<tr><td>3</td><td>Select import target</td><td>Select the target variable table.</td></tr>
</table>

Step	Operation	Description
4	Confirm import result	The result of importing variables will be displayed in a pop-up window. • Import failed Caused by the sheet tab title not being "Variable".  • Import completed with errors Variable information in the table is abnormal (e.g., incomplete data).; Details are recorded in the log file.  • Import completed Variable information in the table is valid. All is imported. 
5	Import ended	If there are errors in the import result, handle according to the log content. When the import target conflicts with the name of an existing variable table, only the variable will be imported; when there is no conflict, the corresponding node will be created and the variable will be imported. For variable import rules, see 13.2.6.2 Importing and Exporting Variables.

Exporting a variable table

Variable tables support single and batch export, with export format as xlsx.

Batch selection of variable tables and variable groups supports Ctrl or Shift keys. Variable table export is performed via the corresponding command in the right-click menu. If a table with the same name exists in the storage path, it will be overwritten.

13.2.4.4 Copying and Pasting a Variable Table

Copy

Select the object to be copied in the project tree, and trigger copying via the right-click menu command or Ctrl+C.

Paste

Pasting can be performed by selecting the "Variable" node or "Variable group" node.

When pasting a variable table, "_n" is appended to the name by default, with n starting at 1 and incrementing automatically.

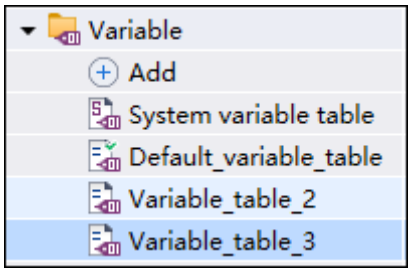

Figure 13-2-4-4-1 Paste result

13.2.4.5 Deleting a Variable Table

Regular variable tables support deletion. When a variable table is deleted, all variables within it will also be deleted.

Variable tables support single or batch deletion. Select multiple target variable tables using the **Ctrl** or **Shift** key, and then delete via the right-click menu command or the **Delete** key.

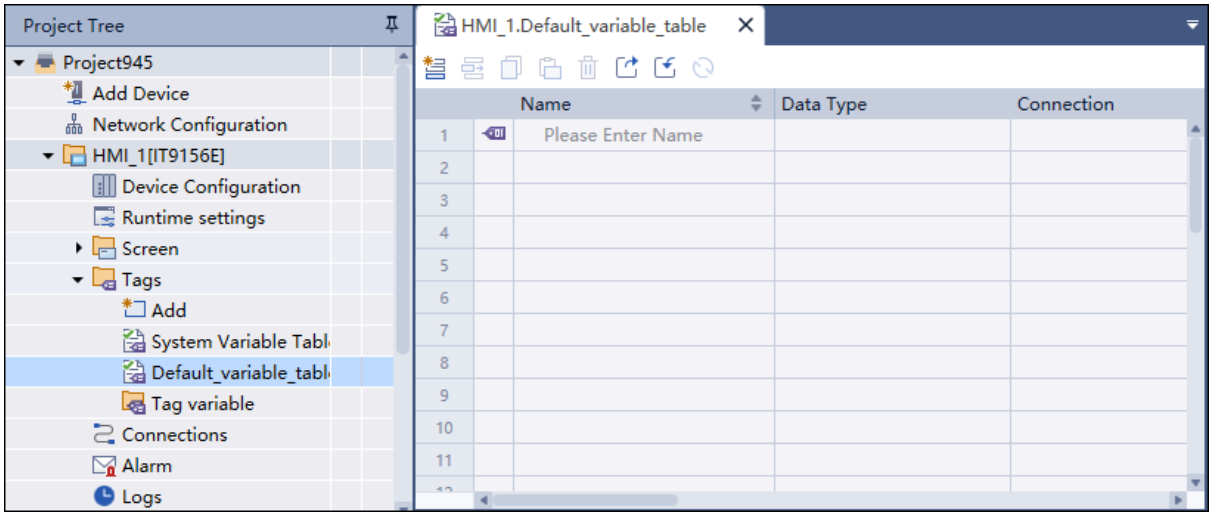
13.2.5 Configuring Variables

- 13.2.5.1 Adding an Internal Variable
- 13.2.5.2 Adding an External Variable
- 13.2.5.3 Setting Variable Properties
- 13.2.5.4 Setting Properties in Batch
- 13.2.5.5 Multiplex Variables
- 13.2.5.2.3 Synchronizing Variable Names
- 13.2.5.6 Storing Variable Data
- 13.2.5.7 Configuring Variable Events

13.2.5.1 Adding an Internal Variable

Internal variables are stored within the HMI device and have no connection to the PLC. Internal variables are used to monitor internal system calculations.

Internal and external variables are distinguished by **connection** property. For example, in the figure below, Var1 is an internal variable and Var2 is an external variable.



Both the 13.2.2 Default Variable Table and the regular variable table support adding internal variables. For details on adding a regular table, see 13.2.4.2 Adding a Variable Table.

This section takes the default variable table as an example to illustrate the method for adding internal variables.

1. Open the variable table editing window.

   Double-click the "Default variable table" node in the **project tree**.

2. Add variables.

   Variables are managed in a list format, with each row representing one variable, identified by .

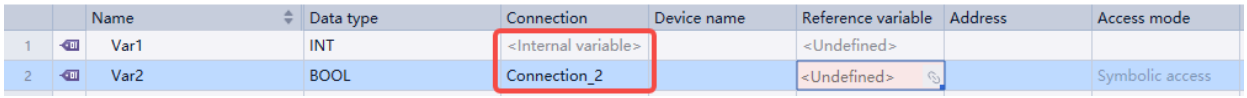
Number	Procedure	Example
One	Manual input: Double-click the text box Please Enter Name, enter a valid variable name, and press Enter to add the variable. The software will automatically fill in the **data type** with the default value.	Var_example INT
One	Command input: Select or to add a variable. The variable name and data type are filled with default values. The name is named as Tag_n, where n starts at 1 and increments automatically.	Tag_1 INT

Number	Procedure	Example
Multiple	Click on the name of an existing variable, drag the square at the lower-right corner of the cell downward , and select "Insert new variable" to add a new variable. The new variable will copy all properties from the target variable (e.g., Tag_1), including alarm, recording, and event configurations. The software automatically checks for duplicate variable names. Non-consecutive variable numbers indicate missing entries exist in other variable tables of the current device.  Add or insert new variables in the drop-down area. Existing variables will shift down automatically.	
Multiple	Variables can also be added by batch import. For details, see Importing variables.	-

Once an internal variable is added, it can be applied in the project configuration.

13.2.5.2 Adding an External Variable

- 13.2.5.2.1 Adding an External Variable
- 13.2.5.2.2 Naming an External Variable
- 13.2.5.2.3 Synchronizing Variable Names



13.2.5.2.1 Adding an External Variable

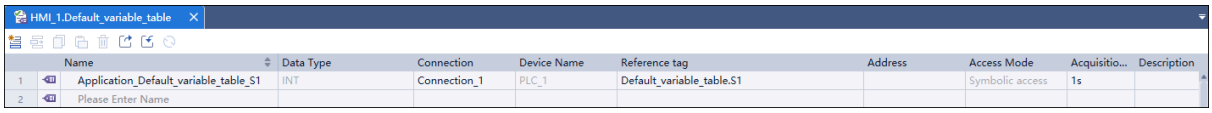
Introduction

External variables can access PLC addresses through PLC variables. Addressing is performed in the following ways:

- Symbolic addressing
- Absolute addressing

Internal and external variables are distinguished by **connection** property. For example, in the figure below, Var1 is an internal variable and Var2 is an external variable.

Both the 13.2.2 Default Variable Table and the regular variable table support adding external variables. For details on adding a regular table, see 13.2.4.2 Adding a Variable Table.

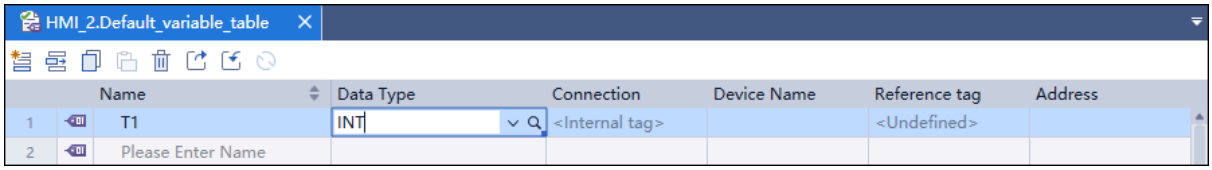


Requirements

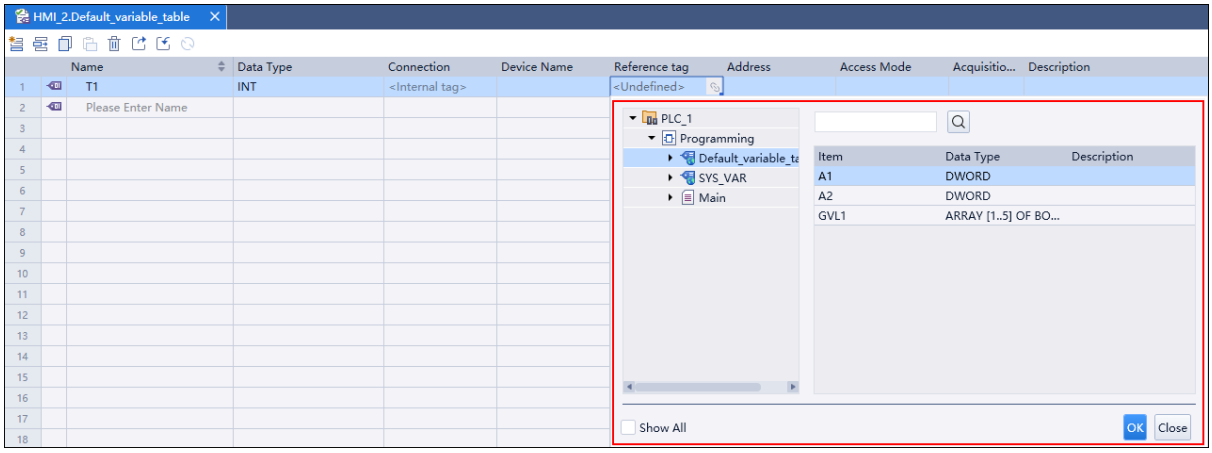
- The HMI and PLC belong to the same project.
- The HMI has been added.
- The PLC has been added and variables have been made public.

Add by drag-and-drop

This section takes the default variable table as an example to illustrate the method for adding external variables.



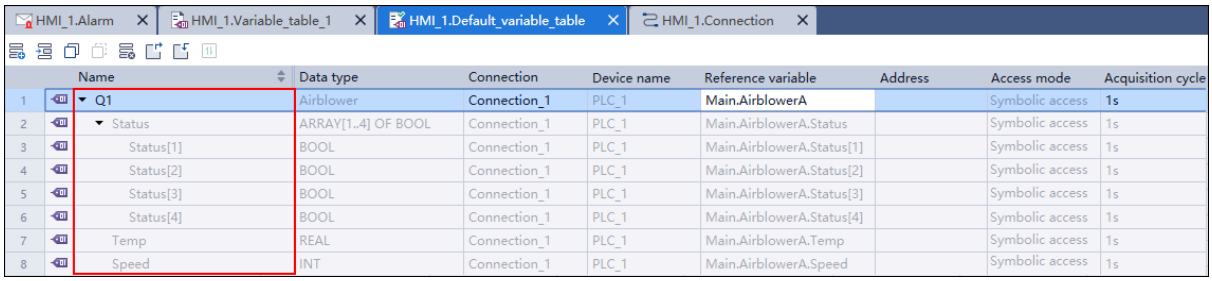
1. Open the default variable table on the HMI side
2. In the project tree, select the node containing the PLC public variables. The corresponding variable list will be displayed in the "Details" area. For example, PLC variable S1 is of INT type and public read-only.
3. Select the desired PLC public variables and drag them to a blank row in the default variable table on the HMI side.
   The system will automatically generate corresponding external variables. The default variable name is generated based on the connection configuration. For details, see 13.2.5.2.2 Naming an External Variable. For example, the name **Application_Default Variable Table_S1** may be automatically generated.



Add by reference

This section takes the default variable table as an example to illustrate the method for adding external variables.

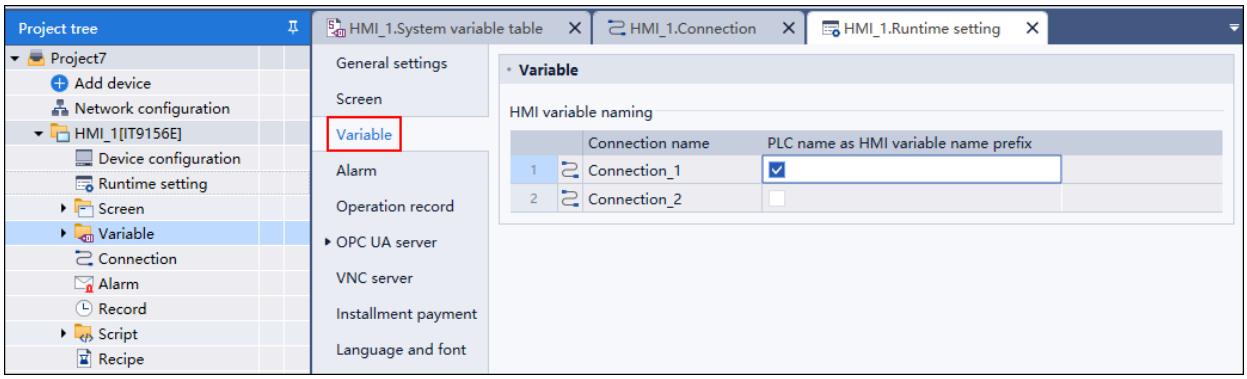
1. 13.2.5.1 Add an internal variable
   For example, add an INT variable T1.



2. Select a reference variable
   Select the reference variable cell, and click to open the variable selection window.

3. Select the target variable and confirm
   The data type of the internal variable will automatically adjust according to the type of the referenced variable to ensure consistency in data types. For example, in step 2, if T1 references a variable A1 of type

DWORD, the data type of T1 will automatically be set to UDINT.
For array types (including arrays of basic types, arrays of structures, and nested arrays within structures), the total number of referenced elements must not exceed 2,000.
For structure types, the total number of referenced members must not exceed 20,000.
For example, if the internal variable Q1 references an array of structures named AirblowerA, the number of sub-members is 6.



4. Click the synchronization button to make the HMI-side variable name consistent with the referenced variable name. For details, see 13.2.5.2.3 Synchronizing Variable Names.

An external variable has been added and mapped to a variable in the PLC.

13.2.5.2.2 Naming an External Variable

External variable names in the HMI can be configured. The configuration is done on the "Runtime setting" interface of the device.

For HMI and PLC in the same project, the HMI external variable name depends on the "PLC name as HMI variable name prefix" setting and how it is added.

Add by direct drag-and-drop

When you drag variables from PLC to the HMI variable table or screen, the HMI variable naming is determined by the "PLC name as HMI variable name prefix" setting.

- Checked: Variable name prefix will be added

Prefix	Naming Format	Applicable Device Driver
PLC device name	**PLC device name**_Application_PLC variable table name_PLC variable name For example, PLC1_Application_GVL_Relay connect	• Inovance Ethernet/IP Tags Protocol • Inovance AC800 Tags Protocol (AC/AI/AM/AP Series)

Prefix	Naming Format	Applicable Device Driver
PLC device name	**PLC device name**_PLC variable name For example, PLC1_Relay connect	• Omron EtherNet/IP (NJ/NX/NY Series) • Rockwell (AB) EtherNet/IP • OPC UA, OPC UA Client

- Unchecked: No variable name prefix will be added

Add by manual association

When you manually associate HMI internal variables with PLC variables, the HMI variable naming is not affected by the"PLC name as HMI variable name prefix" setting.

You can use the "13.2.5.2.3 Synchronizing Variable Names" command to automatically add a prefix to match the PLC variable name.

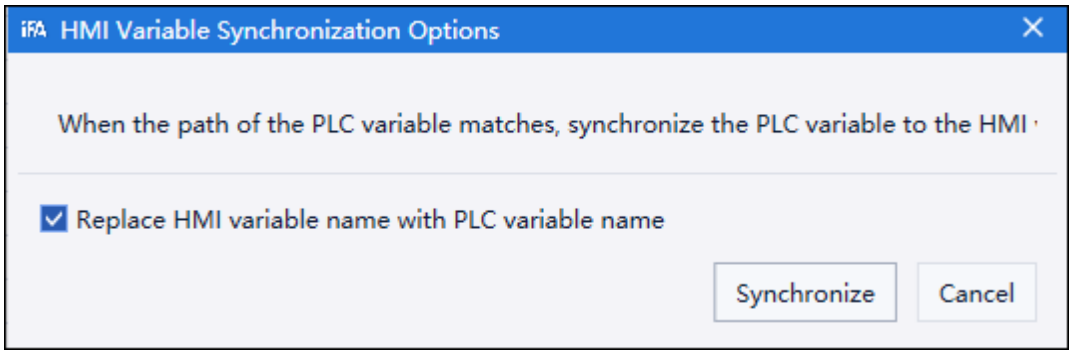
13.2.5.2.3 Synchronizing Variable Names

When the PLC and HMI are in the same project, the "Sync PLC variables" function ensures HMI variable names match PLC variable names.

Requirements

- The PLC variable name and HMI variable name for an external variable are inconsistent.
- The "Network public" property of the PLC variable is not "Private".
- Synchronization with PLC tag variable names is not supported.

Synchronization result



- Re-establish the reference relationship from HMI variables to PLC variables.
- Rename the HMI variables using the PLC variable names, with the naming format determined by the device configuration. For details, see 13.2.5.2.2 Naming an External Variable.
- Synchronize the number of structure variable members.

Synchronization operation for a single variable table

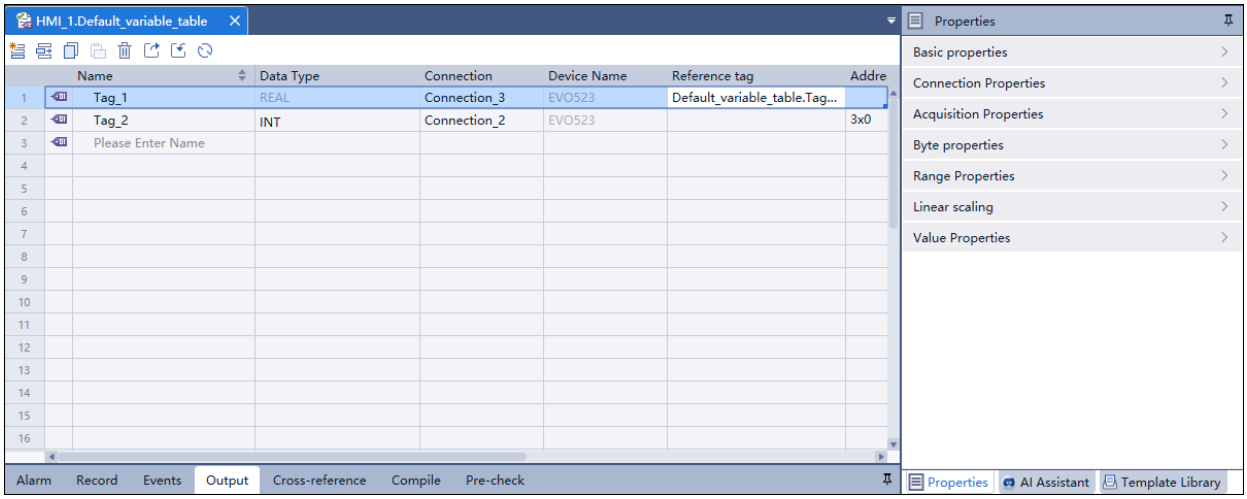
1. Select the external variables to be synchronized from the variable table.

	Name	Data Type	Connection	Device Name	Reference tag	Address	Access Mode
16	T1	UDINT	Connection_3	PLC_1	Default_variable_table.A1		Symbolic access
17	Tip	STRING	<Internal tag>		<Undefined>		
18	P1	INT	<Internal tag>		<Undefined>		
19	Array1	ARRAY[1..3] OF BOOL	<Internal tag>		<Undefined>		
23	Please Enter Name						

2. Click the button to set the synchronization scope.
   Click the "Synchronize" button to open the synchronization option settings window.

If synchronization options are unchecked, only variable references are re-established. If checked, variable names are also updated in addition to reference setup.

3. Complete the synchronization
   For example, the variable name replacement result is shown in the figure below.



Synchronization operation for the entire device

1. Select the variable node of the HMI device.
2. In the quick menu, select "Sync PLC variables".
3. Synchronize the corresponding content based on the option settings. For detailed description, see step 2 in Synchronization operation for a single variable table.
4. Check the synchronization result.

13.2.5.3 Setting Variable Properties

All properties of variables added in the default variable table and the regular variable table are displayed in the right-side panel. You can modify variable information in the table or in the right-side property panel.

Internal and external variables have different property items. The following is a comprehensive description of their property items. You can select the corresponding parameter description based on the selected variable type.

Basic properties

- Name
  It is the unique identifier of variables in the software, and the naming rules are:
  (1) Consist of Chinese characters, letters, numbers, spaces, and special characters
  (2) Spaces cannot be placed at the beginning or end
  (3) Support a maximum length of 128 characters
  (4) Names are case-insensitive
  (5) The default is "Tag_n", where n starts at 1 and increments automatically.

- Description
  The description of variables. Up to 128 characters is supported.
- Data type
  Data type supports basic types and complex types. If the data types of internal variables and referenced variables are inconsistent, the internal variable will automatically adjust to ensure consistency.
  - Basic types

Category	Data Type	Value Range	Length	Memory Usage
Boolean	BOOL	TRUE, FALSE	1-bit	1 bytes
Integer	SINT	-128 to 127	8-bit	1 byte
	USINT	0 to 255	8-bit	1 byte
	INT	-32768 to 32767	16-bit	2 bytes
	UINT	0 to 65535	16-bit	2 bytes
	DINT	-2147483648 to 2147483647	32-bit	4 bytes
	UDINT	0 to 4294967295	32-bit	4 bytes
	LINT	-9223372036854775808 to 9223372036854775807	64-bit	8 bytes
	ULINT	0 to 18446744073709551615	64-bit	8 bytes
Floating-point number	REAL	-3.402823e+38 to -1.175495e-38 ±0.0 +1.175495e-38 to +3.402823e+38 +∞/-∞	32-bit	4 bytes
	LREAL	-1.7976931348623157e+308 to -2.2250738585072014e-308 ±0.0 +2.2250738585072014e-308 to +1.7976931348623157e+308 +∞/-∞	64-bit	8 bytes

Category	Data Type	Value Range	Length	Memory Usage
String	STRING	Encoding format is UTF-8. Supports 0 to 255 bytes. Any excess will be truncated.	/	Each character occupies 1 to 4 bytes. English letters and numbers generally occupy 1 byte.
	WSTRING	Encoding format is UNICODE. Supports 0 to 255 characters. Any excess will be truncated.	/	Each character occupies 2 bytes.
Time	DATETIME	1970-01-01-00:00:00.000 to 9999-12-31-23:59:59.999 Default format: yyyy-mm-dd-hh:mm:ss	4 bytes	4 bytes
	TIME	0ms to 71582m47s295ms	32-bit	4 bytes
	LTIME	0ms to 213503d23h34m33s709ms551μs615ns	64-bit	8 bytes
	TIME_OF_DAY(TOD)	00:00:00.000 to 23:59:59.999	32-bit	4 bytes
	DATE	1970-01-01 to 2106-02-07	32-bit	4 bytes
	DATE_AND_TIME(DT)	1970-01-01 00:00:00 to 2106-02-07 06:28:15	32-bit	4 bytes

NOTE

HMI devices cannot directly create internal variables of the time types: TIME, LTIME, TIME_OF_DAY (TODAY), DATE, and DATE_AND_TIME (DT). However, these types can be added successfully when referencing public variables from EVO series PLCs.

◦ Complex types

Category	Restrictions
Array	Both internal and external variables can be defined as arrays. When configuring external variables as an array, the following conditions must be met. ▪ Total number of elements does not exceed 20,000. ▪ Basic type elements are supported (see the table above). ▪ Nested arrays are not supported. ▪ Communication driver is the EtherNet/IP protocol.
Alias	The data type of external variables will be displayed as the original type of the alias. Alias variables for HMI communication are only supported for PLCs that are configured in the iFA software.
Enumeration	The data type of external variables will be displayed as integer types defined by enumeration, such as INT, LINT, and SINT. Enumeration variables for HMI communication are only supported for PLCs that are configured in the iFA software.
Structure	Either internal or external variables can be defined as structure types. Internal variables: Created by instantiating HMI User-Defined Types (located in the template library). External variables: Reference the PLC's structure variables. The communication driver must be the EtherNet/IP protocol.

- Alarm group
  Select the target alarm group. For details on adding alarm groups, see 13.5.5 Alarm Group Configuration.
- Length
  The length of string type can be configured, with a range of 1 to 255 characters, defaulting to 80.

Connection property

- Reference variable
  The associated variable must meet the following conditions to establish a mapping relationship between the current variable and the PLC variable.
  ◦ When the PLC where the variable resides and the monitoring device belong to the same project, the public property of the variable must be set to a value other than "Private".
  ◦ Tag variables import are supported.
  ◦ Only a single element of an array can be associated.

  When the PLC is not connected to the monitoring device, the software automatically creates a connection between them by associating a variable of the PLC. For more information, see Automatically establishing a connection via variable table.
- Connection
  The connection name is automatically filled based on the referenced variable.

- Device name
  The device name is automatically filled based on the referenced variable.
- Address
  The device driver type of the connection determines the address settings. Address configuration is supported when the access mode is set to absolute access.
  The address format generated by different **device drivers** (communication protocols) varies:

Communication Object	Address Format	Example
Mitsubishi FX3U/FX3UC/FX5U/Q series	Area address	SM 0
Siemens S7-1200/S7-1500 series	%Area address %Area address.Bit	%MW0 %QX0.5
Inovance AM/AC/MD/EVO series		
Inovance H5U/Easy series	Area address	R17

  When the connected device driver is changed, the address automatically reverts to its initial value. For example, **%QX3.0** in the figure automatically adapts to **%QX0.0**.

	Name	Data Type	Connection	Device Name	Reference tag	Address	Access Mode
1	Fan_start	BOOL	Connection_PLC2	PLC2		%QX3.0	Absolute Access

- Access mode
  The access mode depends on the connection creation method and the connected device driver.
  Symbolic access: When a variable is associated with an identified connection or the connected device driver supports EtherNet/IP protocol, the access mode is displayed as symbolic access.
  Absolute access: When a variable is associated with an identified connection or the connected device driver supports Modbus TCP protocol, the access mode is displayed as absolute access.

Range property

Range upper/lower limit: Sets the measuring range.

Acquisition property

Acquisition cycle: The time interval at which the HMI device reads data from other devices. Configuration range: 50 ms to 3,600,000 ms.

CAUTION

When an IT9000 series device communicates with an EVO1000 series PLC, if the acquisition cycle of the communication variable is set to less than 500 ms, the new value may flicker after being written via the screen (symptom: the new value briefly jumps back to the old value before being written, and then returns to the new value). To avoid this phenomenon, it is recommended to set the acquisition cycle to 500 ms or longer.

Byte property

High/Low byte swap: Set as required for the field application. Supported data types: UINT, INT, UDINT, DINT, ULINT, LINT, REAL, and LREAL.

Linear scaling

Configures the value ranges for connection object variables and HMI variables to derive the conversion relationship between value. Supported data types: USINT, SINT, UINT, INT, UDINT, DINT, ULINT, LINT, REAL, and LREAL.

Numeric property

Initial value: Value displayed between downloading the variable configuration to the monitoring device and acquiring the first set of data.

Retain

Retention of internal variables: Determines how internal variable values are selected when the device recovers from an error.  Restore to value before error; Restore to initial value

These settings affect the behavior of the **"Retain the variable's current value"** option in the "Save As Target File" dialog. For details, see 13.13.2 Saving As Compiled File.

13.2.5.4 Setting Properties in Batch

Variable properties support batch processing. You can hold and pull down the square 

in the lower right corner of the cell () to select the range for batch processing.

In the pop-up "Reminder" window, select "**Cover**" to complete batch modifications of multiple rows of properties.

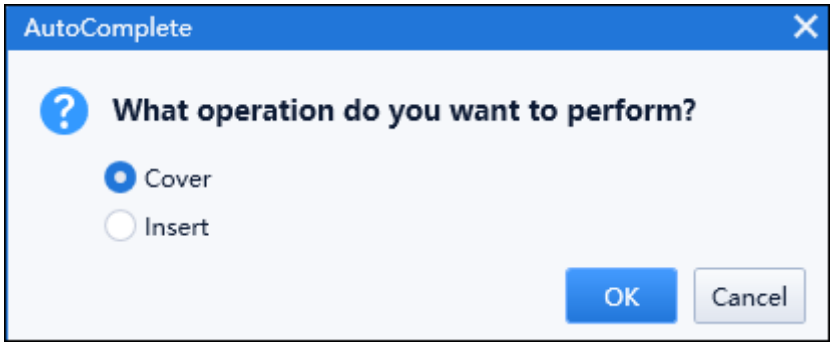


Figure 13-2-5-4-1 Set operation method

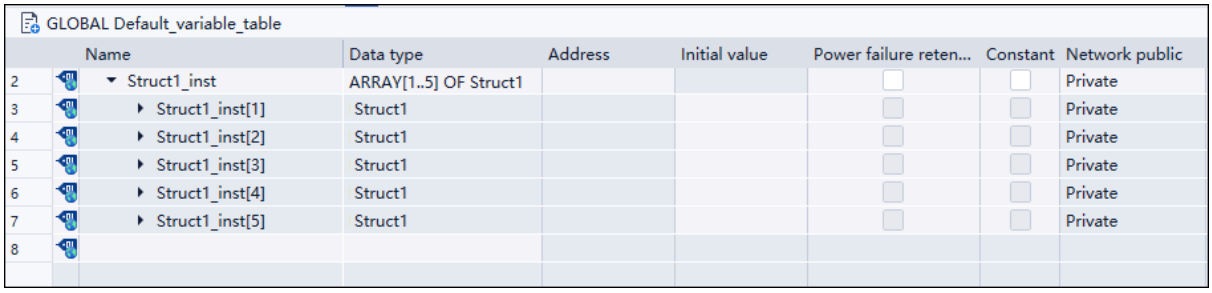
13.2.5.5 Multiplex Variables

Multiplexed variables access multiple PLC memory locations within an address range using a single variable, enabling read/write operations without defining individual variable for each address.

When multiplexing with symbolic addressing, multiplexed variables and index variables can be used to access different elements of array variables of the connected PLC.

Prerequisites

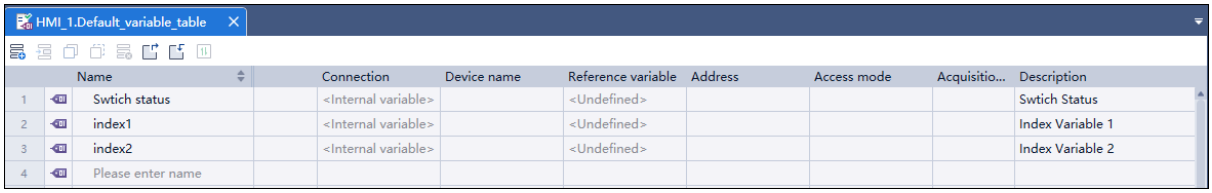
- Support one-dimensional arrays with standard data types.
- Up to two index variables can be configured by default, which are the first two indices of the array, for example, 1 and 2 in **Struct1_inst[1].A[2].**



- Support communication protocols: Inovance EtherNet/IP Tags protocol and AC 800 Tags protocol.

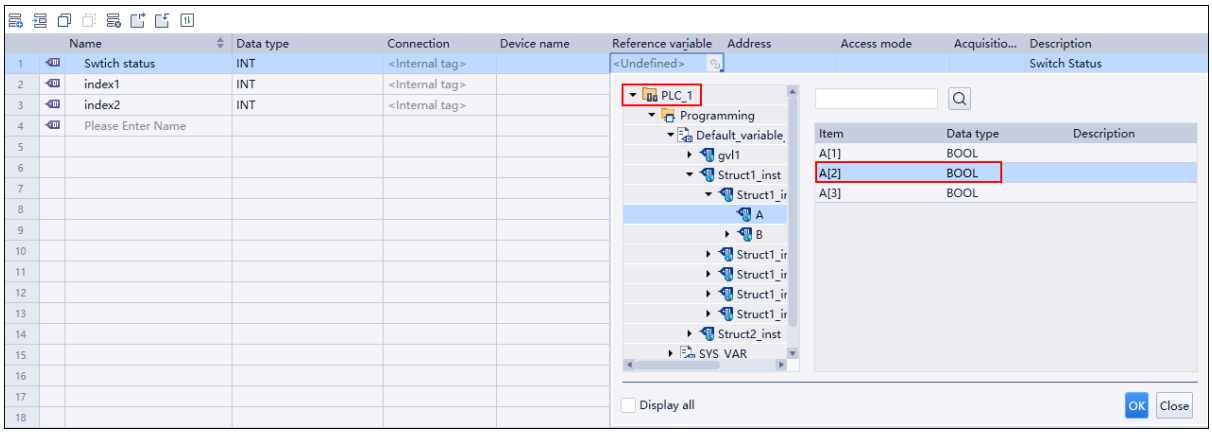
Requirements

The PLC device and HMI device have been added.

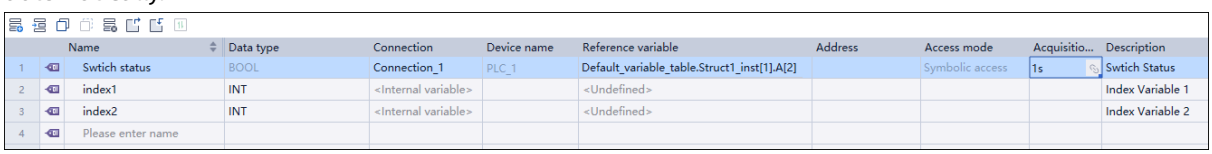


Operation

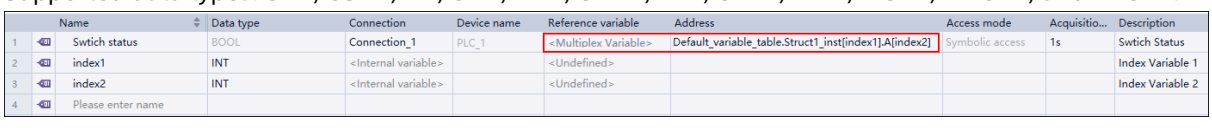
1. Add a one-dimensional array variable in the PLC
   Add a one-dimensional array variable in the variable table under the "Programming" node of the PLC device. For example, add a one-dimensional array named **Struct1_inst** in the default variable table, with data type as user-defined structure **Struct1**.



2. Set the "Network public" property of the one-dimensional array, for example, set it to **read-only**.



3. In the variable table under the "Variable" node of the HMI device, add three regular variables. For example, add regular variables named **Switch status, index1**, and **index2** in the default variable table.



4. Associate PLC variables with reference variables, for example, associate **Switch status** with the variable **Struct1_inst[1].A[2]** in the **default variable table** of PLC_1 device.

Select "OK" and enter the "Reference variable". The connection between PLC_1 and HMI_1 will be created automatically.

5. Set the index address of the reference variable
   In the address cell of **Switch status**, use variables index1 and index2 to control access to array element indexes.
   Supported data types: SINT, USINT, INT, UINT, DINT, UDINT, LINT, ULINT, BYTE, WORD, DWORD, and LWORD.

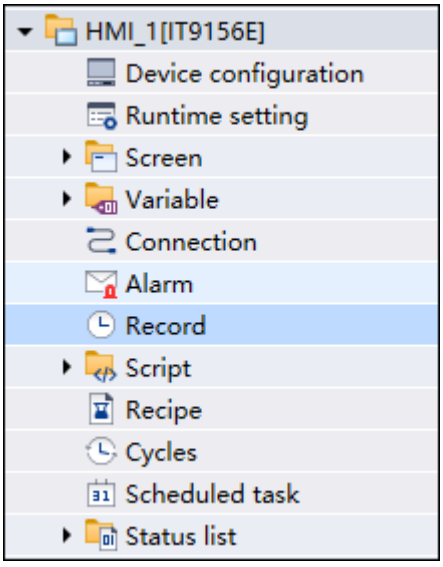
The reference variable location for **Switch status** is identified as **<Multiplex Variables>**.

> NOTE
>
> If an index variable is accidentally deleted during configuration without error clearing, compilation or saving, its association will be automatically restored when a new variable with the same name is created or an existing variable is renamed to the index variable name.

During online operation, if the index variable value exceeds the sub-element index range of the multiplexed variable:

- The multiplexed variable value is abnormal and marked .
- In the F(t) curve view, the historical trend is connected by a line from the moment the range is exceeded until it returns to normal.

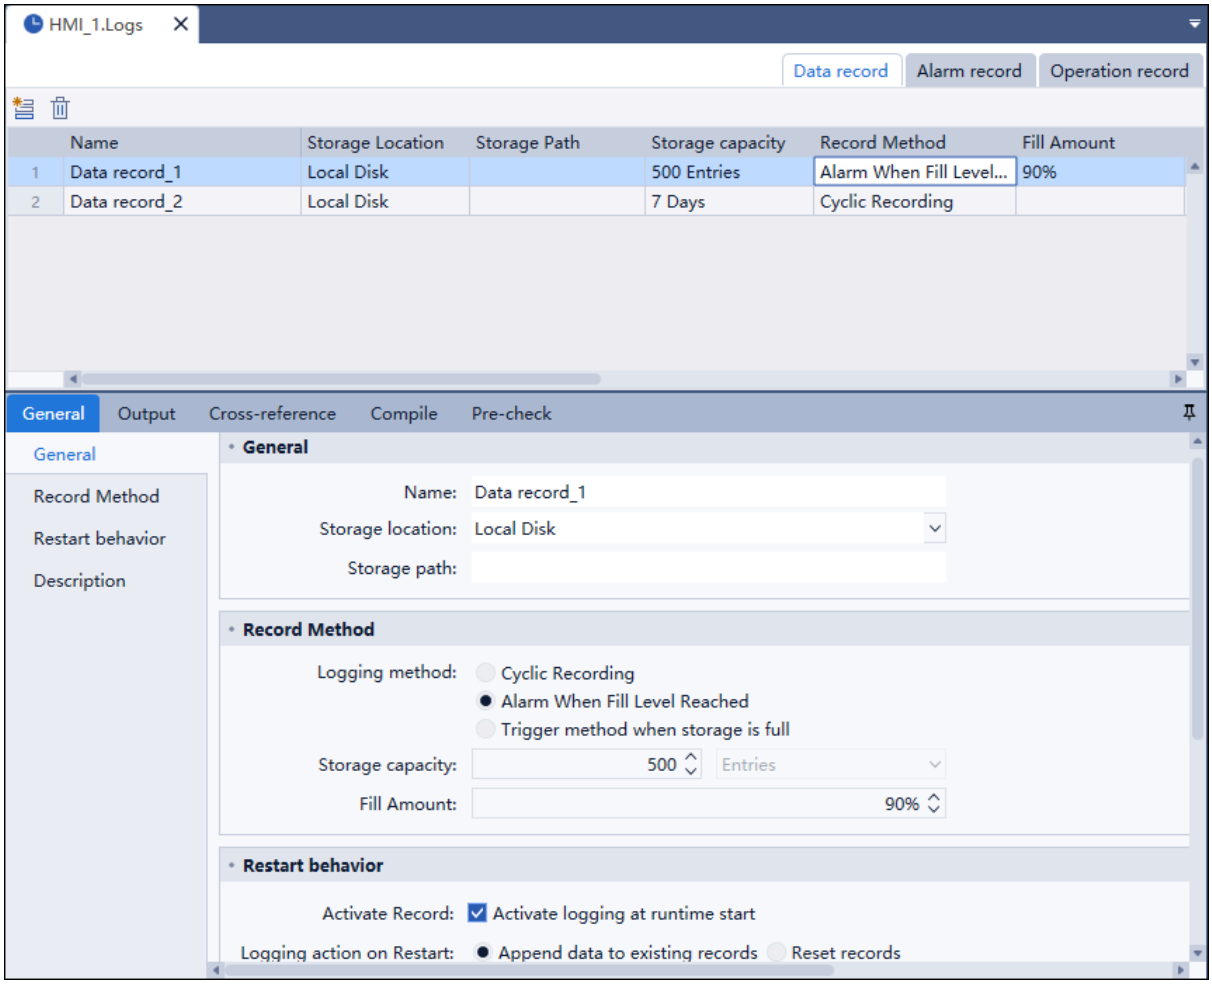
13.2.5.6 Storing Variable Data



- 13.2.5.6.1 Setting Recording Rules for Data
- 13.2.5.6.2 Variable-Associated Recording Rules

13.2.5.6.1 Setting Recording Rules for Data

Data logging is used to collect, process, and record process data from field devices, reflecting device status such as temperature or motor run/stop status.



Logging rules specify the storage location and the handling method when the storage space is full.

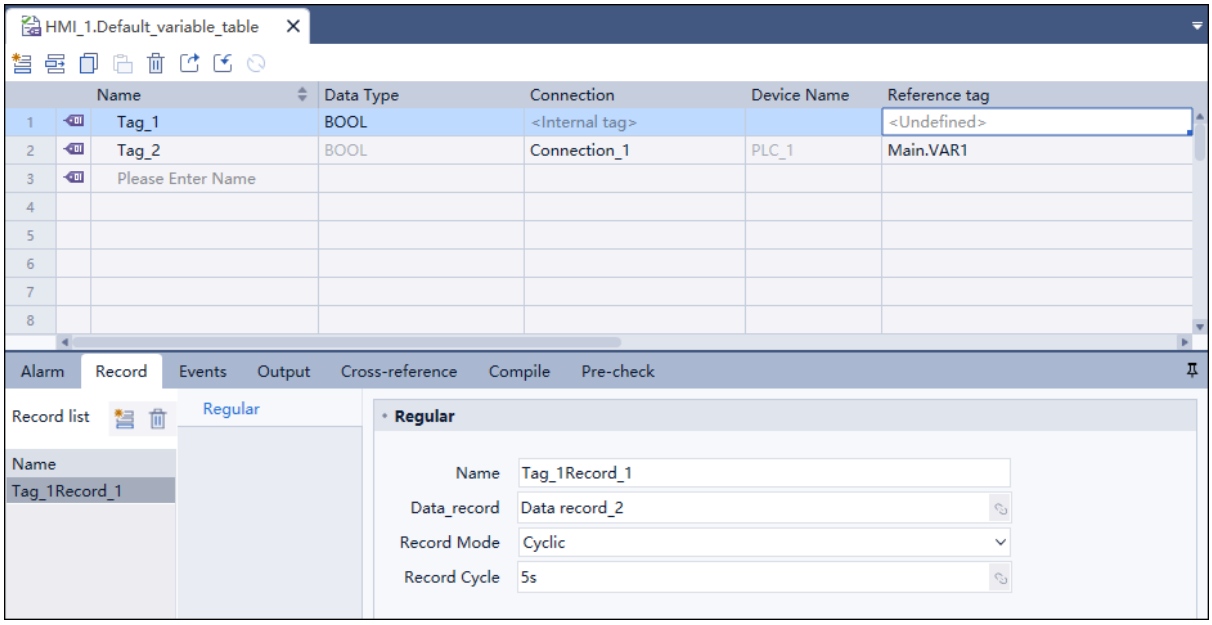
1. Double-click the "Record" node in the project tree to open the settings interface.

2. Switch to the "Data record" tab.
3. Add logging rules.

   Use right-click commands or icons in the editing area. A maximum of 256 rows can be added. Each row represents one logging rule, and rules are independent of each other.
4. Set storage parameters.
   Detailed parameters for data recording are displayed in the monitoring area below the window.

The following table introduces the properties of monitoring area in top-to-bottom order.

Type	Parameter	Description
General Settings	Name	By default, named as "Data record_n", where n starts at 1 and increments automatically. For details, see Naming rules.
	Storage location	The options for storage location depend on the device hardware. There are three typical categories: ◦ Local disk: The disk path of the monitoring device hardware, which does not need to be specified. Touch screen: Default path is **\Inodata**; PC: Default path is **D:\Logs**. ◦ SD card: Default path is **/Logs**. ◦ USB: Default path is **/Logs**.
	Storage path	



Type	Parameter	Description
Recording method	Recording method	◦ Cyclic recording: When storage space is full, the oldest data is overwritten by the latest data. ◦ Alarm at fill level: When storage usage reaches a high threshold (e.g., 90% as configured), the iFA software triggers a system alarm to indicate near-full storage and prompt space release. After the system alarm is triggered, data logging stops until the space usage drops below the fill level. ◦ Trigger at full storage: An overflow event is triggered when storage is full, and data logging stops. The predefined overflow event is used to free up storage space. Common events include 19.6.1 Clearing a Record, 19.6.6 Exporting a Data Record, 19.6.2 Starting Recording, and 19.6.3 Stopping Recording. For details, see 19.6 Record.
	Storage capacity	Set according to the number of data entries or storage days, which need to be estimated based on data volume. Number of records: 1 to 5,000,000; default: 500 Days range: 1 to 10,000; default: 7
	Fill level	Storage space utilization. The setting range is 1% to 100%.
Restart behavior	Activate record	Enable data recording when the system starts. This option is selected by default.
	Record handling on restart	Handling of logged data when the monitoring device restarts. Append data to existing records: Retain existing data and add new data. Reset records: Clear existing data and start recording anew.
Description	Description	Remarks on the current logging rules.

Specify the storage location and configure the handling mechanism for full storage space.

13.2.5.6.2 Variable-Associated Recording Rules

To store values of variables in the default and regular variable tables, you must associate variables with applicable logging rules, so target variable values are saved to the specified location.

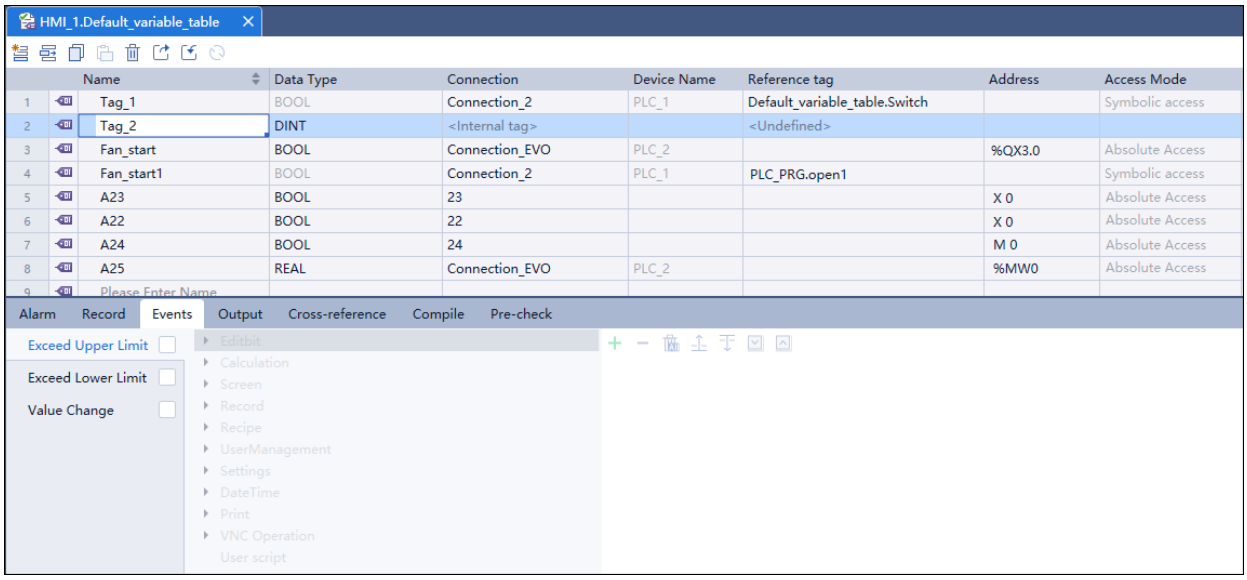
1. Open the variable table.
2. Select and set the target variable.
   Click the target variable row and its storage properties are summarized in the "Record" tab of the monitoring area.

You can click the icon to establish storage conditions for variables. Up to 16 conditions are supported per variable.

Parameter	Description
Name	Name of the variable logging condition. The default name isVariableName_Record_n, where n starts at 1 and increments automatically.
Data record	Associated with a predefined logging rule.
Recording mode	◦ Cyclic logging: Logs values according to the time cycle specified in "Record cycle". A variable supports data logging at multiple time intervals, but duplicate configurations at the same time are not allowed. ◦ Change-based logging: Data is logged only when the variable value changes. A variable can be configured only once. ◦ On-demand logging: The logging action is dynamically controlled by user-preset trigger conditions. Each trigger condition is judged based on the specific bit status of one variable (trigger variable). Multiple trigger conditions can be configured for one variable. For example, when bit 3 of variable A changes to 0, the current value of variable C is logged.

Parameter	Description
Trigger mode	Adapt to **on-demand logging** mode. When the value of the specified bit of the trigger variable changes (e.g., 0→1) and the trigger mode is satisfied (e.g., rising edge), the value of the target variable is logged once. The data type of the trigger variable supports integer and BOOL types: ◦ For BOOL variable, the bit number is set to 0. ◦ For integer variable, the lower limit of the bit number is 0, and the upper limit is the total number of occupied bits minus 1. For example, the upper limit for INT is 16-1=15, so the bit number configuration range is 0 to 15.
Trigger variable	
Bit number	

The variable logging conditions have been created and set successfully.



NOTE

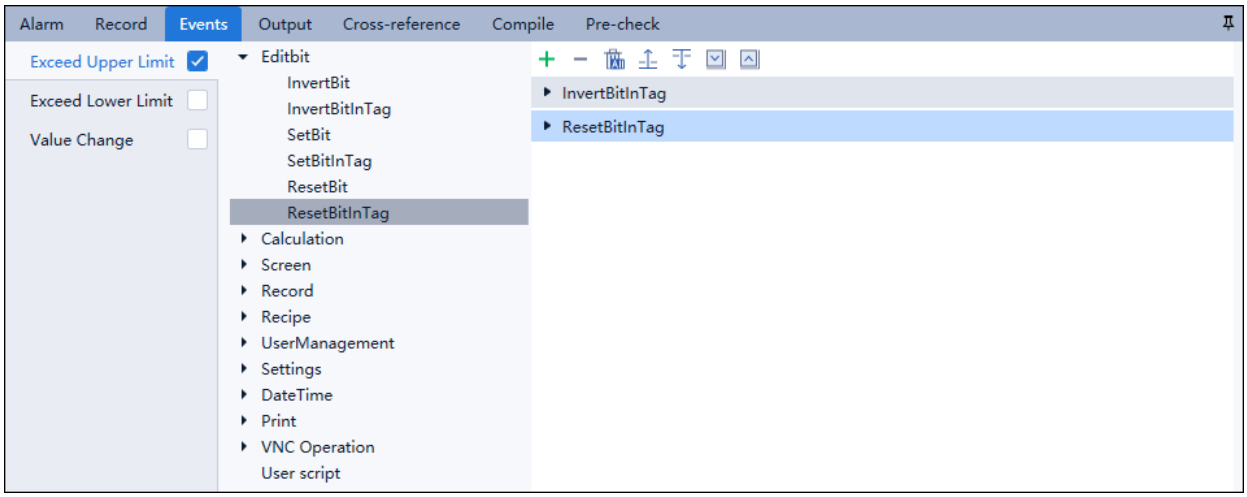
Record variables with the same logging rule in the same data record to reduce redundancy.

13.2.5.7 Configuring Variable Events

The status of the variable value serves as the trigger condition. The preset operation is executed when the condition is met.

Select any variable row in the variable table, and its corresponding event properties will be displayed in the monitoring area.

Trigger condition



The trigger condition for the event, which is set based on the variable value.

Out of upper/lower limit: The event configuration is triggered when the real-time value of the variable exceeds the upper or lower limit of the measuring range. Applicable to integer variables.

Value change: The event configuration is triggered when the real-time value of the variable changes. Applicable to integer and Boolean-type variables.

Event configuration

A variable supports adding multiple events. When the trigger condition is met, events are executed in top-to-bottom order.

13.2.6 Operating Variables

13.2.6.1 Copying and Pasting Variables

Copying variables

Copying variables means duplicating all property information of the target variable, including alarms, records, and event configurations.

1. Select the target variable row.

   Click the identifier  of the variable row to select the target variable. For multiple selections, use the **Ctrl** or **Shift** key to pick objects (or by dragging).

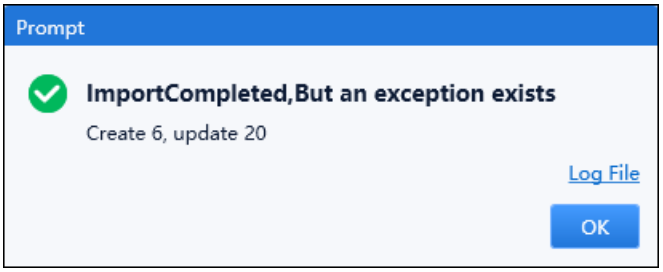
2. Command source.

   Click  or select "Copy" from the right-click menu.

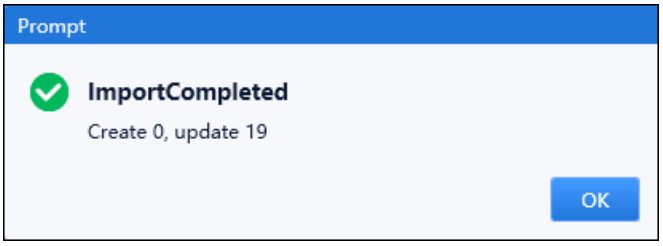
Pasting variables

In the target variable table, click the icon  or select "Paste" from the right-click menu. The pasted variable is placed below an existing variable, with the variable name appended with a "_n" suffix, where n starts at 1 and increments.

The paste operation is supported both within the same table and across pages. Cross-table operation refers to copy a variable from Variable Table A and pasting it into Variable Table B.



13.2.6.2 Importing and Exporting Variables



The import and export function of the variable enables cross-device reuse of variables and reduces configuration time.

Importing variables

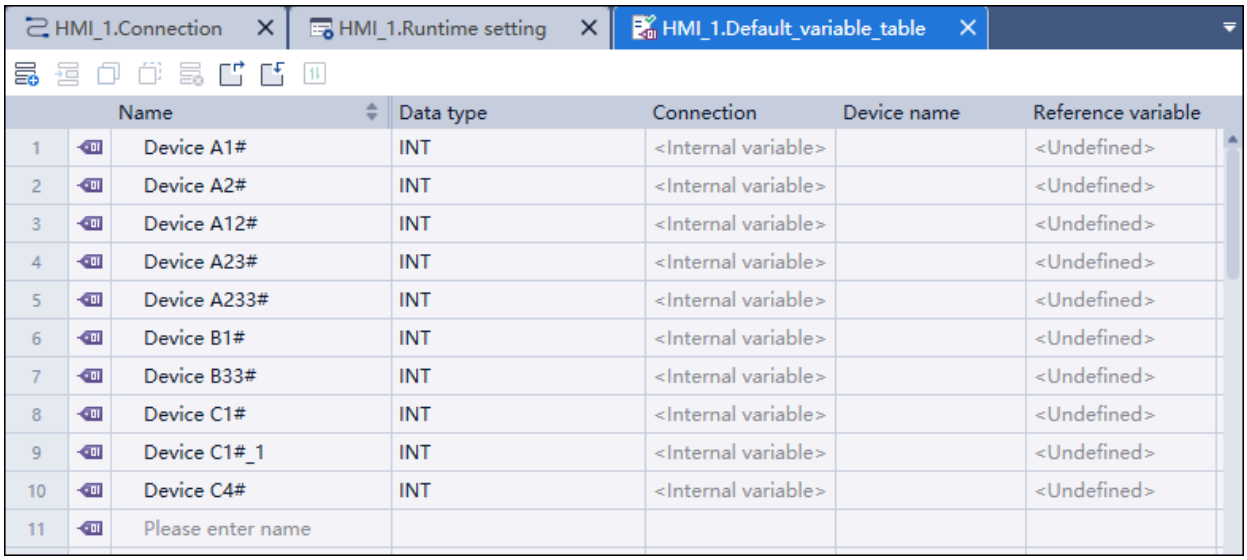
Variables are imported into the iFA software in table file format (.xlsx). For constraints of the table file, see Importing a variable table.

Provided that the variable table meets import requirements, the following mainly describes the processing rules for abnormal variable information during the import process.

<table>
<tr><th>No.</th><th>Import File</th><th>Rules</th><th>Example</th></tr>
<tr><td>1</td><td>Variable properties not configured</td><td>If the variable table provides only the variable name with all other items empty, the software will automatically fill with default values after import.</td><td rowspan="3">

Storage path of log file: Inovance\iFA\Bin\config\ExImport under the iFA software installation directory.</td></tr>
<tr><td>2</td><td>Variable properties written incorrectly</td><td>Property errors in the variable table, such as writing "bool" instead of "Bool" for the data type, will be automatically filled with default values by the software after import.</td></tr>
<tr><td>3</td><td>Variable name conflict</td><td>From top to bottom, only the first occurrence of a variable is imported. Subsequent variables with the same name are discarded and recorded in the log file.</td></tr>
<tr><td>4</td><td>Conflict with existing variables in the software</td><td>Existing variables with the same name are overwritten after import.</td><td>
</td></tr>
</table>

Exporting variables



The operation for exporting a variable is the same as that for exporting a variable table. For details, see 13.2.4.3 Importing and Exporting a Variable Table.

When exporting multiplexed variables for symbolic access, the "Reference variable" column records the initial state of the referenced PLC variable, while the "Address" column records the state of the configured index variable. The differences are shown in the figure below.

Name	Data Type	Connection	Device name	Reference variable	Address	Access mode
Swtich status	BOOL	Connection_1	PLC_1	Application.Default_variable_table.Struct1_inst[1].A[2]	Application.Default_variable_table.Struct1_inst[index1].A[index2]	Symbol access
index1	INT					
index2	INT					

13.2.6.3 Sorting Variables

New variables added to the variable table are sorted by the order in which they were added by default. The figure below shows an example of ascending order sorting.

To adjust the sorting, you can click the header of the "Name" column to switch between the following three sorting methods.

- Default sorting: Sort variables in the order they were added, with identifier .
- Name ascending: Sort variables in ascending order based on the content of names (same rules as sorting 13.3.4 screen names), with identifier .
- Name descending: Sorts variables in descending order based on the content of names, with identifier .

You can click the header to cycle through the three methods, and quickly locate and organize variables.

13.3 Creating a Screen

- 13.3.1 Screen Types
- 13.3.2 Adding a Screen
- 13.3.3 Screen Properties
- 13.3.5 Selecting Objects
- 13.3.6 Gallery Usage
- 13.3.7 Configuring a Screen
- 13.3.8 Configuring Animation
- 13.3.9 Using Layers
- 13.3.10 Screen Management

13.3.1 Screen Types

Screens are divided into four types according to application scenarios and displayed content: main screen, picture-in-picture, pop-up screen, and template screen.

- Main screen
  The main screen serves as the basic screen and provides the user interface for monitoring and operation. It is primarily used for centralized monitoring of key processes and data. Applications are created by calling up pop-up screens from the main screen or switching to other main screens. A main screen can have up to 500 objects configured.
- Picture-in-picture
  Picture-in-picture screens are only displayed and switched within the 13.3.5.2.16 Picture-in-Picture View, which is usually configured on the main screen. You can monitor the main screen while browsing content in the picture-in-picture view.
- Pop-up screen
  Pop-up screens are used to configure additional content for the main screen, such as displaying parameters of a specific device type, and are called up from the main screen during runtime.
  Pop-up screens are template screens based on the concept of "Page parameter". When configuring screen elements, you can either choose page parameters as a priority or select variables from the variable table for configuration. When a pop-up screen is opened at runtime, variables are passed to replace the page parameters in the pop-up screen.
- Template screen
  A template screen can be regarded as a common screen for main screens. Objects configured in the template are displayed on all main screens that reference this template.
  If the content of the template changes, all referenced screens will automatically update.

13.3.2 Adding a Screen

Screens are classified into four types by purpose: main screen, picture-in-picture, pop-up screen, and template screen. They are all located under the **"Screen"** node in the project tree. All types except the main screen are managed in separate categories.

