UNIT_SPACE	Enumeration
E_STOP_MODE	MC_GROUP_STOP_MODE	Enumeration
E_CORNER_TYPE	MC_CORNER_TYPE	Enumeration
E_HOME_MODE	MC_HOME_MODE	Enumeration
E_LOAD_PATH_STATUS	MC_LOAD_PATH_STATUS	Enumeration
E_PATH_CHOICE	MC_PATH_CHOICE	Enumeration
E_PART_STATUS	MC_PART_STATUS	Enumeration

18.3.3.2.2 Single-Axis Data Object Definitions

18.3.3.2.2.1 AXIS_REF: Axis Structure

Variable	Data Type	Description
wAxisStructID	WORD	Axis structure identifier. It represents that this structure is used for a certain type of axis, such as the ECAT control axis, local control axis, ECAT encoder, or local encoder.
AxisID	INT	Axis identifier.
bVirtual	BOOL	Specify whether it is a simulated axis: 0: Real axis. 1: Virtual axis.
bCommunication	BOOL	Specify whether ECAT communication is established.
eAxisState	18.3.3.2.2.5 MC_AXIS_STATE: Axis State Machine Enumeration	Axis state machine.
bAxisEnableState	BOOL	Axis enable signal state, corresponding to the value of 6041 or the enable state of a local axis.

Variable	Data Type	Description
iCommandAbortCount	INT	Command aborted flag. This variable increases when each instruction is executed, and the increased variable value is recorded. When this value changes during execution, it indicates that the FB is aborted.
fTaskCycle	LREAL	Set value of a task cycle.
uiDriveError	UINT	Drive fault code: Correspond to 603F in the object dictionary.
bError	BOOL	Fault status.
dwErrorID	DWORD	Error identifier.
fbeFBError	ARRAY [0..14] OF 18.3.3.2.2.4 MC_FBERROR_REF: Fault Record Structure	Identify log information and record the fault of an instruction.
fMaxDecelDistance	LREAL	Maximum deceleration distance.
fSwLimitDeceleration	LREAL	Deceleration rate in position limit state.
eDirection	18.3.3.2.2.9 MC_DIRECTION: Motion Direction Enumeration	Current motion direction of an axis.
eRampType	18.3.3.2.2.15 MC_RAMPTYPE: Ramp Type Enumeration	Ramp type. 0: Trapezoidal. 1: S-curve. 2: Sin2.
eControllerMode	18.3.3.2.2.7 MC_CONTROLLER_MODE: Controller Mode Enumeration	Axis control mode. 10: Torque control. 9: Velocity control. 8: Position control.
eRealControllerMode	18.3.3.2.2.7 MC_CONTROLLER_MODE: Controller Mode Enumeration	Actual controller mode from an axis: Corresponds to object dictionary 6061.
iMovementType	INT	Specify the axis type. 0: Cyclic rotary mode. 1: Linear mode.
fSetPosition	LREAL	Set position (unit) calculated in this cycle.

Variable	Data Type	Description
fActPosition	LREAL	Actual position (unit).
dwActPosition	DWORD	Encoder value corresponding to the actual position of an axis in the current cycle, corresponding to the value (pulse) of 6064.
lTurn	LINT	Number of turns the axis position parameter exceeds 2^32.
fPositionPeriod	LREAL	Set modulus length (unit)
dwOneTurn	DWORD	Number of pulses per revolution in rotary mode.
dwRatioTechUnitsDenom	DWORD	Denominator of the gear ratio.
fRatioTechUnitsNum	LREAL	Numerator of the gear ratio.
fOffsetPosition	LREAL	Offset between the linear axis position and the servo position. When the MC_SetPosition instruction is executed, this value changes according to the set value and represents the cumulative offset between the set axis position and the servo position.
fOffsetPeriod	LREAL	Position offset in rotary mode. When the MC_SetPosition instruction is executed, this value changes according to the set value.
wAxNo	WORD	Axis number, corresponding to the axis array index value.
fSetVelocity	LREAL	Set velocity (unit) for current cycle.
fActVelocity	LREAL	Actual velocity (unit).
fSetAcceleration	LREAL	Set acceleration (unit) for current cycle.
fActAcceleration	LREAL	Actual acceleration (unit).
fSetJerk	LREAL	Planned jerk.
fSetTorque	LREAL	Set torque (unit) for current cycle.
fActTorque	LREAL	Actual torque (unit).
fFollowingError	LREAL	Converted following error value.
fSWLimitPositive	LREAL	Positive software limit position.
fSWLimitNegative	LREAL	Negative software limit position.
bSWLimitEnable	BOOL	Software position limit enable flag. TRUE: Enabled.
bHWLimitEnable	BOOL	Hardware position limit enable flag. TRUE: Enabled.
lSetTargetPosition	LINT	Target position (unit) of a pulse axis.

Variable	Data Type	Description
bIsDriverHoming	LREAL	Drive homing and pulse homing flag: Drive homing (TRUE during the drive homing); Pulse axis homing (Done flag of the function block after homing delay).
bHomingWithParaFlag	BOOL	PLC homing start flag.
HomeSwitch	BOOL	Home switch: Corresponds to bit2 of object dictionary 60FD.
PositiveLimitSwitch	BOOL	Positive limit switch: Corresponds to bit1 of object dictionary 60FD.
NegativeLimitSwitch	BOOL	Negative limit switch: Corresponds to bit0 of object dictionary 60FD.
LatchInput	BOOL	Touch probe 1 signal switch.
fRefPosition	LREAL	Filtered position, used for the new MasterSource.
fRefVelocity	LREAL	Filtered velocity, used for the new MasterSource and to calculate fRefPosition.
fExternalVel	LREAL	External velocity reference.
bHomed	BOOL	TRUE when the controller home is defined. The absolute encoder saves the PLC mode, with the home being defined by default upon power-up. Even if the bHomed is set to TRUE, the home must be re-defined in any of the following cases. • Changing the position counter or unit conversion setting. For example, the MC_SetPosition or SMC_ChangeGearingRatio instruction is executed, or related variables for position calculation are modified online. • A fault on the servo drive or missing absolute position information due to an operation. For example, the encoder cable is disconnected or the absolute encoder data is cleared.
uiPhysSlaveAddr	UINT	Physical address of the slave corresponding to an axis.
uiAliasSlaveAddr	UINT	Alias address of the slave corresponding to an axis.

18.3.3.2.2.2 AXIS Communication State Machines

Communication Status Value (Decimal)	Description
65535	Initial.
0	Unknown.
1	Initialized.

Communication Status Value (Decimal)	Description
2	Pre-operational.
3	Booting.
4	Safe operating.
20	Operating with the position system not restored.
90	Absolute encoder position system recovering.
95	Incremental encoder position system recovering.
100	Operating with the position system not restored.
1017	Initialization failure.
1018	Pre-operational fault.
1019	Booting fault.
1020	Safe operating fault.
1024	Operating fault.

18.3.3.2.2.3 MC_BUS_SERVO_AXIS_REF: Bus Servo Axis Structure

Example of accessing CIA402 object : The value of the CIA402 object can be obtained from the axis in the following way: Axis.uAxisEtcRT.stBusServoAxis.diEtcDigitalInput.

Variable	Type	Description
uiEtcControlWord	UINT	Control word (6040Hex)
uiEtcTargetPosition	DINT	Target position (607AHex)
uiEtcProfileVelocity	DINT	Target velocity (60FFHex)
iEtcTargetTorque	INT	Target torque (6071Hex)
siEtcModesOfOperation	SINT	Operation mode (6060Hex)
iEtcTouchProbeFunction	UINT	Touch probe function (60B8Hex)
udiEtcMaxProfileVelocity	UDINT	Maximum velocity (607FHex) 100* equivalent
uiEtcForwardTorqueLimit	UINT	Forward torque limit (60E0Hex)
uiEtcBackwardTorqueLimit	UINT	Backward torque limit (60E1Hex)
diEtcDigitalOutput	DINT	Forced digital output (60FEHex sub-index=1)
diEtcPositionOffset	DINT	Position offset (60B0Hex)
diEtcVelocityOffset	DINT	Velocity offset (60B1Hex)
diEtcTorqueOffset	DINT	Torque offset (60B2Hex)

Variable	Type	Description
udiEtcTorqueSlope	UDINT	Torque slope (6087Hex)
udiEtcProfileVelocity	UDINT	Profile velocity (6081Hex)
udiEtcProfileAcceleration	UDINT	Profile acceleration (6083Hex)
udiEtcProfileDeceleration	UDINT	Profile deceleration (6084Hex)
uiEtcErrorCode	UINT	Fault code (603FHex)
uiEtcStatusWord	UINT	Status word (6041Hex)
uiEtcActualPostion	DINT	Actual position (6064Hex)
iEtcActTorque	INT	Actual torque (6077Hex)
siEtcActModeOfOperation	SINT	Operation mode display (6061Hex)
uiEtcTouchProbeStatus	UINT	Touch probe status (60B9Hex)
diEtcTouchProbePosition1R	DINT	Touch probe position 1 rising edge (60BAHex)
diEtcTouchProbePosition1F	DINT	Touch probe position 1 falling edge (60BBHex)
diEtcTouchProbePosition2R	DINT	Touch probe position 2 rising edge (60BCHex)
diEtcTouchProbePosition2F	DINT	Touch probe position 2 falling edge (60BDHex)
diEtcDigitalInput	DINT	Digital input (60FDHex)
diEtcActVelocity	DINT	Actual velocity (606CHex)
diEtcActFollowingError	DINT	Actual following error (60F4Hex)
uiEtcTouchProbeEdgeCounter1R	UINT	Touch probe position 1 rising edge counter (60D5Hex)
uiEtcTouchProbeEdgeCounter1F	UINT	Touch probe position 1 falling edge counter (60D6Hex)
uiEtcTouchProbeEdgeCounter2R	UINT	Touch probe position 2 rising edge counter (60D7Hex)
uiEtcTouchProbeEdgeCounter2F	UINT	Touch probe position 2 falling edge counter (60D8Hex)

18.3.3.2.2.4 MC_FBERROR_REF: Fault Record Structure

In the fbeFBError structure, up to 15 axis fault messages can be recorded, and they are stored in fbeFBError.wID in the order of occurrence. Once the 15 records are occupied, each new fault will overwrite the oldest record. The values stored in fbeFBError.wID correspond to the decimal value of the MC_XXX.ErrorID.

Variable	Data Type	Description
wID	WORD	Fault code.

Variable	Data Type	Description
strErrorInstance	WSTRING[254]	Source of the fault.
tTimeStamp	TIME	Time stamp of the fault occurrence.
eAxisStateAtError	18.3.3.2.2.5 MC_AXIS_STATE: Axis State Machine Enumeration	Axis state at the time of the fault.
eControllerModeAtError	18.3.3.2.2.7 MC_CONTROLLER_MODE: Controller Mode Enumeration	Controller mode at the time of the fault.
uiDriveErrorAtError	UINT	Drive fault code at the fault occurrence.
wCommunicationStateAtError	WORD	Communication state at the time of the fault.

18.3.3.2.2.5 MC_AXIS_STATE: Axis State Machine Enumeration

Variable	Value	Description
AXIS_POWER_OFF	0	Power-off.
AXIS_ERRORSTOP	1	Error stop.
AXIS_STOPPING	2	Decelerating to stop.
AXIS_STANDSTILL	3	Standstill.
AXIS_DISCRETE_MOTION	4	Discrete motion.
AXIS_CONTINUOUS_MOTION	5	Continuous motion.
AXIS_SYNCHRONIZED_MOTION	6	Synchronized motion.
AXIS_HOMING	7	Homing.

18.3.3.2.2.6 MC_BUFFER_MODE: Buffer Mode Enumeration

Variable	Value	Description
mcAborting	0	Start FB immediately.
mcBuffered	1	Start FB after current motion has finished.
mcBlendingLow	2	Blending with the lowest velocity of both FBs.
mcBlendingPrevious	3	Blending with the velocity of the first FB.
mcBlendingNext	4	Blending with the velocity of the second FB.

Variable	Value	Description
mcBlendingHigh	5	Blending with the highest velocity of both FBs.

18.3.3.2.2.7 MC_CONTROLLER_MODE: Controller Mode Enumeration

Variable	Value	Description
MC_CSP	8	CSP (Cyclic synchronous position).
MC_CSV	9	CSV (Cyclic synchronous velocity).
MC_CST	10	CST (Cyclic synchronous torque).

18.3.3.2.2.8 MC_MOVE_MODE: Move Mode Enumeration

Variable	Value	Description
AbsoluteMode	0	Absolute positioning.
RelativeMode	1	Relative positioning.
VelocityMode	2	Velocity control.

18.3.3.2.2.9 MC_DIRECTION: Motion Direction Enumeration

Variable	Value	Description
DIR_SHORTEST	0	Shortest way.
DIR_POSITIVE	1	Positive direction.
DIR_NEGATIVE	2	Negative direction.
DIR_CURRENT	3	Current direction.
DIR_NODIRECTION	4	No direction.
DIR_FASTEST	5	Fastest way.

18.3.3.2.2.10 MC_STOP_MODE: Stop Mode Enumeration

Variable	Value	Description
ImmediateStop	0	The commanded velocity drops directly to 0 from current velocity.
FreeRunStop	1	The axis immediately stops and the servo drive is turned off.

18.3.3.2.2.11 MC_REFERENCE_TYPE: Data Type Enumeration

Variable	Value	Description
mcCommand	0	Commanded position (Value calculated in the previous task cycle, fSavePosition).
mcFeedback	1	Actual position (Value obtained in the same task cycle, fActPosition).
mcLatestCommand	2	Commanded position (Value calculated in the same task cycle, fSavePosition).
mcMasterPhase	3	Phase of the master axis selected when the slave axis starts camming.
mcPositionFilter	4	RefPosition after the MC_PositionFilter instruction is executed.

18.3.3.2.2.12 MC_COMBINE_MODE: Combine Mode Enumeration

Variable	Value	Description
mcAddAxes	0	Addition.
mcSubAxes	1	Subtraction.

18.3.3.2.2.13 MC_HOMING_MODE: Homing Mode Enumeration

Variable	Value	Description
PassHomeSwHomeSwTurn	1	Home switch + Zero switch + Positive/Negative limit. Traverse the home switch, search for the zero, and then reverse at the home.
InHomeSwHomeSwTurn	2	Home switch + Zero switch + Positive/Negative limit. Search for the zero within the home switch, and then reverse at the home.
PassHomeSwHome	3	Home switch + Zero switch + Positive/Negative limit. Traverse the home switch, search for the zero, and then reverse at the limit.
InHomeSw	4	Home switch + Zero switch + Positive/Negative limit. Search for the zero within the home switch, and then reverse at the limit.

Variable	Value	Description
PassLimitSw	5	Zero switch + Positive/Negative limit. Traverse the limit switch and then search for the zero. Homing can be started outside the limit.
HomeSwMaskDistanceHomeSwTurn	6	Home switch + Zero switch + Positive/Negative limit. Homing at home input mask distance, and then reverse at the home.
OnlyLimit	7	Positive/negative limit only, no zero switch.
HomeSwHoldTimeHomeSwTurn	8	Home switch + Positive/negative limit. Start homing after holding time, and reverse at the home.
ZeroSw	9	Zero switch + Positive/Negative limit. Start homing without a home. Homing cannot be started outside the limit.
ZeroPositionPreset	10	Zero position preset.

18.3.3.2.2.14 MC_LIMIT_REVERSE_MODE: Limit Reverse Mode Enumeration

Variable	Value	Description
Errorstop	0	No reverse turn/fault stop.
RevImmediateStop	1	Reverse turn/immediate stop.
RevDeceleration	2	Reverse turn/Deceleration stop.

18.3.3.2.2.15 MC_RAMPTYPE: Ramp Type Enumeration

Variable	Value	Description
TRAPEZ	0	Trapezoidal curve.
CURVE	1	S-curve.
SINSQUARE	2	Sin2 curve.

18.3.3.2.2.16 MC_ZERO_SIGNAL: Zero Signal Enumeration

Variable	Value	Description
ZPhase	0	Z-phase input.
ExternalSignal	1	External home input.

18.3.3.2.2.17 MC_CONTROLLER_MODE_SWITCH: Controller Mode Switch Mode Enumeration

Variable	Value	Description
MC_AUTO	0	Automatic switching.
MC_MANUAL	1	Manual switching.

18.3.3.2.3 Synchronous Axis Data Object Definitions

18.3.3.2.3.1 MC_CAM_TABLE_REF: Cam Table Structure

Variable	Type	Description
strCamTableName	STRING	Name of the cam table.
iNodeType	INT	Node type: 1: Key node. 2: Dense node.
iNodeNumber	UINT	Number of nodes. Up to 65,535 nodes are supported.
pNodePtr	POINTER TO BYTE	Pointer to node data.

18.3.3.2.3.2 MC_CAM_NODE_TYPE_REF: Cam Node Type Structure

Variable	Type	Description
KeyNode	18.3.3.2.3.3 MC_CAM_KEY_NODE_REF: Key Node Structure	Cam curve key node.
FittingNode	18.3.3.2.3.4 MC_CAM_FITTING_NODE_REF: Dense Node Structure	Cam curve dense node.

18.3.3.2.3.3 MC_CAM_KEY_NODE_REF: Key Node Structure

Variable	Type	Description
fPhase	LREAL	Phase (of the master axis) at the node.
fDistance	LREAL	Displacement (of the slave axis position) at the node.
fVel	LREAL	Velocity at the node.

Variable	Type	Description
fAcc	LREAL	Acceleration at the node.
fJerk	LREAL	Jerk at the node.
iCurveType	INT	Curve type: 1: Straight line. 2: Parabolic curve. 3: Cubic curve. 4: Quintic curve. 5: Septic curve. 6: Cosine acceleration curve. 7: Sine acceleration curve. 8: Modified trapezoidal acceleration curve.

18.3.3.2.3.4 MC_CAM_FITTING_NODE_REF: Dense Node Structure

Variable	Type	Description
fPhase	LREAL	Phase (of the master axis) at the node.
fDistance	LREAL	Displacement (of the slave axis position) at the node.

18.3.3.2.3.5 MC_CAM_IN_STATE_REF: Camming State Structure

Variable	Type	Description
strCamTableName	STRING	Name of the cam table.
iMasterID	INT	Master axis identifier.
iSlaveID	INT	Slave axis identifier.
diCamCnt	DINT	Number of camming cycles executed.
diNodeCnt	DINT	Current node index.
fPhase	LREAL	Master axis phase.
fDistance	LREAL	Slave axis displacement.
fPhaseShift	LREAL	Phase shift.
fPhaseVelocity	LREAL	Velocity for phase shifting.
fPhaseAcc	LREAL	Acceleration for phase shifting.

18.3.3.2.3.6 MC_SWITCH_REF: Switch Structure

Variable	Type	Description
fPosition	REAL	Starting position for the output signal ON.
iMode	INT	Specify the switch mode: 0: Disabled. 1: Position based. 2: Time based.
iDirection	INT	Direction.
fParameter	REAL	Position based: ON end position. Time based: ON duration (ms).

18.3.3.2.3.7 MC_OUTMODE: Desynchronization Mode Enumeration

Variable	Value	Description
mcDecelerationStop	0	Deceleration stop.
mcConstantVelocity	1	Constant velocity before desynchronization.
mcImmediateStop	2	Immediate stop after the camming cycle.

18.3.3.2.3.8 MC_MASTER_DIRECTION: Master Axis Motion Direction Enumeration

Variable	Value	Description
CAM_NO_DIRECTION	0	No direction specified. The slave axis follows the master axis regardless of the motion direction of the master axis.
CAM_ABS_POSITIVE	1	Absolute positive direction. The slave axis follows the master axis when the master axis moves in the positive direction, and stops following if the master axis reverses the direction. The master axis must return to positive direction and reach the reversal point for the slave axis to continue following.
CAM_REL_POSITIVE	2	Relative positive direction. The slave axis follows the master axis when the master axis moves in the positive direction, and stops following if the master axis reverses the direction. The master axis must return to positive direction without reaching the reversal point for the slave axis to continue following.
CAM_ABS_NEGATIVE	3	Absolute negative direction. The slave axis follows the master axis when the master axis moves in the negative position, and stops following if the master axis reverses the direction. The master axis must return to negative direction and reach the reversal point for the slave axis to continue following.

Variable	Value	Description
CAM_REL_NEGATIVE	4	Relative negative direction. The slave axis follows the master axis when the master axis moves in the negative direction, and stops following if the master axis reverses the direction. The master axis must return to negative direction without reaching the reversal point for the slave axis to continue following.

18.3.3.2.4 Axis Group Data Object Definitions

18.3.3.2.4.1 AXES_GROUP_REF: Axis Group Structure

Variable	Type	Description
iId	E_GROUP_ID	Axis group type identifier.
iNo	DWORD	Number of an axis group.
bDisableErrorLogging	BOOL	Specify whether to print logged information.
fbeFBError	ARRAY [0..5] OF 18.3.3.2.2.4 MC_FBERROR_REF: Error Record Structure	Error message.
bError	BOOL	Fault status.
iErrorID	DWORD	Fault ID.
eState	18.3.3.2.4.5 MC_AXES_GROUP_STATE: Axis Group State Enumeration	Axis group state machine.
stWorkSpace	18.3.3.2.4.3 MC_WORK_SPACE_REF: Work Space Configuration Structure	Work space configuration.
stAxisSpace	18.3.3.2.4.2 MC_AXIS_SPACE_REF: Logical Axis Configuration Structure	Logical axis configuration.
stCfg	18.3.3.2.4.4 MC_GROUP_CFG_REF: Axis Group State Structure	Axis group state.
eMoveCoord	18.3.3.2.4.7 MC_COORD_TYPE: Coordinate System Type Enumeration	Motion coordinate type.

Variable	Type	Description
ePartStatus	18.3.3.2.4.20 MC_PART_STATUS: Coordinate System Switch Status Enumeration	Coordinate system switch type.
stCmd	ARRAY [0..1] OF S_PNT	Commanded [ACS/PCS] coordinate position, velocity, and acceleration in the current cycle.
stFrontCmd	ARRAY [0..1] OF S_PNT	Commanded [ACS/PCS] coordinate position, velocity, and acceleration in the previous cycle.
stActual	ARRAY [0..1] OF S_PNT	Actual [ACS/PCS] coordinate position, velocity, and acceleration in the current cycle.
stFrontActual	ARRAY [0..1] OF S_PNT	Actual [ACS/PCS] coordinate position, velocity, and acceleration in the previous cycle.
fCmdPathVel	LREAL	Commanded path velocity of the Tool Center Point (TCP) in the Product Coordinate System (PCS).
fCmdPathAcc	LREAL	Commanded path acceleration of the TCP in the PCS.
fActualPathVel	LREAL	Actual path velocity of the TCP in the PCS.
fActualPathAcc	LREAL	Actual path acceleration of the TCP in the PCS.

18.3.3.2.4.2 MC_AXIS_SPACE_REF: Logical Axis Configuration Structure

Variable	Type	Description
iType	ARRAY [0..(GROUP_DEF.AXIS_NUM- 1)] OF E_LOGIC_AXIS_TYPE	Logical axis type.
iAxisNum	INT	Number of logical axes.
stMaxMove	ARRAY [0..(GROUP_DEF.AXIS_NUM- 1)] OF S_TRAN_PLAN	Planned maximum parameter for a logical axis.
fLowCoeff	LREAL	Scaling factor for low-velocity planning.
fDecCoeff	LREAL	Scaling factor for default planning.
fLimitCoeff	LREAL	Scaling factor for early-warning planning.

Variable	Type	Description
fTransfCoeff	LREAL	Transformation coefficient.
fNegativeLimit	ARRAY [0..(GROUP_DEF.AXIS_NUM- 1)] OF LREAL	Negative limit for a logical axis.
fPositiveLimit	ARRAY [0..(GROUP_DEF.AXIS_NUM- 1)] OF LREAL	Positive limit for a logical axis.

18.3.3.2.4.3 MC_WORK_SPACE_REF: Work Space Configuration Structure

Variable	Type	Description
iAxisType	ARRAY[0..GROUP_DEF.AXIS_NUM-1] OF E_LOGIC_AXIS_TYPE	Space axis type.
iAxisNum	INT	Number of axes in an axis group.
iLinAxisNum	INT	Number of moving axes.
iAngAxisNum	INT	Number of orientation axes.
iAuxAxisNum	INT	Number of auxiliary axes.
stBase	S_CARTESIAN	Base coordinate system for an axis group based on the world coordinate system.
stPart	S_CARTESIAN	Current Cartesian part coordinate system.
stPartSet	S_PART_SET	Part coordinate system setting.
fBaseOffset	LREAL	Base offset.
stTool	S_CARTESIAN	Tool coordinate system.
stKin	MC_KIN_REF	Kinematic parameter table.
stPartList	ARRAY[0..GV_GROUP.TOOL_NUM-1] OF S_CARTESIAN	Part coordinate system.
stToolList	ARRAY[0..GV_GROUP.TOOL_NUM-1] OF S_CARTESIAN	Tool coordinate system.
stMaxLinMove	S_TRAN_PLAN	Planned maximum parameter for a moving axis.
stMaxAngMove	S_TRAN_PLAN	Planned maximum parameter for an orientation axis.

Variable	Type	Description
fLowCoeff	LREAL	Scaling factor for low-velocity planning.
fDecCoeff	LREAL	Scaling factor for default planning.
fLimitCoeff	LREAL	Scaling factor for early-warning planning.
fTransfCoeff	LREAL	Transformation coefficient.

18.3.3.2.4.4 MC_GROUP_CFG_REF: Axis Group State Structure

Variable	Type	Description
bCheck	BOOL	Check enable switch.
eCurveType	18.3.3.2.4.8 MC_CURVE_TYPE: Curve Type Enumeration	Trajectory curve type.
fTrajectUnit	LREAL	Trajectory unit.
fOrientUnit	LREAL	Orientation unit.
iMainUnit	18.3.3.2.4.11 MC_UNIT_SPACE: Main Unit Enumeration	Main unit.
fCycleTime	LREAL	Interpolation cycle for an axis group.
aHomeSequence	ARRAY [0..GROUP_DEF.AXIS_NUM-1] OF INT	Homing sequence for an axis group.
aHomeMode	ARRAY [0..GROUP_DEF.AXIS_NUM-1] OF 18.3.3.2.4.14 MC_HOME_MODE: Homing Mode Enumeration	Homing mode for an axis group.
bInput	ARRAY [0..GV_GROUP.IO_NUM-1] OF BYTE	Input channel.
bOutput	ARRAY [0..GV_GROUP.IO_NUM-1] OF BYTE	Output channel.

18.3.3.2.4.5 MC_AXES_GROUP_STATE: Axis Group State Enumeration

Variable	Value	Description
GROUP_ERRORSTOP	0	Axis group error stop.
GROUP_DISABLED	1	Axis group disabled.
GROUP_STOPPING	2	Axis group emergency stop.
GROUP_STANDBY	3	Axis group standby.

Variable	Value	Description
GROUP_MOVING	4	Axis group moving.
GROUP_HOMING	5	Axis group homing.

18.3.3.2.4.6 MC_CIRCE_TYPE: Circular Path Type Enumeration

Variable	Value	Description
BORDER_ARC	0	Circular interpolation is performed through the border point (AuxPoint) from the current position (start point) to the end point (EndPoint).
CENTER_ARC	1	Circular interpolation is performed for circle specified by the center point (AuxPoint) from the current position (start point) to the end point (EndPoint).
RADIUS_ARC	2	Circular interpolation is performed for the circle specified by the radius (AuxPoint) from the current position (start point) to the end point (EndPoint).

18.3.3.2.4.7 MC_COORD_TYPE: Coordinate System Type Enumeration

Variable	Value	Description
ACS	0	Axes coordinate system.
PCS	1	Part coordinate system.
MCS	2	Machine coordinate system.
WCS	3	World coordinate system.

18.3.3.2.4.8 MC_CURVE_TYPE: Curve Type Enumeration

Variable	Value	Description
TRAPEZOIDAL_CURVE	0	Trapezoidal curve.
CUBIC_CURVE	1	Cubic S-curve.
SEVENTH_CURVE	2	Seventh-order S-curve.

18.3.3.2.4.9 MC_ERROR_STOP: Stop Mode Enumeration

Variable	Value	Description
T_ERROR_STOPPED	0	Error stop completed.
T_ERROR_STOPPING	1	In error stop.
T_ERROR_STOP	2	Error stop activated.

18.3.3.2.4.10 MC_TRANSITION_MODE: Transition Mode Enumeration

Variable	Value	Description
TMNone	0	Insert no transition curve.
TMStartVelocity	1	Transition with start velocity reference.
TMCornerDistance	3	Transition with corner distance reference.
TMMaxCornerDeviation	4	Transition with maximum corner deviation reference.
TMDefinedVelocity	10	Transition with commanded maximum velocity.
TMResetAbort	11	Reset to abort.
TMDecAbort	12	Decelerate to abort.

18.3.3.2.4.11 MC_UNIT_SPACE: Main Unit Enumeration

Variable	Value	Description
UNIT_TRAJECT	0	Trajectory.
UNIT_ORIENT	1	Orientation.
UNIT_PERCENT	2	Single-axis scaling factor.

18.3.3.2.4.12 MC_GROUP_STOP_MODE: Stop Mode Enumeration

Variable	Value	Description
DEC_STOP	0	Deceleration stop.
IMMED_STOP	1	Immediate stop.

18.3.3.2.4.13 MC_CORNER_TYPE: Corner Type Enumeration

Variable	Value	Description
NoneCorner	0	No corner.
CornerDistance	1	Corner distance.
MaxCornerDeviation	2	Maximum corner deviation.
CornerRadius	3	Corner radius.

18.3.3.2.4.14 MC_HOME_MODE: Home Mode Enumeration

Variable	Value	Description
MC_SERVO_HOME	0	Servo homing.
MC_PLANNING_HOME	1	PLC homing.

18.3.3.2.4.15 MC_LOAD_PATH_STATUS: Path Status Enumeration

Variable	Value	Description
PATH_ERROR	0	Path error.
PATH_READY	1	Path ready.
PATH_BUSY	2	Path busy.
PATH_ACTIVE	3	Path active.
PATH_ABORT	4	Path aborted.
PATH_DONE	5	Path done.

18.3.3.2.4.16 MC_PATH_CHOICE: Path Choice Enumeration

Variable	Value	Description
SHORT_ARC	0	Short arc.
LONG_ARC	1	Long arc.

18.3.3.2.4.17 MC_CIRC_PATHCHOICE: Circular Path Choice Enumeration

Variable	Value	Description
SHORTPART	0	Short arc.
LONGPART	1	Long arc.

18.3.3.2.4.18 MC_CIRCMODE: Circular Interpolation Mode Enumeration

Variable	Value	Description
BORDER_ARC_TYPE	0	Circular interpolation is performed through the border point (AuxPoint) from the current position (start point) to the end point (EndPoint).
CENTER_ARC_TYPE	1	Circular interpolation is performed for circle specified by the center point (AuxPoint) from the current position (start point) to the end point (EndPoint).
RADIUS_ARC_TYPE	2	Circular interpolation is performed for the circle specified by the radius (AuxPoint) from the current position (start point) to the end point (EndPoint).

18.3.3.2.4.19 MC_COORDSYSTEM: Coordinate System Enumeration

Variable	Value	Description
ACS	0	Axis coordinate system.
PCS	1	Machine coordinate system.

18.3.3.2.4.20 MC_PART_STATUS: Coordinate System Switch Status Enumeration

Variable	Value	Description
PART_SWITCH	0	Coordinate system switching.
PART_SETTING	1	Coordinate system to be set.
PART_ACTIVE	2	Active coordinate system.
PART_SWITCH_FAITH	3	Coordinate system switching failure.

18.3.3.3 Single Axis

18.3.3.3.1 Instruction List

18.3.3.3.2 MC_Power	Enable axis	MotionControl	Library version 1.1.0.0 and later	√	√	√	×

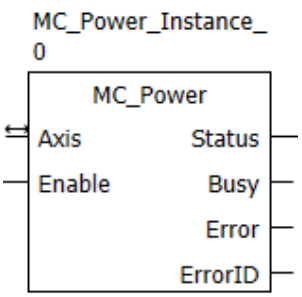
Instruction	Function	Library	Applicable Library Version	Virtual Axis	Bus-Controlled Axis	Local Pulse Axis	Bus Encoder Axis
18.3.3.3.3 MC_ReadActualPosition	Read actual position		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.4 MC_ReadAxisError	Read axis fault		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.5 MC_ReadStatus	Read axis state		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.6 MC_Reset	Reset axis fault		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.7 MC_ReadActualTorque	Read actual torque		Library version 1.1.0.0 and later	×	√	×	×
18.3.3.3.8 MC_ReadActualVelocity	Read actual velocity		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.9 MC_SetPosition	Set current position		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.10 MC_TouchProbe	Touch probe function		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.11 MC_ReadBoolParameter	Read BOOL parameter		Library version 1.1.0.0 and later	√	√	√	×

Instruction	Function	Library	Applicable Library Version	Virtual Axis	Bus-Controlled Axis	Local Pulse Axis	Bus Encoder Axis
18.3.3.3.12 MC_ReadParameter	Read REAL parameter		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.13 MC_VibrationShapping	Vibration shaping		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.14 MC_WriteBoolParameter	Write BOOL parameter		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.15 MC_WriteParameter	Write REAL parameter		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.16 MC_AbortTrigger	Abort triggered operation		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.17 MC_ReadSetPosition	Read set target position		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.18 MC_InPosition	Monitor axis deviation		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.19 MC_ChangeGearingRatio	Set gear ratio and axis type		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.20 MC_SetSoftwareLimits	Set software limits		Library version 1.1.0.0 and later	√	√	√	×

Instruction	Function	Library	Applicable Library Version	Virtual Axis	Bus-Controlled Axis	Local Pulse Axis	Bus Encoder Axis
18.3.3.3.21 MC_ReadDigitalInput	Read digital input		Library version 1.1.0.0 and later	×	√	×	×
18.3.3.3.22 MC_SetControllerMode	Set controller mode		Library version 1.1.0.0 and later	×	√	×	×
18.3.3.3.23 MC_CheckLimits	Check drive reference values against upper limits		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.24 MC_SetTorqueLimit	Set upper torque limit		Library version 1.1.0.0 and later	×	√	×	×
18.3.3.3.25 MC_GetMaxSetAccDec	Read maximum acceleration / deceleration		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.26 MC_GetMaxSetVelocity	Read maximum velocity		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.27 MC_GetTrackingError	Measure actual or maximum tracking error		Library version 1.1.0.0 and later	√	√	×	×
18.3.3.3.28 MC_Halt	Pause axis		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.29 MC_Stop	Stop axis		Library version 1.1.0.0 and later	√	√	√	×

Instruction	Function	Library	Applicable Library Version	Virtual Axis	Bus-Controlled Axis	Local Pulse Axis	Bus Encoder Axis
18.3.3.3.30 MC_Home	Drive homing		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.31 MC_MoveAbsolute	Absolute positioning		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.32 MC_MoveRelative	Relative positioning		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.33 MC_MoveModulo	Positioning in rotary axis mode		Applicable to library version 2.4.0.0 and later	×	√	×	×
18.3.3.3.34 MC_FollowPosition	Specify axis position without any checks		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.35 MC_FollowVelocity	Specify axis velocity without any checks		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.36 MC_FollowPositionVelocity	Specify axis position and velocity without any checks		Library version 2.0.0.0 and later	√	√	√	×
18.3.3.3.37 MC_MoveVelocity	Velocity planning		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.38 MC_Jog	Axis jogging		Library version 1.1.0.0 and later	√	√	√	×

Instruction	Function	Library	Applicable Library Version	Virtual Axis	Bus-Controlled Axis	Local Pulse Axis	Bus Encoder Axis
18.3.3.3.39 MC_TorqueControl	Torque control		Library version 1.1.0.0 and later	×	√	×	×
18.3.3.3.40 MC_ImmediateStop	Immediate stop		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.41 MC_MoveFeed	Interrupt feeding		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.42 MC_SDORead	Read specified SDO data		Library version 2.0.0.0 and later	×	√	×	√
18.3.3.3.43 MC_SDOWrite	Write specified SDO data to input axis		Library version 2.0.0.0 and later	×	√	×	√
18.3.3.3.44 MC_PositionFilter	Position filter		Library version 2.0.0.0 and later	√	√	√	√
18.3.3.3.45 MC_SetOverride	Set override factor		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.46 MC_ResetFollowingError	Reset following error		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.47 MC_HaltSuperImposed	Halt superimposed motion		Library version 1.1.0.0 and later	√	√	√	×



Instruction	Function	Library	Applicable Library Version	Virtual Axis	Bus-Controlled Axis	Local Pulse Axis	Bus Encoder Axis
18.3.3.3.48 MC_MoveSuperImposed	Superimposed motion		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.49 MC_MoveContinuousAbsolute	Move to a specified absolute position ending with the specified velocity		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.50 MC_MoveContinuousRelative	Move to a specified relative position ending with the specified velocity		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.51 MC_CheckAxisCommunication	Check axis communication		Library version 1.1.0.0 and later	×	√	×	×
18.3.3.3.52 MC_Inch	Axis inching		Library version 1.1.0.0 and later	√	√	√	×
18.3.3.3.53 MC_Homing	PLC homing		Library version 1.1.0.0 and later	×	√	×	×
18.3.3.3.54 MC_HomingWithParameter	PLC homing with parameters		Library version 1.1.0.0 and later	×	√	×	×
18.3.3.3.55 MC_SyncMoveVelocityCSV	Velocity control with adjustable pulse width		Library version 1.1.0.0 and later	×	√	√	×

Instruction	Function	Library	Applicable Library Version	Virtual Axis	Bus-Controlled Axis	Local Pulse Axis	Bus Encoder Axis
18.3.3.3.56 MC_BacklashCompensate	Backlash compensation		Library version 1.1.0.0 and later	×	√	√	×
18.3.3.3.57 MC_LeadScrewCompensate	Leadscrew pitch error compensation		Library version 1.1.0.0 and later	×	√	√	×
18.3.3.3.58 MC_MoveAdditive	Add a distance to the last specified target position		Library version 2.3.0.0 and later	√	√	√	×
18.3.3.3.59 MC_GetGearingRatio	Get the gear ratio, rotation cycle, and motion type		Applicable to library version 2.4.0.0 and later	√	√	√	×

18.3.3.3.2 MC_Power

This instruction enables an axis.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_Power	Enable axis		MC_Power_Instance_0(Axis :=, Enable :=, Status =>, Busy =>, Error =>, ErrorID =>);

- **Related variables**

  In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Enable	Enable	BOOL	TRUE, FALSE	FALSE	TRUE: Enabled; FALSE: Disabled

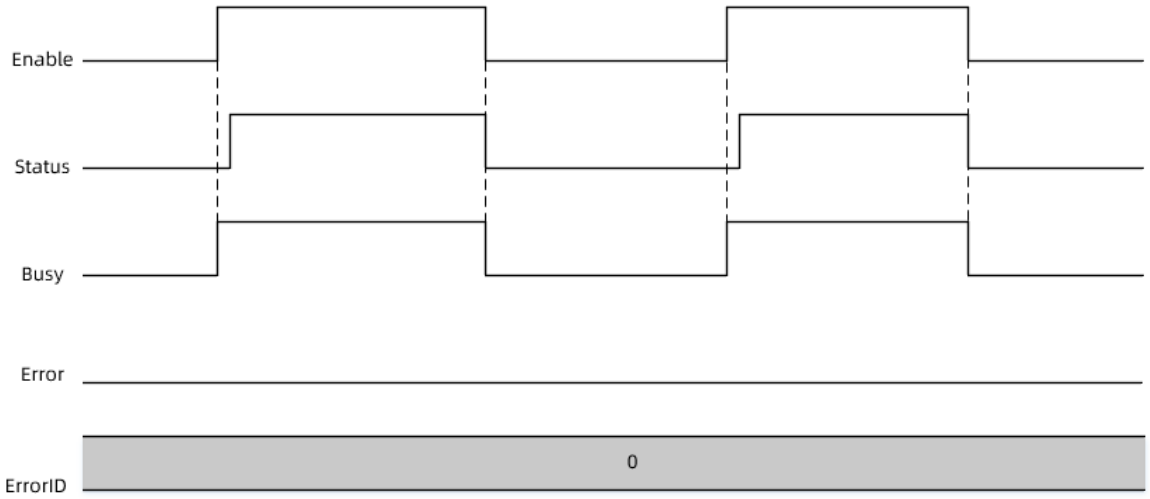
Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Status	Ready for operation	BOOL	TRUE, FALSE	FALSE	TRUE when the axis is enabled.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs in the function block.

- **Function**

  Bus-controlled axis:

  - When the input parameter Enable is set to TRUE, the axis is enabled, and axis control can be performed when the axis is ready for operation. When the input parameter Enable is set to FALSE, the ready status is cleared. You cannot execute any motion control instructions when the axis is disabled. However, you can execute non-motion control instructions such as MC_Power, MC_Reset, and MC_SetPosition.
  - If a power failure occurs during the execution, the axis state will be ErrorStop, and the function block will output a fault code.
  - When the axis state is ErrorStop, it cannot be switched to StandStill if this instruction is re-executed. You must execute the MC_Reset instruction to clear the error message.
  - This instruction can be used for control axes. If it is executed on an encoder axis, the function block will report a fault.
  - Multiple identical instances can be triggered simultaneously on the same axis, and the enable status depends on the input parameter Enable of the last triggered function block in the user program.



Local pulse axis:

- This instruction can be used for local pulse axes.

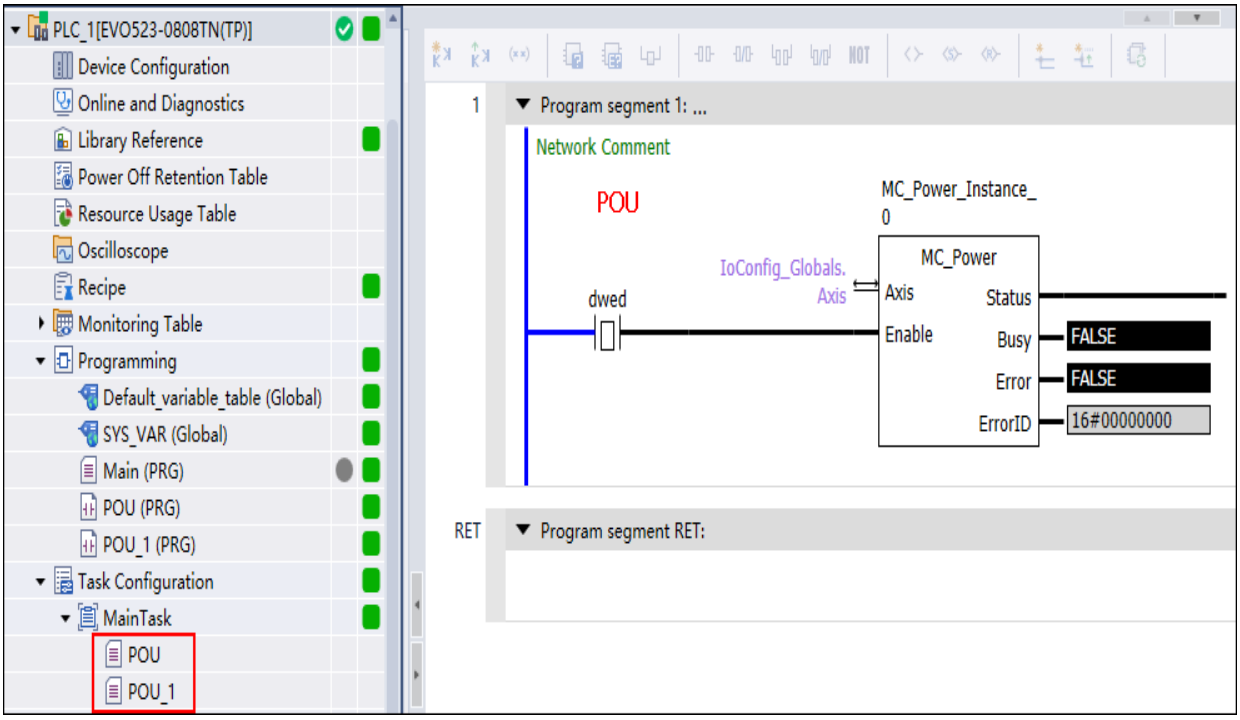
- **Timing diagram**

  When the input parameter Enable is set to TRUE, the output parameter Busy shows the value TRUE; when the axis is ready for operation, the output parameter Status shows the value TRUE.

  When the input parameter Enable is set to FALSE, the output parameter Busy shows the value FALSE; the ready status is cleared; the output parameter Status shows the value FALSE.

- **Re-execution of motion control instructions**

  You cannot re-execute motion control instructions with an input parameter Enable.



- **Multiple execution of motion control instructions**

  When multiple MC_Power instructions are executed in a cycle, the last MC_Power instruction takes priority.

- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

- **Precautions**
  - In the case where the axis-bound servo cannot be enabled:
    1. Check if the variable bound to the address in the program is duplicated with the address in the I/O mapping area of the PDO.
    2. Check if the configured PDOs are valid and within limits.
  - When the input parameter Enable is set to TRUE, the output parameter Status will not show the value TRUE until the servo operation is complete. Perform any axis operations only after the output parameter Status shows the value TRUE.
  - In field applications, it is not recommended to place the MC_Power instruction in multiple POUs:

If the MC_Power instruction in POU1 is triggered but the one in POU is not triggered, the axis may be disabled during the program execution.

18.3.3.3.3 MC_ReadActualPosition

This instruction reads the actual position of an axis.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_ReadActualPosition	Read actual axis position	MC_ReadActualPosition_Instance_0 MC_ReadActualPosition Axis Enable Valid Busy Error ErrorID Position Turns	MC_ReadActualPosition_Instance_0(Axis :=, Enable :=, Valid =>, Busy =>, Error =>, ErrorID =>, Position =>, Turns =>);

- **Related variables**

  In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Enable	Enable	BOOL	TRUE, FALSE	FALSE	TRUE: Enabled. FALSE: Disabled.

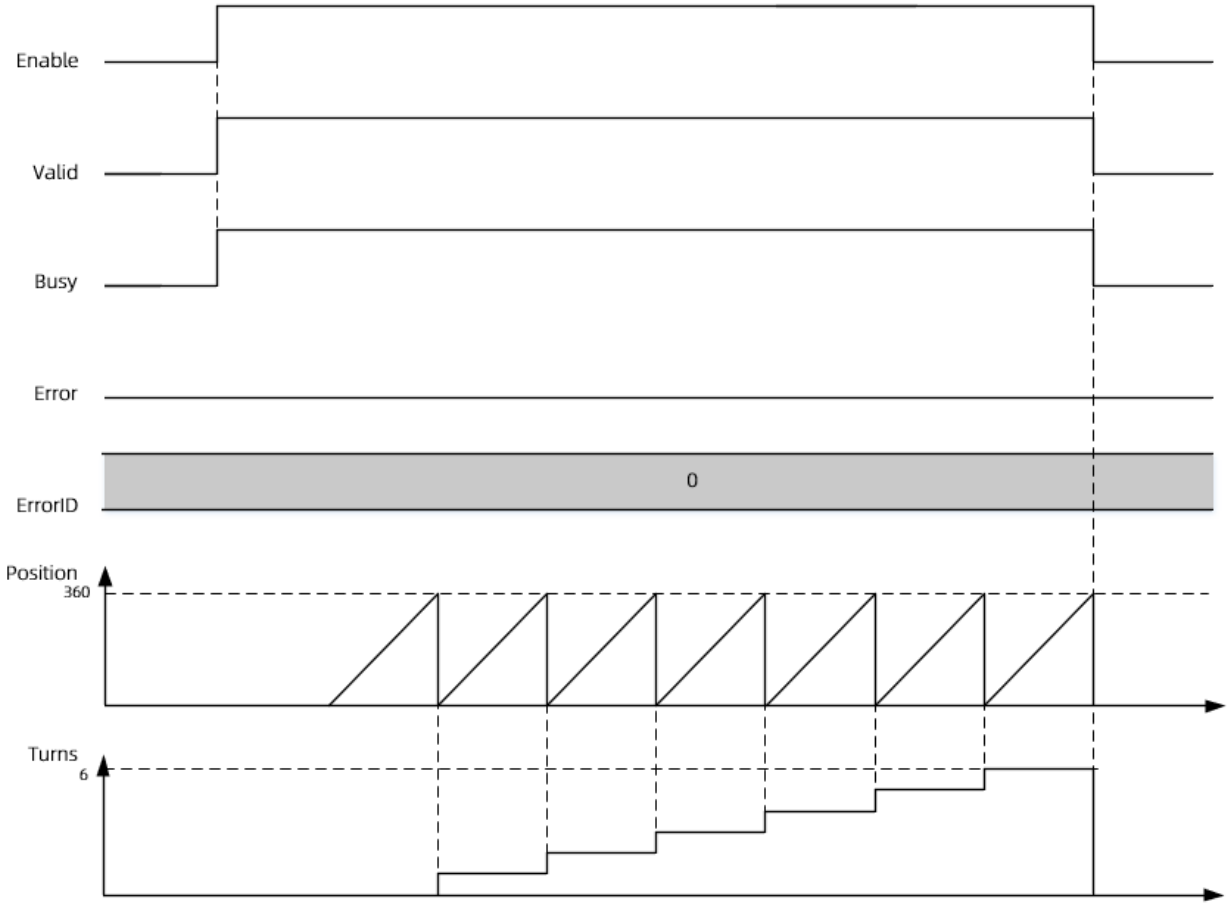
Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Valid	Valid output	BOOL	TRUE, FALSE	FALSE	TRUE when there is a valid output from the function block.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs in the function block.
Position	Axis position	LREAL	-	0	Return to the axis position [user unit].
Turns	Number of turns	DINT	-	0	Number of turns in rotary axis mode.

- **Function**

  Bus-controlled axis:

  - This instruction is a function block controlled by the Enable signal level. When the input parameter Enable is set to TRUE, the instruction reads the actual position of an axis. This instruction can be executed repeatedly without affecting each other. Note: Multiple different instantiated function blocks



of this instruction can be executed simultaneously, instead of multiple identical instantiated function blocks.

- When the axis is in abnormal communication, this instruction issues a fault message with a fault code. After normal communication is recovered, the fault will be automatically cleared.

Local pulse axis:

- This instruction can be used for local pulse axes.

- **Timing diagram**
  - When the input parameter Enable is set to TRUE, the output parameter Busy shows the value TRUE.
  - When the output parameter Valid is set to TRUE, it indicates that the output parameter Position is a valid value.
  - In rotary axis mode, the output parameter Turns indicates the number of turns.

- **Re-execution of motion control instructions**

  You cannot re-execute motion control instructions with an input parameter Enable.

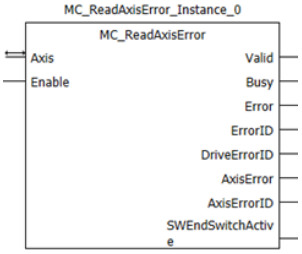
- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

- **Precautions**

  Similarly, other instructions reading related motion parameters also issue fault messages due to abnormal communication.

Although these instructions are executed when the Enable is set to TRUE, if a fault message is still issued after the axis fault is cleared, reset the Enable and then re-trigger it to re-execute the instructions.



The instruction MC_Power automatically clears faults without the above operations.

18.3.3.3.4 MC_ReadAxisError

This instruction reads general faults (associated with axis, drive, communication, etc.).

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_ReadAxisError	Read axis fault		MC_ReadAxisError_Instance_0(Axis :=, Enable :=, Valid =>, Busy =>, Error =>, ErrorID =>, DriveErrorID =>, AxisError => , AxisErrorID =>, SWEndSwitchActive =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Enable	Enable	BOOL	TRUE, FALSE	FALSE	TRUE: Enabled. FALSE: Disabled.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Valid	Valid output	BOOL	TRUE, FALSE	FALSE	TRUE when there is a valid output from the function block.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs in the function block.
DriveErrorID	Drive fault code	DWORD	-	0	A drive fault code is displayed.
AxisError	Axis fault flag	BOOL	TRUE, FALSE	FALSE	TRUE when an axis fault occurs.
AxisErrorID	Axis fault code	DWORD	-	0	An axis fault code is returned.
SWEndSwitchActive	Software limit switch active	BOOL	TRUE, FALSE	FALSE	Check the state of the software limit switch. TRUE: The position is outside the software limit. FALSE: The position is within the software limit.

- **Function**

  Bus-controlled axis:

  - This instruction is a function block controlled by the Enable signal level. When the input parameter Enable is set to TRUE, it reads the fault code from the drive (the value of PDO object 603F) or from the axis (range 10#6000-10#6018)(see 18.3.3.8 Fault Codesfor details). The fault codes from other function blocks cannot be read by this instruction and must be obtained by monitoring the axis member Axis.fbeFBError[0..14] (18.3.3.2.2.4 MC_FBERROR_REF: Fault Record Structure).
  - Multiple instances of this instruction can be used simultaneously without interfering with each other. Note: Multiple different instantiated function blocks of this instruction can be executed simultaneously, instead of multiple identical instantiated function blocks.
  - When the axis is in abnormal communication, this instruction issues a fault message with a fault code. After normal communication is recovered, the fault will be automatically cleared.

  Local pulse axis:

  - This instruction can be used for local pulse axes.

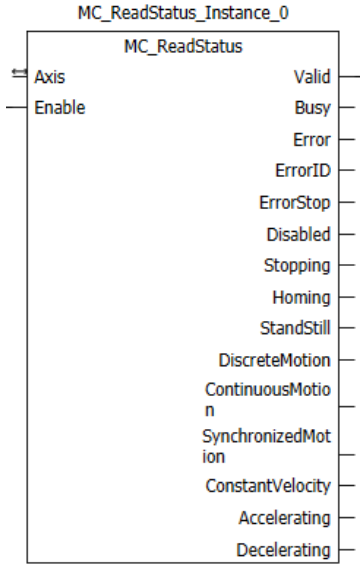
- **Timing diagram**

  When the input parameter Enable is set to TRUE, the output parameter Busy shows the value TRUE. When the output parameter Valid is set to TRUE, it indicates that the output parameters are valid.

  If an axis fault or drive fault occurs during the instruction execution, the axis fault code or drive fault code will be output to the AxisErrorID or DriverErrorID.

- **Re-execution of motion control instructions**

  You cannot re-execute motion control instructions with an input parameter Enable.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.3.5 MC_ReadStatus

This instruction reads the axis state.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_ReadStatus	Read axis state		MC_ReadStatus_Instance_0(Axis :=, Enable :=, Valid =>, Busy =>, Error =>, ErrorID =>, ErrorStop =>, Disabled =>, Stopping =>, Homing =>, StandStill =>, DiscreteMotion =>, ContinuousMotion =>, SynchronizedMotion =>, ConstantVelocity =>, Accelerating =>, Decelerating =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Enable	Enable	BOOL	TRUE, FALSE	FALSE	TRUE: Enabled. FALSE: Disabled.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Valid	Valid output	BOOL	TRUE, FALSE	FALSE	TRUE when there is a valid output from the function block.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs in the function block.
ErrorStop	Error stop	BOOL	TRUE, FALSE	FALSE	TRUE: The axis stops due to a fault.
Disabled	Disabled	BOOL	TRUE, FALSE	FALSE	TRUE: The axis is disabled.
Stopping	Stopping	BOOL	TRUE, FALSE	FALSE	TRUE: The axis is decelerating to stop.
Homing	Homing	BOOL	TRUE, FALSE	FALSE	TRUE: The axis is being homed.
StandStill	Standstill	BOOL	TRUE, FALSE	FALSE	TRUE: The axis is standstill.
DiscreteMotion	Discrete motion	BOOL	TRUE, FALSE	FALSE	TRUE: The axis is in discrete motion.
ContinuousMotion	Continuous motion	BOOL	TRUE, FALSE	FALSE	TRUE: The axis is in continuous motion.
SynchronizedMotion	Synchronized motion	BOOL	TRUE, FALSE	FALSE	TRUE: The axis is in synchronized motion.
ConstantVelocity	Constant velocity	BOOL	TRUE, FALSE	FALSE	TRUE: The axis moves at constant velocity.
Accelerating	Accelerating	BOOL	TRUE, FALSE	FALSE	TRUE: The axis is accelerating.
Decelerating	Decelerating	BOOL	TRUE, FALSE	FALSE	TRUE: The axis is decelerating.

- **Function**

Bus-controlled axis:

- This instruction is a function block controlled by the Enable signal level. When the input parameter Enable is set to TRUE, the instruction reads the axis state. This instruction can be executed repeatedly without affecting each other. Note: Multiple different instantiated function blocks of this instruction can be executed simultaneously, instead of multiple identical instantiated function blocks.
- When the axis is in abnormal communication, this instruction issues a fault message with a fault code.

Local pulse axis:

- This instruction can be used for local pulse axes.

- **Timing diagram**

  The MC_ReadStatus instruction reads the axis state. It is enabled through the Enable signal level. This instruction can be executed repeatedly without affecting each other.

  When the input parameter Enable is set to TRUE, the output parameter Busy shows the value TRUE. When the output parameter Valid is set to TRUE, it indicates that the other output parameters are valid.

  When the axis is disabled, the axis state machine is in the Disabled state.

  When both MC_Power.Enable and MC_Power.Status are set to TRUE, the axis state machine is in the StandStill state.

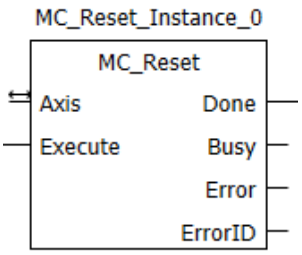
  When the MC_MoveVelocity instruction is executed, the axis state machine is in the ContinuousMotion state.

  When the MC_ImmediateStop instruction is executed, the axis state machine is in the ErrorStop state.

  When the MC_Reset is executed and the MC_Power.Status is set to TRUE, the axis state machine is in the StandStill state.

- **Re-execution of motion control instructions**

  You cannot re-execute motion control instructions with an input parameter Enable.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.3.6 MC_Reset

This instruction resets axis faults.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_Reset	Reset axis faults		MC_Reset_Instance_0(Axis :=, Execute := , Done =>, Busy =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	The function block is executed on a rising edge of this input variable.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs in the function block.

- **Function**

  Bus-controlled axis:

  - This instruction resets communication faults, some servo faults (not associated with restart upon power failure), and axis state faults.
  - This instruction starts fault reset for the specified axis on a rising edge of the input variable Execute. Fault reset is performed regardless of the current axis state. If the reset is successful, the output parameter Done is set to TRUE; otherwise, the output parameter Error is set to TRUE.
  - This instruction only clears faults that occur on a rising edge of the input parameter Execute, but does not clear faults that occur during fault clearing.
  - If there is a drive fault that cannot be cleared by this instruction, restart the servo drive. If the fault is still not cleared, see the guide for the corresponding servo model for remedies.
  - If this instruction is triggered without any axis fault, the output parameter Done is directly set to TRUE.
  - This instruction resets axis faults or FBError except for faults that cannot be cleared as indicated in the servo related documentation.
  - After the instruction has been executed successfully, the axis state switches to Standstill if the current drive is enabled; the axis state switches to Disabled if the drive is not enabled.

  Local pulse axis:

  - This instruction can be used for local pulse axes.

- **Timing diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Done of the function block indicates that the instruction has been executed successfully, and the parameter Busy indicates that the current function block is being executed.

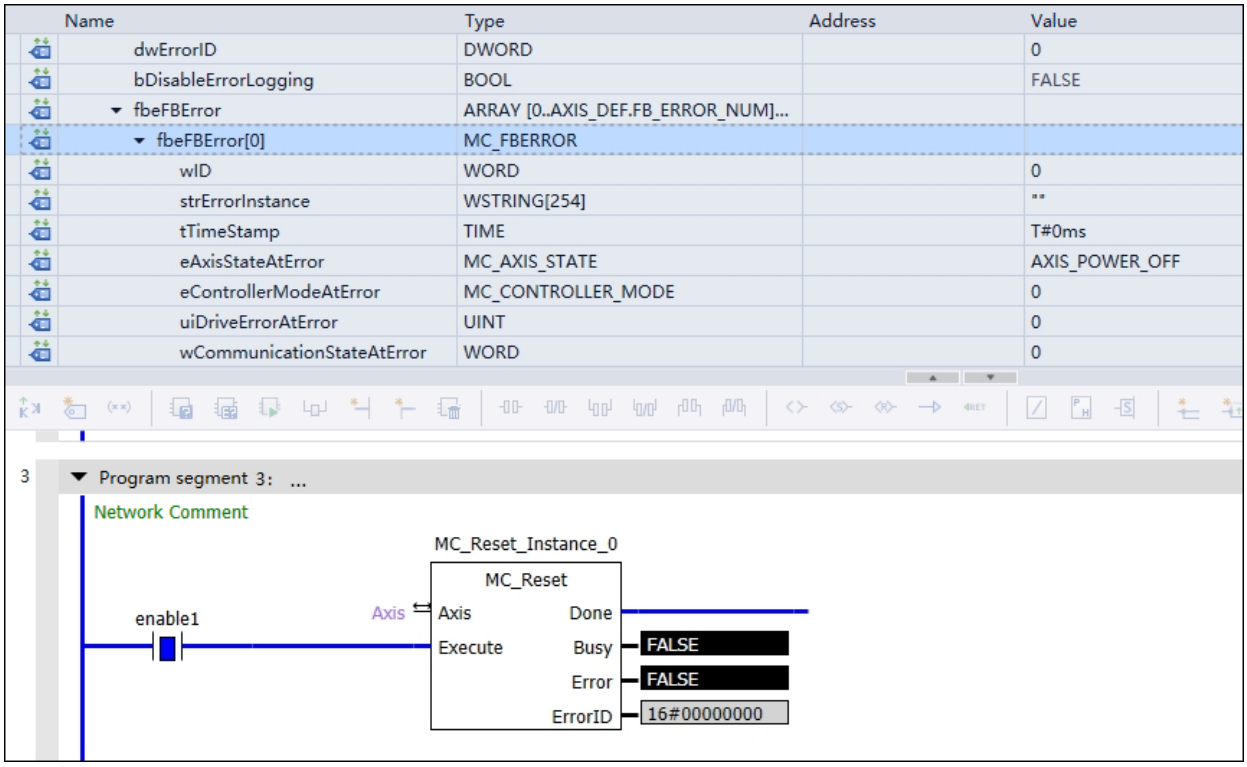
  After this instruction is called, the output parameter Busy becomes TRUE on a rising edge of Execute. After successful reset, the output parameter Done is set to TRUE.

  The following is a timing diagram for calling the MC_Reset instruction to reset the axis fault.

- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

- **Precautions**
  - Fault clearing with this instruction may require more than one control cycle.
  - Execute this instruction only after you confirm that the axes have stopped completely.
- **Example**
  - Add a new watch table to monitor the variables bDisableErrorLogging and fbeFBError.
  - The parameter bDisableErrorLogging is set to FALSE by default. When this parameter is set to TRUE, any instruction faults are not logged in FBError.
  - You can find up to 15 faults by expanding the parameter FBError. No more faults or repeated faults are logged.



Any faults associated with the MC_MoveAbsolute instruction will be logged in fbeFBError[0], where strErrorInstance indicates the location of the fault source, and tTimeStamp records the system time of the fault occurrence.

wID "101D" corresponds to the fault code “101D0BC0” returned by the instruction, where the last four digits “0BC0” indicate the fault cause. To know more information about faults in the FBError, see the Fault Codes.

When the MC_Reset instruction is executed, the axis faults and all faults in FBError will be cleared.

18.3.3.3.7 MC_ReadActualTorque

This instruction reads the value of the current actual torque of an axis.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_ReadActualTorque	Read actual torque	MC_ReadActualTorque_Instance_0 MC_ReadActualTorque Axis Enable Valid Busy Error ErrorID Torque	MC_ReadActualTorque_Instance_0(Axis :=, Enable :=, Valid =>, Busy =>, Error =>, ErrorID =>, Torque =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Enable	Enable	BOOL	TRUE, FALSE	FALSE	TRUE: Enabled. FALSE: Disabled.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Valid	Valid output	BOOL	TRUE, FALSE	FALSE	TRUE when there is a valid output from the function block.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs in the function block.
Torque	Torque	LREAL	-	-	A torque value (unit: 0.1%) is returned.

- **Function**

  Bus-controlled axis:

  - This instruction is a function block controlled by the Enable signal level. When the input parameter Enable is set to TRUE, the instruction reads the current torque value in the drive. This instruction can be executed repeatedly without affecting each other. Resetting the Enable value will invalidate the output data. Note: Multiple different instantiated function blocks of this instruction can be executed simultaneously, instead of multiple identical instantiated function blocks.
  - When the parameter Valid is set to TRUE, the returned torque value is a valid signed number.
  - When the axis is in abnormal communication, this instruction issues a fault message with a fault code.

  Local pulse axis:

  - This instruction cannot be used for local pulse axes.

- **Timing diagram**

  When the input parameter Enable is set to TRUE, the output parameter Busy shows the value TRUE. When the output parameter Valid is set to TRUE, it indicates that the output parameter Torque is valid.

- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.3.8 MC_ReadActualVelocity

This instruction reads the actual velocity of an axis.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_ReadActualVelocity	Read actual velocity	MC_ReadActualVelocity_Instance_0 MC_ReadActualVelocity Axis Enable Valid Busy Error ErrorID Velocity	MC_ReadActualVelocity_Instance_0(Axis :=, Enable :=, Valid =>, Busy =>, Error =>, ErrorID =>, Velocity =>);

- **Related variables**

  In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Enable	Enable	BOOL	TRUE, FALSE	FALSE	TRUE: Enabled. FALSE: Disabled.

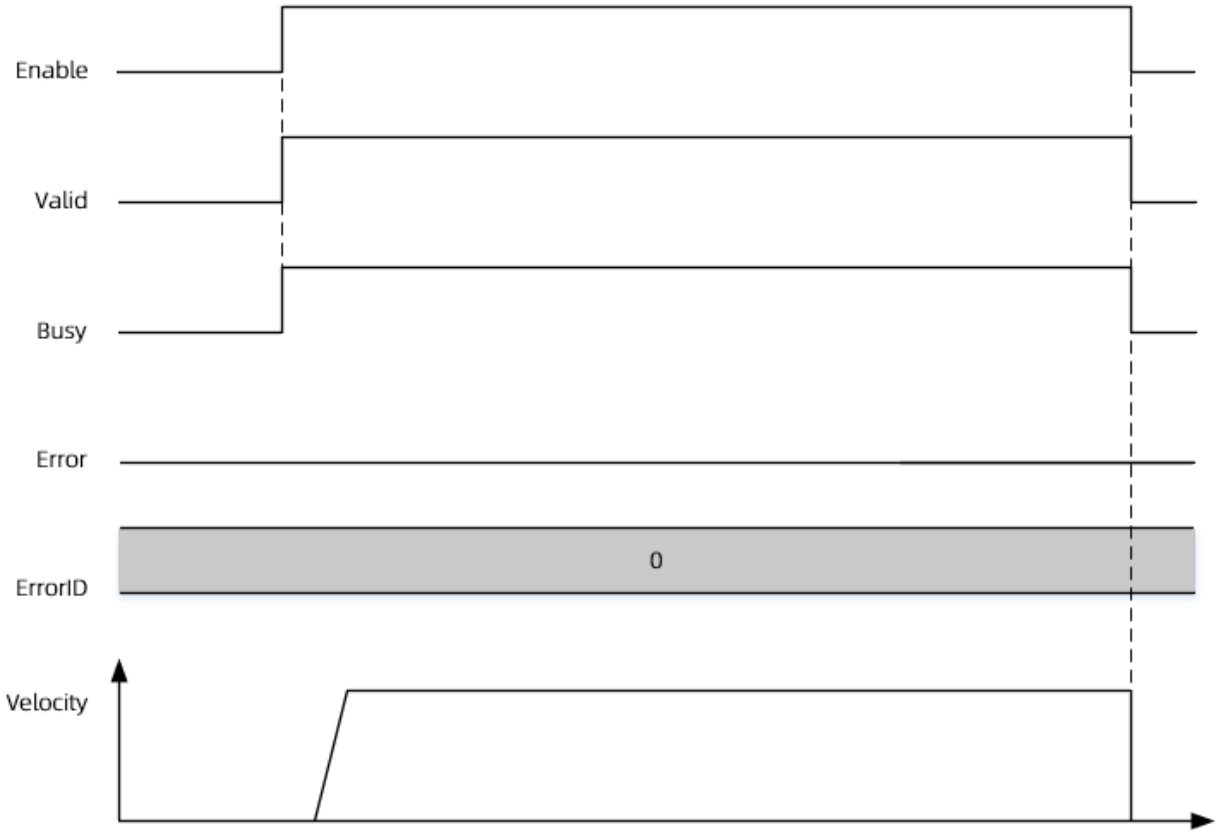
Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Valid	Valid output	BOOL	TRUE, FALSE	FALSE	TRUE when there is a valid output from the function block.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs in the function block.
Velocity	Velocity	LREAL	-	0	Obtained velocity value [u/s] of the axis.

- **Function**

  Bus-controlled axis:

  - This instruction is a function block controlled by the Enable signal level. When the input parameter Enable is set to TRUE, the instruction reads the current velocity of the specified axis. This instruction can be executed repeatedly. Resetting the Enable value will invalidate the output data. Note: Multiple different instantiated function blocks of this instruction can be executed simultaneously, instead of multiple identical instantiated function blocks.
  - When the axis is in abnormal communication, this instruction issues a fault message with a fault code.



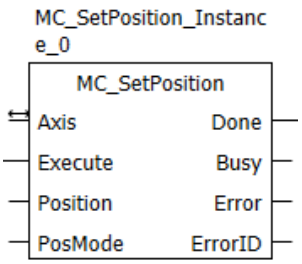
Local pulse axis:

◦ This instruction can be used for local pulse axes.

- **Timing diagram**

  When the input parameter Enable is set to TRUE, the output parameter Busy shows the value TRUE, indicating the current function block is being executed.

  When the output parameter Valid is set to TRUE, it indicates that the output parameter Velocity is valid.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.3.9 MC_SetPosition

This instruction sets the current position of an axis.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_SetPosition	Set current position		MC_SetPosition_Instance _0(Axis :=, Execute :=, Position :=, PosMode :=, Done =>, Busy =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	The function block is executed on a rising edge of this input variable.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Position	Axis position	LREAL	-	0	Set the target position [u] of the axis. Note: In rotary axis mode, there are two modes for the target position: 1. Absolute position: This parameter value is processed as the remainder of the specified Position value divided by the rotation cycle. 2. Relative position: This parameter value is processed as the current position + the remainder of the specified Position value divided by the rotation cycle, ignoring the multi-turn displacement.
PosMode	Position mode	BOOL	TRUE, FALSE	FALSE	TRUE: Relative position. FALSE: Absolute position.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

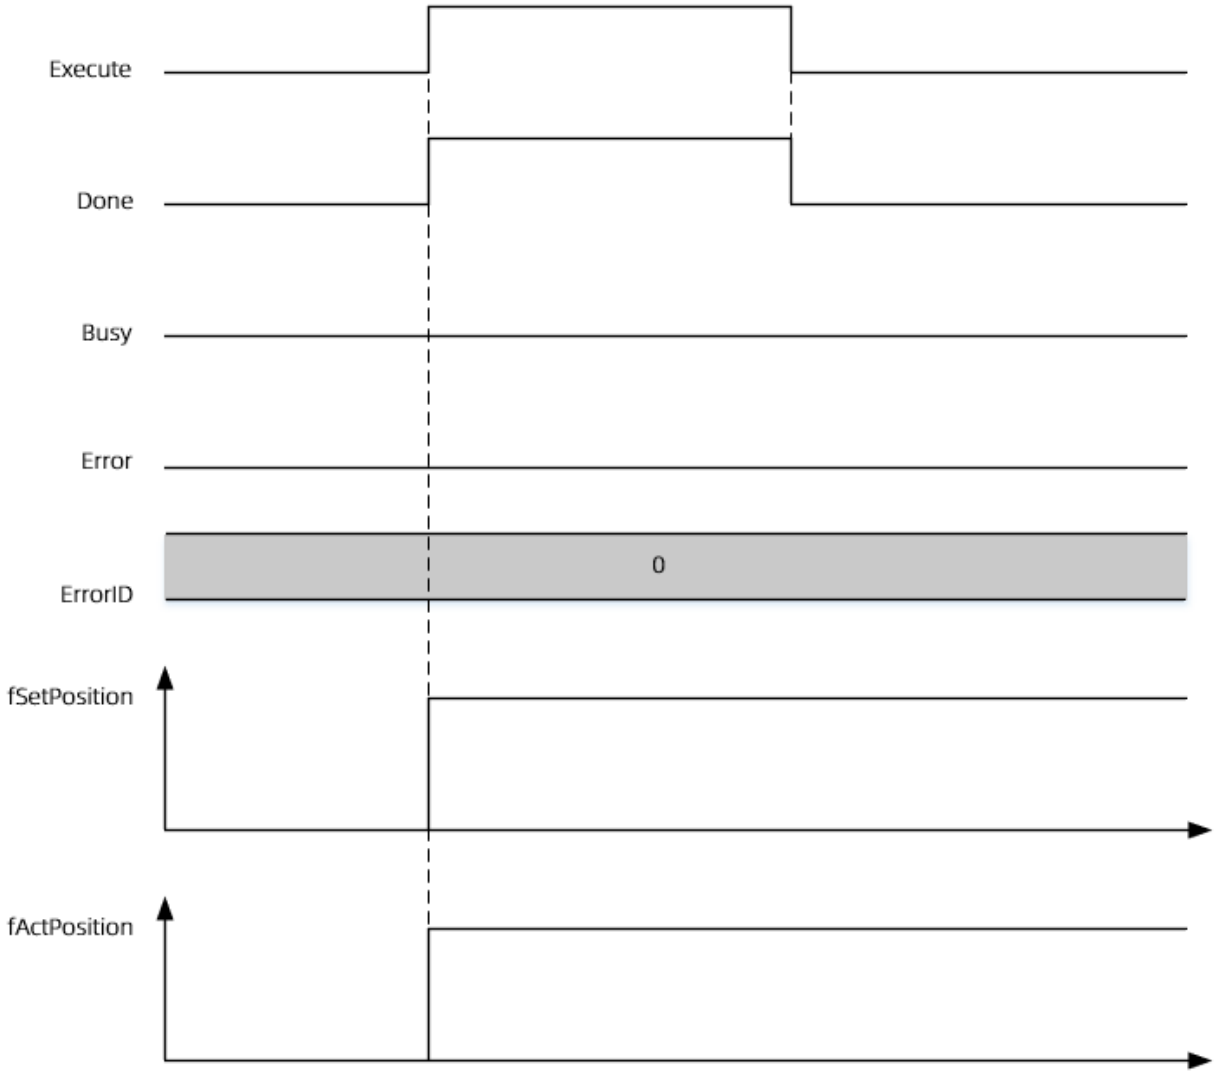
- **Function**

  Bus-controlled axis:

  - This instruction sets the position parameter of an axis and performs an offset operation on the coordinate system only without causing any displacement.
  - This instruction specifies the target position in absolute coordinates. You can modify the position when this instruction is disabled. You can specify the position with this instruction in CSP control mode only.
  - When this instruction is executed during the execution of the MC_MoveAbsolute instruction, the final actual position does not change with the change in the position reference.
  - When this instruction is executed during the execution of the MC_MoveRelative instruction, the final actual position changes with the change in the position reference.
  - When the axis state is AXIS_HOMING, this instruction cannot be triggered. During execution of a synchronization instruction, this instruction can be enabled on both the master axis and slave axis in synchronized motion. If this instruction is enabled on the master axis, the signal source "MasterValueSource" of the synchronization instruction must be set to "mcLatestCommand"; otherwise, the slave axis will overspeed.
  - In rotary axis mode, if you specify the parameter Position to a value greater than the rotation cycle, the parameter value will be processed as the remainder of the specified Position value divided by the rotation cycle.

  Local pulse axis:

  - This instruction can be used for local pulse axes.



- **Timing diagram**

  The change in the current position begins on a rising edge of the input parameter Execute.

  When the input parameter Execute is set to TRUE, the output parameter Busy shows the value TRUE, indicating the current function block is being executed. After the current position changes, the output parameter Done shows the value TRUE, indicating that the instruction is done.

  When the input parameter Execute is set to FALSE, the output parameter Done shows the value FALSE.

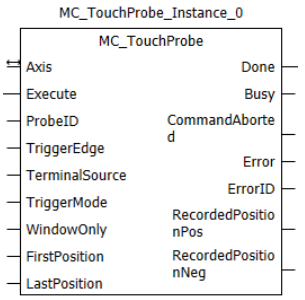
The axis structure variable fSetPosition is the set position (unit) calculated in this task cycle, and the axis structure variable fActPosition is the actual position (unit).

- **Re-execution of motion control instructions**

  This instruction cannot be re-executed.

- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.



- **Precautions**

  When using the MC_SetPosition instruction, do not set an absolute value of the parameter Position greater than 10^17; otherwise, the servo drive issues a fault message.

18.3.3.3.10 MC_TouchProbe

This instruction records an axis position when a trigger signal occurs.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_TouchProbe	Enable touch probe		MC_TouchProbe_Instance_0(Axis :=, Execute :=, ProbeID :=, TriggerEdge :=, TerminalSource :=, TriggerMode :=, WindowOnly :=, FirstPosition :=, LastPosition :=, Done =>, Busy =>, CommandAborted =>, Error =>, ErrorID =>, RecordedPositionPos =>, RecordedPositionNeg =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	The function block is executed on a rising edge of this input variable.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
ProbeID	Touch probe ID	INT	0, 1	0	0: Touch probe 1. 1: Touch probe 2.
TriggerEdge	Trigger edge	INT	0, 1, 2	0	0: Rising edge. 1: Falling edge. 2: Rising edge and falling edge.
TerminalSource	Touch probe signal source	INT	0, 1	0	0: DI terminal. 1: Encoder Z-phase signal.
TriggerMode	Trigger mode	INT	0, 1, 2	0	0: Single trigger. 1: High-performance continuous trigger. 2: Standard continuous trigger (for bus-controlled axes only).
WindowOnly	Specify whether to enable the window to detect touch probe signals	BOOL	TRUE, FALSE	FALSE	FALSE: Disabled. Touch probe signals are detected at any positions. TRUE: Enabled. Touch probe signals are detected only when the current position is within the window.
FirstPosition	First Position	LREAL	-	0	Start position [u] from where the touch probe signals are detected.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
LastPosition	Last Position	LREAL	-	0	Stop position [u] of the window.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.
RecordedPositionPos	Rising edge position	LREAL	-	0	The touch probe signals are detected on a rising edge.
RecordedPositionNeg	Falling edge position	LREAL	-	0	The touch probe signals are detected on a falling edge.

- **Function**

  Bus-controlled axis:

  - This instruction records an axis position when an external signal is input or when the motor Z-phase signal is triggered.
  - Specify the probe signal trigger edge of rising edge, falling edge, or both rising edge and falling edge through the input parameter TriggerEdge.
    - When the TriggerMode is set to "Single trigger" and the TriggerEdge is set to "Rising edge (Falling edge)", the instruction writes the detected value on a rising edge (falling edge) to RecordedPositionPos (RecordedPositionNeg), and the output parameter Done is set when one detection cycle is finished.
    - When the TriggerMode is set to "Continuous trigger" and the TriggerEdge is set to "Rising edge (Falling edge)", the instruction writes the detected value on a rising edge (falling edge) to RecordedPositionPos (RecordedPositionNeg), and the output parameter Done is reset one cycle after being set to continue detecting the signal on next rising edge (falling edge).
    - When the TriggerMode is set to "Single trigger" and the TriggerEdge is set to "Rising edge and falling edge", the instruction immediately writes the detected value on a rising edge to RecordedPositionPos and the detected value on a falling edge to RecordedPositionNeg, and the output parameter Done is set when one detection cycle is finished.
    - When the TriggerMode is set to "Continuous trigger" and the TriggerEdge is set to "Rising edge and falling edge", the instruction immediately writes the detected value on a rising edge to RecordedPositionPos, and the output parameter Done is reset one cycle after being set; the

instruction immediately writes the detected value on a falling edge to RecordedPositionNeg, and the output parameter Done is reset one cycle after being set. This instruction is executed repeatedly as described above.

- This instruction can be executed regardless of the axis state and the control mode. One function block instance represents only one MC_TouchProbe instruction. If this instruction is executed for multiple times, only the axis position when the last trigger signal occurs will be recorded.
- Re-executing this instruction will cause the function block to issue a fault message.
- This instruction issues a fault message when the touch probe channel is occupied.
- The touch probe channel is automatically released when the output parameter Done, Error, or CommandAborted is set.
- This instruction can be aborted by the MC_AbortTrigger, MC_MoveLink, and MC_MoveFeed instructions only during execution.
- **Before this instruction is executed, configure the following PDOs as appropriate:**
  - PDOs that must be configured:

    60B8 (touch probe control word), 60B9 (touch probe status word).
  - ProbeID = 0 and TriggerEdge = 0:

    60BA (touch probe 1 rising edge trigger position).
  - ProbeID = 0 and TriggerEdge = 1:

    60BB (touch probe 1 falling edge trigger position).
  - ProbeID = 0 and TriggerEdge = 2:

    60BA and 60BB.
  - ProbeID = 1 and TriggerEdge = 0:

    60BC (touch probe 2 rising edge trigger position).
  - ProbeID = 1 and TriggerEdge = 1:

    60BD (touch probe 2 falling edge trigger position).
  - ProbeID = 1 and TriggerEdge = 2:

    60BC and 60BD.
- **When the input parameter WindowOnly is set to FALSE**

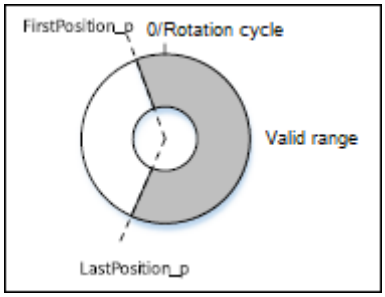
  The instruction does not identify the FirstPosition or LastPosition.
- **When the input parameter WindowOnly is set to TRUE**
  - Linear mode

    The FirstPosition must be less than the LastPosition.

  - Rotary mode

    The FirstPosition can be less than or greater than the LastPosition.



FirstPosition < LastPosition

The window is valid when the actual position is between the FirstPosition and the LastPosition, as shown in the following figure:

FirstPosition > LastPosition

The window is valid when the actual position is greater than the FirstPosition and less than the cycle length, or less than the LastPosition and greater than the cycle length, as shown in the following figure:

- For the EtherCAT bus-controlled axis, the input parameter TerminalSource can be specified as DI terminal or encoder Z-phase signal (requiring drive support). If the Z-phase signal is not supported by the drive, the instruction will not issue a fault message.
- This instruction can be triggered once or continuously, which is specified using the input parameter TriggerMode.
  - When the input parameter TriggerMode is set to 0 (single trigger), the output parameter Done is set when the instruction execution ends.
  - When the input parameter TriggerMode is set to 1 or 2 (continuous trigger), the instruction can continuously detect touch probe signals. The parameter Done is set for one cycle when successful position capture is performed in the continuous trigger mode
  - TriggerMode1: This mode applies to servo axes whose PDO 60B9 supports returning the number of latches in continuous mode. In this mode, continuous latching performance is high, supporting higher trigger frequencies. The following 60B9 objects meet the requirements for this mode:

bit	Description	Note
0	Touch probe 1 enable: 0: Disabled 1: Enable	bit0 to bit2: status of touch probe 1
1	Touch probe 1 latch on a rising edge: 0: Disabled 1: Enabled	

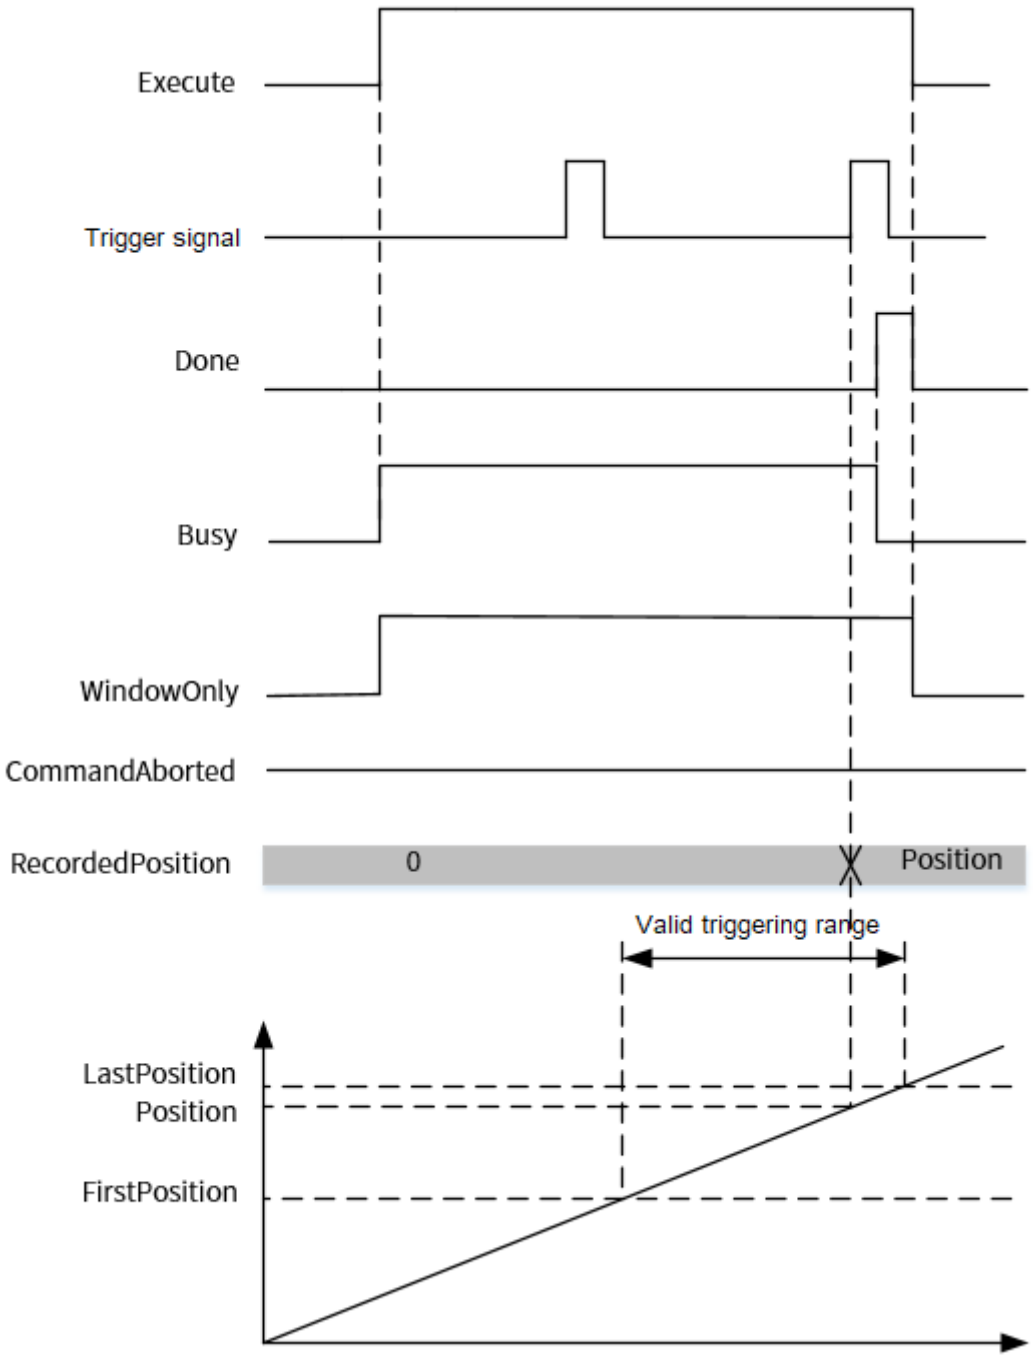
bit	Description	Note
2	Probe 1 latch on a falling edge: 0: Disabled 1: Enabled	
3 to 5	N/A	-
6 to 7	Trigger count of the touch probe when the function of touch probe 1 is set to continuous sampling	Trigger count (0 to 3) of the touch probe when the function of touch probe 1 is set to continuous sampling
8	Touch probe 2 enable: 0: Disabled 1: Enable	bit8 to bit10: status of touch probe 2
9	Touch probe 2 latch on a rising edge: 0: Disabled 1: Enabled	
10	Probe 2 latch on a falling edge: 0: Disabled 1: Enabled	
11 to 13	N/A	-
14 to 15	Trigger count of the touch probe when the function of touch probe 2 is set to continuous sampling	Trigger count (0 to 3) of the touch probe when the function of touch probe 2 is set to continuous sampling

- TriggerMode2: This mode applies to servo axes whose PDO 60B9 does not support returning the number of latches in continuous mode. In this mode, continuous latching performance is lower. In case of higher-frequency touch probe signals, use Mode 1. The following 60B9 objects meet the requirements for this mode:

bit	Description	Note
0	Touch probe 1 enable: 0: Disabled 1: Enabled	bit0 to bit2: status of touch probe 1
1	Touch probe 1 latch on a rising edge: 0: Disabled 1: Enabled	
2	Probe 1 latch on a falling edge: 0: Disabled 1: Enabled	
3 to 7	N/A	-

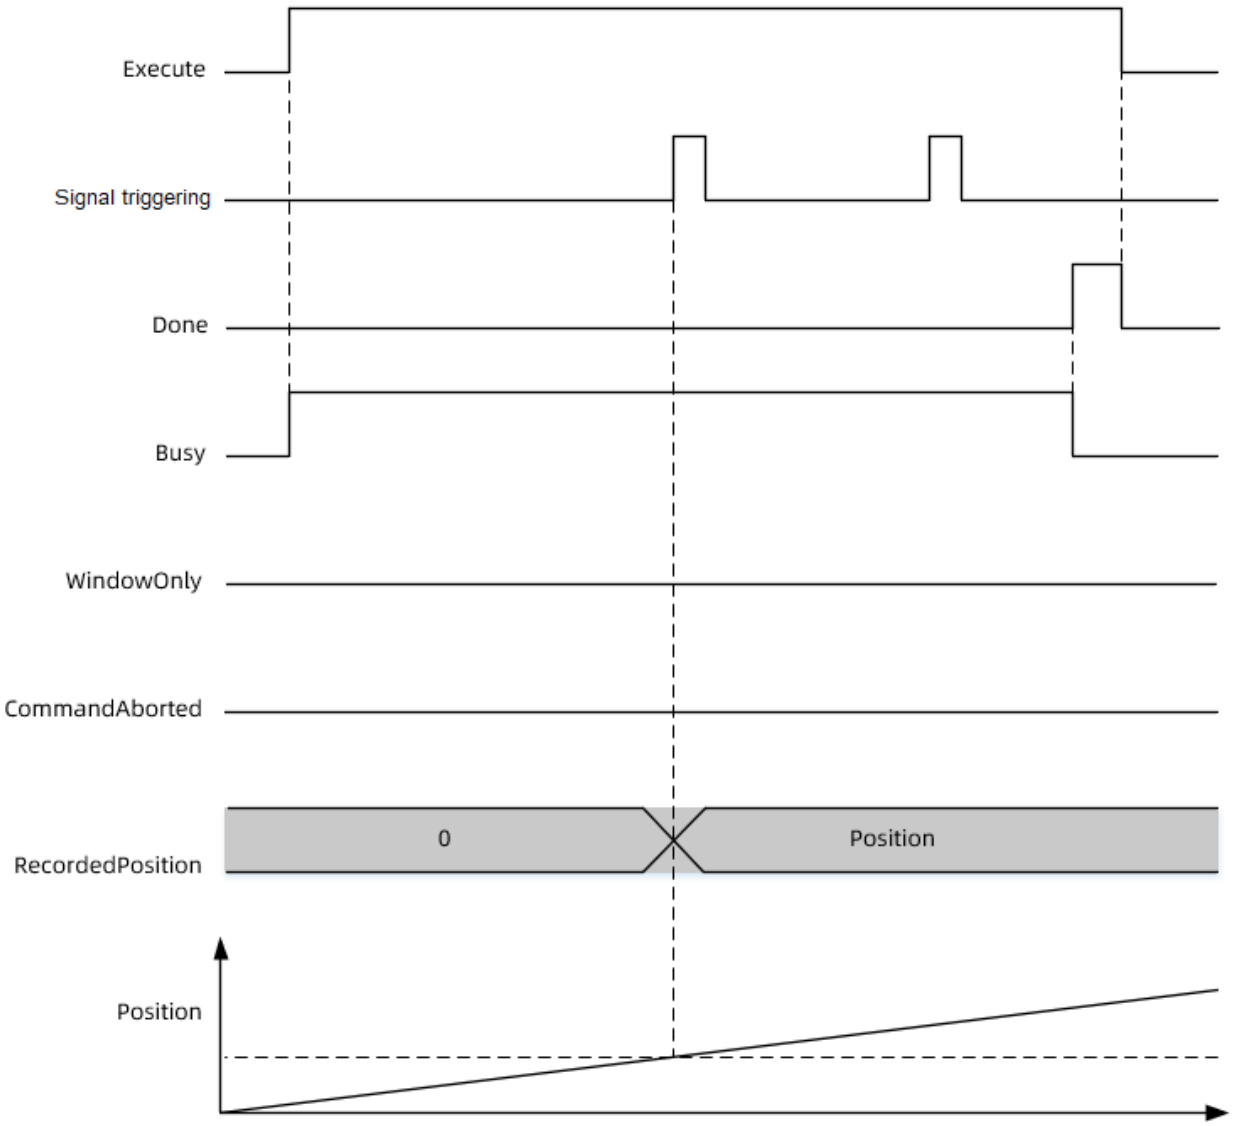
bit	Description	Note
8	Touch probe 2 enable: 0: Disabled 1: Enabled	bit8 to bit10: status of touch probe 2
9	Touch probe 2 latch on a rising edge: 0: Disabled 1: Enabled	
10	Probe 2 latch on a falling edge: 0: Disabled 1: Enabled	
11 to 15	N/A	-

Local pulse axis:



This instruction can be used for local pulse axes.

Virtual axis probe:

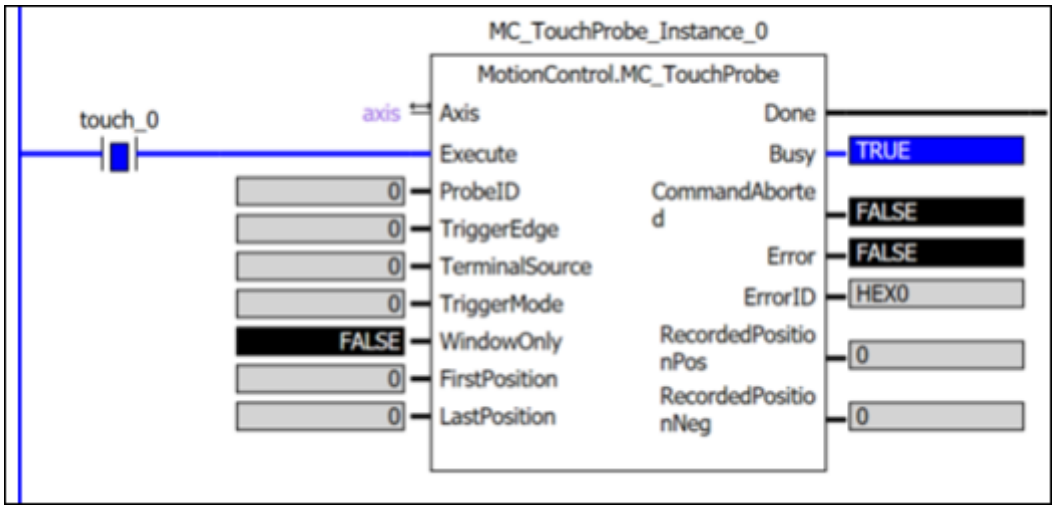


Only two-channel touch probe signals are supported for each controller corresponding to a virtual axis probe.

- **Timing diagram**

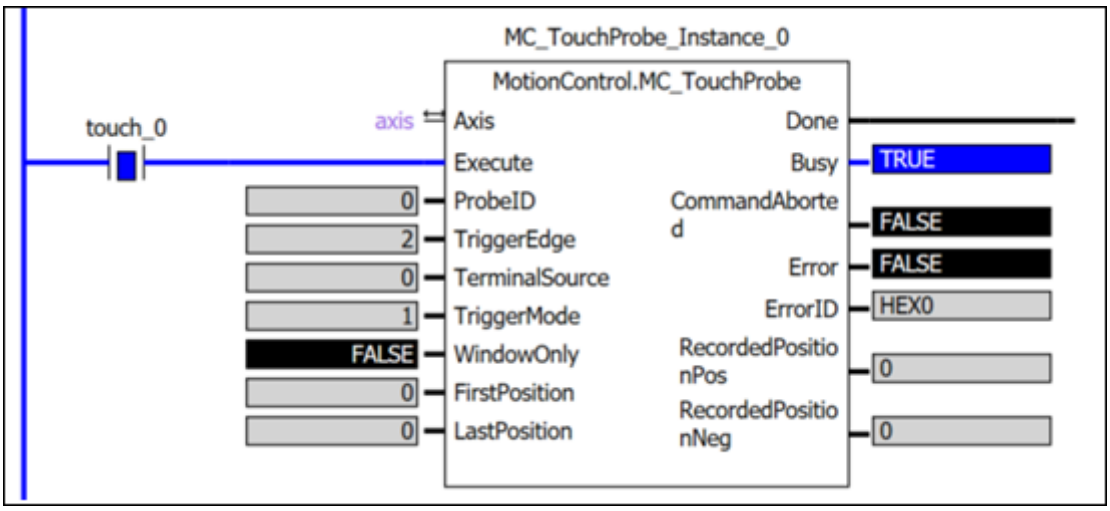
  TriggerEdge = Rising edge and WindowOnly = TRUE

TriggerEdge = Rising edge and WindowOnly = FALSE



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

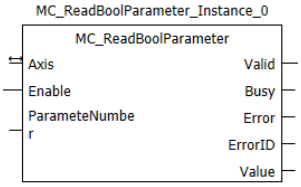


- **Example**

  Add proper probe-specific PDOs, select the first group of PDOs as inputs, and add 60BB and 60BD to the output configuration.

Directly call the instruction to receive the recorded position on a rising edge of drive touch probe 1.

- **Precautions**
  - This instruction is only applicable to bus-controlled axes, virtual axes, and local pulse axes. For local encoder axes or bus encoder axes, use the ENC_TouchProbe instruction.
  - Regarding compatibility with Inovance's common IS620N, the second touch probe is not supported by IS620N. The ProbeID of the axis applicable to IS620N must be set to 1, and no Bit can trigger the touch probe when the TerminalSource is set to 0.
  - For servo products compatible with IS620N, when the TriggerMode is set to "Continuous trigger" and the TriggerEdge is set to "Rising edge and falling edge", the first position cannot be recorded if the RecordedPositionNeg is the first record.



18.3.3.3.11 MC_ReadBoolParameter

This instruction reads the bit parameter of an axis.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_ReadBoolParameter	Read BOOL parameter		MC_ReadBoolParameter _Instance_0(Axis :=, Enable :=, ParameterNumber :=, Valid =>, Busy =>, Error =>, ErrorID =>, Value =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Enable	Enable	BOOL	TRUE, FALSE	FALSE	TRUE: Enabled. FALSE: Disabled.
ParameterNumber	Parameter number	DINT	See 18.3.3.9 ParameterNumberin the appendix	-	Index, subindex, or sequence number for accessing an axis parameter.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Valid	Valid output	BOOL	TRUE, FALSE	FALSE	TRUE when there is a valid output from the function block.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.
Value	Return value	BOOL	TRUE, FALSE	FALSE	Boolean value of the parameter to be read.

- **Function**

  Bus-controlled axis:

  - This instruction reads the bit data status in the drive. It is controlled by the Enable signal level and can be executed repeatedly without affecting each other. Note: Multiple different instantiated function blocks of this instruction can be executed simultaneously, instead of multiple identical instantiated function blocks.
  - This instruction must be re-executed to modify the parameter number (PN). When this instruction reads the current PN value, directly modifying the PN value causes an instruction fault. The instruction's function is restored after the trigger is canceled.
  - When the axis is in abnormal communication, this instruction issues a fault message with a fault code.

  Local pulse axis:

  - This instruction can be used for local pulse axes.

- **Timing diagram**

  The input parameter Enable must be triggered on a rising edge. The input parameter Busy indicates that the current function block is being executed, and the input parameter Valid indicates that the output parameters are valid.

  When the input parameter Enable is set to TRUE, the output parameter Busy shows the value TRUE.

- **Re-execution of motion control instructions**

  This instruction cannot be re-executed.

- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

- **Precautions**

  The ParameterNumber pin can be specified based on the object dictionary index:
  diParameterNumber := -DWORD_TO_DINT(SHL(TO_DWORD(usiDataLength),24) + SHL(TO_DWORD(uiIndex),8) + usisubIndex)
  Where, usiDataLength(USINT) represents the object dictionary data length, such as USINT corresponding to 1 byte 16#01 and UINT corresponding to 2 bytes 16#02; uiIndex(UINT) represents the object dictionary, such as 16#60E0 and 16#60E1; usisubIndex(USINT) represents the object dictionary subindex, such as 16#6091 (01 corresponding to the numerator of the gear ratio, 02 corresponding to the denominator of the gear ratio).
  Example: Read and write object dictionary 16#60E0 with data type = UINT and no subindex. Relevant parameters are shown in the following figure:

```
usiDataLength: USINT := 2;
uiIndex: UINT := 16#60E0;
usisubIndex: USINT := 0;
diParameterNumber: DINT := -DWORD_TO_DINT(SHL(TO_DWORD(usiDataLength),24) + SHL(TO_DWORD(uiIndex),8) + usisubIndex);
```

18.3.3.3.12 MC_ReadParameter

This instruction reads an axis parameter.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_ReadParameter	Read LREAL parameter		MC_ReadParameter_Instance_0(Axis :=, Enable :=, ParameterNumber :=, Valid =>, Busy =>, Error =>, ErrorID =>, Value =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Enable	Enable	BOOL	TRUE, FALSE	FALSE	TRUE: Enabled. FALSE: Disabled.
ParameterNumber	Parameter number	DINT	See 18.3.3.9 ParameterNumberin the appendix	-	Number of the parameter to be read.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Valid	Valid output	BOOL	TRUE, FALSE	FALSE	TRUE when there is a valid output from the function block.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.
Value	Return value	LREAL	-	-	Value of the parameter to be read.

- **Function**

  Bus-controlled axis:

  - This instruction reads an axis parameter. It is a function block controlled by the Enable signal level. This instruction can be executed repeatedly without affecting each other. Note: Multiple different instantiated function blocks of this instruction can be executed simultaneously, instead of multiple identical instantiated function blocks.
  - When the axis is in abnormal communication, this instruction issues a fault message with a fault code.

  Local pulse axis:

  - This instruction can be used for local pulse axes.

- **Timing diagram**

  The input parameter Enable must be triggered on a rising edge. The input parameter Busy indicates that the current function block is being executed, and the input parameter Valid indicates that the output parameters are valid.

  When the input parameter Enable is set to TRUE, the output parameter Busy shows the value TRUE.

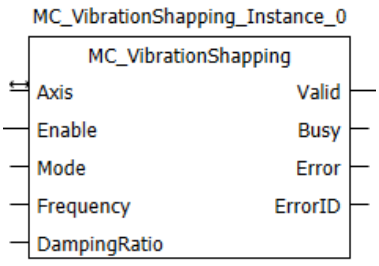
- **Re-execution of motion control instructions**

  This instruction cannot be re-executed.

- **Faults**

For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

- **Precautions**



The ParameterNumber pin can be specified based on the object dictionary index:
diParameterNumber := -DWORD_TO_DINT(SHL(TO_DWORD(usiDataLength),24) + SHL(TO_DWORD(uiIndex),8) + usisubIndex)
Where, usiDataLength(USINT) represents the object dictionary data length, such as USINT corresponding to 1 byte 16#01 and UINT corresponding to 2 bytes 16#02; uiIndex(UINT) represents the object dictionary, such as 16#60E0 and 16#60E1; usisubIndex(USINT) represents the object dictionary subindex, such as 16#6091 (01 corresponding to the numerator of the gear ratio, 02 corresponding to the denominator of the gear ratio).
Example: Read and write object dictionary 16#60E0 with data type = UINT and no subindex. Relevant parameters are shown in the following figure:

```
usiDataLength: USINT := 2;
uiIndex: UINT := 16#60E0;
usisubIndex: USINT := 0;
diParameterNumber: DINT := -DWORD_TO_DINT(SHL(TO_DWORD(usiDataLength),24) + SHL(TO_DWORD(uiIndex),8) + usisubIndex);
```

18.3.3.3.13 MC_VibrationShapping

This instruction performs vibration shaping filtering to reduce residual vibration in a single-mode system.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_VibrationShapping	Input shaping		MC_VibrationShapping_Instance_0 (Axis :=, Enable :=, Mode :=, Frequency :=, DampingRatio :=, Valid =>, Busy =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Enable	Enable	BOOL	TRUE, FALSE	FALSE	Enable flag for the instruction execution.
Mode	Mode	INT	0, 1	0	0: ZV shaper model, suitable for single-frequency stable systems. 1: ZVD shaper model, suitable for multiple-frequency systems; more robust.
Frequency	Frequency	LREAL	> 0	0	Frequency.
DampingRatio	Damping ratio	LREAL	(0,1)	0	Damping ratio.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Valid	Input shaping	BOOL	TRUE, FALSE	FALSE	TRUE: Input shaping is being executed.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE: The function block is being executed.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE: A fault occurs during input shaping.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**

  Bus-controlled axis:

  - If an attempt is made to execute multiple instances of this instruction, the last triggered instance will issue a fault message, without affecting the currently executing instruction.
  - During the output shaping, when the parameter Valid is set and the parameter Enable is set to FALSE, the instruction will issue an axis fault message. It is not recommended to frequently trigger Enable, as this may cause servo overspeed.
  - This instruction dynamically allocates memory during execution, with a maximum allowed array length of 1000. The size of memory allocated depends on the input parameters. If the input parameters are invalid and result in excessive memory allocation, the instruction will issue a fault message.
  - This instruction can be used in linear axis mode only.
  - This instruction can be used for servo axes or local axes, and will issue a fault message for other axis types.
  - This instruction requires the axis to be enabled before execution; otherwise, the instruction will issue a fault message.

- If the slave is disconnected during normal execution of the instruction, the instruction will issue a fault message.
- In the project configuration, there is no requirement on the placement order of this instruction; it may be placed either before or after the function block.
- The input parameters of this instruction take effect only when the instruction is triggered, and any input parameter changes after the trigger will not take effect in real time.
- This instruction can be executed only when the axis is Standstill; otherwise, the instruction will issue a fault message. After the instruction is executed, it will issue a fault message if the axis performs homing or stopping operation, and output in normal shaping mode if the axis performs any other motions.
- This instruction will issue a fault message in a non-CSP control mode.
- The parameter value 0 of the Mode represents the ZV shaper model, and 1 represents the ZVD shaper model. The ZVD shaper is more robust than the ZV shaper.
- When this instruction is triggered, triggering the MC_SetPosition instruction will result in a fault message.
- When this instruction is used with software limits being checked, limit identification is performed based on the planned position at the axis. After the limit position is reached, the shaping position is synchronized to the planned position to prevent jumping change in position.

Local pulse axis:

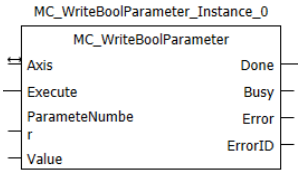
- This instruction can be used for local pulse axes.

- **Timing diagram**

  When the input parameter Enable is set to TRUE, the output parameter Busy shows the value TRUE, indicating the current function block is being executed. When the output parameter Valid is set to TRUE, it indicates that input shaping is being executed.

- **Re-execution of motion control instructions**

  You cannot re-execute motion control instructions with an input parameter Enable.



- **Faults**

For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.3.14 MC_WriteBoolParameter

This instruction writes the BOOL parameters of an axis.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_WriteBoolParameter	Write BOOL parameters		MC_WriteBoolParameter _Instance_0(Axis :=, Execute :=, ParameterNumber :=, Value :=, Done =>, Busy =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	The function block is executed on a rising edge of this input variable.
ParameterNumber	Parameter number	DINT	See 18.3.3.9 ParameterNumberin the appendix	-	Number of the axis parameter to be written.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Value	Setpoint	BOOL	TRUE, FALSE	FALSE	Setpoint of the axis parameter to be written.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**

  Bus-controlled axis:

  ◦ This instruction sets the bit parameters of an axis and is triggered on a rising edge of Execute. This instruction can be executed repeatedly without affecting each other. Note: Multiple different instantiated function blocks of this instruction can be executed simultaneously, instead of multiple identical instantiated function blocks.

  Local pulse axis:

  ◦ This instruction can be used for local pulse axes.

- **Timing diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Value of the function block indicates the setpoint of the axis parameter written; the parameter Done indicates that the instruction has been executed successfully; the parameter Busy indicates that the current function block is being executed.

  After this instruction is called, the output parameter Busy becomes TRUE on a rising edge of Execute. After the written axis parameter is set successfully, the output parameter Done is set to TRUE.

- **Re-execution of motion control instructions**

  This instruction cannot be re-executed.

- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

- **Precautions**

  The ParameterNumber pin can be specified based on the object dictionary index:
  diParameterNumber := -DWORD_TO_DINT(SHL(TO_DWORD(usiDataLength),24) + SHL(TO_DWORD(uiIndex),8) + usisubIndex)
  Where, usiDataLength(USINT) represents the object dictionary data length, such as USINT corresponding to 1 byte 16#01 and UINT corresponding to 2 bytes 16#02; uiIndex(UINT) represents the object dictionary, such as 16#60E0 and 16#60E1; usisubIndex(USINT) represents the object dictionary subindex, such as 16#6091 (01 corresponding to the numerator of the gear ratio, 02 corresponding to the denominator of the gear ratio).
  Example: Read and write object dictionary 16#60E0 with data type = UINT and no subindex. Relevant parameters are shown in the following figure:

```
usiDataLength: USINT := 2;
uiIndex: UINT := 16#60E0;
usisubIndex: USINT := 0;
diParameterNumber: DINT := -DWORD_TO_DINT(SHL(TO_DWORD(usiDataLength),24) + SHL(TO_DWORD(uiIndex),8) + usisubIndex);
```

18.3.3.3.15 MC_WriteParameter

This instruction writes the LREAL parameters of the axis structure.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_WriteParameter	Write LREAL parameters		MC_WriteParameter_Instance_0(Axis :=, Execute :=, ParameterNumber :=, Value :=, Done =>, Busy =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	The function block is executed on a rising edge of this input variable.
ParameterNumber	Parameter number	DINT	See 18.3.3.9 ParameterNumberin the appendix	-	Number of the axis parameter to be written.
Value	Setpoint	LREAL	-	0	Setpoint of the axis parameter to be written.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**

  Bus-controlled axis:

  ◦ This instruction sets the parameters of an axis and is triggered on a rising edge of Execute. This instruction can be executed repeatedly without affecting each other.

  Local pulse axis:

  ◦ This instruction can be used for local pulse axes.

- **Timing diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Value of the function block indicates the setpoint of the axis parameter written; the parameter Done indicates that the instruction has been executed successfully; the parameter Busy indicates that the current function block is being executed.

  After this instruction is called, the output parameter Busy becomes TRUE on a rising edge of Execute. After the written axis parameter is set successfully, the output parameter Done is set to TRUE.

- **Re-execution of motion control instructions**

  This instruction cannot be re-executed.

- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

- **Precautions**

  The ParameterNumber pin can be specified based on the object dictionary index:
  diParameterNumber := -DWORD_TO_DINT(SHL(TO_DWORD(usiDataLength),24) + SHL(TO_DWORD(uiIndex),8) + usisubIndex)
  Where, usiDataLength(USINT) represents the object dictionary data length, such as USINT corresponding to 1 byte 16#01 and UINT corresponding to 2 bytes 16#02; uiIndex(UINT) represents the object dictionary, such as 16#60E0 and 16#60E1; usisubIndex(USINT) represents the object dictionary subindex, such as 16#6091 (01 corresponding to the numerator of the gear ratio, 02 corresponding to the denominator of the gear ratio).
  Example: Read and write object dictionary 16#60E0 with data type = UINT and no subindex. Relevant parameters are shown in the following figure:

```
usiDataLength: USINT := 2;
uiIndex: UINT := 16#60E0;
usisubIndex: USINT := 0;
diParameterNumber: DINT := -DWORD_TO_DINT(SHL(TO_DWORD(usiDataLength),24) + SHL(TO_DWORD(uiIndex),8) + usisubIndex);
```

18.3.3.3.16 MC_AbortTrigger

This instruction aborts the latch operation triggered by the MC_TouchProbe instruction.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_AbortTrigger	Abort triggered operation		MC_AbortTrigger_Instance_0(Axis :=, Execute :=, ProbeID :=, Done =>, Busy =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	The function block is executed on a rising edge of this input variable.
ProbeID	Touch probe ID	INT	0, 1	0	0: Touch probe 1. 1: Touch probe 2.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**

  Bus-controlled axis:

  - This instruction is used in conjunction with the MC_TouchProbe instruction.
  - You can use this instruction to specify the Axis and ProbeID to abort the latch operation triggered by the MC_TouchProbe instruction.
  - If the MC_TouchProbe instruction is not executed on the current axis and the MC_AbortTrigger instruction is applied directly, the Done output flag of the MC_AbortTrigger is set. If the MC_AbortTrigger instruction is executed after the MC_TouchProbe instruction is executed on the current axis with the TriggerMode being set to "Single trigger" and having a successful position recording, the Done output flag of the MC_AbortTrigger is set.

  Local pulse axis:

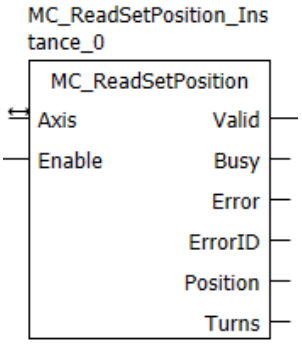
  - This instruction can be used for local pulse axes.

- **Timing diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Done of the function block indicates that the instruction has been executed successfully, and the parameter Busy indicates that the current function block is being executed. After this instruction is called, the output parameter Busy becomes TRUE on a rising edge of Execute. After the latch operation triggered by the MC_TouchProbe instruction is aborted, the output parameter Done is set to TRUE.

- **Re-execution of motion control instructions**

  This instruction cannot be re-executed.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.3.17 MC_ReadSetPosition

This instruction reads the set position of an axis.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_ReadSetPosition	Read set position		MC_ReadSetPosition_Instance_0(Axis :=, Enable :=, Valid =>, Busy =>, Error =>, ErrorID =>, Position =>, Turns =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Enable	Enable	BOOL	TRUE, FALSE	FALSE	TRUE: Enabled. FALSE: Disabled.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Valid	Valid output	BOOL	TRUE, FALSE	FALSE	TRUE when there is a valid output from the function block.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.

ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.
Position	Position	LREAL	-	0	Return the set position [u] for the current task cycle.
Turns	Number of turns	LINT	-	0	Number of turns in rotary mode.

- **Function**

  Bus-controlled axis:

  - This instruction reads the set position of an axis.
  - The value of the output variable Position is the set position for the current task cycle.
  - The output variable Turns is based on the absolute linear position. It counts 0 when the axis position is within the first full revolution in the positive direction. It counts from -1 when the axis position is within the first full revolution in the negative direction.
  - After the parameter Enable of the instruction is reset, the output parameters are reset.
  - The instruction reading is not affected by axis state change or mode switching.
  - This instruction reads the parameter normally even if the MC_Power instruction is not triggered.
  - The axis type must be control axis. Abnormal communication results in an instruction fault.

  Local pulse axis:

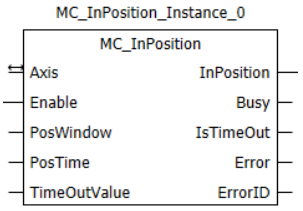
  - This instruction can be used for local pulse axes.

- **Timing diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Valid of the function block indicates valid outputs; the parameter Done indicates that the instruction has been executed successfully; the parameter Busy indicates that the current function block is being executed.

- **Re-execution of motion control instructions**

  This instruction cannot be re-executed.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.3.18 MC_InPosition

This instruction monitors the deviation between the set position and actual position of an axis and identifies whether the axis is within the required deviation range based on a specified deviation window.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_InPosition	Monitor axis deviation		MC_InPosition_Instance_0(Axis :=, Enable :=, PosWindow :=, PosTime :=, TimeOutValue :=, InPosition =>, Busy =>, IsTimeOut =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Enable	Enable	BOOL	TRUE, FALSE	FALSE	TRUE: Enabled. FALSE: Disabled.
PosWindow	Position deviation window	LREAL	Positive number	0	Specify a window for position deviation monitoring.
PosTime	Holding time	LREAL	Positive number	0	If the following error is less than or equal to the input parameter PosWindow for the duration (s) greater than the input parameter PosTime, the output parameter InPosition is set to TRUE.
TimeOut Value	Timeout value	LREAL	-	0	If the following error is greater than the input parameter PosWindow for the duration greater than the input parameter TimeOutValue, the output parameter IsTimeOut is set to TRUE.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
InPosition	In position	BOOL	TRUE, FALSE	FALSE	TRUE when the position deviation is within the specified window for the holding time.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
IsTimeOut	Timeout flag	BOOL	TRUE, FALSE	FALSE	If the InPosition is not set to TRUE after the TimeOutValue, the output parameter IsTimeOut is set to TRUE.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**

  Bus-controlled axis:

  - This instruction monitors the deviation between the set position and actual position of an axis and identifies whether the axis is within the required deviation range based on a specified deviation window.
  - The setpoints of input parameters PosWindow, PosTime, and TimeOutValue must be greater than or equal to 0; otherwise, the function block will issue a fault message.
  - When the Enable shows the value TRUE and the axis state is AXIS_STANDSTILL, AXIS_STOPPING, AXIS_DISCRETE_MOTION, AXIS_CONTINUOUS_MOTION, or AXIS_SYNCHRONIZED_MOTION, if the detected deviation value (Position reference - Actual position) is less than or equal to the setpoint of PosWindow, and the duration for the detected deviation value being less than the setpoint of PosWindow is greater than the setpoint of PosTime, the output parameter InPosition is set to TRUE; otherwise, the InPosition is set to FALSE. When the detected deviation value is greater than the setpoint of PosWindow, the InPosition becomes FALSE and the timer restarts.

- Timing starts from the moment the instruction is triggered. When the duration is greater than the setpoint of TimeOutValue, the output parameter IsTimeOut is set to TRUE. After the IsTimeOut shows the value TRUE, it will not change back to FALSE even if the deviation is less than the setpoint of PosWindow.
- It is recommended to specify the value of TimeOutValue to be greater than the value of PosTime when this instruction is used.
- The axis controlled by this instruction must be bus-controlled axis, local pulse axis, or virtual axis. This instruction will issue a fault message if it is executed on any other axis type.

  Local pulse axis:

- This instruction can be used for local pulse axes.

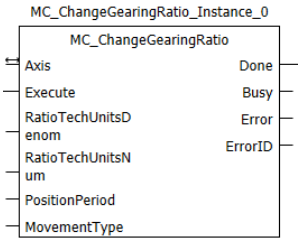
- **Timing diagram**

  When the input parameter Enable is set to TRUE, the output parameter Busy shows the value TRUE, indicating the current function block is being executed. When the input parameter Enable is set to FALSE, the output parameter Busy shows the value FALSE.

  The axis structure variable fFollowingError represents the following error. When the fFollowingError is greater than the setpoint of the PosWindow, the InPosition is set to FALSE immediately, and the timer restarts. If the duration is greater than the value of TimeOutValue at the end of the planning, the output parameter changes to TRUE.

- **Re-execution of motion control instructions**

  You cannot re-execute motion control instructions with an input parameter Enable.



- **Faults**

For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.3.19 MC_ChangeGearingRatio

This instruction sets the gear ratio (pulse unit to user unit) and the axis movement type.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_ChangeGearingRatio	Set gear ratio and axis type		MC_ChangeGearingRatio_Instance_0(Axis :=, Execute :=, RatioTechUnitsDenom :=, RatioTechUnitsNum :=, PositionPeriod :=, MovementType :=, Done =>, Busy =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	The function block is executed on a rising edge of this input variable.

RatioTechUnits Denom	Denominator	DWORD	Not equal to 0	1	Denominator of the conversion factor for converting drive increments into count units.
RatioTechUnits Num	Numerator	LREAL	Not equal to 0	1	Numerator of the conversion factor for converting drive increments into count units.
PositionPeriod	Rotation cycle	LREAL	Greater than 0	-	Rotation cycle [u], for rotary axes only.
MovementType	Movement type	INT	0, 1	0	0: Rotary axis. 1: Linear axis.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**

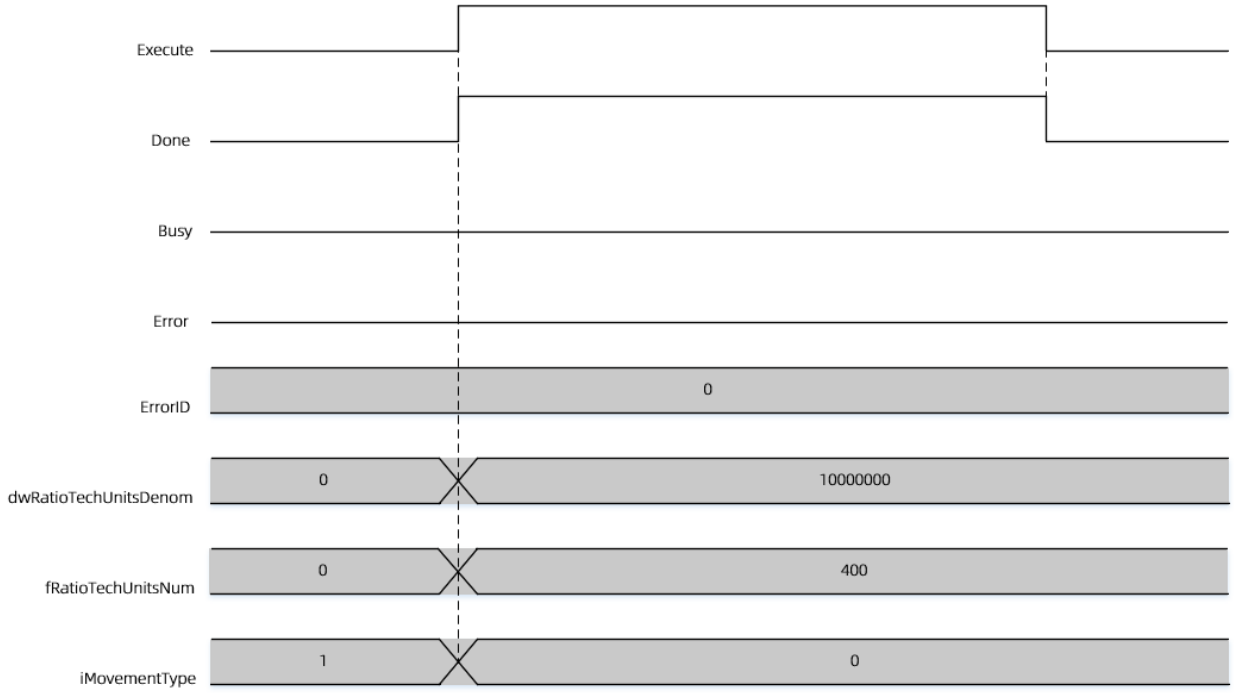
  Bus-controlled axis:

  - This instruction can be called only when the axis state is AXIS_POWEROFF; otherwise, the function block reports a fault.
  - This instruction can be used for bus-controlled axes, local pulse axes, and virtual axes only. This instruction will issue a fault message if it is executed on any other axis type.
  - If the input parameter iMovementType is not 0 or 1, a fault will occur. The input parameters RatioTechUnitsDenom and RatioTechUnitsNum cannot be 0. When the MovementType is set to 0, the

input parameter PositionPeriod must be greater than 0, and the number of pulses corresponding to the rotation cycle cannot be greater than 2,147,483,647.

- If the axis has been connected to an axis group (i.e., the MC_GroupEnable instruction has been executed on the axis group), using this instruction to switch the axis to rotary axis will result in an instruction fault. This instruction is executed normally with the denominator and numerator being specified for a linear axis.
- The relationship between the numerator, denominator, set position, and output pulses: User unit position = RatioTechUnitsNum * Pulse value / RatioTechUnitsDenom.

Local pulse axis:



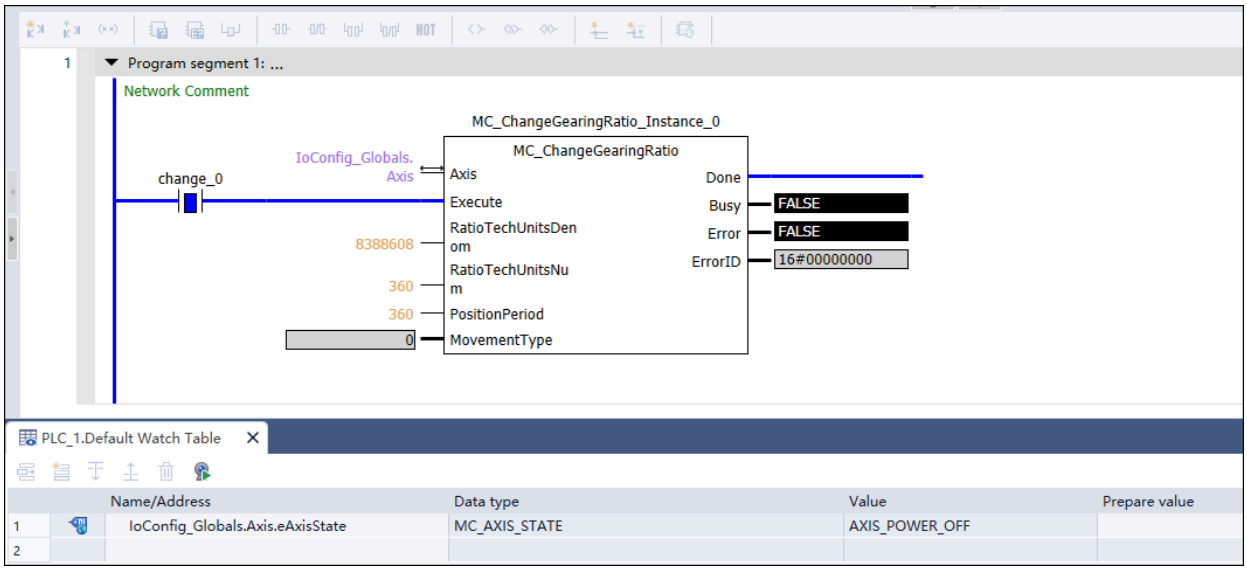
- This instruction can be used for local pulse axes.

- **Timing diagram**

  Specify the input parameter RatioTechUnitsDenom to 8,388,608, the RatioTechUnitsNum to 360, the PositionPeriod to 360, and the MovementType to 0.

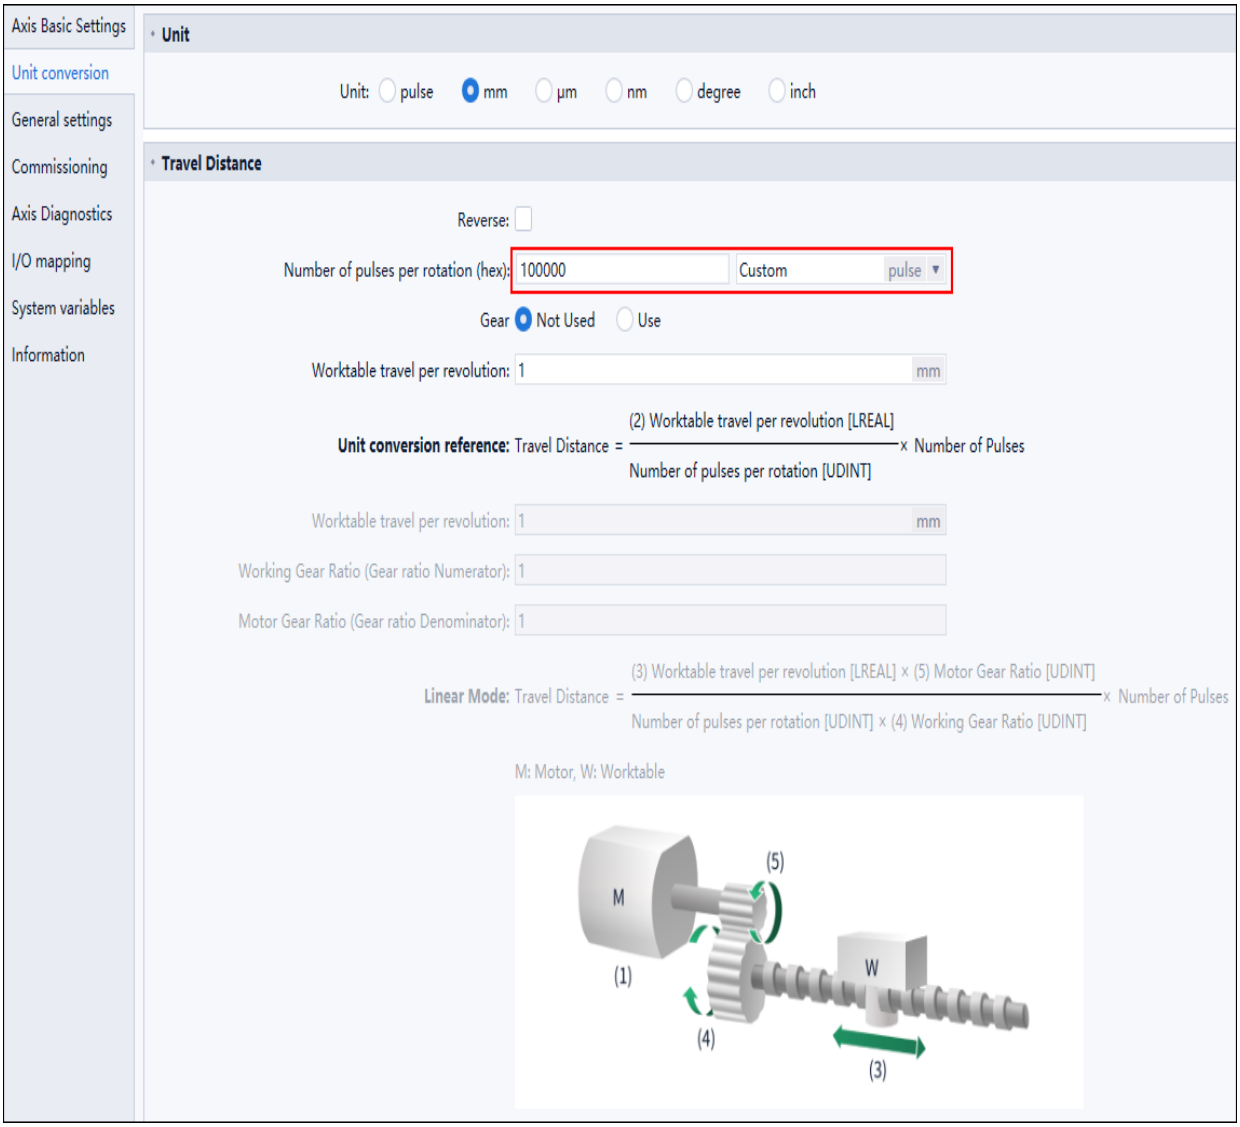
  The structure variable dwRatioTechUnitsDenom is the gear ratio denominator; the fRatioTechUnitsNum is the gear ratio numerator; and the iMovementType represents the axis type.

  The gear ratio and axis movement type change if there are no faults on a rising edge of the input parameter Execute. When the input parameter Execute is set to TRUE, the output parameter Busy shows the value TRUE. After the current instruction completes the specified changes, the output parameter Done is set to TRUE.



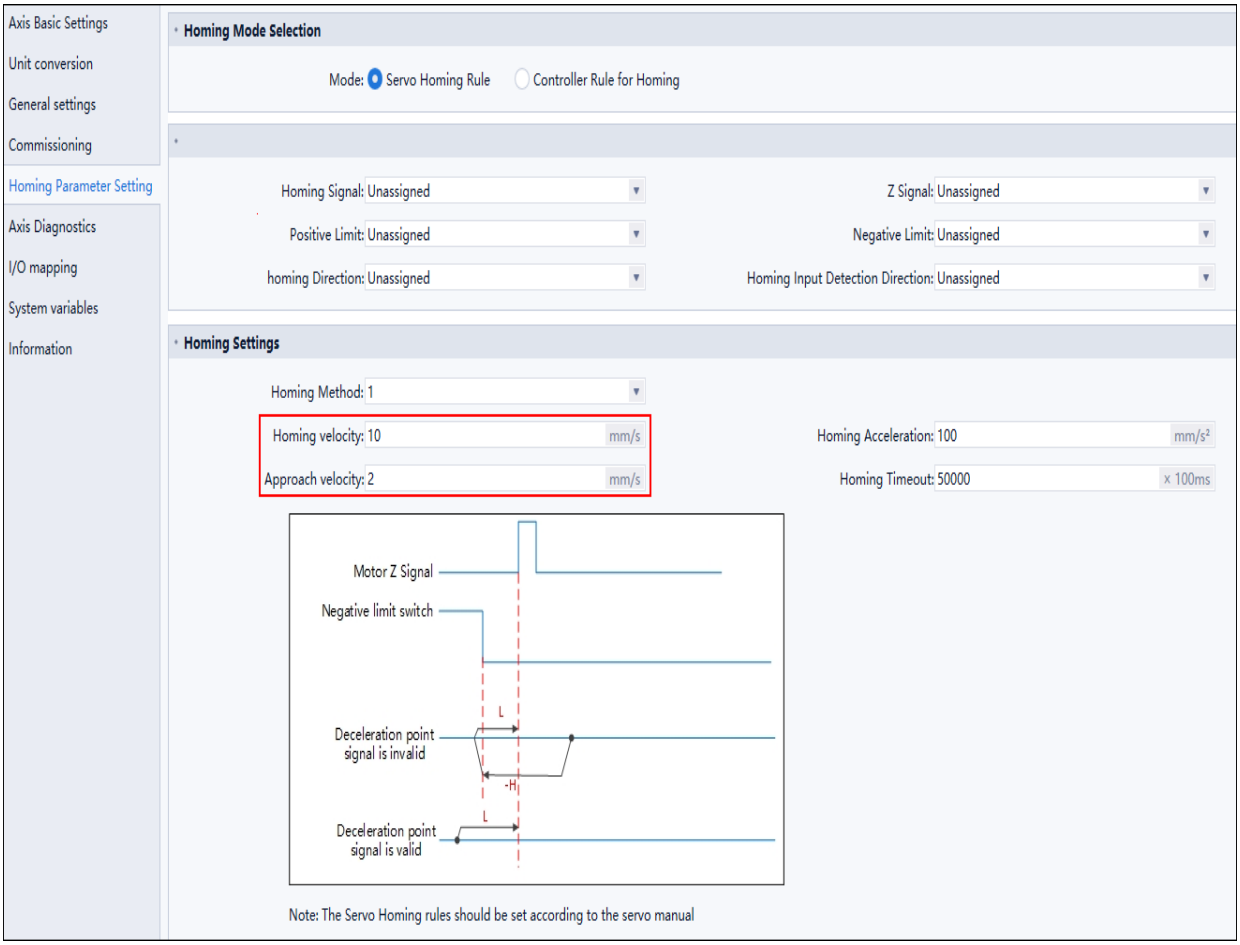
- **Re-execution of motion control instructions**

  This instruction cannot be re-executed.



- **Faults**

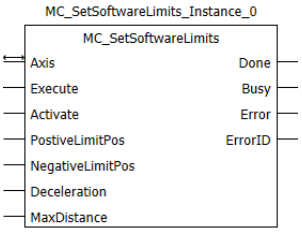
For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.



- **Precautions**
  - To adjust the number of pulses per motor revolution, you can modify the value of RatioTechUnitsDenom. For Inovance's common servo drives (23-bit), the number of pulses per revolution is 8,388,608.
  - The instruction parameters are decimal, while the software parameters are hexadecimal. The number systems must be unified before parameter conversion.
  - After the motor is disabled, adjust the instruction parameters as shown in the figure, and then enable the motor. At this point, the motor serves as a rotary axis, and one full turn of the motor corresponds exactly to 360 degrees of the user's motor.

  - To ensure the accuracy of variables related to the axis and position, when the axis type is a rotary axis and the product of the rotation cycle x gear ratio is greater than 2,147,483,647, this instruction will issue a fault message.
  - After the gear ratio is modified using this instruction, the homing velocity of the axis during the servo homing is inconsistent with the parameter value in Servo Homing Rule mode on the Homing Parameter Setting interface.

In this case, in Servo Homing Rule mode on the Homing Parameter Setting interface, if the homing velocity and approach velocity are specified to 10 and 2 user units respectively, the system will automatically convert them to pulse units, as shown in the following figure.



After the iFA goes online, if the MC_ChangeGearingRatio is used to modify the gearing ratio in this group of parameters, that is, to modify the ratio between user units and pulse units, and the homing instruction is executed, the homing velocity and approach velocity during the axis homing will be displayed according to the modified gearing ratio, and different from those on the Homing Parameter Setting interface.

18.3.3.3.20 MC_SetSoftwareLimits

This instruction sets the limit positions and predictive parameters of an axis.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_SetSoftwareLimits	Set software limits		MC_SetSoftwareLimits_Instance_0(Axis :=, Execute :=, Activate:=, PositiveLimitPos :=, NegativeLimitPos :=, Deceleration :=, MaxDistance :=, Done =>, Busy =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	The function block is executed on a rising edge of this input variable.
Activate	Activate software limit	BOOL	TRUE, FALSE	FALSE	TRUE: Activated. FALSE: Deactivated. The setpoint is not passed to the axis parameters.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
PositiveLimitPos	Positive software limit position	LREAL	-	0	Value of the positive limit position.
NegativeLimitPos	Negative software limit position	LREAL	-	0	Value of the negative limit position.
Deceleration	Stop deceleration	LREAL	Positive number	0	Stop deceleration when the axis position is beyond the limit position (if the setpoint is less than the maximum stop deceleration, the axis will stop according to the maximum stop deceleration).
MaxDistance	Maximum braking distance	LREAL	Positive number	0	Maximum value of the braking distance (if the stopping distance according to the stop deceleration is greater than the maximum braking distance, the axis will stop according to the maximum braking distance).

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**

  Bus-controlled axis:

  - The axis type must be control axis. This instruction is only valid in Linear Mode; otherwise, the instruction will issue a fault message.
  - The setpoint of PostiveLimitPos cannot be less than or equal to that of NegativeLimitPos. If the setpoint of Deceleration or MaxDistance is 0 or invalid, it will not take effect, and the limit deceleration will be self-adaptive to a group of limit deceleration and deceleration distance.
  - Whether the Activate is set to TRUE or not, the parameters and status will be checked as long as the Execute is set.
  - The parameters set by this instruction will not be saved in the project, and when the program is re-downloaded, the parameters will be configured according to the software parameters.
  - When this instruction is triggered during the axis movement, the set parameters will take effect if the parameters Activate and Done are set to TRUE.

  Local pulse axis:

  - This instruction can be used for local pulse axes.

- **Timing diagram**

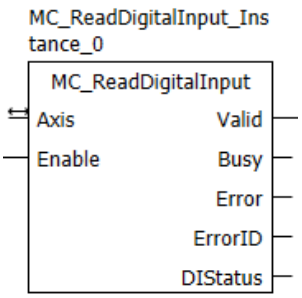
  When the input parameter Execute is set to TRUE, the output parameter Busy shows the value TRUE.

  After the axis limit position and predictive parameters are specified, the output parameter Done shows the value TRUE.

  When the input parameter Activate is set to TRUE, the input parameters will be passed to the axis and take effect. When the Activate is set to FALSE, even if the Done shows the value TRUE, the output parameters will not take effect.

- **Re-execution of motion control instructions**

  This instruction cannot be re-executed.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.3.21 MC_ReadDigitalInput

This instruction reads the digital input of an axis.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_ReadDigitalInput	Read digital input		MC_ReadDigitalInput_Instance_0(Axis :=, Enable :=, Valid =>, Busy =>, Error =>, ErrorID =>, DIStatus =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Enable	Enable	BOOL	TRUE, FALSE	FALSE	TRUE: Enabled. FALSE: Disabled.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Valid	Valid output	BOOL	TRUE, FALSE	FALSE	TRUE when there is a valid output from the function block.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.
DIStatus	Input terminal status	DINT	-	0	Status of the digital input terminal. The standard formats compliant with 402 protocol are defined as follows: bit0: Negative limit signal. bit1: Positive limit signal. bit2: Home signal. bit3 to bit31: User-defined.

- **Function**

  Bus-controlled axis:

  - This instruction cannot be used for virtual axes.
  - If the control object is a bus-controlled axis, the PDO 60FD must be configured.

  Local pulse axis:

  - This instruction cannot be used for local pulse axes.

- **Timing diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Valid of the function block indicates valid outputs, and the parameter Busy indicates that the current function block is being executed.

  After this instruction reads the digital inputs, the status of the input terminal will be output to the DIStatus.

- **Re-execution of motion control instructions**

  This instruction cannot be re-executed.

- **Errors**

  For errors related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

- **Precautions**

  The output variable DIStatus of this instruction is displayed in decimal by default, and must be converted to binary format to check the bit positions of different signals.