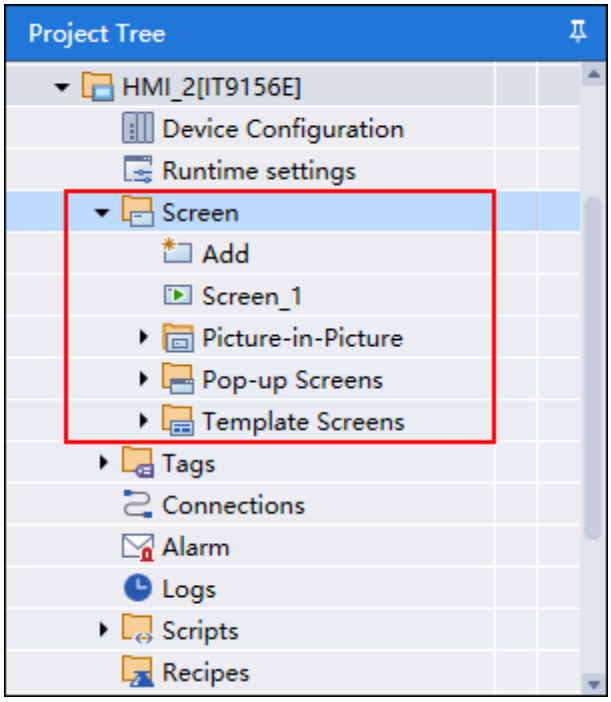


Figure 13-3-2-1 Screen node

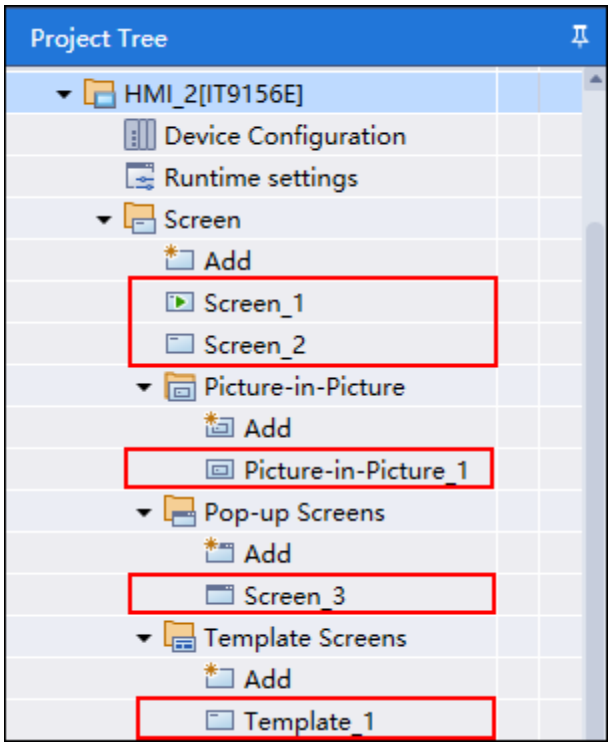
A single HMI device can be configured with up to 2000 screens, regardless of screen type. All screen types are added via the project tree, with two supported methods:

- In the right-click menu of the parent node, select the add command, such as "Add screen".
- Double-click the "Add" node under the parent node.

The result is shown in the figure below. The screens named **Screen_1** and **Screen_2** in the figure are main screens.



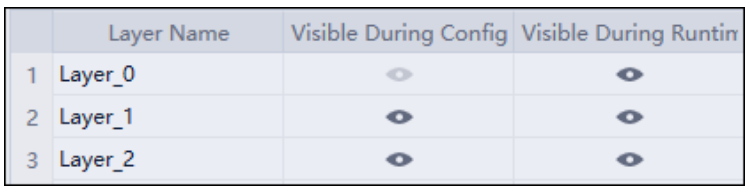


Figure 13-3-2-2 Added screens of each type

13.3.3 Screen Properties

After a screen is added, you need to configure its properties according to the control strategy. Property items vary by screen type. The table below summarizes all screen properties, with notes on the applicable screen objects for easy reference.

Table13-3-3-1 Screen properties

Item		Description	Applicable Screen Type
Basic settings	Dimension	Screen format size. Only picture-in-picture and pop-up screens support custom sizing. For picture-in-picture screens, height range: (60, 4 × screen height), default: ½ screen height; width range: (100, 2 × screen width), default: ½ screen width The sizes of other screens are set automatically according to the screen size of the monitoring device.	Applicable to all four types of screens
Window	Background color	Background color of the screen	Applicable to all four types of screens
	Border style	Style of pop-up window during runtime	Applicable to pop-up screens
	Reference template	Configuration of screen template reference	Applicable to main screens
	Reference screen	Screen reference configuration	Applicable to template screens
Layer	Configuration fully visible	All layers in the screen are visible during configuration. This option is selected by default.	Applicable to all four types of screens
	Runtime fully visible	All layers in the screen are visible during runtime. This option is selected by default.	Applicable to all four types of screens
	Active layer	Selects the current active layer. For details, see 13.3.9.3 Setting an Active Layer.	Applicable to all four types of screens
	Display/ hide configuration	Sets whether each layer is visible during configuration and runtime. Click the icon to toggle the visibility state. For more information, see 13.3.9.4 Displaying or Hiding A Layer.  	Applicable to all four types of screens

Item		Description	Applicable Screen Type
Page parameters	Page parameters	Configures screen parameter. In a pop-up screen, all associated symbols can be associated with either regular variables in monitoring or page parameters of this screen.	Applicable to pop-up screens
Basic information	Display title	The title is displayed in the title bar of the pop-up screen window. This option is selected by default.	Applicable to pop-up screens
	Close button	The close button is displayed in the title bar of the pop-up screen window. This option is selected by default.	Applicable to pop-up screens
	Resizable	The size of the pop-up screen window can be adjusted by dragging. This feature is not supported by default.	Applicable to pop-up screens
	Movable	The pop-up screen can be moved. This option is selected by default.	Applicable to pop-up screens
	Modal	The pop-up screen opens in modal mode. This feature is not supported by default.	Applicable to pop-up screens
	Title text	The title content is displayed in the title bar of the pop-up screen.	Applicable to pop-up screens
	Screen ID	ID must be unique, with a range of 1 to 65535. The current screen ID can be read via the system variable $CurrentScreenId.	Applicable to all four types of screens
	Name	Name of the screen.	Applicable to all four types of screens

13.3.4 Renaming a Screen

When a screen is created, its default name is "Screen_SequenceNumber". The name can be changed according to the following rules.

Naming rules

The naming rules must satisfy all the following conditions.

- Letters (case-insensitive), numbers (0 to 9), Chinese characters, and spaces are supported.
- The length cannot exceed 128 characters.
- The name cannot start or end with a space.

- Invalid characters: \ / : * ? " < > |
- Screen names must be unique.

Sorting rules

After renaming a screen, its order in the project tree is sorted in ascending order based on the following priorities.

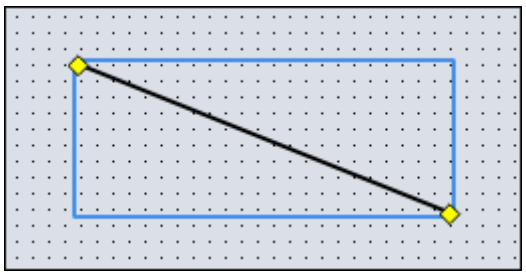
Precedence	Character Type	Note
1	English symbol	English punctuations (space, -, etc.)
2	Number	Sorted by actual numeric value, not by character-by-character comparison For example, in ascending order: A1→A2→A11.
3	Letter	Sorted in a-z order
4	Chinese symbol	Chinese punctuations
5	Chinese characters	Sorted by the first letter of the Pinyin of the first character. If the first character is the same, compare the second character, and so on.
6	Special character	Characters not within the above ranges are sorted last.

13.3.5 Object Selection

Objects are an important part of process screens. They are divided into two parts: elements and graphic symbols.

Elements visually display equipment operating data and status, enhance monitoring, simplify operation and interaction, support alarms and notifications, and enable customized visualization. Elements are stored in the "Toolbox" and categorized into five types based on application scenarios.

- 13.3.5.1 Basic Elements
- 13.3.5.2 Control and Display
- 13.3.5.3 Data Visualization
- 13.3.5.4 Production and Management
- 13.3.5.5 Others



13.3.5.1 Basic Elements

13.3.5.1.1 Line

The "line" is an open object.

The length and slope of a line are defined by the height and width of the bounding box.

There is a yellow control point at each end of the line, which can be directly dragged to change their position.

- **Line creation method**

There are three methods to create a "line":

  - Method 1: Select the object from the toolbox, drag it into the screen area, and release the mouse button to create a default-sized element.
  - Method 2: Click the object in the toolbox, and then click the screen to create a default-sized element.
  - Method 3: Click the object in the toolbox, click the screen to define the starting position of the element, and drag to the end position before releasing. This creates an element of the desired size.

- **Line properties**
  - Basic Settings

Item	Description
Position	Sets the position coordinates (i.e., top-left coordinates) of the element on the screen in pixels: X: X-axis coordinate. Y: Y-axis position coordinate. The coordinate value must be smaller than the screen boundary coordinate value to prevent the elements from extending beyond the screen.
Dimension	Indicates the size of the element on the screen in pixels. The size can be adjusted by manually dragging the control points at both ends. The minimum size can be adjusted to 0 (width) * 0 (height).
Start position	Sets the starting position of the element on the screen in pixels: X: X-axis, position coordinate at the top of the screen. Y: Y-axis, position coordinate at the left of the screen.
End position	Sets the ending position of the element on the screen in pixels: X: X-axis, position coordinate at the top of the screen. Y: Y-axis, position coordinate at the left of the screen.

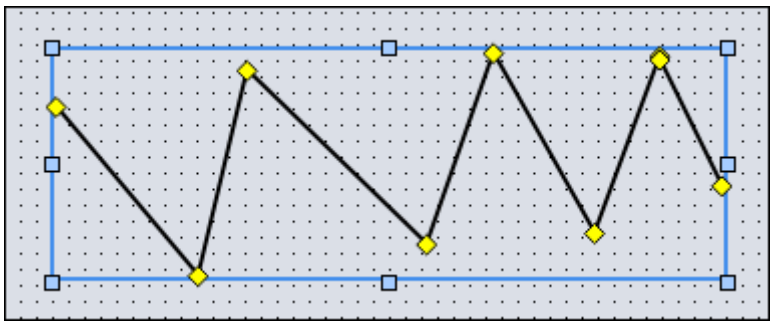
  - Stroke:

Property	Description
Stroke color	Line color and transparency.
Line width	The range is 1 to 10, with a default of 2.

Property	Description
Line type	Line type
Start arrow	Start arrow style of the line
End arrow	End arrow style of the line

◦ Basic information:

Item	Description
Graph element ID	Global identifier number of the element in the system. (automatically assigned by default)
Type	Type information of the element.
Name	Name of the element. The default name is "Element_1", for example "Line_1".
Enable tooltip	Sets whether to use tooltip information: • Selected: Used. • Unselected: Not used. No tooltip by default.
Runtime display	Specifies whether the element is visible in runtime. This option is selected by default.
Enable	Sets whether the element can be operated in the runtime. This option is selected by default.
Permissions	Sets the element permission.
Tooltip	The tooltip information is displayed when the mouse hovers over this element in the runtime. It is empty by default.
Layer	Sets the layer to which the element belongs. The default is layer_0.



◦ Animation: For details, see 13.3.8 Animation Configuration.

◦ Event: For details, see 13.3.7.14 Adding an Event.

13.3.5.1.2 Polyline

A "polyline" consists of connected segments and can have indefinite number of control points (numbered in the order in which they were created).

There is a yellow control point at each corner of the polyline, which can be directly dragged to change their position.

- **Polyline creation**

There are two ways to create a "polyline":

  - Method 1: Select the object in the toolbox without releasing the mouse, drag it into the screen area, and then release the mouse to obtain a default-sized element.
  - Method 2:
    1. Click the target element in the toolbox and move the mouse to the screen.
    2. Click the left mouse button to set the starting position of the polyline, drag the mouse to the target position of the first line segment, and then click the left mouse button again to complete the first segment of the polyline.
    3. Repeat the above steps until the final segment is drawn, and then right-click to generate the desired element.

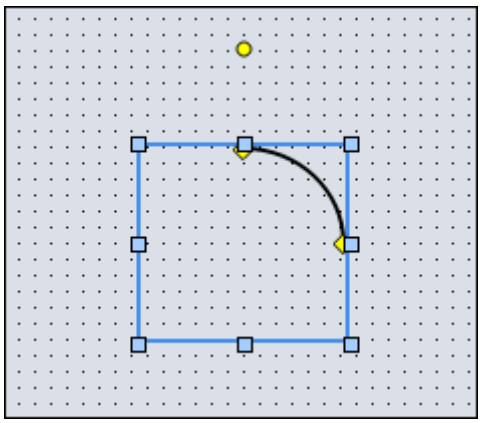
- **Polyline properties**
  - Basic settings:

Item	Description
Position	Sets the position coordinates (i.e., top-left coordinates) of the element on the screen in pixels: X: X-axis coordinate. Y: Y-axis position coordinate. The coordinate value must be smaller than the screen boundary coordinate value to prevent the elements from extending beyond the screen.
Dimension	Sets the size of the element on the screen in pixels. Setting range: 0 to 10000
Rotation	Sets the rotation angle of the element. Range: (-180 to 180].
Relative center	Sets the rotation center position of the object. This position is an offset relative to the object physical center.
Absolute center	Sets the rotation center position of the object. This position is an offset relative to the entire screen.

  - Stroke:

Property	Description
Stroke color	Polyline color and transparency.
Line width	Polyline line width. The range is 1 to 10, with a default value of 2.
Line type	Line type.
Start arrow	Start arrow style.
End arrow	End arrow style.
Corner point	Sets the corner style of the polyline.

- Point set:



Property	Description
Add point set	Click the "Add" button to add a polyline segment.
Delete point set	Click the "Delete" button to remove a polyline segment.
Edit point set	Double-click the X, Y coordinates in the point set to modify the coordinate information of each segment.

- Basic information: For details, see Line > Basic Information.
- Animation: For details, see 13.3.8 Animation Configuration.
- Event: For details, see 13.3.7.14 Adding an Event.

13.3.5.1.3 Arc

The "arc" displays curves of all types.

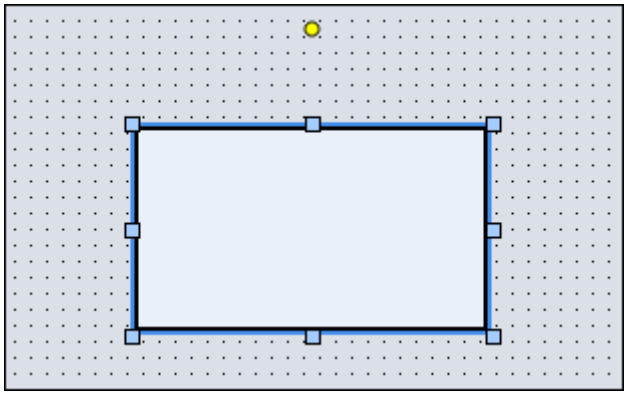
There is a yellow control point at each end of the arc, which can be directly dragged to change their position.

- **Arc creation**

  There are three ways to create an "arc". For details, see the line creation method.

- **Arc properties**
  - Basic settings:

Property	Description
Position	Sets the position coordinates (i.e., top-left coordinates) of the element on the screen in pixels: X: X-axis coordinate. Y: Y-axis position coordinate. The coordinate value must be smaller than the screen boundary coordinate value to prevent the elements from extending beyond the screen.
Dimension	Sets the size of the element on the screen in pixels. Setting range: 1 to 10000
Rotation	Sets the rotation angle of the element. Range: (-180 to 180].
Relative center	Sets the rotation center position of the object. This position is an offset relative to the object physical center.
Absolute center	Sets the rotation center position of the object. This position is an offset relative to the entire screen.



- Stroke properties: For detail, see Line > Stroke.
- Angle:

Item	Description
Start angle	The angle is measured clockwise from the X-axis to the starting point of the arc (in degrees).
Sweep angle	The angle is measured clockwise from the startAngle parameter to the ending point of the arc (in degrees).

- Basic information: For details, see Line > Basic Information.
- Animation: For details, see 13.3.8 Animation Configuration.
- Event: For details, see 13.3.7.14 Adding an Event.

13.3.5.1.4 Rectangle

The "rectangle" is a closed object that can be filled with a background color.

- **Rectangle creation**

  There are three ways to create a "rectangle". For details, see the line creation method.

- **Rectangle properties**

  - Basic settings:

Item	Description
Position	Sets the position coordinates (i.e., top-left coordinates) of the element on the screen in pixels: X: X-axis coordinate. Y: Y-axis position coordinate. The coordinate value must be smaller than the screen boundary coordinate value to prevent the elements from extending beyond the screen.
Dimension	Sets the size of the element on the screen in pixels. Setting range: 1 to 10000
Rotation	Sets the rotation angle of the element. Range: (-180 to 180].
Relative center	Sets the rotation center position of the object. This position is an offset relative to the object physical center.
Absolute center	Sets the rotation center position of the object. This position is an offset relative to the entire screen.
Rounded corner	Sets the rounded corner width and height of the rectangle. A rounded rectangle is created by changing the rounded corner width and height.

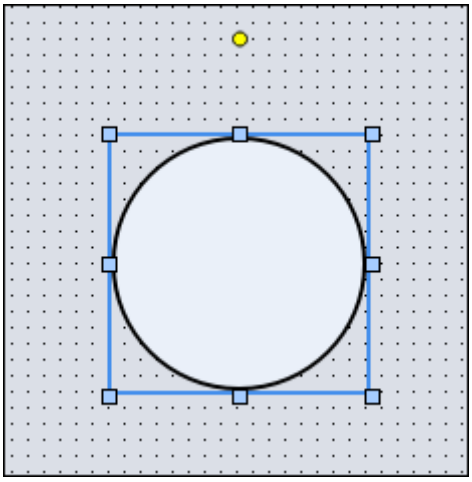
  - Style:

Property	Description
Draw options	Sets the drawing options for the element. Options: draw, fill, and draw and fill.

  - Percentage fill:

Property		Description
Percentage fill mode		There are two fill modes: absolute direction fill and relative direction fill. Absolute direction fill: Regardless of the orientation of the element, the fill direction is always aligned with the absolute vertical direction. Relative direction fill: When the shape of the element changes, the fill direction remains relative to the vertical orientation of the element.
Percentage fill brush	Solid brush	Color: Sets the solid brush color.
		Transparency: Sets the brush transparency to change the brush display effect (0% to 100%).
	Hatch brush	Fill style: Sets the hatch pattern for filling the element.
		Foreground color: Sets the foreground color of the hatch brush to achieve foreground filling of the element.
		Foreground transparency: Sets the brush transparency to change the brush display effect (0% to 100%).
		Background color: Sets the background color of the hatch brush to achieve background filling of the element.
		Background transparency: Sets the brush opacity to change the brush display effect (0% to 100%).
	Texture brush	Fill style: Sets the texture pattern for filling the element.
		Fill mode: Sets the texture fill mode (including normal, tile, and stretch).
		Transparency: Sets the brush transparency to change the brush display effect (0% to 100%).
	Linear brush	Fill style: Sets the linear pattern for filling the element.
		Cycle count: Sets the number of linear brush fill repetitions.
		Rotation angle: Sets the fill rotation angle.
		Start color: Sets the starting color of the linear brush.
		Start color transparency: Sets the brush transparency to change the brush display effect (0% to 100%).
		End color: Sets the ending color of the linear brush.
		End color transparency: Sets the brush transparency to change the brush display effect (0% to 100%).
	Path brush	Gradient style: Sets the gradient style of the path brush (including circular and rectangular).

Property		Description
		Cycle count: Sets the number of path brush fill repetitions.
		Center size: Sets the center size of the path brush (0% to 100%).
		Start color: Sets the starting color of the linear brush.
		Start color transparency: Sets the brush transparency to change the brush display effect (0% to 100%).
		End color: Sets the ending color of the linear brush.
		End color transparency: Sets the brush transparency to change the brush display effect (0% to 100%).
Vertical fill direction		Specifies the fill direction: fill from top to bottom or from bottom to top.
Horizontal fill direction		Specifies the fill direction: fill from left to right or from right to left.
Vertical fill percentage		Sets the vertical fill percentage value of the element (0% to 100%).
Horizontal fill percentage		Sets the horizontal fill percentage value of the element (0% to 100%).



- Fill: For details, see Percentage Fill > Percentage fill brush.
- Border:

Property	Description
Border color	Rectangle color and transparency.
Line width	Rectangle line width. The range is 1 to 10, with a default value of 2.
Line type	Rectangle line type.

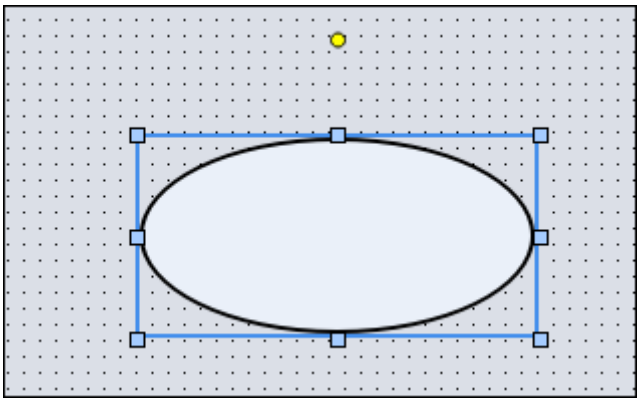
- Basic information: For details, see Line > Basic information .
- Animation: For details, see 13.3.8 Animation Configuration.
- Event: For details, see 13.3.7.14 Adding an Event.

13.3.5.1.5 Circle

The "circle" is a closed object that can have a background color filled.

- **Circle creation**

  There are three ways to create a "circle". For details, see the line creation method.

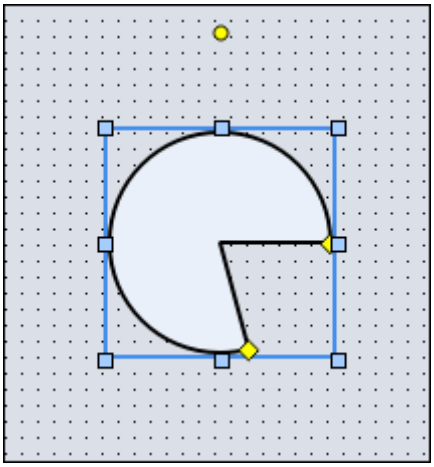


- **Circle properties**
  - Basic settings:

Item	Description
Position	Sets the position coordinates (i.e., top-left coordinates) of the element on the screen in pixels: X: X-axis coordinate. Y: Y-axis position coordinate. The coordinate value must be smaller than the screen boundary coordinate value to prevent the elements from extending beyond the screen.
Dimension	Sets the size of the element on the screen in pixels. Setting range: 1 to 10000
Rotation	Sets the rotation angle of the element. Range: (-180 to 180].
Relative center	Sets the rotation center position of the object. This position is an offset relative to the object physical center.
Absolute center	Sets the rotation center position of the object. This position is an offset relative to the entire screen.
Center point	Sets the position of the circle center.

  - Style: For details, see Rectangle > Ssyle .
  - Percentage fill: For details, see Rectangle > Percentage fill.
  - Fill: For details, see Rectangle > Fill.
  - Border: For details, see Rectangle > Border.
  - Basic information: For details, see Line > Basic information.
  - Animation: For details, see 13.3.8 Animation Configuration.
  - Event: For details, see 13.3.7.14 Adding an Event.

13.3.5.1.6 Ellipse



The "ellipse" is a closed object that can be filled with a background color.

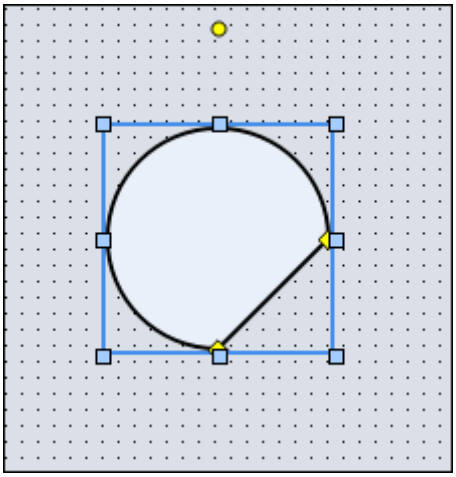
- **Ellipse creation**
  There are three methods to create an "ellipse". For details, see the line creation method.
- **Ellipse properties**
  - Basic settings: For details, see Circle > Basic settings.
  - Style: For details, see Rectangle > Style.
  - Percentage fill: For details, see Rectangle > Percentage fill.
  - Fill: For details, see Rectangle > Fill.
  - Border: For details, see Rectangle > Border.
  - Basic information: For details, see Line > Basic information.
  - Animation: For details, see 13.3.8 Animation Configuration.
  - Event: For details, see 13.3.7.14 Adding an Event.

13.3.5.1.7 Sector

The "sector" is a closed object that can be filled with a background color.

- **Sector creation**
  There are three ways to create a "sector". For details, see the line creation method.
- **Sector properties**
  - Basic settings: For details, see Arc > Basic settings.

- Style: For details, see Rectangle > Style.
- Data:



Item		Description
Start angle		The angle is measured clockwise from the X-axis to the starting point of the arc (in degrees).
Sweep angle		The angle is measured clockwise from the startAngle parameter to the ending point of the arc (in degrees).
Percent fill mode		There are two fill modes: absolute direction fill and relative direction fill. Absolute direction fill: Regardless of the orientation of the element, the fill direction is always aligned with the absolute vertical direction. Relative direction fill: When the shape of the element changes, the fill direction remains relative to the vertical orientation of the element.
Percent fill brush	Solid color brush	Color: Sets the solid brush color.
		Transparency: Sets the brush transparency to change the brush display effect (0% to 100%).
	Hatch brush	Fill style: Sets the hatch pattern for filling the element.
		Foreground color: Sets the foreground color of the hatch brush to achieve foreground filling of the element.
		Foreground transparency: Sets the brush transparency to change the brush display effect (0% to 100%).
		Background color: Sets the background color of the hatch brush to achieve background filling of the element.
		Background transparency: Sets the brush opacity to change the brush display effect (0% to 100%).
	Texture brush	Fill style: Sets the texture pattern for filling the element.
		Fill mode: Sets the texture fill mode (including normal, tile, and stretch).
		Transparency: Sets the brush transparency to change the brush display effect (0% to 100%).
	Linear brush	Fill style: Sets the linear pattern for filling the element.
		Cycle count: Sets the number of linear brush fill repetitions.
		Rotation angle: Sets the fill rotation angle.
		Start color: Sets the starting color of the linear brush.

Item		Description
		Start color transparency: Sets the brush transparency to change the brush display effect (0% to 100%).
		End color: Sets the ending color of the linear brush.
		End color transparency: Sets the brush transparency to change the brush display effect (0% to 100%).
	Path brush	Gradient style: Sets the gradient style of the path brush (including circular and rectangular).
		Cycle count: Sets the number of path brush fill repetitions.
		Center size: Sets the center size of the path brush (0% to 100%).
		Start color: Sets the starting color of the linear brush.
		Start color transparency: Sets the brush transparency to change the brush display effect (0% to 100%).
		End color: Sets the ending color of the linear brush.
		End color transparency: Sets the brush transparency to change the brush display effect (0% to 100%).
Vertical fill direction		Specifies the fill direction: fill from top to bottom or from bottom to top.
Horizontal fill direction		Specifies the fill direction: fill from left to right or from right to left.
Vertical fill percentage		Sets the vertical fill percentage value of the element (0% to 100%).
Horizontal fill percentage		Sets the horizontal fill percentage value of the element (0% to 100%).

- Fill: For details, see Rectangle > Fill.
- Border: For details, see Rectangle > Border.
- Basic information: For details, see Line > Basic information.
- Animation: For details, see 13.3.8 Animation Configuration.
- Event: For details, see 13.3.7.14 Adding an Event.

13.3.5.1.8 Circular Segment

The "circular segment" is a closed object that can be filled with a background color.

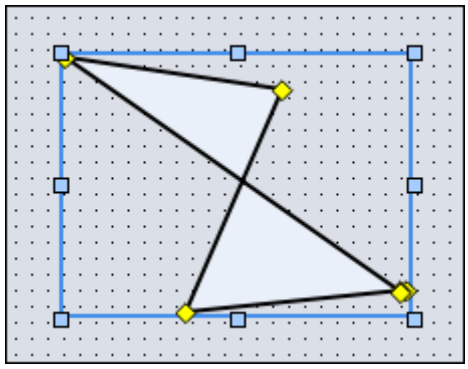
- **Circular segment creation**

  There are three ways to create a "circular segment". For details, see the line creation method.

- **Properties of circular segment**
  - Basic settings: For details, see Arc > Basic settings.
  - Style: For details, see Rectangle > Style.
  - Data:

Item		Description
Start angle		The angle is measured clockwise from the X-axis to the starting point of the arc (in degrees).
Sweep angle		The angle is measured clockwise from the startAngle parameter to the ending point of the arc (in degrees).
Percentage fill mode		There are two fill modes: absolute direction fill and relative direction fill. Absolute direction fill: Regardless of the orientation of the element, the fill direction is always aligned with the absolute vertical direction. Relative direction fill: When the shape of the element changes, the fill direction remains relative to the vertical orientation of the element.
Percentage fill brush	Solid brush	Color: Sets the solid brush color.
		Transparency: Sets the brush transparency to change the brush display effect (0% to 100%).
	Hatch brush	Fill style: Sets the hatch pattern for filling the element.
		Foreground color: Sets the foreground color of the hatch brush to achieve foreground filling of the element.
		Foreground transparency: Sets the brush transparency to change the brush display effect (0% to 100%).
		Background color: Sets the background color of the hatch brush to achieve background filling of the element.

Item		Description
		Background transparency: Sets the brush opacity to change the brush display effect (0% to 100%).
	Texture brush	Fill style: Sets the texture pattern for filling the element.
		Fill mode: Sets the texture fill mode (including normal, tile, and stretch).
		Transparency: Sets the brush transparency to change the brush display effect (0% to 100%).
	Linear brush	Fill style: Sets the linear pattern for filling the element.
		Cycle count: Sets the number of linear brush fill repetitions.
		Rotation angle: Sets the fill rotation angle.
		Start color: Sets the starting color of the linear brush.
		Start color transparency: Sets the brush transparency to change the brush display effect (0% to 100%).
		End color: Sets the ending color of the linear brush.
		End color transparency: Sets the brush transparency to change the brush display effect (0% to 100%).
	Path brush	Gradient style: Sets the gradient style of the path brush (including circular and rectangular).
		Cycle count: Sets the number of path brush fill repetitions.
		Center size: Sets the center size of the path brush (0% to 100%).
		Start color: Sets the starting color of the linear brush.
		Start color transparency: Sets the brush transparency to change the brush display effect (0% to 100%).
		End color: Sets the ending color of the linear brush.
		End color transparency: Sets the brush transparency to change the brush display effect (0% to 100%).
Vertical fill direction		Specifies the fill direction: fill from top to bottom or from bottom to top.
Horizontal fill direction		Specifies the fill direction: fill from left to right or from right to left.
Vertical fill percentage		Sets the vertical fill percentage value of the element (0% to 100%).



Item	Description
Horizontal fill percentage	Sets the horizontal fill percentage value of the element (0% to 100%).

- Fill: For details, see Rectangle > Fill.
- Border: For details, see Rectangle > Border.
- Basic information: For details, see Line > Basic information.
- Animation: For details, see 13.3.8 Animation Configuration.
- Event: For details, see 13.3.7.14 Adding an Event.

13.3.5.1.9 Polygon

The "polygon" is a closed object that can be filled with a background color.

The corners of "polygon" are numbered sequentially in the order of creation. There is a yellow control point at each corner, which can be directly dragged to change their position.

- **Polygon creation**

  There are two ways to create a "polygon":

  - Method 1: Select the object in the toolbox without releasing the mouse, drag it into the screen area, and then release the mouse to obtain a default-sized element.
  - Method 2:
    1. Click the target graphic element in the toolbox and move the mouse to the screen.
    2. Click the left button and drag to create a polygon.
    3. Right-click to generate the target element.

- **Polygon properties**
  - Basic settings: For details, see Polyline > Basic settings.
  - Style: For details, see Rectangle > Style.
  - Data: For details, see Rectangle > Percentage fill.
  - Fill: For details, see Rectangle > Fill.
  - Border properties: For details, see Rectangle > Border.
  - Properties of point set : For details, see Polyline > Point set.
  - Basic information: For details, see Line > Basic information.
  - Animation: For details, see 13.3.8 Animation Configuration.
  - Event: For details, see 13.3.7.14 Adding an Event.

13.3.5.1.10 Text

The "text" is a closed object that allows one or more lines of text input, as well as font and color definition. You can also fill the text background and enter text for all configured languages.

- **Text creation**

  There are two methods to create a "text":

  - Method 1: Select the object from the toolbox, drag it into the screen area, and release the mouse button to create a default-sized element.
  - Method 2: Click the object in the toolbox, and then click the screen to create a default-sized element.

- **Text properties**
  - Basic settings:

Property	Description
Position	Sets the position coordinates (i.e., top-left coordinates) of the element on the screen in pixels: X: X-axis coordinate. Y: Y-axis position coordinate. The coordinate value must be smaller than the screen boundary coordinate value to prevent the elements from extending beyond the screen.
Dimension	The text size automatically adjusts according to the content. Manual setting is not supported.
Rotation	Sets the rotation angle of the element. Range: (-180 to 180].
Relative center	Sets the rotation center position of the object. This position is an offset relative to the object physical center.
Absolute center	Sets the rotation center position of the object. This position is an offset relative to the entire screen.

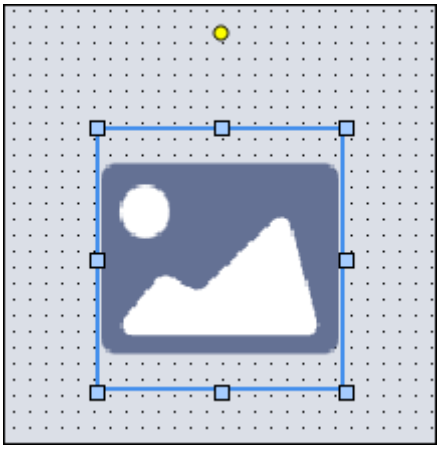
  - Text:

Item	Description
Text content	Sets the text content.
Font	Sets the text font. The default font is Droid Sans Fallback.
Font size	Sets the text size. The default size is 18.

Item	Description
Font style	Sets the text font style. Supports regular, bold, italic, and underline. The default is regular. Supports left alignment, center alignment, and right alignment. The default is left alignment.
Fit size	Specifies whether the text box size automatically adapts to the text content. When selected, the size adapts automatically. When unselected, the size is fixed and must be adjusted manually if needed.

- Border

Item	Description
Border width	Changes the border line thickness. Setting range: 0 to 10, where 0 means no border.
Border color	Changes the border line color.



- Fill:

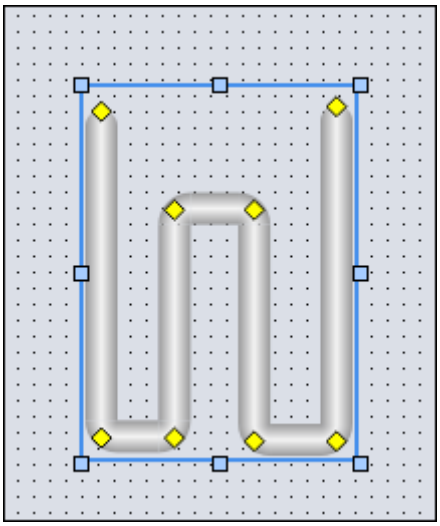
Item	Description
Text color	Sets the text color. The default is black.
Text transparency	Sets the text color transparency from 0% to 100%. The default is 0%.
Background color	Sets the background color. The default is gray.
Background color transparency	Sets the transparency of background color from 0% to 100%. The default is 0%.

- Basic information: For details, see Line > Basic information.
- Animation: For details, see 13.3.8 Animation Configuration.
- Event: For details, see 13.3.7.14 Adding an Event.

13.3.5.1.11 Image

The "image" is a element used to display specified image information.

The image supports displaying the following image types: ico, png, bmp, jpg, jpeg, gif, svg, and tiff.



- **Image creation**
  There are three methods to create an image. For details, see the line creation method.
- **Image properties**
  - Basic settings: For details, see Arc > Basic settings.
  - Style:

Property	Description
Picture	Used to associate and clear specific image file. Image file sources from the system gallery, project gallery, and user gallery. After successful association in a 13.3.2 screen, the image is saved to the 13.3.6.4 project gallery. After successful association in a 13.4.3.2 symbol template, the image is saved to the 13.3.6.5 local gallery.
Display original size	Used to control the display mode of the image. When this option is checked, the image is displayed at its original aspect ratio; when unchecked, the image is stretched or scaled to fit the control's dimensions.

  - Basic information: For details, see Line > Basic information.
  - Animation: For details, see 13.3.8 Animation Configuration.
  - Event: For details, see 13.3.7.14 Adding an Event.

13.3.5.1.12 Pipe

The "pipe" is a graphic with an outer wall and internal flow capability.

- **Pipe creation**

  There are two ways to create a "pipe":

  - Method 1: Select the object in the toolbox without releasing the mouse, drag it into the screen area, and then release the mouse to obtain a default-sized graphic element.
  - Method 2:
    1. Click the target element in the toolbox and move the mouse to the screen.

2. Click the left mouse button to set the starting position of the pipe, drag the mouse to the target position of the first pipe segment, and then click the left mouse button again to complete the first segment of the pipe.
3. Repeat the above steps until the final segment is drawn, and then right-click to generate the desired element.

- **Pipe properties**
  - Basic settings:

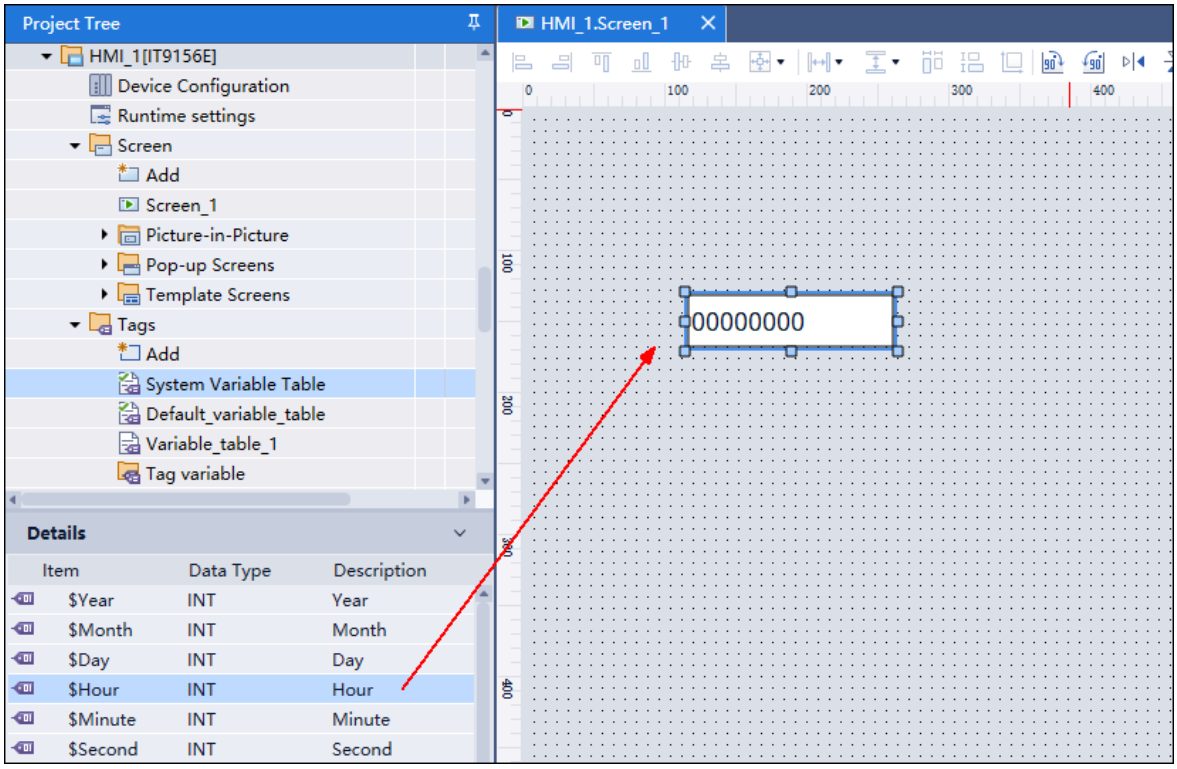
Property	Description
Position	Sets the position coordinates (i.e., top-left coordinates) of the element on the screen in pixels: X: X-axis coordinate. Y: Y-axis position coordinate. The coordinate value must be smaller than the screen boundary coordinate value to prevent the elements from extending beyond the screen.
Dimension	Sets the size of the element on the screen in pixels. When the pipe contains a set of three or more points, the width can be configured. Setting range: 16 to 10000
Rotation	Sets the rotation angle of the element. Range: (-180 to 180].
Relative center	Sets the rotation center position of the object. This position is an offset relative to the object physical center.
Absolute center	Sets the rotation center position of the object. This position is an offset relative to the entire screen.

  - Stroke:

Item	Description
Inner line	Sets the color and transparency (0% to 100%) of the internal flow line during pipe operation.
Inner line width	Sets the width of the internal flow line, including Thiner, Thin, Mid, Wide, and Wider, with Wide as the default.
Outer line	Sets the color and transparency (0% to 100%) of the pipe outer line.
External line width	Sets the external line width of the pipe.

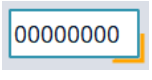
  - Point set: For details, see Polyline > Point set.
  - Basic information: For details, see Line > Basic information.
  - Animation: For details, see 13.3.8 Animation Configuration.
  - Event: For details, see 13.3.7.14 Adding an Event.

13.3.5.2 Control and Display



- 13.3.5.2.1 Numeric I/O Field
- 13.3.5.2.2 Character I/O Field
- 13.3.5.2.3 Date-Time Field
- 13.3.5.2.4 Button
- 13.3.5.2.5 Bit Button
- 13.3.5.2.6 Text Button
- 13.3.5.2.7 Bit Indicator
- 13.3.5.2.8 Text Indicator
- 13.3.5.2.9 Text List
- 13.3.5.2.10 Combobox
- 13.3.5.2.11 List Box
- 13.3.5.2.12 Text Switch
- 13.3.5.2.13 Radio Button
- 13.3.5.2.14 Checkbox
- 13.3.5.2.15 Table
- 13.3.5.2.16 Picture-in-Picture View

13.3.5.2.1 Numeric I/O Field



The "numeric I/O field" is used to modify/display variable values.

- **Numeric I/O field creation**
  - There are three methods to create a "numeric I/O field". For details, see the line creation method.
  - Direct creation with variable: Click the variable table node in the project tree, click a variable in the detail view, and drag it onto the screen. The corresponding numeric I/O field is created.
    The data type of variable does not support DATETIME, BOOL, or STRING.
    For example, dragging the system variable $Hour onto the screen generates the corresponding numeric I/O field as shown in the figure below.

- **Properties** of **numeric I/O field**
  - Basic settings:

Item	Description
Position	Sets the position coordinates (i.e., top-left coordinates) of the element on the screen in pixels: X: X-axis coordinate. Y: Y-axis position coordinate. The coordinate value must be smaller than the screen boundary coordinate value to prevent the elements from extending beyond the screen.
Dimension	Sets the size of the element on the screen in pixels. Setting range: 1 to 10000
Corner radius	Specifies the degree of curvature or smoothness at the corners of the numeric I/O field. The maximum corner radius is half of the shortest side length of the numeric I/O field. For example, for the control in the figure with dimensions 110 x 46, the shortest side length is 46, so the maximum corner radius is 23.  The two sides of the orange corner are the radius of the rounded corner, and the vertex of the corner is the center point.

  - Interface properties:

Property	Description
Mode	Value range: Input, Input/Output, Output; Default value: Input/Output. Special description: 1. Input mode and Input/Output mode:Any attempt to input illegal values or values outside the range, as well as setting such values via script, will be intercepted and the value change will not be executed. 2. Read-only mode: Data cannot be input on the screen. Script function can modify the value. 3. Input mode: Project unit is cleared and hidden. Positive/negative sign is false and hidden.
LCD display	Effective only in "Output" mode and is disabled by default. The LCD display style is . The LCD display does not support displaying in encrypted form.
Same read/ write variable	This option is selected by default. When selecteded, the read and write variables are the same, and the write variable is grayed out. When unselected, the read and write variables can be set separately.
Read/Write variable	Sets the read/ write variables. When the PLC associated with the variable is disconnected, the value remains the previous value, input is disabled, the color changes, and an icon indicates the status. The following figure shows the normal and disconnected states:  In decimal format, if a float exceeds 7 significant digits or a double exceeds 16 significant digits, the float is rounded to 7 significant digits and the double to 16 significant digits. If the set number of integer digits is less than the current number of integer digits in the variable, the variable displays "###".
Project unit	Manual input, up to 64 characters.

Display format

Format range: Hexadecimal / Decimal / Binary / BCD. Default value: Decimal.

BCD: 8421 BCD code is used. Data processed in BCD format does not include a sign bit, meaning that negative numbers cannot be represented in BCD. If it is a negative number, display "###".

Data Type	Display Format
USINT	Decimal, Hexadecimal, Binary, BCD
SINT	Decimal, Hexadecimal, Binary, BCD
UINT	Decimal, Hexadecimal, Binary, BCD
INT	Decimal, Hexadecimal, Binary, BCD
UDINT	Decimal, Hexadecimal, Binary, BCD
DINT	Decimal, Hexadecimal, Binary, BCD
ULINT	Decimal, Hexadecimal, Binary, BCD
LINT	Decimal, Hexadecimal, Binary, BCD
REAL	Decimal
LREAL	Decimal

- The display format takes effect for both input and output of numeric I/O fields:

  During offline configuration, when in input/output or output mode, the display format is validated against the data type of the read variable. If invalid, the user is prompted and a compilation error is reported. In input mode, the display format is validated against the data type of the write variable. If invalid, the user is prompted and a compilation error is reported.

  During runtime, data can only be input and displayed in this format.

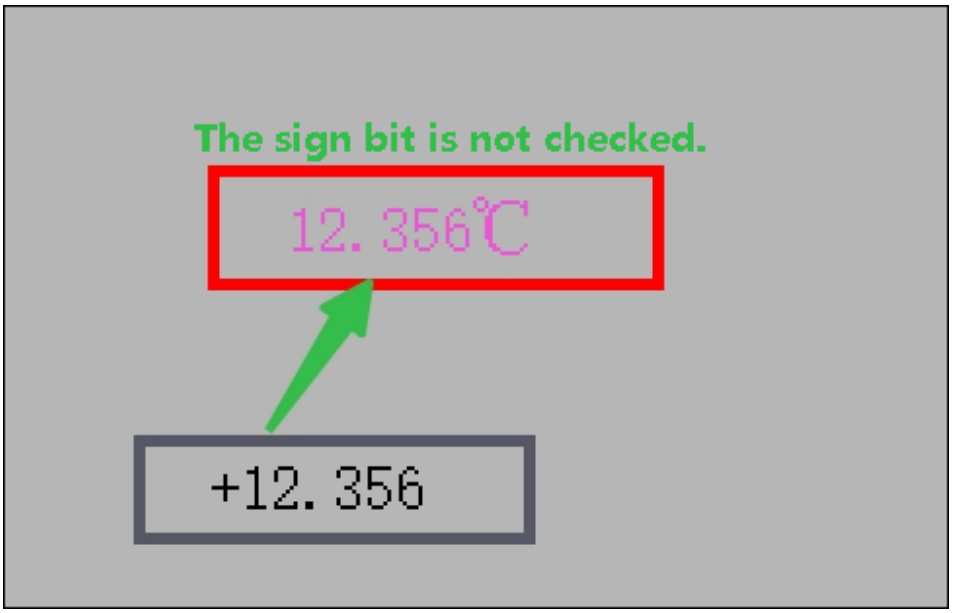
- The display format affects the range of values that can be displayed and input in the numeric I/O control:

  If the integer digit count is set to 4 and the format is decimal, the range is -9999 to 9999;

  If the number of integers is set to 4 and the format is BCD, the range is 0 to 7999. (For UINT type, the upper limit is 9999.)

  If the number of integers is set to 4 and the format is hexadecimal, the range is 0 to FFFF.

  If the number of integers is set to 4 and the format is binary, the range is 0 to 1111.



- The display format affects the display format and range of the variable upper and lower limits:

  For INT type variables, if upper and lower limits are not configured, the default limits are the data type limits: -32768 to 32767.

  If the format is decimal, the limits are -32768 to 32767.

Property	Description
	When the format is BCD, the limits are 0 to 7999. (For UINT type, the upper limit is 9999.) If there is no corresponding BCD value for the limits, the nearest valid value below the lower limit is selected, and the nearest valid value above the upper limit is selected. If the value is negative, it is treated as 0. When the format is binary, the limits are 0 to 1111111111111111. When the format is hexadecimal, the limits are 0 to FFFFF. ➢When the display format is set to BCD, BCD data must be converted to decimal before writing to the variable, and the decimal variable value must be converted to BCD for display. For example, for an INT type variable, if you input 58, the corresponding BCD code is 0101 1000, which converts to decimal 88, so the variable value should be written as 88. Similarly, when the variable value is 88, it should be displayed as 58 in BCD format.
Number of integers	Sets the number of integers. The range is 1 to 32 and the default value is 8. The number of integers must match the display format and applies to both input and output of the numeric I/O field. During runtime, data can only be input and displayed in this format. After configuring the display format, number of integers, and number of decimal places, the corresponding effect is synchronized in the IDE configuration interface: If the display format is decimal or BCD, the number of integers is 2, and the number of decimal places is 2, the IDE interface displays 00.00. If the display format is hexadecimal and the number of integers is 2, the IDE interface displays FF. If the display format is binary and the number of integers is 3, the IDE interface displays 111.

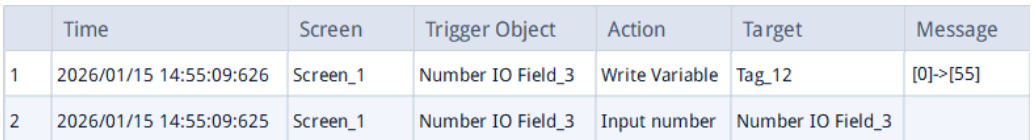
Property	Description
Decimal points	Sets the number of decimal places. The range is 0 to 16 and the default value is 0. When the display format is Binary, Hexadecimal, or BCD, the number of decimal places is reset to the default value 0, grayed out, and disabled for editing. Decimal places support rounding. That is, when the actual number of decimal places exceeds the configured number, the decimal part is rounded, as shown in the figure below:  ➢After configuring integer and decimal places for a variable, when inputting data through a numeric IO field, the input data must adhere to the user-configured limits for the lengths of integer places and decimal places. For example, for a UINT-type variable configured with 2 integers and 2 decimal places, a maximum of 2 integers and 2 decimal digits can be input. ➢After configuring the integer and decimal places for a variable, the display range of the variable is affected. For example, for a UINT-type variable configured with 2 integers and 2 decimal places, the display range of the I/O field is 0.00 to 99.99. When the variable value is 10001, it should be displayed as 100.01, which exceeds the display range of I/O field. "###" is displayed instead. ➢For non-floating-point variables, configuring decimal places is equivalent to scaling the variable, which affects the displayed upper and lower limits: For INT type variables, if upper and lower limits are not configured, the default limits are the data type limits: -32768 to 32767. When the format is decimal and the number of decimal places is 1, the limits are displayed as -3276.8 to 3276.7. When the format is BCD and the number of decimal places is 1, the limits are displayed as 0.0 to 999.9. The binary format is not applicable. The hexadecimal format is not applicable. ➢For floating-point variables, configuring decimal places does not scale the variable, but only affects the number of digits that can be input after the decimal point.

Property	Description
Sign symbol	Specifies whether to display the sign (positive/negative). This option is unselected by default (sign not displayed) and is configurable when the format is decimal. The sign symbol can be selected for signed data types. For other data types, the sign option is unselected and grayed out. ➢When the sign symbol is selected, the sign symbol is displayed. ➢When the sign symbol is not selected: 1. When the actual value is negative, a minus sign (-) is displayed on the screen. 2. When the actual value is positive, no plus sign (+) is displayed on the screen. 3. Negative values can be input because signed data types include negative values in their range, such as integers. 
Leading zero	When selected, leading zeros are automatically added if the display length is insufficient. Editing is only available in decimal/BCD format. This option is not selected by default. When selected, leading zeros are added to the integer part and the decimal part respectively. For example, with 5 integer digits and 3 decimal digits, 12.3 is displayed as 00012.300.
Cipher display	This option cannot be selected simultaneously with "LCD display". Cipher display is only used for numeric values. Project units are displayed in plain text. For display effect, see 13.15.1 Real-Time Variable Monitoring. Cipher text uses * (asterisk) to represent each character. For example, 26.5 is displayed as "****" in cipher text.

◦ Text:

Property	Description
Font	Sets the text font. The default font is Droid Sans Fallback.
Font size	Sets the text size. The default size is 18.

Property	Description
Font style	Sets the text font style. Supports regular, bold, italic, and underline. The default is regular. Supports left alignment, center alignment, and right alignment. The default is left alignment.

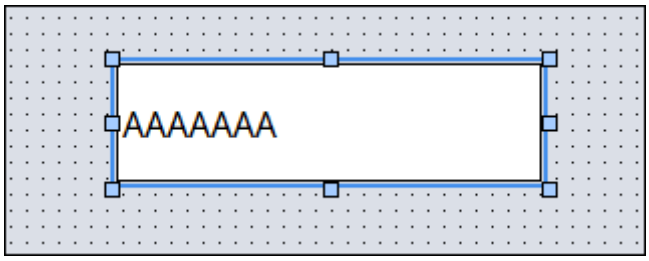


- Border:

Property	Description
Border width	The value range is 0 to 10 and the default is 1. The value can be manually input, or changed by clicking the up/down increment/decrement buttons.
Border color	Sets the border color. The default is black #000000.

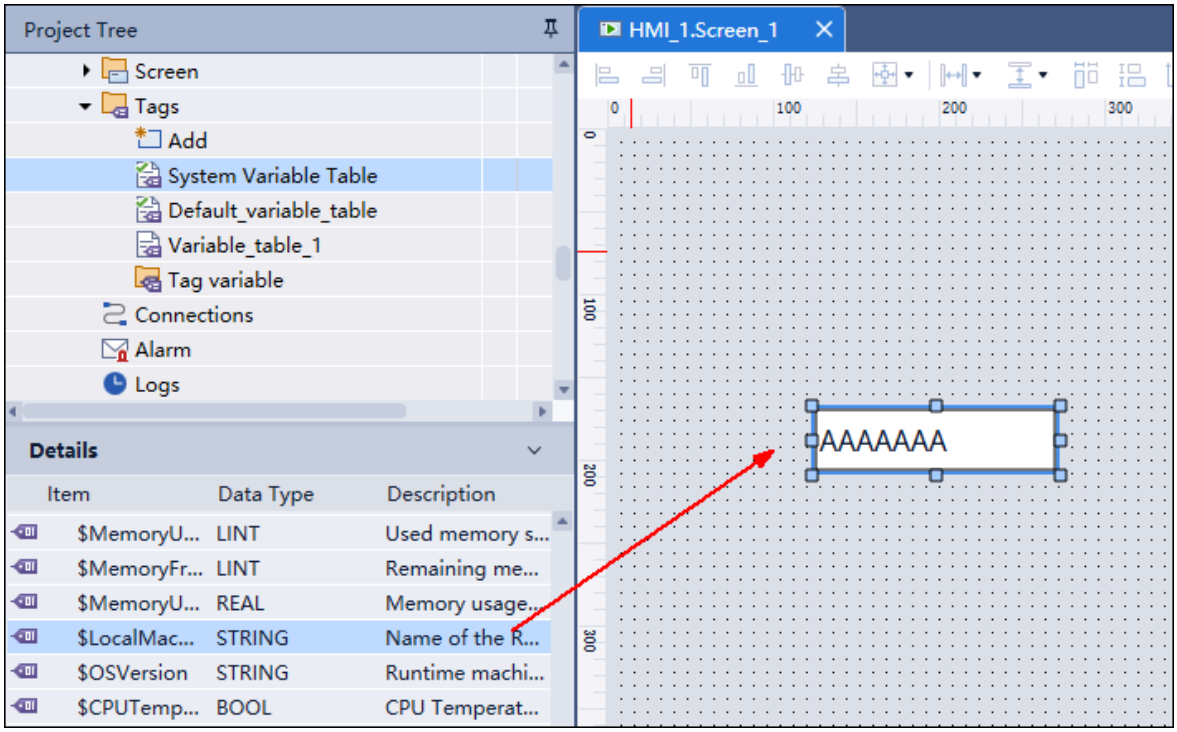
- Fill:

Property	Description
Text color	Sets the text color and transparency of the control, defaulting to black with 0%. A higher transparency value indicates a more transparent text.
Background color	Sets the background color and transparency of the control, defaulting to white with 0%. A higher transparency value indicates a more transparent background.



- Operation record:

Property	Description
Record	When the current control performs a write operation, this action is not recorded by default. If recorded, two records will be generated: one for the input value action and another for the variable write action. For example, the two logs generated when "Numeric I/O field_3" writes "55" are shown in the figure below.  Time / Screen / Trigger Object / Action / Target / Message 1 / 2026/01/15 14:55:09:626 / Screen_1 / Number IO Field_3 / Write Variable / Tag_12 / [0]->[55] 2 / 2026/01/15 14:55:09:625 / Screen_1 / Number IO Field_3 / Input number / Number IO Field_3 /
Action description	Description can be up to 256 characters, which will be displayed in the 13.3.5.4.8 Operation Records.



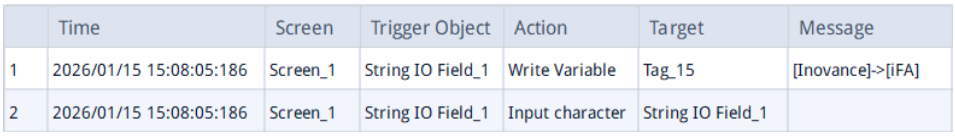
- Basic information: For details, see Line > Basic information.
- Animation: For details, see 13.3.8 Animation Configuration.
- Event: For details, see 13.3.7.14 Adding an Event.

13.3.5.2.2 Character I/O Field

The "character I/O field" reads/displays string variables.

- **Character I/O field creation**
  - There are three methods to create a "numeric I/O field". For details, see the line creation method.
  - Direct creation with variable: Click the variable table node in the project tree, click a STRING-type variable in the detail view, and drag it onto the screen. The corresponding character I/O field is created.
    For example, dragging the system variable $LocalMachineName onto the screen generates the corresponding character I/O field as shown in the figure below.

- Properties of **character I/O field**
  - For basic settings, see Numeric I/O Field > Basic settings.
  - Interface:



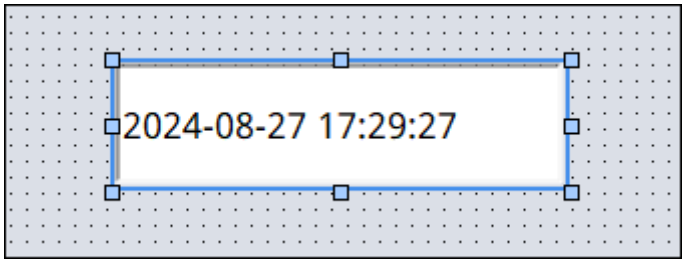
Item	Description
Mode	Value range: Input, Input/Output, Output. Default value: Input/Output. Note 1 (Input mode and Input/Output mode): Any attempt to input illegal values, set illegal values via script, or set values outside the range will be intercepted, and the value change will not be executed. Note 2 (Read-only mode): Data cannot be input on the screen. Script function can modify the value.

Item	Description
Same read/write variable	This option is selected by default. When selecteded, the read and write variables are the same, and the write variable is grayed out. When unselected, the read and write variables can be set separately.
Read variable	Sets the read variable.
Write variable	Sets the write variable.
Cipher display	Cipher text uses * (asterisk) to represent each character. For example, "Overtemperature" is displayed as "****" in cipher text. For display effect, see 13.15.1 Real-Time Variable Value Monitoring.

- Text: For details, see Numeric I/O Field > Text.
- Border:

Item	Description
Border width	The value range is 0 to 10 and the default is 1. The value can be manually input, or changed by clicking the up/down increment/decrement buttons.
Border color	Sets the border color. The default is black.

- Fill: For details, see Numeric I/O Field > Fill.
- Operation record:



Item	Description
Record	When the current control performs a write operation, this action is not recorded by default. If recorded, two records will be generated: one for the input character action and another for the variable write action. For example, the two logs generated when "Character I/O field_1" writes "iFA" are shown in the figure below. 
Action description	Description can be up to 256 characters, which will be displayed in the 13.3.5.4.8 Operation Records.

	Time	Screen	Trigger Object	Action	Target	Message
1	2026/01/15 15:08:05:186	Screen_1	String IO Field_1	Write Variable	Tag_15	[Inovance]->[iFA]
2	2026/01/15 15:08:05:186	Screen_1	String IO Field_1	Input character	String IO Field_1	

- Basic information: For details, see Line > Basic information.
- Animation: For details, see 13.3.8 Animation Configuration.
- Event: For details, see 13.3.7.14 Adding an Event.

13.3.5.2.3 Date-Time Field

The "date-time field" is used to display time.

- **Date-time field creation**

  There are three methods to create a "date-time field". For details, see the line creation method.

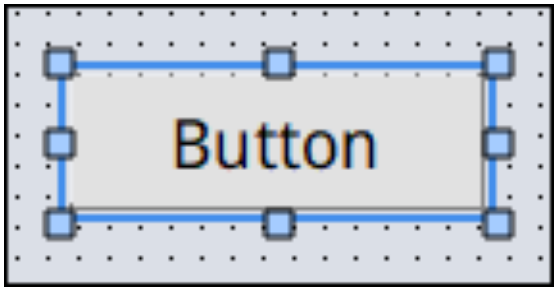
- **Properties of date-time field**
  - Basic settings: For details, see Numeric I/O Field > Basic settings.
  - Text: For details, see Numeric I/O Field > Text.
  - Interface:

Item	Description
Mode	Mode support: Output, Input/Output. When the **time source** is set to **variables**, both modes are supported. The default is Input/Output. When the **time source** is set to **system time**, only output mode is supported.
Time source	You can choose to display system time or use variables. The default is to display system time.
Variable	When selected, the time of the configured variable is displayed. It is empty by default. Supported data type is DATETIME.
Format	Time format is composed of date and time values.

  - Border:

Item	Description
Border width	The value range is 0 to 10 and the default is 1. The value can be manually input, or changed by clicking the up/down increment/decrement buttons.
Border color	Sets the border color. The default is black #000000.

  - Fill:



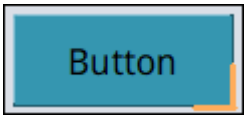
Item	Description
Text color	Sets the text color and transparency of the control, defaulting to black with 0%. A higher transparency value indicates a more transparent text.

Item	Description
Background color	Sets the background color and transparency of the control, defaulting to white with 0%. A higher transparency value indicates a more transparent background.

- Basic information: For details, see Line > Basic information.
- Animation: For details, see 13.3.8 Animation Configuration.
- Event: For details, see 13.3.7.14 Adding an Event.

13.3.5.2.4 Button

The "button" is used to execute a command at run time. Click the button to execute the command.



- **Button creation**

There are three methods to create a "button". For details, see the line creation method.

- **Button properties**
  - Basic settings:

Item	Description
Position	Sets the position coordinates (i.e., top-left coordinates) of the element on the screen in pixels: X: X-axis coordinate. Y: Y-axis position coordinate. The coordinate value must be smaller than the screen boundary coordinate value to prevent the elements from extending beyond the screen.
Dimension	Sets the size of the element on the screen in pixels. Setting range: 1 to 10000

Item	Description
Corner radius	Specifies the degree of curvature or smoothness at the corners of the button (flat style). The maximum corner radius is half of the shortest side length of the button. For example, for the control in the figure with dimensions 110 x 46, the shortest side length is 46, so the maximum corner radius is 23.  The two sides of the orange corner are the radius of the rounded corner, and the vertex of the corner is the center point.

◦ Text:

Item	Description
Text content	Sets the text displayed on the button.
Display mode	Display modes include single line and multi-line. The default is single line display.
Font	Sets the text font. The default font is Droid Sans Fallback.
Font size	Sets the text size. The default size is 18.
Font style	Sets the text font style. Supports regular, bold, italic, and underline. The default is regular.

◦ Fill:

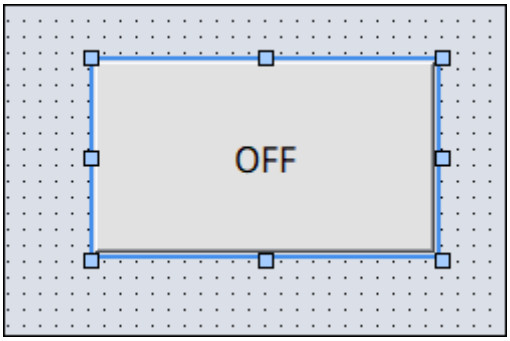
Fill style: Sets the fill style of the default background color for buttons.

◦ Style:

Property	Description
Icon	Displays the image on the button.
Icon size	Sets the display size of the image.
Button style	Normal: 3D display. Flat: Flat display. Flat-style buttons can adjust the corner radius through the "Corner radius" option in "Basic setting".
Icon layout	Image layout on the button: Icon Only: Displays the image with no text. Left/Right/Top/Bottom: Position of the image around the text.

◦ Border:

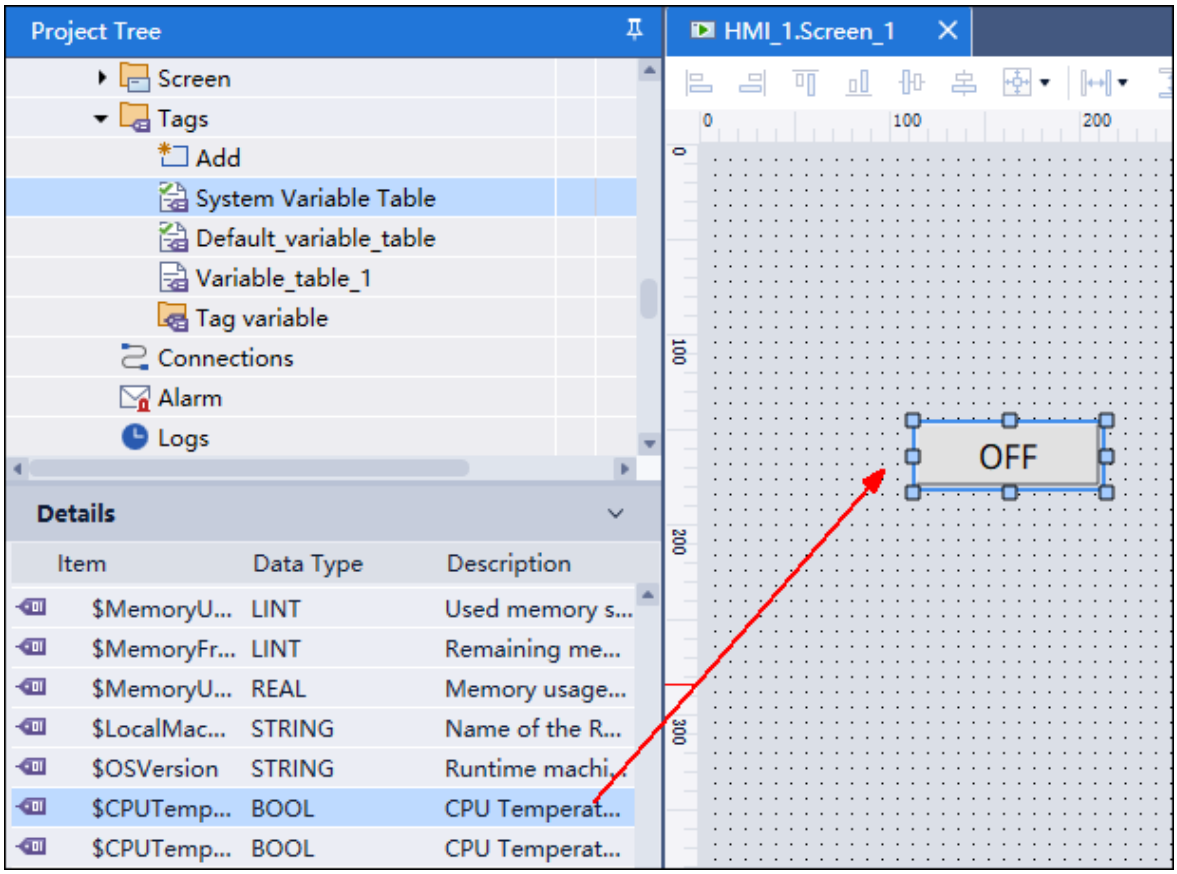
Item	Description
Border width	Applies to flat-style buttons. The range of border width is 0 to10, where 0 indicates no border.
Border color	Sets the border line color and transparency.
Default text color	Sets the default color and transparency of the button text.
Default background color	Sets the default background color and transparency of the button.
Pressed background color	Sets the background color and transparency when the button is pressed.
Disabled background color	Sets the background color and transparency when the button is disabled.



- Operation record:

Item	Description
Record	When the current control performs a click operation, this action is not recorded by default. If recorded, a record will be generated. For example, the following figure shows the log generated by clicking "Button_2". | | Time | Screen | Trigger Obje | Action | Target | | 1 | 2026/01/15 15:14:13:597 | Screen_1 | Button_2 | Click the Button , open screen_2 | Button_2 |
Action description	Description can be up to 256 characters, which will be displayed in the 13.3.5.4.8 Operation Records.

- Basic information: For details, see Line > Basic information.
- Animation: For details, see 13.3.8 Animation Configuration.
- Event: For details, see 13.3.7.14 Adding an Event.



13.3.5.2.5 Bit Button

The "bit button" sets, modifies and displays the value of a variable at a specified bit position.

- **Bit button creation**
  - There are three methods to create a "bit button". For details, see the line creation method.

◦ Direct creation with variable: Click the variable table node in the project tree, click a BOOL-type variable in the detail view, and drag it onto the screen. The corresponding bit button is created. For example, dragging the system variable $CPUTemperatureHigh onto the screen generates the corresponding bit button as shown in the figure below.

- **Properties of bit button**

◦ For basic settings, see Button > Basic settings.

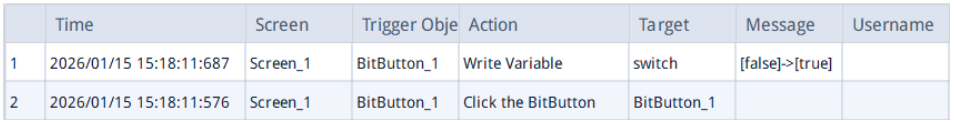
◦ Data:

Item	Description
Same read/ write variable	Specifies whether the read value and write value of the bit button are associated with the same variable. This option is selected by default.
Invert read output	Specifies whether the bit button state is inverted relative to the associated variable value. This option is selected by default.
Read variable	Selects the read variable to associate with the control.
Write variable	Selects the write variable to associate with the control.
Write mode	Set: Set the bound variable to 1 when the button is released. Reset: Set the bound variable to 0 when the button is released. Invert: Write the inverted value. Press ON: Set to 1 when pressed; set to 0 when released. Press OFF: Set to 0 when pressed; set to 1 when released.

Item	Description
Read bit number	When a variable of integer data type is selected as the read variable, the bit number is enabled. The default value is 0. The value range changes according to the variable type. For example, when the associated variable is INT, the range is 0 to 15; when the variable type is LINT, the range is 0 to 63.
Write bit number	When a variable of integer data type is selected as the write variable, the bit number is enabled. The default value is 0. The value range changes according to the variable type. For example, when the associated variable is INT, the range is 0 to 15; when the variable type is LINT, the range is 0 to 63. When the read/write variables are the same, this option is grayed out and cannot be edited. The write bit number is automatically synchronized with the read bit number.
Click animation	The animation is scaled when you click this button in runtime. This option is selected by default.
Minimum press duration	Specifies the minimum press duration (in ms) required to trigger the associated event. Used to prevent accidental operation on the touch screen. Value range: 0 to 60,000.
Auto repeat	When the button is pressed, the event can be repeatedly triggered. This option is not selected by default.

◦ Text:

Item	Description
Text position	The position of text display on the button. Position options: top-left, top-center, top-right, middle-left, center, middle-right, bottom-left, bottom-center, bottom-right, text left-aligned, text right-aligned, text top-aligned, and text bottom-aligned.
Font	Sets the text font. The default font is Droid Sans Fallback.
Font size	Sets the text size. The default size is 18.
Font style	Sets the text font style. Supports regular, bold, italic, and underline. The default is regular. Supports left alignment, center alignment, and right alignment. The default is left alignment.

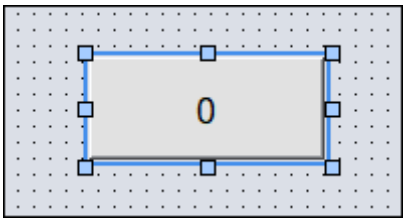


◦ Bit state settings:

Item	Description
State [0]	The state displayed on the button when the specified bit value of the associated variable is 0. Text: The text content on the button when the associated variable value is 0. Flashing: The flashing state when the associated variable value is 0. Flashing options: No, Text Color Alternation, and Display/Hide. The default is No. Style: Effect Preview Text color: The color of the text on the button when the associated variable value is 0. Background color: The background color of the button when the associated variable value is 0. Background image: The image displayed on the button when the associated variable value is 0.
State[1]	The state displayed on the button when the specified bit value of the associated variable is 1. Text: The text content on the button when the associated variable value is 1. Flashing: The flashing state when the associated variable value is 1. Flashing options: No, Text Color Alternation, and Display/Hide. The default is No. Style: effect preview Text color: The color of the text on the button when the associated variable value is 1. Background color: The background color of the button when the associated variable value is 1. Background image: The image displayed on the button when the associated variable value is 1.

- Border: For details, see Button > Border.
- Fill:

Item	Description
Fill style	Sets the background fill style of the button.
Button style	Normal: 3D display  Flat: Flat display  Flat-style buttons can adjust the corner radius through the "Corner radius" option in "Basic setting".



- Operation record:

Item	Description
Record	When the current control performs a write operation, this action is not recorded by default. If recorded, two records will be generated: one for the click action and another for the variable write action. For example, the two logs shown in the figure below are generated when the state of "Bit button_1" switches to "ON".  | | Time | Screen | Trigger Obje | Action | Target | Message | Username | | 1 | 2026/01/15 15:18:11:687 | Screen_1 | BitButton_1 | Write Variable | switch | [false]->[true] | | | 2 | 2026/01/15 15:18:11:576 | Screen_1 | BitButton_1 | Click the BitButton | BitButton_1 | | |
Action description	Description can be up to 256 characters, which will be displayed in the 13.3.5.4.8 Operation Records.

- Basic information: For details, see Line > Basic information.
- Animation: For details, see 13.3.8 Animation Configuration.
- Event: For details, see 13.3.7.14 Adding an Event.

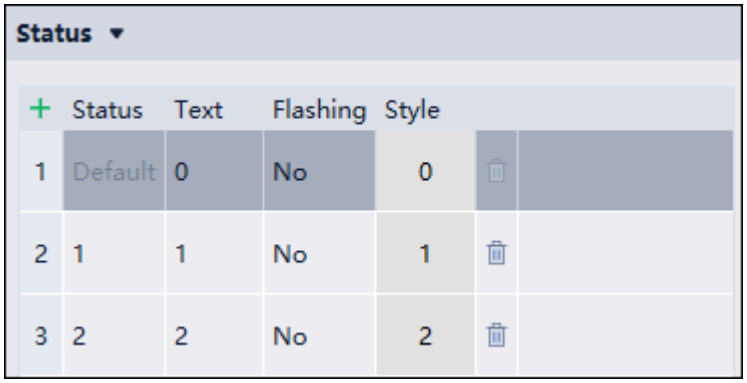
13.3.5.2.6 Text Button

The "text button" sets, modifies, and displays an integer variable value.

- **Text button creation**

There are three methods to create a "text button". For details, see the line creation method.

- **Properties of word button**
  - For basic settings, see Button > Basic settings.
  - Data:



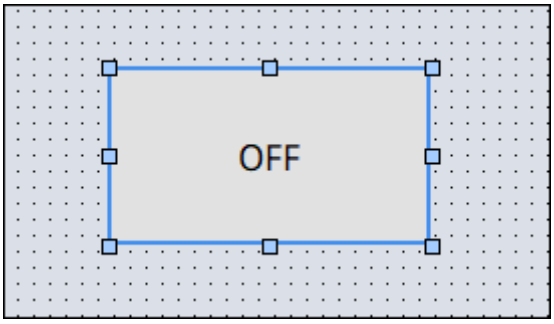
Item	Description
Same read/write variable	Specifies whether the read value and write value of the word button are associated with the same variable. This option is selected by default.
Read variable	Selects the read variable to associate with the control. Only integer variables are supported.
Write variable	Selects the write variable to associate with the control. Only integer variables are supported.

Item	Description
Mode	1. Increment: The write variable increases by a target value (variable or constant) each time. 2. Decrement: The write variable decreases by a target value (variable or constant) each time. 3. Cycle increment: The write variable increases by the next value in the ordered sequence of states. If the write variable value is outside the state range, the last state value is used. When the current value is the last one, it increments to the first value. 4. Cycle decrement: The write variable decreases by the next value in the ordered sequence of states. If the write variable value is outside the state range, the last state value is used. When the current value is the first one, it decrements to the last value. 5. State increment: The write variable increases by the next value in the ordered sequence of states. If the write variable value is outside the state range, the last state value is used. Increment stops when the current value is the last value. 6. State decrement: The write variable decreases by the next value in the ordered sequence of states. If the write variable value is outside the state range, the last state value is used. Decrement stops when the current value is the first value. 7. Custom: After clicking the button, set the write variable value to a custom target value, which can be a constant or variable. The default mode is increment. When same read/write variable is not selected, only increment, decrement and custom mode are supported.
Constant	Sets the target values for increment, decrement, and custom, which can be any real number. The default value is 1.
Variable	Sets the target variable for increment, decrement, and custom.
Click animation	The animation is scaled when you click this button in runtime. This option is selected by default.
Minimum press duration	Specifies the minimum press duration (in ms) required to trigger the associated event. Used to prevent accidental operation on the touch screen. Value range: 0 to 60,000.
Auto repeat	When the button is pressed, the event can be repeatedly triggered. This option is not selected by default.

- Fill: For details, see Bit Button > Fill.
- Border: For details, see Button > Border.
- Operation record:

Item	Description
Record	When the current control performs a write operation, this action is not recorded by default. If recorded, two records will be generated: one for the click action and another for the variable write action. For example, the two logs shown in the figure below are generated when the state of "Text button_2" switches to "3". | | Time | Screen | Trigger Object | Action | Target | Message | | 1 | 2026/01/15 15:23:43:983 | Screen_1 | WordButton_2 | Write Variable | Tag_3 | [2]->[3] | | 2 | 2026/01/15 15:23:43:866 | Screen_1 | WordButton_2 | Click the WordButton | WordButton_2 | |
Action description	Description can be up to 256 characters, which will be displayed in the 13.3.5.4.8 Operation Records.

- Text: For details, see Bit Button > Text.
- Word state: Multiple word states can be added to the word state property. Click the "Add" button to add a state. Each text indircator control has a default state that cannot be deleted. The default state value is "Default", and the default text is 0, with a maximum of 256 characters.



Property		Description
Status		Sets the state value, supporting single values or value range. When the variable value matches the state value, or falls within the value range, the button displays the text content.
Text		Sets the text content to be displayed when the state value is met.
Flashing		Sets the flashing method when the state value is met. Flashing methods: ▪ No: No flashing. ▪ Text Color Alternation: The text content flashes, while the button does not. ▪ Display/Hide: The entire button flashes.
Style	Text color	Text color for state value display
	Background color	Background color for state value display

Property		Description
	Background image	Background image for state value display

- For basic information, see Line > Basic information.
- For animation, see 13.3.8 Animation Configuration.
- Event: For details, see 13.3.7.14 Adding an Event.

13.3.5.2.7 Bit Indicator

The "bit indicator" displays the value of a variable at a specified bit position.

- **Bit indicator creation**

  There are three methods to create a "bit indicator". For details, see the line creation method.

- **Properties of bit status display**
  - For basic settings, see Button > Basic settings.
  - Data:

Item	Description
Invert read output	Specifies whether the bit indicator is inverted relative to the read value of the associated variable. This option is selected by default.
Read variable	Selects the read variable to associate with the control.
Bit number	When the read variable is of integer data type, bit enable is active by default, with a default value of 0. The value range changes according to the variable type. For example, when the associated variable is INT, the range is 0 to 15; when the variable type is LINT, the range is 0 to 63.

  - Text: For details, see Bit Button > Text.
  - Bit state settings: For details, see Bit Button > Bit state.
  - Border:

Item	Description
Border width	The range of border width is 0 to10, where 0 indicates no border.
Border color	Sets the border line color and transparency.

  - Fill properties:

Item	Description
Fill style	Sets the background fill style of the button.

- Basic information: For details, see Line > Basic information.
- Animation: For details, see 13.3.8 Animation Configuration.

13.3.5.2.8 Text Indicator

The "text indicator" is used to display variable values.

- **Text indicator creation**

  There are three methods to create a "text indicator". For details, see the line creation method.

- **Properties of text indicator**
  - Basic Settings: For details, see Button > Basic settings.
  - Data: Read variable is used to specify the variable associated with the text indicator.
  - Text: For details, see Bit Button > Text.
  - Text indicator settings: For details, see Text Button > Text state.
  - Border:

Item	Description
Border width	The range of border width is 0 to10, where 0 indicates no border.
Border color	Sets the border line color and transparency.

  - Fill:

Item	Description
Fill style	Sets the background fill style of the button.

  - Basic information: For details, see Line > Basic information.
  - Animation: For details, see 13.3.8 Animation Configuration.

13.3.5.2.9 Text List

The "text list" is used to edit its associated variables based on its setpoints, and to display the corresponding text according to the current values of the associated variables.

- **Text list creation**

  There are three methods to create a "text list". For details, see the line creation method.

- **Properties of text list**

  - For basic settings, see Numeric I/O Field > Basic settings.
  - Options:

Item	Description
Text list	Selects the text list to bind. Text lists with empty content are not supported.
Mode	Input/Output mode: control style  Output mode: control style  The default value is "Input/Output" mode.
Visible entries	The number of texts available for user selection. It is displayed when "Mode" is set to "Input/Output". The range is 1 to 100 with a default value of 3.
Variable	The correspondence between the variable values and entry values (or Bit No.) is: ▪ Integer variable: If the "Selection" value of the text is "Bit (0, n)": Bit n corresponds to 2^n. For example, bit 0 corresponds to 2^0, which is 1. If the "Selection" value of the text is "Value/Range": Item values corresponds one-to-one with the variable values. ▪ Boolean type: If the "Selection" value of the text is "Bit (0,1)": Bit 0 corresponds to the variable value False, and bit 1 corresponds to the variable value True.

  - Text: For details, see Numeric I/O Field > Text.
  - Stroke:

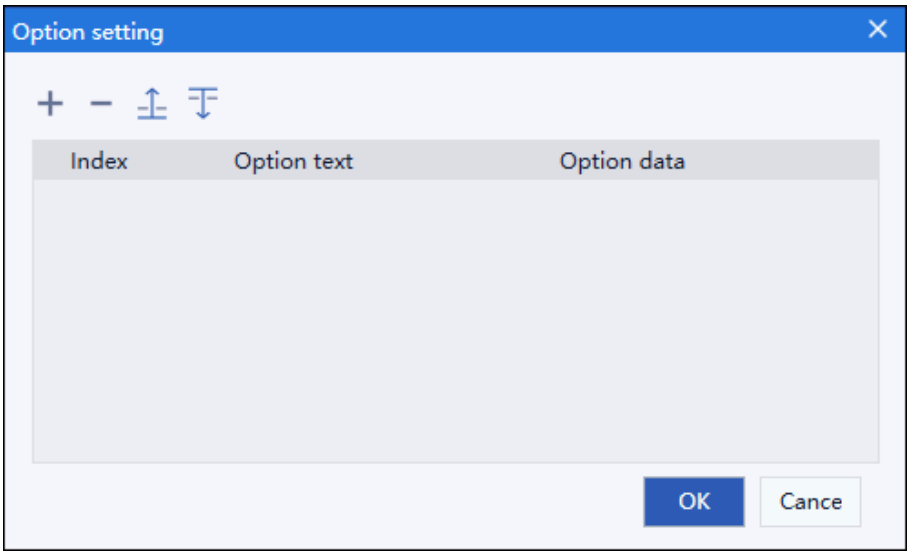
Item	Description
Border	Sets whether the text list displays a border. This option checked by default.
Border width	Sets the border width range from 0 to 10. The default is 1.
Border color	Sets the border color of the text list. The default is #B9C2D5.

  - Fill:

Item	Description
Text color	Specifies the text color. The default is #0C1A34.
Background color	Specifies the color value and transparency (0% to 100%). The default color value is #FFFFFF and transparency is 0%.

- Basic information: For details, see Line > Basic information.
- Animation: For details, see 13.3.8 Animation Configuration.
- Event: For details, see 13.3.7.14 Adding an Event.

13.3.5.2.10 Combobox



The "combobox" is used to display and select specific values.

- **Combobox creation**

  There are three methods to create a "combobox". For details, see the line creation method.

- **Combobox properties**
  - For basic settings, see Numeric I/O Field > Basic settings.
  - Text: For details, see Numeric I/O Field > Text.
  - Options:

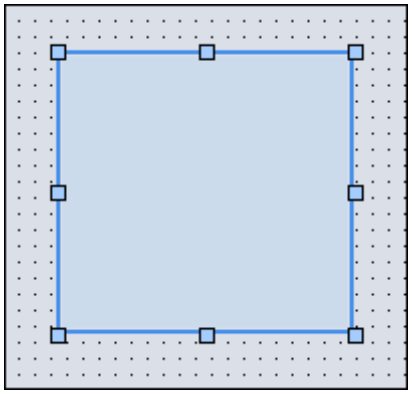
Item	Description
Option settings	Configures the combobox options.  ▪ Click the "Add/Delete" button:  Adds or deletes options. New options are named "Option n" by default. Option indices are automatically generated and cannot be modified, starting from 0 and incrementing. The maximum number of options is 32 (index row range: 0 to 31). ▪ Click the "Move up/Move down" button:  Adjusts the order of options. Only the option text is rearranged. The option index positions remain unchanged.
Variable bound to option	During runtime, the option data corresponding to the selected text in the drop-down list will be output to the bound variable here. Supports inversion display of the bound variable: when the bound variable changes, the selected item of the control automatically follows the change. If the variable value does not match any option data of the current control and inversion display cannot be performed, the combobox displays "***".
Visible entries	The number of visible entries dropdown at runtime. The range is 1 to 32 with a default of value of 3.

◦ Fill:

Item	Description
Text color	Sets the text color of the control. The default is black.
Background color	Sets the background color of the control. The default is white.

◦ Border:

Item	Description
Border	Sets whether the combobox displays a border. This option is checked by default.
Border width	Sets the combobox width range from 0 to 10. The default is 1.
Border color	Sets the border color of the combobox.



- Operation record:

Item	Description
Record	When the current control performs a write operation, this action is not recorded by default. If recorded, two records will be generated: one for the click action and another for the variable write action. For example, the two logs generated when selecting "Brown" in the initial state of "Combobox_1" are shown in the figure below. Time / Screen / Trigger Obje / Action / Target / Message 1 / 2026/01/15 15:31:00:536 / Screen_1 / ComboBox_1 / Write Variable / Tag_3 / [0]->[145] 2 / 2026/01/15 15:31:00:535 / Screen_1 / ComboBox_1 / Click the ComboBox / ComboBox_1 / [***]->[Brown]
Action description	Description can be up to 256 characters, which will be displayed in the 13.3.5.4.8 Operation Records.

- Basic information: For details, see Line > Basic information.
- Animation: For details, see 13.3.8 Animation Configuration.
- Event: For details, see 13.3.7.14 Adding an Event.

13.3.5.2.11 List Box

The "list box" is used to display and select specific values.

- **List box creation**

  There are three methods to create a "list box". For details, see the line creation method.

- **Properties of list box**
  - For basic settings, see Numeric I/O Field > Basic settings.
  - Text: For details, see Numeric I/O Field > Text.

◦ Options:

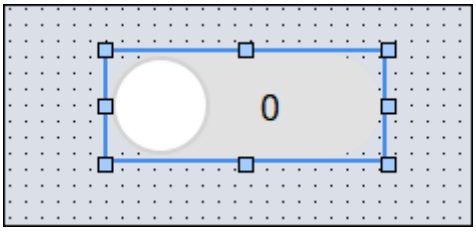
Item	Description
Option settings	Configures the list box options. ▪ Click the Add/Delete buttons: Adds or deletes options. New options are named "Option n" by default. Option indices are automatically generated and cannot be modified, starting from 0 and incrementing. The maximum number of options is 32 (index row range: 0 to 31). ▪ Click the Direction button: Adjusts the order of the option text without affecting the index numbers.
Variable bound to option	During runtime, the option data corresponding to the selected text in the drop-down list will be output to the bound variable here. Supports inversion display of the bound variable: when the bound variable changes, the selected item of the control automatically follows the change. If the variable value does not match any option data of the current control and inversion display cannot be performed, the list box displays no selection.

◦ Fill:

Item	Description
Text color	Sets the text display color of the list box.
Background color	Sets the background color of the list box.
Selected item color	Sets the selection color for the selected item in the list box.

◦ Border:

Item	Description
Border	Manages the validity of border property.
Border width	Selects the line width for the list box outline. The line width range is 1 to 10, with a default value of 1.
Border color	Selects the color for the list box outline.



◦ Operation record:

Item	Description
Record	When the current control performs a write operation, this action is not recorded by default. If recorded, two records will be generated: one for the click action and another for the variable write action. For example, the two logs generated when "List box_1" selects "Blue" are shown in the figure below. | | Time | Screen | Trigger Object | Action | Target | Message | | --- | --- | --- | --- | --- | --- | --- | | 1 | 2026/01/16 10:56:45:713 | Screen_1 | Listbox_1 | Write Variable | Tag_3 | [5]->[7] | | 2 | 2026/01/16 10:56:45:712 | Screen_1 | Listbox_1 | Click the ListControl | Listbox_1 | [Red]->[Blue] |
Action description	Description can be up to 256 characters, which will be displayed in the 13.3.5.4.8 Operation Records.

- Basic information: For details, see Line > Basic information.
- Animation: For details, see 13.3.8 Animation Configuration.
- Event: For details, see 13.3.7.14 Adding an Event.

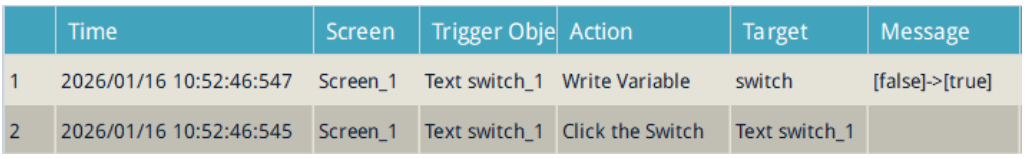
13.3.5.2.12 Text Switch

The "text switch" is associated with a Boolean value and displays the project meaning of whether the Boolean value is set to TRUE or FALSE.

- **Text switch creation**

  There are three methods to create a "text switch". For details, see the line creation method.

- **Properties of text switch**
  - For basic settings, see Numeric I/O Field > Basic settings.
  - Text: For details, see Numeric I/O Field > Text.
  - Interface:

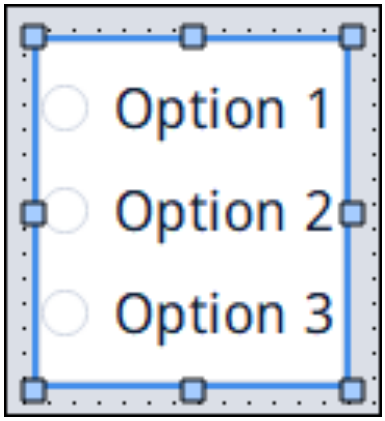


Item	Description
Switch	Specifies whether to display the switch button. This option is selected by default.
Click animation	Animation enabled. This option is selected by default.
ON state text	ON state text. The default value is 1. The text length is limited to 128.

Item	Description
OFF state text	OFF state text. The default value is 0. The text length is limited to 128.
Delay (ms)	Animation delay. The value range is 0 to 60000 ms.
Variable	Sets the reference variable.

- Fill:

Item	Description
Text color	Sets the text color of the control. The default is black.
Background color	Sets the background color of the control. The default is #ECE9DB.

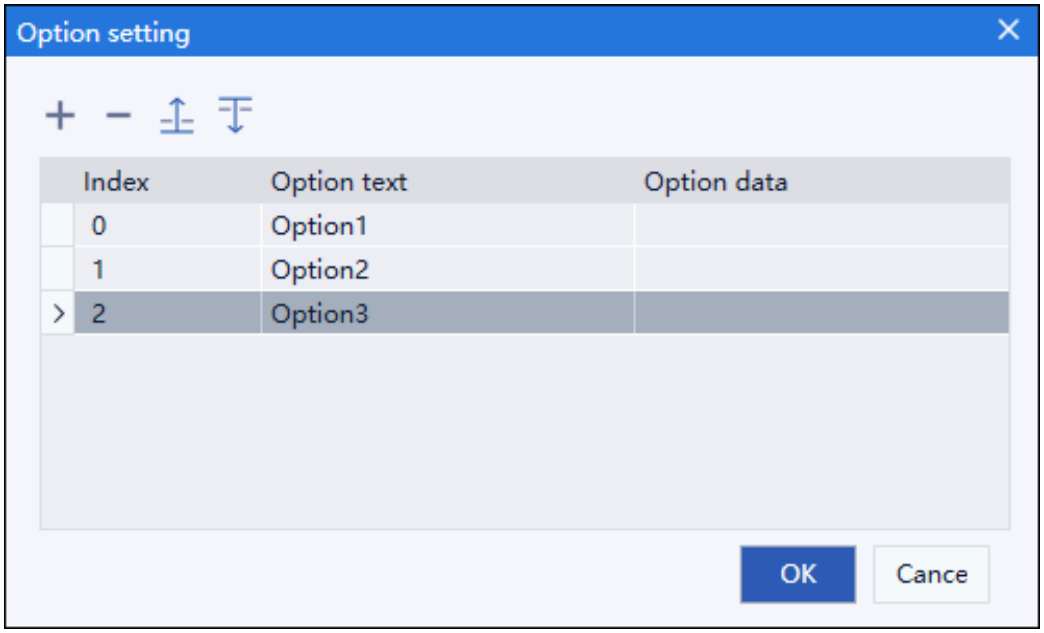


- Operation record:

Item	Description
Record	When the current control performs a write operation, this action is not recorded by default. If recorded, two records will be generated: one for the click action and another for the variable write action. For example, the two logs shown in the figure below are generated when the state of "Text switch_1" switches to "Running".  | | Time | Screen | Trigger Obje | Action | Target | Message | | 1 | 2026/01/16 10:52:46:547 | Screen_1 | Text switch_1 | Write Variable | switch | [false]->[true] | | 2 | 2026/01/16 10:52:46:545 | Screen_1 | Text switch_1 | Click the Switch | Text switch_1 | |
Action description	Description can be up to 256 characters, which will be displayed in the 13.3.5.4.8 Operation Records.

- Basic information: For details, see Line > Basic information.
- Animation: For details, see 13.3.8 Animation Configuration.
- Event: For details, see 13.3.7.14 Adding an Event.

13.3.5.2.13 Radio Button

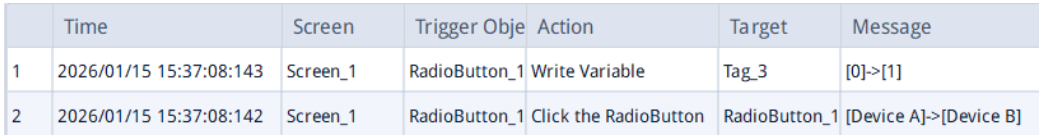


The radio button is used to select a specific value.

- **Radio button creation**

There are three methods to create a radio button. For details, see the line creation method.

- **Radio button properties**
  - For basic settings, see Numeric I/O Field > Basic settings.
  - Text: For details, see Numeric I/O Field > Text.
  - Options:



Property	Description
Option settings	Configures the options of the radio button.  A radio button has three options by default. ▪ Click the "Add/Delete" button:  Adds or deletes options. New options are named "Option n" by default. Option indices are automatically generated and cannot be modified, starting from 0 and incrementing. The maximum number of options is 32 (index row range: 0 to 31). ▪ Click the "Move up/Move down" button:  Adjusts the order of options. Only the option text is rearranged. The option index positions remain unchanged.

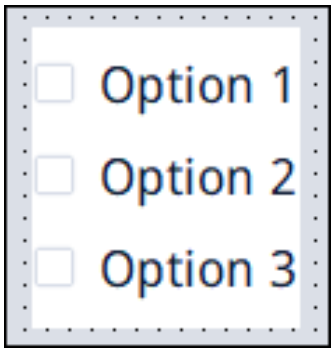
Property	Description
Variable bound to option	The bound variable types include signed integer arrays, unsigned integer arrays, and one-dimensional boolean arrays. • Signed integer data: The variable value corresponds one-to-one with the option index. For example, if the variable value is 5, the sixth option from the top is selected. • Unsigned integer data: The options correspond one-to-one with bits in the integer variable. For example, option 1 corresponds to bit 0, and option 2 corresponds to bit 1. When an option is selected, the corresponding bit is set. • Boolean one-dimensional array: The array elements (from top to bottom) correspond one-to-one with the option index numbers. The first array element corresponds to the option with index 0. When the second array element is true, the second option is selected.
Option docking	Sets the option docking mode, including left and right. The default is left.
Option layout	Sets the layout mode for options, including vertical and horizontal, with vertical as default.

◦ Fill:

Property	Description
Text color	Sets the color of the radio button text.
Background color	Sets the background color and transparency (0% to 100%) of the group box.

◦ Operation record:

Record	When the current control performs a write operation, this action is not recorded by default. If recorded, two records will be generated: one for the click action and another for the variable write action. For example, the two logs generated when the "Radio button_1" selects the option "Device B" are shown in the figure below.  Time / Screen / Trigger Obje / Action / Target / Message 1 / 2026/01/15 15:37:08:143 / Screen_1 / RadioButton_1 / Write Variable / Tag_3 / [0]->[1] 2 / 2026/01/15 15:37:08:142 / Screen_1 / RadioButton_1 / Click the RadioButton / RadioButton_1 / [Device A]->[Device B]
Action description	Description can be up to 256 characters, which will be displayed in the 13.3.5.4.8 Operation Records.



◦ Basic information: For details, see Line > Basic information.

◦ Animation: For details, see 13.3.8 Animation Configuration.

◦ Event: For details, see 13.3.7.14 Adding an Event.

13.3.5.2.14 Checkbox

The "checkbox" allow multiple options to be selected at once.

- **Checkbox creation**

  There are three methods to create a "checkbox". For details, see the line creation method.

- **Checkbox properties**
  - For basic settings, see Numeric I/O Field > Basic settings.
  - Text: For details, see Numeric I/O Field > Text.
  - Options: Checkboxes support binding variable types of Boolean one-dimensional arrays and unsigned integers. Other property settings are the same as for radio buttons. For details, see Radio Button > Options.

> **NOTE**
>
> If the number of options added in the option settings exceeds the number of bits of the bound variable, the excess options will fail during online operation. For example, if 10 options are added and the bound variable is of USINT type, then the last two options of the checkbox will not be operable online.

  - Fill: For details, see Radio Button > Fill.
  - Operation record:

Item	Description
Record	When the current control performs a write operation, this action is not recorded by default. If recorded, two records will be generated: one for the click action and another for the variable write action. For example, the two logs generated when the "Checkbox_1" checks the option "Behind" are shown in the figure below. | | Time | Screen | Trigger Obje | Action | Target | Message | | 1 | 2026/01/16 09:37:12:740 | Screen_1 | CheckBox_1 | Write Variable | Array1 | [true][false][false][false]->[true][false][false][true] | | 2 | 2026/01/16 09:37:12:740 | Screen_1 | CheckBox_1 | Click the CheckBo | CheckBox_1 | [Left]->[Left][Back] |
Action description	Description can be up to 256 characters, which will be displayed in the 13.3.5.4.8 Operation Records.

- Basic information: For details, see Line > Basic information.
- Animation: For details, see 13.3.8 Animation Configuration.
- Event: For details, see 13.3.7.14 Adding an Event.

13.3.5.2.15 Table

The "table" control is used to arrange controls on the screen.

- **Table creation**

  There are three methods to create a "table". For details, see the line creation method.

- **Table properties**
  - For basic settings, see Numeric I/O Field > Basic settings.
  - Border:

Property	Description
Border color	Specifies the border color.
Line width	Sets the line width inside the table. The range is 1 to 10, with a default value of 2.
Line type	Sets the line type inside the table.

  - Fill:

Property	Description
Background color	Sets the table background color and transparency (0% to 100%).

  - Interface properties:

Property	Description
Row count	Sets the number of table rows (range: 1 to 64). When the table spacing mode is set to "Equal", the number of rows can be modified in the property bar. When the spacing mode is set to Custom, the number of rows cannot be modified in the property bar; rows can only be dynamically added or deleted via the right-click menu during table editing.
Column count	Sets the number of table columns (range: 1 to 64). When the table spacing mode is set to "Equal", the number of columns can be modified in the property bar. When the spacing mode is set to Custom, the number of columns cannot be modified in the property bar; rows can only be dynamically added or deleted via the right-click menu during table editing.

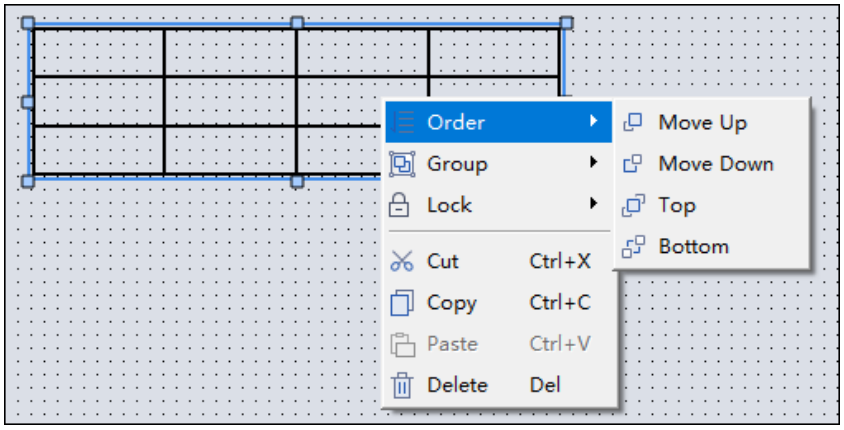
  - Alignment:

Property	Description
Text alignment	Sets the position of the control within the cell relative to the cell. ▪ Left align: The control aligns with the left border of the cell. ▪ Center: The control is centered within the cell. ▪ Right align: The control aligns with the right border of the cell. The settings apply to all controls in all table cells.

◦ Spacing:

Property	Description
Spacing	Sets the spacing mode for row height and column width: Equal / Custom. The default is Equal. ▪ Equal: Distributes the row height and column width evenly based on the overall width and height of the table. ▪ Custom: Allows dynamic adjustment of each row height (column width). Each row height (column width) can be different.

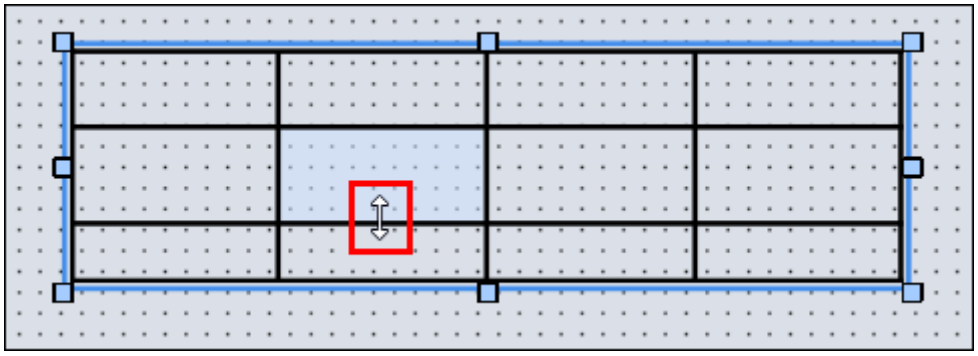
◦ Cell properties:



Property	Description
Background color	Sets the background color and transparency of selected cells.
Alignment	Sets the layout position of controls inside selected cells relative to the cell. ▪ Left align: The control aligns with the left border of the cell. ▪ Center: The control is centered within the cell. ▪ Right align: The control aligns with the right border of the cell. The settings apply to controls in selected cells only.

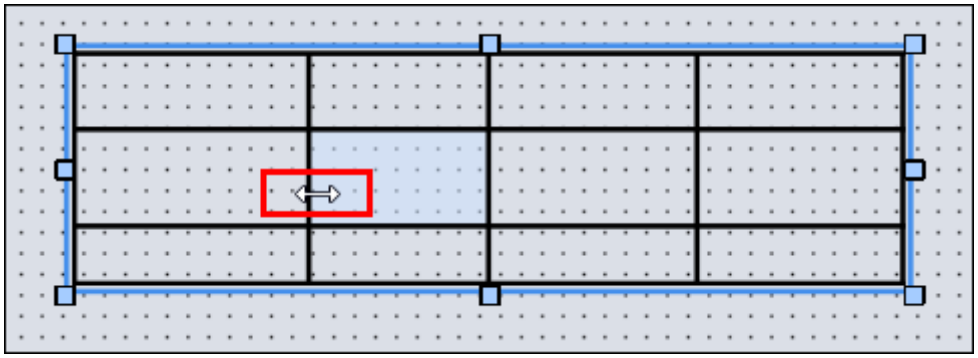
◦ Basic information: For details, see Line > Basic information.

◦ Animation: For details, see 13.3.8 Animation Configuration.



- **Table editing**

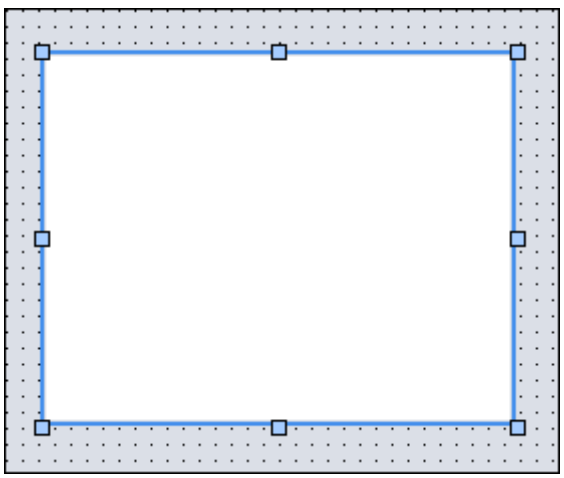
◦ In design mode, the table control can be edited, including adding or removing rows and columns, merging or splitting cells, and adjusting row height and column width inside the table. Double-click the table to enter edit mode, where you can perform editing operations. Right-click to open the edit menu:



- Insert row/column: Adds a row above or below the selected cell, or add a column to the left or right of the selected cell.
- Merge cells: Merges selected cells into a single cell. The merged cell can continue to be merged with a single cell.
- Split cell: Splits a merged cell back into individual cells, down to the smallest possible cells.
- Delete row/column: Deletes the row or column containing the selected cell.

◦ When the table spacing mode is set to Custom, row height can be adjusted dynamically. Double-click the table to enter edit mode. Move the mouse near the row adjustment area. When the mouse pointer changes to the icon shown below, drag the mouse to adjust the row height.

◦ When the table spacing mode is set to Custom, column width can be adjusted dynamically. Double-click the table to enter edit mode. Move the mouse near the column adjustment area. When the mouse pointer changes to the icon shown below, drag the mouse to adjust the column width.



- **Layout rules for tables and other controls**
  - ◦ All controls except tables can be dragged into the table for layout.
  - ◦ When moving a control within the table cell range, its position is automatically adjusted according to the configured alignment after moving. Controls move with the table when dragging.
  - ◦ If a control already exists in a cell, no additional control can be added to it. Even if dragged into the table, its position will not be adjusted automatically, and it will not move when the table is dragged.

- If the display area of a table cell is smaller than that of the control, the control will not be scaled. For better appearance, scaling the control manually is recommended.
- When the entire table is moved or scaled, the control positions inside the table automatically adjust according to the cell positions. Only display positions are adjusted without scaling.
- Move a control inside the table.
  - The control position in the cell is automatically adjusted according to the configured alignment after movement.
  - When moved out of the table, the control is removed from the cell layout.
- Deleting the table does not delete the controls laid out inside the table.
- When copying a table, only the table is copied. The controls laid out inside the table are not copied.
- Controls inside a table cannot be grouped with other controls.
- Controls already laid out inside a table cannot be grouped with each other.
- Grouped graphic elements laid out inside a table cannot be ungrouped.
- In runtime mode, only the table is drawn. All table operations in design mode are not supported in runtime mode.
- After the table is locked, it cannot enter edit mode.
- Graphic elements laid out within a table cannot be moved using the keyboard. Their position and size cannot be modified via the property bar. Alignment, equal size, and equal spacing operations are not allowed.
- Graphic elements can only be placed into the table by mouse dragging. Positioning into the table via other methods (keyboard movement, property bar position modification, alignment, etc.) will not integrate the graphic elements into the table layout, nor will it move with the table.
- After a graphic element laid out in the table has undergone animation such as scaling, moving, or rotating, its final position and size after animation take precedence, and it is no longer controlled by the layout position.

13.3.5.2.16 Picture-in-Picture View

The "picture-in-picture view" control allows multiple views to be displayed simultaneously on the same screen, with the sub-picture placed within the main screen.

> **NOTE**
>
> Only the current screen supports picture-in-picture view. The picture-in-picture control is hidden when other screens are opened.

- **Picture-in-Picture view creation**

  There are three methods to create a "picture-in-picture view". For details, see the line creation method.

- **Properties of picture-in-picture view**
  - For basic settings, see Numeric I/O Field > Basic settings.
  - Interface:

Item	Description
Picture-in-picture	Includes the options of "screen" and "variable".
Screen	Selects a screen via the screen selection box to display the established picture-in-picture view.
Variable	Selects the variable via the variable selection box. Supported data types: USINT, UINT, UDINT, ULINT. When the variable value corresponds to a different screen ID, the picture-in-picture view switches to the corresponding screen.
Horizontal scrollbar	Sets whether a horizontal scrollbar is needed, including "As needed", "Always off", and "Always show". The default is "As needed".
Vertical scrollbar	Sets whether a vertical scrollbar is needed, including "As needed", "Always off", and "Always show". The default is "As needed".
Start position	Sets the starting view position, including "Top-left, Top-center, Top-right, Middle-left, Center, Middle-right, Bottom-left, Bottom-center, and Bottom-right". The default is "Center".

  - Basic information: For details, see Line > Basic information.

13.3.5.3 Data Visualization

- 13.3.5.3.1 Bar graph
- 13.3.5.3.2 Slider
- 13.3.5.3.3 Progress bar
- 13.3.5.3.4 Circular progress bar
- 13.3.5.3.5 Pie chart
- 13.3.5.3.6 F(t) trend curve
- 13.3.5.3.7 F(x) trend curve
- 13.3.5.3.8 Scale

13.3.5.3.1 Bar Graph

The "bar graph" control is used to monitor process values in a predefined range.

- **Bar creation**

  There are three methods to create a "bar graph". For details, see the line creation method.

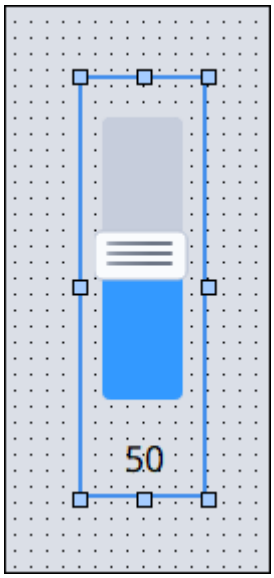
- **Properties of bar graph**

  - For basic settings, see Numeric I/O Field > Basic settings.
  - Style:

Property	Description
Text color	Sets the text display color of the bar graph.
Background color	Sets the background color of the bar graph.
Fill style	Sets the background fill style of the bar graph.
Font	Sets the text font of the bar graph. The default font is Droid Sans Fallback.
Font size	Sets the text font size of the bar graph. The default size is 16.
Font style	Sets the font style of the bar graph text. Supports regular, bold, italic, and underline. The default is regular.

  - Interface:

Property	Description
Max. value (static)	Sets the maximum value of the bar scale. The default value is 100.



Property	Description
Max. value (variable)	Sets the variable reference for the maximum value of the bar scale. When a variable is associated, the property Max. value (Constant) is not editable. NOTE When the Max. value (variable) is associated with a variable, the Max. value (static) is grayed out and cannot be set.
Min. value (static)	Sets the minimum value of the bar scale. The default value is 0.
Min. value (variable)	Sets the variable reference for the minimum value of the bar scale. When a variable is associated, the property Min. value (Constant) is not editable. NOTE When the Min. value (variable) is associated with a variable, the Min. value (static) is grayed out and cannot be set.
Reference variable	Variable used to display the process value on the bar graph.
Progress bar inversion	Specifies whether the normal value color is displayed on top. This option is not selected by default.
Scale label display	Display scale values when selected. This option is selected by default.
Limit line display	Display limit lines when selected. This option is selected by default.
Limit mark display	Display limit marks when selected. This option is not selected by default.
Major scale value	Number of intervals for major scale values. The default value is 5.
Minor scale value	Number of intervals for minor scale value. The default value is 5.
Decimal places	Number of decimal places for display text. The value range is 0 to 16 with a default value of 1.
Scale position	Sets the position for scale label display. Value range: No/Left/Right/Top/Bottom. The default value is Left.
Background color of bar graph	Sets the background color of the bar graph.
Normal color	Sets the color displayed when the process value is within the normal range.

Property	Description
Color above upper limit	The color displayed when the process tag value exceeds the upper limit. The default is red.
Color below lower limit	The color displayed when the process tag value exceeds the lower limit. The default is yellow.

- Basic information: For details, see Line > Basic information.
- Animation: For details, see 13.3.8 Animation Configuration.

13.3.5.3.2 Slider

The "slider" is used to adjust and display process variable value information.

- **Slider creation**

  There are three methods to create a "slider". For details, see the line creation method.

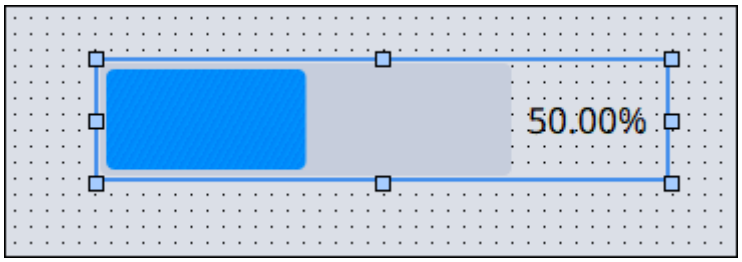
- **Slider properties**
  - For basic settings, see Numeric I/O Field > Basic settings.
  - Text:

Property	Description
Font	Sets the text font. The default font is Droid Sans Fallback.
Font size	Sets the text size. The default size is 18.
Font style	Sets the text font style. Supports regular, bold, italic, and underline. The default is regular.
Font color	Sets the font color. The default is black.

  - Interface:

Property	Description
Maximum value	Maximum value type of slider: Static, Variable. Static (default value): The maximum value is a static value. The property is not editable. Variable: The maximum value reads from a variable. The property is not editable.
Max. value (static)	Slider maximum value. The range is -9998 to 99999 with a default value of 100.
Max. value (read variable)	Variable associated with the slider's maximum value.
Minimum value	Minimum value type of slider: Static, Variable. Static (default value): The minimum value is a static value. The property is not editable. Variable: The minimum value reads from a variable. The property is not editable.
Min. value (static)	Slider minimum value. The range is -9999 to 99998 with a default value of 0.
Min. value (read variable)	Variable associated with the slider's minimum value.
Process value	Variable associated with the slider's process value.
Slider direction	Slider display direction: left to right, right to left, bottom to top, and top to bottom. Default: bottom to top.
Process value visible	Specifies whether to display the associated variable value. This option is selected by default.
Scale visible	Specifies whether to display the slider scale. This option is selected by default.
Process value decimal places	Number of decimal places for displaying the process value. The range is 0 to 16 with a default value of 0.
Scale position	Sets the scale position after "Scale visible" is selected. For horizontal slider, top/bottom are available; for vertical slider, left/right are available.
Scale decimal places	Sets the number of decimal places retained for the scale after "Scale visible" is selected. The default value is 0.
Major scale divisions	Sets the number of major scale divisions after "Scale visible" is selected. The default value is 5.
Minor scale divisions	Sets the number of minor scale divisions after "Scale visible" is selected. The default value is 5.

- Style:



Property	Description
Fill	Sets the fill style of the slider. For specific style settings, see Rectangle > Fill.

Property	Description
Bar background color	Sets the color of the slider bar part.
Progress color	Sets the color of the slider progress part.
Slider color	Sets the slider color.
Slider border color	Sets the slider border color.
Color above upper limit	Color displayed by progress bar when variable value exceeds maximum value.
Color below lower limit	Color displayed by progress bar when variable value exceeds minimum value.

- Basic information: For details, see Line > Basic information.
- Animation: For details, see 13.3.8 Animation Configuration.

13.3.5.3.3 Progress Bar

The "progress bar" is used to monitor and adjust a process value within a defined range.

- **Progress bar creation**

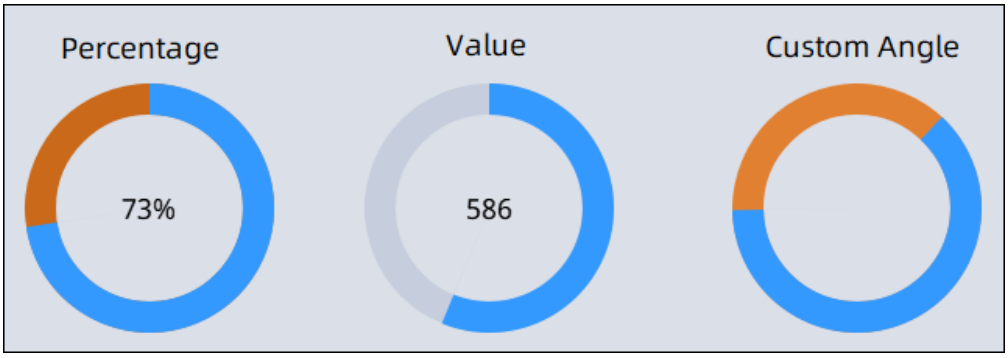
  There are three methods to create a "progress bar". For details, see the line creation method.

- **Progress bar properties**
  - For basic settings, see Numeric I/O Field > Basic settings.
  - Interface properties:

Property	Description
Max. value (constant)	Maximum value of the progress range. The default is 100.
Max. value (variable)	Variable associated with the maximum value of the progress range. When a variable is associated, the property Max. value (Constant) is not editable. NOTE Variables with data types STRING, DATETIME, or BOOL are not supported for association.

Property	Description
Min. value (constant)	Minimum value of the progress range. The default is 0.
Min. value (variable)	Variable associated with the minimum value of the progress range. When a variable is associated, the property Min. value (Constant) is not editable. NOTE Variables with data types STRING, DATETIME, or BOOL are not supported for association.
Reference variable	Sets the associated variables.
Direction	Sets the direction of the progress bar, including horizontal and vertical. The default is horizontal.
Text visible	Sets whether to display progress text. This option is selected by default.
Display decimal point	Sets whether progress information displays decimal points. Two decimal places are displayed by default.

- Text:

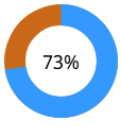


Property	Description
Font	Sets the text font. The default font is Droid Sans Fallback.
Font size	Sets the text size. The default size is 18.
Font style	Sets the text font style. Supports regular, bold, italic, and underline. The default is regular.
Text position	Outside the graphic: Progress information is displayed outside the graphic. When the direction property is horizontal, it is displayed on the right; when the direction property is vertical, it is displayed below. Inside the graphic: Progress information is displayed inside the graphic, centered by default.
Text color	Sets the display color of progress text.
Background color	Sets the background color.
Fill	Sets the fill style of the progress bar. For specific style settings, see Rectangle > Fill.
Color above upper limit	Color displayed by progress bar when variable value exceeds maximum value.

Property	Description
Color below lower limit	Color displayed by progress bar when variable value exceeds minimum value.

- Basic information: For details, see Line > Basic information.
- Animation: For details, see 13.3.8 Animation Configuration.

13.3.5.3.4 Circular Progress Bar



The "circular progress bar" control offers three display modes for visualizing process variables such as level, progress and completion.

- **Circular progress bar creation**

  There are three methods to create a "circular progress bar". For details, see the line creation method.

- **Properties of circular progress bar**
  - For basic settings, see Numeric I/O Field > Basic settings.
  - Data:

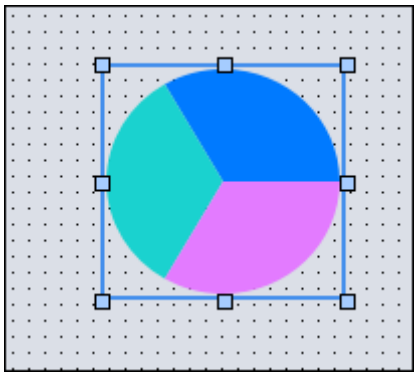
Property	Description
Display mode	Percentage: The fill percentage is calculated automatically based on the set range limits and real-time values. It is filled in a clockwise direction. Fill percentage = [(Real-time value - Minimum value) / (Maximum value - Minimum value)] * 100% 
	Value: The real-time value is directly displayed, and the fill range conversion formula is the same as for percentage. It is filled in a clockwise direction. 