18.3.3.3.22 MC_SetControllerMode

This instruction sets the current operation mode of the servo, which is CSP (cyclic synchronous position control mode) by default.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_SetControllerMode	Set current operation mode		MC_SetControllerMode_Instance_0(Axis :=, Execute :=, ControllerMode :=, ManualSwitch :=, Done =>, Busy =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	The function block is executed on a rising edge of this input variable.
ControllerMode	Controller mode	18.3.3.2.2.7 MC_CONTROLLER_MODE: Controller Mode Enumeration	10: MC_CST 9: MC_CSV 8: MC_CSP	MC_CSP	10: MC_CST (cyclic synchronous torque control mode). 9: MC_CSV (cyclic synchronous velocity control mode). 8: MC_CSP.
ManualSwitch	Controller mode switch mode	18.3.3.2.2.17 MC_CONTROLLER_MODE_SWITCH: Controller Mode Switch Mode Enumeration	0: MC_AUTO 1: MC_MANUAL	MC_AUTO	0: MC_AUTO: Automatic switch. 1: MC_MANUAL: Manual switch.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**

  Bus-controlled axis:

  - After this instruction completes the controller mode switching, signal output will immediately follow the switched mode. For example, if the MC_MoveAbsolute instruction is in the planning state in CSP mode, and a position instruction is output to the axis, the planned velocity by the MC_MoveAbsolute will remain unchanged after switching to CSV mode until the MC_MoveAbsolute planning ends.
  - The input parameter ManualSwitch of this instruction is used to specify the switch mode of control modes for different motion control instructions based on the input parameters after the Done is set. If the ManualSwitch is set to MC_AUTO, subsequent control mode switch will be performed internally by the instruction. If the ManualSwitch is set to MC_MANUAL, subsequent control mode switch will be performed through this instruction. The ManualSwitch is set to MC_AUTO by default.
  - The input parameter ManualSwitch is used to specify the switch mode of control modes for different motion control instructions.
    - MC_AUTO: Automatic switch. The logic for this method is as follows: ① When the current control mode matches the required control mode for the instruction, the instruction is executed in the current control mode. ② When the current control mode does not match the required control mode for the instruction, the instruction is executed after switching the control mode to the required mode.
    - MC_MANUAL: Manual switch. The logic for this method is as follows: ① When the current control mode matches the required control mode for the instruction, the instruction is executed directly. ② When the current control mode does not match the required control mode for the motion control instruction, the instruction must be executed after the MC_SetControllerMode instruction is executed to switch the control mode to the required one; otherwise, the motion control instruction will issue a fault message. When the MC_SetControllerMode instruction is executed with the ManualSwitch = 1, if an instruction is being executed, it will be aborted with the axis state switching to AXIS_STANDSTILL.
  - Different control modes for applicable motion control instructions are shown in the following table.

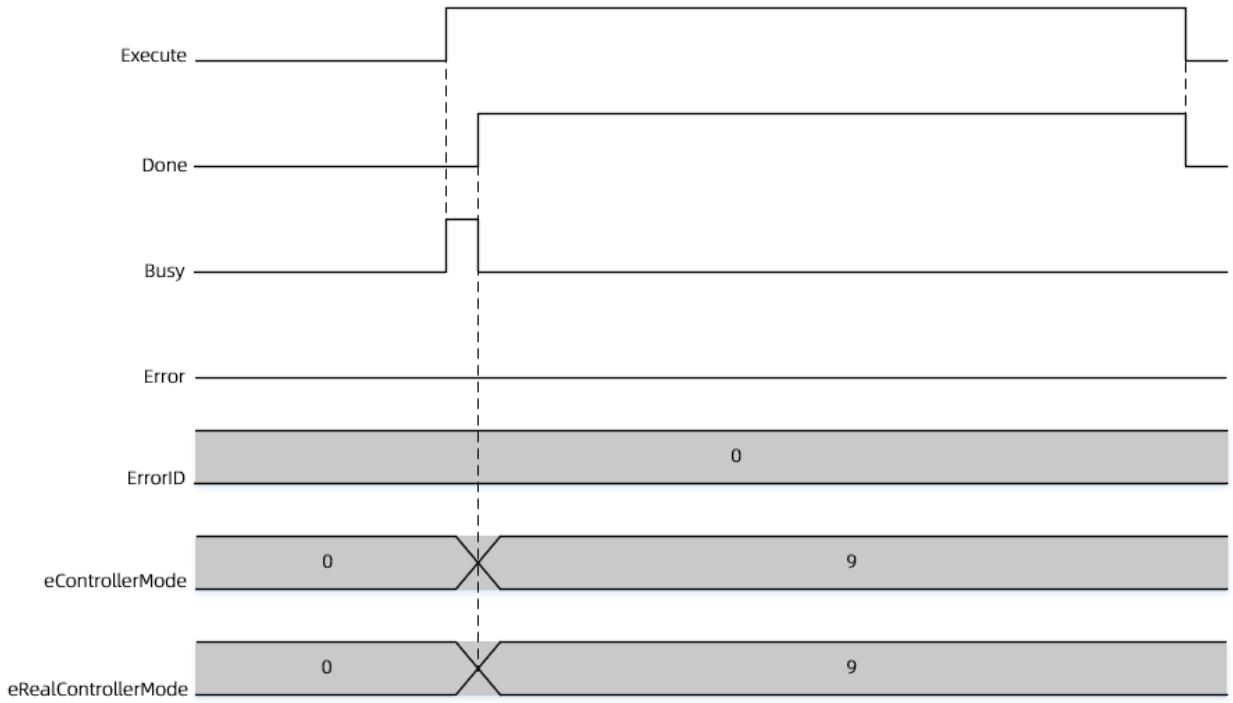
Controller mode	Motion Control Instruction
MC_CSP	MC_MoveAbsolute, MC_MoveRelative, MC_MoveContinuousAbsolute, MC_MoveContinuousRelative, MC_MoveFeed, MC_Inch, MC_CamIn, MC_CamInV2
MC_CSV	MC_SyncMoveVelocityCSV

Controller mode	Motion Control Instruction
MC_CST	MC_TorqueControl
MC_CSP/MC_CSV	MC_MoveVelocity, MC_Jog, MC_FollowPosition, MC_FollowVelocity, MC_FollowPositionVelocity, MC_GearIn, MC_GearInPos, MC_MoveLink, MC_CombineAxes, MC_GearOut, MC_CamOut

Notes: ① Regardless of the input parameter ManualSwitch, this instruction does not affect the MC_MoveSuperImposed instruction, which can be executed in the MC_CSP mode only. When the current control mode is MC_CST, a fault message will appear if the MC_MoveSuperImposed instruction is executed. ② For instructions that can be executed in both CSP and CSV mode, if high accuracy of position information is required, it is recommended to execute the instructions in the CSP mode; if only velocity information is needed, the instructions can be executed in either control mode.

- Control mode switching is supported under any mode and conditions, but control mode switching during operation may cause a sudden change in velocity.
- If the control mode is switched to CSV without PDO objects 60FF and 606C being configured, a fault message will appear.
- If the control mode is switched to CST without PDO objects 6077 and 6071 being configured, a fault message will appear.
- Control mode switching is supported among CSP, CSV, and CST modes only, and the axis type must be a control axis.
- This instruction cannot be triggered when the axis state is AXIS_STOPPING, AXIS_HOMING, or AXIS_ER RORSTOP.
- This instruction does not abort the motion control instructions. It only modifies the current control mode.
- This instruction can be executed even if PDO objects 6060 and 6061 are not configured.
- Repeated or multiple execution of this instruction results in a fault. This instruction cannot be called again before the mode switching is completed.

Local pulse axis:



- This instruction cannot be used for local pulse axes.

- **Timing diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Done of the function block indicates that the instruction has been executed successfully, and the parameter Busy indicates that the current function block is being executed.

  After this instruction is called, the output parameter Busy is set to TRUE on a rising edge of Execute. When the control mode switching is completed, the output parameter Done is set to TRUE.

  The axis structure variable eControllerMode represents the axis control mode, and the eRealControllerMode represents the actual control mode of an axis.

- **Re-execution of motion control instructions**

  This instruction cannot be re-executed.

- **Faults**

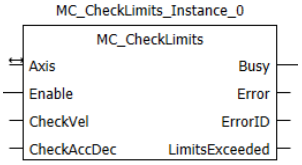
  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

- **Example**

  Currently, positioning instructions and velocity instructions are executed in the CSP mode by default. If you want such an instruction to be executed in the CSV mode, you must use the MC_SetControllerMode instruction to switch the control mode.

  First, configure the PDOs: Select the first group of input parameters and configure the 606C. Select the output parameters other than the first and second group of output parameters, or select the first group of output parameters and add the 60FF.

  Call a motion control instruction. After the instruction is executed, the parameter Busy serves as the trigger condition for the MC_SetControllerMode instruction. When the ControllerMode is set to CSV, the control mode can be switched after the MC_MoveAbsolute instruction is triggered.



- **Precautions**

  It is not recommended to execute positioning instructions in the CSV mode, as it may cause significant deviation.

18.3.3.3.23 MC_CheckLimits

This instruction checks if the reference values for the current axis exceed the upper limits configured in the controller.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_CheckLimits	Check axis reference values against upper limits		MC_CheckLimits_Instance_0(Axis :=, Enable :=, CheckVel :=, CheckAccDec :=, Busy =>, Error =>, ErrorID =>, LimitsExceeded =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Enable	Enable	BOOL	TRUE, FALSE	FALSE	TRUE: Enabled. FALSE: Disabled.
CheckVel	Check velocity	BOOL	TRUE, FALSE	FALSE	TRUE: Enabled. FALSE: Disabled.
CheckAccDec	Check acceleration/ deceleration	BOOL	TRUE, FALSE	FALSE	TRUE: Enabled. FALSE: Disabled.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.
LimitsExceeded	Limits exceeded	BOOL	TRUE, FALSE	FALSE	TRUE if the velocity or acceleration/deceleration reference exceeds the upper limit setpoint.

- **Function**

  Bus-controlled axis:

  - This instruction only checks if the velocity or acceleration/deceleration reference exceeds the upper limit setpoint in the software and does not stop the axis movement.
  - When the input parameter CheckVel is set to TRUE, this instruction checks if the velocity reference exceeds the upper limit.
  - When the input parameter CheckAccDec is set to TRUE, this instruction checks if the acceleration/deceleration reference exceeds the upper limit.
  - When input parameters CheckVel and CheckAccDec are set to TRUE, and either the velocity or acceleration/deceleration reference exceeds the upper limit, the output parameter LimitsExceeded flag will be set. This flag is refreshed periodically. If the velocity and acceleration/deceleration reference in the next cycle do not exceed the upper limits, the flag will be reset automatically.

  Local pulse axis:

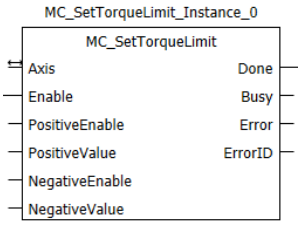
  - This instruction can be used for local pulse axes.

- **Timing diagram**

  When the input parameter Enable is set to TRUE, the output parameter Busy shows the value TRUE. If the velocity or acceleration/deceleration reference exceeds the upper limit setpoint, the output parameter LimitsExceeded will be set to TRUE.

- **Re-execution of motion control instructions**

  This instruction cannot be re-executed.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.3.24 MC_SetTorqueLimit

This instruction limits the axis torque output using the torque limiting function of the servo drive.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_SetTorqueLimit	Set upper torque limit		MC_SetTorqueLimit _Instance_0(Axis :=, Enable :=, PositiveEnable :=, PositiveValue :=, NegativeEnable :=, NegativeValue :=, Done =>, Busy =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Enable	Enable	BOOL	TRUE, FALSE	FALSE	TRUE: Enabled. FALSE: Disabled.
PositiveEnable	Positive enable	BOOL	TRUE, FALSE	FALSE	TRUE: Enabled. FALSE: Disabled.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
PositiveValue	Positive torque limit	LREAL	0.1 to 1000	0	Set the positive torque limit, in increments of 0.1%. If the value is greater than the axis parameter PositiveValue, the positive torque limit will be clamped to the PositiveValue.
NegativeEnable	Negative enable	BOOL	TRUE, FALSE	FALSE	TRUE: Enabled. FALSE: Disabled.
NegativeValue	Negative torque limit	LREAL	0.1 to 1000	0	Set the negative torque limit, in increments of 0.1%. If the value is greater than the axis parameter NegativeValue, the negative torque limit will be clamped to the NegativeValue.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**

  Bus-controlled axis:

  - This instruction sets the torque limit of an axis.
  - When the parameter Enable is set to TRUE, the limit will be the setpoint of the input parameter PositiveValue if the input parameter PositiveEnable shows the value TRUE; the limit will be the setpoint of the input parameter NegativeValue if the input parameter NegativeEnable shows the value TRUE.
  - When the PositiveEnable is set to FALSE, the PositiveValue will not take effect, and the axis torque limit will return to the setpoint in the software. Similarly, when the NegativeEnable is set to FALSE, the NegativeValue will not take effect, and the axis torque limit will return to the setpoint in the software.
  - When the parameter Enable is set to FALSE, you can specify the [PositiveValue] and [NegativeValue] on the servo drive, and set the Busy to FALSE.
  - If the set value of PositiveValue or NegativeValue is less than or equal to 0, it will be treated as 0. If the setpoint of PositiveValue or NegativeValue is greater than or equal to the setpoint in the software, it will be treated as setpoint in the software.
  - If the control object is a bus-controlled axis, the PDOs 60E0 (PositiveValue) and 60E1 (NegativeValue) must be configured; otherwise, the execution of this instruction will result in an error.

  Local pulse axis:

  - This instruction cannot be used for local pulse axes.

- **Timing diagram**

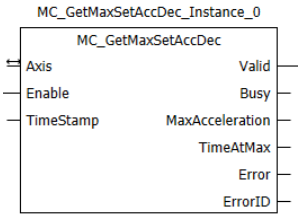
  When the input parameter Enable is set to TRUE, the output parameter Busy shows the value TRUE. When the axis torque limit is specified during execution, the output parameter Done shows the value TRUE.

- **Re-execution of motion control instructions**

  You cannot re-execute motion control instructions with an input parameter Enable.

- **Multiple execution of motion control instructions**

  When multiple MC_SetTorqueLimit instructions are triggered simultaneously, the parameters of the last triggered instruction take effect.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.3.25 MC_GetMaxSetAccDec

This instruction reads the maximum acceleration/deceleration of an axis and records the time at which the maximum acceleration/deceleration is reached.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_GetMaxSetAccDec	Read maximum acceleration/ deceleration		MC_GetMaxSetAccDec_Instance_0(Axis :=, Enable :=, TimeStamp :=, Valid =>, Busy =>, MaxAcceleration =>, TimeAtMax =>, Error =>, ErrorID =>);

Related variables

In-out variables

MaxAcceleration	Maximum acceleration/ deceleration	LREAL	Positive number, negative number, or 0	0	Maximum value of acceleration /deceleration [u/s^2] (positive value for acceleration, negative value for deceleration; the absolute maximum value of acceleration /deceleration is the final value).
TimeAtMax	Time stamp at the maximum acceleration/ deceleration	DWORD	-	0	This value is continuously updated while the acceleration/ deceleration is increasing and the recorded time stamp is returned when the maximum acceleration/ deceleration is reached.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18 .3.3.8 Fault Codes) is output when a fault occurs.

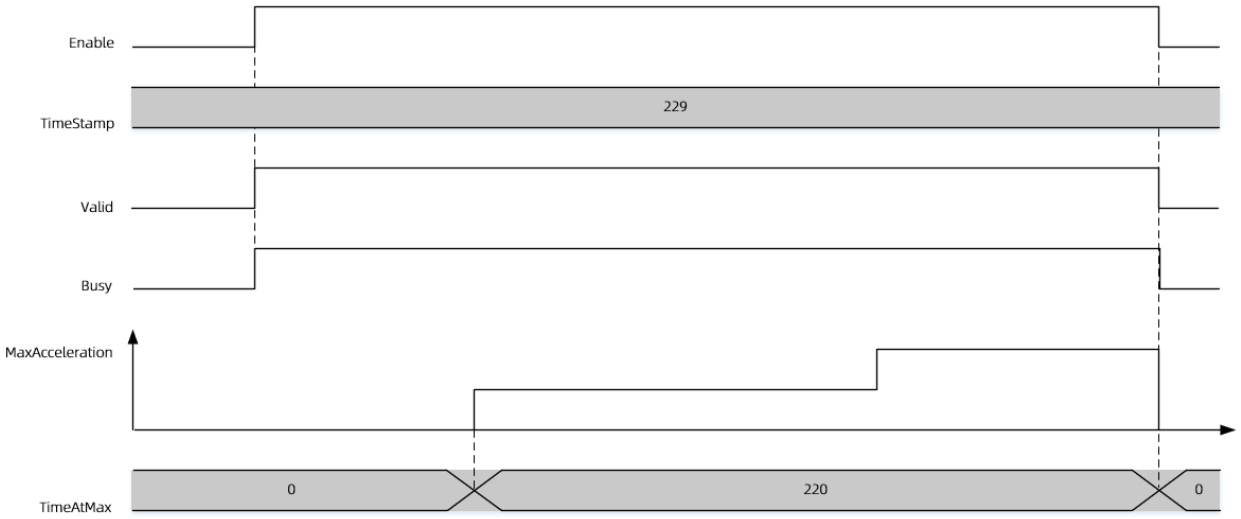
- **Function**

  Bus-controlled axis:

  - If the parameter Enable is set to TRUE and there are no faults, the instruction will start reading the maximum acceleration/deceleration of an axis with the parameter Valid being set.

- If the absolute value of acceleration/deceleration is greater than the recorded value in the previous cycle, the MaxAcceleration and TimeAtMax will be refreshed continuously. The value of TimeAtMax corresponds to the value of TimeStamp when the maximum acceleration/deceleration is reached. Therefore, the parameter TimeStamp can be specified as a variable, such as a count value varying with the task cycle or the fixed interval.
- When the axis is in abnormal communication, this instruction issues a fault message with a fault code.

Local pulse axis:



- This instruction can be used for local pulse axes.

- **Timing diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Valid of the function block indicates valid outputs, and the parameter Busy indicates that the current function block is being executed.

  When the input parameter Enable is set to TRUE, the output parameter Valid shows the value TRUE and this instruction checks the maximum acceleration/deceleration of the axis and records the time at which the maximum acceleration/deceleration is reached. If the absolute value of acceleration/deceleration is greater than the recorded value, the MaxAcceleration and TimeAtMax will be refreshed.

  The value of TimeAtMax corresponds to the value of TimeStamp when the maximum velocity is reached. Therefore, the parameter TimeStamp can be specified as a variable, such as a count value varying with the task cycle or the fixed interval.

- **Re-execution of motion control instructions**

  This instruction cannot be re-executed.

- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

- **Example**

  You can configure DWORD data that increases in a cycle and associate it with TimeStamp. In the following example, the timeStamp_0 that increases by 1 every second is associated with the input terminal TimeStamp of this instruction. When the instruction detects the maximum velocity, it records the maximum acceleration and the corresponding TimeStamp on the output terminals MaxAcceleration and TimeAtMax. You can check the time when the maximum acceleration is reached.

18.3.3.3.26 MC_GetMaxSetVelocity

This instruction reads the maximum velocity of an axis and records the time at which the maximum velocity is reached.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_GetMaxSetVelocity	Read maximum velocity		MC_GetMaxSetVelocity_Instance_0(Axis :=, Enable :=, TimeStamp :=, Valid =>, Busy =>, MaxVelocity =>, TimeAtMax =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Enable	Enable	BOOL	TRUE, FALSE	FALSE	TRUE: Enabled. FALSE: Disabled.
TimeStamp	Time stamp	DWORD	-	-	Optional time reference source (for example, varying with the task cycle or the fixed interval).

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Valid	Valid output	BOOL	TRUE, FALSE	FALSE	TRUE when there is a valid output from the function block.

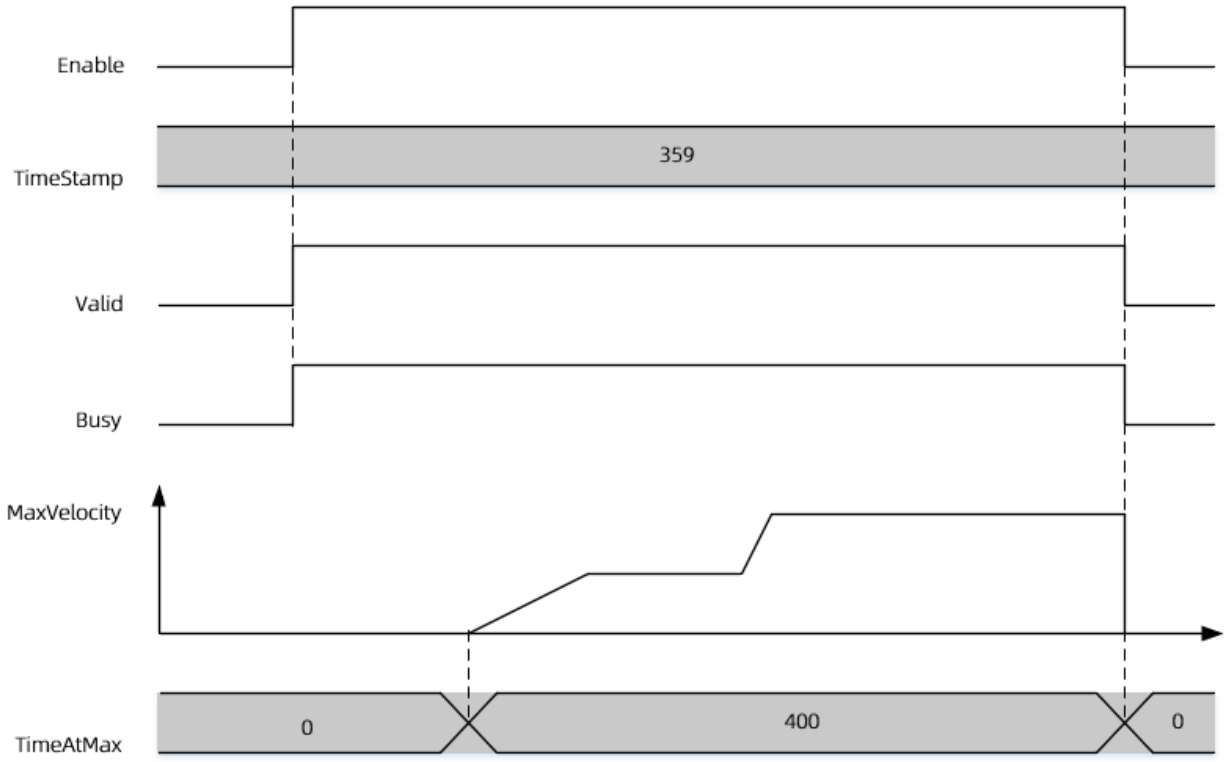
Output Variable	Name	Data Type	Valid Range	Default Value	Description
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
MaxVelocity	Maximum velocity	LREAL	-	0	Maximum value of velocity [u/s] (positive value for acceleration, negative value for deceleration; the absolute maximum value of velocity is the final value).
TimeAtMax	Time stamp at the maximum acceleration/ deceleration	DWORD	-	0	This value is continuously updated while the velocity is increasing and the recorded time stamp is returned when the maximum velocity is reached.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**

  Bus-controlled axis:

  - If the parameter Enable is set to TRUE and there are no faults, the instruction will start detecting the maximum velocity of an axis with the parameter Valid being set.
  - If the absolute value of velocity is greater than the recorded value, the MaxVelocity and TimeAtMax will be refreshed continuously. The value of TimeAtMax corresponds to the value of TimeStamp when the maximum velocity is reached. Therefore, the parameter TimeStamp can be specified as a variable, such as a count value varying with the task cycle or the fixed interval.
  - When the axis is in abnormal communication, this instruction issues a fault message with a fault code.

Local pulse axis:



- This instruction can be used for local pulse axes.

- **Timing diagram**

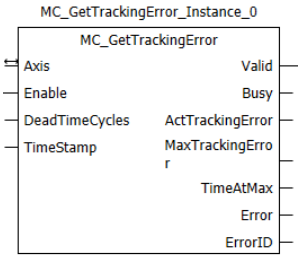
  The parameter Execute of the function block must be triggered on a rising edge. The parameter Valid of the function block indicates valid outputs, and the parameter Busy indicates that the current function block is being executed.

  When the input parameter Enable is set to TRUE, the output parameter Valid shows the value TRUE. This instruction reads the maximum velocity of an axis and records the time at which the maximum velocity is reached. If the absolute value of velocity is greater than the recorded value, the MaxVelocity and TimeAtMax will be refreshed.

  The value of TimeAtMax corresponds to the value of TimeStamp when the maximum velocity is reach ed. Therefore, the parameter TimeStamp can be specified as a variable, such as a count value varying with the task cycle or the fixed interval.

- **Re-execution of motion control instructions**

  This instruction cannot be re-executed.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.3.27 MC_GetTrackingError

This instruction measures the actual or maximum tracking error.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_GetTrackingError	Measure actual or maximum tracking error		MC_GetTrackingError_Instance_0(Axis :=, Enable :=, DeadTimeCycles :=, TimeStamp :=, Valid =>, Busy =>, ActTrackingError =>, MaxTrackingError =>, TimeAtMax =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Enable	Enable	BOOL	TRUE, FALSE	FALSE	TRUE: Enabled. FALSE: Disabled.
DeadTimeCycles	Dead time cycles	BYTE	-	2	Delay duration before starting lag detection after the Enable trigger.
TimeStamp	Time stamp	DWORD	-	-	Optional time reference source (for example, varying with the task cycle or the fixed interval).

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Valid	Valid output	BOOL	TRUE, FALSE	FALSE	TRUE when there is a valid output from the function block.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
ActTrackingError	Actual tracking error	LREAL	-	0	Actual deviation (positive value for delay, negative value for lead; the absolute maximum value is the final value).
MaxTrackingError	Maximum tracking error	LREAL	-	0	Maximum deviation (positive value for delay, negative value for lead; the absolute maximum value is the final value).
TimeAtMax	Time stamp at the maximum tracking error	DWORD	-	0	Time stamp at the maximum deviation.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**

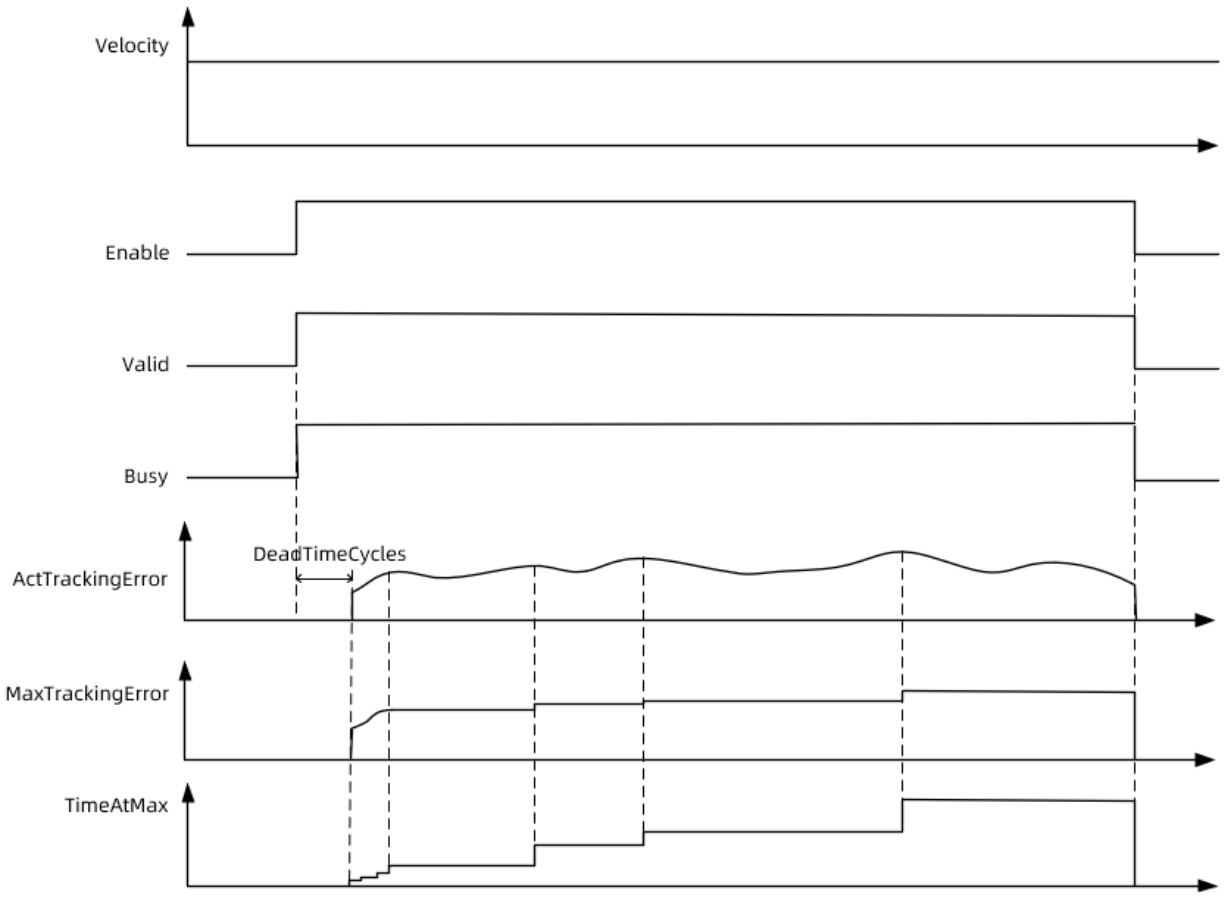
  Bus-controlled axis:

  - When the TimeStamp is less than the DeadTimeCycles, no tracking error is recorded. The maximum tracking error is recorded after the TimeStamp exceeds the DeadTimeCycles. When the tracking error is greater than the recorded value, the MaxTrackingError and TimeAtMax are refreshed continuously. The

parameter value of TimeAtMax corresponds to the value of TimeStamp when the maximum tracking error is detected. Therefore, the parameter TimeStamp can be specified as a variable, such as a count value varying with the task cycle or the fixed interval.

- In CSV and CST modes, the tracking error remains 0 when there is no position reference output.
- When the axis is in abnormal communication, this instruction issues a fault message with a fault code.
- This instruction can be used for bus-controlled axes.

Local pulse axis:



- This instruction cannot be used for local pulse axes.

- **Timing diagram**

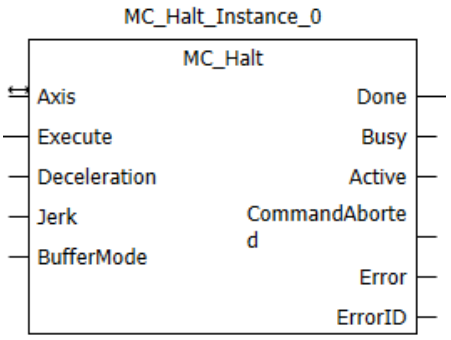
  When the input parameter Enable is set to TRUE, the output parameter Valid shows the value TRUE and this instruction measures the actual or maximum tracking error.

  When the absolute deviation is greater than the recorded value, the MaxTrackingError and TimeAtMax are refreshed.

  The value of TimeAtMax corresponds to the value of TimeStamp when the maximum tracking error is detected. Therefore, the parameter TimeStamp can be specified as a variable, such as a count value varying with the task cycle or the fixed interval.

- **Re-execution of motion control instructions**

  This instruction cannot be re-executed.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.3.28 MC_Halt

This instruction pauses an axis in normal motion.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_Halt	Pause axis		MC_Halt _Instance_0(Axis :=, Execute :=, Deceleration :=, Jerk :=, BufferMode :=, Done =>, Busy =>, Active =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	The function block is executed on a rising edge of this input variable.
Deceleration	Deceleration	LREAL	Positive number	0	Specify the deceleration [u/s^2] for an axis to decelerate.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Jerk	Jerk	LREAL	Positive number	0	Slope of deceleration [u/s^3]. Note: This parameter is ignored when the T-curve is specified in the software; This parameter must be greater than 0 when the S-curve is specified in the software.
BufferMode	Buffer mode	18.3.3.2.2.6 MC_BUFFER_MODE: Buffer Mode Enumeration	0: mcAborting 1: mcBuffered	0	0: mcAborting (Aborting). 1: mcBuffered (Buffered).

- **Output variables**

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Active	Controlling	BOOL	TRUE, FALSE	FALSE	TRUE when the axis is being controlled.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs in the function block.

- **Parameter correction**

Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Deceleration	Deceleration	Any deceleration that exceeds the motion parameter limit will be automatically corrected to the deceleration limit.	Any deceleration less than 0 will be automatically corrected to 10% of the deceleration limit.	The deceleration equal to 0 will be automatically corrected to 10% of the deceleration limit.
Jerk	Jerk	If the motion profile is set to S-curve, any jerk that exceeds the software limit will be automatically corrected to the jerk limit.	If the motion profile is set to S-curve, any jerk less than 0 will be automatically corrected to 10% of the jerk limit.	If the motion profile is set to S-curve, the jerk equal to 0 will be automatically corrected to 10% of the jerk limit.

- **Function**

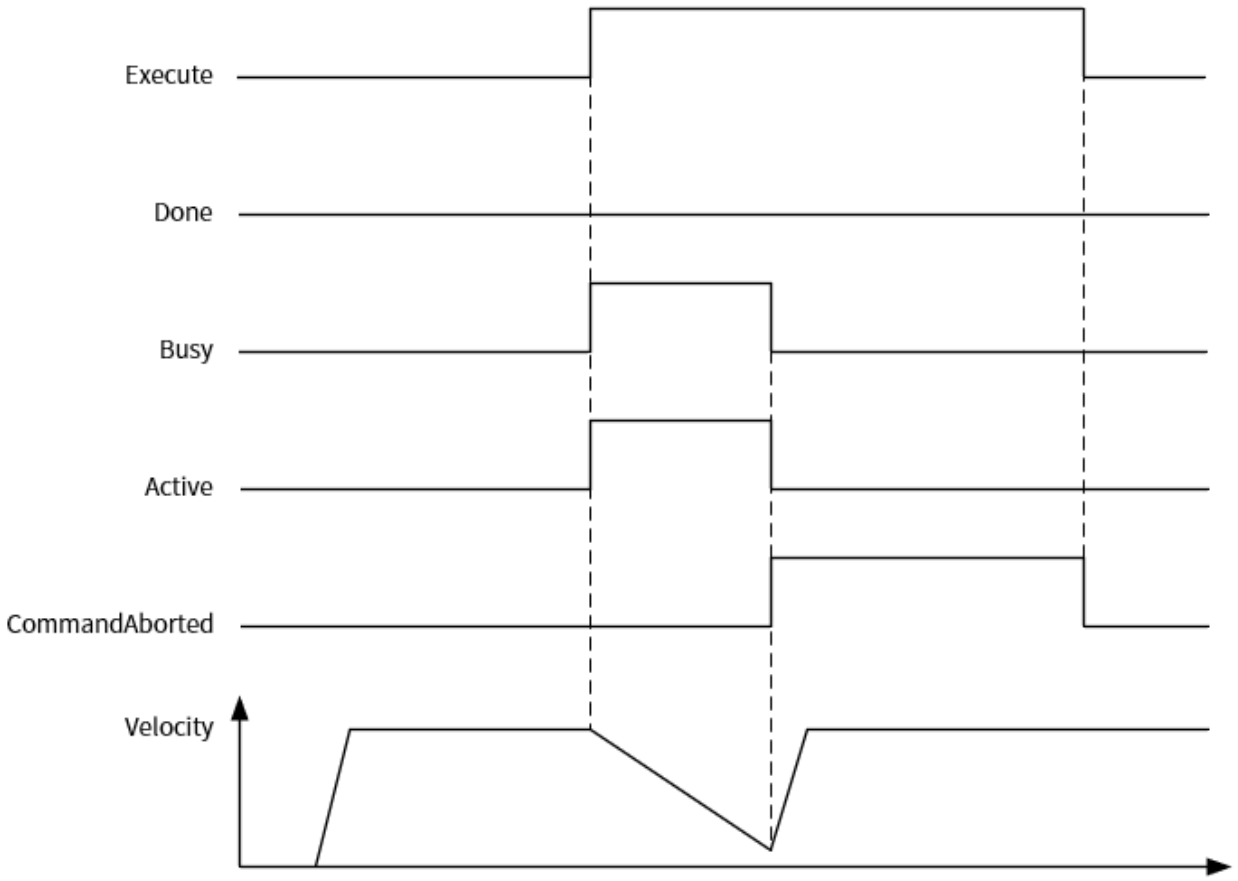
  Bus-controlled axis:

  - This instruction pauses an axis in normal motion. Triggering other motion control instructions abort the execution of this instruction.
  - During the execution of this instruction, do not modify the input parameter BufferMode to a mode other than MC_ABORTING before re-executing the instruction; otherwise, the function block reports a fault and the axis decelerates to stop according to the set motion parameters in the software.
  - This instruction does not support BLENDING mode. If the input parameter BufferMode is set improperly, the function block will report a fault and the axis will decelerate to stop under a T-curve planning, using the maximum deceleration limit in the software.
  - When the axis state is AXIS_ERRORSTOP, triggering this instruction causes the function block to report a fault. When the axis state is AXIS_HOMING or AXIS_STOPPING, the MC_halt instruction is aborted. During the execution of this instruction, the axis state is AXIS_DISCRETE_MOTION; after completion of this instruction, the axis state is AXIS_STANDSTILL.
  - The axis type must be control axis.
  - In CSV mode, this instruction is used to halt the motion of the axis, while the servo axis remains in CSV mode.

  Local pulse axis:

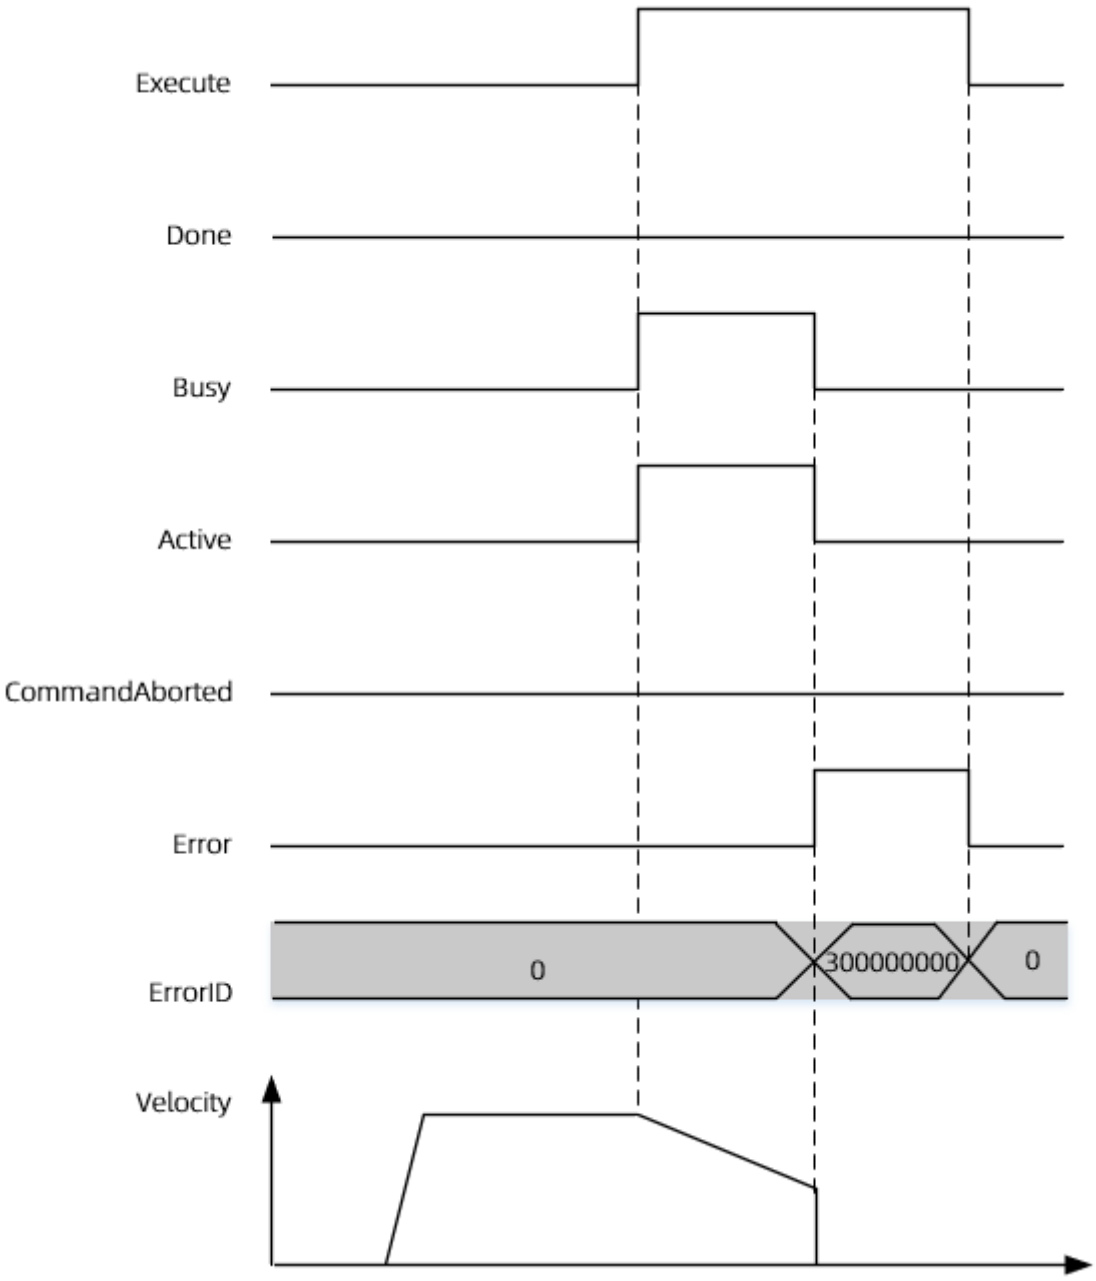
  This instruction can be used for local pulse axes.

- **Timing diagram**



The parameter Execute of the function block must be triggered on a rising edge. The parameter Done of the function block indicates the instruction has been executed successfully; the parameter Busy indicates that the current function block is being executed; the parameter CommandAborted indicates that the instruction is aborted by another motion control instruction, at which point the flag is set to TRUE.

The parameter Busy shows the value TRUE on a rising edge of Execute. In the next cycle, the output parameter Active shows the value TRUE.



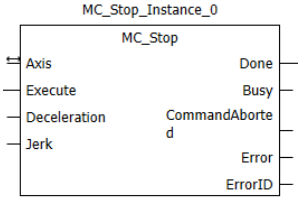
◦ After the MC_MoveVelocity instruction is called, trigger the MC_Halt instruction.

◦ After the MC_Halt instruction is triggered, re-call the MC_MoveVelocity instruction to abort the MC_Halt instruction.

◦ The drive stops upon a fault during execution of the MC_Halt instruction.

- **Re-execution of motion control instructions**

  The re-executed instruction will perform planning according to new motion parameters, and the current buffered instructions will be cleared.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.3.29 MC_Stop

This instruction decelerates an axis to stop.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_Stop	Stop		MC_Stop _Instance_0(Axis :=, Execute :=, Deceleration :=, Jerk :=, Done =>, Busy =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

  In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

  Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	The function block is executed on a rising edge of this input variable.
Deceleration	Deceleration	LREAL	Positive number	0	Specify the deceleration [u /s^2] for an axis to decelerate.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Jerk	Jerk	LREAL	Positive number	0	Slope of deceleration [u /s^3]. Note: This parameter is ignored when the T-curve is specified in the software; This parameter must be greater than 0 when the S-curve is specified in the software.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs in the function block.

- **Parameter correction**

Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Deceleration	Deceleration	Any deceleration that exceeds the motion parameter limit will be automatically corrected to the deceleration limit.	Any deceleration less than 0 will be automatically corrected to 10% of the deceleration limit.	The deceleration equal to 0 will be automatically corrected to 10% of the deceleration limit.
Jerk	Jerk	If the motion profile is set to S-curve, any jerk that exceeds the software limit will be automatically corrected to the jerk limit.	If the motion profile is set to S-curve, any jerk less than 0 will be automatically corrected to 10% of the jerk limit.	If the motion profile is set to S-curve, the jerk equal to 0 will be automatically corrected to 10% of the jerk limit.

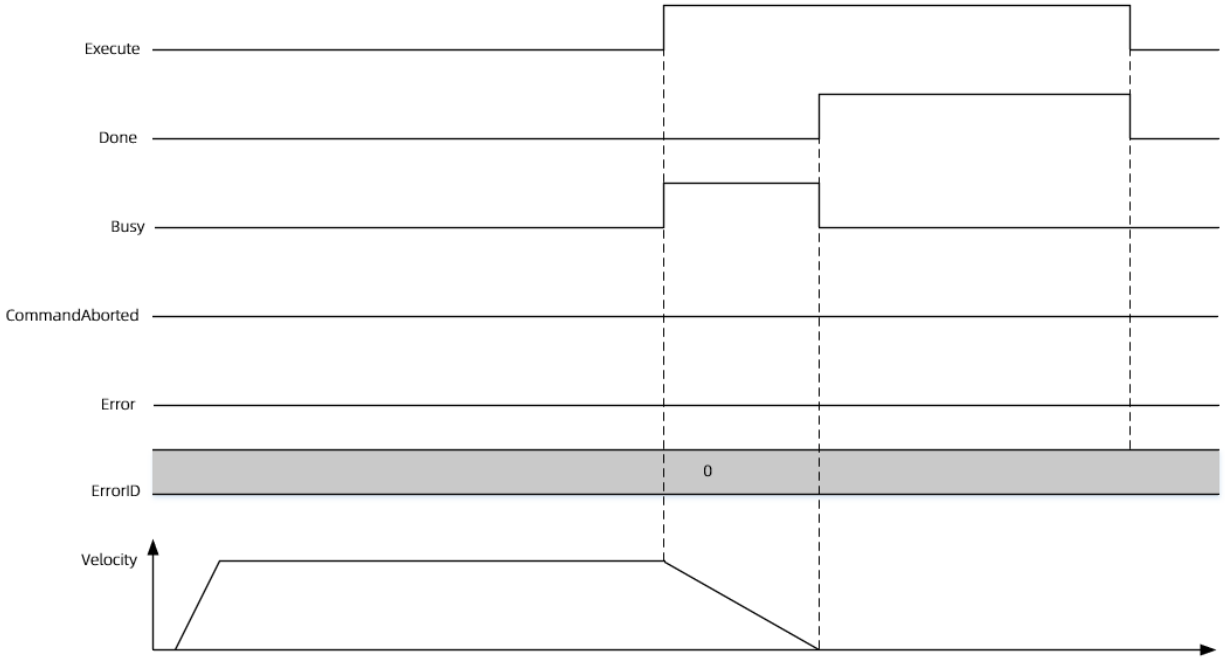
- **Function**

  Bus-controlled axis:

  - This instruction controls the deceleration of an axis. If the axis state is AXIS_POWEROFF or AXIS_ERROR STOP, or the single axis being operated is bound to an axis group, triggering this instruction will cause the function block to report a fault.
  - On a rising edge of Execute, the axis decelerates from the current velocity to 0 according to the input parameters Deceleration and Jerk; once the axis is standstill, the output parameter Done is set.
  - During the execution of this instruction, the axis state is AXIS_STOPPING. After this instruction is done, the axis state remains AXIS_STOPPING. If you want to switch the axis state to AXIS_STANDSTILL, reset the input parameter Execute of the function block.
  - This instruction can be aborted by the MC_ImmediateStop instruction only. When the instruction is aborted during execution, the output parameter CommandAborted is set.
  - During the execution of this instruction, you can re-execute it after modifying parameters. If the instruction is triggered while the axis state is AXIS_STANDSTILL, the axis state will switch to AXIS_STOPPING with the output parameter Done being set.
  - During the execution of this instruction, do not execute another instance of this instruction; otherwise, the subsequently triggered function block will issue a fault message.
  - After the instruction is done, the axis is in the Stopping state. If another MC_Stop instruction is triggered, the subsequently triggered function block will issue a fault message.
  - The axis controlled by this instruction must be control axis.
  - If you want to switch the control mode to CSP mode with the PDO, ensure that 6060 and 6061 in the object dictionary are correctly configured; otherwise, switch the control mode to CSP mode with the SDO.

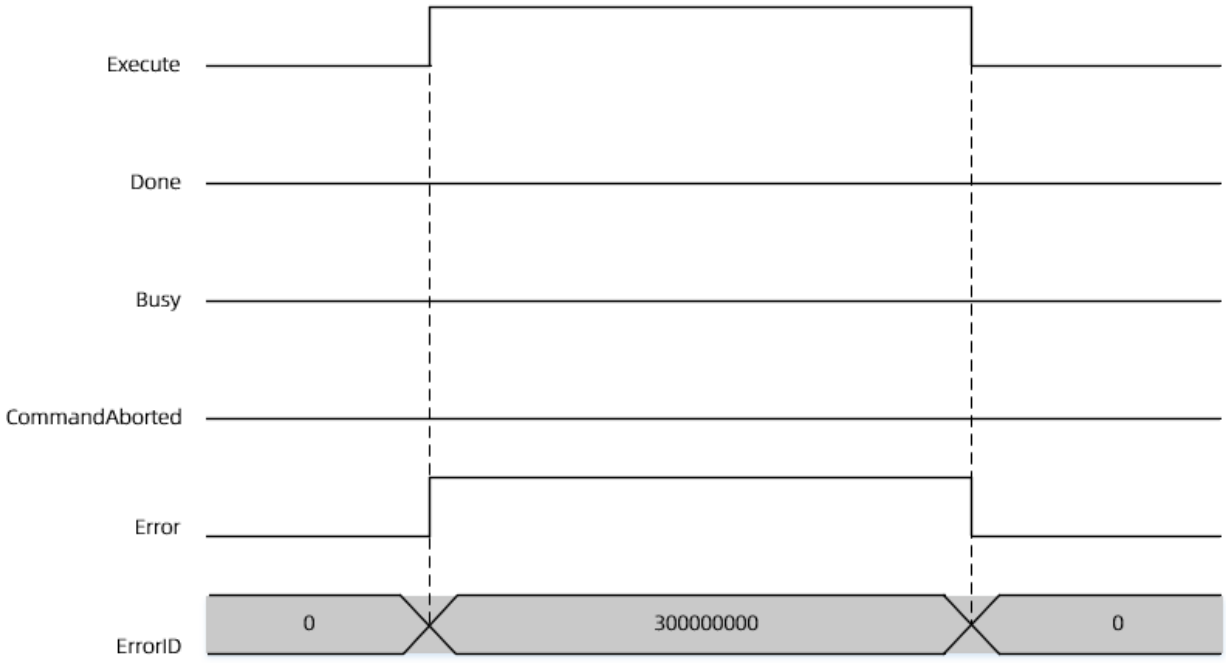
  Local pulse axis:

  - This instruction can be used for local pulse axes.



- **Timing diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Done of the function block indicates the instruction has been executed successfully; the parameter Busy indicates that the current function block is being executed; the parameter CommandAborted



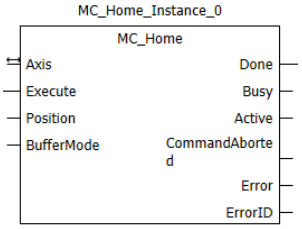
indicates that the instruction is aborted by another motion control instruction, at which point the flag is set to TRUE.

The parameter Busy shows the value TRUE on a rising edge of Execute. In the next cycle, the output parameter Active shows the value TRUE.

- After the MC_MoveVelocity instruction is called, trigger the MC_Stop instruction.

- The drive malfunctions during the instruction execution.

- **Multiple execution of motion control instructions**
  - When multiple MC_Stop instructions are executed simultaneously, the first instruction takes effect, while subsequent instructions are aborted.
  - If the current axis state is AXIS_STOPPING and the MC_Stop instruction is executed, the output parameter CommandAborted of the instruction will be set, without affecting the active MC_Stop instruction or the deceleration stop process.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.3.30 MC_Home

This instruction operates the drive to define the home.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_Home	Drive homing		MC_Home _Instance_0(Axis :=, Execute :=, Position :=, BufferMode :=, Done =>, Busy =>, Active =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

  In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

  Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	Execute the instruction.
Position	Position	LREAL	Positive number, negative number, or 0	0	Target position [u] in absolute coordinates.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
BufferMode	Buffer mode (reserved)	18.3.3.2.2.6 MC_BUFFER_MODE: Buffer Mode Enumeration	0: mcAborting 1: mcBuffered	0	0: mcAborting (Aborting). 1: mcBuffered (Buffered).

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Active	Controlling	BOOL	TRUE, FALSE	FALSE	TRUE when the axis is being controlled by the current FB.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**

  Bus-controlled axis:

  - This instruction can be triggered only when the axis state is AXIS_STANDSTILL. During the execution of the instruction, the axis state is AXIS_HOMING. After the instruction is done, the axis state switches to AXIS_STANDSTILL.
  - On a rising edge of Execute, this instruction records the value of the input parameter Position, which is used for defining the home offset.
  - Configure the PDOs 6060 and 6061 before calling this instruction; otherwise, switch the control mode with the SDO.
  - When the axis state is AXIS_ERRORSTOP, homing cannot be performed, and a fault message will appear if an attempt is made to execute this instruction.

- This instruction can be aborted by the MC_Stop or MC_ImmediateStop instruction only during execution.
- This instruction cannot be re-called. When this instruction is triggered and the axis state switches to AXIS_HOMING, calling other MC_Home instructions result in a fault, without affecting the ongoing homing.
- If homing is aborted by the MC_ImmediateStop instruction, the control mode will not be directly switched to CSP mode. You must call the MC_Reset instruction to clear the axis fault and then switch the control mode.
- The axis type must be control axis.
- Software limits have no effect on this instruction.
- Frequently triggering this instruction may bring warnings regarding frequently reading single data from the servo drive. Taking the SV660N servo drive as an example, you can set bit 6 of H0A.71 to 1 to disable such a warning. For other servo drives, see their user guides for details.
- The arrival check function is only applicable to MotionControl library version 2.4.0.0 or later. Based on the "Positioning range" and "Positioning check time" parameters in the "General setting" of the axis configuration page, it checks in real time whether the actual position has entered the specified target range. After the instruction output for the target position is completed, positioning is complete and the Done output is set if the difference between the actual position and the target position is smaller than the "Positioning range". If positioning is not completed within the "Positioning check time", a fault will occur.

  Local pulse axis:

- This instruction can be used for local pulse axes.

- **Timing diagram**

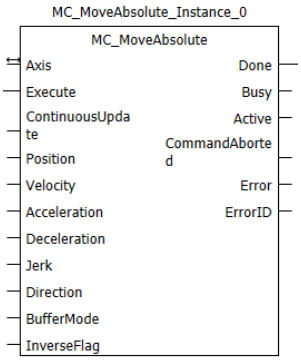
  The parameter Execute of the function block must be triggered on a rising edge. The parameter Done of the function block indicates the instruction has been executed successfully; the parameter Busy indicates that the current function block is being executed; the parameter CommandAborted indicates that the instruction is aborted by another motion control instruction, at which point the flag is set to TRUE.

  After this instruction is called, the output parameter Busy is set to TRUE on a rising edge of Execute In the next cycle, the output parameter Active shows the value TRUE. After homing is done, the output parameter Done is set to TRUE.

- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

- **Precautions**
  - This instruction will cause slight jitter in the axis position reference due to control mode switching if it is executed immediately after a positioning instruction or a relative move instruction; if the axis is the master axis of a synchronization instruction, the slave axis velocity may experience a sudden change.
  - Checking Reverse on the interface has no effect on the MC_Home instruction.



- After the servo drive homing is done, there may be jitter. If the Direction of the subsequent instruction is set to Current, it may be inconsistent with the planned direction at the end of the homing. It is recommended that users define proper motion direction when using the subsequent instruction.

18.3.3.3.31 MC_MoveAbsolute

This instruction moves an axis to a specified absolute target position.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_MoveAbsolute	Absolute positioning		MC_MoveAbsolute_Instance_0(Axis :=, Execute :=, ContinuousUpdate :=, Position :=, Velocity :=, Acceleration :=, Deceleration :=, Jerk :=, Direction :=, BufferMode :=, InverseFlag :=, Done =>, Busy =>, Active =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	Execute the instruction.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Continuous Update	Continuous update	BOOL	TRUE, FALSE	FALSE	Continuous parameter update effective flag. Prerequisite: The parameter ContinuousUpdate shows the value TRUE and the parameter Active shows the value TRUE. Effective parameters: Position, Velocity. Note: The modified parameter values must differ from the original parameter values by more than 0.01.
Position	Position	LREAL	Positive number, negative number, or 0	0	Target position [u] in absolute coordinates.
Velocity	Velocity	LREAL	Positive number	0	Maximum velocity [u/s], which may not be reached (cannot be zero).
Acceleration	Acceleration	LREAL	Positive number	0	Acceleration [u/s^2] of the acceleration phase.
Deceleration	Deceleration	LREAL	Positive number	0	Deceleration [u/s^2] of the deceleration phase.
Jerk	Jerk	LREAL	Positive number	0	Slope [u/s^3] of acceleration or deceleration. (Only valid for S-curve planning).
Direction	Motion direction	18.3.3.2.2.9 MC_DIRECTION: Motion Direction Enumeration	0: DIR_SHORTEST 1: DIR_POSITIVE 2: DIR_NEGATIVE 3: DIR_CURRENT 4: DIR_NODIRECTION 5: DIR_FASTEST	1	Specify the rotation direction in Rotary Mode: 0: DIR_SHORTEST (Direction based on the shortest way). 1: DIR_POSITIVE (Positive direction). 2: DIR_NEGATIVE (Negative direction). 3: DIR_CURRENT (Current direction). 4: DIR_NODIRECTION (No direction). 5: DIR_FASTEST (Direction based on the shortest movement time).

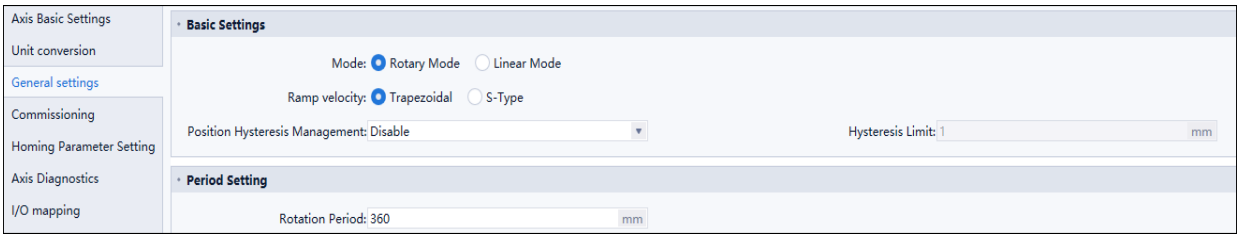
Input Variable	Name	Data Type	Valid Range	Default Value	Description
BufferMode	Buffer mode	18.3.3.2.2.6 MC_BUFFER_MODE: Buffer Mode Enumeration	0: mcAborting 1: mcBuffered 2: mcBlendingLow 3: mcBlendingPrevious 4: mcBlendingNext 5: mcBlendingHigh	0	0: mcAborting (Aborting). 1: mcBuffered (Buffered). 2: mcBlendingLow (Blending with the lowest velocity of both FBs). 3: mcBlendingPrevious (Blending with the velocity of the first FB). 4: mcBlendingNext (Blending with velocity of the second FB). 5: mcBlendingHigh (Blending with highest velocity of both FBs).
InverseFlag	Inverse enable	BOOL	TRUE, FALSE	FALSE	FALSE:The planned position cannot be beyond the target position. When the target velocity is not reached, the planned parameters (End Velocity, Acceleration/Deceleration, Jerk) will be modified to meet the planning requirements. TRUE: The planned position can be beyond the target position. If the axis moves beyond the target position, it will move for an additional cycle.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Active	Controlling	BOOL	TRUE, FALSE	FALSE	TRUE when the axis is being controlled by the current FB.

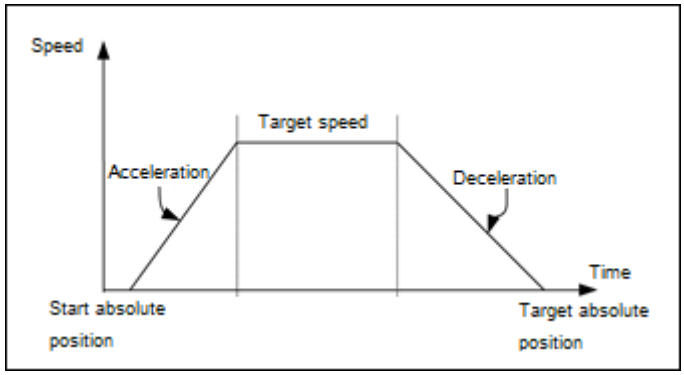
Output Variable	Name	Data Type	Valid Range	Default Value	Description
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Parameter correction**



Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Velocity	Velocity	Any velocity that exceeds the motion parameter limit will be automatically corrected to the velocity limit.	Any velocity less than 0 will be automatically corrected to 1e-5.	• When the MotionControl library version is 2.1.0.0 or earlier, the velocity equal to 0 will be automatically corrected to 1e-5. • When the MotionControl library version is 2.2.0.0 or later, the velocity equal to 0 will not be corrected.
Acceleration	Acceleration	Any acceleration that exceeds the motion parameter limit will be automatically corrected to the acceleration limit.	• When the MotionControl library version is 2.3.0.0 or earlier, the acceleration less than 0 will be automatically corrected to 10% of the acceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the acceleration less than 0 will be automatically corrected to 10 times the velocity.	• When the MotionControl library version is 2.3.0.0 or earlier, the acceleration equal to 0 will be automatically corrected to 10% of the acceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the acceleration equal to 0 will be automatically corrected to 10 times the velocity.

Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Deceleration	Deceleration	Any deceleration that exceeds the motion parameter limit will be automatically corrected to the deceleration limit.	• When the MotionControl library version is 2.3.0.0 or earlier, the deceleration less than 0 will be automatically corrected to 10% of the deceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the deceleration less than 0 will be automatically corrected to 10 times the velocity.	• When the MotionControl library version is 2.3.0.0 or earlier, the deceleration equal to 0 will be automatically corrected to 10% of the deceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the deceleration equal to 0 will be automatically corrected to 10 times the velocity.
Jerk	Jerk	If the motion profile is set to S-curve, any jerk that exceeds the software limit will be automatically corrected to the jerk limit.	If the motion profile is set to S-curve, any jerk less than 0 will be automatically corrected to 10% of the jerk limit.	If the motion profile is set to S-curve, the jerk equal to 0 will be automatically corrected to 10% of the jerk limit.



- **Function**

  Bus-controlled axis:

  - This instruction specifies an absolute target position for positioning. The absolute positioning starts on a rising edge of Execute. You can specify the values of Position, Velocity, Acceleration, Deceleration, and Jerk in the input parameters.
  - When the T-curve is specified in the software, the input parameter Jerk is invalid.

Acceleration/deceleration under T-curve planning:

Acceleration/deceleration under S-curve planning:

- When the setpoint of the input parameter Position is equal to the current position reference, the axis will not move after this instruction is executed, but the output parameter Done will show the value TRUE.
- When the input parameter ContinuousUpdate is set to TRUE, modified parameters Position and Velocity will take effect only when the function block is in the Active state. Parameter changes greater than 0.01 are considered updates. Modified BufferMode cannot take effect during this period, and the buffer mode at the time of the instruction trigger is retained. When the output parameter Done is set, it indicates that the instruction has completed the motion, and any changes to the parameters will not take effect.
- Direction and InverseFlag flags:
  - Linear axis

    When reversal is caused due to insufficient displacement: If the InverseFlag is set to True, the Jerk or Acceleration/Deceleration will not be adjusted. If the InverseFlag is set to False, the Jerk or Acceleration/Deceleration will be adjusted to ensure no change in the velocity sign.
  - Rotary axis

    If the InverseFlag is set to True, parameter self-adaptation will not be performed, and insufficient displacement will be compensated by adding circles. If the InverseFlag is set to False, the Jerk or Acceleration/Deceleration will be adjusted to avoid overshooting the target position and then reversing.
- **Input parameter Direction:**
  - Linear mode

    Ignore the value of the input parameter Direction, and determine the positive or negative direction of motion based on the relationship between the setpoint of the input parameter Position and the current position reference.
  - Rotary mode

    1. Input parameter Direction = 0 (DIR_SHORTEST)

       The axis moves to the target position along the shortest way. When the setpoint of Position exceeds one rotation cycle, the target position is the remainder of the setpoint divided by the rotation cycle. At the moment the instruction is executed, the relationship between the position reference after the current axis velocity decelerates to zero and the target position is determined. If it is within half a cycle in the positive direction, the axis trajectory is consistent with the Positive direction. If it is within half a cycle in the negative direction, the axis trajectory is consistent with the Negative direction. If it is exactly half the cycle length, the axis moves in the positive direction.

2. Input parameter Direction = 1 (DIR_POSITIVE)

The axis moves to the target position in the positive direction. When the setpoint of Position exceeds one rotation cycle, the target position is the remainder of the setpoint divided by the rotation cycle. For a rotary axis, the positive direction is the direction in which the position (user units) increases within one cycle. If the current velocity is greater than zero, the axis will continue to move in the current direction until it stops at the position specified by Position. If the current velocity is less than zero, the axis will decelerate to zero and then start moving in the positive direction. If the setpoint of Position is the same as the current position reference, the axis will not move.

3. Input parameter Direction = 2 (DIR_NEGATIVE)

The axis moves to the target position in the negative direction. When the setpoint of Position exceeds one rotation cycle, the target position is the remainder of the setpoint divided by the rotation cycle. For a rotary axis, the negative direction is the direction in which the position (user units) decreases within one cycle. If the current velocity is less than zero, the axis will continue to move in the current direction until it stops at the position specified by Position. If the current velocity is greater than zero, the axis will decelerate to zero and then start moving in the opposite direction. If the setpoint of Position is the same as the current position reference, the axis will not move.

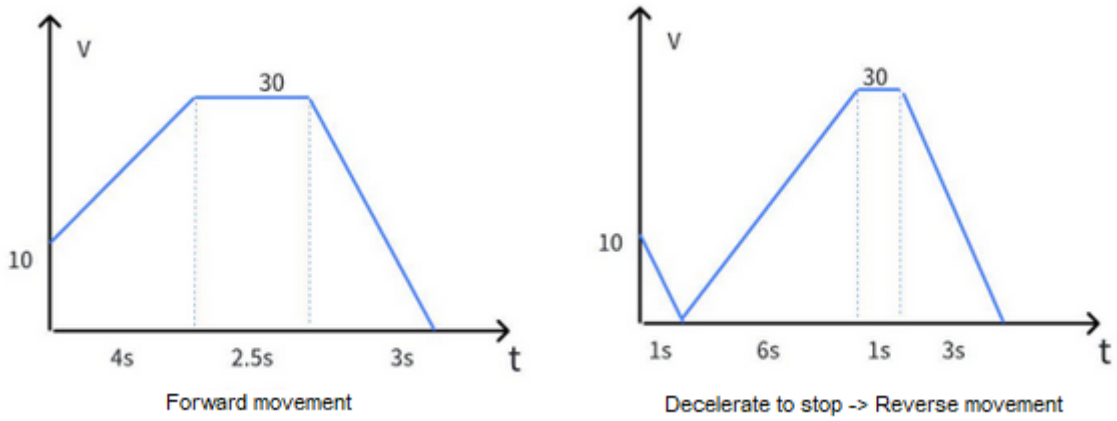
4. Input parameter Direction = 3 (DIR_CURRENT)

The axis moves to the target position in the direction of the previous movement on a rising edge of Execute. When the setpoint of Position exceeds one rotation cycle, the target position is the remainder of the setpoint divided by the rotation cycle. During the first power-on, the axis moves in the positive direction (target velocity greater than zero). If the setpoint of Position is the same as the current position reference, the axis will not move.

5. Input parameter Direction = 4 (DIR_NODIRECTION)

In this mode, the Position can be specified as a value exceeding one rotation cycle. When the Position is specified as a value equal to one rotation cycle, the axis moves in the positive or negative direction to the position in the current rotation cycle (equivalent to SHORTEST). When the Position is specified as a value less than zero, the axis moves to an absolute target position in the negative direction of zero position in the current cycle. When the Position is specified as a value greater than zero and exceeding one rotation cycle, the axis moves to an absolute target position in the positive direction of 360 position in the current cycle

6. Input parameter Direction = 5 (DIR_FASTEST)



The axis moves in the direction that reaches the target position the fastest. When the setpoint of Position exceeds one rotation cycle, the target position is the remainder of the setpoint divided by the rotation cycle. When the instruction is executed, if the initial velocity and acceleration of the axis are zero, the behavior of the axis moving in the direction specified by DIR_FASTEST is the same as that in direction specified by DIR_SHORTEST. When the velocity and acceleration are not zero, the direction of the axis moving in direction specified by DIR_FASTEST may not be the same as the direction of the axis moving in direction specified by DIR_SHORTEST. The examples are provided for illustration:

Example 1. When the instruction is executed, the axis moves at a velocity of 0 with the specified initial position = 50, target position = 150, acceleration = 5, deceleration = 10, target velocity = 20, and jerk = 5, and the Direction is set to 5(DIR_FASTEST). Which direction will the axis move? (Using T-curve planning as an example)

Analysis: Since the initial velocity of the axis is 0, the positive displacement increment is 100 and it takes 8s; the negative displacement increment is -260 and it takes 16s. Therefore, the axis will move in the positive direction to reach the target position.

Example 2. When the instruction is executed, the axis moves at a velocity of 10 with the specified initial position = 50, target position = 250, acceleration = 5, deceleration = 10, target velocity = 30, and jerk = 5, and the Direction is set to 5(DIR_FASTEST). Which direction will the axis move? (Using T-curve planning as an example)

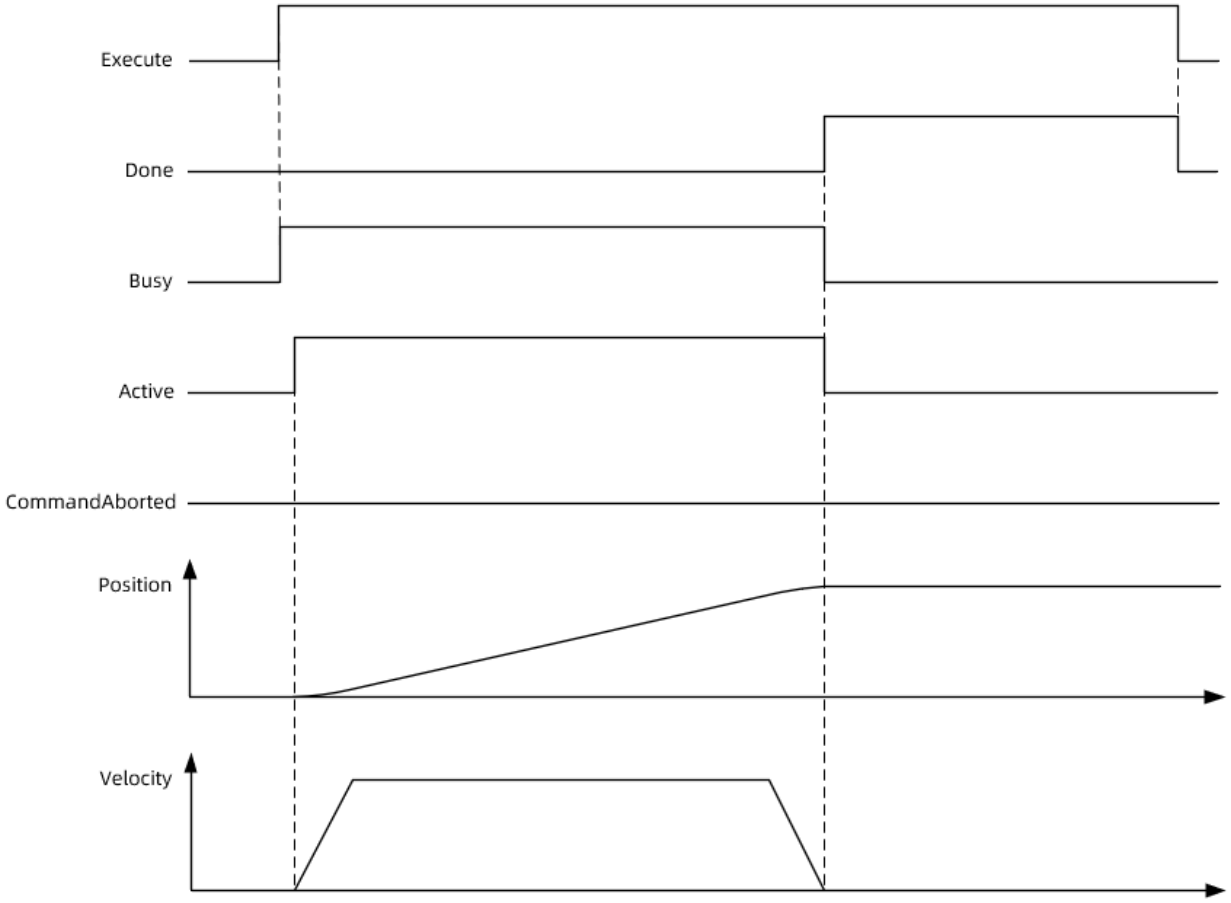
Analysis: When the instruction is executed, the axis velocity is 10. If the axis moves in the positive direction, the displacement increment is 200 (i.e., 250-50), and it takes 9.5s for the master axis to reach the target position. If the axis moves in the negative direction, the master axis first decelerates to 0 (at this point, the axis is at position 55; which takes 1s), and then moves in the opposite direction to reach the target position, with a displacement increment of (250-55-360=-165), which takes 10s. The total time is 11s (1s + 10s). Although the displacement increment when the axis move in the positive direction to reach the target position is larger, due to its shorter time consumption, the DIR_FASTEST will be selected, rather than the DIR_SHORTEST. The velocity curves for the axis moving in the positive and negative directions are shown below:

- When the instruction is triggered on a rising edge of the input parameter Execute, the input parameters are checked for validity. If any of invalid parameters is detected, it will be automatically corrected by the function block with no fault message; any buffered instructions after this instruction will be cleared.
- If there is no buffered instruction when this instruction is executed, this instruction will end at a velocity of zero. If there is a buffered instruction with the input parameter BufferMode not being set to MC_Aborting or MC_Buffered, the instruction will end at the velocity corresponding to the transition mode of the subsequent buffered instruction.
- If the current axis state is not AXIS_STANDSTILL, AXIS_DISCRETE_MOTION, AXIS_CONTINUOUS_MOTION, or AXIS_SYNCHRONIZED_MOTION, this instruction cannot be executed.
- The axis type must be control axis.
- If any setpoint of related motion parameters is outside the limits and the current velocity reference is not zero, the axis will decelerate to stop under a T-curve planning, using the maximum deceleration in the software.
- After PDOs 6060 and 6061 are configured, control mode switching between instructions does not rely on the MC_SetControllerMode instruction. You can directly call instructions under different control modes. Each instruction internally checks if the current mode meets the requirements and automatically switches the mode if necessary.
- During the deceleration stop due to limits, the axis state is AXIS_STOPPING with the output status of the instruction unchanged. After the axis stops and comes to rest, whether to switch to AXIS_ERRORSTOP will be determined based on the IDE interface options, and the instruction will output a fault message.
- During the deceleration due to limits, do not execute the MC_Reset instruction to reset fault messages.
- This instruction cannot be changed to buffered mode for re-execution during execution.
- During the execution of this instruction, the MC_MoveSuperImposed instruction can be used.
- When the axis is enabled after PLC cold reset and the MC_Home instruction is executed using No. 35 homing method, if this instruction is executed with DIR_CURRENT being set, the motion direction of this instruction will be affected.
- When this instruction is executed with the ContinuousUpdate being set to TRUE along with the MC_SuperImposed instruction, the MC_SuperImposed instruction will be aborted if any modifiable parameters are modified.
- Switching the MC_SetControllerMode to a non-CSP mode during motion causes inaccurate positioning.
- The arrival check function is only applicable to MotionControl library version 2.4.0.0 or later. Based on the "Positioning range" and "Positioning check time" parameters in the "General setting" of the axis

configuration page, it checks in real time whether the actual position has entered the specified target range. After the instruction output for the target position is completed, positioning is complete and the Done output is set if the difference between the actual position and the target position is smaller than the "Positioning range". If positioning is not completed within the "Positioning check time", a fault will occur.

Local pulse axis:

- This instruction can be used for local pulse axes.
- When the local pulse axis is used with Y0 or Y1 single-ended output, it is not recommended to use this instruction. ① No pulse output; ② No position feedback.



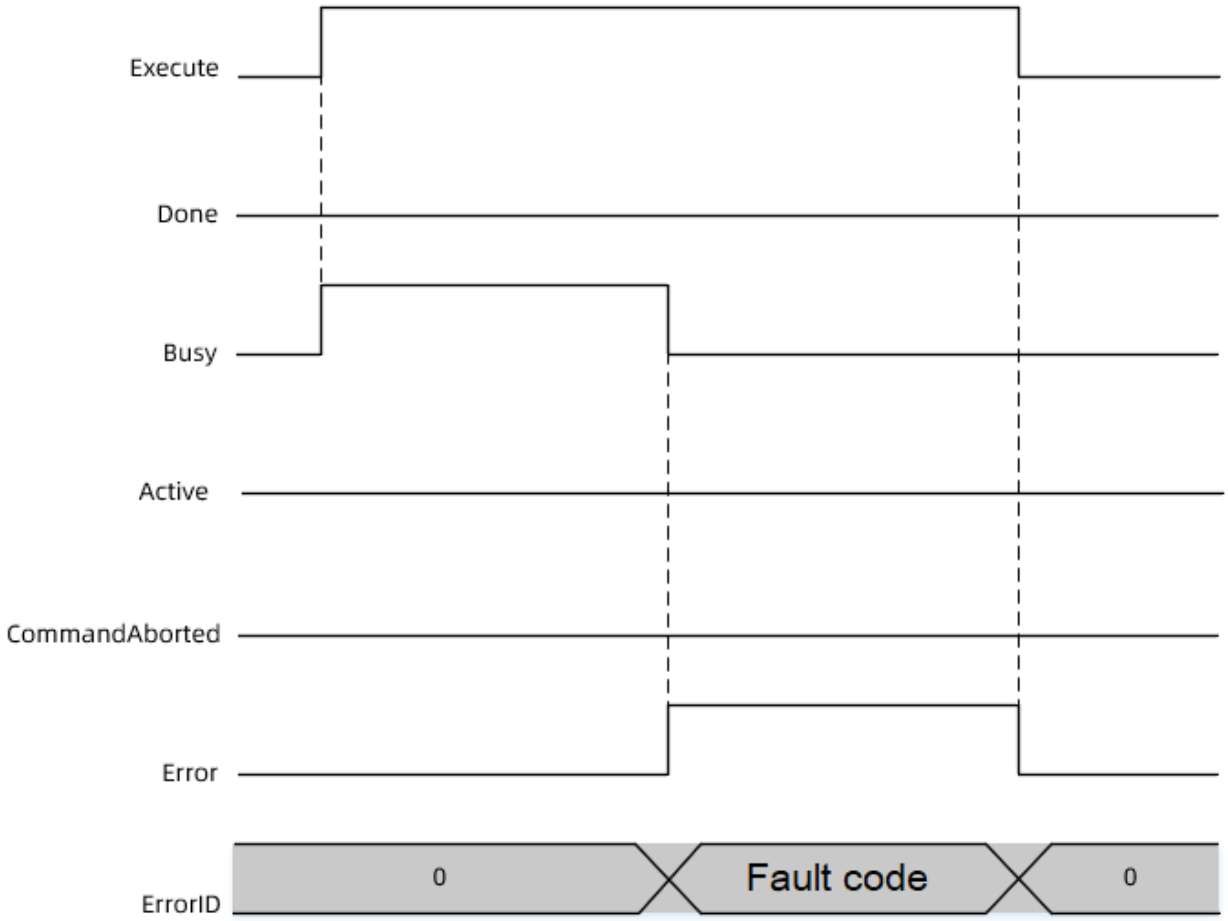
- **Timing diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Done of the function block indicates the instruction has been executed successfully; the parameter Busy indicates that the current function block is being executed; the parameter CommandAborted indicates that the instruction is aborted by another motion control instruction, at which point the flag is set to TRUE.

  The parameter Busy shows the value TRUE on a rising edge of Execute. In the next cycle, the output parameter Active shows the value TRUE. When the setpoint of Position is reached and positioning is complete, the parameter Done shows the value TRUE.

  When this instruction is aborted by another instruction, the CommandAborted is set to TRUE, and the Busy and Active are set to FALSE.

  - When this instruction is called to perform absolute positioning under a T-curve planning while the axis state is StandStill, the output variable Done will show the value TRUE if the MC_MoveAbsolute_Instance_0 function block reaches the position reference (with a velocity 0).



- When another MC_MoveAbsolute instruction is executed during the absolute positioning, and the second MC_MoveAbsolute_Instance_1 FB is executed during the execution of first MC_MoveAbsolute_Instance_0 FB, the absolute positioning is aborted by the second FB. Even though the first FB has not reached the position reference, the second FB directly moves to the position reference.

Execute
Done
Busy

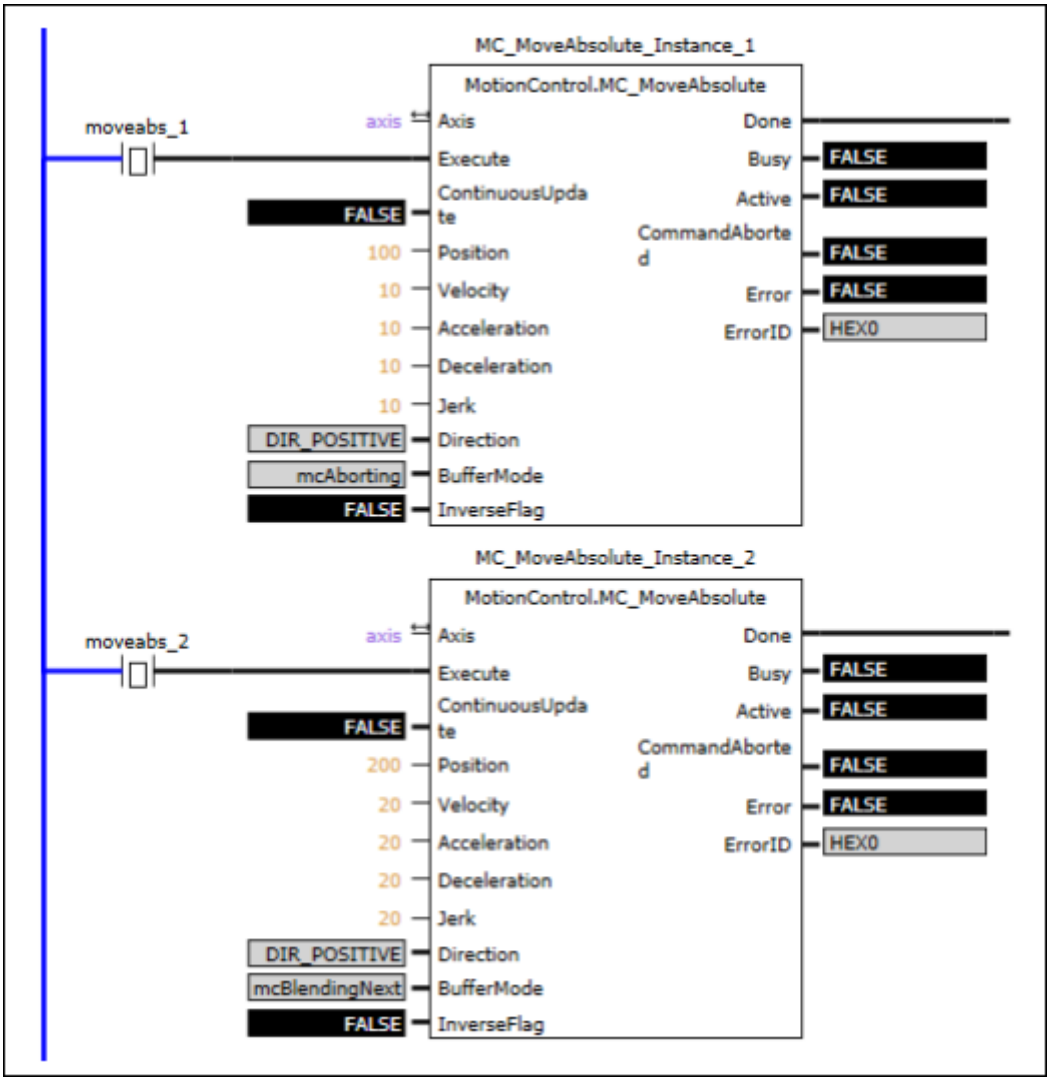
CommandAborted
New positioning
instruction triggered
Execute
Done
Busy
Active
CommandAborted
Position
Velocity

◦ Absolute positioning of the axis is aborted by MC_Stop instruction.

◦ The drive malfunctions during the absolute positioning of the axis.



- **Faults**

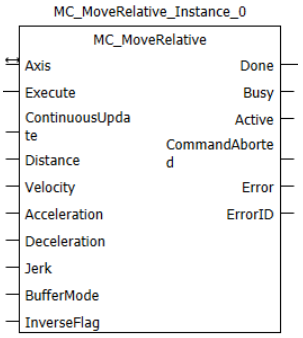
  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

- **Example**

  Instantiate two MC_MoveAbsolute instructions with the motion parameters being specified according to actual process requirements. Specify the velocity as 10 for the first instruction and 20 for the second instruction. Specify the BufferMode as mcBlendingNext for the second executed instruction.

◦ If the second instruction is executed during the execution of the first instruction, the second instruction will be buffered.

◦ The first instruction finally stops to position 100 at a velocity of 20, and then the second instruction starts moving at the inherited velocity of 20 and stops at position 200.



- **Precautions**

  This instruction can be re-executed. The motion parameters can be modified and re-triggered while the instruction is being executed or in the buffer. However, during the execution of the instruction, only mcAborting can be re-triggered, especially when the instruction just starts moving from the buffer. The BufferMode cannot be modified when the instruction is re-triggered in the buffer; otherwise, the instruction will issue a fault message.

18.3.3.3.32 MC_MoveRelative

This instruction moves an axis a specified distance relative to the actual position at the time of the execution.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_MoveRelative	Relative positioning		MC_MoveRelative _Instance_0(Axis :=, Execute :=, ContinuousUpdate :=, Distance :=, Velocity :=, Acceleration :=, Deceleration :=, Jerk :=, BufferMode :=, InverseFlag :=, Done =>, Busy =>, Active =>, CommandAborted =>, Error =>, ErrorID =>);

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	The function block is executed on a rising edge of this input variable.

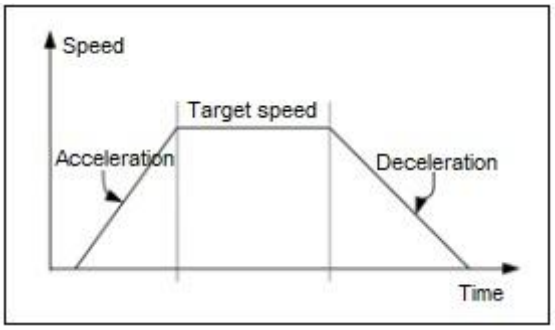
Input Variable	Name	Data Type	Valid Range	Default Value	Description
Continuous Update	Continuous update	BOOL	TRUE, FALSE	FALSE	Continuous parameter update effective flag. Prerequisite: The parameter ContinuousUpdate shows the value TRUE and the parameter Active shows the value TRUE. Effective parameters: Position, Velocity. Note: The modified parameter values must differ from the original parameter values by more than 0.01.
Distance	Relative distance	LREAL	Positive number, negative number, or 0	0	Distance [u] the axis moves relative to its current position.
Velocity	Velocity	LREAL	Positive number	0	Maximum velocity [u/s].
Acceleration	Acceleration	LREAL	Positive number	0	Acceleration [u/s^2] of the acceleration phase.
Deceleration	Deceleration	LREAL	Positive number	0	Deceleration [u/s^2] of the deceleration phase.
Jerk	Jerk	LREAL	Positive number	0	Slope [u/s^3] of acceleration or deceleration. (Only valid for S-curve planning).
BufferMode	Buffer mode	18.3.3.2.2.6 MC_BUFFER_MODE: Buffer Mode Enumeration	0: mcAborting 1: mcBuffered 2: mcBlendingLow 3: mcBlendingPrevious 4: mcBlendingNext 5: mcBlendingHigh	0	0: mcAborting (Aborting). 1: mcBuffered (Buffered). 2: mcBlendingLow (Blending with the lowest velocity of both FBs). 3: mcBlendingPrevious (Blending with the velocity of the first FB). 4: mcBlendingNext (Blending with velocity of the second FB). 5: mcBlendingHigh (Blending with highest velocity of both FBs).

Input Variable	Name	Data Type	Valid Range	Default Value	Description
InverseFlag	Inverse enable	BOOL	TRUE, FALSE	FALSE	FALSE: If the velocity cannot be reached, the velocity in the next segment will be changed. The planned position does not exceed the target position. TRUE: The planned position can be beyond the target position. In this case, the axis will move in the opposite direction to the target position.

Output variables

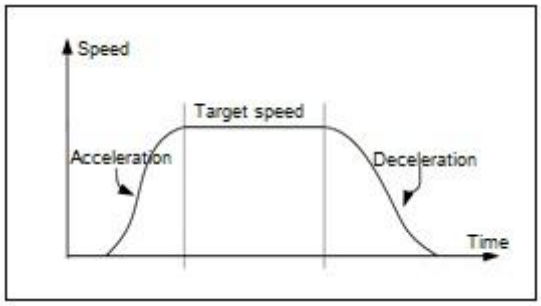
Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Active	Controlling	BOOL	TRUE, FALSE	FALSE	TRUE when the axis is being controlled by the current FB.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Parameter correction**



Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Velocity	Velocity	Any velocity that exceeds the motion parameter limit will be automatically corrected to the velocity limit.	Any velocity less than 0 will be automatically corrected to 1e-5.	• When the MotionControl library version is 2.1.0.0 or earlier, the velocity equal to 0 will be automatically corrected to 1e-5. • When the MotionControl library version is 2.2.0.0 or later, the velocity equal to 0 will not be corrected.
Acceleration	Acceleration	Any acceleration that exceeds the motion parameter limit will be automatically corrected to the acceleration limit.	• When the MotionControl library version is 2.3.0.0 or earlier, the acceleration less than 0 will be automatically corrected to 10% of the acceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the acceleration less than 0 will be automatically corrected to 10 times the velocity.	• When the MotionControl library version is 2.3.0.0 or earlier, the acceleration equal to 0 will be automatically corrected to 10% of the acceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the acceleration equal to 0 will be automatically corrected to 10 times the velocity.
Deceleration	Deceleration	Any deceleration that exceeds the motion parameter limit will be automatically corrected to the deceleration limit.	• When the MotionControl library version is 2.3.0.0 or earlier, the deceleration less than 0 will be automatically corrected to 10% of the deceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the deceleration less than 0 will be automatically corrected to 10 times the velocity.	• When the MotionControl library version is 2.3.0.0 or earlier, the deceleration equal to 0 will be automatically corrected to 10% of the deceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the deceleration equal to 0 will be automatically corrected to 10 times the velocity.
Jerk	Jerk	If the motion profile is set to S-curve, any jerk that exceeds the software limit will be automatically corrected to the jerk limit.	If the motion profile is set to S-curve, any jerk less than 0 will be automatically corrected to 10% of the jerk limit.	If the motion profile is set to S-curve, the jerk equal to 0 will be automatically corrected to 10% of the jerk limit.

- **Function**



Bus-controlled axis:

- This instruction specifies a relative target position for positioning. The relative positioning starts on a rising edge of Execute. You can specify the values of Distance, Velocity, Acceleration, Deceleration, and Jerk in the input parameters.
- When the instruction is triggered on a rising edge of the input parameter Execute, the input parameters are checked for validity. If any of invalid parameters is detected, it will be automatically corrected by the function block with no fault message; any buffered instructions after this instruction will be cleared.
- When the T-curve is specified in the software, the input parameter Jerk is invalid.

  Acceleration/deceleration under T-curve planning:

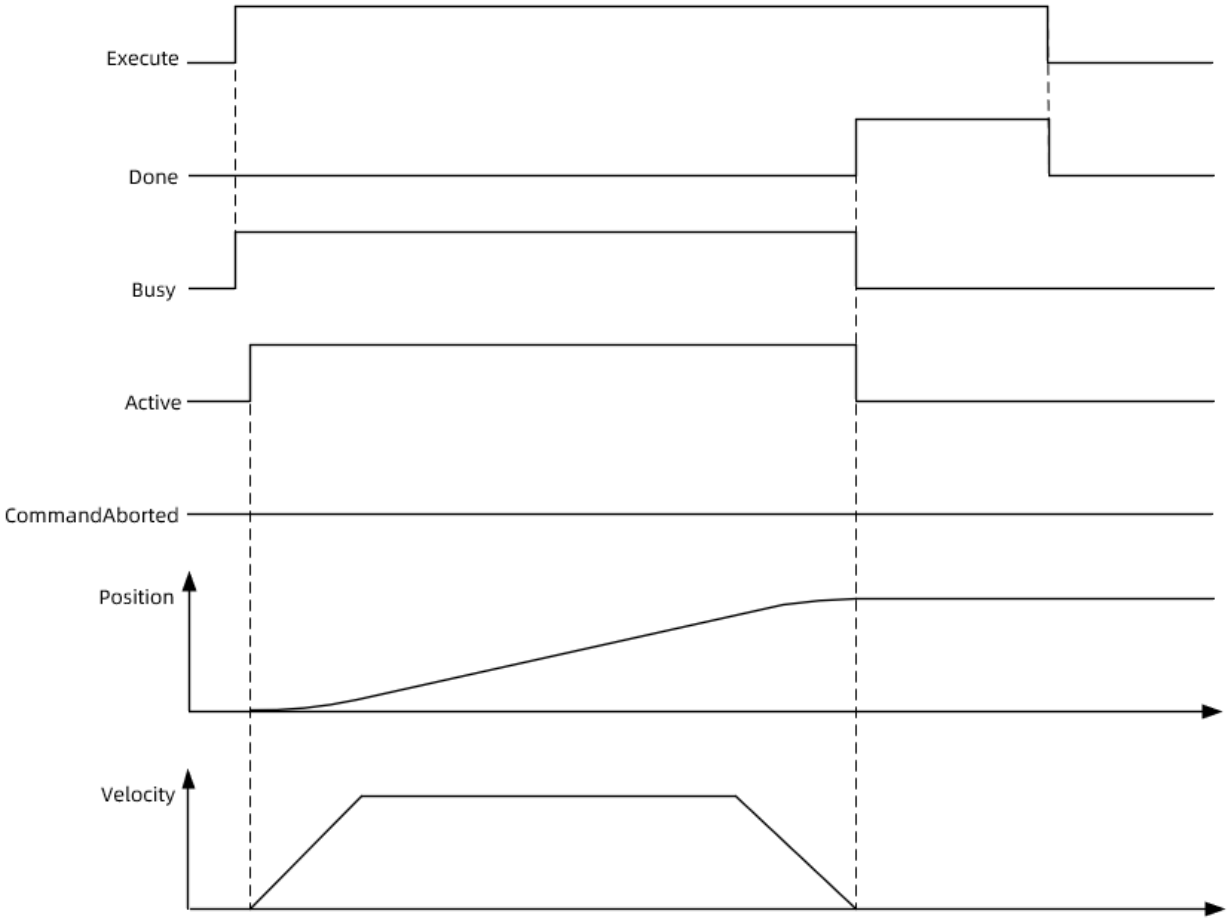
  Acceleration/deceleration under S-curve planning:

- When the input parameter ContinuousUpdate is set to TRUE, modified parameters Distance and Velocity will take effect only when the function block is in the Active state. Parameter changes greater than 0.01 are considered updates. Modified BufferMode cannot take effect during this period, and the buffer mode at the time of the instruction trigger is retained. When the output parameter Done is set, it indicates that the instruction has completed the motion, and any changes to the parameters will not take effect.
- In Rotary Mode, when the setpoint of the input parameter Distance is greater than one cycle, multi-turn positioning can be performed.
- If there are no other pending operations, the instruction will be done at a velocity of 0.
- If the setpoint of the input parameter BufferMode is neither MC_Aborting nor MC_Buffered, the end velocity will depend on the specified transition mode.
- If the current axis state is not AXIS_STANDSTILL, AXIS_DISCRETE_MOTION, AXIS_CONTINUOUS_MOTION, or AXIS_SYNCHRONIZED_MOTION, this instruction cannot be executed.
- The axis type must be control axis.
- If any setpoint of related motion parameters is outside the limits and the current velocity reference is not 0, the axis will decelerate to stop under a T-curve planning, using the maximum deceleration in the software.

- After PDOs 6060 and 6061 are configured, control mode switching between instructions does not rely on the MC_SetControllerMode instruction. You can directly call instructions under different control modes. Each instruction internally checks if the current mode meets the requirements and automatically switches the mode if necessary.
- During the decelerate-to-stop process due to limits, the axis state is AXIS_STOPPING with the output status of the instruction unchanged. After the axis stops and comes to rest, whether to switch to AXIS_ERRORSTOP will be determined based on the IDE interface options, and the instruction will output an error message.
- During the deceleration due to limits, do not execute the MC_Reset instruction to reset error messages.
- This instruction cannot be changed to buffered mode for re-execution during execution.
- During the execution of this instruction, the MC_MoveSuperImposed instruction can be used.
- When the axis is enabled after PLC cold reset and the MC_Home instruction is executed using No. 35 homing method, if this instruction is executed with DIR_CURRENT being set, the motion direction of this instruction will be affected.
- When this instruction is executed with the ContinuousUpdate being set to TRUE along with the MC_SuperImposed instruction, the MC_SuperImposed instruction will be aborted if any modifiable parameters are modified.
- The arrival check function is only applicable to MotionControl library version 2.4.0.0 or later. Based on the "Positioning range" and "Positioning check time" parameters in the "General setting" of the axis configuration page, it checks in real time whether the actual position has entered the specified target range. After the instruction output for the target position is completed, positioning is complete and the Done output is set if the difference between the actual position and the target position is smaller than the "Positioning range". If positioning is not completed within the "Positioning check time", a fault will occur.

  Local pulse axis:

- This instruction can be used for local pulse axes.
- When the local pulse axis is used with Y0 or Y1 single-ended output, it is not recommended to use this instruction. ① No pulse output; ② No position feedback.

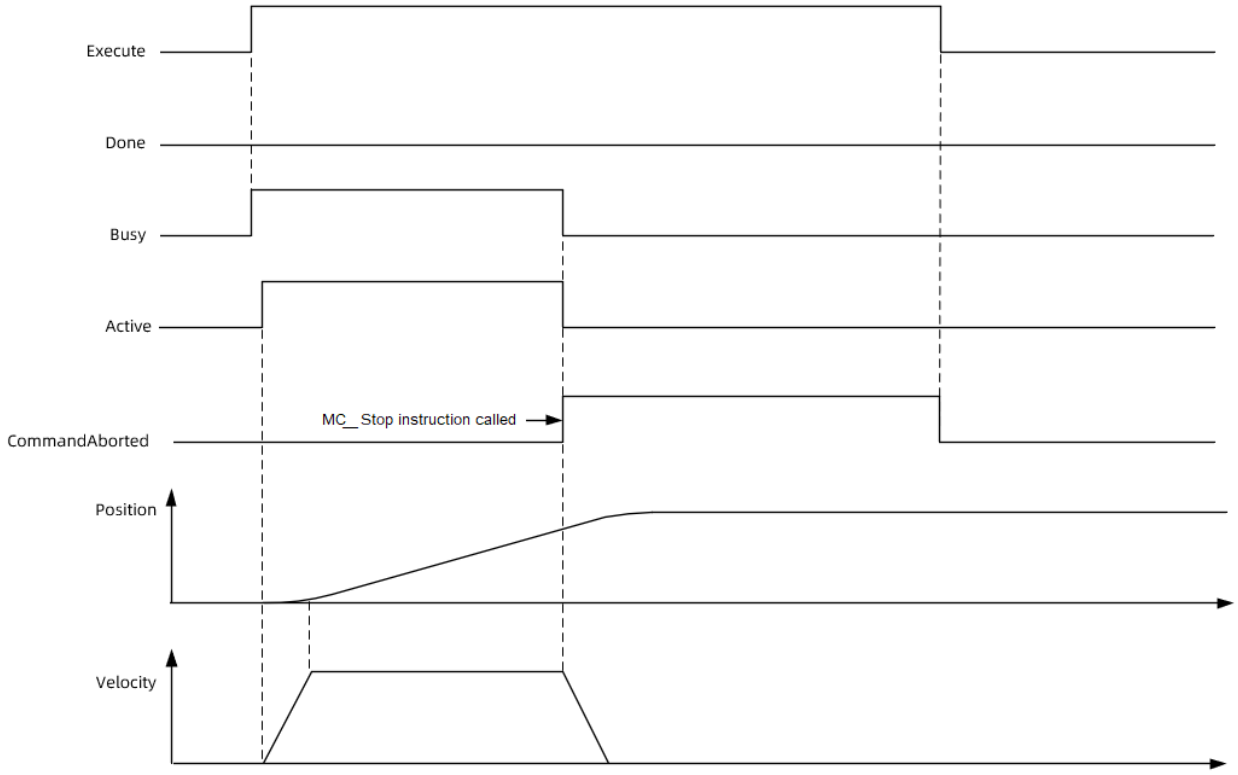


- **Timing diagram**

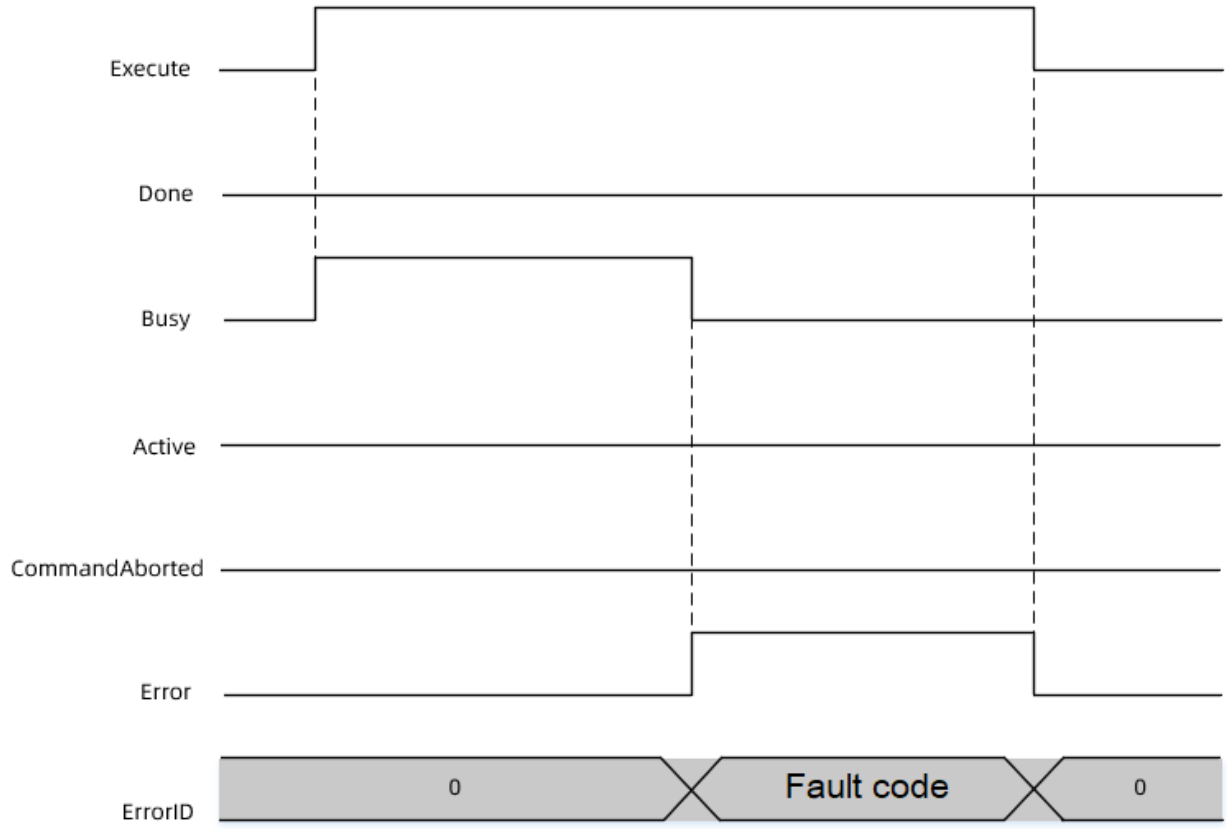
  The parameter Execute of the function block must be triggered on a rising edge. The parameter Done of the function block indicates the instruction has been executed successfully; the parameter Busy indicates that the current function block is being executed; the parameter CommandAborted indicates that the instruction is aborted by another motion control instruction, at which point the flag is set to TRUE.

  The parameter Busy shows the value TRUE on a rising edge of Execute. In the next cycle, the output parameter Active shows the value TRUE. When the setpoint of Position is reached and positioning is complete, the parameter Done shows the value TRUE.

  When this instruction is aborted by another instruction, the CommandAborted is set to TRUE, and the Busy and Active are set to FALSE.



- When this instruction is called while the axis state is StandStill, the output variable Done will show the value TRUE if the MC_MoveAbsolute_Instance_0 function block reaches the position reference (with a velocity of zero).



- When another MC_MoveRelative instruction is executed during the relative positioning, and the second MC_MoveRelative_Instance_1 FB is executed during the execution of first MC_MoveRelative_Instance_0 FB, the first FB is aborted by the second FB during. Even though the first FB has not reached the position reference, the second FB directly moves to the position reference.

ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**
  - This instruction specifies an absolute target position for positioning. The absolute positioning starts on a rising edge of Execute. You can specify the values of Position, Velocity, Acceleration, Deceleration, and Jerk in the input parameters.
  - When the T-curve is specified in the software, the input parameter Jerk is invalid.
  - When the setpoint of the input parameter Position is equal to the current position reference, the axis will not move after this instruction is executed, but the output parameter Done will show the value TRUE.
  - When the input parameter ContinuousUpdate is set to TRUE, modified parameters Position and Velocity will take effect only when the function block is in the Active state. Parameter changes greater than 0.01 are considered updates. Modified BufferMode, ModuloWindow, and Direction cannot take effect during this period, and the buffer mode at the time of the instruction trigger is retained.
  - If the InverseFlag is set to True, parameter auto-tuning will not be performed, and insufficient displacement will be compensated by adding circles. If the InverseFlag is set to False, the Jerk or Acceleration/Deceleration will be adjusted to avoid overshooting the target position and then reversing.
  - **Input parameter Position:**
    Unlike the MC_MoveAbsolute, the MC_MoveModulo enables the axis to rotate multiple turns when the Position is greater than or equal to the specified rotation cycle. Negative positions are not permitted.

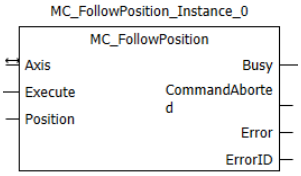
    For example, if the rotation cycle is 360, the start position is 10, the input value for Position is 360, and Direction is DIR_POSITIVE, the axis moves in positive direction by 710 and finally positions to 0. If multi-turn rotations are not required and positive movement to 0 is desired, Position must be input as 0. In this case, the axis rotates in positive direction by 350 and finally positions to 0.
  - **Input parameter ModuloWindow:**
    When the difference between the current position and the target position is less than or equal to the specified tolerance window, the system automatically selects the shortest way to move to the target position, behaving the same as if the Direction were set to DIR_SHORTEST. In this case, the user-defined Direction will be invalid. Note that the permitted window is ± ModuloWindow, resulting in an effective error window that is twice the configured value.
    As shown in the figures below, when the direction is set to DIR_POSITIVE and the current position is outside the ModuloWindow, the axis moves in the DIR_POSITIVE direction (upper two figure); when the

current position is within the ModuloWindow, the axis moves in the DIR_SHORTEST direction (lower two figures).

- **Input parameter Direction:**
  - Direction = 0 (DIR_SHORTEST)
    The axis moves to the target position along the shortest way. When the setpoint of Position exceeds one rotation cycle, the target position is the remainder of the setpoint divided by the rotation cycle. At the moment the instruction is executed, the relationship between the position reference after the current axis velocity decelerates to zero and the target position is determined. If it is within half a cycle in the positive direction, the axis trajectory is consistent with the Positive direction. If it is within half a cycle in the negative direction, the axis trajectory is consistent with the Negative direction. If it is exactly half the cycle length, the axis moves in the positive direction.
  - Direction = 1 (DIR_POSITIVE)
    The axis moves to the target position in the positive direction. When the setpoint of Position exceeds one rotation cycle, the target position is the remainder of the setpoint divided by the rotation cycle. For a rotary axis, the positive direction is the direction in which the position (user units) increases within one cycle. If the current velocity is greater than zero, the axis will continue to move in the current direction until it stops at the position specified by Position. If the current velocity is less than zero, the axis will decelerate to zero and then start moving in the positive direction. If the setpoint of Position is the same as the current position reference, the axis will not move.
  - Direction = 2 (DIR_NEGATIVE)
    The axis moves to the target position in the negative direction. When the setpoint of Position exceeds one rotation cycle, the target position is the remainder of the setpoint divided by the rotation cycle. For a rotary axis, the negative direction is the direction in which the position (user units) decreases within one cycle. If the current velocity is less than zero, the axis will continue to move in the current direction until it stops at the position specified by Position. If the current velocity is greater than zero, the axis will decelerate to zero and then start moving in the opposite

direction. If the setpoint of Position is the same as the current position reference, the axis will not move.

- Input parameter Direction = 3 (DIR_CURRENT)
  The axis moves to the target position in the direction of the previous movement on a rising edge of Execute. When the setpoint of Position exceeds one rotation cycle, the target position is the remainder of the setpoint divided by the rotation cycle. During the first power-on, the axis moves in the positive direction (target velocity greater than zero). If the setpoint of Position is the same as the current position reference, the axis will not move.



- **Example of displacement calculation:**
  Assume the rotation cycle is 360°.

Direction	Start position	Position	ModuloWindow	Displacement
DIR_POSITIVE	90	0	1	270
DIR_POSITIVE	90	360	1	630
DIR_POSITIVE	90	89.5	1	-0.5
DIR_POSITIVE	90	88.5	1	358.5
DIR_NEGATIVE	90	0	1	-90
DIR_NEGATIVE	90	360	1	-450
DIR_NEGATIVE	90	90.8	1	0.8
DIR_NEGATIVE	90	92	1	-358

18.3.3.3.34 MC_FollowPosition

This instruction enables the position reference to be written into the axis without any checks.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_FollowPosition	Specify axis position without any checks		MC_FollowPosition_Instance_0(Axis :=, Execute :=, Position :=, Busy =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

  In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	The function block is executed on a rising edge of this input variable.
Position	Position	LREAL	Positive number, negative number, or 0	0	Specify the position reference [u] for the axis in the current cycle.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is being executed.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**

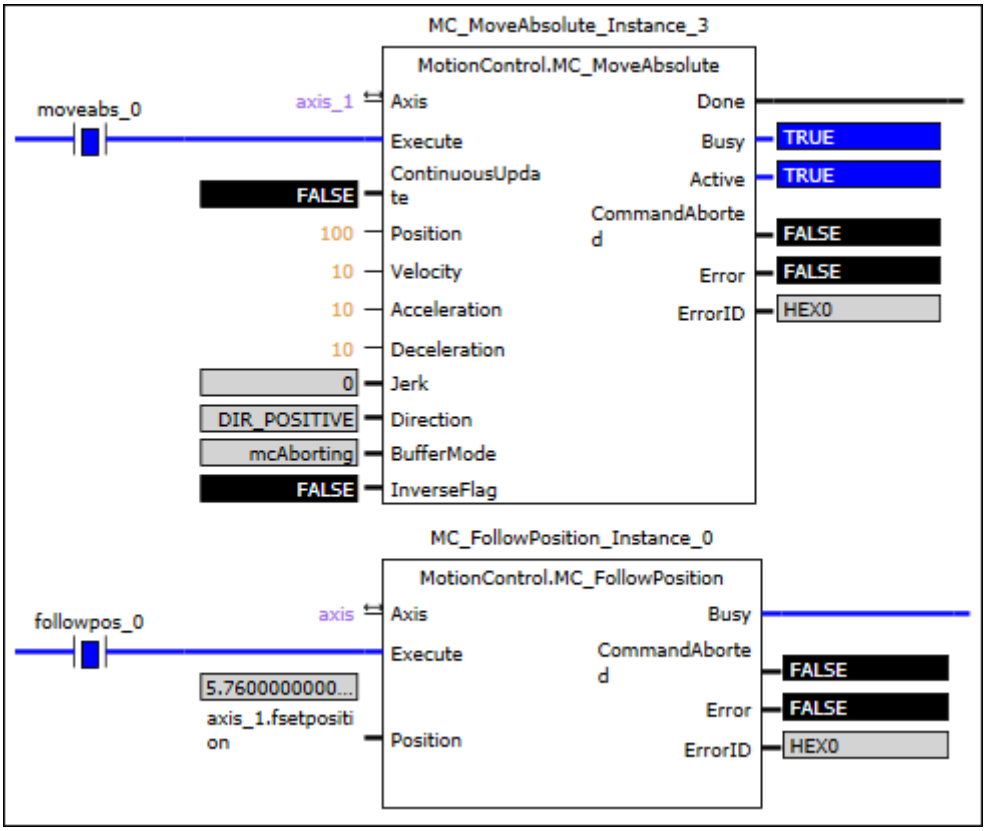
  Bus-controlled axis:

  - Unlike the MC_MoveAbsolute instruction, the position reference is sent to the axis in each task cycle after this instruction is executed on a rising edge. This instruction can be used for camming.

- When the current axis state is AXIS_STOPPING or AXIS_HOMING, triggering this instruction causes it to be immediately aborted and terminated.
- The velocity reference of the axis is: ΔL / Δt (ΔL is the difference between the position reference in current cycle and the position reference in previous cycle; Δt is the period time).
- For this instruction, the velocity reference is calculated based on the difference between the position reference in current cycle and the position reference in previous cycle. Therefore, after this instruction is executed, use the MC_SetPosition instruction with caution to prevent excessive position differences between adjacent cycles, which may cause overspeed.
- When this instruction is executed: ① If the control mode is MC_CSP mode, input the Position value with caution to prevent the difference between the current axis position and the Position value from causing excessive single-period displacement, which may cause a servo fault; ② If the control mode is MC_CSV mode, input the Position value with caution to prevent the difference between the current axis position and the Position value from causing the velocity back-calculated based on the single-period displacement to be greater than the maximum servo velocity, which may result in a deviation between the actual position and the position reference.
- This instruction does not apply any velocity limitation to either rotary or linear axes; however, linear axes are subject to software limit.
- For this instruction, the motion direction in one cycle is the Shortest way, and the motion direction in half a cycle is the positive direction.
- This instruction does not allow target positions beyond the limit. If the position is beyond the software limit, the axis will stop with the maximum deceleration.
- The axis type must be control axis.
- Control mode switching between instructions does not rely on the MC_SetControllerMode instruction. You can directly call instructions under different control modes. Each instruction internally checks if the current mode meets the requirements and automatically switches the mode if necessary.
- The instruction can be aborted by other instructions during execution, at which point the output parameter CommandAborted is set.
- During the execution of this instruction, the MC_MoveSuperImposed instruction cannot be used; once the MC_MoveSuperImposed instruction is triggered, CommandAborted is set for the MC_MoveSuperImposed instruction.

  Local pulse axis:

- This instruction can be used for local pulse axes.

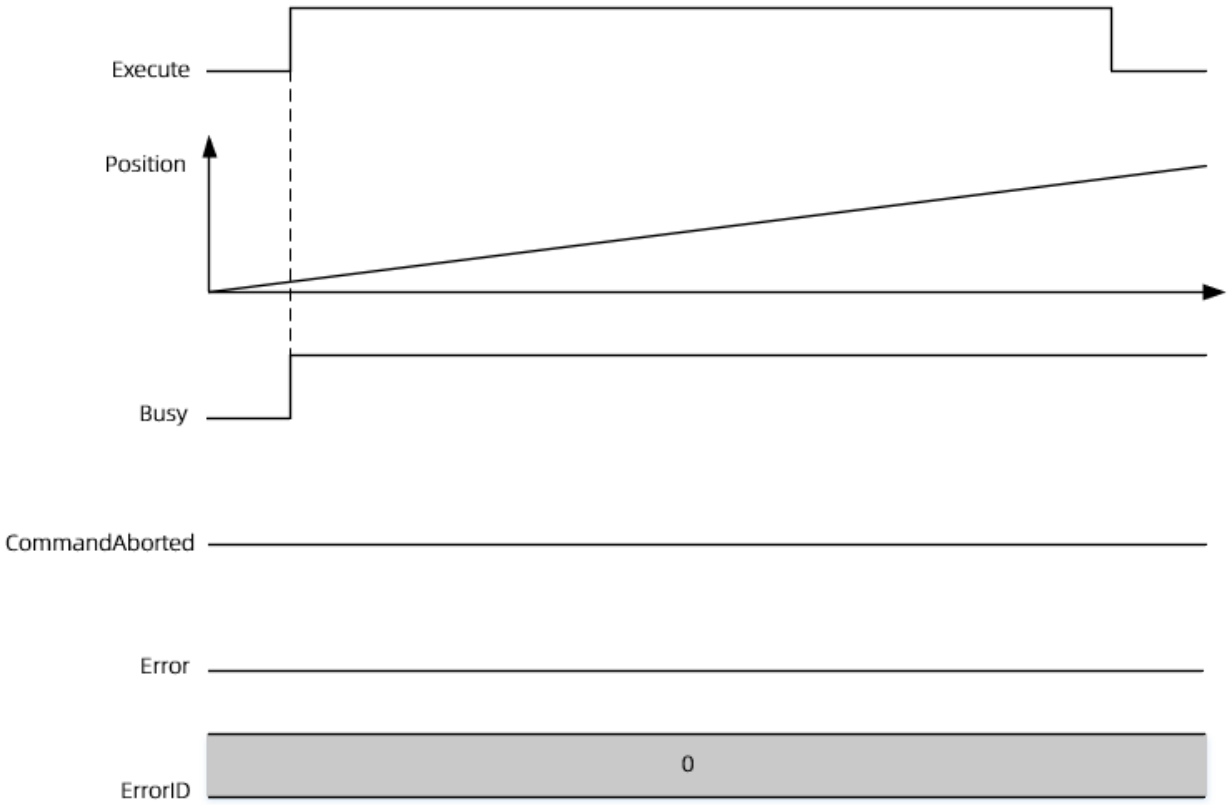


- **Example**

  This instruction enables simple following motion. Configure two axes, where Axis_1 is a virtual axis (master axis), and Axis is a real axis (slave axis).

  First, execute the MC_SetPostion instruction to assign the position of the master axis to the slave axis, ensuring that their start positions are synchronized.

Execute the MC_MoveAbsolute instruction on Axis_1, execute the MC_FollowPosition instruction on Axis, and assign the position reference (fSetPosition) for the Axis_1 to the input parameter Position of the MC_FollowPosition instruction, thus achieving synchronization.



- **Timing diagram**

  After the instruction is executed on a rising edge of Execute, the velocity reference is sent to the axis i n each task cycle.

  When the Execute signal is TRUE, the output parameter Busy shows the value TRUE. If this instruction is aborted by another control instruction, the output parameter Busy shows the value FALSE, and the output parameter CommandAborted is set.

- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.3.35 MC_FollowVelocity

This instruction specifies an axis velocity without any checks.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_FollowVelocity	Specify axis velocity without any checks	MC_FollowVelocity_Instance_0 MC_FollowVelocity Axis Execute Velocity Busy CommandAborted Error ErrorID	MC_FollowVelocity_Instance_0(Axis :=, Execute :=, Velocity :=, Busy =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

  In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	The function block is executed on a rising edge of this input variable.
Velocity	Velocity	LREAL	Positive number, negative number, or 0	0	Specify the velocity reference [u/s] for an axis.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is being executed.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**

  Bus-controlled axis:

  - Unlike the MC_MoveVelocity instruction, a velocity reference is sent to the axis in each task cycle after this instruction is triggered.

- When the parameter Busy shows the value TRUE, the modified input parameter Velocity takes effect immediately without re-execution of the instruction.
- After the output parameter Busy is set, the axis is in SYNCHRONIZED_MOTION state.
- When the current axis state is AXIS_STOPPING or AXIS_HOMING, triggering this instruction causes it to be immediately aborted and terminated.
- If the position is beyond the software limit, the axis will stop with the maximum deceleration.
- The axis type must be control axis.
- Control mode switching between instructions does not rely on the MC_SetControllerMode instruction. You can directly call instructions under different control modes. Each instruction internally checks if the current mode meets the requirements and automatically switches the mode if necessary.
- The instruction can be aborted by other instructions during execution, at which point the output parameter CommandAborted is set.
- During the execution of this instruction, the MC_MoveSuperImposed instruction cannot be used; once the MC_MoveSuperImposed instruction is triggered, CommandAborted is set for the MC_MoveSuperImposed instruction.

  Local pulse axis:

- This instruction can be used for local pulse axes.

- **Timing diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Busy of the function block indicates that the current function block is being executed, and the parameter CommandAborted indicates that the instruction is aborted by another motion control instruction, at which point the flag is set to TRUE.

  After the instruction is executed on a rising edge of Execute, a velocity reference is sent to the axis in each task cycle.
  When the Execute signal is TRUE, the output parameter Busy shows the value TRUE. If this instruction is aborted by another control instruction, the output parameter Busy shows the value FALSE, and the output parameter CommandAborted is set.

- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.3.36 MC_FollowPositionVelocity

The instruction enables the position and velocity reference to be written into the axis without any checks. In CSP control mode, the specified position parameter takes effect. In CSV control mode, the specified velocity parameter takes effect.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_FollowPositionVelocity	Specify axis position and velocity without any checks	MC_FollowPositionVelocity_Instance_0 MC_FollowPositionVelocity Axis Execute Position Velocity Busy CommandAborted Error ErrorID	MC_FollowPositionVelocity_Instance_0(Axis :=, Execute :=, Position :=, Velocity :=, Busy =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	The function block is executed on a rising edge of this input variable.
Position	Position	LREAL	Positive number, negative number, or 0	0	Specify the position reference [u] for the axis in the current cycle.
Velocity	Velocity	LREAL	Positive number, negative number, or 0	0	Specify the velocity reference [u] for the axis in the current cycle.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is being executed.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.

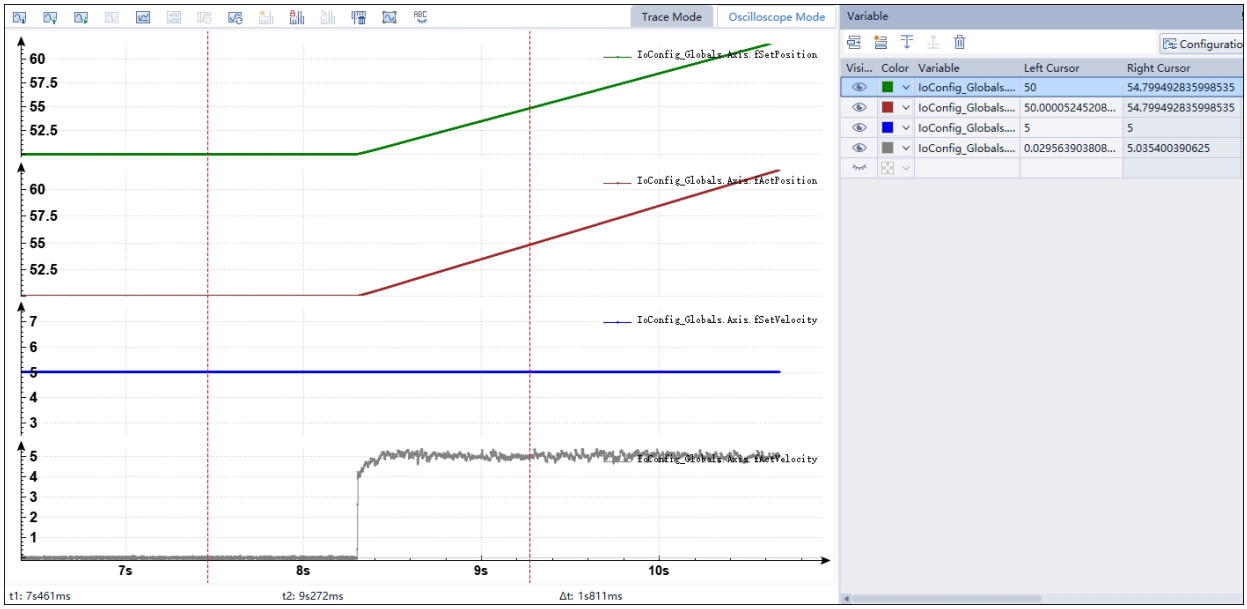
Output Variable	Name	Data Type	Valid Range	Default Value	Description
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**

  Bus-controlled axis:

  - After this instruction is triggered on a rising edge of Execute, the position and velocity references are sent to the axis in each task cycle, and they take effect immediately once being modified during the motion.
  - If the axis is not in CSP or CSV mode when the instruction is triggered on a rising edge, the instruction will terminate immediately with a fault message.
  - When the axis is in CSP mode, the position reference refreshed in each cycle takes effect**.** If the input velocity does not match the actual rate of position change, the velocity reference may be not equal the actual velocity.
  - In CSP mode, the motion direction of a rotary axis over one cycle is the Shortest way. When the position difference deltaPos is greater than half a PositionPeriod in the positive direction, the axis moves in the negative direction by PositionPeriod - deltaPos to the target position. When the position difference deltaPos is less than half a PositionPeriod in the negative direction, the axis moves in the positive direction by PositionPeriod + deltaPos to the target position.
  - In CSP mode, when this instruction is executed for position setting after the MC_SetPosition instruction is executed, the actual axis position is not the position reference but the sum of the SetPosition and the position difference between adjacent cycles.
  - When the axis is in CSV mode, the velocity reference refreshed in each cycle takes effect. At this time, the position reference aligns with the actual position in each cycle, and the input position does not take effect.
  - After this instruction is triggered, the axis is in synchronized motion. When the control mode of the axis switches from CSP to CSV or from CSV to CSP, the instruction execution continues, and the axis moves according to the current mode and parameter references. In case of switching to another mode, the instruction will terminate immediately with a fault message.
  - During the execution of this instruction, the MC_MoveSuperImposed instruction cannot be used; once t he MC_MoveSuperImposed instruction is triggered, CommandAborted is set for the MC_MoveSuperImposed instruction.
  - When the axis is in CSP or CSV control mode, and the corresponding 607A/60FF is not configured, the function block is terminated with a fault message.
  - When the current axis state is Stopping or Homing, this instruction is immediately aborted and terminated.
  - This instruction does not allow target positions beyond the limit. If the position is beyond the software limit, the axis will stop at the maximum deceleration.
  - The function block has no buffer mode. It can abort or be aborted by other motion function blocks.

Local pulse axis:



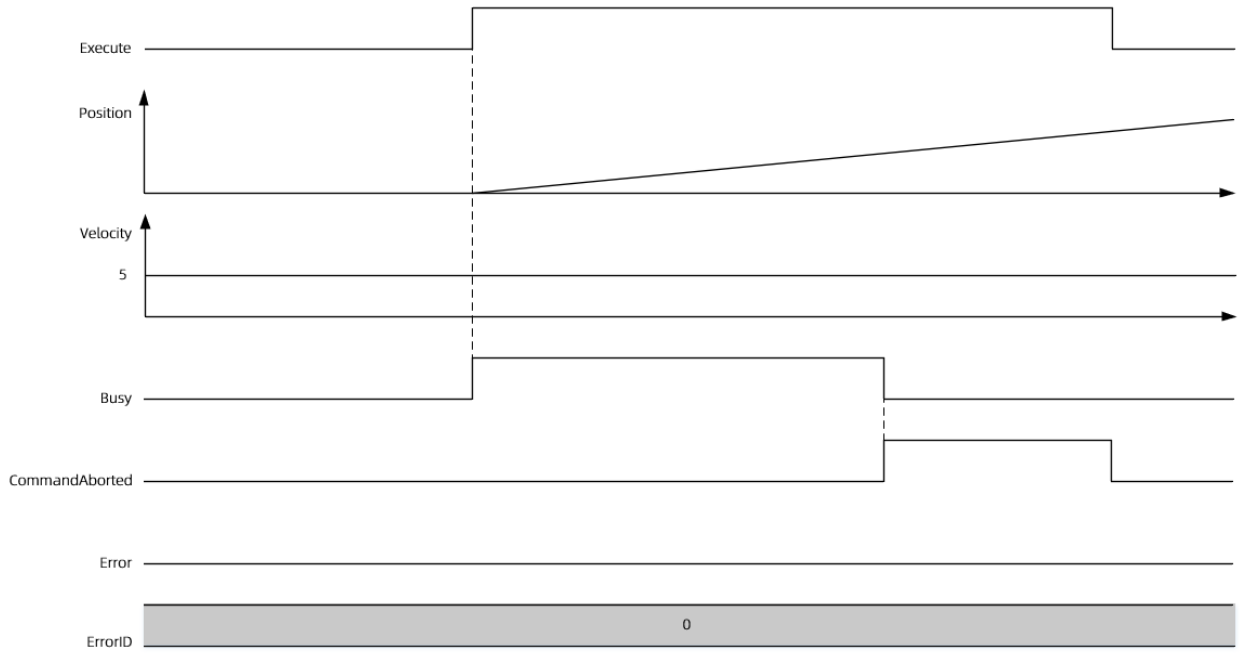
- This instruction can be used for local pulse axes in CSP mode. If the position reference is too large, causing the velocity to exceed 200 kHz, the function block will be terminated with a fault message.

- **Example**

  This instruction enables position following and velocity following during the motion. The following is an instance of how to execute the MC_FollowPositionVelocity instruction. The set position is 50, and the velocity is 5.

  After the instruction is triggered, the axis first moves to position 50 in CSP mode, and then switches to CSV mode without re-executing the function block and moves at the velocity of 5.

  Next, the axis switches to CSP mode and moves to position 50 according to the set position.



- **Timing diagram**

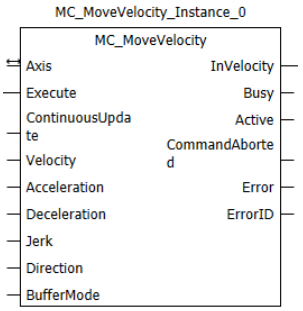
  The parameter Execute of the function block must be triggered on a rising edge. The parameter Busy of the function block indicates that the current function block is being executed, and the parameter CommandAborted indicates that the instruction is aborted by another motion control instruction, at which point the flag is set to TRUE.

  After the instruction is executed on a rising edge of Execute, the position and velocity references are sent to the axis in each task cycle.

  When the Execute signal is TRUE, the output parameter Busy shows the value TRUE. If this instruction is aborted by another control instruction, the output parameter Busy shows the value FALSE, and the output parameter CommandAborted is set.

- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.



- **Precautions**

The set velocity must satisfy the change in set position, i.e., Set velocity = The first derivative of the difference in set positions between adjacent task cycles with respect to time. For example, if the set positions for two adjacent cycles are the same, the velocity will be set to 0.

18.3.3.3.37 MC_MoveVelocity

This instruction controls the axis velocity in CSP mode.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_MoveVelocity	Velocity planning		MC_MoveVelocity _Instance_0(Axis :=, Execute :=, ContinuousUpdate :=, Velocity :=, Acceleration :=, Deceleration :=, Jerk :=, Direction:=, BufferMode :=, InVelocity =>, Busy =>, Active =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	The function block is executed on a rising edge of this input variable.
ContinuousUpdate	Continuous update	BOOL	TRUE, FALSE	FALSE	Continuous parameter update effective flag. Prerequisite: The parameter ContinuousUpdate shows the value TRUE and the parameter Active shows the value TRUE. Applicable parameters: Velocity, Acceleration, Deceleration, Jerk, Direction. Note: The modified parameter values must differ from the original parameter values by more than 0.01.
Velocity	Velocity	LREAL	Positive number or 0	0	Maximum velocity [u/s] for the motion. When the velocity is 0, the InVelocity flag of the axis is TRUE, but the axis is standstill.
Acceleration	Acceleration	LREAL	Positive number	0	Acceleration [u/s^2] of the acceleration phase.
Deceleration	Deceleration	LREAL	Positive number	0	Deceleration [u/s^2] of the deceleration phase.
Jerk	Jerk	LREAL	Positive number	0	Slope [u/s^3] of acceleration or deceleration (Valid for S-curve planning only).
Direction	Motion direction	18.3.3.2.2.9 MC_DIRECTION: Motion Direction Enumeration	1: DIR_POSITIVE 2: DIR_NEGATIVE 3: DIR_CURRENT	1	1: DIR_POSITIVE (Positive direction). 2: DIR_NEGATIVE (Negative direction). 3: DIR_CURRENT (Current direction).
BufferMode	Buffer mode	18.3.3.2.2.6 MC_BUFFER_MODE: Buffer Mode Enumeration	0: mcAborting 1: mcBuffered	0	0: mcAborting (Aborting). 1: mcBuffered (Buffered).

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
InVelocity	Velocity reference reached	BOOL	TRUE, FALSE	FALSE	TRUE when the axis reaches the velocity reference.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Active	Controlling	BOOL	TRUE, FALSE	FALSE	TRUE when the axis is being controlled by the current FB.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Parameter correction**

Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Velocity	Velocity	Any velocity that exceeds the motion parameter limit will be automatically corrected to the velocity limit.	Any velocity less than 0 will be automatically corrected to 1e-5.	No correction.

Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Acceleration	Acceleration	Any acceleration that exceeds the motion parameter limit will be automatically corrected to the acceleration limit.	• When the MotionControl library version is 2.3.0.0 or earlier, the acceleration less than 0 will be automatically corrected to 10% of the acceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the acceleration less than 0 will be automatically corrected to 10 times the velocity.	• When the MotionControl library version is 2.3.0.0 or earlier, the acceleration equal to 0 will be automatically corrected to 10% of the acceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the acceleration equal to 0 will be automatically corrected to 10 times the velocity.
Deceleration	Deceleration	Any deceleration that exceeds the motion parameter limit will be automatically corrected to the deceleration limit.	• When the MotionControl library version is 2.3.0.0 or earlier, the deceleration less than 0 will be automatically corrected to 10% of the deceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the deceleration less than 0 will be automatically corrected to 10 times the velocity.	• When the MotionControl library version is 2.3.0.0 or earlier, the deceleration equal to 0 will be automatically corrected to 10% of the deceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the deceleration equal to 0 will be automatically corrected to 10 times the velocity.
Jerk	Jerk	If the motion profile is set to S-curve, any jerk that exceeds the software limit will be automatically corrected to the jerk limit.	If the motion profile is set to S-curve, any jerk less than 0 will be automatically corrected to 10% of the jerk limit.	If the motion profile is set to S-curve, the jerk equal to 0 will be automatically corrected to 10% of the jerk limit.

- **Function**

  Bus-controlled axis:

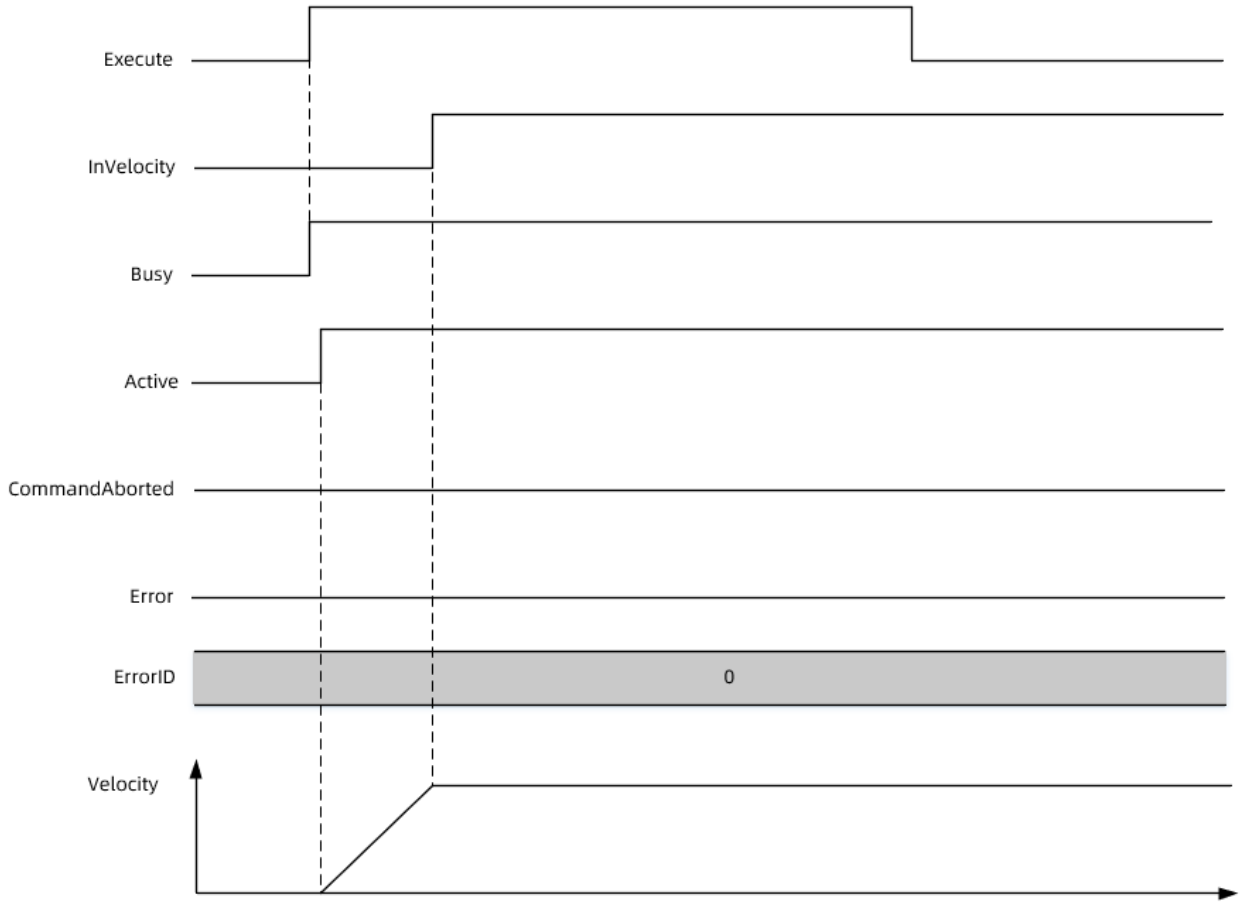
  ◦ This instruction controls the velocity based on position. It starts velocity control on a rising edge of Execute and switches the axis state to AXIS_CONTINUOUS_MOTION.

  ◦ When the input parameter Direction is specified as DIR_POSITIVE (Positive direction), the axis moves in the positive direction. When input parameter Direction is specified as DIR_NEGATIVE (Negative direction), the axis moves in the negative direction. When the Direction is specified as DIR_CURRENT, the axis moves in the direction in which it was traveling previously.

  ◦ When this instruction is aborted by another motion control instruction, the CommandAborted is set, and the subsequent instruction starts planning the axis motion.

- When used with the MC_MoveSuperimposed instruction, the output parameter InVelocity is set to TRUE as soon as this instruction's contribution to velocity equals the value of its input parameter Velocity.
- Online update is not supported for the buffer mode, which is determined by the mode specified when this instruction is triggered for the first time. Online update is supported for Velocity, Acceleration, Deceleration, Jerk, and Direction. If the change in a variable is greater than 0.01, the variable will be considered modified, and the motion will be planned according to the modified variable.
- This instruction supports MC_ABORTING and MC_BUFFERED modes only. During execution of this instruction, do not modify the input parameter BufferMode to MC_BUFFERED mode for re-execution; otherwise, the function block will report a fault.
- The starting velocity of a buffered instruction after this instruction is the velocity when the output parameter InVelocity is set to TRUE.
- During execution of this instruction, you can call MC_Stop, MC_Halt, or MC_ImmediateStop instruction to stop the motion of the axis.
- This instruction automatically switches modes internally, so control mode switching between instructions does not rely on the MC_SetControllerMode instruction. You can directly call instructions under different control modes. Each instruction internally checks if the current mode meets the requirements and automatically switches the mode if necessary.
- During the execution of this instruction, the MC_MoveSuperImposed instruction can be used.
- When the instruction is triggered on a rising edge of the input parameter Execute, the input parameters are checked for validity. If any of invalid parameters is detected, it will be automatically corrected by the function block without a fault message; any buffered instructions after this instruction will be cleared.
- When the axis is enabled after PLC cold reset and the MC_Home instruction is executed using No. 35 homing method, if this instruction is executed with DIR_CURRENT being set, the motion direction of this instruction will be affected.

  Local pulse axis:



- This instruction can be used for local pulse axes.
- When the local pulse axis is used with Y0 or Y1 single-ended output, it is not recommended to use this instruction. ① No pulse output; ② No position feedback.

- **Timing diagram**

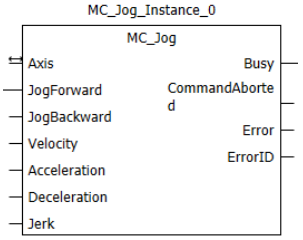
  The parameter Execute of the function block must be triggered on a rising edge. The parameter Done of the function block indicates the instruction has been executed successfully; the parameter Busy indicates that the current function block is being executed; the parameter CommandAborted indicates that the instruction is aborted by another motion control instruction, at which point the flag is set to TRUE.

  The parameter Busy shows the value TRUE on a rising edge of Execute. In the next cycle, the output parameter Active shows the value TRUE.

  - The MC_MoveVelocity instruction is executed to implement continuous motion based on the T-curve when the axis is in StandStill state.

◦ Axis motion is aborted by the MC_Stop instruction.