Property	Description
	Custom angle: The fill range of the progress bar is determined by user-defined start and end angles. Filling proceeds clockwise from the start angle to the end angle. For example, the reference 0° is at 90° (3 o'clock direction), the start angle is 0°, and the end angle is 180°, with the fill range shown as the blue area in the figure. 
Max. value (constant/ variable)	Maximum fill value. Default: 100. Setting range: -9999 to 99999 Variable types supported: UINT, INT, USINT, SINT, UDINT, DINT, ULINT, LINT, REAL, and LREAL.
Min. value (constant/ variable)	Minimum fill value. Default: 100. Setting range: -9999 to 99999 Variable types supported: UINT, INT, USINT, SINT, UDINT, DINT, ULINT, LINT, REAL, and LREAL.
Process variables	Data types supported for display variables: UINT, INT, USINT, SINT, UDINT, DINT, ULINT, LINT, REAL, and LREAL.
Start angle	Absolute angle relative to the "Reference 0°", used as the fill start point.
End angle	Absolute angle relative to the "Reference 0°", used as the fill end point.
Reference 0°	It defines the absolute reference point for the fill start and end points. Setting range: 0° to 360°, where 0° is at the 12 o'clock direction and 90° is at the 3 o'clock direction. Default: 0°.

- Text:

Property	Description
Font	Sets the text font. The default font is Droid Sans Fallback.
Font size	Sets the text size. The default size is 18.
Font style	Sets the text font style. Supports regular, bold, italic, and underline. The default is regular.

- Appearance:



Property	Description
Text visible	Sets whether to display progress text. This option is selected by default.
Display decimal point	Sets whether progress information displays decimal points. Two decimal points are displayed by default.
Decimal point	Number of decimal points displayed for progress, range 0 to 16, default 2.

Property	Description
Outer ring size	Ring size, range 1 to 999, default 12. Maximum value is half the control width. Display style at maximum outer ring size: 
Text color	Sets the display color of progress text.
Background color	Sets the background color.
Progress color	Sets the color of progress bar.
Color above upper limit	Color displayed by progress bar when process variable value exceeds max imum value.
Color below lower limit	Color displayed by progress bar when process variable value is less than mi nimum value.

- For basic information, see Line > Basic information.
- Animation: For details, see 13.3.8 Animation Configuration.

13.3.5.3.5 Pie Chart

The "pie chart" is used to display data proportions.

- **Pie chart creation**

  There are three methods to create a "pie chart". For details, see the line creation method.

- **Pie chart properties**
  - For basic settings, see Numeric I/O Field > Basic settings.
  - Text:

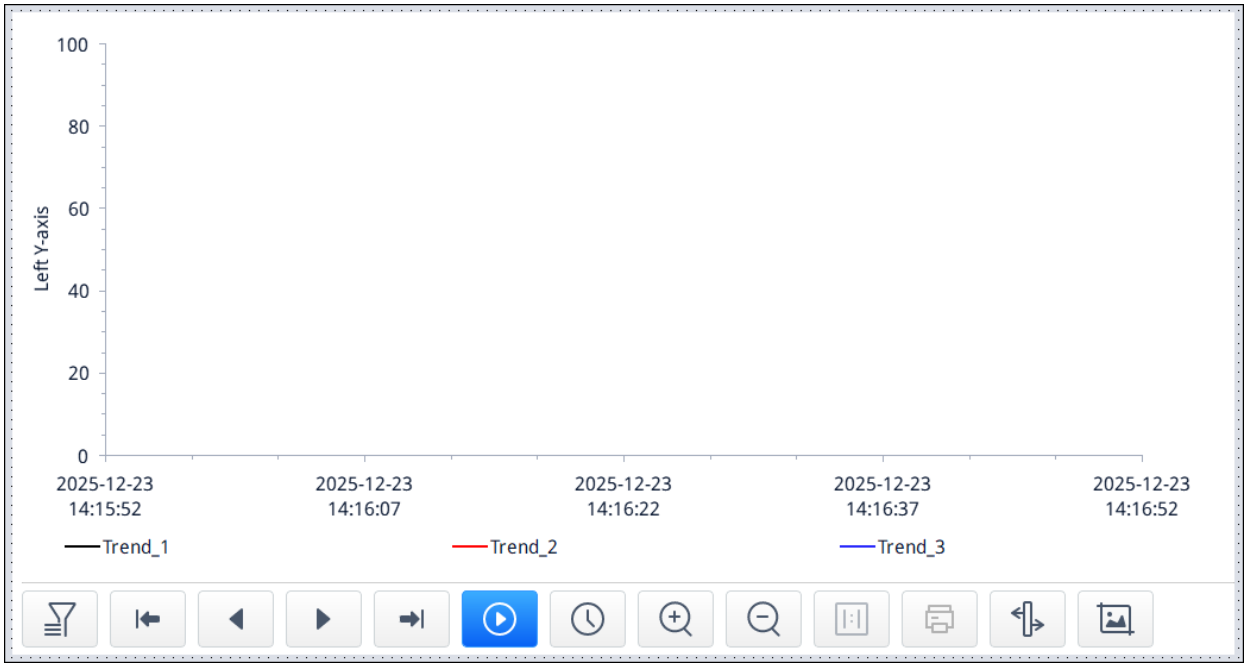
Property	Description
Font	Sets the text font. The default font is Droid Sans Fallback.
Font size	Sets the text size. The default size is 18.

Property	Description
Font style	Sets the text font style. Supports regular, bold, italic, and underline. The default is regular.

◦ Interface:

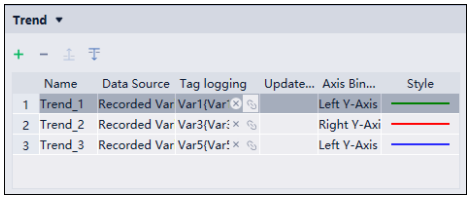
Property	Description
Style	Sets the text to be displayed on the pie chart. Options include no data, value, and percentage. Default: no data.
Number of channels	Sets the number of pie chart segments (up to 8 segments can be set). The default value is 3.
Channel settings	Sets the variable associated with the pie chart channel and the display color.  Channel: A pie chart has three channels by default. ▪ Click the button to add a channel. ▪ Click the button to delete the selected channel. Variable: Set the variable associated with the channel. Supported data types for associated variables: USINT, UINT, UDINT, ULINT. Color: Set the display color of the channel.

◦ Fill:



Property	Description
Text color	Specifies the text color of pie chart.
Background color of outer frame	Specifies the background color of pie chart with transparency (0% to 100%).
Scaling ratio	Sets the scaling ratio when drawing the pie chart (0% to 100%).

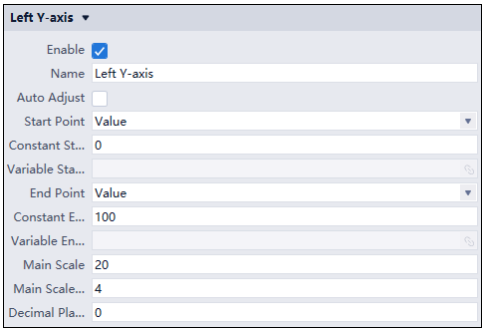
◦ For basic information, see Line > Basic information.



◦ Animation: For details, see 13.3.8 Animation Configuration.

13.3.5.3.6 F(t) Trend Curve

The "F(t) trend curve" is an enhanced screen object used to display the trend of a variable over time.

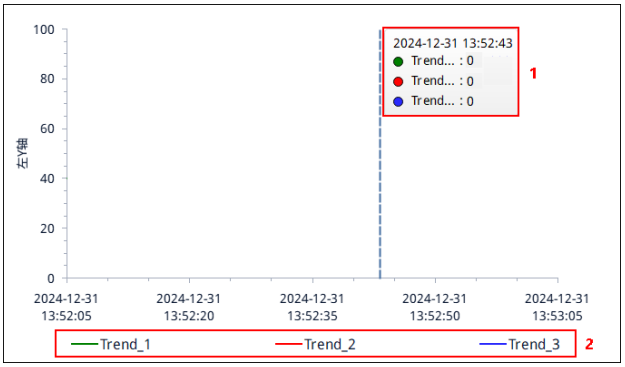


- **F(t) trend curve creation There are three methods to create an "F(t) trend curve". For details, see the** line creation method.
- **F(t) trend curve properties**
  - For basic settings, see Numeric I/O Field > Basic Settings.
  - Trend:

Item	Description	Example
Name	The legend name of the curve. One name corresponds to one curve. New curves are named as Trend_n by default, with n starting from 1. Addition and deletion of curves are performed by clicking icons + and −, supporting up to 100 curves.	
Data source	The location from which variable values are retrieved during online operation. Real-time variable: Retrieves real-time values from the database. Record variable: Retrieves historical values from data records.	
Variable recording	Associated variables	
Update interval	Applicable when a real-time variable is used as the data source. The period at which the current control acquires the real-time value.	
Axis binding	Binds to the Y-axis. Supports configuration when the left or right Y-axis is enabled.	
Style	Configuration of line style and color.	

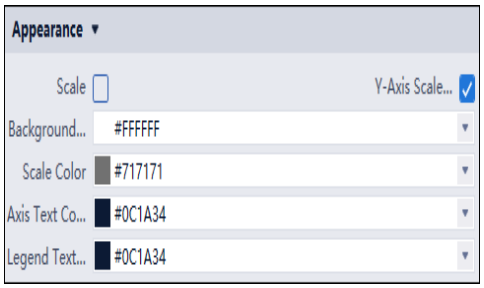
◦ Time axis:

Item	Description	Example
Time span	The time interval displayed in the view window.	
Horizon value		
Time format	Time display format	
Time format	Supports 24-hour format and 12-hour format.	
Scale value	Manages the display and hiding of time text on the time axis.	



◦ Left/Right Y-axis:

Item	Description	Example
Enable	Check this option to display the current axis on the control and enables editing of related parameters.	
Name	Y-Axis name	
Automatic adjustment	By default, three decimal points are retained based on the start and end values, and the display space for Y-axis scale values is automatically adjusted.	
Start/End	Y-axis tick range	
Constant start/end values	Supports constant or variable values as the maximum and minimum scale values.	
Variable start/end values		
Major scale	Sets the unit of scale length and precision of scale values.	
Major scale segments		
Decimal points		



◦ Screenshot:

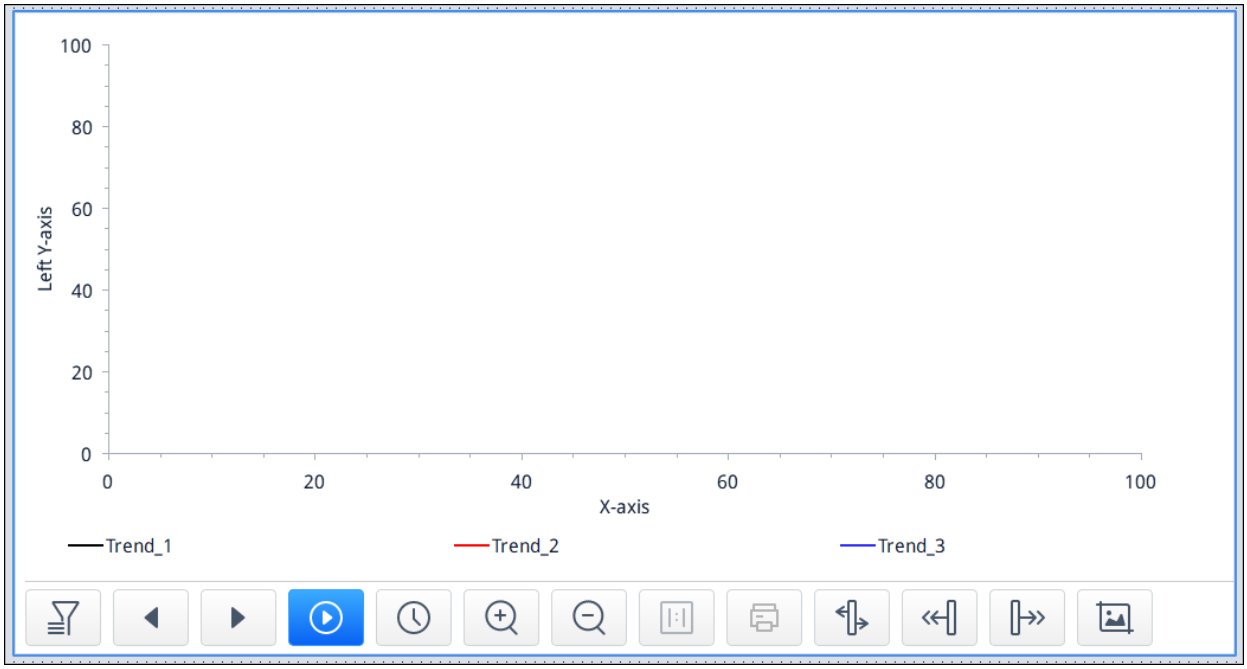
Item	Description	Example
Storage location	Supported storage locations include local disk, SD card, and USB, with SD card and USB applicable to touch screen devices. ▪ Local disk: The maximum number of screenshot files stored is 100. For more details, see 13.12.1 Screen Display Configuration. ▪ SD card and USB: The number of stored screenshots depends on the file size and available storage space. If the storage is full, the screenshot operation will fail.	
Constant path	Settings for the storage path of screenshot files. ▪ Local disk: The storage path is fixed as the screenshot directory and cannot be changed. ▪ SD card and USB: Only the folder name needs to be entered, such as **screen**, without entering the full path. If the folder **screen** does not exist, the software will automatically create it.	

◦ Text:

Item	Description	Example
Axis text	Font, size, and style of the text on the coordinate axes.	
Ruler text	Font, size, and style of the variable information text (position 1) on the ruler when the control is running online.	
Legend text	Font, size, and style of the legend text (position 2).	

◦ Appearance:

Item	Description	Example
Ruler	Specifies whether to display the ruler button  when the control runs online. Selected: display; not selected: hide.	
Y-axis scale value	Manages the display and hiding of Y-axis scale values.	



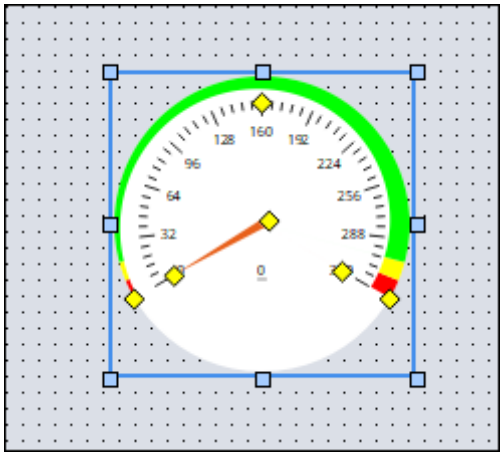
Item	Description	Example
Background color	Sets the trend chart background color. The default is white #FFFFFF.	
Ruler color	Sets the ruler color. The default is #717171.	
Axis text color	Sets the text display color on the X/Y axis. The default is #0C1A34.	
Legend text color	Sets the legend text color. The default is #0C1A34.	

  - For basic information, see Line > Basic information.
  - For animation, see 13.3.8 Animation Configuration.

- **Online operations of the**
  F(t) trend curve For details on supported operations, see 13.15.3 Online Historical Data Viewing.

13.3.5.3.7 F(x) Trend Curve

The "F(x) trend curve" is an enhanced screen object used to display the changing trends among multiple variables.



- **F(x) trend curve creation**
  There are three methods to create an "F(x) trend curve". For details, see the line creation method.
- **F(x) trend curve properties**
  - For basic settings, see Numeric I/O Field > Basic information.
  - For trend, see F(t) Trend Curve > Trend.
  - For time axis, see F(t) Trend Curve > Time axis.
  - For screenshot, see F(t) Trend Curve > Trend.

- For text, see F(t) Trend Curve > Text.
- For appearance, see F(t) Trend Curve > Appearance.
- For basic information, see Line > Basic information.
- For animation, see 13.3.8 Animation Configuration.

- **Online operations of the F(x) trend curve**
  For details on supported operations, see 13.15.3 Online Historical Data Viewing.

13.3.5.3.8 Scale

The "scale" is an animated graphic that simulates a rotating pointer instrument, used to display the value of the connected variable. The pointer continuously changes position based on the variable value, and the scale pointed to by the pointer represents the value of the connected variable.

- **Scale creation**

  There are three methods to create a "scale". For details, see the line creation method.

- **Scale properties**
  - For basic settings, see Numeric I/O Field > Basic settings.
  - Style:

Property	Description
Draw options	Sets the drawing style for the scale background fill, including drawing fill, fill, and drawing.
Fill brush	Sets the background color fill style of the scale. For specific style settings, see Rectangle > Fill.
Border color	Sets the border color and transparency of the scale background fill.
Line width	Sets the border width of the scale background fill.
Line type	Sets the border line style of the scale background fill.

  - Dial information:

Property	Description
Background color	Sets the fill background color and transparency within the dial.

Property	Description
Font color	Sets the font color for the label text, unit text, and current value within the dial.
Font	Sets the text font. The default font is Droid Sans Fallback.
Font size	Sets the text size. The default size is 16.
Label text	Sets the dial label text.
Unit text	Sets the dial unit text.
Current value variable	Sets the variables associated with the current value of the dial. Supported data types: SINT, USINT, INT, UINT, DINT, UDINT, LINT, ULINT, REAL, LREAL.
Display current value	Specifies whether to display the current value of the dial. Enabled by default.
Hide background	Specifies whether to hide the dial background. Disabled by default.

◦ Start data:

Property	Description
Start angle	The start position is determined by the starting angle. The default value for the starting angle is 330, and the start angle range is 0 to 360. When entering values, the input box displays the range. If the value exceeds the range, it cannot be entered.
Start value	The start value corresponds to the value at the start angle. The default value for the start value is 320, and the value range is -2147483648 to 2147483647. When entering values, the input box displays the range. If the value exceeds the range, it cannot be entered.
Warning value	The warning value corresponds to the value at the start angle. The default value for the warning value is 300, and the value range is -2147483648 to 2147483647. When entering values, the input box displays the range. If the value exceeds the range, it cannot be entered.
Error value	The error value corresponds to the value at the start angle. The default value for the error value is 310, and the value range is -2147483648~2147483647. When entering values, the input box displays the range. If the value exceeds the range, it cannot be entered.

◦ End data:

Property	Description
End angle	The end position is determined by the end angle. The default value for the end angle is 210, and the end angle range is 0 to 360. When entering values, the input box displays the range. If the value exceeds the range, it cannot be entered.
End value	The end value corresponds to the value at the end angle. The default value for the end value is 0, and the value range is -2147483648 to 2147483647. When entering values, the input box displays the range. If the value exceeds the range, it cannot be entered.
Warning value	The warning value corresponds to the value at the end angle. The default value for the warning value is 20, and the value range is -2147483648 to 2147483647. When entering values, the input box displays the range. If the value exceeds the range, it cannot be entered.
Error value	The error value corresponds to the value at the end angle. The default value for the error value is 10, and the value range is -2147483648 to 2147483647. When entering values, the input box displays the range. If the value exceeds the range, it cannot be entered.

◦ Scale information:

Property		Description
Major scale	Bisection	Sets the number of major scales. Data type is UINT. Value range is 0 to 255. Default value is 10.
	Color	Sets the color of the major scale. Default is black #000000.
	Width and height	Sets the width and height of the major scale. Data type is UINT. Value range is 0 to 255. Default width is 2 and height is 16.
Minor scale	Bisection	Sets the number of minor scales. Data type is UINT. Value range is 0 to 255. Default value is 5.
	Color	Sets the color of the minor scale. Default is black #000000.
	Width and height	Sets the width and height of the minor scale. Data type is UINT. Value range is 0 to 255. Default width is 2 and height is 8.
Scale radius		Distance from the center axis to the outer edge of the scale. Data type is UINT. Default value is 145.
Annotation radius		Distance from the center axis to the outer edge of the label font. Data type is UINT. Default value is 110.
Font color		Sets the dial color. Default is black #000000.
Font size		Sets the font size. Default is 16, unit: px.

Property	Description
Coincident display	Select the value to display when values overlap on the scale. Options: maximum value or minimum value.
Display text	Specifies whether to display the text within the dial. Enabled by default.
Callout interval display	Specifies whether to enable interval display of scale values. Disabled by default.

◦ Pointer information:

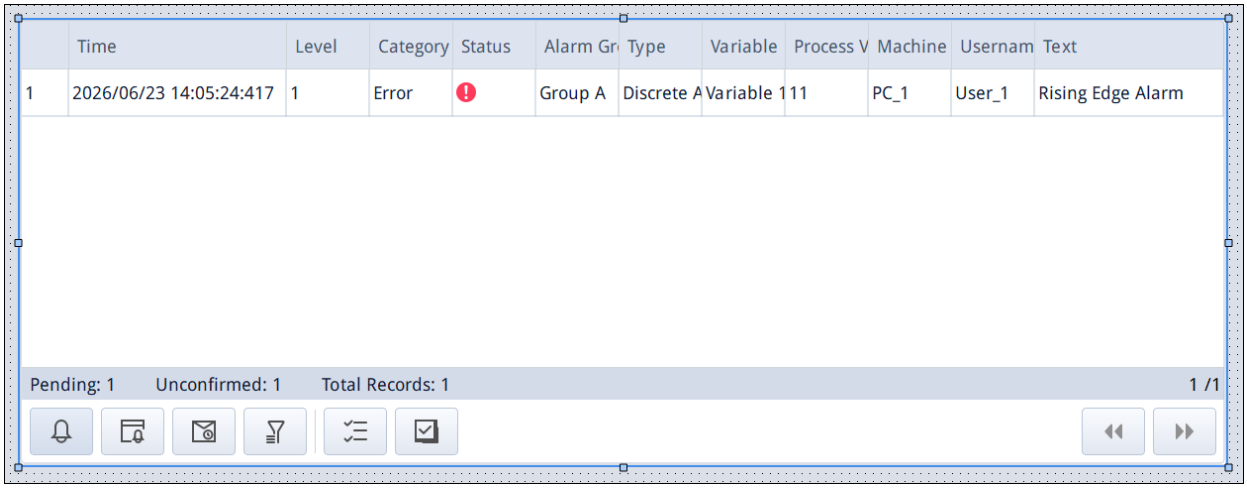
Property	Description
Pointer color	Configures the fill color of the pointer. Default is red #E8601A.
Pointer width	Sets the width of the pointer and the center axis width. Data type: INT; Range: 0 to 255; Default width: 10.
Pointer radius	Sets the long radius value of the pointer. Data type is INT. Range is 0 to 255. Default length is 120.
Short pointer radius	Sets the short radius value of the pointer. Data type is INT. Range is 0 to 255. Default length is 0.
Axis color	Configures the fill color of the pivot point. Default is white #FFFFFF.
Pivot radius	Configures the radius of the pivot point. Default value is 2.

◦ Warning ring information:

Property	Description
Start width	Sets the width at the start of the scale ring. Default value is 26.
End width	Sets the width at the end of the scale ring. Default value is 4.
Normal color	Color when the process variable value is within the normal range. Default is green #00FF00.
Warning color	Color when the process variable value is within the alarm range. Default is yellow #FFFF00.
Error color	Color when the process variable value is within the error range. Default is red #FF0000.

◦ Basic information: For details, see Line > Basic information.

◦ Animation: For details, see 13.3.8 Animation Configuration.



13.3.5.4 Production and Management

- 13.3.5.4.1 Alarm View
- 13.3.5.4.2 Alarm Bar

- 13.3.5.4.3 Recipe View
- 13.3.5.4.4 User Login
- 13.3.5.4.5 User View
- 13.3.5.4.6 Variable Log View
- 13.3.5.4.7 System Diagnostics
- 13.3.5.4.8 Operation Log
- 13.3.5.4.9 SFC View
- 13.3.5.4.10 Code View

13.3.5.4.1 Alarm View

The "Alarm view" window dynamically displays information of a specified category that meets certain conditions in the running system.

- **Alarm view creation**

  There are three methods to create an alarm view. For details, see the line creation method.

- **Alarm view properties**

  - For basic settings, see Numeric I/O Field > Basic settings.
  - Data:

Property	Description
Column header	Sets whether to display the header row of the alarm view. Default is selected.
Toolbar	Sets whether to display the toolbar of the alarm view. Default is selected.
Status bar	Sets whether to display the status bar of the alarm view. Default is selected.
Time (Milliseconds)	Sets whether to display the time column in milliseconds; selected by default.
Show grid	Sets whether to display grid lines. Default is selected.

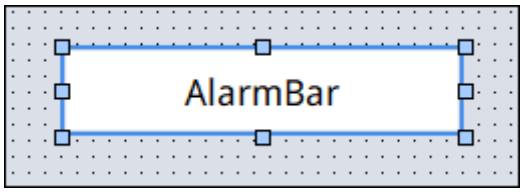
Property	Description
Default display	Sets the content to be displayed by default in the alarm view. Options: Real-time alarms, real-time alarm events, and historical alarm events. Default is real-time alarms.
Sorting method	Options: Sorting by time descending, sorting by level ascending, and sorting by level descending. Default is sorting by time descending. When sorting by level, alarms with the same level are sorted by time in descending order. During runtime, clicking the headers of Time and Level columns can switch the sorting methods. When not sorting by level, click the header of the Level column to sort the alarms by level, and then click again to switch to descending order.
Column setting	Sets the columns to be displayed in the alarm view. Default display shows "<Select columns to display>". All columns are displayed by default. After column width configuration, if there is remaining width in the table, the last column automatically stretches; if the table width is insufficient, a horizontal scroll bar is automatically displayed.
Header row height	Sets the height of the header row in the alarm view.
Content row height	Sets the height of the content rows in the alarm view.
Filter conditions	Sets the filter conditions for displayed alarms in the alarm view.

◦ Fill:

Property	Description
Header text color	Sets the foreground color of the header row. Default is black #000000.
Header background color	Sets the background color of the header row. Default is #E5E6EC.
Selected row color	Sets the color of selected content rows. Default is #0078D7.
Grid line color	Sets the grid line color. Default is #CFD5D8.

◦ Text:

Property	Description
Font	Sets the font for the header row. Default is Droid Sans Fallback.
Font size	Sets the font size for the header row. Default is 16.
Font style	Sets the font style for the header row. Supports regular, bold, italic, and underline. Default is regular.



Property	Description
Content font	Sets the font for the content row. Default is Droid Sans Fallback.
Content font size	Sets the font size for the content row. Default is 16.
Content font style	Sets the font style for the content row. Supports regular, bold, italic, and underline. Default is regular.

  - Basic information: Refer to Line > Basic information.
  - Animation: For details, see 13.3.8 Animation Configuration.

- Online operations
  For the operations supported when the alarm view is running online, see 13.15.4 Online Alarm View Operations.

13.3.5.4.2 Alarm Bar

The alarm bar is used to display the active alarm.

- **Alarm bar creation**

  There are three methods to create an alarm bar. For details, see the line creation method.

- **Alarm bar properties**
  - For basic settings, see Numeric I/O Field > Basic settings.
  - Text:

Property	Description
Font	Sets the font for the alarm bar text. Default is Droid Sans Fallback.
Font size	Sets the font size for the alarm bar text. Default is 18.
Font style	Sets the font style of the alarm bar text. Supports regular, bold, italic, and underline. Default is regular.

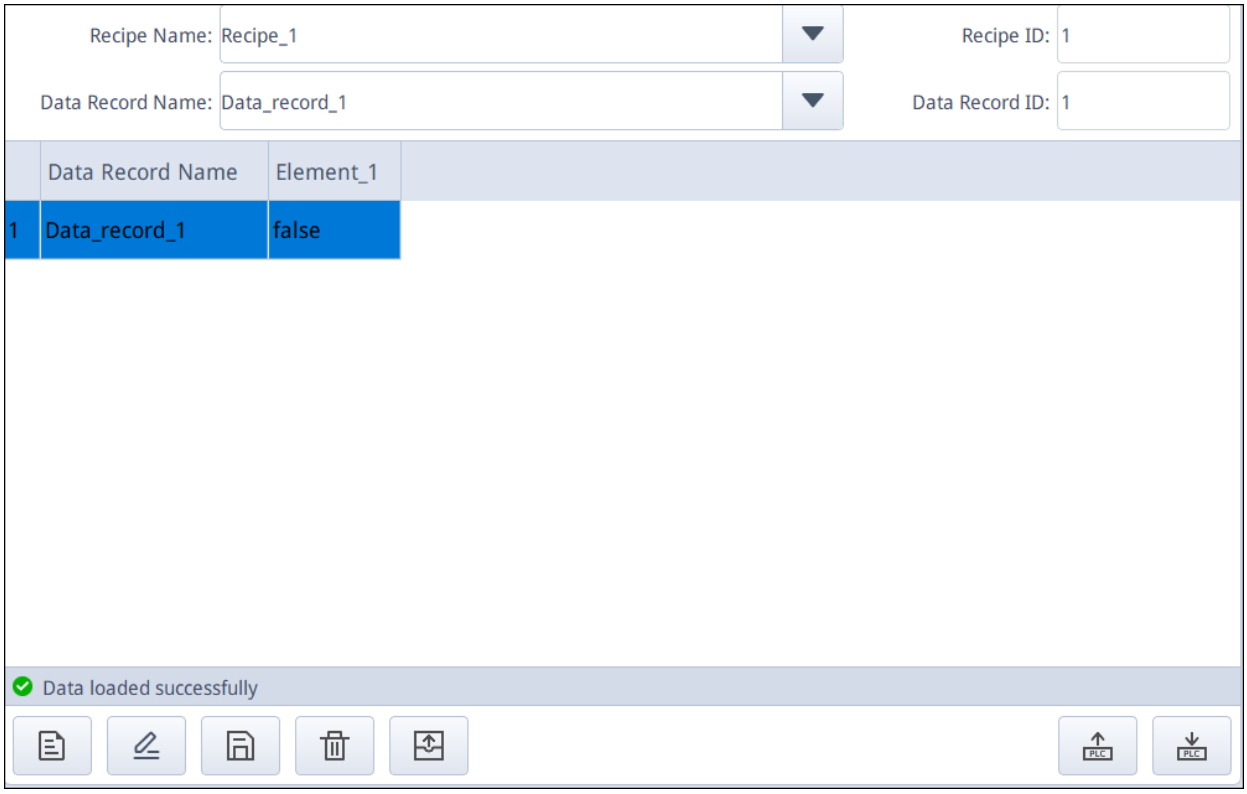
  - Flashing:

Property	Description
Process variables	Sets the standard flashing-associated variable. When the variable value is TRUE, the alarm bar flashes. When the variable value is FALSE, the alarm bar does not flash.

Property	Description
Flashing mode	Sets the flashing mode to no flashing or standard flashing. Default is no flashing. No flashing: The alarm bar does not flash during system operation. Standard flashing: The alarm bar flashes during system operation.

- Display:

Property	Description
Display date	Sets whether to display the date when an alarm is generated. Default is selected.
Display message	Sets whether to display the alarm message. Default is selected.
Display time	Sets whether to display the time when an alarm is generated. Default is selected.
Auto hide	Sets whether the alarm bar is displayed only when there is a message. Default is not selected.
Fault	Sets whether to display messages of error type. Default is selected.
Warning	Sets whether to display messages of warning type. Default is selected.
System	Sets whether to display messages of system type. Default is selected.
User operation	Sets whether to display user operation information. Default is selected.
Scroll speed	Sets the scroll speed of text when an alarm is generated in pixels. The configurable value ranges from 0 to 25. Default is 1.
Scroll direction	Sets the scroll direction of alarm text. Options include RTL (right to left), LTR (left to right). Default is RTL.
Alarm sequence	Sets the alarm display sequence. Options include time order (default) and time reverse order.



- Fill:

Property	Description
Text color	Sets the alarm bar text color.
Background color	Sets the alarm bar background color.
Fill style	Sets the alarm bar fill mode.

- Basic information: For detaIils, see Line > Basic information.
- Animation: For details, see 13.3.8 Animation Configuration.

13.3.5.4.3 Recipe View

The recipe view is a general-purpose enhanced screen object for displaying and editing recipes, and managing recipe data records. It presents data records in tables. In the recipe view, the values displayed and input can be stored in data records, which exchange data with the PLC through system features.

- **Recipe view creation**

  There are three methods to create a recipe view. For details, see the line creation method.

- **Recipe view properties**

  - For basic settings, see Numeric I/O Field > Basic settings.
  - Interface:

Property	Description
Recipe name	The recipe name can be selected. The selected recipe name can be cleared using the clear icon. Note: When selecting a recipe name, the runtime system can only operate on the currently selected recipe; when no recipe name is selected, the runtime system can operate on any recipe.
Recipe variable	Select an integer variable for the recipe number. The runtime system dynamically controls the selected recipe number by modifying the variable value, thereby controlling the selected recipe. Note: There are several ways to switch recipes: 1. Switch the recipe number by changing the variable value. 2. Switch recipes manually by selection. 3. Switch recipes by changing the recipe number.

Property	Description
Data record variables	Select an integer variable for the data record number. The runtime system dynamically controls the selected recipe data record by modifying the variable value. Note: After selecting a variable, the runtime system can select a data record by changing the variable value, or manually switch the selected data record.
Activate edit mode	Default is selected. When selected, the runtime system can edit recipe data records.

◦ Display:

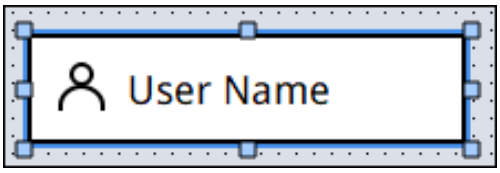
Property	Description
Alternate table display	Sets whether the table displays alternately. Default is selected.
Show grid	Sets whether to display grid lines. Default is selected.
Toolbar display	Sets the buttons to display in the recipe view toolbar, including "Create data record", "Save data record", "Delete data record", "Export recipe", "Read from PLC", and "Write to PLC". By default, all buttons are displayed.

◦ Fill:

Property	Description
Background color	Sets the recipe view background color. Default is white #FFFFFF.
Text color	Sets the recipe view text color. Default is #454E66.
Header background color	Sets the header background color. Default is #E2E8F2.
Header foreground color	Sets the header foreground color. Default is black #000000.
Table background color	Sets the table background color. Default is white #FFFFFF.
Table foreground color	Sets the table foreground color. Default is #000000.
Table alternate color	Sets the alternate color for table row display. Default is #F1F4F8.
Grid line color	Sets the grid line color. Default is #CFD5D8.
Selected row color	Sets the color of selected content rows. Default is #0078D7.

◦ Text:

Property	Description
Font	Sets the font for the recipe view text. Default is Droid Sans Fallback.



Property	Description
Font size	Sets the font size for the recipe view text. Default is 18.
Font style	Sets the font style of the recipe view text. Supports regular, bold, italic, and underline. Default is regular.

- Basic information: For details, see Line > Basic Information.
- Animation: For details, see 13.3.8 Animation Configuration.

- **Recipe view online operations**
  For the operations supported when the recipe view is running online, see 13.15.2 Online Recipe View Operations.

13.3.5.4.4 User Login

User login management control.

- **User login control creation**

  There are three methods to create a user login control. For details, see the line creation method.

- **User login control properties**
  - For basic settings, see Numerical I/O Field > Basic Settings .
  - Text:

Property	Description
Font	Sets the font for the user login text. Default is Droid Sans Fallback.
Font size	Sets the font size for the user login text. Default is 18.
Font style	Sets the font style for the user login text. Supports regular, bold, italic, and underline. Default is regular.

  - Interface:

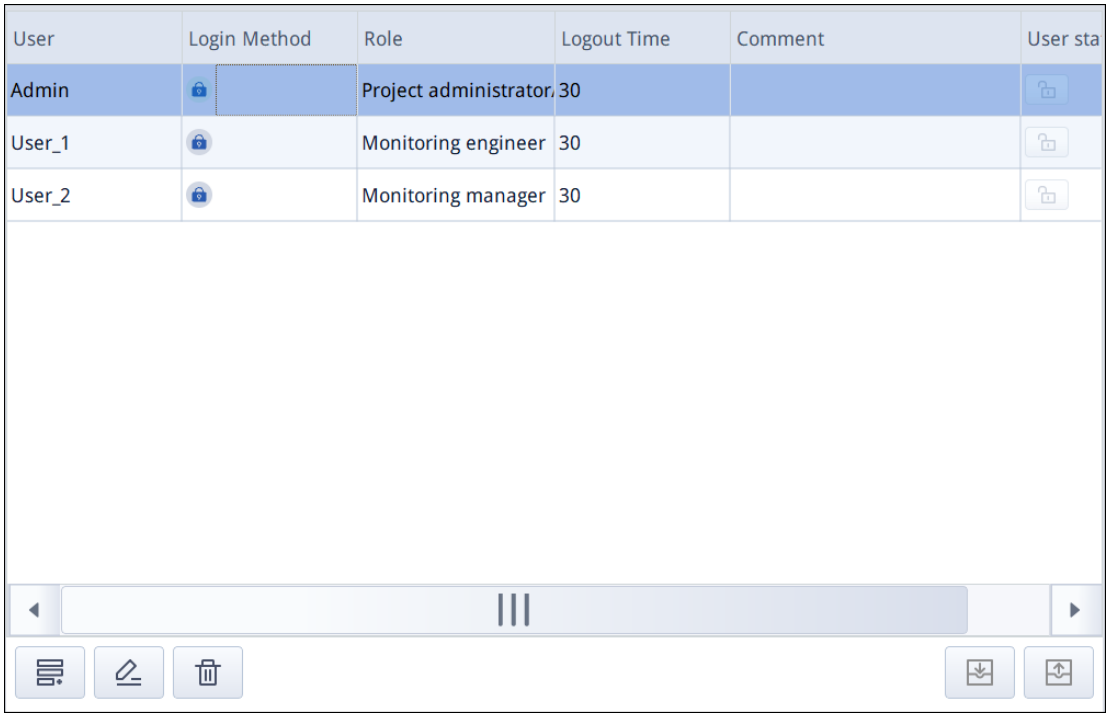
Property	Description
Verify identity when logout	Sets whether to verify identity when a user logs out. Default is selected.
Display login role	Sets whether to display the role information of the logged-in user. Default is not selected.
Display login time	Sets whether to display the user login time. Default is not selected.

  - Fill:

Property	Description
Text color	Sets the text color of the user login control.
Background color	Sets the background color of the user login control.

- Border:

Property	Description
Border color	Sets the border color and transparency of the user login control.
Line width	Sets the border line width of the user login control. Configurable range is 1 to 10. Default is 2.
Line type	Sets the border line type of the user login control.



- Basic information: For details, see Line > Basic Information.
- Animation: For details, see 13.3.8 Animation Configuration.

NOTE

The complexity requirements and validation rules for user login passwords are configured and managed under "Safety settings > Settings". For related instructions, see 9.6 HMI Security Authentication Policy.

13.3.5.4.5 User View

The user view control is used to display and manage user information for the current device. When the user view is in operation mode, it manages user login information, allowing users to add/delete users and import/export user data.

- **User view creation**

There are three methods to create a user view. For details, see the line creation method.

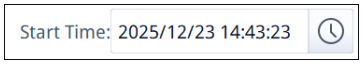
- **User view properties**
  - For size and layout settings: see Numerical I/O Field > Basic Settings.
  - Table appearance:

Property	Description
Alternate table display	Sets whether the table row background color alternates. Default is selected.
Show grid	Sets whether to display grid lines. Default is selected.
Background color	Sets the table background color. Default is white #FFFFFF.
Header text color	Sets the table header text color. Default is black #000000.
Header background color	Sets the table header background color. Default is #E5E6EC.
Table text color	Sets the table text color. Default is black #000000.
Odd row background color	Sets the odd row background color. Default is white #FFFFFF.
Even row background color	Sets the even row background color. Default is #EDEEF1.
Grid line color	Sets the grid line color. Default is #CFD5D8.
Selected row color	Sets selected row background color. Default is #A0BBE9.

  - Table text:

Property	Description
Header text	Sets the font, size, and style of the table header text. For details, see Number I/O Filed > Text.
Table text	Sets the font, size, and style of the table text. For details, see Number I/O Filed > Text.

  - Basic information: For details, see Line > Basic Information.
  - Animation: For details, see 13.3.8 Animation Configuration.
- **User view online operations**
  For the operations supported when the user view is running online, see 13.15.5 Online User View Operations.



13.3.5.4.6 Variable Log View

The variable log view is used for statistics. It displays archived records of variables over a certain period of time.

- **Variable log view creation**

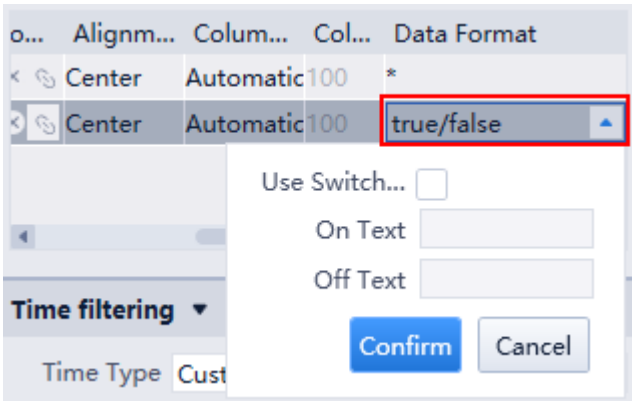
There are three methods to create a variable log view. For details, see the line creation method.

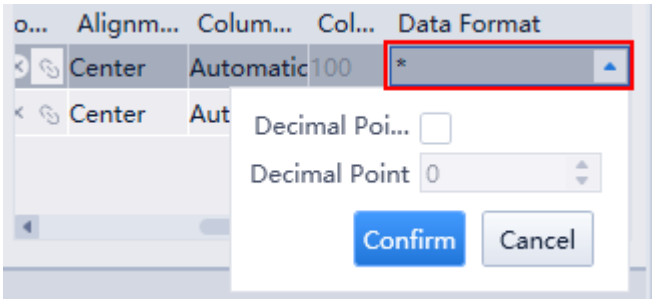
- **Icons in the variable log view during operation**

Item	Icon	Description
Starting time		Variable start time (default is 1 minute before the current system time)
End time		Variable end time (default is the current system time). Note: The end time cannot be earlier than or equal to the start time.
Query		Click to query the variables within the range of start time and end time.
Configuration		Sets whether to display configured fields in edit mode during runtime.
Statistics		Displays statistical query results (including the list of queried variables, maximum value, minimum value, average value, and cumulative value).
Export		Exports the queried data.
Ascending		Sorts query results in ascending order based on the time field.
Descending		Sorts query results in descending order based on the time field.
Back		Goes to the previous page of query results. This icon is grayed out when the current page is the first page.
Next		Goes to the next page of query results. This icon is grayed out when the current page is the last page.

- **Variable log view properties**
  - For basic settings, see Numerical I/O Field > Basic Settings .
  - Text:

Property	Description
Header font	Sets the header font. Default is Droid Sans Fallback.
Header font size	Sets the header font size. Default is 18.





Property	Description
Header font style	Sets the header font style. Supports regular, bold, italic, and underline. Default is regular.
Content font	Sets the font for the content row. Default is Droid Sans Fallback.
Content font size	Sets the font size for the content row. Default is 18.
Content font style	Sets the font style for the content row. Supports regular, bold, italic, and underline. Default is regular.

◦ Interface:

Property	Description
Data record	Select the data record to query. All variables associated with the fields in the table belong to this data record.
Statistics	Sets whether the statistics function is available at runtime. Default is selected.
Refresh interval	Sets the automatic refresh interval (in seconds) for displaying historical data online. This setting takes effect when "Time type" is set to "All records" or "Fixed time". Range: 0 to 65535. 0 indicates historical data is refreshed only once when the screen is opened, with no further automatic refresh.

◦ Record variables:

Property	Description
Name	Name of the added field. Default is Field x (x starts from 1 and increments automatically). Double-click to modify the name.
Variable recording	Associated variable.
Alignment	Alignment of field content. Supports left alignment, center alignment (default), and right alignment.
Column width adjustment method	Supports automatic and manual adjustment. Default is automatic.
Column width	When column width adjustment method is set to manual, column width can be set. The value range is 5 to 5000. Default is 100.

Property	Description
Data format	Sets the data display format. Only supported when the field-associated variable is of BOOL, REAL, or LREAL type. • When the field-associated variable is of BOOL type, the following options are displayed. Users can set the text to show when the variable is True or False.  • When the field-associated variable is of REAL or LREAL type, the following options are displayed to configure the formatted display of the data. If not configured, the value is displayed according to the default settings. The decimal place range is 0 to 7, with a default value of 0.  • When the field-associated variable is of time type, display format is yyyy-MM-dd hh:mm:ss (not editable).

◦ Time filtering:

Property	Description
Time type	Sets the time conditions for historical data filtering. Options include all records, fixed time, and custom time (default). • All records: In runtime, displays data from all records of the statistical variables. • Fixed time: In runtime, displays data from records within the configured time range. Fixed time can be either a constant or a variable, with a maximum supported range of 2 years. ◦ For a constant, seconds, minutes, hours, days, weeks, and months are supported, with a default value of 60 minutes. For a variable, unsigned integer variables are supported. If the runtime variable value exceeds the 2-year range, statistics are calculated based on the maximum 2-year range. • Custom time: The custom time can be set by the default time or variables. ◦ Default time: In runtime, the query range is set based on the start and end time setting controls in the record table. ◦ Variables: The start and end time of the query range are associated with specific time variables.

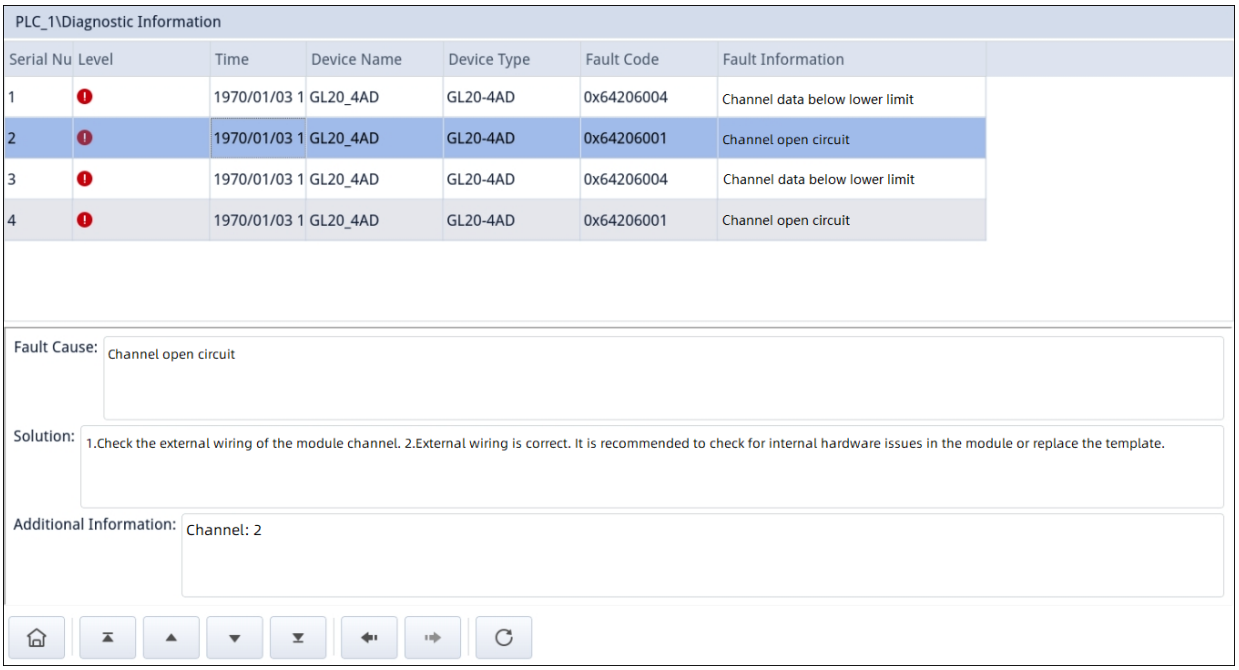
◦ Column settings:

Property	Description
Time	Sets whether the time column is displayed for runtime data. Default is selected.
ID	Sets whether the ID column is displayed for runtime data. Selected by default.
Header row height	Sets the header row height for runtime data. Default is 28.
Content row height	Sets the content row height for runtime data. Default is 42.

◦ Display: Sets whether to display the grid lines.

◦ Fill:

Property	Description
Background color	Set the background color of control. Default is white #FFFFFF.
Text color	Sets the text color. Default is black #000000.
Header text color	Sets the table header text color. Default is black #000000.
Header background color	Sets the table header background color. Default is #E5E6EC.
Text color	Sets the table text color. Default is black #000000.
Table background color	Set the table background color. Default is white #FFFFFF.
Alternate background color	Set the alternate background color. Default is gray #F1F4F8.



Property	Description
Grid line color	Sets the grid line color of the table. Default is gray #E5E6EC.
Selected row color	Sets selected row background color. Default is #A0BBE9.

- Basic information: For details, see Line > Basic Information.
- Animation: For details, see 13.3.8 Animation Configuration.

- **Record variable table online operation**
  For the operations supported by the record variable table during online runtime, see 13.15.3 Online Historical Data Viewing.

13.3.5.4.7 System Diagnostics

The system diagnostics control is used to display the PLC operating status, as well as diagnostic information for I/O modules and coupler modules. The diagnostic information displayed is synchronized with the content under the 10.11.20 "Online and diagnostics" node in the PLC device.

- **System diagnostics control creation**

  There are three methods to create a system diagnostics control. For details, see the line creation method.

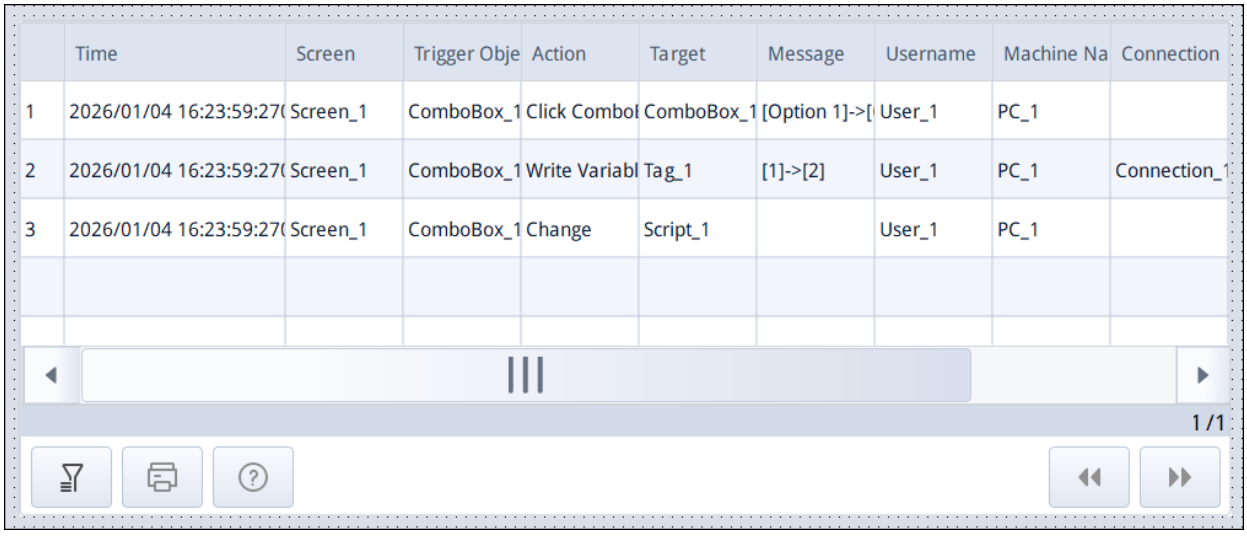
- **System diagnostics control properties**
  - For basic settings, see Numerical I/O Field > Basic Settings .
  - Column settings:

Property	Description
Column setting	Sets the column content and column width of the system diagnostics table.
Header row height	Sets the header row height of the system diagnostics table.
Content row height	Sets the content row height of the system diagnostics table.

  - Fill:

Property	Description
Header text color	Sets the table header text color. Default is black #000000.
Header background color	Sets the table header background color. Default is #E5E6EC.
Header text color	Sets the table header text color. Default is black #000000.
Header background color	Sets the table header background color. Default is #E5E6EC.
Content text color	Sets the table content text color. Default is black #000000.
Content background color	Set the table content background color. Default is white #FFFFFF.
Selected row color	Sets selected row background color. Default is #A0BBE9.
Grid line color	Sets the grid line color of the table. Default is gray #CFD5D8.

  - Text properties:



Property	Description
Title text	Sets the font, size, and style of the title text.
Header text	Sets the font, size, and style of the header text.
Content text	Sets the font, size, and style of the content text.

  - Basic information: For details, see Line > Basic information.
  - Animation: For details, see 13.3.8 Animation Configuration.

- **System diagnostics online operation**
  For the operations supported by the system diagnostics control during runtime, see 13.15.7 Online System Diagnostics.

13.3.5.4.8 Operation Records

The operation log is used to display user operation logs and can be synchronously updated in real time.

- **Operation log creation**

  There are three methods to create an operation log. For details, see the line creation method.

- **Operation log properties:**

  - For basic settings, see Numerical I/O Field > Basic Settings .
  - Column settings:

Item	Description
Visible	Controls the visibility of corresponding columns in the view window.
Name	Default column name, not editable.
Width	Sets the column width with a range of 20 to 1000.
Display name	Column name displayed in the view window, with a length of 0 to 256. Default name is displayed when the display name is empty.

  - Display:

    Sets the table style and data arrangement in the view window.

Property	Description
Column header	Sets the visibility of the table header.
Toolbar	Sets the visibility of the toolbar.
Pagination bar	Sets the visibility of page numbers.
Time (ms)	Sets whether operation time is displayed to the millisecond level. When selected, the content is displayed as 2025/05/30 14:34:39:059 ; when not selected, the content is displayed as 2025/05/30 14:34:39.
Show grid	Sets the visibility of grid lines in the operation log table.
Refresh interval (s)	Data refresh interface, with a range of 2 to 65535.
Sort	Default sorting method for operation logs.
Date range	Default display range for operation logs.
Header row height	Height of the table header row.
Content row height	Height of the table content rows.

◦ Function:
Sets the function icons displayed in the view window.

◦ Fill:
Sets the color of the view window.

Property	Description	
Background color	Sets the background color of the area outside the operation log table in the view window, as shown in position ①.	
Text color	Page navigation text color, as shown in position ②.	
Header background color	Table header background color, as shown in position ③.	
Header foreground color	Table header text color, as shown in position ④.	
Table background color	Table background color, as shown in position ⑤.	
Table foreground color	Table text color, as shown in position ⑥.	
Alternate background color	Alternate background color of the table, as shown in position ⑦.	
Grid line color	Inner border line color of the table, as shown in position ⑧.	
Selected row color	Selected row color of the table, as shown in position ⑨.	

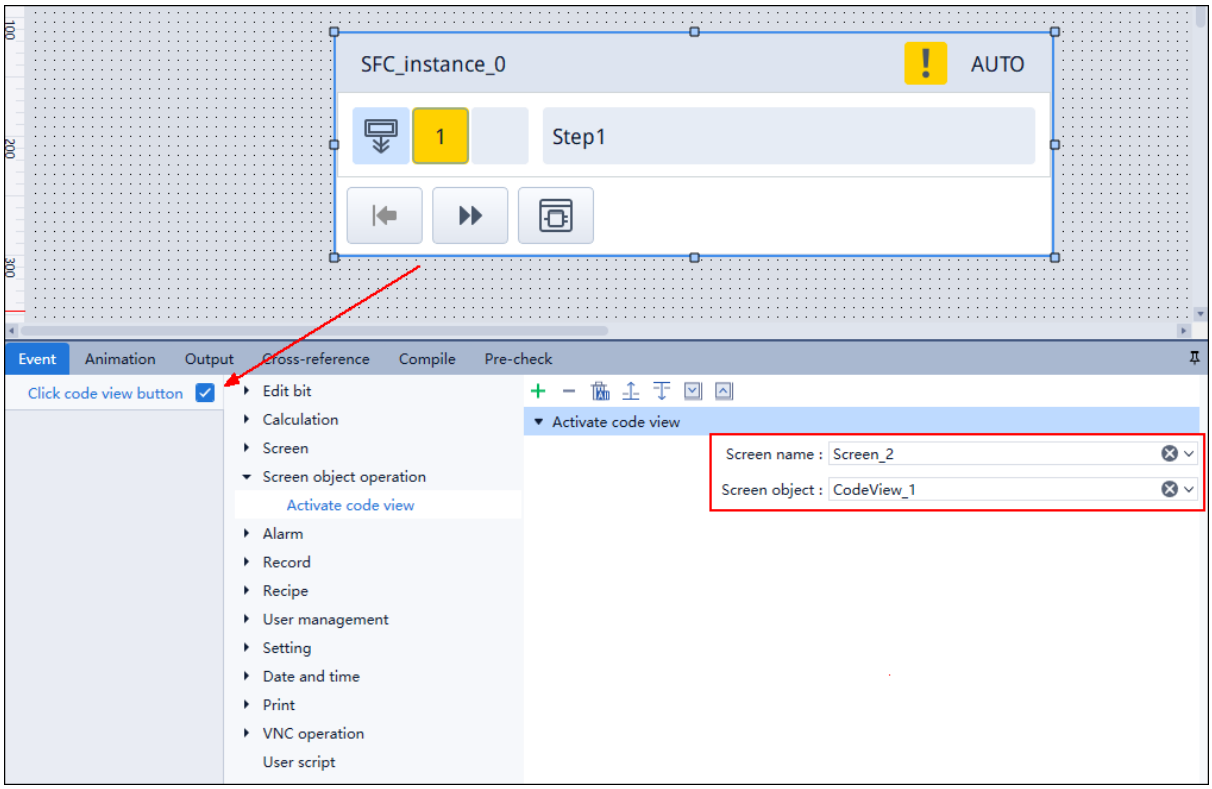
- Text:
  Sets the font, size, and style for header text and content text.
- Basic information: For details, see Line > Basic Information.
- Animation: For details, see 13.3.8 Animation Configuration.

13.3.5.4.9 SFC View

The "SFC view" control is used to display the current execution status of a sequential control program in real time. If an error occurs during execution, the system indicates the exception at the corresponding step. SFC view needs to be used with the 13.3.5.4.10 code view control.

- **Requirements**
  - The PLC has at least one instance of a sequential control program. The PLC and HMI are in the same project.
  - The network public property of the instance variables of the sequential control program is "Public".
- **Creating an SFC view**

  There are three methods to create an SFC view. For details, see Line creation method.
- **SFC view property**
  - Basic settings:



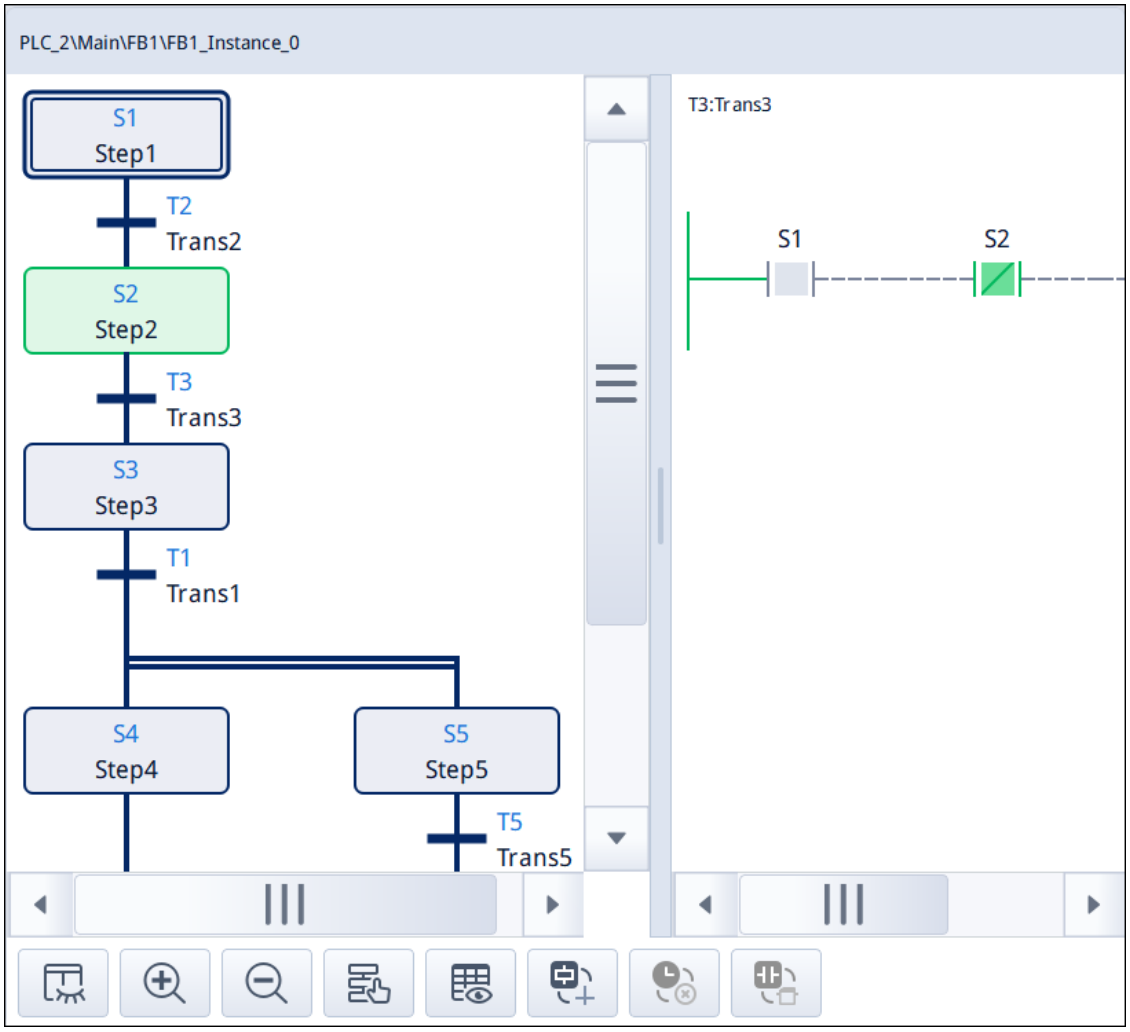
Property	Description
Position	Sets the position coordinates (i.e., top-left coordinates) of the element on the screen in pixels: X: X-axis coordinate. Y: Y-axis position coordinate. The coordinate value must be smaller than the screen boundary coordinate value to prevent the elements from extending beyond the screen.
Dimension	Sets the size of the element on the screen in pixels. Width range: 1 to 10000 Height is fixed and cannot be modified.

  - Variable:
    Process variable: Associates a sequential control program instance from the PLC.
  - Fill:
    Sets the colors for various display objects in the control view (e.g., background color, text color).
  - Text:
    Sets the font and font size for the table header and step description text.
  - Basic information: For details, see Line > Basic Information.
- **Associating a 13.3.5.4.10 code view control**

  The SFC view and code view must be used together. Both must be placed on a process screen. One SFC view can be associated with multiple code views. The related operations are as follows.

  1. Add a code view control to the current view.
  2. Double-click the SFC view control to open the "Event" tab.
  3. Associate a code view.

Add a specific event and associate the current screen and the code view instance.



The SFC view and code view controls are successfully associated.

- **SFC program online operation**
  For details on the online interaction between the SFC view and code view, see 13.15.8 Online PLC Program Viewing.

13.3.5.4.10 Code View

The code view control is used to dynamically display the sequential control program (in SFC and LD languages) of the PLC during runtime. By synchronizing real-time data, it shows the execution status of the program logic. Users can intuitively monitor the running status of the sequential control program for easier commissioning and diagnostics.

The code view must be used with the 13.3.5.4.9 SFC view control.

- **Requirement**
  An SFC view control has been added, and its "Process variable" property is associated with a valid variable.
- **Creating a code view**
  There are three methods to create a code view. For details, see the line creation method.
- **Code view properties**
  - Basic settings:

Property	Description
Position	Sets the position coordinates (i.e., top-left coordinates) of the element on the screen in pixels: X: X-axis coordinate. Y: Y-axis position coordinate. The coordinate value must be smaller than the screen boundary coordinate value to prevent the elements from extending beyond the screen.
Dimension	Sets the size of the element on the screen in pixels. Width range: 1 to 10000 Height range: 132 to 10000

Property	Description
Detail view width	Column width ratio of the detail view display area.

- Fill:

  Sets the colors for various display objects in the control view (e.g., background color, text color).

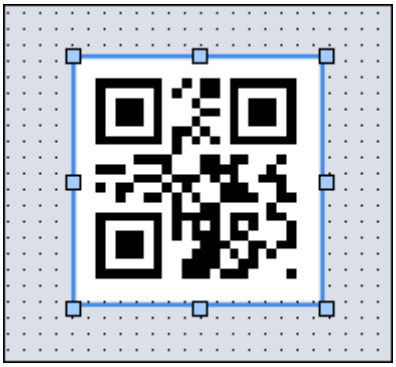
- Text:

  Sets the font and font size for the table header and step description text.

- Symbol table:

  Displays the internal variable information that activates transition condition in table form.

Property	Description
Item	Information about variables in the transition condition. Symbol name: variable name Absolute address: storage address of a variable Description: Variable description
Displayed row count	Number of rows displayed in the table online. Range: 1 to 20
Grid line	Sets the visibility of grid lines in the table.



- **Associating an SFC view control**
  The SFC view and code view must be used together. Both must be placed on a process screen. One SFC view can be associated with multiple code views. For related operations, see SFC View.
- **SFC program online operation**
  For details on the online interaction between the SFC view and code view, see 13.15.8 Online PLC Program Viewing.

13.3.5.5 Others

- 13.3.5.5.1 QR Code
- 13.3.5.5.2 Barcode
- 13.3.5.5.3 PDF
- 13.3.5.5.4 Clock
- 13.3.5.5.5 Browser

13.3.5.5.1 QR Code

The QR code control encodes the associated variable's real-time value into a QR graphic for scanning.

- **QR code creation**

  There are three methods to create a QR code. For details, see the line creation method.

- **QR code properties**

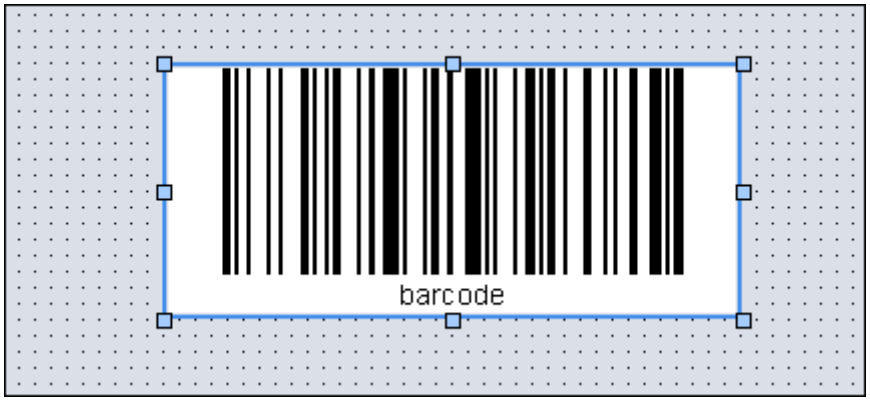
  - For basic settings, see Numeric I/O Field > Basic Settings.
  - Data:

Property	Description
Fault tolerance	Sets the fault tolerance level of the QR code. The required fault tolerance level depends on the expected damages the QR code may endure in its intended environment. Options include: L (7%), M (15%), Q (25%), and H (30%). The percentages in parentheses indicate the maximum damage ratio. Default: H (30%)
Encoding	Sets the parsing type of the QR code. Currently supported types are: UTF-8 (default), ISO-8859-1, and GBK.

  - Interface:

Property	Description
Static value	Static text: At runtime, the QR code corresponding to the static text is displayed. Default is "qrcode"; other text can be entered.
Read variable	Supports basic variable types. At runtime, the QR code corresponding to the variable value is displayed. For details, see 13.2.5.3 Setting Variable Properties.

  - Fill:



Property	Description
Foreground color	Sets the color of the QR code. Default is black.
Background color	Sets the background color of the QR code. Default is white. Sets the transparency of the QR code background (range: 0% to 100%).
Text transparency	Sets the transparency of the QR code from 0% to 100%. Default is 0%. Integers and decimals can be entered.

Property	Description
Border margin	Sets the border margin of the QR code from 1 to 4 pixels. Default is 2 pixels.

- Basic information: For details, see Line > Basic Information.
- Animation: For details, see 13.3.8 Animation Configuration.

13.3.5.5.2 Barcode

The barcode control encodes the associated variable's real-time value into a barcode graphic for scanning.

- **Barcode creation**

  There are three methods to create a barcode. For details, see the line creation method.

- **Barcode properties**
  - For basic settings, see Numerical I/O Field > Basic Settings .
  - Text:

Property	Description
Text display	Sets whether to display text. Default is selected.
Text position	Sets the position of the text, either at the bottom or top. If text is not displayed, this option is grayed out and cannot be edited.

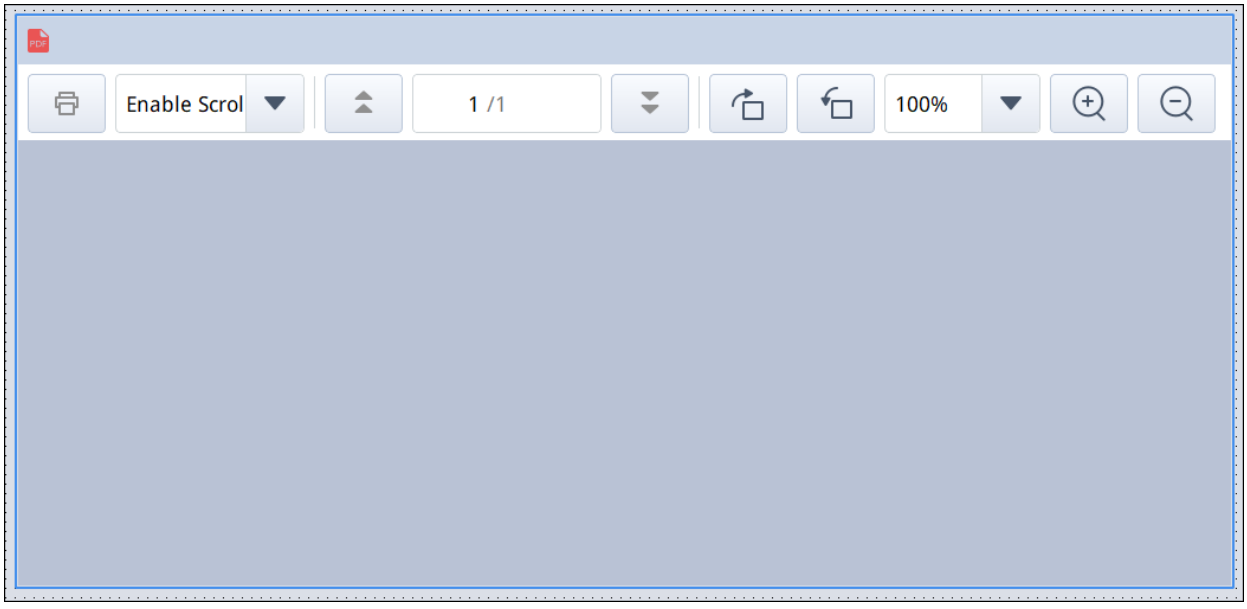
  - Barcode type:

Property	Description
Barcode type	Sets the decoding type of the barcode, supporting Code128.

  - Interface:

Property	Description
Static value	Static text: Conforms to the character limits of Code128. It consists of uppercase letters, numbers, and control characters (such as #, /, -). A maximum of 9 characters is supported. The barcode corresponding to the static text is displayed during runtime.

Property	Description
Read variable	Supports basic variable types. At runtime, the barcode corresponding to the variable value is displayed. For details, see 13.2.5.3 Setting Variable Properties.



- Fill properties:

Property	Description
Text color	Sets the color of the barcode. Default is black.
Background color	Sets the barcode background color. Default is white. Sets the background transparency level from 0% to 100%. Default is 0%.
Text transparency	Sets the transparency of the barcode from 0% to 100%. Default is 0%. Integers and decimals can be entered.

- Basic information: For details, see Line > Basic Information.
- Animation: For details, see 13.3.8 Animation Configuration.

13.3.5.5.3 PDF

The PDF control is used to display PDF documents.

- **PDF creation**

  There are three methods to create a PDF control. For details, see the line creation method.

- **Icons of the PDF control during operation**

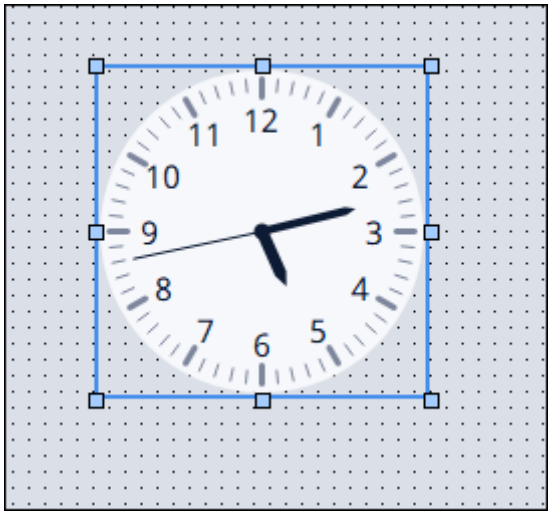
Item	Icon	Description
Column header		Displays the PDF file name. Default is empty.
Print		Prints the file.

Item	Icon	Description
Page display (drop-down box)		Sets single-page view or enables scrolling mode for PDF display. Default is scrolling mode.
Back		Displays the previous PDF page. Disabled when the current page is the first page.
Current page / Total pages		Displays the current page. You can enter a page number and press Enter to jump to the specified page. A prompt is displayed if the entered number exceeds the total number of pages.
Next		Displays the next PDF page. Disabled when the current page is the last page.
Clockwise rotation		Rotates all PDF pages clockwise (zoom ratio remains unchanged). Click once to rotate 90 degrees clockwise.
Counterclockwise rotation		Rotates all PDF pages counterclockwise (zoom ratio remains unchanged). Click once to rotate 90 degrees counterclockwise.
Scale ratio		Selects the PDF display ratio from the drop-down menu. Options include 10%, 25%, 50%, 75%, 100%, 125%, 150%, 200%, and 300%.
Zoom in		Zooms in on the entire PDF. Click once to zoom in one level. Options include 10%, 25%, 50%, 75%, 100%, 125%, 150%, 200%, and 300%.
Zoom out		Zooms out on the entire PDF. Click once to zoom out one level. Options include 10%, 25%, 50%, 75%, 100%, 125%, 150%, 200%, and 300%.
Vertical scroll bar		Automatically follows the vertical position of the currently displayed page.
Horizontal scroll bar		Automatically follows the horizontal position of the currently displayed page.

- **PDF properties**
  - For basic settings, see Numerical I/O Field > Basic Settings .
  - Interface properties:

Property	Description
Path source	Sets the source path of the PDF, supporting a constant and a variable.

Property	Description
Storage location	Sets the storage location of the PDF. Options include SD card, USB1, and USB2.
Constant path	Enter the absolute path where the PDF file is stored, without including the root directory. The specific filename (including the .pdf extension) must be included.
Variable path	Select a STRING type variable associated with the PDF path.



- Function configuration:

Property	Description
File selection	Sets whether to allow selecting a specific PDF file for browsing at runtime. Default is not selected.
Print	Sets whether PDF supports printing. Default is selected.

- Basic information: For details, see Line > Basic Information.
- Animation: For details, see 13.3.8 Animation Configuration.

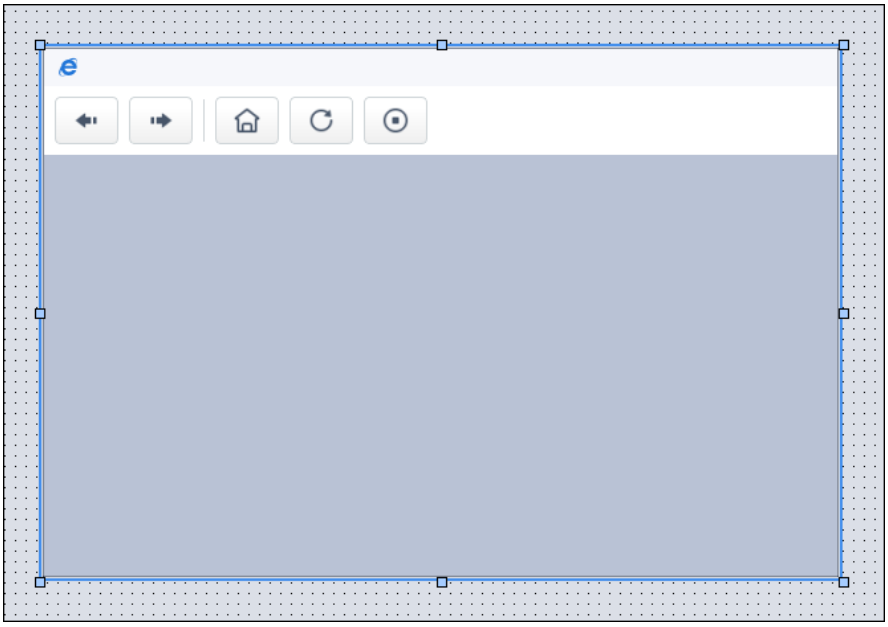
13.3.5.5.4 Clock

The clock control is used to display the current system time.

- **Clock creation**

  There are three methods to create a clock. For details, see the line creation method.

- **Clock properties**
  - For basic settings, see Numerical I/O Field > Basic settings .
  - Properties:



Property	Description
Text color	Sets the clock text color and transparency (0% to 100%).

Property	Description
Background color	Sets the clock background color and transparency (0% to 100%).
Tick color	Sets the clock tick color and transparency (0% to 100%).
Pointer fill color	Sets the fill colors and transparency (0% to 100%) for the hour, minute, and second hands.
Font	Sets the clock text font. Default is Droid Sans Fallback.
Font size	Sets the clock text size. Default is 16.
Font style	Sets the clock text font style. Supports regular, bold, italic, and underline. Default is regular.

- Basic information: Refer to Line > Basic information.
- Animation: For details, see 13.3.8 Animation Configuration.

13.3.5.5.5 Browser

The browser control is used to display the page corresponding to a specified URL link. At runtime, it functions as an embedded browser, allowing users to interact with the displayed page.

- **Browser creation**

  There are three methods to create a browser. For details, see the line creation method.

- **Icons of the browser during operation**

Item	Icon	Description
Back		Switches to the previous page. If the current page is the home page, this icon is grayed out.

Item	Icon	Description
Forward		Switches to the next page. The operation takes effect only if the next page is cached; otherwise, this icon is grayed out.
Refresh		Reloads the current URL page.
Stop		Stops loading the current URL page.
Homepage		Returns to the URL link page set in edit mode.

- **Browser properties**
  - For basic settings, see Numerical I/O Field > Basic Settings .
  - Interface properties:

Property	Description
URL	Sets the static URL address of the page to access. Default is empty. The length must not exceed 4096 characters.
URL variable	URL variables can only be of STRING type. • If the URL variable is not set, the static URL takes effect. • If the URL variable is set, the URL variable takes effect.
Toolbar	By default, the toolbar is selected during runtime. 

  - Border properties:

Property	Description
Border	Default is selected to enable the border function.
Border width	Default is 1, with a value range of 0 to 10. It can be entered manually, or adjusted by clicking the up/down icons. When "Border" is not selected, the border width is grayed out and cannot be edited. When "Border" is selected, the border width can be edited.
Color value	Sets the border color. Default is black. When "Border" is not selected, the border color is grayed out and cannot be edited. When "Border" is selected, the border color can be edited.

  - Basic information: For details, see Line > Basic Information.
  - Animation: For details, see 13.3.8 Animation Configuration.

13.3.5.5.6 Media Player

The media player control is used to display the page corresponding to a specified URL link. At runtime, it functions as an embedded browser, allowing users to interact with the displayed page.

Supported file formats include MP4, MKV, AVI, MOV, FLV, ASF/WMV, WAV, MP3, FLAC, and AAC.

Use restrictions

- Applicable screen: Only supported in the main screen.
- Configuration count: Only one media player can be added per main screen.

Control configuration

Media player creation

There are three methods to create a media player. For details, see the line creation method.

CAUTION

- When arranging the screen, other controls or graphic elements (including those on higher layers) must not obscure the display area of the multimedia control.
- Only pop-ups triggered at runtime are allowed to temporarily overlay the multimedia control.

Media player properties

- **Basic settings**

Item	Description
Position	Sets the position coordinates (top-left corner) of the element on the screen in pixels. The coordinate values must be within the screen boundaries to prevent the element from extending beyond the visible area.
Size	Sets the size of the element on the screen in pixels. Minimum size (W*H): 336*131.

- **Interface property**

Property	Description
Path source	Sets the input method for the path. Constant: A fixed path. Variable: A variable path.
Storage location	Sets the path where the media file is stored.
Constant path	Enter an absolute path.
Variable path	Select a variable of STRING/WSTRING type that is associated with the media file. The file path is determined by the variable value. An absolute path must be entered.

- **Playback control**

  The playback mode and volume are controlled via variables.

Property	Description	Remarks
Play/Pause	Supports BOOL type variables. 0: Pause; 1: Play	If no variable is associated, the video is controlled by the icons during runtime.
Replay control	Supports BOOL type variables. 0 -> 1: Replay 1 -> 0: No operation	
Loop playback control	Supports INT type variables. 0: No loop 1: Loop single file 2: Loop folder contents	
Volume control	Supports INT type variables. The value range is 0 to 100, corresponding to minimum and maximum volume.	

- **Output Parameters**

Property	Description
Current file name	Writes the name of the currently playing file into the specified variable. Supports STRING/WSTRING types.
Playback status	Associates with an INT type variable to feed back video playback status to the variable. 0: Playing 1: Paused 2: Playback completed

- **Playback settings**

Property	Description
Resume mode	Sets whether the video resumes from the last playback position after switching screens. Resume from current position: Continues from where playback left off before the screen switch. Replay: Restarts playback from the beginning of the video.
Play mode	Loop disabled: Plays the current file and stops at the end. Folder loop: Plays all videos in the same folder sequentially and repeats. Single file loop: Repeats the current file continuously.
Default volume	Sets the volume used when the control is online.

- **Functions**
  Sets the operation icons on the video control.
- **Fill**
  Sets the background color and display angle of the video control.
- **Basic information**: For details, see Line > Basic Information.
- **Animation**: For details, see 13.3.8 Animation Configuration.
- **Event**: For details, see 13.3.7.14 Adding an Event.

13.3.6 Gallery Usage

- 13.3.6.1 Overview
- 13.3.6.4 Project Gallery Usage
- 13.3.6.2 System Gallery Usage
- 13.3.6.3 User Gallery Usage
- 13.3.6.5 Local Gallery Usage

13.3.6.1 Overview

Gallery contains a wealth of graphic resources to enhance the intuitiveness and professionalism of process screens. Based on the graphic sources, there are project gallery, system gallery, and user gallery.

Project gallery

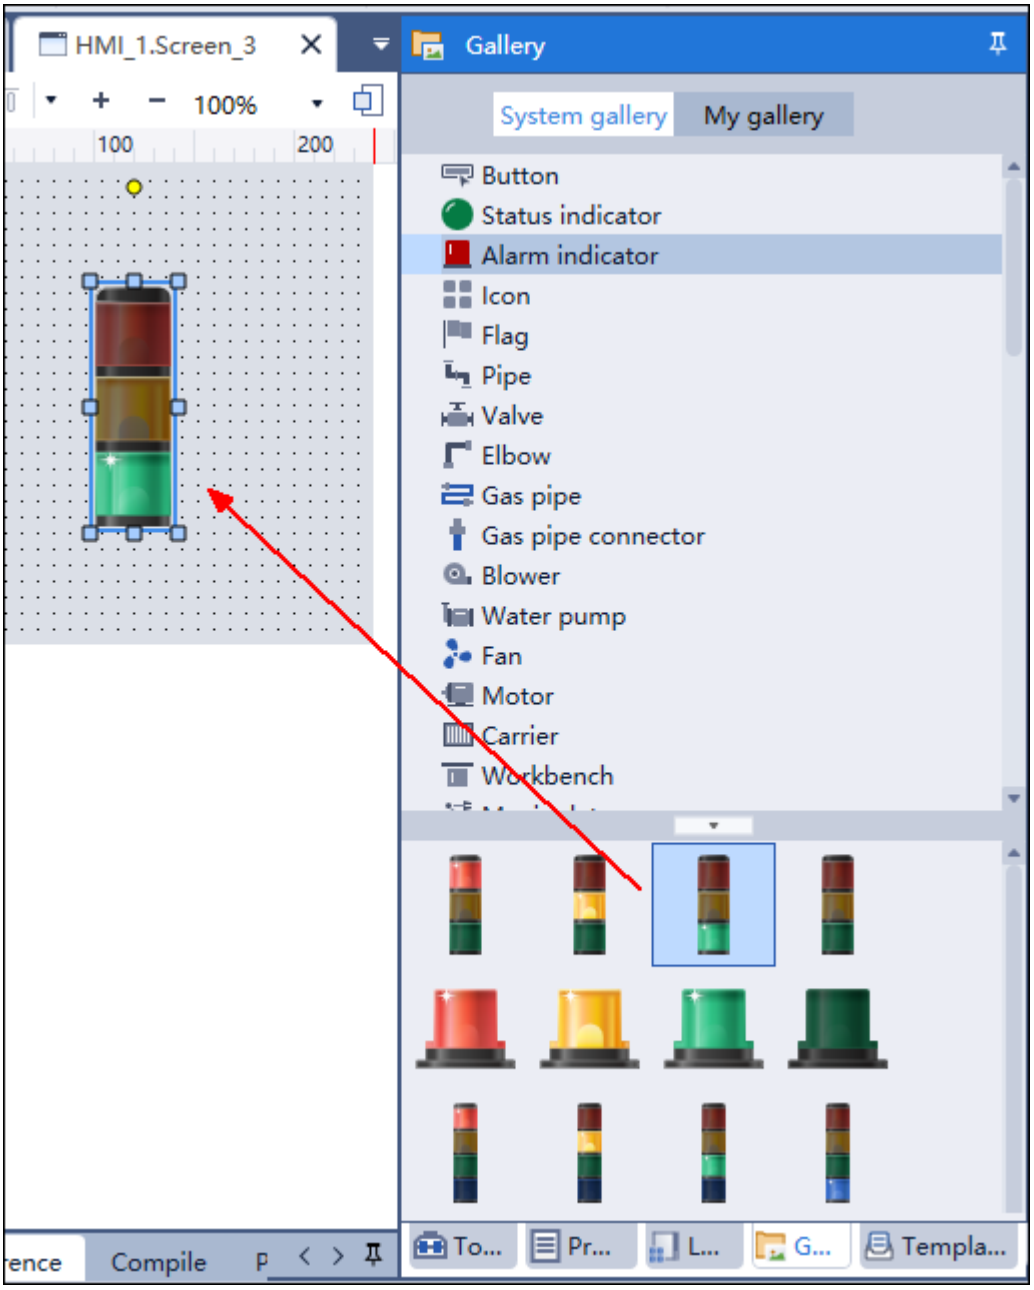
Graphics used within a project are automatically added to the project gallery for unified management. The project gallery can be used across all HMI devices in the current project.

System gallery

The system gallery is installed along with the software monitoring development environment. Its path follows the that of the development environment and cannot be specified. The main categories in the system gallery include: buttons, indicators, alarm indicators, pipes, valves, elbows, gas pipes, gas pipe connectors, fans, water pumps, motors, carriers, etc.

User gallery

The user gallery is a user-defined gallery that supports importing images in formats (bmp, ico, gif, tiff, svg, jpeg, jpg, png) that meet the requirements, and using them when creating screens.



Local gallery

The local gallery is used to store image resources referenced in symbol templates. Each symbol template has its own local gallery, where all images referenced by all versions of that template are stored. These galleries are independent of each other.

13.3.6.2 System Gallery Usage

Procedure

1. Select an image from the gallery and directly drag it into the screen. The width and height of the image are its actual size in the gallery (including SVG format). Once placed, its appearance and size can be adjusted directly using the mouse.
   - To replace an image, select the new image from the gallery and drag it over the original one to overwrite it.
   - To overlap objects from different galleries, place the second image near the original one, and adjust its position for stacking.

NOTE

- During software uninstallation, the system gallery is removed together with the software. User-defined galleries are unaffected by software uninstallation and remain in their original directories.
- During software updates, user-defined gallery settings are preserved. Whether the system gallery is updated depends on whether the update package contains changes to the system gallery.

2. Click a node in the system gallery to display the gallery information under each category:

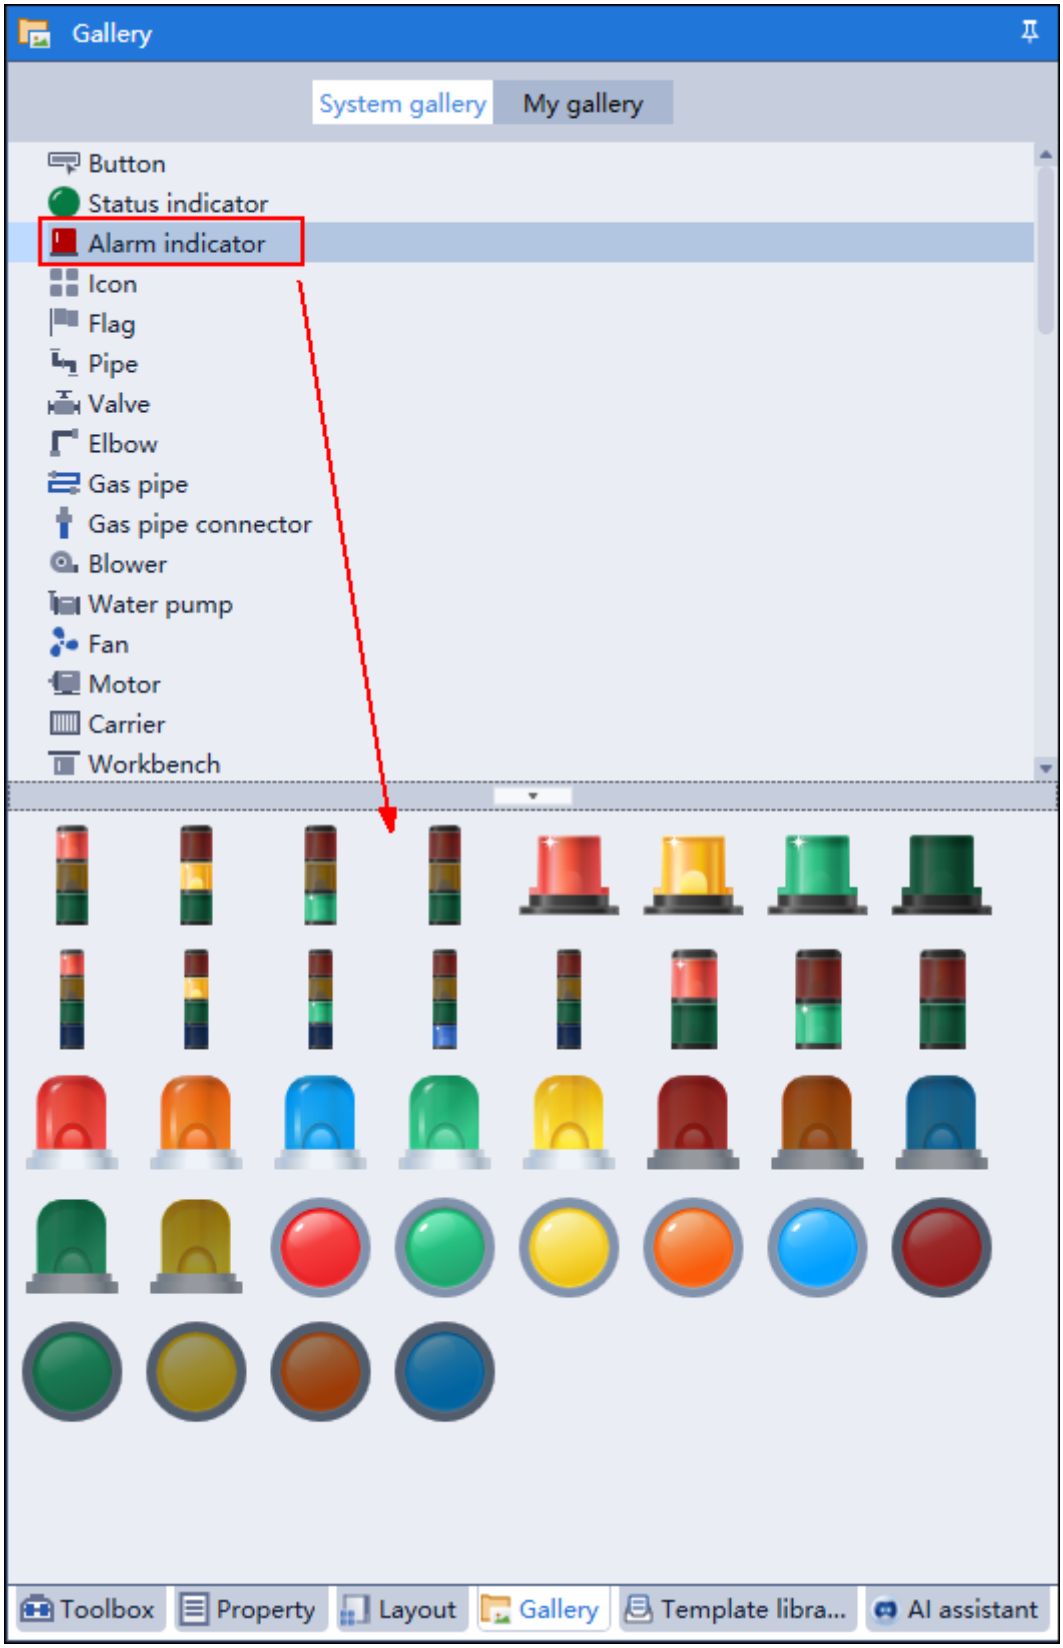


Image properties

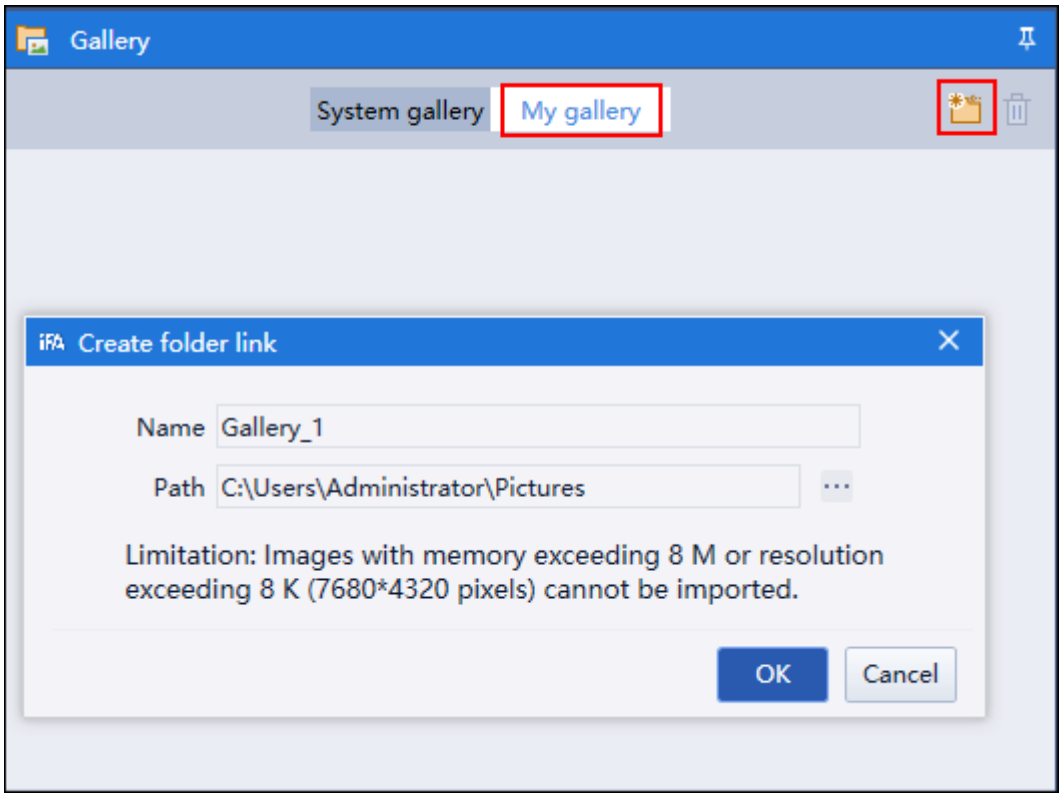
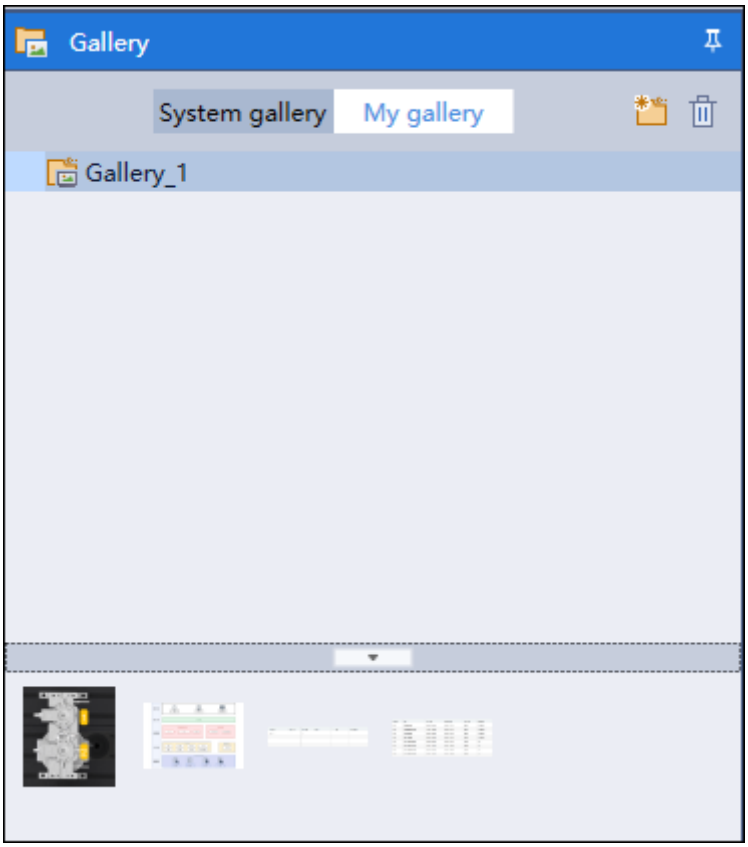
- Basic settings



Item	Description
Position	Sets the position coordinates (i.e., top-left coordinates) of the element on the screen in pixels: • X: X-axis coordinate. • Y: Y-axis position coordinate. The coordinate value must be smaller than the screen boundary coordinate value to prevent the elements from extending beyond the screen.
Size	Sets the size of the graphic element on the screen in pixels: • W: Element width. • H: Element height. The minimum size for the graphic element is 1*1.
Rotation	Sets the rotation angle of the graphic element, with a range from -180 to 180.

- Basic information: For details, see Line > Basic Information.
- Animation: For details, see 13.3.8 Animation Configuration.
- Event: For details, see 13.3.7.14 Adding an Event.



13.3.6.3 User Gallery Usage

Procedure

1. Select "My gallery", click the "Add" icon in the upper right corner, and the "Create folder link" window pops up:
   - Name: The name of the created gallery (default: Graphics_1, Graphics_2, …, Graphics_n).
   - Path: Points to a Windows folder. After creation, the software will automatically display supported images from this folder as previews in the gallery.

2. After successful addition, the gallery information can be viewed in "My gallery". Elements in the gallery can be added to screens.

> **NOTE**
>
> Images with memory exceeding 8 M or resolution exceeding 8 K (7680*4320 pixels) cannot be imported.

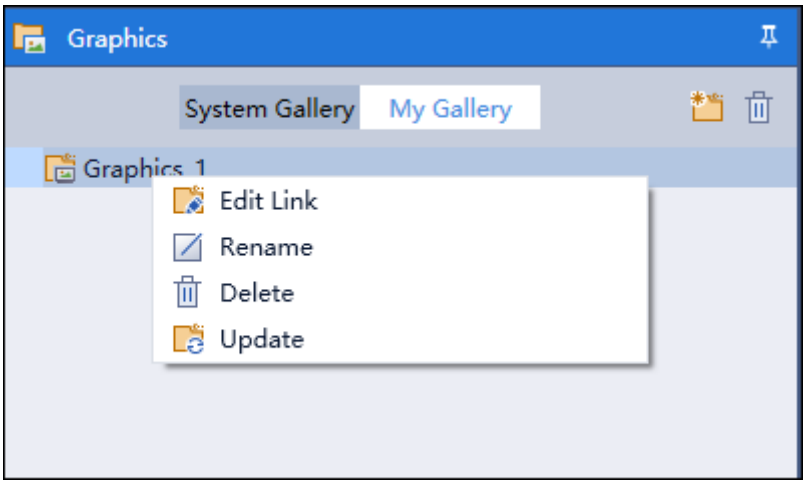


Image properties

- Basic settings

Item	Description
Position	Sets the position coordinates (i.e., top-left coordinates) of the element on the screen in pixels: • X: X-axis coordinate. • Y: Y-axis position coordinate. The coordinate value must be smaller than the screen boundary coordinate value to prevent the elements from extending beyond the screen.
Size	Sets the size of the graphic element on the screen in pixels: • W: Element width. • H: Element height. The minimum size for the graphic element is 1*1.
Rotation	Sets the rotation angle of the graphic element, with a range from -180 to 180.

- Basic information: For details, see Line > Basic Information.

- Animation: For details, see 13.3.8 Animation Configuration.
- Event: For details, see 13.3.7.14 Event Configuration.
- Right-click a folder in "My gallery" to edit:

  - Edit link: Modify the gallery name and path information.
  - Rename: Modify the gallery name.
  - Delete: Delete the selected gallery.
  - Update: Refresh the gallery information. When images are added or removed in the specified Windows folder, the preview will be refreshed to list valid images.

Gallery data retention

When uninstalling the iFA software, select how to handle user gallery data via the "Keep local settings" option:

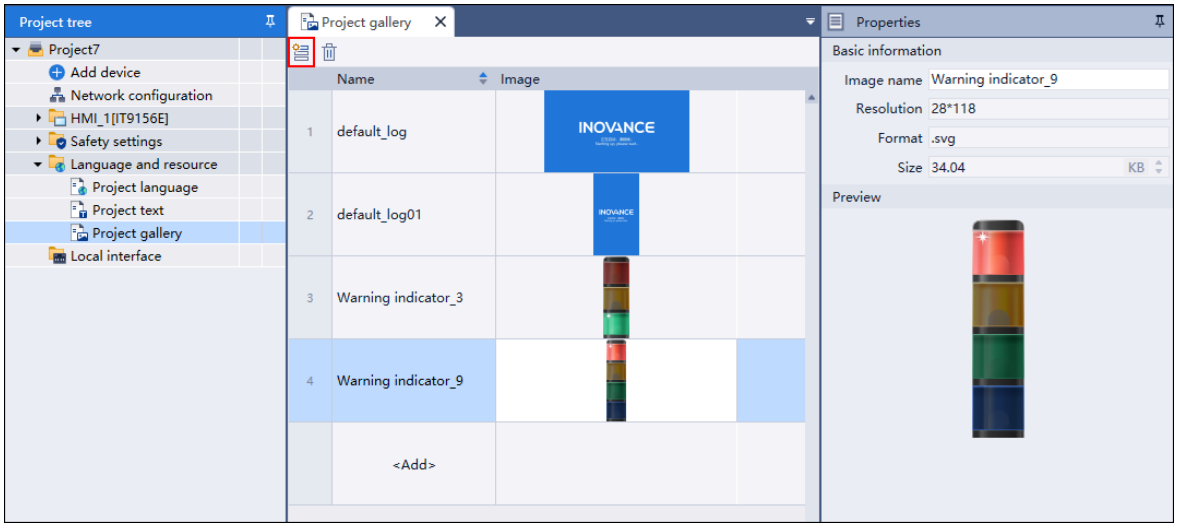
Checked: After uninstallation, images and access paths in the user gallery will be retained. If the iFA software is reinstalled on the same computer, the gallery data and related settings will be automatically restored.

Unchecked: User gallery data will be deleted simultaneously during uninstallation. After reinstalling, you will need to rebuild the gallery.

13.3.6.4 Project Gallery Usage

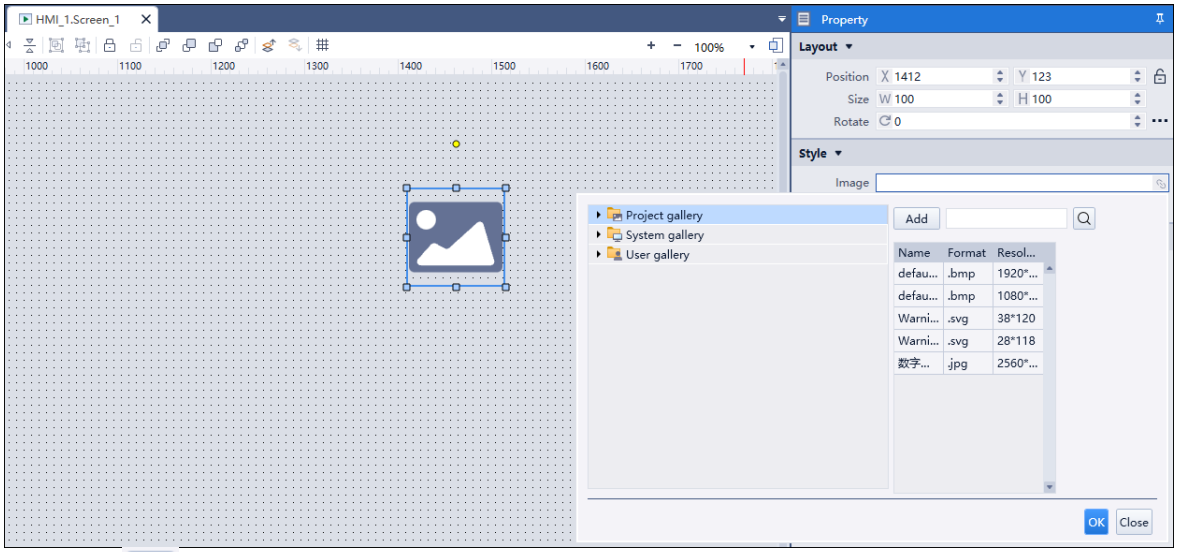
Image specification limits

Each referenced image must be smaller than 8 MB in size and have a resolution below 8 K (7680 x 4320 pixels).



Storage capacity limits

Whichever limit is reached first will trigger a system alert:



- Maximum number of images: 10000.
- Maximum total image size: 1024 MB.

Procedure

1. Double-click "Project gallery" under "Language and resources" in the left project tree to open the project gallery.
2. Add images.
   - Manual addition: Click , select the images to be added, and click "Open" to import the images into the project gallery.

   - Automatic addition: Graphics used within a project are automatically added to the project gallery for unified management.
     Example: When adding an image via the 13.3.5.1.11 Image control, all related operations are performed in the property tab of the 13.3.5.1.11 Image control. The image will be automatically added to the project gallery.

- Search

  Search based on the entered keyword in the selected gallery on the left.

- Add

  Add resources from local PC to the local gallery.

> **NOTE**
>
> The project gallery can be used across all HMI devices in the current project.

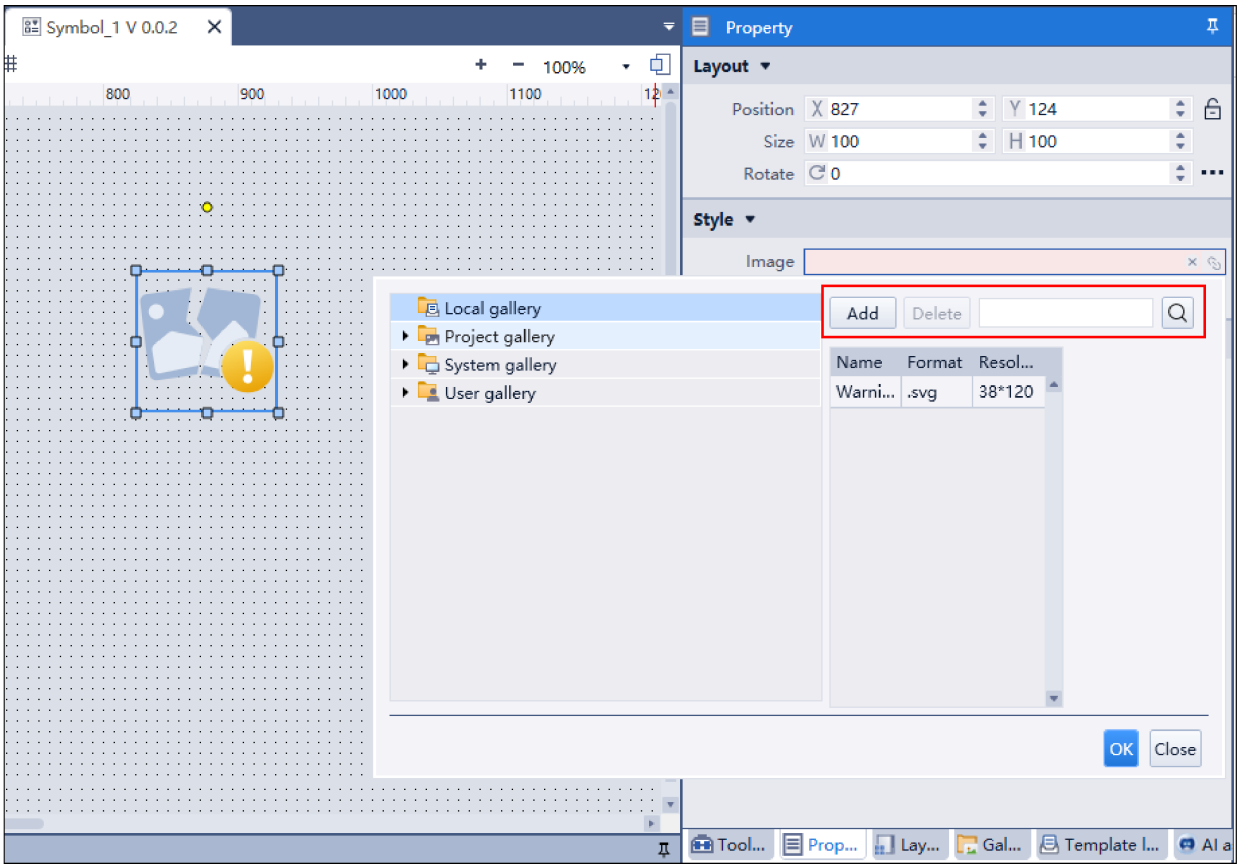
3. Delete an image. Select an image and click to delete it from the project gallery. After deletion, the corresponding image control is as follows.

13.3.6.5 Local Gallery Usage

The local gallery is used to store the specific images associated with the 13.3.5.1.11 Image control in the symbol template. Each 13.4.3.2 Symbol Template has its own local gallery, independent of each other.

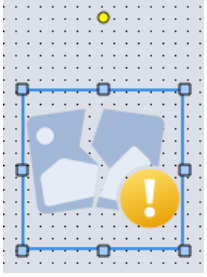
Image specification limits

Each referenced image must be smaller than 8 MB in size and have a resolution below 8 K (7680 x 4320 pixels).



Storage capacity limits

Whichever limit is reached first will trigger a system alert:



- Maximum number of images: 100.
- Maximum total image size: 32 MB.

Procedure

Operations related to the local gallery are performed on the property tab of the 13.3.5.1.11 Image control.

- Search
  Search based on the entered keyword in the selected gallery on the left.
- Add
  Add resources from local PC to the local gallery.
- Delete
  Delete images from the local gallery. After deletion, the corresponding image control is as follows.

13.3.7 Screen Configuration

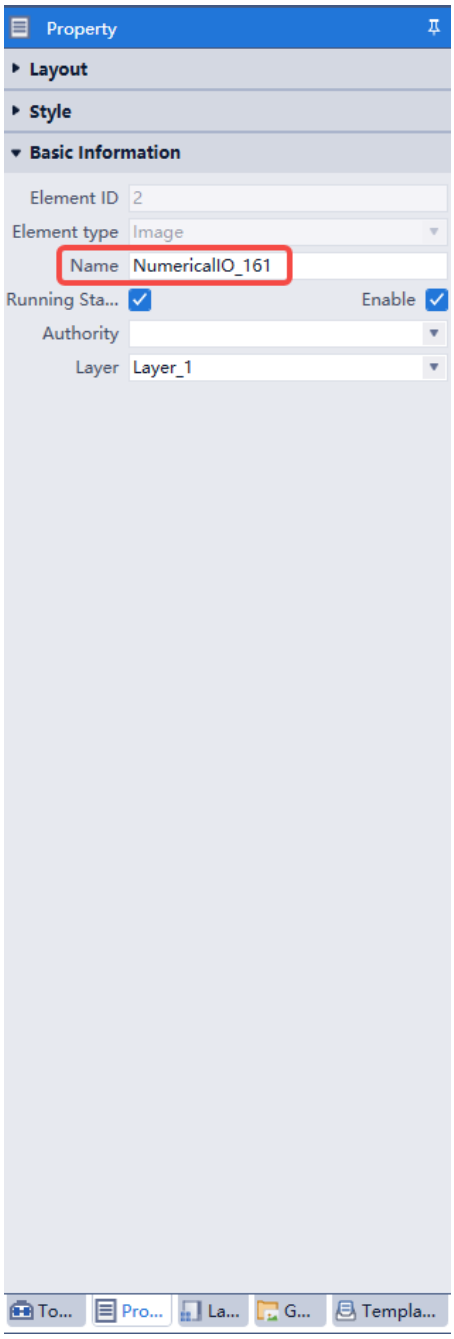
- 13.3.7.1 Creating an Object

- 13.3.7.2 Renaming an Object
- 13.3.7.3 Copying/Pasting an Object
- 13.3.7.4 Cutting/Pasting an Object
- 13.3.7.5 Deleting an Object
- 13.3.7.6 Rotating an Object
- 13.3.7.7 Flipping an Object
- 13.3.7.8 Aligning Objects
- 13.3.7.9 Grouping Objects
- 13.3.7.10 Ungrouping Objects
- 13.3.7.11 Locking an Object
- 13.3.7.12 Unlocking an Object
- 13.3.7.13 Adding an Animation
- 13.3.7.14 Adding an Event
- 13.3.7.15 Configuring a Picture-in-Picture Screen
- 13.3.7.16 Resizing an Object
- 13.3.7.17 Moving an Object
- 13.3.7.18 Adjusting Object Spacing
- 13.3.7.19 Configuring a Pop-up Screen

13.3.7.1 Creating an Object

A screen supports up to 500 objects, with grouped objects counted by their members and picture-in-picture counted as one object. For example, a grouped object containing four lines and one text element is counted as five objects.

- There are three ways to create an object with default size:
  - Select an object in the toolbox, then click on the screen to create a default-sized element at the specified location.
  - Select an object in the toolbox and drag it into the screen to create a default-sized element.
  - Drag a variable from the detailed view into the screen to automatically create the corresponding element and establish a link between the variable and the element. For example, a BOOL variable corresponds to a bit button, and a REAL variable corresponds to a numeric I/O field.
- To create an object with custom size, follow these steps:
  1. Select an object in the toolbox.
  2. Click and hold the mouse at the start position on the screen, drag to the end position, and then release.
- To create a polyline, polygon, and pipeline object, follow these steps:
  1. Select the target element in the toolbox.
  2. Click at the start position on the screen, move to the end of the first segment, and click again to complete the first segment.
  3. Repeat the above steps for each segment, and then right-click to generate the desired element.



13.3.7.2 Renaming an Object

Each object on the screen has a unique name, which is automatically assigned by the software in the order they are created. The default naming format is "Object name (Name in toolbar)_Number", such as "Line_1".

Objects can be renamed. The new name can consist of Chinese characters, English letters, numbers, and special characters. It cannot start or end with a space, and supports up to 128 characters.

Renaming steps:

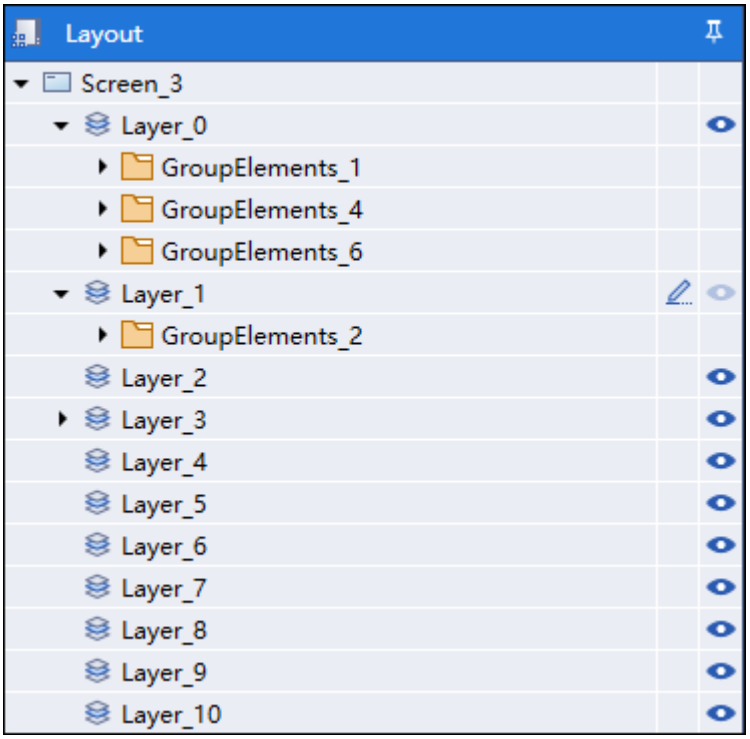
- Object properties
  1. Double-click an object on the screen, such as a numeric I/O field.
  2. Enter the new name in "Name".

  3. Press **Enter** to confirm.

- Screen layout
  1. Open the "Layout" tab of the screen.
  2. Select an object node in the layer tree.

3. Press **F2** or select "Rename" from the right-click menu.
4. After entering the new name, press **Enter** to confirm.

13.3.7.3 Copying/Pasting an Object



Objects on the screen can be copied and pasted within the same screen or across different screens.

Operating on the screen

1. Select the target object on the screen.
   When copying multiple objects, use the **Ctrl** key or box selection to select multiple objects.
2. Copy the object.
   Press **Ctrl+C** or click "Copy" in the right-click menu to copy the selected object along with all its properties, events, and animation settings.
3. Paste the object.
   Press **Ctrl+V** or click "Paste" in the right-click menu to paste the object onto the currently active layer. Multiple pastes are supported. Object names will automatically be adjusted to avoid duplicates. If the copied object is locked, it will be automatically unlocked after pasting.

Operating in the layout

1. Select the target object in the layout.
   When copying multiple objects, use the **Ctrl** key to select multiple objects.

2. Copy the object.
   Press **Ctrl+C** or click "Copy" in the right-click menu to copy the selected object along with all its properties, events, and animation settings.
3. Paste the object.
   Press **Ctrl+V** or click "Paste" in the right-click menu to paste the object onto the selected layer. Multiple pastes are supported. Object names will automatically be adjusted to avoid duplicates. If the copied object is locked, it will be automatically unlocked after pasting.

13.3.7.4 Cutting/Pasting an Object

Objects on the screen can be cut and within the same screen or across different screens.

1. Select the target object on the screen.
   When cutting multiple objects, use the **Ctrl** key or box selection to select multiple objects.
2. Copy the object.
   Press **Ctrl+X** or click "Cut" in the right-click menu to cut the selected object along with all its properties, events, and animation settings.
3. Paste the object.
   Press **Ctrl+V** or click "Paste" in the right-click menu to paste the object. Objects are typically pasted onto the active layer.
   Supports cutting once and pasting multiple times. When pasting, all properties, events, and animation settings of the object are included.
   When pasting multiple times, object names will automatically be adjusted to avoid duplicates.

13.3.7.5 Deleting an Object

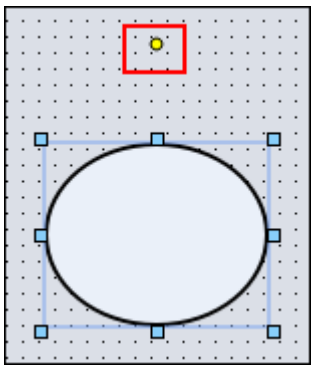
Used to delete one or more objects, without affecting their associated variables or scripts.

Operation:

1. Select the object to delete from the screen or layout tree.
   When selecting from the layout tree, to delete one of the objects from a group containing two objects, 13.3.7.10 ungroup it first.
2. Click "Delete" from the right-click menu or press **Delete** to delete the selected object.

13.3.7.6 Rotating an Object

There are three ways to rotate an object:



- Click the rotate icons on the toolbar to rotate.

Icon	Description
	Rotates the selected object clockwise by 90 degrees around its center point.
	Rotates the selected object counterclockwise by 90 degrees around its center point.

  Applicable objects include:
  - Basic element: 13.3.5.1.3 arc, 13.3.5.1.4 rectangle, 13.3.5.1.5 circle, 13.3.5.1.6 ellipse, 13.3.5.1.7 sector, 13.3.5.1.8 circular segment, 13.3.5.1.10 text, and 13.3.5.1.11 image;
  - Control and display: 13.3.5.2.1 numeric I/O field, 13.3.5.2.2 character I/O field, 13.3.5.2.3 date/time field, and 13.3.5.2.12 text switch;
  - Data visualization: 13.3.5.3.1 bar chart;

◦ Others: 13.3.5.5.2 barcode.

- Rotate the object by any angle using the mouse.
  1. Select the object to be rotated, and the yellow rotation icon will appear, as shown in the figure below.

  2. Press and hold the rotation icon to rotate by any angle.

- Rotate the object through the property window.

13.3.7.7 Flipping an Object

Select one or more graphic objects to flip, then click the flip icons button on the toolbar. Flipping is supported by only some objects.