◦ The drive malfunctions during the axis acceleration.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.3.38 MC_Jog

This instruction enables the axis to jog at the specified target velocity.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_Jog	Jog		MC_Jog _Instance_0(Axis :=, JogForward :=, JogBackword :=, Velocity :=, Acceleration :=, Deceleration :=, Jerk :=, Busy =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
JogForward	Jog forward	BOOL	TRUE, FALSE	FALSE	TRUE: The axis starts moving forward. FALSE: The axis stops moving forward.
JogBackward	Jog backward	BOOL	TRUE, FALSE	FALSE	TRUE: The axis starts moving backward. FALSE: The axis stops moving forward.
Velocity	Target velocity	LREAL	Positive number or 0	0	Target velocity [u/s] for the motion.
Acceleration	Acceleration	LREAL	Positive number	0	Acceleration [u/s^2] of the acceleration phase.
Deceleration	Deceleration	LREAL	Positive number	0	Deceleration [u/s^2] of the deceleration phase.
Jerk	Jerk	LREAL	Positive number	0	Slope [u/s^3] of acceleration or deceleration (Valid for S-curve planning only). The value 0 indicates T-curve acceleration or deceleration.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Parameter correction**

Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Velocity	Velocity	Any velocity that exceeds the commissioning parameter limit will be automatically corrected to the velocity limit.	Any velocity less than 0 will be automatically corrected to 1e-5.	No correction.
Acceleration	Acceleration	Any acceleration that exceeds the commissioning parameter limit will be automatically corrected to the acceleration limit.	• When the MotionControl library version is 2.3.0.0 or earlier, the acceleration less than 0 will be automatically corrected to 10% of the acceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the acceleration less than 0 will be automatically corrected to 10 times the velocity.	• When the MotionControl library version is 2.3.0.0 or earlier, the acceleration equal to 0 will be automatically corrected to 10% of the acceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the acceleration equal to 0 will be automatically corrected to 10 times the velocity.

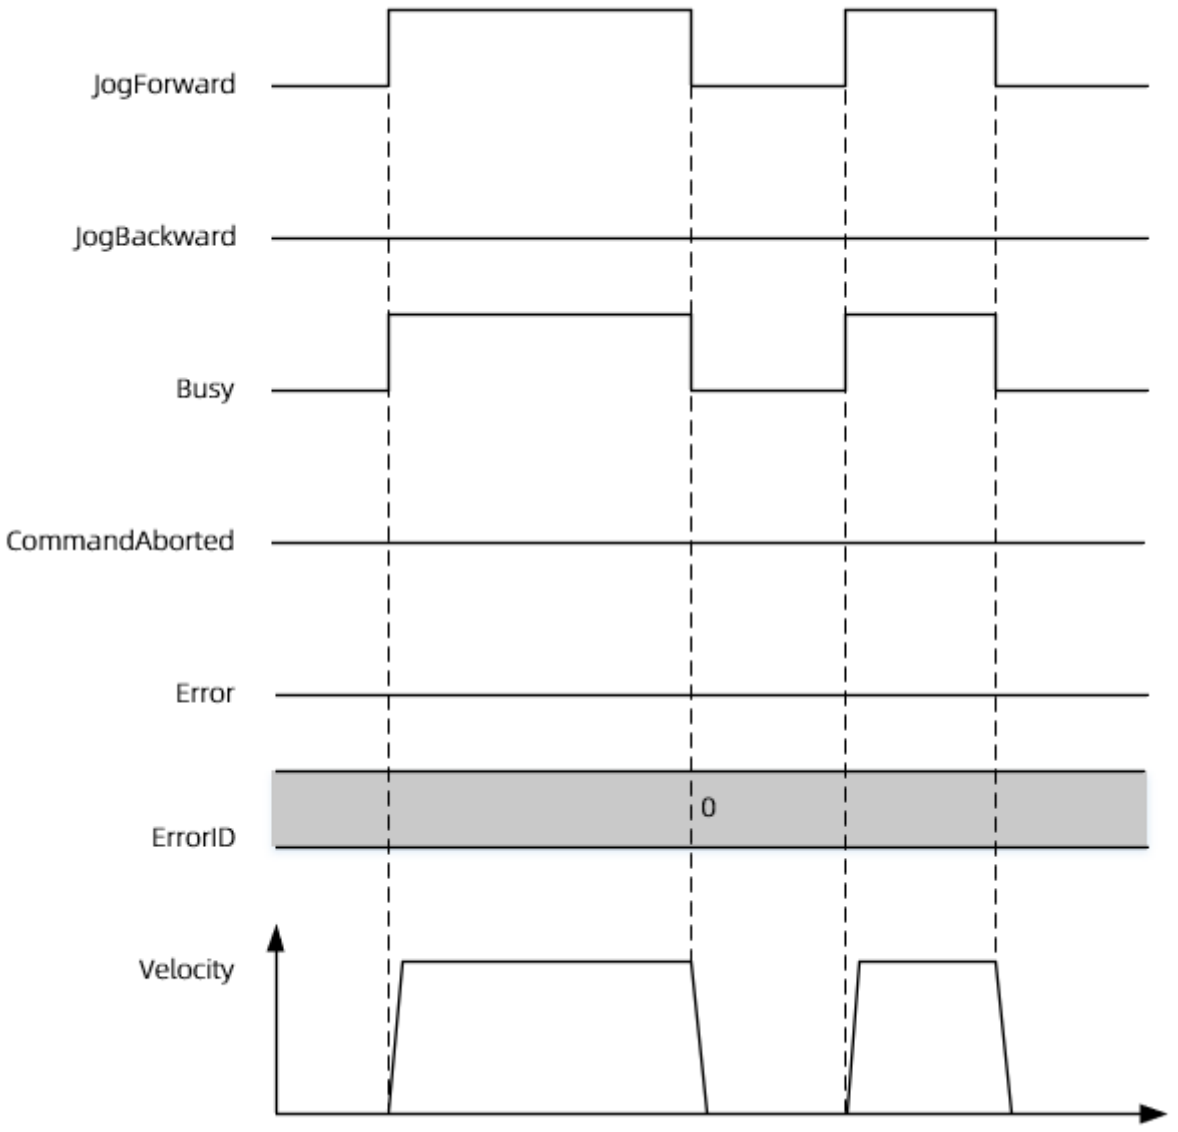
Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Deceleration	Deceleration	Any deceleration that exceeds the commissioning parameter limit will be automatically corrected to the deceleration limit.	• When the MotionControl library version is 2.3.0.0 or earlier, the deceleration less than 0 will be automatically corrected to 10% of the deceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the deceleration less than 0 will be automatically corrected to 10 times the velocity.	• When the MotionControl library version is 2.3.0.0 or earlier, the deceleration equal to 0 will be automatically corrected to 10% of the deceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the deceleration equal to 0 will be automatically corrected to 10 times the velocity.
Jerk	Jerk	If the motion profile is set to S-curve, any jerk that exceeds the software limit will be automatically corrected to the jerk limit.	If the motion profile is set to S-curve, any jerk less than 0 will be automatically corrected to 10% of the jerk limit.	If the motion profile is set to S-curve, the jerk equal to 0 will be automatically corrected to 10% of the jerk limit.

- **Function**

  Bus-controlled axis:

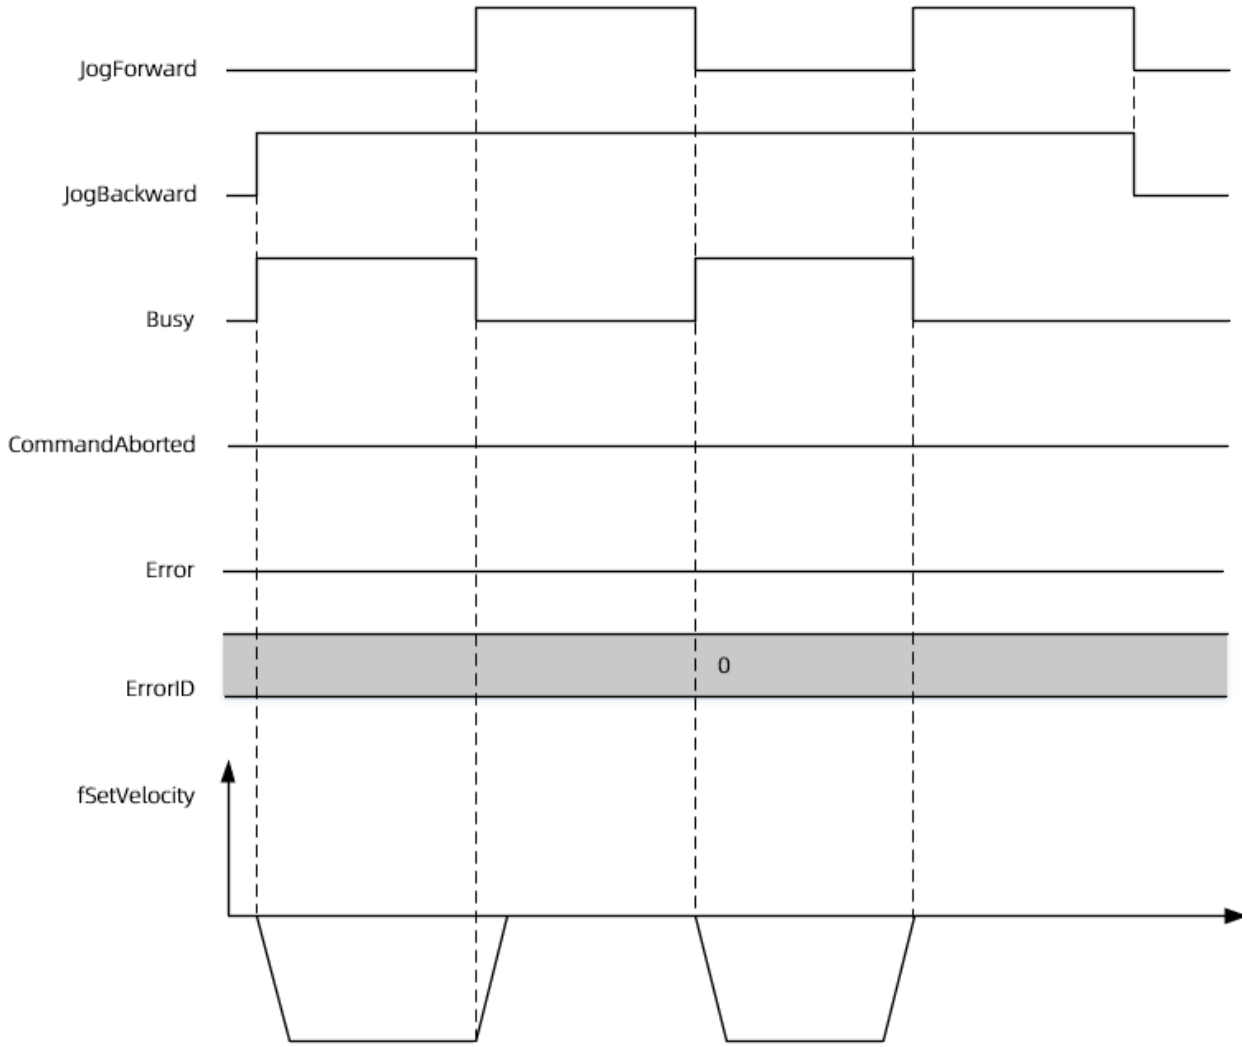
  - After this instruction is triggered, the setpoints of the input parameters Velocity, Acceleration, Deceleration, and Jerk are latched, and the instructions controls the velocity for jogging and switches the axis state to AXIS_CONTINUOUS_MOTION.
  - If you want the axis to move forward, set the input parameter JogForward to TRUE. If you want the axis to move backward, set the input parameter JogBackward to TRUE. When both JogForward and JogBackward are set to TRUE, the axis remains standstill. After the axis is moving with JogForward or JogBackward being set, the axis will decelerate to stop and be kept in DiscreteMotion mode during the deceleration if both JogForward and JogBackward are set to TRUE simultaneously.
  - For the input parameters Velocity, Acceleration, or Deceleration of this instruction, if the setpoint of any parameter is greater than the maximum limit in the software, the parameter will be automatically corrected by the function block without a fault message.
  - If the axis hits a limit switch while moving in one direction, the instruction will report a fault, and the axis enters ErrorStop state. If the software is configured to not report faults associated with limit switches, the axis state will automatically return to StandStill after deceleration to stop.
  - When the current axis state is Stopping or Homing, this instruction is immediately aborted and terminated.
  - The control object for this instruction must be control axis. During the execution of this instruction, if there is a fault on the axis, the function block will report the fault and exit.

- This instruction automatically switches control modes internally, so control mode switching between instructions does not rely on the MC_SetControllerMode instruction. You can directly call instructions under different control modes. Each instruction internally checks if the current mode meets the requirements and automatically switches the mode if necessary.
- During the execution of this instruction, the MC_MoveSuperImposed instruction cannot be used; once the MC_MoveSuperImposed instruction is triggered, CommandAborted is set for the MC_MoveSuperImposed instruction.



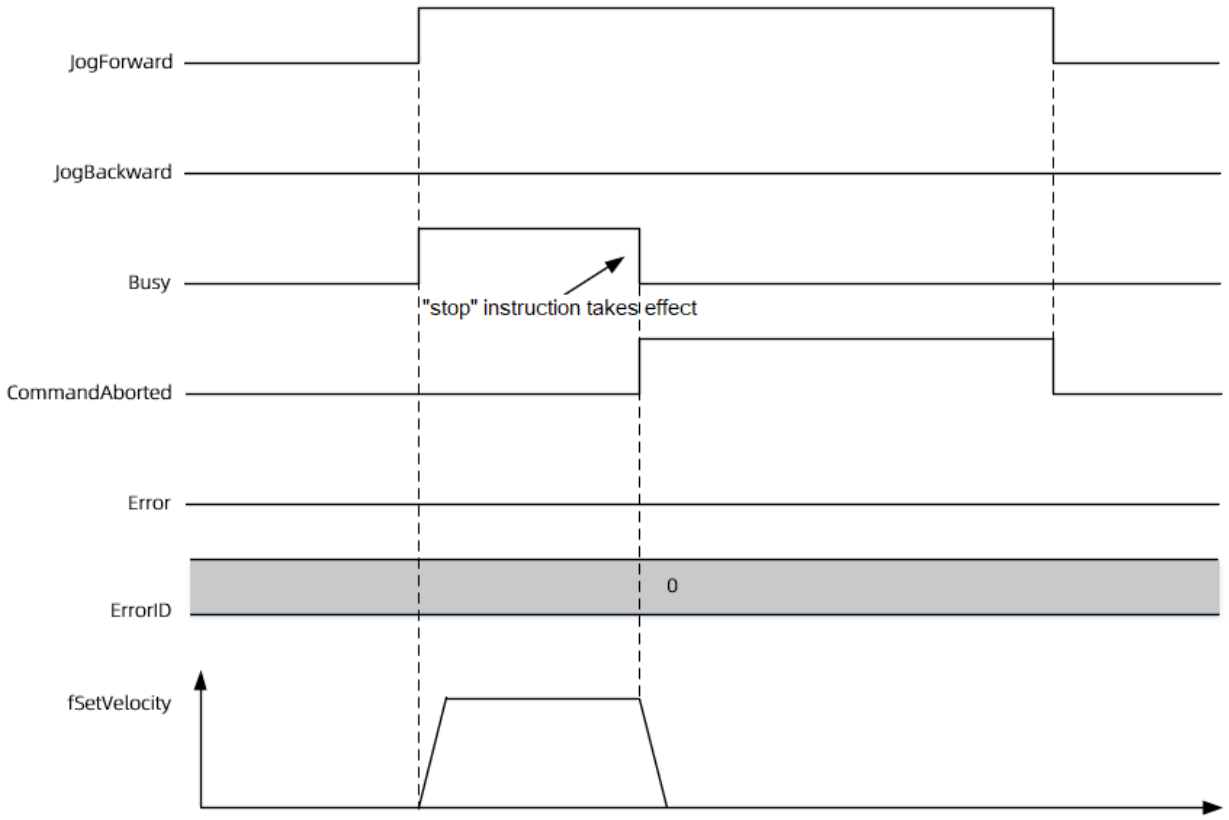
Local pulse axis:

- This instruction can be used for local pulse axes.

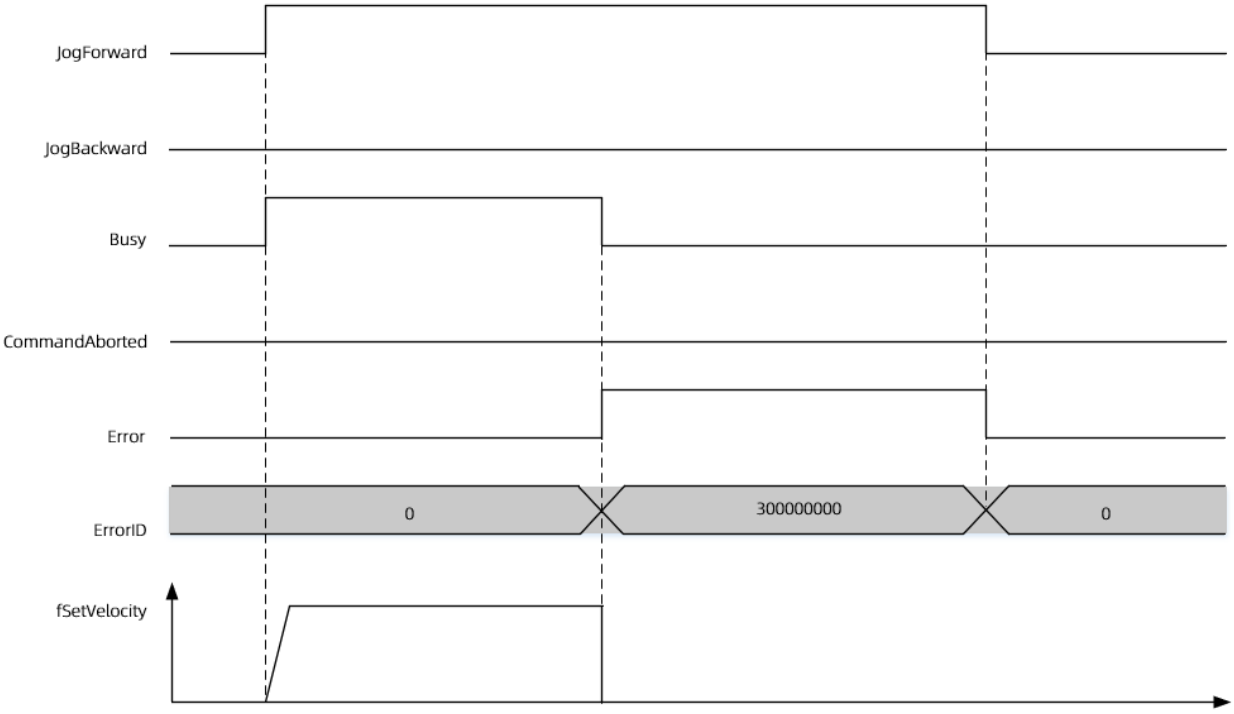


- **Timing diagram**

When JogForward or JogBackward is enabled, the parameter Busy shows the value TRUE.
When the axis starts decelerating to stop on a falling edge of JogForward or JogBackward, the parameter Busy shows the value FALSE.
When this instruction is aborted by another instruction, the CommandAborted is set to TRUE, and the Busy is set to FALSE.



- Timing diagram when the JogForward is set to TRUE



- Timing diagram when the JogBackward is set to TRUE

◦ Timing diagram when the instruction is aborted by the MC_Stop instruction during execution

◦ Timing diagram when the axis reports a fault

- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

- **Precautions**

  ◦ This instruction can be followed by a buffered instruction. The buffered motion starts after the commissioning of this instruction ends.

◦ The axis is in AXIS_CONTINUOUSMOTION state during the jogging, and AXIS_DISCRETEMOTION during the deceleration phase.

18.3.3.3.39 MC_TorqueControl

This instruction controls the torque.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_TorqueControl	Torque control		MC_TorqueControl_Instance_0(Axis :=, Execute :=, ContinuousUpdate :=, Torque :=, TorqueRamp :=, Velocity :=, BufferMode :=, InTorque =>, Busy =>, Active =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	The function block is executed on a rising edge of this input variable.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
ContinuousUpdate	Continuous update	BOOL	TRUE, FALSE	FALSE	Continuous parameter update effective flag. Prerequisite: The ContinuousUpdate is set to TRUE. Applicable parameters: Torque, TorqueRamp, Velocity.
Torque	Target torque	LREAL	Torque value: Target torque to output to the servo drive in increments of 0.1%.	300	Positive torque cannot be greater than the fMaxPositiveTorque of the axis structure, and the absolute value of negative torque cannot be greater than the fMaxNegativeTorque of the axis structure. Torque value: Target torque to output to the servo drive in increments of 0.1%.
TorqueRamp	Torque ramp	LREAL	Positive number or 0	0	Change rate of torque from the current value to the target torque. The value 0 indicates direct output at the target torque.
Velocity	Velocity	LREAL	Positive number or 0	0	Maximum velocity.
BufferMode	Buffer mode	18.3.3.2.2.6 MC_BUFFER_MODE: Buffer Mode Enumeration	0: mcAborting 1: mcBuffered	0	0: mcAborting (Aborting). 1: mcBuffered (Buffered).

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
InTorque	Target torque reached	BOOL	TRUE, FALSE	FALSE	TRUE when the target torque is reached.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Active	Controlling	BOOL	TRUE, FALSE	FALSE	TRUE when the axis is being controlled by the current FB.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Parameter correction**

Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Velocity	Velocity	Any velocity that exceeds the motion parameter limit will be automatically corrected to the velocity limit.	Any velocity less than 0 will be automatically corrected to 1e-5.	No correction.
Torque	Target torque	Any torque that exceeds the torque limit in the software will be automatically corrected to the torque limit.	No correction.	No correction.
TorqueRamp	Torque ramp	No limit.	Any torque ramp less than 0 will be automatically corrected to 0.	No correction.

- **Function**

  Bus-controlled axis:

  - This instruction switches the control mode to torque mode (MC_CST) for controlling the output torque of the servo motor. The target torque is specified in increments of 0.1%. The actual torque output by the drive is limited by the maximum positive/negative torque specified for the configuration parameters.
  - The input parameter Velocity is a positive value, and its direction depends on the torque or load.
  - When the input parameter ContinuousUpdate is set to TRUE, online modification is supported for Torque, TorqueRamp, and Velocity.
  - Before triggering this instruction, configure the PDOs 6060, 6061, 6071 and 6077; otherwise, the function block will report a fault.
  - When the actual torque deviation from the target torque is less than 5%, the parameter InTorque is set. The InTorque is set only when the condition is first met and will not be refreshed periodically thereafter.
  - Before using this instruction, check whether the servo device corresponding to the axis executing the instruction is a stepper drive. Torque control is not supported for stepper drives. If it is not a stepper drive, configure the corresponding PDOs.
  - If 607F is not configured, the Velocity is converted into pulse units by this instruction and written to the 607F object via the SDO channel. After the MC_TorqueControl instruction terminates, triggering the MC_Home instruction may limit the homing velocity.

- **Velocity control in torque mode:**
  - For Inovance servo drives

    The PDO to be configured for torque control is 6071 (Torque). If 6071 is not configured, the function block will report a fault.
  - For third-party drives

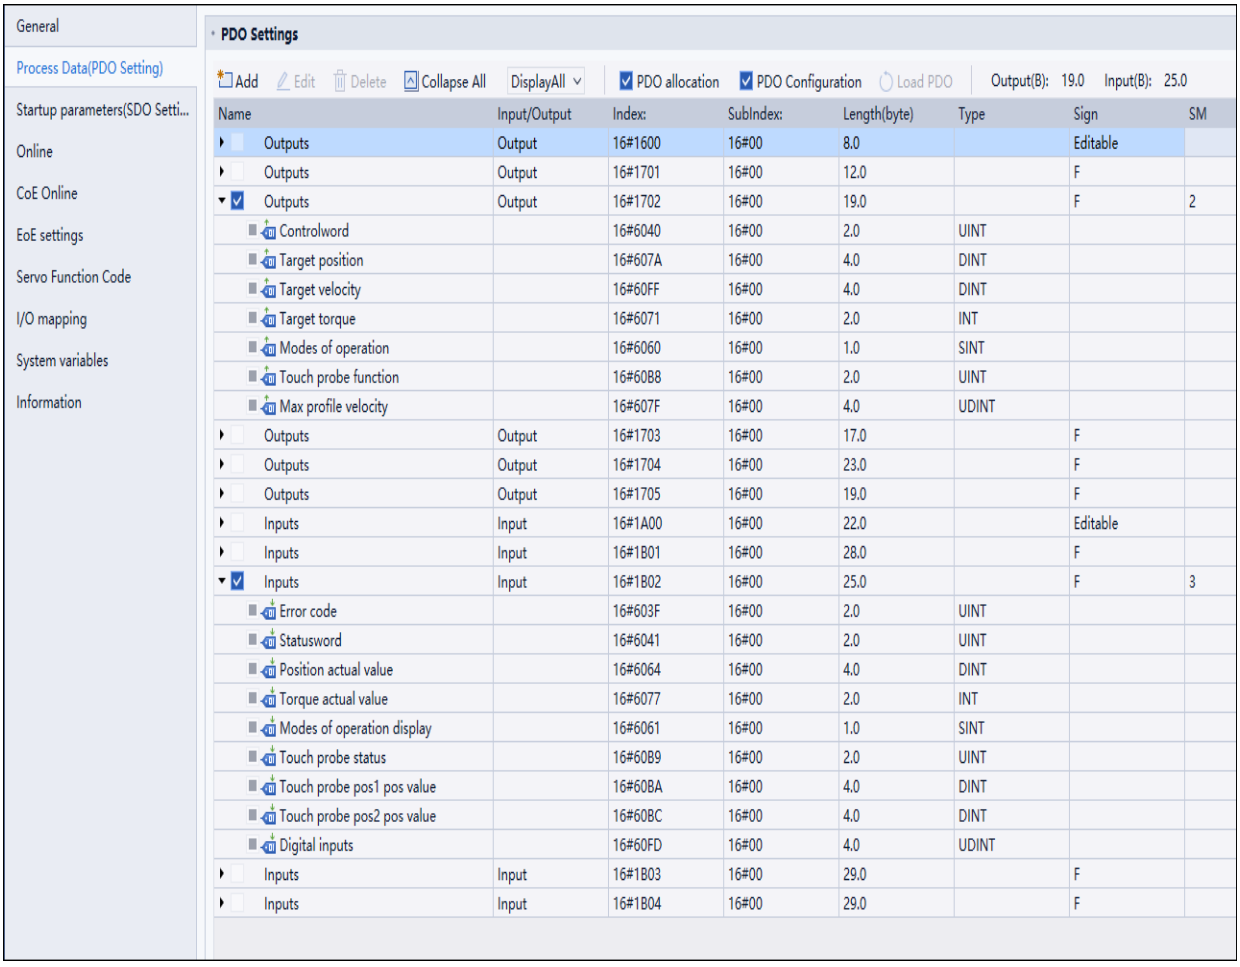
    Configure 607F (Maximum servo motor velocity).
- **Stop control in torque mode:**
  - In torque mode, the MC_Stop instruction can be executed to stop the drive. After the MC_Stop instruction is received, the drive switches to the synchronous position mode and decelerates according to the deceleration specified by the MC_Stop instruction.
  - During the execution of this instruction, the MC_MoveSuperImposed instruction cannot be used; once the MC_MoveSuperImposed instruction is triggered, CommandAborted is set for the MC_MoveSuperImposed instruction.

  Local pulse axis:
- This instruction cannot be used for local pulse axes.

- **Timing diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Busy of the function block indicates that the current function block is being executed, and the parameter CommandAborted indicates that the instruction is aborted by another motion control instruction, at which point the flag is set to TRUE.

  After this instruction is called, the output parameter Busy is set to TRUE on a rising edge of Execute. When the parameter fActVelocity reaches the limit, the actual torque will no longer ramp up, but the commanded torque will still ramp up normally without the InTorque being set.

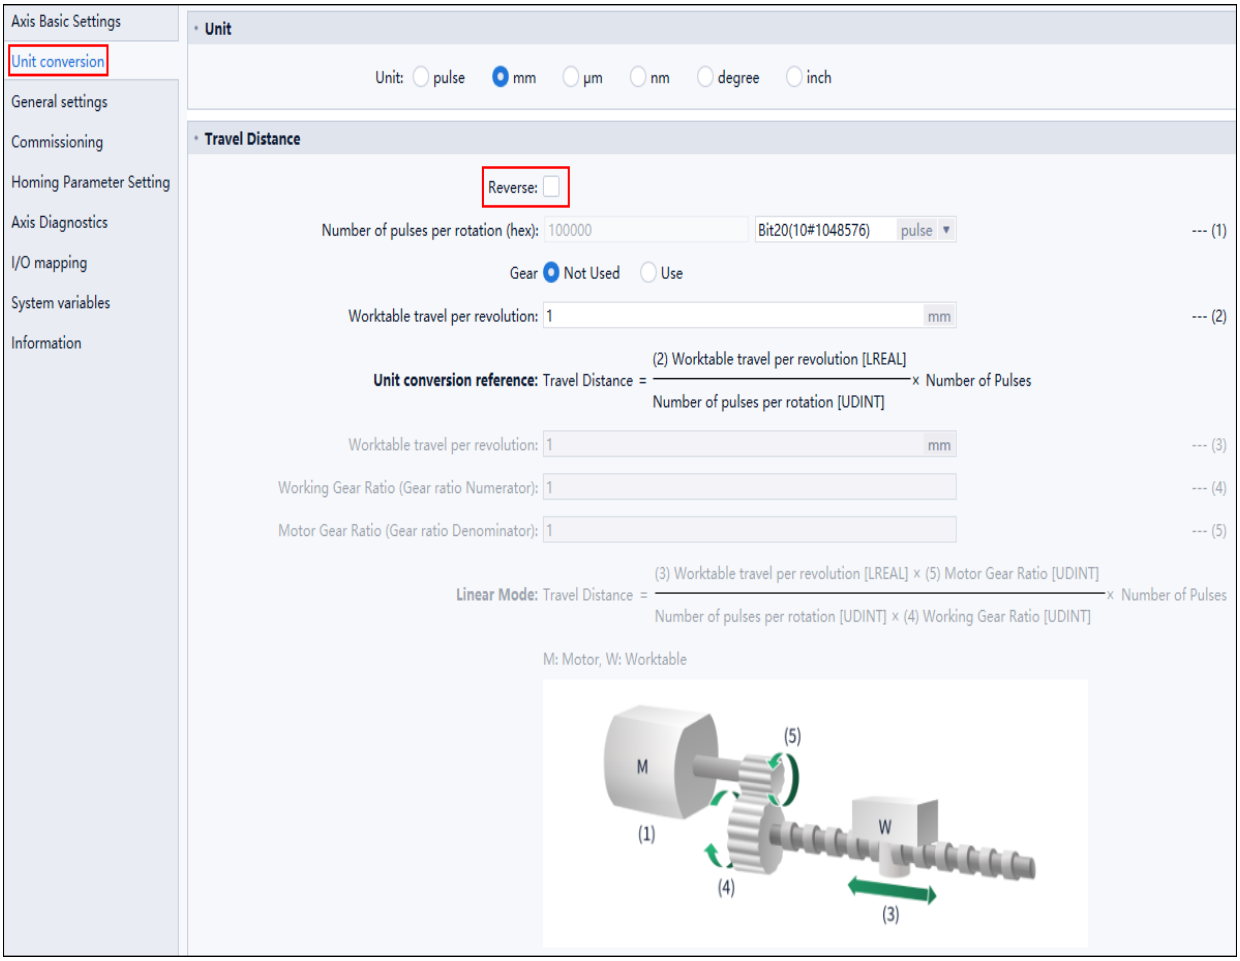


- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

- **Example**

  To configure the PDO in the software, you can select the third group of inputs and outputs directly, or select the first group of inputs and outputs and add the 607A, 6060, 6077, and 6061.



Configure the target torque. To prevent the torque from reaching the maximum value directly, you can configure the TorqueRamp. The torque will ramp up according to the specified TorqueRamp.

When the velocity parameter reaches the limit, the actual torque will no longer ramp up, but the commanded torque will still ramp up normally without the InTorque being set.

- **Precautions**
  - The parameter InTorque of this instruction is not checked in real time. If the torque ramp Tramp is not configured, the initial torque will reach the torque reference, at which point the InTorque is set. However, as the velocity ramps up and reaches the velocity limit, the corresponding torque limit will ramp down and no longer meet the actual torque range, at which point the InTorque is still not reset.
  - Checking Reverse on the interface has no effect on the MC_TorqueControl instruction.

18.3.3.3.40 MC_ImmediateStop

This instruction stops an axis using the specified mode.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_ImmediateStop	Immediate stop	MC_ImmediateStop_Instance_0 MC_ImmediateStop Axis Done Execute Busy StopMode Error ErrorID	MC_ImmediateStop_Instance_0(Axis :=, Execute :=, StopMode :=, Done =>, Busy =>, Error =>, ErrorID =>);

- **Related variables**

  In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	The function block is executed on a rising edge of this input variable.
StopMode	Stop mode	18.3.3.2.2.10 MC_STOP_MODE: Stop Mode Enumeration	0, 1	0	0: Perform an immediate stop. 1: Perform an immediate stop, and turn OFF the servo.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs in the function block.

- **Function**

  Bus-controlled axis:

  - This instruction can abort a single axis attached to the axis group, causing the axis group to perform an immediate stop.

- This instruction can be executed at any axis state. Even if the axis is in deceleration stop due to a fault, it can immediately stop with this instruction.
- After this instruction is triggered, all currently executing instructions are aborted, and the axis performs an immediate stop according to the specified value of the input parameter StopMode. When the StopMode is set to 1, the axis cannot be enabled after the immediate stop until the MC_Reset instruction is executed for reset.
- When this instruction is triggered with the axis state of POWER_OFF, the instruction is done directly without switching the axis state to a faulty state.
- The control object of this instruction is the control axis.

  Local pulse axis:

- This instruction can be used for local pulse axes.

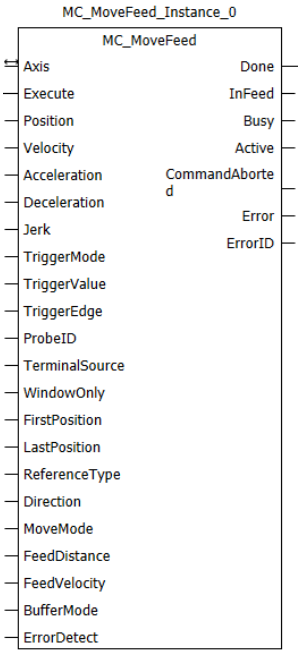
- **Timing diagram**

The input parameter Execute must be triggered on a rising edge. When the output parameter Done is set to TRUE, it indicates that the instruction has been executed successfully. When the output parameter Busy is set to TRUE, it indicates the current function block is being executed.

After this instruction is called, the output parameter Busy is set to TRUE on a rising edge of Execute After the axis group performs an immediate stop, the output parameter Done is set to TRUE.

- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.



- **Precautions**

  It is not recommended to use this instruction when the axis state is AXIS_POWER_OFF.

18.3.3.3.41 MC_MoveFeed

This instruction performs positioning for the specified travel distance from the position where an external device triggers an interrupt input. Interrupt feeding is possible for absolute positioning, relative positioning, and velocity control.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_MoveFeed	Interrupt feeding		MC_MoveFeed_Instance_0(Axis :=, Execute :=, Position :=, Velocity :=, Acceleration :=, Deceleration :=, Jerk :=, TriggerMode :=, TriggerValue :=, TriggerEdge :=, ProbeID :=, TerminalSource :=, WindowOnly :=, FirstPosition :=, LastPosition :=, ReferenceType :=, Direction :=, MoveMode :=, FeedDistance :=, FeedVelocity :=, BufferMode :=, ErrorDetect :=, Done =>, InFeed =>, Busy =>, Active =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

  In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	The function block is executed on a rising edge of this input variable.
Position	Target position	LREAL	Positive number, negative number, or 0	0	Specify the absolute target position [u].
Velocity	Target velocity	LREAL	Positive number	0	Specify the target velocity [u/s].
Acceleration	Acceleration	LREAL	Positive number	0	Specify the acceleration [u/s^2].
Deceleration	Deceleration	LREAL	Positive number	0	Specify the deceleration [u/s^2].
Jerk	Jerk	LREAL	Positive number	0	Specify the slope of acceleration (deceleration) [u/s^3] (Valid for S-curve planning only).
TriggerMode	Trigger mode	INT	0, 1	0	0: Drive mode. 1: Controller mode.
TriggerValue	Trigger value	BOOL	TRUE, FALSE	FALSE	Trigger value.
TriggerEdge	Trigger edge	INT	0, 1	0	0: Rising edge. 1: Falling edge.
ProbeID	Touch probe identification	INT	0, 1	0	For ECAT axes, only touch probe 0/1 is supported. 0: Touch probe 1. 1: Touch probe 2. For local axes, it depends on the actual hardware channel.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
TerminalSource	Trigger source	INT	0, 1	0	0: DI terminal. 1: Z-phase signal.
WindowOnly	Window only	BOOL	TRUE, FALSE	FALSE	TRUE: Enabled. FALSE: Disabled.
FirstPosition	First position	LREAL	-	0	Specify the position [u] to enable the touch probe.
LastPosition	Last position	LREAL	-	0	Specify the position [u] to disable the touch probe.
ReferenceType	Position type selection	18.3.3.2.2.11 MC_REFERENCE_TYPE: Data Type Enumeration	0: mcCommand 1: mcFeedback	0	0: Value calculated in the previous task cycle (fSavePosition). 1: Value obtained in the same task cycle (fActPosition). (Reserved parameter)
Direction	Motion direction	18.3.3.2.2.9 MC_DIRECTION: Motion Direction Enumeration	0: DIR_SHORTEST 1: DIR_POSITIVE 2: DIR_NEGATIVE 3: DIR_CURRENT 4: DIR_NODIRECTION	1	0: DIR_SHORTEST (Direction based on the shortest way). 1: DIR_POSITIVE (Positive direction). 2: DIR_NEGATIVE (Negative direction). 3: DIR_CURRENT (Current direction). 4: DIR_NODIRECTION (No direction).
MoveMode	Move mode	18.3.3.2.2.8 MC_MOVE_MODE: Move Mode Enumeration	0: AbsoluteMode 1: RelativeMode 2: VelocityMode	-	Selects the move mode.
FeedDistance	Feed distance	LREAL	Positive number, negative number, or 0	0	Travel distance after the interrupt feed input. Specify a positive value [u] to feed in the same direction as the axis is moving before the interrupt input and a negative value [u] to feed in the opposite direction. Note: For rotary axes, the target position for feeding is the remainder of the capture position + feed distance divided by the rotation cycle, ignoring multi-turn displacement.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
FeedVelocity	Feed velocity	LREAL	Positive number	0	Travel velocity [u/s] after the interrupt feed input.
BufferMode	Buffer mode	18.3.3.2.2.6 MC_BUFFER_MODE: Buffer Mode Enumeration	0: mcAborting 1: mcBuffered	0	0: mcAborting (Aborting). 1: mcBuffered (Buffered).
ErrorDetect	Error detection	BOOL	TRUE, FALSE	FALSE	Specify whether to enable fault detection when there is no interrupt feed input. TRUE: Enabled. FALSE: Disabled.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
InFeed	Feeding	BOOL	TRUE, FALSE	FALSE	TRUE when feeding after receiving a latch input.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Active	Controlling	BOOL	TRUE, FALSE	FALSE	TRUE when the axis is being controlled.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Parameter correction**

Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Velocity	Velocity	Any velocity that exceeds the motion parameter limit will be automatically corrected to the velocity limit.	Any velocity less than 0 will be automatically corrected to 1e-5.	• When the MotionControl library version is 2.1.0.0 or earlier, the velocity equal to 0 will be automatically corrected to 1e-5. • When the MotionControl library version is 2.2.0.0 or later, the velocity equal to 0 will not be corrected.
Acceleration	Acceleration	Any acceleration that exceeds the motion parameter limit will be automatically corrected to the acceleration limit.	• When the MotionControl library version is 2.3.0.0 or earlier, the acceleration less than 0 will be automatically corrected to 10% of the acceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the acceleration less than 0 will be automatically corrected to 10 times the velocity.	• When the MotionControl library version is 2.3.0.0 or earlier, the acceleration equal to 0 will be automatically corrected to 10% of the acceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the acceleration equal to 0 will be automatically corrected to 10 times the velocity.

Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Deceleration	Deceleration	Any deceleration that exceeds the motion parameter limit will be automatically corrected to the deceleration limit.	• When the MotionControl library version is 2.3.0.0 or earlier, the deceleration less than 0 will be automatically corrected to 10% of the deceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the deceleration less than 0 will be automatically corrected to 10 times the velocity.	• When the MotionControl library version is 2.3.0.0 or earlier, the deceleration equal to 0 will be automatically corrected to 10% of the deceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the deceleration equal to 0 will be automatically corrected to 10 times the velocity.
Jerk	Jerk	If the motion profile is set to S-curve, any jerk that exceeds the software limit will be automatically corrected to the jerk limit.	If the motion profile is set to S-curve, any jerk less than 0 will be automatically corrected to 10% of the jerk limit.	If the motion profile is set to S-curve, the jerk equal to 0 will be automatically corrected to 10% of the jerk limit.
FeedVelocity	Feed velocity	Any velocity that exceeds the motion parameter limit will be automatically corrected to the velocity limit.	Any velocity less than 0 will be automatically corrected to 1e-5.	• When the MotionControl library version is 2.1.0.0 or earlier, the velocity equal to 0 will be automatically corrected to 1e-5. • When the MotionControl library version is 2.2.0.0 or later, the velocity equal to 0 will not be corrected.

- **Function**

  Bus-controlled axis:

  - This instruction performs positioning in one of the travel methods (Absolute positioning, Relative positioning, and Velocity control) specified by the input parameter MoveMode on a rising edge of Execute, based on the input parameters Position, Velocity, Direction, Acceleration, and Deceleration.
  - When Absolute positioning is selected, specify the target position in the input parameter Position. When Relative positioning is selected, specify the target distance in the input parameter Position. Regardless of the travel method, the axis moves at the velocity specified by the input parameter Velocity.

- Relative positioning is performed at the FeedVelocity from the actual position where the external input is turned ON or OFF (according to the set value of TriggerEdge) during travel for the distance specified by the FeedDistance. The movement distance is specified by FeedDistance, starting from the actual position at FeedVelocity.
- When this instruction is aborted by the MC_ImmediateStop instruction, the MC_AbortTrigger instruction must be used to release the occupied channel (if any).
- If no interrupt signal is input before the axis reaches the target position during interrupt feeding in absolute or relative move mode, the axis will stop at the target position.
- You can specify whether to detect abnormal output through ErrorDetect. When there is no interrupt input and the axis stops moving, if the ErrorDetect is set to TRUE, the function block will report a fault after the motion stops, but the axis state will be Standstill rather than ErrorStop; if the ErrorDetect is set to FALSE, the output parameter Done will be set after the motion stops.
- To execute this instruction, set the WindowOnly to TRUE, and then specify FirstPosition and LastPosition. Interrupt feeding is performed for the interrupt signal generated by the actual position between the FirstPosition and the LastPosition.
- For bus-controlled axes, the PDOs 60B8/60B9 must be configured; otherwise, a fault will occur. When the instruction is executed on a rising edge with ProbeID = 0, a fault will occur if the 60BA object is not configured; when the instruction is executed on a falling edge, a fault will occur if the 60BB object is not configured. When the instruction is executed on a rising edge wit ProbeID = 1, a fault will occur if the 60BC object is not configured; when the instruction is executed on a falling edge, a fault will occur if the 60BD object is not configured.
- The motion parameters Acceleration, Deceleration, and Jerk are shared for the first segment of motion and fixed-length motion.
- When the input parameter WindowOnly is set to FALSE:

  The instruction does not identify the FirstPosition or LastPosition.

- When the input parameter WindowOnly is set to TRUE:
  - Linear mode

    The FirstPosition must be less than the LastPosition.

  - Rotary mode

    The FirstPosition can be less than or greater than the LastPosition.

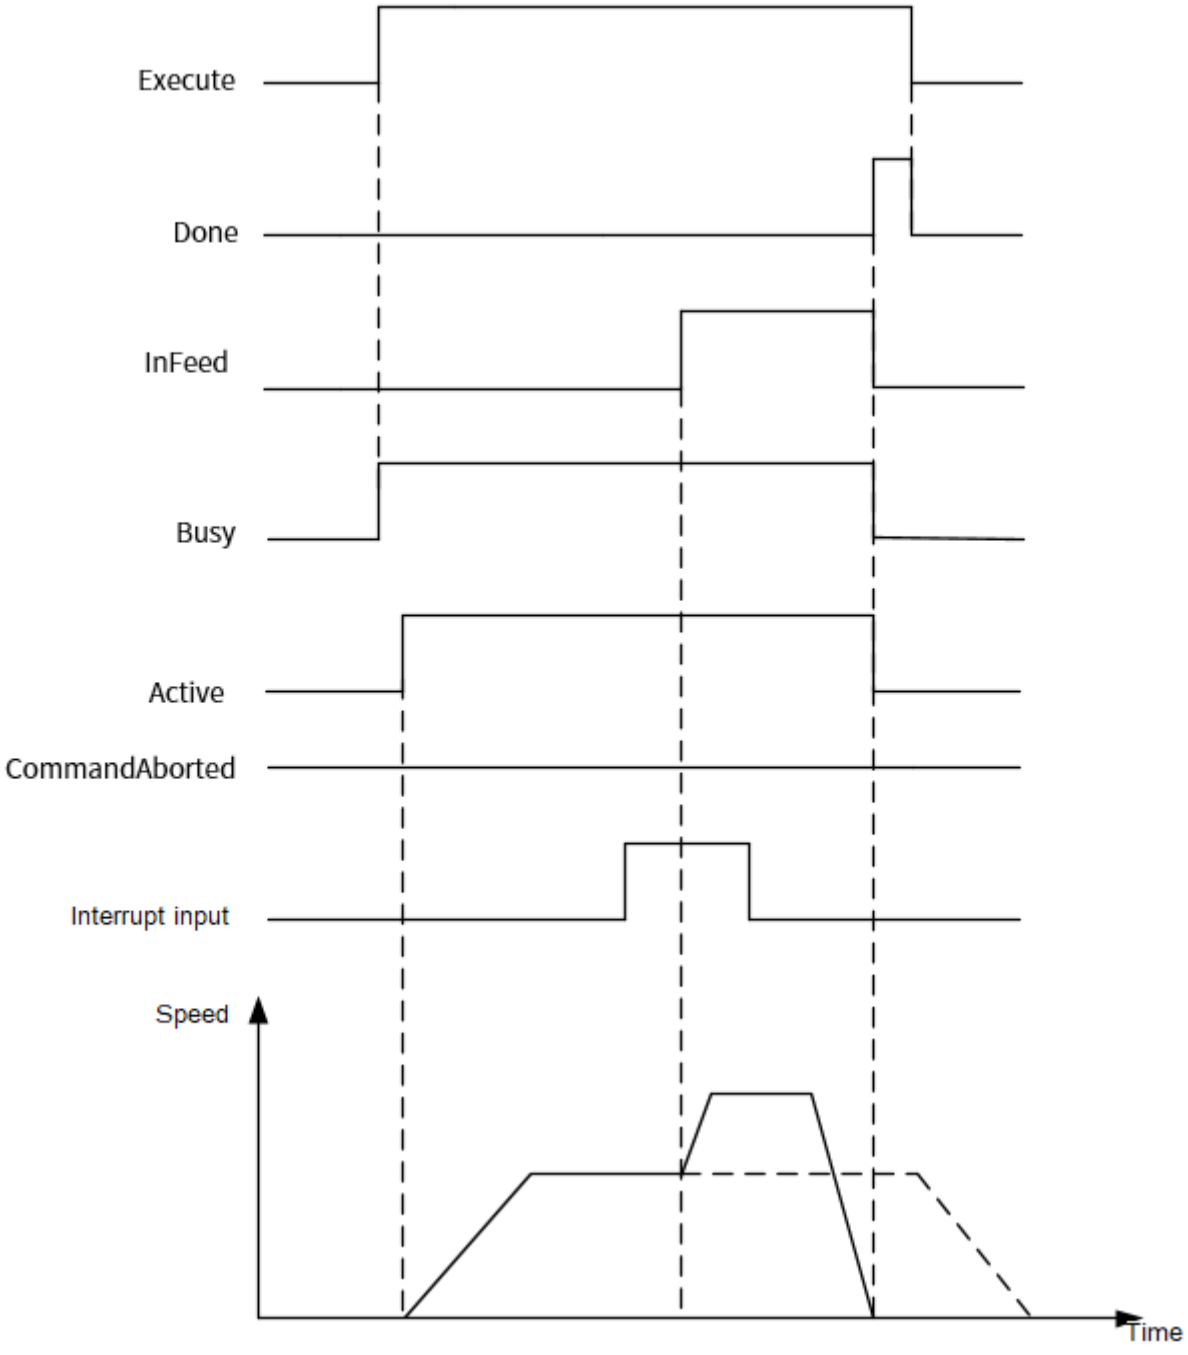
    1. FirstPosition < LastPosition

       The window is valid when the actual position is between the FirstPosition and the LastPosition, as shown in the following figure:

2. FirstPosition > LastPosition

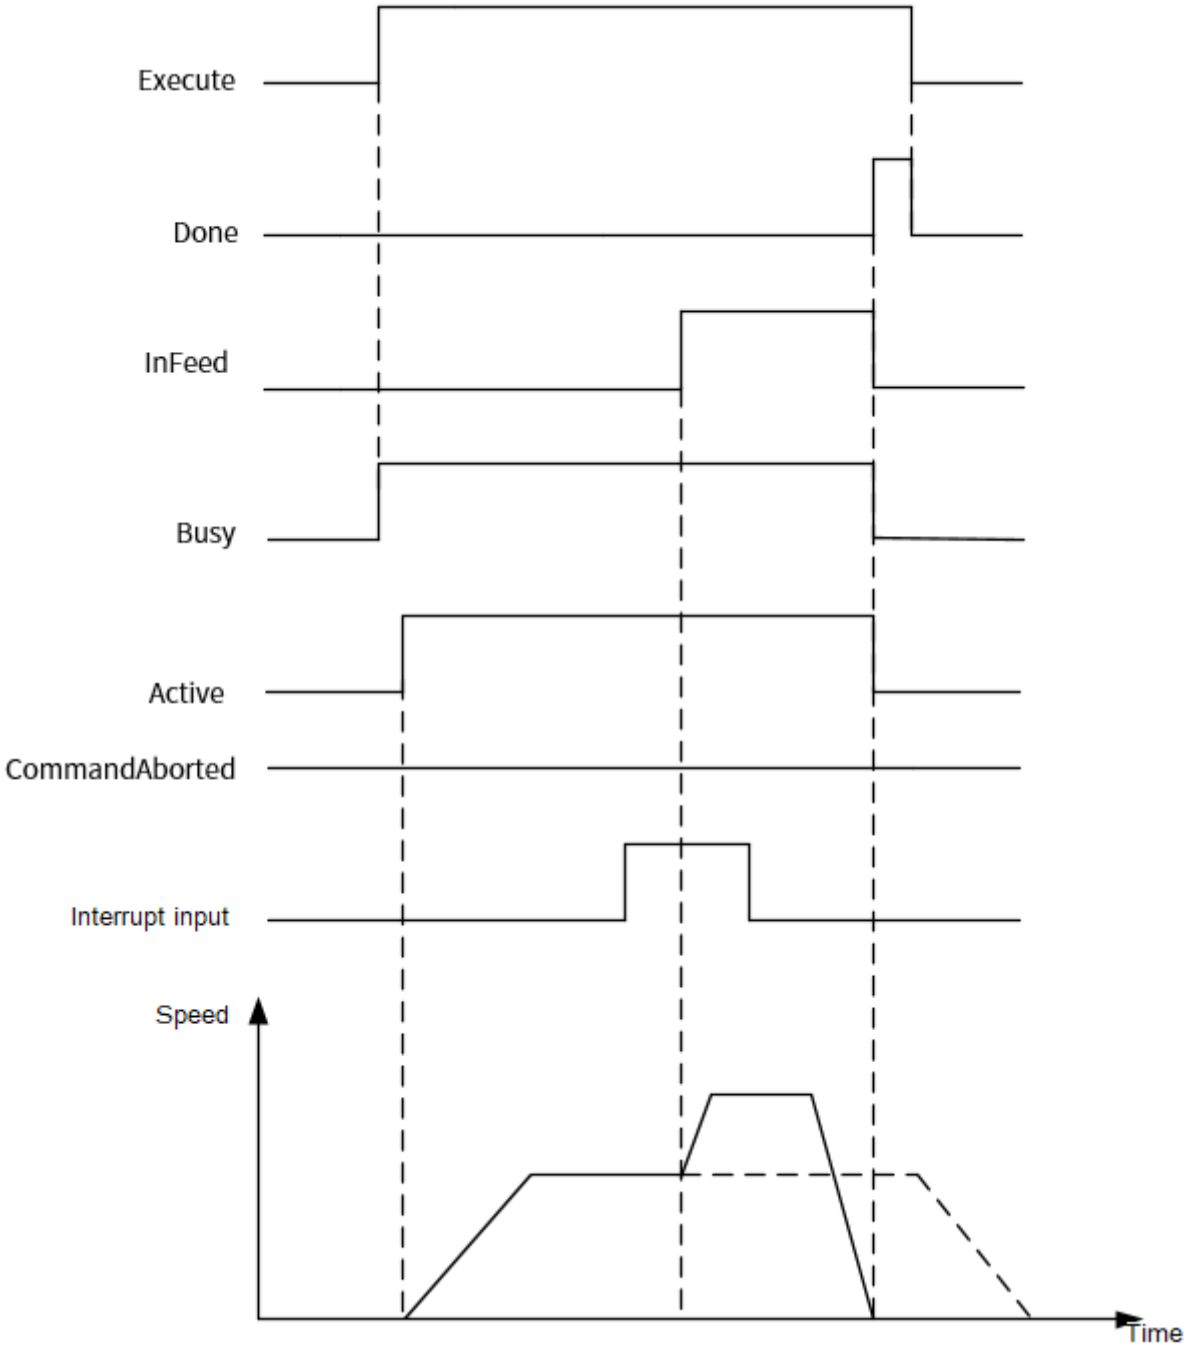
The window is valid when the actual position is greater than the FirstPosition and less than the cycle length, or greater than 0 and less than the LastPosition, as shown in the following figure:

- In Rotary Mode, if the MoveMode is set to Absolute positioning, this instruction will check the value of Direction, which must be one of the five direction modes specified by the instruction; if the MoveMode is set to Velocity control, the instruction will check whether the direction is Positive, Negative, or Current; in other cases, the direction parameter will not be checked.
- This instruction does not occupy the probe channel when in the buffer. If the probe channel is occupied during execution, this instruction will abort the current instruction occupying the probe channel.
- In PLCopen specification, this instruction is valid with the axis state being Discrete_Motion. Other instructions that can place the axis in Discrete_Motion or comply with PLCopen state machine transitions can abort this instruction. When this instruction is aborted, the output parameter CommandAborted is set.
- During the execution of this instruction, if the axis decelerates to stop due to hitting the software limit, the output parameter Error will be set when the axis state being switched to Errorstop.
- This instruction automatically switches the control mode internally, so control mode switching between instructions does not rely on the MC_SetControllerMode instruction. You can directly call instructions. Each instruction internally checks if the current mode meets the requirements and automatically switches the mode if necessary.
- When this instruction is used for a virtual axis, it must be executed with a configured corresponding probe; otherwise, a fault will occur.



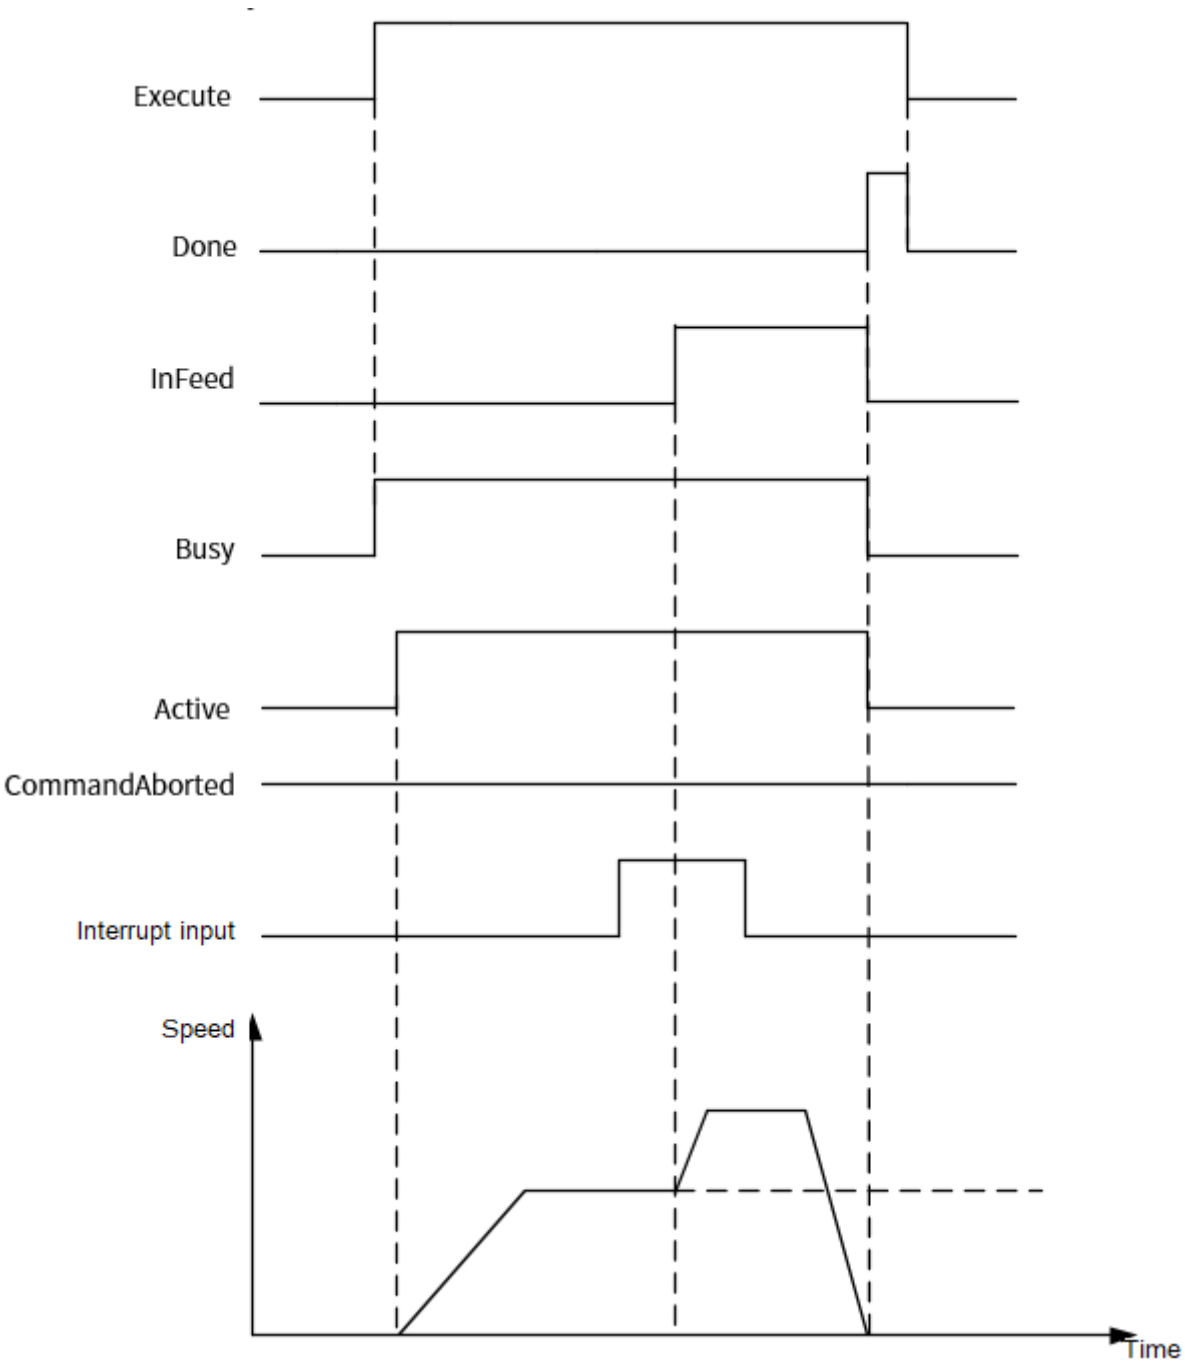
- During the execution of this instruction, the MC_MoveSuperImposed instruction cannot be used; once the MC_MoveSuperImposed instruction is executed, the input parameter CommandAborted is set for the MC_MoveSuperImposed instruction.
- When the axis is enabled after PLC cold reset and the MC_Home instruction is executed using No. 35 homing method, if this instruction is executed with DIR_CURRENT being set, the motion direction of this instruction will be affected.

Local pulse axis:

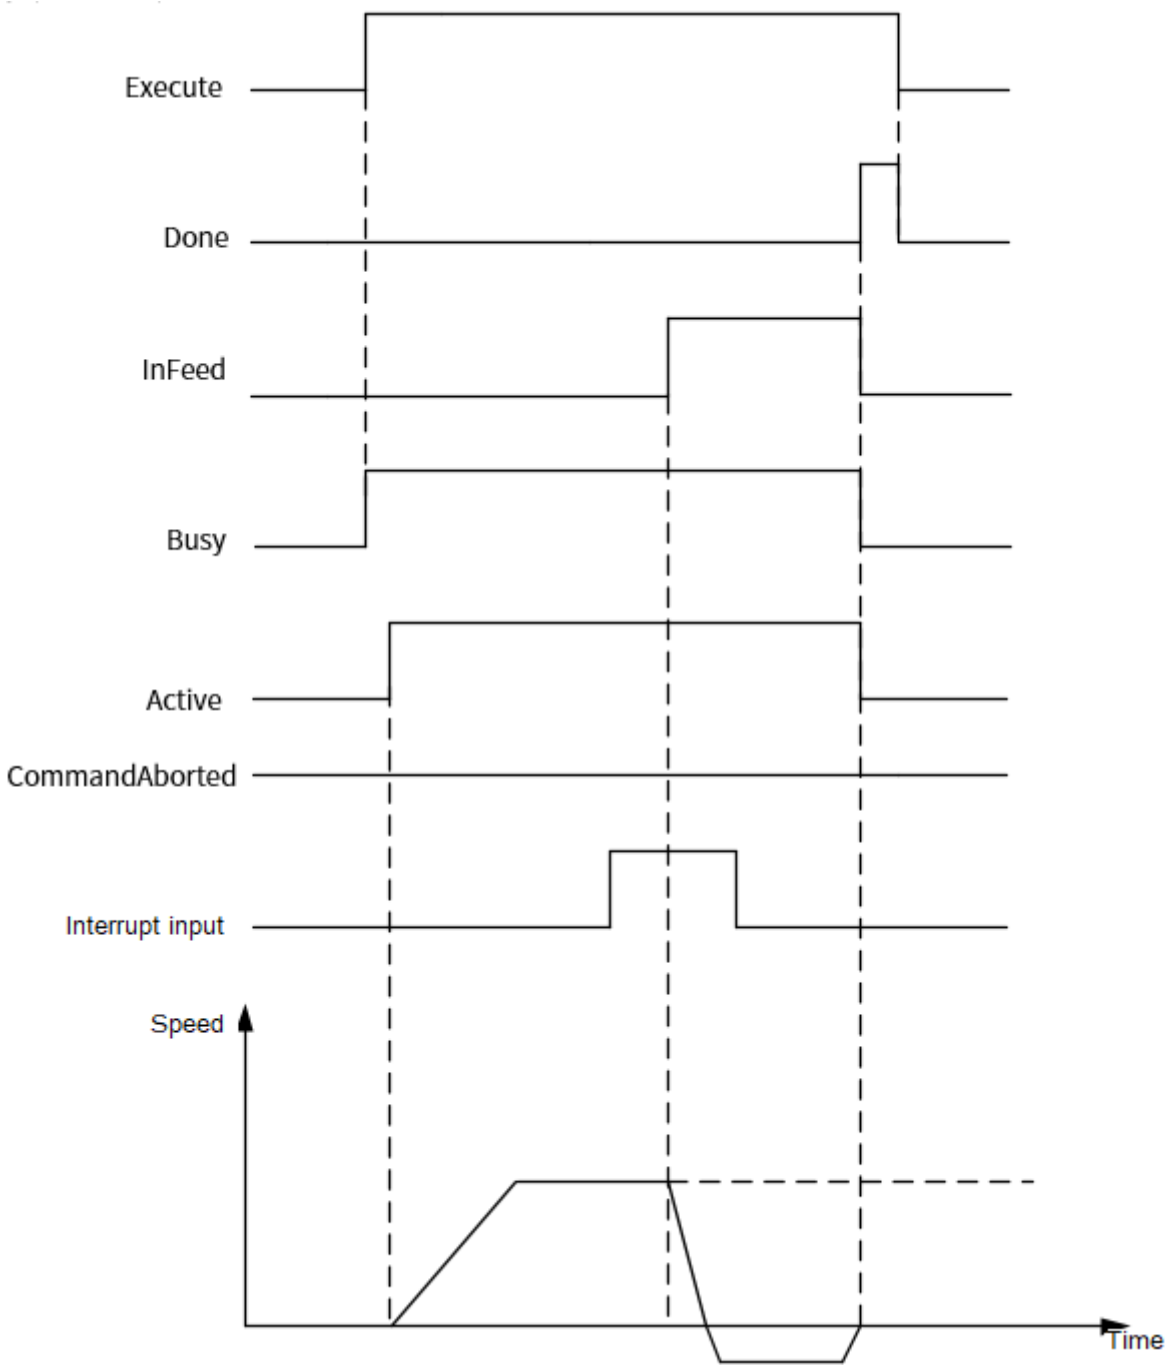


- This instruction can be used for local pulse axes.

- **Timing diagram**



MoveMode = Absolute positioning



MoveMode = Relative positioning

MoveMode = Velocity control

Reversing after the interruption input

- **Re-execution of motion control instructions**

  This instruction cannot be re-executed.

- **Faults**

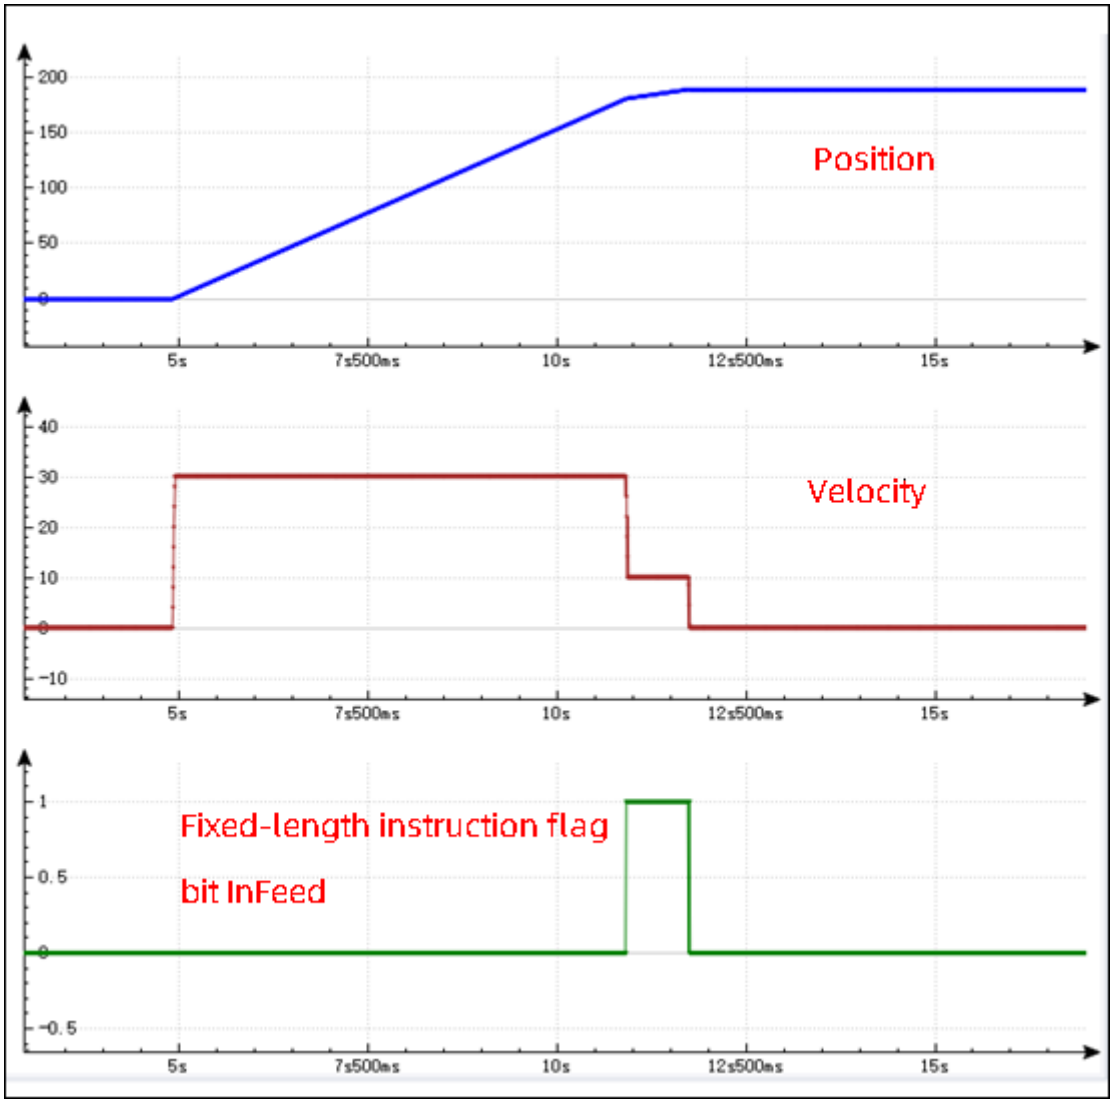
  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

- **Example**

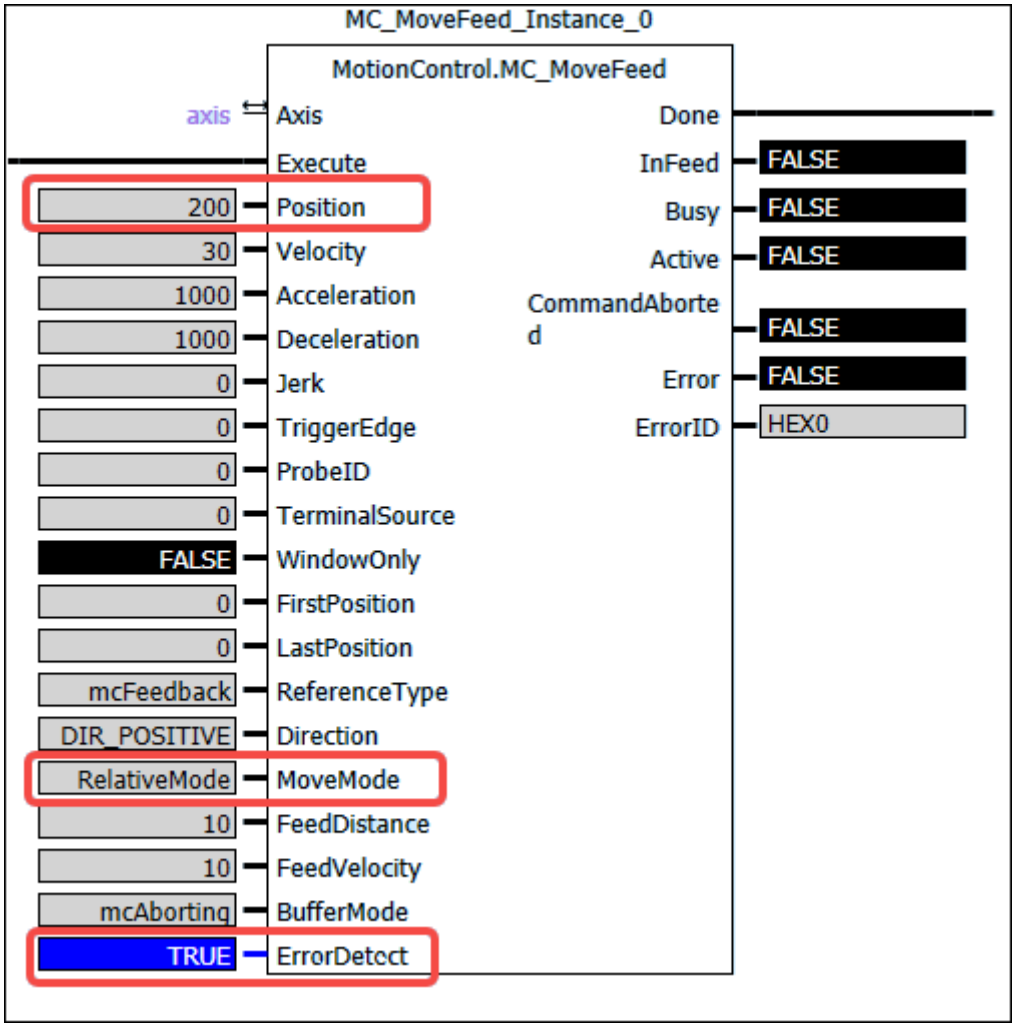
  Simulating a fixed-length marking scenario: Specify the main conveyor belt as Axis and the marking axis as Axis_1. When the main conveyor belt moves for a fixed length of 10 cm upon identifying the photo mark, the marking machine starts marking. After marking is complete, the interrupted fixed-length operation is restarted.

  First, configure the PDO. The rising edge of touch probe 1 is guaranteed by default PDO configuration. See the MC_TouchProbe instruction for other configurations.

Select the running program for the main conveyor belt, set MoveMode = VelocityMode, and specify the Direction as Positive direction or Negative direction.

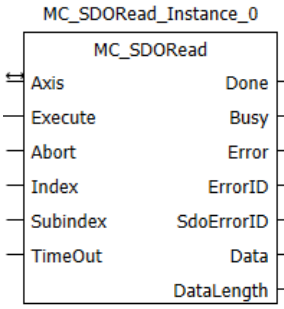


Specify the motion parameters Velocity, Acceleration, and Deceleration to prevent the motor reversal due to fixed-length deceleration. It is recommended to change the acceleration/deceleration to the limit values in the software. Specify the motion parameters FeedDistance and FeedVelcity for fixed-length movement.



By default, the value 0 corresponds to the rising edge trigger of touch probe 1. You can specify the probe source. See the MC_TouchProbe instruction for specific configurations.

The instruction controls the axis to move in a straight line at the velocity set by Velocity. After the photo mark is identified, the InFeed will be set. Once the axis moves for a fixed length of 10 cm at the set value of FeedVelocity, the main motion will stop and the marking machine will start working. After the marking is complete, re-executing the MoveFeed instruction will start the next cycle.



- **Precautions**
  - When the fixed-length position is close to the photo mark position, the marking machine can use the InFeed of this instruction as a flag to start printing during the fixed-length movement, improving the efficiency.
  - You can modify the MoveMode to RelativeMode and specify the Position as a distance covering multiple item spacing. You can specify the unit of the preceding distance on the FA interface. When the ErrorDetect is set, and the program will stop with a fault message if no photo mark is detected after a travel distance greater than 200.

18.3.3.3.42 MC_SDORead

This instruction reads SDO data. Reading SDO is independent of the axis state. The instruction can be triggered regardless of the axis state.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_SDORead	Read specified SDO data		MC_SDORead_Instance_0(Axis :=, Execute :=, Abort :=, Index :=, Subindex :=, TimeOut :=, Done =>, Busy =>, Error =>, ErrorID =>, SdoErrorID =>, Data =>, DataLength =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	The function block is executed on a rising edge of this input variable.
Abort	Abort	BOOL	TRUE, FALSE	FALSE	The function block is aborted on a rising edge of this input variable.
Index	Object dictionary index	WORD	Positive number or 0	0	Object dictionary index of SDO to be read.
Subindex	Object dictionary subindex	BYTE	Positive number or 0	0	Object dictionary subindex of SDO to be read.
TimeOut	Timeout period	UDINT	Positive number or 0	0	SDO read timeout period (ms).

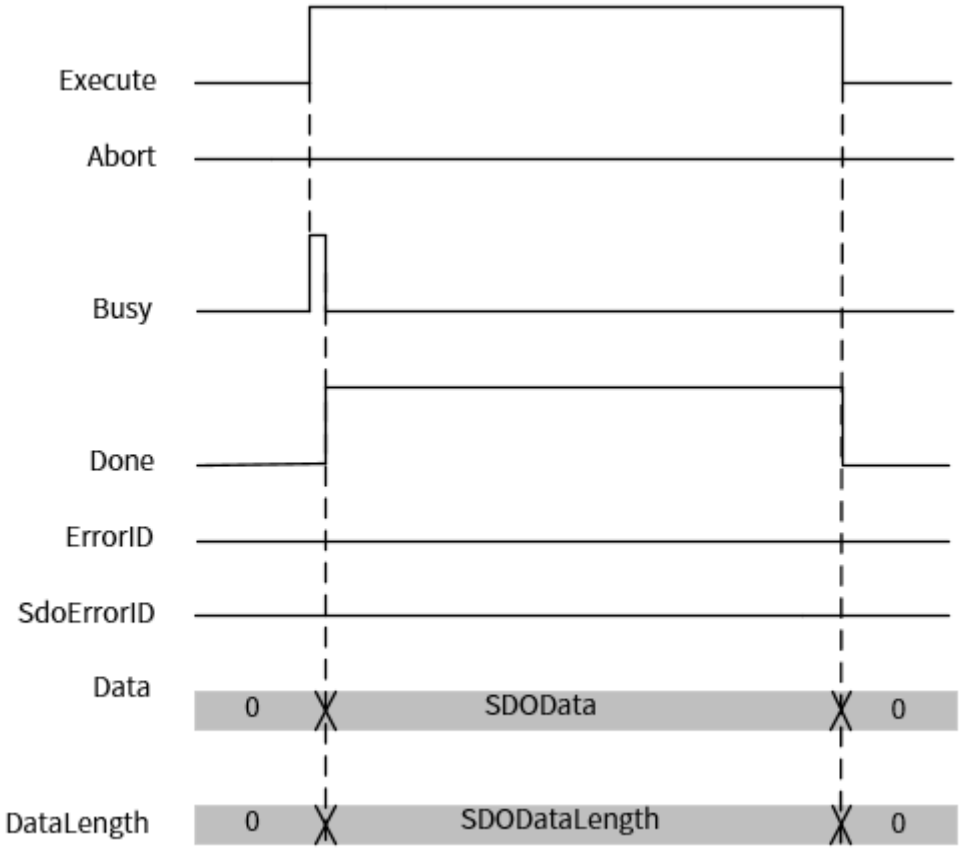
Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is being executed.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs in the function block.
SdoErrorID	SDO fault code	UDINT	Positive number or 0	0	If a fault occurs in the device, more information about the fault can be obtained with this output variable. For details, see 18.4.9.17 SDO Fault Codes.
Data	Read data	DWORD	-	0	SDO data read. It is effective only when the parameter Done is set to TRUE.
DataLength	Read data length	BYTE	1 to 4	0	SDO data length read. It is effective only when the parameter Done is set to TRUE.

- **Function**

  Bus-controlled axis:

  - This instruction is triggered on a rising edge of Execute. The input parameters other than Abort are latched on the rising edge, among which any modified parameters will not be effective during the execution of the instruction.
  - You can specify SDO read timeout period (ms) through the parameter TimeOut. The value 0 indicates 1000 task cycles by default. If the read operation times out, the function block will report a timeout fault.
  - The MC_SDORead instruction is independent of the axis state. It can be triggered regardless of the axis state. If the instruction is triggered before successful communication with the axis, it will be executed after the communication is established. If no communication is established within the specified TimeOut value, the function block will report a timeout fault.
  - If the parameter Abort is set to TRUE, the function block will be aborted with the output parameters being reset.
  - The fault codes of this function block include both function block-specific fault codes and SDO fault codes. When a function block-specific fault occurs, the function block reports the fault via ErrorID only. When an SDO read/write fault occurs, the function block reports the fault via ErrorID and SdoErrorID.



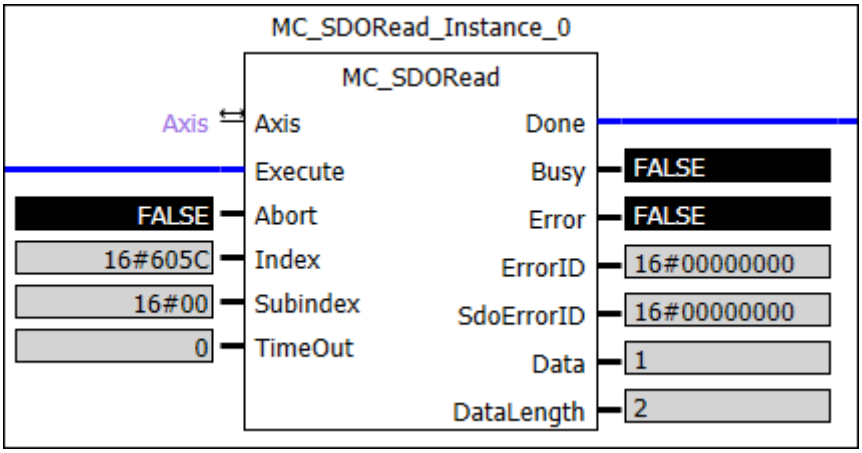
Local pulse axis

◦ This instruction cannot be used for local pulse axes.

- **Timing diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Busy of the function block indicates that the current function block is being executed. When the parameter Abort is set to TRUE, the function block is aborted and reset.

  After this instruction is called, the output parameter Busy will be set to TRUE if the Execute signal is TRUE; the output parameter Done will be set to TRUE upon successful reading, with the Busy showing the value FALSE.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

- **Example**

  Using the bus-controlled axis as an example, input the specified axis, index 0x605C, and subindex 0. The execution result is as follows:

18.3.3.3.43 MC_SDOWrite

This instruction writes SDO data. Writing SDO is independent of the axis state. The instruction can be triggered regardless of the axis state.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_SDOWrite	Write specified SDO data to input axis		MC_SDOWrite_Instance_0(Axis :=, Execute :=, Abort :=, Index :=, Subindex :=, Data :=, DataLength :=, TimeOut :=, Done =>, Busy =>, Error =>, ErrorID =>, SdoErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	The function block is executed on a rising edge of this input variable.
Abort	Abort	BOOL	TRUE, FALSE	FALSE	The function block is aborted on a rising edge of this input variable.
Index	Object dictionary index	WORD	Positive number or 0	0	Object dictionary index of SDO to be written.
Subindex	Object dictionary subindex	BYTE	Positive number or 0	0	Object dictionary subindex of SDO to be written.
Data	Data to be written	DWORD	-	0	SDO data to be written.
DataLength	Written data length	BYTE	1 to 4	0	Length of the SDO data to be written.
TimeOut	Timeout period	UDINT	Positive number or 0	0	SDO write timeout period (ms).

Output variables

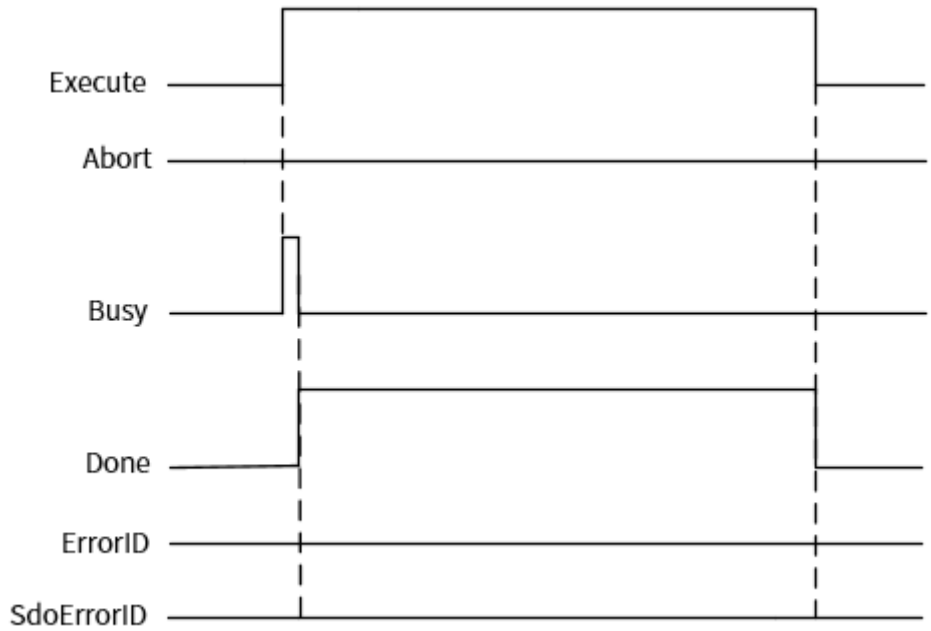
Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is being executed.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs in the function block.
SdoErrorID	SDO fault code	UDINT	Positive number or 0	0	If a fault occurs in the device, more information about the fault can be obtained with this output variable. For details, see 18.4.9.17 SDO Fault Codes.

- **Function**

  Bus-controlled axis:

  - This instruction is triggered on a rising edge of Execute. The input parameters other than Abort are latched on the rising edge, among which any modified parameters will not be effective during the execution of the instruction.

- You can specify SDO write timeout period (ms) through the parameter TimeOut. The value 0 indicates 1000 task cycles by default. If the write operation times out, the function block will report a timeout fault.
- When SDO parameters are written, the length of the written parameters must be between 1 and 4; otherwise, the function block reports a fault.
- The MC_SDOWrite instruction is independent of the axis state. It can be triggered regardless of the axis state. If the instruction is triggered before successful communication with the axis, it will be executed after the communication is established. If no communication is established within the specified TimeOut value, the function block will report a timeout fault.
- If the parameter Abort is set to TRUE, the function block will be aborted with the output parameters being reset.
- The fault codes of this function block include both function block-specific fault codes and SDO fault codes. When a function block-specific fault occurs, the function block reports the fault via ErrorID only. When an SDO read/write fault occurs, the function block reports the fault via ErrorID and SdoErrorID.



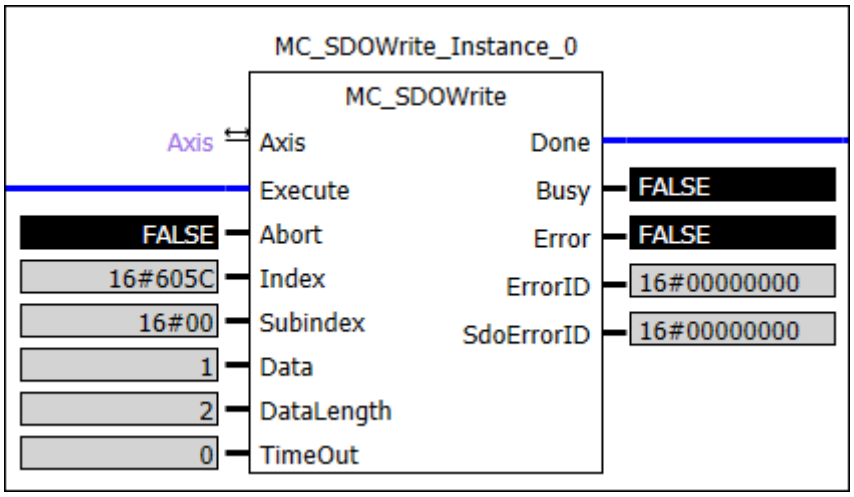
Local pulse axis

- This instruction cannot be used for local pulse axes.

- **Timing diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Busy of the function block indicates that the current function block is being executed. When the parameter Abort is set to TRUE, the function block is aborted and reset.

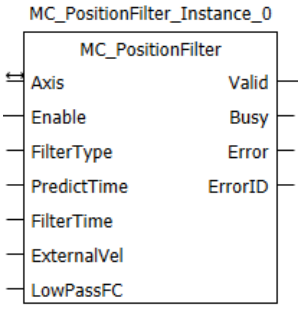
  After this instruction is called, the output parameter Busy will be set to TRUE if the Execute signal is TRUE; the output parameter Done will be set to TRUE upon successful writing, with the Busy showing the value FALSE.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

- **Example**



Using the bus-controlled axis as an example, input the specified axis, index 0x605C, subindex 0, Data = 1, and DataLength = 2. The execution result is as follows:

18.3.3.3.44 MC_PositionFilter

This instruction filters the position and velocity information based on the specified filter type and outputs the filtered velocity and position. It does not affect the position reference, velocity reference, actual position, or actual velocity, so the actual output of the corresponding axis will not be affected. The filtered position and velocity will be used as the signal source for the master axis in synchronized motion.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_PositionFilter	Position filter		MC_PositionFilter_Instance_0(Axis :=, Enable :=, FilterType :=, PredictTime :=, FilterTime :=, ExternalVel :=, LowPassFC :=, Valid =>, Busy =>, Error =>, ErrorID =>);

- **Related variables**

  In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Enable	Execute	BOOL	TRUE, FALSE	FALSE	Execute the instruction.
FilterType	Filter type	INT	0 to 11	0	Position source selection. For details, see Filter types.
PredictTime	Predicted cycles	INT	Compliant with data type	3	Predicted number of cycles. Positive and negative values are supported. A positive value indicates lead; a negative value indicates delay. This parameter is effective when the FilterType is not set to 0 or 1.
FilterTime	Filtering cycle/ window	INT	2 to 100	0	Cycle/Window for filtering. Value range: 2 to 100. This parameter is effective when the FilterType is not set to 0 or 1. It has different meanings with different values of the FilterType.
External Vel	External velocity	LREAL	Compliant with data type	0.0	External velocity reference, effective when the FilterType is set to 4 or 5.
LowPass Fc	Cut-off frequency	LREAL	Positive number	0.0	Higher cut-off frequency results in less filter delay and decreased high-frequency noise suppression capability. Conversely, lower cut-off frequency results in smoother signal and increased phase lag.

Output variables

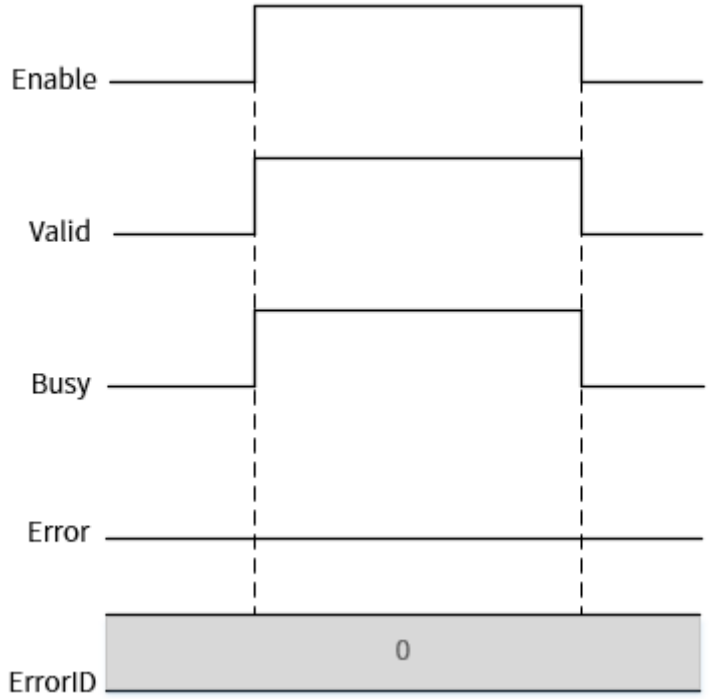
Output Variable	Name	Data Type	Valid Range	Default Value	Description
Valid	Input shaping	BOOL	TRUE, FALSE	FALSE	TRUE: Input shaping is being executed.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE: The function block is being executed.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE: A fault occurs during input shaping.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs in the function block.

- **Function**
  - This instruction does not affect the position reference, velocity reference, actual position, or actual velocity, so the actual output of the corresponding axis will not be affected. The filtered position and velocity will be used as the signal source for the master axis in synchronized motion.
  - This instruction is level-triggered. Continuous update of the input parameter ExternalVel is supported only when the FilterType is set 4 or 5; any other parameters modified during the execution of the instruction will not be effective.
  - FilterTime is an input parameter for this instruction. When the value of FilterType is between 2 and 5, it indicates the filtering cycle. When the value of FilterType is 8 or 9, it indicates the filtering cycle for moving filter. When the value of FilterType is 10 or 11, it indicates the window for median filter.
  - Filter types

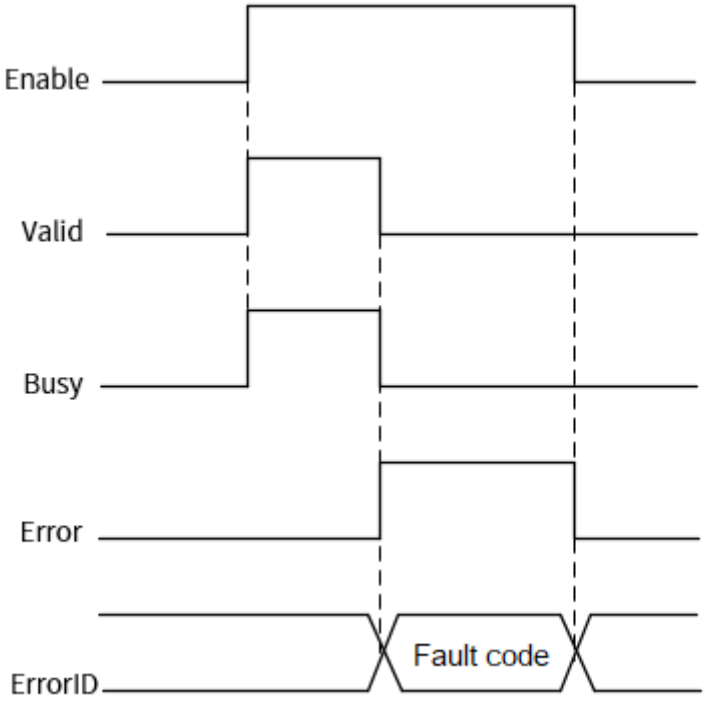
    The MC_PositionFilter instruction determines the filter type based on the input parameter FilterType, performs filtering according to the related filter parameters, and outputs the filtered position of the fRefPosition and filtered velocity of the fRefVelocity. The value range of FilterType is 0 to 11, corresponding to the following filter types:

Reference Source	Condition	Output
Master axis position reference (Direct mode)	FilterType = 0	$fPosition = fSetPosition$ $fVelocity = fSetVelocity$
Actual master axis position (Direct mode)	FilterType = 1	$fPosition = fActPosition$ $fVelocity = fActVelocity$
Actual master axis position + Actual master axis velocity	FilterType = 2	$fVelocity = \frac{\sum_{1}^{FilterTime} fActVelocity}{FilterTime}$ $fAcceleration = \frac{fVelocity_{FilterTime} - fVelocity_{FilterTime-1}}{\Delta t}$ $fPosition = fActPosition + fVelocity * \Delta t * \Pr edictTime + (\Delta t * \Pr edictTime)^2 * \frac{1}{2} * fAcceleration$



Reference Source	Condition	Output
Master axis position reference + Master axis velocity reference	FilterType = 3	$fVelocity = \frac{\sum_{1}^{FilterTime} fSetVelocity}{FilterTime}$ $fAcceleration = \frac{fVelocity_{FilterTime} - fVelocity_{FilterTime-1}}{\Delta t}$ $fPosition = fSetPosition + fVelocity * \Delta t * \Pr edictTime +$ $(\Delta t * \Pr edictTime)^2 * \frac{1}{2} * fAcceleration$
Actual master axis position + External velocity	FilterType = 4	$fVelocity = \frac{\sum_{1}^{FilterTime} fExternalVel}{FilterTime}$ $fAcceleration = \frac{fVelocity_{FilterTime} - fVelocity_{FilterTime-1}}{\Delta t}$ $fPosition = fActPosition + fVelocity * \Delta t * \Pr edictTime +$ $(\Delta t * \Pr edictTime)^2 * \frac{1}{2} * fAcceleration$
Master axis position reference + External velocity	FilterType = 5	$fVelocity = \frac{\sum_{1}^{FilterTime} fExternalVel}{FilterTime}$ $fAcceleration = \frac{fVelocity_{FilterTime} - fVelocity_{FilterTime-1}}{\Delta t}$ $fPosition = fSetPosition + fVelocity * \Delta t * \Pr edictTime +$ $(\Delta t * \Pr edictTime)^2 * \frac{1}{2} * fAcceleration$
Low-pass filter: position and velocity reference	FilterType = 6	$fVelocity_n = (1-\alpha) fVelocity_{n-1} + \alpha fSetVelocity$ $fPosition_n = (1-\alpha) fPosition_{n-1} + \alpha fSetPosition$ $a = \frac{\Delta t}{\Delta t + \frac{1}{2 * \pi * LowPassFc}}$
Low-pass filter: actual position and velocity	FilterType = 7	$fVelocity_n = (1-\alpha) fVelocity_{n-1} + \alpha fActVelocity$ $fPosition_n = (1-\alpha) fPosition_{n-1} + \alpha fActPosition$ $a = \frac{\Delta t}{\Delta t + \frac{1}{2 * \pi * LowPassFc}}$

Reference Source	Condition	Output
Moving average filter: position and velocity reference	FilterType = 8	$fVelocity = \frac{\sum_{1}^{FilterTime} fSetVelocity}{FilterTime}$ $fPosition = \frac{\sum_{1}^{FilterTime} fSetPosition}{FilterTime}$
Moving average filter: actual position and velocity	FilterType = 9	$fVelocity = \frac{\sum_{1}^{FilterTime} fActVelocity}{FilterTime}$ $fPosition = \frac{\sum_{1}^{FilterTime} fActPosition}{FilterTime}$
Median filter: position and velocity reference	FilterType = 10	The filter window is determined through FilterTime. The fSetPosition and fSetVelocity are placed into the window periodically and continuously refreshed (FIFO). The values within the window are sorted in an ascending order, with the median value being output.
Median filter: actual position and velocity	FilterType = 11	The filter window is determined through FilterTime. The fActPosition and fActVelocity are placed into the window periodically and continuously refreshed (FIFO). The values within the window are sorted in an ascending order, with the median value being output.



- **Timing diagram**

  The input parameter Enable indicates the start of executing the function block. The input parameter Busy indicates that the current function block is being executed, and the input parameter Valid indicates that the output parameters are valid.

  - When the input parameter Enable is set to TRUE, the output parameter Busy shows the value TRUE.

  - when a fault occurs during the execution of this instruction, the parameter Error shows the value TRUE. You can find the cause of the fault through the output value of ErrorID.

- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

- **Precautions**
  - You cannot execute this instruction in multiple instances simultaneously, i.e., triggering another MC_PositionFilter instruction while this instruction is being executed; otherwise, the later-triggered instruction reports a fault, without affecting the ongoing filter operation.

- When using filter types 2, 3, 4, 5, 8, and 9, note that if the actual position or position reference of the axis and the FilterTime are set to a large value, there may be a significant deviation between the filtered position output in pre-filter periods (input value of FilterTime) and the input position. Specify proper parameter values based on your actual application.
- This instruction checks the value range of input parameters based on the selected filter type. If an input parameter is not applicable to the selected filter type, this instruction will not report a fault even if the parameter value is invalid.
- Note the value of the input parameter PredictTime. When the parameter is set to a large value, the filtered position may differ significantly from the actual position. Specify a proper value for PredictTime based on your needs.
- If a synchronization instruction is executed, and the mcPositionFilter signal source is selected, this instruction must be executed first; otherwise, the synchronization instruction will report a fault. If this instruction and a synchronization instruction are executing, and the mcPositionFilter signal source is selected, disabling this instruction will cause the synchronization instruction to report a fault.
- You cannot execute this instruction while the parameter PowerOff, ErrorStop, or Homing is TRUE.
- Since the fSetXXX information of the encoder axis is 0 and not updated, do not specify the FilterType to 0, 3, 5, 6, 8, or 10 when using this instruction on the encoder axis.
- You can execute this instruction in CSP/CSV control mode only.

18.3.3.3.45 MC_SetOverride

This instruction changes the target velocity of an axis.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_SetOverride	Change target velocity	MC_SetOverride_Instance_0 MC_SetOverride Axis Enabled Enable Busy VelFactor Error AccFactor ErrorID JerkFactor	MC_SetOverride_Instance_0(Axis :=, Enable :=, VelFactor :=, AccFactor :=, JerkFactor :=, Enabled =>, Busy =>, Error =>, ErrorID =>);

- **Related variables**

  In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Enable	Enable	BOOL	TRUE, FALSE	FALSE	TRUE: The function block is enabled. FALSE: Disabled.
VelFactor	Velocity override factor	LREAL	0 to 200	100	Specify the velocity override factor. The valid range of the override factor is between 0.01 and 200.00. The unit is %. 100 means 100%. The override factor will be 0 only when 0 is specified. Any values less than 0 will be corrected to the minimum value of 0.01 without a fault message. Any values greater than 200 will be corrected to the maximum value of 200 without a fault message. Note: When the MotionControl library version is 2.2.0.0 or later, the valid range is adjusted to between 0.01 and 500.00.
AccFactor	Acceleration/ Deceleration override factor	LREAL	0 to 100	100	Reserved parameter.
JerkFactor	Jerk override factor	LREAL	0 to 100	100	Reserved parameter.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Enabled	Enabled	BOOL	TRUE, FALSE	FALSE	TRUE when the factor is successfully set.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is being executed.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Parameter correction**

Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
VelFactor	Velocity override factor	Any values greater than 200 are treated as 200.	Any values less than 0 are treated as 0.01.	No correction.

- **Function**

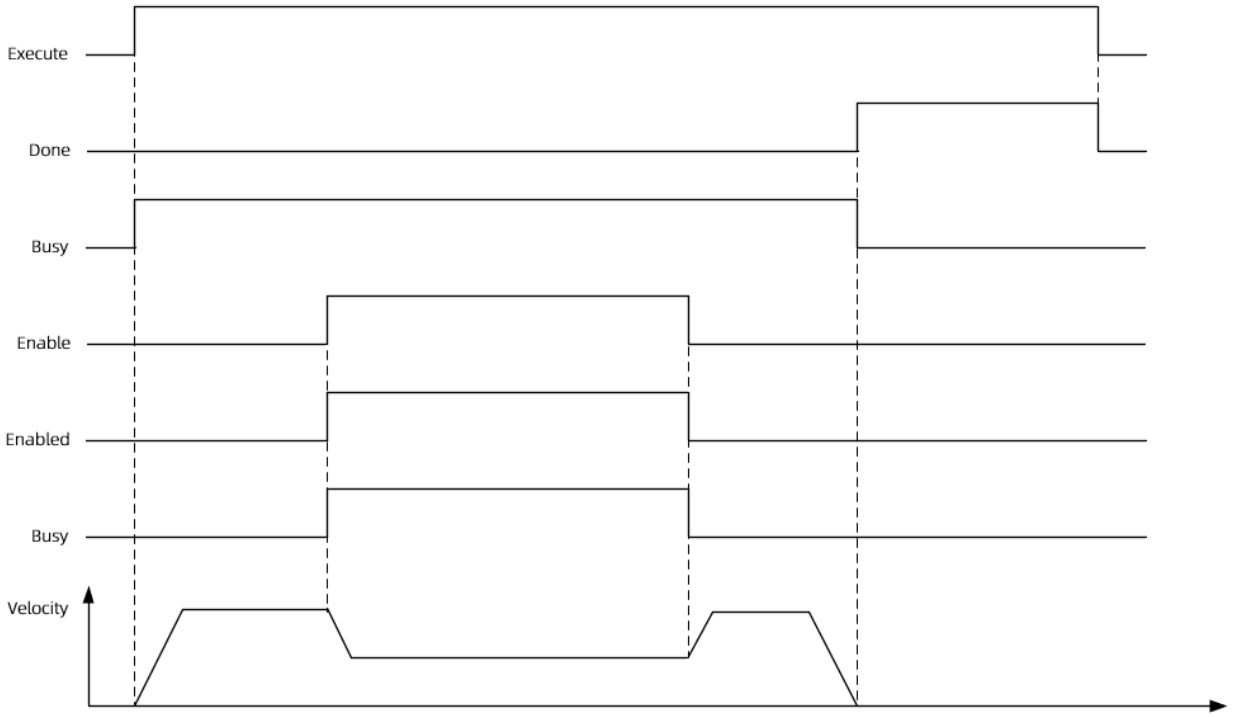
  Bus-controlled axis:

  - You can change the target velocity by changing the override factor of the parameter VelFactor for this instruction. For example: New target velocity = Currently velocity reference × Override factor (%).
  - You can change the override factor through the following instructions:

Instructions	
MC_MoveAbsolute	MC_MoveRelative
MC_MoveVelocity	MC_MoveContinuseAbsolute
MC_MoveContinuseRelative	MC_Jog
MC_MoveFeed	MC_Inch

  - When the target velocity after change exceeds the upper limit of the velocity in the software, the axis moves at the maximum velocity.
  - The axis accelerates or decelerates to the target velocity after change. After the setpoint of VelFactor is modified, if the target velocity exceeds the upper limit of the velocity in the software, the axis will move at the maximum velocity, regardless of whether the current axis state is AXIS_STANDSTILL or in motion.
  - When the VelFactor is set to 0, the axis will decelerate if the axis velocity is greater than 0; otherwise the axis will accelerate. When the target velocity becomes 0, the axis is Standstill with no change in the axis state machine. In practical applications, if you want to pause the motion without changing the axis state, you can set the VelFactor to 0.

- This instruction does not affect the slave axis in synchronous motion.
- If the input parameter Enable of this instruction remains high level, the value of the VelFactor can be changed at any time and directly affects the executing motion control instruction. When the Enable is manually set to FALSE or the axis alarm is reset, the override factor changes to 100, which remains unchanged after the axis is disabled and then enabled.
- If the axis state is ERRORSTOP, executing this instruction will result in a fault. When the axis state is STOPPING, this instruction cannot be executed.



Local pulse axis:

- This instruction can be used for local pulse axes.

- **Timing diagram**
  - Modifying the override factor of the MC_MoveAbsolute instruction

    The following is a timing diagram illustrating the use of the MC_SetOverride instruction for the MC_MoveAbsolute instruction.

    The input parameter Execute of the MC_MoveAbsolute instruction must be triggered on a rising edge. When the parameter Busy is set to TRUE, it indicates that the current function block is being executed. During this process, the input parameter Enable of the MC_SetOverride instruction must be triggered on a rising edge. When the output parameter Enabled is set to TRUE, it indicates that the instruction has been executed normally. When the output parameter Busy is set to TRUE, it indicates that the current function block is being executed.

  - Modifying the override factor of the MC_MoveVelocity

    The following is a timing diagram illustrating the use of the MC_SetOverride instruction for the MC_MoveVelocity.

    The input parameter Execute of the MC_MoveVelocity instruction must be triggered on a rising edge. When the parameter Busy is set to TRUE, it indicates that the current function block is being executed. During this process, the input parameter Enable of the MC_SetOverride instruction must be triggered on a rising edge. When the output parameter Enabled is set to

TRUE, it indicates that the instruction has been executed normally. When the output parameter Busy is set to TRUE, it indicates that the current function block is being executed.

- **Re-execution of motion control instructions**

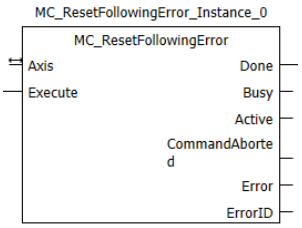
  You cannot re-execute motion control instructions with an input parameter Enable.

- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

- **Precautions**

  If another instances of MC_SetOverride are executed on the same axis during MC_SetOverride instruction execution, the last MC_SetOverride instance that is executed takes priority in processing. If this instruction is executed with the following configurations, the velocity of the final instruction will be 30% of the original velocity, as shown in the following figure.



At this point, canceling any of the MC_SetOverride instructions will reset the VelFactor to 100%, even if the canceled instruction is not the currently active one, and the currently active instruction will no longer be active. If the instruction with VelFactor = 50% is canceled, the currently active instruction with VelFactor = 30% will no longer be active, as shown in the following figure.

18.3.3.3.46 MC_ResetFollowingError

This instruction resets the following error between the current position reference and the current actual position.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_ResetFollowingError	Reset following error		MC_ResetFollowingError_Instance_0(Axis :=, Execute :=, Done =>, Busy =>, Active =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	The function block is executed on a rising edge of this input variable.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Active	Controlling	BOOL	TRUE, FALSE	FALSE	TRUE when the axis is being controlled.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**

  Bus-controlled axis:

  - This instruction resets the following error between the current position reference and the current actual position to 0 in MC_CSP mode.
  - During the execution of this instruction, do not execute another instance of this instruction; otherwise, the subsequently triggered function block will report a fault.
  - This instruction can be triggered only when the axis type is control axis and the control mode is MC_CSP; otherwise, the function block will report a fault.
  - When the parameter Execute is set to TRUE, the actual position at that point is used as the position reference (i.e., the target position).
  - When this instruction is triggered, the axis state switches to AXIS_STOPPING. After the instruction is done, the axis state switches to AXIS_STANDSTILL.
  - When the axis state is AXIS_HOMING, this instruction cannot be triggered; otherwise, the function block will report a fault.
  - When the axis state is AXIS_STOPPING, this instruction will exit immediately after being triggered, with the output parameter CommandAborted showing the value TRUE.
  - Do not trigger the MC_Stop or MC_SetPosition instruction during the execution of this instruction.
  - In Rotary Mode, when this instruction is called for compensation, compensation is performed in the direction with the shortest distance, and the compensation position is calculated based on the difference between the target position and the actual position after multiple rotation cycles.
  - If this instruction is triggered during the axis motion, there is a jitter deviation after the first error elimination. It is recommended to trigger the instruction again after the axis stops to eliminate the deviation.

  Local pulse axis:

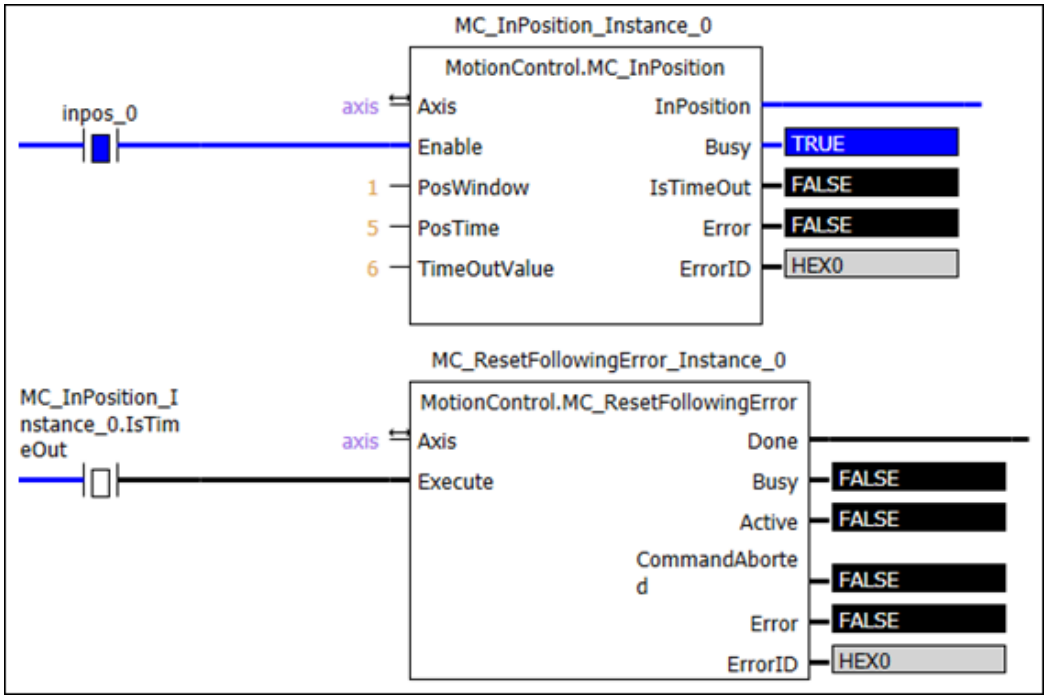
  - This instruction can be used for local pulse axes.

- **Timing diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Done of the function block indicates the instruction has been executed successfully; the parameter Busy indicates that the current function block is being executed; the parameter CommandAborted of the function block indicates that the instruction is aborted by another motion control instruction, at which point the flag is set to TRUE.

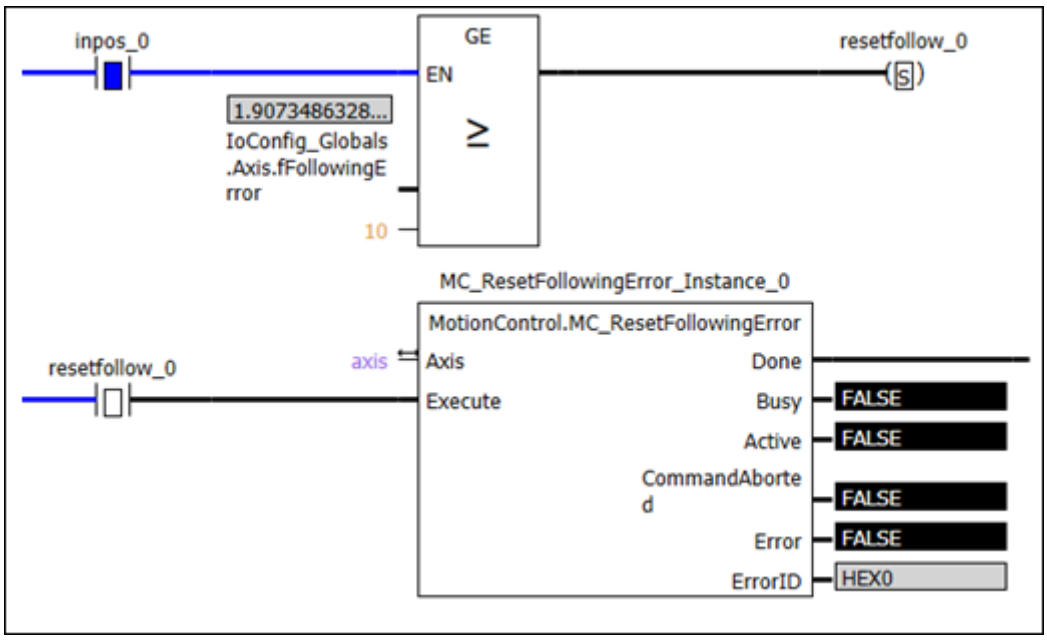
  Use the MC_InPosition instruction to check the current deviation. Use the IsTimeOut output flag as the input for the variable Execute. The output parameter Busy is set to TRUE on a rising edge of Execute. In the next cycle, the output parameter Active shows the value TRUE.

  The axis clears the deviation according to the parameters of this instruction until the following error between the current position reference and the actual position is 0, at which point the output parameter Done is set to TRUE.



- **Re-execution of motion control instructions**

  This instruction cannot be re-executed.

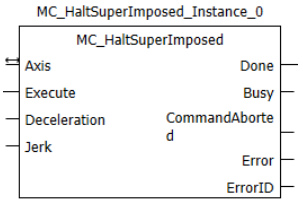


- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

- **Example**
  - If the actual trajectory does not reach the planned trajectory, you can use this instruction to abort the current motion, clear the deviation, and recheck the user program. You can first use the MC_InPosition instruction to check the current deviation, specify a proper deviation for the parameter PosWindow, and specify the TimeOutValue (s). If the deviation does not fall within a reasonable range within the specified cycle, the IsTimeOut instruction will be set. You can use the IsTimeOut output flag as the input for the MC_FollowPositionError instruction.

◦ In case of motor stalling or excessive deviation due to external factors, it is necessary to constantly monitor the operation to avoid more serious issues such as servo drive stall or deviation error. At this time, you can observe the variable FfollowingError, and execute the MC_ResetFollowingError instruction to terminate motion and clear the deviation when the deviation exceeds the threshold.



- **Precautions**
  - ◦ The actual deviation source may be insufficient rigidity. Therefore, you must ensure sufficient servo rigidity (H09.01 for our product). This instruction is not applicable to some applications requiring lower rigidity.
  - ◦ The actual deviation source may be an excessively high motor speed. Therefore, you must manually adjust the maximum value for deviation detection based on different speed conditions. To prevent jitter error, a hold-off time is recommended to be included in the user-designed deviation detection program.
  - ◦ The instruction clears the deviation according to the maximum velocity limit in the software. You must design a proper axis velocity limit to prevent stalling due to too rapid velocity planning after the instruction is triggered.

18.3.3.3.47 MC_HaltSuperImposed

This instruction halts the superimposed motion of an axis and remains its basic motion unchanged.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_HaltSuperImposed	Halt superimposed motion		MC_HaltSuperImposed_Instance_0(Axis :=, Execute :=, Deceleration :=, Jerk :=, Done =>, Busy =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	The function block is executed on a rising edge of this input variable.
Deceleration	Deceleration	LREAL	Positive number	0	Deceleration of the deceleration phase.
Jerk	Jerk	LREAL	Positive number	0	Slope of acceleration or deceleration.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is being executed.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Parameter correction**

Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Deceleration	Deceleration	Any deceleration that exceeds the motion parameter limit will be automatically corrected to the deceleration limit.	Any deceleration less than 0 will be automatically corrected to 10% of the deceleration limit.	The deceleration equal to 0 will be automatically corrected to 10% of the deceleration limit.
Jerk	Jerk	If the motion profile is set to S-curve, any jerk that exceeds the software limit will be automatically corrected to the jerk limit.	If the motion profile is set to S-curve, any jerk less than 0 will be automatically corrected to 10% of the jerk limit.	If the motion profile is set to S-curve, the jerk equal to 0 will be automatically corrected to 10% of the jerk limit.

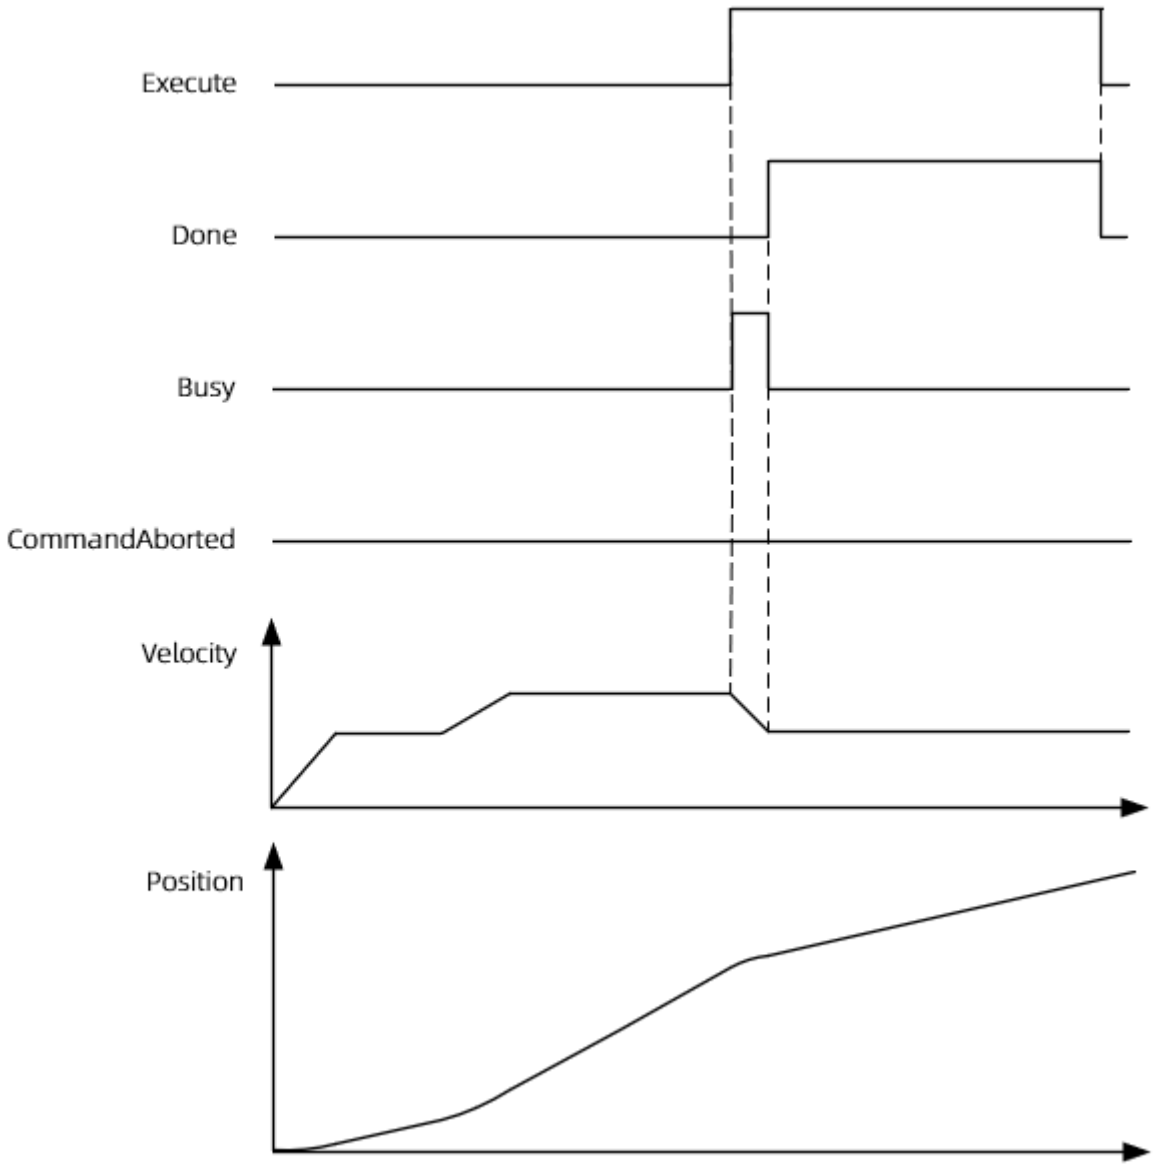
- **Function**

  Bus-controlled axis:

  - This instruction is used to halt the ongoing superimposed motion for an axis and remain its basic motion unchanged.
  - When the axis state is AXIS_STOPPING or AXIS_HOMING, this instruction will exit immediately after being triggered, with the output parameter CommandAborted showing the value TRUE.
  - The axis type must be control axis.

- If the MC_MoveSuperImposed instruction is not executing, triggering this instruction will result in a fault.
- This instruction cannot be triggered repeatedly during execution; otherwise, the function block reports a fault.
- If this instruction reports a fault, the executing instruction will be aborted.
- This instruction can be aborted by other motion control instructions during execution.
- In PLC projects, this instruction cannot be placed and triggered before the main motion of the specified axis.

Local pulse axis:



- This instruction can be used for local pulse axes.

- **Timing diagram**

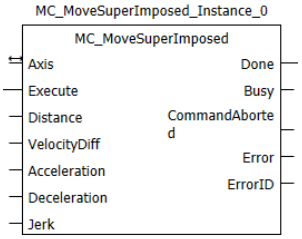
  The parameter Execute of the function block must be triggered on a rising edge. The parameter Done of the function block indicates the instruction has been executed successfully; the parameter Busy indicates that the current function block is being executed; the parameter CommandAborted indicates that the instruction is aborted by another motion control instruction, at which point the flag is set to TRUE.

  After this instruction is called, the output parameter Busy is set to TRUE on a rising edge of Execute.

  The output parameter Done is set to TRUE when the axis decelerates to the velocity before the superimposed motion according to the parameters of this instruction.

- **Re-execution of motion control instructions**

  This instruction cannot be re-executed.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.3.48 MC_MoveSuperImposed

This instruction enables the axis to move with additional velocity and distance on top of the original velocity and distance reference.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_MoveSuperImposed	Superimposed motion		MC_MoveSuperImposed_Instance_0(Axis :=, Execute :=, Distance :=, VelocityDiff :=, Acceleration :=, Deceleration :=, Jerk :=, Done =>, Busy =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is being executed.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Parameter correction**

Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Acceleration	Acceleration	Any acceleration that exceeds the motion parameter limit will be automatically corrected to the acceleration limit.	• When the MotionControl library version is 2.3.0.0 or earlier, the acceleration less than 0 will be automatically corrected to 10% of the acceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the acceleration less than 0 will be automatically corrected to 10 times the velocity.	• When the MotionControl library version is 2.3.0.0 or earlier, the acceleration equal to 0 will be automatically corrected to 10% of the acceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the acceleration equal to 0 will be automatically corrected to 10 times the velocity.
Deceleration	Deceleration	Any deceleration that exceeds the motion parameter limit will be automatically corrected to the deceleration limit.	• When the MotionControl library version is 2.3.0.0 or earlier, the deceleration less than 0 will be automatically corrected to 10% of the deceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the deceleration less than 0 will be automatically corrected to 10 times the velocity.	• When the MotionControl library version is 2.3.0.0 or earlier, the deceleration equal to 0 will be automatically corrected to 10% of the deceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the deceleration equal to 0 will be automatically corrected to 10 times the velocity.
Jerk	Jerk	If the motion profile is set to S-curve, any jerk that exceeds the software limit will be automatically corrected to the jerk limit.	If the motion profile is set to S-curve, any jerk less than 0 will be automatically corrected to 10% of the jerk limit.	If the motion profile is set to S-curve, the jerk equal to 0 will be automatically corrected to 10% of the jerk limit.

Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Velocity Diff	Additional velocity	Any velocity that exceeds the motion parameter limit will be automatically corrected to the velocity limit.	Any velocity less than 0 will be automatically corrected to 1e-5.	• When the MotionControl library version is 2.1.0.0 or earlier, the velocity equal to 0 will be automatically corrected to 1e-5. • When the MotionControl library version is 2.2.0.0 or later, the velocity equal to 0 will not be corrected.

- **Function**

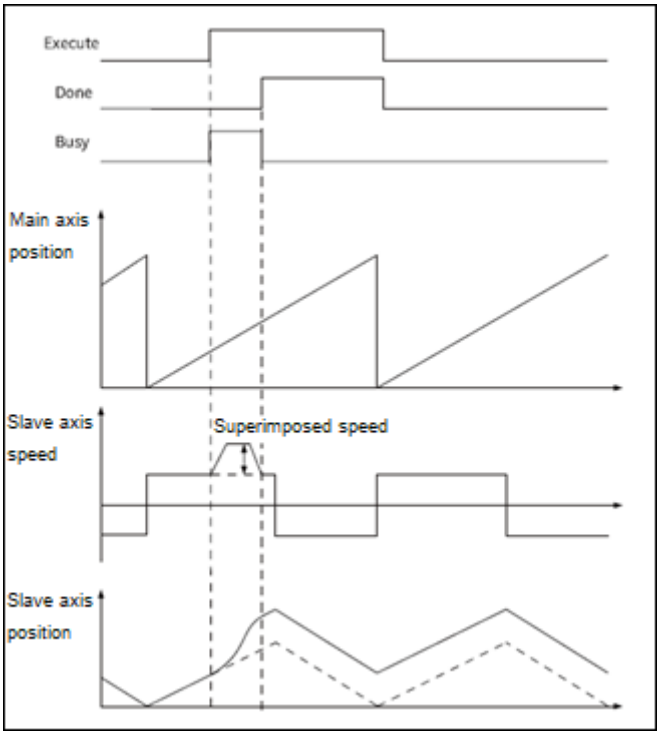
  Bus-controlled axis:

  - This instruction enables the axis to move with additional distance and velocity on top of the active motion control instruction, compensating for the error caused by the clearance between the belt and gears in actual project.
  - The input parameters VelocityDiff and Distance are the velocity and distance to be added on the active motion control instruction.
  - This instruction must be triggered in CSP mode.
  - During the execution of this instruction, do not execute another instance of this instruction; otherwise, the function block reports a fault.
  - When the axis state is STOPPING or HOMING, this instruction will exit immediately after being triggered, with the output parameter CommandAborted showing the value TRUE.
  - This instruction cannot be called during the execution of the MC_Halt instruction; otherwise, the function block reports a fault.
  - When multiple instructions are buffered, the specified additional values for superimposed motion must be reached as much as possible before the active main motion is finished. The specified additional values for superimposed motion will not be carried over to the motion in the buffer. When a buffered instruction is executed, this instruction is aborted with the reached additional values for superimposed motion being retained.
  - If a fault occurs during execution and the current velocity reference is not 0, the axis will decelerate to stop under a T-curve planning, using the maximum deceleration in the software.
  - The motion status of the master axis is not affected by this instruction.
  - If this instruction reports a fault, the executing instruction will be aborted.
  - **Instruction execution in different control modes**

    Single axis positioning instructions

    - When the axis state is AXIS_STANDSTILL, this instruction performs a function equivalent to the MC_MoveRelative instruction during execution, with the axis state switching to AXIS_DISCRETE_MOTION.

- When this instruction is called during the execution of other instructions that put a servo axis in CSP mode (MC_MoveVelocity, MC_MoveAbsolute, MC_MoveRelative, MC_MoveContinuousAbsolute, MC_MoveContinuousRelative, MC_GearIn, MC_CamIn, MC_GearInPos), it performs superimposed motion. The current axis state is determined by the main motion. It switches to AXIS_DISCRETE_MOTION of superimposed motion only after the motion has ended.



- If any other instructions that put an axis in CSP mode (MC_MoveVelocity, MC_MoveAbsolute, MC_MoveRelative, MC_MoveContinuousAbsolute, MC_MoveContinuousRelative, MC_GearIn, MC_CamIn, MC_GearInPos) are triggered during the execution of this instruction, this instruction will be aborted.

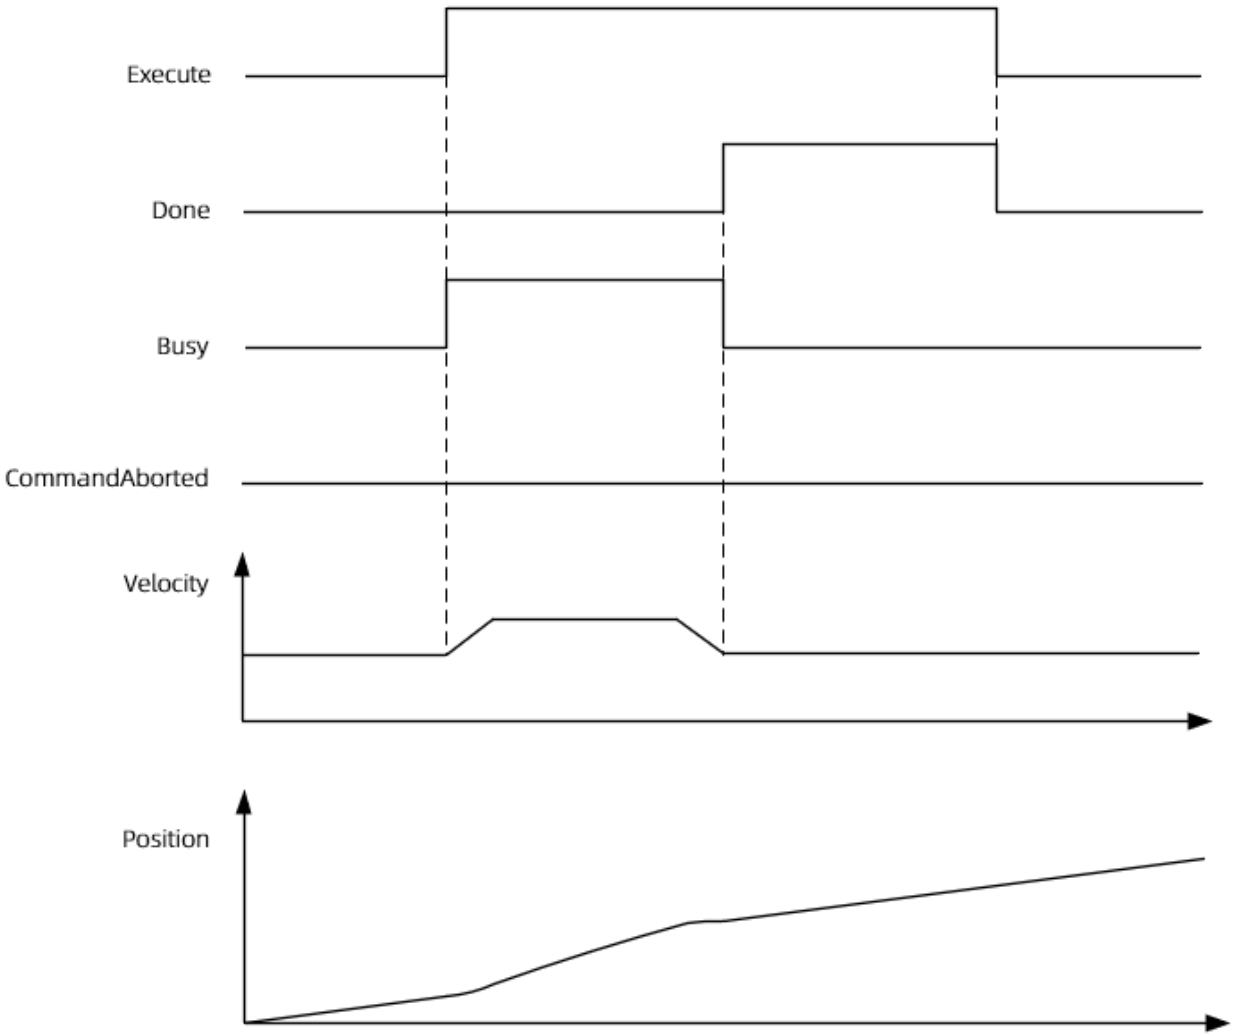
Axis group instructions

- If this instruction is called during the execution of an axis group instruction, it will report a fault without performing the superimposed motion.

Synchronous axis instructions

- When this instruction is called during the execution of the MC_GearIn or MC_CamIn instruction by the slave axis, it performs the superimposed action.

- If the MC_GearIn instruction is re-executed during the execution of this instruction, this instruction will be aborted.
- If the MC_CamIn instruction is buffered, the re-triggered parameters can take effect. If the MC_CamIn instruction has been executed, re-executing this instruction will report a fault.
- If this instruction is executed together with a synchronous motion control instruction, the MC_GearOut and MC_CamOut instructions can terminate their execution.



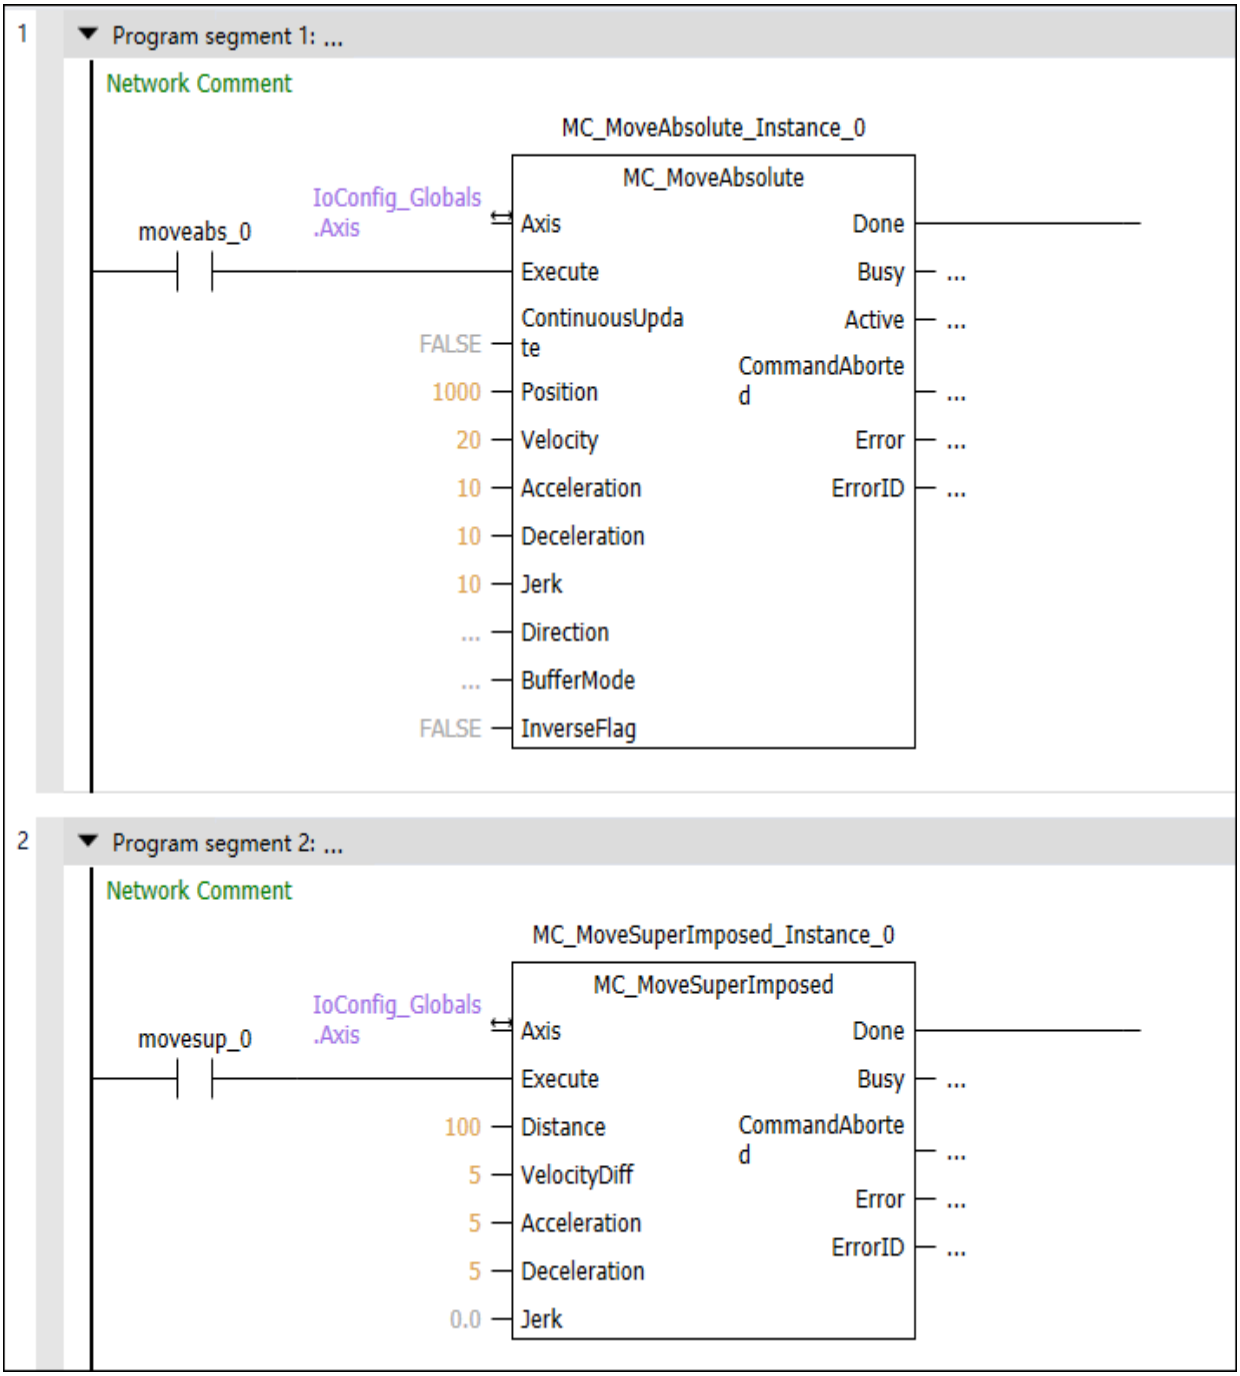
Local pulse axis:

- This instruction can be used for local pulse axes.

- **Timing diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Done of the function block indicates the instruction has been executed successfully; the parameter Busy indicates that the current function block is being executed; the parameter CommandAborted indicates that the instruction is aborted by another motion control instruction, at which point the flag is set to TRUE.

  After this instruction is called, the output parameter Busy is set to TRUE on a rising edge of Execute. The output parameter Done is set to TRUE when the axis reaches the specified Distance and VelocityDiff on the top of original distance and velocity reference.



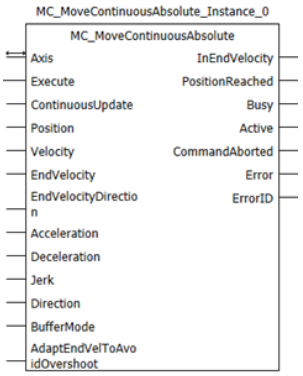
- **Re-execution of motion control instructions**

  This instruction cannot be re-executed.

- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

- **Precautions**
  - Superimposed motion cannot be carried over to the buffered instructions.
  - The instruction must be triggered after the main motion has been triggered and completed; otherwise, the logic determines that the main motion aborts the superimposed motion instead of the superimposed motion being added to the main motion.



◦ If the combined velocity of this instruction and the main motion exceeds the velocity limit, the instruction will be terminated with a fault message, while the main motion will not be affected. Note the current master axis state before execution of this instruction.