Icon	Description
	Displays the selected object in horizontal symmetry.
	Displays the selected object in vertical symmetry.

13.3.7.8 Aligning Objects

Select two or more graphic objects to align, then click the align icons on the toolbar.

Icon	Description
	Aligns the left edges of the object and the reference object.
	Aligns the right edges of the object and the reference object.
	Aligns the top edges of the object and the reference object.
	Aligns the bottom edges of the object and the reference object.
	Aligns the selected objects with the vertical center axis of the reference object.
	Aligns the selected objects with the horizontal center axis of the reference object.

Icon	Description
	Aligns the selected objects with the center point of the reference object.
	Places the geometric center of the selected objects on the horizontal center line of the entire screen, while keeping the vertical position of each object unchanged.
	Places the geometric center of the selected objects on the vertical center line of the entire screen, while keeping the horizontal position of each object unchanged.
	Places the geometric centers of the selected objects at the center point of the entire screen.

13.3.7.9 Grouping Objects

Group two or more objects into a single entity, which is referred to as a group object or group element (default).

Grouping operation

Objects can be grouped on the screen or in the "Layout" tab:

1. Select at least two objects on the screen or in the layer tree.
2. Click "Group" in the right-click menu.

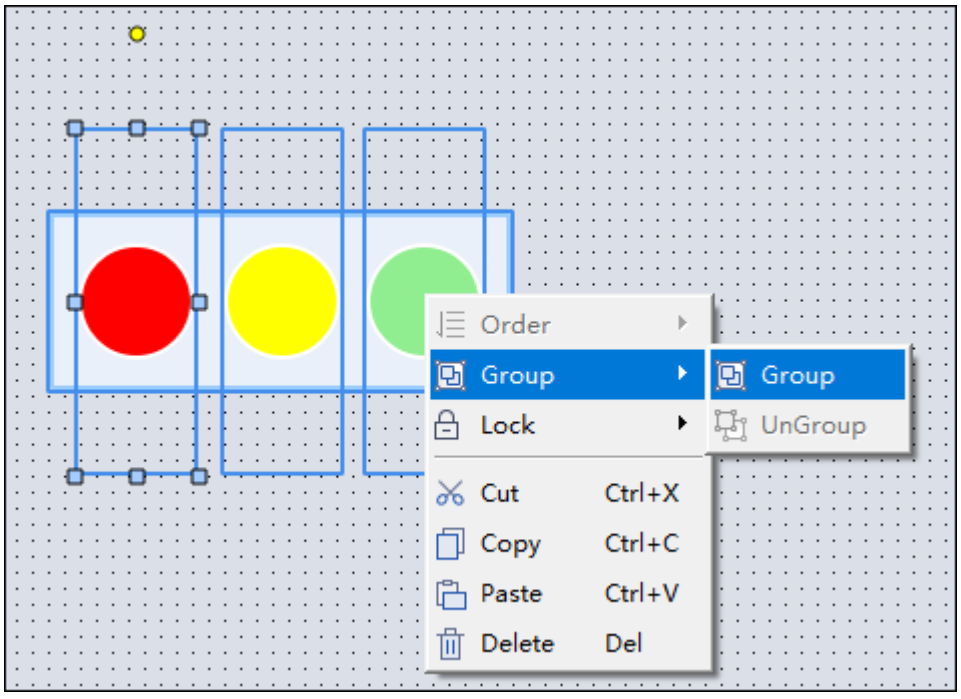


Figure 13-3-7-9-1 Grouping on the screen

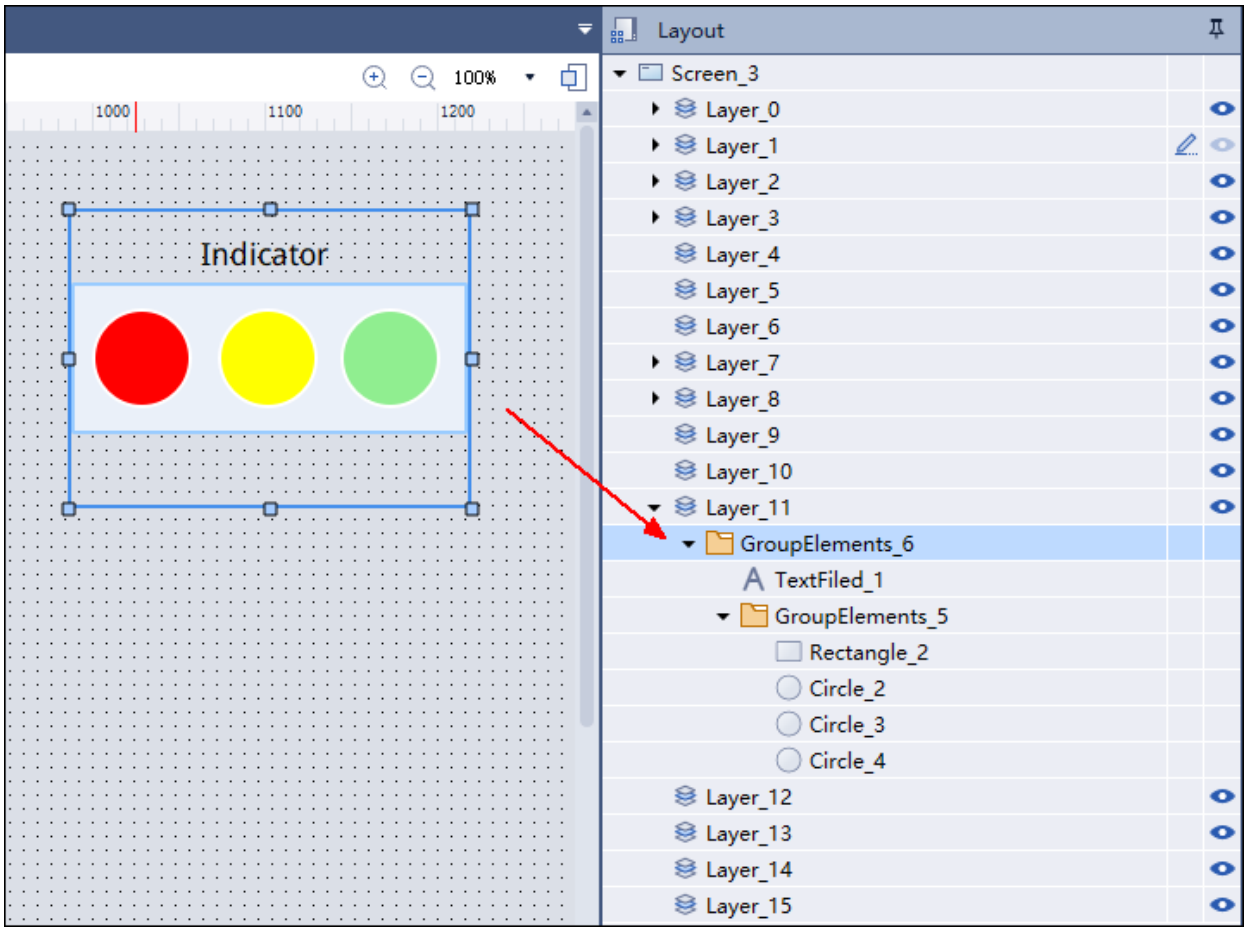
If the members for grouping are located on different layers, they will all be moved to the layer with the higher number after grouping.

Group objects are named "GroupElements_n" in the layer tree, which can be renamed. For details, see 13.3.7.2 Renaming an Object.

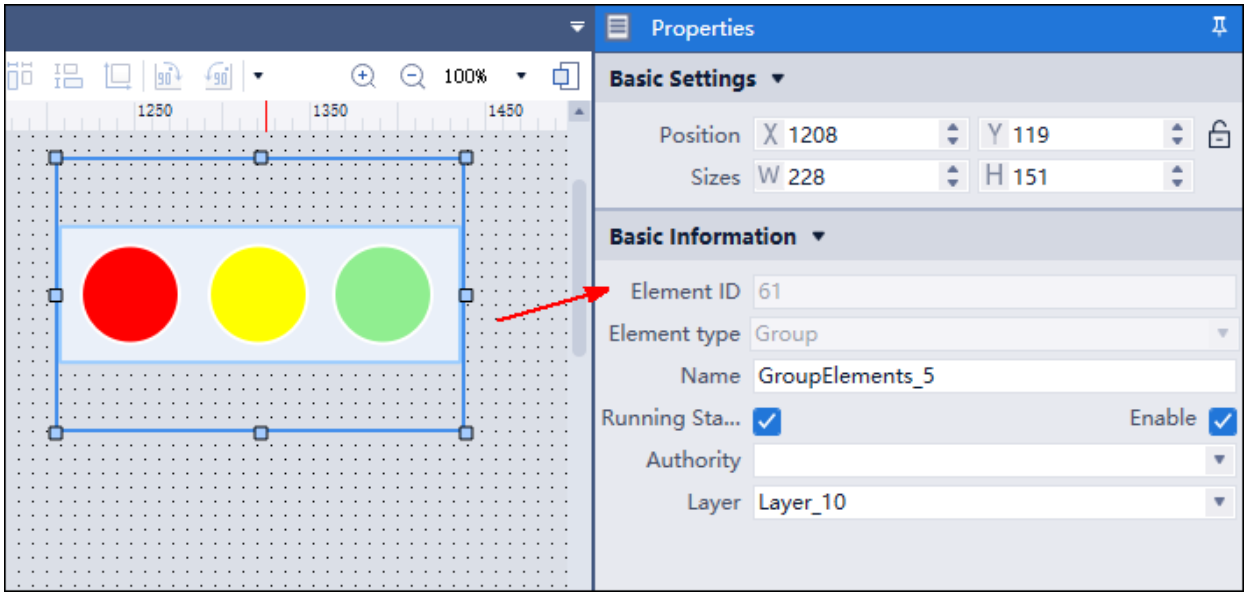
Adding members to a group



Other objects can be added to an existing group to form a new nested group.

Select an existing group object and the objects to be added on the screen or from the layer tree, then select

"Group" in the right-click menu.

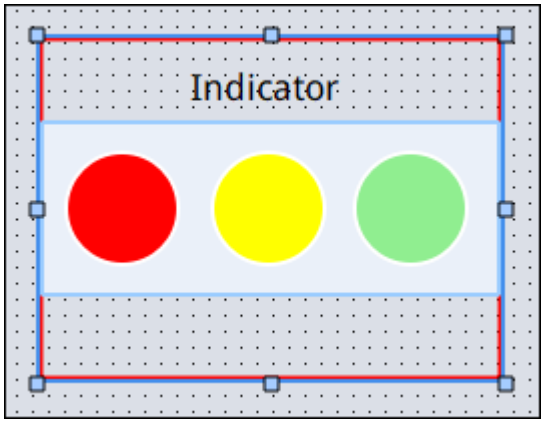


If the members for grouping are located on different layers, they will all be moved to the layer with the higher number after grouping.

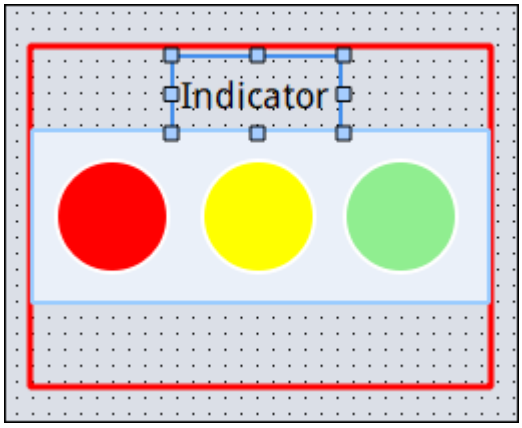
The hierarchical relationships among group members can be viewed through the layer tree.

Setting group properties

Groups have their own properties, such as permissions. When a property is set for a group, all its members inherit this property. When a property is set differently on a group member than on the group itself, the member's value takes precedence at runtime. Select a group on the screen, and its related properties will be displayed in the property box.



Users can adjust the size and position of the group.



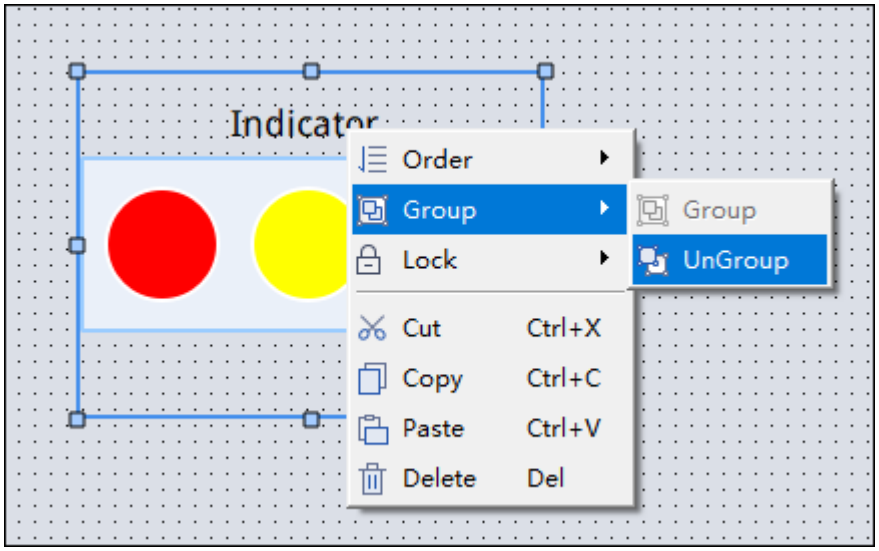
Modifying group member properties

The property values of group members can be modified without ungrouping.

- Modifying on the screen
  1. Double-click a group on the screen and its surrounding rectangle becomes red.

  2. Click the member to modify to open its property box.

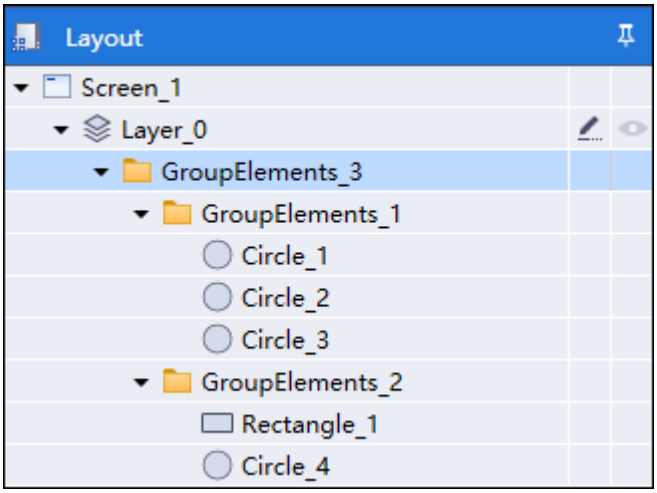
  3. Modify the property values of the selected member.
     Some properties cannot be modified, depending on the object type. Refer to the software for details.
- Modifying on the layer tree
  1. Select a group member on the layer node.
  2. Open the "Property" tab.
  3. Modify the property values of the selected member.
     Some properties cannot be modified, depending on the object type. Refer to the software for details.



13.3.7.10 Ungrouping Objects

Ungrouping refers to restoring a group to individual objects before grouping. Properties of the group will be automatically canceled during ungrouping.

Ungrouping can be performed in two ways. Nested groups must be ungrouped step by step from the outermost level inward.

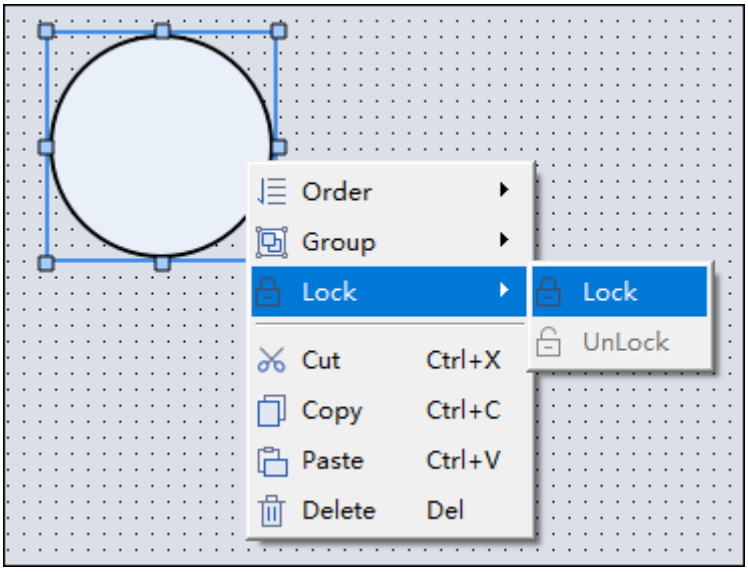


Operation on the screen

1. Select the target group on the screen.
2. Select "Group > Ungroup" in the right-click menu.

Operation in the layout

1. In the "Layer" tab, select the target group node. If the group is nested, select its parent node.

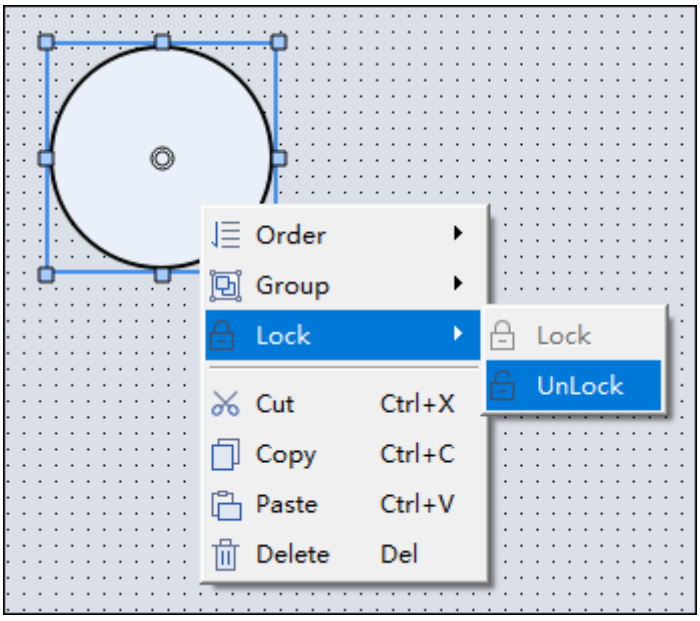


2. Click "Ungroup" in the right-click menu.

13.3.7.11 Locking an Object

Select one or more objects to be locked. Locked objects cannot be moved, scaled, or rotated. There are two locking methods:

- Right-click the target object on the screen and select "Lock > Lock".

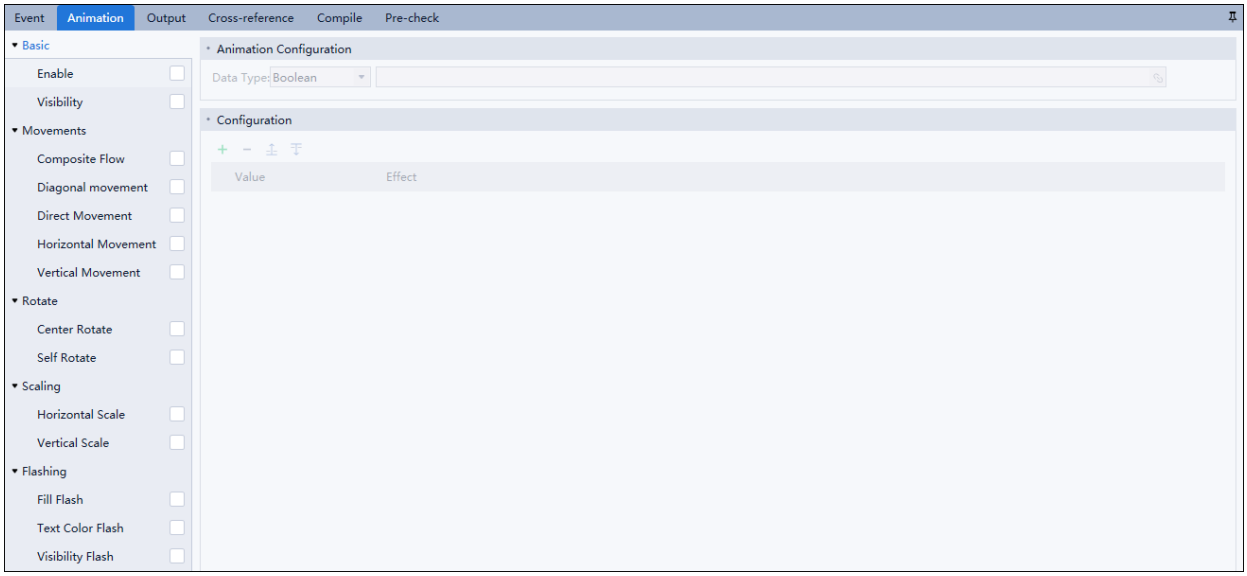


- In the property window of the target object, click the lock-shaped icon to the right of "Position".

13.3.7.12 Unlocking an Object

Select one or more objects to unlock. Unlocked objects can then be moved, scaled, and rotated. There are two unlocking methods:

- Right-click the target object on the screen and select "Lock > Unlock".



- In the property window of the target object, click the lock-shaped icon to the right of "Position".

13.3.7.13 Adding an Animation

The visualization platform offers rich element animation design for appearance, fill, movement, rotation, and scaling.

Procedure

1. Select the element to edit;
2. Click "Animation" in the monitoring area to enter the animation configuration interface, as shown below:

13.3.7.14 Adding an Event

The visualization platform provides screen events and element events for users.

A screen event refers to the action executed by the screen when entering the runtime environment. It can be triggered when a screen opens, when a screen closes, or by a timer. An element event refers to the action executed by the runtime system when the mouse interacts with an element. They are both implemented by configuring system functions or scripts to define the conditions that trigger the execution of related tasks.

Procedure

The screen event and element event are configured in the same way, as shown below:

1. Select the screen or element to edit;
2. Click "Event" in the monitoring area to display the screen or element event list, as shown below:

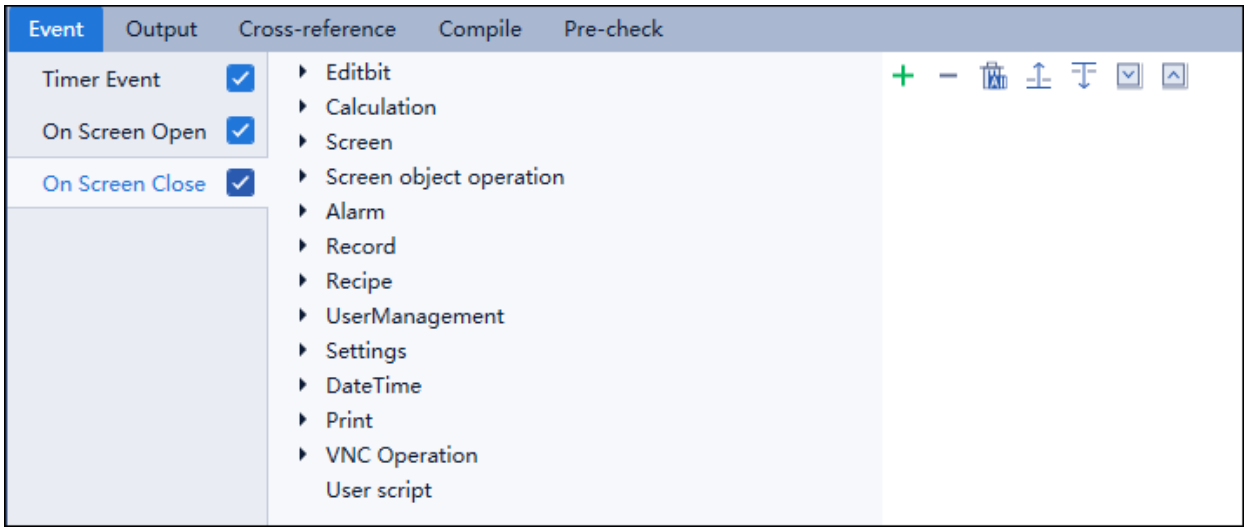


Figure 13-3-7-14-1 Screen event list

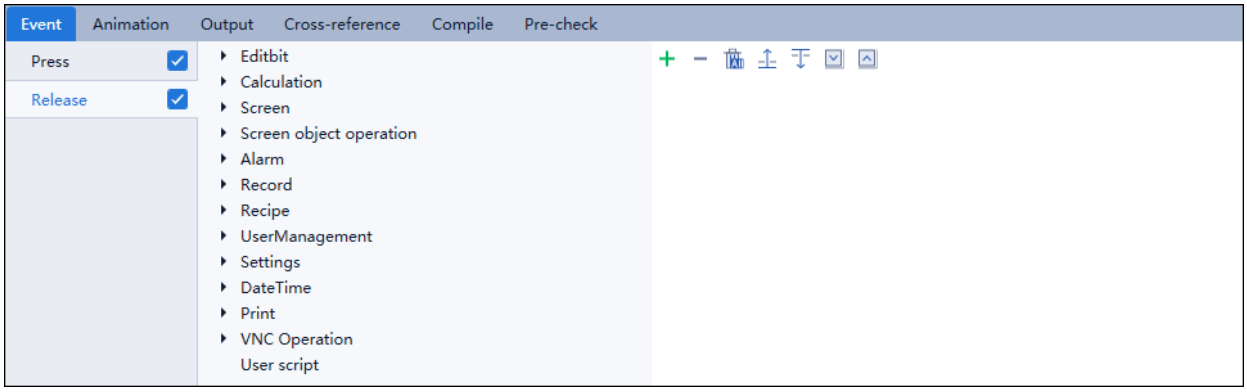

Figure 13-3-7-14-2 Element event list

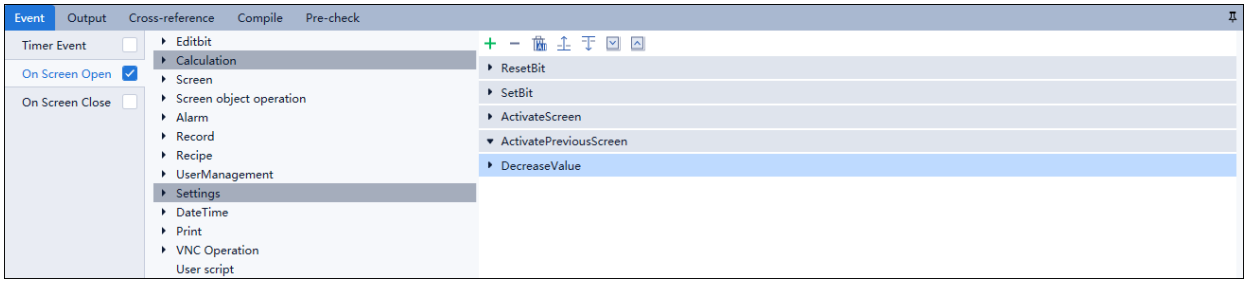
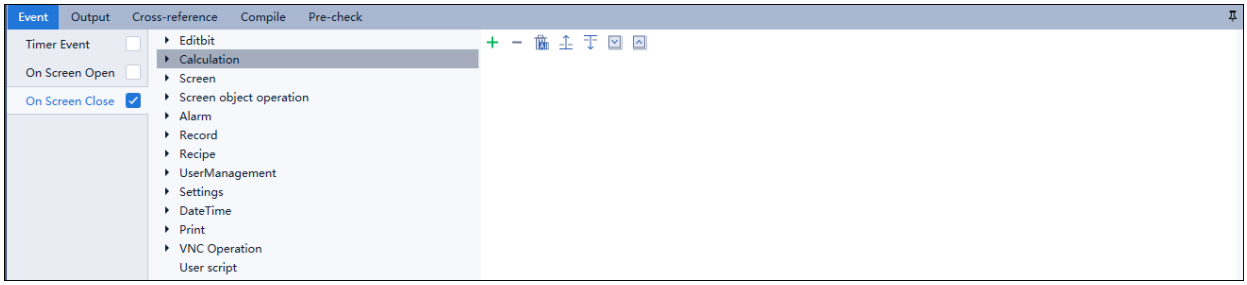
Function



- **Event configuration function**
  Select an event and add the event function using the following two methods:
  - Method 1: Expand a built-in function category and double-click the target function to add it to the selected function list on the right.
  - Method 2: Expand a built-in function category, select the target script function, then click the "+" icon to add it to the selected function list on the right.

  The function list includes string operation functions, bit operation functions, calculation functions, screen functions, recipe operation functions, alarm functions, record functions, date and time functions, user and login management functions, setting functions, and user script functions. Element events and screen events support the same functions, and any function from any category can be added.
- **Element event**
  After configuring an event for an element, the runtime system executes the corresponding function when the element meets the trigger condition.
  - Press: Triggered when the touchscreen or the mouse button is pressed.
  - Release: Triggered when the touchscreen or the mouse button is released.
  - Change: Triggered when the object is modified via mouse or touchscreen operation.
  - Input completed: Triggered when an I/O field input is completed via mouse or touchscreen operation.
  - Open: Triggered when a switch is turned on.
  - Close: Triggered when a switch is turned off.
- **Group event**
  - Group event response rules:
    - Only the group is configured with an event: The event responds to clicks in the group area, but not clicks in blank areas.
    - The group and some sub-elements are configured with events: The sub-element event responds to clicks in the sub-element area; the group event responds to clicks in other area within the group; blank areas do not respond.
    - The group and all sub-elements are configured with events: Only sub-element events respond, and the group event does not respond.
    - To respond to clicks in blank areas, add a background element configured with an event.



- Impact of visibility on event response: When an element is obscured or hidden, its event cannot be triggered. If all sub-elements of a group are hidden, the group event cannot be triggered either.
- Event response for special control group: When a special control is grouped with a basic element, only the basic element responds to the configured group event, because the special control has its own built-in events.
- Impact of enable on event response:
  - When a sub-element is enabled, clicking its area triggers the sub-element event.
  - When a sub-element is disabled, clicking its area triggers the group event.
- Rules for group selection and event prompt:
  - Sub-element selection: In offline mode, you can select a sub-element via the "Layout" tab or by double-clicking the element within the group.
  - Group operation: In offline or runtime mode, clicking the blank area of the group is treated as operating the entire group.
  - Event prompt: For any element (single or group) configured with an event, the mouse cursor changes to a hand shape only when the event can be triggered.

- **Screen event**

  A screen event can be triggered when a screen opens, when a screen closes, or by a timer.
  - On screen open: Triggered when the screen is opened in runtime.

  - On screen close: Triggered when the screen is closed in runtime.

  - Timer event: Periodically triggered at a defined cycle in runtime.

> **NOTE**
>
> Time configuration: The default execution cycle is 1s. The cycle can be selected from existing cycles, but cannot be manually entered.

13.3.7.15 Configuring a Picture-in-Picture Screen

Before configuring a picture-in-picture in the process screen, first complete the drawing of the target picture-in-picture.

Procedure:

1. Add a picture-in-picture view
   Select the **picture-in-picture view** in the toolbox and drag it to any location on the process screen.

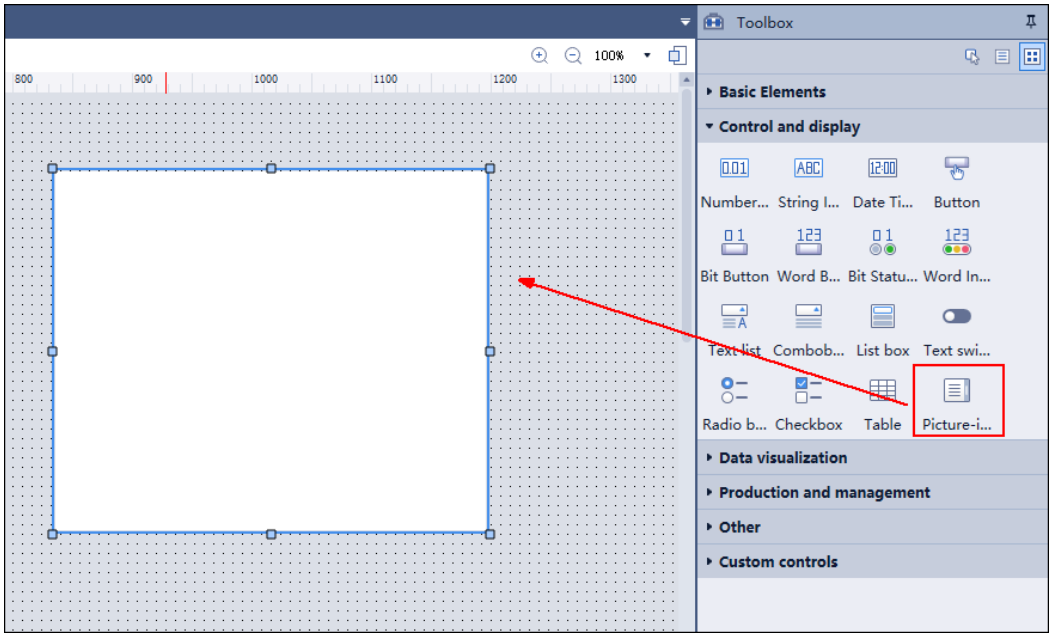


Figure 13-3-7-15-1 Adding a picture-in-picture view

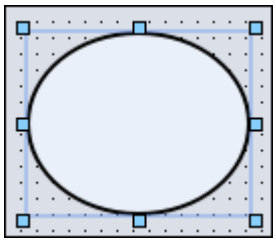
2. Adjust the position and display window size of the picture-in-picture view
   Set the space occupied by the picture-in-picture object in the process screen according to its dimensions.
3. Associate the picture-in-picture
   In the property window of the picture-in-picture view, enter the information of the target picture-in-picture. See 13.3.5.2.16 Picture-in-picture View for details on the property items.
4. Simulation test
   Start simulation mode to preview the display effect of the picture-in-picture.

The configuration of the picture-in-picture view on the process screen is complete.



13.3.7.16 Resizing an Object

There are three ways to resize an object:

- Click the resize icons on the toolbar (supports selecting two or more graphic objects).

Icon	Description
	Adjust all selected graphic objects to the same width.
	Adjust all selected graphic objects to the same height.
	Adjust all selected graphic objects to the same width and height.

- Resize by dragging with the mouse.
  1. Select the object to resize, and a selection rectangle appears, as shown below:

  2. Drag a size control point of the rectangle to resize the object.
- Resize through the object property window.

13.3.7.17 Moving an Object

An object can be moved within the same layer and across layers:

Moving within the same layer

The position of an object within the same layer includes coordinate position and front-to-back order.

- Coordinate position
  Move the coordinate position by dragging, using direction keys, or entering coordinate values in the property window.
  Ensure the object is 13.3.7.12 unlocked before moving.

Key	Description
←	Moves the target object to the left.
→	Moves the target object to the right.
↑	Moves the target object up.
↓	Moves the target object down.

- Front-to-back order
  Objects may overlap or intersect within the same layer. Use the icons on the toolbar to adjust the front-to-back order of these objects and change their occlusion relationship.

Icon	Description
	Moves the target object to the top.
	Moves the target object to the bottom.

Icon	Description
	Moves the target object up one layer.
	Moves the target object down one layer.

Moving across layers

Use the icons on the toolbar or drag-and-drop to move an object from one layer to another.

- Icons
  Select an object on the screen and move it to another layer using the following icons.

Icon	Description
	Moves the layer containing the target object up one layer.
	Moves the layer containing the target object down one layer.

- Drag-and-drop
  In the "Layout" window, select the target object and drag it to the target layer.
  Movable objects include individual objects and members of groups. For groups with two members, only moving members into the group is supported.

  The drop position when moving the target object into a group affects its order in the group object tree:
  - When dragging the target object into the group folder node, it will be placed at the end.
  - When dragging the target object into a specific group member node, it will be inserted above that member.

13.3.7.18 Adjusting Object Spacing

Select two or more graphic objects, and click the corresponding toolbar icon to adjust the object spacing.

Icon	Description
	Equalizes horizontal spacing between the geometric centers of multiple selected objects (Note: At least three objects must be selected).
	Equalizes horizontal spacing between multiple selected objects (Note: At least three objects must be selected).
	Reduces horizontal spacing between multiple selected objects until their geometric centers align on the same vertical line.
	Increases horizontal spacing between multiple selected objects.

Icon	Description
	Sets horizontal spacing between multiple selected objects to 0.
	Equalizes vertical spacing between the geometric centers of multiple selected objects (Note: At least three objects must be selected).
	Equalizes vertical spacing between multiple selected objects (Note: At least three objects must be selected).
	Reduces vertical spacing between multiple selected objects until their geometric centers align on the same horizontal line.
	Increases vertical spacing between multiple selected objects.
	Sets vertical spacing between multiple selected objects to 0.

13.3.7.19 Configuring a Pop-up Screen

Before configuring a pop-up window on the screen, first complete the drawing of the pop-up window.

Procedure:

1. Add an object
   Add an object on the screen used to open the pop-up window. Typically, a button is used, but other elements or symbols can also be used depending on project requirements.
   Select the **button** element from the toolbox and drag it to the screen.

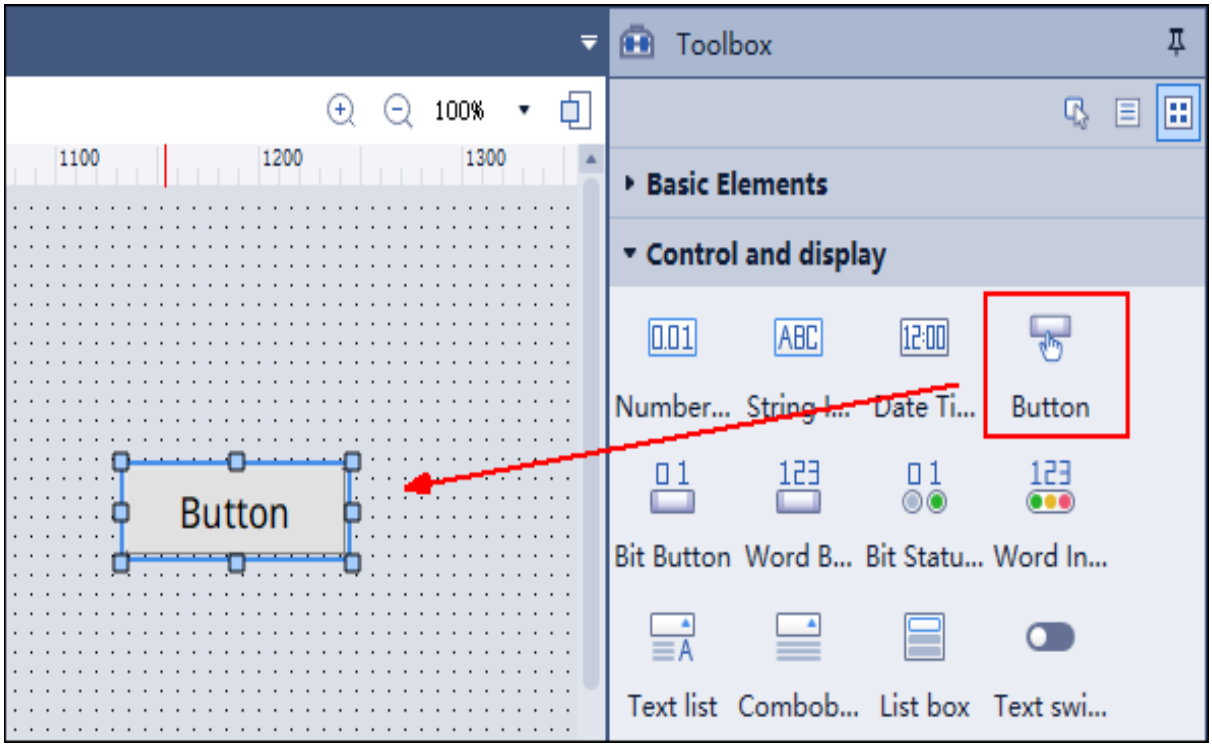


Figure 13-3-7-19-1 Adding a button

2. Move button position

   Move the button to the target position.

3. Set button style

4. Set button event

   Set the trigger condition and target pop-up window (such as the pop-up screen when the button is pressed). The configuration is shown in the figure below.

   Enter the pop-up window information in the "Event" window. See 19.4.4 Showing the Pop-up Screen for descriptions of each parameter.

5. Start simulation

   Start the simulation mode to test the display result of the pop-up window.

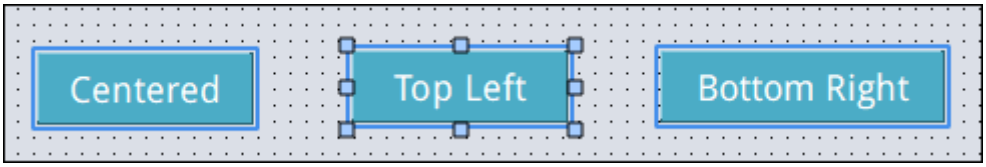
The pop-up screen configuration is complete.

13.3.7.20 Setting Properties in Batch

When multiple objects of the same type need to be uniformly adjusted on the screen, batch modification allows users to efficiently edit multiple objects, reducing repetitive operations.

Prerequisites

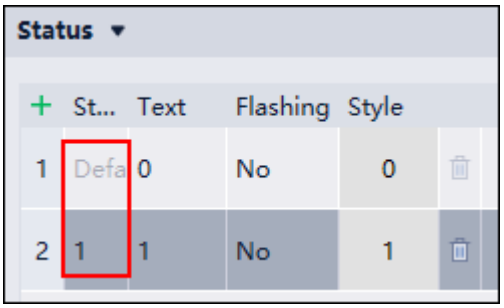
- The objects are of the same type.
- Object names, events, and animations do not support batch modification.



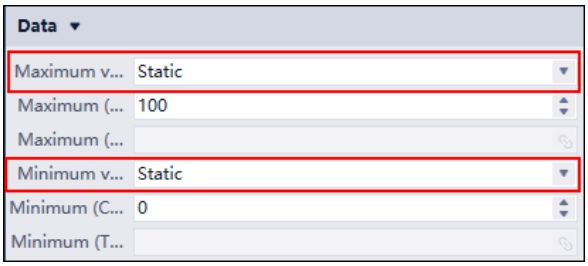
Applicable objects

Supported objects include:

- Basic elements: Line, polyline, arc, rectangle, circle, ellipse, sector, circular segment, polygon, text, image, and pipeline.
- Control and display: Numeric I/O field, character I/O field, time/date field, button, bit button, character button, bit status display, character status display, text list, combo box, list box, text switch, radio button, and checkbox.
- Data visualization: Bar chart, slider, progress bar, circular progress bar, pie chart, and gauge.



Property range



After selecting multiple objects of the same type, the system automatically disables properties that cannot be modified. Users can only modify objects with control points (such as the "Top left" button in the figure below); property changes will automatically synchronize to other selected objects. Modifying other objects will not trigger automatic synchronization.

- Individual objects
  Before batch modifying certain properties of an individual object, specific rules must be met. For example, the "Status" property of a text button requires that the selected objects have identical status values, counts, and order; otherwise, batch modification is not allowed. The following table lists objects with similar property requirements.

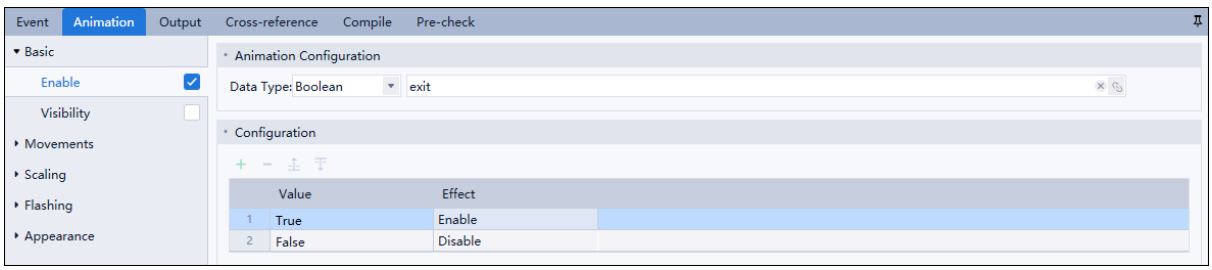
Table13-3-7-20-1

Object	Property	Batch Modification Condition
Text button Text indicator		Batch modification of status-related information is supported only when the status values, count, and order must be identical across selected objects.

Object	Property	Batch Modification Condition
Pie Chart		Batch modification of color is supported only when the number of channels must be the same across selected objects.
Bar Graph Slider		Batch modification of maximum /minimum values (static) is supported only when the values are static across all selected objects.

- Group
  When batch modifying multiple groups, consistency in member count or member type is not required.
  The properties that support batch modification include: basic settings and basic information.
  For members of the same type in a group, the batch modification method are the same as for as individual objects.

13.3.8 Animation Configuration



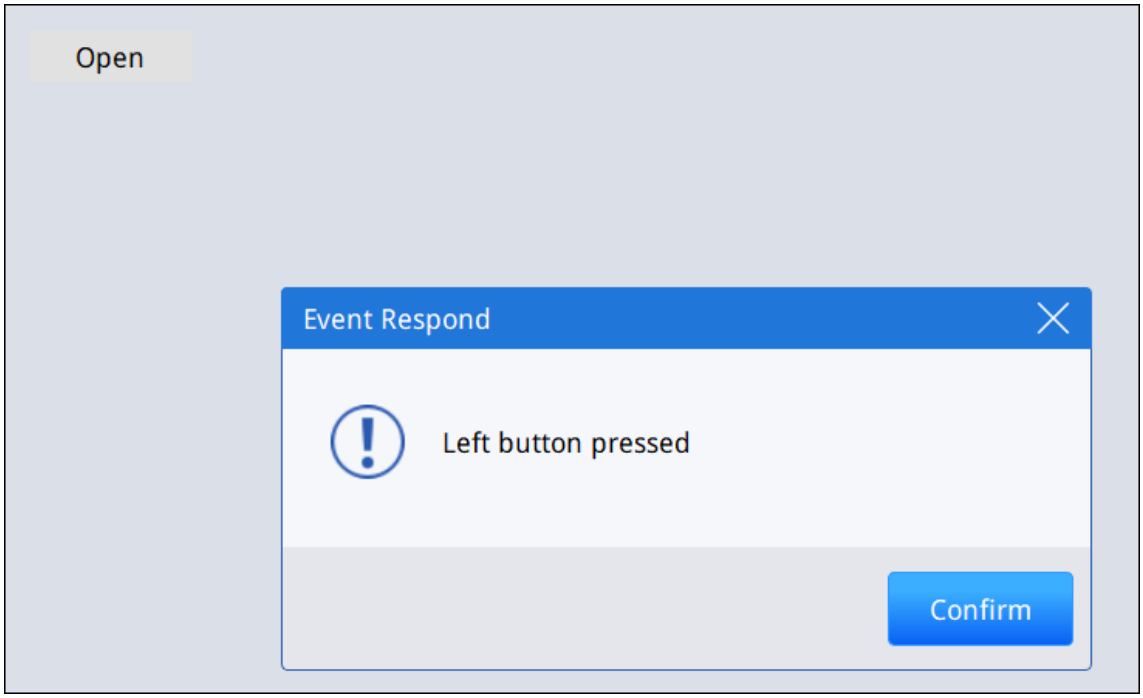
- 13.3.8.1 Basic Animation
- 13.3.8.2.1 Movement Animation
- 13.3.8.3 Rotation Animation
- 13.3.8.4 Scaling Animation
- 13.3.8.5 Flashing Animation
- 13.3.8.6 Appearance Animation

13.3.8.1 Basic Animation

This tab is used to dynamically control the visibility and operability of basic animation objects.

In the runtime, visibility and operability is determined by the configuration variable values.

The following shows the configuration interface for a basic animation object that is enabled:



- 

  Configuration is mainly divided into the two parts:
  - Animation configuration: Configures the type of configuration variables, which supports boolean (default), bit, and range (integer).
    - A "Boolean" variable configures the effect of "True" (enable) and "False" (disable).

- A "Bit" variable configures the effect of "1" (enable) and "0" (disable).
- When the variable type is "Range (integer)", click "+" to add a new row, and set the effect of the corresponding "Value" (enable or disable).

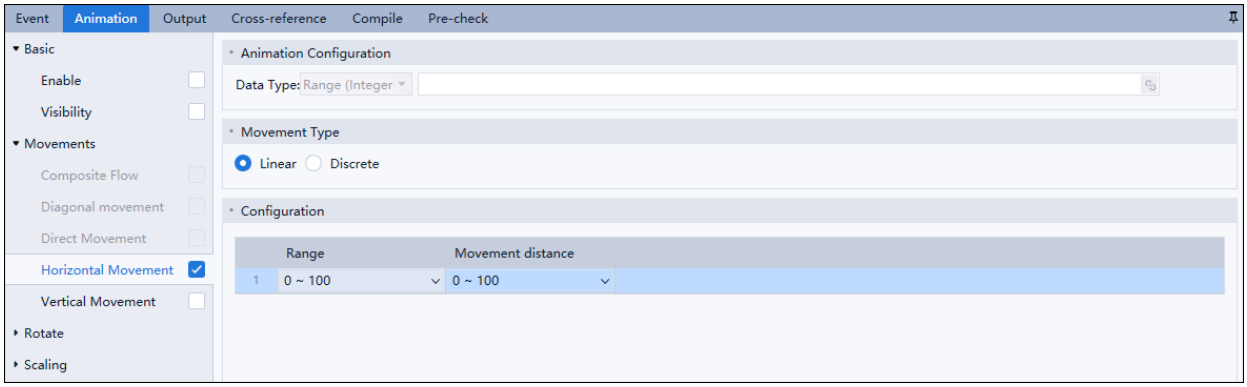
- Configuration: Enables/disables the graphic element by selecting TRUE/FALSE. TRUE: Enabled by default; FALSE: Disabled by default.

- Example:
  - Detailed steps for enabling an object are as follows:
    1. Select a button object, open the "Animation" interface under its property view. Check "Enable" to activate the animation configuration.
    2. Add an event. Select "Press > Screen > Show message box", and enter "Left button pressed".
  - After initiating onsite monitoring, the display effect in the simulation environment is as follows:
    - When exit = TRUE, pressing the button shows a "Left button pressed" dialog, as shown below:

    - When exit is FALSE, the button element is grayed out and becomes non-operational 

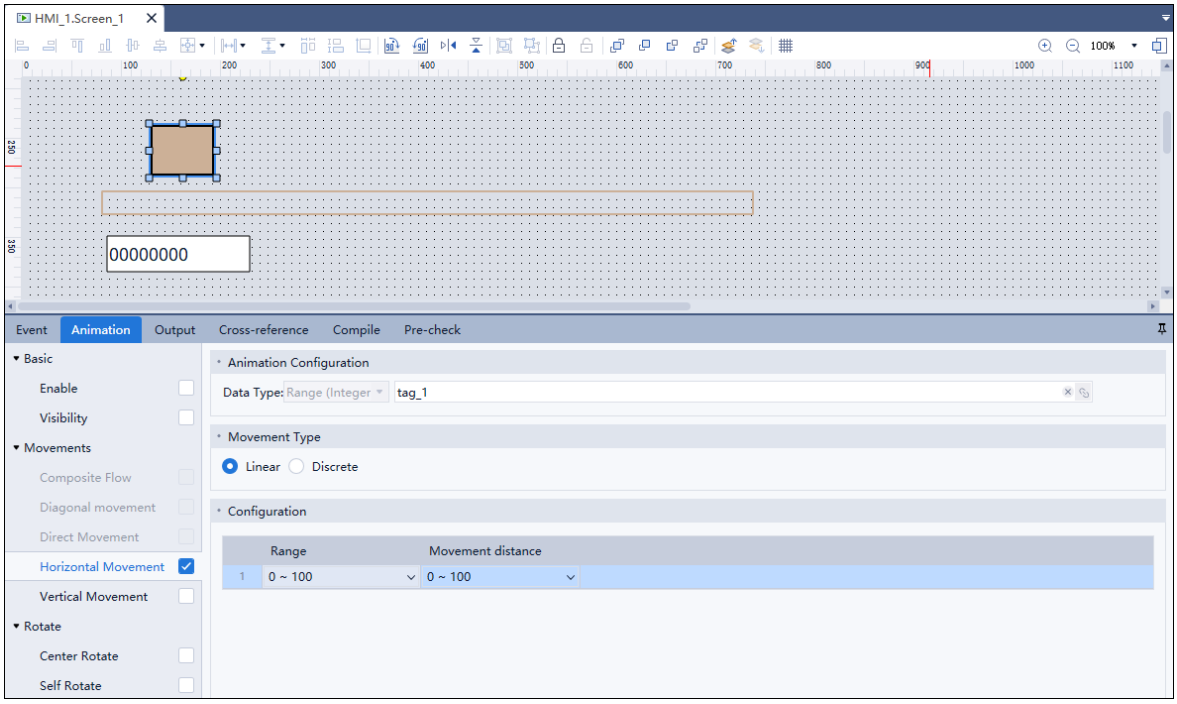
.

- For details about the "Left button pressed" dialog configuration, see 13.3.7.14 Adding an Event.



13.3.8.2 Movement Animation

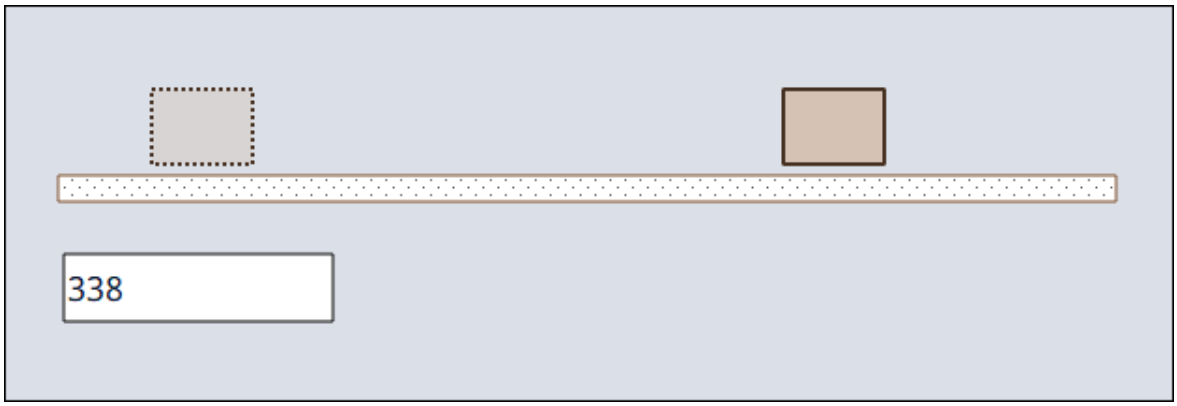
13.3.8.2.1 Movement Animation



Configuring the movement of an object allows it to move along a specific trajectory. The object movement is controlled by variables. When the variable changes, the object moves along the configured trajectory.

Movement types include: combined movement, diagonal movement, direct movement, horizontal movement, and vertical movement. Horizontal and vertical movements can be used together; the other types can only be used independently.

The following is the configuration interface for "Horizontal movement":



- The configuration consists of three parts:
  - Animation configuration:
    - Data types: Supports range (integer), bit, and boolean. The variable data type supports integer and boolean.
      The configuration here is related to the movement type (if applicable).
  - Movement type:
    - Linear: The object moves continuously along a straight line, with a smooth trajectory, no jumps or pauses.
    - Discrete: The object moves between discrete points, with noticeable intervals or jumps between each step; the movement trajectory is discontinuous.
  - Configuration: Specifies the relationship between variable (bit) values and movement distance.
- Example:
  In the following example, the horizontal movement of a rectangle object is configured. For details, see the following steps.
  1. Select the rectangle object, then expand the "Animation" property in its properties view, and select "Movement > Horizontal movement".
  2. Configure items in "Animation configuration", and select the variable to control object operability, such as tag1.
  3. Configure items in "Configuration" and define the relationship between the variable value (tag1) and the movement distance. The following example shows a 1:1 relationship, meaning the movement distance changes by the same amount as the value change.

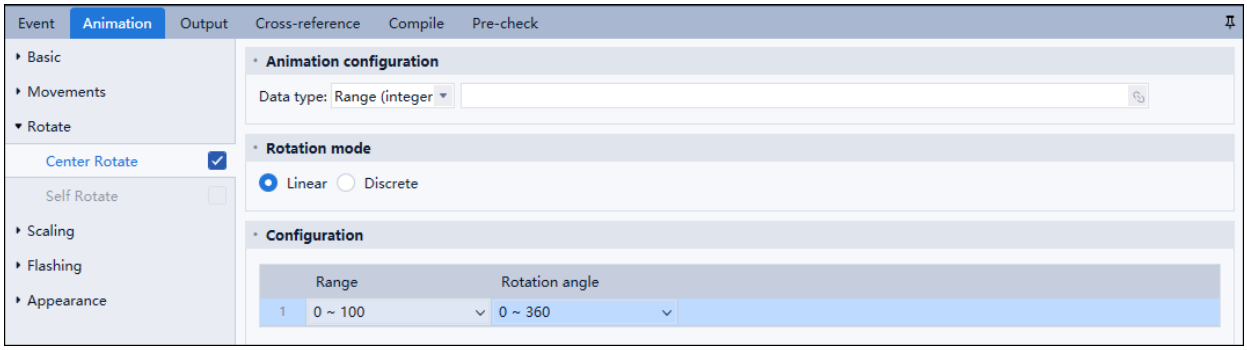
4. Enable simulation.

   Enter "338" in the control for variable "tag1", the movement animation is shown in the figure below:

13.3.8.2.2 Pipe Flow

"Pipe flow" animation is a dynamic visualization effect in flowcharts specifically designed for pipeline graphic objects. It simulates the liquid flow state in a pipe, enhancing the intuitiveness and real-time capability of process monitoring.

The following shows the configuration interface for "Pipe flow" animation:

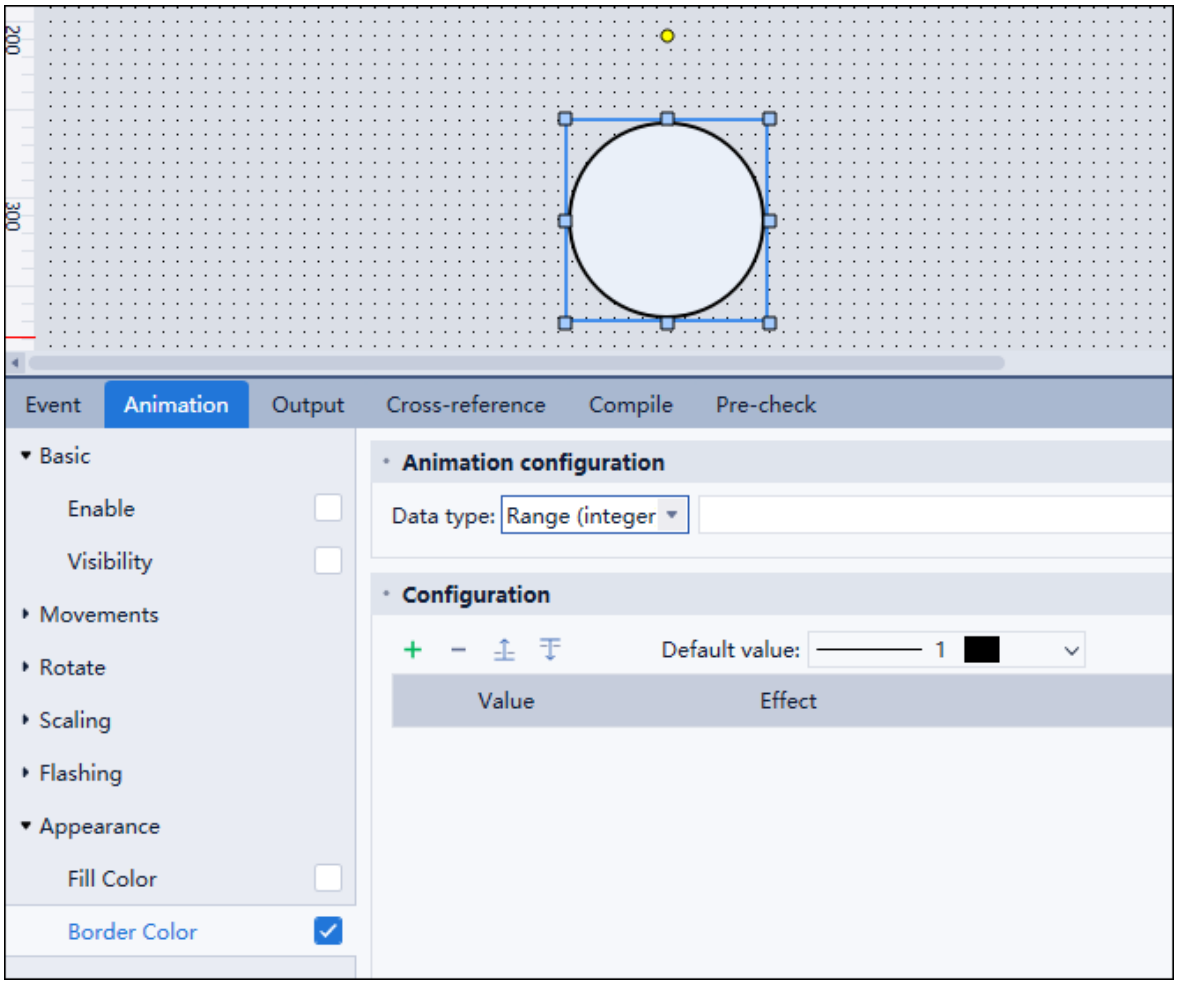


The configuration consists of four parts:

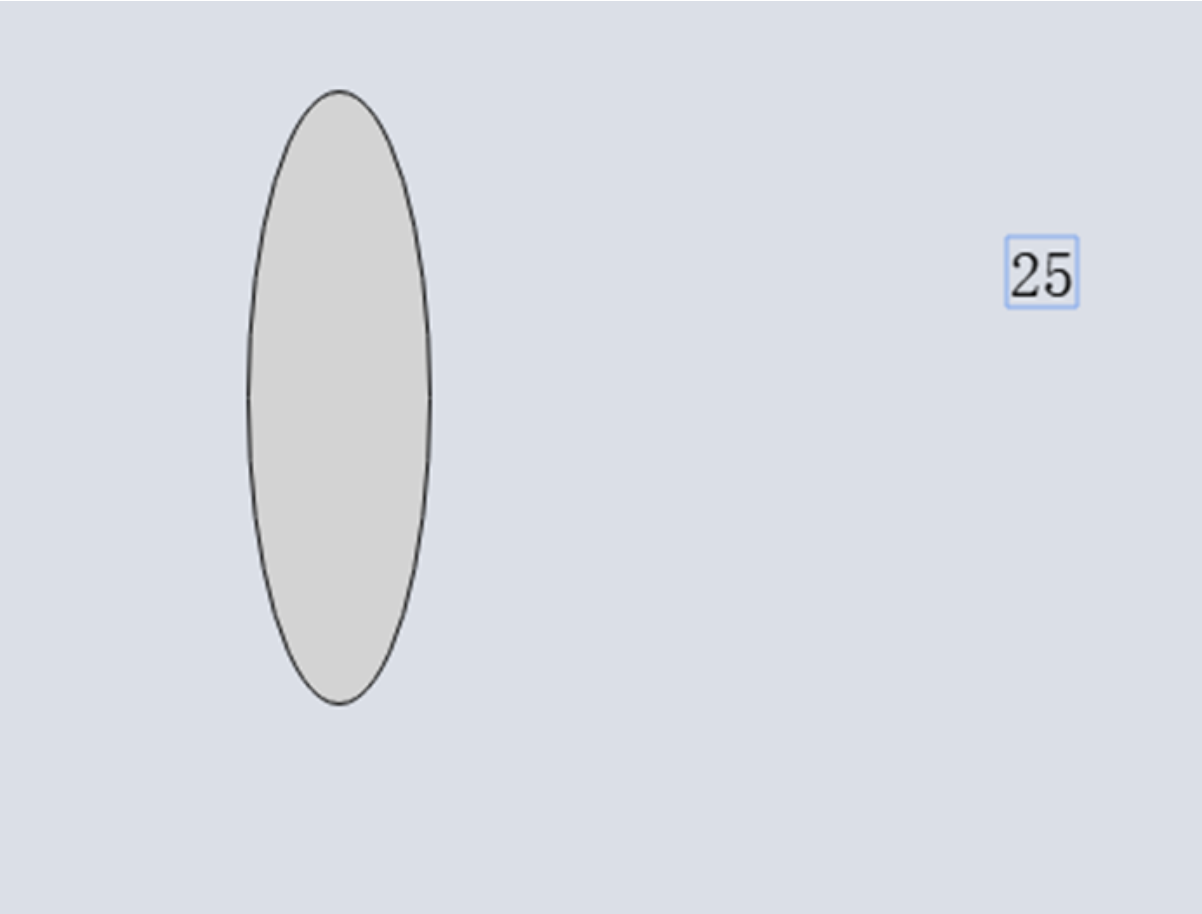
- Animation configuration: Associates one boolean variable or expression to control whether the liquid flows in the pipe (start/stop).
- Flow speed: The speed at which the liquid flows.
- Flow direction:
  - Forward: Liquid flows from left to right or from top to bottom.
  - Reverse: Liquid flows from right to left or from bottom to top.
- Configuration: Sets the animation effect corresponding to the value of the variable or expression.

13.3.8.3 Rotation Animation

20241105113943acaa8d58c16ab49536e915bd49b78844-EN.pngDynamic objects can rotate around a specific point at a specific angle. Users can set the rotation point and angle based on variables.



The following is the "Center rotate" configuration interface for an object:

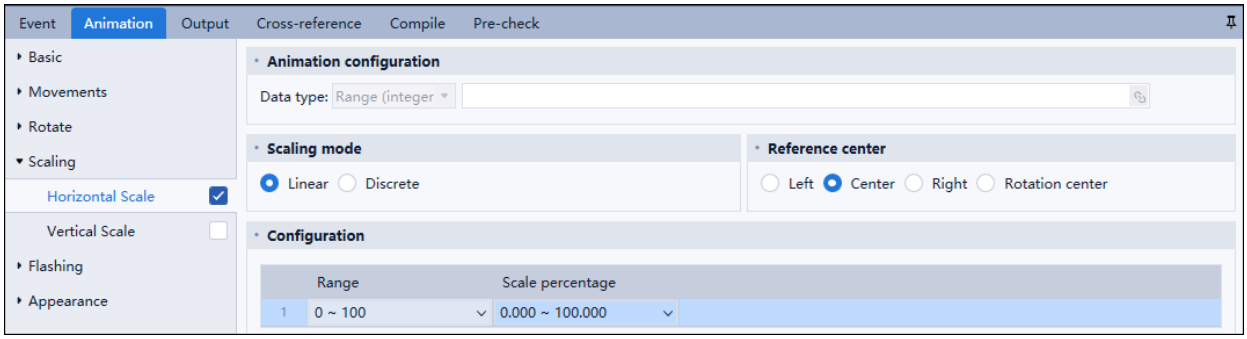


- The configuration mainly consists of the following parts:
  - Animation configuration:
    - Data type: Specifies the data type of the variable, which is fixed to range (integer) and cannot be modified.
    - Variable: Specifies the relative position of the object along the path, supporting integer and boolean types.

- Rotation mode: Specifies the rotation mode of the object, including linear and discrete.
  - Linear: Configures the relationship between input value and rotation angle (start/end value and start/end angle).
  - Discrete: Users need to configure the central rotation table, including comparison operators, values, rotation angles, default values, and so on.
- Configuration:
  - Range: Specifies the start/end angle value for the variable.
  - Rotation angle: Specifies the start/end angle for the variable.

- Example:
  - The following procedure shows how to configure central rotation for an ellipse object.
    1. Select the ellipse object, expand the "Animation" tab in the monitoring area, and select "Central rotation".
    2. Configure the variables on the "Animation" tab. Select the variable to control the object's operability from the "Variable" drop-down list. Select the data type of the variable (in this example, x is a 16-bit integer variable).
    3. Configure "Range" and "Rotation angle".
  - The configuration is as follows:

  - After starting onsite monitoring, the effect shown in the simulator is as follows:
    Enter "25" in the I/O field, the ellipse rotates 180 degrees around its own center.

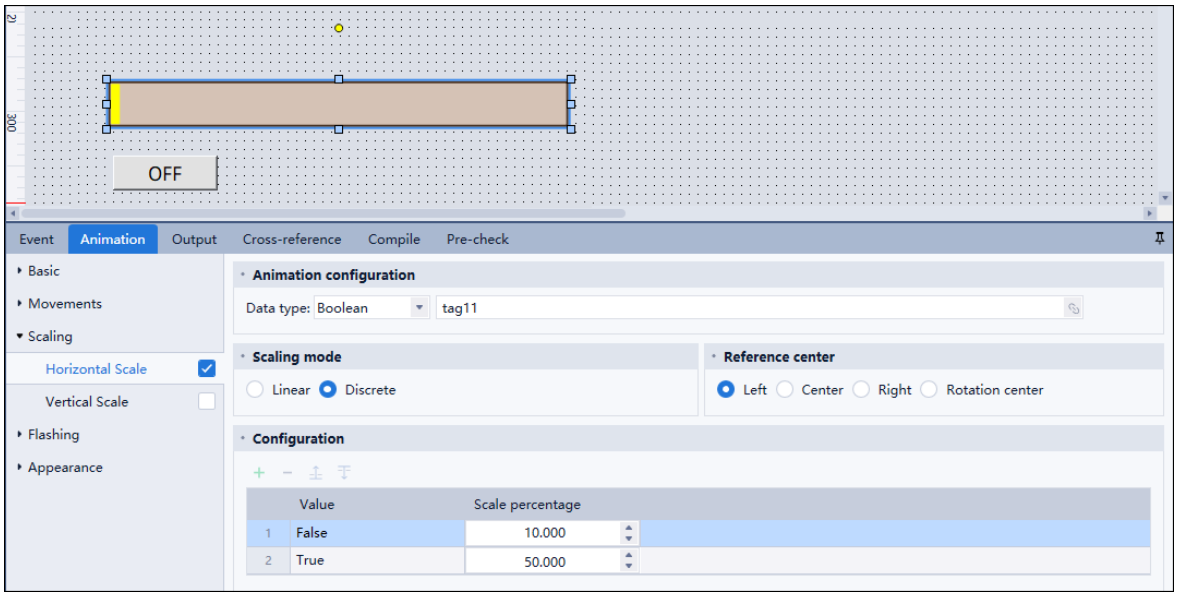


13.3.8.4 Scaling Animation

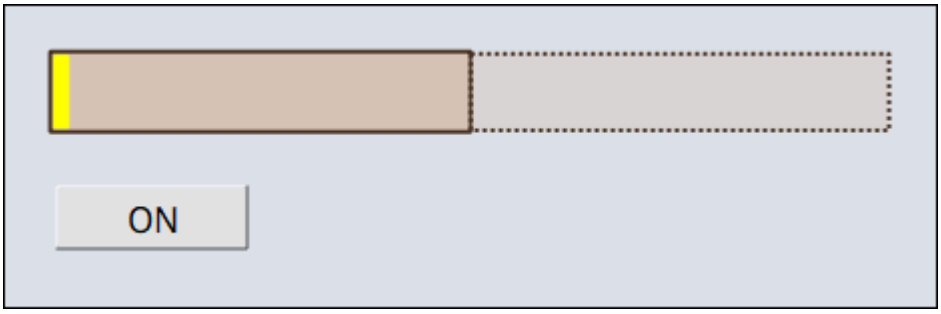
Scaling animation makes an object to be scaled around a specific center. The scaling is controlled by variables. When the variable changes, the object scales according to the set ratio.

Individual elements support scaling animations, while elements in grouped objects and symbol templates do not.

The following is the configuration interface for "Horizontal scale":



The configuration consists of four parts:



- Animation configuration:
  - Data types: Supports range (integer), bit, and boolean. The variable data type supports integer and boolean.
    The configuration here is related to the scaling mode.
  - Scaling mode:
    - Linear: The scaling ratio changes continuously, with no jumps or pauses in the trajectory.

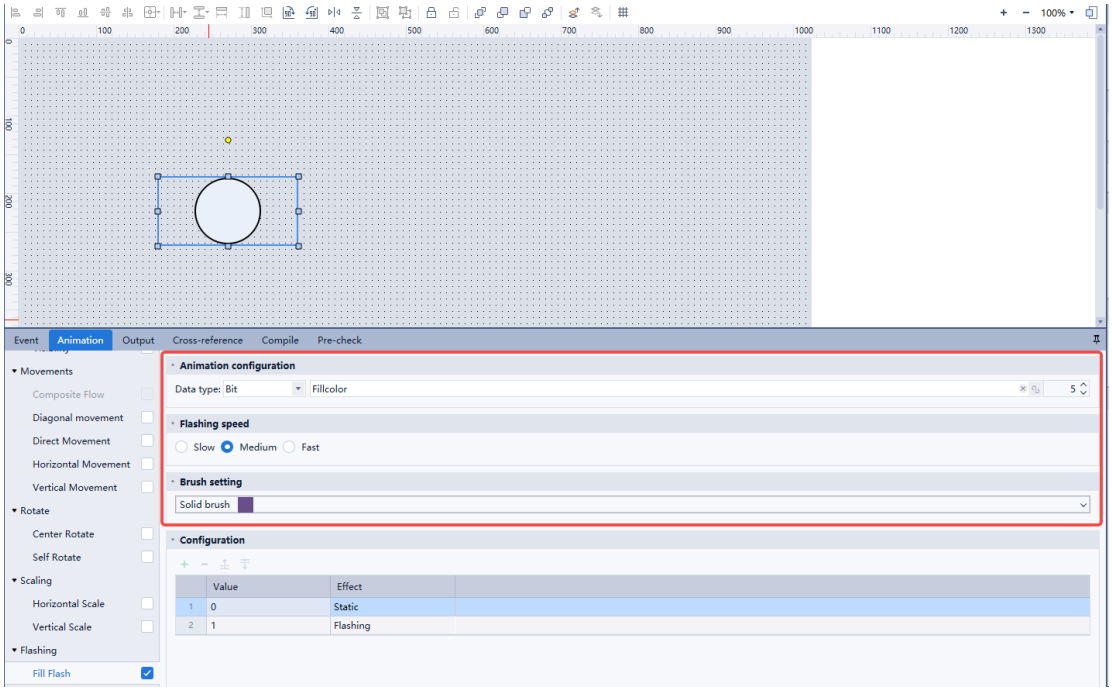
  - Discrete: The scaling ratio is discontinuous, with noticeable intervals between operations and a discontinuous trajectory.
- Reference center: Specifies the point that remains fixed when the object is scaled, around which the object's shape will be adjusted.
- Configuration: Specifies the relationship between variable (bit) values and scaling ratio.

- Example:
  In the following example, the horizontal scaling of a rectangle object is configured. For details, see the following steps.
  1. Select the rectangle object, then expand the "Animation" property in its properties view, and select "Scaling > Horizontal scaling".
  2. Set the "Scaling mode" and "Animation configuration", and select the variable to control the object's operability.
  3. Set the "Reference center" to the left boundary.
  4. Define the relationship between the variable value (tag11) and scaling ratio. In the example below, when the value is True, it is scaled down to 50% of the original; when the value is False, it is scaled down to 10% of the original.

  5. Start simulation.
     When the control for the variable "tag11" is switched to **ON**, the rectangular object is centered on the left boundary and scaled to 50%. The figure below shows the zooming results on the simulator.

13.3.8.5 Flashing Animation

Flashing animation makes the connected element flash when the condition expression is true. There are three flashing types: fill flashing (or color flashing), border flashing, and visibility flashing.



The following is the "Fill flashing" configuration interface for a circle object:

- The configuration mainly consists of the following parts:
  - Animation configuration: Sets whether the element flashes. Supports boolean (default), bit, and range (integer).
  - Flashing speed: Sets the flashing speed of fill color (or pattern). Includes slow, medium (default), and fast.
  - Brush configuration: Sets the brush type and color.
  - Configuration: Sets the color corresponding to the variable or bit value.
- Example:

  To configure the "Fill flashing" properties for the circle object, follow the steps below:

  1. Select the circle object, expand the "Animation" tab in the monitoring area, and select "Flashing > Fill flashing".
  2. Configure "Animation configuration" to specify the data type and the variable of the associated control object that can be operated.
     For example, configure the animation to change based on bit 5 of the INT variable Fillcolor.
  3. Set "Flashing speed" to "Fast".
  4. Set "Brush setting" to a solid color brush with purple fill.

5. Configure the animation effect.

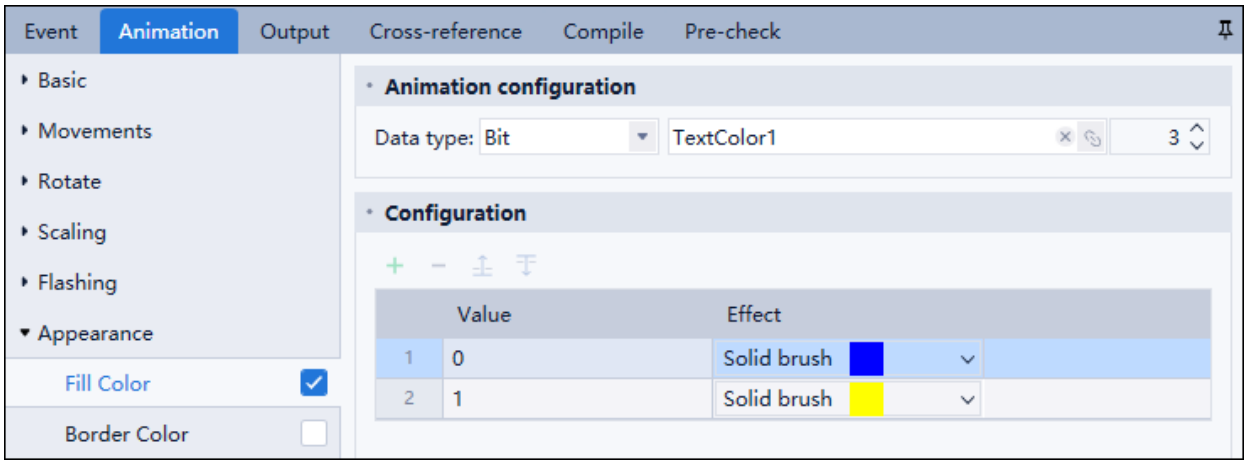
   The animation effect remains at the default setting.

   Result:

   During online operation, the fill color of the circle object changes based on the bit 5 of the Fillcolor variable.

   When the value of Fillcolor is 32 to 63, 96 to 127 (that is, the bit 5 is 1) ..., the area is filled with purple and flashes quickly.

   When the value of Fillcolor is 0 to 31, 64 to 95 (that is, the bit 5 is 0) ..., the default fill color is displayed statically.



13.3.8.6 Appearance Animation

Appearance animation allows appearance properties such as the border color, fill color, background color, and text color of elements to change dynamically and automatically based on specified conditions (e.g., variable values). The supported properties vary among different elements. See the table below for the supported properties for commonly used elements.

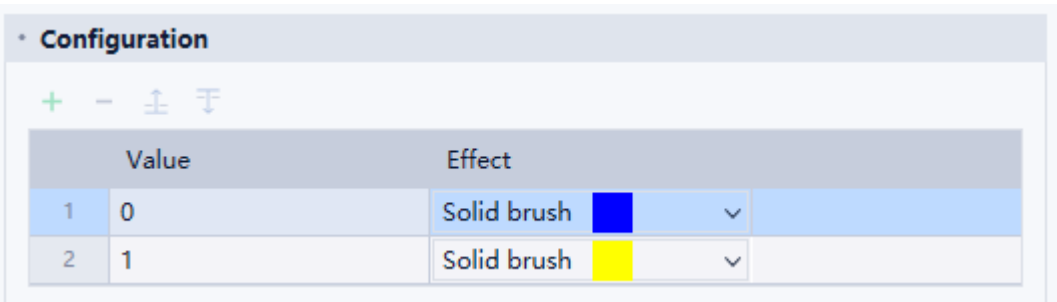
Element	Border Color	Fill Color	Background Color	Text Color
Line	√	×	×	×
Polyline	√	×	×	×
Arc	√	×	×	×
Rectangle	√	√	×	×
Circle	√	√	×	×
Ellipse	√	√	×	×
Sector	√	√	×	×
Circular Segment	√	√	×	×
Polygon	√	√	×	×

Element	Border Color	Fill Color	Background Color	Text Color
Text	×	×	√	√
Numeric I/O field	×	×	√	√
Character I/O field	×	×	√	√
Date-Time Field	×	×	√	√
Button	×	×	√	√

The configuration methods for different areas in the animation are identical. The following uses the "Fill color" configuration of a text object as an example.

- Animation configuration: Configures the type of configuration variables, which supports boolean (default), bit, and range (integer).
  Variable types support boolean and integer.
- Configuration: Sets the color corresponding to the variable or bit value.

Step



1. Select the screen object to be dynamically controlled. For example, a text box.

2. In the monitoring area, select "Animation > Appearance".
3. Check "Background color" to display the parameter configuration page.
4. Set the data type and associate the variable.
   For example, set the second bit of variable "TextColor1" to control the color.

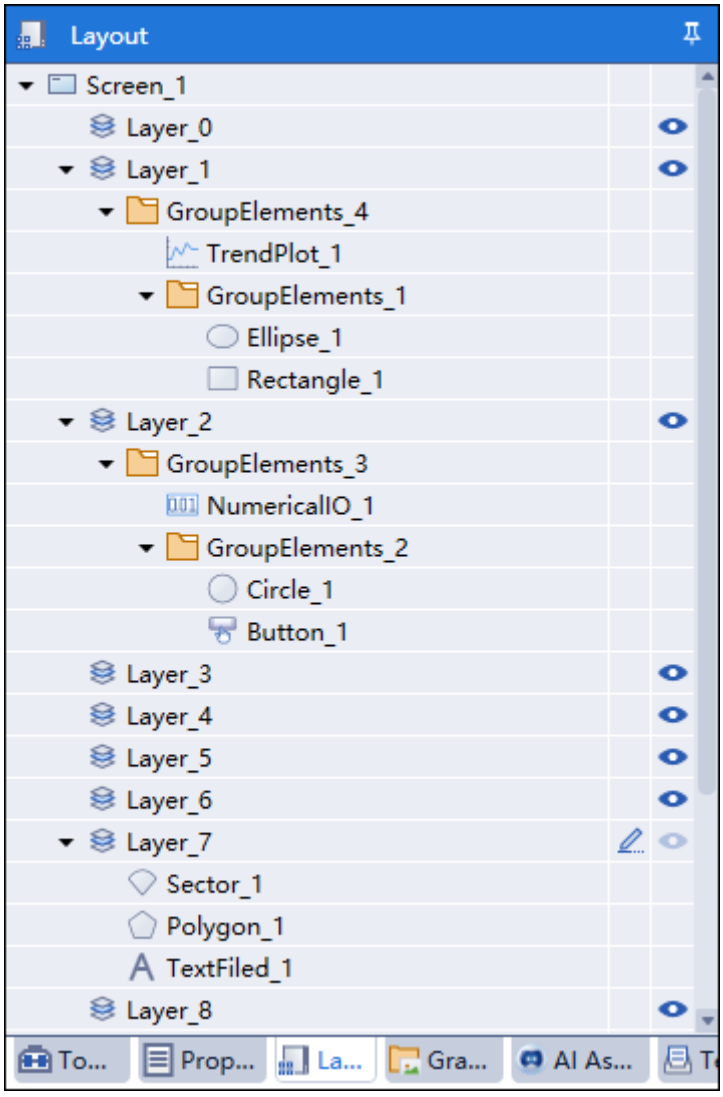
5. Configure animation colors.

Result:
During online operation, the background color of the text box will change according to the value of the second bit of variable "TextColor1".
When the value of "TextColor1" is 4 to 7, 12 to 15 (that is, the second bit is 1) ..., the text box background is yellow.
When the value of "TextColor1" is 0 to 3, 8 to 11 (that is, the second bit is 0) ..., the text box background is blue.

13.3.9 Layer Usage

- 13.3.9.1 Overview
- 13.3.9.2 Renaming Layers
- 13.3.9.3 Setting Active Layers
- 13.3.9.4 Displaying or Hiding Layers
- 13.3.9.5 Common Operations for Layer Tree

13.3.9.1 Overview



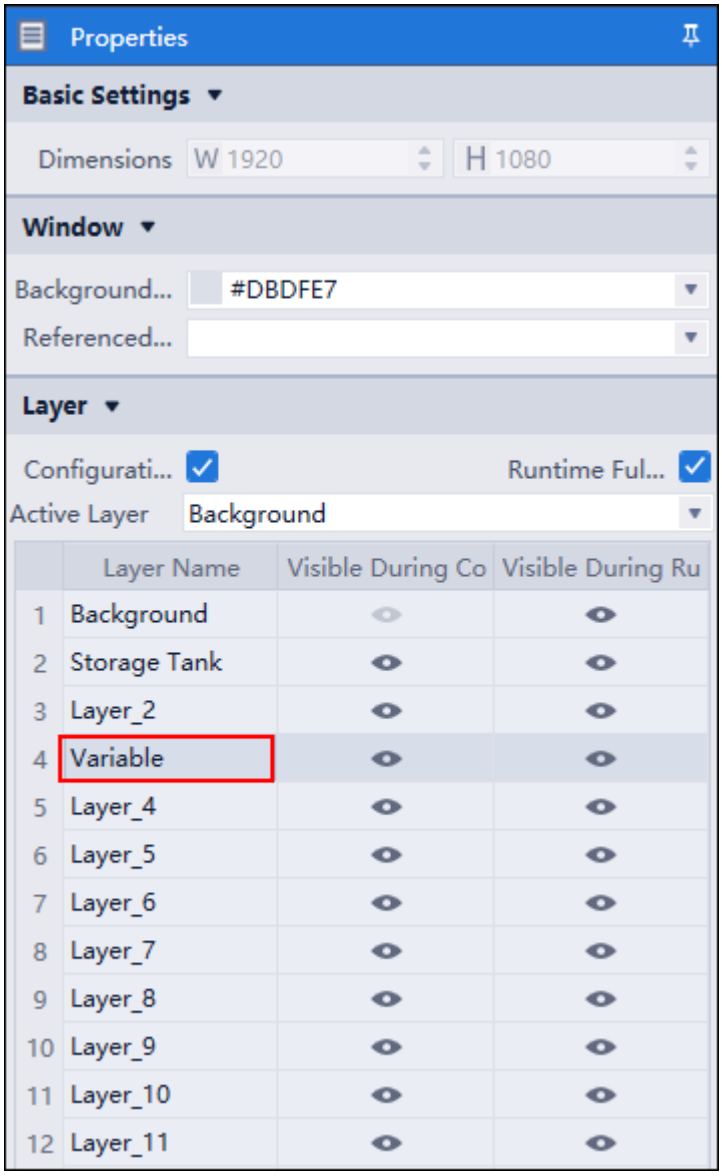
Layers are used to organize, manage, and present different information and data views. With multiple layers, you can group different types of elements (such as text, charts, dashboards, etc.) and display them logically, making the interface clearer and easier to understand.

Main functions of the layer:

- Organization and management: You can organize and categorize information by creating different layers. For example, alarm information, process flow diagrams, and real-time data views during on-site control can be placed on separate layers, making it easier for operators to view and understand.
- Independent operation: Each layer can be edited independently, including adjusting displayed elements, layout, colors, and more. This ensures that modifying a specific part does not affect other parts of the entire interface.

A single screen or symbol template contains 16 layers, numbered 0 to 15, with layer 0 at the bottom (background) and layer 15 at the top (foreground).

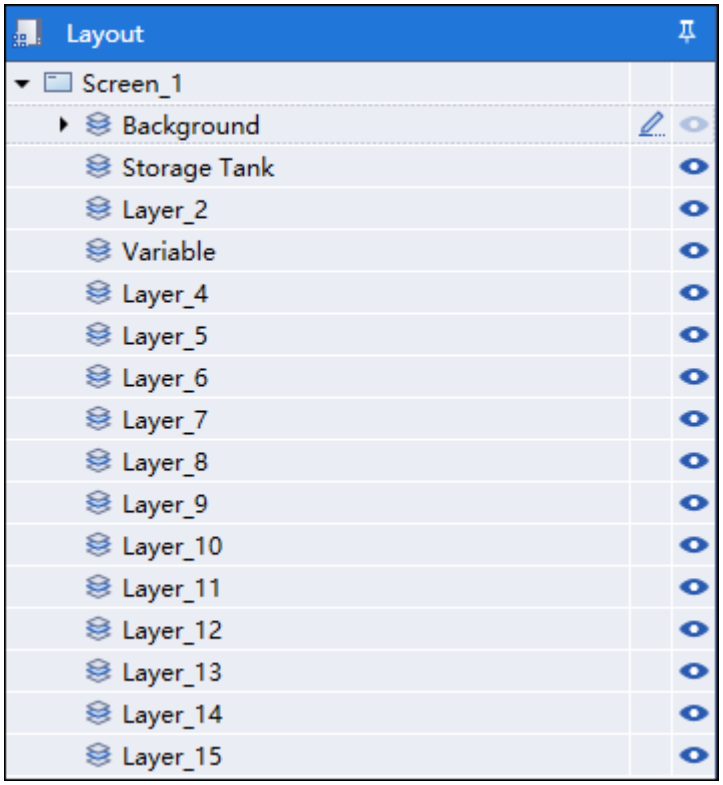
Objects within the same layer are arranged in the order they were added, and are displayed in a tree structure within the layout container of the screen or symbol template.



13.3.9.2 Renaming a Layer

The default format for layer names is "Layer_n", where n ranges from 0 to 15. You can customize layer names, which include Chinese, English, numbers, and special characters, but cannot start or end with a space. The maximum length is 128 characters.

Layer renaming can be performed in two different locations. Changes made in either place will be automatically synchronized to the other to ensure consistent naming.



- Property window

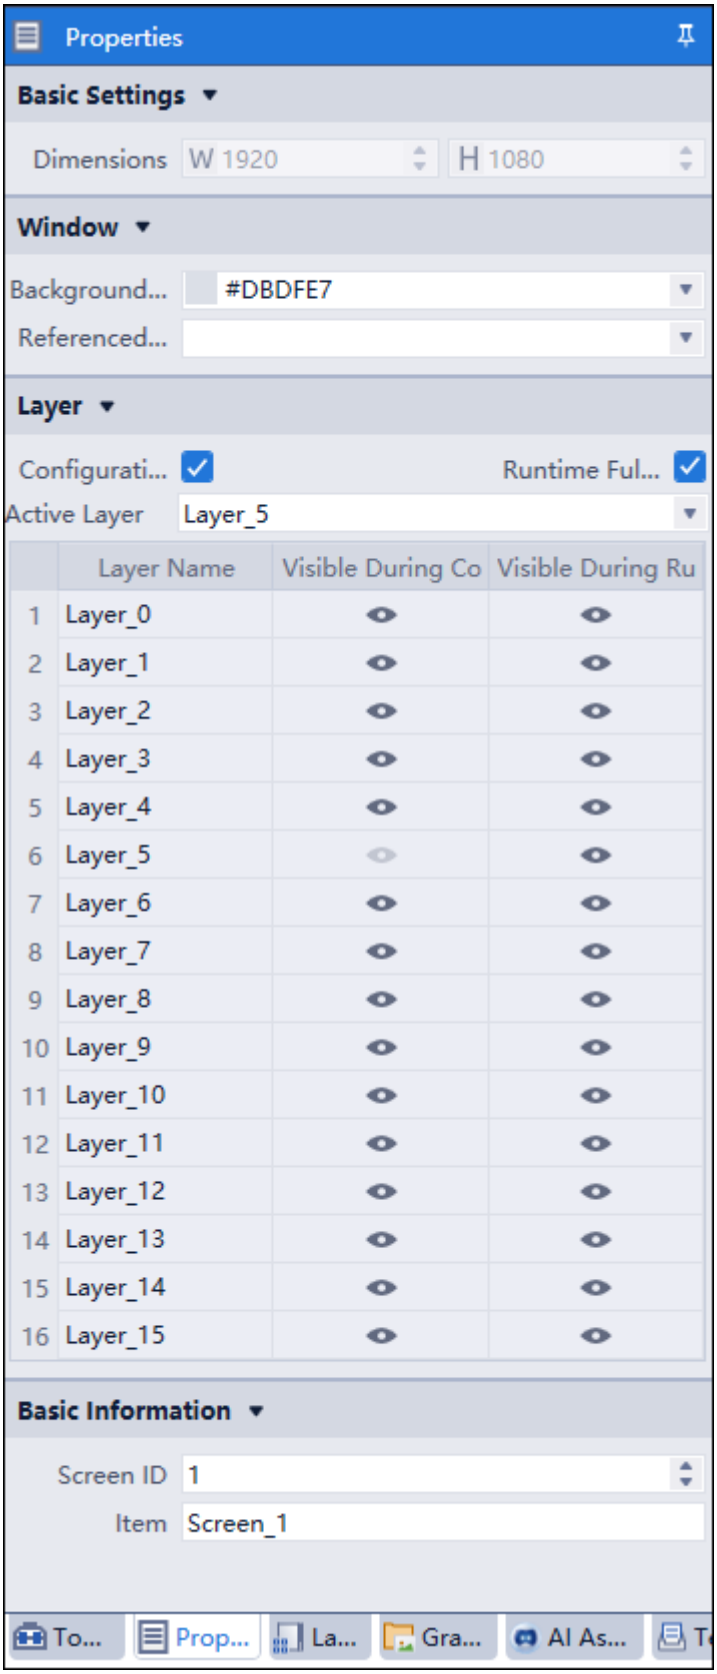
Click a layer name, enter the new name, and press Enter to apply.

The new name will be automatically synchronized to the layout container.

- Layout container

1. Select a layer node, press **F2**, or select the "Rename" command from quick menu to enter edit mode.
2. Enter the new name and press Enter to apply.
   The new name will be automatically synchronized to the properties window.

13.3.9.3 Setting an Active Layer



An active layer refers to the layer currently being edited or operated on during offline configuration of a project. When a layer is set as the active layer, you can perform operations on that layer. By setting an active layer, you can focus on the layer currently being edited without affecting operations on other layers.

Layer 0 is the default layer.

There are two ways to set the active layer.

Set in the properties window

1. Double-click the blank area of the screen or symbol template to open the properties window.

2. Set the active layer.

   The active layer is a state during screen configuration. When a layer is set as active, its corresponding configuration indicator appears gray, and hiding the layer is not supported.

   For example, in the figure below, **Layer_5** is the active layer, and the corresponding configuration indicator is gray.

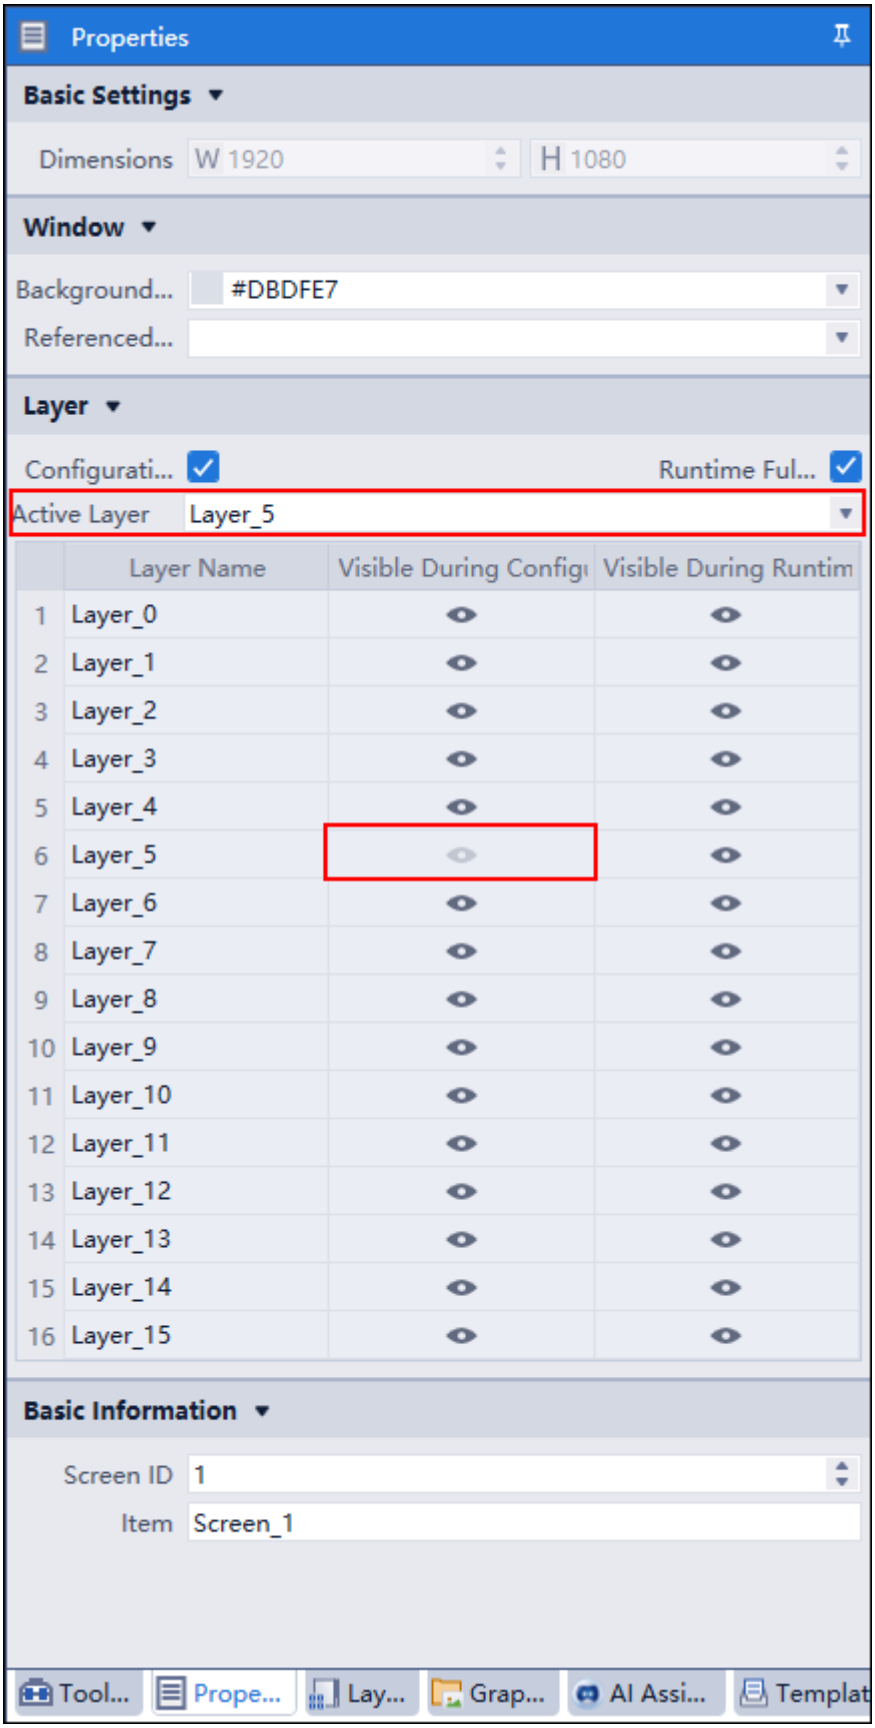


Figure 13-3-9-3-1 Layer_5 active layer

Set in the layout container

1. Open the layout container of the screen or symbol template.
2. Select the shortcut menu for the target layer and select the "Activate layer" command.

   The current active layer is indicated by the icon .

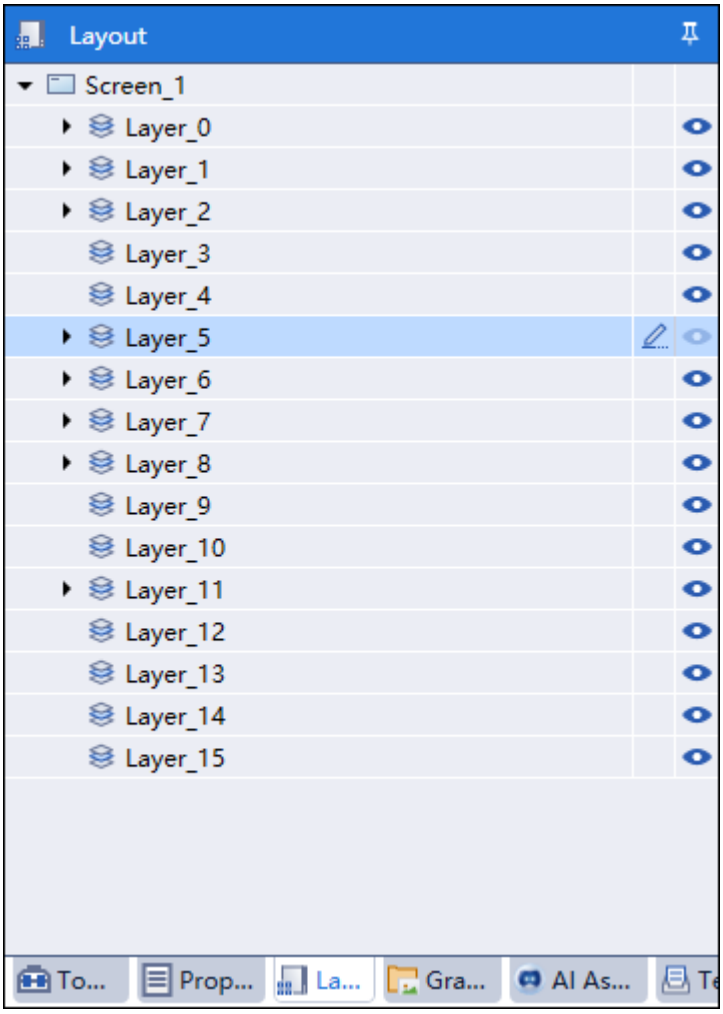

Figure 13-3-9-3-1 Layer_5 active layer

13.3.9.4 Displaying or Hiding a Layer

By selectively displaying or hiding layers, you can focus on the area to be adjusted, reduce visual clutter, and improve work efficiency and design clarity.

Layer visibility settings are supported in both configuration and runtime environments.

Configuration environment

- Single layer

  In the property box or layout box of a screen or symbol template, operate the visibility toggle icon for the specified layer to hide or display the layer and its associated objects.

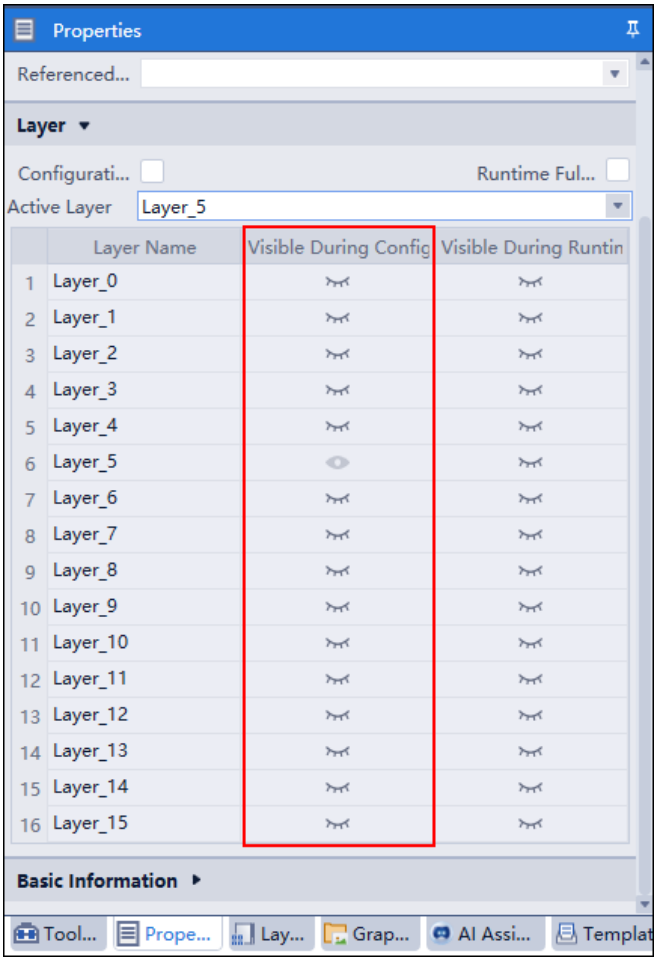

Figure 13-3-9-4-1 Screen properties window

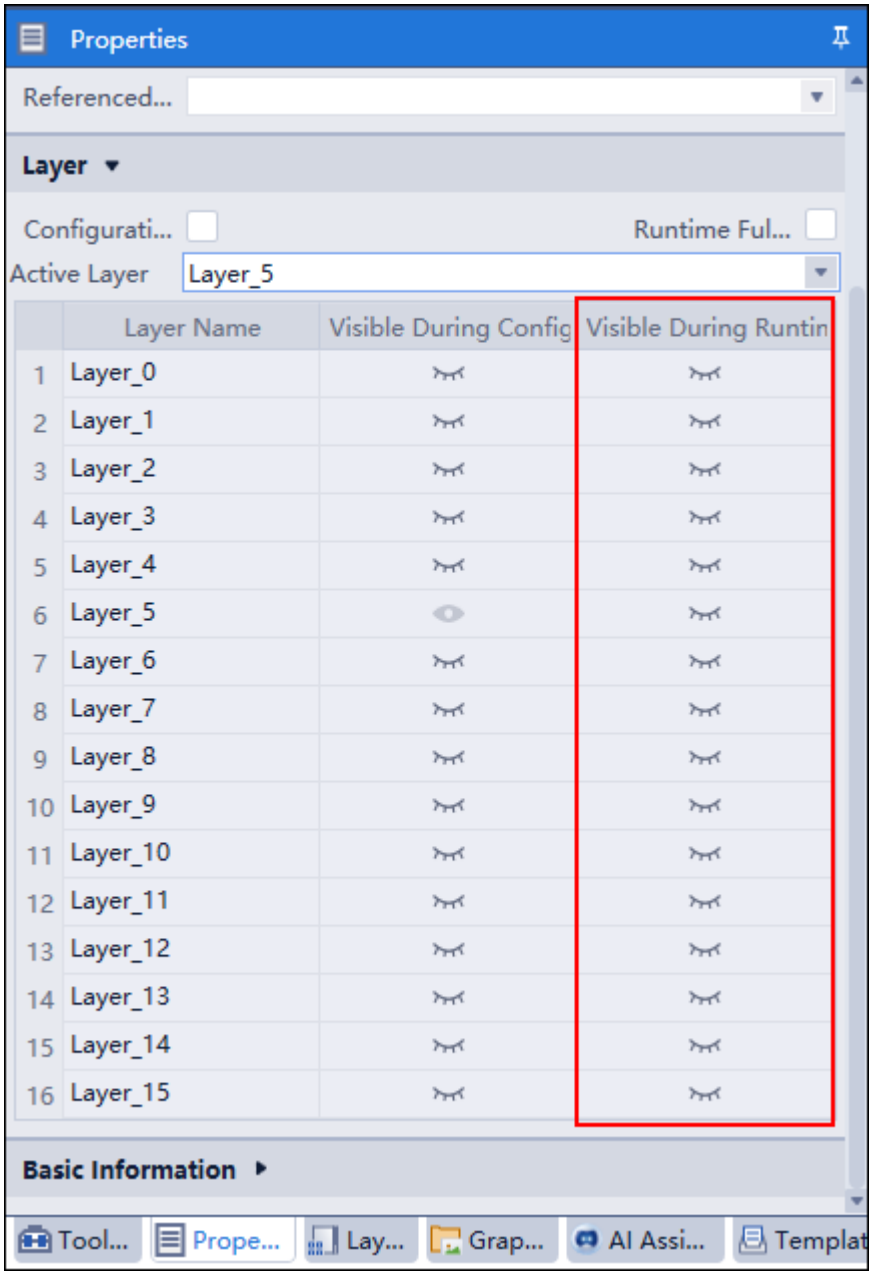


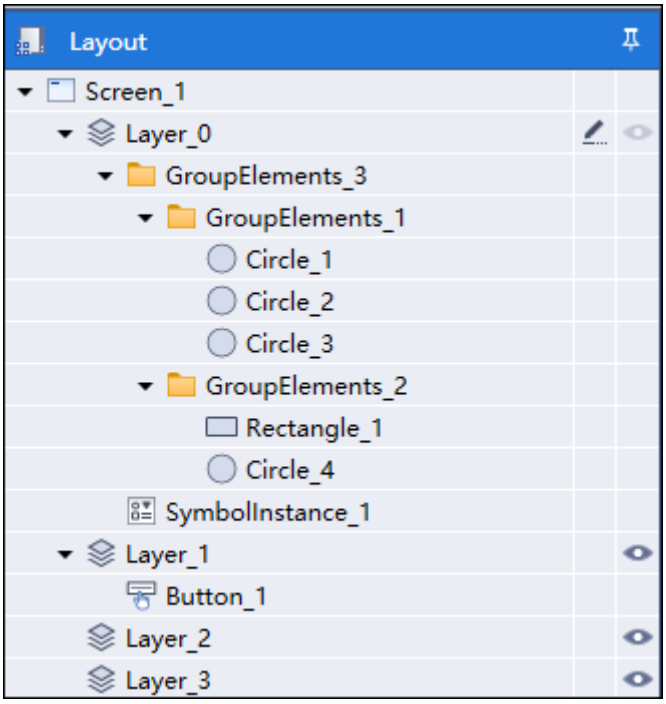
- All layers

  In the property box of a screen or symbol template, operate the radio button "Configuration fully visible" to batch hide or display layers (excluding the active layer) and their associated objects.

Operating environment

- Single layer

  In the property box of a screen or symbol template, operate the visibility toggle icon  for the specified layer to hide or display the layer and its associated objects.



- All layers
  In the property box of a screen or symbol template, operate the radio button "Operation fully visible" to batch hide or display layers (excluding the active layer) and their associated objects.

13.3.9.5 Common Operations for Layer Tree

Objects added to the screen generate child nodes in the corresponding layer. The node name is the object name.

Node naming rules

- Instance of a symbol template: As a whole, the node is named by default as "Symbol instance_n". For example, "Symbol instance_1" under "Layer_0", as shown in the figure below.
- Grouped objects: Displayed as folders, the node is named by default as "Grouped element_n". For example, "Grouped element_1" under "Layer_0", as shown in the figure below.
- Single object: Displayed as a single node, the node is named by default as "Control name_n". For example, "Button_1" under "Layer_1", as shown in the figure below.

Common operations

Object nodes in the layer tree support several common operations, which are described in the 13.3.7 Configuration Screen.

- For operations combining multiple objects, see 13.3.7.9 Grouping Objects.
- For operations to ungroup grouped objects, see 13.3.7.10 Ungrouping Objects.
- For operations to delete objects, see13.3.7.5 Deleting an Object.
- For operations to copy and paste objects, see13.3.7.3 Copying/Pasting an Object.
- For operations to cut and paste objects, see 13.3.7.4 Cutting/Pasting an Object.
- For operations to rename objects13.3.7.2 , see Renaming an Object.
- For operations to change the layer of an object13.3.7.17 , see Moving an Object.

13.3.10 Screen Management

- 13.3.10.1 Screen Grouping
- 13.3.10.2 Zooming a Screen
- 13.3.10.3 Copying a Screen
- 13.3.10.4 Changing Screen Resolution

13.3.10.1 Grouping Screens

The screen configuration function enables visual control of the on-site production process. During configuration, screens can be grouped and managed using screen groups.

Screens and pop-up screens support screen group management.

Create a screen group

Take adding a screen group to a screen as an example:

1. In the project tree, click "Screen > Add group" to create "Screen group_1".

2. Click "Screen group_1 > Add" to add a screen node.

Edit a screen group

Screen group properties can be edited via the right-click menu and keyboard shortcuts: Copy (Ctrl+C), Paste (Ctrl+V), Delete (Delete), and Rename (F2).

Screen groups support undo/redo functionality.

Screen groups support nesting. Screens can be selected and dragged into other groups.

13.3.10.2 Zooming a Screen

The zoom factor for screens in the offline editing environment can be set. When the screen is zoomed, all objects inside it are zoomed proportionally.

The zooming scope can be configured in the iFA software.

Supported screen types include
Main screen, picture-in-picture, pop-up screen, template screen, and symbol screen.

Set the zoom factor for a single screen

1. Select the "Tools > 6.2 Options" command in the iFA software to open the configuration window.
2. On the "Screen" tab, uncheck the "Globally effective" option.
3. Select the zoom button and adjust the display ratio of current screen.

The zoom factor of each screen will then remain independent of each other.

Set the zoom factor for multiple screens

1. Select the "Tools > 6.2 Options" command in the iFA software to open the configuration window.
2. On the "Screen" tab, check the "Globally effective" option.
   Note: When switching from "unchecked" to "checked", the zoom factor of all screens automatically resets to 100%.
3. Select the zoom button and adjust the screen zoom factor.

When the display zoom of any screen is adjusted, the zoom factor of all screens in the project is updated synchronously.

13.3.10.3 Copying a Screen

The screen can be copied and pasted across different projects.

Applicable range

Applicable screen types include:

- Screen
- Picture-in-picture
- Pop-up screen
- Template Screen

> **NOTE**
>
> This feature applies to projects created by iFA Evolution.

Procedure

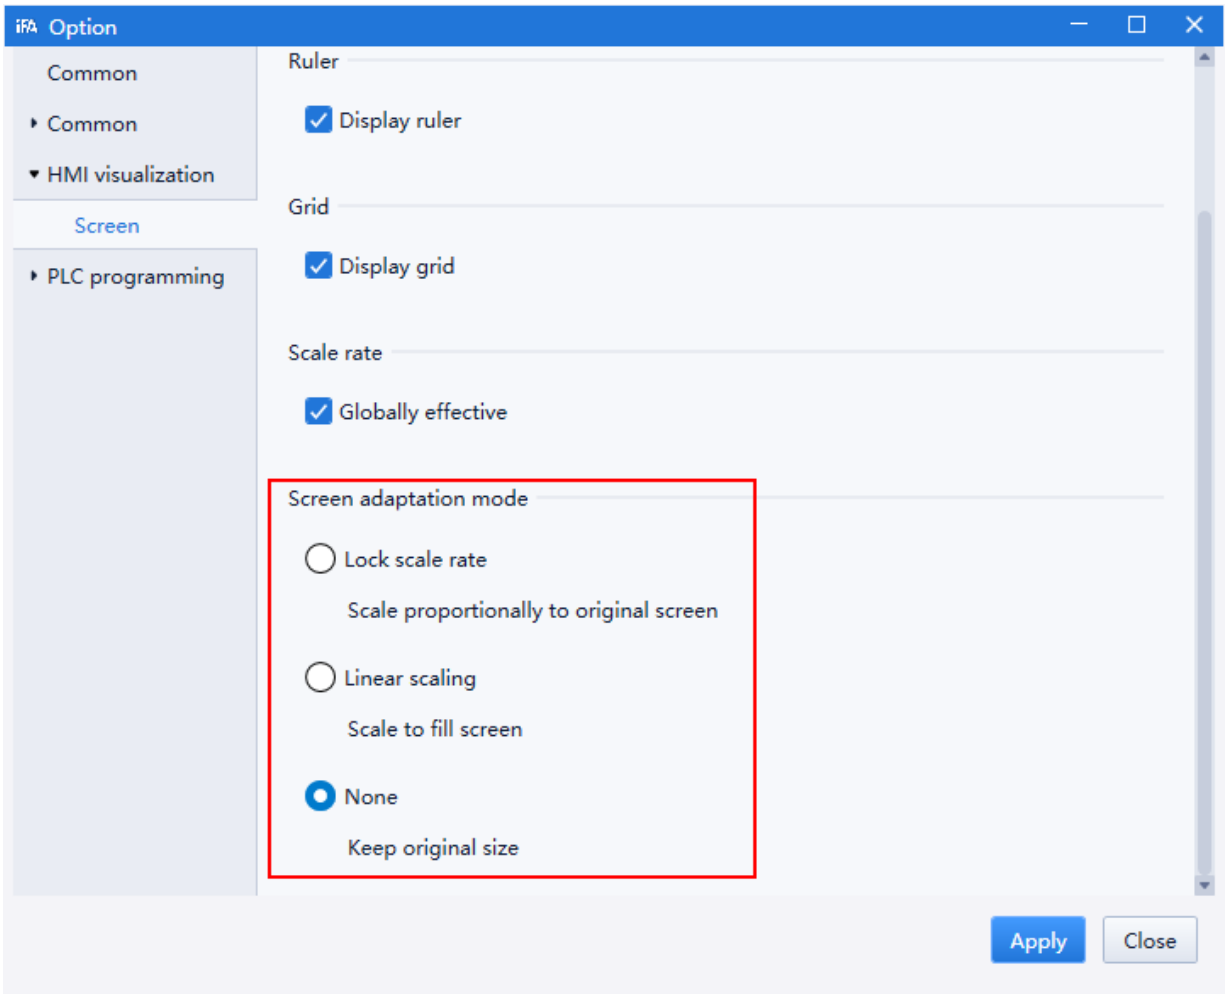
1. In the project tree of the source project, select the screen to copy.
2. Click "Copy" in the right-click menu.
3. In the project tree of the target project, select the "Paste" command from the right-click menu.
   After pasting, the copied screen retains its original name by default. If there is a screen with the same name in the target project, the system will automatically add a number to it.

Precautions

- Device compatibility
  - If the device model of the target project is different from the source project, check and manually adjust the screen layout.
  - "Screen" and "Template screen" will automatically adapt to the new device size. "Picture-in-picture" and "Pop-up screen" will adjust according to the settings under "Tools > Options".
  - The text font size of all screens will be automatically adjusted based on the preset value for the screen adaptation method.
- Processing of associated templates
  - When copying a screen, its associated template screen is not copied.
  - If a template screen with the same name exists in the target project (even if its content differs), the copied screen will automatically associate with that template. Please check whether the association is correct.

13.3.10.4 Changing Screen Resolution

When the HMI device model in the project changes (e.g., being replaced with a different model) or the device orientation changes (e.g., from landscape to portrait), the resolution of the screen will change. You need to check and adjust the screen layout to ensure proper display.



Auto-adjustment of the screen

Screen Types	Adjustment Mode
Screen	Automatically adapts to new device or new orientation.
Template Screen	Automatically adapts to new device or new orientation.
Picture-in-picture	Adjusted according to settings under "Tools > Options".
Pop-up screen	

The text font size of all screens will be automatically adjusted based on the preset value for the screen adaptation mode. The following describes the settings of the screen adaptation mode.

Scaling mode comparison

The adaptation methods for "Picture-in-picture" and "Pop-up screen" can be set under "Tools > Options". There are three options; please select one according to the following instructions.

Adaptation Method	Feature	Applicable Scenario
Lock scale rate	Maintains the screen's aspect ratio; blank areas may appear around the edges.	Prioritizes preserving the aspect ratio; blank margins are acceptable.
Linear scaling	Fills the entire screen area, but the screen may become distorted.	Prioritizes using all available screen space; distortion is acceptable.
/	Maintains the original size; some content may extend beyond the screen.	Requires maintaining original size and layout.

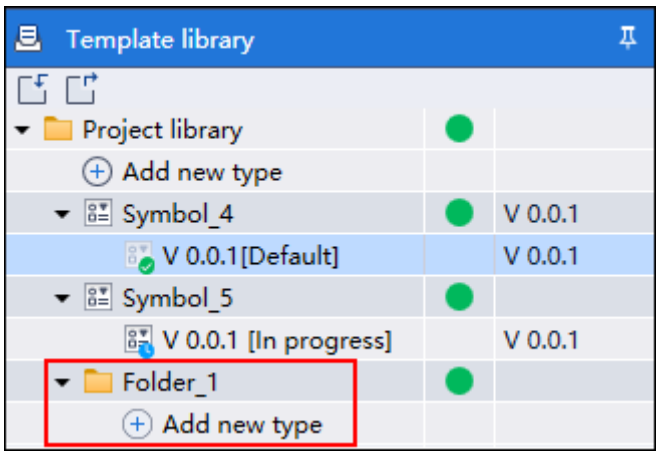
13.4 Template Library Usage

- 13.4.1 Introduction
- 13.4.2 Folder Usage
- 13.4.3 Symbol Template Usage
- 13.4.4 User-Defined Types
- 13.4.5 Template Status Management

- 13.4.6 Common Operations on Template
- 13.4.7 Copying and Pasting a Template Across Projects
- 13.4.8 Copying and Pasting a Template instance Across Projects

13.4.1 Introduction

During the configuration phase, resources with common characteristics are encapsulated into libraries and published as template libraries for reuse across multiple projects in the form of template libraries. Cross-project use must be achieved via the cross-project copy and paste template function.



Template libraries support user modifications and editing, and are managed by version through template library versions. Different devices within the same project may use different versions of the template library.

13.4.2 Folder Usage

Folders are used to categorize templates, making them easier to find and manage.

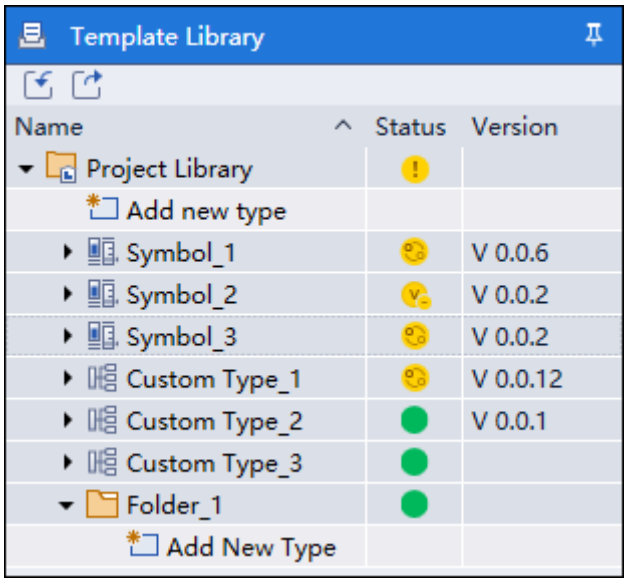
13.4.2.1 Adding a Folder

1. Select the root node "Project library" in the template library.
2. Select "Add new folder" from the right-click menu.

Symbols and user-defined data types can be added to the folder. For detailed instructions, see 13.4.3 Symbol Template Usageand 13.4.4 User-defined Types.