18.3.3.3.49 MC_MoveContinuousAbsolute

This instruction controls the axis to continuously move in absolute position.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_MoveContinuousAbsolute	Move to a specified absolute position ending with the specified velocity		MC_MoveContinuousAbsolute _Instance_0(Axis :=, Execute :=, ContinuousUpdate :=, Position :=, Velocity :=, EndVelocity :=, EndVelocityDirection :=, Acceleration :=, Deceleration :=, Jerk :=, Direction :=, BufferMode :=, AdaptEndVelToAvoidOvershoot := , InEndVelocity =>, PositionReached => , Busy =>, Active =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	The function block is executed on a rising edge of this input variable.
Continuous Update	Continuous update	BOOL	TRUE, FALSE	FALSE	Continuous parameter update effective flag. Prerequisite: The parameter ContinuousUpdate shows the value TRUE and the parameter Active shows the value TRUE. Effective parameters: Position, Velocity, EndVelocity, EndVelocityDirection. Note: The modified parameter values must differ from the original parameter values by more than 0.01.
Position	Absolute Position	LREAL	Positive number, negative number, or 0	0	Target position in absolute coordinates.
Velocity	Velocity	LREAL	Positive number	0	Maximum velocity.
EndVelocity	End velocity	LREAL	Positive number or 0	0	End velocity.
EndVelocity Direction	End velocity direction	18.3.3.2.2.9 MC_DIRECTION: Motion Direction Enumeration	1: DIR_POSITIVE 2: DIR_NEGATIVE 3: DIR_CURRENT	3	1: DIR_POSITIVE: Positive direction. 2: DIR_NEGATIVE: Negative direction. 3: DIR_CURRENT: Current direction.
Acceleration	Acceleration	LREAL	Positive number	0	Acceleration of the acceleration phase.
Deceleration	Deceleration	LREAL	Positive number	0	Deceleration of the deceleration phase.
Jerk	Jerk	LREAL	Positive number or 0	0	Slope of acceleration or deceleration.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Direction	Motion direction	18.3.3.2.2.9 MC_DIRECTION: Motion Direction Enumeration	0: DIR_SHORTEST 1: DIR_POSITIVE 2: DIR_NEGATIVE 3: DIR_CURRENT 4: DIR_NODIRECTION 5: DIR_FASTEST	1	Specify one of the following directions for linear axes: 1: DIR_POSITIVE (Positive direction). 2: DIR_NEGATIVE (Negative direction). Specify one of the following rotation directions for rotary axes: 0: DIR_SHORTEST (Direction based on the shortest way). 1: DIR_POSITIVE (Positive direction). 2: DIR_NEGATIVE (Negative direction). 3: DIR_CURRENT (Current direction). 4: DIR_NODIRECTION (No direction). 5: DIR_FASTEST (Direction based on the shortest movement time).
BufferMode	Buffer mode	18.3.3.2.2.6 MC_BUFFER_MODE: Buffer Mode Enumeration	0: mcAborting 1: mcBuffered	0	0: mcAborting (Aborting). 1: mcBuffered (Buffered).
AdaptEndVelToAvoidOvershoot	End velocity adaptation flag	BOOL	TRUE, FALSE	FALSE	TRUE: Adapt the end velocity to avoid overshoot. FALSE: No adaptation.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
InEndVelocity	End velocity reached	BOOL	TRUE, FALSE	FALSE	TRUE when the end velocity is reached.
PositionReached	Position reached	BOOL	TRUE, FALSE	FALSE	TRUE when the expected position is reached.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is being executed.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Active	Controlling	BOOL	TRUE, FALSE	FALSE	TRUE when the axis is being controlled by the current FB.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Parameter correction**

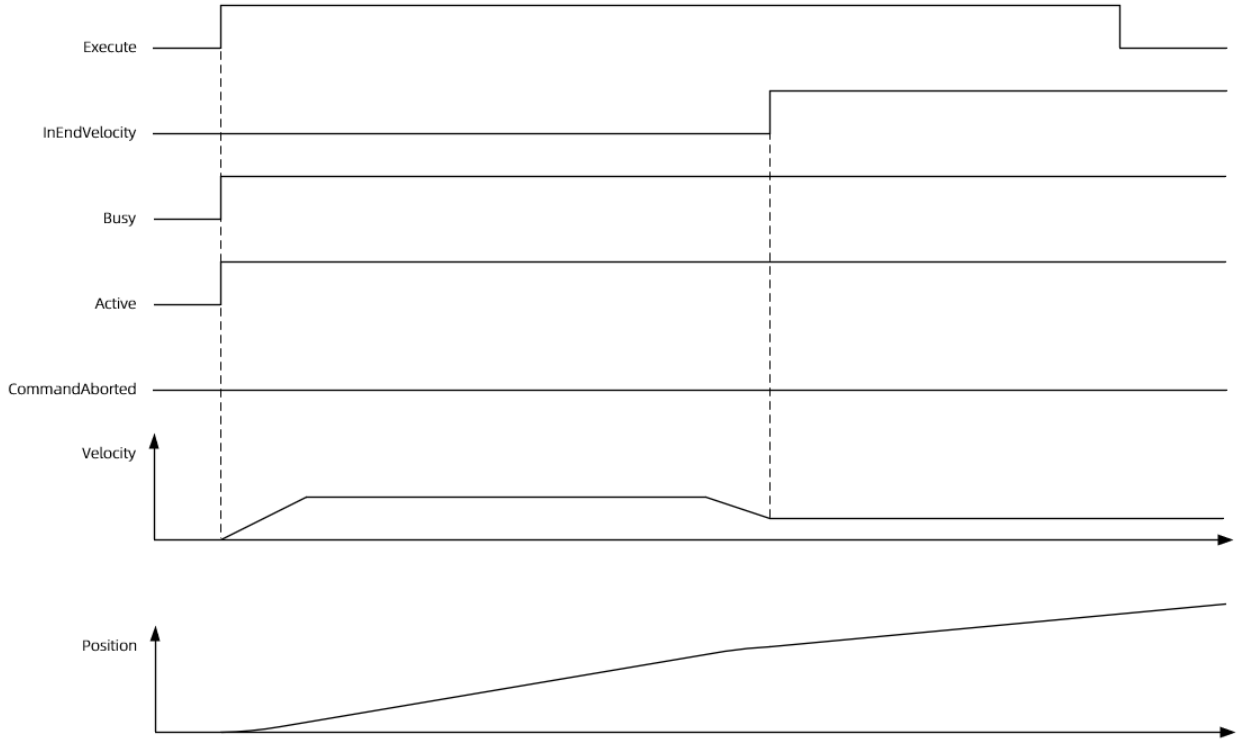
Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Velocity	Velocity	Any velocity that exceeds the motion parameter limit will be automatically corrected to the velocity limit.	Any velocity less than 0 will be automatically corrected to 1e-5.	• When the MotionControl library version is 2.1.0.0 or earlier, the velocity equal to 0 will be automatically corrected to 1e-5. • When the MotionControl library version is 2.2.0.0 or later, the velocity equal to 0 will not be corrected.

Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Acceleration	Acceleration	Any acceleration that exceeds the motion parameter limit will be automatically corrected to the acceleration limit.	• When the MotionControl library version is 2.3.0.0 or earlier, the acceleration less than 0 will be automatically corrected to 10% of the acceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the acceleration less than 0 will be automatically corrected to 10 times the velocity.	• When the MotionControl library version is 2.3.0.0 or earlier, the acceleration equal to 0 will be automatically corrected to 10% of the acceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the acceleration equal to 0 will be automatically corrected to 10 times the velocity.
Deceleration	Deceleration	Any deceleration that exceeds the motion parameter limit will be automatically corrected to the deceleration limit.	• When the MotionControl library version is 2.3.0.0 or earlier, the deceleration less than 0 will be automatically corrected to 10% of the deceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the deceleration less than 0 will be automatically corrected to 10 times the velocity.	• When the MotionControl library version is 2.3.0.0 or earlier, the deceleration equal to 0 will be automatically corrected to 10% of the deceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the deceleration equal to 0 will be automatically corrected to 10 times the velocity.
Jerk	Jerk	If the motion profile is set to S-curve, any jerk that exceeds the software limit will be automatically corrected to the jerk limit.	If the motion profile is set to S-curve, any jerk less than 0 will be automatically corrected to 10% of the jerk limit.	If the motion profile is set to S-curve, the jerk equal to 0 will be automatically corrected to 10% of the jerk limit.
EndVelocity	End velocity	Any velocity that exceeds the motion parameter limit will be automatically corrected to the velocity limit.	Any velocity less than 0 will be automatically corrected to 1e-5.	No correction.

- **Function**

Bus-controlled axis:

- This instruction controls the axis to move to an absolute position ending with the velocity reference.
- The setpoint of the input parameter Position specifies the absolute position where the axis velocity reaches the specified end velocity. The setpoint of the input parameter Velocity specifies the maximum velocity during the planning process. The setpoint of the input parameter EndVelocity specifies the end velocity of the axis.
- The setpoint of the input parameter EndVelocityDirection specifies the direction of the EndVelocity. The setpoint of the input parameter Direction specifies the direction of the Velocity, which is valid in Rotary Mode only. In Linear Mode, the direction of the Velocity is determined by the positive or negative value of the Position.
- When the instruction is triggered on a rising edge of the input parameter Execute, the input parameters are checked for validity. If any of invalid parameters is detected, it will be automatically corrected by the function block without a fault message; any buffered instructions after this instruction will be cleared.
- When the input parameter ContinuousUpdate is set to TRUE, modified parameters Position, Velocity, EndVelocity and EndVelocityDirection will take effect only when the instruction is in the Active state. Parameter changes greater than 0.01 are considered updates. Modified BufferMode cannot take effect during this period, and the buffer mode at the time of the instruction trigger is retained.
- The axis type must be control axis.
- If the software limit is hit during the instruction execution, the parameter Error is set with the axis state being set to ErrorStop.
- During the deceleration due to limits, do not execute the MC_Reset instruction to reset fault messages.
- During the execution of this instruction, modifying the BufferMode and re-executing the instruction will cause the buffer to be cleared with a fault message.
- When the current axis is not in CSP mode, the instruction internally switches the control mode.
- During the execution of this instruction, the MC_MoveSuperImposed instruction can be used.
- When the axis is enabled after PLC cold reset and the MC_Home instruction is executed using No. 35 homing method, if this instruction is executed with DIR_CURRENT being set, the motion direction of this instruction will be affected.
- When this instruction is executed with the ContinuousUpdate being set to TRUE along with the MC_SuperImposed instruction, the MC_SuperImposed instruction will be aborted if any modifiable parameters are modified.



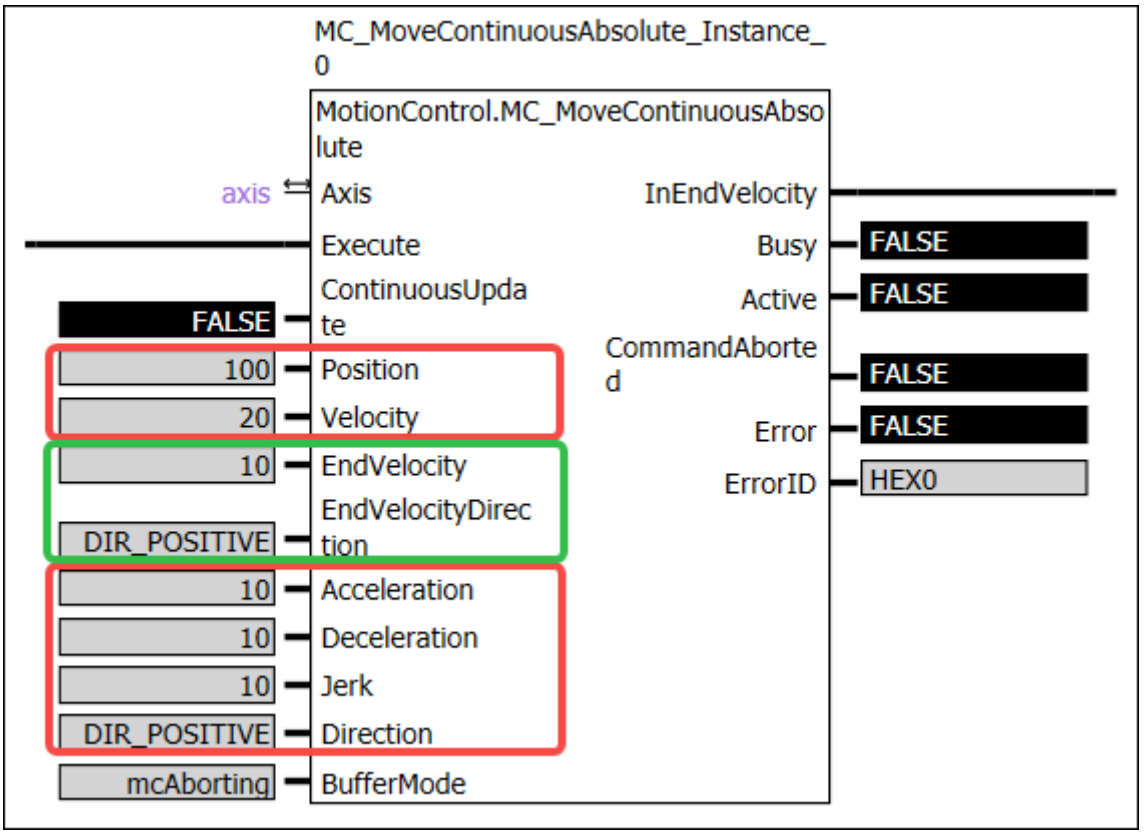
Local pulse axis:

- This instruction can be used for local pulse axes.
- When the local pulse axis is used with Y0 or Y1 single-ended output, it is not recommended to use this instruction. ① No pulse output; ② No position feedback.

- **Timing diagram**

  The input parameter Execute must be triggered on a rising edge. When the output parameter Busy is set to TRUE, it indicates that the current function block is being executed. When the output parameter Busy is set to TRUE, it indicates the current function block is being executed.

After this instruction is called, the output parameter Busy is set to TRUE on a rising edge of Execute. The output parameter Active shows the value TRUE in the same cycle. When the end velocity is reached, the output parameter InEndVelocity is set to TRUE.

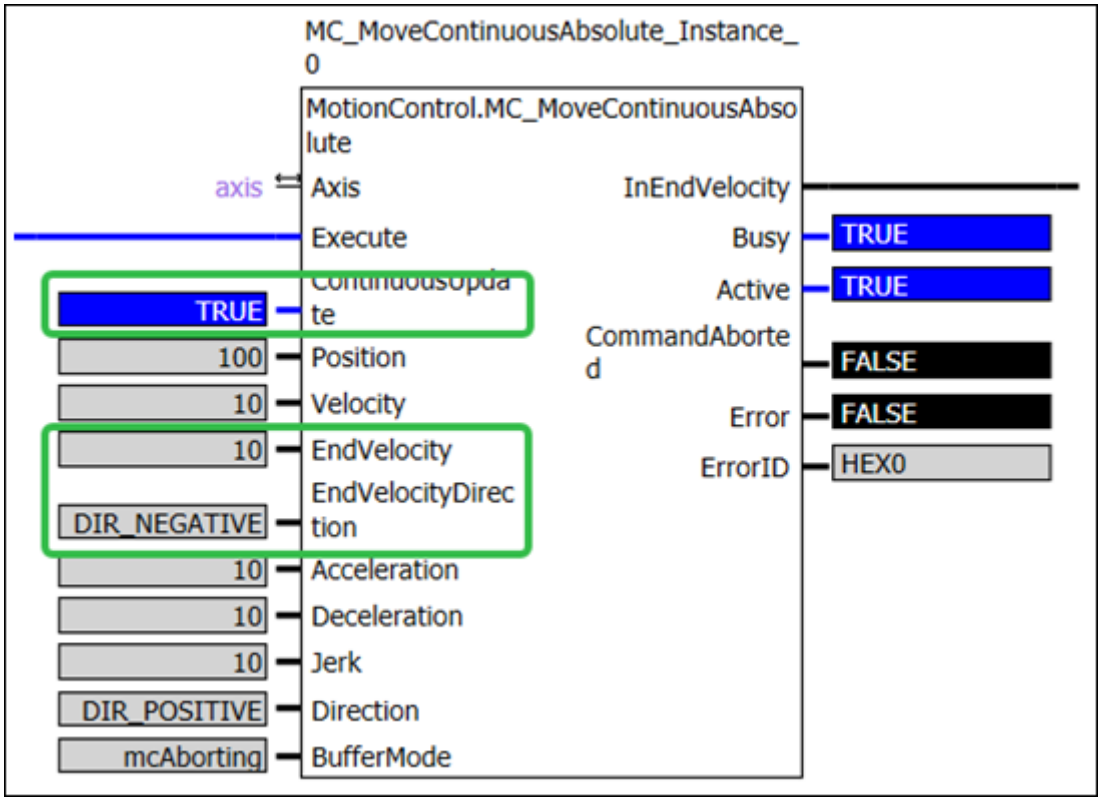


- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

- **Example**

  Specify the planned values for the motion parameters Position, Velocity, Acceleration, Deceleration, Jerk, and Direction of this instruction, and then specify the EndVelocity and EndVelocityDirection.



After the Execute of this instruction is set, the instruction controls the axis to move from the initial position to position 100 according to the specified motion parameters and then continue moving at a velocity of 10.

- **Precautions**

  The ContinuousUpdate function is effective for modified basic motion parameters before the axis reaches the target position. After the InEndVelocity of the instruction is set, only the EndVelocity and EndVelocityDirection can be modified.

18.3.3.3.50 MC_MoveContinuousRelative

This instruction controls the axis to move with a specified relative distance.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_MoveContinuousRelative	Move to a specified relative position ending with the specified velocity		MC_MoveContinuousRelative_Instance_0(Axis :=, Execute :=, ContinuousUpdate :=, Distance :=, Velocity :=, EndVelocity :=, EndVelocityDirection :=, Acceleration :=, Deceleration :=, Jerk :=, BufferMode :=, AdaptEndVelToAvoidOvershoot :=, InEndVelocity =>, DistanceTravelled => , Busy =>, Active =>, CommandAborted =>, Error =>, ErrorID =>);

Acceleration	Acceleration	Any acceleration that exceeds the motion parameter limit will be automatically corrected to the acceleration limit.	• When the MotionControl library version is 2.3.0.0 or earlier, the acceleration less than 0 will be automatically corrected to 10% of the acceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the acceleration less than 0 will be automatically corrected to 10 times the velocity.	• When the MotionControl library version is 2.3.0.0 or earlier, the acceleration equal to 0 will be automatically corrected to 10% of the acceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the acceleration equal to 0 will be automatically corrected to 10 times the velocity.
Deceleration	Deceleration	Any deceleration that exceeds the motion parameter limit will be automatically corrected to the deceleration limit.	• When the MotionControl library version is 2.3.0.0 or earlier, the deceleration less than 0 will be automatically corrected to 10% of the deceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the deceleration less than 0 will be automatically corrected to 10 times the velocity.	• When the MotionControl library version is 2.3.0.0 or earlier, the deceleration equal to 0 will be automatically corrected to 10% of the deceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the deceleration equal to 0 will be automatically corrected to 10 times the velocity.
Jerk	Jerk	If the motion profile is set to S-curve, any jerk that exceeds the software limit will be automatically corrected to the jerk limit.	If the motion profile is set to S-curve, any jerk less than 0 will be automatically corrected to 10% of the jerk limit.	If the motion profile is set to S-curve, the jerk equal to 0 will be automatically corrected to 10% of the jerk limit.
EndVelocity	End velocity	Any velocity that exceeds the motion parameter limit will be automatically corrected to the velocity limit.	Any velocity less than 0 will be automatically corrected to 1e-5.	No correction.

- **Function**

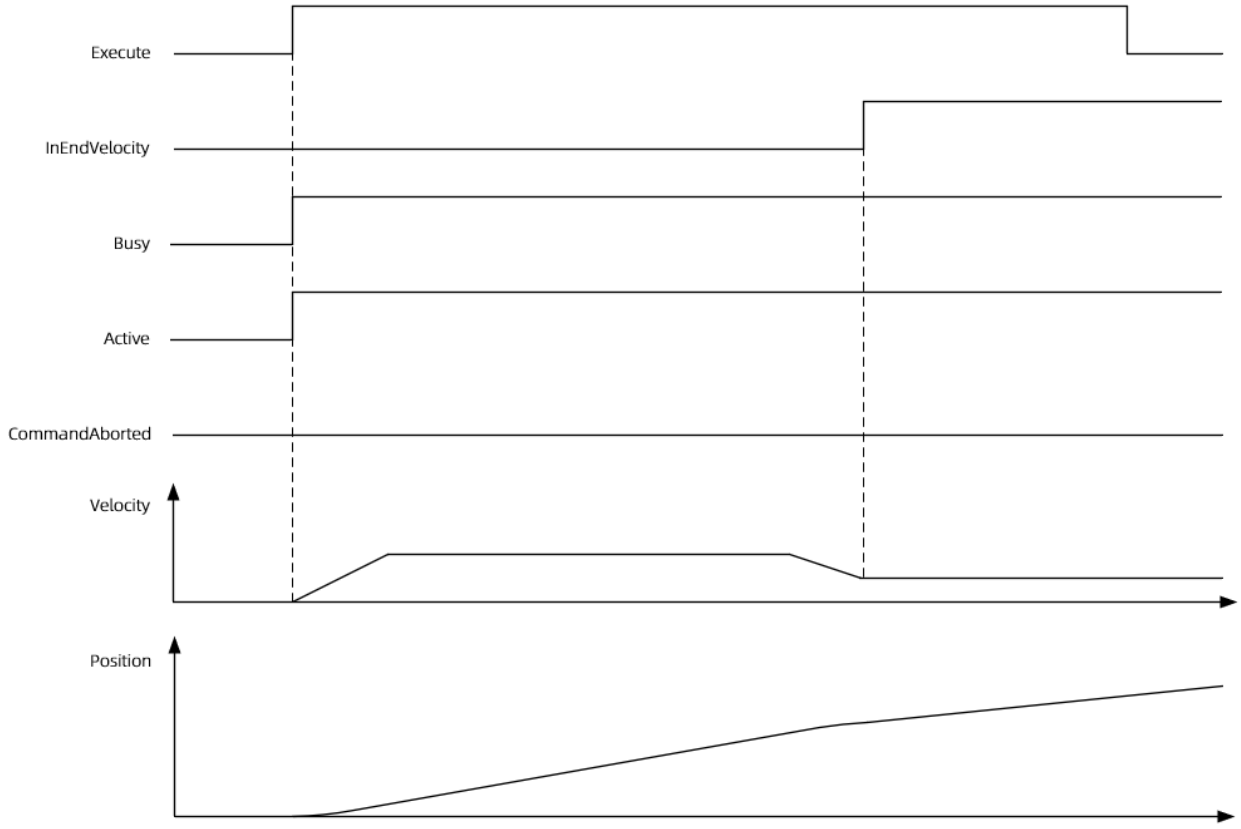
  Bus-controlled axis:

  ◦ This instruction controls the axis to move to a relative position ending with the specified end velocity.

  ◦ The setpoint of the input parameter Distance specifies the relative position where the axis velocity reaches the specified end velocity. The setpoint of the input parameter Velocity specifies the maximum

velocity during the planning process. The setpoint of the input parameter EndVelocity specifies the end velocity of the axis.

- When the instruction is triggered on a rising edge of the input parameter Execute, the input parameters are checked for validity. If any of invalid parameters is detected, it will be automatically corrected by the function block without a fault message; any buffered instructions after this instruction will be cleared.
- The setpoint of the input parameter EndVelocityDirection specifies the direction of the EndVelocity.
- In Linear Mode, the positive or negative setpoint of the input parameter Distance determines the direction of the Velocity. In rotary mode, when the setpoint of the input parameter Distance exceeds one cycle, multi-turn positioning is performed, and the direction of the Velocity is determined by the positive or negative value of the Distance.
- When the input parameter ContinuousUpdate is set to TRUE, modified parameters Distance, Velocity, EndVelocity and EndVelocityDirection will take effect only when the instruction is in the Active state. Parameter changes greater than 0.01 are considered updates. Modified BufferMode cannot take effect during this period, and the buffer mode at the time of the instruction trigger is retained.
- The axis type must be control axis.
- When the current axis is not in CSP mode, the instruction internally switches the control mode.
- If the software limit is hit during the instruction execution, the parameter Error is set with the axis state being set to ErrorStop.
- During the deceleration due to limits, do not execute the MC_Reset instruction to clear fault messages.
- During the execution of this instruction, modifying the BufferMode and re-executing the instruction will cause the buffer to be cleared with a fault message.
- During the execution of this instruction, the MC_MoveSuperImposed instruction can be used.
- When the axis is enabled after PLC cold reset and the MC_Home instruction is executed using No. 35 homing method, if this instruction is executed with DIR_CURRENT being set, the motion direction of this instruction will be affected.
- When this instruction is executed with the ContinuousUpdate being set to TRUE along with the MC_SuperImposed instruction, the MC_SuperImposed instruction will be aborted if any parameters are modified.



Local pulse axis:

- This instruction can be used for local pulse axes.
- When the local pulse axis is used with Y0 or Y1 single-ended output, it is not recommended to use this instruction. ① No pulse output; ② No position feedback.

- **Timing diagram**

  The input parameter Execute must be triggered on a rising edge. When the output parameter InEndVelocity is set to TRUE, it indicates that the instruction has been executed normally. When the output parameter Busy is set to TRUE, it indicates that the current function block is being executed. When the output parameter Active is set to TRUE, it indicates that the axis in current function block is being controlled.

  After this instruction is called, the output parameter Busy is set to TRUE on a rising edge of Execute. The output parameter Active shows the value TRUE in the same cycle. When the end velocity is reached, the output parameter InEndVelocity is set to TRUE.

- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.3.51 MC_CheckAxisCommunication

This instruction checks the current communication state of the drive with the axis.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_CheckAxisCommunication	Check axis communication	MC_CheckAxisCommunication_Instance_0 MC_CheckAxisCommunication Axis Enable Valid Error ErrorID Operational ComState	MC_CheckAxisCommunication_Instance_0(Axis :=, Enable :=, Valid =>, Error =>, ErrorID =>, Operational =>, ComState =>);

- **Function**

  Bus-controlled axis:

  - This instruction checks the current communication state of the drive with the axis.
  - The output parameters Operational and ComState output the axis communication state and related information.
  - This instruction cannot be executed for virtual axes. The type of the axis being operated must be control axis.

  Local pulse axis:

  - This instruction cannot be used for local pulse axes.

- **Timing diagram**

  The parameter Enable of the function block indicates whether to check the current communication state of the drive, and the parameter Valid indicates valid outputs.

  When the input parameter Enable is set to TRUE, the current instruction is executed. When there are no faults, the output parameter Valid shows the value TRUE, and the axis communication state is checked.

- **Re-execution of motion control instructions**

  This instruction cannot be re-executed.

- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.3.52 MC_Inch

CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is aborted.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Parameter correction**

Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Velocity	Velocity	Any velocity that exceeds the commissioning parameter limit will be automatically corrected to the velocity limit.	Any velocity less than 0 will be automatically corrected to 1e-5.	• When the MotionControl library version is 2.1.0.0 or earlier, the velocity equal to 0 will be automatically corrected to 1e-5. • When the MotionControl library version is 2.2.0.0 or later, the velocity equal to 0 will not be corrected.
Acceleration	Acceleration	Any acceleration that exceeds the commissioning parameter limit will be automatically corrected to the acceleration limit.	• When the MotionControl library version is 2.3.0.0 or earlier, the acceleration less than 0 will be automatically corrected to 10% of the acceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the acceleration less than 0 will be automatically corrected to 10 times the velocity.	• When the MotionControl library version is 2.3.0.0 or earlier, the acceleration equal to 0 will be automatically corrected to 10% of the acceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the acceleration equal to 0 will be automatically corrected to 10 times the velocity.

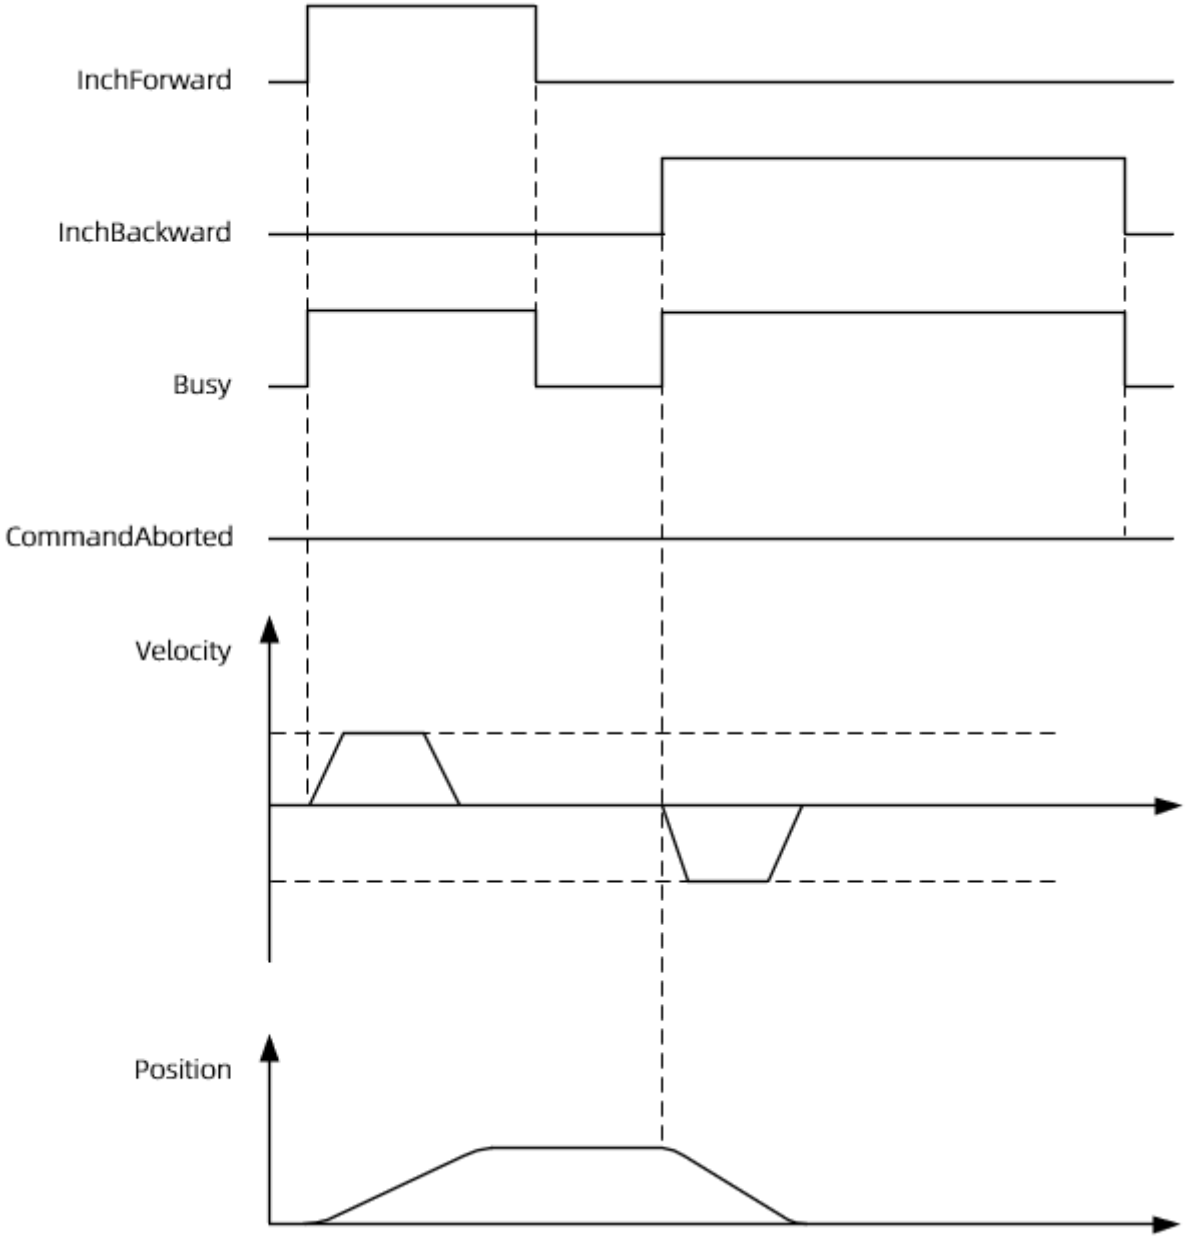
Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Deceleration	Deceleration	Any deceleration that exceeds the commissioning parameter limit will be automatically corrected to the deceleration limit.	• When the MotionControl library version is 2.3.0.0 or earlier, the deceleration less than 0 will be automatically corrected to 10% of the deceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the deceleration less than 0 will be automatically corrected to 10 times the velocity.	• When the MotionControl library version is 2.3.0.0 or earlier, the deceleration equal to 0 will be automatically corrected to 10% of the deceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the deceleration equal to 0 will be automatically corrected to 10 times the velocity.
Jerk	Jerk	If the motion profile is set to S-curve, any jerk that exceeds the software limit will be automatically corrected to the jerk limit.	If the motion profile is set to S-curve, any jerk less than 0 will be automatically corrected to 10% of the jerk limit.	If the motion profile is set to S-curve, the jerk equal to 0 will be automatically corrected to 10% of the jerk limit.

- **Function**

  Bus-controlled axis:

  - This instruction is used to achieve single-step axis control.
  - When the input parameter InchForward shows the value TRUE, the axis moves forward at the specified velocity to the specified distance of Distance. This instruction cannot be re-triggered unless the InchForward is set to FALSE and then back to TRUE. If the InchForward is set to FALSE before the axis reaches the specified position, the axis will immediately decelerate to 0 and the output parameter Busy will be set to FALSE.
  - When the input parameter InchBackward is set to TRUE, the axis moves backward with other conditions being the same as for forward motion.
  - If the input parameters InchForward and InchBackward are set to TRUE, the axis stops moving.
  - When this function block is triggered with the axis state being AXIS_STOPPING or AXIS_HOMING, the MC_Inch instruction is aborted; the axis state is DISCRETE_MOTION when the MC_Inch instruction is executed.
  - If a fault occurs during execution and the current velocity reference is not 0, the axis will decelerate to stop under a T-curve planning, using the maximum deceleration in the software.
  - The axis type must be control axis.
  - When the current axis is not in CSP or CSV mode, the instruction internally switches the control mode.
  - This instruction can abort or be aborted by another motion control instruction.

◦ During the execution of this instruction, the MC_MoveSuperImposed instruction cannot be used; once the MC_MoveSuperImposed instruction is triggered, CommandAborted is set for the MC_MoveSuperImposed instruction.



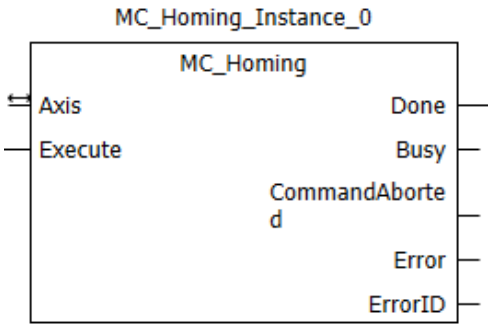
Local pulse axis:

◦ This instruction can be used for local pulse axes.

- **Timing diagram**

  The InchForward and InchBackward of the function block must support both TRUE and FALSE conditions.

  The parameter Busy of the function block indicates that the current function block is being executed. The parameter CommandAborted of the function block indicates that the instruction is aborted by another motion control instruction, at which point the flag is set to TRUE.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.3.53 MC_Homing

This instruction enables the PLC to be homed.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_Homing	Homing		MC_Homing _Instance_0(Axis :=, Execute :=, Done =>, Busy =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

Deceleration	Deceleration	Any deceleration that exceeds the motion parameter limit will be automatically corrected to the deceleration limit.	• When the MotionControl library version is 2.3.0.0 or earlier, the deceleration less than 0 will be automatically corrected to 10% of the deceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the deceleration less than 0 will be automatically corrected to 10 times the velocity.	• When the MotionControl library version is 2.3.0.0 or earlier, the deceleration equal to 0 will be automatically corrected to 10% of the deceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the deceleration equal to 0 will be automatically corrected to 10 times the velocity.

- **Function**

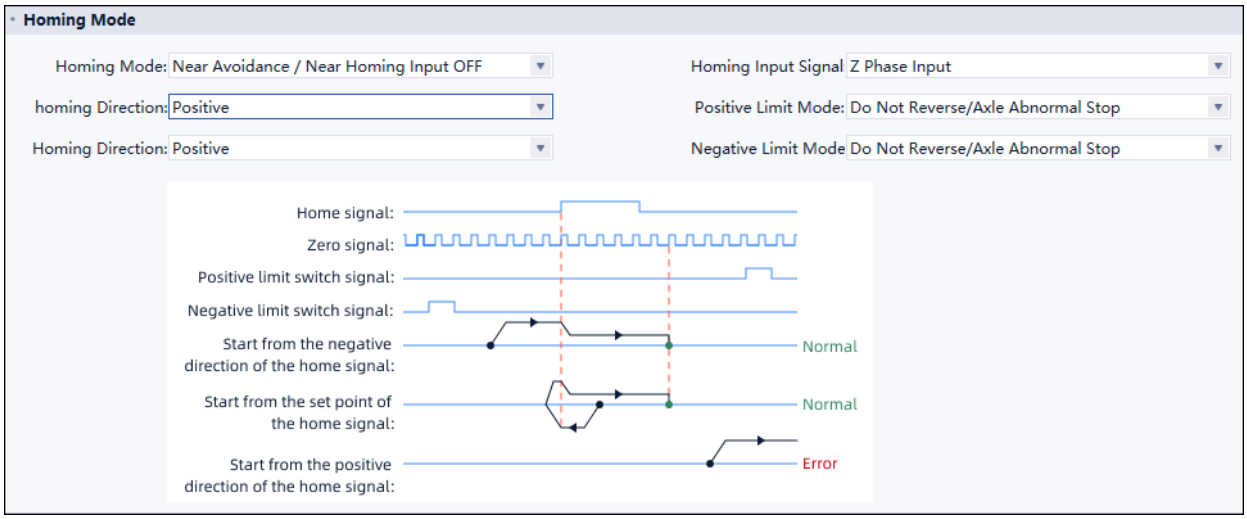
  Bus-controlled axis:

  - Homing starts on a rising edge of Execute. The MC_Homing instruction can be executed only when the axis is in the Standstill state. If the current axis state is STOPPING or HOMING, the instruction will be directly aborted with the output parameter CommandAborted being set. If the current axis state is Disabled, ErrorStop, Discrete Motion, Continuous Motion, or Synchronized Motion, the function block will stop running with a fault message. If the current control mode is not CSP, the function block will stop running with a fault message.
  - The MC_Homing instruction can only be aborted by the MC_Stop or MC_ImmediateStop instruction during execution. Once being aborted, the output parameter CommandAborted is set.
  - You can specify axis parameters for homing in the software and select any of the following 10 operations to define home:

    1. Proximity reverse turn/home proximity input OFF
    2. Proximity reverse turn/home proximity input ON
    3. Home proximity input OFF
    4. Home proximity input OFF
    5. Limit input OFF
    6. Proximity reverse turn/home input mask distance
    7. Limit inputs only
    8. Proximity reverse turn/holding time

9. No home proximity input/holding home input

10. Zero position preset



- Before calling the MC_Homing instruction, configure relevant PDOs in the software according to different homing operation modes:
  - For homing operation modes: 7 Limit inputs only; 8 Proximity reverse turn/holding time; 10 Zero position preset

    Configure PDO 60FD.
  - For other homing operation modes

    Configure PDOs 60B8, 60B9, 60BA, and 60FD.
- Operation selection at "Positive limit input" and "Negative limit input" during homing:

  Select the operation when the axis reaches a limit input in the operating direction during homing: do not reverse the axis, create an error, and stop the axis, or reverse the axis and continue with homing. To reverse the axis, also select the stopping method.
  - No reverse turn/fault stop

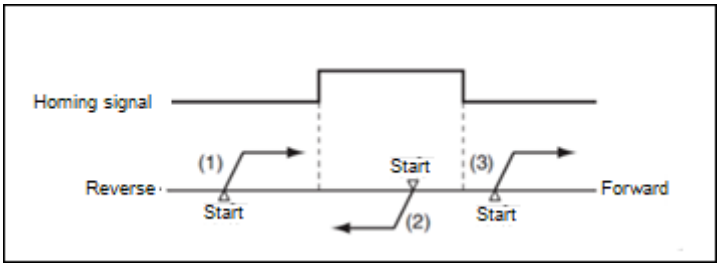
    During homing, if a limit is detected, the axis will experience a fault stop with a fault message.

  - Reverse turn/immediate stop

    During homing, if a limit is detected, the axis will stop immediately and reverse its direction.

- Reverse turn/Deceleration stop

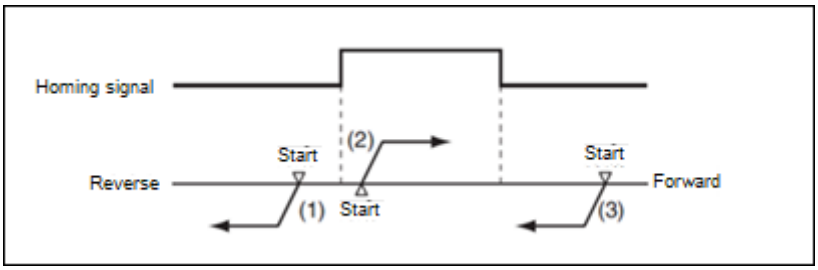
  During homing, if a limit is detected, the axis will also reversely move at the maximum deceleration.



- **Homing start direction**

  It refers to the direction in which the axis starts moving when homing is started.

  If homing starts while the home proximity input signal is ON in a homing operation mode that includes reversal operation, the axis starts moving in the direction opposite to the home input detection direction.



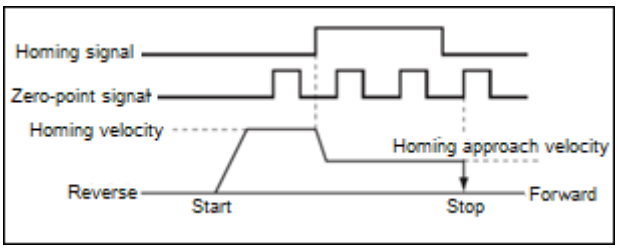
- Homing start direction: positive; Home input detection direction: positive

(1), (3): The home proximity input signal is OFF, so the axis starts moving in the homing start direction.

(2): The home proximity input signal is ON, so the axis starts moving in the direction opposite to the home input detection direction.

- Homing start direction: negative; Home input detection direction: negative

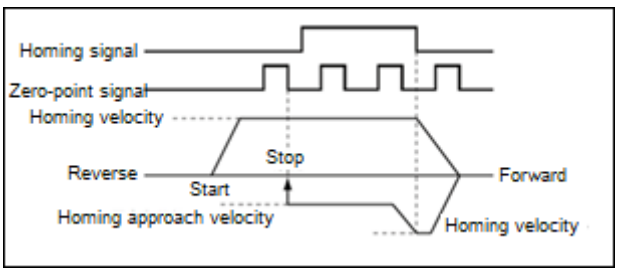
(1), (3): The home proximity input signal is OFF, so the axis starts moving in the homing start direction.



(2): The home proximity input signal is ON, so the axis starts moving in the direction opposite to the home input detection direction.

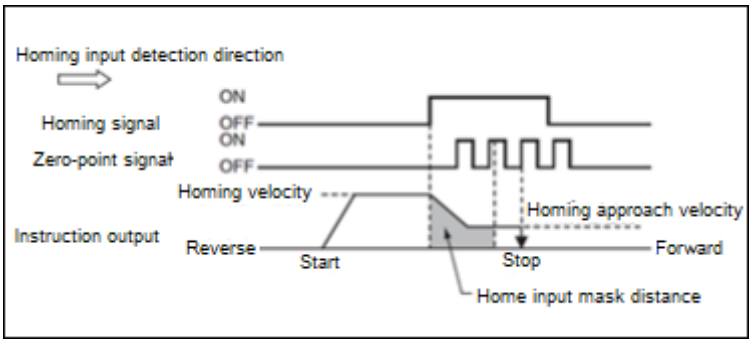
◦ **Home input detection direction**

It specifies the direction of the homing approach velocity.



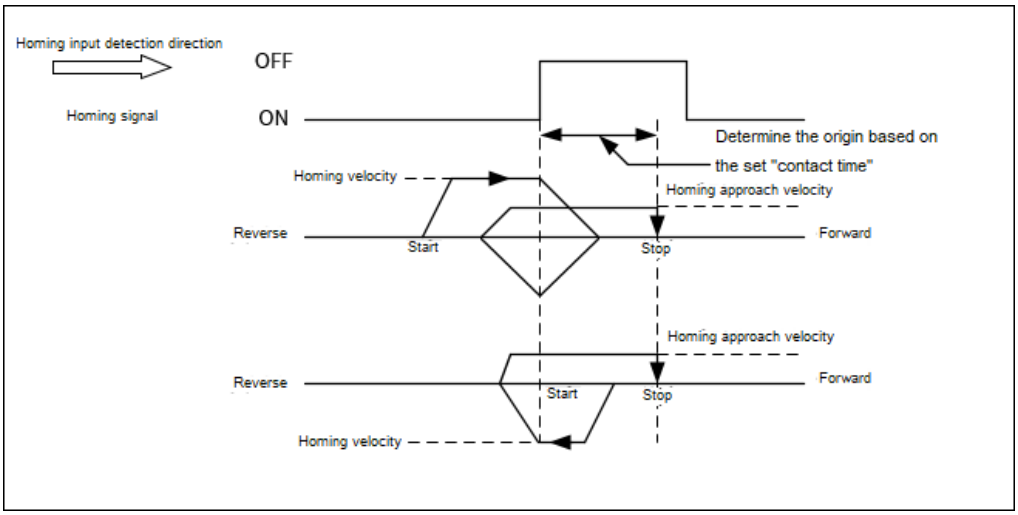
- The following figure shows the operation when the home input detection direction is positive direction.

Operation example: Proximity reverse turn/home proximity input OFF



- The following figure shows the operation when the home input detection direction is negative direction.

Operation example: Proximity reverse turn/home proximity input OFF



◦ **Home input mask distance**

When the home proximity input signal turns ON, mechanical home is defined on the first rising edge of the home input signal after the axis moves the distance set by "Home input mask distance". This parameter is valid when the homing operation mode is specified as "Proximity reverse turn/home input mask distance."

- **Homing holding time**

  When the home proximity input signal turns ON, mechanical home is defined after the axis move for the time set by "Homing holding time". This parameter is valid when the homing operation mode is specified as "Proximity reverse turn/holding time."

- **Homing compensation value**

  It refers to the homing compensation value that is applied after the home input signal is detected. After the mechanical home is defined in a mechanical system, it is often difficult to adjust the workpiece position. Sometimes fine tuning is required. In this case, the offset of the initially defined mechanical home can be set as compensation value.

- **Home position offset**

  It is used to preset the actual position after homing is completed.

- **Homing velocity**

  It refers to the high velocity during homing.

- **Homing acceleration**

  It refers to the acceleration during homing.

- **Homing jerk**

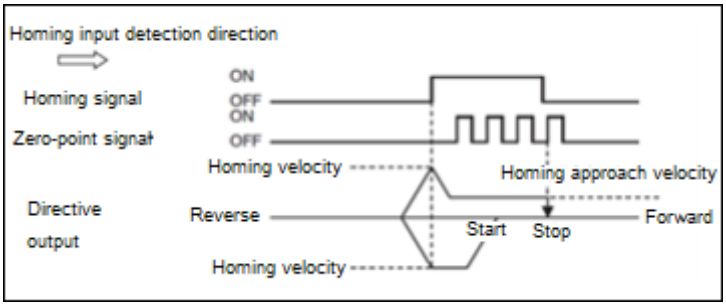
  It refers to the jerk during homing.

- **Homing deceleration**

It refers to the deceleration during homing.

◦ **Homing approach velocity**

It refers to the proximity velocity during homing.



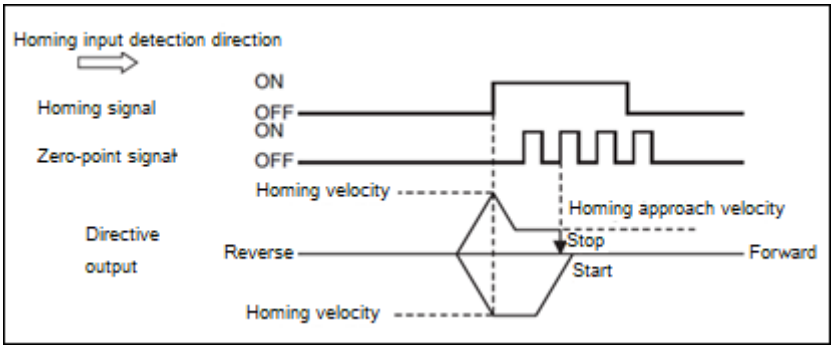
◦ **Homing definition operation**

The following describes the 10 homing operation modes.

1. Proximity reverse turn/home proximity input OFF

a. After the instruction is triggered, the axis starts moving at the homing velocity. When the home proximity input signal turns ON, the axis starts decelerating to the homing approach velocity.

b. After the axis reaches the homing approach velocity, the axis stops on the first rising edge of the home input signal after the home proximity input signal turns OFF. In this way, the mechanical home is defined.



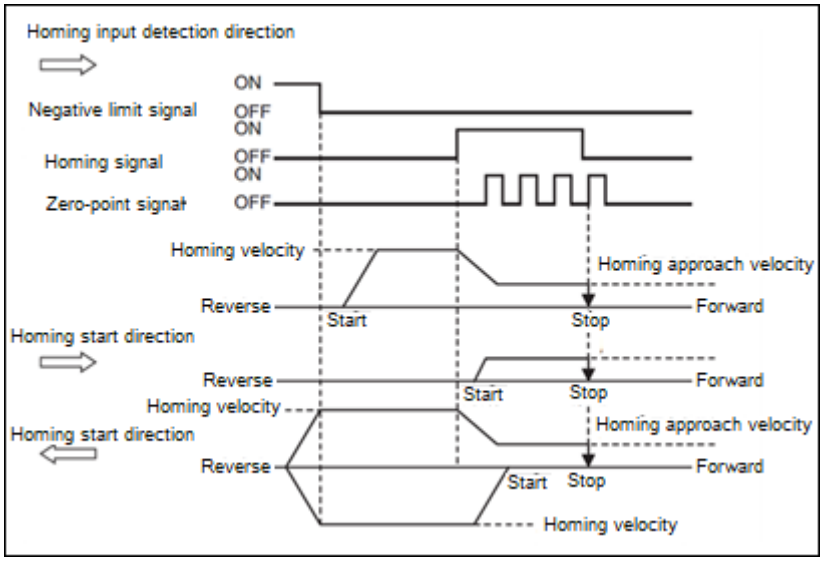
- If you start homing while the home proximity input signal is ON, homing will start at the homing velocity in the direction opposite to the home input detection direction. After the home proximity input signal turns OFF, the axis starts decelerating to 0 at the homing deceleration, and then accelerates at the homing acceleration in reverse direction to the homing velocity. After the home proximity input signal turns ON, the axis starts decelerating to the homing approach velocity.
- After homing is started, the mechanical home is defined when the home input signal turns ON after the home proximity input signal turns ON and then OFF while the velocity is below the homing approach velocity.

2. Proximity reverse turn/home proximity input ON

a. After the instruction is triggered, the axis starts moving at the homing velocity. When the home proximity input signal turns ON, the axis starts decelerating to the homing approach velocity.

b. After the axis reaches the homing approach velocity, the axis stops on the first rising edge of the home input signal. In this way, the mechanical home is defined. After the home proximity input signal turns ON, its status does not affect operation.

- If you start homing while the home proximity input signal is ON, homing will start at the homing velocity in the direction opposite to the home input detection direction. After the home proximity



input signal turns OFF, the axis starts decelerating to 0 at the homing deceleration, and then accelerates at the homing acceleration in reverse direction to the homing velocity. After the home proximity input signal turns ON, the axis starts decelerating to the homing approach velocity.

- After homing is started, the mechanical home is defined when the home input signal turns ON after the home proximity input signal turns ON while the velocity is below the homing approach velocity.

3. Home proximity input OFF

a. After the instruction is triggered, the axis starts moving at the homing velocity. When the home proximity input signal turns ON, the axis starts decelerating to the homing approach velocity.

b. After the axis reaches the homing approach velocity, the axis stops on the first rising edge of the home input signal after the home proximity input signal turns OFF. In this way, the mechanical home is defined.

- If you start homing while the home proximity input signal is ON, the axis performs the following operation depending on the setting of the homing start direction.

  Homing start direction same as home input detection direction

  The axis does not perform a reverse turn and homing starts in the home input detection direction at the homing approach velocity.

  Homing start direction different from home input detection direction

  Homing starts in the homing start direction at the homing velocity, regardless of the status of the home proximity input signal. If you set the operation at the limit input in the homing start direction to "Reverse turn/Immediate stop" or "Reverse turn/Deceleration stop", the axis reverses its direction when limit input is detected, and performs homing in the home input detection direction.

- After homing is started, the mechanical home is defined when the home input signal turns ON after the home proximity input signal turns ON and then OFF while the velocity is below the homing approach velocity.

4. Home proximity input ON

a. After the instruction is triggered, the axis starts moving at the homing velocity. When the home proximity input signal turns ON, the axis starts decelerating to the homing approach velocity.

b. After the axis reaches the homing approach velocity, the axis stops on the first rising edge of the home input signal. In this way, the mechanical home is defined. After the home proximity input signal turns ON, its status does not affect operation.

- If you start homing while the home proximity input signal is ON, the axis performs the following operation depending on the setting of the homing start direction.

  Homing start direction same as home input detection direction

  The axis does not perform a reverse turn and homing starts in the home input detection direction at the homing approach velocity.

  Homing start direction different from home input detection direction

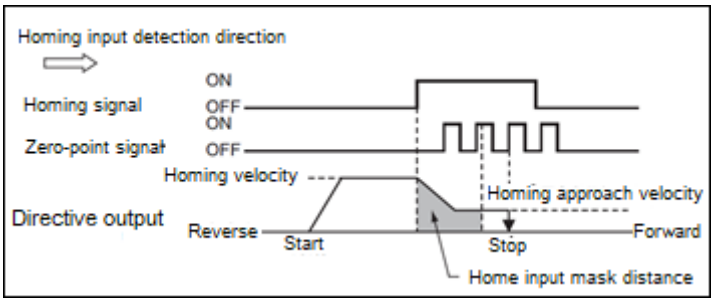
  Homing starts in the homing start direction at the homing velocity, regardless of the status of the home proximity input signal. If you set the operation at the limit input in the homing start direction to "Reverse turn/Immediate stop" or "Reverse turn/Deceleration stop", the axis reverses its direction when limit input is detected, and performs homing in the home input detection direction.

- After homing is started, the mechanical home is defined when the home input signal turns ON after the home proximity input signal turns ON while the velocity is below the homing approach velocity.

5. Limit input OFF

a. After the instruction is triggered, the axis starts moving at the homing velocity. When the limit signal in the direction opposite to the home input detection direction turns ON, the axis starts decelerating to the homing approach velocity.

b. After the axis reaches the homing approach velocity, the axis stops on the first rising edge of the home input signal after the limit signal turns OFF. In this way, the mechanical home is defined.



- If you perform homing while the limit input on the opposite side of the home input detection direction is ON, homing starts at the homing approach velocity in the home input detection direction.
- After homing is started, the mechanical home is defined when the home input signal turns ON after the limit signal in the direction opposite to the home input detection direction turns ON and then OFF while the velocity is below the homing approach velocity.

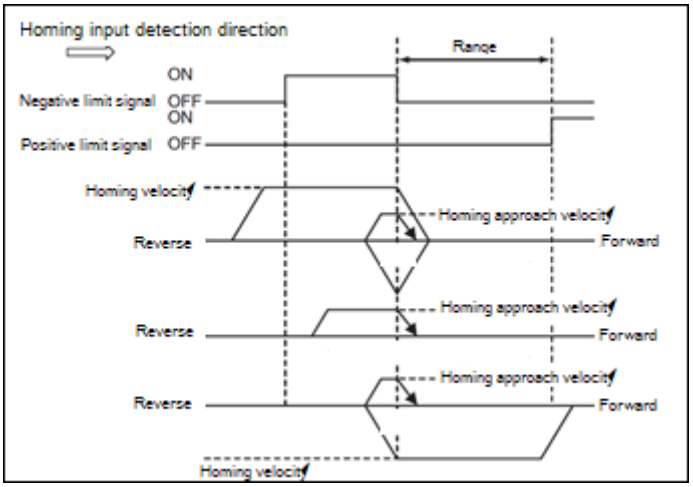
6. Proximity reverse turn/home input mask distance

a. After the instruction is triggered, the axis starts moving at the homing velocity. When the home proximity input signal turns ON, the axis starts decelerating to the homing approach velocity.

b. The axis moves by the home input mask distance after the home proximity input signal turns ON and stops on the first rising edge of the home input signal. In this way, the mechanical home is defined.

- If you start homing while the home proximity input signal is ON, homing will start at the homing velocity in the direction opposite to the home input detection direction. After the home proximity input signal turns OFF, homing will start at the homing approach velocity in the home input detection direction

  .



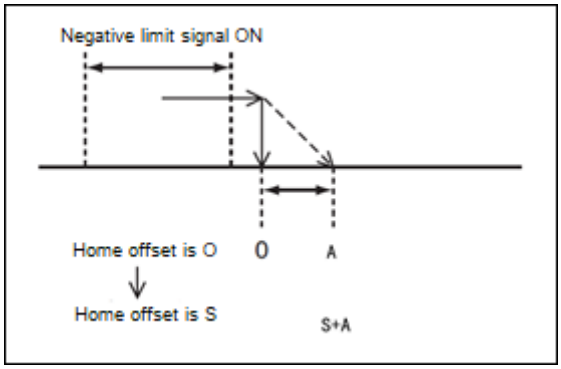
- After homing is started, the mechanical home is defined when the home input signal turns ON after the axis move by the home input mask distance after the home proximity input signal turns ON while the velocity is below the homing approach velocity.

7. Limit inputs only

a. After the instruction is triggered, the axis starts moving at the homing velocity. When the limit signal in the direction opposite to the home input detection direction turns OFF, the axis decelerates to stop.

b. After the axis stops, the axis moves in the other direction at the homing velocity and decelerates to a stop when the limit signal turns ON.

c. After the axis stops, the axis moves in the other direction at the homing approach velocity. The position where the limit signal turns OFF is defined as home and an immediate stop is performed. However, the axis does not return to the mechanical home position.

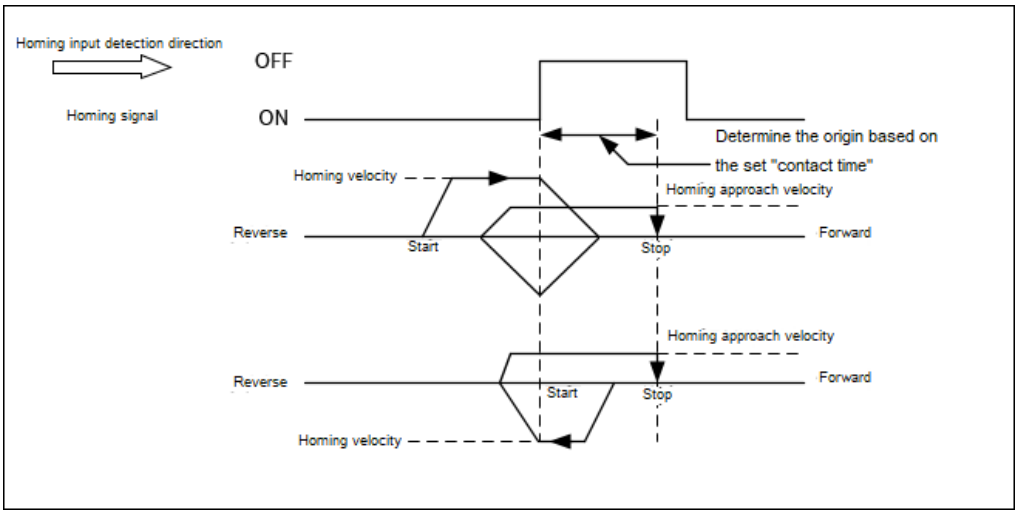


- If you use only the limit signals to perform homing, the point at which the limit signal turns OFF during operation in the home input detection direction is set as the home detection position.
- If you start homing while the limit signal in the home input detection direction is ON, homing will start at the homing velocity in the direction opposite to the home input detection direction. When the limit signal in the direction opposite to the home input detection direction turns ON, the axis decelerates to stop.
- After the limit signal is detected, even if the limit signal is set to OFF before deceleration stop, the mechanical home cannot be defined and deceleration continues. In this case, no fault will occur.
- Home is defined if the limit signal turns OFF before the homing approach velocity is reached and after the axis moves in the other direction or starts moving while the limit signal is ON.

Differences between this mode and other homing operation modes

In this mode, the MC function block detects when the limit signal turns OFF to define home. It differs from a homing operation mode that uses the home input signal as an external latch signal in the following ways.

- The MC function block detects the limit input without an external latch function, such as one provided by a servo drive. MC function block processing is the processing performed in the task cycle. Therefore, the precision of the home definition will depend on the homing approach velocity and the task control cycle.
- The axis does not return to the mechanical home position. If the homing compensation value is 0, processing for homing will end with the axis at a different position (i.e., not at the mechanical home). If the homing compensation value is not 0, homing compensation is performed with the homing compensation value as a relative position from mechanical home in the same way as for other homing operation modes.
- The home position offset is used to change the position of mechanical home. If the stop position is offset from home by distance A, as shown in the following figure, the position after the completion of processing for homing will be S + A if the home position offset is S and the homing compensation value is 0.

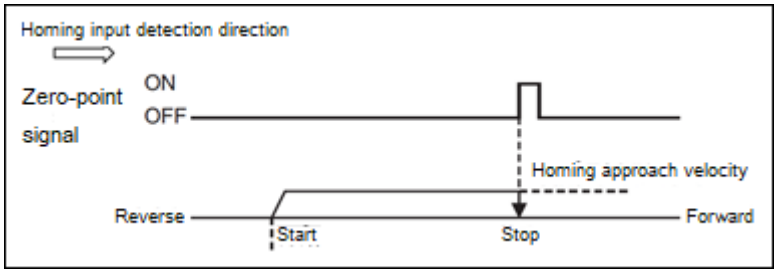


8. Proximity reverse turn/holding time

a. After the instruction is triggered, the axis starts moving at the homing velocity. When the home proximity input signal turns ON, the axis starts decelerating to 0 at the homing deceleration and then accelerates at the homing acceleration in reverse direction to the homing velocity.

b. When the home proximity input signal turns OFF, the axis decelerates to 0 at the homing deceleration and then accelerates at the homing acceleration in reverse direction to the homing approach velocity.

c. When the home proximity input signal turns ON, time monitoring starts and the mechanical home is defined after the defined "Holding time". After the home proximity input signal turns ON, its status does not affect operation.

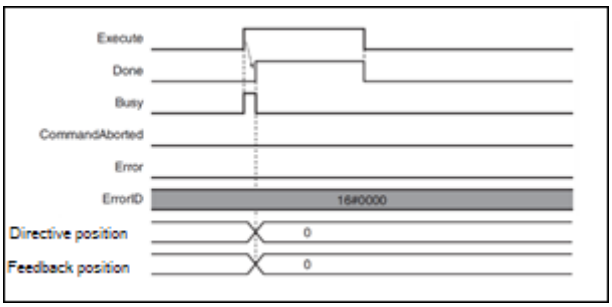


- If you start homing while the home proximity input signal is ON, homing will start at the homing velocity in the direction opposite to the home input detection direction. When the home proximity input signal turns OFF, the axis decelerates to 0 and then accelerates at the homing acceleration in reverse direction to the homing approach velocity. Homing starts when the home proximity input signal turns ON.
- After homing is started, the mechanical home is defined if the holding time elapses after the home proximity input signal turns ON while the velocity is below the homing approach velocity.

9. No home proximity input/holding home input

a. After the instruction is triggered, the axis starts moving at the homing approach velocity.

b. The mechanical home is defined when the home input signal turns ON.

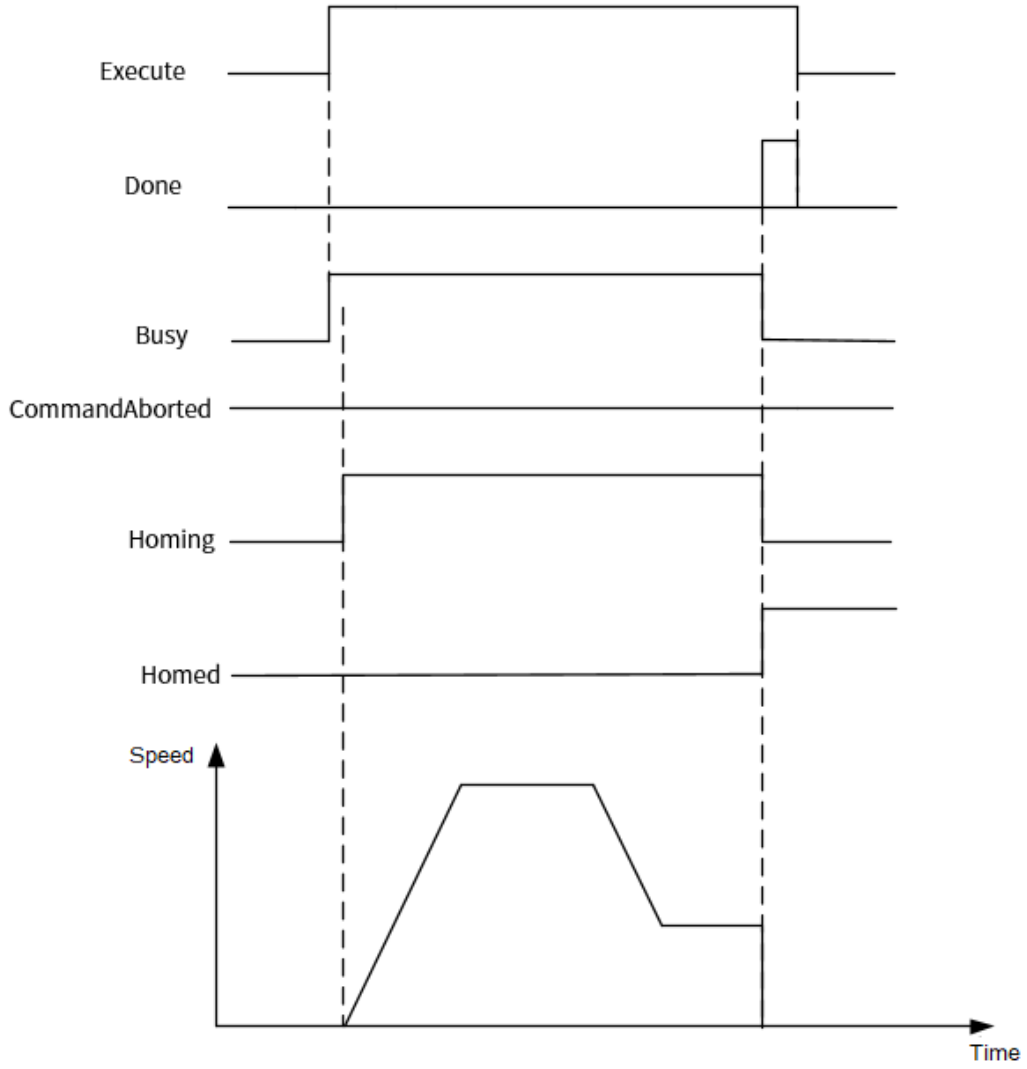


- After homing is started, the mechanical home is defined when the home input signal turns ON before the homing approach velocity is reached.

10. Zero position preset

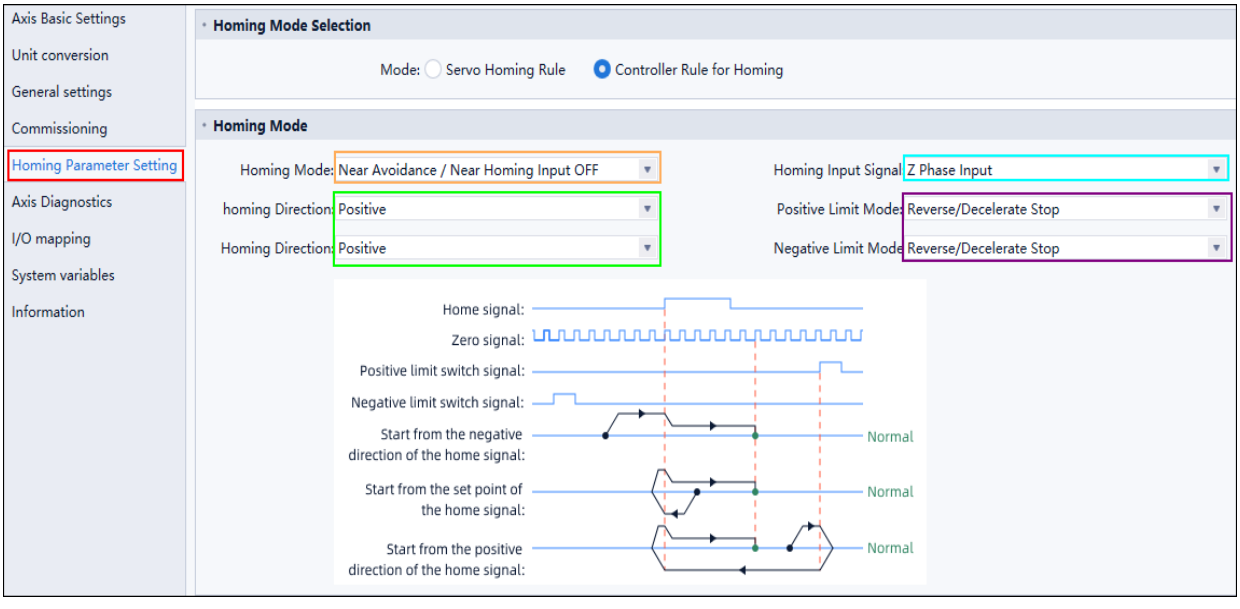
a. The current position reference and the actual position are set to the home position offset to define the mechanical home. Also, the following error between the current position reference and the actual position is retained.

The operation when the home position offset is set to 0 is shown in the following figure:



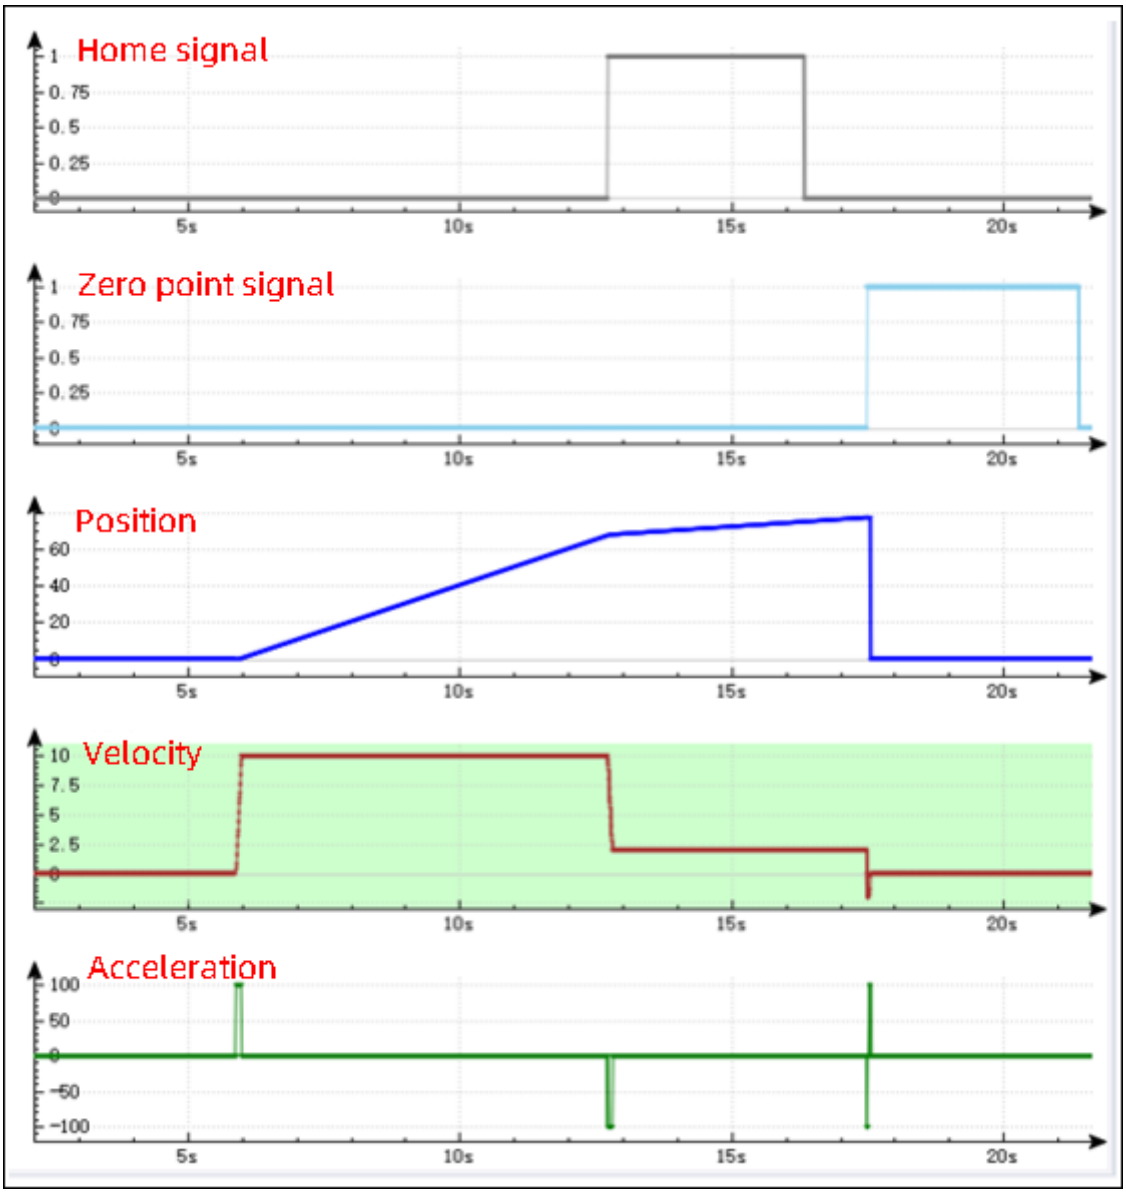
◦ The arrival check function is only applicable to MotionControl library version 2.4.0.0 or later. Based on the "Positioning range" and "Positioning check time" parameters in the "General setting" of the axis configuration page, it checks in real time whether the actual position has entered the specified target range. After the instruction output for the target position is completed, positioning is complete and the Done output is set if the difference between the actual position and the target position is smaller than the "Positioning range". If positioning is not completed within the "Positioning check time", a fault will occur.

Local pulse axis:



◦ This instruction cannot be used for local pulse axes.

- **Timing diagram**



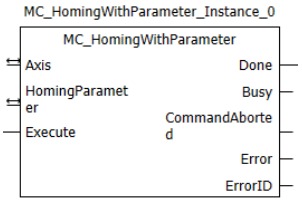
- **Example**

  Open the servo axis settings interface, access the Homing Setting interface, modify the Homing Method to select an external signal that meets the on-site requirements; modify the Homing Start Direction and Home Input Detection Direction to select a homing method that fits the on-site process; modify the Positive Limit Input and Negative Limit Input to "Reverse turn/immediate stop", and modify the Home Input Signal to the signal source for on-site homing. The motion parameters are the required motion parameters.

Call the MC_Homing instruction and directly trigger the parameter Execute of the instruction. The axis will start moving according to the trajectory set in the software.

- **Precautions**
  - Unlike the MC_Home, the number of revolutions of a rotatory axis will not be reset when the MC_Homing is executed.
  - To maintain absolute precision, when the instruction detects the home input signal at the low velocity, it moves back a certain distance to search for the home position. Therefore, after homing is completed and a motion control instruction is called, if the motion direction is specified as Current, the actual motion direction may be inconsistent with the homing parameter "Home input detection direction".
  - If a slave device bound to the servo axis (e.g., a servo) supports Z-phase signal and probe functions, it can support all homing operation modes. If a slave device bound (e.g., a module) does not support Z-phase signal but supports probe functions, set the home input signal to be probe signal to complete homing.
  - Currently, the positive and negative limit terminals are, by default, assigned to the positive and negative limit signals of the servo end, and binding general-purpose terminals as limit signals is not supported. Therefore, if you select the deceleration mode for "Positive/negative limit input", the axis will stop immediately.

- Do not check the reverse configuration when using the MC_Homing instruction; otherwise, the servo end will give an alarm if the positive/negative limit is triggered during execution.
- When the MotionControl library version is 2.2.0.0 or later, the PLC homing function is supported for local pulse axes.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.3.54 MC_HomingWithParameter

This instruction sets the homing parameters and controls the motor to define the home.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_HomingWithParameter	Homing with parameters		MC_HomingWithParameter_Instance_0(Axis :=, HomingParameter :=, Execute :=, Done =>, Busy =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

  In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description

Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Parameter correction**

Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Velocity	Velocity	Any velocity that exceeds the motion parameter limit will be automatically corrected to the velocity limit.	Any velocity less than 0 will be automatically corrected to 1e-5.	The velocity equal to 0 will be automatically corrected to 1e-5.

Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Acceleration	Acceleration	Any acceleration that exceeds the motion parameter limit will be automatically corrected to the acceleration limit.	• When the MotionControl library version is 2.3.0.0 or earlier, the acceleration less than 0 will be automatically corrected to 10% of the acceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the acceleration less than 0 will be automatically corrected to 10 times the velocity.	• When the MotionControl library version is 2.3.0.0 or earlier, the acceleration equal to 0 will be automatically corrected to 10% of the acceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the acceleration equal to 0 will be automatically corrected to 10 times the velocity.
Deceleration	Deceleration	Any deceleration that exceeds the motion parameter limit will be automatically corrected to the deceleration limit.	• When the MotionControl library version is 2.3.0.0 or earlier, the deceleration less than 0 will be automatically corrected to 10% of the deceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the deceleration less than 0 will be automatically corrected to 10 times the velocity.	• When the MotionControl library version is 2.3.0.0 or earlier, the deceleration equal to 0 will be automatically corrected to 10% of the deceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the deceleration equal to 0 will be automatically corrected to 10 times the velocity.

Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Jerk	Jerk	If the motion profile is set to S-curve, any jerk that exceeds the software limit will be automatically corrected to the jerk limit.	If the motion profile is set to S-curve, any jerk less than 0 will be automatically corrected to 10% of the jerk limit.	If the motion profile is set to S-curve, the jerk equal to 0 will be automatically corrected to 10% of the jerk limit.
ApproachVel	Homing approach velocity	Any velocity that exceeds the motion parameter limit will be automatically corrected to the velocity limit.	Any velocity less than 0 will be automatically corrected to 1e-5.	Any velocity less than 0 will be automatically corrected to 1e-5.
CompensationVelocity	Compensation velocity	Any velocity that exceeds the motion parameter limit will be automatically corrected to the velocity limit.	Any velocity less than 0 will be automatically corrected to 1e-5.	Any velocity less than 0 will be automatically corrected to 1e-5.

- **Function**

  Bus-controlled axis:

  - Homing starts on a rising edge of Execute.
  - Specify the homing parameters through the in-out variable HomingParameter. The axis parameters are not changed when the MC_HomingWithParameter instruction is executed.
  - The only difference between the MC_HomingWithParameter instruction and the MC_Home instruction is how to specify the parameters. For this instruction, the parameters are specified using the in-out parameter HomingParameter. For the MC_Homing instruction, the homing parameters are specified in the software.
  - When the HomeTimeOut is set to 0, there is no limit on the homing timeout period.
  - Description of the HomingParameter structure

Parameter	Definition	Data Type	Valid Range	Description
HomeMode	Homing mode	18.3.3.2.2.13 MC_HOMING_MODE: Homing Mode Enumeration	1: PassHomeSwHomeSwTurn 2: InHomeSwHomeSwTurn 3: PassHomeSwHome 4: InHomeSw 5: PassLimitSw 6: HomeSwMaskDistanceHomeSwTurn 7: OnlyLimit 8: HomeSwHoldTimeHomeSwTurn 9: ZeroSw 10: ZeroPositionPreset	1: Proximity reverse turn/home proximity input OFF 2: Proximity reverse turn/home proximity input ON 3: Home proximity input OFF 4: Home proximity input ON 5: Limit input OFF 6: Proximity reverse turn/home input mask distance 7: Limit inputs only 8: Proximity reverse turn/holding time 9: No home proximity input/holding home input 10: Zero position preset

Parameter	Definition	Data Type	Valid Range	Description
Vel	Homing velocity	LREAL	Positive number	Homing approach velocity ≤ Homing velocity (in user units/s).
ApproachVel	Homing approach velocity	LREAL	Positive number	Homing approach velocity ≤ Homing velocity (in user units/s).
Acc	Homing acceleration	LREAL	Positive number or 0	Specify the homing acceleration (in user units/s^2).
Dec	Homing deceleration	LREAL	Positive number or 0	Specify the homing deceleration (in user units/s^2).
Jerk	Homing jerk	LREAL	Positive number or 0	Specify the homing jerk (in user units /s^2).
MaskDistance	Home input mask distance	LREAL	Positive number or 0	Specify the home input mask distance (in user units).
HomePositionOffset	Home position offset	LREAL	Positive number, negative number, or 0	Presets the actual position (in user units) after homing. In Rotary Mode, lower limit ≤ offset < upper limit.
PushTime	Homing holding time	UINT	0 to 10000	Specify the homing holding time (in ms).
Compensation	Homing compensation value	LREAL	Positive number, negative number, or 0	Specify the homing compensation value (in user units) after the home is defined.
HomeTimeOut	Homing timeout period	UDINT	0 to 655350	Specify the homing timeout period (in ms). When it is set to 0, homing timeout is not checked.
RoundTripEnable	Round trip enable	BOOL	TRUE, FALSE	TRUE: Enabled. FALSE: Disabled.

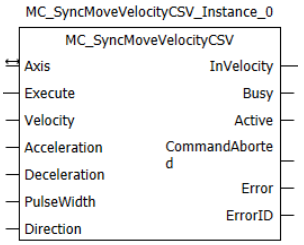
- The arrival check function is only applicable to MotionControl library version 2.4.0.0 or later. Based on the "Positioning range" and "Positioning check time" parameters in the "General setting" of the axis configuration page, it checks in real time whether the actual position has entered the specified target range. After the instruction output for the target position is completed, positioning is complete and the Done output is set if the difference between the actual position and the target position is smaller than the "Positioning range". If positioning is not completed within the "Positioning check time", a fault will occur.

Local pulse axis:

- This instruction cannot be used for local pulse axes.

- **Timing diagram**

- **Precautions**
  - If a slave device bound to the servo axis (e.g., a servo) supports Z-phase signal and probe functions, it can support all homing operation modes. If a slave device bound (e.g., a module) does not support Z-phase signal but supports probe functions, set the home input signal to be probe signal to complete homing.
  - Currently, the positive and negative limit terminals are, by default, assigned to the positive and negative limit signals of the servo end, and binding general-purpose terminals as limit signals is not supported. Therefore, if you select the deceleration mode for "Positive/negative limit input", the axis will stop immediately.
  - Do not check the reverse configuration when using the MC_Homing instruction; otherwise, the servo end will give an alarm if the positive/negative limit is triggered during execution.
  - When the MotionControl library version is 2.2.0.0 or later, the PLC homing function is supported for local pulse axes.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.3.55 MC_SyncMoveVelocityCSV

This instruction is used for CSV-based velocity control with adjustable pulse width.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_SyncMoveVelocityCSV	Velocity control with adjustable pulse width		MC_SyncMoveVelocityCSV_Instance_0(Axis :=, Execute :=, Velocity :=, Acceleration :=, Deceleration :=, PulseWidth :=, Direction :=, InVelocity =>, Busy =>, Active =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	Execute the instruction.
Velocity	Velocity	LREAL	Positive number or 0	0	Target velocity.

Acceleration	Acceleration	LREAL	Positive number or 0	0	Target acceleration.
Deceleration	Deceleration	LREAL	Positive number or 0	0	Target deceleration.
PulseWidth	Pulse width	INT	1 to 9999	5000	Pulse width (in 0.01%).
Direction	Motion direction	18.3.3.2.2.9 MC_DIRECTION: Motion Direction Enumeration	1: DIR_POSITIVE 2: DIR_NEGATIVE 3: DIR_CURRENT	1	1: DIR_POSITIVE (Positive direction). 2: DIR_NEGATIVE (Negative direction). 3: DIR_CURRENT (Current direction).

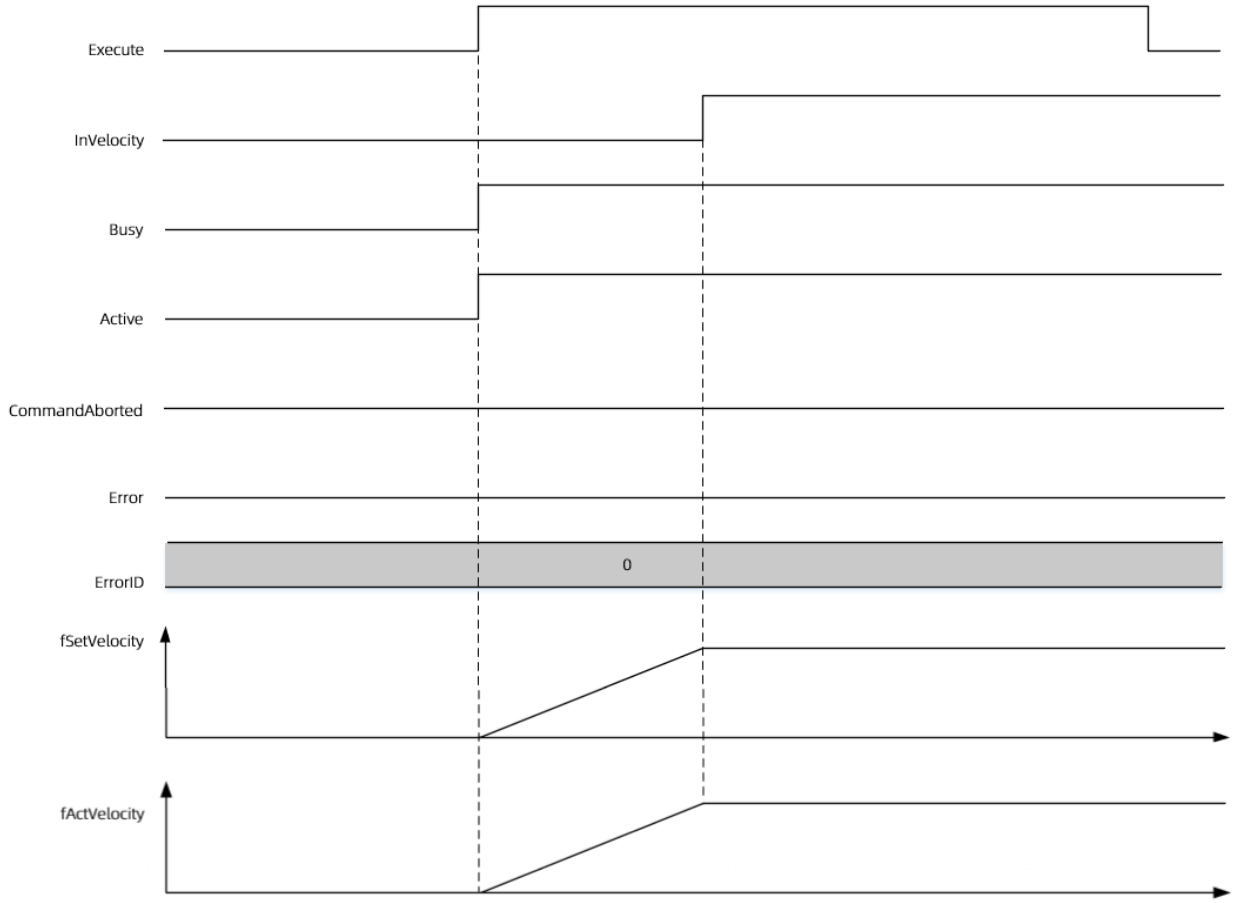
Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
InVelocity	Velocity reference reached	BOOL	TRUE, FALSE	FALSE	TRUE when the axis reaches the velocity reference.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Active	Controlling	BOOL	TRUE, FALSE	FALSE	TRUE when the axis is being controlled by the current FB.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.

ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Parameter correction**

Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Velocity	Velocity	Any velocity that exceeds the motion parameter limit will be automatically corrected to the velocity limit.	Any velocity less than 0 will be automatically corrected to 1e-5.	No correction.
Acceleration	Acceleration	Any acceleration that exceeds the motion parameter limit will be automatically corrected to the acceleration limit.	• When the MotionControl library version is 2.3.0.0 or earlier, the acceleration less than 0 will be automatically corrected to 10% of the acceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the acceleration less than 0 will be automatically corrected to 10 times the velocity.	• When the MotionControl library version is 2.3.0.0 or earlier, the acceleration equal to 0 will be automatically corrected to 10% of the acceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the acceleration equal to 0 will be automatically corrected to 10 times the velocity.
Deceleration	Deceleration	Any deceleration that exceeds the motion parameter limit will be automatically corrected to the deceleration limit.	• When the MotionControl library version is 2.3.0.0 or earlier, the deceleration less than 0 will be automatically corrected to 10% of the deceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the deceleration less than 0 will be automatically corrected to 10 times the velocity.	• When the MotionControl library version is 2.3.0.0 or earlier, the deceleration equal to 0 will be automatically corrected to 10% of the deceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the deceleration equal to 0 will be automatically corrected to 10 times the velocity.



Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
PulseWidth	Pulse width	If the value exceeds 9999, it will be corrected to 9999.	If the value is less than 1, it will be corrected to 1.	It will be corrected to 1.

- **Function**
  - This instruction can be used for bus-controlled axes and local pulse axes. When the bus-controlled axis is controlled in the Cyclic Synchronous Velocity (CSV) control mode or the local pulse axis is controlled in the Cyclic Synchronous Position (CSP) control mode, set the axis in the AXIS_CONTINUOUS_MOTION state.
  - Before this instruction is executed on a bus-controlled axis, configure three PDOs: 0x6060, 0x6061, and 0x60FF.
  - When a local pulse axis is used, this instruction enables PWM (pulse width modulation) output with acceleration/deceleration and without acceleration/deceleration: When the input parameters Acceleration and Deceleration are set to non-zero, the PWM output is based on the specified values of the parameters Acceleration and Deceleration. When the input parameters Acceleration and Deceleration are set to zero or one of them is set to zero, the target velocity is reached without acceleration or deceleration in one cycle after the instruction is executed and the PWM output starts. The input parameter PulseWidth is used to control the pulse width of the PWM waveform.
  - The EVO760 series devices have no single-terminal Y0 or Y1. Therefore, it is not recommended to use this instruction on the EVO760 series devices through a pulse axis.
  - During the execution of this instruction, if you want to stop the axis, you can call the MC_Stop, MC_Halt, or MC_ImmediateStop instruction; it is prohibited to call the MC_MoveSuperImposed instruction for motion superimposition.
- **Timing diagram**

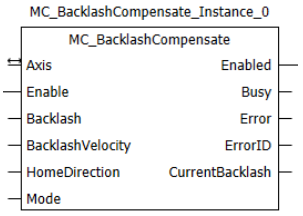
  The parameter Execute of the function block must be triggered on a rising edge. The InVelocity state of the function block indicates the velocity reference is reached; the parameter Busy indicates that the current function block is being executed; the parameter Active indicates the axis is being controlled; the parameter CommandAborted indicates that the instruction is aborted by another motion control instruction, at which point the flag is set to TRUE.

  After this instruction is called, the output parameter Busy is set to TRUE on a rising edge of Execute. In the next cycle, the output parameter Active shows the value TRUE.

  When the axis reaches the velocity reference, the output parameter InVelocity is set to TRUE.

- **Precautions**
  - If this instruction is executed on a local pulse axis, select the output device as Y0 or Y1. If you select dual-ended output, a fault will occur.

  - If this instruction is executed on a bus-controlled axis, do not use the MC_SetPosition instruction.
  - When this instruction is executed on a local pulse axis, it is recommended that the minimum pulse frequency be 5 Hz.
  - When a servo axis is enabled after PLC project cold reset and the MC_Home instruction is executed using No. 35 homing method, if this instruction is executed with DIR_CURRENT being set, the motion direction of this instruction will be affected.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.3.56 MC_BacklashCompensate

This instruction enables backlash compensation and is used to compensate for the dead travel in the mechanical system.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_BacklashCompensate	Backlash compensation		MC_BacklashCompensate_Instance_0(Axis :=, Enable :=, Backlash :=, BacklashVelocity :=, HomeDirection :=, Mode :=, Enabled =>, Busy =>, Error =>, ErrorID =>, CurrentBacklash =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Enable	Enable	BOOL	TRUE, FALSE	FALSE	Enable flag for backlash compensation.
Backlash	Backlash compensation value	LREAL	Greater than 0	0	Backlash compensation value, greater than 0. The positive or negative direction of the compensation value is determined by internal calculation.

BacklashVelocity	Compensation velocity	LREAL	Greater than or equal to 0	0	Velocity for backlash compensation. When the compensation velocity is set to 0, the backlash is compensated over one cycle; if greater than 0, the backlash is compensated according to the specified compensation velocity.
HomeDirection	Absolute homing direction	BOOL	TRUE, FALSE	FALSE	TRUE: Positive direction. FALSE: Negative direction.
Mode	Compensation mode	INT	0	0	0: Linear compensation. Other: To be determined (not yet implemented).

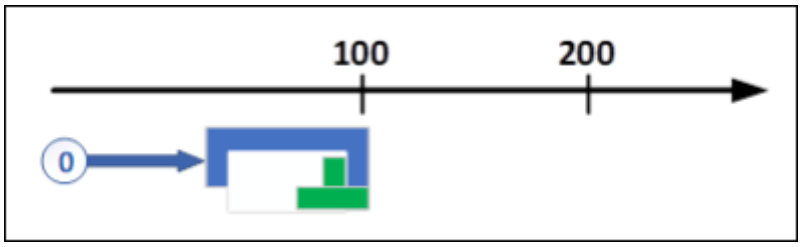
Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Enabled	Enabled	BOOL	TRUE, FALSE	FALSE	TRUE: Compensation enabled. FALSE: Compensation not enabled.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Error	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.
CurrentBacklash	Current backlash compensation	LREAL	-	0	Current backlash compensation value.

- **Function**
  - Sources of backlash:

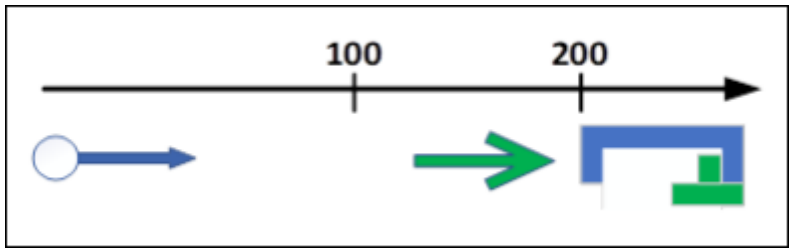
    Clearance introduced by keyed connection between the motor shaft and gear, clearance between the gears, clearance introduced by keyed connection between the gear and screw, clearance introduced by keyed connection in the coupling, and clearance between the screw

and its nut. These clearances are negligible in one direction and mainly occur during reverse motion.



- Impacts of backlash:

  When the worktable moves from positive to negative direction, its actual displacement deviates the theoretical value, and the deviation accumulates in the total worktable displacement. Due to the backlash, the motor may be idling during direction reversal without actual worktable movement, which also affects positioning accuracy and repeatability.



- Method for measuring backlash:

  1. Start homing to define the reference position.

  2. Install a dial gauge and set the scale to 0.

  3. Move absolutely in the positive direction by 200.

  4. Move absolutely in the negative direction to 0.

  5. Read the dial gauge. The reading represents the error.

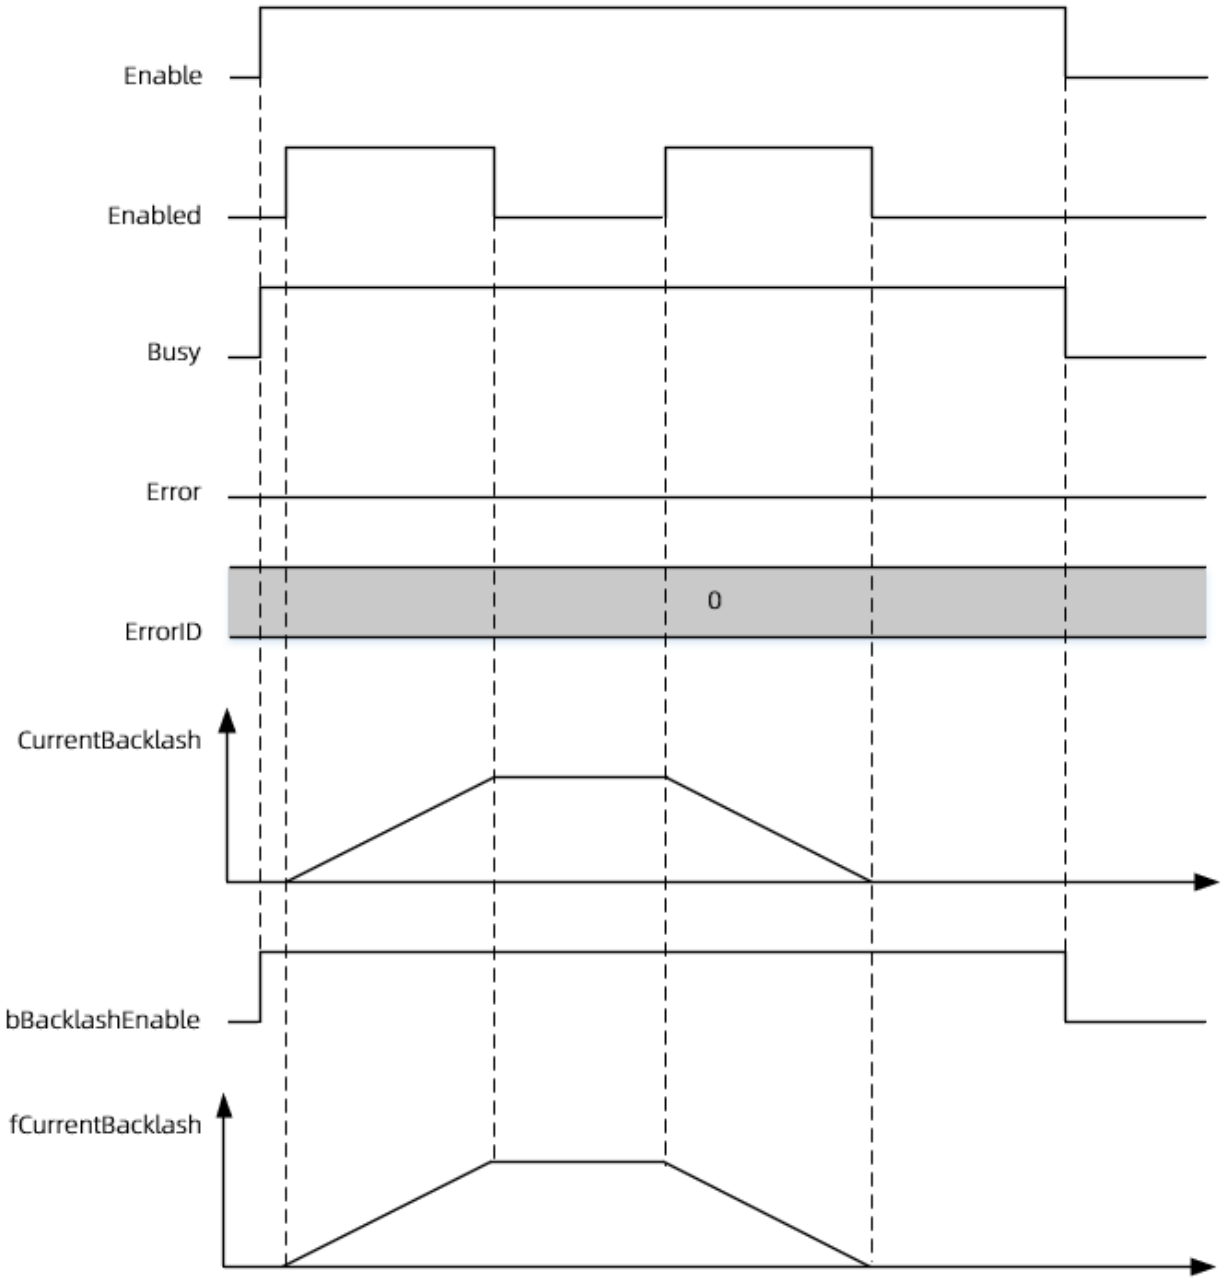
Shaft end variable parameter names

Data Type	Parameter	Definition
BOOL	bBacklashEnable	Enable flag for backlash compensation
LREAL	fCurrentBacklash	Backlash compensation value

To use the backlash compensation function block, first perform homing or confirm whether the motion direction is the same as the previous motion's end direction. The compensation during the first execution of the instruction is shown in the following figure, where A represents the compensation amount. Without performing homing, the compensation may be incomplete, or the worktable displacement may be inaccurate.

Homing end direction and moving direction upon instruction execution	Compensation value
Same direction	0
Different direction	± A

- **Precautions**
  - It is not recommended to modify input parameters during the compensation; modified parameters will not take effect until the instruction is re-executed.
  - If backlash error and pitch error exist simultaneously, compensate the backlash error before the pitch error.
  - The instruction can be executed only when the axis is in the Standstill state; otherwise, a fault will occur.
  - You must specify proper compensation velocity and compensation value; otherwise, it may cause servo overspeed. When the compensation velocity is 0, the compensation value is added to the planned value over one cycle. This may cause a significant jump in the actual velocity, so it must be used with caution.
  - If the Enable is set, Enabled is set during the compensation and then reset after the compensation is completed.
  - The CurrentBacklash shows the current compensation value in real time. The compensation value will be cleared if the Enable is reset or a fault occurs, resulting in that the compensation ramp-down to 0 at the maximum velocity.
  - The instruction can be placed in any order.
  - After the motion stops, disabling the MC_BacklashCompensate instruction may cause slight axis movement.
  - In multi-instance scenarios, if a subsequent instruction triggers a fault, it will not affect the normal compensation of the first instruction. When the second function block is triggered during the execution of the first function block, the second function block will report a fault but not affect the normal execution of the first function block.
  - The compensation velocity must be less than or equal to the velocity limit set in the software. Excessive compensation velocity may cause servo overspeed.
  - The compensation function can be used for servo axes, virtual axes, and pulse axes.



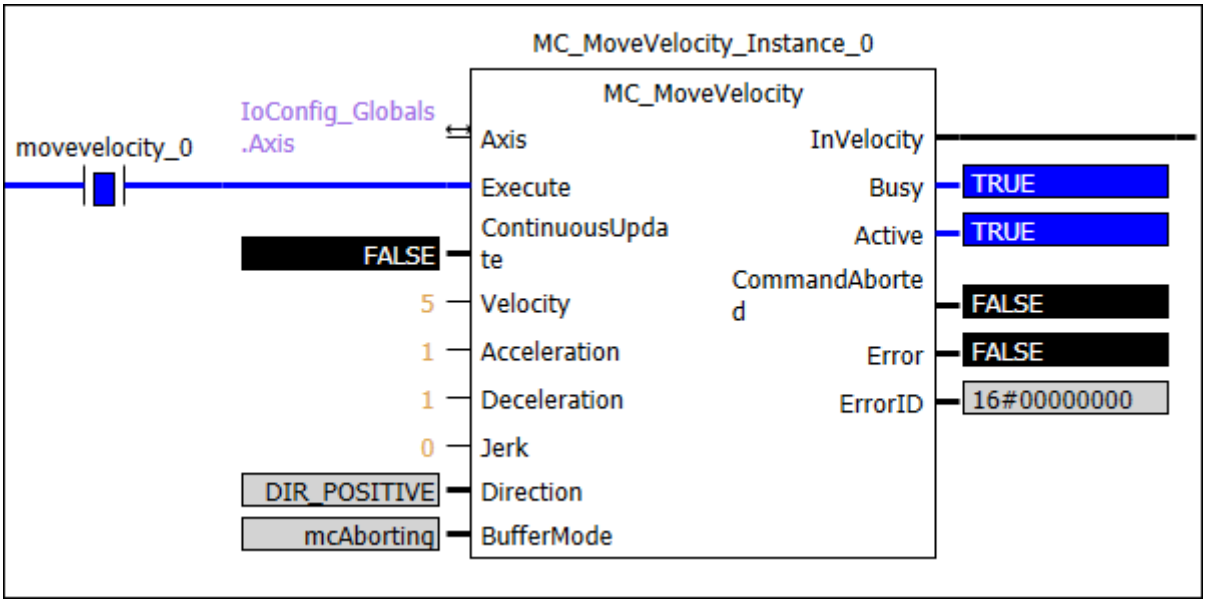
- If homing is triggered upon the start of compensation, a fault will occur.
- Although this instruction is a single axis instruction, it can also be applied to synchronous axes or axes groups.
- During axis commissioning, the compensation value is retained and the compensation continues without a fault message.
- When this instruction is triggered in a mode other than CSP or CSV control mode, a fault occurs. To use any instructions in other control modes, first clear the compensation value.
- For a rotary axis, the compensation value must be less than the rotation cycle; otherwise, the actual axis position may be inaccurate.
- Disabling or enabling the servo stop mode of immediate stop instruction during compensation can cause a sudden position change over one cycle.
- This instruction enables compensation in position mode only. It will not take effect for single-ended pulse axes.

- **Timing diagram**

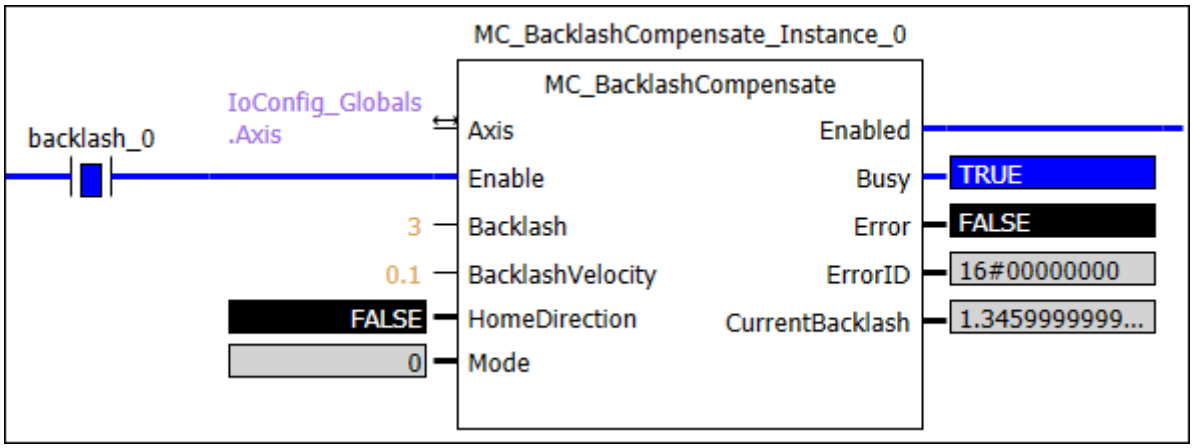
  After this instruction is called, the output parameter Busy is set to TRUE on a rising edge of Execute.

  At this point, execute the MC_MoveVelocity instruction in the positive direction. While the axis is being compensated, the output parameter Enabled is set to TRUE; after the compensation, the output parameter Enabled is set to FALSE.

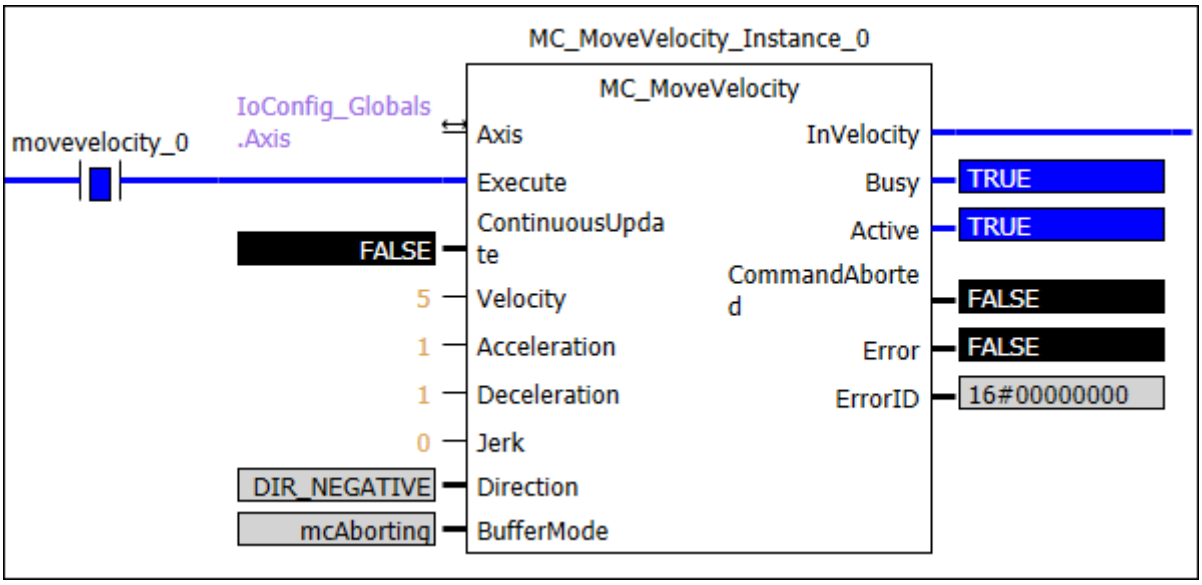
  Change the direction of the MC_MoveVelocity instruction to negative for reverse operation. While the axis is being compensated, the output parameter Enabled is set to TRUE; after the compensation, the output parameter Enabled is set to FALSE.



- **Example**



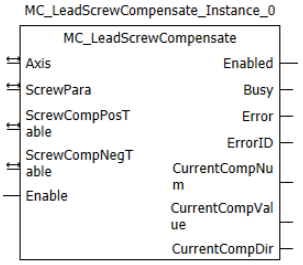
1. Execute the instruction.



2. Trigger the velocity instruction in the positive direction.

3. At this point, the instruction is being executed.

4. Change the direction of the velocity instruction to negative.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.3.57 MC_LeadScrewCompensate

Pitch error generally occurs when leadscrews are used. During the transmission of the leadscrew pairs, various errors exist between the leadscrew and nut, such as pitch error, thread raceway error, and diameter error. At the same time, the leadscrew stretching, extruding, or parallelism during assembly may introduce pitch errors. To improve the actual motion accuracy of the leadscrew, it is necessary to compensate for proper error values in the motion planning.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_LeadScrewCompensate	Leadscrew pitch error compensation		MC_LeadScrewCompensate_Instance_0(Axis :=, ScrewPara :=, ScrewCompPosTable :=, ScrewCompNegTable :=, Enable :=, Enabled =>, Busy =>, Error =>, ErrorID =>, CurrentCompNum =>, CurrentCompValue =>, CurrentCompDir =>);

- **Related variables**

  In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.
ScrewPara	Screw compensation structure	ScrewConStruct	-	0	Screw compensation structure.
ScrewCompPosTable	Positive screw compensation table	Variable-length array	-	0	Positive screw compensation table with 0 as the first element value.

ScrewCompNegTable	Negative screw compensation table	Variable-length array	-	0	Negative screw compensation table with 0 as the first element value.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Enable	Enable	BOOL	TRUE, FALSE	FALSE	TRUE: Compensation enabled. FALSE: Compensation disabled.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Enabled	Enabled	BOOL	TRUE, FALSE	FALSE	TRUE: Compensation enabled. FALSE: Compensation not enabled.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Error	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.
CurrentCompNum	Current compensated segment number	INT	-	0	Current compensated segment number.
CurrentCompValue	Current segment compensation value	LREAL	-	0	Current segment compensation value.

CurrentCompDir	Current compensation direction	INT	-	0	Current compensation direction: Positive direction: 1. Negative direction: 0.

ScrewConStruct structure

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Mode	Compensation mode	INT	0, 1	0	0: Unidirectional. 1: Bidirectional.
StartPos	Start position	LREAL	-	0	Compensation start position.
EndPos	End position	LREAL	-	0	Compensation end position.

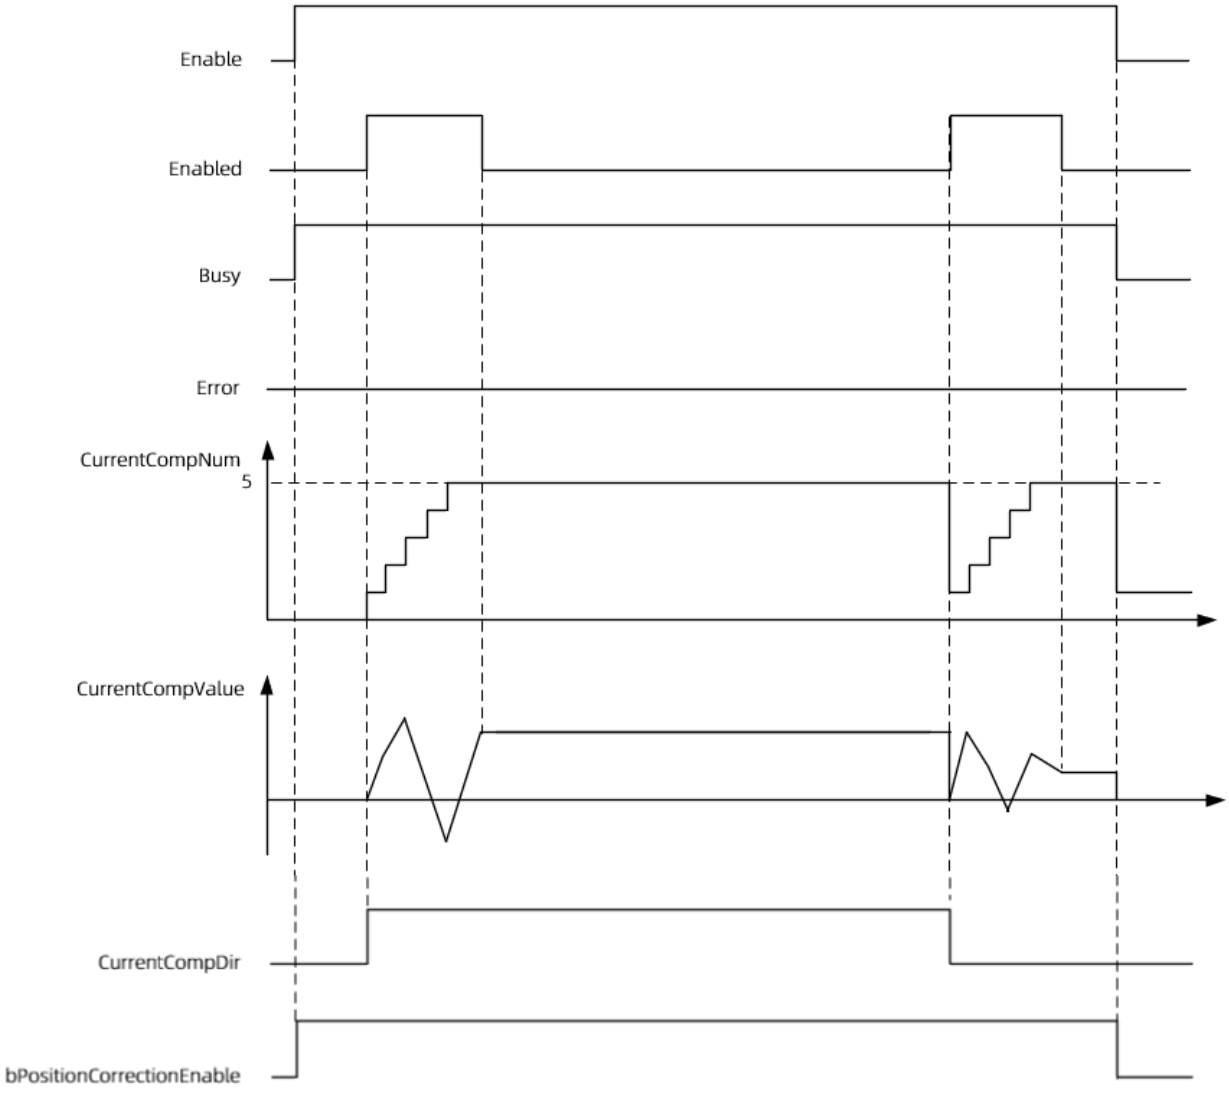
- **Function**

  Method for obtaining the screw compensation table:

  - First, select a section of the travel path with the start position specified as startPos and the stop position specified as endPos (endPos > startPos), and determine the number of segments the selected travel is divided into. Assume the travel is divided into N segments, the axis moves in the positive direction from startPos. At each position spaced by (endPos - startPos)/N, the position reference and the actual position are recorded to calculate their difference cmpVal, resulting in N compensation values.
  - Next, after the axis reaches the actual endPos in the positive direction, it starts moving in the negative direction from endPos. Use the same method described above to obtain N negative compensation values.
  - Finally, generate a compensation table with a length of N + 1 based on the number of segments N. For the positive compensation table, add a starting compensation value of 0 at the startPos. For the negative compensation table, add a starting compensation value of 0 at the endPos.

- **Precautions**
  - The parameter check for the compensation structure and compensation tables are only performed once when the instruction is triggered. It is prohibited to modify the parameters in the structure after the instruction is executed.
  - In Mode 0, StartPos < EndPos indicates forward compensation. Conversely, when the value of the start position is greater than that of the end position, it is considered negative compensation. When the

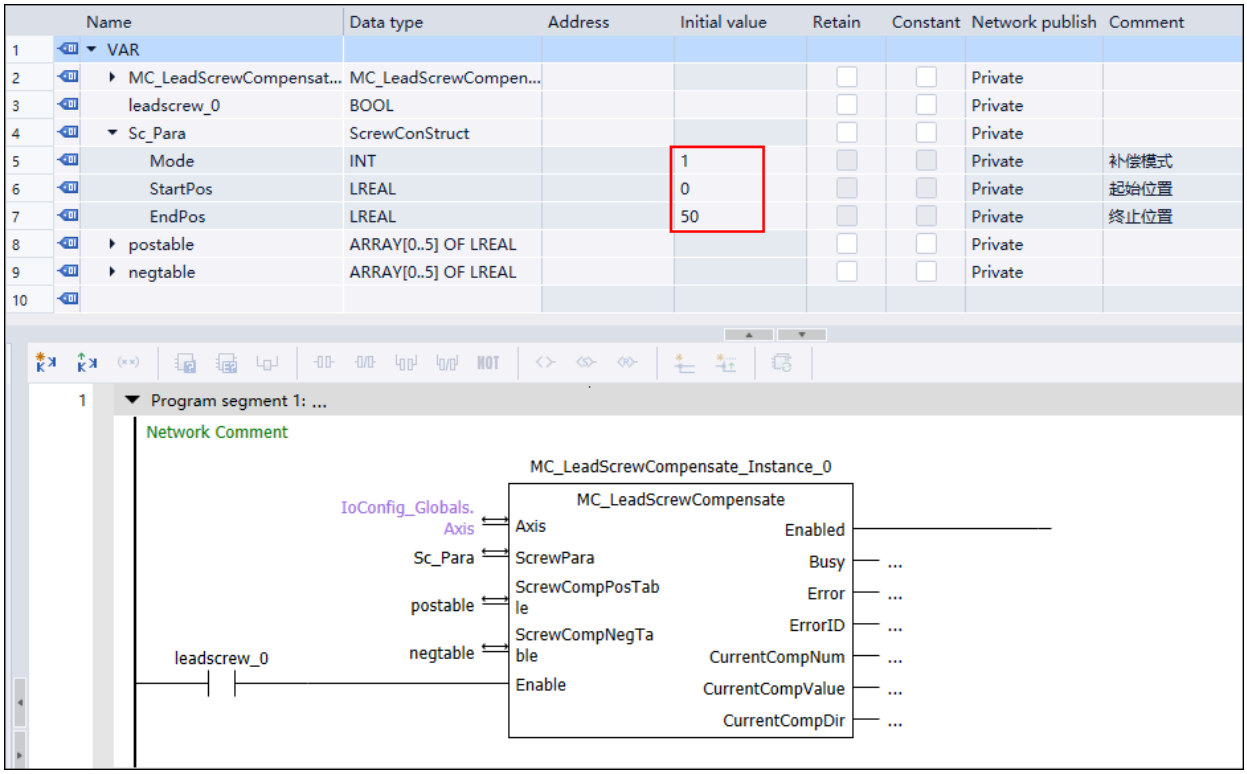
Mode is set to 1, the function block automatically calculates the start and end positions. For positive direction, the value of the start position is less than that of the stop position; for negative direction, the value of the start position is greater than that of the end position.



- When the value of the start position is greater than that of the end position, perform negative compensation based on the negative compensation table with 0 as the first element.
- When the value of the start position is less than that of the end position, perform positive compensation based on the positive compensation table with 0 as the first element.
- After the Enable is reset or a fault occurs, clear the compensation value at the maximum velocity.
- After the MC_LeadScrewCompensate instruction is executed, it is prohibited to execute the MC_Setposition instruction.
- Leadscrew pitch compensation is not supported for rotary axes.
- Specify proper value for the error parameter in the compensation table. An improper error compensation may result in overspeed. It is recommended to test the parameter value within a proper range. Generally, the errors in the compensation table are very small, often several orders of magnitude smaller than the user units.
- During the pitch error measurement, if the backlash of the screw is relatively large, it is recommended to set the backlash parameters of the screw before measuring the pitch error. This is because if the backlash is large, the pitch error measured during the reversal will be compensated in an instant, which may cause the motor to fail to respond or trigger an overspeed alarm.
- In multi-instance scenarios, if a subsequent instruction triggers a fault, it will not affect the normal compensation of the first instruction. When the second function block is executed during the execution of the first function block, the second function block will report a fault but not affect the normal execution of the first function block.
- Pitch compensation, as a property of a single axis, is also supported by synchronous axes and axis groups.
- During axis commissioning, the compensation value is retained and the compensation continues without a fault message.
- When this instruction is triggered in a mode other than CSP or CSV control mode, a fault occurs. To use any instructions in other control modes, first clear the compensation value. Before using a homing or torque instruction, reset and then execute the instruction; otherwise, it will cause inaccurate actual velocity.
- This instruction enables compensation in position mode only. It will not take effect for single-ended pulse axes.
- The compensation for reciprocating motion will be cleared to 0.
- Disabling or enabling the servo stop mode of immediate stop instruction during compensation can cause a sudden position change over one cycle.
- Up to 1000 points of compensation are supported.
- If multiple segments need to be compensated, a longer table can be set, with segments that do not require compensation being set to 0.

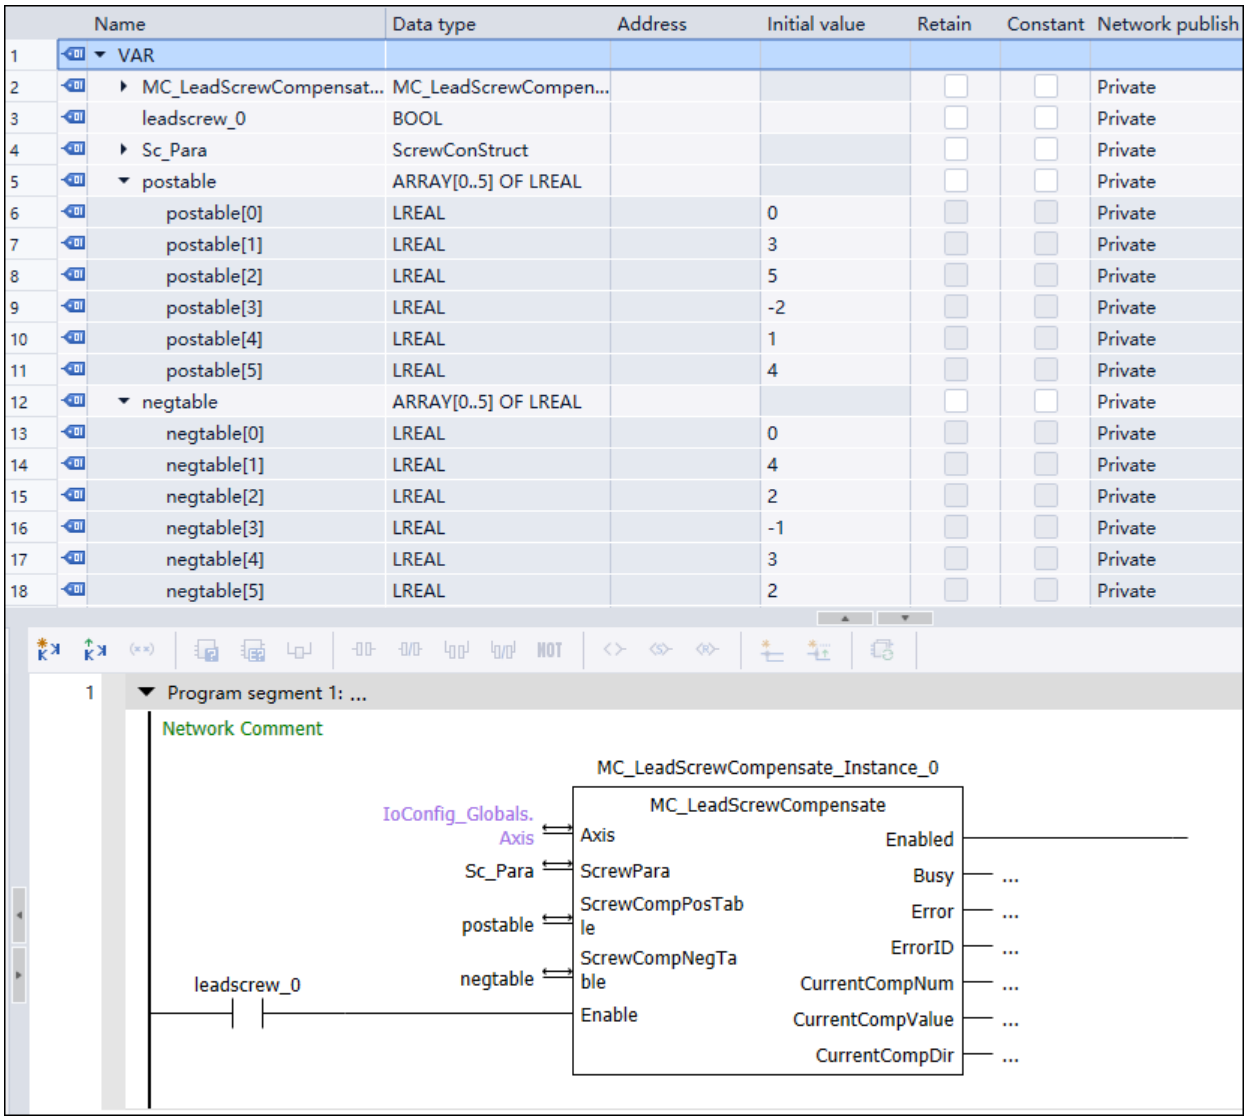
- **Timing diagram**

  After this instruction is called, the output parameter Busy is set to TRUE on a rising edge of Execute.



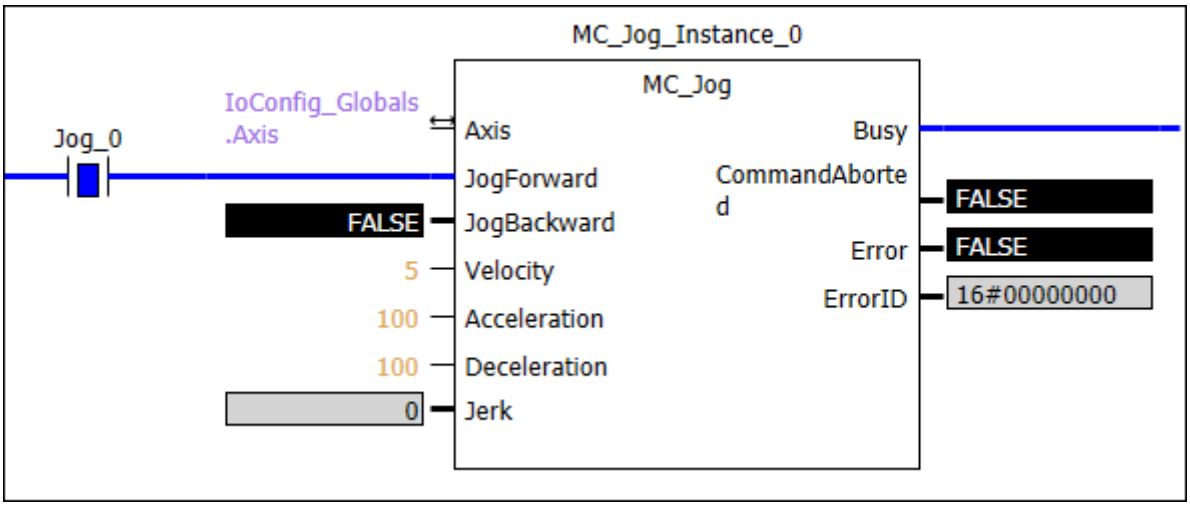
At this point, when the MC_Jog is executed, the axis motion is being compensated with the output parameter Enabled being set to TRUE and the output parameter CurrentCompDir being set to 1 (Positive direction); after the compensation, the output parameter Enabled is set to FALSE.

When the MC_Jog is executed in the negative direction, the axis motion is being compensated with the output parameter Enabled being set to TRUE and the output parameter CurrentCompDir being set to 0 (Negative direction); after the compensation, the output parameter Enabled is set to FALSE.

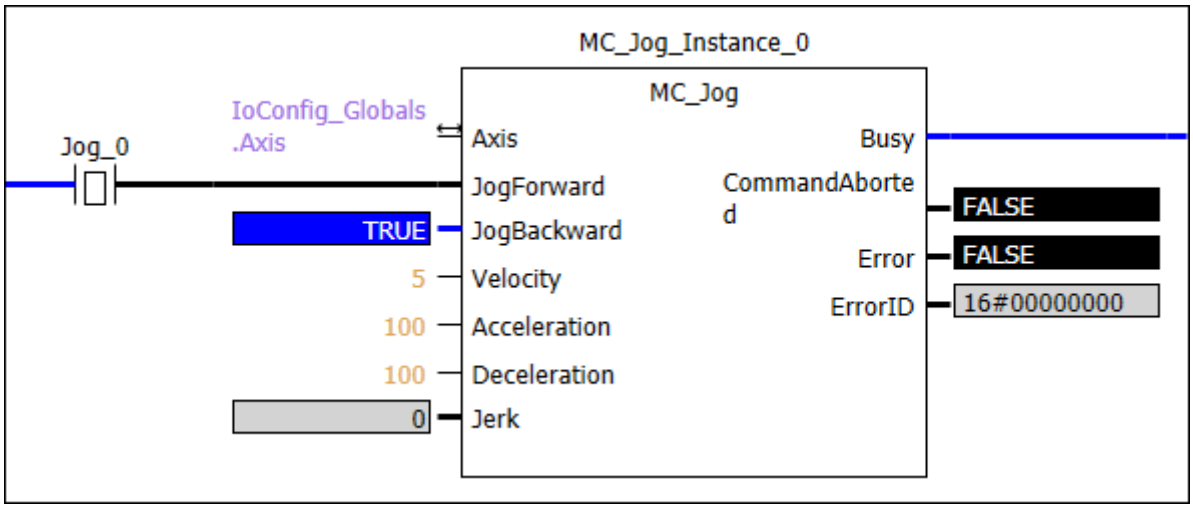


- **Example**

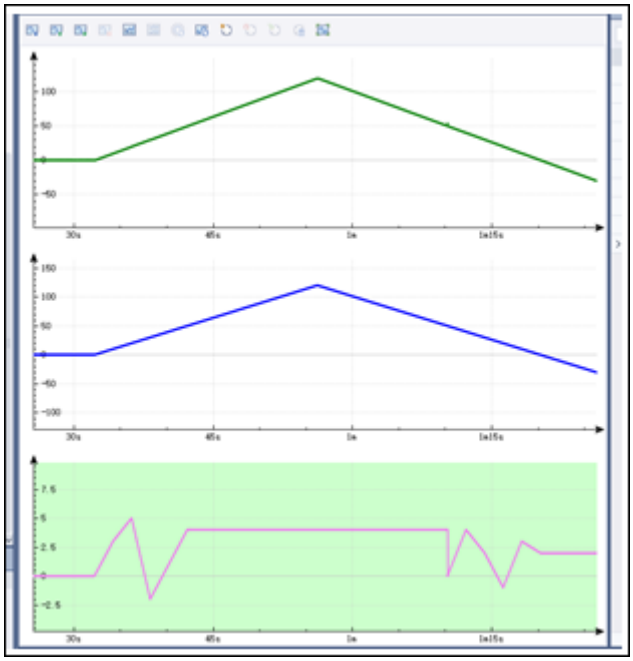
  1. Input the structure parameters, with the start and end points for bidirectional compensation being 0 and 50.



2. Input the positive and negative compensation tables.



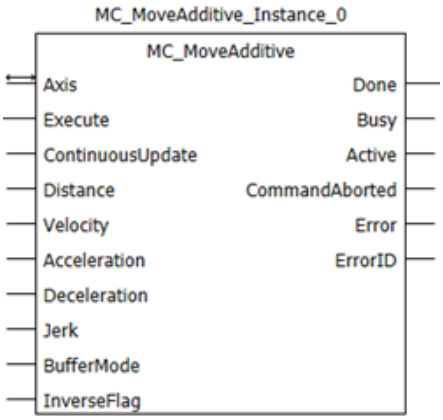
3. Execute the compensation instruction.



4. Execute the motion control instruction.

5. Execute the motion control instruction in the negative direction.

6. The actual position, planned position, and compensation value collected by the oscilloscope are shown in the following figure.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.3.58 MC_MoveAdditive

This instruction enables the original axis position reference to be added with a value specified in Distance. It is used for online position superimposition in the axis control process. This instruction can be executed at any time when the axis is in the Discrete Motion state. When the axis is in the Standstill state, this instruction is equivalent to MC_MoveRelative.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_MoveAdditive	Add a distance to the last specified target position		MC_MoveAdditive_Instance_0(Axis :=, Execute :=, ContinuousUpdate :=, Distance := , Velocity := , Acceleration :=, Deceleration :=, Jerk := , BufferMode := , InverseFlag :=, Done =>, Busy => , Active =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	Execute the instruction.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
ContinuousUpdate	Continuous update	BOOL	TRUE, FALSE	FALSE	Continuous parameter update effective flag. Prerequisite: The parameter ContinuousUpdate shows the value TRUE and the parameter Active shows the value TRUE. Effective parameters: Position, Velocity. Note: The modified parameter values must differ from the original parameter values by more than 0.01.
Distance	Position reached	LREAL	Positive number, negative number, or 0	0	Position data [u] to be added.
Velocity	Velocity	LREAL	Positive number	0	Maximum velocity [u/s], which may not be reached (cannot be zero).
Acceleration	Acceleration	LREAL	Positive number	0	Acceleration [u/s^2] of the acceleration phase.
Deceleration	Deceleration	LREAL	Positive number	0	Deceleration [u/s^2] of the deceleration phase.
Jerk	Jerk	LREAL	Positive number	0	Slope [u/s^3] of acceleration or deceleration. (Only valid for S-curve planning).

Input Variable	Name	Data Type	Valid Range	Default Value	Description
BufferMode	Buffer mode	18.3.3.2.2.6 MC_BUFFER_MODE: Buffer Mode Enumeration	0: mcAborting 1: mcBuffered 2: mcBlendingLow 3: mcBlendingPrevious 4: mcBlendingNext 5: mcBlendingHigh	0	0: mcAborting (Aborting). 1: mcBuffered (Buffered). 2: mcBlendingLow (Blending with the lowest velocity of both FBs). 3: mcBlendingPrevious (Blending with the velocity of the first FB). 4: mcBlendingNext (Blending with velocity of the second FB). 5: mcBlendingHigh (Blending with highest velocity of both FBs).
InverseFlag	Inverse enable	BOOL	TRUE, FALSE	FALSE	FALSE:The planned position cannot be beyond the target position. When the target velocity is not reached, the planned parameters (End Velocity, Acceleration/Deceleration, Jerk) will be modified to meet the planning requirements. TRUE: The planned position can be beyond the target position. If the axis moves beyond the target position, it will move for an additional cycle.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Active	Controlling	BOOL	TRUE, FALSE	FALSE	TRUE when the axis is being controlled by the current FB.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Parameter correction**

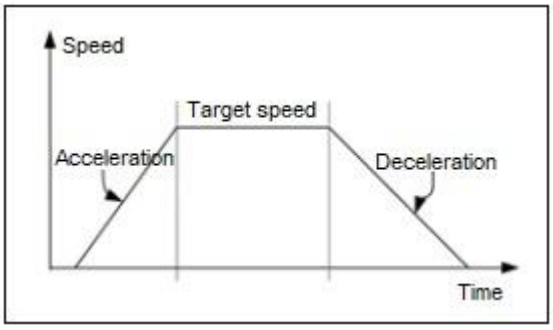
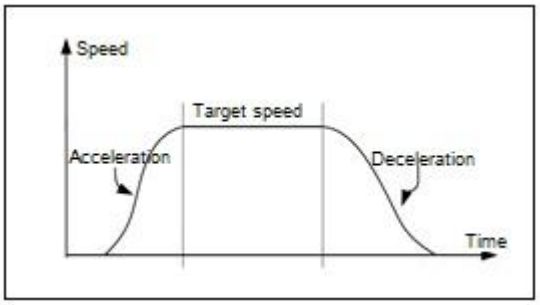
Velocity	Velocity	Any velocity that exceeds the motion parameter limit will be automatically corrected to the velocity limit.	Any velocity less than 0 will be automatically corrected to 1e-5.	• When the MotionControl library version is 2.1.0.0 or earlier, the velocity equal to 0 will be automatically corrected to 1e-5. • When the MotionControl library version is 2.2.0.0 or later, the velocity equal to 0 will not be corrected.



Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Acceleration	Acceleration	Any acceleration that exceeds the motion parameter limit will be automatically corrected to the acceleration limit.	• When the MotionControl library version is 2.3.0.0 or earlier, the acceleration less than 0 will be automatically corrected to 10% of the acceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the acceleration less than 0 will be automatically corrected to 10 times the velocity.	• When the MotionControl library version is 2.3.0.0 or earlier, the acceleration equal to 0 will be automatically corrected to 10% of the acceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the acceleration equal to 0 will be automatically corrected to 10 times the velocity.
Deceleration	Deceleration	Any deceleration that exceeds the motion parameter limit will be automatically corrected to the deceleration limit.	• When the MotionControl library version is 2.3.0.0 or earlier, the deceleration less than 0 will be automatically corrected to 10% of the deceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the deceleration less than 0 will be automatically corrected to 10 times the velocity.	• When the MotionControl library version is 2.3.0.0 or earlier, the deceleration equal to 0 will be automatically corrected to 10% of the deceleration limit. • When the MotionControl library version is 2.4.0.0 or later, the deceleration equal to 0 will be automatically corrected to 10 times the velocity.

Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Jerk	Jerk	If the motion profile is set to S-curve, any jerk that exceeds the software limit will be automatically corrected to the jerk limit.	If the motion profile is set to S-curve, any jerk less than 0 will be automatically corrected to 10% of the jerk limit.	If the motion profile is set to S-curve, the jerk equal to 0 will be automatically corrected to 10% of the jerk limit.



- **Function**

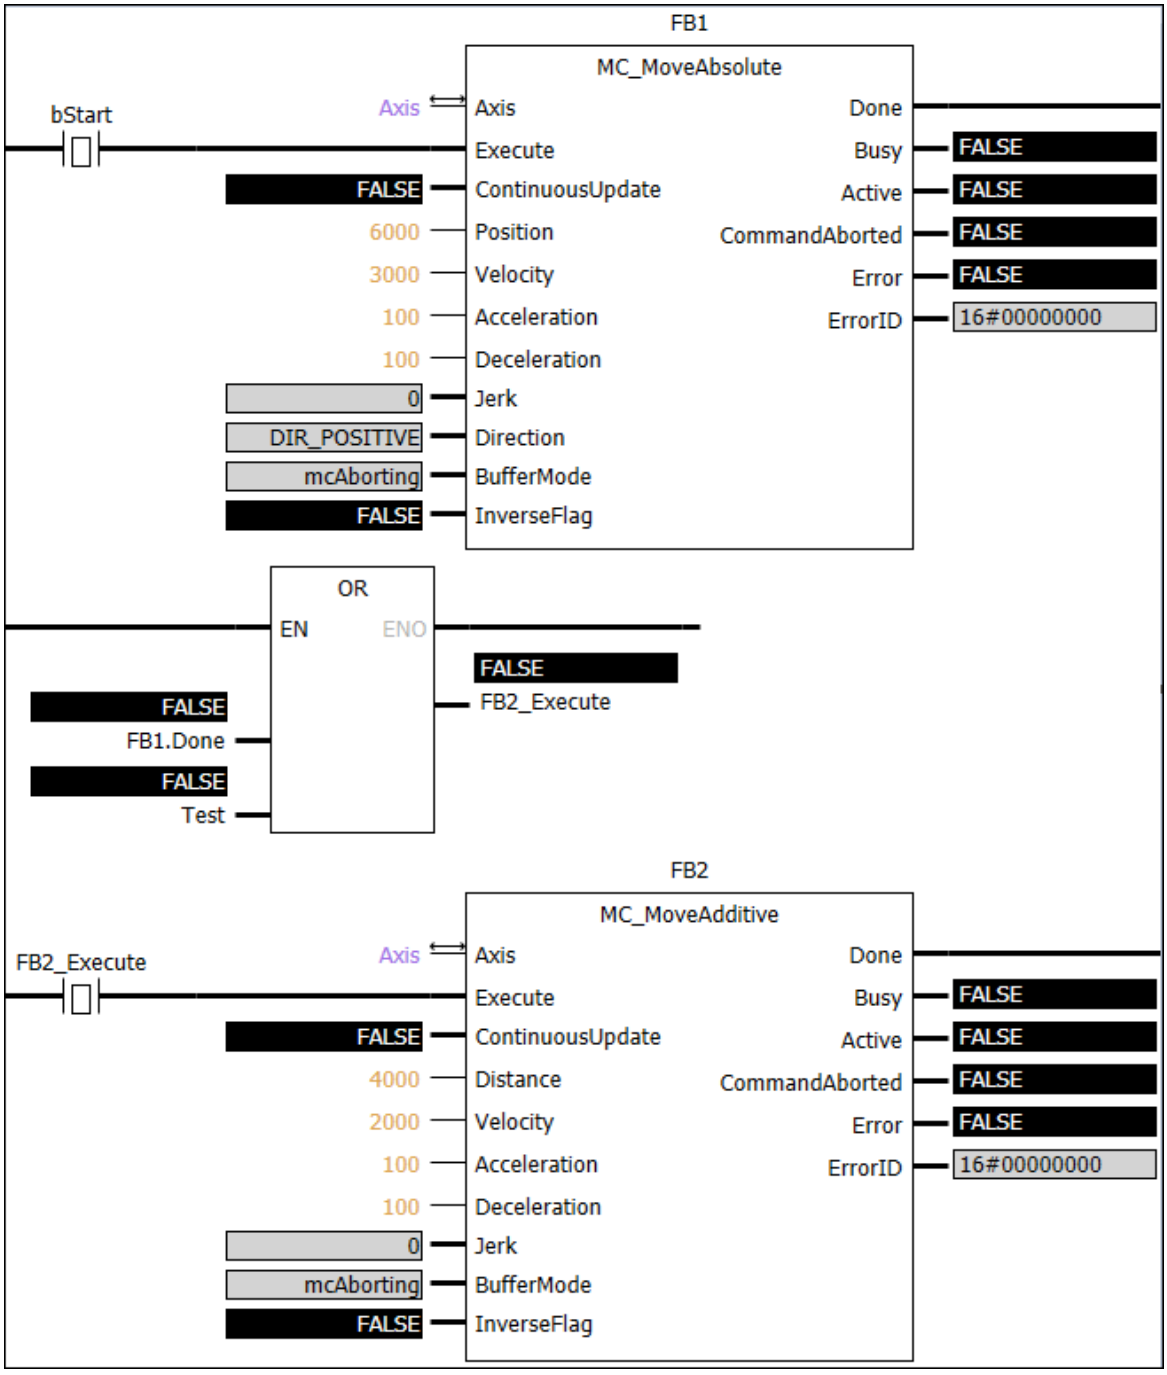
  Bus-controlled axis:

  - This function block is used to add a Distance to an active motion instruction for an axis.
  - When the axis state is Discrete Motion, CommandAborted of other instructions will be set when this function block is running.
  - When the axis state is Standstill, this instruction can be executed independently to achieve relative positioning.
  - This function block is executed on the rising edge of Execute.
  - When the input parameter ContinuousUpdate is set to TRUE, modified parameters Distance and Velocity will take effect only when the function block is in the Active state. Parameter changes greater than 0.01 are considered updates. Modified BufferMode cannot take effect during this period, and the buffer mode at the time of the instruction trigger is retained. When the output parameter Done is set, it indicates that the instruction has completed the motion, and any changes to the parameters will not take effect.
  - When the T-curve is specified in the software, the input parameter Jerk is invalid.
    T-curve acceleration/deceleration motion:

    S-curve acceleration/deceleration motion:

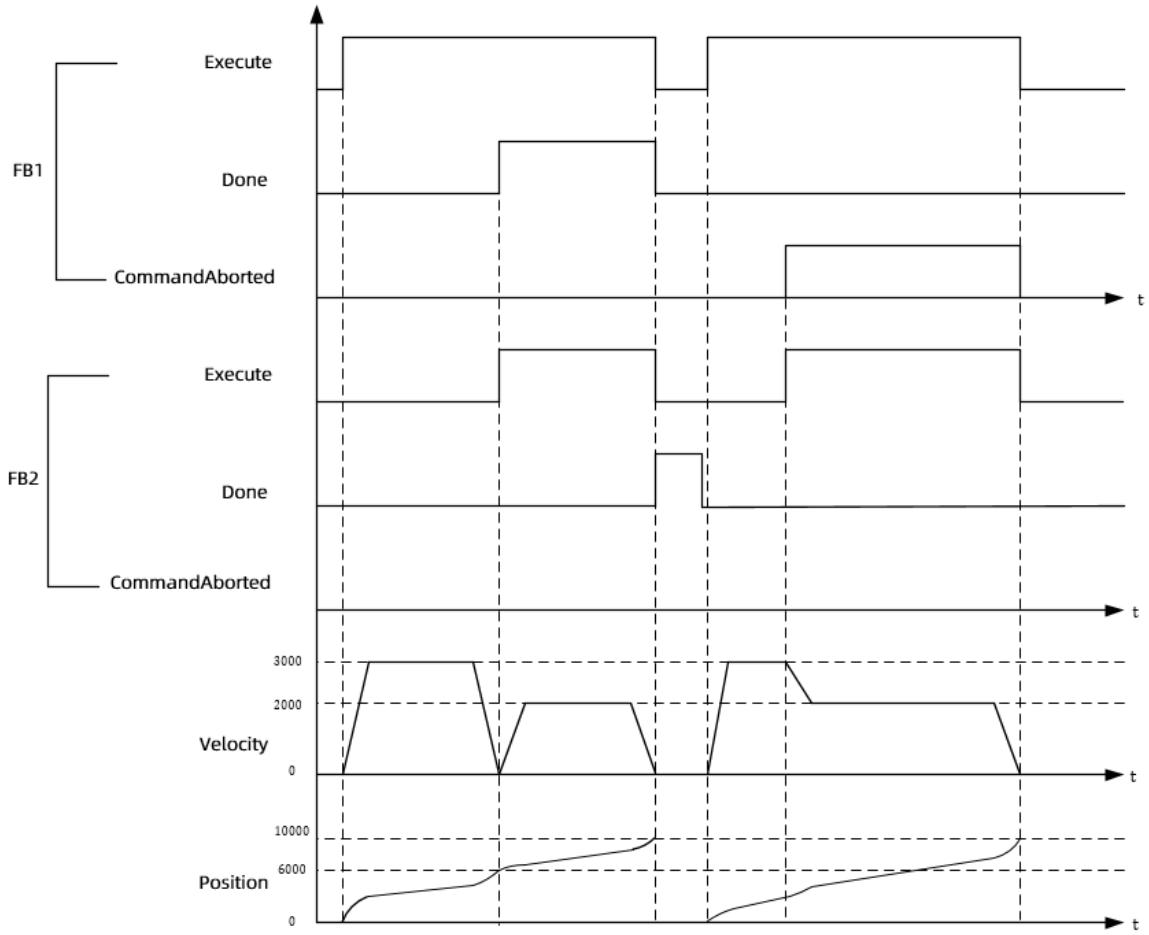
  - The arrival check function is only applicable to MotionControl library version 2.4.0.0 or later. Based on the "Positioning range" and "Positioning check time" parameters in the "General setting" of the axis configuration page, it checks in real time whether the actual position has entered the specified target range. After the instruction output for the target position is completed, positioning is complete and the Done output is set if the difference between the actual position and the target position is smaller than

the "Positioning range". If positioning is not completed within the "Positioning check time", a fault will occur.



Local pulse axis:

This instruction can be used for local pulse axes.

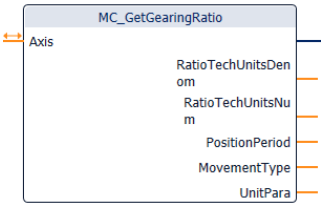


- **Timing diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Done of the function block indicates the instruction has been executed successfully; the parameter Busy indicates that the current function block is being executed; the parameter CommandAborted indicates that the instruction is aborted by another motion control instruction, at which point the flag is set to TRUE.

  This instruction is usually used in combination with primary motion instructions such as MC_MoveAbsolute and MC_MoveRelative. For example, it can be executed after or during absolute positioning. An example is shown below.

The timing diagram is shown below.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.3.59 MC_GetGearingRatio

This instruction reads the electronic gear ratio, rotation cycle, and motion type parameters of the axis.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_GetGearingRatio	Get the electronic gear ratio, rotation cycle, and motion type of the axis		:= MC_GetGearingRatio(Axis := , RatioTechUnitsDenom => , RatioTechUnitsNum => , PositionPeriod => , MovementType => , UnitPara =>);

- **Related variables**

  In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
RatioTechUnitsDenom	Denominator of gear ratio	DWORD	Depends on data type	0	Denominator of the conversion factor for converting pulse unit to user unit.
RatioTechUnitsNum	Numerator of gear ratio	LREAL	Depends on data type	0	Numerator of the conversion factor for converting pulse unit to user unit.
PositionPeriod	Rotation cycle	LREAL	Depends on data type	0	Valid only in rotary mode.
MovementType	Motion type	INT	0, 1	0	0: Rotary mode. 1: Linear mode.
UnitPara	Unit conversion parameter	MC_UNITCONVERSION_PARAMETER	Depends on data type	-	Includes user display unit, reversal direction, number of instruction pulses per motor rotation, reducer use, worktable travel per rotation, gear ratio on the workpiece side, and gear ratio on the motor side.

- **Function**

  Bus-controlled axis:

  - This instruction is valid only for bus-controlled axes and local pulse axes.
  - The data type of UnitPara is MC_UNITCONVERSION_PARAMETER. The meanings of the structure members are shown in the table below.

Variable	Data Type	Description
eUnitDisplay	MC_UNITS	User display unit 0: pulse 1: mm 2: μm 3: nm 4: degree 5: inch
xInvertDirection	BOOL	If set to TRUE, the direction is reversed.
udiCmdPlsCountPerMotorRotation	UDINT	Number of command pulses per motor rotation
fWorkTravelDistancePerMotorRotation	LREAL	Worktable travel per rotation
xReducerUse	BOOL	TRUE when the reducer is used.
udiWorkSideGearRatio	UDINT	Gear ratio on the workpiece side
udiMotorSideGearRatio	UDINT	Gear ratio on the motor side

- This function block dynamically modifies the content in the axis configuration interface during program execution, as shown below.

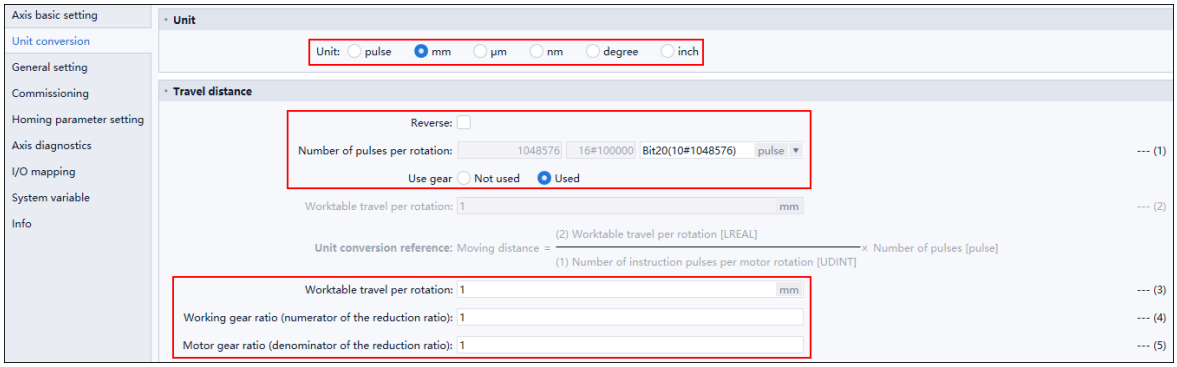


Figure 18-3-3-3-59-1 Unit conversion interface

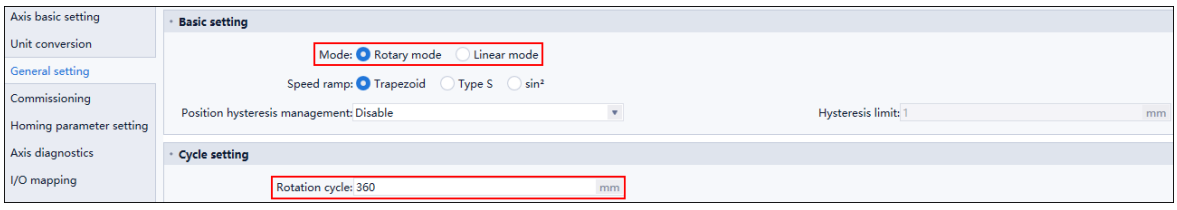

Figure 18-3-3-3-59-2 General setting interface

- During program execution, if the gear ratio related data is modified using the function block MC_ChangeGearingRatio or other methods, the data in the parameter UnitPara will not be updated and will remain consistent with the value set in the axis configuration interface.

Local pulse axis:

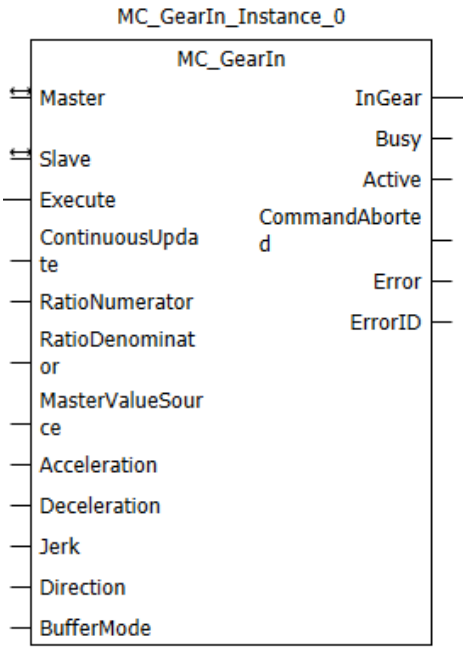
This instruction can be used for local pulse axes.

- **Faults**

This instruction is a function (FC). When the function return value is FALSE, it indicates that the "Axis" parameter is not an axis instance or the axis type is mismatched.

18.3.3.4 Cam

18.3.3.4.1 Instruction List



Instruction	Function	Library	Applicable Library Version
18.3.3.4.2 MC_GearIn	Start gearing	MotionControl	Library version 1.1.0.0 and later
18.3.3.4.3 MC_GearOut	Desynchronize gearing		Library version 1.1.0.0 and later
18.3.3.4.4 MC_Phasing	Master axis phase shifting		Library version 1.1.0.0 and later
18.3.3.4.5 MC_StopPhasing	Stop master axis phase shifting		Library version 1.1.0.0 and later
18.3.3.4.6 MC_GearInPos	Start gearing with specified positions		Library version 1.1.0.0 and later
18.3.3.4.7 MC_GetCamTablePhase	Get cam table phase		Library version 1.1.0.0 and later
18.3.3.4.8 MC_GetCamTableDistance	Get cam table displacement		Library version 1.1.0.0 and later
18.3.3.4.9 MC_DigitalCamSwitch	Enable digital cam switch		Library version 1.1.0.0 and later
18.3.3.4.10 MC_GenerateCamTable	Update the cam table with specified cam data		Library version 1.1.0.0 and later
18.3.3.4.11 MC_WriteCAM	Store the edited cam table as a file		Library version 1.1.0.0 and later
18.3.3.4.12 MC_ReadCAM	Read the cam data file into a cam table		Library version 1.1.0.0 and later
18.3.3.4.13 MC_CAMBounds	Calculate maximum position, velocity, and acceleration of the slave axis		Library version 1.1.0.0 and later
18.3.3.4.14 MC_CamIn	Start camming		Library version 1.1.0.0 and later
18.3.3.4.15 MC_CamInV2	Start camming		Library version 2.0.0.0 and later
18.3.3.4.16 MC_CamOut	Desynchronize camming		Library version 1.1.0.0 and later
18.3.3.4.17 MC_CombineAxes	Output the sum or difference of the position references of two axes as a new position reference		Library version 1.1.0.0 and later
18.3.3.4.18 MC_AxesObserve	Observe position deviation between master and slave axes		Library version 1.1.0.0 and later
18.3.3.4.19 MC_CheckCamTable	Check cam table node data		Library version 2.0.0.0 and later

Instruction	Function	Library	Applicable Library Version
18.3.3.4.20 MC_CamNodeBinding	Cam node binding		Library version 2.1.0.0 and later
18.3.3.4.21 MC_MoveLink	Synchronous positioning		Library version 1.1.0.0 and later
18.3.3.4.22 MC_PhasingEx	Complete phase shifting within specified master axis travel distance		Library version 1.1.0.0 and later

18.3.3.4.2 MC_GearIn

Start electronic gearing according to the specified gear ratio of the master axis to the slave axis.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_GearIn	Start electronic gearing		MC_GearIn_Instance_0(Master :=, Slave :=, Execute :=, ContinuousUpdate :=, RatioNumerator :=, RatioDenominator :=, MasterValueSource :=, Acceleration :=, Deceleration :=, Jerk :=, Direction :=, BufferMode :=, InGear =>, Busy =>, Active =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

  In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Master	Master axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the master axis; an instance of AXIS_REF.
Slave	Slave axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the slave axis; an instance of AXIS_REF.

Input variables

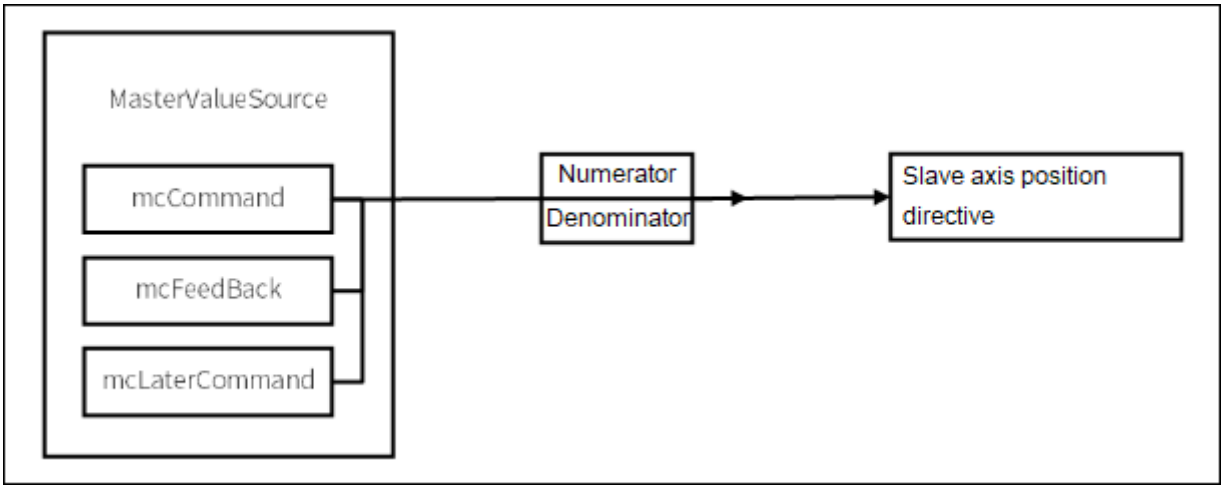
Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	Execute the instruction on a rising edge.
ContinuousUpdate	Continuous update	BOOL	TRUE, FALSE	FALSE	TRUE: Modified parameter values are valid with no need for re-executing this instruction. FALSE: Modified parameter values are valid only after this instruction is re-executed.
RatioNumerator	Gear ratio numerator	DINT	Positive number or negative number	1	Specify the gear ratio numerator. A negative value indicates that the slave axis moves in the opposite direction of the master axis.
RatioDenominator	Gear ratio denominator	UDINT	Positive number	1	Specify the gear ratio denominator (range: 0–2^{31}).
MasterValueSource	Master axis data type	18.3.3.2.2.11 MC_REFERENCE_TYPE: Data Type Enumeration	0: mcCommand 1: mcFeedback 2: mcLaterCommand	0	0: Value calculated in the previous task cycle (fSavePosition). 1: Value obtained in the same task cycle (fActPosition). 2: Value calculated in the same task cycle (fSetPosition).
Acceleration	Acceleration	LREAL	Positive number	0	Specify the maximum acceleration [u/s^2] of the slave axis during the catching phase.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Deceleration	Deceleration	LREAL	Positive number	0	Specify the maximum deceleration [u/s^2] of the slave axis during the catching phase.
Jerk	Jerk	LREAL	0	0	Reserved parameter. It currently applies to the T-curve only.
Direction (reserved parameter for future function development)	Direction	18.3.3.2.2.9 MC_DIRECTION: Motion Direction Enumeration	1: DIR_POSITIVE 2: DIR_NEGATIVE 4: DIR_NODIRECTION	1	1: DIR_POSITIVE: The slave axis follows the master axis only when the master axis moves in the positive direction. The slave axis decelerates to stop according to settings when the master axis moves in the negative direction, at which point the InGear state is inactive. The InGear state is active when the master axis moves in the positive direction again. 2: DIR_NEGATIVE: Opposite of POSITIVE. 4: DIR_NODIRECTION: The slave axis follows the master axis regardless of the motion directions of the master axis. The InGear state remains latched once active.
BufferMode	Buffer mode	18.3.3.2.2.6 MC_BUFFER_MODE: Buffer Mode Enumeration	0: mcAborting 1: mcBuffered	0	0: Aborting. 1: Buffered.

Output variables

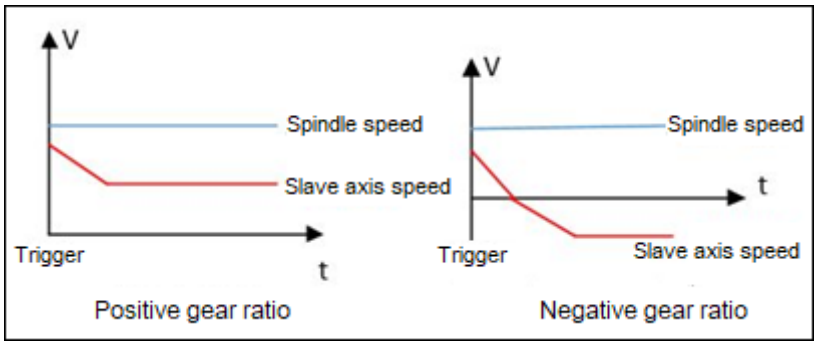
Output Variable	Name	Data Type	Valid Range	Default Value	Description
InGear	Gear ratio reached	BOOL	TRUE, FALSE	FALSE	Conditions for setting the variable to TRUE: 1. The velocity reference equals the target velocity. 2. Slave axis acceleration: Velocity greater than the target velocity. 3. Slave axis deceleration: Velocity less than the target velocity.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Active	Controlling	BOOL	TRUE, FALSE	FALSE	TRUE when the axis is being controlled.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.



- **Parameter correction**

Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Acceleration	Acceleration	Any acceleration that exceeds the motion parameter limit will be automatically corrected to the acceleration limit.	Any acceleration less than 0 will be automatically corrected to 10% of the acceleration limit.	Any acceleration equal to 0 will be automatically corrected to 10% of the acceleration limit.
Deceleration	Deceleration	Any deceleration that exceeds the motion parameter limit will be automatically corrected to the deceleration limit.	Any deceleration less than 0 will be automatically corrected to 10% of the deceleration limit.	The deceleration equal to 0 will be automatically corrected to 10% of the deceleration limit.
Jerk	Jerk	If the motion profile is set to S-curve, any jerk that exceeds the software limit will be automatically corrected to the jerk limit.	If the motion profile is set to S-curve, any jerk less than 0 will be automatically corrected to 10% of the jerk limit.	If the motion profile is set to S-curve, the jerk equal to 0 will be automatically corrected to 10% of the jerk limit.



- **Function**

  Bus-controlled axis:

  - This instruction can be used to specify the slave axis as the target axis and specify the RatioNumerator, RatioDenominator, MasterValueSource, Acceleration, and Deceleration for gearing.
  - When the instruction is triggered on a rising edge of the input parameter Execute, the input parameters are checked for validity. If any of invalid parameters is detected, it will be automatically corrected by the function block without a fault message; any buffered instructions after this instruction will be cleared.

- After the corresponding instruction is started, the slave axis accelerates or decelerates to the target velocity, which is the product of the master axis velocity multiplied by the gear ratio.
- The period before reaching the target velocity is called the catching phase, and the period after reaching the target velocity is called the InGear phase.
- When the gear ratio is positive, the slave axis moves in the same direction as the master axis. When the gear ratio is negative, the slave axis moves in the opposite direction to the master axis. The relationships of the master and slave axis velocity with the gear ratio are shown in the following figure.

Relationships of the master and slave axis velocity with the gear ratio

- The master and slave axes specified in this instruction cannot be the same.
- This instruction starts electronic gearing on a rising edge of the parameter Execute.
- This instruction can be used in combination with other synchronous control instructions. Its in-out variable Master can be the master or slave axis of other synchronous control instructions; its in-out variable Slave can serve as the master axis of other synchronous control instructions.
- If bus cycle is specified for the cycle task of the master axis, the velocity of the slave axis may show a sudden jump after synchronization. It is recommended that users specify EtherCAT cycle for the cycle task of both the master and slave axes before enabling a synchronization instruction.
- MC_Home, MC_Homing, or MC_HomingWithParameter can be used during the instruction execution.

  This instruction places the master axis in the AXIS_HOMING state. If the instruction is executed while the master axis is already in this state, the signal source "MasterValueSource" must be set to "mcLatestCommand"; otherwise, the slave axis will overspeed.

Software limit:

- During the gearing with specified positions, if the slave axis position is beyond the software limit, this instruction will be aborted, and the slave axis will decelerate to 0 within one cycle with the axis state switched from AXIS_SYNCHRONIZED_MOTION to AXIS_ERRORSTOP.

Position type selection:

You can specify the MasterValueSource for synchronizing the slave axis based on the following options.

- mcCommand: Commanded position (Value calculated in the previous task cycle, fSavePosition)

  For the current cycle, use the master axis position calculated in the previous task cycle.

- mcFeedback: Actual position (Value obtained in the same task cycle, fActPosition).

  Use the actual master axis position obtained in the same task cycle.

- mcLaterCommand: Commanded position (Value calculated in the same task cycle, fSetPosition).

  Use the master axis position calculated in the same task cycle.

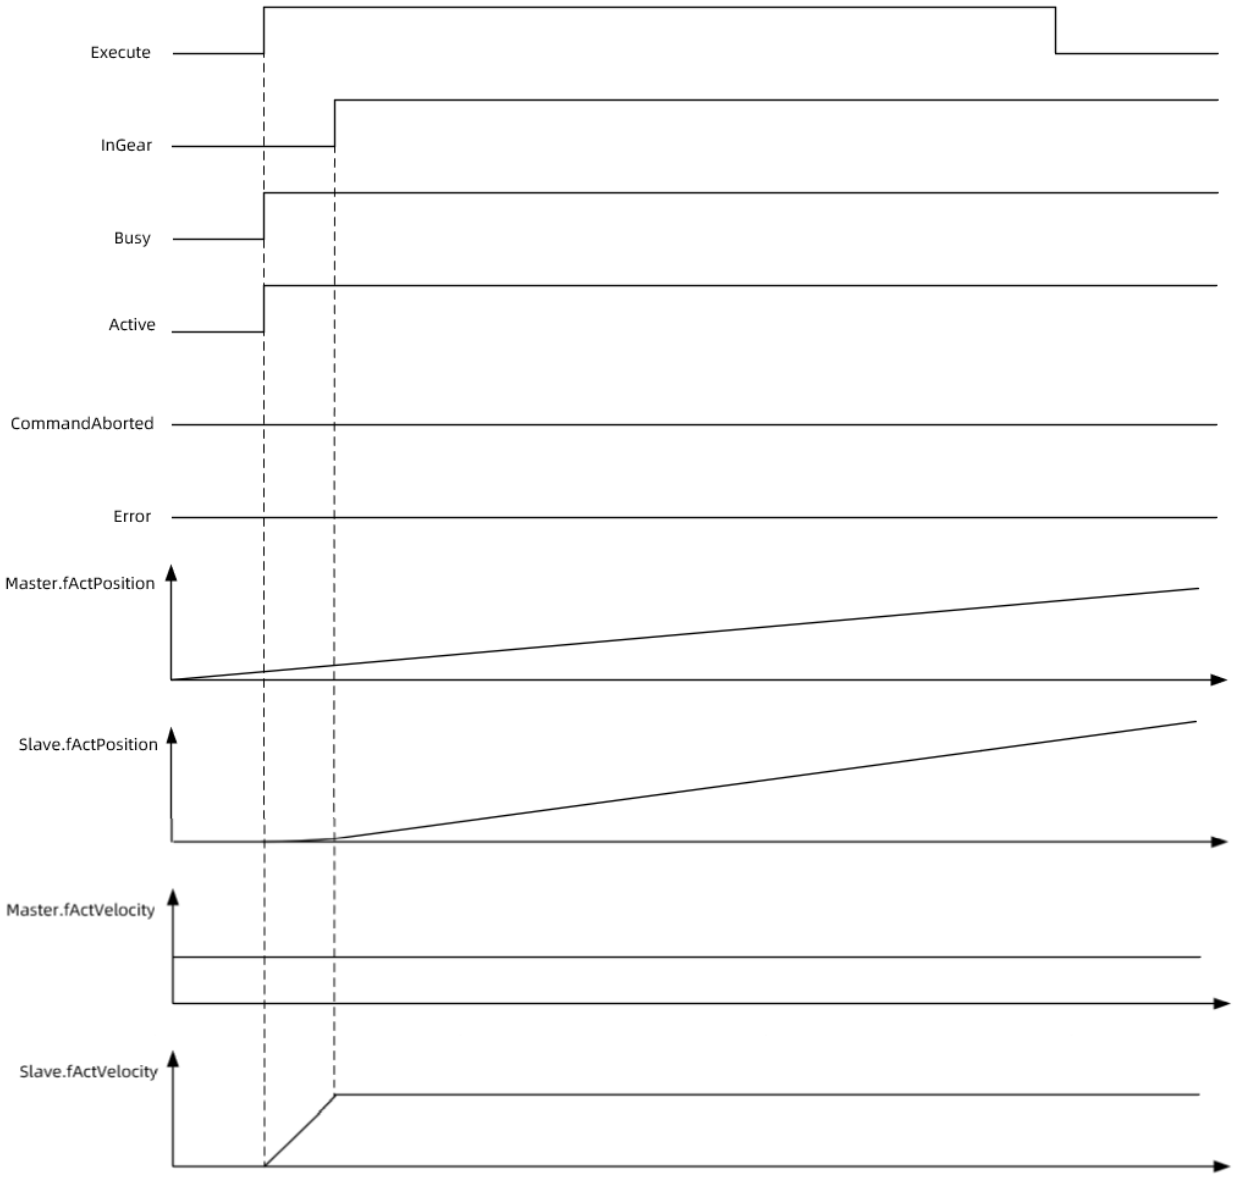
- When the master axis starting electronic gearing is specified as a virtual axis, the value of the input variable MasterValueSource cannot be set to 1 (mcFeedback); otherwise, a fault will occur.

Local pulse axis:

- This instruction can be used for local pulse axes.
- When the local pulse axis is used as the master axis with Y0 or Y1 single-ended output, it is not recommended to use this instruction. ① No pulse output; ② No position feedback.

Re-execution of motion control instructions:

- If this instruction is activated (Active = TRUE), re-executing it in mcBuffered mode will result in a fault, while re-triggering in mcAborting mode will allow it to run normally.
- If this instruction is not activated (Active = FALSE), it can be re-executed after its input parameters are modified.



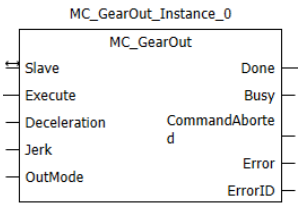
- **Timing diagram**

  When the parameter “Execute” is activated, the parameter “Busy” shows the value TRUE. After this instruction is activated, the parameter “Active” shows the value TRUE.

  When the target velocity is reached, the output parameter “InGear” shows the value TRUE.

  When this instruction is aborted by another instruction, the parameter “CommandAborted” shows the value TRUE, and the parameters “Busy”, “Active”, and “InGear” show the value FALSE.

  To terminate electronic gearing mid-way, use the MC_GearOut or MC_Stop instruction.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.4.3 MC_GearOut

This instruction desynchronizes electronic gearing between the master and slave axes triggered by the MC_GearIn or MC_GearInPos instruction.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_GearOut	Desynchronize gearing		MC_GearOut_Instance_0(Slave :=, Execute :=, Deceleration :=, Jerk :=, OutMode :=, Done =>, Busy =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Slave	Slave axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the slave axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	Execute the instruction on a rising edge.
Deceleration	Deceleration	LREAL	Positive number	0	Specify the maximum deceleration [u /s^2] of the slave axis when the electronic gearing between the master and slave axes is desynchronized.
Jerk	Jerk	LREAL	Positive number or 0	0	Slave axis jerk parameter.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
OutMode	Desynchronization mode	18.3.3.2.3.7 MC_OUTMODE: Desynchronization Mode Enumeration	0: mcDeceleration Stop 1: mcConstantVelocity	0	0: Deceleration stop. 1: Constant velocity before desynchronization.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Parameter correction**

Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Deceleration	Deceleration	Any deceleration that exceeds the motion parameter limit will be automatically corrected to the deceleration limit.	Any deceleration less than 0 will be automatically corrected to 10% of the deceleration limit.	The deceleration equal to 0 will be automatically corrected to 10% of the deceleration limit.
Jerk	Jerk	If the motion profile is set to S-curve, any jerk that exceeds the software limit will be automatically corrected to the jerk limit.	If the motion profile is set to S-curve, any jerk less than 0 will be automatically corrected to 10% of the jerk limit.	If the motion profile is set to S-curve, the jerk equal to 0 will be automatically corrected to 10% of the jerk limit.

- **Function**

Bus-controlled axis:

- This instruction can be used to specify the slave axis as the target axis, specify the OutMode, Deceleration, and Jerk, and abort the executing MC_GearIn or MC_GearInPos instruction.
- This instruction is executed on a rising edge of the input variable Execute.
- This instruction does not affect the operation of the master axis specified by the MC_GearIn or MC_GearInPos instruction.
- This instruction must be executed after the slave axis has executed the MC_GearIn or MC_GearInPos instruction. A fault occurs when this instruction is executed on an axis that does not start gearing.
- During the execution of this instruction, the MC_MoveSuperImposed instruction cannot be used. When the MC_MoveSuperImposed instruction is triggered, CommandAborted is set for the MC_MoveSuperImposed instruction.

Desynchronization mode:

- You can specify the mode by which the slave axis disengages from the master axis by defining the value of the input variable OutMode.
- When the OutMode is set to 0, the slave axis decelerates to "0" according to the Deceleration specified in this instruction. In the deceleration stop mode, the slave axis state switches from SynchronizedMotion to DiscreteMotion, and becomes StandStill when its velocity reaches 0.
- When the OutMode is set to 1, the slave axis continues to move at a constant velocity while the gearing stops, and switches from SynchronizedMotion to ContinuousMotion state.

Local pulse axis:

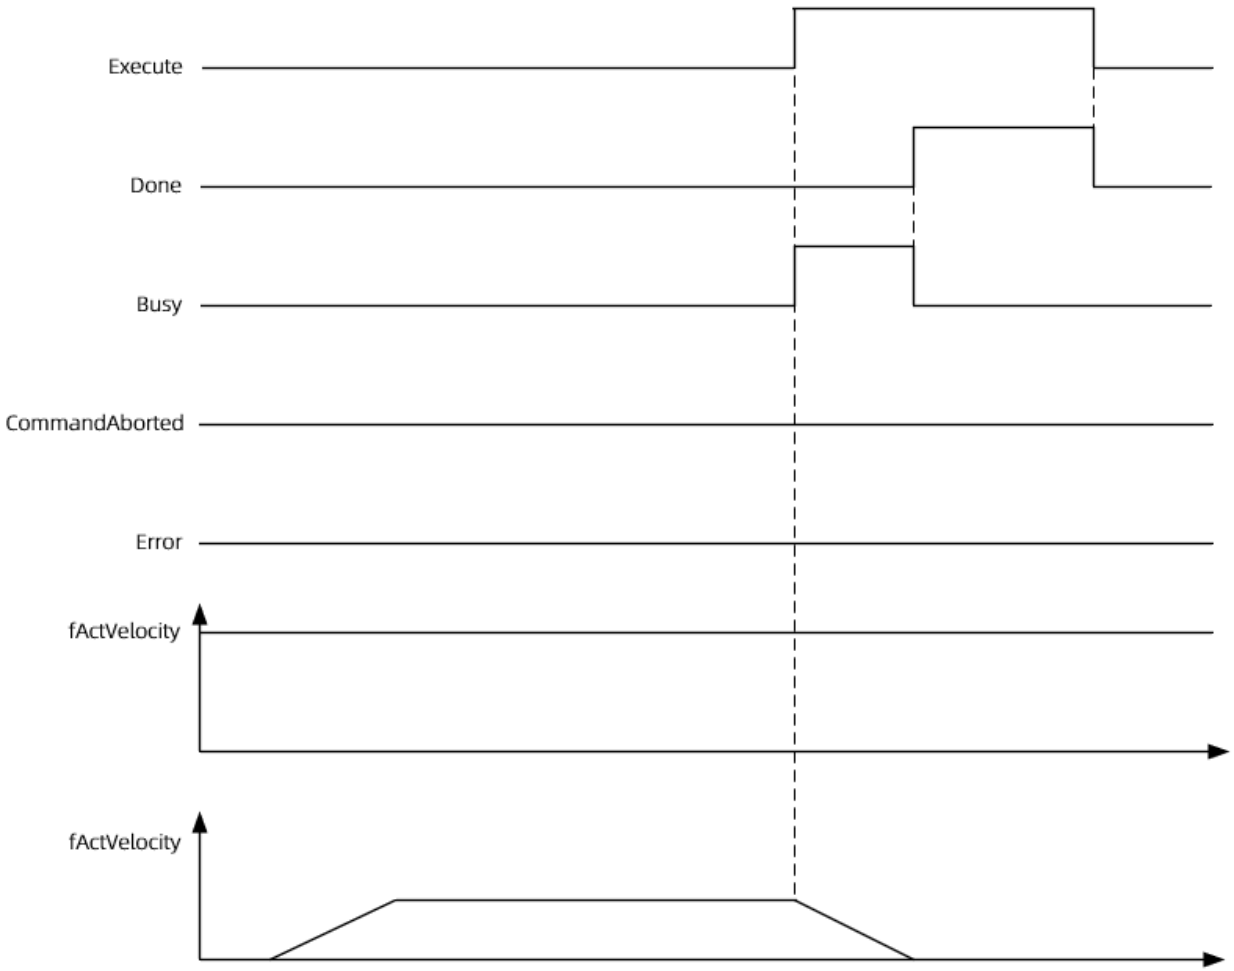
- This instruction can be used for local pulse axes.

Re-execution of motion control instructions:

- This instruction can be re-executed.
- Do not modify the value of OutMode when this instruction is re-executed.
- When the OutMode is set to 0 (mcDecelerationStop), and this instruction is re-triggered after modifying the Deceleration and Jerk values, the slave axis disengages from the master axis in the deceleration stop mode according to the modified parameter values.
- If either of the modified Deceleration and Jerk values is invalid, it will be automatically corrected by the function block without a fault message. The slave axis velocity will decelerate to 0 within one cycle, with the axis state switching from ContinuousMotion to ErrorStop.

Software limit:

- When the slave axis position is beyond the software limit while disengaging from the master axis, this instruction is aborted, and the slave axis velocity decelerates to 0 within one cycle. In the mcDecelerationStop mode, the slave axis state switches from DiscreteMotion to ErrorStop. In the mcConstantVelocity mode, the slave axis state switches from ContinuousMotion to ErrorStop.



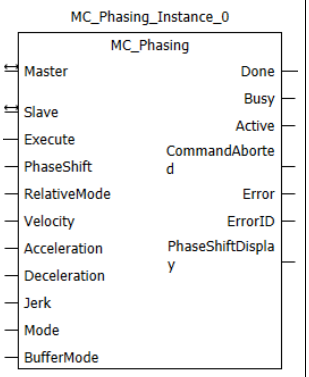
- **Precautions**
  - When the OutMode is set to 1 (mcConstantVelocity) and the instruction is executed, the parameter Done is set to TRUE, and the parameter Busy remains TRUE until this instruction is aborted by next instruction, at which point the parameter Busy is set to FALSE. Therefore, to stop the slave axis in the mcConstantVelocity mode, this instruction must be used in conjunction the MC_Stop instruction.
  - During the execution of this instruction, if a fault occurs on the slave axis, the command aborted flag will be set, and the slave axis will stop immediately.

- This instruction can abort an executing MC_MoveSuperImposed instruction.
- If the MC_MoveSuperImposed instruction is executed during the execution of this instruction, the OutMode = 0 (mcDecelerationStop) will cause the MC_MoveSuperImposed instruction to abort directly.
- When the OutMode is set to 0 (mcDecelerationStop) or 1 (mcConstantVelocity) by this instruction, the MC_SetOverride (Change the motion parameter scaling factor) instruction is disabled.

- **Timing diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Done of the function block indicates the instruction has been executed successfully; the parameter Busy indicates that the current function block is being executed; the parameter CommandAborted indicates that the instruction is aborted by another motion control instruction, at which point the flag is set to TRUE.

  This instruction is executed on a rising edge of the parameter Execute to end electronic gearing, with the output parameter Busy showing the value TRUE. After electronic gearing ends completely, the output parameter Done shows the value TRUE. If the OutMode is set to mcDecelerationStop, the parameter Busy shows the value FALSE. If the OutMode is set to mcConstantVelocity, the parameter Busy remains the value TRUE. The following is the timing diagram when the OutMode is set to mcDecelerationStop.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.4.4 MC_Phasing

This instruction starts master axis phase shifting according to the phase shift reference.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_Phasing	Master axis phase shifting		MC_Phasing_Instance_0(Master :=, Slave :=, Execute :=, PhaseShift :=, RelativeMode :=, Velocity :=, Acceleration :=, Deceleration :=, Jerk :=, Mode :=, BufferMode :=, Done =>, Busy =>, Active =>, CommandAborted =>, Error =>, ErrorID =>, PhaseShiftDisplay =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Master	Master axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the master axis; an instance of AXIS_REF.
Slave	Slave axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the slave axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	Execute the instruction on a rising edge.
PhaseShift	Phase shift	LREAL	-	0	Phase shift [u] between the master and slave axes. Positive values indicate that the slave axis leads the master axis.
RelativeMode	Phase shifting mode	BOOL	TRUE, FALSE	FALSE	FALSE: Specify PhaseShift to be an absolute phase shift. TRUE: Specify PhaseShift to be the original phase shift plus an additional phase.
Velocity	Target velocity	LREAL	Positive number	0	Specify the target velocity [u/s] for phase shifting.
Acceleration	Target acceleration	LREAL	Positive number	0	Specify the target acceleration [u/s^2] for phase shifting.
Deceleration	Target deceleration	LREAL	Positive number	0	Specify the target deceleration [u/s^2] for phase shifting.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Jerk	Jerk	LREAL	Positive number or 0	0	Specify the target jerk [u/s^3] for phase shifting. 0: T-curve. Non-zero: S-curve.
Mode	Compensation mode	INT	0, 1	0	0: Phase shifting continues when the master axis velocity is 0. 1: Phase shifting stops when the master axis velocity is 0, with the slave axis performing an immediate stop; phase shifting resumes when the master axis moves again.
BufferMode	Buffer mode	18.3.3.2.2.6 MC_BUFFER_MODE: Buffer Mode Enumeration	0: mcAborting	0	0: Aborting. (Reserved for other modes)

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Active	Controlling	BOOL	TRUE, FALSE	FALSE	TRUE when the axis is being controlled.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.
PhaseShiftDisplay	Phase shift display	LREAL	-	0	Real-time display of the master axis phase shift [u].

- **Parameter correction**

Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Velocity	Velocity	Any velocity that exceeds the motion parameter limit will be automatically corrected to the velocity limit.	Any velocity less than 0 will be automatically corrected to 1e-5.	The velocity equal to 0 will be automatically corrected to 1e-5.
Acceleration	Acceleration	Any acceleration that exceeds the motion parameter limit will be automatically corrected to the acceleration limit.	Any acceleration less than 0 will be automatically corrected to 10% of the acceleration limit.	Any acceleration equal to 0 will be automatically corrected to 10% of the acceleration limit.
Deceleration	Deceleration	Any deceleration that exceeds the motion parameter limit will be automatically corrected to the deceleration limit.	Any deceleration less than 0 will be automatically corrected to 10% of the deceleration limit.	The deceleration equal to 0 will be automatically corrected to 10% of the deceleration limit.

Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Jerk	Jerk	If the motion profile is set to S-curve, any jerk that exceeds the software limit will be automatically corrected to the jerk limit.	If the motion profile is set to S-curve, any jerk less than 0 will be automatically corrected to 10% of the jerk limit.	If the motion profile is set to S-curve, the jerk equal to 0 will be automatically corrected to 10% of the jerk limit.

- **Function**

  Bus-controlled axis:

  - When this instruction is executed in the synchronous control mode, the master axis phase shifting is started based on the PhaseShift, Velocity, Acceleration, and Deceleration references.
  - This instruction is triggered on a rising edge of the input parameter Execute.
  - This instruction must be used during the execution of the synchronous control instructions. If it is triggered in a non-synchronous control state, a fault will occur.
  - If this instruction reports a fault, any buffered instructions after this instruction will be cleared.
  - Once a synchronous control instruction is completed, any incomplete phase shifting will stop and a fault will occur.
  - You can shift the phase of the master axis for the following synchronous control instructions: MC_CamIn, MC_GearIn, MC_GearInPos, and MC_MoveLink.

  PhaseShift

  - This parameter is used to specify the master axis phase shift relative to the slave axis.
  - Positive PhaseShift values indicate that the slave axis position leads the master axis position.

  Velocity, Acceleration, Deceleration, Jerk

  - The target velocity, target acceleration, target deceleration, and target jerk for phase shifting are specified through the input parameters Velocity, Acceleration, Deceleration, and Jerk.
  - If the Velocity, Acceleration, and/or Deceleration are set to values less than or equal to 0, they will be automatically corrected by the function block without any fault message.
  - If the input value of Jerk is not equal to 0 and the slave axis motion profile is set to T-curve, the Jerk value will not be valid. If the slave axis motion profile is set to S-curve, the Jerk value will be checked for validity, and any input values less than or equal to 0 will be automatically corrected by the function block without any fault message.

  Phase shifting mode (RelativeMode)

  Set the phase shifting mode by defining the input variable RelativeMode.

  FALSE: Specify PhaseShift to be an absolute phase shift.

  TRUE: Specify PhaseShift to be the original phase shift plus an additional phase.

  When multiple instantiated MC_Phasing instructions are executed sequentially or the same MC_Phasing instruction is executed multiple times, phase addition is performed cumulatively, which means that the previously added phases affect the phase addition specified by subsequent instantiated MC_Phasing instructions. The instances are as follows.

  For example:

① When MC_Phasing_Instance_0 is executed with RelativeMode = FALSE and PhaseShift = 500, phase addition is performed; when MC_Phasing_Instance_1 is executed with RelativeMode = TRUE and PhaseShift = 400 after the phase addition specified by MC_Phasing_Instance_0, phase addition is performed again.

That is, when MC_Phasing_Instance_1 is executed with RelativeMode = TRUE, the PhaseShift specified in this instruction is added on top of the previously added phases.

② When MC_Phasing_Instance_0 is executed with RelativeMode = FALSE and PhaseShift = 500, phase addition is performed; when MC_Phasing_Instance_1 is executed with RelativeMode = FALSE and PhaseShift = 400 after the phase addition specified by MC_Phasing_Instance_0, phase addition is performed again.

Regardless of how many phases have been added based on previous instructions, the finally executed MC_Phasing_Instance_1 with RelativeMode = FALSE results in an absolute phase addition of 400 relative to the master axis.

Phase shifting mode (Mode)

You can set the shifting mode by defining the input variable Mode for this instruction.

Mode = 0: Phase shifting continues when the master axis velocity is 0.

Mode = 1: When the instruction is executed and the master axis velocity is 0, both Busy and parameter Actives are set for the instruction with no phase shifting performed; during the instruction execution, if the master axis velocity is not 0, phase shifting is started; when the master axis velocity drops to 0, the slave axis velocity decelerates to 0 within one cycle, causing the end of phase shifting, and phase shifting resumes when the master axis velocity is not 0 again.

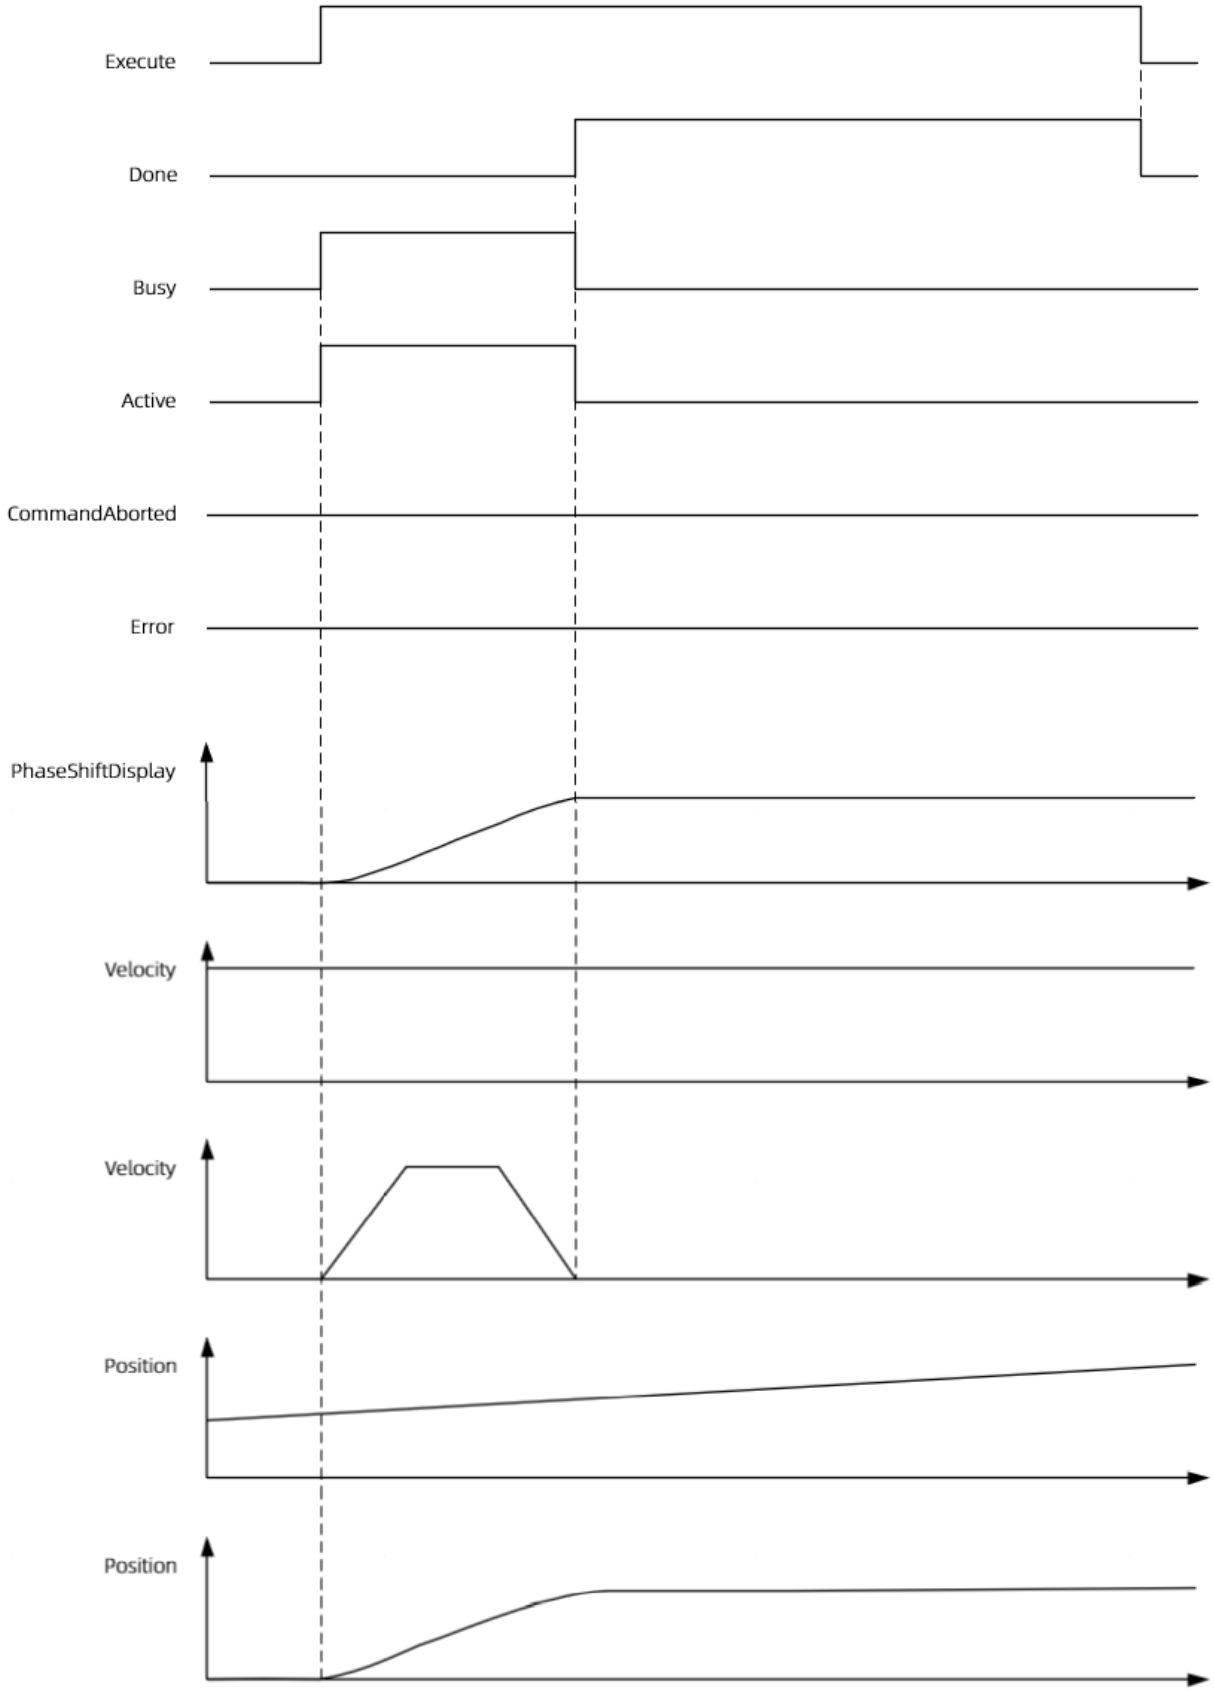
Re-execution of motion control instructions

- This instruction can be re-executed.
- If this instruction is re-executed after input variables such as PhaseShift, Velocity, Acceleration, Deceleration, and Jerk are modified, it will be executed with the modified parameter values.
- If any of the modified parameter values is invalid, it will be automatically corrected by the function block with no fault message.

Software limit

During phase shifting, if the slave axis position is beyond the software limit, the slave axis will decelerate to 0 within one cycle with the state switching from SynchronizedMotion to ErrorStop, and the corresponding synchronous control instruction for the slave axis will be aborted.

Local pulse axis:



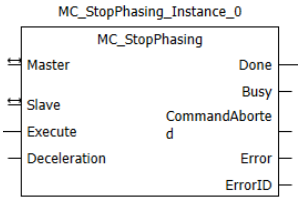
This instruction can be used for local pulse axes.

- **Precautions**
  - During the execution of this instruction, it is prohibited to execute the MC_SetPosition instruction on the master axis.
  - Phase shifting start time:
    - MC_GearIn instruction: After the output variable InGear is set.
    - MC_GearInPos instruction: After the output variable InSync is set.
    - MC_CamIn instruction: After the output variable InSync is set.
  - If the sum of the target velocity specified in this instruction plus the master axis velocity exceeds the maximum velocity reference for the master axis set in the software, the instruction profile will remain unchanged.
  - A fault will occur if the phase shifting has not yet ended after the synchronization instruction is executed.
- **Timing diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Done of the function block indicates the instruction has been executed successfully; the parameter Busy indicates that the current function block is being executed; the parameter CommandAborted of the function block indicates that the instruction is aborted by another motion control instruction, at which point the flag is set to TRUE.

  Phase shifting is triggered on a rising edge of the input parameter Execute. The slave axis automatically calculates a smooth curve to complete the phase shift relative to the master axis. The phase shift between the master and slave axes is the value of the input signal PhaseShift, with positive values indicating that the slave axis lags behind the master axis. The phase shift between the master and slave axes is displayed as the value of the output signal PhaseShiftDisplay. When the PhaseShiftDisplay value is equal to the PhaseShift value, the output parameter Done is set to TRUE.

  After the adjustment, the phase shift between the slave and master axes is the value set for "PhaseShift".



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.4.5 MC_StopPhasing

This instruction stops the phase shifting corresponding to the MC_Phasing and MC_PhasingEx instructions, without affecting the cam or gear motion of the master and slave axes.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_StopPhasing	Stop master axis phase shifting		MC_StopPhasing_Instance_0(Master :=, Slave :=, Execute :=, Deceleration :=, Done =>, Busy =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

  In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Master	Master axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the master axis; an instance of AXIS_REF.
Slave	Slave axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the slave axis; an instance of AXIS_REF.

  Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	Execute the instruction on a rising edge.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Deceleration	Target deceleration	LREAL	Positive number or 0	0	Specify the target deceleration [u/s^2] when the phase shifting stops. If it is set to 0, phase shifting stops immediately.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Parameter correction**

Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Deceleration	Deceleration	Any deceleration that exceeds the motion parameter limit will be automatically corrected to the deceleration limit.	Any deceleration less than 0 will be automatically corrected to 10% of the deceleration limit.	No correction.

- **Function**

  Bus-controlled axis:

  - This instruction stops the phase shifting.
  - This instruction is executed on a rising edge of the input variable Execute.
  - This instruction must be used during the execution of a synchronous control instruction. A fault will occur if this instruction is executed in a non-synchronous control state.
  - If this instruction reports a fault, any buffered instructions after this instruction will be cleared.
  - In case of no phase shifting between the current master and slave axes, this instruction will be called with the output variable of Done being set immediately.

  Deceleration

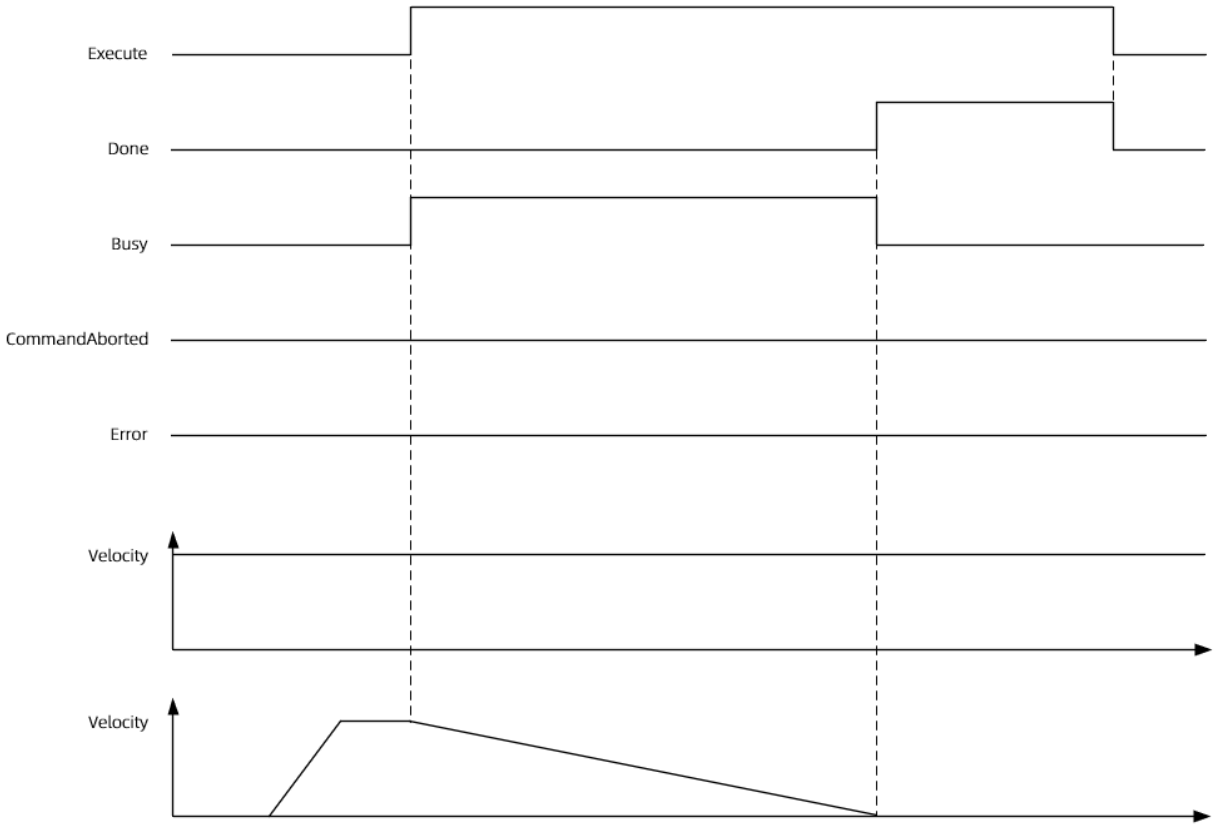
  - You can specify the method of stopping phasing by specifying the value of the input variable Deceleration.
  - When the Deceleration is set to 0, phase shifting stops immediately.
  - If the phase shift between the current master and slave axes is 0, this instruction will be called with the output variable Done being set immediately.
  - A too small Deceleration may result in the total phase shift after stopping phasing being greater than the original total phase shift reference.
  - If the Deceleration is set to less than 0, a fault will occur.

  Re-execution of motion control instructions

  - This instruction can be re-executed.
  - If the value of Deceleration is modified and the instruction is re-executed, the instruction will be executed with the modified parameter value.
  - If the modified value of Deceleration is 0 and the instruction is re-executed, the slave axis velocity will promptly decelerate to 0, with the output variable Done being set immediately.

  Software limit

  When phase shifting stops, if the slave axis position is beyond the software limit, the slave axis will decelerate to 0 within one cycle with the state switching from SynchronizedMotion to ErrorStop, and the corresponding synchronous control instruction for the slave axis will be aborted.



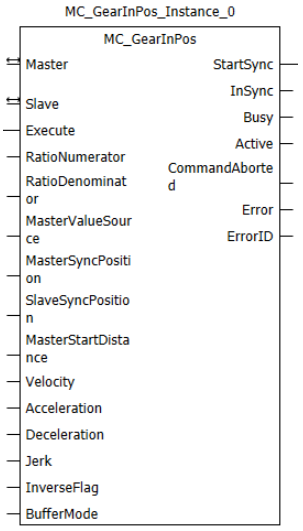
Local pulse axis:

This instruction can be used for local pulse axes.

- **Timing diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Done of the function block indicates the instruction has been executed successfully; the parameter Busy indicates that the current function block is being executed; the parameter CommandAborted of the function block indicates that the instruction is aborted by another motion control instruction, at which point the flag is set to TRUE.

  Phase shifting stops on a rising edge signal of the input parameter Execute. When the velocity for phase shifting decelerates to 0, the output parameter Done is set to TRUE.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.4.6 MC_GearInPos

This instruction performs electronic gearing when the gear ratio between the master and slave axes is established at the specified synchronization positions.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_GearInPos	Start gearing at specified position		MC_GearInPos_Instance_0(Master :=, Slave :=, Execute :=, RatioNumerator :=, RatioDenominator :=, MasterValueSource :=, MasterSyncPosition :=, SlaveSyncPosition :=, MasterStartDistance :=, Velocity :=, Acceleration :=, Deceleration :=, Jerk :=, InverseFlag :=, BufferMode :=, StartSync =>, InSync =>, Busy =>, Active =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

  In-out variables

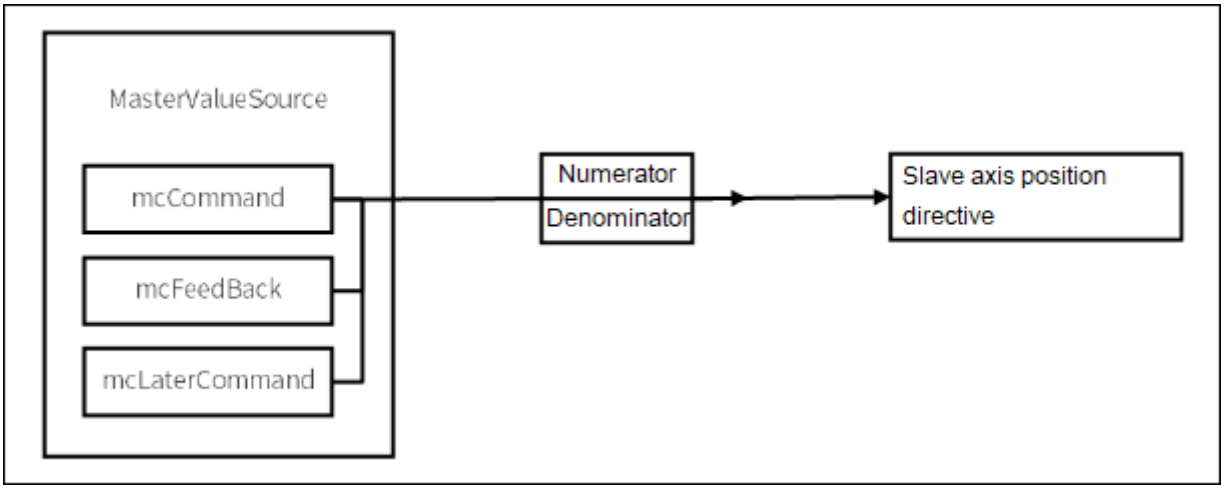
In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Master	Master axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the master axis; an instance of AXIS_REF.
Slave	Slave axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the slave axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	Execute the instruction on a rising edge.
RatioNumerator	Gear ratio numerator	DINT	Positive number or negative number	1	Specify the numerator of the gear ratio. Negative values indicate that the slave axis moves in the opposite direction of the master axis. An input value of 0 is automatically corrected to 1.
RatioDenominator	Gear ratio denominator	UDINT	Positive number	1	Specify the denominator of the gear ratio. Any input value of less than 0 is automatically corrected to 1.
MasterValueSource	Master axis data type	18.3.3.2.2.11 MC_REFERENCE_TYPE: Data Type Enumeration	0: mcCommand 1: mcFeedback 2: mcLaterCommand	0	0: Value calculated in the previous task cycle (fSavePosition). 1: Value obtained in the same task cycle (fActPosition). 2: Value calculated in the same task cycle (fSetPosition).
MasterSyncPosition	Master axis synchronization position	LREAL	Positive number, negative number, or 0	0	Absolute position [u] of the master axis when the gear ratio is established.
SlaveSyncPosition	Slave axis synchronization position	LREAL	Positive number, negative number, or 0	0	Absolute position [u] of the slave axis when the gear ratio is established.
MasterStartDistance	Master axis leading distance	LREAL	Positive number, negative number, or 0	0	Travel distance [u] of the master axis after entering the catching phase. If the input value is 0, the slave axis immediately enters the catching phase, and StartSync is set to TRUE.
Velocity (reserved)	Velocity	LREAL	Positive number	0	Specify the maximum velocity [u/s] of the slave axis during the catching phase.
Acceleration (reserved)	Acceleration	LREAL	Positive number	0	Specify the maximum acceleration [u/s^2] of the slave axis during the catching phase.

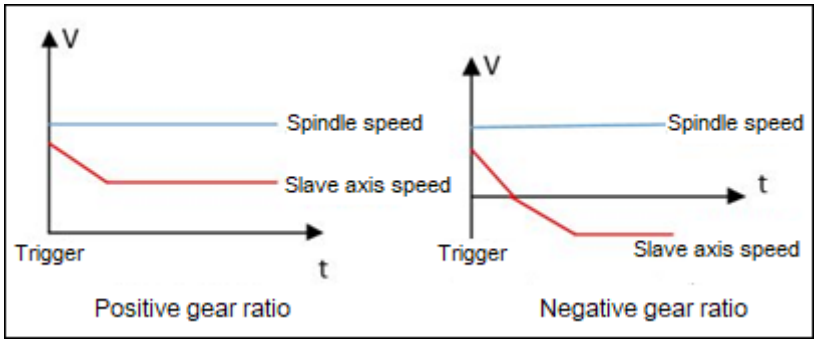
Input Variable	Name	Data Type	Valid Range	Default Value	Description
Deceleration (reserved)	Deceleration	LREAL	Positive number	0	Specify the maximum deceleration [u/s^2] of the slave axis during the catching phase.
Jerk (reserved)	Jerk	LREAL	0	0	Reserved parameter.
InverseFlag	Inverse enable	BOOL	TRUE, FALSE	FALSE	TRUE: Enable the slave axis to run reversely during the catching phase. FALSE: Disable the slave axis to run reversely during the catching phase.
BufferMode	Buffer mode	18.3.3.2.2.6 MC_BUFFER_MODE: Buffer Mode Enumeration	0: mcAborting	0	0: Aborting.

Output variables



Output Variable	Name	Data Type	Valid Range	Default Value	Description
StartSync	Start synchronization	BOOL	TRUE, FALSE	FALSE	TRUE when the master and slave axes enter the catching phase, that is, when the master axis arrives at the (MasterSyncPosition - MasterStartDistance) position.
InSync	In synchronization	BOOL	TRUE, FALSE	FALSE	TRUE when the master and slave axes reach the specified synchronization positions and the specified gear ratio.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Active	Controlling	BOOL	TRUE, FALSE	FALSE	TRUE when the axis is being controlled.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.



- **Function**

  Bus-controlled axis:

  - This instruction can be used to specify the slave axis as the target axis and specify the RatioNumerator, RatioDenominator, MasterValueSource, Acceleration, and Deceleration for gearing.

  - When the instruction is triggered on a rising edge of the input parameter Execute, the input parameters are checked for validity. If any of invalid parameters is detected, the function block will report a fault, abort the active motion, and clear any buffered instructions.
  - The period before reaching the target velocity is called the catching phase, and the period after reaching the target velocity is called the InGear phase.
  - When the gear ratio is positive, the slave axis moves in the same direction as the master axis.

Relationships of the master and slave axis velocity with the gear ratio

- The master and slave axes specified in this instruction cannot be the same.
- This instruction starts electronic gearing on a rising edge of the parameter Execute.
- After the InSync state is reached, the slave axis is forced to follow the master axis according to the specified gear ratio.
- This instruction can be used in combination with other synchronous control instructions. The in-out variable Master of this instruction can be the master or slave axis of other synchronous control instructions; the in-out variable Slave of this instruction can serve as the master axis of other synchronous control instructions.
- During the execution of this instruction, the MC_MoveSuperImposed instruction can be used.
- If bus cycle is specified for the cycle task of the master axis, the velocity of the slave axis may show a sudden jump after synchronization. It is recommended that users specify EtherCAT cycle for the cycle task of both the master and slave axes before enabling a synchronization instruction.
- MC_Home, MC_Homing, or MC_HomingWithParameter can be used during the instruction execution.

  This instruction places the master axis in the AXIS_HOMING state. If the instruction is executed while the master axis is already in this state, the signal source "MasterValueSource" must be set to "mcLatestCommand"; otherwise, the slave axis will overspeed.

Software limit

- During gearing, if the master axis position is beyond the software limit, the velocity of the master axis will decelerate to 0 within one cycle, and the velocity of the slave axis will also decelerate to 0, maintaining the synchronized motion (SynchronizedMotion) state.
- During gearing, if the slave axis position is beyond the software limit, a fault will occur, and the velocity of the slave axis will decelerate to 0 within one cycle, with no impact on the motion status of the master axis.

Conditions for executing the instruction

- This instruction can be executed when the master axis (Master) specified by the instruction is in the ErrorStop or PowerOff state.
- This instruction can be executed when the slave axis specified by the instruction is not in the ErrorStop, Stopping, Homing, or PowerOff state.

Not meeting the conditions for catching up

- If the slave axis is a linear axis and the InverseFlag is set to FALSE, and when the instruction is executed, the target motion direction of the slave axis (determined by the sign of the product of the gear ratio and MasterStartDistance). deviates from the synchronization position, the master and slave axes cannot start electronic gearing, and a fault occurs.

Position type selection

You can select the MasterValueSource for synchronizing the slave axis based on the following options.

- mcCommand: Commanded position (Value calculated in the previous task cycle, fSavePosition).

  For the current cycle, use the master axis position calculated in the previous task cycle.

- mcFeedback: Actual position (Value obtained in the same task cycle, fActPosition).

  Use the actual master axis position obtained in the same task cycle.

- mcLaterCommand: Commanded position (Value calculated in the same task cycle, fSetPosition).

  Use the master axis position calculated in the same task cycle.

- When the master axis starting electronic gearing is specified as a virtual axis, the value of the input variable MasterValueSource cannot be set to 1 (mcFeedback); otherwise, a fault will occur.

MasterSyncPosition (Master axis synchronization position), MasterStartDistance (Master axis distance), SlaveSyncPosition (Slave axis synchronization position)

- If the master axis is specified as a rotary axis, you can specify the MasterSyncPosition outside the rotation cycle as the reminder of MasterSyncPosition divided by the rotation cycle.
- If the slave axis is specified as a rotary axis, you can specify the SlaveSyncPosition outside the rotation cycle as the reminder of SlaveSyncPosition divided by the rotation cycle.
- Inconsistent signs of MasterStartDistance and master axis velocity may result in the master and slave axes failing to achieve the gear ratio, maintaining the instruction in a parameter Busy and preventing it from reaching InSync.

Master axis position, slave axis position, and synchronization position

- When this instruction is executed with the master axis being specified as a rotary axis, and the master axis moves in the positive direction at positions greater than MasterSyncPosition - MasterStartDistance, the slave axis enters the catching phase when the master axis position reaches MasterSyncPosition - MasterStartDistance. (This also applies to reverse motion)
- When this instruction is executed with the slave axis being specified as a rotary axis, and the slave axis position moves in the positive direction at positions greater than the SlaveSyncPosition, the gear ratio is established when the slave axis reaches the SlaveSyncPosition.

Inverse enable (InverseFlag)

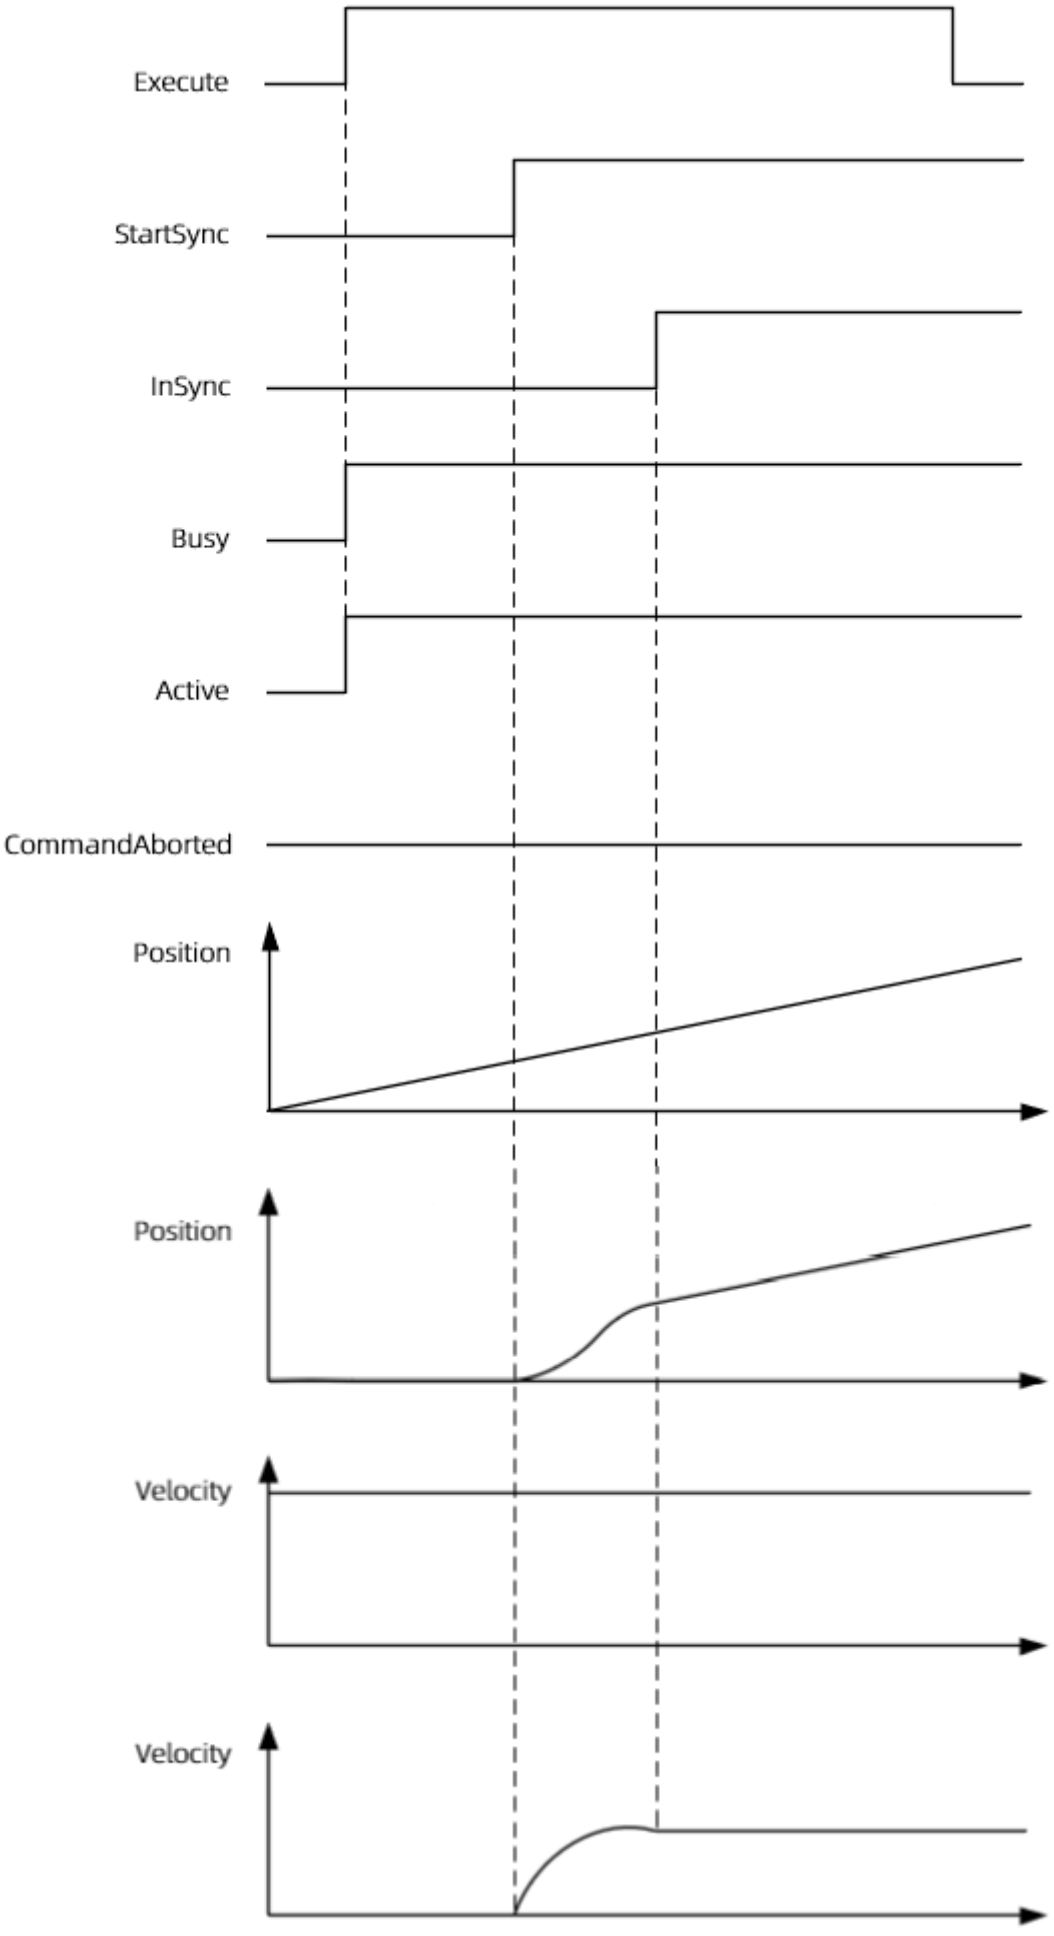
- This instruction determines whether the slave axis is allowed to run reversely during the catching phase by specifying the value of the input variable InverseFlag.

Local pulse axis:

- This instruction can be used for local pulse axes.

- **Precautions**
  - After this instruction is triggered, if the master axis velocity is 0, a fault will occur.
  - If the values of RatioNumerator and RatioDenominator are set to 0, they will be automatically corrected to 1.
  - If the value of RatioDenominator is set to a negative value, it will be automatically corrected to 1.
  - The MC_Phasing instruction can take effect at any time during the execution of this instruction, but phase shifting only begins after reaching the InGear.

- If the slave axis velocity exceeds the software-specified maximum velocity or deceleration during the catching process, a fault will occur.



- **Timing diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Busy of the function block indicates that the current function block is being executed; the parameter Active indicates that the axis is being controlled; the parameter CommandAborted indicates that the instruction is aborted by another motion control instruction, at which point the flag is set to TRUE.

  Electronic gearing starts on a rising edge of the input parameter Execute. The parameter Busy shows the value TRUE at the same time as Execute is set to TRUE. After the gearing starts, the parameter "Active" shows the value TRUE. When the master axis position reaches the input variable "MasterStartDistance", the output variable "StartSync" shows the value TRUE, and the slave axis starts gearing.

  When the input variables "MasterSyncPosition" and "SlaveSyncPosition" are reached, the parameter "InSync" shows the value TRUE.

  When this instruction is aborted by another instruction, the parameter CommandAborted shows the value TRUE, while the parameters Busy, Active, StartSync, and InSync show the value FALSE.

- **Faults**

For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.4.7 MC_GetCamTablePhase

This instruction gets the phase of a specified displacement between two key nodes in the cam table (currently supported cam curve types include: straight line, parabolic curve, cubic curve and quintic curve).

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_GetCamTablePhase	Get cam table phase		MC_GetCamTablePhase_Instance_0(Execute :=, StartPoint :=, EndPoint :=, SlaveDistance :=, Done =>, PhaseNumber =>, Phase =>, Error =>, ErrorID =>);

- **Related variables**

  Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	Execute the instruction on a rising edge.
StartPoint	Start point	18.3.3.2.3.3 MC_CAM_KEY_NODE_REF: Key node structure	-	-	Specify a key node for the cam curve.
EndPoint	End point	18.3.3.2.3.3 MC_CAM_KEY_NODE_REF: Key node structure	-	-	Specify a key node for the cam curve.
SlaveDistance	Slave axis displacement	LREAL	-	0	Specify the displacement [u] for which the phase must be obtained.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
PhaseNumber	Phase number	DINT	-1 to 5	0	Number of phases corresponding to the displacement. -1: Infinite. 0: No phase for the specified displacement. Greater than 0: Number of phases.
Phase	Phase	LREAL[6]	Positive number, negative number, or 0	0	Array of master axis phases corresponding to the slave axis.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

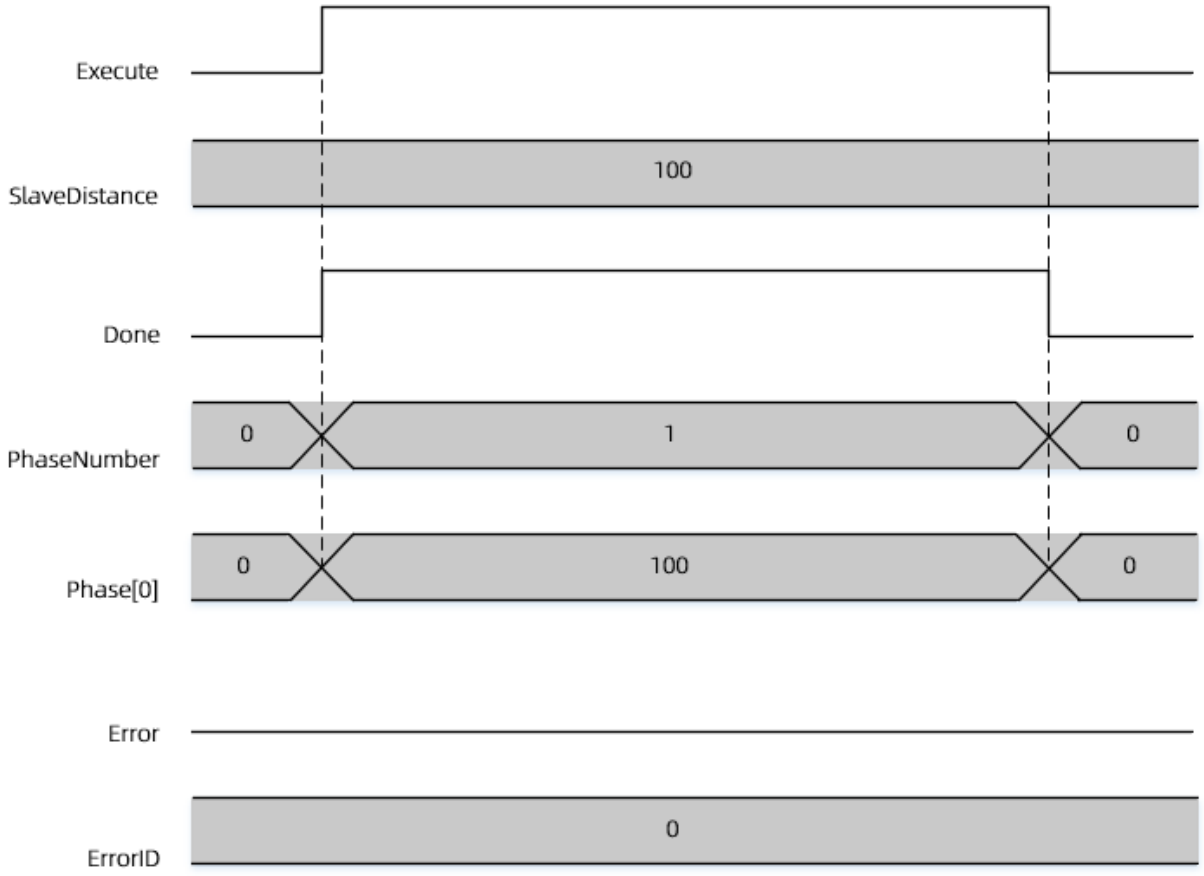
Key node structure of StartPoint

Input Variable	Name	Data Type	Valid Range	Default Value	Description
fPhase	Phase	LREAL	-	-	Phase at the node.
fDistance	Displacement	LREAL	-	-	Displacement at the node.
fVel	Velocity	LREAL	-	-	Velocity at the node.
fAcc	Acceleration	LREAL	-	-	Acceleration at the node.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
fJerk	Jerk	LREAL	-	-	Jerk at the node.
iCurveType	Curve type	INT	1, 2, 3, 4, 5, 6, 7, 8	-	Curve type: 1: Straight line. 2: Parabolic curve. 3: Cubic curve. 4: Quintic curve. 5: Septic curve. 6: Cosine acceleration curve. 7: Sine acceleration curve. 8: Modified trapezoidal acceleration curve.

Key node structure of EndPoint

Input Variable	Name	Data Type	Valid Range	Default Value	Description
fPhase	Phase	LREAL	-	-	Phase at the node.
fDistance	Displacement	LREAL	-	-	Displacement at the node.
fVel	Velocity	LREAL	-	-	Velocity at the node.
fAcc	Acceleration	LREAL	-	-	Acceleration at the node.
fJerk	Jerk	LREAL	-	-	Jerk at the node.



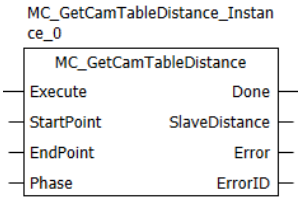
Input Variable	Name	Data Type	Valid Range	Default Value	Description
iCurveType	Curve type	INT	1, 2, 3, 4, 5, 6, 7, 8	-	Curve type: 1: Straight line. 2: Parabolic curve. 3: Cubic curve. 4: Quintic curve. 5: Septic curve. 6: Cosine acceleration curve. 7: Sine acceleration curve. 8: Modified trapezoidal acceleration curve.

The StartPoint and EndPoint are user-defined as required.

- **Function**
  - This instruction gets the phase of a specified displacement between two key nodes in the cam table.
  - This instruction does not support phase calculation for advanced curves. If an advanced curve (polynomic 7 curve, cosine acceleration curve, sine acceleration curve, modified trapezoidal acceleration curve) is selected, an error will occur.
  - This instruction is executed on a rising edge of the input variable Execute.
  - When the phase of the EndPoint specified in this instruction is less than the phase of the StartPoint, a fault occurs.
  - When the phase of the EndPoint specified in this instruction coincides with the phase of the StartPoint (a phase shift less than 0.0001 is considered coincident), a fault occurs.
  - The cam curve types currently supported by this instruction are: linear curve, parabolic curve, cubic curve, and quintic curve.
  - When the iCurveType of the EndPoint or StartPoint specified in this instruction is out of the specified range, a fault occurs.
  - The value of SlaveDistance must be between the maximum and minimum slave axis displacement values of the cam curve from StartPoint to EndPoint; otherwise, the PhaseNumber is set to 0, with no phase for the specified displacement, and a fault occurs.
- **Timing diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Done of the function block indicates that the instruction has been executed successfully.

Note: The following example shows the timing diagram with the curve types of the input variables StartPoint and EndPoint being specified as straight line, the output variable "PhaseNumber" being set to "1", and the output variable "Phase" being set to "100".



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.4.8 MC_GetCamTableDistance

This instruction gets the displacement at a specified phase between two key nodes in the cam table.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_GetCamTableDistance	Get cam table displacement		MC_GetCamTableDistance_Instance_0(Execute :=, StartPoint :=, EndPoint :=, Phase :=, Done =>, SlaveDistance =>, Error =>, ErrorID =>);

- **Related variables**

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	Execute the instruction on a rising edge.
StartPoint	Start point	18.3.3.2.3.3 MC_CAM_KEY_NODE_REF: Key node structure	-	-	Specify a key node for the cam curve.
EndPoint	End point	18.3.3.2.3.3 MC_CAM_KEY_NODE_REF: Key node structure	-	-	Specify a key node for the cam curve.
Phase	Phase	LREAL	-	0	Specify the phase [u] for which displacement is required.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
SlaveDistance	Slave axis displacement	LREA	Positive number, negative number, or 0	0	Slave axis displacement [u].
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

Key node structure of StartPoint

The StartPoint and EndPoint are user-defined as required.

- **Function**

  Bus-controlled axis:

  - This instruction gets the displacement at a specified phase between two key nodes in the cam table.
  - This instruction is executed on a rising edge of the input variable Execute.
  - When the phase of the EndPoint specified in this instruction is less than the phase of the StartPoint, a fault occurs.
  - When the phase of the EndPoint specified in this instruction coincides with the phase of the StartPoint (a phase shift less than 0.0001 is considered coincident), a fault occurs.
  - When the specified phases of StartPoint and/or EndPoint are negative, a fault occurs.
  - This instruction currently supports the following cam curve types: linear curve, parabolic curve, cubic curve, quintic curve, septic curve, sine acceleration curve, cosine acceleration curve, and modified trapezoidal acceleration curve.
  - When the iCurveType of the EndPoint or StartPoint specified in this instruction is out of the specified range, a fault occurs.
  - The value of Phase must be between the fPhase of the StartPoin and the fPhase of the EndPoint (inclusive); otherwise, a fault occurs.

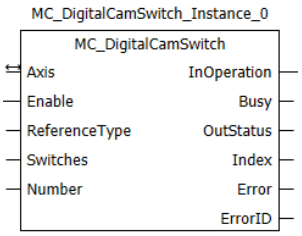
  Local pulse axis:

  - This instruction can be used for local pulse axes.

- **Timing diagram**

The parameter Execute of the function block must be triggered on a rising edge. The parameter Done of the function block indicates that the instruction has been executed successfully.

Note: The following example shows the timing diagram with the curve type of input variables "StartPoint" and "EndPoint" being specified as straight line and the output variable "SlaveDistance" being specified as "100".



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.4.9 MC_DigitalCamSwitch

This instruction outputs a specific signal at the specified axis position.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_DigitalCamSwitch	Enable digital cam switch		MC_DigitalCamSwitch_Instance_0(Axis :=, Enable :=, ReferenceType :=, Switches :=, Number :=, InOperation =>, Busy =>, OutStatus =>, Index =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Axis	Axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Enable	Enable	BOOL	TRUE, FALSE	FALSE	TRUE: Enabled; FALSE: Disabled.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Reference Type	Position type selection	18.3.3.2.2.11 MC_REFERENCE_TYPE: Data Type Enumeration	0: mcCommand 1: mcFeedback 2: mcLaterCommand 3: mcMasterPhase	0	0: Value calculated in the previous task cycle (fSavePosition). 1: Value obtained in the same task cycle (fActPosition). 2: Value calculated in the same task cycle (fSetPosition). 3: Phase of the master axis when the axis specified by Axis works as the cam slave axis (fMasterPhase).
Switches	Switch state	ARRAY [1..64] OF 18.3.3.2.3.6 MC_SWITCH_REF: Switch structure	-	-	Address of the variable used to input the switch state.
Number	Switch number	INT	1-64	-	Up to 64 switches.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
InOperation	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
OutStatus	Output status	BOOL	TRUE, FALSE	FALSE	Output status of the switch.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Index	Index	INT	1-64	0	Index of the comparison point to be executed.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

Switches structure

Input Variable	Name	Data Type	Valid Range	Default Value	Description
fPosition	Position for the output to turn ON.	REAL	-	0	Absolute position for the output to turn ON.
iMode	Switch mode	INT	0, 1, 2	0	Switch mode selection. 0: Disabled; 1: Position based; 2: Time based.
iDirection	Direction	INT	0, 1, 2	0	Master axis direction selection. 0: Positive; 1: Negative; 2: No direction.
fParameter	Position type	REAL	-	0	iMode = 1: fParameter is the position where the switch turns OFF; iMode = 2: fParameter is the duration (in ms) for which the switch remains ON; in time-based mode, the decimal part is ignored, and the value of fParameter cannot be more than 10,000 ms.

- **Function**

  Bus-controlled axis:

  - This instruction outputs a specific signal at the specified axis position.
  - The instruction is executed when the input variable Enable is set, after which modifying the input parameters is invalid. When Enable is reset, the OutStatus and Index are cleared.

  Local pulse axis:

  - This instruction can be used for local pulse axes.

OutStatus

- The output parameter "OutStatus" can be bound to a boolean variable or the address of an IO signal, allowing the value of the bound variable or IO signal to be controlled via the MC_DigitalCamSwitch instruction.
- The output parameter OutStatus indicates the tappet output status of the MC_DigitalCamSwitch instruction. When the axis position information matches the fPosition in the input parameter Switch structure, OutStatus is set to TRUE and remains so for the specified time or distance.

I/O mapping

Search: Filter: Show all Reset mapping Continuous IO address The channel address follows the variable address.

Variable	Variable table	Channel	Address	Type	Default value	Current value	Prepared value	Unit	Description
		IB(I)	%IB0	USINT		0			
		I0	%IX0.0	BOOL	FALSE	FALSE			
		I1	%IX0.1	BOOL	FALSE	FALSE			
		I2	%IX0.2	BOOL	FALSE	FALSE			
		I3	%IX0.3	BOOL	FALSE	FALSE			
		I4	%IX0.4	BOOL	FALSE	FALSE			
		I5	%IX0.5	BOOL	FALSE	FALSE			
		I6	%IX0.6	BOOL	FALSE	FALSE			
		I7	%IX0.7	BOOL	FALSE	FALSE			
		QB(I)	%QB0	USINT		2			
		Q0	%QX0.0	BOOL	FALSE	FALSE			
		Q1	%QX0.1	BOOL	FALSE	TRUE			
		Q2	%QX0.2	BOOL	FALSE	FALSE			
		Q3	%QX0.3	BOOL	FALSE	FALSE			
		Q4	%QX0.4	BOOL	FALSE	FALSE			
		Q5	%QX0.5	BOOL	FALSE	FALSE			
		Q6	%QX0.6	BOOL	FALSE	FALSE			
		Q7	%QX0.7	BOOL	FALSE	FALSE			

ReferenceType

You can specify the ReferenceType based on the following options.

- mcCommand: Commanded position (Value calculated in the previous task cycle, fSavePosition).

  For the current cycle, use the master axis position calculated in the previous task cycle.
- mcFeedback: Actual position (Value obtained in the same task cycle, fActPosition).

  Use the actual master axis position obtained in the same task cycle.
- mcLaterCommand: Commanded position (Value calculated in the same task cycle, fSetPosition).

  Use the master axis position calculated in the same task cycle.
- mcMasterPhase: Phase of the master axis when the axis specified by Axis works as the cam slave axis.

When this type is selected, the axis must be a cam slave axis; otherwise, a fault occurs.

When the slave axis velocity is 0, there is no output for OutStatus.

iMode

- You can specify the switch mode by defining the value of iMode in Switches of this instruction.
- When iMode is set to 1 (Position based mode), the fParameter in Switches is the position where the switch turns OFF. When the switch terminal output position is insufficient for one complete ETC cycle, there is no output for OutStatus.
- When iMode is set to 2 (Time based mode), the fParameter in Switches is the duration (in ms) for which the switch remains ON. In time-based mode, the value of fParameter cannot be more than 10,000 ms. When the ON duration of the switch terminal output is shorter than the time of one ETC cycle, OutStatus remains active for the duration of one complete ETC cycle.

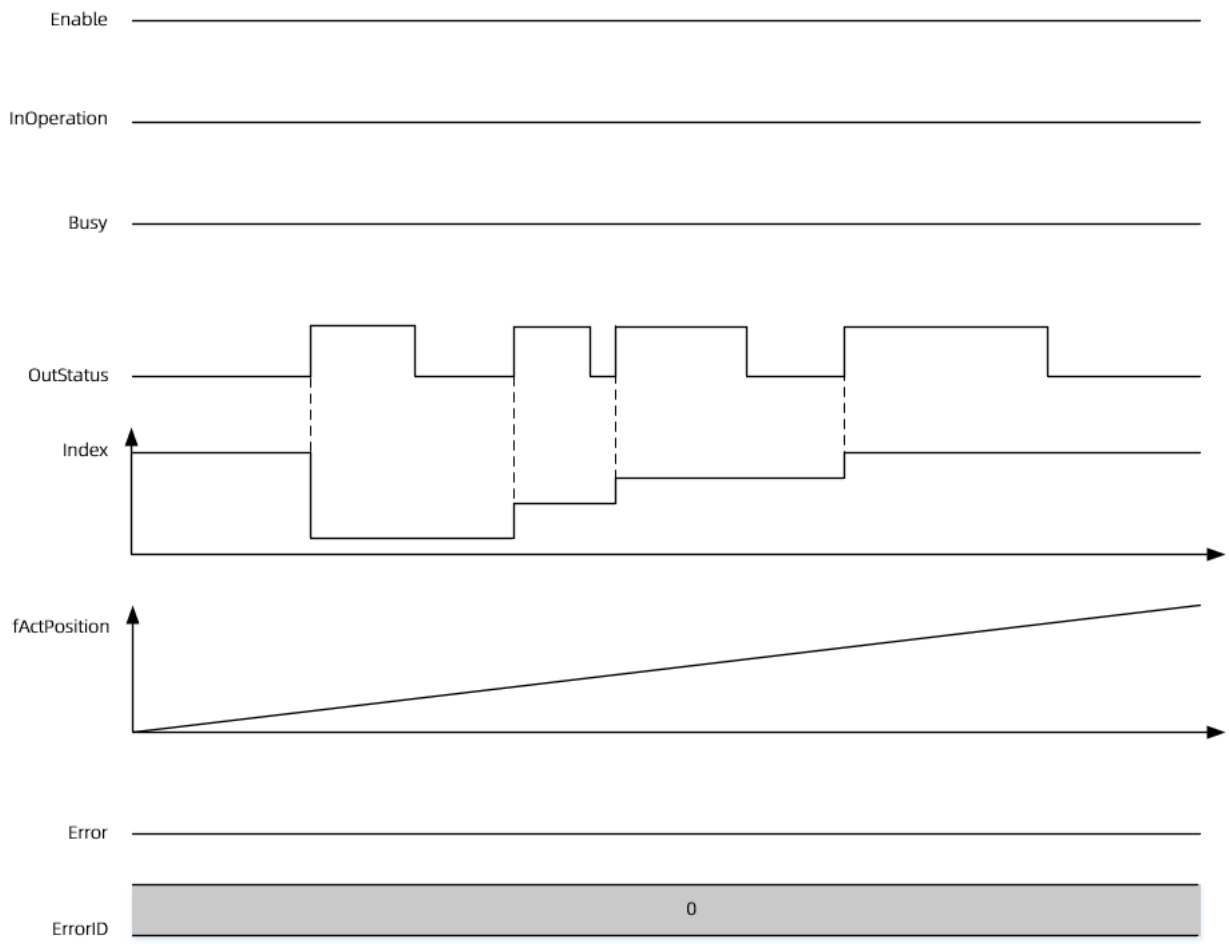
- **Precautions**
  - When the axis is specified as a linear axis, the fPosition of the input variable Switches must be less than the fParameter.
  - When the axis is specified as a rotary axis, the fPosition and fParameter of the input variable Switches must be greater than 0 and less than or equal to the rotation cycle specified in this instruction.
  - When the axis is specified as a slave axis for camming, the fPosition and fParameter of the input variable Switches must be greater than 0 and less than or equal to the phase of the master axis synchronized to the axis for camming specified in this instruction.
  - When this instruction is executed in the homing mode, a fault occurs.
  - Index and OutStatus are not refreshed in the same task cycle, as Index evaluates if the target point is reached within the displacement range of a single cycle.
- **Timing diagram**

  Start and end of the switch comparison output: After this instruction is executed, the tappet point array is sorted internally to identify the tappet point closest to the current position of the axis. When the axis reaches this point, the switch is turned ON immediately.

  iMode is used to set the comparison mode:

  - When iMode is set to 0, this comparison point is disabled. When the axis passes this point, the switch has no output.
  - When iMode is set to 1, fParameter is the position where the switch turns OFF.
  - When iMode is set to 2, fParameter is the duration (in ms) during which the switch remains ON.

  iDirection specifies the running direction of the master axis. It must be used together with iMode.

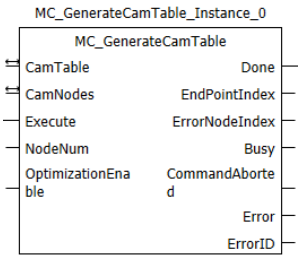


No.	fPosition	fParameter	iMode	iDirection
1	10	15	1	0
2	20	25	1	0
3	24	30	1	0
4	35	100	2	0
5	40	45	0	0

No.	fPosition	fParameter	iMode	iDirection
6	10	15	1	1
7	20	25	1	1
8	24	30	1	1
9	35	100	2	1

When the master axis moves in the forward direction:

When the master axis moves in the negative direction:



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.4.10 MC_GenerateCamTable

This instruction checks or updates the cam table data.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_GenerateCamTable	Update the cam table with specified cam data		MC_GenerateCamTable_Instance_0(CamTable :=, CamNodes :=, Execute :=, NodeNum :=, OptimizationEnable :=, Done =>, EndPointIndex =>, ErrorNodeIndex =>, Busy =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Value Range	Default Value	Description
CamTable	Cam table	18.3.3.2.3.1 MC_CAM_TABLE_REF: Cam table structure	-	-	Cam table.
CamNodes	Cam nodes	ARRAY[*] OF 18.3.3.2.3.3 MC_CAM_KEY_NODE_REF: Key node structure	-	-	Array of cam table node data structures.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	Execute the instruction on a rising edge.
NodeNum	Number of nodes	UINT	-	0	Number of cam table nodes. If it is specified as 0, use the original number of cam table nodes.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
OptimizationEnable	Velocity optimization switch	BOOL	TRUE, FALSE	FALSE	TRUE: Optimize the suddenly changed velocity at node connections. FALSE: Do not optimize the suddenly changed velocity.

MC_CAM_KEY_NODE_REF structure composition

Input Variable	Name	Data Type	Valid Range	Default Value	Description
fPhase	Phase	LREAL	-	0	Phase (of the master axis) at the node.
fDistance	Displacement	LREAL	-	0	Displacement (of the slave axis position) at the node.
fVel	Velocity	LREAL	-	0	Velocity at the node.
fAcc	Acceleration	LREAL	-	0	Acceleration at the node.
fJerk	Jerk	LREAL	-	0	Jerk at the node.
iCurveType	Curve type	INT	1, 2, 3, 4, 5, 6, 7, 8	-	Curve type: 1: Straight line. 2: Parabolic curve. 3: Cubic curve. 4: Quintic curve. 5: Septic curve. 6: Cosine acceleration curve. 7: Sine acceleration curve. 8: Modified trapezoidal acceleration curve.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
EndPointIndex	End point index	UINT	-	-	Output the cam table end point index after the instruction is executed.
ErrorNodeIndex	Error node index	UINT	-	-	Output the number of any fault node.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**
  - This instruction generates a cam table by specifying cam table data through input parameters.
  - This instruction is executed on a rising edge of the input variable Execute.
  - By setting the input parameter OptimizationEnable, you can optimize the suddenly changed velocity between nodes while updating cam nodes to the cam table, and adjust the acceleration and jerk according to the optimized velocity.

    Re-execution of motion control instructions

  - This instruction can be re-executed.
  - During the execution of this instruction with the output variable Busy being set, if the instruction is re-executed after any parameters are modified, it will be executed with the modified parameter values.

    Velocity optimization

Currently, you can optimize sudden velocity changes due to the following two scenarios. The optimization is performed for the velocity of the entire cam table, rather than the velocity between two nodes.

- When a parabolic, cubic, quintic, or septic curve is followed by a linear curve, the velocity of the current node and subsequent nodes is adjusted to match the velocity of the linear curve.
- When a parabolic, cubic, quintic, or septic curve is followed by a cosine acceleration curve, a sine acceleration curve, or a modified trapezoidal acceleration curve, the velocity at the current node and the next node is set to 0.

The acceleration and jerk are adjusted based on the optimized velocity.

Parameter validity check

- This instruction performs a validity check on the input values of CamNodes.
- If any value of CamNodes is invalid, the corresponding node number is output to ErrorNodeIndex.
- The phase and displacement of the first CamNodes must be 0; otherwise, a fault will occur.
- The phase, displacement, and velocity ratio cannot be more than 9,999,999; otherwise, a fault will occur.
- The number of key nodes for CamNodes cannot be more than 20000, and the number of dense nodes cannot be more than 65535; otherwise, a fault will occur.
- The value of CamNodes cannot be less than 2; otherwise, a fault will occur.
- The phases of CamNodes must be in ascending order; otherwise, a fault will occur.
- The phase shift between adjacent nodes for CamNodes must be greater than 0.0001; otherwise, a fault will occur.
- The curve type for CamNodes must be within the valid range; values outside the range are treated as a quintic curve.

CamNodes

- The instruction only allows input of key nodes for CamNodes.
- CamNodes is an in-out variable and can be compiled successfully with input parameters. CamNodes is bound to automatically declared variable-length array, the declared variables must be assigned valid values. The data in CamNodes is the **data to be updated**.

NodeNum

- The NodeNum value of this instruction should be less than or equal to the number of nodes in CamNodes.
- The NodeNum value of this instruction cannot be greater than the number of nodes in CamTable.

Velocity ratio adjustment

- When this instruction is executed to update cam node parameters, any improper parameter value of velocity ratio at the node is automatically adjusted.
- If the curve type between adjacent nodes is a straight line:

  When the coordinates of point A1 are (x1, y1) and the coordinates of point A2 are (x2, y2), V2 = (y2 - y1) / (x2 - x1), and the ratio value of V2 is automatically adjusted.

- When a quintic curve is followed by a linear curve:

Points A1 and A2 define a quintic curve, and points A2 and A3 define a linear curve. To prevent a sudden velocity change from the quintic curve to the linear curve, the velocity ratio must be automatically adjusted.

First, calculate the velocity ratio of the straight line segment, set the velocity value of the straight line segment as V3, and then update the value of V3 to V2: V3 = (y3 - y2) / (x3 - x2), V2 = V3.

- When a quintic curve is followed by another quintic curve, no adjustment is made.
- If the curve type is a straight line followed by another straight line, a sudden change in velocity ratio will be allowed.

The specific behaviors of this instruction are as follows when the input parameter CamNodes is the data to be updated and NodeNum is equal to 0 or not equal to 0.

- **CamNodes is the data to be updated, and NodeNum is specified as 0**

  With this parameter combination, the number of cam nodes for Cam_0 in the cam table is updated with the number of nodes for CamNodes, and the updated data is checked for validity. If any invalid data is detected, a fault will occur.

  If the number of nodes for CamNodes is greater than the number of nodes for Cam_0 in the cam table, the node data will be updated according to the number of nodes for Cam_0 in the cam table, followed by the validity check.

  If the number of nodes for CamNodes is less than the number of nodes for Cam_0 in the cam table, a fault will occur.

- **CamNodes is the data to be updated, and NodeNum is specified as a value other than zero**

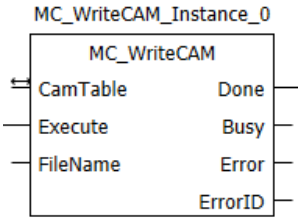
  With this parameter combination, the number of cam nodes for Cam_0 in the cam table is updated with the number of nodes for CamNodes, and the updated data is checked for validity. If any invalid data is detected, a fault will occur. After a successful update, the number of nodes for Cam_0 in the cam is equal to the value of NodeNum.

  The value of NodeNum cannot be more than the number of nodes for Cam_0 in the cam table; otherwise, a fault will occur.

- **Precautions**
  - When the in-out variable CamTable is a user-defined cam table, you must first use this instruction MC_CheckCamTable to check the validity of the user-defined cam table before executing the instruction to generate the cam table.
  - This instruction cannot be executed during the execution of MC_WriteCam or MC_ReadCam instruction; otherwise, a cam data read/write fault occurs.
  - Modifying the cam table by using methods other than the MC_GenerateCamTable instruction may result in abnormal results for the MC_CamIn or MC_CamInV2 instruction that are currently executing or about to execute.
- **Timing diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Done of the function block indicates the instruction has been executed successfully; the parameter Busy indicates that the current function block is being executed; the parameter CommandAborted of the function block indicates that the instruction is aborted by another motion control instruction, at which point the flag is set to TRUE.

The output variable Busy shows the value TRUE on a rising edge of the variable Execute, and the output variable Done shows the value TRUE in the next cycle.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.4.11 MC_WriteCAM

This instruction stores the cam table created within the cam table editor to a file at runtime and makes it the available in the module.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_WriteCAM	Store the edited cam table as a file		MC_WriteCAM_Instance_0(CamTable :=, Execute :=, FileName :=, Done =>, Busy =>, Error =>, ErrorID =>);

- **Related variables**

  In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
CamTable	Cam table	18.3.3.2.3.1 MC_CAM_TABLE_REF: Cam table structure	-	-	Specify the cam table to be stored.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	Execute the instruction on a rising edge.
FileName	File name	STRING	-	''	Contain the cam description in the specified ASCII format.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**
  - This instruction stores the cam table created within the cam table editor into a file.
  - This instruction is executed on a rising edge of the input variable Execute.

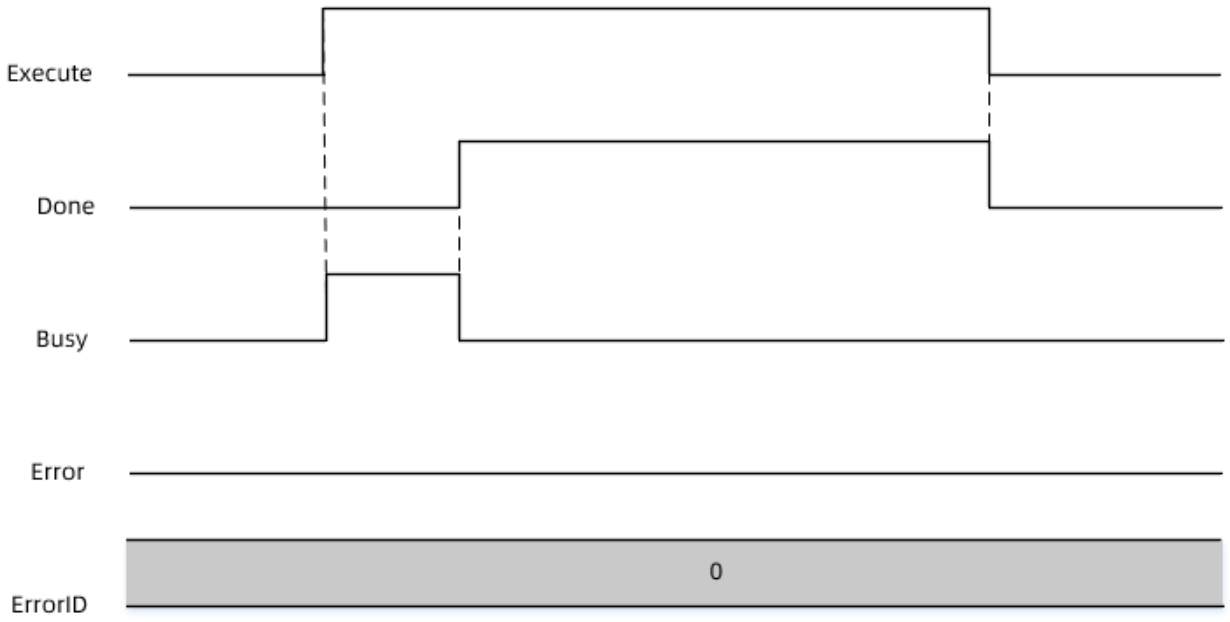
File write format

  - The format of the file written by this instruction is as follows. Each element is written with a maximum of 20 bytes.

Name	Data Type	Description
CamTable version	STRING	Used to distinguish whether it is a CamTable text.
CamTable name	STRING	Name of a cam table.
Node type	INT	Used to distinguish whether it is written as key or dense nodes.
Number of nodes	INT	Number of nodes written.
fPhase	LREAL	Master axis phase.
fDistance	LREAL	Slave axis displacement.
fVel	LREAL	Velocity ratio (only written in key nodes).
fAcc	LREAL	Acceleration ratio (only written in key nodes).
Jerk	LREAL	Jerk ratio (only written in key nodes).
iCurveType	INT	Curve type (only written in key nodes).

FileName

  - When read/write is executed, a fixed suffix ".cam" is added internally.
  - The input variable FileName of this instruction cannot contain Chinese characters; otherwise, a fault will occur.



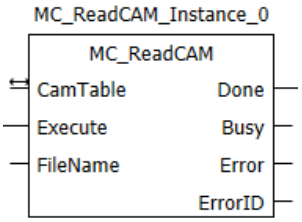
Node type

- The node type of CamTable must be key or dense nodes; otherwise, a fault will occur.
- When key nodes are specified for CamTable, the number of nodes must be between 2 and 20000; otherwise, a fault will occur.
- When dense nodes are specified for CamTable, the number of nodes cannot be less than 2 or more than 65,536; otherwise, a fault will occur.

- **Precautions**
  - It is recommended to execute this instruction in a non-real-time task.
  - Do not use the MC_GenerateCamTable instruction during the execution of this instruction.
  - Absolute path writing is not supported.
- **Timing diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Done of the function block indicates that the instruction has been executed successfully, and the parameter Busy indicates that the current function block is being executed.

  After this instruction is called, the output parameter Busy is set to TRUE on a rising edge of Execute. After the edited cam table is stored, the output parameter Done shows a value TRUE.



- **Faults**
  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.4.12 MC_ReadCAM

This instruction reads a cam table file, loads the file at runtime, and makes it available for the other instructions (MC_CamIn).

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_ReadCAM	Read the cam data file into a cam table		MC_ReadCAM_Instance_0(CamTable :=, Execute :=, FileName :=, Done =>, Busy =>, Error =>, ErrorID =>);

- **Related variables**

  In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
CamTable	Cam table	18.3.3.2.3.1 MC_CAM_TABLE_REF: Cam table structure	-	-	Specify the cam table to be stored.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	Execute the instruction on a rising edge.
FileName	File name	STRING	-	''	Cam table storage location.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**
  - This instruction reads a cam table file, loads the file at runtime, and makes it available for the other instructions (MC_CamIn).
  - This instruction is executed on a rising edge of the input variable Execute.

    FileName

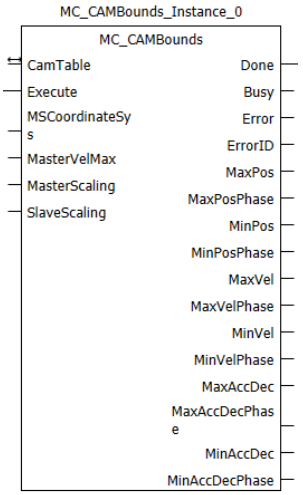
  - The input variable FileName of this instruction specifies the file name to be written to CamTable. If another file is read, a fault will occur.
  - When read/write is executed, a fixed suffix ".cam" is added internally.
  - The input variable FileName of this instruction cannot contain Chinese characters; otherwise, a fault will occur.

    Node type

  - The node type of CamTable must be key or dense nodes; otherwise, a fault will occur.
  - When key nodes are specified for CamTable, the number of nodes must be between 2 and 20000; otherwise, a fault will occur.
  - When dense nodes are specified for CamTable, the number of nodes must be between 2 and 65535; otherwise, a fault will occur.
- **Precautions**
  - It is recommended to execute this instruction in a non-real-time task.
  - The number of nodes for the in-out variable CamTable of this instruction cannot be less than that in the cam table file to be read.
  - The node type for the in-out variable CamTable of this instruction must match the node type in the cam table file being read; otherwise, a fault will occur.
- **Timing diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Done of the function block indicates that the instruction has been executed successfully, and the parameter Busy indicates that the current function block is being executed.

  After this instruction is called, the output parameter Busy is set to TRUE on a rising edge of Execute. After the cam data file is read into a cam table, the output parameter Done is set to TRUE.



- **Faults**
  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.4.13 MC_CAMBounds

This instruction calculates the position, velocity and acceleration values of the slave axis being coupled to a master axis, which is moved according to a specified maximum velocity. It is used to check the curve when a cam table is created.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_CAMBounds	Calculate the maximum values of the slave axis motion parameters		MC_CAMBounds_Instance_0(CamTable :=, Execute :=, MSCoordinateSys :=, MasterVelMax :=, MasterScaling :=, SlaveScaling :=, Done =>, Busy =>, Error =>, ErrorID =>, MaxPos =>, MaxPosPhase =>, MinPos =>, MinPosPhase =>, MaxVel =>, MaxVelPhase =>, MinVel =>, MinVelPhase =>, MaxAccDec =>, MaxAccDecPhase =>, MinAccDec =>, MinAccDecPhase =>);

- **Related variables**

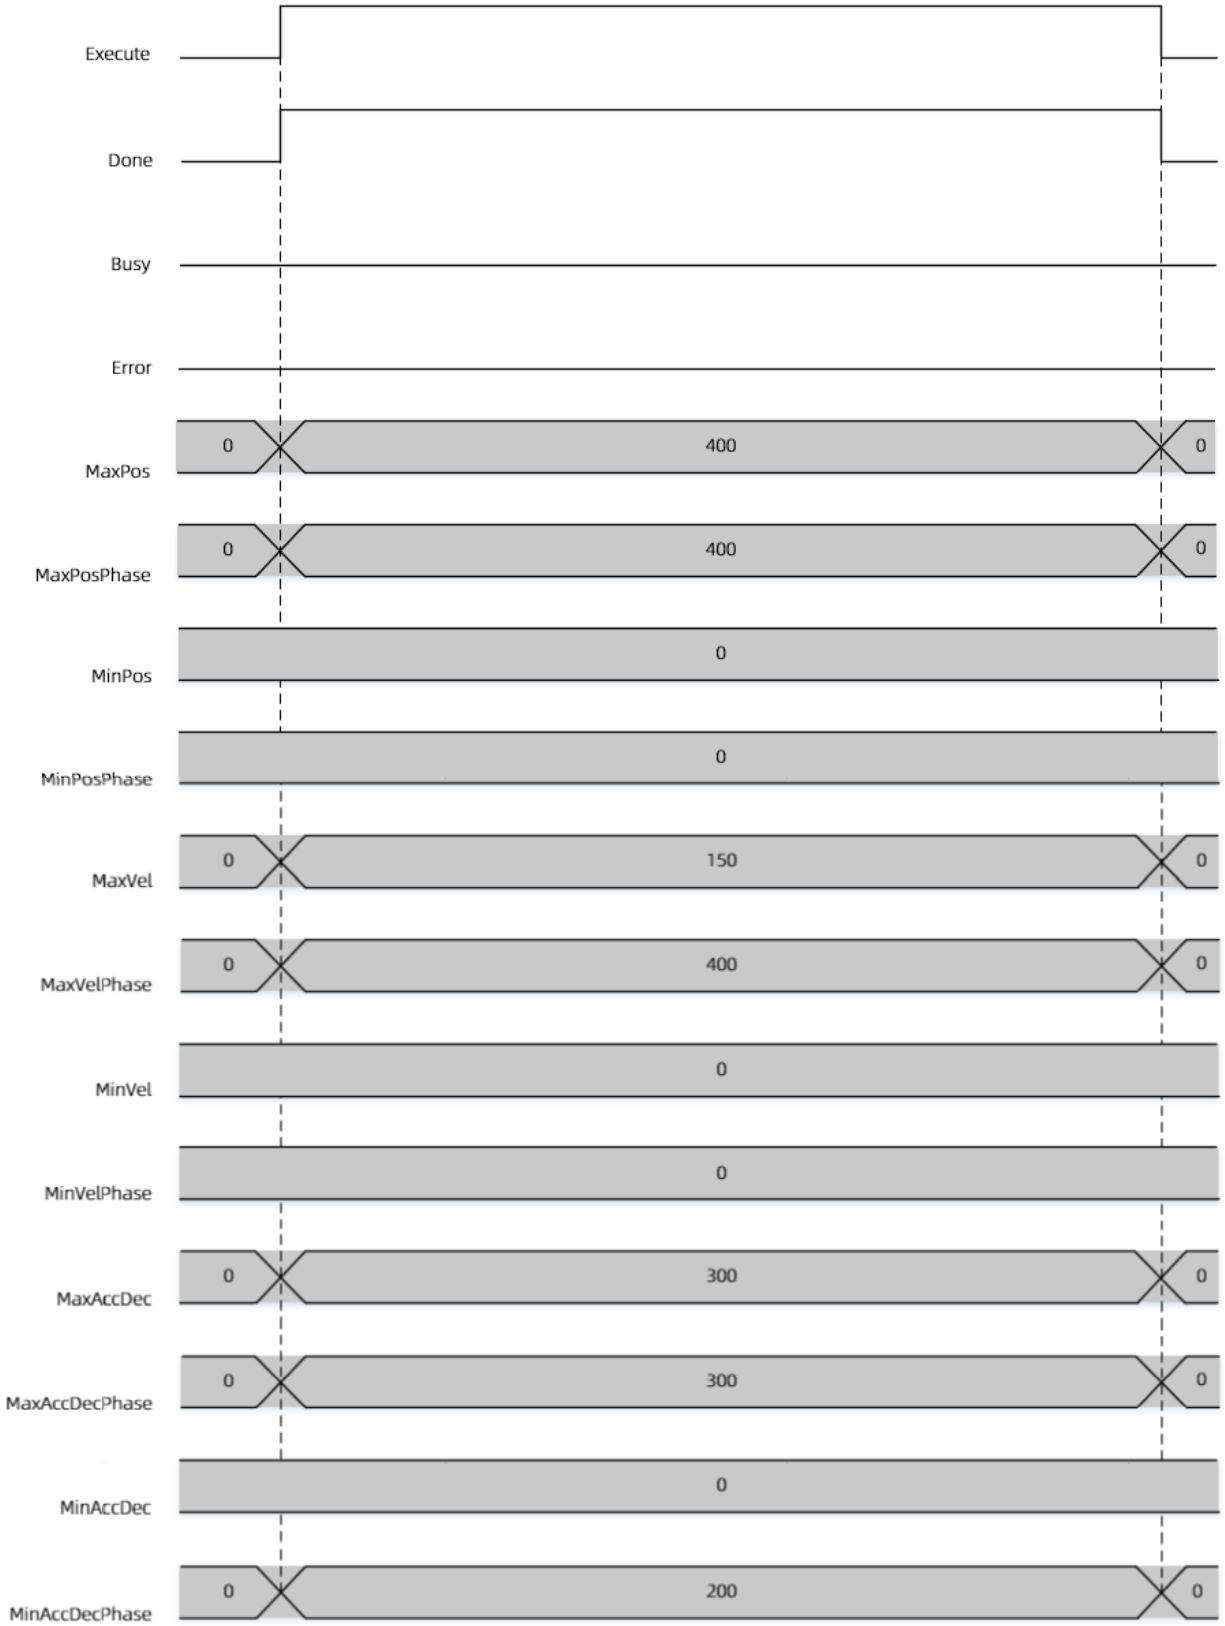
  In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
CamTable	Cam table	18.3.3.2.3.1 MC_CAM_TABLE_REF: Cam table structure	-	-	Specify the cam table to be stored.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	Execute the instruction on a rising edge.
MScoordinateSys	MS coordinate system	BOOL	TRUE, FALSE	FALSE	FALSE: Physical coordinate system TRUE: Master-slave coordinate system
MasterVelMax	Maximum velocity	LREAL	Positive number	0	Maximum velocity of the master axis.
MasterScaling	Master axis scaling	LREAL	Positive number	1	Scaling factor for the master axis applied to cam.
SlaveScaling	Slave axis scaling	LREAL	Positive number	1	Scaling factor for the slave axis applied to cam.

Output variables



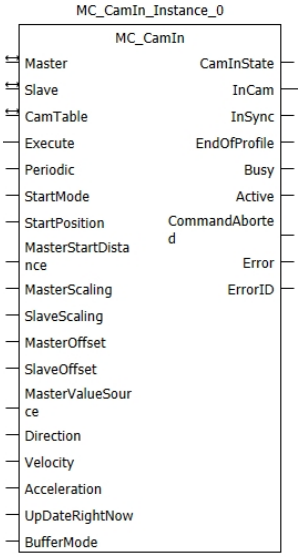
Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
MaxPos	Maximum position	LREAL	-	0	Calculate the maximum position of the slave axis based on the cam table.
MaxPosPhase	Phase at the maximum position	LREAL	-	0	Master axis phase at the maximum displacement of the cam curve.
MinPos	Minimum position	LREAL	-	0	Calculate the minimum position of the slave axis based on the cam table.
MinPosPhase	Phase at the minimum position	LREAL	-	0	Master axis phase at the minimum displacement of the cam curve.
MaxVel	Maximum velocity	LREAL	-	0	Maximum velocity.
MaxVelPhase	Phase at the maximum velocity	LREAL	-	0	Master axis phase at the maximum velocity of the cam curve.
MinVel	Minimum velocity	LREAL	-	0	Minimum velocity.
MinVelPhase	Phase at the minimum velocity	LREAL	-	0	Master axis phase at the minimum velocity of the cam curve.
MaxAccDec	Maximum acceleration	LREAL	-	0	Maximum acceleration.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
MaxAccDecPhase	Phase at the maximum acceleration	LREAL	-	0	Master axis phase at the maximum acceleration of the cam curve.
MinAccDec	Minimum acceleration	LREAL	-	0	Minimum acceleration.
MinAccDecPhase	Phase at the minimum acceleration	LREAL	-	0	Master axis phase at the minimum acceleration of the cam curve.

- **Function**
  - This instruction is executed on a rising edge of the input variable Execute.
  - You can use this instruction to calculate information such as the velocity and acceleration of the slave axis, regardless of the states of the master and slave axes.
- **Precautions**
  - If the in-out variable CamTable of this instruction is in read/write or update state, a fault will occur.
  - If the in-out variable CamTable of this instruction is user-defined, the MC_GenerateCamTable (Update the cam table with specified cam data) instruction must be used to check the validity of the cam table. After the check results are acceptable, this instruction can be executed to calculate information such as the velocity and acceleration of the slave axis; otherwise, a fault will occur.
  - If the input variables MasterScaling and/or SlaveScaling of this instruction are less than or equal to 0, they will be automatically corrected to 1.
  - When other input variables of this instruction are specified improperly, a fault occurs.
  - When dense nodes are specified for the in-out variable CamTable of this instruction, a fault occurs.
- **Timing diagram**

  When the parameter “Execute” is activated, the parameter “Busy” shows the value TRUE. After the position, velocity, and acceleration of the slave axis are calculated, the parameter Done shows the value TRUE.



- **Faults**
  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.4.14 MC_CamIn

This instruction controls the camming of the specified master and slave axis according to a specified cam table.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_CamIn	Start camming		MC_CamIn_Instance_0(Master :=, Slave :=, CamTable :=, Execute :=, Periodic :=, StartMode :=, StartPosition :=, MasterStartDistance :=, MasterScaling :=, SlaveScaling :=, MasterOffset :=, SlaveOffset :=, MasterValueSource :=, Direction :=, Velocity :=, Acceleration :=, UpDateRightNow :=, BufferMode :=, CamInState =>, InCam =>, InSync =>, EndOfProfile =>, Busy =>, Active =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

  In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Master	Master axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the master axis; an instance of AXIS_REF.
Slave	Slave axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the slave axis; an instance of AXIS_REF.

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
CamTable	Cam table	18.3.3.2.3.1 MC_CAM_TABLE_REF: Cam table structure	-	-	Specify the cam table for camming.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	Execute the instruction on a rising edge.
Periodic	Periodic	INT	Positive number or 0	0	Specify the number of executing the cam table. 0: Periodically. Others: Number of cycles.
StartMode	Start position mode	INT	0, 1, 2	0	0: Absolute position. 1: Relative position. 2: Immediate start.
StartPosition	Cam table start position	LREAL	Positive number, negative number, or 0	0	Start position of the cam table.
MasterStartDistance	Master axis position	LREAL	Positive number, negative number, or 0	0	Position [u] of the master axis when the slave axis starts camming.
MasterScaling	Master axis scaling	LREAL	Positive number	1	Extend or contract the master axis phase with the specified scale.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
SlaveScaling	Slave axis scaling	LREAL	Positive number	1	Extend or contract the slave axis phase with the specified scale.
MasterOffset	Master axis offset	LREAL	Positive number, negative number, or 0	0	Shift the phase of the master axis with the specified offset.
SlaveOffset	Slave axis offset	LREAL	Positive number, negative number, or 0	0	Shift the displacement of the slave axis with the specified offset.
MasterValueSource	Master axis data type	18.3.3.2.2.11 MC_REFERENCE_TYPE: Data Type Enumeration	0: mcCommand 1: mcFeedback 2: mcLatestCommand	0	0: Value calculated in the previous task cycle (fSavePosition). 1: Value obtained in the same task cycle (fActPosition). 2: Value calculated in the same task cycle (fSetPosition).
Direction	Direction	18.3.3.2.2.9 MC_DIRECTION: Motion Direction Enumeration	1: DIR_POSITIVE 2: DIR_NEGATIVE 4: DIR_NODIRECTION	1	1: Positive direction. 2: Negative direction. 4: No direction specified.
Velocity	Velocity	LREAL	Positive number	-	Maximum superimposed velocity during dynamic coupling.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Acceleration	Acceleration/ deceleration	LREAL	Positive number or 0	0	Maximum superimposed acceleration during smooth coupling. The input value of 0 indicates that coupling is disabled and the slave axis velocity directly jumps to the sum of the camming velocity and coupling velocity. After the coupling ends, the superimposed velocity is directly removed.
UpDateRightNow	Immediate effect flag	BOOL	TRUE, FALSE	TRUE	TRUE: Take effect immediately. FALSE: Take effect in the next cycle.
BufferMode	Buffer mode	18.3.3.2.2.6 MC_BUFFER_MODE: Buffer Mode Enumeration	0: mcAborting 1: mcBuffered	0	0: Aborting. 1: Buffered.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
CamInState	Camming state	18.3.3.2.3.5 MC_CAM_IN_STATE_REF: Camming state structure	-	-	Describe the current execution state of the cam table, including master and slave axis IDs, master axis phase, slave axis displacement, number of cycles executed, etc. See the variable description for structure information.
InCam	Camming	BOOL	TRUE, FALSE	FALSE	TRUE when the master axis passes the start point of the cam table.
InSync	Synchronizing	BOOL	TRUE, FALSE	FALSE	TRUE when the slave axis starts camming.
EndOfProfile	End of camming cycle	BOOL	TRUE, FALSE	FALSE	TRUE when the end point of the cam table is used as the position reference, and FALSE in the next cycle.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Active	Controlling	BOOL	TRUE, FALSE	FALSE	TRUE when the axis is being controlled.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is aborted by another instruction.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Parameter correction**

Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Velocity	Velocity	Any velocity that exceeds the motion parameter limit will be automatically corrected to the velocity limit.	Any velocity less than 0 will be automatically corrected to 1e-5.	The velocity equal to 0 will be automatically corrected to 1e-5.
Acceleration	Acceleration	Any acceleration that exceeds the motion parameter limit will be automatically corrected to the acceleration limit.	Any acceleration less than 0 will be automatically corrected to 10% of the acceleration limit.	No correction.

- **Function**

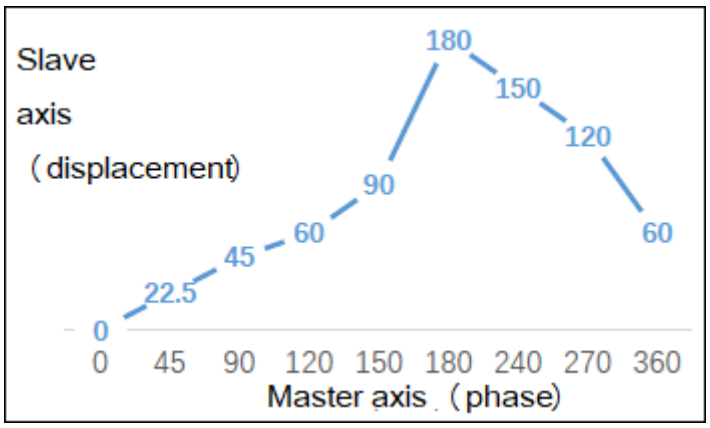
  Bus-controlled axis:

  - This instruction synchronizes the camming of the master and slave axes according to the cam table.
  - This instruction is executed on a rising edge of the input variable Execute.
  - The master and slave axes executing the camming cannot be the same.
  - This instruction can be used in combination with other synchronous control instructions. Its in-out variable Master can be the master or slave axis of other synchronous control instructions; its in-out variable Slave can serve as the master axis of other synchronous control instructions.
  - During the execution of this instruction, the MC_MoveSuperImposed instruction can be used.

- When the instruction is triggered on a rising edge of the input parameter Execute, the input parameters are checked for validity. If any of invalid parameters is detected, it will be automatically corrected by the function block with no fault message; any buffered instructions after this instruction will be cleared.
- The cam table specified by the in-out variables CamTable of this instruction must be edited within the cam editor and downloaded to the controller in advance. When it is a user-defined cam table, the MC_GenerateCamTable instruction must be used to check the validity of the cam table before executing the MC_CamIn instruction.

Cam table 1

Master Axis (Phase)	Slave Axis (Displacement)
0	0
90	45
180	180
270	120
360	60



Position references of the master and slave axes executing camming (large phase interval)

Cam table 2

Master Axis (Phase)	Slave Axis (Displacement)
0	0
45	22.5
90	45
120	60
150	90
180	180
240	150
270	120

Master Axis (Phase)	Slave Axis (Displacement)
360	60

Position references of the master and slave axes executing camming (small phase interval)

- The phase of the master axis and the displacement of the slave axis in the cam table start from "0". The minimum interval between adjacent phases cannot be less than 0.0001.
- The relative mode is set for the cam table, which means all values in the cam table are relative to the start point of the table.
- If bus cycle is specified for the cycle task of the master axis, the velocity of the slave axis may show a sudden jump after synchronization. It is recommended that users specify EtherCAT cycle for the cycle task of both the master and slave axes before enabling a synchronous control instruction.
- MC_Home, MC_Homing, or MC_HomingWithParameter can be used during the instruction execution.

  This instruction places the master axis in the AXIS_HOMING state. If the instruction is executed while the master axis is already in this state, the signal source "MasterValueSource" must be set to "mcLatestCommand"; otherwise, the slave axis will overspeed.

Software limit

- During camming, if the master axis position is beyond the software limit, the master axis velocity will decelerate to 0 within one cycle, without affecting the synchronization state of the slave axis. At this point, if the master axis is reset and restarts its motion, the slave axis will remain position synchronized.
- During camming, if the slave axis position is beyond the software limit, the instruction will be aborted, and the slave axis will decelerate to 0 within one cycle with the state switching from SynchronizedMotion to ErrorStop.

Re-execution

This instruction can be re-executed:

1. You can re-trigger this instruction only after modifying the parameters Periodic, Direction, MasterValueSource, MasterScaling, and SlaveScaling. When you re-execute the instruction after modifying other parameters, a fault occurs. After the instruction is re-executed, the modified parameters will be checked for validity.
2. The changes to the parameters will take effect in the next camming cycle after the instruction is re-executed.
3. If the instruction is re-executed, the number of executed camming cycles will be recalculated.

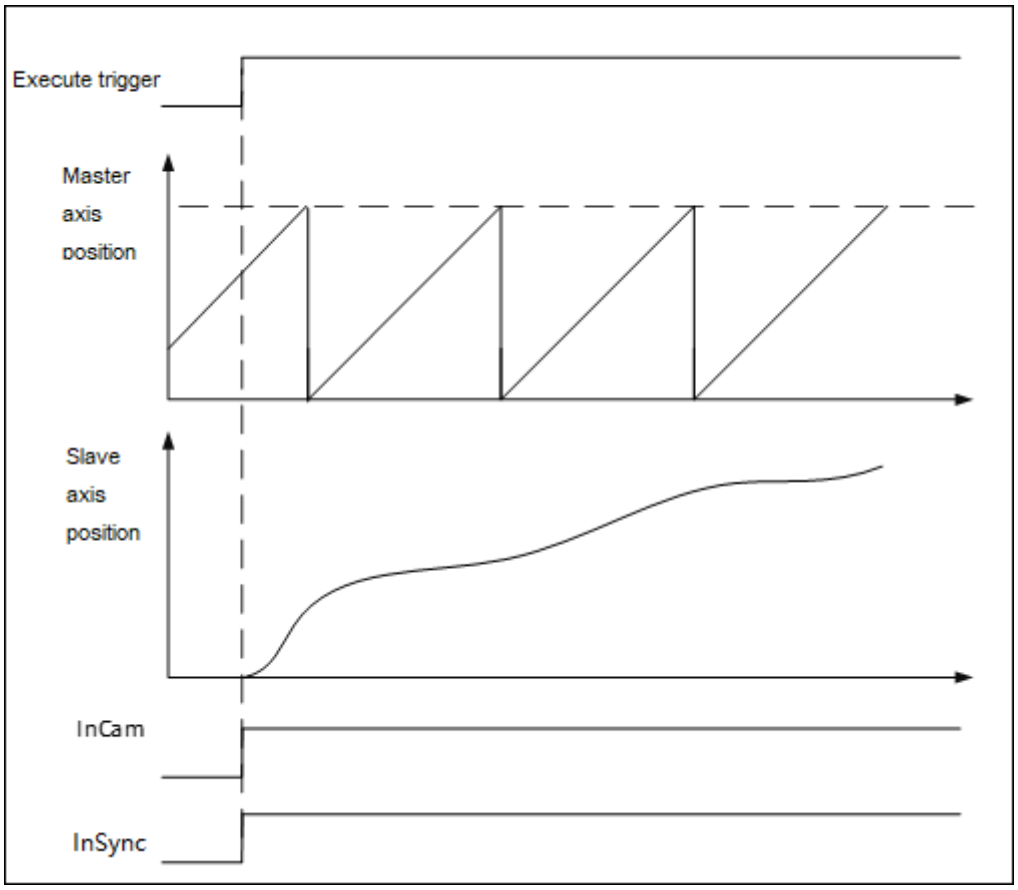
4. If any instructions are buffered after this instruction, the buffered instructions will be aborted after this instruction is re-executed, and must be re-buffered.
5. After the instruction is re-executed with the modified value of Direction, if the motion direction of the master axis is opposite to the modified Direction after the current camming cycle ends, the slave axis will perform an emergency stop and start to follow the master axis when the master axis direction matches the active following direction.
6. When this instruction is re-executed, a new camming cycle will start directly with StartMode = 2 at the end of the current camming cycle.
7. When the MC_CamIn instruction is being executed with a triggered phase superposition instruction, re-executing the MC_CamIn instruction will abort the phase superposition instruction.
8. During the execution of the MC_CamIn instruction, if this instruction is re-executed with a new cam table, it will be executed according to the new cam table and re-executed parameters after the current cycle ends.

Conditions for executing the instruction

- This instruction can be executed when the master axis (Master) specified by the instruction is in the ErrorStop or PowerOff state.
- This instruction can be triggered when the slave axis specified by the instruction is not in the ErrorStop or PowerOff state. If the slave axis is in the STOPPING or HOMING state, the instruction will be aborted.

Start of camming

After the instruction is executed, the master axis has to reach the StartPosition. After the master axis passes the StartPosition, the cable table start point is executed with the output flag InCam showing the value TRUE, which means that the synchronous motion between the master and slave axes is about to start at the current position. For example, if the count mode of the master axis is 0° to 360° in Rotary mode, the StartPosition is 60. The absolute position of the master axis is the phase of the cam table plus the value of the StartPosition. The absolute position of the slave axis is the displacement from the cam table plus the absolute position of the slave axis at the cam table start point.



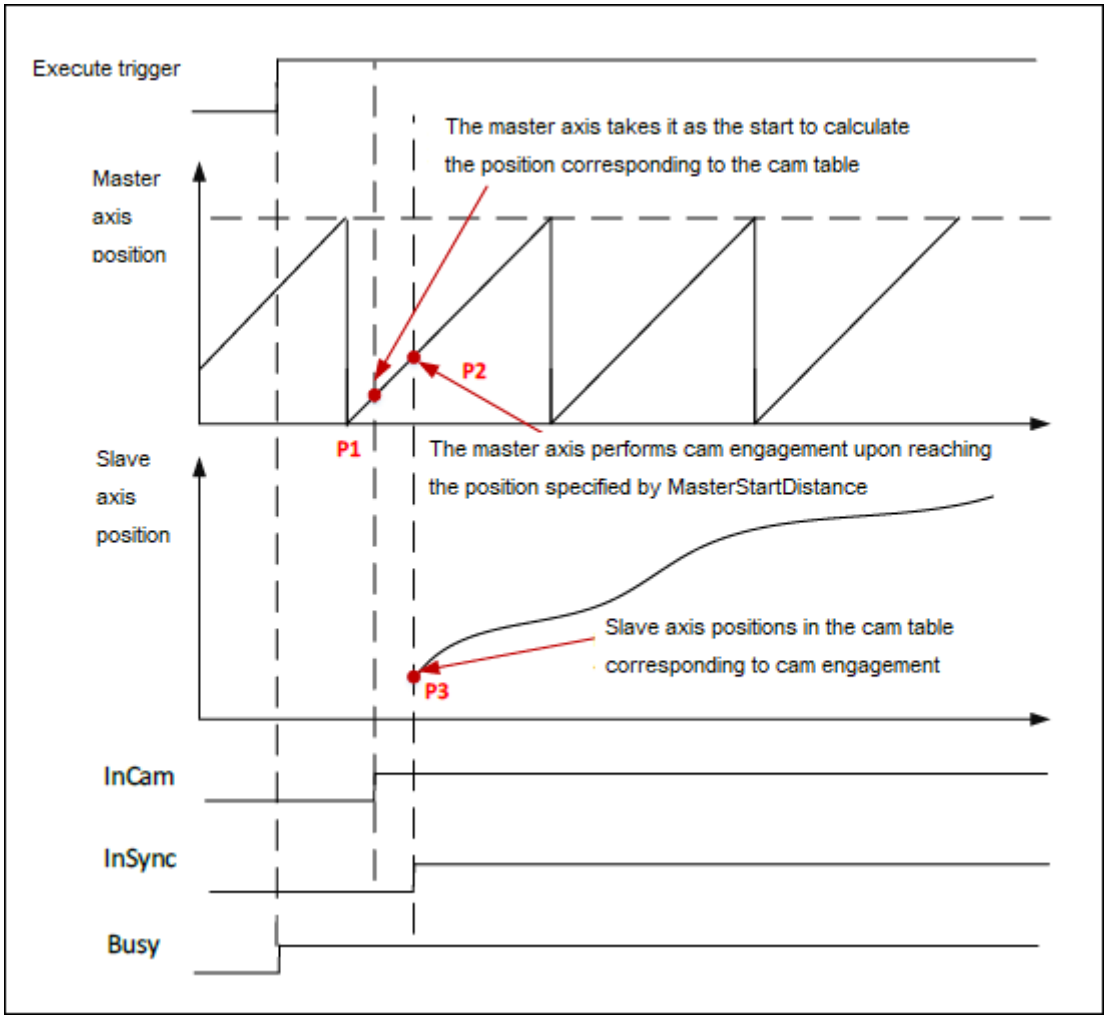
Absolute positions of the master and slave axes in the cam table 3

Master Axis (Phase)	Slave Axis (Displacement)
60	0
150	45
240	180
330	120
60	60

- **StartMode**

  You can specify the start mode through StartMode for this instruction. There are three start modes, two of which specify the parameter MasterStartDistance: one is Relative Position mode, which specifies the start position of the camming to be calculated based on the cam table start point; the other is Absolute Position mode, which directly specifies the start position of the camming. The last mode is Immediate Start mode, which means that the camming starts immediately after the instruction is triggered.

(1) For Immediate Start mode, the output flags InCam and InSync of MC_CamIn are set as shown in the following figure:



(2) You can start camming with specified positions in Relative Position mode (StartMode = 1) and Absolute Position mode (StartMode = 0).

After the instruction is executed, the output variable InCam shows the value TRUE when the master axis reaches the StartPosition.

StartMode = 0: When the master axis moves in the specified motion direction and reaches the MasterStartDistance, the slave axis starts to follow the master axis, and the output variable InSync shows the value TRUE.

StartMode = 1: When the master axis moves in the specified motion direction and reaches the MasterStartDistance + StartPosition position, the slave axis starts to follow the master axis, and the output variable InSync shows the value TRUE.

The execution of the cam table is shown in the following figure:

◦ **InCam and InSync**

- When the master axis is specified as a rotary axis:

  If the value of StartPosition is greater than one cycle length, the start position will be identified as the StartPosition modulo the cycle length.

  If the value of MasterStartDistance is greater than one camming cycle and the StartMode is set to 0, the InSync position will be identified as the MasterStartDistance modulo the camming cycle.

- With certain parameter combinations, the InSync cannot be set to TRUE. Specifically, this includes the following cases:

  1. Absolute mode:

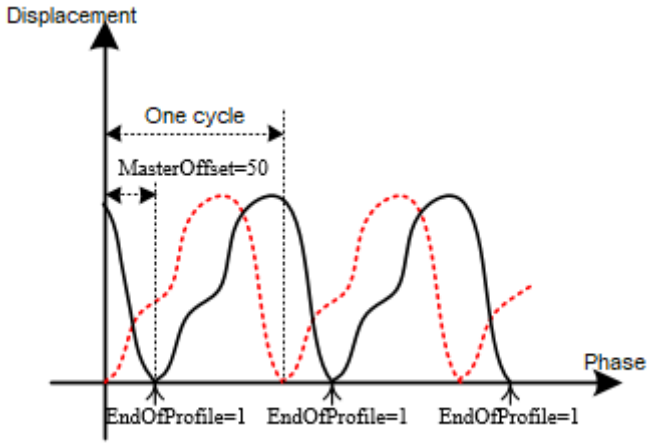
  a. The master axis is specified as a linear axis; the value of StartPosition is greater than the value of MasterStartDistance; the master axis motion direction is specified as DIR_POSITIVE.

  b. The master axis is specified as a linear axis; the value of StartPosition is less than the value of MasterStartDistance; the master axis motion direction is specified as DIR_NEGATIVE.

  2. Relative mode:

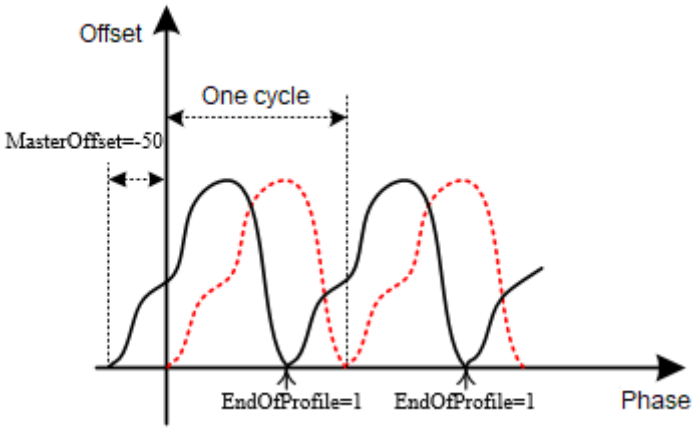
  a. The value of MasterStartDistance is less than 0; the master axis motion direction is specified as DIR_POSITIVE.

b. The value of MasterStartDistance is greater than 0; the master axis motion direction is specified as DIR_NEGATIVE.



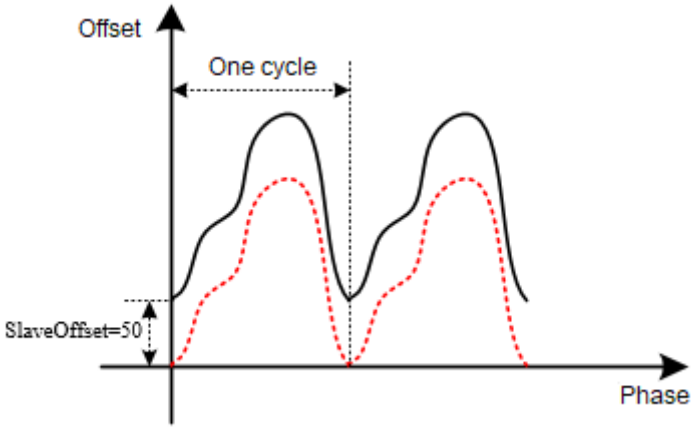
- The InSync will be set to TRUE only when the master axis moves in the specified direction and passes the specified synchronization position.
- The InCam will be set to TRUE only when the master axis moves in the specified direction and passes the specified cam table start point.
- The InSync is set only after the InCam has been set, or both InSync and InCam may be set simultaneously.
- When the StartMode is set to 2, the InSync and InCam instructions are set to TRUE after the MC_CamIn is executed, and this start mode does not trigger the validity check of the MasterStartDistance, as this parameter has no actual effect. In this mode, whether to enable coupling depends on the values of MasterOffset, SlaveOffset, and Acceleration.

◦ **MasterOffset and SlaveOffset**

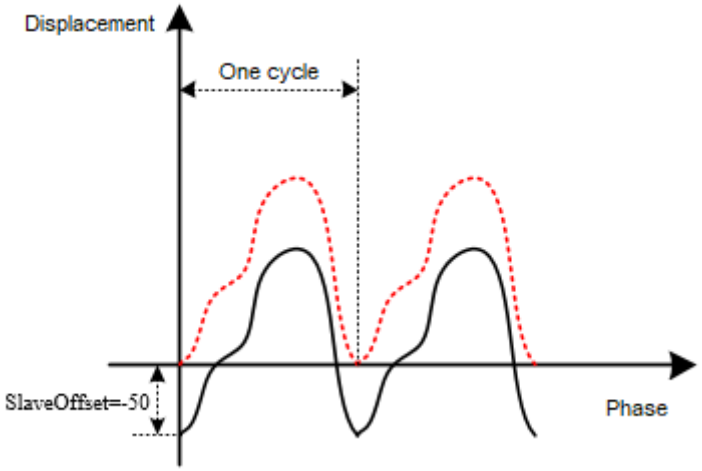


After the StartPositon of the cam is determined, the cam is scaled proportionally and then applied with an offset, the value of which is not affected by the scaling factor.

If the value of the input variable MasterOffset is greater than one camming cycle, the modulo operation will be performed.

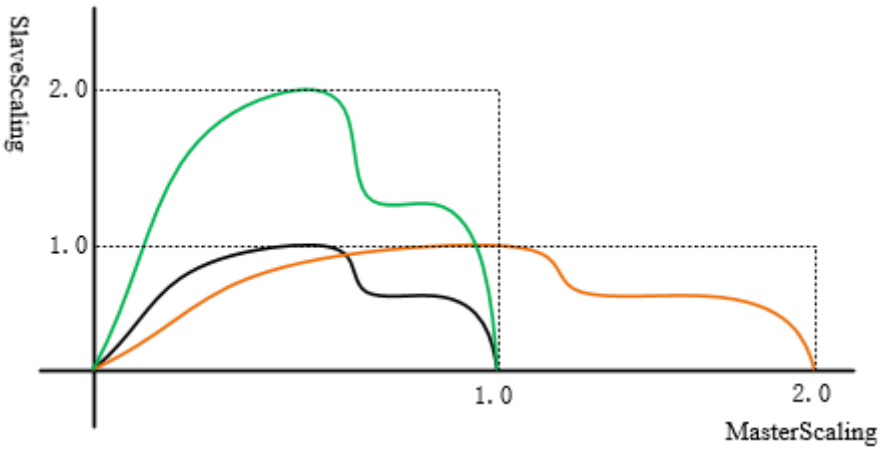


MasterOffset > 0



MasterOffset < 0

SlaveOffset > 0



SlaveOffset < 0

- **MasterScaling and SlaveScaling**

  The master axis phase and slave axis displacement can be scaled according to a specified scale. Different scaling coefficients can be set for the master axis and slave axis, respectively. If the input variables MasterScaling and/or SlaveScaling of this instruction are less than or equal to 0, they will be automatically corrected to 1.

- **Periodic**

  You can specify the number of times the MC_CamIn instruction is executed by defining the value of the input variable Periodic. If this variable is set to 0, the instruction will be executed periodically. In this case, there are two types of motion for the slave axis: one is reciprocating motion, and the other is unidirectional contour following motion.

When the Periodic is set to N, the slave axis automatically ends synchronization after the specified cycles have been completed. If the slave axis still moves at the velocity of non-zero after the cam table is executed, it will perform an immediate stop.

Changes in the master axis phase and slave axis displacement during periodic execution

- **EndOfProfile**

  The output variable EndOfProfile is set to TRUE when the cam table end point is used as the position reference, and changes to FALSE in the next cycle.

- **End of camming**

  To abort camming midway, you can execute the MC_CamOut, MC_Stop, or MC_ImmediateStop instruction on the slave axis.

- **Position type selection**

  You can select the MasterValueSource for synchronizing the slave axis based on the following options.

  - mcCommand: Commanded position (Value calculated in the previous task cycle, fSavePosition).

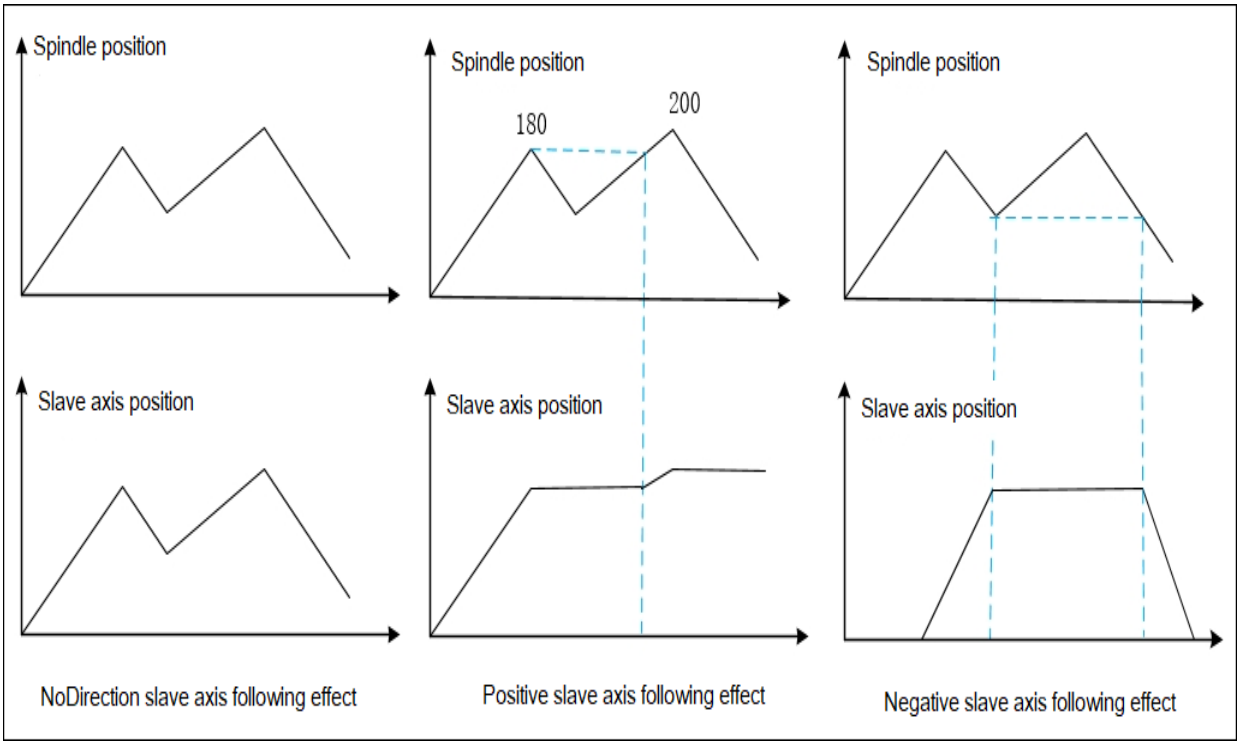
    For the current cycle, use the master axis position calculated in the previous task cycle.

  - mcFeedback: Actual position (Value obtained in the same task cycle, fActPosition).

    Use the actual master axis position obtained in the same task cycle.

  - mcLaterCommand: Commanded position (Value calculated in the same task cycle, fSetPosition).

    Use the master axis position calculated in the same task cycle.



- **Direction**

  The slave axis executes camming when the master axis moves in the specified direction. In other words, the camming operation is started for the slave axis only when the master axis moves in the direction specified by Direction.

DIR_NODIRECTION: Camming starts regardless of whether the motion direction of the master axis.

DIR_POSITIVE: Camming starts when the master axis moves in the positive direction.

DIR_NEGATIVE: Camming starts when the master axis moves in the negative direction.

- **Precautions**
  - When this instruction is buffered with Active not being set, you can re-execute the instruction after modifying parameters.
  - During the execution of this instruction, the master and slave axes cannot be changed; otherwise, a fault occurs.
  - If the StartMode of a buffered MC_CamIn instruction is set to Immediate start, the buffered instruction will immediately execute the corresponding cam table following the end of the previous MC_CamIn instruction.
  - During smooth coupling, there may be instances where the slave axis does not strictly follow the camming of the master axis.
- **Example**

  This instruction is a synchronous motion control instruction. The cam motion is based on a master axis and one or more slave axes. The master axis can be a physical axis or a virtual axis.

  When the master axis is a virtual axis, the motion is called electronic camming. Electronic camming enables convenient definition of machining trajectories with simple changes to the cam table, eliminating the need to frequent mechanical cam replacement.

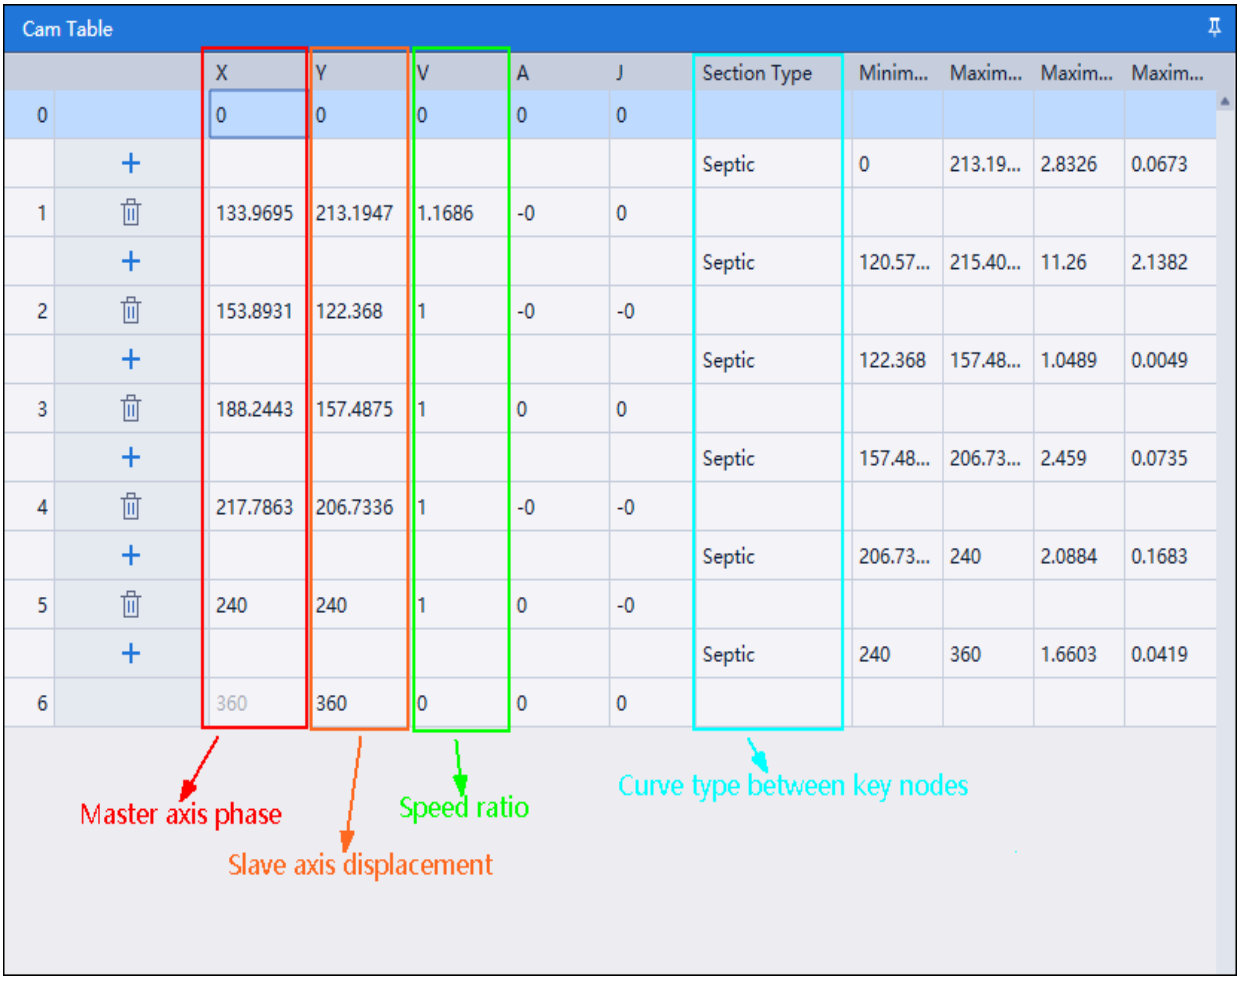
  The following shows the steps for using synchronization instructions:

  ① Specify the master and slave axes for synchronous motion based on the specific application scenario. The master axis for a synchronous motion control instruction can be a slave axis of another synchronous motion control instruction. The slave axis of one synchronous motion control instruction can also serve as the master axis of another synchronous motion control instruction.

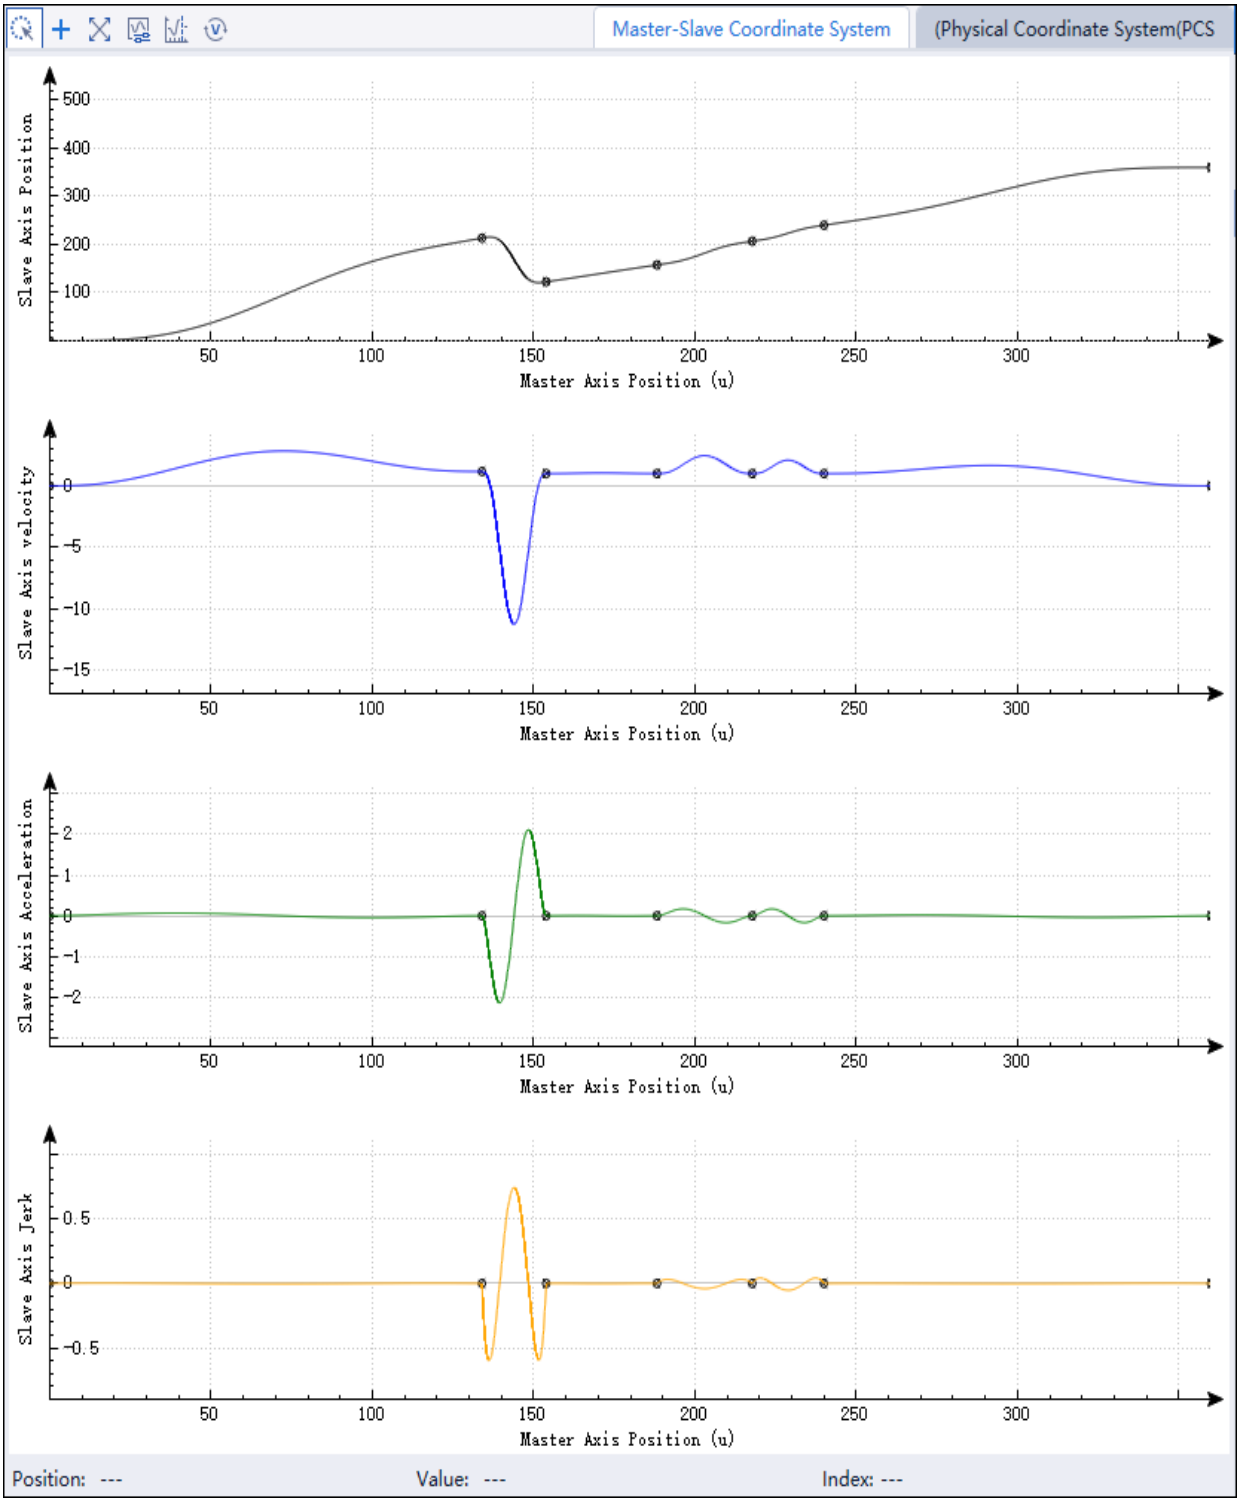
  ② Based on the specific application scenario, determine the position relationship between the master and slave axes, and create a cam table. In multiple different instantiated MC_CamIn instructions,

when Axis is specified as the master axis and Axis_1 is specified as the slave axis, the cam table for each instruction can be different.

③ Use the MC_CamIn instruction to bind the master axis, slave axis, and cam table.

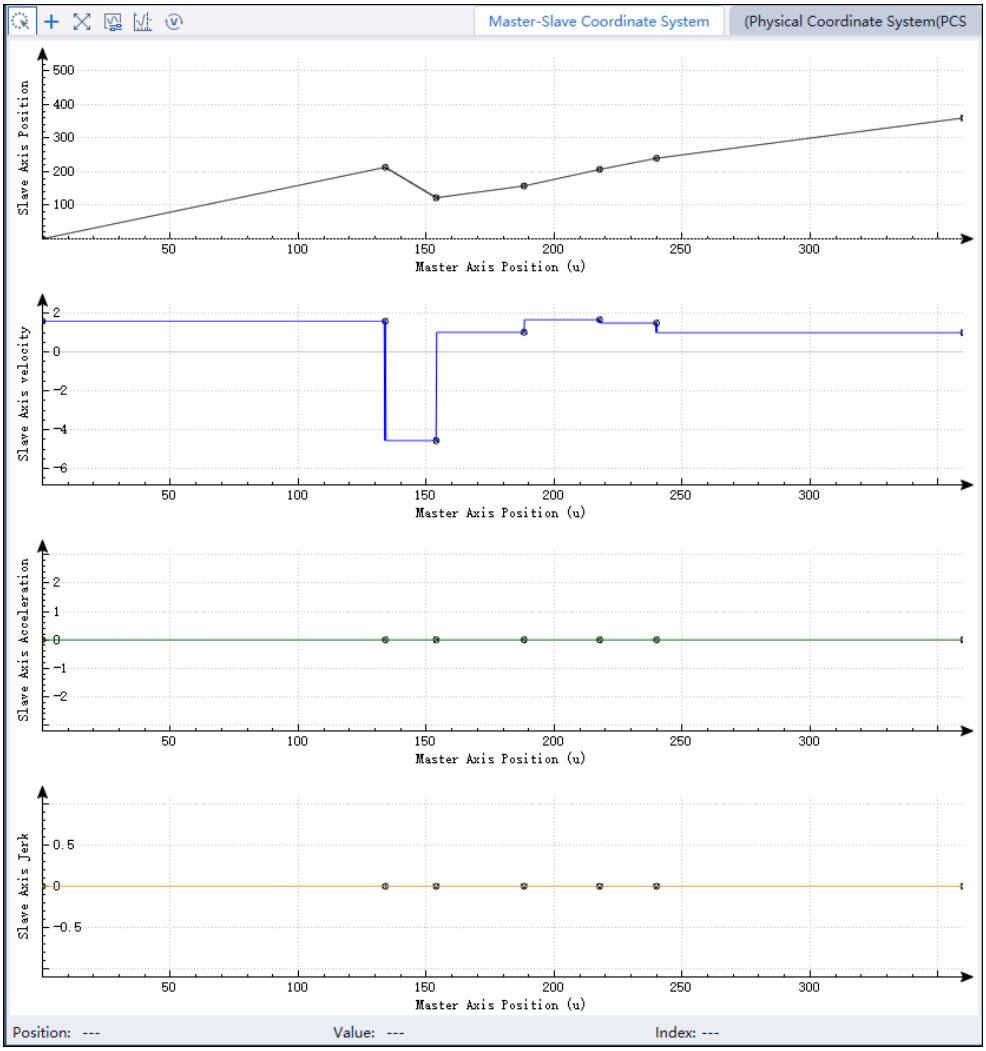


④ Based on the specific application scenario, specify the input parameters of the MC_CamIn instruction and execute this instruction.



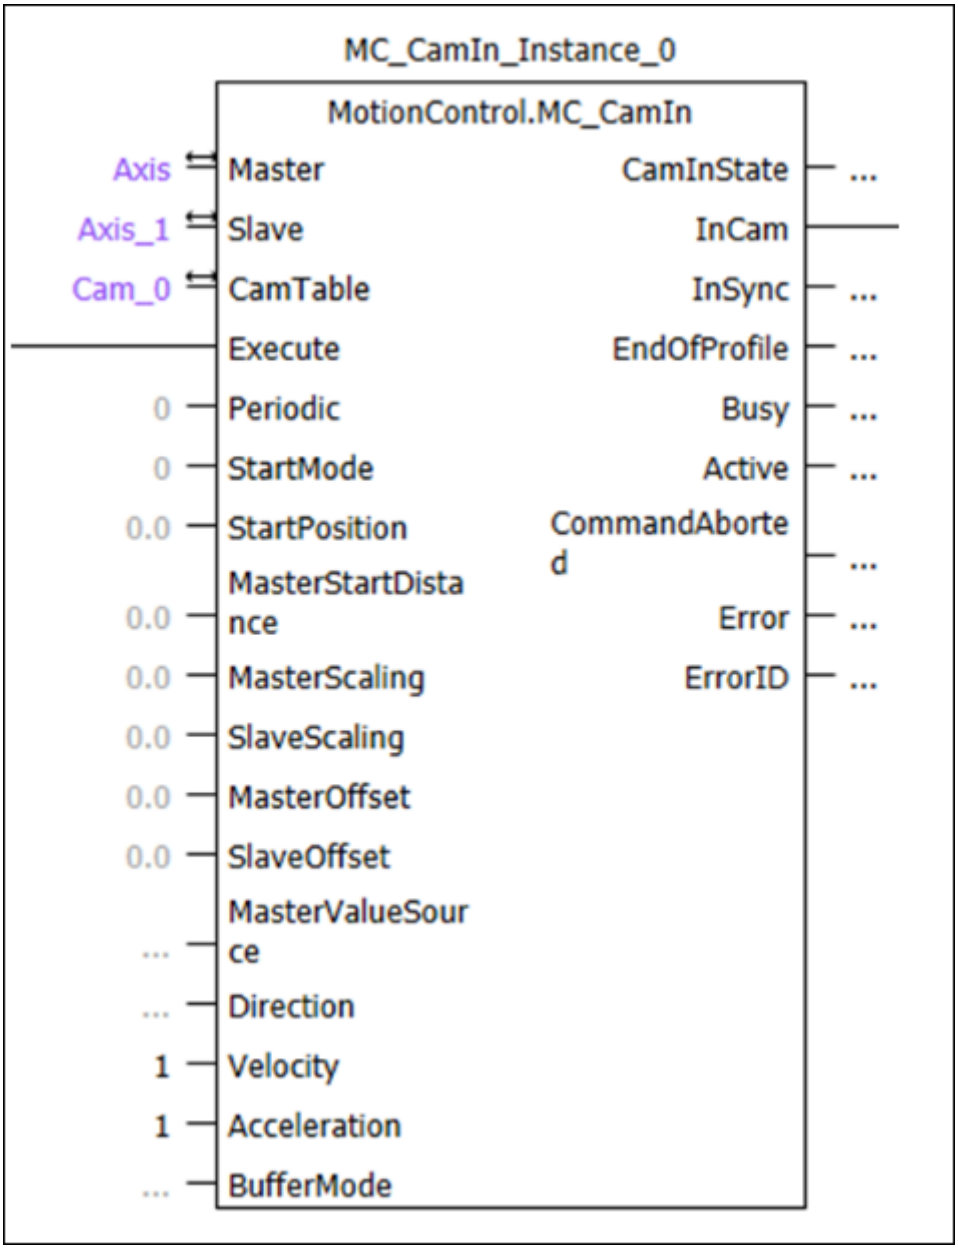
⑤ Wait for the synchronous motion control instruction to complete, or use the MC_CamOut instruction to end the synchronization between the master and slave axes.

In the following program example, the MC_CamIn instruction is executed with the parameter UpDateRightNow defaulting to FALSE.

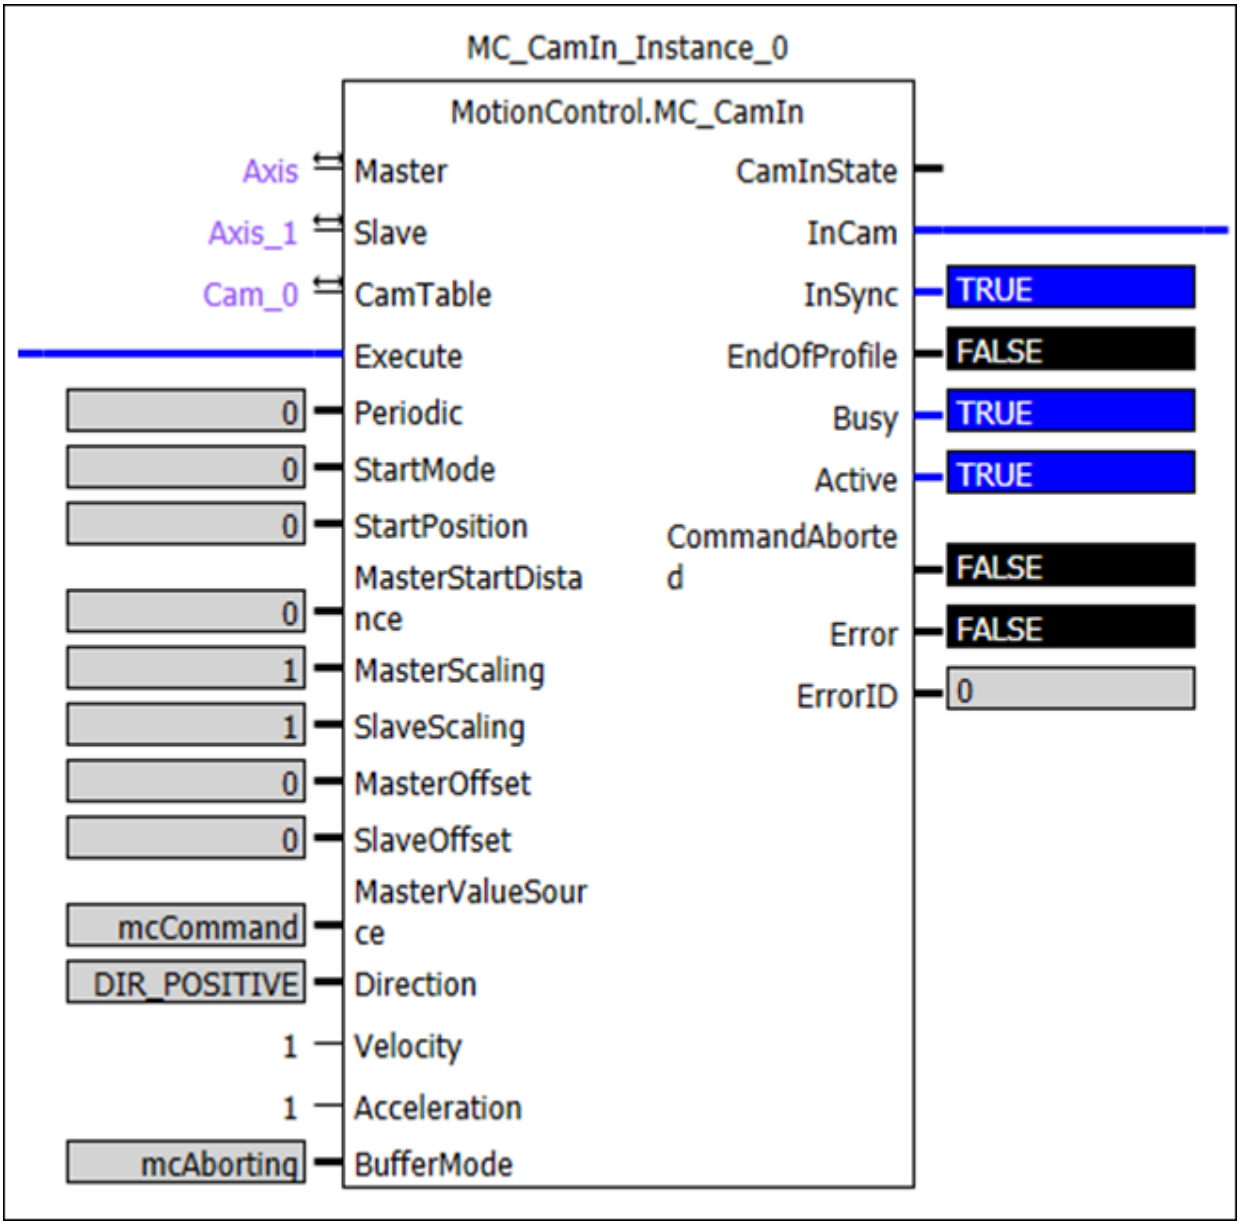


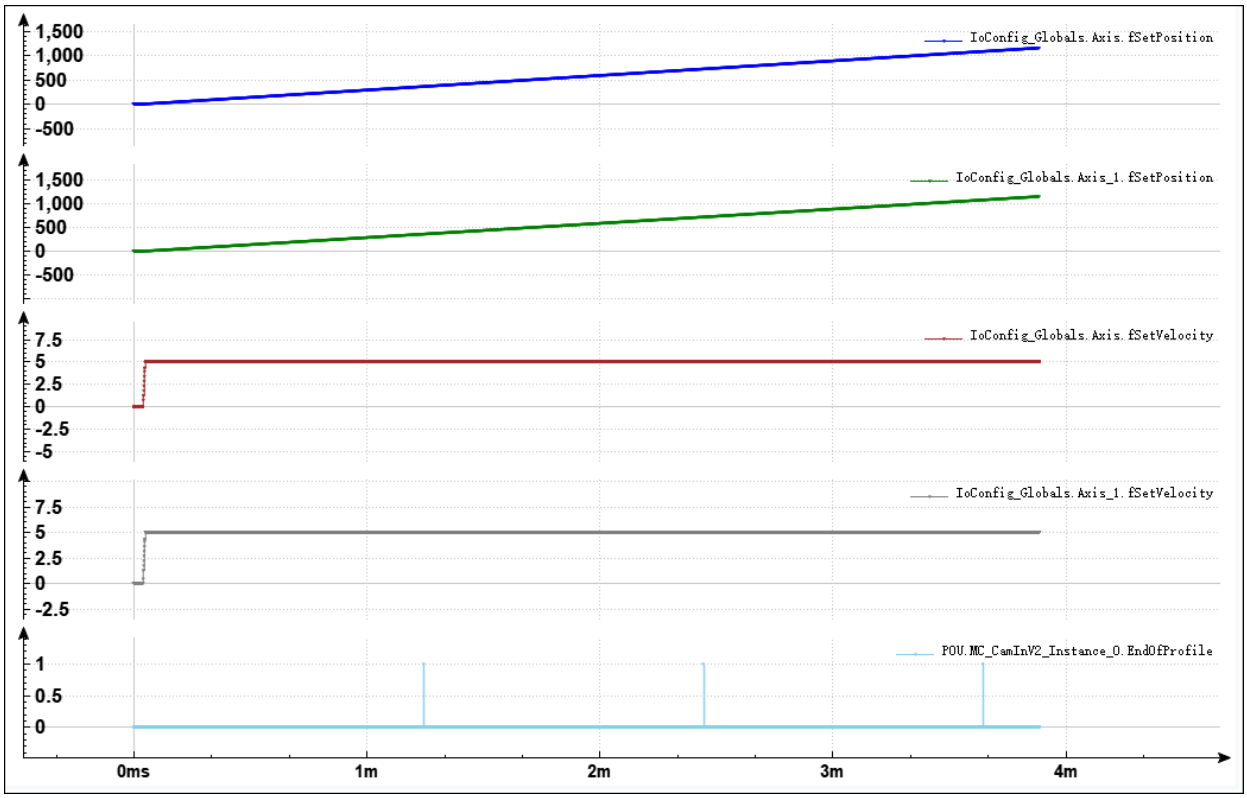
The created cam table automatically generates the position relationship between the master and slave axes, and the velocity information of the slave axis at key nodes. You can adjust the data in the cam table to fit specific application scenarios.

When the master axis phase and the slave axis displacement are adjusted, the velocity ratio is automatically adjusted based on the curve type between key nodes.



When the curve type between key nodes is changed to "Straight line", the velocity, acceleration, and jerk of the slave axis also change.





Create a cam table, specify the position relationship between the master and slave axes, and specify the input parameters of the MC_CamIn instruction according to specific application scenarios.

You can specify the number of times the cam table is executed through the parameter Periodic. When the Periodic is set to 0, it indicates that this instruction is executed repeatedly according to the cam table. When the Periodic is set to a specific value, this instruction is executed according to the specified number of cycles.

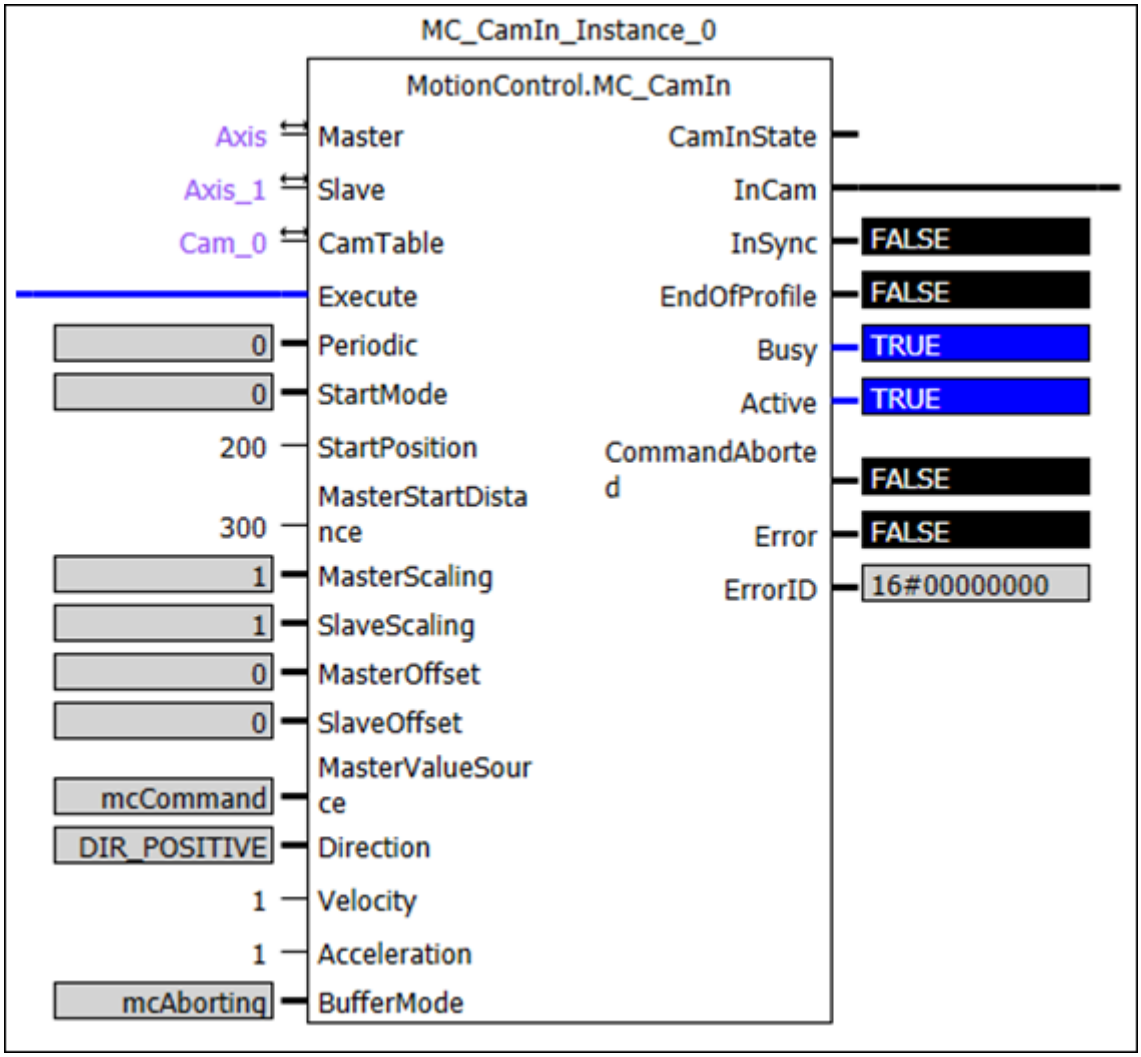
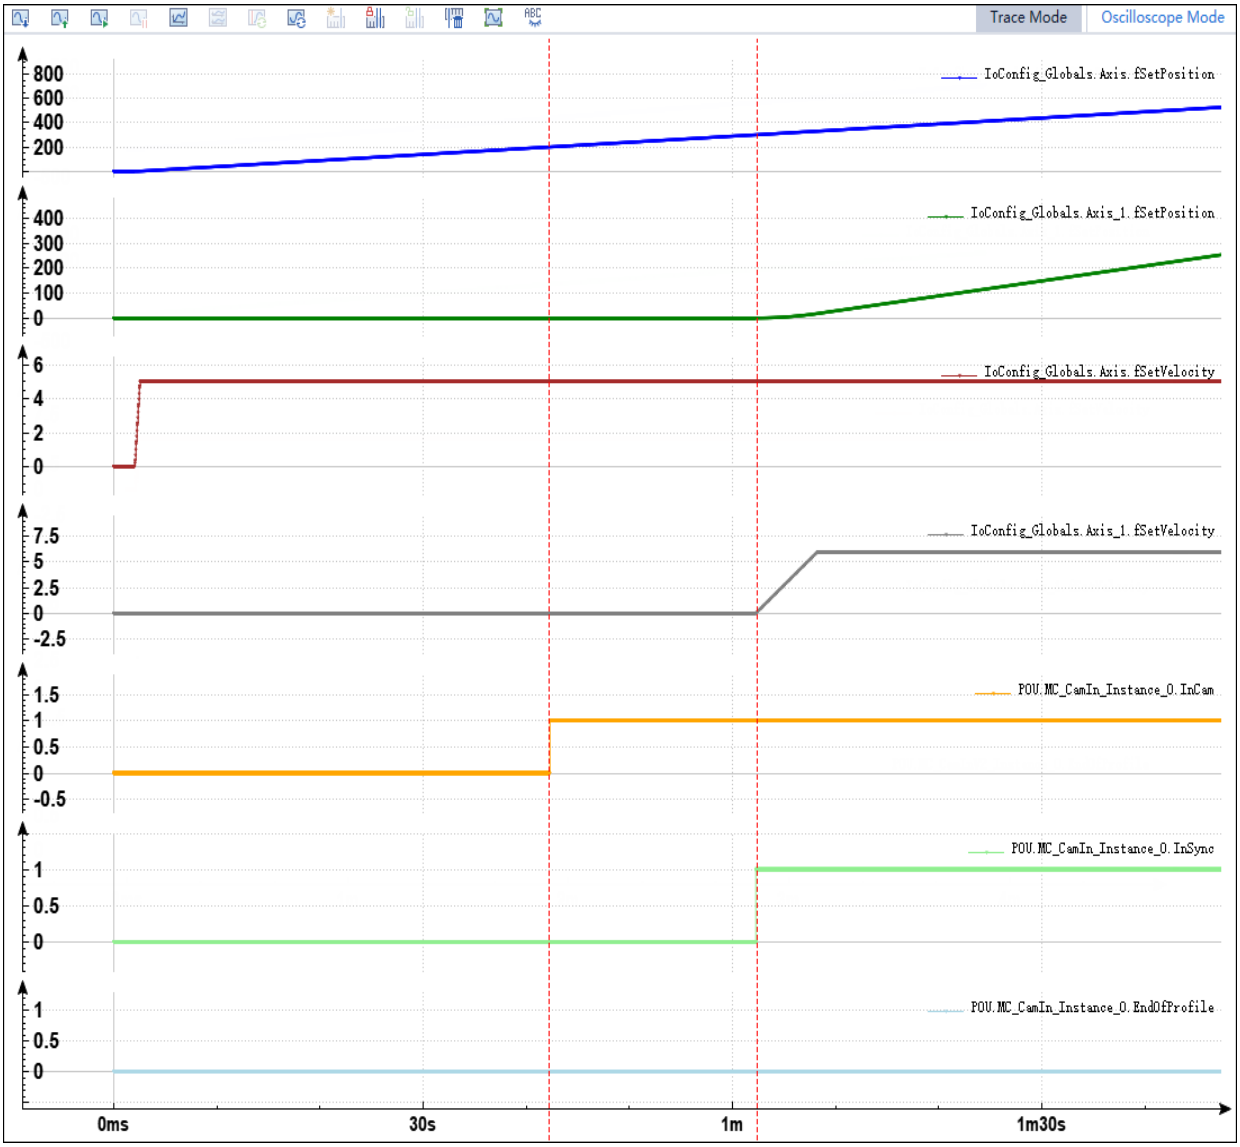
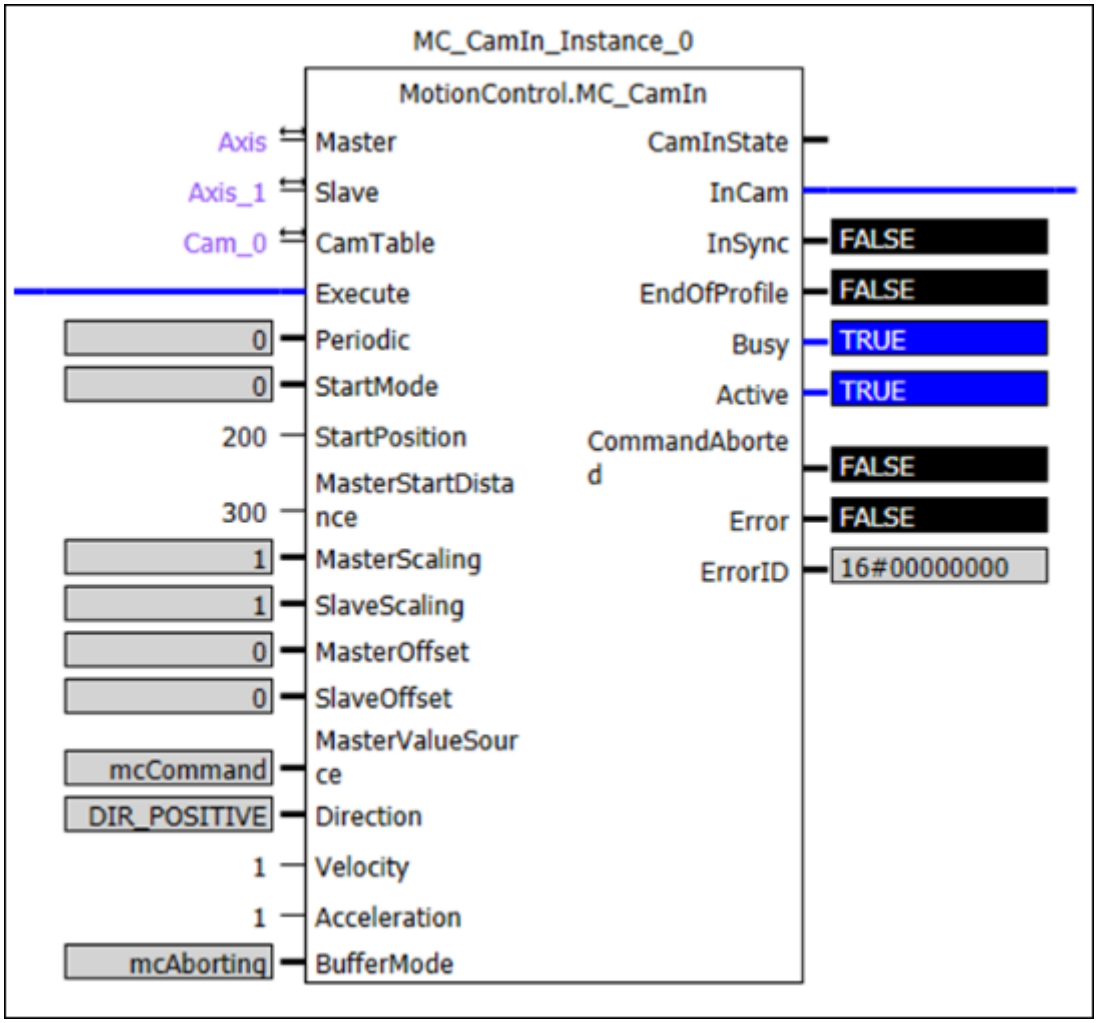
The EndOfProfile is set once for each execution of the cam table, and then reset in the next cycle.



Periodic = 1:



The EndOfProfile is set once for each execution of the cam table, and then reset in the next cycle. After the last cycle ends, the EndOfProfile is kept set.



StartPosition: The value of StartPosition indicates the start point of the cam table for the absolute position of the master axis. If the master axis position does not match the specified value of StartPosition, the InCam will not be set.

MasterStartDistance : The value of MasterStartDistance indicates the position of the master axis when the slave axis starts camming. If the master axis position does not match the specified value of MasterStartDistance, the InSync will not be set, and the slave axis will not start moving. When the value of StartPosition is greater than the value of MasterStartDistance, a fault occurs.

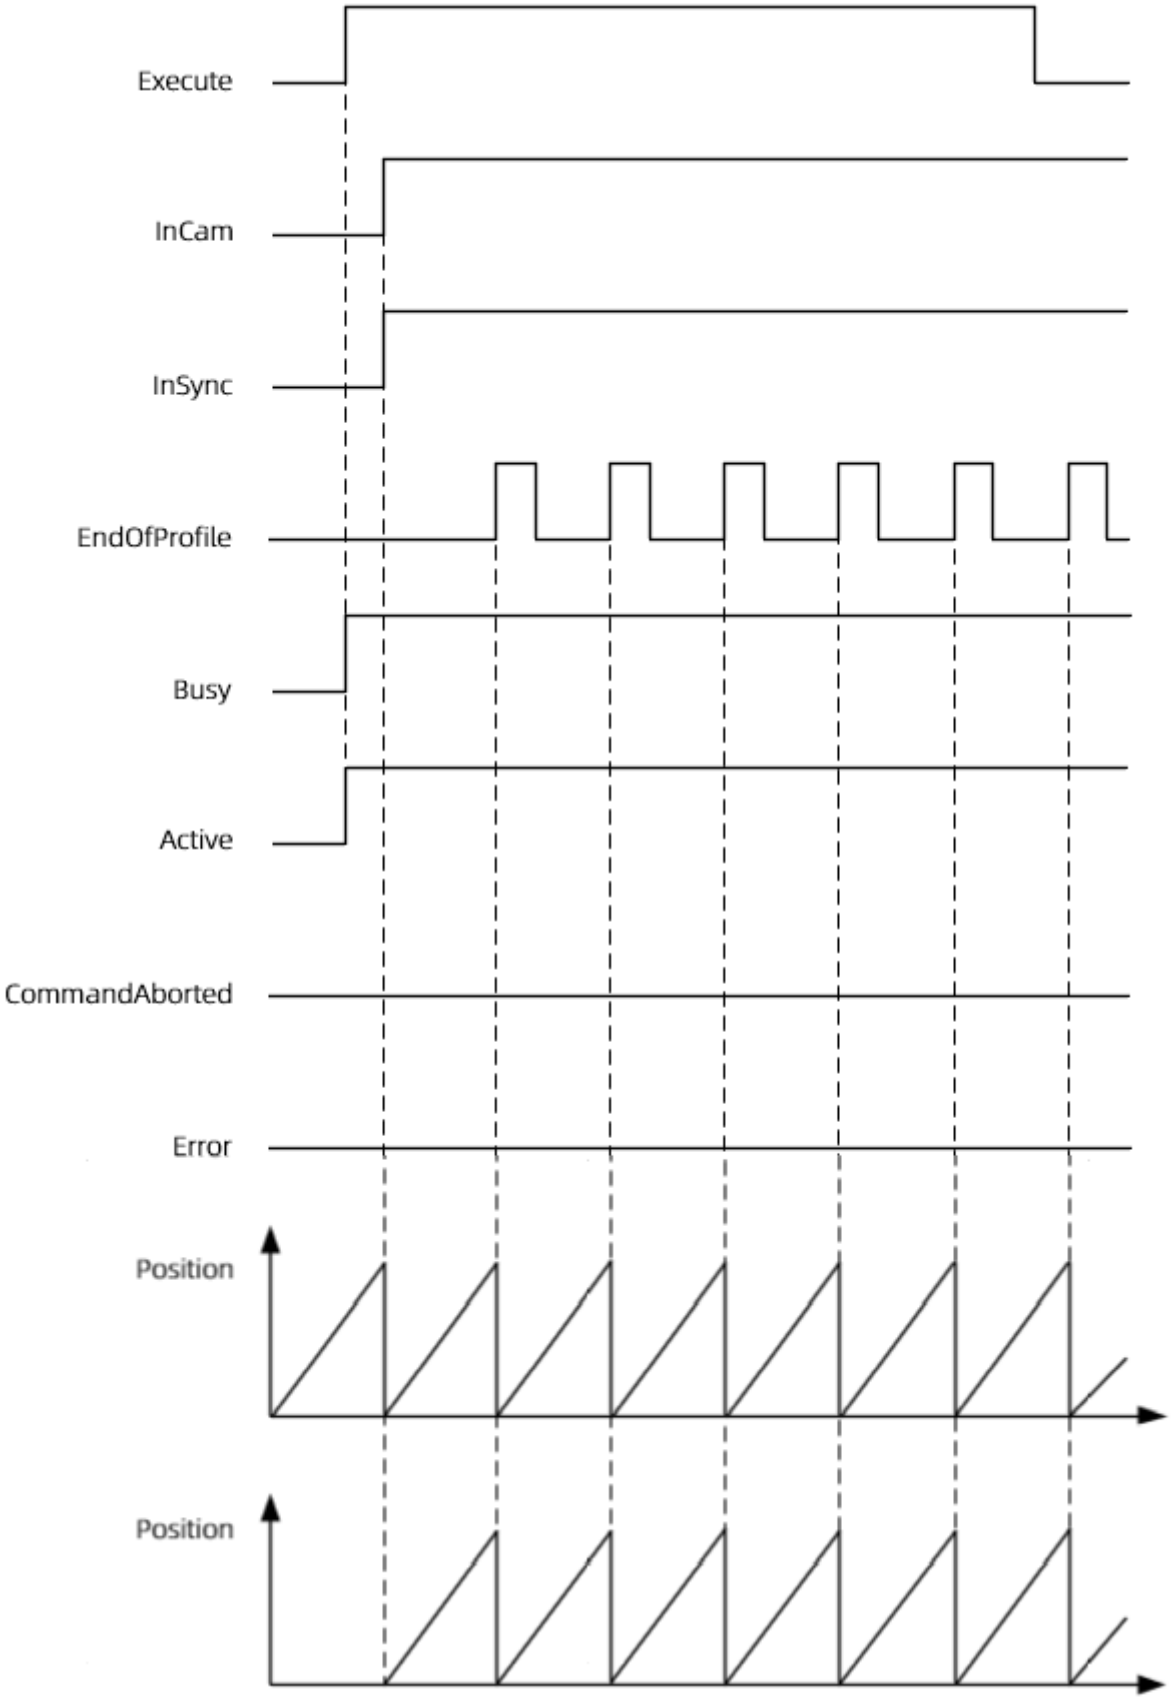
For the slave axis specified as a rotary axis:



Local pulse axis:

- This instruction can be used for local pulse axes.
- When the local pulse axis is used as the master axis with Y0 or Y1 single-ended output, it is not recommended to use this instruction. ① No pulse output; ② No position feedback.

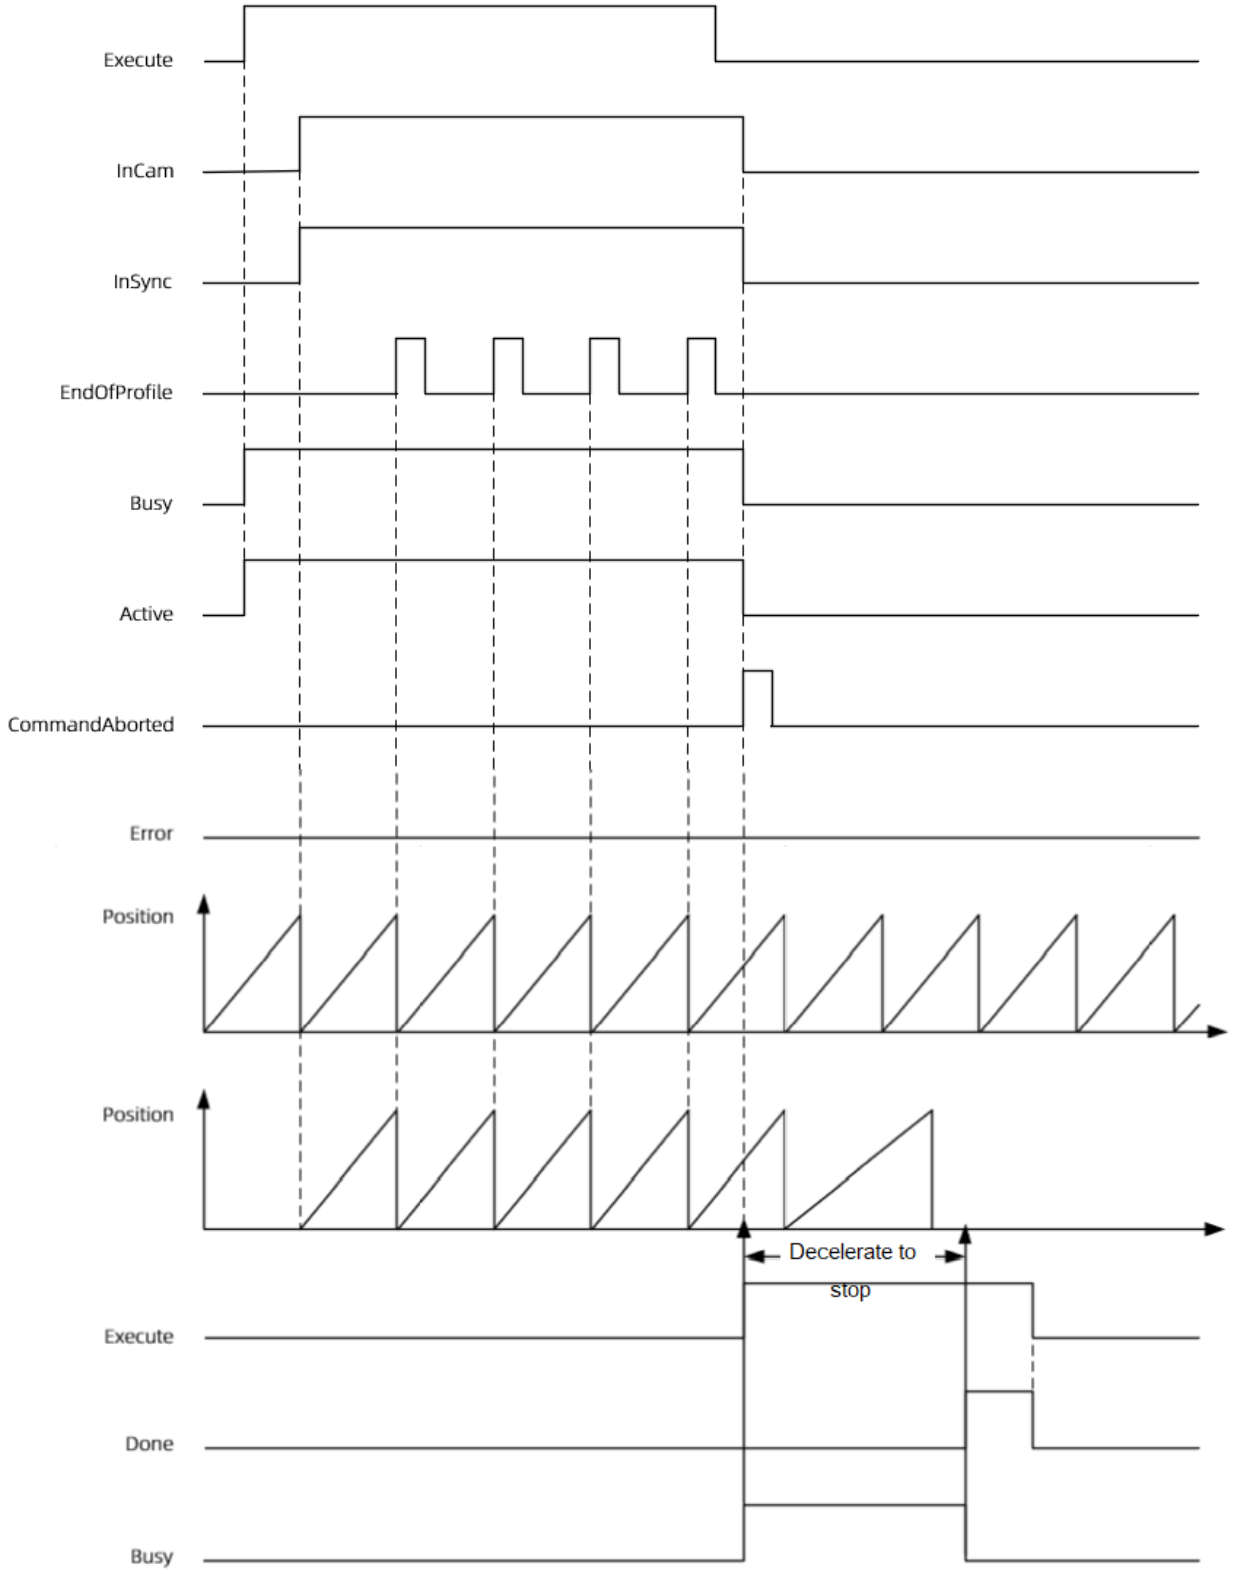
- **Timing diagram**
  - During periodic execution

    When the Periodic of the MC_CamIn instruction is set to 0, the timing diagram is shown in the following figure.

◦ With a number of cycles

Camming is repeated. When the MC_CamOut instruction is executed to stop the camming, the slave axis decelerates to 0 without affecting the master axis.

When the Periodic of the MC_CamIn instruction is set to 5 and the MC_CamOut instruction is executed, the timing diagram is shown in the following figure.

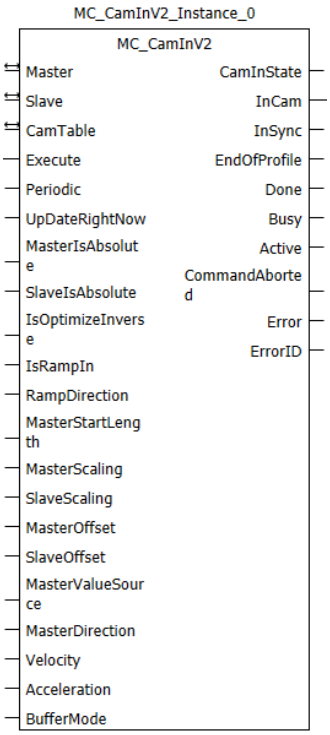


◦ MC_Stop

When the MC_Stop instruction is executed on the master axis during camming, the master and slave axes remain synchronized.

When the MC_Stop instruction is executed on the slave axis during camming, the synchronization between the master and slave axes is terminated.

When the Periodic of the MC_CamIn instruction is set to 5 and the MC_Stop instruction is executed on the slave axis, the timing diagram is shown in the following figure.



- **Faults**
  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.4.15 MC_CamInV2

This instruction controls the camming of the specified master and slave axes according to a specified cam table.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_CamInV2	Start camming		MC_CamInV2_Instance_0(Master :=, Slave :=, CamTable :=, Execute :=, Periodic :=, UpDateRightNow :=, MasterIsAbsolute :=, SlaveIsAbsolute :=, IsOptimizeInverse :=, IsRampIn :=, RampDirection :=, MasterStartLength :=, MasterScaling :=, SlaveScaling :=, MasterOffset :=, SlaveOffset :=, MasterValueSource :=, MasterDirection :=, Velocity :=, Acceleration :=, BufferMode :=, CamInState =>, InCam =>, InSync =>, EndOfProfile =>, Done =>, Busy =>, Active =>, CommandAborted =>, Error =>, ErrorID =>);

  In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Master	Master axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the master axis; an instance of AXIS_REF.
Slave	Slave axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the slave axis; an instance of AXIS_REF.
CamTable	Cam table	18.3.3.2.3.1 MC_CAM_TABLE_REF: Cam table structure	-	-	Specify the cam table for camming.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	The function block is executed on a rising edge of this input variable.
Periodic	Periodic	INT	Positive number or 0	0	Specify the number of executing the cam table. 0: Periodically. Other: Number of cycles. Any number less than 0 will result in a fault.
UpDateRightNow	Effective immediately after modifying the cam table data	BOOL	TRUE, FALSE	TRUE	TRUE: Effective immediately after modifying the cam table data. FALSE: Effective in the next cycle after modifying the cam table data.
MasterIsAbsolute	Master axis absolute mode	BOOL	TRUE, FALSE	FALSE	TRUE: The master axis in the cam table is in absolute coordinate mode. FALSE: The master axis in the cam table is in relative coordinate mode.
SlaveIsAbsolute	Slave axis absolute mode	BOOL	TRUE, FALSE	FALSE	TRUE: The slave axis in the cam table is in absolute coordinate mode. FALSE: The slave axis in the cam table is in relative coordinate mode.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
IsOptimizeInverse	Optimize slave axis inverse motion during coupling	BOOL	TRUE, FALSE	FALSE	This parameter is valid only when the IsRampIn is set to TRUE. TRUE: When the actual motion direction of the slave axis is opposite the velocity direction obtained from the cam table during the RampIn, the optimization function is enabled to prevent the slave axis from inverse motion. FALSE: Do not intervene the coupling process.
IsRampIn	Coupling enabled	BOOL	TRUE, FALSE	FALSE	Specify whether to enable coupling when the slave axis starts to follow the master axis. TRUE: Enabled. The slave axis smoothly transits into cam following. FALSE: Disabled. The slave axis directly jumps to the target position.
RampDirection	Dynamic slave axis coupling direction	18.3.3.2.2.9 MC_DIRECTION: Motion Direction Enumeration	0: DIR_SHORTEST 1: DIR_POSITIVE 2: DIR_NEGATIVE	0	This parameter is valid when the IsRampIn is set to TRUE. DIR_SHORTEST: Based on the shortest compensation way. DIR_POSITIVE: Based on the positive compensation value. DIR_NEGATIVE: Based on the negative compensation value. Parameters DIR_POSITIVE and DIR_NEGATIVE are only applicable to rotary axes; all three parameters have the same effect for linear axes.
MasterStartLength	Master axis leading length	LREAL	Positive number or 0	0	After the instruction is triggered, the slave axis starts camming after the master axis moves for the distance specified by MasterStartLength.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
MasterScaling	Master axis scaling	LREAL	Positive number	1	Extend or contract the master axis phase with the specified scale. When the MasterScaling is set to > 1, the phase range is extended; when the MasterScaling is set to < 1, the phase range is contracted. If the setpoint is less than or equal to 0, it will be automatically corrected to 1 by the function block.
SlaveScaling	Slave axis scaling	LREAL	Positive number	1	Extend or contract the slave axis phase with the specified scale. When the SlaveScaling is set to > 1, the phase range is extended; when the SlaveScaling is set to < 1, the phase range is contracted. If the setpoint is less than or equal to 0, it will be automatically corrected to 1 by the function block.
MasterOffset	Master axis offset	LREAL	Positive number, negative number, or 0	0	Shift the phase of the master axis with the specified offset. When the MasterOffset is set to > 0, the cam curve shifts to the right along the coordinate axis; when the MasterOffset is set to < 0, the cam curve shifts to the left along the coordinate axis.
SlaveOffset	Slave axis offset	LREAL	Positive number, negative number, or 0	0	Shift the displacement of the slave axis with the specified offset. When the SlaveOffset is set to > 0, the cam curve shifts upward; when the SlaveOffset is set to < 0, the cam curve shifts downward.
MasterValueSource	Master axis data type	18.3.3.2.2.11 MC_REFERENCE_TYPE: Data Type Enumeration	0: mcCommand 1: mcFeedback 2: mcLatestCommand	0	0: Value calculated in the previous task cycle (fSavePosition). 1: Value obtained in the same task cycle (fActPosition). 2: Value calculated in the same task cycle (fSetPosition).

Input Variable	Name	Data Type	Valid Range	Default Value	Description
MasterDirection	Master axis effective direction	18.3.3.2.3.8 MC_MASTER_DIRECTION: Master Axis Motion Direction Enumeration	0: CAM_NO_DIRECTION 1: CAM_ABS_POSITIVE 2: CAM_REL_POSITIVE 3: CAM_ABS_NEGATIVE 4: CAM_REL_NEGATIVE	0	When the master axis moves in the specified direction, the slave axis starts camming. CAM_NO_DIRECTION: No direction specified, which means the slave axis follows the master axis regardless of the motion direction of the master axis. CAM_ABS_POSITIVE: Absolute positive. The slave axis follows the master axis when the master axis moves in the positive direction, and stops following if the master axis reverses the direction. The master axis must return to positive direction and reach the reversal point for the slave axis to continue following. CAM_REL_POSITIVE: Relative positive. The slave axis follows the master axis when the master axis moves in the positive direction, and stops following if the master axis reverses the direction. The master axis must return to positive direction without reaching the reversal point for the slave axis to continue following. CAM_ABS_NEGATIVE: Absolute negative. The slave axis follows the master axis when the master axis moves in the negative position, and stops following if the master axis reverses the direction. The master axis must return to negative direction and reach the reversal point for the slave axis to continue following. CAM_REL_NEGATIVE: Relative negative. The slave axis follows the master axis when the master axis moves in the negative direction, and stops following if the master axis reverses the direction. The master axis must return to negative direction without reaching the reversal point for the slave axis to continue following.
Velocity	Velocity	LREAL	Positive number	-	Maximum superimposed velocity during dynamic coupling.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Acceleration	Acceleration/deceleration	LREAL	Positive number or 0	0	Maximum superimposed acceleration during smooth coupling.
BufferMode	Buffer mode	18.3.3.2.2.6 MC_BUFFER_MODE: Buffer Mode Enumeration	0: mcAborting 1: mcBuffered	0	0: Aborting. 1: Buffered.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
CamInState	Camming state	18.3.3.2.3.5 MC_CAM_IN_STATE_REF: Camming state structure	-	-	Describe the current execution state of the cam table, including master and slave axis IDs, master axis phase, slave axis displacement, number of cycles executed, etc.
InCam	Camming	BOOL	TRUE, FALSE	FALSE	TRUE when the cumulative movement of the master axis reaches the MasterStartLength value after the instruction is executed.
InSync	Synchronizing	BOOL	TRUE, FALSE	FALSE	TRUE when the slave axis fully follows the cam curve after coupling. When IsRampIn is set to FALSE, InSync and InCam are set to TRUE in the same cycle.
EndOfProfile	End of camming cycle	BOOL	TRUE, FALSE	FALSE	TRUE when the end point of the cam table is used as the position reference, and FALSE in the next cycle.
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE after execution for the specified number of cycles; this flag remains FALSE when Periodic is set to 0.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Active	Controlling	BOOL	TRUE, FALSE	FALSE	TRUE when the axis is being controlled.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is aborted by another instruction.

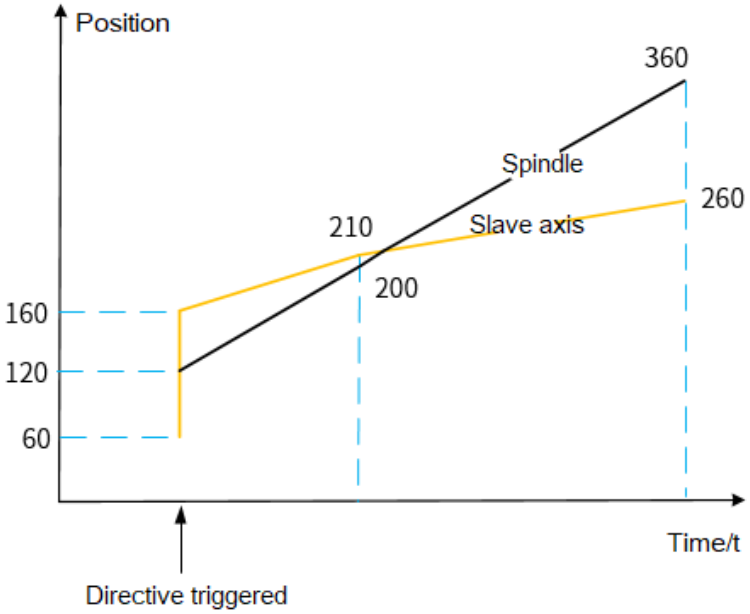
Output Variable	Name	Data Type	Valid Range	Default Value	Description
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**
  - MC_Home, MC_Homing, or MC_HomingWithParameter can be used during the instruction execution.

    This instruction places the master axis in the AXIS_HOMING state. If the instruction is executed while the master axis is already in this state, the signal source "MasterValueSource" must be set to "mcLatestCommand"; otherwise, the slave axis will overspeed.
  - **Master and slave axis modes of the cam table**

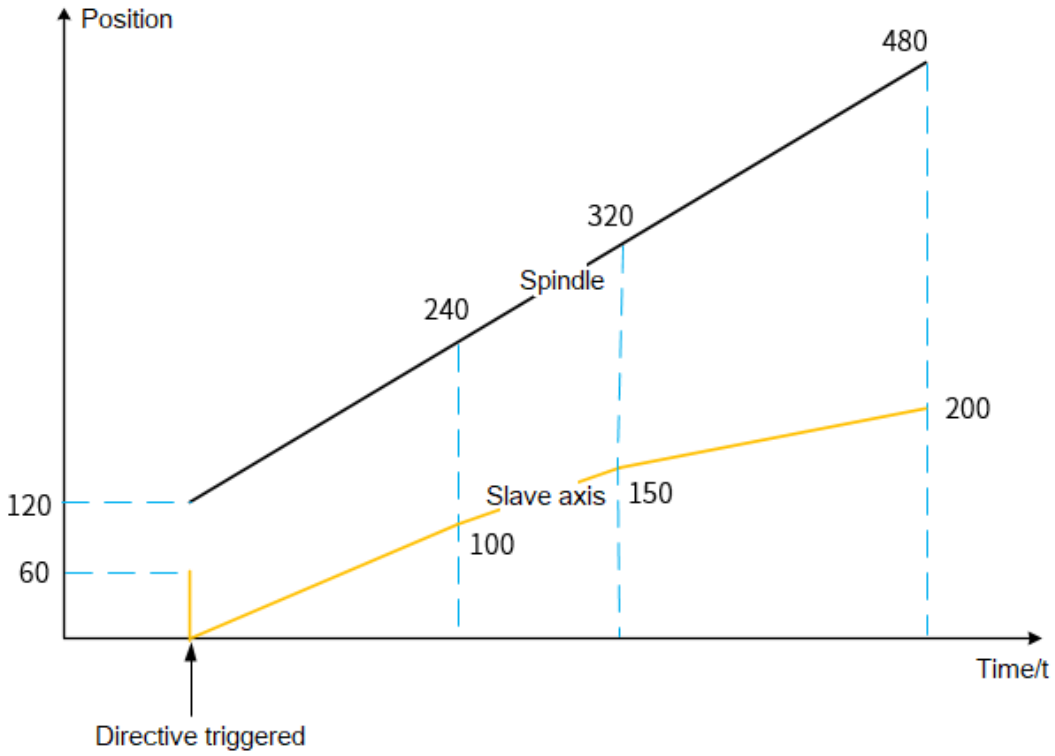
    This instruction supports four master and slave axis position modes. You can specify the master axis mode through the parameter MasterIsAbsolute. When the MasterIsAbsolute is set to TRUE, the master axis is in absolute position mode. When the MasterIsAbsolute is set to FALSE, the master axis is in relative position mode. You can specify the slave axis mode through the parameter SlaveIsAbsolute. When the SlaveIsAbsolute is set to TRUE, the slave axis is in absolute position mode. When the SlaveIsAbsolute is set to FALSE, the slave axis is in relative position mode.

Axis	Mode 1	Mode 2	Mode 3	Mode 4
Master axis	Absolute	Absolute	Relative	Relative
Slave axis	Absolute	Relative	Absolute	Relative

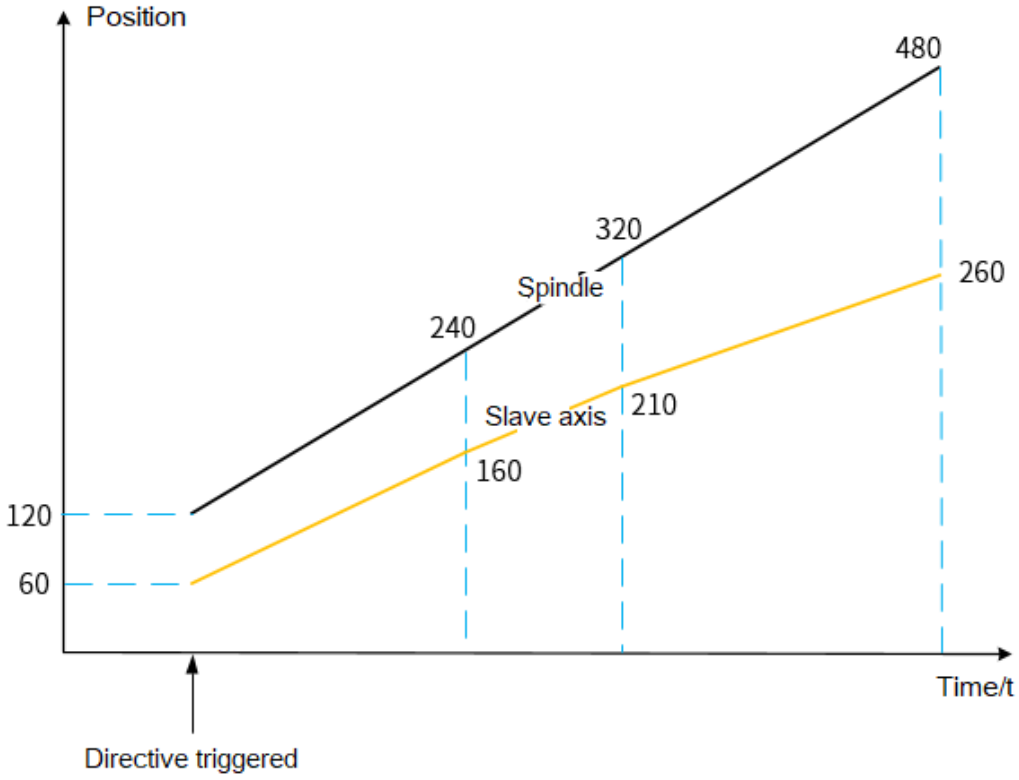


The following examples illustrate the relationship between the master and slave axis positions under each mode. Assume there is a cam table as follows: **(The master axis start position is 120, and the slave axis start position is 60; MasterStartLength = 0, IsRampIn = FALSE)**

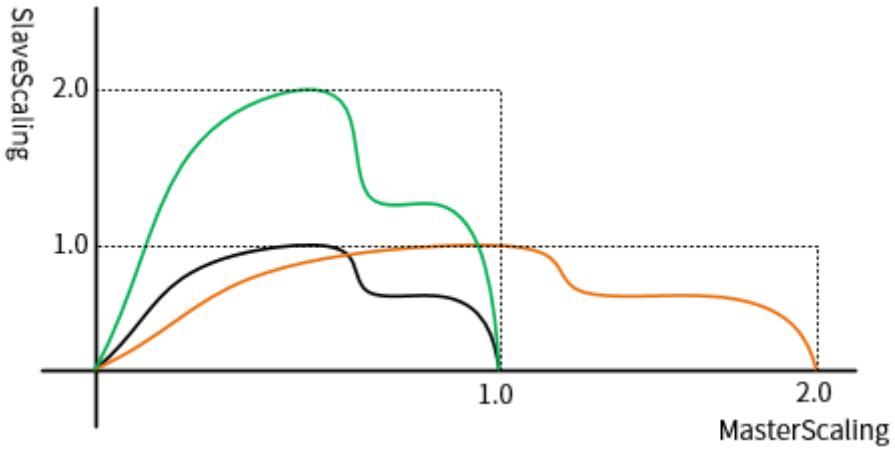
Master axis position	0	120	200	360
Slave axis position	0	100	150	200



(1) Mode 1–Master axis in absolute mode, slave axis in absolute mode

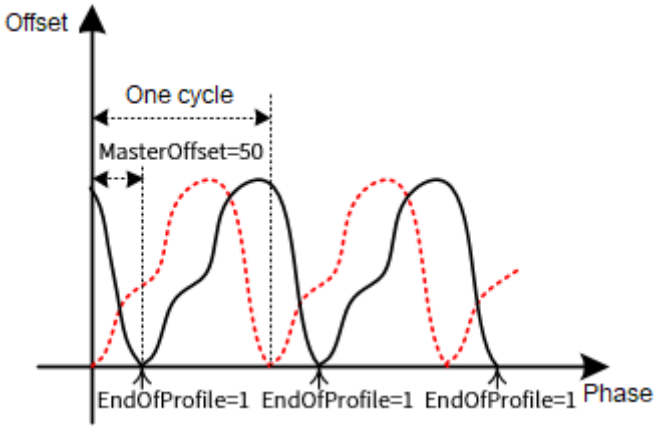


(2) Mode 2–Master axis in absolute mode, slave axis in relative mode

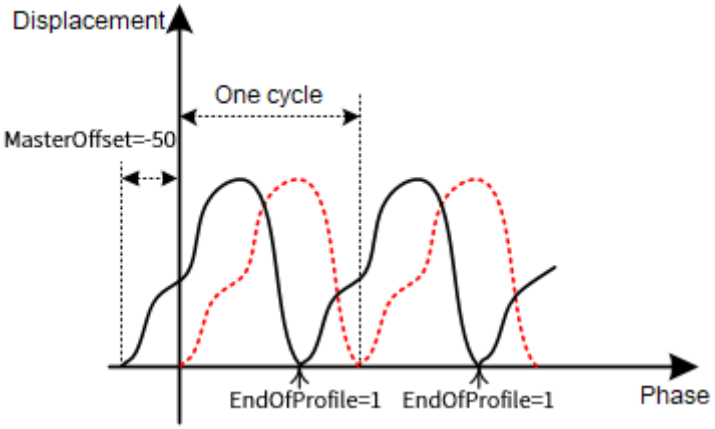


(3) Mode 3–Master axis in relative mode, slave axis in absolute mode

(4) Mode 4–Master axis in relative mode, slave axis in relative mode

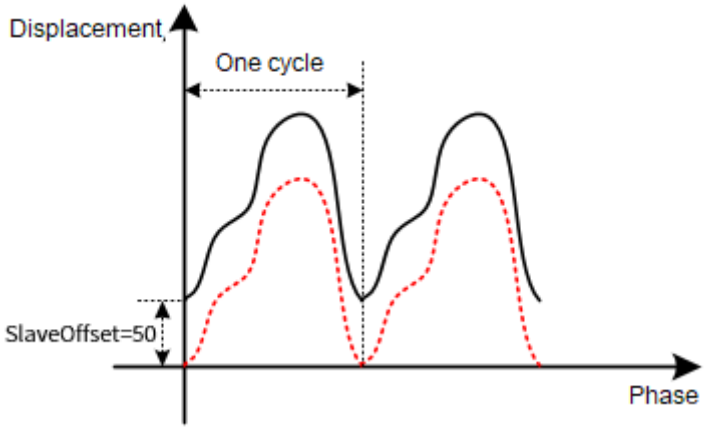


◦ **MasterScaling and SlaveScaling**

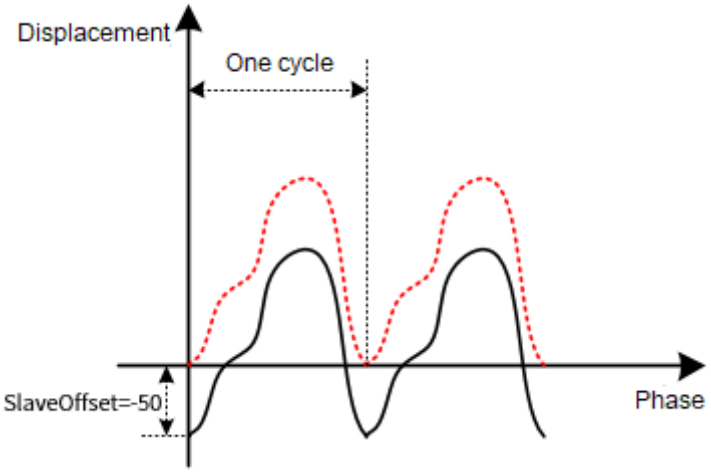


- For the master axis, when the MasterScaling is set to > 1, its phase range is extended; when the MasterScaling is set to < 1, its phase range is contracted.
- For the slave axis, when the SlaveScaling is set to > 1, its displacement is extended; when the SlaveScaling is set to < 1, its displacement is contracted.
- When the input value of MasterScaling is less than 0, it will be automatically corrected to 1 by the function block;
- When the input value of SlaveScaling is less than 0, it will be automatically corrected to 1 by the function block;
- The output values of phase and displacement in C_CAM_IN_STATE have been scaled according to corresponding scaling factors for the master and slave axes.

◦ **MasterOffset and SlaveOffset**



MasterOffset > 0

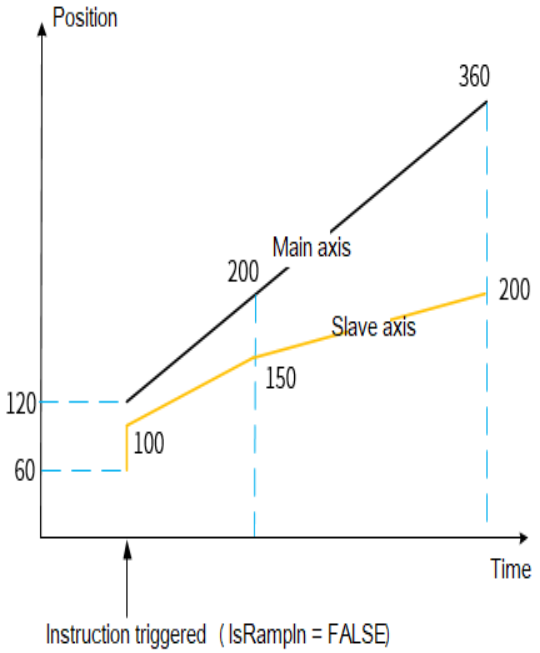


MasterOffset < 0

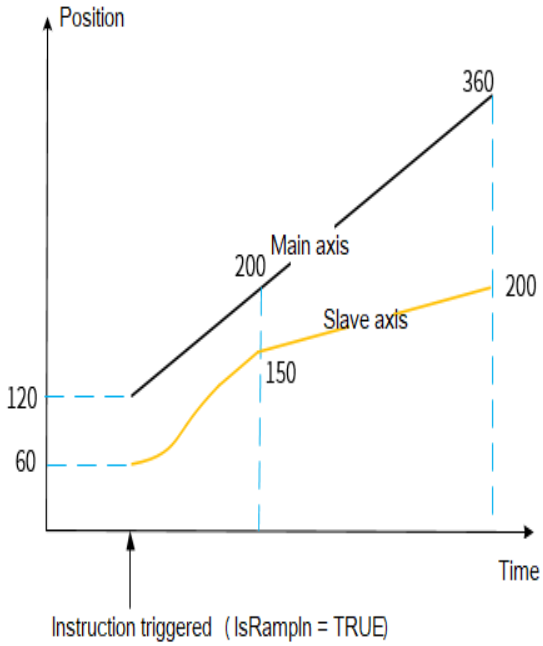
SlaveOffset > 0

SlaveOffset < 0

- When the MasterOffset is set to > 0, the cam curve shifts to the right; when the MasterOffset is set to < 0, the cam curve shifts to the left.
- When the SlaveOffset is set to > 0, the cam curve shifts upward; when the SlaveOffset is set to < 0, the cam curve shifts downward.
- The output value of displacement in C_CAM_IN_STATE includes the SlaveOffset.



◦ **IsRampIn**



Enabling this function ensures that a smooth velocity transition during camming of the slave axis, but acceleration may be discontinuous. When you select to start camming in a non-periodic mode, a fault

will occur if the coupling compensation has not been fully executed after all camming cycles have been executed.

The following example illustrates the difference in effects when coupling is enabled and disabled. Assume there is a cam table as follows: **(The master axis start position is 120, and the slave axis start position is 60; MasterStartLength = 0)**

Master axis position	0	120	200	360
Slave axis position	0	100	150	200

◦ **RampDirection**

For linear axes, this parameter has no effect on the coupling curve regardless of its value; for rotary axes, different coupling directions result in different coupling curves.

Assume there is a cam table as follows: **(Both master and slave axes in absolute mode)**

Master axis position	0	120	200	360
Slave axis position	0	120	300	0

When the IsRampIn is enabled with the master axis start position of 120 and the slave axis start position of 100:

- For the slave axis specified as **a rotary axis**:

  DIR_SHORTEST: Coupling compensation = 20.

  DIR_POSITIVE: Coupling compensation = 20.

  DIR_NEGATIVE: Coupling compensation = -340 (20 - 360).

- For the slave axis specified **as a linear axis**: The effects are the same for the three coupling directions, with a compensation of 20.

◦ **MasterDirection**

- When the CAM_REL_POSITIVE or CAM_REL_NEGATIVE is selected, the slave axis stops following the master axis when the master axis reverses to the opposite direction, and immediately resumes following when the master axis reverses back to the specified direction.
- When the CAM_ABS_POSITIVE or CAM_ABS_NEGATIVE is selected, the slave axis stops following the master axis when the master axis reverses to the opposite direction, and immediately resumes following when the master axis reverses back to the specified direction and returns to the reversal point. In case of a rotary axis, the number of cycles during reversal will be recorded, and the slave axis will resume following only when the master axis returns to its original cycle count.

◦ **MasterStartLength**

- A positive or negative input value for MasterStartLength does not affect the normal operation of the function block; the input value is processed by the function block based on the motion direction of the master axis. For example, when the MasterDirection is set to positive direction, the MasterStartLength is internally processed as a positive value. When the MasterDirection is set to NoDirection, the sign of MasterStartLength is determined by the motion direction of the master axis when its velocity first becomes non-zero after the instruction is triggered.

- After the instruction is triggered, if the motion direction of the master axis matches the specified MasterDirection, the master axis begins to record the following distance. When this distance reaches the setpoint for MasterStartLength, InCam is set, and the slave axis begins to follow the master axis.

◦ **Velocity overlimit and hitting the position limit**

- When the slave axis follows the master axis, velocity monitoring is executed to see if the velocity exceeds the software limit; if yes, a fault will occur.
- When the master axis position is beyond the software limit, the master axis velocity decelerates to 0 within one cycle, without affecting the state of the slave axis. When the master axis resets and resumes movement, the slave axis continues to follow the master axis.
- When the slave axis position is beyond the software limit, the instruction is aborted, and the slave axis decelerates to 0 within one cycle with the state switching to ErrorStop.

◦ **InCam and InSync**

- When the MasterStartLength is set to 0, InCam is set to TRUE in the same cycle after the instruction is triggered. When the MasterStartLength is set to non-zero, the InCam is set to TRUE when the master axis moves in the specified direction and its cumulative movement reaches MasterStartLength after the instruction is triggered.
- When the IsRampIn is not set, the InCam and InSync are set to TRUE in the same cycle.
- When the IsRampIn is set (IsRampIn = TRUE), the InCam is set to TRUE first; the InSync is set to TRUE after the coupling ends.

◦ **EndOfProfile**

- The output variable EndOfProfile is set to TRUE when the cam table end point is used as the position reference, and changes to FALSE in the next cycle. After the last camming cycle is completed, the EndOfProfile remains TRUE.

◦ **BufferMode**

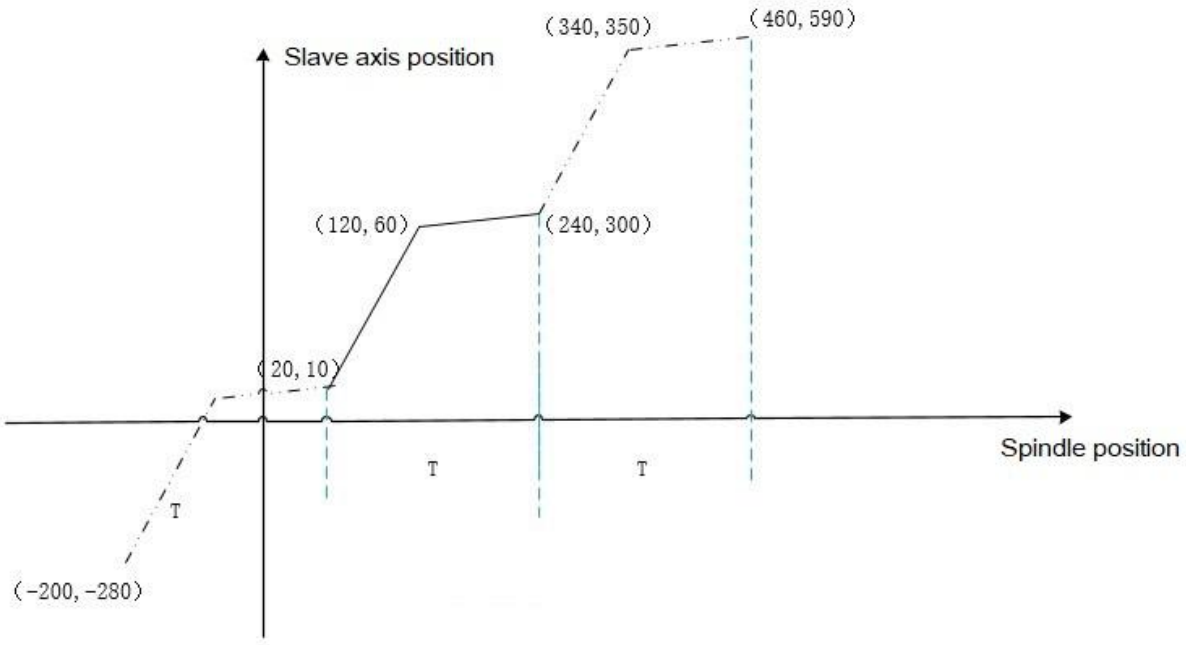
- The CamInV2 instruction supports BufferMode, allowing the instruction to be triggered in buffered mode. When Periodic is set to 0 (cyclic cam motion) and a buffered instruction follows, the buffered instruction takes effect after the current camming cycle completes.

◦ **Cam table parameter update methods**

- You can select one of the two cam table parameter update methods through the parameter UpDateRightNow. When the instruction is re-executed with changes to the cam table parameters, the modified cam table data will take effect immediately, rather than following the UpDateRightNow mode. If you want the modified cam table data to take effect without re-executing the instruction, the instruction will respond to the new cam data based on the value of the parameter UpDateRightNow. For the specific way the parameter UpDateRightNow takes effect, see UpDateRightNow in the instance description.

◦ **Table switching**

- During the table switching, internal smoothing is applied within the instruction to prevent velocity overlimit due to sudden change. Additionally, if there is any residual motion due to coupling, it will be superimposed to the new table for execution.



◦ **Support for setting cam table start point phase and displacement to non-zero**

Assume there is a cam table as follows: **(Key nodes are connected by straight lines)**

Master axis position	20	120	240

Slave axis position	10	60	300

When cam table following starts, if the master axis position is beyond the end point of the cam table, the slave axis position is obtained by forward extension of the cam curve; if the master axis position is before the start point of the cam table, the slave axis position is obtained by backward extension of the cam curve. The extended cam curve is as follows (the figure shows the extension of one camming cycle in positive and negative directions).

◦ **Re-execution**

▪ During the execution of the instruction (Active = TRUE), you can modify parameters online and then re-execute the instruction to make the modified parameters take effect. In this case, the corresponding number of cycles will be reset to 0, and the MasterStartLength will also take effect again. If you want the slave axis to immediately follow the master axis upon re-execution, set the MasterStartLength to 0. You can also re-execute the buffered instruction (Active = FALSE) after modifying parameters.

- **Example**

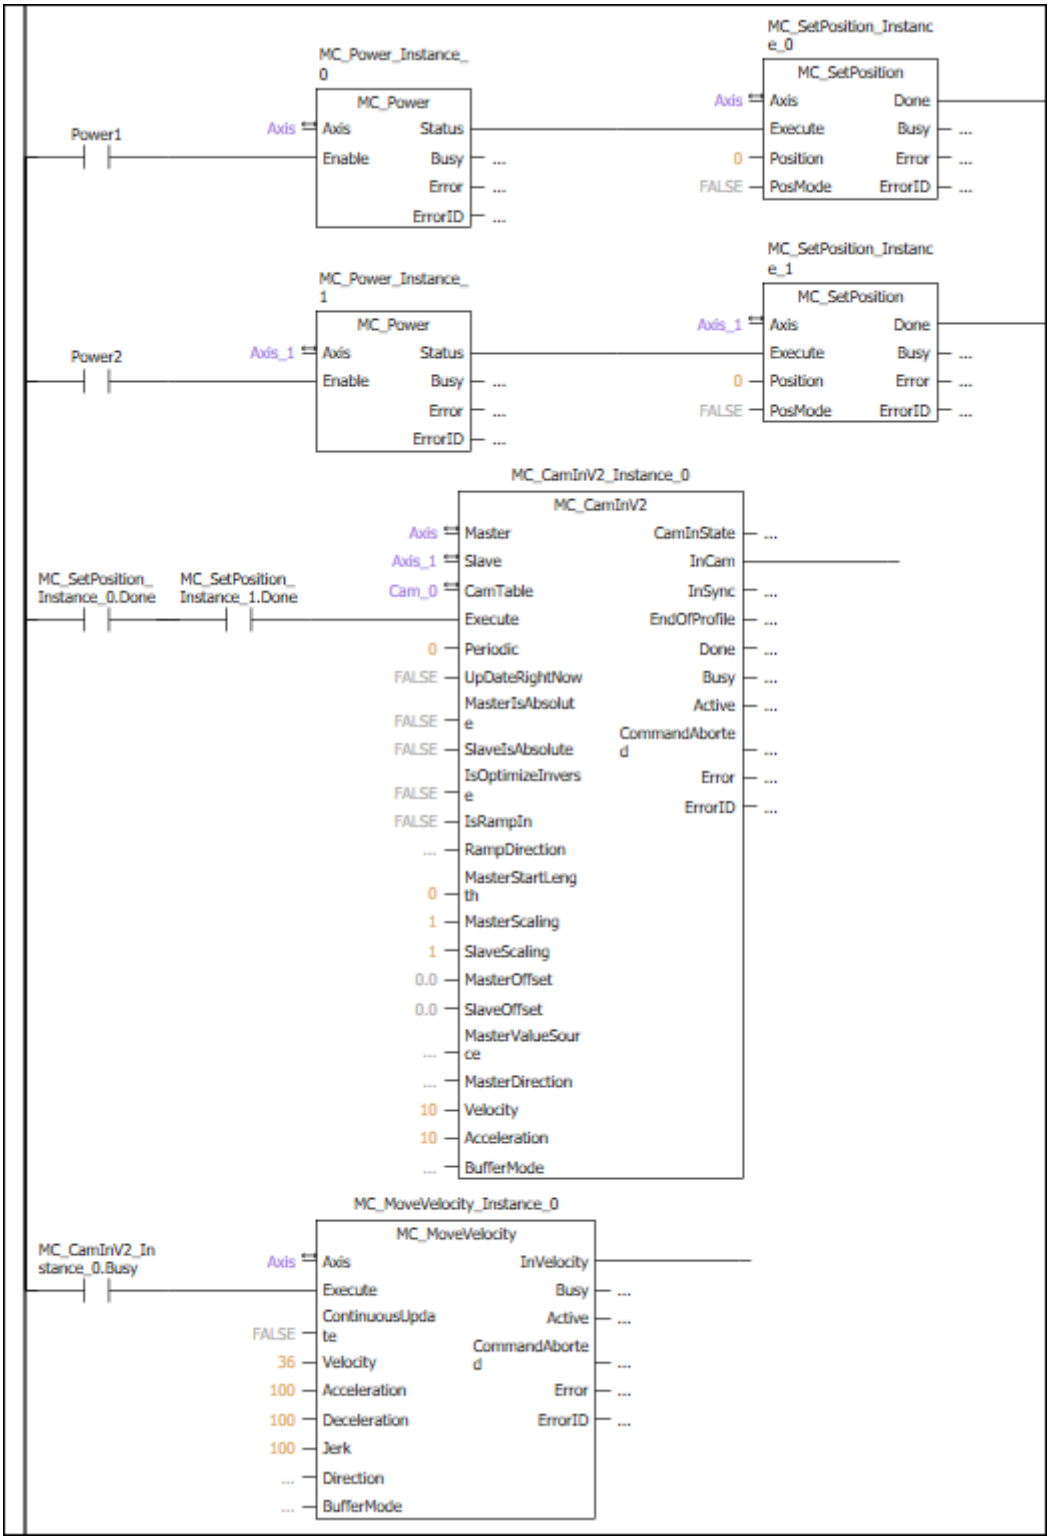
This instruction is a synchronous control instruction. Camming motion is based on a master axis and one or more slave axes. The master axis can be a physical axis or a virtual axis.

The following shows the steps for using synchronization instructions:

① **Specify the master and slave axes:** Specify the master and slave axes for synchronous motion based on the specific application scenario. The master axis for a synchronous motion control instruction can be a slave axis of another synchronous motion control instruction. The slave axis of one synchronous motion control instruction can also serve as the master axis of another synchronous motion control instruction.

② **Create a cam table:** Based on the specific application scenario, determine the position relationship between the master and slave axes, and create a cam table. In multiple different instantiated MC_CamInV2 instructions, when Axis is specified as the master axis and Axis_1 is specified as the slave axis, the cam table for each instruction can be different.

③ **Call the cam function block:** Use the MC_CamInV2 instruction to bind the master axis, slave axis, and cam table.

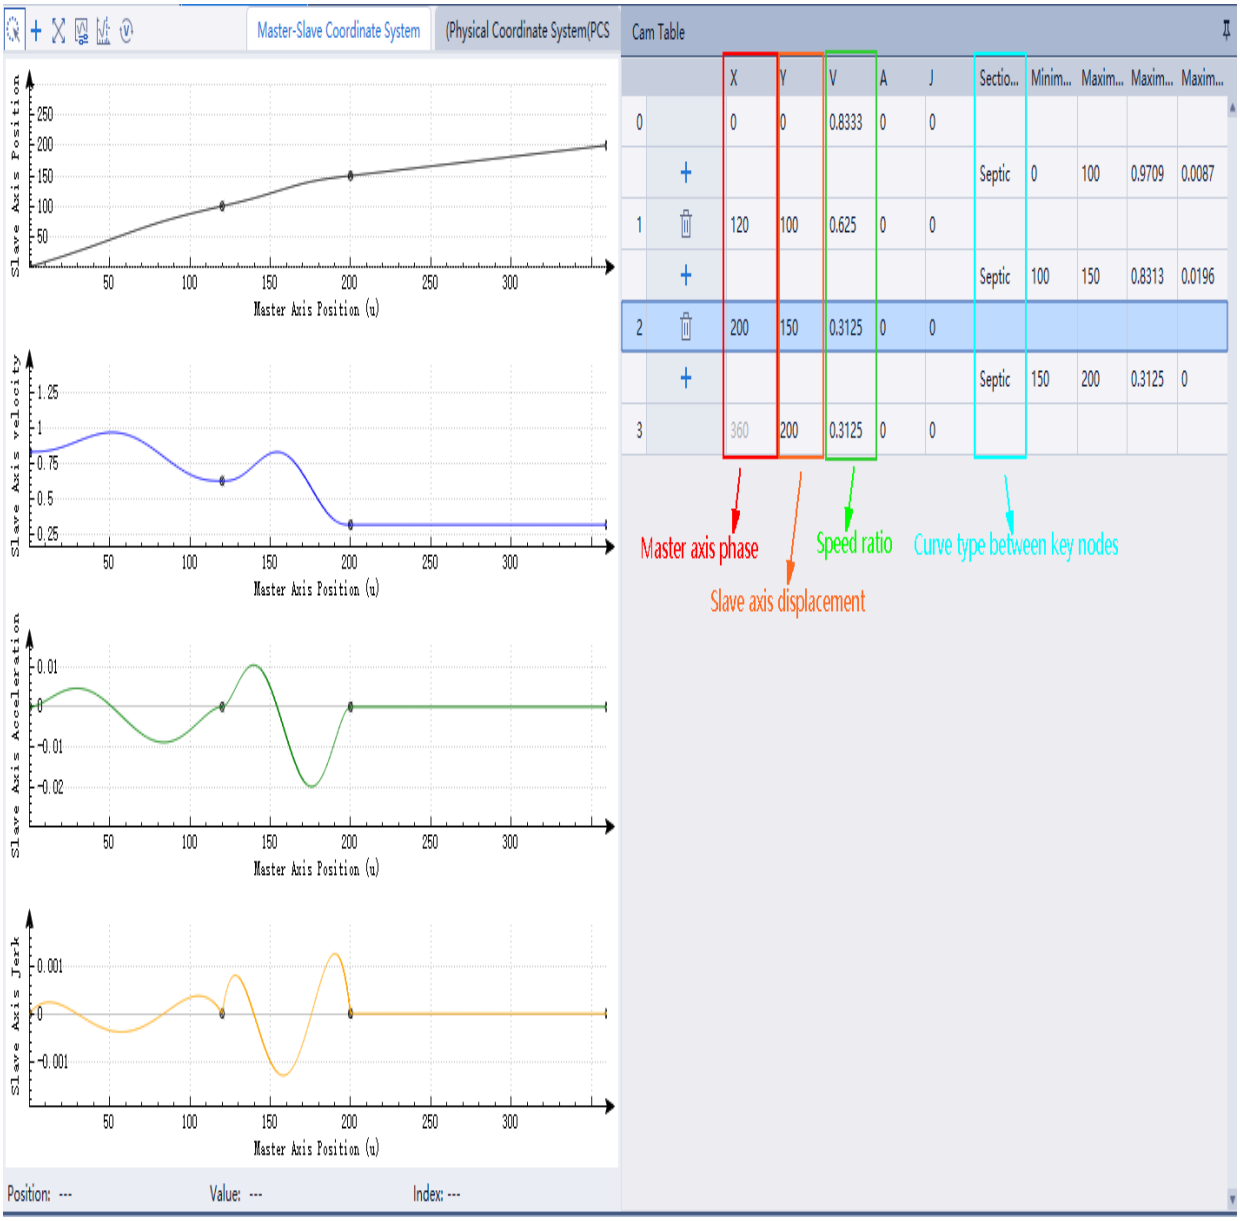


④ **Axis enable and current axis position setting function block:** Use the MC_Power instruction to switch the axis to the enabled state, and then use the MC_SetPosition instruction to set the current position of the axis.

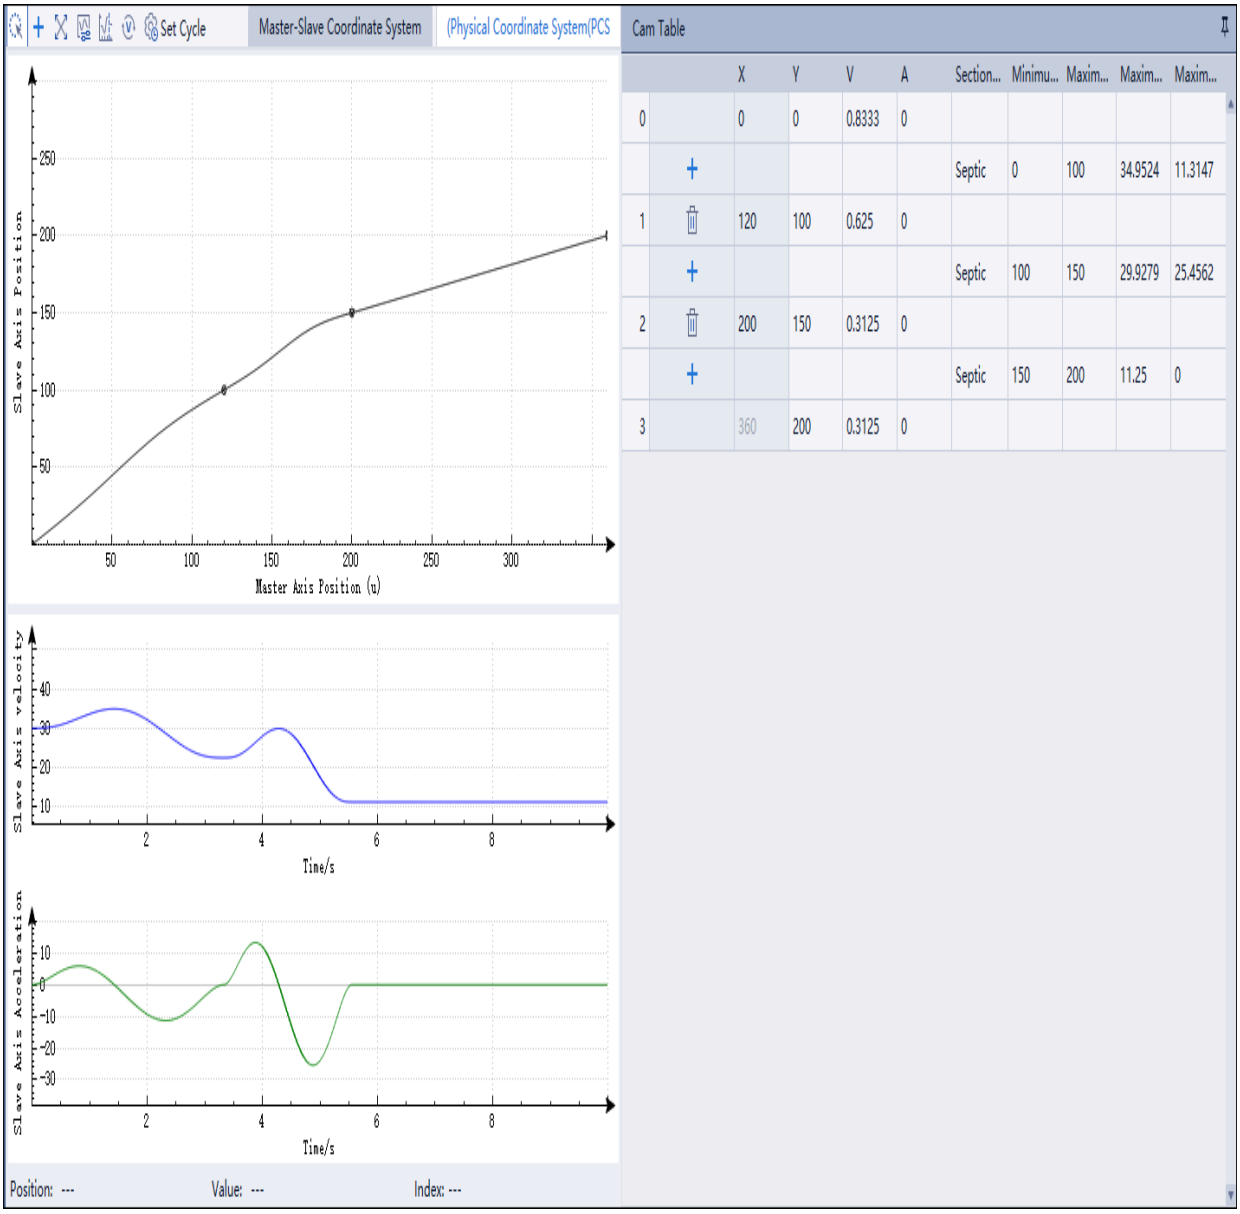
⑤ **Specify the input parameters of the function block:** Based on the specific application scenario, specify the input parameters of the MC_CamInV2 instruction and execute this instruction.

⑥ **Master axis motion function block:** Use the displacement/velocity control instruction to move the master axis. In the example, the MC_MoveVelocity instruction is used to control the velocity of the axis.

⑦ **Desynchronize the master and slave axes:** Wait for the synchronous control instruction to complete, or use the MC_CamOut instruction for desynchronization of the master and slave axes.



The following example illustrates how to execute simple camming. Configure two axes: Axis as the master axis and Axis_1 as the slave axis. Create a cam table Cam_0. First, execute the MC_Power instruction to switch the axis to the enabled state, and then specify the current axis position through the MC_SetPosition instruction, which is triggered by the Busy output. After the execution of the MC_SetPosition instruction, camming is started when the MC_CamInV2 instruction has been triggered by the Done output. After the execution of the MC_CamInV2 instruction, enable the Axis to start moving according to the input parameters of the MC_MoveVelocity instruction, which is triggered by the Busy output. At the same time, the slave axis starts the camming according to the input parameters of the MC_CamInV2 instruction and the created cam table.

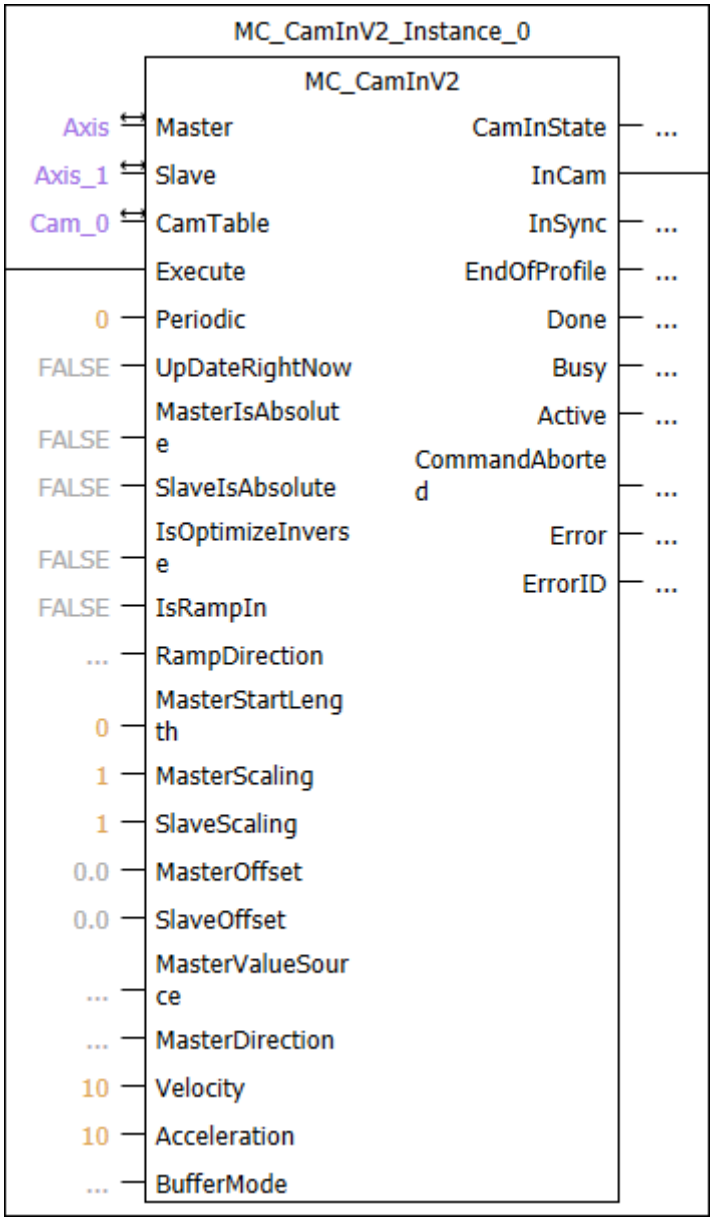


- **Create a cam table**

  The created cam table automatically generates the position relationship between the master and slave axes, and the velocity information of the slave axis at key nodes. You can adjust the data in the cam table to fit specific application scenarios.

  As shown in the following figure, the master-slave coordinate systems show the relationships between the master axis position and the slave axis position, velocity, acceleration, and jerk.

As shown in the following figure, the physical coordinate systems show the relationships between time and the slave axis position, velocity, and acceleration.

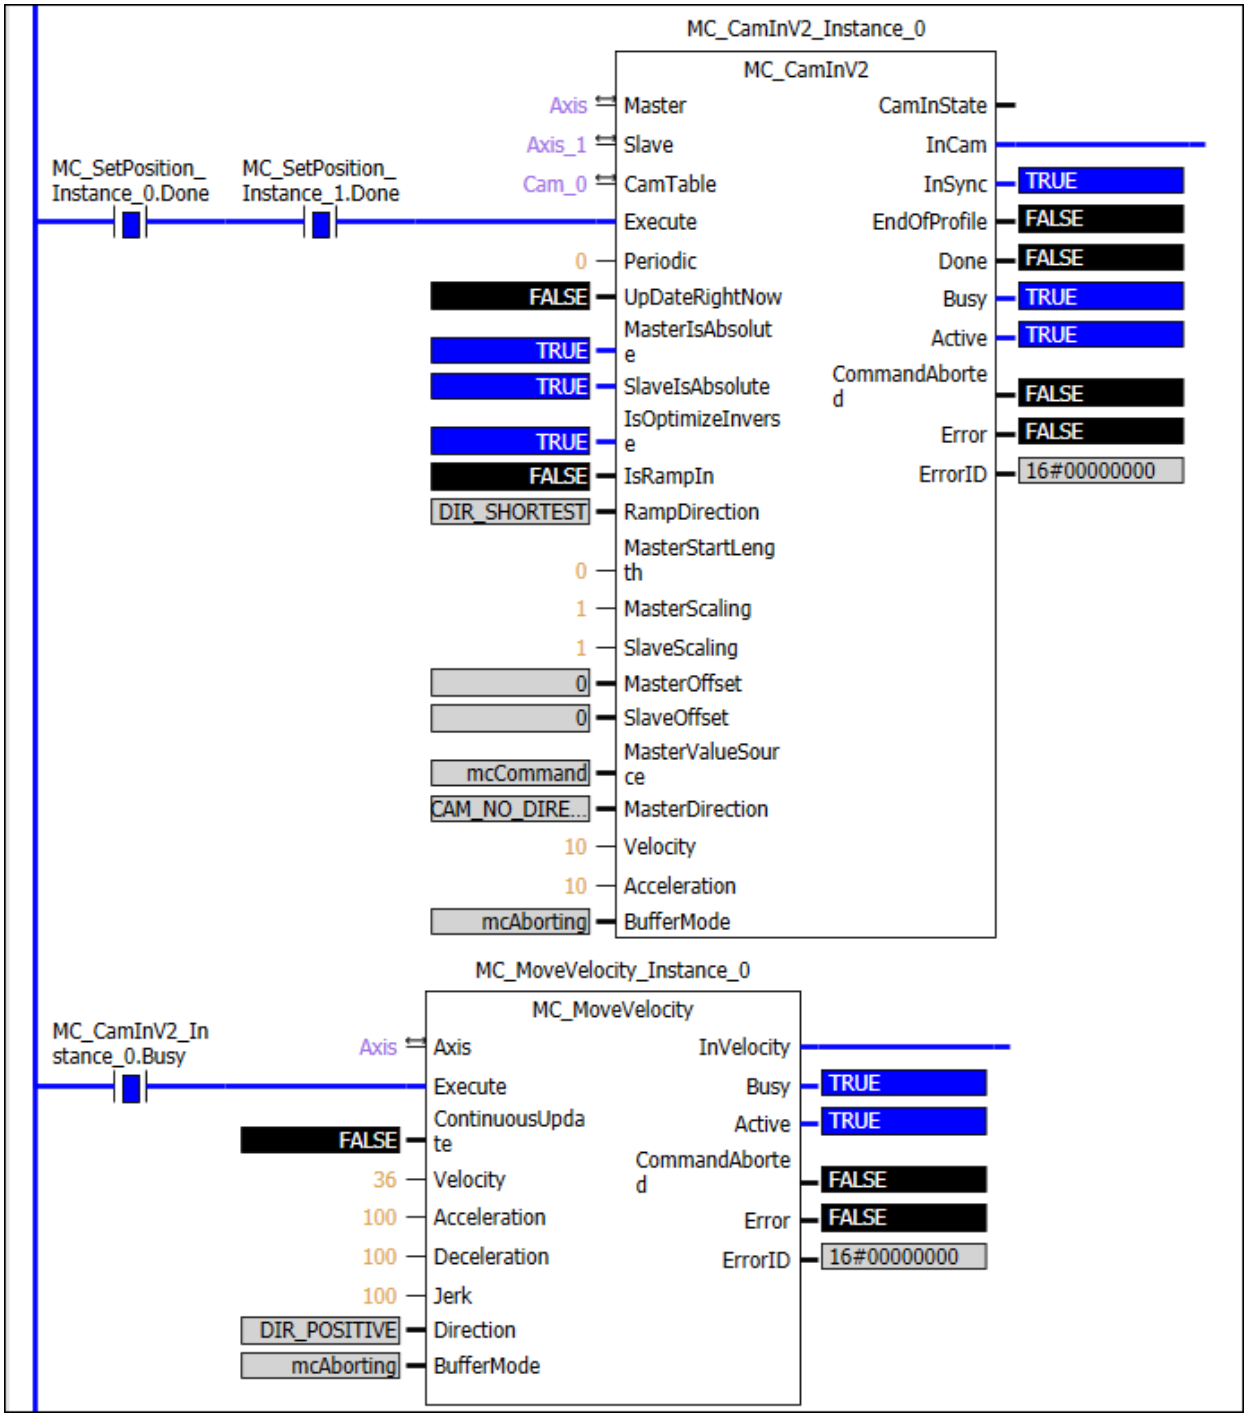


When the curve type between key nodes is changed, the velocity, acceleration, and jerk of the slave axis also change. As shown in the following figure, the curve type between key nodes is changed to "Straight line".

- **Call the cam function block**

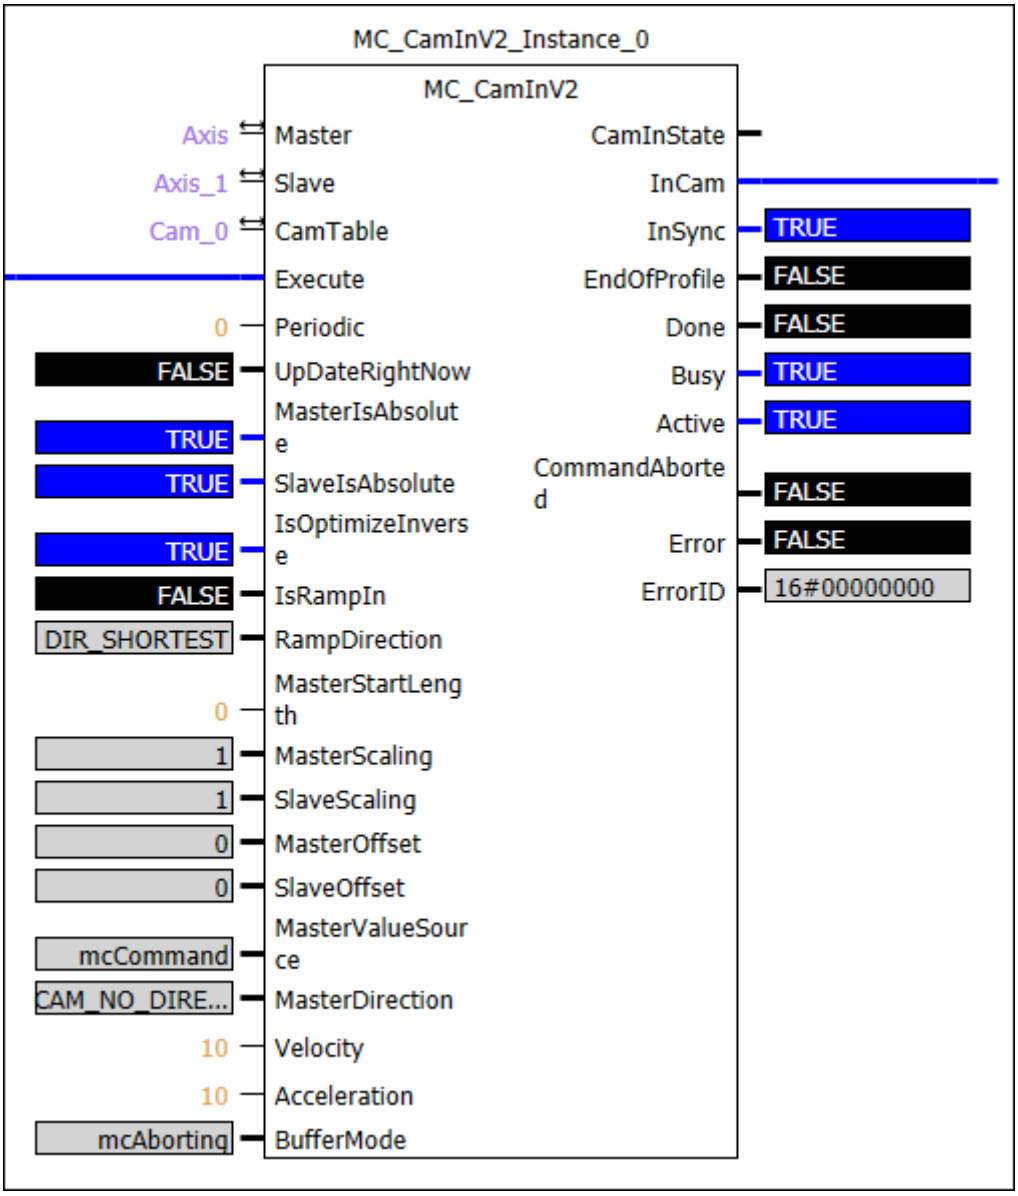
  Create a cam table, specify the position relationship between the master and slave axes, specify the input parameters of the MC_CamInV2 instruction according to specific application scenarios, and then execute this instruction.

  In the following program example, the MC_CamInV2 instruction is executed with the cam table created above and the input parameter UpDateRightNow defaulting to FALSE.

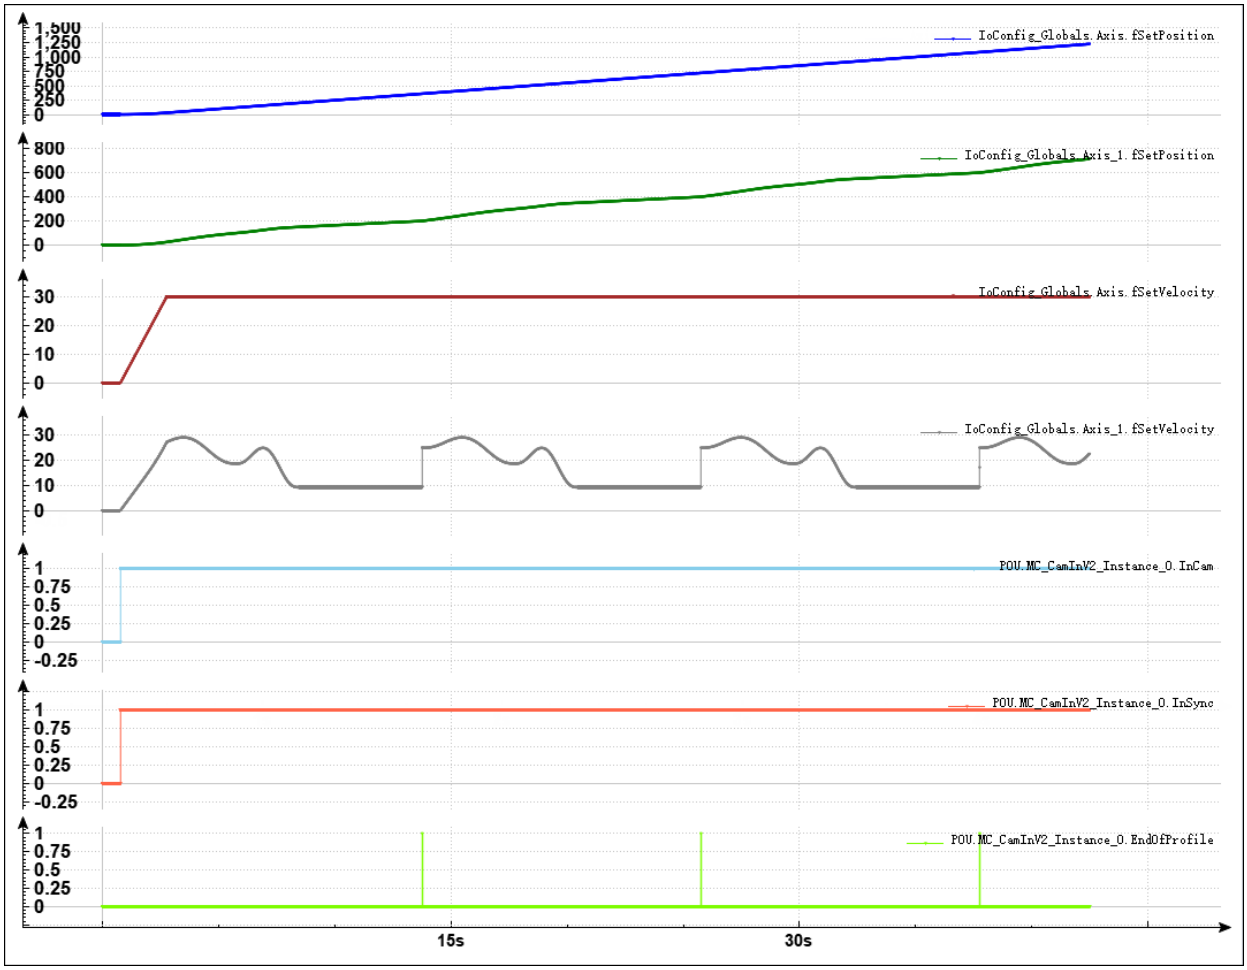


- **Axis enable and current axis position setting function block**

  Set contacts Power1 and Power2 to high level to trigger the MC_Power and MC_SetPosition instructions.



- **Execute the MC_CamInV2 instruction**



While the MC_CamInV2 instruction is being executed, execute the MC_MoveVelocity instruction to control the velocity of the Axis. Specify the velocity to 36 to make the Axis start moving. At this time, the slave axis starts the camming according to the created cam table.

- You can specify the number of times the cam table is executed through the parameter Periodic. When the Periodic is set to 0, it indicates that the cam table is executed periodically, and this instruction is executed repeatedly according to the cam table. When the Periodic is set to a specific value, this instruction is executed according to the specified number of cycles.

  Periodic = 0, master axis in absolute position mode, and slave axis in absolute position mode (The master axis start position is 0, and the slave axis start position is 0)

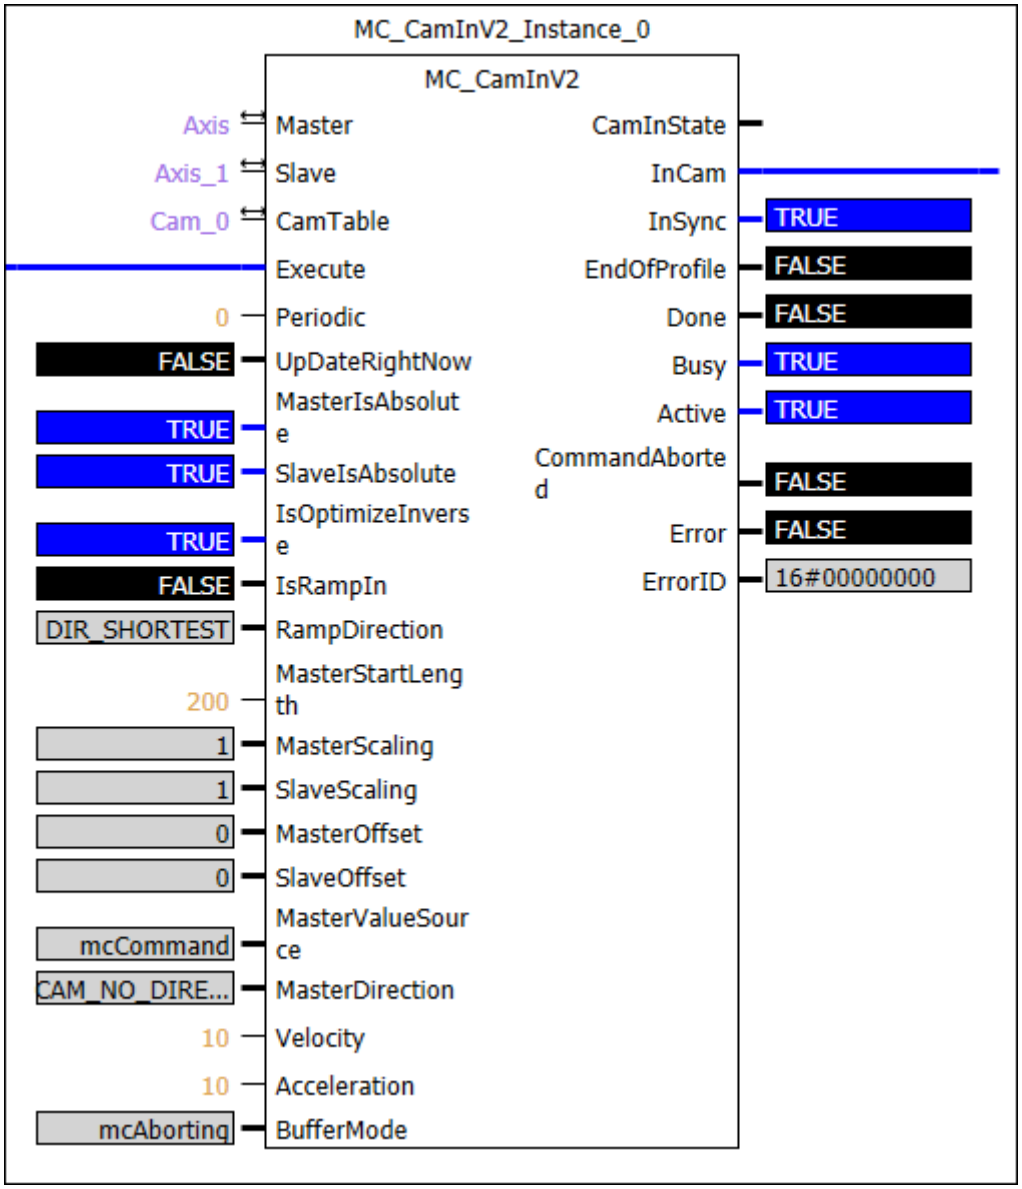
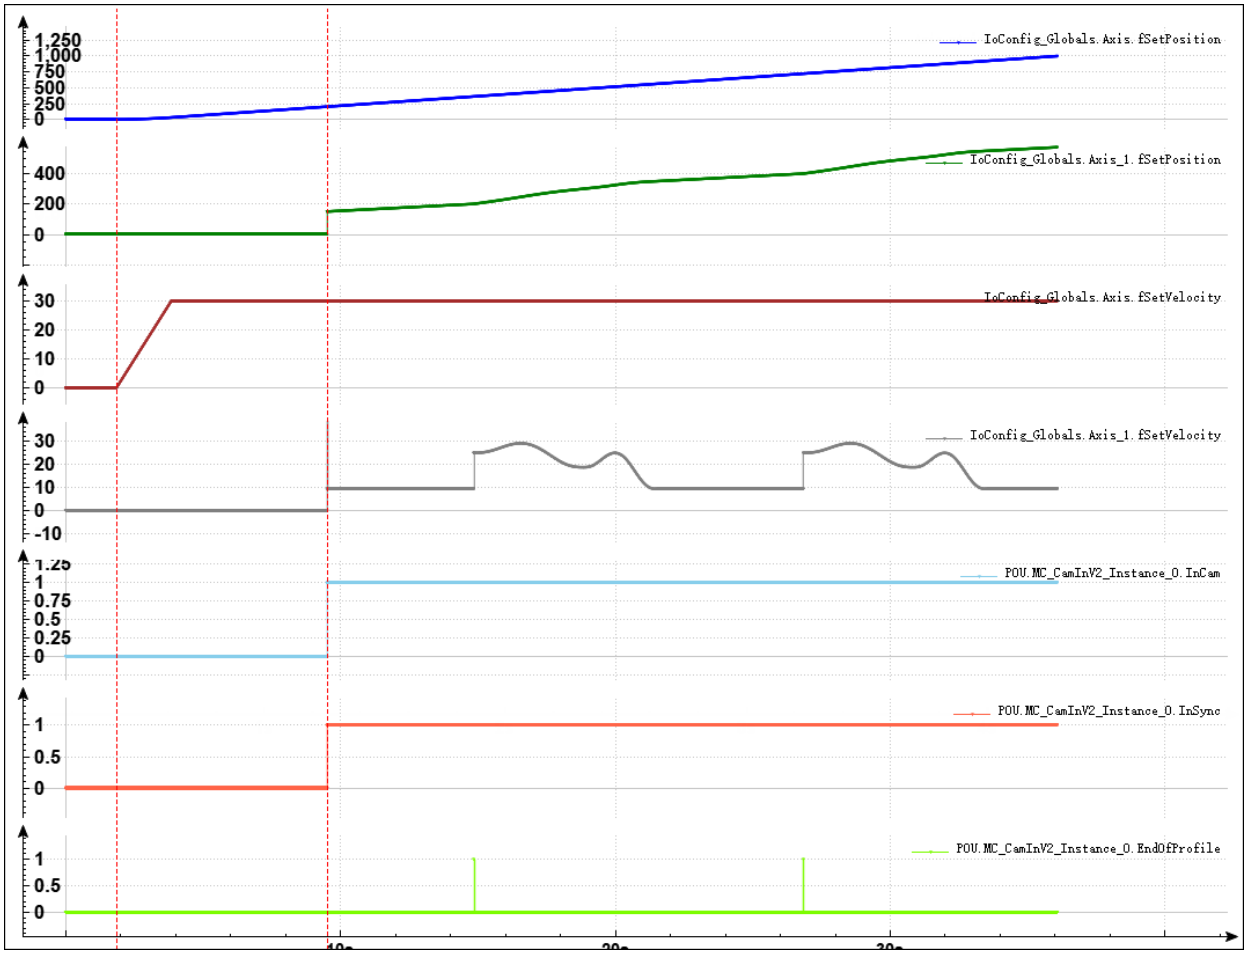
- RampDirection: For linear axes, this parameter has no effect on the coupling curve regardless of its value; for rotary axes, different coupling directions result in different coupling curves.

  RampDirection = DIR_NEGATIVE, IsRampIn = TRUE, master axis in absolute position mode, and slave axis in absolute position mode (The master axis start position is 120, and the slave axis start position is 60)

Slave axis = Rotary axis, DIR_NEGATIVE: Coupling compensation = -320 (40 - 360).





Slave axis = Linear axis, DIR_NEGATIVE: Coupling compensation = 40.

- MasterStartLength: After the instruction is triggered, the slave axis does not immediately follow the master axis. When the cumulative master axis travel distance is equal to the input value of MasterStartLength, the slave axis starts following the master axis, and the InCam is set.

  MasterStartLength = 200, master axis in absolute position mode, and slave axis in absolute position mode (The master axis start position is 0, and the slave axis start position is 0)

Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received. OutMode = 0: The variable shows the value FALSE after the instruction is executed. OutMode = 1: The variable still shows the value TRUE after the instruction is executed until it is aborted by the next instruction.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is aborted by another instruction.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Parameter correction**

Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Deceleration	Deceleration	Any deceleration that exceeds the motion parameter limit will be automatically corrected to the deceleration limit.	Any deceleration less than 0 will be automatically corrected to 10% of the deceleration limit.	The deceleration equal to 0 will be automatically corrected to 10% of the deceleration limit.

Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Jerk	Jerk	If the motion profile is set to S-curve, any jerk that exceeds the software limit will be automatically corrected to the jerk limit.	If the motion profile is set to S-curve, any jerk less than 0 will be automatically corrected to 10% of the jerk limit.	If the motion profile is set to S-curve, the jerk equal to 0 will be automatically corrected to 10% of the jerk limit.

- **Function**

  Bus-controlled axis:

  - The MC_CamOut instruction desynchronizes the camming of the slave axis.
  - This instruction is executed on a rising edge of the input variable Execute.
  - This instruction must be executed after the MC_CamIn instruction is enabled. If you execute this instruction on an axis that is not in camming, a fault will occur.
  - During the execution of this instruction, the MC_MoveSuperImposed instruction cannot be used; once the MC_MoveSuperImposed instruction is triggered, CommandAborted is set for the MC_MoveSuperImposed instruction.
  - During the execution of the MC_CamIn and MC_MoveSuperImposed instructions, if the MC_CamOut instruction is triggered, the superimposed motion will not be aborted during the camming; when the camming ends, the slave axis performs an immediate stop with the superimposed motion aborted.

    OutMode

    You can specify the mode by which the slave axis disengages from the master axis by defining the value of the input variable OutMode.

  - mcDecelerationStop: Deceleration stop.

    The slave axis decelerates to stop according to the Deceleration specified in this instruction.

  - mcConstantVelocity: Constant velocity.

    The slave axis continues to move at a constant velocity while the camminng is desynchronized.

  - mcImmediateStop: Immediate stop.

    The slave axis immediately stops after performing the current cam table.

  Local pulse axis:

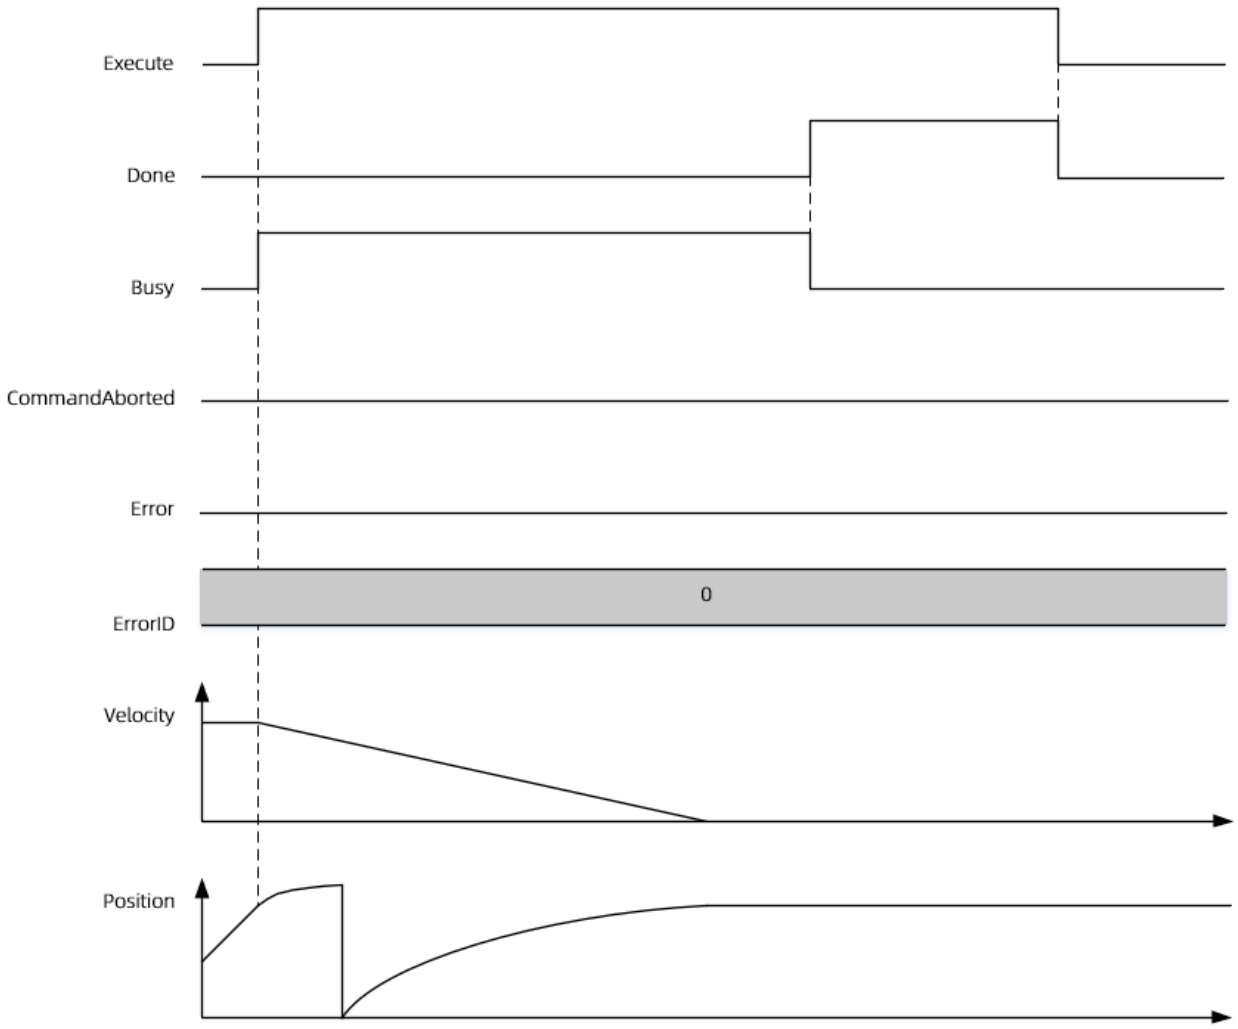
  This instruction can be used for local pulse axes.

  Re-execution of motion control instructions

  - This instruction can be re-executed.
  - Do not modify the value of OutMode when this instruction is re-executed.
  - When the OutMode is set to 0 (mcDecelerationStop), and this instruction is re-executed after modifying the Deceleration and Jerk values, the slave axis disengages from the master axis in the deceleration stop mode according to the modified parameter values.
  - If either of the modified Deceleration and Jerk values is invalid, it will be automatically corrected by the function block without a fault message. The slave axis velocity will decelerate to 0 within one cycle, with the axis state switching from DiscreteMotion to ErrorStop.

Software limit

When the slave axis position is beyond the software limit while disengaging from the master axis, this instruction is aborted, and the slave axis velocity decelerates to zero within one cycle. In the mcDecelerationStop mode, the slave axis state switches from DiscreteMotion to ErrorStop. In the mcConstantVelocity mode, the slave state switches from ContinuousMotion to ErrorStop. In the mcImmediateStop mode, the slave axis state switches from SynchronizedMotion to ErrorStop.



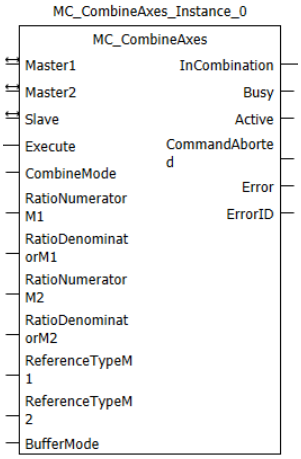
- **Precautions**
  - When the OutMode is set to 1 (mcConstantVelocity) After the instruction is executed, the parameter Done is set to TRUE, and the parameter Busy remains TRUE until this instruction is aborted by next instruction, at which point the parameter Busy is set to FALSE. Therefore, to stop the slave axis in the mcConstantVelocity mode, this instruction must be used in conjunction the MC_Stop instruction.
  - When the OutMode is set to 1, the slave axis state switches SynchronizedMotion to AXIS_CONTINUOUSMOTION after the instruction is executed. When the OutMode is set to 0 (mcDecelerationStop), the slave axis state switches from SynchronizedMotion to DiscreteMotion after the instruction is executed, and becomes StandStill after the output variable Done is set. When the OutMode is set to 2 (mcImmediateStop), the slave axis state remains SynchronizedMotion after the instruction is executed until the current camming ends, and becomes StandStill after the output variable Done is set.
  - During the execution of this instruction, if a fault occurs on the slave axis, the command aborted flag will be set, and the slave axis will stop immediately.
  - This instruction can abort an executing MC_MoveSuperImposed instruction.
  - If the MC_MoveSuperImposed instruction is executed during the execution of this instruction, the OutMode = 0 (mcDecelerationStop) will cause the MC_MoveSuperImposed instruction to abort directly.
  - If the MC_MoveSuperImposed instruction is executed during the execution of this instruction, the OutMode = 2 (mcImmediateStop) will cause the MC_MoveSuperImposed instruction to abort after the current camming cycle ends, with the velocity being set to zero.
- **Timing diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Done of the function block indicates the instruction has been executed successfully; the parameter Busy indicates that the current function block is being executed; the parameter CommandAborted of the function block indicates that the instruction is aborted by another motion control instruction, at which point the flag is set to TRUE.

  The camming of the slave axis is desynchronized on a rising edge of the input variable Execute. At this point, the slave axis may not be stopped.

  If the velocity of the slave axis is not zero before this instruction is executed, the camming will be desynchronized after the output variable Done is set, but the slave axis will keep moving at its previous velocity.

  When this instruction is executed on a slave axis not in camming, the output variable Error shows the value TRUE.



- **Faults**
  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.4.17 MC_CombineAxes

This instruction outputs the sum or difference of the instruction positions of two axes as a combined instruction position. It is designed primarily for use in scenarios requiring multiple master axes.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_CombineAxes	Output the sum or difference of the instruction positions of two axes as a combined instruction position.		MC_CombineAxes_Instance_0(Master1 :=, Master2 :=, Slave :=, Execute :=, CombineMode :=, RatioNumeratorM1 :=, RatioDenominatorM1 :=, RatioNumeratorM2 :=, RatioDenominatorM2 :=, ReferenceTypeM1 :=, ReferenceTypeM2 :=, BufferMode :=, InCombination =>, Busy =>, Active =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

  In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Master1	Master axis 1	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the master axis 1; an instance of AXIS_REF.
Master2	Master axis 2	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the master axis 2; an instance of AXIS_REF.
Slave	Slave axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the slave axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	Execute the instruction on a rising edge.
CombineMode	Combine mode	18.3.3.2.2.12 MC_COMBINE_MODE: Combine Mode Enumeration	0: mcAddAxes 1: mcSubAxes	0	0: Addition. 1: Subtraction.
RatioNumeratorM1	Master axis 1 gear ratio numerator	DINT	Not equal to 0	1	Master axis 1 gear ratio numerator.
RatioDenominatorM1	Master axis 1 gear ratio denominator	UINT	Positive number	1	Master axis 1 gear ratio denominator.
RatioNumeratorM2	Master axis 2 gear ratio numerator	DINT	Not equal to 0	1	Master axis 2 gear ratio numerator
RatioDenominatorM2	Master axis 2 gear ratio denominator	UINT	Positive number	1	Master axis 2 gear ratio denominator.
ReferenceTypeM1	Master axis 1 position type selection	18.3.3.2.2.11 MC_REFERENCE_TYPE: Data Type Enumeration	0: mcCommand 1: mcFeedback 2: mcLaterCommand	0	0: Value calculated in the previous task cycle (fSavePosition). 1: Value obtained in the same task cycle (fActPosition). 2: Value calculated in the same task cycle (fSetPosition).

Input Variable	Name	Data Type	Valid Range	Default Value	Description
ReferenceType M2	Master axis 2 position type selection	18.3.3.2.2.11 MC_REFERENCE_TYPE: Data Type Enumeration	0: mcCommand 1: mcFeedback 2: mcLaterCommand	0	0: Value calculated in the previous task cycle (fSavePosition). 1: Value obtained in the same task cycle (fActPosition). 2: Value calculated in the same task cycle (fSetPosition).
BufferMode	Buffer mode	18.3.3.2.2.6 MC_BUFFER_MODE: Buffer Mode Enumeration	0: mcAborting	0	0: Aborting. (Reserved for other modes)

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
InCombination	Axes combined	BOOL	TRUE, FALSE	FALSE	TRUE when axes are combined.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Active	Controlling	BOOL	TRUE, FALSE	FALSE	TRUE when the axis is being controlled.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is aborted by another instruction.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**

  Bus-controlled axis:

  - You can calculate the position reference of the slave axis by specifying parameters such as Master1, Master2, CombineMode, RatioNumeratorM1, RatioDenominatorM1, RatioNumeratorM2, RatioDenominatorM2, ReferenceTypeM1, and ReferenceTypeM2.
  - This instruction is executed on a rising edge of the input variable Execute.
  - If bus cycle is specified for the cycle task of the master axis, the velocity of the slave axis may show a sudden jump after synchronization. It is recommended that users specify EtherCAT cycle for the cycle task of both the master and slave axes before enabling a synchronization instruction.
  - MC_Home, MC_Homing, or MC_HomingWithParameter can be used during the instruction execution.

    This instruction places the master axis in the AXIS_HOMING state. If the instruction is executed while the master axis is already in this state, the master axis signal source "ReferenceTypeM1" or "ReferenceTypeM2" must be set to "mcLatestCommand"; otherwise, the slave axis will overspeed.

    Local pulse axis:

  - This instruction can be used for local pulse axes.
  - When the local pulse axis is used as the master axis with Y0 or Y1 single-ended output, it is not recommended to use this instruction. ① No pulse output; ② No position feedback.

    Re-execution of motion control instructions

    This instruction cannot be re-executed.

    Position type selection

    You can specify ReferenceTypeM1 and ReferenceTypeM2 for Master1 and Master2 based on the following options:

  - mcCommand: Commanded position (Value calculated in the previous task cycle, fSavePosition).

    For the current cycle, use the master axis position calculated in the previous task cycle.
  - mcFeedback: Actual position (Value obtained in the same task cycle, fActPosition).

    Use the actual master axis position obtained in the same task cycle.
  - mcLaterCommand: Commanded position (Value calculated in the same task cycle, fSetPosition).

    Use the master axis position calculated in the same task cycle.

    CombineMode

  - You can select the mode for calculating the position reference of the Slave by defining the value of CombineMode of this instruction. When CombineMode is set to 0 (Addition), the position reference of the Slave is the sum of the relative positions of Master1 and Master2.
  - When CombineMode is set to 1 (Subtraction), the position reference of the Slave is the difference of the relative positions of Master1 and Master2.

- **Precautions**
  - It is not recommended to use this instruction in combination with the MC_Phasing instruction.
  - The variables Master1, Master2, and Slave must be different; otherwise, this instruction will issue a fault message.
  - The Slave position output by this instruction can be used as the master axis input parameter for synchronous control instructions.
  - If this instruction encounters a fault or is aborted, the Slave will stop immediately, without affecting the operation of Master1 and Master2.
- **Timing diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Active of the function block indicates the axis is being controlled; the parameter Busy indicates that the current function block is being executed; the parameter CommandAborted indicates that the instruction is aborted by another motion control instruction, at which point the flag is set to TRUE.

  The output variable Busy shows the value TRUE at the same time as Execute is set to TRUE. In the next cycle, the output parameter Active shows the value TRUE.

  The output variable InCombination shows the value TRUE in the cycle where the combined output starts.

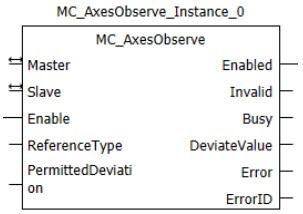
  When this instruction is aborted by another instruction, the output variable CommandAborted shows the value TRUE, and the variables Busy, Active, and InCombination show the value FALSE.

  - When CombineMode is set to _mcAddAxes, the timing diagram is as follows.

Execute
InCombination
Busy
Active
CommandAborted
Error
Position
Position
Position
Velocity
Velocity
Velocity
Velocity

◦ When CombineMode is set to _mcSubAxes, the timing diagram is as follows.

◦ When the instruction is aborted, the timing diagram is as follows.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.4.18 MC_AxesObserve

This instruction observes the deviation between the position references or actual positions for the specified axes to see if it exceeds the permitted value.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_AxesObserve	Observe position deviation between master and slave axes		MC_AxesObserve_Instance_0(Master :=, Slave :=, Enable :=, ReferenceType :=, PermittedDeviation :=, Enabled =>, Invalid =>, Busy =>, DeviateValue =>, Error =>, ErrorID =>);

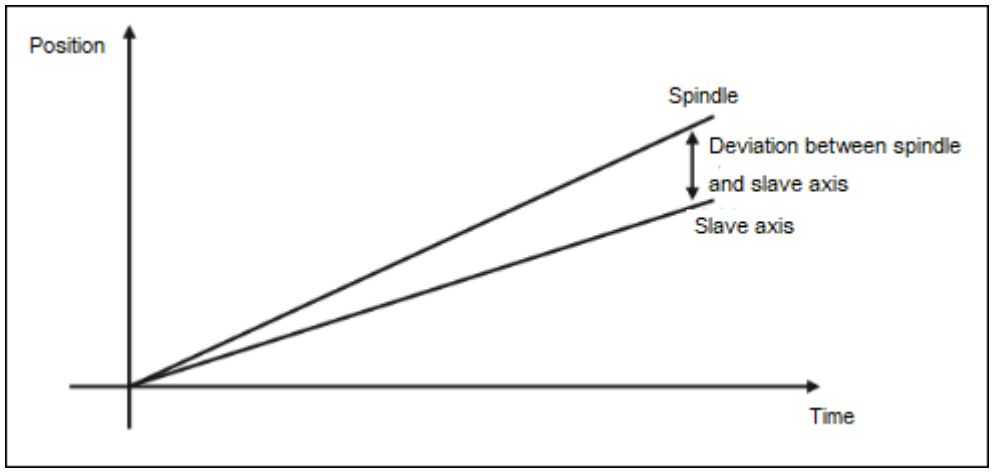
- **Related variables**

  In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Master	Master axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the master axis; an instance of AXIS_REF.
Slave	Slave axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the slave axis; an instance of AXIS_REF.

  Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Enable	Enable	BOOL	TRUE, FALSE	FALSE	TRUE: Enabled. FALSE: Disabled.



Input Variable	Name	Data Type	Valid Range	Default Value	Description
ReferenceType	Position type selection	18.3.3.2.2.11 MC_REFERENCE_TYPE: Data Type Enumeration	0: mcCommand 1: mcFeedback 2: mcLaterCommand	0	0: Value calculated in the previous task cycle (fSavePosition). 1: Value obtained in the same task cycle (fActPosition). 2: Value calculated in the same task cycle (fSetPosition).
PermittedDeviation	Permitted position deviation between master and slave axes	LREAL	Positive number or 0	0	Permitted maximum position deviation between master and slave axes.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Enabled	Enabled	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is enabled.
Invalid	Invalid	BOOL	TRUE, FALSE	FALSE	TRUE when the position deviation is out of the PermittedDeviation; FALSE if not (this flag is continuously updated as long as Enable shows the value TRUE).
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
DeviateValue	Real-time position deviation between axes	LREAL	-	-	Output the position difference between the specified master and slave axes.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**
  - This instruction observes the deviation between the position references or actual positions for the specified axes to see if it exceeds the permitted value.

- This instruction is executed when the input variable Enable shows the value TRUE.
- This instruction does not affect the motion of the master and slave axes.
- When DeviatedValue is greater than PermittedDeviation, the variable Invalid shows the value TRUE.

Position type selection

You can select ReferenceType for the in-out variable Master of this instruction based on the following options.

- mcCommand: Commanded position (Value calculated in the previous task cycle, fSavePosition).

  For the current cycle, use the master axis position calculated in the previous task cycle.

- mcFeedback: Actual position (Value obtained in the same task cycle, fActPosition).

  Use the actual master axis position obtained in the same task cycle.

- mcLaterCommand: Commanded position (Value calculated in the same task cycle, fSetPosition).

  Use the master axis position calculated in the same task cycle.

Method for calculating DeviatedValue

The master and slave positions depend on the selected ReferenceType. If ReferenceType is set to mcCommand, the master and slave positions are calculated based on the position references.

- When the variables Master and Slave are specified as linear axis

  DeviatedValue = Master position - Slave position.

- When the variables Master and Slave are specified as rotary axis with consistent rotation cycle.

  The DeviatedValue is the shorter distance between the Master position and Slave position in the rotation range.

  If Master position is ≥ Slave position, the sign of DeviatedValue is “+”.

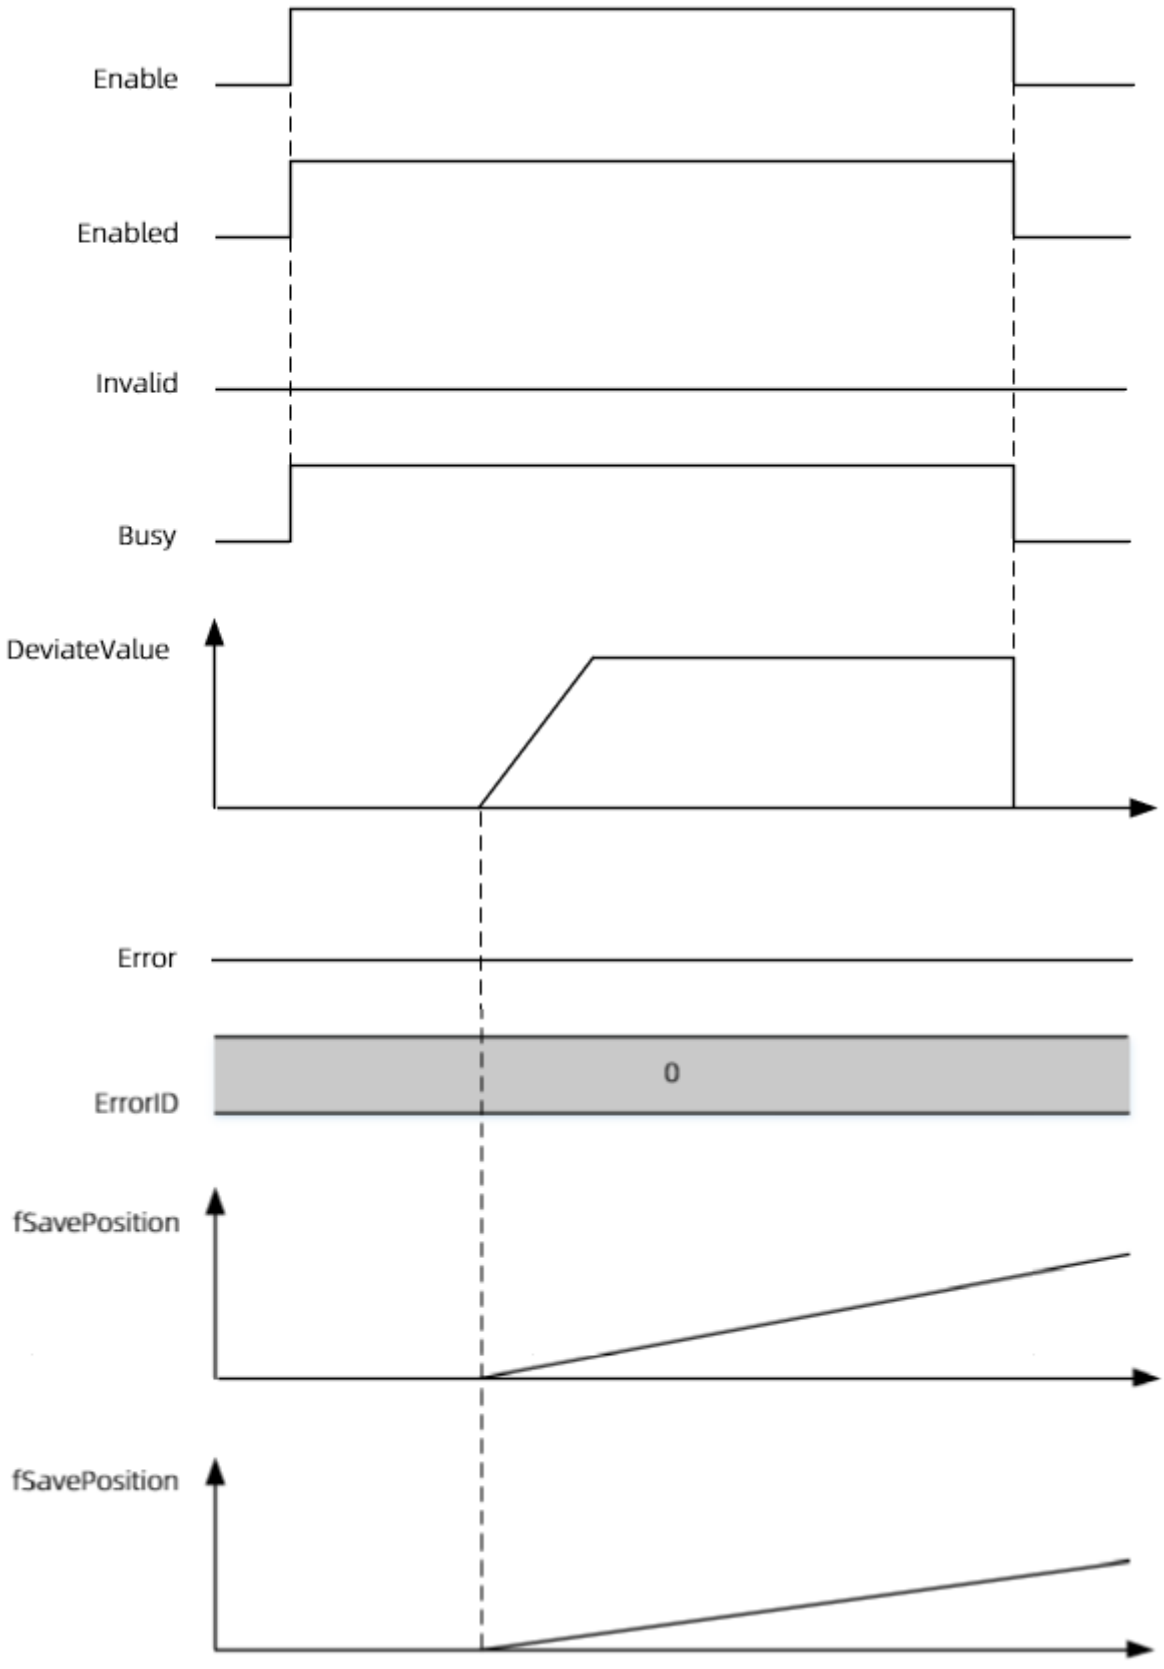
  If Master position is < Slave position, the sign of DeviatedValue is “-”.

- When the variables Master and Slave are specified as rotary axis with inconsistent rotation cycles.

  DeviatedValue = Master position - Slave position.

- When the variables Master and Slave are specified as different axes

  DeviatedValue = Master position - Slave position.



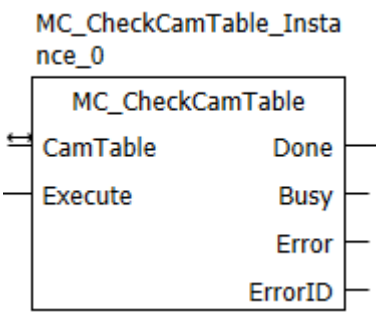
- **Precautions**
  - The master and slave axes specified in this instruction cannot be the same; otherwise, a fault will occur.

- The slave axis specified in this instruction must be bus-controlled axis or local pulse axis; otherwise, a fault will occur.

- **Timing diagram**

  Any fault issued by this instruction does not affect the operation of the axis or axis group.

  With an input parameter PermittedDeviation of 10.0, the output parameter Busy shows the value TRUE on a rising edge of Enable. When the output parameter Enabled shows the value TRUE, it indicates that the instruction has been enabled.



- **Faults**
  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.4.19 MC_CheckCamTable

This instruction checks the validity of user-defined cam table node data.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_CheckCamTable	Check cam table node data		MC_CheckCamTable_Instance_0(CamTable :=, Execute :=, Done =>, Busy =>, Error =>, ErrorID =>);

- **Related variables**

  In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
CamTable	Cam table	18.3.3.2.3.1 MC_CAM_TABLE_REF: Cam table structure	-	-	Specify the cam table to be checked.

  Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**
  - If the input cam table data corresponds to a cam table newly created by the system, the instruction will be directly done.
  - This instruction is designed for checking the validity of user-defined cam table node data. If this instruction is not called to check the data validity, a fault will be reported by the MC_GenerateCamTable, MC_CamIn, and MC_CamInV2 instructions.
- **Example**

The following describes how to crease a user-defined cam table.

1. First, declare the required variables in the variable declaration block of the POU:
   - Declare CamTest: User-defined cam table; Type: MC_CAM_TABLE_REF.

     This variable consists of the following members:

     You can specify the node type through iNodeType, for which the initial value is set to "1" in the preceding figure, indicating the key node. You can specify the number of nodes as required through

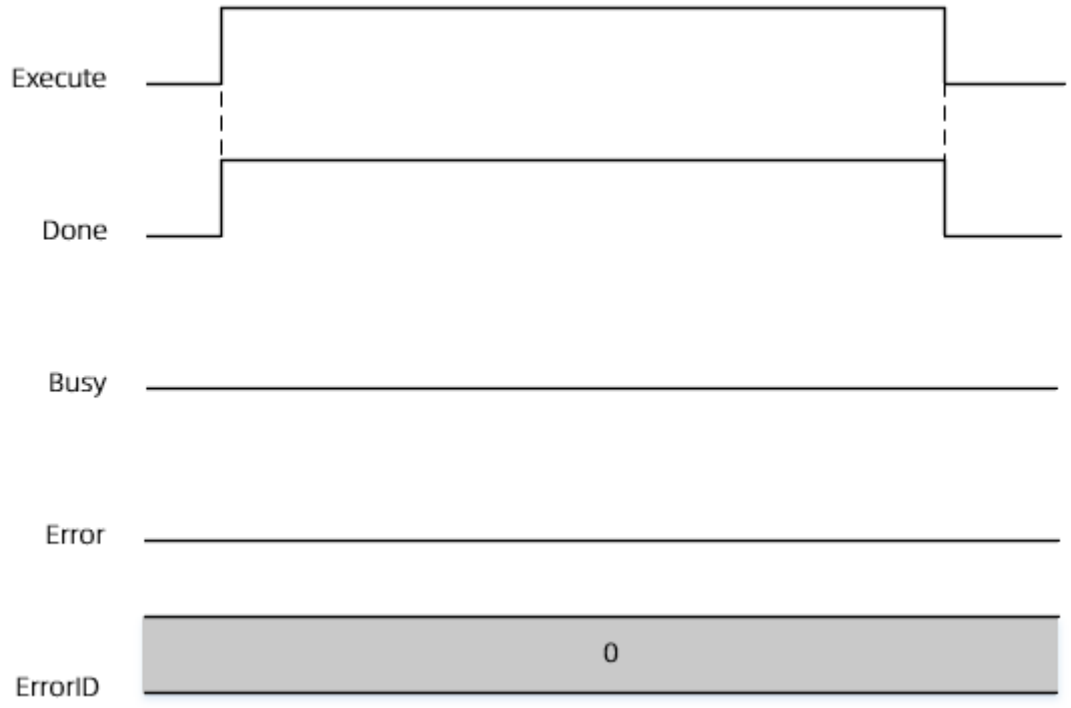
iNodeNumber, which is set to 5 in the figure. pNodePtr indicates the address of the variable for the cam node data, so you must declare a variable of MC_KEY_NODE_REF and enter the address here.

◦ Declare NodesTest: Cam node data; Type: MC_CAM_KEY_NODE_REF. Enter the address of NodesTest as the initial value of CamTest. pNodePtr.

2. Write cam data to the nodes of NodesTest by manual entry or programming in the programming area. Ignore the type of the curve to the first cam node.

The above is the process of creating a user-defined cam table. When the MC_CamIn instruction is executed with such a cam table, it must check the cam table validity first.

3. Use MC_CheckCamTable to check the validity of the cam table.



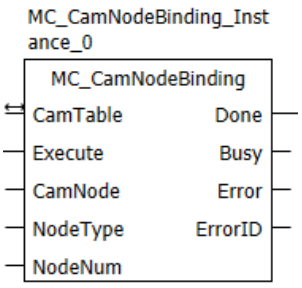
4. Execute the MC_CamIn instruction.

5. During the execution of the instruction, you can use the MC_GenerateCamTable instruction to update the cam node data. Input the node data to be replaced through CamNodes, and input the number of nodes to be replaced through NodeNum.

- **Precautions**

  The number of nodes (iNodeNumber) in a user-defined cam table must be less than the length of the key node array bound to pNodePtr; otherwise, a system fault will occur.

- **Timing diagram**



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.4.20 MC_CamNodeBinding

This instruction binds user-defined cam nodes to a user-defined cam table.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_CamNodeBinding	Cam node binding		MC_CamNodeBinding_Instance_0(CamTable :=, Execute :=, CamNode :=, NodeType :=, NodeNum :=, Done =>, Busy =>, Error =>, ErrorID =>);

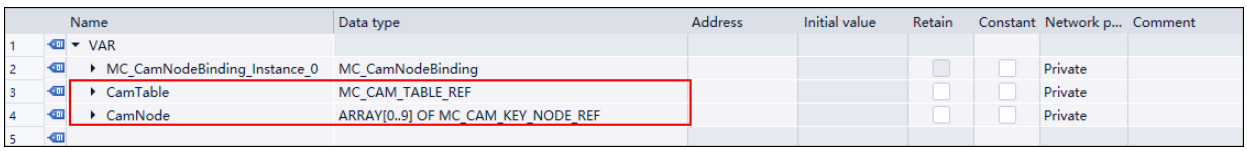
- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
CamTable	User-defined cam table	18.3.3.2.3.1 MC_CAM_TABLE_REF: Cam table structure	-	-	Cam table to which the nodes will be bound.

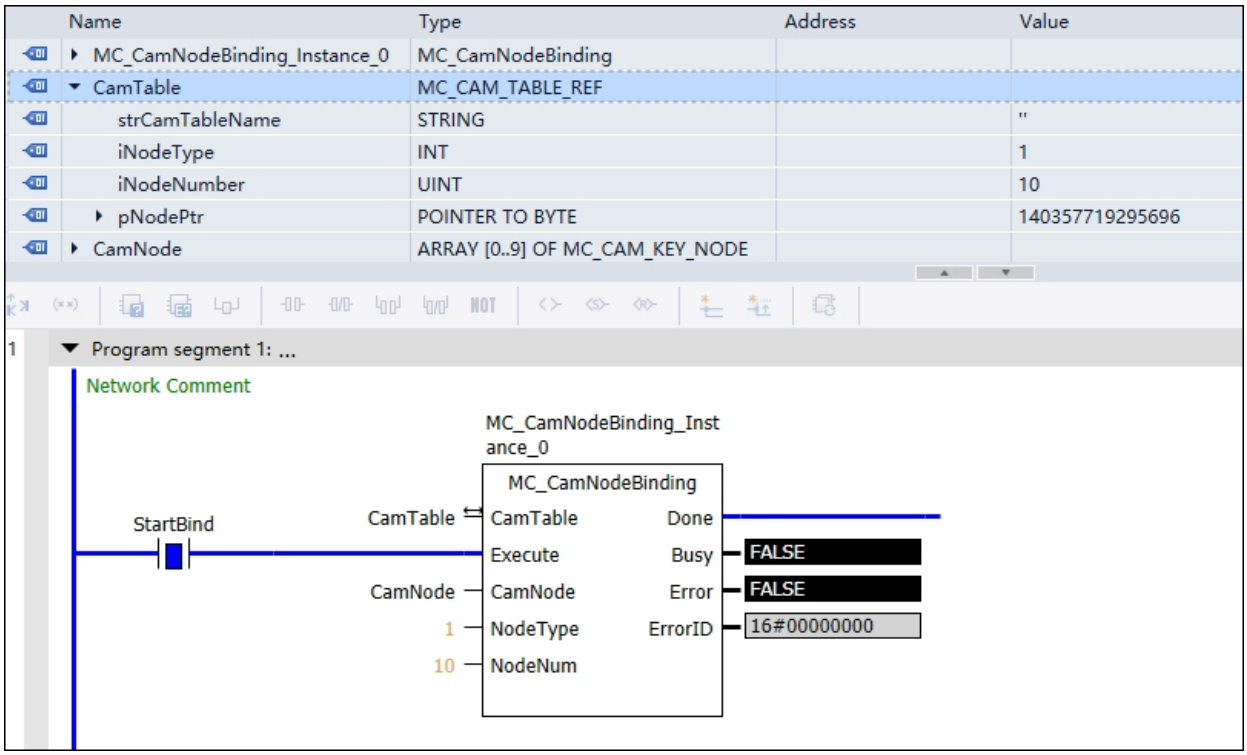
Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Enable	BOOL	TRUE, FALSE	FALSE	The function block is executed on a rising edge of this input variable.
CamNode	Cam node	ARRAY[*] OF 18.3.3.2.3.3 MC_CAM_KEY_NODE_REF: Key node structure ARRAY[*] OF 18.3.3.2.3.4 MC_CAM_FITTING_NODE_REF: Dense node structure	-	-	Array of cam nodes to be bound.



Input Variable	Name	Data Type	Valid Range	Default Value	Description
NodeType	Node type	INT	1, 2	0	Cam table node type to be associated: 1: Key node 2: Dense node
NodeNum	Node number	UDINT	2 to 65535	0	Number of key nodes: 2 to 20000. Number of dense nodes: 2 to 65535.

Output variables



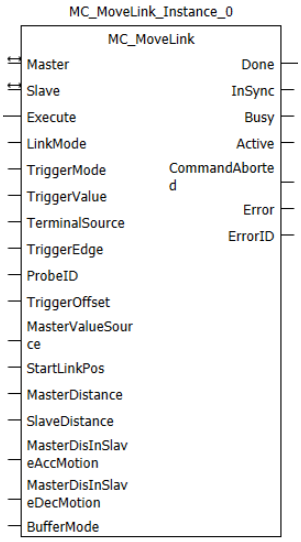
Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**
  - This instruction binds user-defined cam nodes to a cam table. After binding, it initializes the cam table node type, node number, and other information.
  - This instruction starts the cam parameter check, including whether the cam type matches the specified cam node array type, the cam node type, and whether the number of cam nodes is within the specified range.
  - This instruction initializes the maximum number of nodes in the cam table. After the cam table is bound with this instruction, if the number of cam nodes exceeds the specified number when calling the MC_GenerateCamTable instruction to update the number of cam table nodes, the MC_GenerateCamTable instruction will report fault 0FB5.
- **Precautions**
  - Do not execute the MC_CamNodeBinding instruction during the execution of MC_GenerateCamTable, MC_CamIn, or MC_CamInV2; otherwise, a fault may occur.
  - The MC_CamNodeBinding instruction is mainly used for user-defined cam tables. When a system-created cam table is used, do not use this instruction to bind the cam node array.
- **Example**

  First, declare a user-defined cam table and specify a cam node array as key node.

Then call the function block (FB) and specify the cam node type as key node. The instruction is triggered when the number of nodes matches the number of cam nodes.

- **Timing diagram**



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.4.21 MC_MoveLink

This instruction is used for positioning the slave axis in sync with the master axis with specified conditions for triggering synchronized motion between the master and slave axes.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_MoveLink	Synchronous positioning		MC_MoveLink_Instance_0(Master :=, Slave :=, Execute :=, LinkMode :=, TriggerMode :=, TriggerValue :=, TerminalSource :=, TriggerEdge :=, ProbeID :=, TriggerOffset :=, MasterValueSource :=, StartLinkPos :=, MasterDistance :=, SlaveDistance :=, MasterDisInSlaveAccMotion :=, MasterDisInSlaveDecMotion :=, BufferMode :=, Done =>, InSync =>, Busy =>, Active =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

  In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Master	Master axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the master axis; an instance of AXIS_REF.

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Slave	Slave axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the slave axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	The function block is executed on a rising edge of this input variable.
LinkMode	Synchronization start condition	INT	0, 1, 2	0	0: When the instruction is executed. 1: When the master axis reaches the position specified by StartLinkPos. 2: When the TriggerValue is detected to be TRUE.
TriggerMode	Trigger mode	INT	0, 1	0	0: Drive mode. 1: Controller mode. (This parameter is valid only when the LinkMode is set to 2)
TriggerValue	Trigger switch in controller mode	BOOL	TRUE, FALSE	FALSE	TRUE: Triggered. FALSE: Untriggered. (This parameter is valid only when the TriggerMode is set to 1)
TerminalSource	Touch probe signal source	INT	0, 1	0	0: DI terminal. 1: Encoder Z-phase signal. (Used when the TriggerMode is specified as Drive mode)
TriggerEdge	Trigger edge	INT	0, 1	0	0: Rising edge. 1: Falling edge.
ProbeID	Touch probe ID	INT	0, 1	0	0: Touch probe 1. 1: Touch probe 2. (Used when the TriggerMode is specified as Drive mode)

Input Variable	Name	Data Type	Valid Range	Default Value	Description
TriggerOffset	Master axis synchronization offset	LREAL	-	0	Describe the offset between the actual synchronized position of the master and slave axes and the trigger position. Position of the master axis when the slave axis starts the synchronized motion: Latched trigger position + TriggerOffset. (This parameter is valid only when the LinkMode is set to 2)
MasterValueSource	Master axis data type	18.3.3.2.2.11 MC_REFERENCE_TYPE: Data Type Enumeration	0, 1, 2	0	0: mcCommand: Value calculated in the previous task cycle (fSavePosition). 1: mcFeedback: Value obtained in the same task cycle (fActPosition). 2: mcLaterCommand: Value calculated in the same task cycle (fSetPosition).
StartLinkPos	Master axis position at camming start	LREAL	Positive number, negative number, or 0	0	Specify the absolute position [u] of the master axis when the slave axis starts following the master axis. In Rotary mode, if the parameter value is a negative number or greater than the number of rotation cycles, it will be converted to a positive value and then taken modulo.
MasterDistance	Master axis travel distance	LREAL	Positive number or 0	0	Travel distance [u] of the master axis. If a negative value is entered, a fault will occur. The sign of MasterDistance is determined by the velocity of the master axis at the time of triggering synchronization. In Rotary Mode, the number of cycles is counted.
SlaveDistance	Slave axis travel distance	LREAL	Positive number, negative number, or 0	0	Travel distance [u] of the slave axis during the synchronization between the master and slave axes. When the input value is greater than 0, the slave axis moves in the same direction as the master axis. When the input value is less than 0, the slave axis moves in the opposite direction of the master axis. In Rotary Mode, the number of cycles is counted.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
MasterDisInSlaveAccMotion	Master axis travel distance during slave axis acceleration	LREAL	Positive number or 0	0	If a negative value is entered, a fault will occur. The sign of MasterDisInSlaveAccMotion is determined by the velocity of the master axis at the time of triggering synchronization.
MasterDisInSlaveDecMotion	Master axis travel distance during slave axis deceleration	LREAL	Positive number or 0	0	If a negative value is entered, a fault will occur. The sign of MasterDisInSlaveDecMotion is determined by the velocity of the master axis at the time of triggering synchronization.
BufferMode	Buffer mode	18.3.3.2.2.6 MC_BUFFER_MODE: Buffer Mode Enumeration	0, 1	0	mcAborting = 0: Aborting. mcBuffered = 1: Buffered.

Output variables

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
InSync	Synchronizing	BOOL	TRUE, FALSE	FALSE	TRUE when the master and slave axes are synchronizing.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Active	Controlling	BOOL	TRUE, FALSE	FALSE	TRUE when the axis is being controlled.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is aborted.
Error	Error	BOOL	TRUE, FALSE	FALSE	TRUE when an error occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**
  - This instruction is used for positioning the slave axis in sync with the master axis with specified conditions for triggering synchronized motion between the master and slave axes.
  - During the execution of this instruction, you cannot execute the MC_SetOverride instruction on the slave axis.
  - During the execution of this instruction, no checks are performed to see if the acceleration of the slave axis exceeds the limit; however, a fault will occur if the velocity of the slave axis exceeds the software limit.
  - During the execution of this instruction, the MC_MoveSuperImposed instruction can be used.
  - When the instruction is triggered on a rising edge of the input parameter Execute, the input parameters are checked for validity. If any of invalid parameters is detected, it will be automatically corrected by the function block without a fault message; any buffered instructions after this instruction will be cleared.
  - If bus cycle is specified for the cycle task of the master axis, the velocity of the slave axis may show a sudden jump after synchronization. It is recommended that users specify EtherCAT cycle for the cycle task of both the master and slave axes before enabling a synchronous control instruction.
  - When the local pulse axis is used as the master axis with Y0 or Y1 single-ended output, it is not recommended to use this instruction. ① No pulse output; ② No position feedback.
  - When the InSync is sent to TRUE, the master axis moves in the effective trigger direction. If the master axis reverses during subsequent synchronization with the slave axis following the master axis, the slave axis will stop moving when the master axis moves in reverse direction to the position specified by StartLinkPos, and the InSync will be set to FALSE. Synchronization can be re-triggered when the master axis moves in the effective trigger direction and reaches the position specified by StartLinkPos.
  - MC_Home, MC_Homing, or MC_HomingWithParameter can be used during the instruction execution.

    This instruction places the master axis in the AXIS_HOMING state. If the instruction is executed while the master axis is already in this state, the signal source "MasterValueSource" must be set to "mcLatestCommand"; otherwise, the slave axis will overspeed.
  - The arrival check function is only applicable to MotionControl library version 2.4.0.0 or later. Based on the "Positioning range" and "Positioning check time" parameters in the "General setting" of the axis configuration page, it checks in real time whether the actual position has entered the specified target

range. After the instruction output for the target position is completed, positioning is complete and the Done output is set if the difference between the actual position and the target position is smaller than the "Positioning range". If positioning is not completed within the "Positioning check time", a fault will occur.

- **Precautions**
  - Invalid parameter input values:
    - If the input value of the TriggerMode, LinkMode, ProbeID, TerminalSource, or MasterValueSource is out of the limit, a fault will occur.
    - If the input value of the MasterDistance, MasterDisInSlaveAccMotion, or MasterDisInSlaveDecMotion is negative, a fault will occur.
  - If the constant-velocity travel distance of the master axis is negative (MasterDistance - MasterDisInSlaveAccMotion - MasterDisInSlaveDecMotion < 0), a fault will occur.
  - If you want the slave axis velocity to equal the master axis velocity in the stable synchronization zone (both axes moving at constant velocity), you can set the SlaveDistance to:

$$\text{MasterDistance} + \frac{MasterDisInSlaveAccMotion}{2} + \frac{\text{MasterDisInSlaveDecMotion}}{2}$$

  - If you want the slave axis velocity to be greater than the master axis velocity in the stable synchronization zone (both axes moving at constant velocity), you can set the SlaveDistance to be greater than:

$$\text{MasterDistance} + \frac{MasterDisInSlaveAccMotion}{2} + \frac{\text{MasterDisInSlaveDecMotion}}{2}$$

  - If you want the slave axis velocity to be less than the master axis velocity in the stable synchronization zone (both axes moving at constant velocity), you can set the SlaveDistance to be less than:

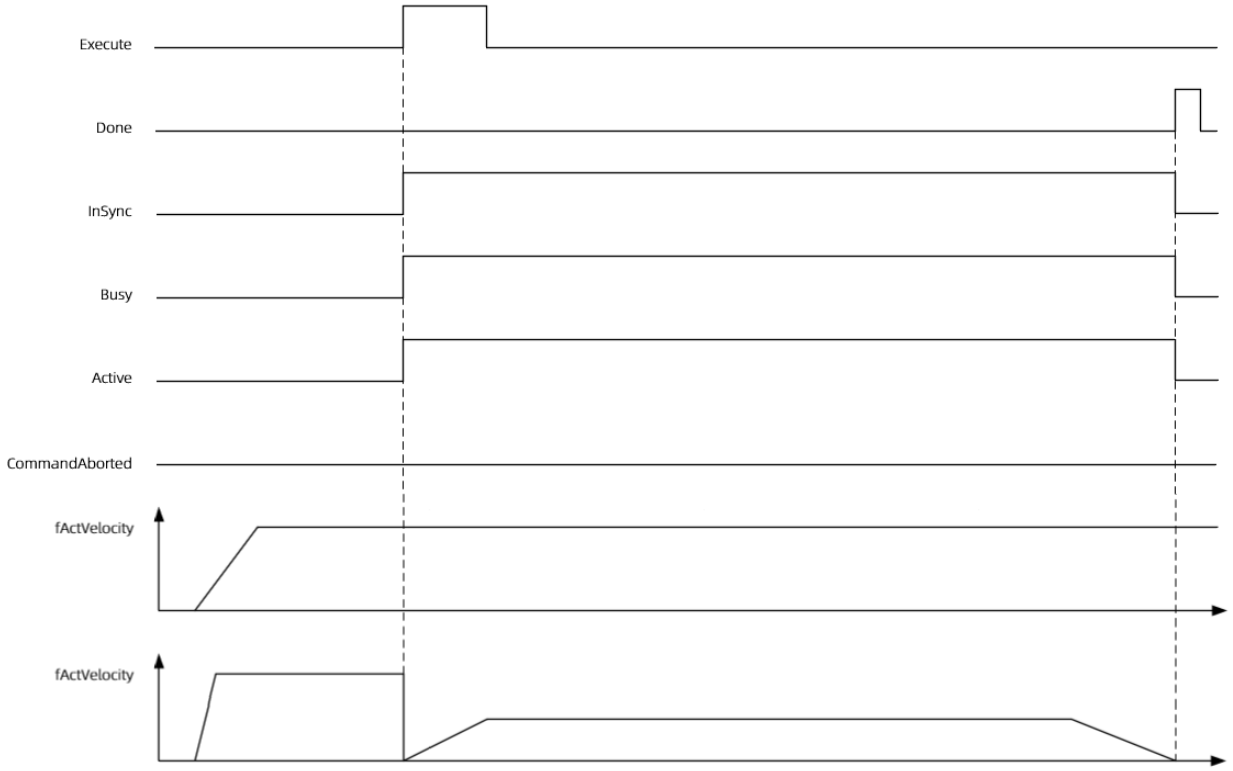
$$\text{MasterDistance} + \frac{MasterDisInSlaveAccMotion}{2} + \frac{\text{MasterDisInSlaveDecMotion}}{2}$$

  - When the TriggerMode is set to Drive mode, the touch probe signal comes from the external touch probe signal of the master axis.
  - In Drive mode, the touch probe signal occupies the probe channel and conflicts with the MC_TocuhProbe and MC_MoveFeed instructions. To use the MC_Movelink instruction, do not use the MC_MoveFeed or MC_TouchProbe instruction with the same probe channel on the master axis.
  - When the MC_MoveLink instruction is executed with the TriggerMode being set to Drive mode, the touch probe channel may be cleared by the MC_AbortTrigger instruction, resulting in the same effect as the instruction being aborted.
  - When the TriggerMode is set to Controller mode, the instruction does not occupy the touch probe channel, and the settings of the touch probe channel are invalid.
  - The touch probe recorded position in Controller mode may have a position deviation within one task cycle.
  - There are only two touch probe channels, so a maximum of one master axis with two slave axes can be configured in Drive mode. To configure a single master axis with multiple slave axes, modify the TriggerMode to Controller mode, and then map the variable Trigger of each axis to the corresponding IO device, replacing the touch probe signal from a drive with the IO device.

- **Timing diagram**
  - Starting this instruction

    LinkMode = When the instruction is executed

    LinkMode = When the master axis reaches the position specified by StartLinkPos

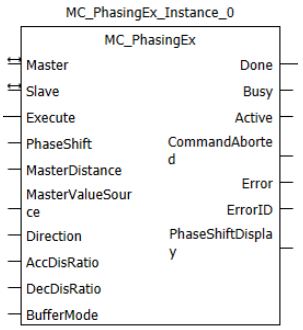


◦ When the BufferMode is set to Aborting in the previous operation

When the MC_MoveAbsolute instruction is executed in the previous operation with the start of this instruction being specified through LinkMode, the execution of this instruction is as follows.

When the previous MC_MoveAbsolute instruction is executed

When the current instruction is executed



- **Faults**
  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.4.22 MC_PhasingEx

This instruction enables phase shifting completed within the specified master axis travel distance (which has an effect on the slave axis but no effect on the master axis), so that the slave axis is synchronized to the shifted master axis phase. You can specify the master axis travel distance (in percentage) corresponding to the shifted slave axis motion during the acceleration and deceleration phases.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_PhasingEx	Complete phase shifting within specified master axis travel distance		MC_PhasingEx_Instance_0(Master :=, Slave :=, Execute :=, PhaseShift :=, MasterDistance :=, MasterValueSource :=, Direction :=, AccDisRatio :=, DecDisRatio :=, BufferMode :=, Done =>, Busy => , Active =>, CommandAborted =>, Error =>, ErrorID =>, PhaseShiftDisplay =>);

- **Related variables**

  In-out variables

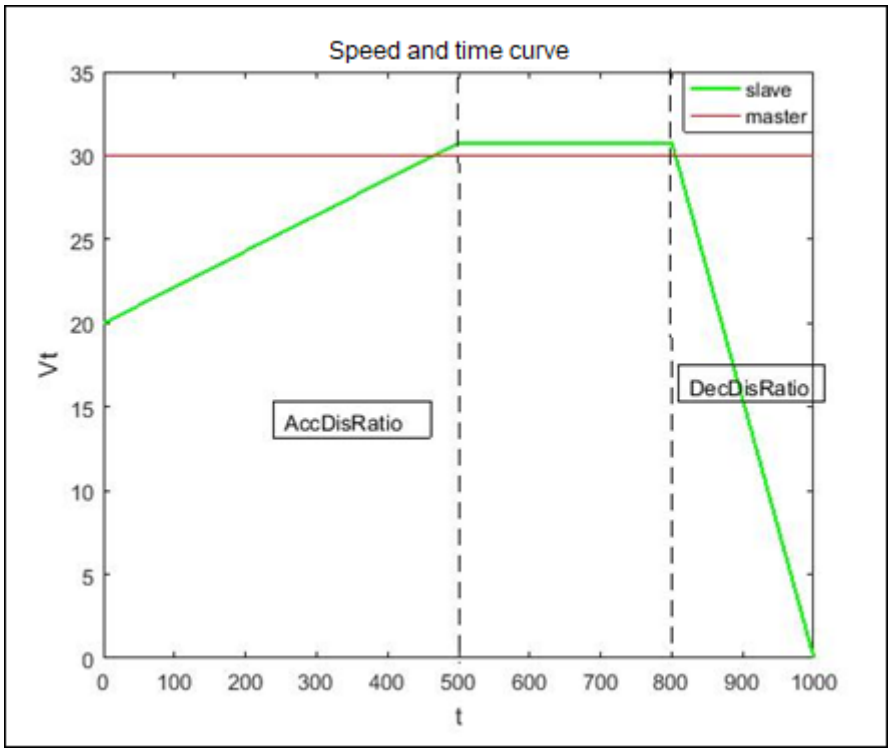
In-out Variable	Name	Data Type	Valid Range	Default Value	Description
Master	Master axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the master axis; an instance of AXIS_REF.
Slave	Slave axis	18.3.3.2.2.1 AXIS_REF: Axis Structure	-	-	Reference to the slave axis; an instance of AXIS_REF.

Input variables

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	The function block is executed on a rising edge of this input variable.

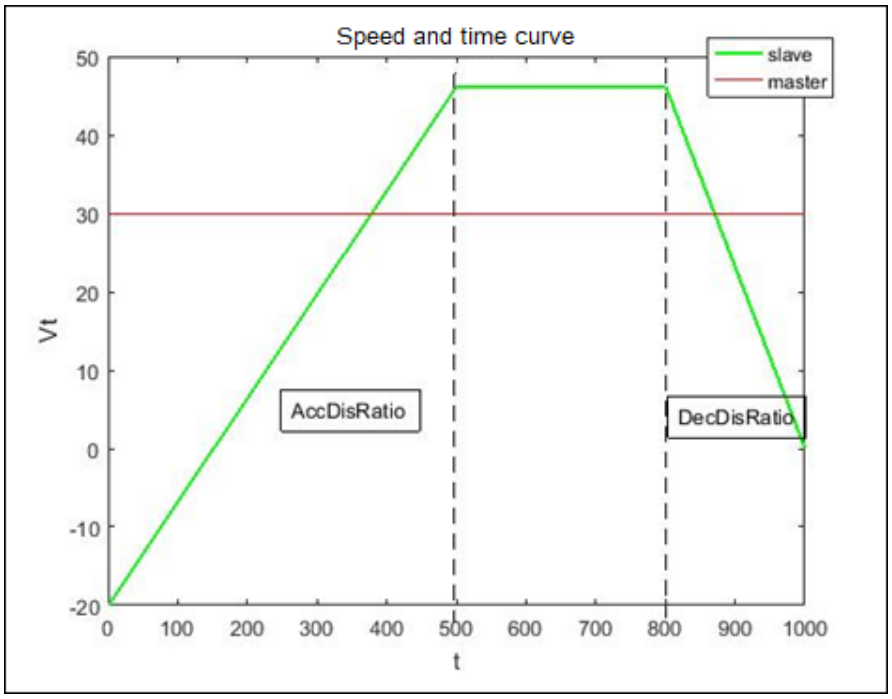
Input Variable	Name	Data Type	Valid Range	Default Value	Description
PhaseShift	Phase shift	LREAL	Positive number, negative number, or 0	0	Phase shift [u] between the master and slave axes.
MasterDistance	Master axis travel distance	LREAL	Positive number	0	Travel distance [u] of the master axis during phase shifting.
MasterValueSource	Master axis data type	18.3.3.2.2.11 MC_REFERENCE_TYPE: Data Type Enumeration	0, 1, 2	0	0: mcCommand: Value calculated in the previous task cycle (fSavePosition). 1: mcFeedback: Value obtained in the same task cycle (fActPosition). 2: mcLaterCommand: Value calculated in the same task cycle (fSetPosition).
Direction	Direction	18.3.3.2.2.9 MC_DIRECTION: Motion Direction Enumeration	1, 2	1	Phase shifting is executed on the slave axis when the master axis moves in the specified direction. 1: DIR_POSITIVE: Positive direction. 2: DIR_NEGATIVE: Negative direction.
AccDisRatio	Acceleration distance ratio	LREAL	0 to 1	0	Ratio of the master axis travel distance to the specified value of MasterDistance during the change process from the compensated velocity at the instruction triggering to the target velocity (calculated based on the input conditions) on the phase shifting curve.
DecDisRatio	Deceleration distance ratio	LREAL	0 to 1	0	Ratio of the master axis travel distance to the specified value of MasterDistance during the change process from the target velocity to 0 on the phase shifting curve.
BufferMode	Buffer mode	18.3.3.2.2.6 MC_BUFFER_MODE: Buffer Mode Enumeration	0	0	mcAborting = 0. Other values: Reserved

Output variables



Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the PhaseShift is reached.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Active	Controlling	BOOL	TRUE, FALSE	FALSE	TRUE when the phase shifting is started.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the current instruction is aborted.
Error	Error	BOOL	TRUE, FALSE	FALSE	TRUE when an error occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.
PhaseShiftDisplay	Phase shift display	LREAL	-	0	Real-time display of the master axis phase shifting value.

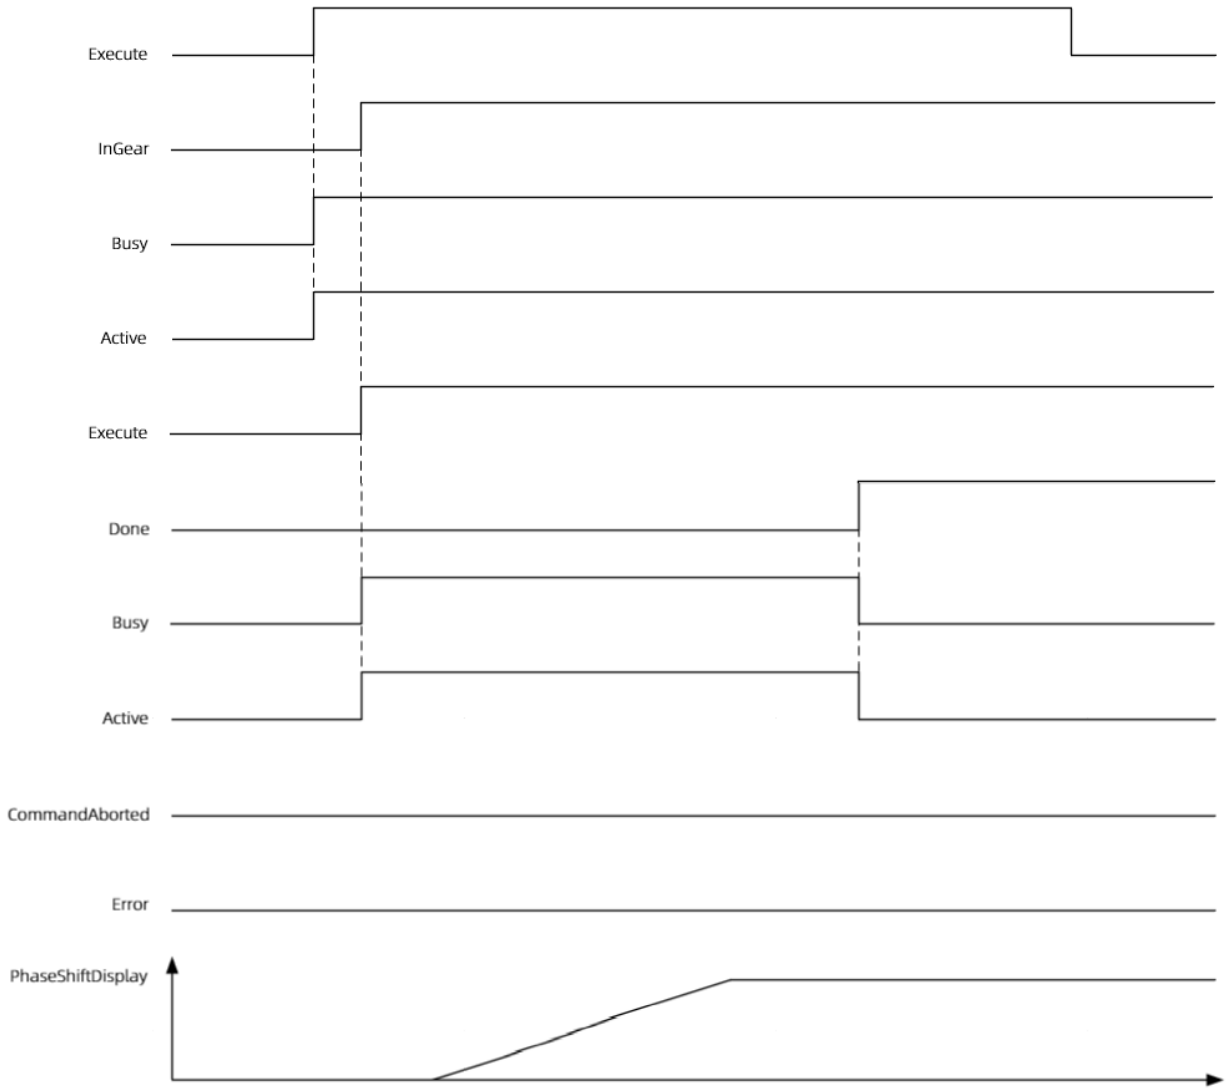


- **Function**
  - You can shift the phase of the master axis for the following synchronous control instructions: MC_GearIn, MC_CamIn, MC_GearInPos, and MC_MoveLink. A fault will occur if this function block is executed in non-synchronous control.
  - This instruction can be re-executed. However, multiple MC_PhasingEx instructions cannot be executed simultaneously. When an MC_PhasingEx instruction is being executed, it is prohibited to trigger a new MC_PhasingEx instruction; otherwise, the subsequently triggered instruction reports an error.
  - The master and slave axes cannot be specified as the same axis.
  - The instruction will issue a fault message if it is executed with the slave axis in non-synchronized motion.
  - Phase shifting start time:
    1. MC_GearIn: After the input variable InGear is set.
    2. MC_GearInPos: After the input variable InSync is set.
    3. MC_CamIn: After the input variable InSync is set.
    4. MC_MoveLink: After the input variable InSync is set.
  - Faults for parameter check:
    1. A fault occurs when the input parameter MasterDistance is set to be less than or equal to 0.

2. A fault occurs when the input parameter AccDisRatio or DecDisRatio is set to be less than 0 or greater than 1.
3. A fault occurs when the sum of the input parameters AccDisRatio and DecDisRatio is greater than 1.
4. A fault occurs when the slave axis is specified as a non-supported axis type. The supported axis types include ECT control axis and local control axis.
5. A fault occurs when any other input parameters are outside the limits.

- When the input parameter AccDisRatio is set to 0, the phase shifting curve contains no acceleration phase, which means that the phase shifting velocity jumps to the calculated target velocity immediately, resulting in significant velocity fluctuation and increased impact on the slave axis. When the input parameter DecDisRatio is set to zero, the phase shifting curve contains no deceleration phase.
- When the input parameter PhaseShift is set to zero, the instruction ends normally without affecting the synchronization, and the Done is set normally.
- This instruction is executed when the master axis moves in the direction specified by Direction. During shifting, if the master axis changes its direction, the instruction is aborted. When the master axis moves in the specified direction again and reaches the reversal point, phase shifting restarts for the slave axis to complete the remaining amount of phase shift.
- If the instruction is executed with a master axis velocity equal to zero, phase shifting will be started until the master axis velocity changes to non-zero.
- AccDisRatio and DecDisRatio: (The compensated velocity curve of the slave axis is in green, and the velocity curve of the master axis is in red)

(a) The initial compensated velocity has the same sign as the phase shift amount



(b) The initial compensated velocity has a different sign from the phase shift amount

- **Precautions**
  It is not recommended to execute two same instances of MC_PhasingEx simultaneously.
- **Timing diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Done of the function block indicates the instruction has been executed successfully; the parameter Busy indicates that the current function block is being executed; the parameter Active indicates the axis is being controlled; the parameter CommandAborted indicates that the instruction is aborted by another motion control instruction, at which point the flag is set to TRUE.

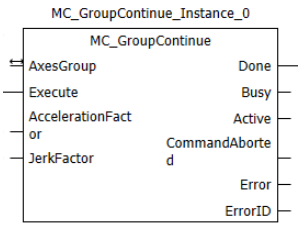
  For the MC_GearIn instruction, the parameter InGear being set is the rising edge for the parameter Execute of this instruction, at which point the output parameter Busy shows the value TRUE and the Active shows the value TRUE in the next cycle.

  When the input variable PhaseShift is set to 40.0 and the output variable PhaseShiftDisplay shows the value specified by PhaseShift, the output parameter Done shows the value TRUE.

- **Faults**
  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.5 Axis Group

18.3.3.5.1 Instruction List



Instruction	Function	Library	Applicable Library Version
18.3.3.5.2 MC_GroupContinue	Continue axis group motion	MotionControl	Library version 1.1.0.0 and later
18.3.3.5.3 MC_GroupDisable	Disable axis group		Library version 1.1.0.0 and later
18.3.3.5.4 MC_GroupEnable	Enable axis group		Library version 1.1.0.0 and later
18.3.3.5.5 MC_GroupHalt	Stop axis group		Library version 1.1.0.0 and later
18.3.3.5.6 MC_GroupHome	Axis group homing		Library version 1.1.0.0 and later

Instruction	Function	Library	Applicable Library Version
18.3.3.5.7 MC_GroupInterrupt	Axis group pause		Library version 1.1.0.0 and later
18.3.3.5.8 MC_GroupReadActualAcceleration	Read axis group actual acceleration		Library version 1.1.0.0 and later
18.3.3.5.9 MC_GroupReadActualPosition	Read axis group actual position		Library version 1.1.0.0 and later
18.3.3.5.10 MC_GroupReadActualVelocity	Read axis group actual velocity		Library version 1.1.0.0 and later
18.3.3.5.11 MC_GroupReadError	Axis group error reading		Library version 1.1.0.0 and later
18.3.3.5.12 MC_GroupReadStatus	Axis group status reading		Library version 1.1.0.0 and later
18.3.3.5.13 MC_GroupReset	Reset axis group		Library version 1.1.0.0 and later
18.3.3.5.14 MC_GroupSetOverride	Axis group override setting		Library version 1.1.0.0 and later
18.3.3.5.15 MC_GroupSetPosition	Set axis group current position		Library version 1.1.0.0 and later
18.3.3.5.16 MC_GroupStop	Axis group emergency stop		Library version 1.1.0.0 and later
18.3.3.5.17 MC_MoveCircularAbsolute	Circular absolute motion		Library version 1.1.0.0 and later
18.3.3.5.18 MC_MoveCircularRelative	Circular relative motion		Library version 1.1.0.0 and later
18.3.3.5.19 MC_MoveDirectAbsolute	Point-to-point absolute motion		Library version 1.1.0.0 and later
18.3.3.5.20 MC_MoveDirectRelative	Point-to-point relative motion		Library version 1.1.0.0 and later
18.3.3.5.21 MC_MoveLinearAbsolute	Linear absolute motion		Library version 1.1.0.0 and later
18.3.3.5.22 MC_MoveLinearRelative	Linear relative motion		Library version 1.1.0.0 and later
18.3.3.5.23 MC_SetCartesianTransform	Set transformation between part coordinate system and machine coordinate system		Library version 1.1.0.0 and later
18.3.3.5.24 MC_TrackConveyorBelt	Conveyor belt tracking		Library version 1.1.0.0 and later
18.3.3.5.25 MC_GroupPower	Enable/disable axes in axis group		Library version 2.3.0.0 and later

18.3.3.5.2 MC_GroupContinue

This instruction resumes the axis group, allowing a paused or pausing motion to continue along its original trajectory.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_GroupContinue	Continue axis group motion		MC_GroupContinue_Instance_0(AxesGroup := , Execute := , AccelerationFactor := , JerkFactor := , Done => , Busy => , Active =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

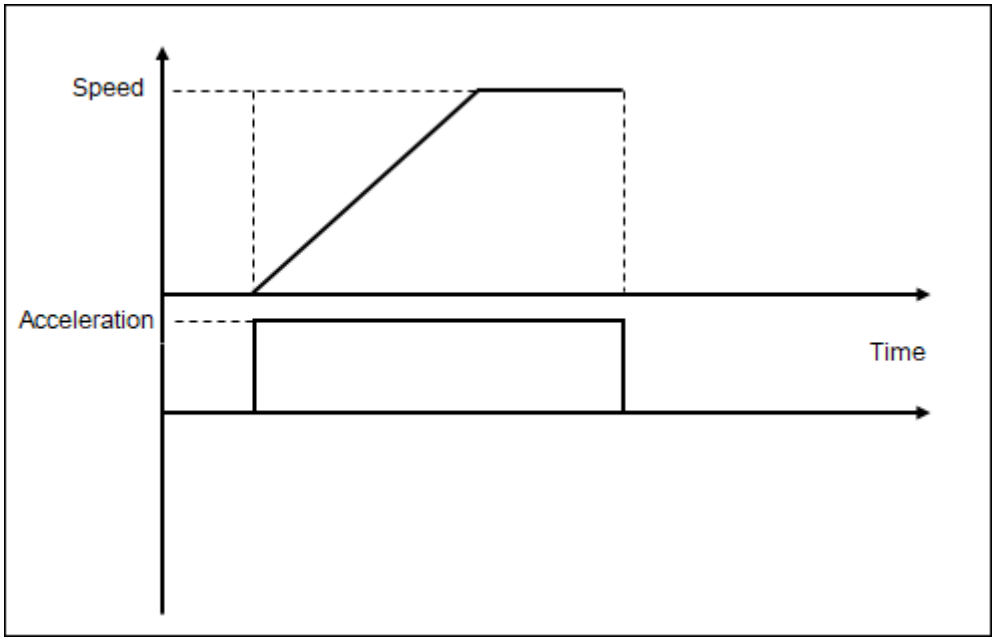
In-out Variable	Name	Data Type	Valid Range	Default Value	Description
AxesGroup	Axis group	18.3.3.2.4.1 AXES_GROUP_REF: Axis Group Structure	-	-	Mapped to an axis group, which is an instance of AXES_GROUP_REF.

Input variable

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	Execute the instruction on a rising edge.
AccelerationFactor	Acceleration factor	LREAL	[0.01,1.0]	0.3	Factor relative to the maximum acceleration of the axis group. If the factor is greater than 1, it will be corrected to 1. If the factor is less than 0.01, it will be corrected to 0.3.

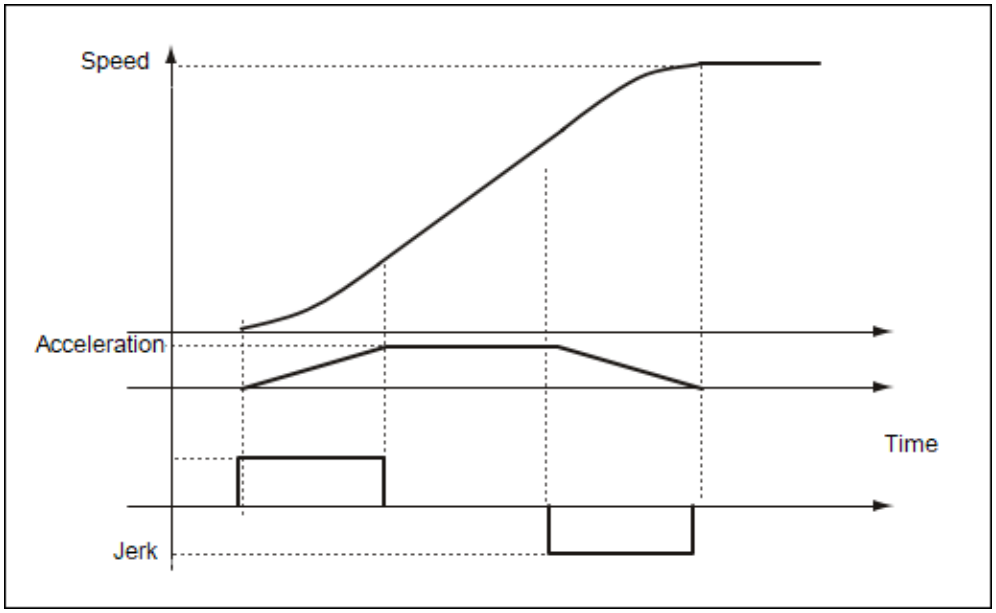
Input Variable	Name	Data Type	Valid Range	Default Value	Description
JerkFactor	Jerk factor	LREAL	[0.0,1.0]	0.3	Factor relative to the maximum jerk of the axis group. For the non-trapezoidal motion profiling, the factor will be corrected to 1 if it is greater than 1. If it is less than or equal to 0, it will be corrected to 0.3.

Output variable



Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Active	Instruction has controlled the axis group	BOOL	TRUE, FALSE	FALSE	TRUE when the axis is being controlled.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	Set to TRUE when the instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Parameter correction**



Input Variable	Name	Correction Description for Values Greater Than 1 or Backend Limit	Correction Description for Parameters Below Minimum Value Range	Correction Description for Parameters Equal to Minimum Value Range
AccelerationFactor	Acceleration factor	If the acceleration factor is greater than 1, it is automatically corrected to 1.	If the acceleration factor is less than 0.01, it is automatically corrected to 0.3.	If the acceleration factor is equal to 0.01, no correction is applied.
JerkFactor	Jerk factor	If the jerk factor is greater than 1 in the non-trapezoidal motion profiling, it is automatically corrected to 1.	If the jerk factor is less than 0 in the non-trapezoidal motion profiling, it is automatically corrected to 0.3 for operation.	If the jerk factor is equal to 0 in the non-trapezoidal motion profiling, it is automatically corrected to 0.3 for operation.

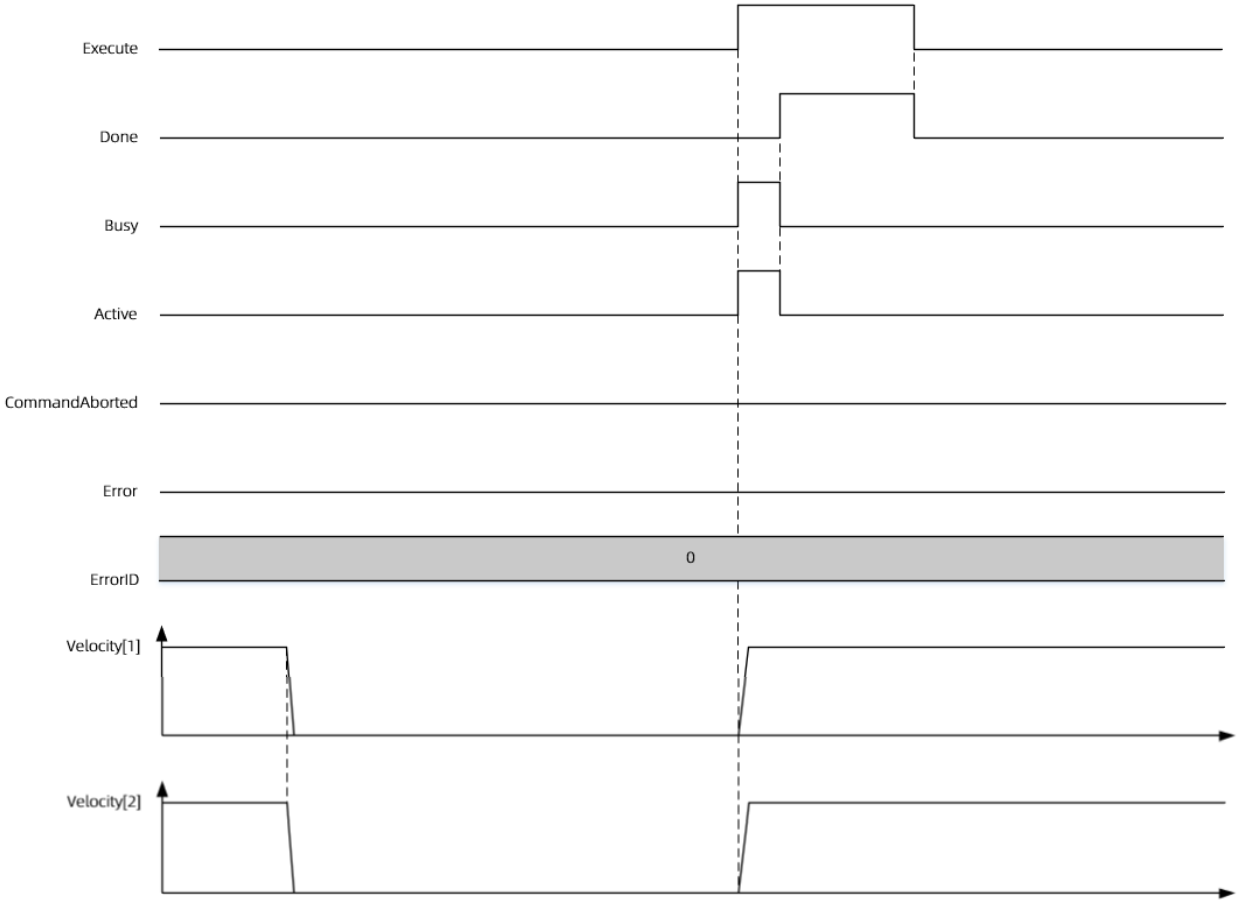
- **Function**
  - This instruction is executed on the rising edge of Execute and is used to restart AxesGroup, allowing the currently paused or pausing motion to return to its original path.
  - After this instruction starts and both instructions Busy and Active are activated, Active of the axis group motion instructions previously paused by the MC_GroupInterrupt instruction will become TRUE again. The axis group will accelerate according to the instruction parameters until it returns to the speed at which it was paused, set the Done instruction to TRUE.
  - This instruction is used in conjunction with the MC_GroupInterrupt instruction.
  - This instruction can be interrupted by MC_GroupInterrupt, MC_GroupHalt, MC_GroupStop, and other MC_GroupContinue instructions, or it can be interrupted by new motion instructions for AxesGroup.
  - **AccelerationFactor, JerkFactor**
    - The acceleration and jerk during the instruction execution are determined by the input variables AccelerationFactor and JerkFactor.
    - In joint space (ACS), the restart operation is performed based on the product of the maximum axis acceleration limited by software for each Axis variable in AxesGroup and AccelerationFactor, and the product of the maximum axis jerk limited by software for each axis and JerkFactor.
    - In work space (PCS), the restart operation is performed based on the product of the maximum acceleration of AxesGroup and AccelerationFactor, and the product of the maximum jerk of the axis group and JerkFactor.
    - JerkFactor

      Velocity and acceleration curves with JerkFactor = 0

Velocity, acceleration, and jerk curves with JerkFactor ≠ 0

- **Re-triggering the instruction**
  - This instruction cannot be re-triggered.
- **Precautions**
  - When AxesGroup is in the GroupStandby, GroupErrorstop, GroupDisabled, GroupHoming, or GroupStopping state, this instruction cannot be started. Otherwise, the instruction will return an error.
  - When AxesGroup is controlled by the MC_GroupHalt instruction and the axis group is in the homing process, this instruction cannot be started. Otherwise, the instruction will return an error.
  - The trajectory planning curve type of AxesGroup must be set as required. If the planning curve type is set to a trapezoidal curve, the input variable JerkFactor becomes invalid, and the instruction performs the motion resumption based on AccelerationFactor. If the planning curve type is set to a cubic curve or a septic curve, the instruction performs the motion resumption based on both AccelerationFactor and JerkFactor.
  - Whether the planning curve type of each Axis variable in AxesGroup is set to a trapezoidal curve or an S-curve does not affect the planning method of AxesGroup.

- During the execution of the instruction, all axes in AxesGroup must be in the enabled status. Otherwise, an error will be reported.



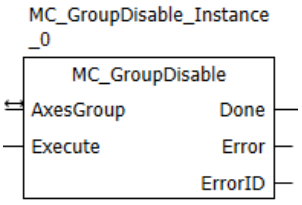
- **Sequence diagram**

  The Execute input of the function block must be triggered on a rising edge. The Done output of the function block indicates the instruction is executed successfully. The Busy output of the function block indicates that the current function block is being executed. The CommandAborted output of the function block indicates that the instruction is aborted by another motion control instruction, at which point the flag is set to TRUE.

  Call the motion control instruction to put the axis group in the GROUP_MOVING status, and then the axis group is controlled by the MC_GroupInterrupt instruction, all axes in the axis group reach a speed of "0".

  After this instruction is called, the output parameter Busy is set to TRUE on a rising edge of Execute, and "Active" also becomes TRUE.

  The axis group accelerates according to the instruction parameters until it returns to the speed under the paused status, and the output parameter "Done" is set to TRUE.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.5.3 MC_GroupDisable

This instruction disables the axis group, changing its state to GroupDisabled.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_GroupDisable	Disable axis group		MC_GroupDisable_Instance_0(AxesGroup := , Execute := , Done => , Error => , ErrorID =>);

- **Related variables**

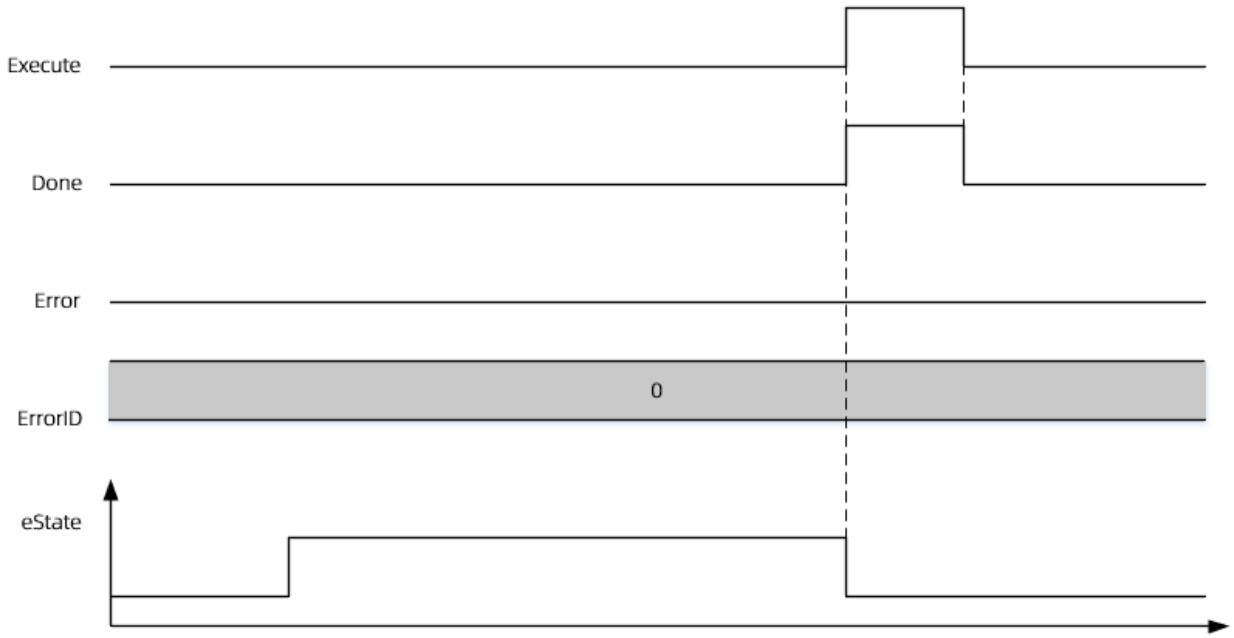
  In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
AxesGroup	Axis group	18.3.3.2.4.1 AXES_GROUP_REF: Axis Group Structure	-	-	Mapped to an axis group, which is an instance of AXES_GROUP_REF.

  Input variable

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	Execute the instruction on a rising edge.

  Output variable



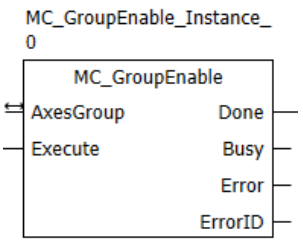
Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	Set to TRUE when the instruction is done.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**
  - This instruction can disable the axis group specified by AxesGroup, changing its axis group status to GroupDisabled.

- When AxesGroup is in the GroupDisabled state, enable this instruction to directly set the output variable Done to TRUE.
- When AxesGroup is in the GroupDisabled state, the single axis instruction can be executed on the Axis variable in AxesGroup.
- This instruction may change the state of the Axis variable in the axis group specified by AxesGroup. When the output variable Done of this instruction becomes TRUE, if the Axis variable in AxesGroup is already in the ErrorStop or Disabled state, its state remains unchanged. Otherwise, if the axis is actually enabled, the state of the Axis variable will be changed to StandStill. If the axis is not yet enabled, the Axis variable is in the Disabled state.

- **Precautions**
  - This instruction can be used when the axis group (AxesGroup) is in the GroupStandby, GroupDisabled, GroupStopping, or GroupErrorStop state. Do not use this instruction in any other states. Otherwise, the instruction will return an error.
  - After the instruction has been used, the single axis instruction can be executed on the axes in AxesGroup.
- **Sequence diagram**

  When the input parameter "Execute" is TRUE, the state of the AxesGroup will be changed from GroupStandby to GroupDisabled. The output parameter "Done" becomes TRUE.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.5.4 MC_GroupEnable

The instruction can enable the axis group, transitioning its state from GroupDisabled to GroupStandby.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_GroupEnable	Enable axis group		MC_GroupEnable_Instance_0(AxesGroup := , Execute := , Done =>, Busy =>, Error =>, ErrorID =>);

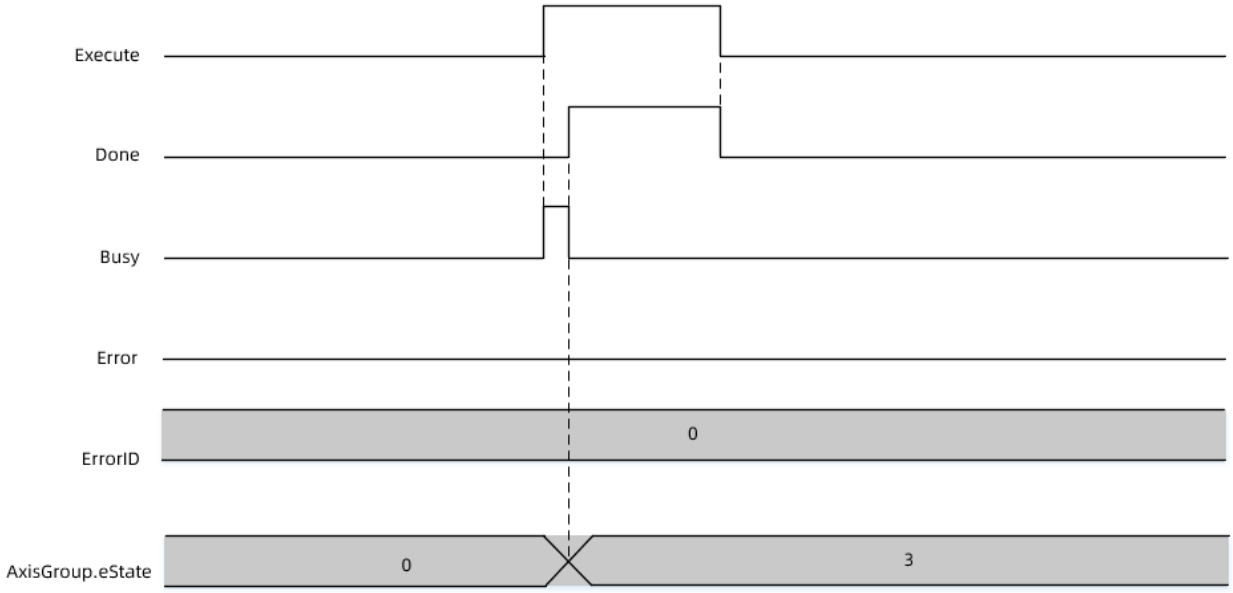
- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
AxesGroup	Axis group	18.3.3.2.4.1 AXES_GROUP_REF: Axis Group Structure	-	-	Mapped to an axis group, which is an instance of AXES_GROUP_REF.

Input variable

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	Execute the instruction on a rising edge.



Output variable

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**
  - This instruction can change the axis group state specified by AxesGroup from GroupDisabled to GroupStandby.
  - When the axis group is in the GroupStandby state, other axis group instructions can be executed.
  - This instruction will change the state of the Axis variable within the axis group specified by AxesGroup. When the output variable Done of this instruction becomes TRUE, **if AxesGroup is already enabled, the state of the Axis variable will be changed to Synchronized_Motion. If AxesGroup is not yet enabled, the Axis variable will not enter the group synchronized status. The bound axis can still be independently controlled.**
- **Precautions**
  - If the axes in the axis group type specified by AxesGroup of the instruction are not configured with the corresponding Axis variable, the instruction will return an error. Configure the Axis variable for the axis group specified by AxesGroup as required.
  - If the axis group type is SCARA, use MC_SetPosition or MC_Home to set the position of the corresponding axis for each joint within the SCARA configuration range before using the MC_GroupEnable instruction.
  - When this instruction is enabled, the Axis variable mapped to the axis group specified by AxesGroup of the instruction must be in the PowerOff or StandStill state.
  - When this instruction is enabled, if the Axis variable mapped to the axis group specified by AxesGroup of the instruction is in the ErrorStop state, output the error code of the corresponding axis.
  - **The same Axis variable can be added to different AxesGroup variables, but only one of these AxesGroup variables can be enabled.** If an AxesGroup variable that includes the configured Axis variable is already enabled, all other AxesGroup variables that include this configured Axis variable cannot be enabled. Only after the MC_GroupDisable instruction is used on the AxesGroup that includes this configured Axis, all other AxesGroup variables that include this Axis can be enabled.
  - After the output variable Done of this instruction becomes TRUE, it indicates that the axis group specified by AxesGroup has been enabled, and the single axis instruction cannot be executed on any Axis variable in AxesGroup.
  - The Axis variable in AxesGroup can be used as Master in a synchronous control instruction.
  - The Axis variable in AxesGroup must be in CSP or CSV mode, otherwise the instruction will return an error.
  - **The Axis variable in AxesGroup can only be configured in linear mode, otherwise the instruction will return an error.**
- **Sequence diagram**

When the input parameter Execute is set to TRUE, the output parameter Busy shows the value TRUE. The AxesGroup state is changed from GroupDisabled to GroupStandby, and the output parameter "Done" becomes TRUE.

- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.5.5 MC_GroupHalt

This instruction stops the motion of an axis group. It is generally used under normal conditions.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_GroupHalt	Stop axis group	MC_GroupHalt_Instance_0 MC_GroupHalt AxesGroup Execute DecelerationFactor JerkFactor Done Busy Active CommandAborted Error ErrorID	MC_GroupHalt_Instance_0(AxesGroup := , Execute := , DecelerationFactor := , JerkFactor := , Done => , Busy => , Active =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

  In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
AxesGroup	Axis group	18.3.3.2.4.1 AXES_GROUP_REF: Axis Group Structure	-	-	Mapped to an axis group, which is an instance of AXES_GROUP_REF.

Input variable

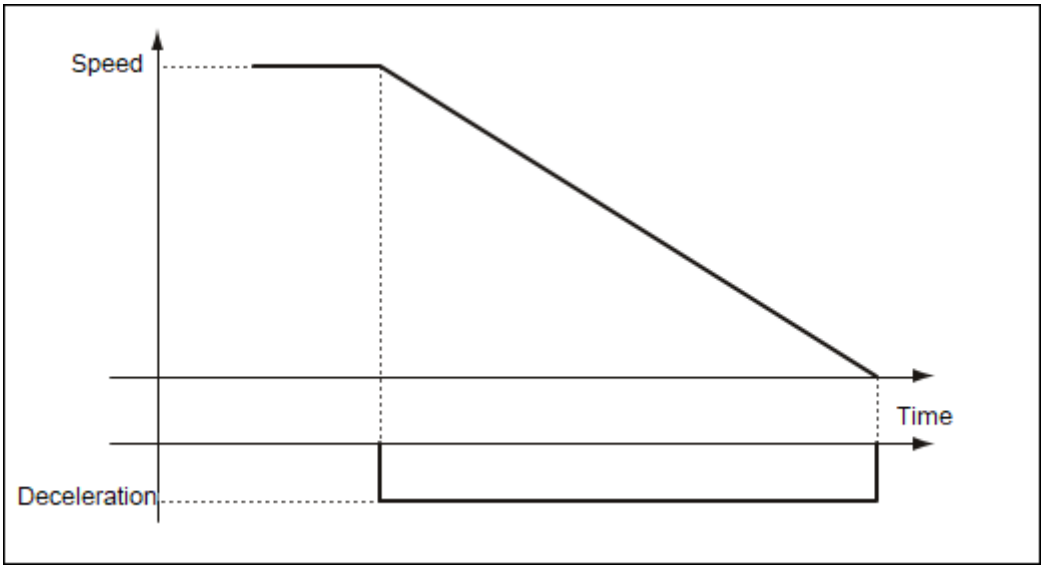
Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	Execute the instruction on a rising edge.
DecelerationFactor	Deceleration factor	LREAL	[0.01,1.0]	0.5	Ratio relative to the maximum deceleration in the axis group workspace/joint space. If the factor is greater than 1, it is corrected to 1. If the factor is less than 0.01, it is corrected to 0.5. If the factor equals 0.01, no correction is applied.
JerkFactor	Jerk factor	LREAL	[0.0,1.0]	0.5	Ratio relative to the maximum jerk in the axis group workspace/joint space. For the non-trapezoidal motion profiling, the factor will be corrected to 1 if it is greater than 1. If the factor is less than or equal to 0, it will be corrected to 0.5.

Output variable

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Active	Instruction has controlled the axis group	BOOL	TRUE, FALSE	FALSE	Set to TRUE when the axis is being controlled.
Commandborted	Command aborted	BOOL	TRUE, FALSE	FALSE	Set to TRUE when the instruction is aborted.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Parameter correction**



Input Variable	Name	Correction Description for Values Greater Than 1 or Backend Limit	Correction Description for Parameters Below Minimum Value Range	Correction Description for Parameters Equal to Minimum Value Range
DecFactor	Deceleration factor	If the deceleration factor is greater than 1, it is automatically corrected to 1.	If the deceleration factor is less than 0.01, it is automatically corrected to 0.5 for operation.	If the deceleration factor is equal to 0.01, no correction is applied.
JerkFactor	Jerk factor	If the jerk factor is greater than 1 in the non-trapezoidal motion profiling, it is automatically corrected to 1.	If the jerk factor is less than 0 in the non-trapezoidal motion profiling, it is automatically corrected to 0.5 for operation.	If the jerk factor is equal to 0 in the non-trapezoidal motion profiling, it is automatically corrected to 0.5 for operation.

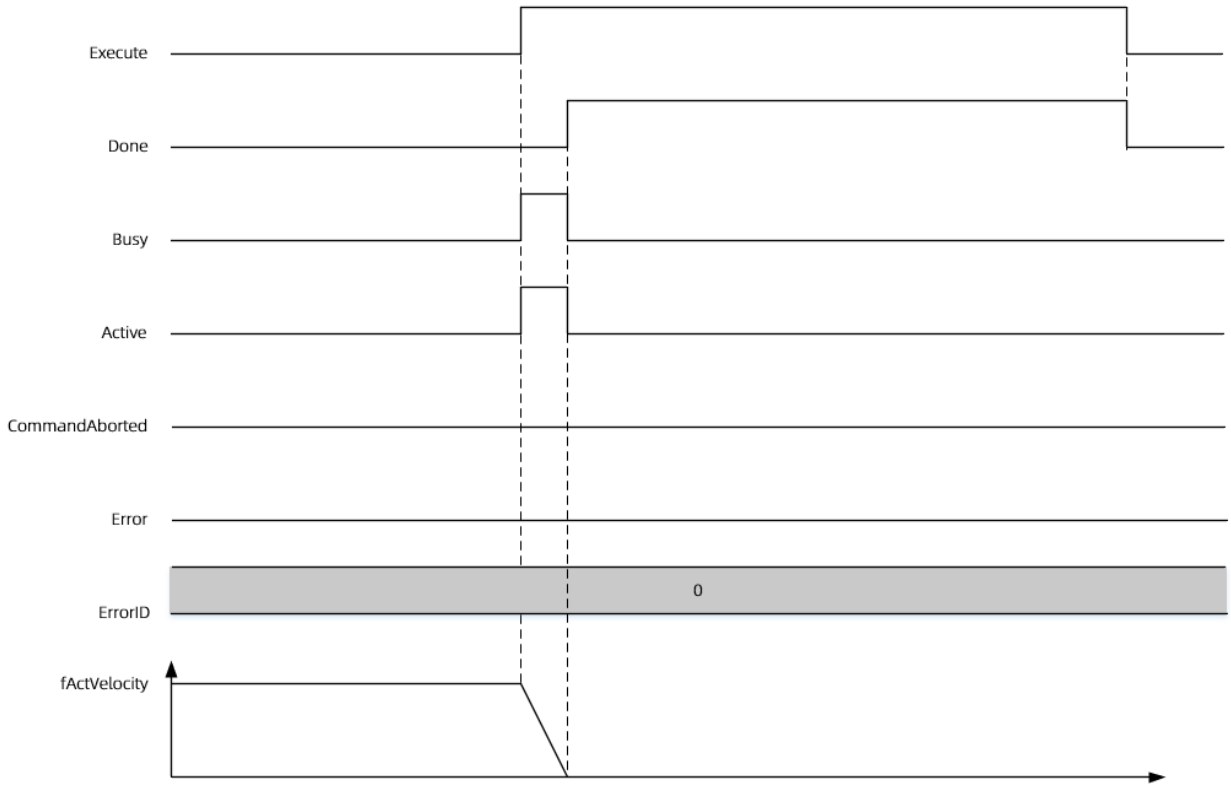
- **Function**

  This instruction is executed on the rising edge of Execute and is used to stop the AxesGroup during its normal operation.

  - **DecelerationFactor, JerkFactor**
    - The deceleration and jerk during the execution of this instruction are determined by the input variables DecelerationFactor and JerkFactor.
    - In the ACS coordinate system, the deceleration stop is performed on each Axis variable in AxesGroup according to the product of the software-limited maximum axis deceleration and DecelerationFactor, and the product of the software-limited maximum axis jerk and JerkFactor. In the PCS coordinate system, the deceleration stop is performed according to the product of the maximum deceleration for AxesGroup and DecelerationFactor, and the product of the maximum axis group jerk and JerkFactor.
    - JerkFactor

      For JerkFactor = 0, the velocity curve and deceleration curve are shown as follows.

For JerkFactor ≠ 0, the velocity curve, deceleration curve, and jerk curve are shown as follows.



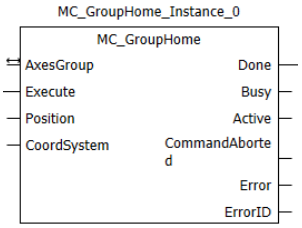
- This instruction can only be initiated when the axis group is in the GroupMoving or GroupStandby state. Attempting to start this instruction in any other state will result in an error.
- This instruction can interrupt the current motion of AxesGroup. AxesGroup remains in the GroupMoving state until the combined velocity of the axes in the current motion space (work space/axis space) reaches 0. Then, the instruction Done is set to TRUE, and the group state returns to GroupStandby or remains in GroupMoving, with the following status changes:
  - If the current motion is in a static coordinate system, this instruction will switch the AxesGroup from GroupMoving to GroupStandby.
  - If the current motion is in a dynamic coordinate system, this instruction remains in the GroupMoving state.
- This instruction can be aborted by other motion control instructions.
- When AxesGroup is in the homing process, this instruction cannot be used, otherwise an error will occur.
- When the AxesGroup is in the GroupStopping state, this instruction cannot be used, otherwise an error will occur.

- This instruction can be interrupted by other MC_GroupHalt instructions, which can interrupt each other sequentially. That is, the MC_GroupHalt instruction that starts later can interrupt the one that starts earlier, and the operation from deceleration to stop will be performed according to the parameters of the MC_GroupHalt instruction that starts later.
- During the execution of the instruction, all axes in AxesGroup must be in the enabled status. Otherwise, an error will be reported.

- **Re-triggering the instruction**
  - This instruction cannot be re-executed.
- **Precautions**
  - The trajectory planning curve type of AxesGroup must be set as required. If the planning curve type is set to a trapezoidal curve, the input variable JerkFactor for this instruction becomes invalid, and the instruction executes a deceleration to a stop according to DecelerationFactor. If the planning curve type is set to a cubic curve or a septic curve, the instruction executes a deceleration to a stop according to DecelerationFactor and JerkFactor.
  - Whether the planning curve type of each Axis variable in AxesGroup is set to a trapezoidal curve or an S-curve does not affect the planning method of AxesGroup.
- **Sequence diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Done of the function block indicates the instruction has been executed successfully; the parameter Busy indicates that the current function block is being executed; the parameter CommandAborted indicates that the instruction is aborted by another motion control instruction, at which point the flag is set to TRUE.

  The parameter Busy shows the value TRUE on a rising edge of Execute. In the next cycle, "Active" becomes TRUE.



- **Faults**

For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.5.6 MC_GroupHome

The instruction homes the axis group.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_GroupHome	Axis group homing		MC_GroupHome_Instance_0(AxesGroup := , Execute := , Position := , CoordSystem := , Done => , Busy => , Active =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
AxesGroup	Axis group	18.3.3.2.4.1 AXES_GROUP_REF: Axis Group Structure	-	-	Mapped to an axis group, which is an instance of AXES_GROUP_REF.

Input variable

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	Execute the instruction on a rising edge.
Position	Position	ARRAY [1..GROUP_DEF.AXIS_NUM] OF LREAL	-	[0,0,0…]	Absolute coordinates of the mechanical homing position

Input Variable	Name	Data Type	Valid Range	Default Value	Description
CoordSystem	Coordinate system type	18.3.3.2.4.19 MC_COORDSYSTEM: Coordinate System Enumeration	ACS	ACS	Select the application coordinate system type.

Output variable

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Active	Instruction has controlled the axis group	BOOL	TRUE, FALSE	FALSE	TRUE when the axis is being controlled.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	Set to TRUE when the instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**
  - This instruction is triggered on the rising edge of Execute, moving AxesGroup to its mechanical homing position.
  - This instruction can define the homing sequence of each axis in the AxesGroup through the iFA interface, as shown in the following figure:

  - The defined homing sequence must not contain descending order, and the homing sequence number of the first axis must be 1.
  - Take the XYZA axis group type as an example: The definable axis group homing sequences include: 1, 1, 1, 1; 1, 2, 3, 4; 1, 2, 2, 2; 1, 2, 2, 3; 1, 2, 3, 3; and other sequences.
  - The homing sequence is currently only allowed to be defined in the axis group structure.

- **Re-triggering the instruction**
  - This instruction cannot be re-triggered.
- **Precautions**
  - This instruction can only be executed when the AxesGroup is in the GroupStandby status (also in the GroupStandby status when not following in a dynamic coordinate system). An error is reported when this instruction is activated in other AxesGroup states.
  - This instruction can only be interrupted by the MC_GroupStop instruction.
  - This instruction only supports homing in the ACS coordinate system.
  - Before executing the MC_GroupHome instruction, verify that the post-homing joint angles will place the axis group within its defined workspace limits according to the motion range of the axis group configuration in the workspace. Otherwise, it may lead to abnormal operation or errors of the axis group.
  - This instruction currently supports the servo homing method. Other homing methods will be developed later.
- **Sequence diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Done of the function block indicates the instruction has been executed successfully; the parameter Busy indicates that the current function block is being executed; the parameter CommandAborted indicates that the instruction is aborted by another motion control instruction, at which point the flag is set to TRUE.

  The parameter Busy shows the value TRUE on a rising edge of Execute. In the next cycle, "Active" becomes TRUE.

- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.5.7 MC_GroupInterrupt

This instruction pauses an axis group along the current motion path of the axis group, which does not change the current motion state of the axis group.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_GroupInterrupt	Axis group pause	MC_GroupInterrupt_Instance_0 MC_GroupInterrupt AxesGroup Execute DecelerationFactor JerkFactor Done Busy Active CommandAborted Error ErrorID	MC_GroupInterrupt_Instance_0(AxesGroup := , Execute := , DecelerationFactor := , JerkFactor := , Done => , Busy => , Active =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

  In-out variables

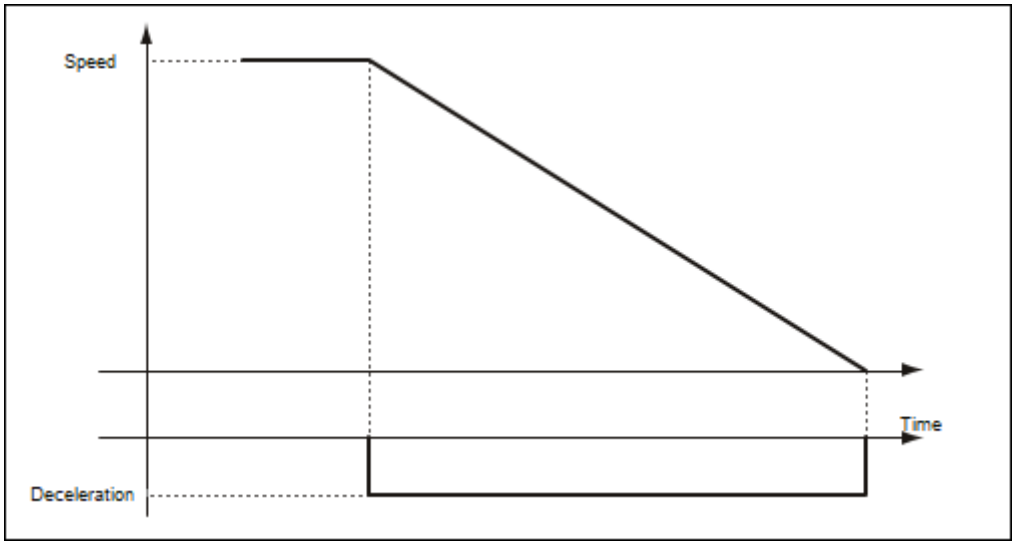
In-out Variable	Name	Data Type	Valid Range	Default Value	Description
AxesGroup	Axis group	18.3.3.2.4.1 AXES_GROUP_REF: Axis Group Structure	-	-	Mapped to an axis group, which is an instance of AXES_GROUP_REF.

Input variable

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	Execute the instruction on a rising edge.
DecelerationFactor	Deceleration factor	LREAL	[0.01,1.0]	0.3	Ratio relative to the maximum deceleration in the axis group workspace/joint space. If the factor is greater than 1, it will be corrected to 1. If the factor is less than 0.01, it will be corrected to 0.3.
JerkFactor	Jerk factor	LREAL	[0.0,1.0]	0.3	Ratio relative to the maximum jerk in the axis group workspace/joint space. For the non-trapezoidal motion profiling, the factor will be corrected to 1 if it is greater than 1. If it is less than or equal to 0, it will be corrected to 0.3.

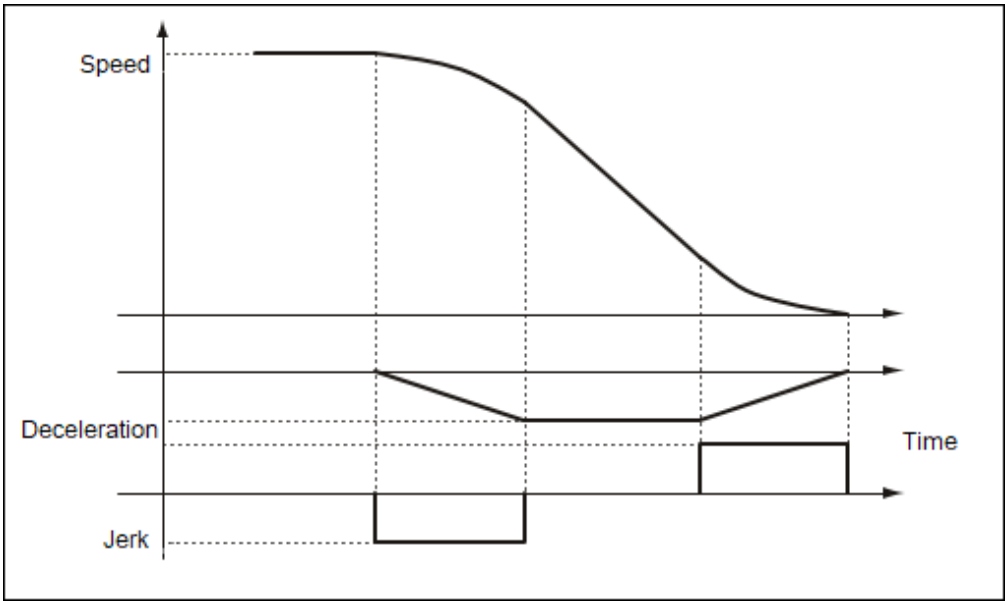
Output variable

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Active	Instruction has controlled the axis group	BOOL	TRUE, FALSE	FALSE	TRUE when the axis is being controlled.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	Set to TRUE when the instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.



Output Variable	Name	Data Type	Valid Range	Default Value	Description
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Parameter correction**



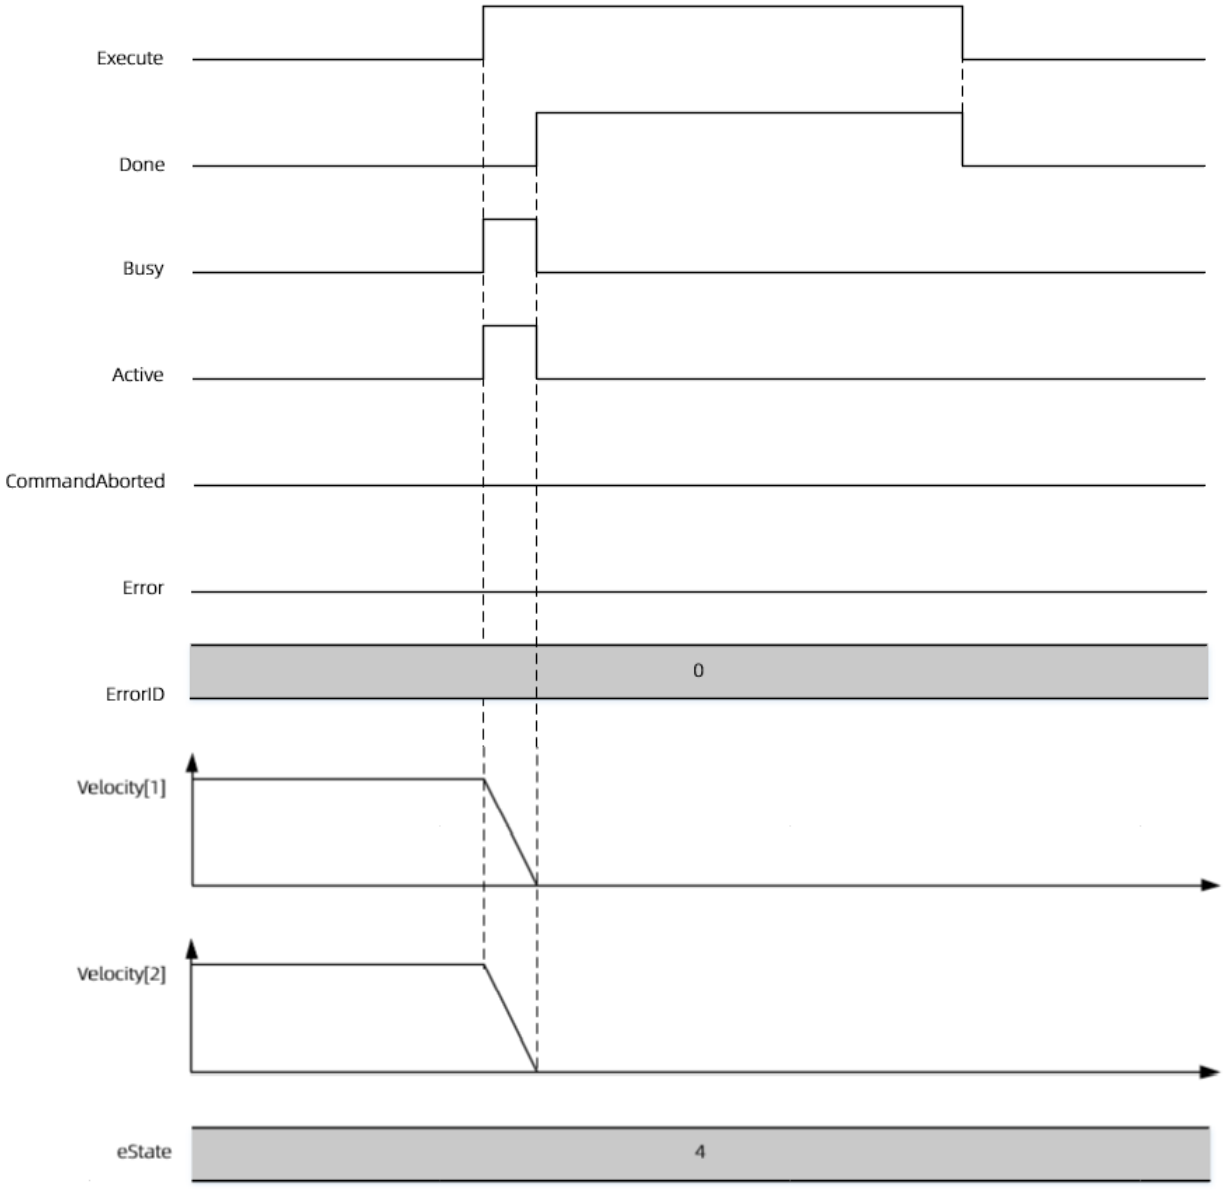
Input Variable	Name	Correction Description for Values Greater Than 1 or Backend Limit	Correction Description for Parameters Below Minimum Value Range	Correction Description for Parameters Equal to Minimum Value Range
DecelerationFactor	Deceleration factor	If the deceleration factor is greater than 1, it is automatically corrected to 1.	If the deceleration factor is less than 0.01, it is automatically corrected to 0.3.	If the deceleration factor is equal to 0.01, no correction is applied.
JerkFactor	Jerk factor	If the jerk factor is greater than 1 in the non-trapezoidal motion profiling, it is automatically corrected to 1.	If the jerk factor is less than 0 in the non-trapezoidal motion profiling, it is automatically corrected to 0.3 for operation.	If the jerk factor is equal to 0 in the non-trapezoidal motion profiling, it is automatically corrected to 0.3 for operation.

- **Function**
  - This instruction is executed on the rising edge of Execute to pause an AxesGroup. It will temporarily stop along the current motion path of the AxesGroup without changing its current motion status.
  - After this instruction has been activated, the deceleration motion is performed based on DecelerationFactor and JerkFactor. After activation, the currently executing motion instruction of the axis group is not interrupted, the Busy flag remains set, the Active flag is reset, and the axis group maintains its original state.
  - To resume the motion paused by this instruction, the MC_GroupContinue instruction must be triggered.
  - This instruction can be interrupted by MC_GroupContinue, MC_GroupHalt, MC_GroupStop, and other MC_GroupInterrupt instructions, or by new motion instructions for AxesGroup.
  - **DecelerationFactor, JerkFactor**
    - The deceleration and jerk during the execution of this instruction are determined by the input variables DecelerationFactor and JerkFactor.
    - In joint space (ACS), the pause operation is performed based on the product of the maximum axis deceleration limited by software for each Axis variable in AxesGroup and DecelerationFactor, and the product of the maximum axis jerk limited by software for each axis and JerkFactor.
    - In work space (PCS), the pause operation is performed based on the product of the maximum deceleration for AxesGroup and DecelerationFactor, and the product of the maximum axis group jerk and JerkFactor.
    - JerkFactor

      For JerkFactor = 0, the velocity curve and deceleration curve are shown as follows.

For JerkFactor ≠ 0, the velocity curve, deceleration curve, and jerk curve are shown as follows.

- **Re-triggering the instruction**
  - This instruction cannot be re-triggered.
- **Precautions**
  - When AxesGroup is in the GroupStandby, GroupErrorstop, GroupDisabled, GroupHoming, or GroupStopping state, this instruction cannot be started. Otherwise, the instruction will return an error.
  - When AxesGroup is controlled by the MC_GroupHalt instruction or the axis group is in the homing process, this instruction cannot be started. Otherwise, an error will be generated.
  - The trajectory planning curve type of AxesGroup must be set as required. If the planning curve type is set to a trapezoidal curve, the input variable JerkFactor for this instruction becomes invalid, and the instruction performs the pause operation according to DecelerationFactor. If the planning curve type is set to a cubic curve or a septic curve, the instruction performs the pause operation according to DecelerationFactor and JerkFactor.
  - Whether the planning curve type of each Axis variable in AxesGroup is set to a trapezoidal curve or an S-curve does not affect the planning method of AxesGroup.
  - During the execution of the instruction, all axes in AxesGroup must be in the enabled status. Otherwise, an error will be reported.



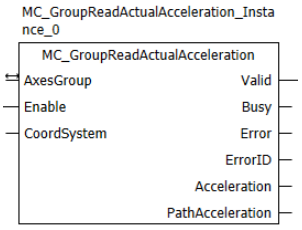
- **Sequence diagram**

  The Execute input of the function block must be triggered on a rising edge. The Done output of the function block indicates the instruction is executed successfully. The Busy output of the function block indicates that the current function block is being executed. The CommandAborted output of the function block indicates that the instruction is aborted by another motion control instruction, at which point the flag is set to TRUE.

  On the rising edge of Execute, both Busy and Active outputs are set to TRUE.

  When the velocity of all axes reaches "0", "Done" becomes TRUE. During this process, "eState" (Axis group state machine) remains at 4, with the axis group state machine in GROUP_MOVING.

  When this instruction is aborted by another instruction, CommandAborted becomes TRUE, and "Busy" and "Active" become FALSE.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.5.8 MC_GroupReadActualAcceleration

The instruction reads the actual acceleration of the axis group in the selected coordinate system.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_GroupReadActualAcceleration	Read axis group actual acceleration		MC_GroupReadActualAcceleration_Instance_0(AxesGroup := , Enable := , CoordSystem := , Valid => , Busy =>, Error =>, ErrorID => , Acceleration => , PathAcceleration =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
AxesGroup	Axis group	18.3.3.2.4.1 AXES_GROUP_REF: Axis Group Structure	-	-	Mapped to an axis group, which is an instance of AXES_GROUP_REF.

Input variable

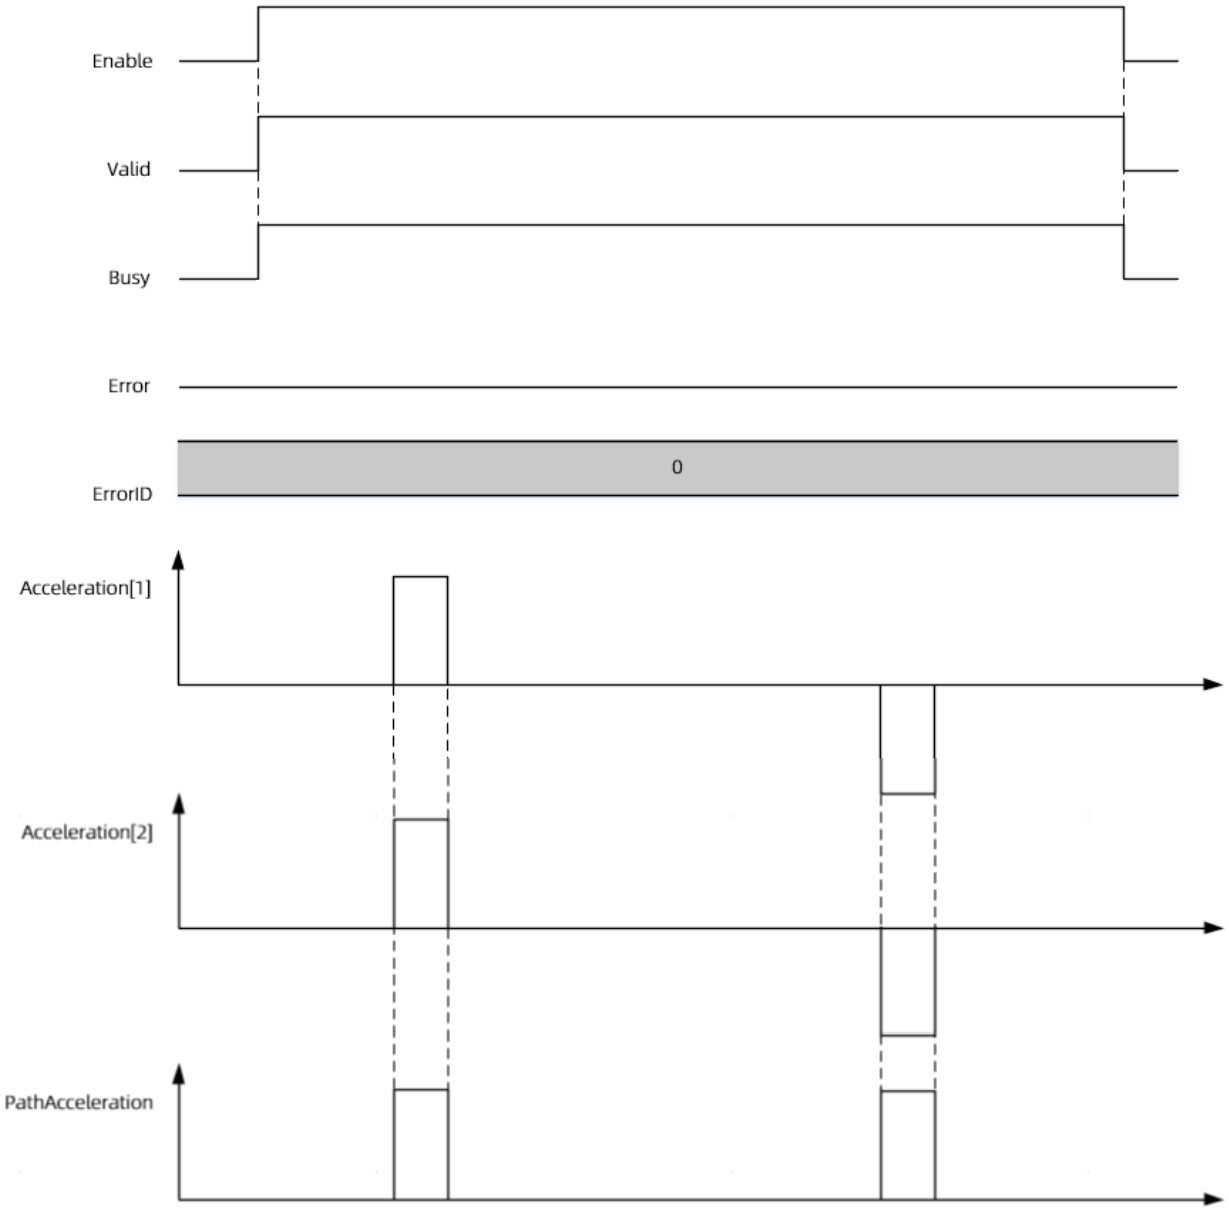
Input Variable	Name	Data Type	Valid Range	Default Value	Description
Enable	Enable	BOOL	TRUE, FALSE	FALSE	TRUE: The instruction is enabled. FALSE: The instruction is not enabled.
CoordSystem	Coordinate system type	18.3.3.2.4.19 MC_COORDSYSTEM: Coordinate System Enumeration	ACS, PCS	ACS	Select the application coordinate system type.

Output variable

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Valid	Valid output	BOOL	TRUE, FALSE	FALSE	TRUE when the axis is being controlled.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.
Acceleration	Acceleration component	ARRAY [1..GROUP_DEF.AXIS_NUM] OF LREAL	-	[0,0,…]	Return the acceleration component of the axis group in the corresponding coordinate systemAxis group type description.
PathAcceleration	Resultant acceleration	LREAL	-	0	Returns the resultant acceleration of the TCP of the axis group in the primary dimension space.

- **Function**
  - When the Valid output is TRUE, this function captures two sets of data per control cycle: the actual acceleration components of all Axis variables in AxesGroup under the selected CoordSystem and the resultant acceleration of the axis group in the PCS coordinate system.
- **Re-triggering the instruction**
  - An "Enable"-type instruction does not allow re-triggering while it is active (Busy).
- **Precautions**
  - During the execution of the instruction, the axis group specified by AxesGroup must not be in the GroupDisabled state.
  - During the execution of the instruction, if the axis group specified by AxesGroup is in the GroupErrorStop state and an error occurs in the Axis variable within the axis group, the instruction will return an error. When the axis group is in any other states, there is no requirement for the state of the Axis variable.
  - The output variable Acceleration refers to the acceleration components in the given coordinate system (ACS/PCS), and the unit of each acceleration component is consistent with the user unit of the corresponding axis type in the given coordinate system.
  - The output variable PathAcceleration is the resultant acceleration of the path in the primary dimension space. Regardless of whether the PCS or ACS coordinate system is selected, this parameter returns the resultant acceleration of the TCP of the axis group in the user's primary dimension subspace of the part coordinate system PCS (position, orientation).

    When the primary dimension is set to position: The instruction outputs the resultant linear acceleration of the TCP in the position subspace of the user part coordinate system.



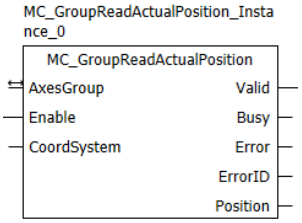
When the primary dimension is set to orientation: The instruction outputs the orientation angular acceleration in the orientation subspace of the user part coordinate system.

When the primary dimension is set to ratio: The instruction outputs the resultant acceleration of the TCP in the user part coordinate system (dimensionless).

- **Sequence diagram**

  When the input parameter "Enable" is set to TRUE, the output parameter "Valid" becomes TRUE, indicating that the output values "Acceleration" and "Path Acceleration" are valid; the output parameter "Busy" becomes TRUE, indicating that the current function block is executing.

  When the input parameter "Enable" is set to FALSE, the output parameter "Valid" becomes FALSE, and the output parameter "Busy" becomes FALSE.



- **Error description**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.5.9 MC_GroupReadActualPosition

This instruction reads the actual position of an axis group in the selected coordinate system.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_GroupReadActualPosition	Read axis group actual position		MC_GroupReadActualPosition_Instance_0(AxesGroup := , Enable := , CoordSystem := , Valid => , Busy =>, Error =>, ErrorID => , Position =>);

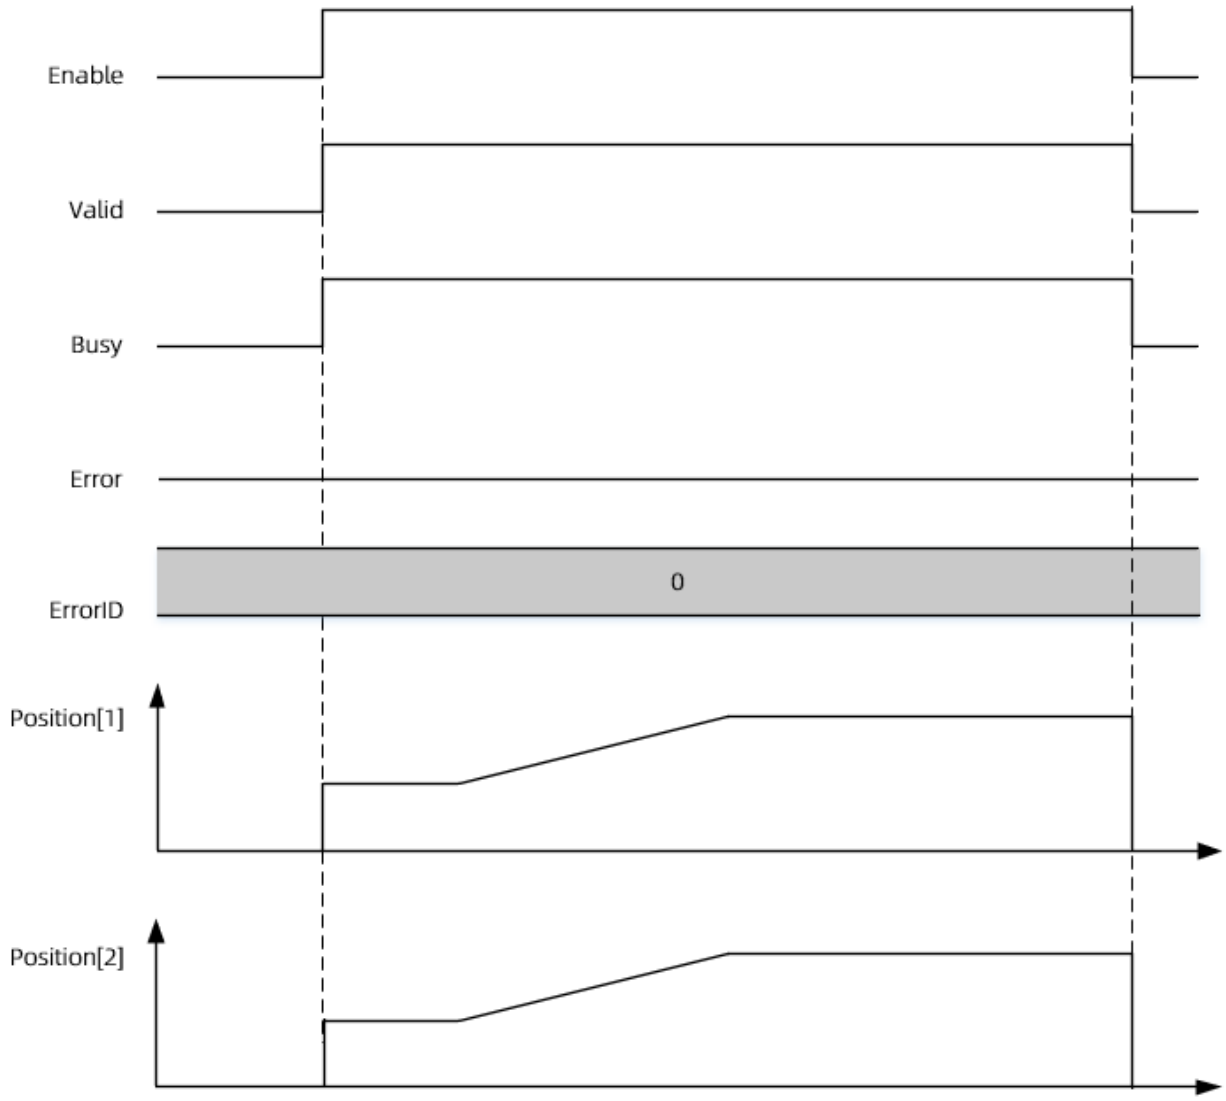
- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
AxesGroup	Axis group	18.3.3.2.4.1 AXES_GROUP_REF: Axis Group Structure	-	-	Mapped to an axis group, which is an instance of AXES_GROUP_REF.

Input variable

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Enable	Enable	BOOL	TRUE, FALSE	FALSE	TRUE: The instruction is enabled. FALSE: The instruction is not enabled.
CoordSystem	Coordinate system type	18.3.3.2.4.19 MC_COORDSYSTEM: Coordinate System Enumeration	ACS, PCS	ACS	Select the application coordinate system type.



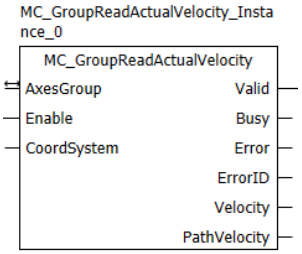
Output variable

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Valid	Valid output	BOOL	TRUE, FALSE	FALSE	TRUE when the axis is being controlled.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.
Position	Position	ARRAY [1..GROUP_DEF.AXIS_NUM] OF LREAL	-	[0,0,…]	Returns the current position [u] of the axis group in the specified coordinate systemAxis group type description.

- **Function**
  - When the Valid output is TRUE, the actual positions of all Axis variables in the axis group specified by AxesGroup of the instruction under the selected CoordSystem are obtained per control cycle.
- **Re-triggering the instruction**
  - An "Enable"-type instruction does not allow re-triggering while it is active (Busy).
- **Precautions**
  - During the execution of the instruction, the axis group specified by AxesGroup must not be in the GroupDisabled state.
  - During the execution of the instruction, if the axis group specified by AxesGroup is in the GroupErrorStop state and an error occurs in the Axis variable within the axis group, the instruction will return an error. When the axis group is in any other states, there is no requirement for the state of the Axis variable.
  - The output variable Position represents the position components of the axis group in the given coordinate system (ACS/PCS). The unit of each position component is consistent with the user unit of the corresponding axis type in the given coordinate system.
- **Sequence diagram**

  When the input parameter "Enable" is set to TRUE, the output parameter "Valid" becomes TRUE, indicating that the output value "Position" is valid. The output parameter "Busy" becomes TRUE, indicating that the current function block is executing.

  When the input parameter "Enable" is set to FALSE, the output parameter "Valid" becomes FALSE, and the output parameter "Busy" becomes FALSE.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.5.10 MC_GroupReadActualVelocity

This instruction reads the actual velocity of an axis group in the selected coordinate system.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_GroupReadActualVelocity	Read axis group actual velocity		MC_GroupReadActualVelocity_Instance_0(AxesGroup := , Enable := , CoordSystem := , Valid => , Busy =>, Error =>, ErrorID => , Velocity => , PathVelocity =>);

- **Related variables**

In-out variables

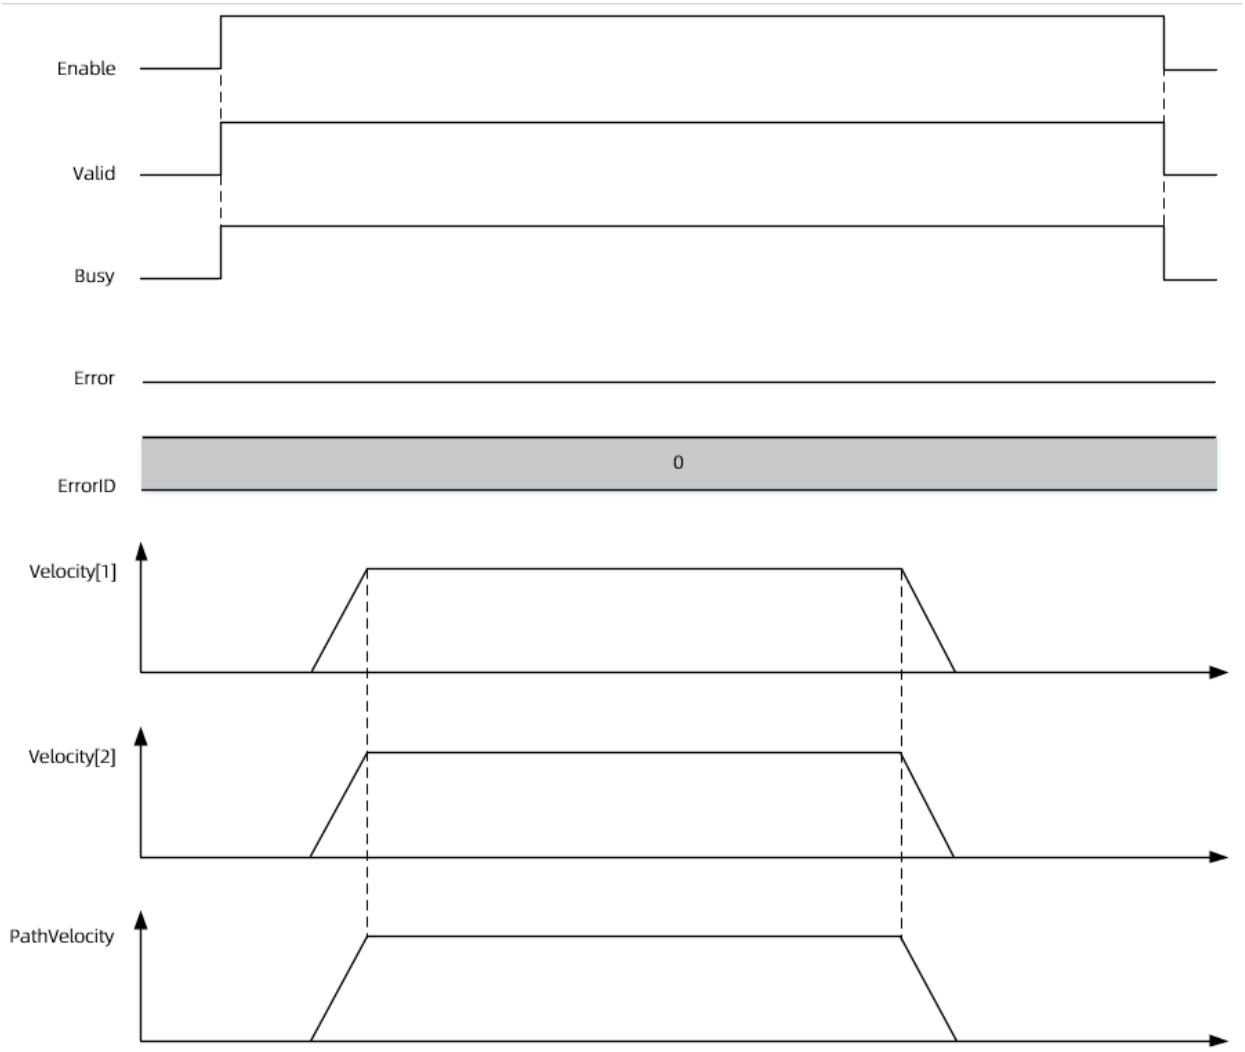
In-out Variable	Name	Data Type	Valid Range	Default Value	Description
AxesGroup	Axis group	18.3.3.2.4.1 AXES_GROUP_REF: Axis Group Structure	-	-	Mapped to an axis group, which is an instance of AXES_GROUP_REF.

Input variable

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Enable	Enable	BOOL	TRUE, FALSE	FALSE	TRUE: The instruction is enabled. FALSE: The instruction is not enabled.
CoordSystem	Coordinate system type	18.3.3.2.4.19 MC_COORDSYSTEM: Coordinate System Enumeration	ACS, PCS	ACS	Select the application coordinate system type.

Output variable

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Valid	Valid output	BOOL	TRUE, FALSE	FALSE	TRUE when the axis is being controlled.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.
Velocity	Velocity component	ARRAY [1..GROUP_DEF.AXIS_NUM] OF LREAL	-	[0,0,….]	Return the velocity component [u] of the axis group in the corresponding coordinate systemAxis group type description.
PathVelocity	Resultant velocity	LREAL	-	0	Returns the resultant velocity of the TCP of the axis group in the primary dimension space.



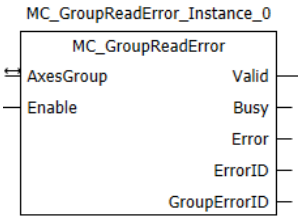
- **Function**
  - When the Valid output is TRUE, this function captures two sets of data per control cycle: the actual velocity components of all Axis variables in the axis group specified by AxesGroup under the selected CoordSystem and the resultant acceleration of the axis group in the PCS coordinate system.
- **Re-triggering the instruction**
  - An "Enable"-type instruction does not allow re-triggering while it is active (Busy).
- **Precautions**
  - During the execution of the instruction, the axis group specified by AxesGroup must not be in the GroupDisabled state.
  - During the execution of the instruction, if the axis group specified by AxesGroup is in the GroupErrorStop state and an error occurs in the Axis variable within the axis group, the instruction will return an error. When the axis group is in any other states, there is no requirement for the state of the Axis variable.
  - The output variable Velocity represents the velocity components in the given coordinate system (ACS/PCS). The unit of each velocity component is consistent with the user unit of the corresponding axis type in the given coordinate system.
  - The output variable PathVelocity represents the resultant velocity in the primary dimension space path. Regardless of whether PCS or ACS coordinate system is selected, this parameter returns the resultant velocity of the TCP of the axis group in the user's primary dimension subspace of the part coordinate system PCS (position, orientation).
    - When the primary dimension is set to position: The instruction outputs the resultant linear velocity of the TCP in the position subspace of the user part coordinate system.

- When the primary dimension is set to orientation: The instruction outputs the orientation angular velocity in the orientation subspace of the user part coordinate system.
- When the primary dimension is set to ratio: The instruction outputs the resultant velocity of the TCP in the user part coordinate system (dimensionless).

- **Sequence diagram**

  When the input parameter "Enable" is set to TRUE, the output parameter "Valid" becomes TRUE, indicating that the output values "Velocity" and "PathVelocity" are valid. The output parameter "Busy" becomes TRUE, indicating that the current function block is executing.

  When the input parameter "Enable" is set to FALSE, the output parameter "Valid" becomes FALSE, and the output parameter "Busy" becomes FALSE.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.5.11 MC_GroupReadError

This instruction reads the error message of the specified axis group and describes the general axis group errors that are not related to the axis group instruction error.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_GroupReadError	Axis group error reading		MC_GroupReadError_Instance_0(AxesGroup := , Enable := , Valid =>, Busy =>, Error =>, ErrorID => , GroupErrorID =>);

- **Related variables**

In-out variables

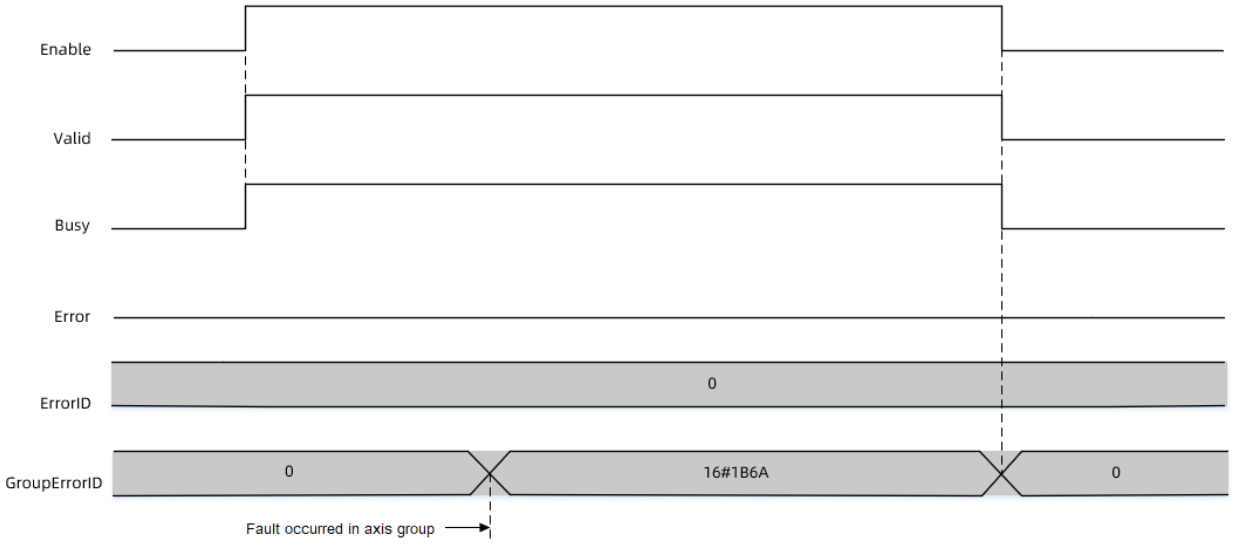
In-out Variable	Name	Data Type	Valid Range	Default Value	Description
AxesGroup	Axis group	18.3.3.2.4.1 AXES_GROUP_REF: Axis Group Structure	-	-	Mapped to an axis group, which is an instance of AXES_GROUP_REF.

Input variable

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Enable	Enable	BOOL	TRUE, FALSE	FALSE	TRUE: The instruction is enabled. FALSE: The instruction is not enabled.

Output variable

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Valid	Valid output	BOOL	TRUE, FALSE	FALSE	TRUE when the axis is being controlled.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.



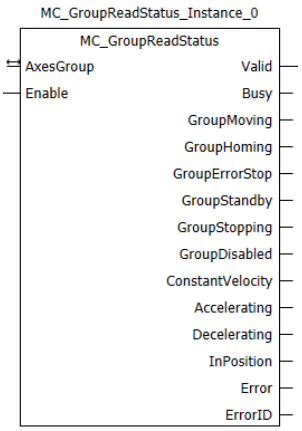
Output Variable	Name	Data Type	Valid Range	Default Value	Description
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.
GroupErrorID	Fault code	DWORD	-	0	Axis group fault code.

- **Function**
  - When the variable Valid is TRUE, get the error information of the axis group specified by AxesGroup of the instruction. If an error occurs in the axis group, GroupErrorID outputs the corresponding error code. If the axis group has no error information, GroupErrorID outputs 0.
- **Re-triggering the instruction**
  - An "Enable"-type instruction does not allow re-triggering while it is active (Busy).
- **Precautions**
  - When the instruction is used, the axis group specified by AxesGroup must not be in the GroupDisabled state. However, there is no requirement for the state of the Axis variable in AxesGroup.
  - The output variable ErrorID of this instruction is the error code corresponding to the execution error of the instruction itself; GroupErrorID is the error code corresponding to the error information read from AxesGroup during the execution of the instruction.
- **Sequence diagram**

  When the input parameter Enable is set to TRUE, the output parameter Busy shows the value TRUE.

  When the output parameter Valid is set to TRUE, it indicates that the other output parameter GroupErrorID is valid.

  If a fault occurs on the axis group side during operation, the axis group fault code will be output to "GroupErrorID" on the instruction side.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.5.12 MC_GroupReadStatus

This instruction is used to read the status information of the specified axis group.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_GroupReadStatus	Obtaining the axis group state		MC_GroupReadStatus_Instance_0(AxesGroup := , Enable := , Valid =>, Busy => , GroupMoving => , GroupHoming => , GroupErrorStop => , GroupStandby => , GroupStopping => , GroupDisabled => , ConstantVelocity =>, Accelerating =>, Decelerating => , InPosition => , Error => , ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
AxesGroup	Axis group	18.3.3.2.4.1 AXES_GROUP_REF: Axis Group Structure	-	-	Mapped to an axis group, which is an instance of AXES_GROUP_REF.

Input variable

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Enable	Enable	BOOL	TRUE, FALSE	FALSE	TRUE: Enable the instruction; FALSE: Disable the instruction.

Output variable

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Valid	Valid output	BOOL	TRUE, FALSE	FALSE	Set to TRUE when under instruction control.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	Set to TRUE when the instruction is received.
GroupMoving	The axis group is in motion.	BOOL	TRUE, FALSE	FALSE	The axis group state machine indicates that the axis group is moving.
GroupHoming	Axis group homing	BOOL	TRUE, FALSE	FALSE	The axis group state machine indicates that the axis group is performing homing.
GroupErrorStop	Axis group stopped due to an error	BOOL	TRUE, FALSE	FALSE	The axis group state machine indicates an axis group error stop.
GroupStandby	Axis group standby	BOOL	TRUE, FALSE	FALSE	The axis group state machine indicates that the axis group is in standby state.
GroupStopping	Axis group stopping	BOOL	TRUE, FALSE	FALSE	The axis group state machine indicates the axis group is stopping.
GroupDisabled	Disable axis group	BOOL	TRUE, FALSE	FALSE	The axis group state machine indicates the axis group is disabled.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
ConstantVelocity	Constant speed	BOOL	TRUE, FALSE	FALSE	Move at a constant velocity along the instruction path.
Accelerating	Acceleration	BOOL	TRUE, FALSE	FALSE	Accelerating motion along the instruction path.
Decelerating	Deceleration	BOOL	TRUE, FALSE	FALSE	Decelerating motion along the instruction path.
InPosition	Target arrival	BOOL	TRUE, FALSE	FALSE	Target position reached
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**
  - When "Valid" is TRUE, get the status of the axis group specified by AxesGroup of the instruction.
- **Re-triggering the instruction**
  - An "Enable"-type instruction does not allow re-triggering while it is active (Busy).
- **Precautions**
  - During the execution of the instruction, there is no state requirement for the axis group specified by AxesGroup. There is no state requirement for the Axis variable in AxesGroup.
- **Sequence diagram**

  The MC_GroupReadStatus instruction reads each status of the axis group. It is enabled through the Enable signal level. This instruction can be executed repeatedly without affecting each other.

  When the input parameter Enable is set to TRUE, the output parameter Busy shows the value TRUE. When the output parameter Valid is TRUE, it indicates that the other output parameters are valid.

  When the axis group is not enabled, the axis group state machine is in the GroupDisabled state.

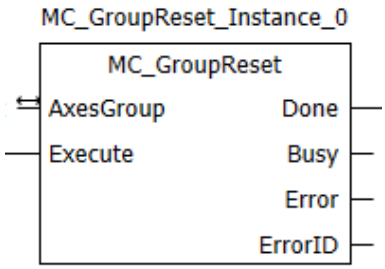
  When all axes in the axis group are mapped to the axis group, and all axes in the axis group have no error information, after the axis group is enabled, the axis group state machine is switched to the GroupStandby state.

  When the motion control instruction is called to perform speed control based on position, the axis group state machine is switched to the GroupMoving state. "ConstantVelocity" is TRUE when the axis

group is moving at a constant velocity along the path. "InPosition" is TRUE when the axis group move to the target position.

When the MC_GroupStop instruction is executed to perform the emergency stop function, the axis group state machine is switched to the GroupStopping state.

When the output variable Done of the MC_GroupStop instruction is set, and the input variable Execute is reset, the axis group state machine is switched to the GroupStandby state.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.5.13 MC_GroupReset

This instruction resets the axis group, switching the axis group state from GroupErrorStop to GroupStandby by resetting the relevant errors within the axis group. It also resets axis errors on all axes within the axis group.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_GroupReset	Reset axis group		MC_GroupReset_Instance_0(AxesGroup := , Execute := , Done =>, Busy =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

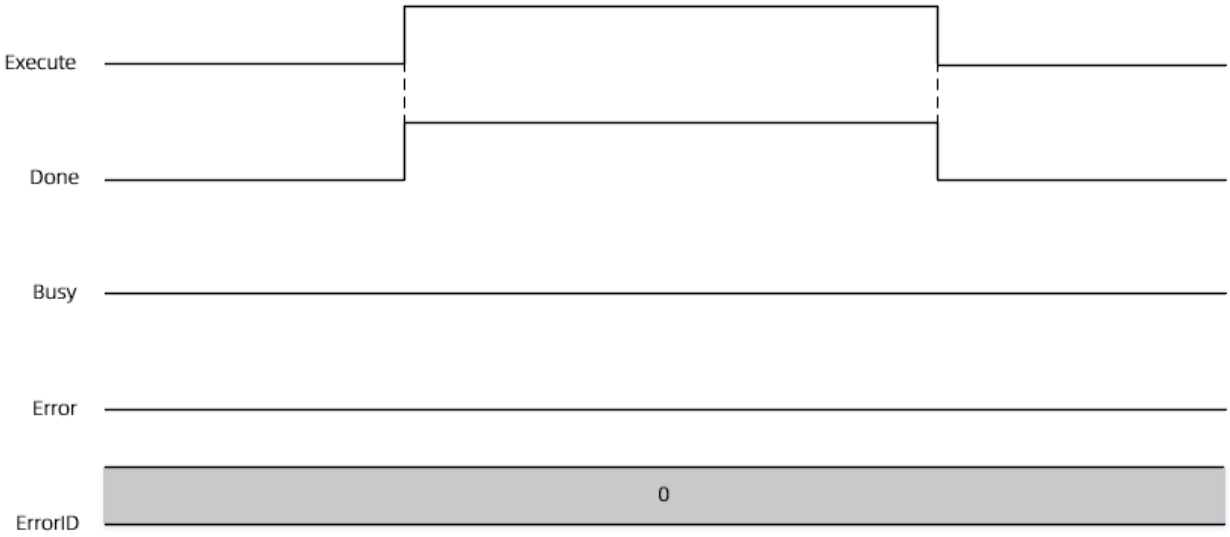
In-out Variable	Name	Data Type	Valid Range	Default Value	Description
AxesGroup	Axis group	18.3.3.2.4.1 AXES_GROUP_REF: Axis Group Structure	-	-	Mapped to an axis group, which is an instance of AXES_GROUP_REF.

Input variable

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	Execute the instruction on a rising edge.

Output variable

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.



Output Variable	Name	Data Type	Valid Range	Default Value	Description
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**
  - On the rising edge of Execute, this instruction resets errors in an axis group that is in the GroupErrorStop state, including errors of individual axes within the group.
  - **Execution of the other instructions when executing this instruction**
    - If multiple instances of the MC_GroupReset instruction are executed for the same AxesGroup, the instructions for the axis groups are processed sequentially in the order of their triggers.
    - When the MC_GroupReset instruction is executed on AxesGroup and the MC_Reset instruction is simultaneously executed on the Axis variable within the specified AxesGroup, the two instructions will be executed in the order of their triggers.
- **Precautions**
  - During the execution of the instruction, if the axis group is in the GroupErrorStop state, but the stop action has not yet been completed, the axis group fails to be reset. The instruction will return an error.
  - When an error occurs on an Axis variable in AxesGroup, all Axis variables can be reset using this instruction. A timeout during the reset process will trigger an error. Once the reset process is complete, AxesGroup is reinitialized and its coordinate systems (ACS/PCS) are updated. The AxesGroup state is changed from GroupErrorStop to GroupStandby. If the axis in AxesGroup is already enabled, the state of the Axis variable is changed to Synchronized_Motion. If the axis in AxesGroup are not yet enabled, the Axis variable remains in the Disabled state.
  - It is not allowed to use this instruction when the axis group is in the GroupDisabled status; otherwise, an error is reported. When the axis group is not in the GroupErrorStop or GroupDisabled status, Done is directly set to TRUE using this instruction, and the status of AxesGroup remains unchanged.
- **Sequence diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Done of the function block indicates that the instruction has been executed successfully, and the parameter Busy indicates that the current function block is being executed.

  After this instruction is called, the output parameter Busy becomes TRUE on a rising edge of Execute. After successful reset, the output parameter Done is set to TRUE.

  The MC_GroupReset instruction is called when the axis group fails, and the faults of the axis group are successfully reset.

- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.5.14 MC_GroupSetOverride

The axis group override instruction sets a scaling factor for the axis group's coordinated motion within the coordinate system. The override parameter acts as a factor on the velocity, acceleration, deceleration, and jerk of each function block in the axis group simultaneously.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_GroupSetOverride	Axis group override setting	MC_GroupSetOverride_Instance_0 MC_GroupSetOverride AxesGroup Enabled Enable Busy VelFactor Error AccFactor ErrorID JerkFactor	MC_GroupSetOverride_Instance_0(AxesGroup := , Enable := , VelFactor := , AccFactor := , JerkFactor := , Enabled =>, Busy =>, Error =>, ErrorID =>);

- **Related variables**

  In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
AxesGroup	Axis group	18.3.3.2.4.1 AXES_GROUP_REF: Axis Group Structure	-	-	Mapped to an axis group, which is an instance of AXES_GROUP_REF.

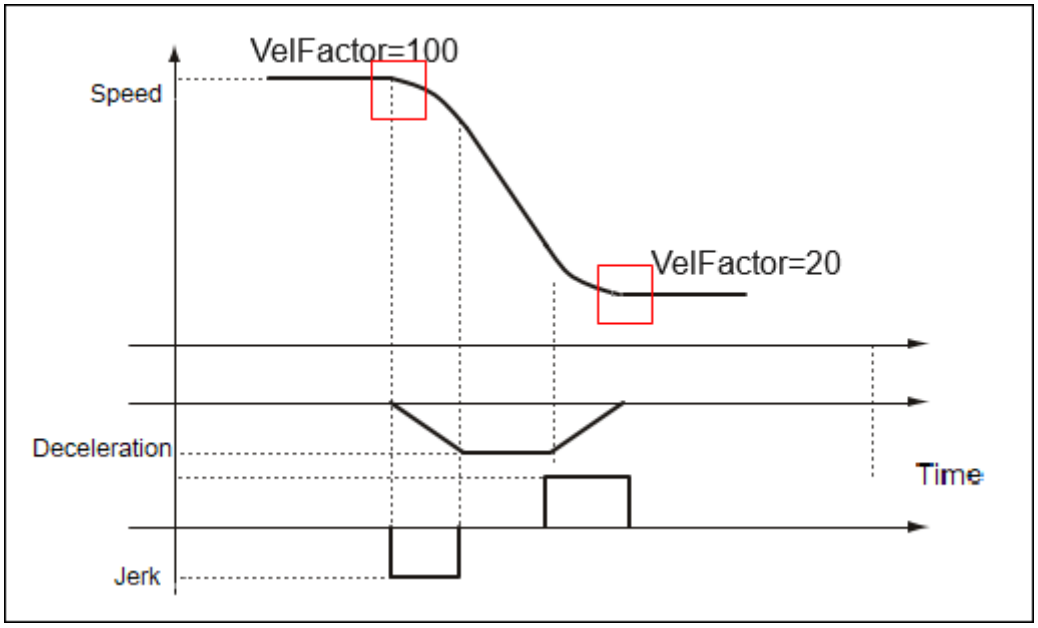
Input variable

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Enable	Enable	BOOL	TRUE, FALSE	FALSE	TRUE: The instruction is enabled. FALSE: The instruction is not enabled. When Enable = FALSE, the velocity, acceleration, and jerk overrides revert to their default values (1).
VelFactor	Velocity override factor	LREAL	[0.0,100.0]	100.0	Scaling factor for velocity, expressed as a percentage. If the factor is greater than 100, it is corrected to 100. If the factor is less than 0, it is corrected to 1. If the factor equals 0, no correction is applied.
AccFactor	Acceleration factor	LREAL	[1.0,100.0]	100.0	Factor relative to the maximum acceleration of the axis group. If the factor is greater than 100, it is corrected to 100. If the factor is less than 1, it is corrected to 1. If the factor equals 1, no correction is applied.
JerkFactor	Jerk factor	LREAL	[0.0,100.0]	100.0	Factor relative to the maximum jerk of the axis group. For the non-trapezoidal motion profiling, the factor will be corrected to 100 if it is greater than 100. If the factor is less than or equal to 0, it will be corrected to 1.

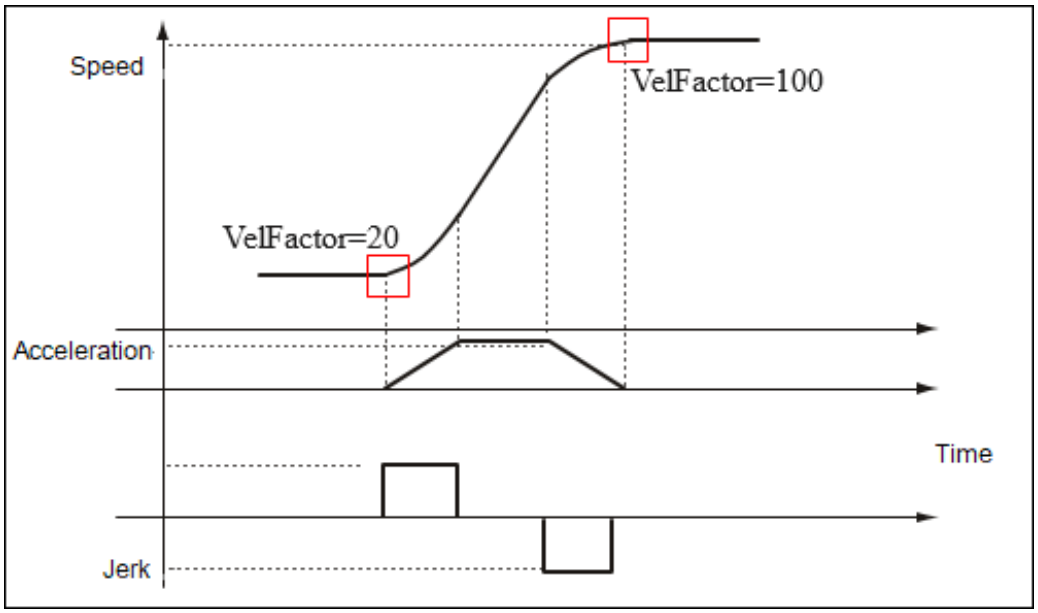
Output variable

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Enabled	Instruction executed successfully	BOOL	TRUE, FALSE	FALSE	Set to TRUE when the override factor is successfully set.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	Set to TRUE when the function block is not completed.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.



- **Parameter correction**



Input Variable	Name	Correction Description for Values Greater Than 1 or Backend Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
VelFactor	Velocity factor	If the velocity factor is greater than 100, it is automatically corrected to 100.	If the velocity factor is less than 0, it is automatically corrected to 1.	No correction.
AccFactor	Acceleration factor	If the acceleration factor is greater than 100, it is automatically corrected to 100.	If the acceleration factor is less than 1, it is automatically corrected to 1 for operation.	If the acceleration factor is equal to 1, no correction is applied.
JerkFactor	Jerk factor	If the jerk factor is greater than 100 in the non-trapezoidal motion profiling, it is automatically corrected to 100.	If the jerk factor is less than 0 in the non-trapezoidal motion profiling, it is automatically corrected to 1 for operation.	If the jerk factor is equal to 0 in the non-trapezoidal motion profiling, it is automatically corrected to 1 for operation.

- **Function**

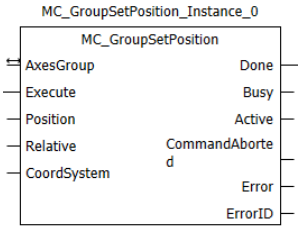
  This instruction is executed on the rising edge of Enable to set the rate for the AxesGroup during coordinate system motion.

  - The default value for VelFactor, AccFactor, and JerkFactor is 100.0. Both VelFactor and JerkFactor can be set to 0.0.
  - The unit for the override factor is [%], "100" represents 100%, and "50" represents 50%.
  - When Enable is set to FALSE, VelFactor, AccFactor, and JerkFactor revert to their default values.
  - For VelFactor = 0, the AxesGroup will run at a speed of 0, but the AxesGroup state will not return to GroupStandby. Instead, AxesGroup will continue running at a speed of 0.
  - This instruction does not interrupt the current motion of AxesGroup. It only affects the current motion speed of AxesGroup.
  - VelFactor can respond in real time and affect the current motion. When the instruction output Enabled becomes TRUE, it indicates that the velocity override factor has been successfully set, but it takes some time for the actual override to respond to the target value. AccFactor and JerkFactor reflect the override adjustment response time and are effective only during changes in the motion override.

  - Deceleration factor and jerk factor are effective for both PCS/ACS spatial motion instructions. Rate adjustments are made based on the ratio of the maximum planning parameters for the axis group in the current motion space (working space/axis space). However, these adjustments do not guarantee that the planning parameters will be exactly equal.
  - The trajectory planning curve type of AxesGroup is set according to requirements. If the planning curve type is a trapezoidal curve, the JerkFactor variable does not take effect.

- **Re-triggering the instruction**
  - When the input is an "Enable-type" instruction, the instruction will not be re-triggered.
- **Precautions**
  - This instruction can only be initiated when AxesGroup is in the GroupMoving or GroupStandby state. Otherwise, the instruction will return an error.
  - When AxesGroup is controlled by the MC_GroupStop, MC_GroupHalt, or MC_GroupInterrupt instructions, this instruction cannot be initiated. Otherwise, the instruction will return an error.
- **Sequence diagram**

  The input parameter "Enable" must have a valid level signal. When the output parameter "Enabled" is TRUE, it indicates that the target override has been successfully set. When the output parameter "Busy" is TRUE, it indicates that the current function block is being executed.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.5.15 MC_GroupSetPosition

This instruction can be used to set the current position of each axis in the axis group in the given coordinate system.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_GroupSetPosition	Set axis group current position		MC_GroupSetPosition_Instance_0(AxesGroup := , Execute := , Position := , Relative := , CoordSystem := , Done => , Busy => , Active =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
AxesGroup	Axis group	18.3.3.2.4.1 AXES_GROUP_REF: Axis Group Structure	-	-	Mapped to an axis group, which is an instance of AXES_GROUP_REF.

Input variable

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	Execute the instruction on a rising edge.
Position	Position	ARRAY [1..GROUP_DEF.AXIS_NUM] OF LREAL	-	[0,0…]	Position in the corresponding coordinate type.
Relative	Enabling relative coordinates	BOOL	TRUE, FALSE	FALSE	RELATIVE = TRUE. ABSOLUTE = FALSE.
CoordSystem	Coordinate system type	18.3.3.2.4.19 MC_COORDSYSTEM: Coordinate System Enumeration	ACS, PCS	ACS	Select the application coordinate system type.

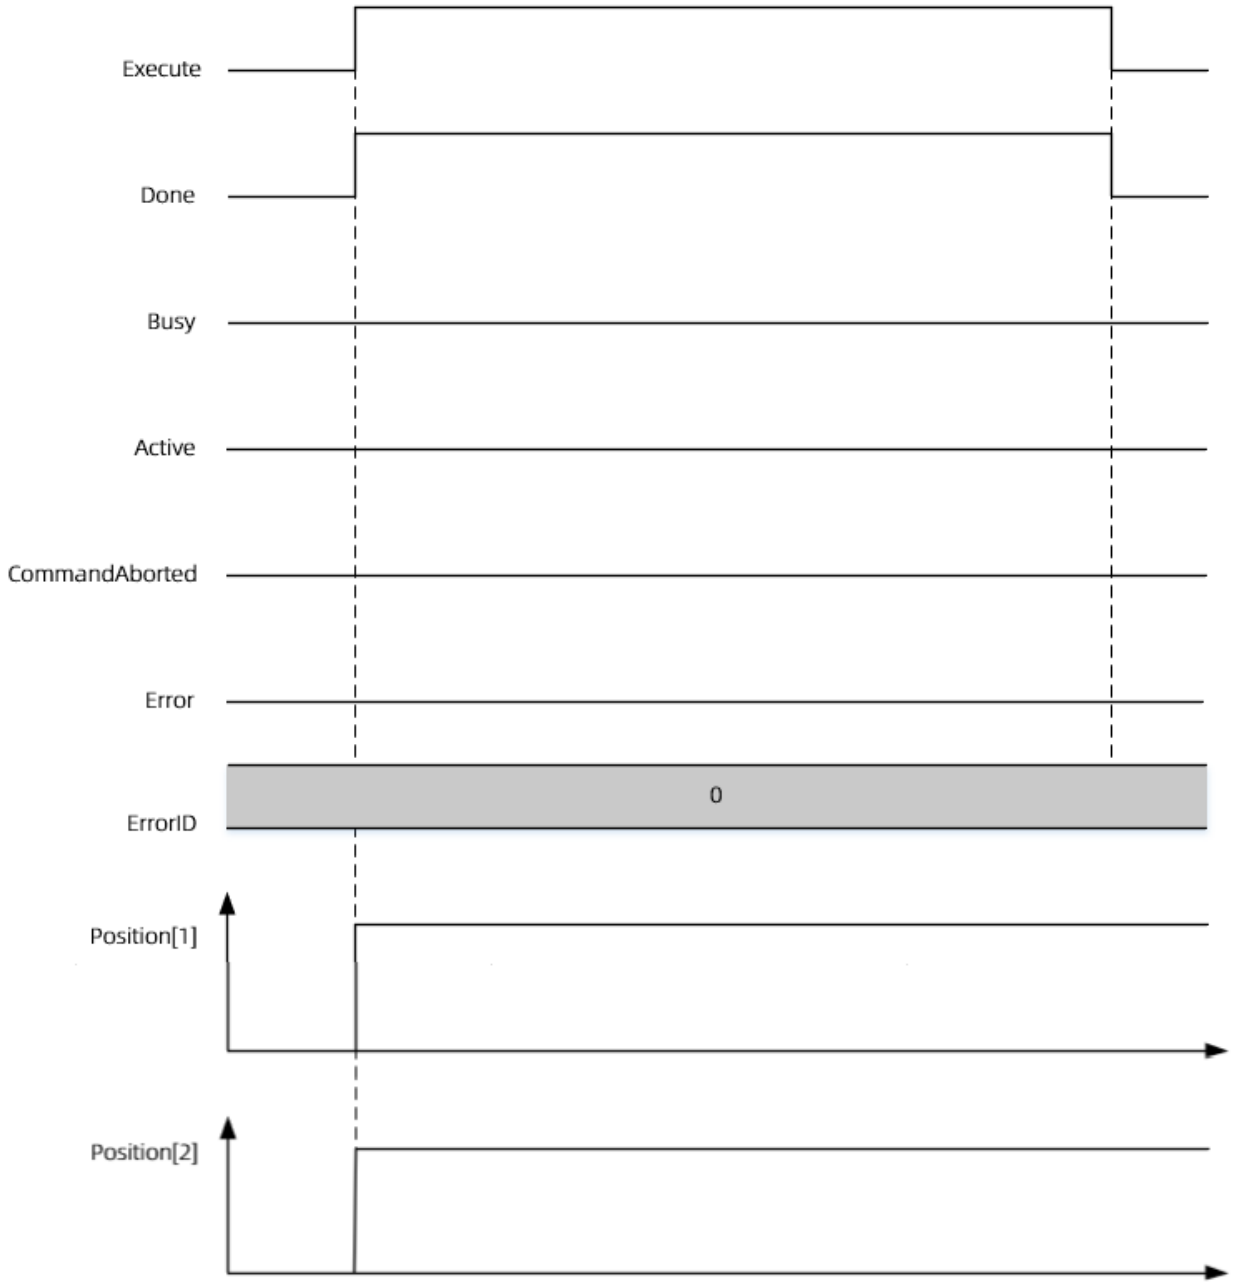
Output variable

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Active	Instruction has controlled the axis group	BOOL	TRUE, FALSE	FALSE	Set to TRUE when the axis group is being controlled.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**
  - With this instruction, you can set the current position of each axis in the specified AxesGroup.
  - You can set the current position of each Axis variable in the coordinate system specified by AxesGroup under ACS or PCS coordinate system, update the axis offset or part coordinate system without changing the type of the part coordinate system, and support the position setting in a dynamic coordinate system.
  - With the Relative input, you can select the method to set the position by setting the input variable Relative of this instruction:

    If the Relative input is FALSE, it is an absolute coordinate system. After the instruction is used, the actual position of each Axis variable in AxesGroup equals the value set by the input parameter Position of this instruction.

    If the Relative input is TRUE, it is a relative coordinate system. After the instruction is used, the actual position of each Axis variable in AxesGroup equals the value set by the input parameter Position for this instruction plus the actual position of each Axis variable in AxesGroup before this instruction is used.



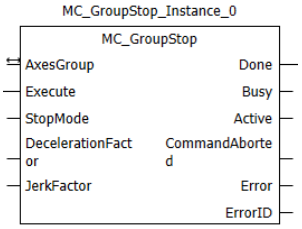
- **Precautions**
  - When the instruction is used, the axis group specified by AxesGroup must be in the GroupStandby, GroupMoving and axis group idle status. There is no state requirement for the Axis variable in AxesGroup.

- Setting the position under the ACS will affect the position of the axis group under the PCS. Setting the position under the PCS will not affect the position of the axis group under the ACS.
- Do not set the coordinate system during continuous trajectory module execution. Otherwise, the function block reports an error, and the axis group status remains unchanged.
- Before the axis group coordinate system is set in Setting, but not activated (Active), it is prohibited to set the coordinate system. Otherwise, the function block reports an error.

- **Sequence diagram**

  When the input parameter "Execute" is TRUE, the output parameter "Busy" becomes TRUE, indicating that the current function block is executing. The output parameter "Active" becomes TRUE, indicating that the instruction has controlled the axis group. After the current position changes, the output parameter "Done" becomes TRUE, indicating that the instruction has completed its execution.

  When the input parameter Execute is set to FALSE, the output parameter Done shows the value FALSE.



- **Faults**

For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.5.16 MC_GroupStop

This instruction makes the motion stop immediately. It is generally used for stopping an axis group under an abnormal situation, and the current motion cannot be recovered.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_GroupStop	Axis group emergency stop		MC_GroupStop_Instance_0(AxesGroup := , Execute := , StopMode := , DecelerationFactor := , JerkFactor := , Done => , Busy => , Active =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
AxesGroup	Axis group	18.3.3.2.4.1 AXES_GROUP_REF: Axis Group Structure	-	-	Mapped to an axis group, which is an instance of AXES_GROUP_REF.

Input variable

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	Execute the instruction on a rising edge.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
StopMode	Stop mode	18.3.3.2.4.12 MC_GROUP_STOP_MODE: Stop Mode Enumeration	0: DEC_STOP 1: IMMED_STOP	0	DEC_STOP: Decelerate to stop. IMMED_STOP: Stop immediately.
DecelerationFactor	Deceleration factor	LREAL	[0.01,1.0]	0.5	Ratio relative to the maximum deceleration of the axis group
JerkFactor	Jerk factor	LREAL	[0.0,1.0]	0.5	Factor relative to the maximum jerk of the axis group.

Output variable

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Active	Instruction has controlled the axis group	BOOL	TRUE, FALSE	FALSE	TRUE when the axis is being controlled.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	Set to TRUE when the instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Function**

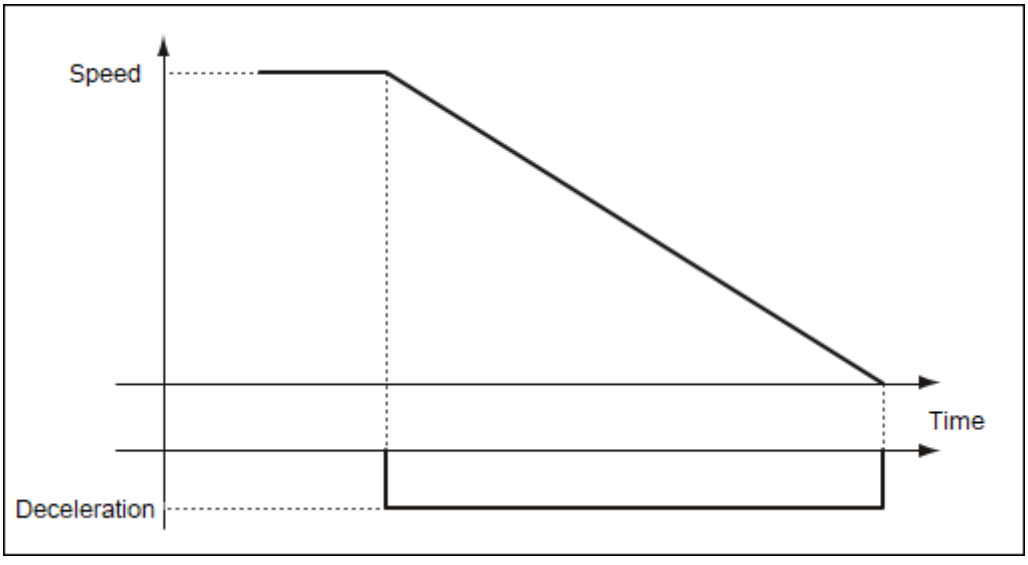
  This instruction is executed on the rising edge of Execute and is used for emergency stop during abnormal operation of the axis group (AxesGroup).

  - **StopMode**
    - This instruction sets the emergency stop method for abnormal operation of the axis group (AxesGroup) by inputting the variable StopMode.

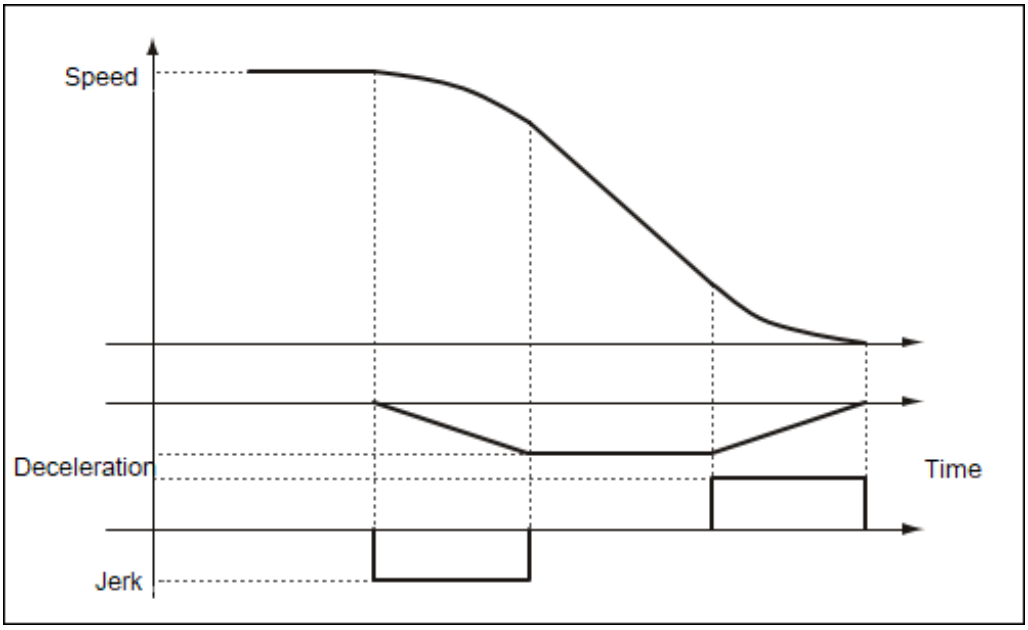
      In StopMode = 0, DEC_STOP, the deceleration stop is performed on each Axis variable in AxesGroup according to the parameters set by the instruction. After the deceleration stop is

completed, the Done output of the instruction is set to TRUE, and the axis group state is switched to GroupStopping.

In StopMode = 1, IMMED_STOP, the speed of each Axis variable in AxesGroup is reduced to 0 within one cycle. The Done output of the instruction is set to TRUE, and the axis group state is switched to GroupStopping.



◦ **DecelerationFactor, JerkFactor**



- The deceleration and jerk during the execution of this instruction are determined by the input variables DecelerationFactor and JerkFactor.
- In StopMode = 0, DEC_STOP, the deceleration stop is performed on each Axis variable in AxesGroup according to the product of the maximum axis acceleration limited by software and DecelerationFactor, and the product of the maximum axis jerk limited by software and JerkFactor.
- JerkFactor

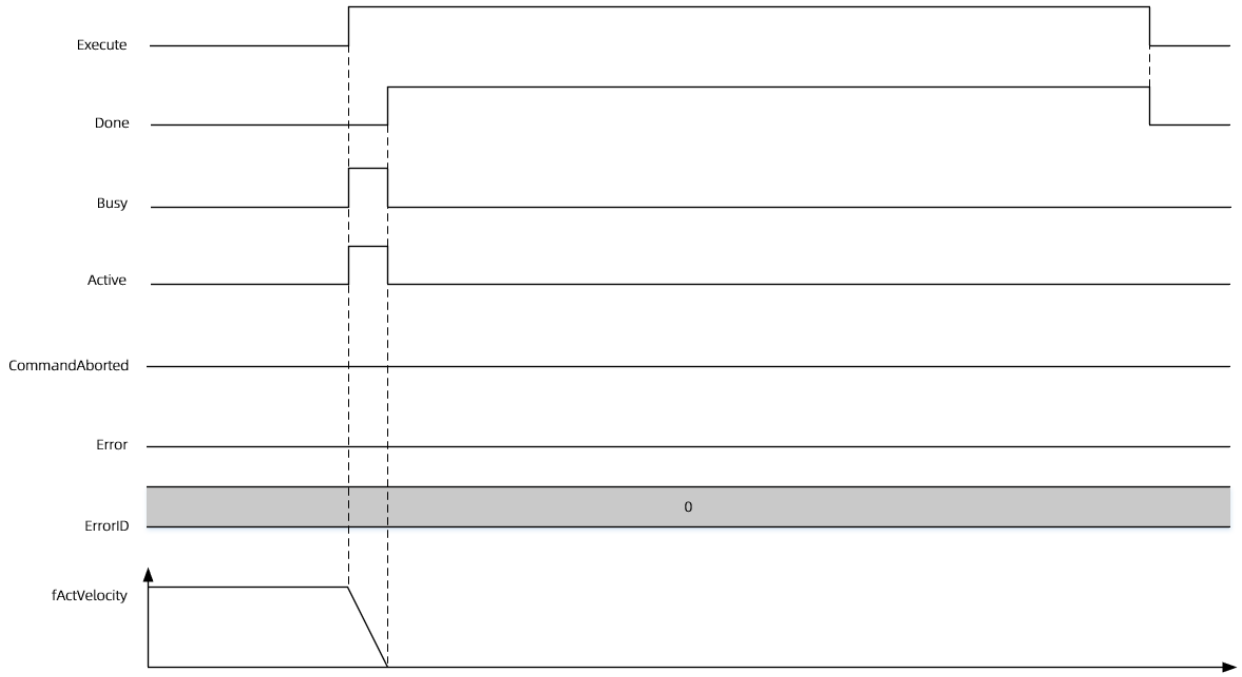
  The jerk factor parameter is invalid for the T-profile, but valid for the S-profile.

  For JerkFactor = 0, the velocity curve and deceleration curve are shown as follows.

  For JerkFactor ≠ 0, the velocity curve, deceleration curve, and jerk curve are shown as follows.

  - StopMode is set to DEC_STOP by default.
  - When StopMode is set to IMMED_STOP, DecelerationFactor and JerkFactor are invalid.
  - When this instruction is used, the axis group must be in the GroupStandby, GroupMoving, or GroupHoming state. Attempting to start this instruction in any other state will result in an error.
  - This instruction can interrupt the motion instruction currently being executed by AxesGroup and set the axis group to GroupStopping. **In this status, no motion instructions are allowed to execute for AxesGroup. Otherwise, an error will be generated for the corresponding motion instruction**.
  - If the instruction is used during the homing process of AxesGroup, StopMode, DecelerationFactor, and JerkFactor are all invalid. A deceleration stop along the current path is not guaranteed. Instead, AxesGroup will decelerate to a stop according to the servo stop method.
  - **When AxesGroup is in the GroupStopping state, do not execute other motion instructions. Otherwise, an error will occur. However, for an MC_GroupStop instruction instances that have triggered the axis group to enter the GroupStopping state, it is permitted to re-trigger the instruction after modifying the parameters. (For example, start stopping in DEC_STOP mode, then change the mode to IMMED_STOP during stop and re-trigger the instruction.)**

- **Re-triggering the instruction**
  - This instruction can be re-executed. If the instruction is re-triggered after the parameter modification, execute the instruction according to the modified parameters. If the modified parameters are invalid, the instruction will return an error. The speed of the axis group (AxesGroup) will quickly reduce to 0, and the axis group state will change to GroupErrorStop.



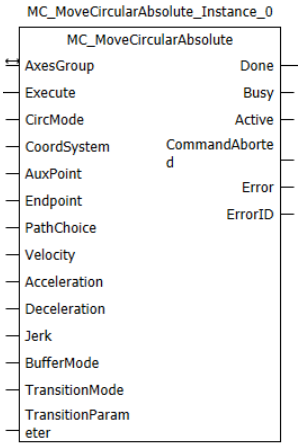
- **Precautions**
  - The trajectory planning curve type of AxesGroup must be set as required. If the planning curve type is set to a trapezoidal curve, the input variable JerkFactor for this instruction becomes invalid, and the instruction executes a deceleration to a stop according to DecelerationFactor. If the planning curve type is set to a cubic curve or a septic curve, the instruction executes a deceleration to a stop according to DecelerationFactor and JerkFactor.
  - Whether the planning curve type of each Axis variable in AxesGroup is set to a trapezoidal curve or an S-curve does not affect the planning method of AxesGroup.
- **Sequence diagram**

  The parameter Execute of the function block must be triggered on a rising edge. The parameter Done of the function block indicates the instruction has been executed successfully; the parameter Busy indicates that the current function block is being executed; the parameter CommandAborted indicates that the instruction is aborted by another motion control instruction, at which point the flag is set to TRUE.

  The parameter Busy shows the value TRUE on a rising edge of Execute. In the next cycle, the output parameter Active shows the value TRUE.

  When the velocity of all axes reaches "0", "Done" becomes TRUE.

  When this instruction is aborted using another instruction, CommandAborted becomes TRUE, and "Busy" and "Active" become FALSE.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.5.17 MC_MoveCircularAbsolute

This enables the arc interpolation motion of the axis group from the current TCP point to the absolute position point under the given coordinate system.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_MoveCircularAbsolute	Circular absolute motion		MC_MoveCircularAbsolute_Instance_0(AxesGroup := , Execute := , CircMode := , CoordSystem := , AuxPoint := , Endpoint := , PathChoice := , Velocity := , Acceleration :=, Deceleration :=, Jerk := , BufferMode := , TransitionMode := , TransitionParameter := , Done => , Busy => , Active =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
AxesGroup	Axis group	18.3.3.2.4.1 AXES_GROUP_REF: Axis Group Structure	-	-	Mapped to an axis group, which is an instance of AXES_GROUP_REF.

Input variable

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	Execute the instruction on a rising edge.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
CircMode	Circular mode	18.3.3.2.4.18 MC_CIRCMODE: Arc Mode Enumeration	0, 1, 2	0	0: Three-point arc. 1: Center-point arc. 2: Radius-defined arc.
CoordSystem	Coordinate system type	18.3.3.2.4.19 MC_COORDSYSTEM: Coordinate System Enumeration	ACS, PCS	PCS	Currently only supports PCS.
AuxPoint	Auxiliary point	ARRAY [1..GROUP_DEF.AXIS_NUM] OF LREAL	-	[0,0,...]	For the auxiliary point position of each dimension in the specified coordinate system, see Axis group type description.
EndPoint	End point	ARRAY [1..GROUP_DEF.AXIS_NUM] OF LREAL	-	[0,0,...]	For the end position in each dimension in the specified coordinate system, see Axis group type description.
PathChoice	Path choice	18.3.3.2.4.17 MC_CIRC_PATHCHOICE: Arc Path Choice Enumeration	0, 1	0	This parameter is valid when CircMode is set to CENTER_ARC or RADIUS_ARC arc mode.
Velocity	Velocity	LREAL	> 0	-	Maximum linear velocity. This value may not necessarily be reached.
Acceleration	Acceleration	LREAL	> 0	-	Maximum linear acceleration. This value may not necessarily be reached.
Deceleration	Deceleration	LREAL	> 0	-	Maximum linear deceleration. This value may not necessarily be reached.
Jerk	Jerk	LREAL	>=0	-	Maximum linear jerk. This value may not necessarily be reached.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
BufferMode	Buffer mode	18.3.3.2.2.6 MC_BUFFER_MODE: Buffer Mode Enumeration	0: mcAborting 1: mcBuffered 2: mcBlendingLow 3: mcBlendingPrevious 4: mcBlendingNext 5: mcBlendingHigh	0	0: mcAborting (Aborting). 1: mcBuffered (Buffered). 2: mcBlendingLow (Blending with the lowest velocity of both FBs). 3: mcBlendingPrevious (Blending with the velocity of the first FB). 4: mcBlendingNext (Blending with velocity of the second FB). 5: mcBlendingHigh (Blending with the highest velocity of both FBs). Note: Buffer modes 2 to 5 currently have the same effect. All are blending modes. The behavior depends on the TransitionMode and TransitionParameter parameters.
TransitionMode	Transition mode	18.3.3.2.4.10 MC_TRANSITION_MODE: Transition Mode Enumeration	0: TMNone 1: TMStartVelocity 3: TMCornerDistance 4: TMMaxCornerDeviation 10: TMDefinedVelocity 11: TMResetAbort 12: TMDecAbort	0	Definition of the transition trajectory characteristic types. When BufferMode is set to MC_ABORTING, only the transition mode parameters TMNone, TMResetAbort, and TMDecAbort are allowed. When BufferMode is set to MC_BUFFERED, the transition mode is invalid. When BufferMode is a blending mode (2 to 5), TMResetAbort or TMDecAbort is not allowed.
TransitionParameter	Transition parameter	LREAL	Velocity [0.0,1.0] Distance [0.0,+∞)	1	Transition parameters vary with the transition mode.

Output variable

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.

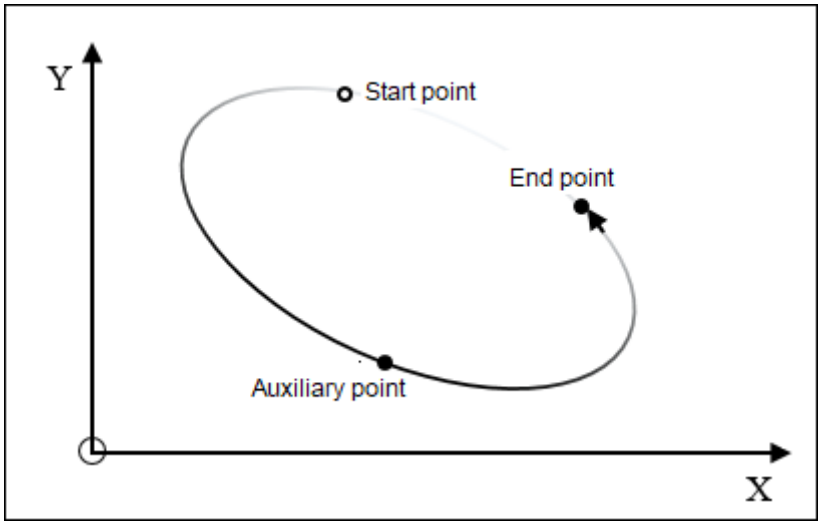
Output Variable	Name	Data Type	Valid Range	Default Value	Description
Active	Instruction has controlled the axis group	BOOL	TRUE, FALSE	FALSE	TRUE when the axis is being controlled.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	Set to TRUE when the instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

- **Parameter correction**

  Position dimension

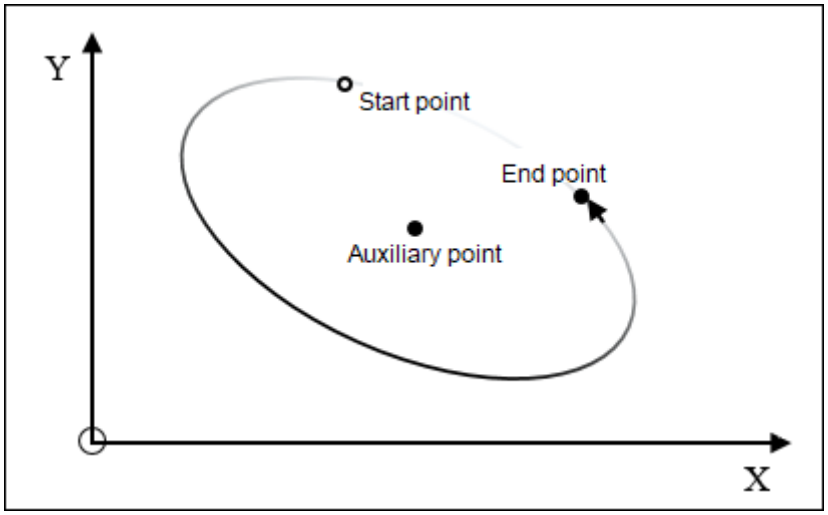
Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Velocity	Velocity	Any velocity that exceeds the motion parameter limit will be automatically corrected to the velocity limit.	Any velocity less than 0 will be automatically corrected to 1e-5.	The velocity equal to 0 will be automatically corrected to 1e-5.
Acceleration	Acceleration	Any acceleration that exceeds the motion parameter limit will be automatically corrected to the acceleration limit.	Any acceleration less than 0 will be automatically corrected to 10% of the acceleration limit.	Any acceleration equal to 0 will be automatically corrected to 10% of the acceleration limit.
Deceleration	Deceleration	Any deceleration that exceeds the motion parameter limit will be automatically corrected to the acceleration limit.	Any deceleration less than 0 will be automatically corrected to 10% of the acceleration limit.	Any deceleration equal to 0 will be automatically corrected to 10% of the acceleration limit.
Jerk	Jerk	For the non-trapezoidal motion profiling, any jerk that exceeds the software limit will be automatically corrected to the jerk limit.	For the non-trapezoidal motion profiling, any jerk that exceeds the software limit will be automatically corrected to 10% of the jerk limit.	For the non-trapezoidal motion profiling, any jerk that exceeds the software limit will be automatically corrected to 10% of the jerk limit.

  Percentage dimension



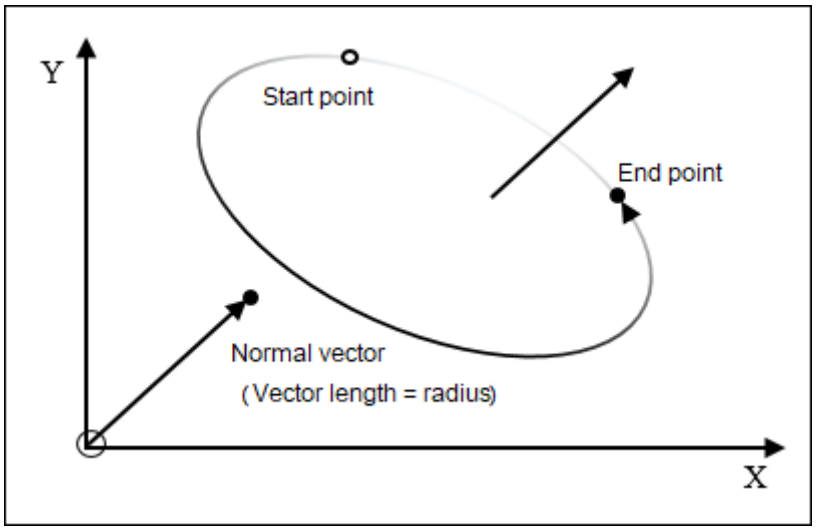
Input Variable	Name	Correction Description for Parameter Greater than 1	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Velocity	Velocity	Any velocity exceeding 1 is automatically corrected to 1.	Any velocity less than 0 will be automatically corrected to 1e-5.	The velocity equal to 0 will be automatically corrected to 1e-5.
Acceleration	Acceleration	Any acceleration exceeding 1 is automatically corrected to 1.	Any acceleration less than 0 will be automatically corrected to 10%.	Any acceleration equal to 0 will be automatically corrected to 10%.
Deceleration	Deceleration	The value exceeding 1 is automatically corrected to 1.	Any deceleration less than 0 will be automatically corrected to 10%.	Any deceleration equal to 0 will be automatically corrected to 10%.
Jerk	Jerk	For the non-trapezoidal motion profiling, the value exceeding 1 is automatically corrected to 1.	For the non-trapezoidal motion profiling, the value exceeding 1 is automatically corrected to 10%.	For the non-trapezoidal motion profiling, the value exceeding 1 is automatically corrected to 10%.

- **Function**
  - This instruction is executed on the rising edge of Execute and performs an absolute arc motion, supporting planar or spatial arcs.
  - CircMode, CoordSystem, AuxPoint, EndPoint, PathChoice, Velocity, Acceleration, Deceleration, Jerk, BufferMode, TransitionMode, and TransitionParameter can be specified in the input variables.
  - For the instruction, blending modes 2, 3, 4, and 5 for BufferMode have the same behavior. The transition effect depends on the TransitionMode and TransitionParameter settings.
  - Supports the same-cycle triggering of instructions. The Done output signal of the instruction serves as the trigger signal for Execute.
  - **AuxPoint**
    - For the axis type corresponding to each position vector in the AuxPoint array, see Axis group type description. Only PCS coordinates are supported.
    - The ABC rotation axes of the coordinate system correspond sequentially to the ZYX-type Euler angles. If the configuration supports orientation motion, the orientation parameters set for the auxiliary points will not be included in the orientation trajectory planning.
  - **EndPoint**
    - For the axis type corresponding to each position vector in the EndPoint array, see Axis group type description. Only PCS coordinates are supported.
    - In absolute motion mode, the axis group uses the set values in the EndPoint array as the target position.
    - If the target position would exceed any joint axis limit after kinematic transformation into joint space, starting this instruction will cause an error.
    - If the configuration supports orientation motion, the axis group will move to the target orientation along the shortest path.



- The ABC rotation axes of the coordinate system correspond sequentially to the ZYX-type Euler angles. If the configuration supports orientation motion, the configured ABC absolute positions must be within ±180°, otherwise an error will be generated. Note that for the EVO500 series PLC (version V1.2), when the axis group type is set to "XYZA configuration", the A-axis functions as an auxiliary axis. Its movement is not limited to ±180 degrees. If it exceeds ±180 degrees, the axis continues moving according to the preset position.

◦ **CircMode**



- BORDER_ARC three-point circular arc: a circular arc defined by three points—the current position of AxesGroup as start point, AuxPoint, and EndPoint. **If the three points are collinear or two of them coincide, the trajectory is a straight line connecting the start point and the end point**. If the three points are not collinear, the trajectory is a circular arc passing through the three points in sequence. The range of the arc angle is (0, 2π). The figure shows a three-point arc in space. It follows the right-hand rule, with the Z-axis pointing out of the screen.

- CENTER_ARC center circular arc: a circular arc is defined by the current position of AxesGroup as start point, AuxPoint as the center, and EndPoint. The arc is specified as either a long arc or short arc through PathChoice. The arc angle range is less than 2π, and the arc angle range is not equal to π. **When the three points are collinear, the trajectory is a straight line.** If the distance between the start point and the end point to the center of the circle deviates too much, an error will be reported. The distance from the start point to the center is named L1, and the distance from the end point to the center is named L2. The center will be automatically corrected if $|L1-L2| < 0.01 \times \min(L1,L2)$. Exceeding this deviation will trigger an error. (Due to floating-point arithmetic precision issues, no strict equality exists.) The figure shows the composition of a center-point arc in space, with axis Z facing off-screen.

- RADIUS_ARC radius arc: **the radius of the arc is determined by the vector length of** AuxPoint, and the vector direction determines the normal vector of the arc. PathChoice determines whether the arc is long or short. The arc angle range is less than 2π. When the start and end points are not perpendicular to the normal vector, an error will be reported if the deviation angle is too large. If the deviation is small (<10°), the direction of the normal vector will be corrected according to the parameter. If the distance from the endpoint exceeds twice the length of the normal vector and also exceeds one ten-thousandth of the length (that is, radius), an arc error is reported. When the deviation is within one ten-thousandth, the arc radius is corrected to a semicircle. An error is reported when the length of the normal vector or the distance between start and end points is less than the computational precision of 1e-6. **For an axis group configured with only two position axes, AuxPoint[0] indicates the radius of the circular arc. A positive value indicates rotation about the arc's normal axis in the positive direction (typically following the right-hand rule), while a negative value indicates rotation in the opposite (negative) direction.**

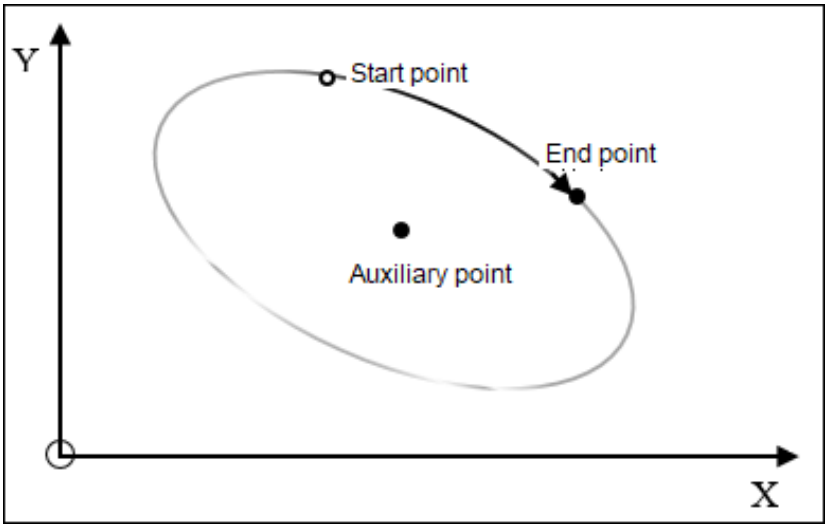
◦ **CoordSystem**

- Specify the coordinate system for circular absolute motion. Currently, only absolute circular motion under the PCS is supported.

◦ **Velocity constraint**

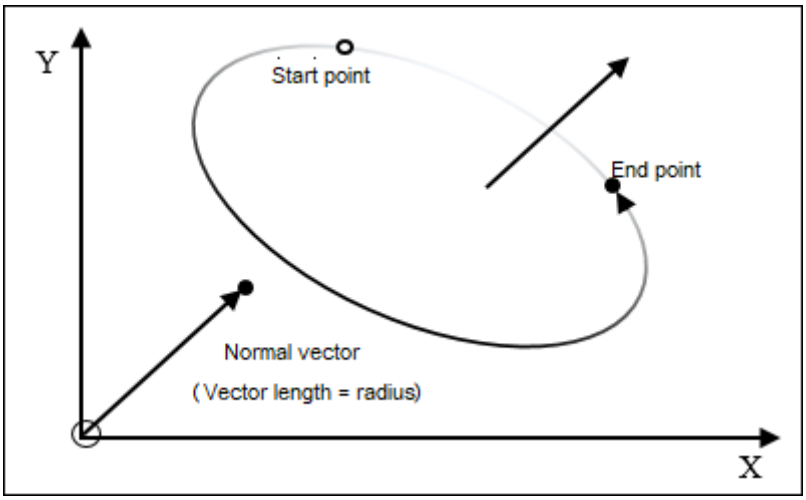
- The arc trajectory is bound by the maximum acceleration and deceleration parameters of the system. The centripetal acceleration is kept within limits by restricting the velocity along the trajectory segment. The velocity is constrained as follows:

  Vmax = Sqrt(Amax *R*Ccoef)

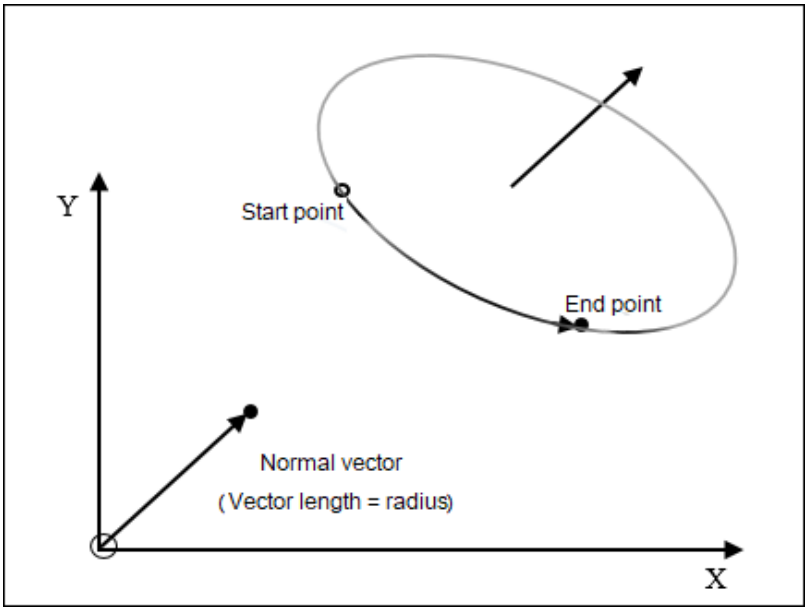


Here, Ccoef indicates the transition factor, R indicates the arc radius, and Amax indicates the maximum allowable acceleration of the system.

◦ **PathChoice**

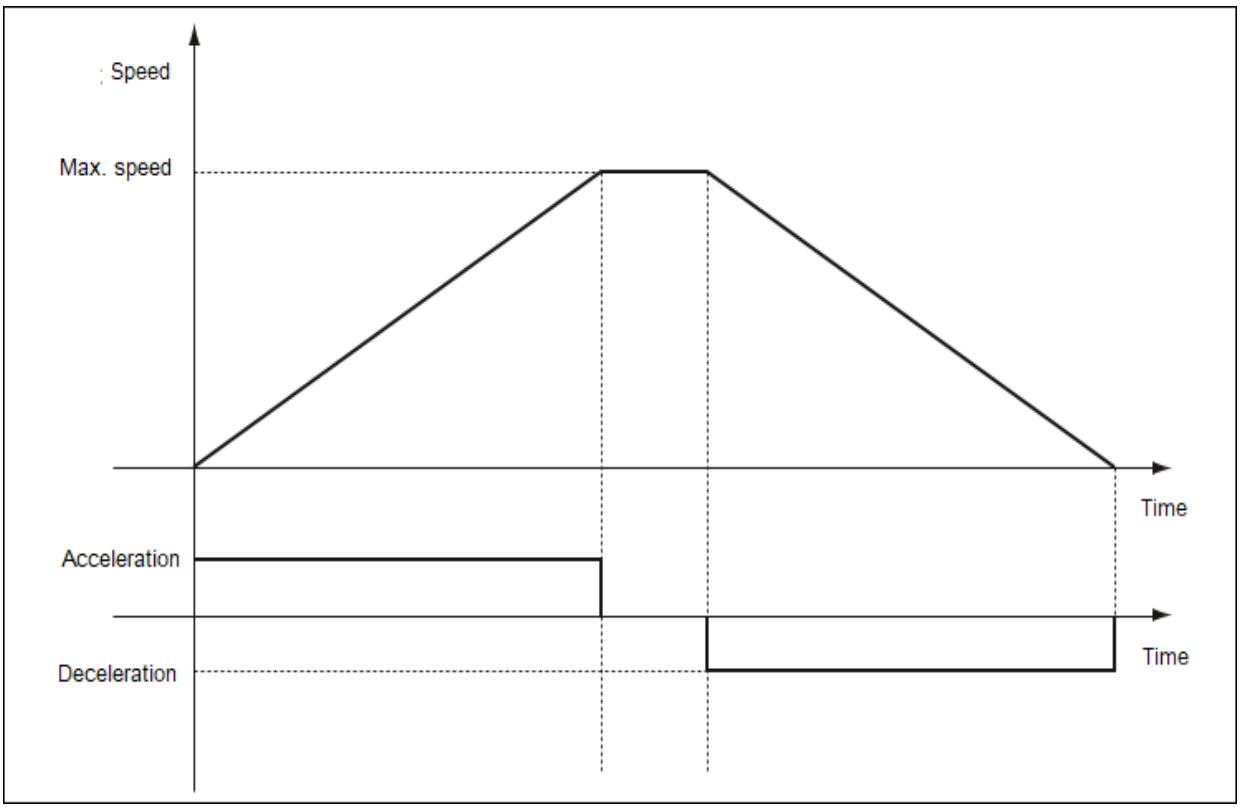


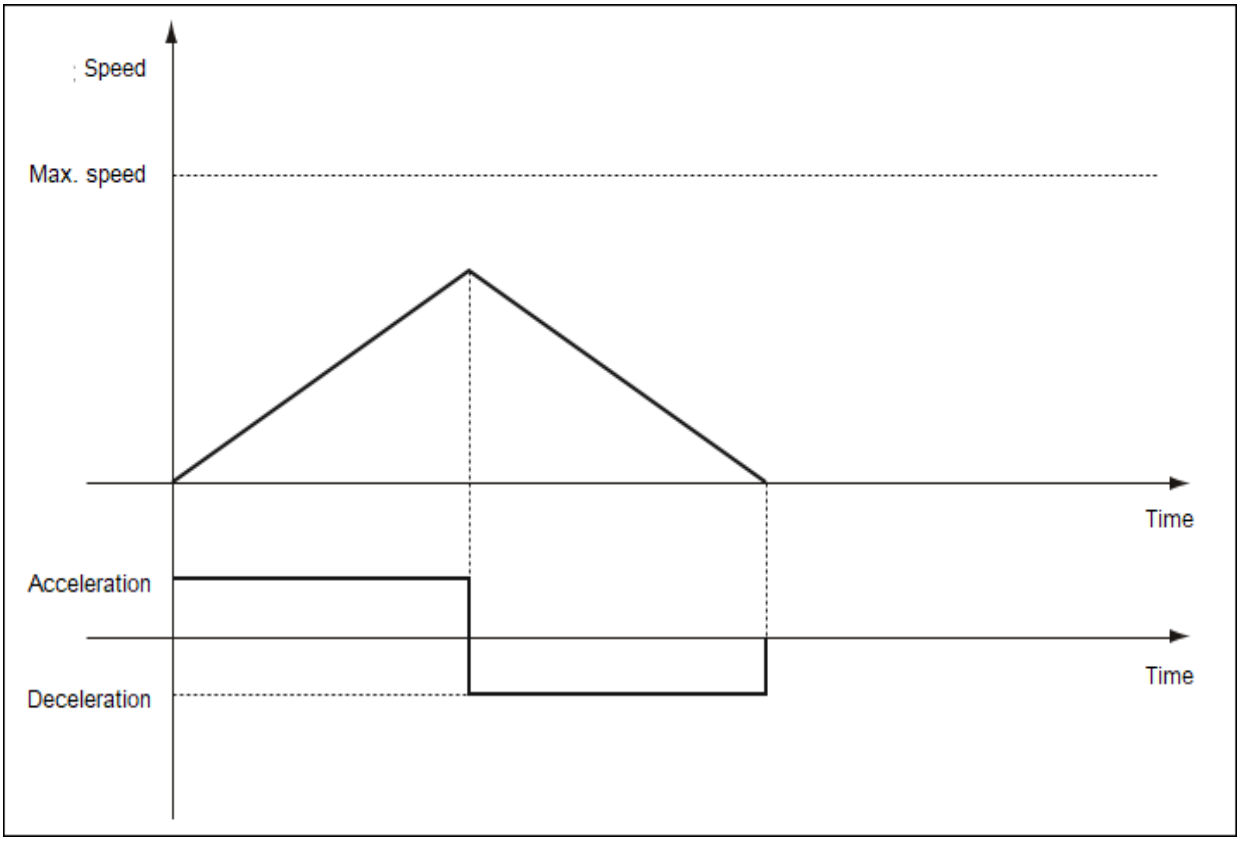
Depending on the CircMode, there are different choices for the arc direction and length.



- CENTER_ARC center circular arc: In the figure below, the first setting is the LONG_ARC path, and the second setting is the SHORT_ARC path.

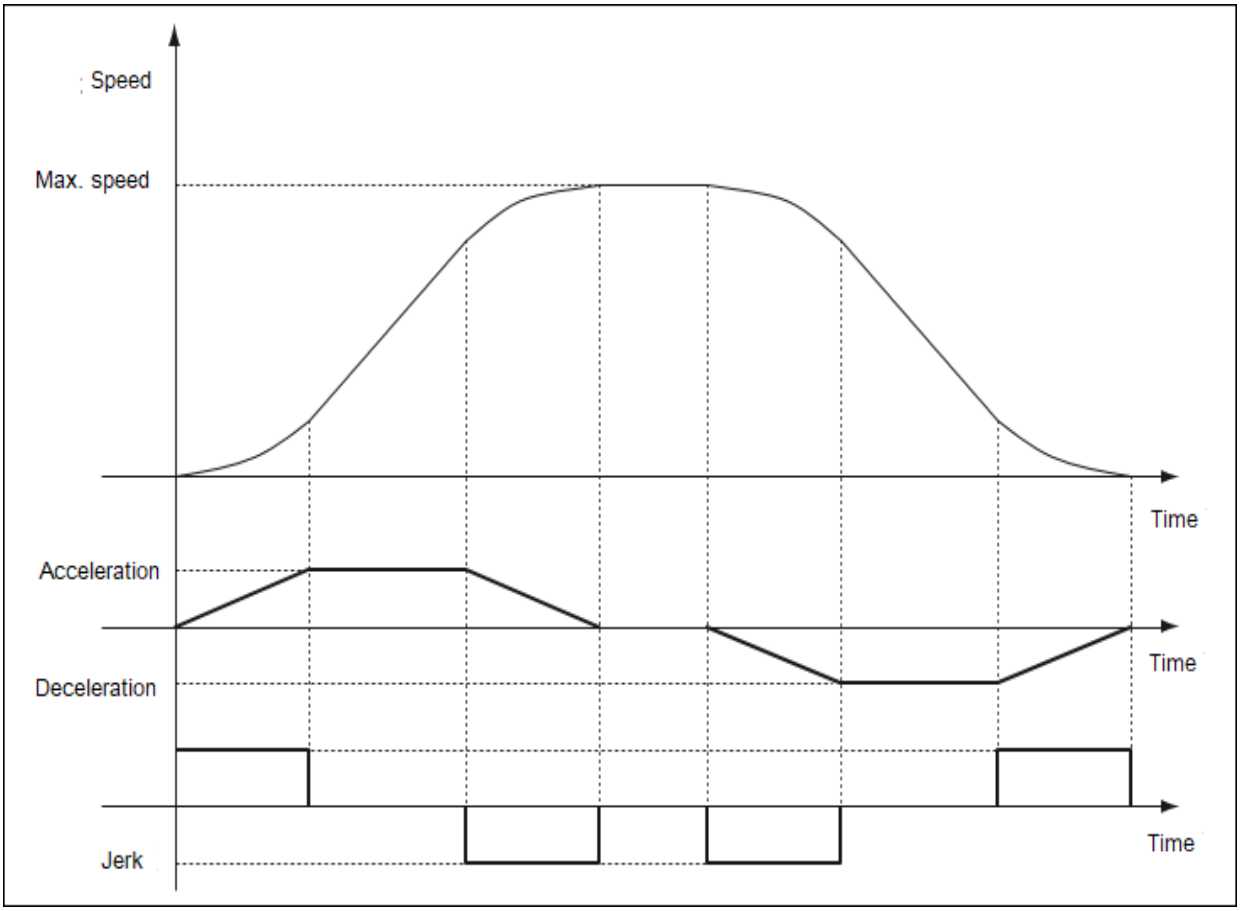
- RADIUS_ARC radius arc: In the figure below, the first setting is the LONG_ARC path, and the second setting is the SHORT_ARC path. .



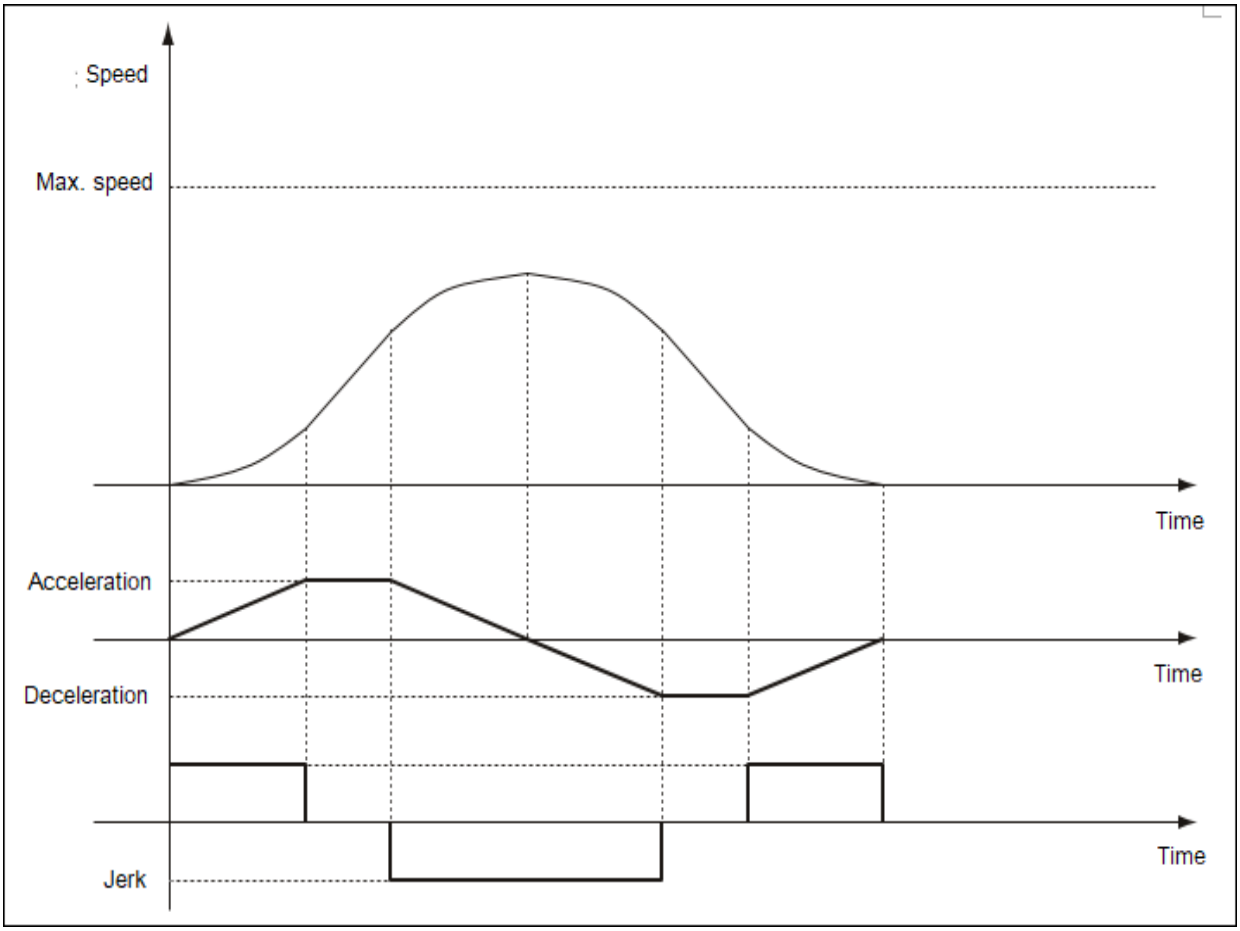


◦ **Velocity, Acceleration, Deceleration, Jerk**

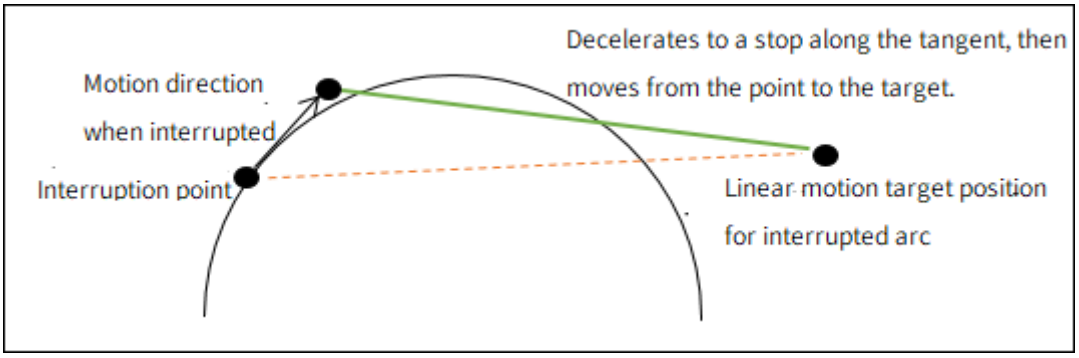
- If the velocity of any Axis variable in AxesGroup exceeds the maximum axis velocity set by the software multiplied by the warning planning scaling factor, it will trigger an error-stop condition.
- The trajectory planning curve type of AxesGroup is set according to requirements. If the planning curve type is a trapezoidal curve, the Jerk variable does not take effect and is treated as 0. (The planning curve type of AxesGroup is specified in the axis group data structure.)
- For Jerk = 0 or Jerk ≠ 0, the velocity, acceleration, deceleration, and jerk curves are shown in the figure below.



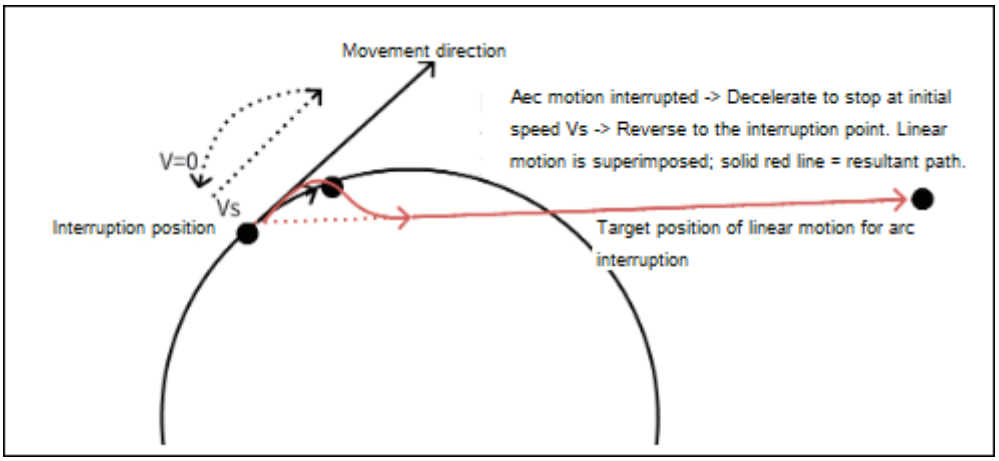
For Jerk = 0, the axis group can reach the maximum interpolation velocity.



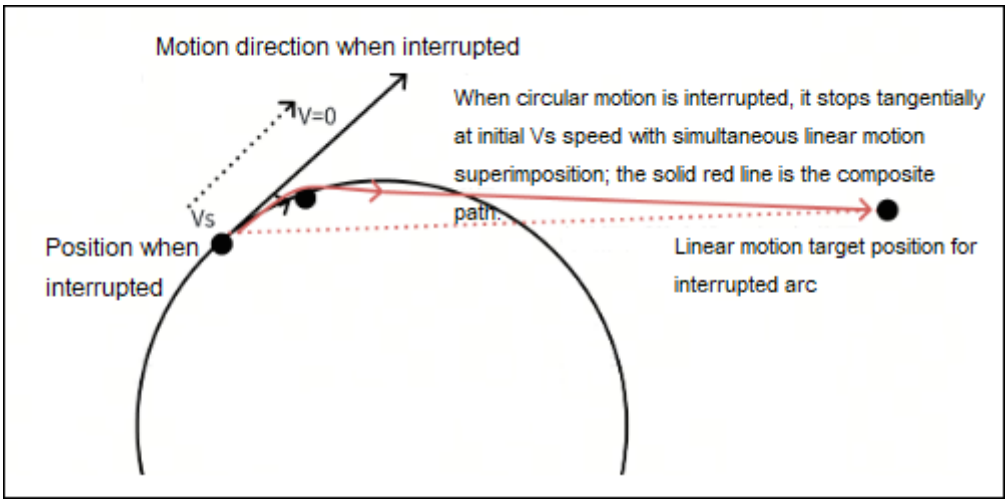
For Jerk = 0, the axis group cannot reach the maximum interpolation velocity due to too short travel distance.



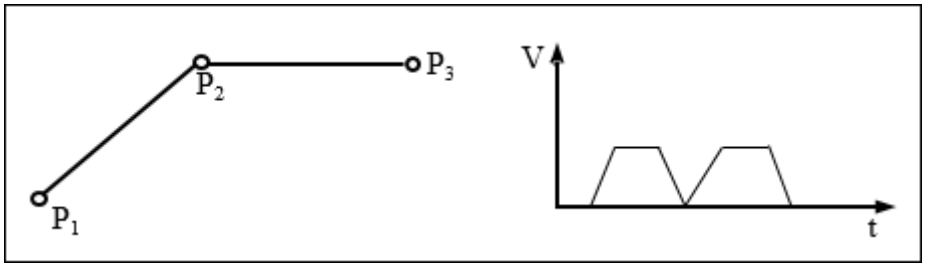
For Jerk ≠ 0, the axis group can reach the maximum interpolation velocity. (Non-trapezoidal planning curve)



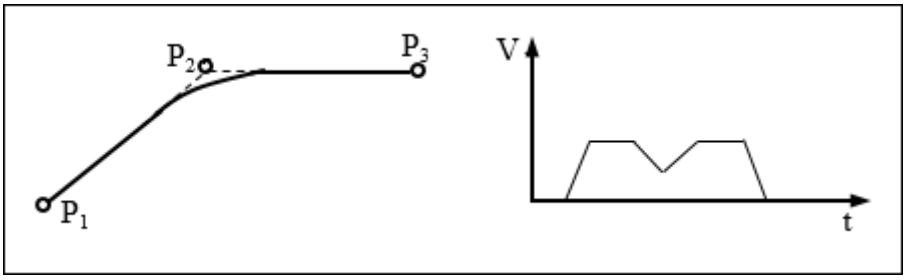
For Jerk ≠ 0, the axis group cannot reach the maximum interpolation velocity due to too short travel distance. (Non-trapezoidal planning curve)



- **Re-triggering the instruction**
  - While the instruction is in motion, that is, when the instruction output parameters "Busy" and "Active" are both TRUE, this instruction cannot be re-triggered.
  - While the instruction is in buffer mode, that is, when Busy is TRUE and Active is FALSE, this instruction can be re-triggered after parameter modification. If the modified parameters are invalid, or if the buffered instruction data has already been used in motion calculations, retriggering the buffered instruction will cause an error. Then, the axis group will enter the GroupStop state, and the currently executing instruction will also report an error.
- **Multiple execution of motion instructions**
  - When this instruction is issued while another motion instruction is being executed, the new instruction can either be switched to immediately or buffered for later execution. Each axis group can buffer up to 8 instructions. In the case of multiple executions, the behavior of this instruction is determined by BufferMode.
  - BufferMode
    - Aborting: MC_ABORTING aborts the currently executing instruction and begins executing this instruction. The abort operation supports three modes, configurable via TransitionMode: TMNone, TMResetAbort, and TMDecAbort.
      TMNONE mode: During execution, the motion decelerates to a stop along the tangential direction from the point of interruption. The next motion segment then starts from this stop point, as shown in the figure below.

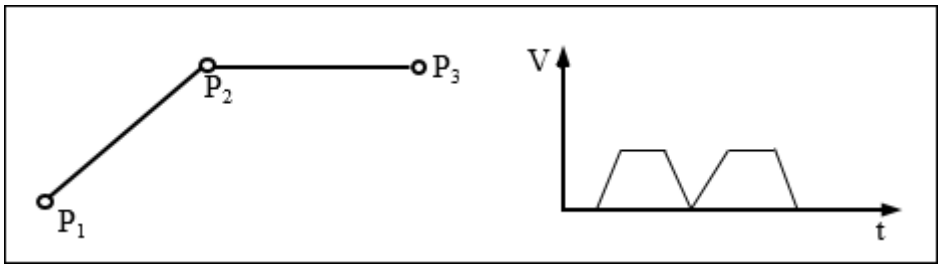


TMResetAbort mode: During execution, the axis decelerates along the tangential direction at the initial velocity of the interruption point, reverses its direction to return to that point, while simultaneously superimposing (blending) with the next motion segment, as shown in the figure below.

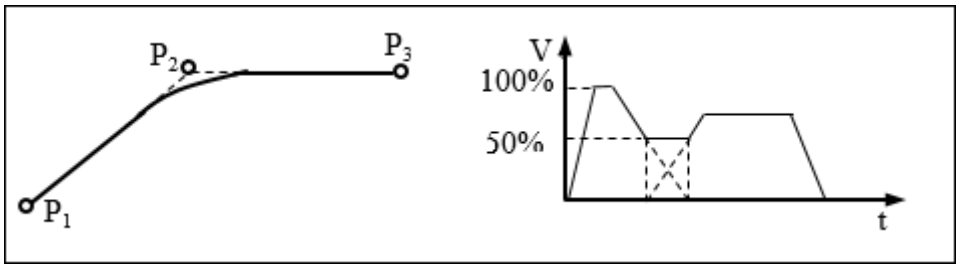


TMDecAbort mode: During execution, the axis decelerates to 0 along the tangential direction at the initial velocity of the interruption point, while simultaneously superimposing (blending) with the next motion segment, as shown in the figure below.

- Buffer: MC_BUFFERED, this instruction is buffered and executed after the current instruction is completed.



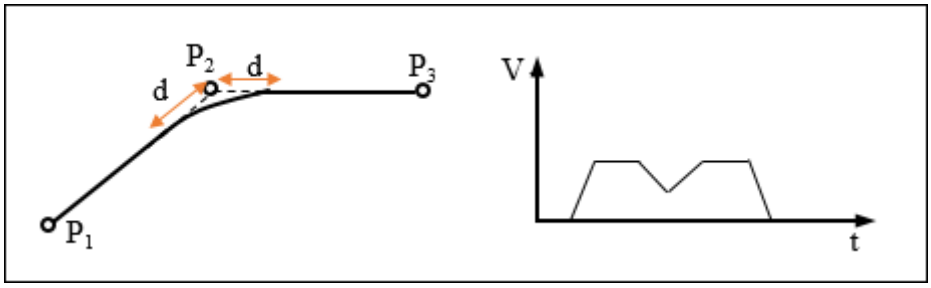
- Blending: MC_BLEND_XX, the velocities of the two adjacent instructions are blended in the specified manner. This manner is specified in TransitionMode.



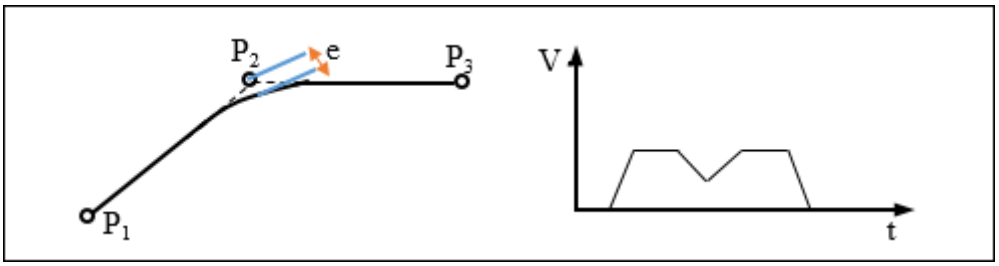
◦ TransitionMode

This variable specifies how to blend the velocities of two instructions when Blending is specified for the BufferMode.

- TMNone: Insert no transition curve. If TMNone is selected in a blending mode, the result is currently consistent with the transition between the velocities of the two instructions in buffered mode. Further extensions are planned.

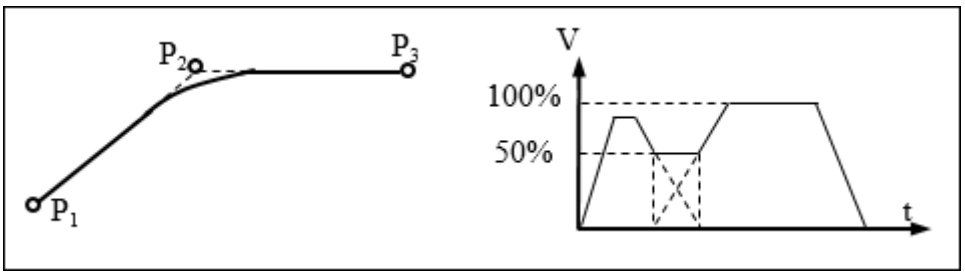


- TMStartVelocity: Transition with given start velocity. Blending transition at a certain ratio (0, 1] of the actual maximum velocity of the current motion control instruction. Effective for transitions between any motion control instructions.



- TMCornerDistance: Corner transition mode In Cartesian space, this parameter specifies the distance before the end of the previous instruction, measured in the main dimension space. The transition trajectory is initiated at this distance to connect with the adjacent trajectory. The distance here is a generalized distance, which depends on the main dimension type setting of the axis group.
  When the primary dimension is set to position: the parameter is the displacement from the transition point to the end point.

  When the primary dimension is set to ratio: The parameter is the ratio (0 to 1) of the resultant distance from the transition point to the endpoint to the total resultant displacement.



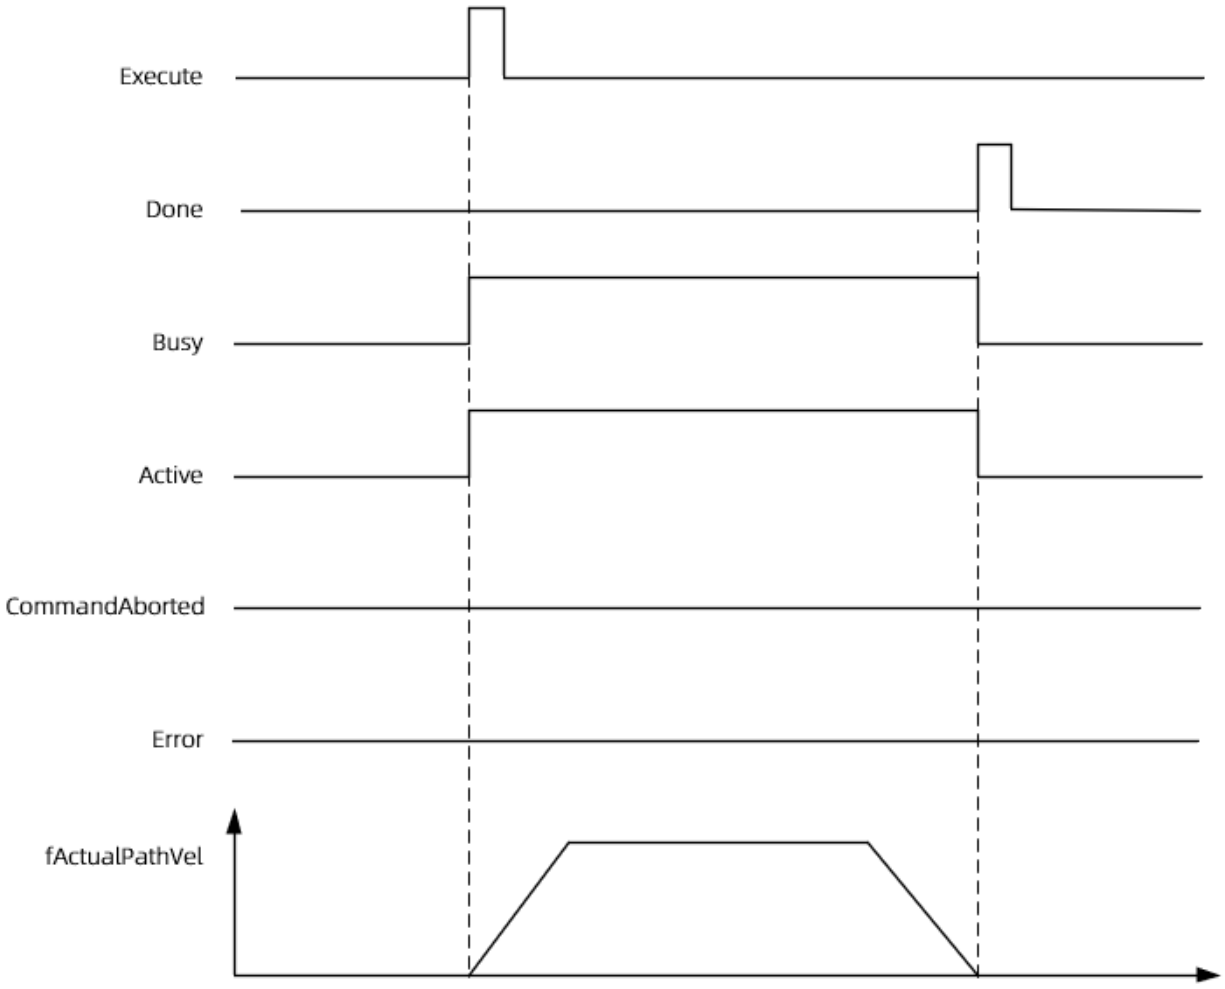
- TMMaxCornerDeviation: Transition mode using the maximum corner position deviation. In Cartesian space, this parameter specifies the maximum position deviation in the position subspace during the transition between adjacent instructions. An appropriate transition trajectory is constructed to connect the two adjacent paths, keeping the maximum position deviation within this

limit. This is only the position deviation, independent of the main unit. Effective when both adjacent instructions are Cartesian space instructions (LIN/CIRC). Otherwise, they are processed with transition disabled.

- TMDefinedVelocity: Transition with defined velocity. Blending transition at a certain ratio (0, 1] of the actual maximum velocity of the instruction following the current motion control instruction. Effective for transitions between any motion control instructions.

- **Precautions**
  - This instruction only supports absolute circular motion in PCS coordinates.
  - The dimensions of the axis group planning parameters (velocity, acceleration, deceleration, and jerk) depend on the primary dimension set during axis group initialization. Different primary dimension types result in different dimensions and meanings for these parameters, and the parameter units are consistent with the axis group settings for the user.
    - UNIT_TRAJECT position. The input planning parameters are processed according to workspace position planning parameters.
    - UNIT_PERCENT maximum planning parameter ratio. The input planning parameters are processed as a combined ratio coefficient based on workspace pose planning parameters.
  - When the current motion instruction is interrupted, circular motion constructs a transition trajectory in working space along the direction of the velocity at the breakpoint to ensure smooth connection with the subsequent trajectory. This ensures velocity continuity only. However, the acceleration continuity is not guaranteed. For details on the three transition modes supported for aborting, see the motion abort description.
  - The transition trajectory calculation for the aborting instruction is planned according to the acceleration segment parameters set in the instruction. The higher the acceleration segment parameter value, the shorter the transition trajectory and the faster the transition.
  - **If the instruction motion mode is set to an interruption mode and the deceleration distance is insufficient, the function block reports an error. But the axis group does not enter the GroupErrorStop state; the original motion continues to execute.**
  - This instruction can only be initiated when the axis group is in the GroupMoving or GroupStandby state. Attempting to start this instruction in any other state will result in an error.
  - During the execution of this instruction, it can be interrupted by other motion instructions, MC_GroupStop, or MC_GroupHalt.

- After the execution of this instruction, the axis group (AxesGroup) state is changed from GroupMoving to GroupStandby, or remains in the GroupMoving state.
- If the current motion is in a static coordinate system, the axis group is changed from the GroupMoving state to the GroupStandby state. If the current motion is in a dynamic coordinate system, the axis group remains in the GroupMoving state.
- If the motion includes orientation information, the orientation of the intermediate point for the BORDER_ARC three-point arc instruction is ignored; only the orientations of the start and end points are considered.



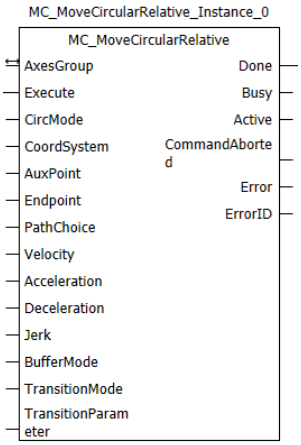
- **Program example**

  The example program for this instruction can refer to the MC_MoveDirectRelative instruction. This instruction can also be combined with other AxesGroup motion instructions.

- **Sequence diagram**

  When "Execute" is started, the output variables "Busy" and "Active" become TRUE. When the target position is reached, the axis group speed becomes 0, the output variable "Done" becomes TRUE, and the output variables "Busy" and "Active" become FALSE.

  An arc interpolation instruction is called to perform interpolation along the X-axis and Y-axis.



- **Faults**

  For faults related to this instruction with specific descriptions, causes and remedies, see the Fault Codes.

18.3.3.5.18 MC_MoveCircularRelative

This enables a circular relative motion for an axis group, executing a circular interpolation from the current TCP position to a relative target position in the specified coordinate system.

- **Instruction format**

Instruction	Name	LD Representation	ST Representation
MC_MoveCircularRelative	Circular relative motion		MC_MoveCircularRelative_Instance_0(AxesGroup := , Execute := , CircMode := , CoordSystem := , AuxPoint := , Endpoint := , PathChoice := , Velocity := , Acceleration :=, Deceleration :=, Jerk := , BufferMode := , TransitionMode := , TransitionParameter := , Done => , Busy => , Active =>, CommandAborted =>, Error =>, ErrorID =>);

- **Related variables**

In-out variables

In-out Variable	Name	Data Type	Valid Range	Default Value	Description
AxesGroup	Axis group	18.3.3.2.4.1 AXES_GROUP_REF: Axis Group Structure	-	-	Mapped to an axis group, which is an instance of AXES_GROUP_REF.

Input variable

Input Variable	Name	Data Type	Valid Range	Default Value	Description
Execute	Execute	BOOL	TRUE, FALSE	FALSE	Execute the instruction on a rising edge.
CircMode	Circular mode	18.3.3.2.4.18 MC_CIRCMODE: Circular Interpolation Mode Enumeration	0, 1, 2	0	0: Three-point arc. 1: Center-point arc. 2: Radius-defined arc.
CoordSystem	Coordinate system type	18.3.3.2.4.19 MC_COORDSYSTEM: Coordinate System Enumeration	ACS, PCS	PCS	Currently only supports PCS.
AuxPoint	Auxiliary point	ARRAY [1..GROUP_DEF.AXIS_NUM] OF LREAL	-	[0,0,…]	For the auxiliary point position (relative to the start point) of each dimension in the specified coordinate system, see Axis group type description.
EndPoint	End point	ARRAY [1..GROUP_DEF.AXIS_NUM] OF LREAL		[0,0,…]	For the end point position (relative to the start point) of each dimension in the specified coordinate system, see Axis group type description.
PathChoice	Path choice	18.3.3.2.4.17 MC_CIRC_PATHCHOICE: Circular Path Choice Enumeration	0, 1	0	This parameter is valid when CircMode is set to CENTER_ARC or RADIUS_ARC arc mode.
Velocity	Velocity	LREAL	> 0	-	Maximum linear velocity. This value may not necessarily be reached.
Acceleration	Acceleration	LREAL	> 0	-	Maximum linear acceleration. This value may not necessarily be reached.
Deceleration	Deceleration	LREAL	> 0	-	Maximum linear deceleration. This value may not necessarily be reached.
Jerk	Jerk	LREAL	>= 0	-	Maximum linear jerk. This value may not necessarily be reached.

Input Variable	Name	Data Type	Valid Range	Default Value	Description
BufferMode	Buffer mode	18.3.3.2.2.6 MC_BUFFER_MODE: Buffer Mode Enumeration	0: mcAborting 1: mcBuffered 2: mcBlendingLow 3: mcBlendingPrevious 4: mcBlendingNext 5: mcBlendingHigh	0	0: mcAborting (Aborting). 1: mcBuffered (Buffered). 2: mcBlendingLow (Blending with the lowest velocity of both FBs). 3: mcBlendingPrevious (Blending with the velocity of the first FB). 4: mcBlendingNext (Blending with velocity of the second FB). 5: mcBlendingHigh (Blending with the highest velocity of both FBs). Note: Buffer modes 2 to 5 currently have the same effect. All are blending modes. The behavior depends on the TransitionMode and TransitionParameter parameters.
TransitionMode	Transition mode	18.3.3.2.4.10 MC_TRANSITION_MODE: Transition Mode Enumeration	0: TMNone 1: TMStartVelocity 3: TMCornerDistance 4: TMMaxCornerDeviation 10: TMDefinedVelocity 11: TMResetAbort 12: TMDecAbort	0	Definition of the transition trajectory characteristic types. When BufferMode is set to MC_ABORTING, only the transition mode parameters TMNone, TMResetAbort, and TMDecAbort are allowed. When BufferMode is set to MC_BUFFERED, the transition mode is invalid. When BufferMode is a blending mode (2 to 5), TMResetAbort or TMDecAbort is not allowed.
TransitionParameter	Transition parameter	LREAL	Velocity [0.0,1.0] Distance [0.0,+∞)	1	Transition parameters vary with the transition mode.

Output variable

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Done	Done	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is done.

Output Variable	Name	Data Type	Valid Range	Default Value	Description
Busy	Executing	BOOL	TRUE, FALSE	FALSE	TRUE when the instruction is received.
Active	Instruction has controlled the axis group	BOOL	TRUE, FALSE	FALSE	TRUE when the axis is being controlled.
CommandAborted	Command aborted	BOOL	TRUE, FALSE	FALSE	Set to TRUE when the instruction is aborted.
Error	Fault	BOOL	TRUE, FALSE	FALSE	TRUE when a fault occurs.
ErrorID	Fault code	DWORD	-	0	A fault code (18.3.3.8 Fault Codes) is output when a fault occurs.

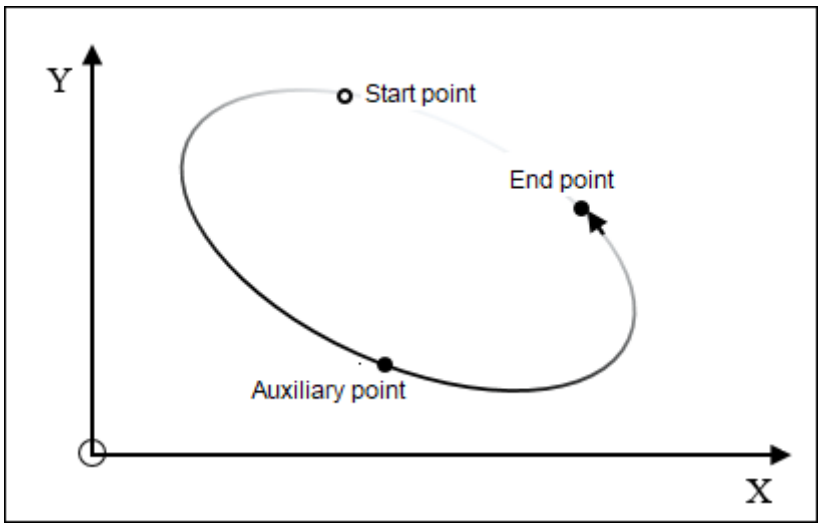
- **Parameter correction**

  Position dimension

Input Variable	Name	Correction Description for Parameter Value Greater than the Software Limit	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Velocity	Velocity	Any velocity that exceeds the motion parameter limit will be automatically corrected to the velocity limit.	Any velocity less than 0 will be automatically corrected to 1e-5.	The velocity equal to 0 will be automatically corrected to 1e-5.
Acceleration	Acceleration	Any acceleration that exceeds the motion parameter limit will be automatically corrected to the acceleration limit.	Any acceleration less than 0 will be automatically corrected to 10% of the acceleration limit.	Any acceleration equal to 0 will be automatically corrected to 10% of the acceleration limit.
Deceleration	Deceleration	Any deceleration that exceeds the motion parameter limit will be automatically corrected to the acceleration limit.	Any deceleration less than 0 will be automatically corrected to 10% of the acceleration limit.	Any deceleration equal to 0 will be automatically corrected to 10% of the acceleration limit.
Jerk	Jerk	For the non-trapezoidal motion profiling, any jerk that exceeds the software limit will be automatically corrected to the jerk limit.	For the non-trapezoidal motion profiling, any jerk that exceeds the software limit will be automatically corrected to 10% of the jerk limit.	For the non-trapezoidal motion profiling, any jerk that exceeds the software limit will be automatically corrected to 10% of the jerk limit.

  Percentage dimension

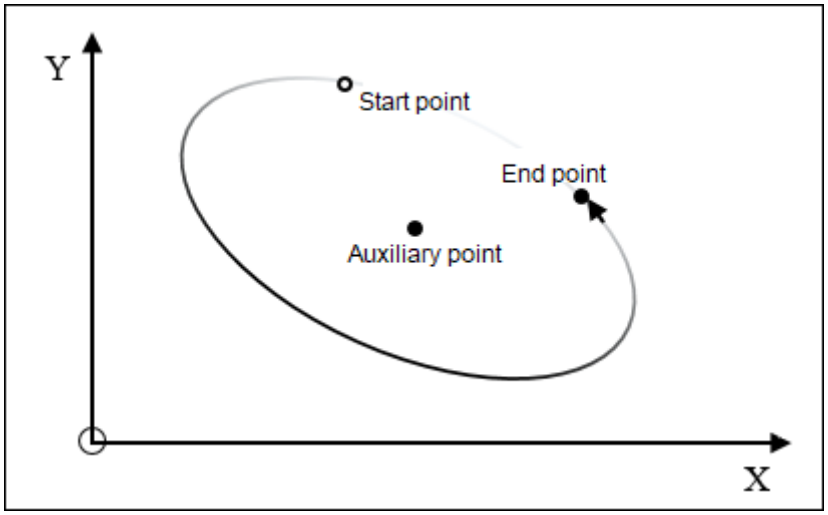
Input Variable	Name	Correction Description for Parameter Greater than 1	Correction Description for Parameter Value Less than 0	Correction Description for Parameter Value Equal to 0
Velocity	Velocity	Any velocity exceeding 1 is automatically corrected to 1.	Any velocity less than 0 will be automatically corrected to 1e-5.	The velocity equal to 0 will be automatically corrected to 1e-5.
Acceleration	Acceleration	Any acceleration exceeding 1 is automatically corrected to 1.	Any acceleration less than 0 will be automatically corrected to 10%.	Any acceleration equal to 0 will be automatically corrected to 10%.
Deceleration	Deceleration	The value exceeding 1 is automatically corrected to 1.	Any deceleration less than 0 will be automatically corrected to 10%.	Any deceleration equal to 0 will be automatically corrected to 10%.
Jerk	Jerk	For the non-trapezoidal motion profiling, the value exceeding 1 is automatically corrected to 1.	For the non-trapezoidal motion profiling, the value exceeding 1 is automatically corrected to 10%.	For the non-trapezoidal motion profiling, the value exceeding 1 is automatically corrected to 10%.



- **Function**
  - This instruction is executed on the rising edge of Execute and performs an absolute arc motion, supporting planar or spatial arcs.
  - CircMode, CoordSystem, AuxPoint, EndPoint, PathChoice, Velocity, Acceleration, Deceleration, Jerk, BufferMode, TransitionMode, and TransitionParameter can be specified in the input variables.
  - For the instruction, blending modes 2, 3, 4, and 5 for BufferMode have the same behavior. The transition effect depends on the TransitionMode and TransitionParameter settings.
  - Supports the same-cycle triggering of instructions. The Done output signal of the instruction serves as the trigger signal for Execute.
  - **AuxPoint**
    - For the axis type corresponding to each position vector in the AuxPoint array, see Axis group type description. Only PCS coordinates are supported.
    - The ABC rotation axes of the coordinate system correspond sequentially to the ZYX-type Euler angles. If the configuration supports orientation motion, the orientation parameters set for the auxiliary points will not be included in the orientation trajectory planning.
  - **EndPoint**
    - For the axis type corresponding to each position vector in the EndPoint array, see Axis group type description. Only PCS coordinates are supported.
    - The ABC rotation axes of the coordinate system correspond sequentially to the ZYX-type Euler angles. If the configuration supports orientation motion, the configured ABC relative positions must be within ±180°, otherwise an error will be generated.
    - In relative motion mode, the rules for calculating the target position of the axis group are shown in the table below.

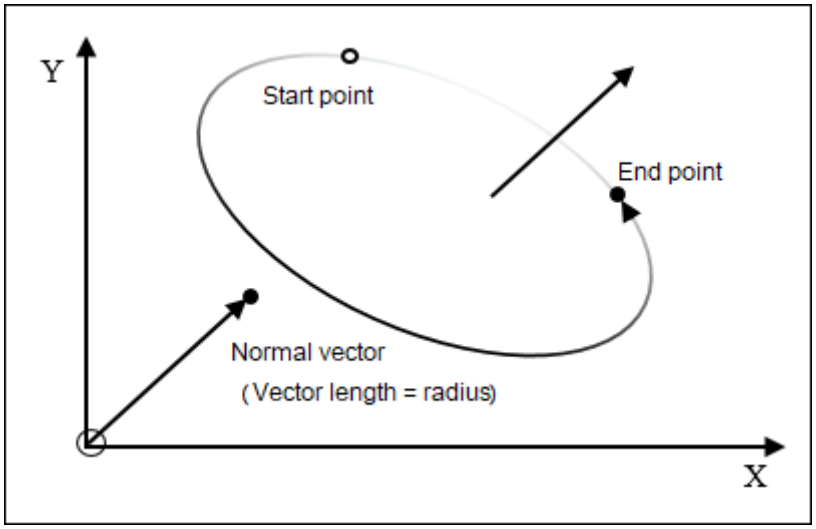
Coordinate system type (calculation of target positions for each axis in the existing axis group configuration)
PCS
X-axis target position = X- axis current position + EndPoint [1]
Y-axis target position = Y-axis current position + EndPoint [2]
Z-axis target position = Z-axis current position + EndPoint [3]
A-axis target position = A-axis current position + EndPoint [4]

- If the A-axis target position is not within ±180°, the system will make the following adjustments: if the A-axis target position is greater than 180°, the system will subtract 360° until the result falls within ±180°; if the A-axis target position is less than -180°, the system will add 360° until the result falls within ±180°. Example: $A_{\text{calculated target position}}$ = 260°, $A_{\text{converted target position}}$ = -100°. Note that for the EVO500 series PLC (version V1.2), when the axis group type is set to "XYZA configuration", the A-axis functions as an auxiliary axis. Its movement is not limited to ±180 degrees. If it exceeds ±180 degrees, the axis continues moving according to the preset position.
- If the target position would exceed any joint axis limit after kinematic transformation into joint space, starting this instruction will cause an error.
- If the configuration supports orientation motion, the axis group will move to the target orientation along the shortest path.



◦ **CircMode**

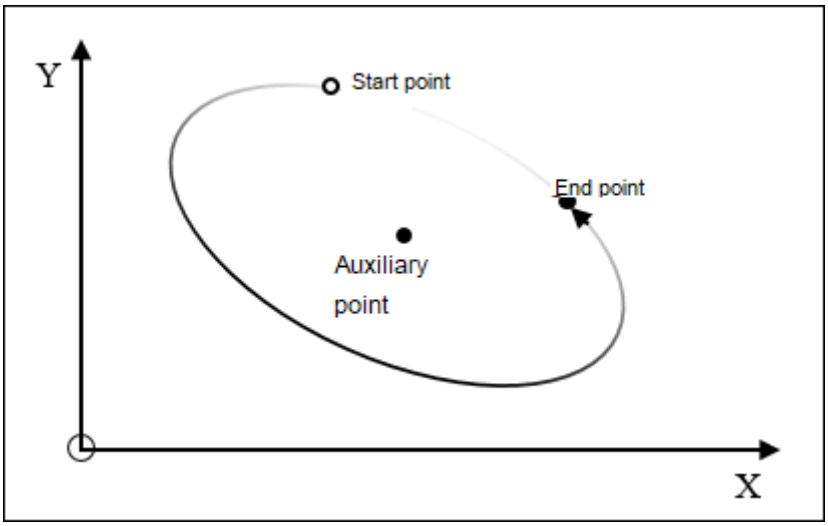
- BORDER_ARC three-point circular arc: a circular arc defined by three points—the current position of AxesGroup as start point, AuxPoint, and EndPoint. **If the three points are collinear or two of them coincide, the trajectory is a straight line connecting the start point and the end point**. If the three points are not collinear, the trajectory is a circular arc passing through the three points in sequence. The range of the arc angle is (0, 2π). The figure shows the composition of a three-point arc in space, with axis Z facing off-screen.

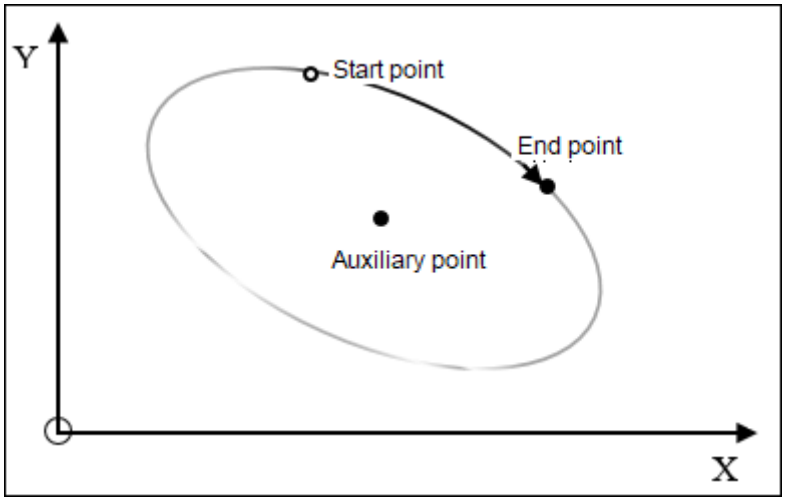


- CENTER_ARC center circular arc: a circular arc is defined by the current position of AxesGroup as start point, AuxPoint as the center, and EndPoint. The arc is specified as either a long arc or short arc through PathChoice. The arc angle range is less than 2π, and the arc angle range is not equal to π. **When the three points are collinear, the trajectory is a straight line.** If the distance between the start point and the end point to the center of the circle deviates too much, an error will be reported. The distance from the start point to the center is named L1, and the distance from the end point to the center is named L2. The center will be automatically corrected if $|L1-L2| < 0.01 \times \min(L1,L2)$.

Exceeding this deviation will trigger an error. (Due to floating-point arithmetic precision issues, no strict equality exists.) The figure shows the composition of a center-point arc in space, with axis Z facing off-screen.

- RADIUS_ARC radius arc: **the radius of the arc is determined by the vector length of** AuxPoint, and the vector direction determines the normal vector of the arc. PathChoice determines whether the arc is long or short. The arc angle range is less than 2π. When the start and end points are not perpendicular to the normal vector, an error will be reported if the deviation angle is too large. If the deviation is small (<10°), the direction of the normal vector will be corrected according to the parameter. If the distance from the endpoint exceeds twice the length of the normal vector and also exceeds one ten-thousandth of the length (that is, radius), an arc error is reported. When the deviation is within one ten-thousandth, the arc radius is corrected to a semicircle. An error is reported when the length of the normal vector or the distance between start and end points is less than the computational precision of 1e-6. **For an axis group configured with only two position axes, AuxPoint[0] indicates the radius of the circular arc. A positive value indicates rotation about the arc's normal axis in the positive direction (typically following the right-hand rule), while a negative value indicates rotation in the opposite (negative) direction.**





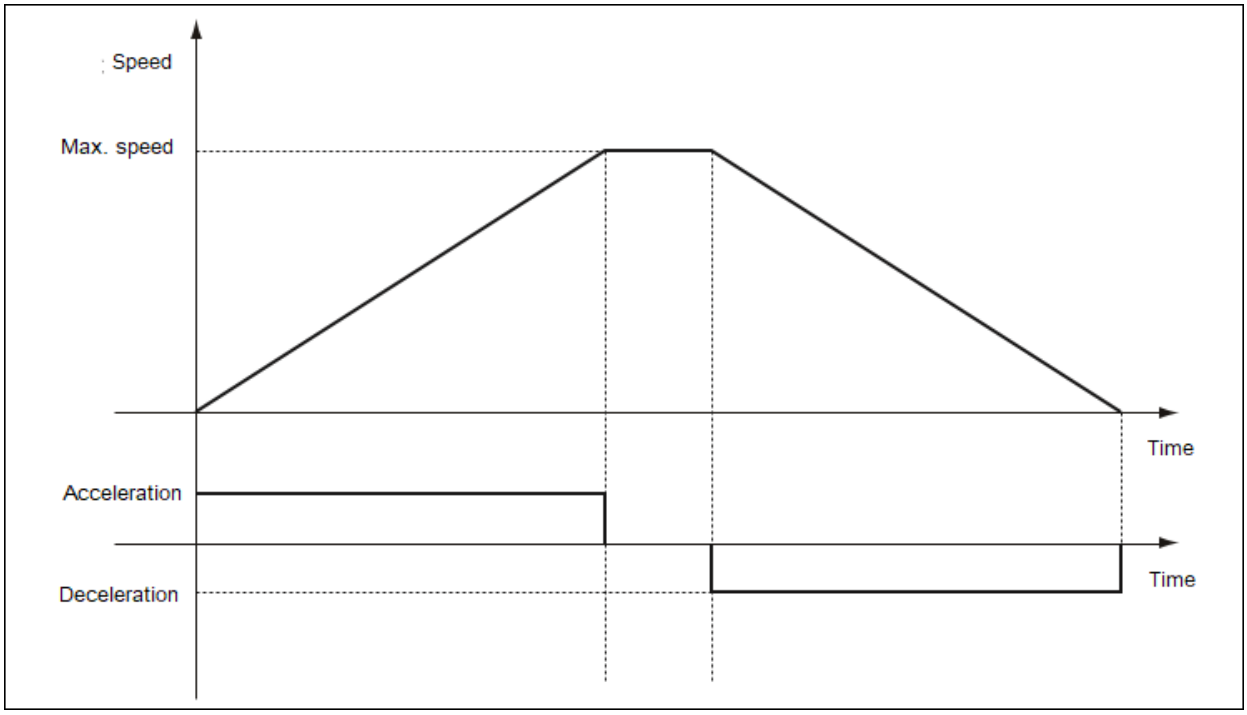
- **CoordSystem**
  - Specify the coordinate system for circular relative motion. Currently, only relative circular motion under the PCS is supported.
- **Velocity constraint**
  - The arc trajectory is bound by the maximum acceleration and deceleration parameters of the system. The centripetal acceleration is kept within limits by restricting the velocity along the trajectory segment. The velocity is constrained as follows:

    Vmax = Sqrt(Amax *R*Ccoef)

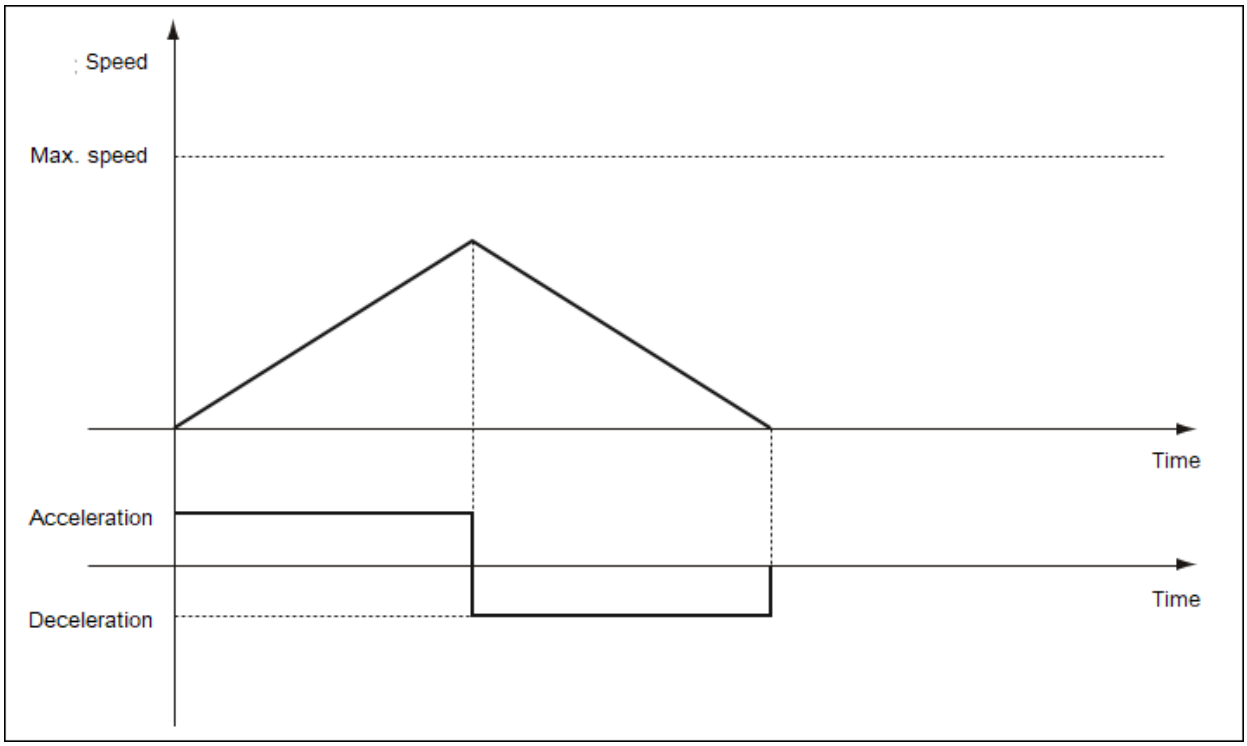
    Here, Ccoef indicates the transition factor, R indicates the arc radius, and Amax indicates the maximum allowable acceleration of the system.
- **PathChoice**

  Depending on the CircMode, there are different choices for the arc direction and length.
  - CENTER_ARC center circular arc: In the figure below, the first setting is the LONG_ARC path, and the second setting is the SHORT_ARC path.

- RADIUS_ARC radius arc: In the figure below, the first setting is the LONG_ARC path, and the second setting is the SHORT_ARC path.

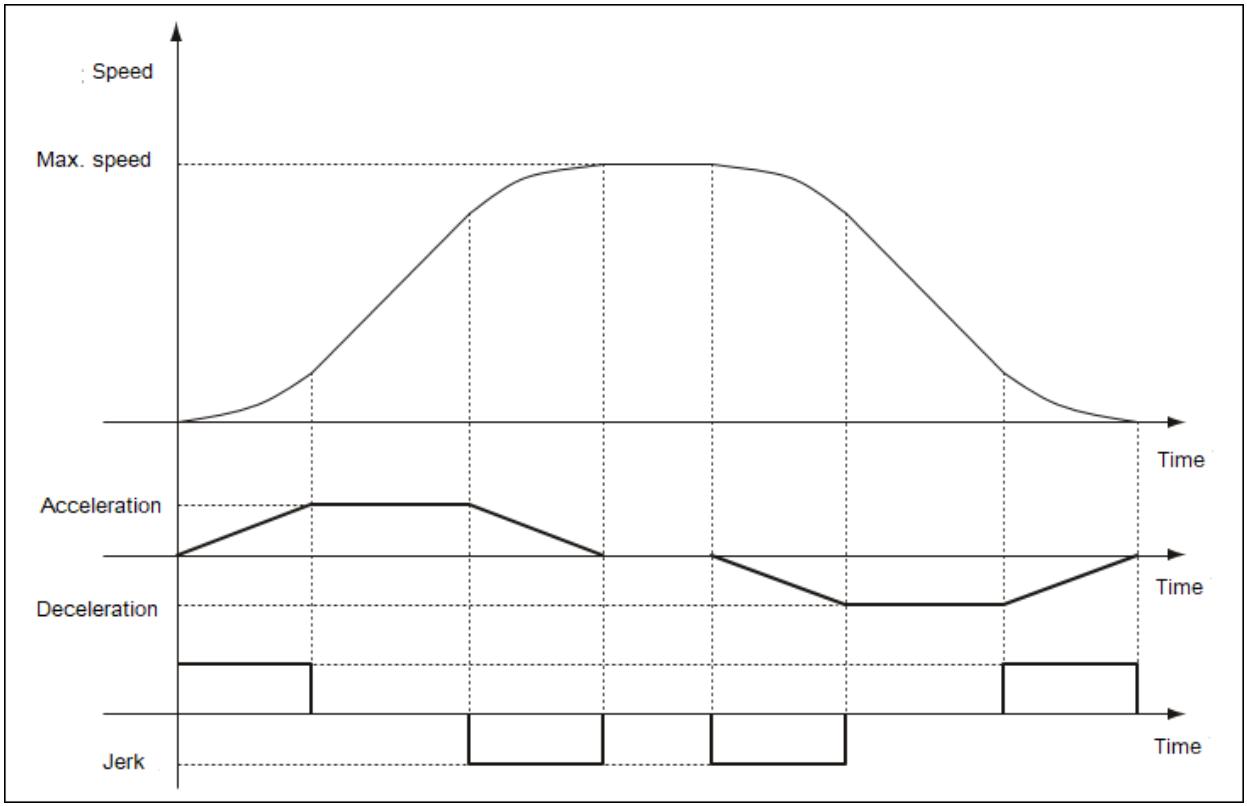


◦ **Velocity, Acceleration, Deceleration, Jerk**

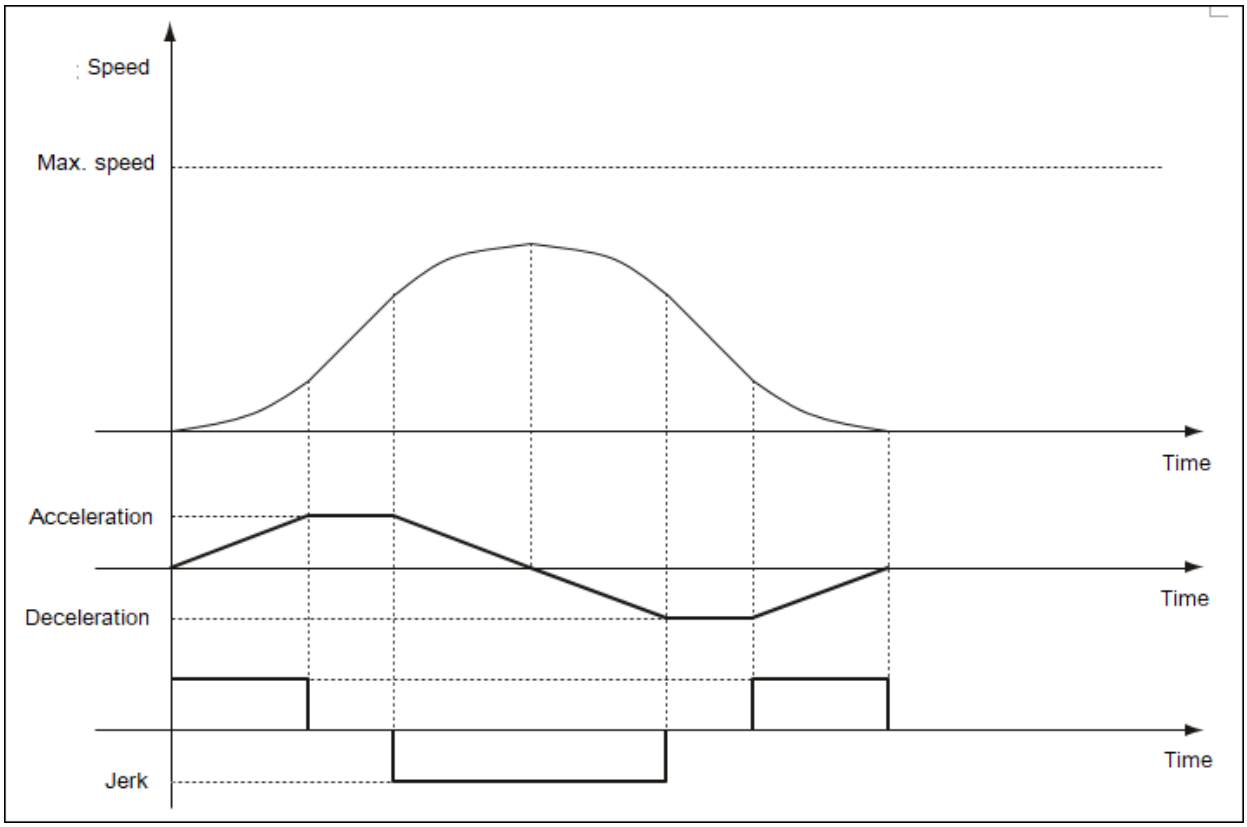


- If the velocity of any Axis variable in AxesGroup exceeds the maximum axis velocity set by the software multiplied by the warning planning scaling factor, it will trigger an error-stop condition.

- The trajectory planning curve type of AxesGroup is set according to requirements. If the planning curve type is a trapezoidal curve, the Jerk variable does not take effect and is treated as 0. (The planning curve type of AxesGroup is specified in the axis group data structure).
- For Jerk = 0 or Jerk ≠ 0, the velocity, acceleration, deceleration, and jerk curves are shown in the figure below.

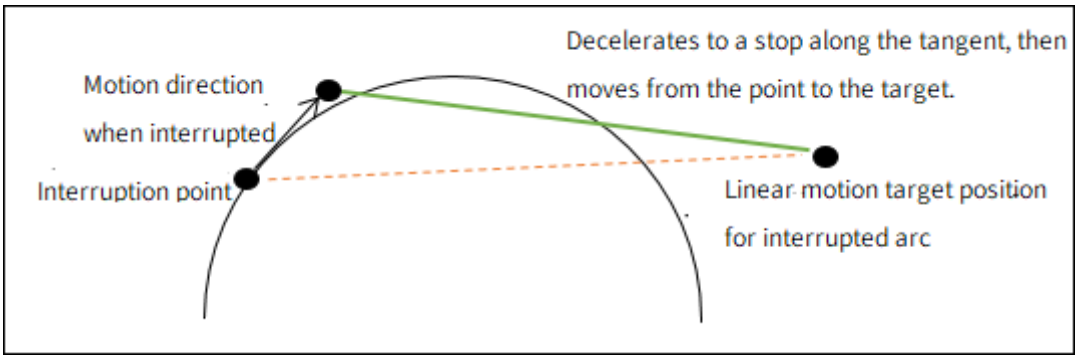


For Jerk = 0, the axis group can reach the maximum interpolation velocity.

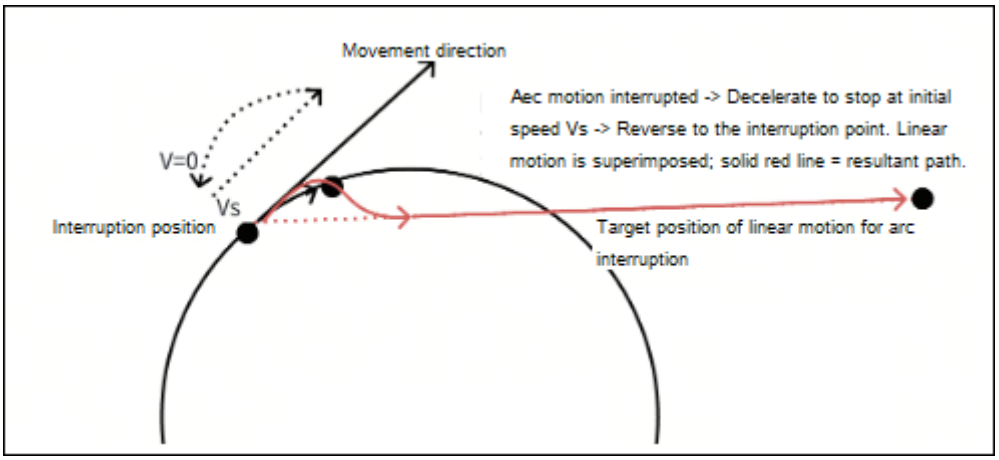


For Jerk = 0, the axis group cannot reach the maximum interpolation velocity due to too short travel distance.

For Jerk ≠ 0, the axis group can reach the maximum interpolation velocity. (Non-trapezoidal planning curve)

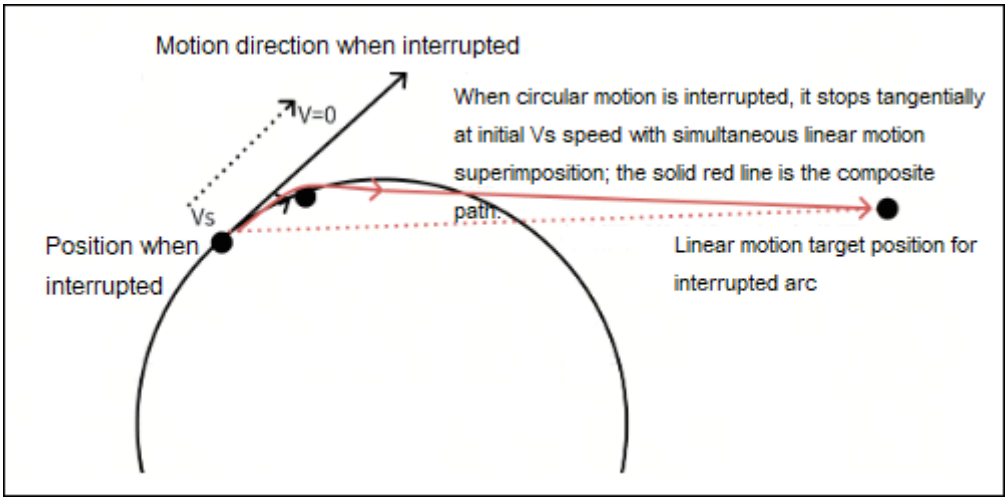


For Jerk ≠ 0, the axis group cannot reach the maximum interpolation velocity due to too short travel distance. (Non-trapezoidal planning curve)

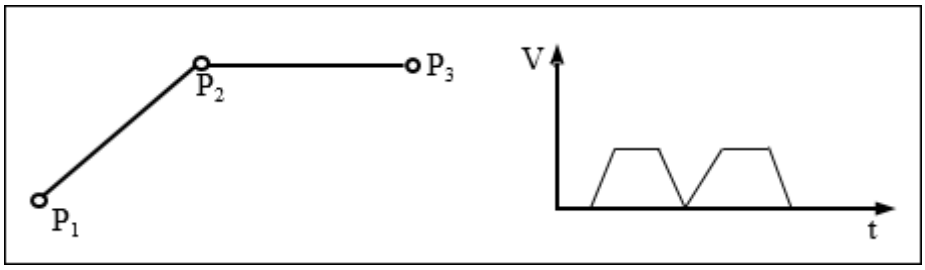


- **Re-triggering the instruction**
  - While the instruction is in motion, that is, when the instruction output parameters "Busy" and "Active" are both TRUE, this instruction cannot be re-triggered.
  - While the instruction is in buffer mode, that is, when Busy is TRUE and Active is FALSE, this instruction can be re-triggered after parameter modification. If the modified parameters are invalid, or if the buffered instruction data has already been used in motion calculations, retriggering the buffered

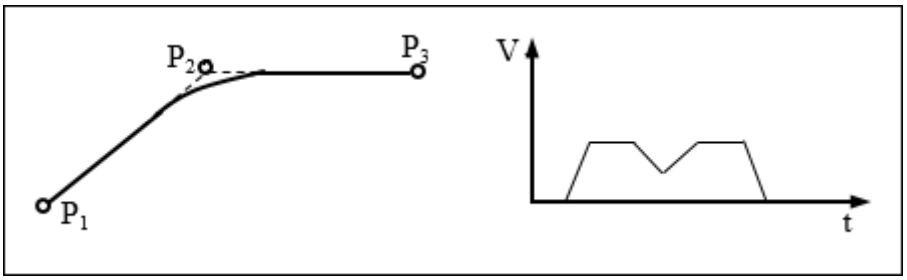
instruction will cause an error. Then, the axis group will enter the GroupStop state, and the currently executing instruction will also report an error.



- **Multiple execution of motion instructions**
  - When this instruction is issued while another motion instruction is being executed, the new instruction can either be switched to immediately or buffered for later execution. Each axis group can buffer up to 8 instructions. In the case of multiple executions, the behavior of this instruction is determined by BufferMode.
  - BufferMode
    - Aborting: MC_ABORTING aborts the currently executing instruction and begins executing this instruction. The abort operation supports three modes, configurable via TransitionMode: TMNone, TMResetAbort, and TMDecAbort.
      TMNONE mode: During execution, the motion decelerates to a stop along the tangential direction from the point of interruption. The next motion segment then starts from this stop point, as shown in the figure below.

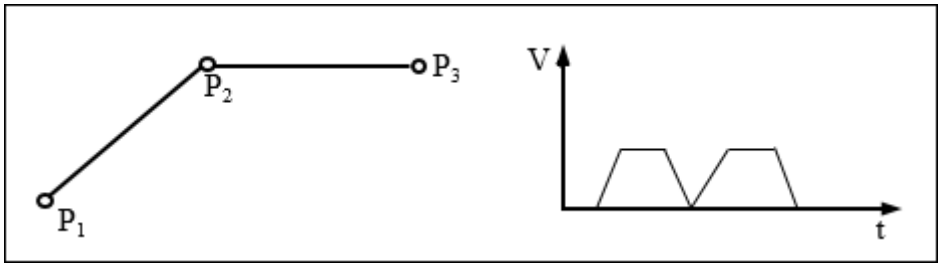


TMResetAbort mode: During execution, the axis decelerates along the tangential direction at the initial velocity of the interruption point, reverses its direction to return to that point, while simultaneously superimposing (blending) with the next motion segment, as shown in the figure below.

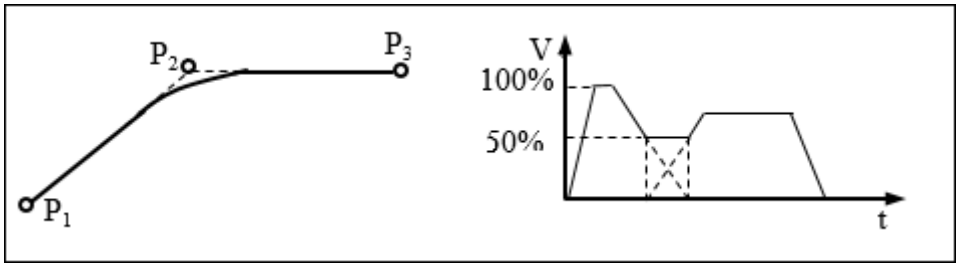


TMDecAbort mode: During execution, the axis decelerates to 0 along the tangential direction at the initial velocity of the interruption point, while simultaneously superimposing (blending) with the next motion segment, as shown in the figure below.

- Buffer: MC_BUFFERED, this instruction is buffered and executed after the current instruction is completed.



- Blending: MC_BLEND, the velocities of the two adjacent instructions are blended in the specified manner. This manner is specified in TransitionMode.



◦ TransitionMode