Subfolders can be added within the folder.

13.4.2.2 Deleting a Folder



The delete folder operation will clear the folder and all templates within it.

Requirements

- All versions in the folder must be in released state, and the node identifier must be or .
- The data types in the folder cannot be referenced by templates outside the folder.

13.4.2.3 Renaming a Folder

The folder name can be changed, for example, the selected node shown in the figure below.

Naming rules:

- It is composed of letters, numbers, Chinese characters, or spaces. It cannot start or end with a space.
- English is case-insensitive, for example, Aa and AA, aa and aA are considered the same name.
- The maximum name length is 128 characters.
- Unsupported special characters include \ , / , : , * , ?, " , < , > , and |.
- It cannot have the same name as an existing peer folder in the template library.

13.4.3 Symbol Template Usage

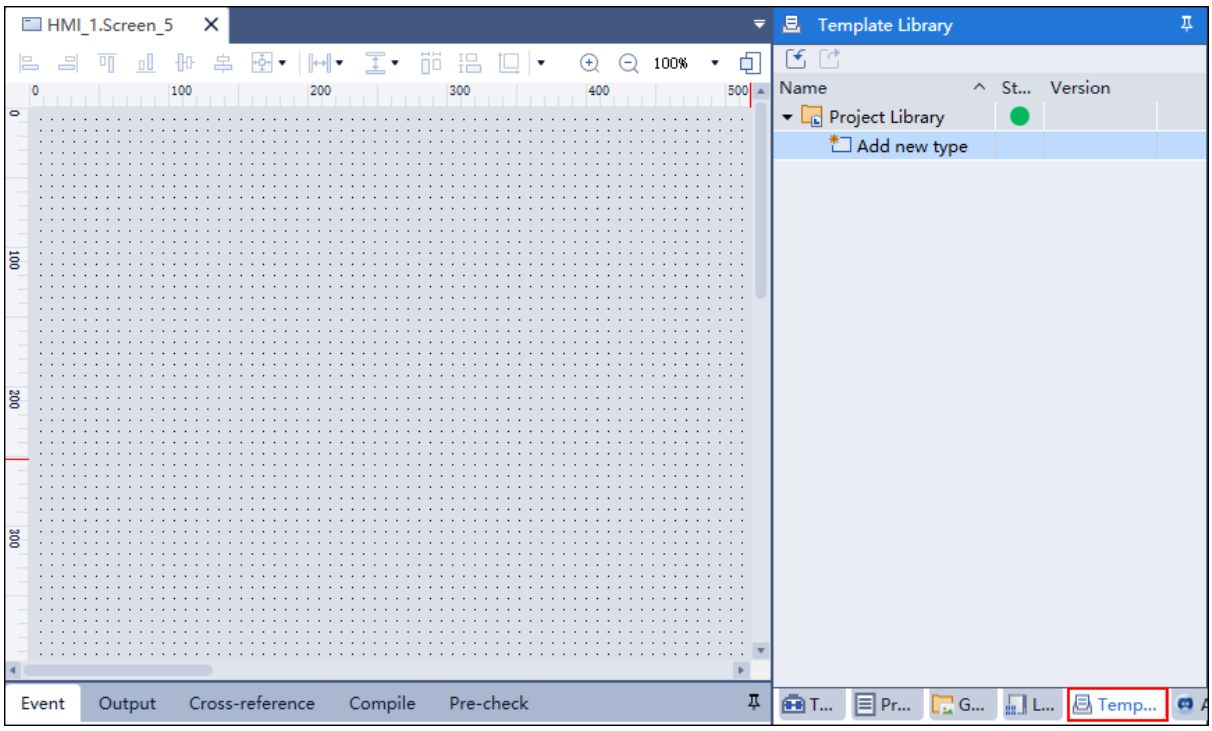
The symbols allow you to reuse common HMI screens as templates within the current project. Symbol can be edited, and the modified template can be synchronized to the instance.

13.4.3.1 Overview of Symbol Template

Symbol templates enable efficient and standardized configuration of screens. They allow you to save commonly used configurations, screens, or data objects as reusable standard templates. By using symbol templates, you can ensure consistency of repetitive elements in your project and significantly enhance configuration efficiency.

Symbol templates are stored within a single project and are only available for use within that project.

You can copy, move, and version-control graphic symbol templates using the template library management functions.

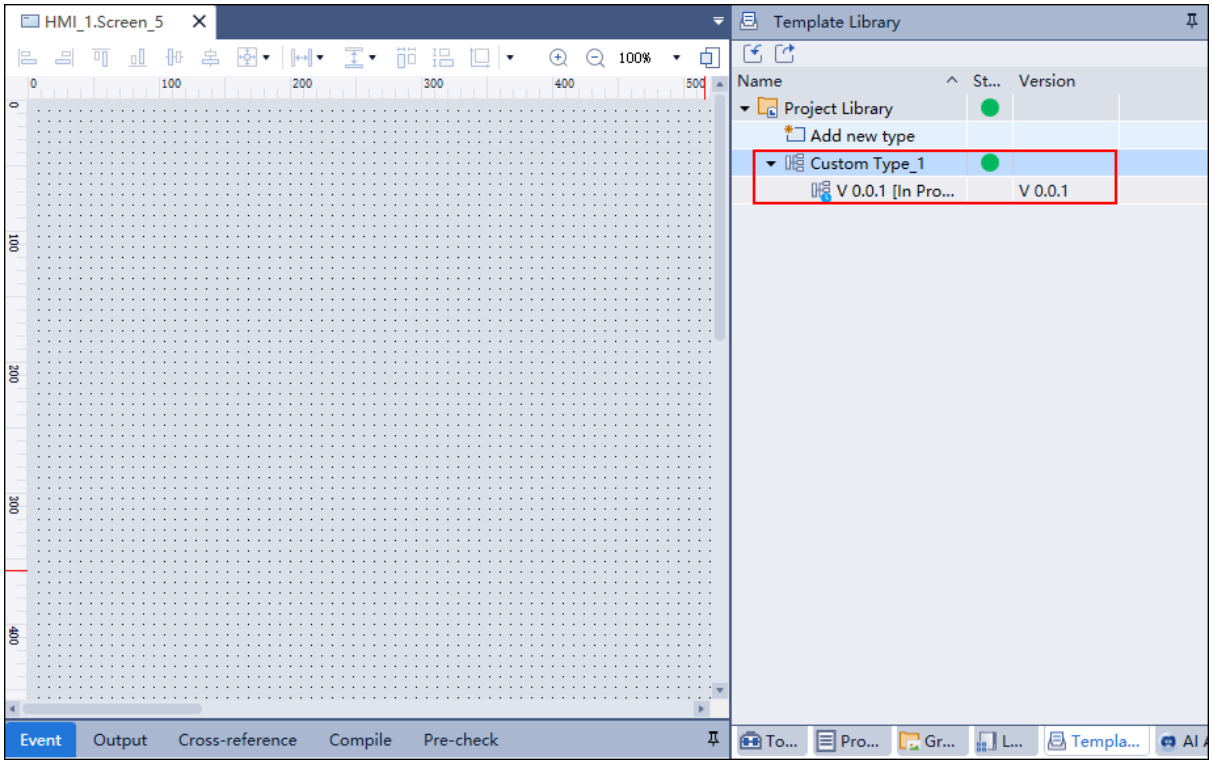


13.4.3.2 Adding a Symbol Template

Introduction

A symbol template is a display and operational object composed of multiple objects. A project can add up to 2000 symbols.

Operation



1. Open the default variable table or any user screen
2. Open the "Template library" tab

3. Add a new type

   Double-click the "Add new type" node and enter the symbol name in the pop-up window.

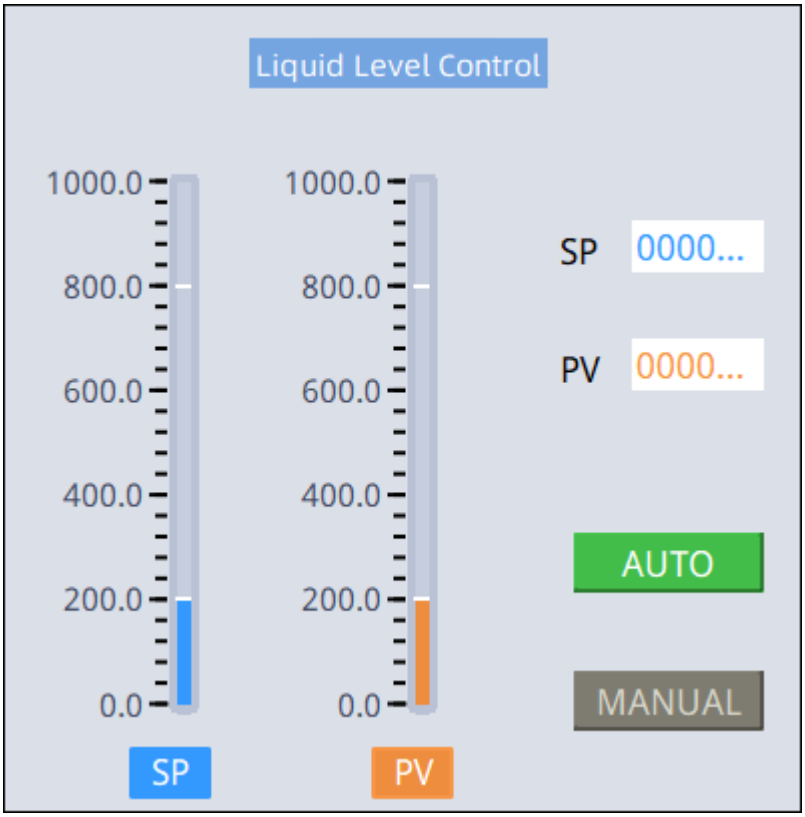
   The new symbol template has been added and is displayed on the project library tree node.

   The version of the new symbol template starts at **0.0.1** and the status is [In Progress].

13.4.3.3 Modifying a Symbol Template

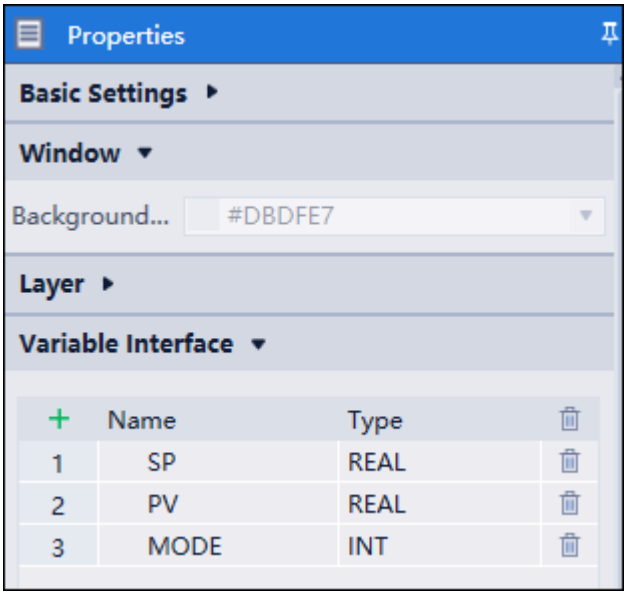
- 13.4.3.3.1 Modifying a Symbol Template
- 13.4.3.3.2 Adding a Variable Interface

- 13.4.3.3.3 Adding a Property Interface
- 13.4.3.3.4 Adding an Event Interface
- 13.4.3.3.5 Adding a Local Variable



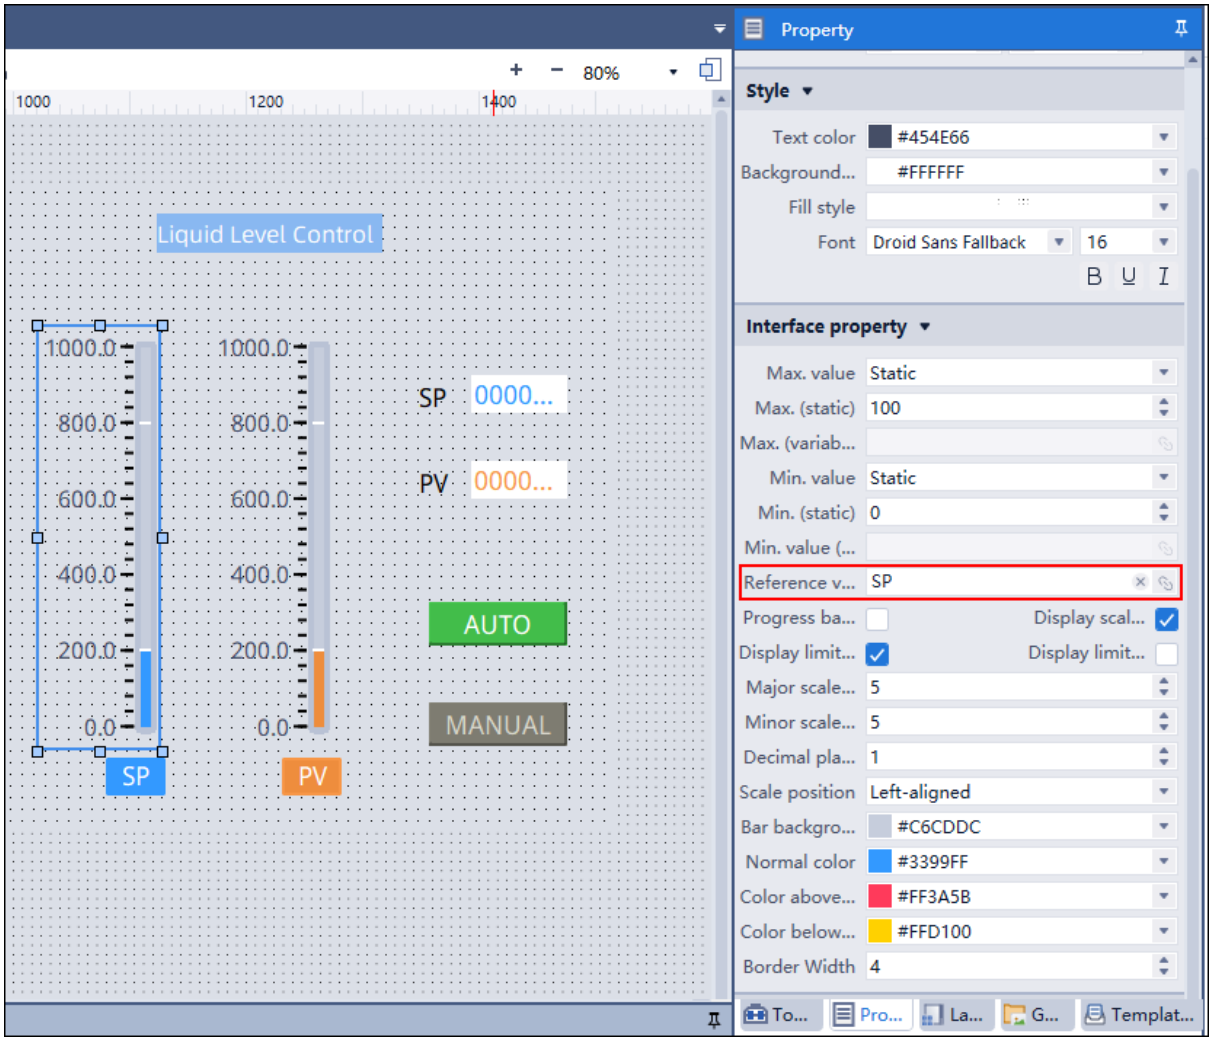
13.4.3.3.1 Modifying a Symbol Template

Requirements



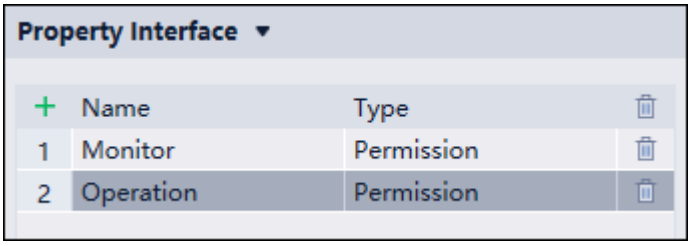
The symbol template has been added to the template library and its status indicator is [In Progress].

Operation

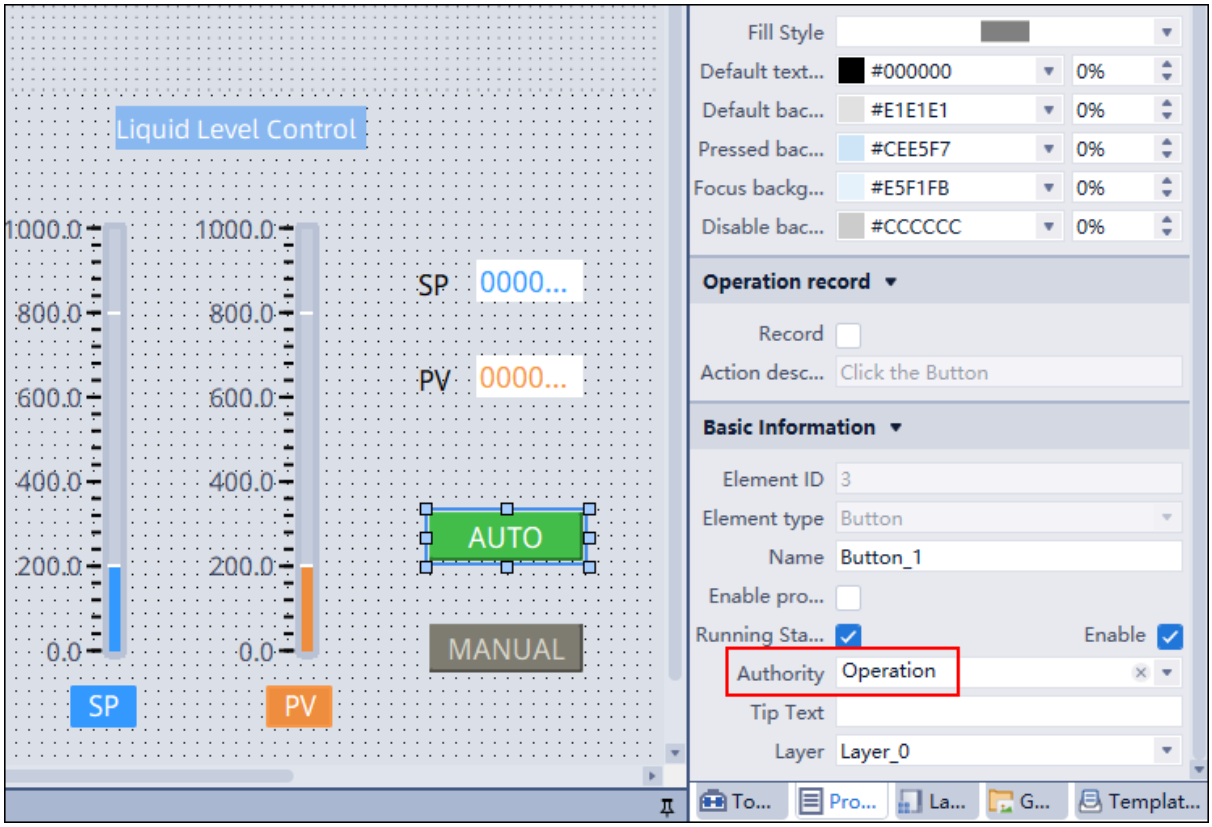


1. Open the symbol editor.
   There are following methods:
   - Select the symbol node, and then choose the "Open" command from the right-click menu.
   - Double-click the symbol version node.
   - Select the symbol version node, and then choose the "Open" command from the right-click menu.
2. Draw objects for display and operation.
   The symbol editor does not support the following six types of controls: Variable Log View, Text List, F(t) Trend, F(x) Trend, Table, Picture-in-Picture.
   For example, you can add bar graph and numeric I/O field in the legend to monitor and operate PV (Process Value) and SP (Setpoint).

3. Add variables to the symbol template
   These variables serve as interfaces for connecting the current symbol to project data. When the symbol is instantiated, they are associated with user-defined variables. Through this association, symbol instances can adjust and respond based on real-time data input from external sources.
   Double-click on the blank area of the symbol screen to open the properties window of symbol. In the "Variable interface" area, click + the button to add a new variable, which will appear in the list.



4. Bind the "Variable interface" variables to the respective properties of the objects.



5. Add properties to the symbol template

   In the "Property interface" area, click the button + and specify the property type. The new property will appear in the list.

6. Bind the "Property interface" types to the respective properties of the objects.
   For example, to configure permissions for the operations of two buttons, you need to configure the relevant 13.4.3.3.4 events for the buttons.

7. Release the symbol template.
   After completing the configuration of the symbol template, release it in the template library so that it can be instantiated on the screen.

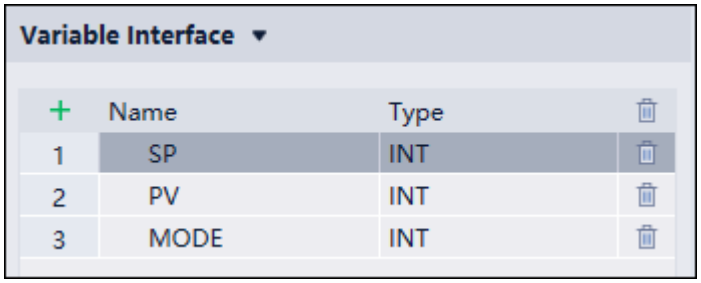
13.4.3.3.2 Adding a Variable Interface

Create interface variables in the symbol template and bind them to objects within the symbol template. When the template is instantiated, map project variables to interface variables to pass parameter values from project variables to objects.

A symbol template can support up to 20,000 interface variables.

Supported data types for interface variables: basic data types, arrays, and structures. Structures are limited to released versions of 13.4.4 User-defined Types.

Requirements

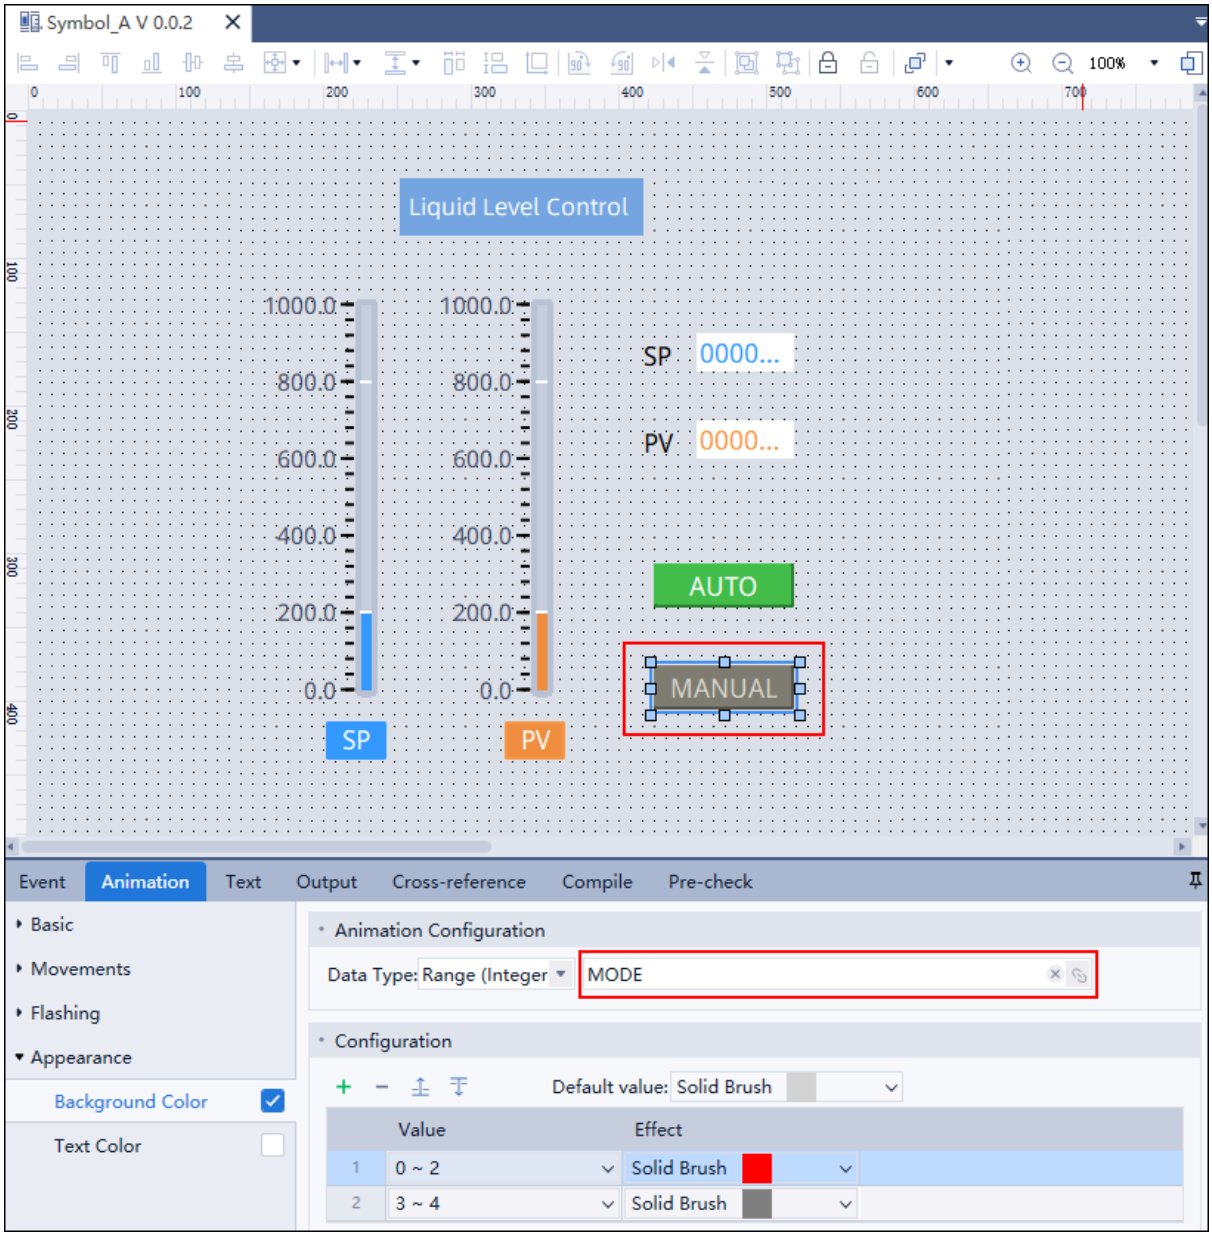


- The symbol template has been added and is in edit mode.
- Restrictions for variables referencing user-defined (struct) types:
  - Do not mix multiple versions of the same type
    In a symbol template, only one version of a type can be used.

For example, if variable 1 uses version V 0.0.2 of DatatypeA, and variable 2 uses version V 0.0.5 of DatatypeA, this is an incorrect operation.

- Do not mix types with nested dependencies
  . If a user-defined type A has a member that references another user-defined type B, both types cannot be used directly as variable types in the same symbol template.
  For example, if a member of type DatatypeA is of type DatatypeB, and variable 1 and variable 2 are declared as these two types respectively, this is an incorrect operation.

Operation



1. Double-click on the blank area of the symbol template to open the properties window of symbol template.
2. Add variables in the "Variable interface" area
   The variable data type can be a basic data type or a user-defined type released in the template library.

NOTE

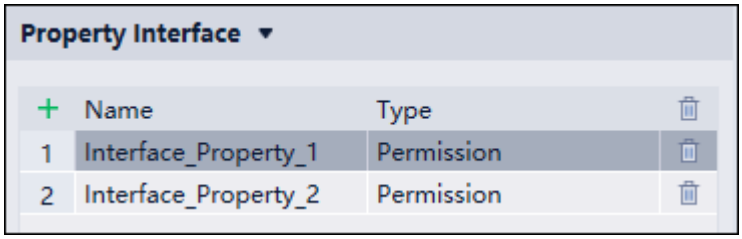
If the variable type uses a user-defined type from the template library, there is no limit on the number of types, but only one version of each type can be used. Multiple versions cannot be used simultaneously.

3. Double-click on the target object in the symbol template to open the monitoring window (or properties window). For example, the target object is a button.
4. In the button monitoring window, under "Animation > Appearance > Background color," bind the variable added in step 2 and set the color corresponding to the variable value. Then, achieve the function where the button color changes according to the variable value.

5. Repeat the above steps to complete the association of each object with the "Variable interface".

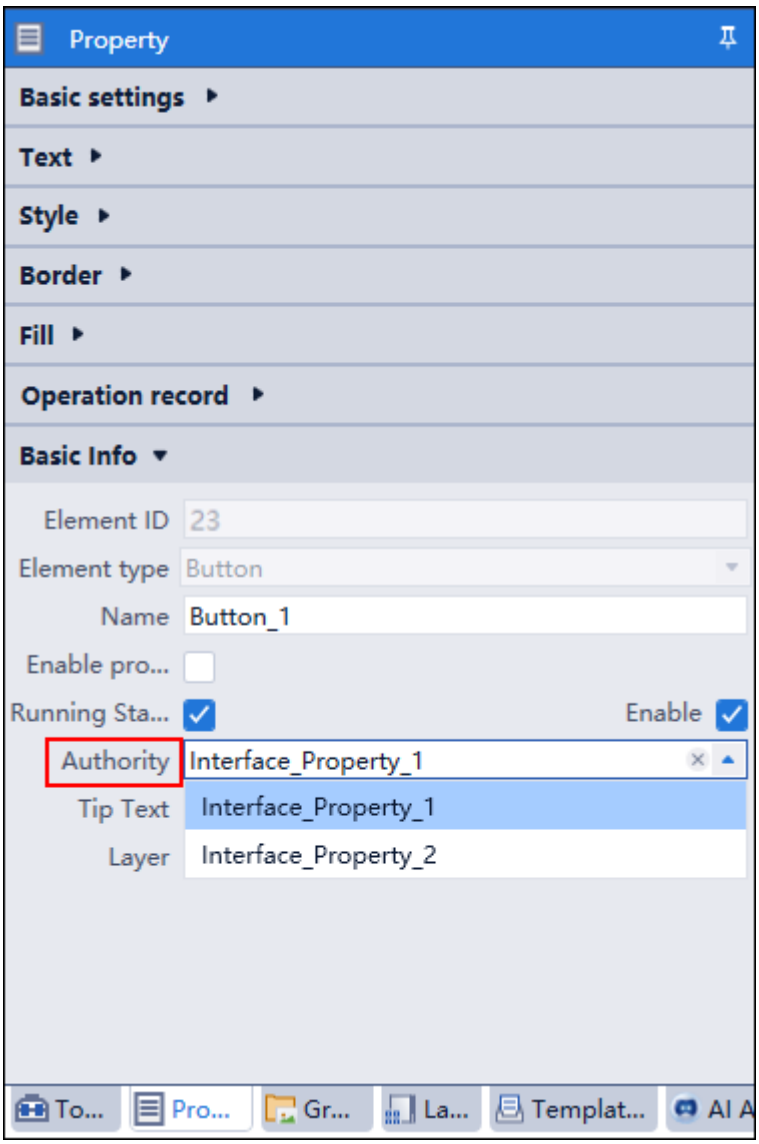
13.4.3.3.3 Adding a Property Interface

Create property interfaces in the symbol template and bind them to objects within the symbol template. When the template is instantiated, map project properties to interface properties to enable customizing object styles within the project.



A symbol template can support up to 128 property interfaces.

Requirements



- A graphic symbol template has been added and has a version that is in progress.
- Property interface supports data types: permissions and text list.

Procedure

1. Open the editing interface for the version that is in progress.
2. Double-click the blank area of the workspace to open the property box for the current version.
3. Add properties in the "Property interface" area and assign property types. For example, set the type of **Interface_Property_1** to **Permission**.

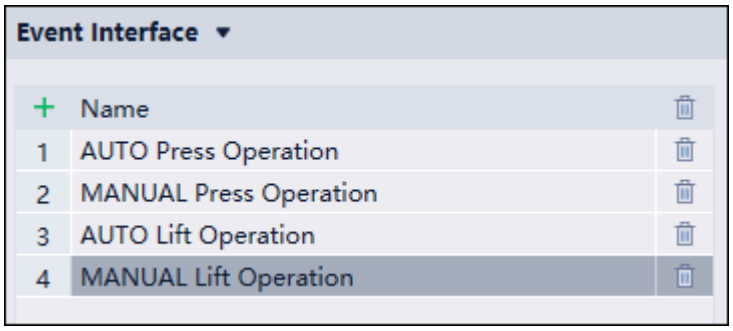
4. Bind the property of a target object (e.g., a button) in the template to the interface property.
   For example, bind the "Basic info > Authority" of a button to **Interface_Property_1**.

Property Interface Type	Applicable Object	Associated Property
Authoritiess	All graphic objects	Basic information > Authority
Text list	Text list	Options > Text list

5. Repeat the above steps to bind all object properties to the corresponding "Property interface".
6. Publish the symbol template.

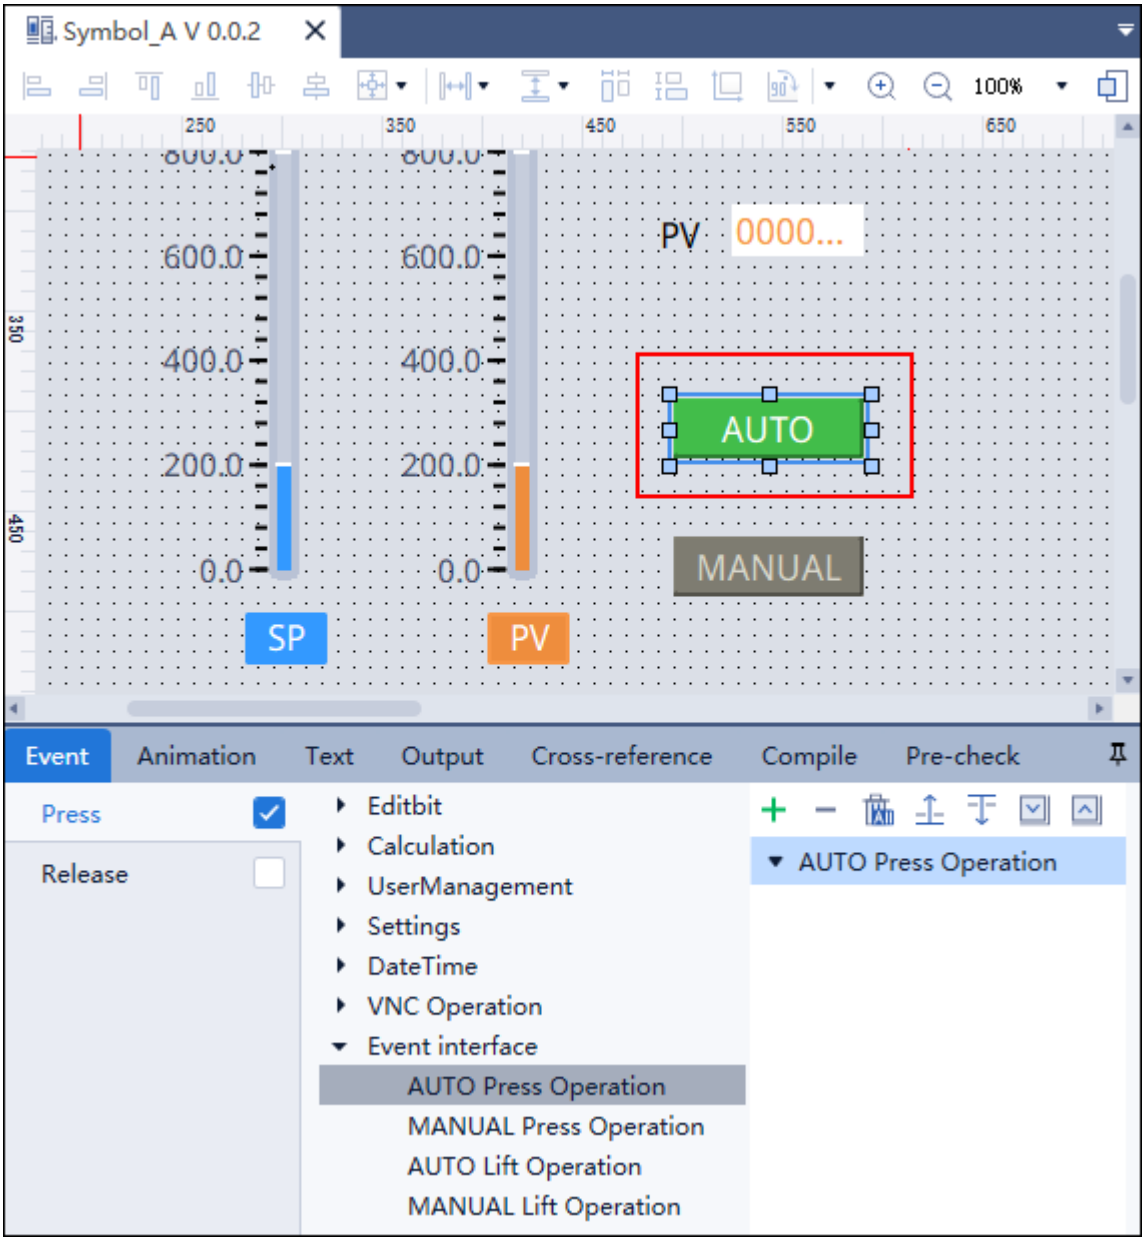
13.4.3.3.4 Adding an Event Interface

Create interface events in the symbol template and bind them to objects within the symbol template. When the template is instantiated, customize object styles in the project through interface properties.



A symbol template supports up to 16 interface events.

Requirements



The symbol template has been added and is in edit mode.

Operation

1. Double-click on the blank area of the symbol template to open the properties window of symbol template.
2. Add events in the "Event interface" area and specify the purpose of each event. For example, **AUTO press operation**.

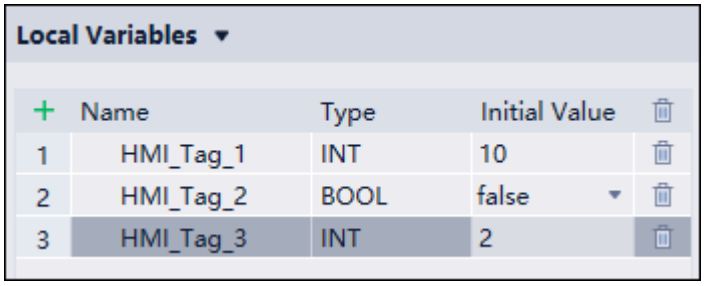
3. Double-click the target object in the symbol template to open the "Event" tab in the monitoring area. For example, the target object is a button.
4. Bind the object to an event. Click "Event > Press" to bind **the AUTO press operation** in step 2.

5. Repeat the above steps to complete the binding of events for all objects with the "Event interface".

13.4.3.3.5 Adding a Local Variable

Local variables are variables used for internal logic processing within a symbol template and do not require association with user variables when the symbol is instantiated.

A symbol template supports up to 128 local variables.



Supported data types for local variables: basic data types and arrays.

Requirements

The symbol template has been added and is in edit mode.

Operation

1. Double-click on the blank area of the symbol template to open the properties window of symbol template.
2. Add variables in the "Local variable" area

The variable name must not be the same as the names in the variable interface and property interface.

13.4.3.3.6 Adding an Animation to Object

Objects in symbol templates support animation configuration, with various dynamic effects such as movement, rotation, and flashing.

Requirements

Identifies the symbol version node and ensure that the object has been added.

Operation

The operation to configure animation for objects in symbol templates is exactly the same as for objects in user interfaces. For details, see 13.3.8 Animation Configuration. The difference lies in that variables associated with the former can only be variable interfaces or local variables, while variables associated with the latter are user variables.

13.4.3.3.7 Adding an Event to Object

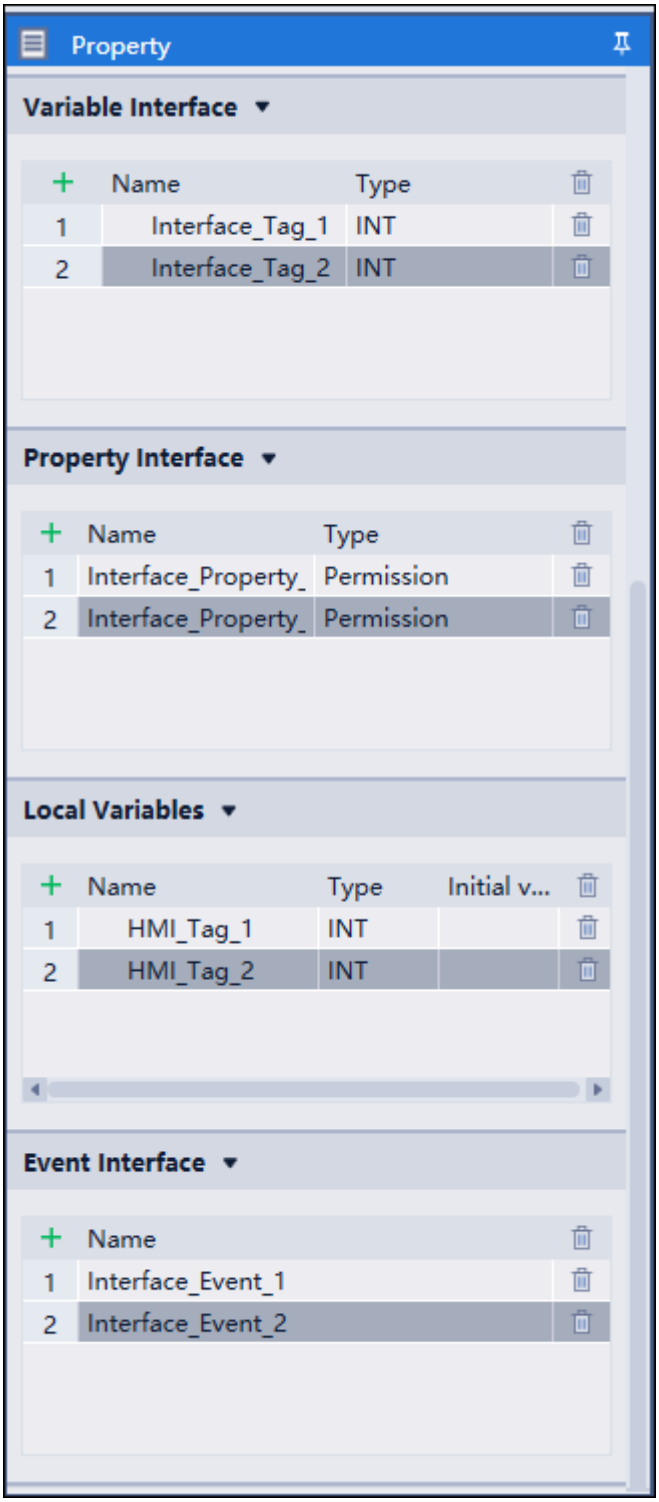
Objects in symbol templates support event configuration.

Requirements

Identifies the symbol version node and ensure that the object has been added.

Operation

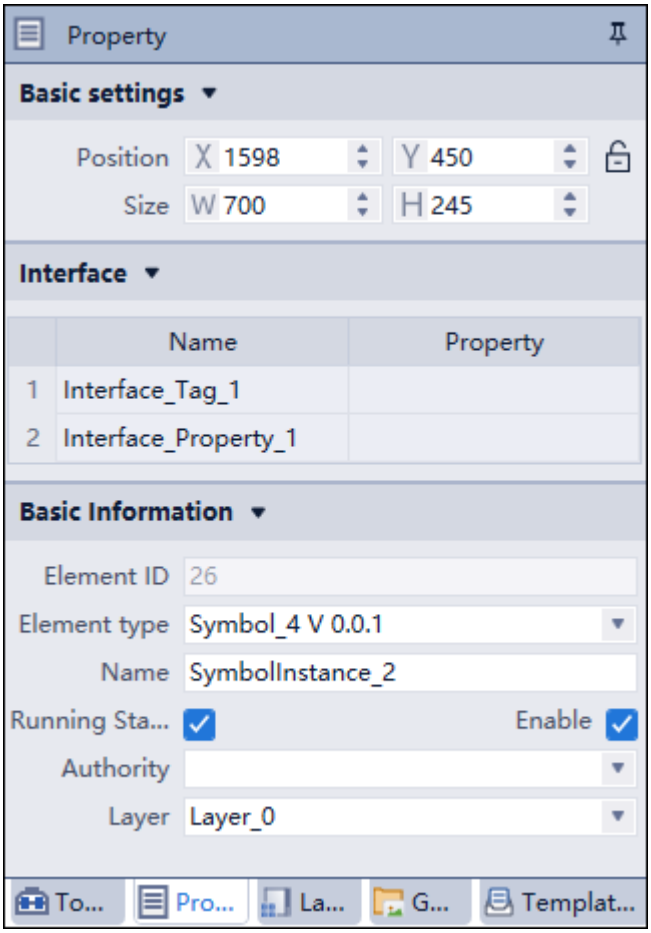
The operation to configure events for objects in symbol templates is exactly the same as the operation for objects in user interfaces. For details, see 13.3.7.14 Adding an Event. The difference is that the former can configure system functions and event interfaces, while the latter can only configure system functions.



13.4.3.4 Applying a Symbol Template

After the symbol template is published, it can be applied to user screens for instantiation.

User screen refer to the screen type under the "Screen" node in the project tree, such as picture-in-picture screens or pop-up screens.

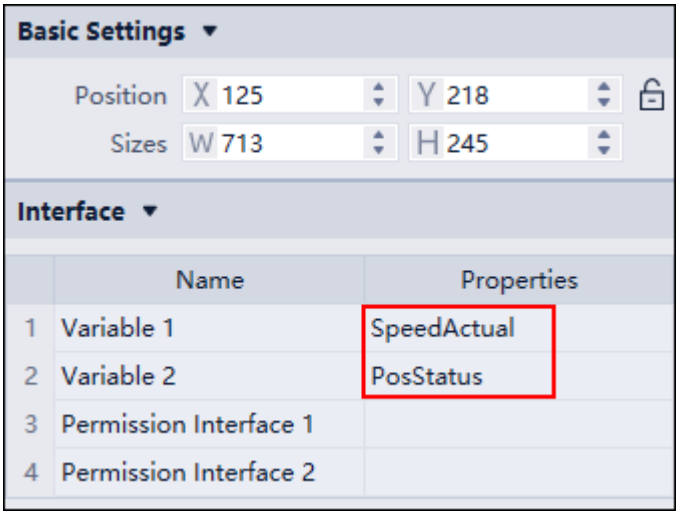


Operation

1. Select the symbol template
   In the template library, select the published version of the desired symbol. The version node is identified , for example, version V0.0.3 of "Symbol_1"
   Open this version to review the interface configuration and ensure full understanding of subsequent steps.

2. Drag the symbol template onto the application screen
   Drag version V 0.0.3 to the template application screen, such as "Screen_1". Instantiate the symbol content.

3. Open the properties tab
   Double-click the symbol template in "Screen_1" to open the "Property" tab.



4. Configure variable interface

   When associating the template's variable interface with the associated variable in the project, the data types must be consistent.

   If the variable interface data type is a user-defined structure from PLCs, the associated variable must be an HMI external variable.

   Additionally, this external variable must be associated with an instance variable of the same structure in the PLCs.

5. Configure permission interface

   a. Add user permissions under the "9.8 User and role" node, and specify the target device in the "Device name".

   b. In the properties window, associate the permission interface with the user permissions.

6. Configure event interface

   Double-click the symbol instance in "Screen_1" to open the "Event" tab, and associate the event interface with user events.

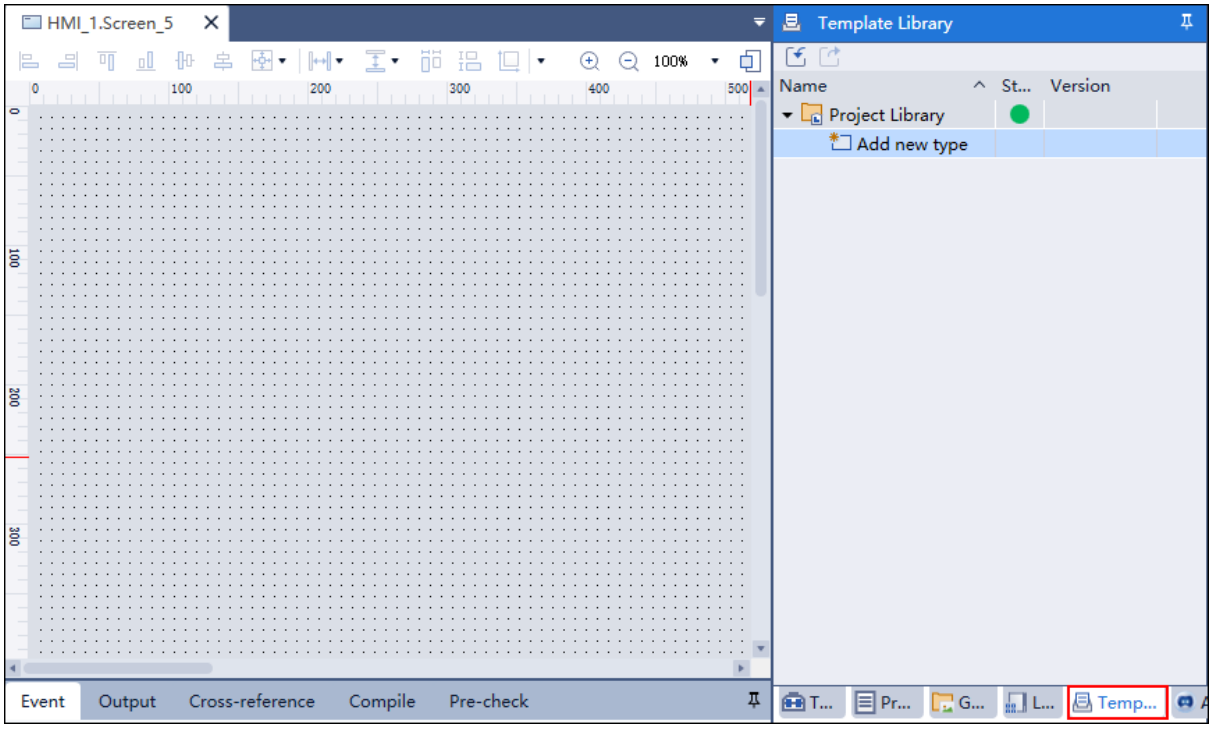
7. Save the project

   After completing all configurations, save the project to ensure all changes are applied.

13.4.4 User-Defined Types

A user-defined type is a generic, reusable data type created by the user, similar to a structure type, and contained within a library file, which can be reused across devices.

13.4.4.1 Adding a User-Defined Type



The template library supports two methods for defining struct types, facilitating reuse and management.

HMI user-defined type

You can manually create a structure type within the template library and directly define the structure name and member types.

1. Opening a Project
2. Open the "Template library" tab

   After opening the user screen, switch to the "Template library" tab. Even if no HMI device has been added to the project, this switch can still be performed in the right area of the interface.

3. Add a new type

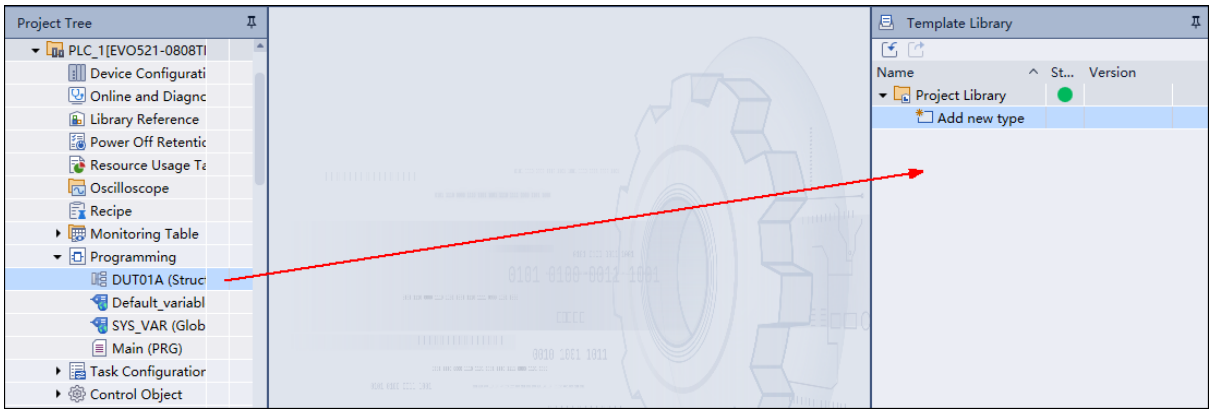
   Double-click the "Add new type" node, select "Custom type" in the pop-up window, and enter the data type name.

   The user-defined type has been added and is displayed on the tree node in the project library.

   The version of the user-defined type starts at **0.0.1** and the status is [In Progress].

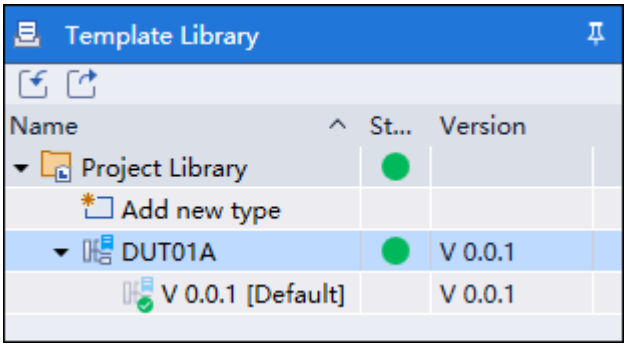
PLC user-defined type

Drag and drop the user-defined structure created in the PLCs into the template library to template the PLC user-defined structure.



Prerequisites

The user-defined structure types that can be dragged must simultaneously meet the following conditions:



- User-defined data types have been created or imported in the current project.
- Only user-defined 10.1.1.8.1 Standard Data Types and array-type structures are supported for templating. Arrays support multi-dimensional arrays and array nesting, with the number of array elements not exceeding 2000. Standard data types with specified upper/lower limits and arrays with non-numeric boundaries are not supported.
- Enumerations, unions, aliases, FBs, FCs, PRGs, and library types are not supported.
- Structure inheritance is not supported.

Procedure

1. In the PLC device tree, select the structure to reference.
2. Drag the selected structure into the template library.

3. The structure node will automatically appear in the template library and be defined as version V 0.0.1.

Both the node in the PLC device tree and the node in the template library are identified .
During the templating process, if the referenced object contains nested structures and these sub-structures are also of user-defined types, all nested sub-structures will be automatically templated.

> **NOTE**
>
> Once a structure type has been successfully templated, it cannot be templated again if no modifications have been made to the structure members (except for changes to the type name).

13.4.4.2 Modifying a User-Defined Type

After successfully adding a structure type to the template library, the next step is to configure member variables and types.

HMI user-defined type

User-defined type identifier  The user-defined type editor can be opened via the "Open" command in the right-click menu:

1. Select the first row and click the button  to add a new row.
   Add a new data row at the bottom of the table. The default member variable name is number_x where x starts at 1 and increments. The name must be unique and will be renamed automatically if duplicate. The default data type is INT.
2. User-defined data types support basic properties such as name, description, and data type.
3. Creation by entering a name is supported.
4. The data type of members supports basic types, arrays, and structures (excluding user-defined structures referenced from PLCs).

User-defined type members support insertion, copying, pasting, moving up, moving down, deletion, and nesting:

- The rules for inserting, copying, pasting, moving up, moving down, and deleting user-defined type members are the same as those for variables.
- User-defined data types support up to 8 levels of nesting.
- Recursive use is prohibited. User-defined data types that are recursive cannot be used as members of other user-defined types. You will be prompted if recursive use is detected.

PLC user-defined type

For these structures in the template library, except for the struct name and comment, other information cannot be edited and can only be viewed.

13.4.4.3 Impact of User-Defined Type Version Upgrade

To ensure consistency across the template library, upgrading the version of a user-defined type may trigger cascading effects once it is referenced by a symbol template. The specific rules and impacts are as follows.

Version upgrade rules for symbol templates and user-defined (structure) types

The core rule depends on the current state of the symbol template:

- Scenario 1: Linked upgrade
  Condition: Both the symbol template and the referenced user-defined (structure) type are in the "Released" state.
  Result: Once a new version of the user-defined type is released, all released symbol templates referencing it will automatically create a new version (entering the "Editing" state) and update the reference to the latest type version.
- Scenario 2: Independent upgrade
  Condition: The symbol template itself is in the "Editing" state.
  Result: Regardless of how the referenced user-defined (structure) type is upgraded, the symbol template remains unaffected and continues to use the original type version.

Prerequisites

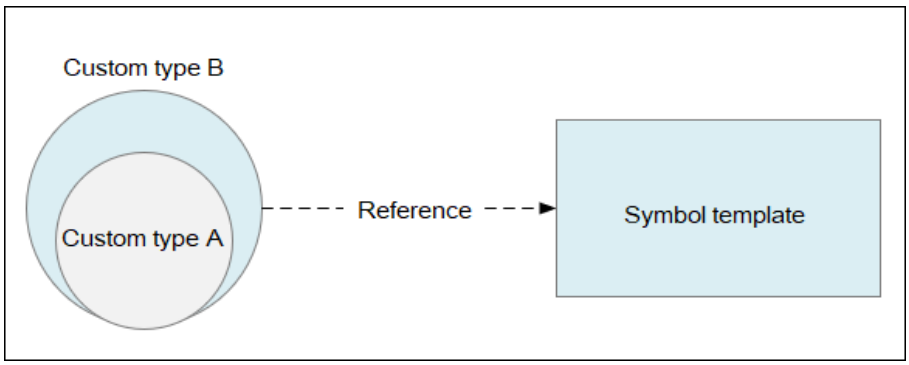
A symbol template and a user-defined (structure) type have already been created.

A relationship has been established: The variable type of the symbol template references a specific version of the user-defined (structure) type.

Procedure

When upgrading the version of the user-defined type, the scope of impact is determined jointly by its internal structure and reference relationships. The key point lies in determining whether the related user-defined type contains nested structures. You must understand this before upgrading.

- Upgrade a structure type without nesting



To better illustrate the above upgrade rules, the following table shows typical version evolution scenarios (including linked and independent upgrades) after a reference relationship is established between a user-defined type (e.g., object Datatype) and a symbol template (e.g., object Symbol).

Step	Operation	User-defined type	Symbol Template	Result
1	A reference relationship is established between version V0.0.1 of Datatype and version V0.0.1 of Symbol.	V 0.0.1 released	V 0.0.1 released	The reference relationship is locked
2	The Datatype is upgraded from version V 0.0.1 to V 0.0.2. The Symbol is upgraded to V 0.0.2 automatically.	V 0.0.2 released	V 0.0.2 in progress	The referenced version in the Symbol is automatically upgraded to V 0.0.2.
3	The Datatype is upgraded from version V 0.0.2 to V 0.0.3.	V 0.0.3 released	V 0.0.2 in progress	The version V 0.0.3 of Datatype is not referenced by the Symbol.
4	The version V 0.0.2 of Symbol has been successfully released.	V 0.0.3 released	V 0.0.2 released	The reference relationship between V 0.0.2 of Datatype and V 0.0.2 of Symbol is locked.
5	The Datatype is upgraded from version V 0.0.3 to V 0.0.4. The Symbol is upgraded to V 0.0.3 automatically.	V 0.0.4 released	V 0.0.3 in progress	The referenced version in the Symbol is automatically upgraded to V 0.0.4.

- Upgrade a structure type with nesting

This specifically refers to PLC user-defined types. When a symbol template uses nested PLC user-defined types, upgrading the type affects its entire reference chain.

The reference relationship is shown in the diagram below. The PLC user-defined type B nests type A, and the data type of symbol template 1 is associated (instantiated) with type B.

When type B undergoes a version upgrade, it triggers a linked upgrade of the symbol template and type A. Even if type A itself is not modified, it will be forcibly upgraded to a new version.

The prerequisite for upgrading a symbol template is that it must be in a released state.

Recommendations

- Plan upgrades: Before editing a "Released" user-defined (structure) type, check whether any symbol templates depend on it to avoid unintended chain upgrades. If an unnecessary symbol template upgrade is triggered, use the "Discard Changes" command to undo it.
- State management: Release symbol templates in "In progress" state promptly to maintain synchronization of version dependencies within the project.

13.4.4.4 Applying a User-defined Type

There are two locations in the template library where user-defined types can be applied:

User-defined type	Use Position
HMI user-defined type	Apply within the HMI variable table. Apply within the "Variable interface" property of a symbol template. For details, see 13.4.3.4 Applying a Symbol Template.
PLC user-defined type	Apply within other PLCs. Apply within the "Variable interface" property of a symbol template. For details, see 13.4.3.4 Applying a Symbol Template.

This section explains how to apply PLC user-defined type within other PLCs.

Procedure

1. Template user-defined structure in PLCs
   For example, when a user-defined structure A from PLC_1 device is dragged into the template library, a node with the same name as structure A is created in the template library, and an initial version (V 0.0.1) is generated.
2. Apply in other PLCs
   Select the structure A node in the template library and drag it into the "Programming" node of PLC_2 device. The default version of structure A will be added to PLC_2.
   If multiple versions of structure A exist, you can select a specific version to drag, and that specific version will be added to PLC_2.

Result

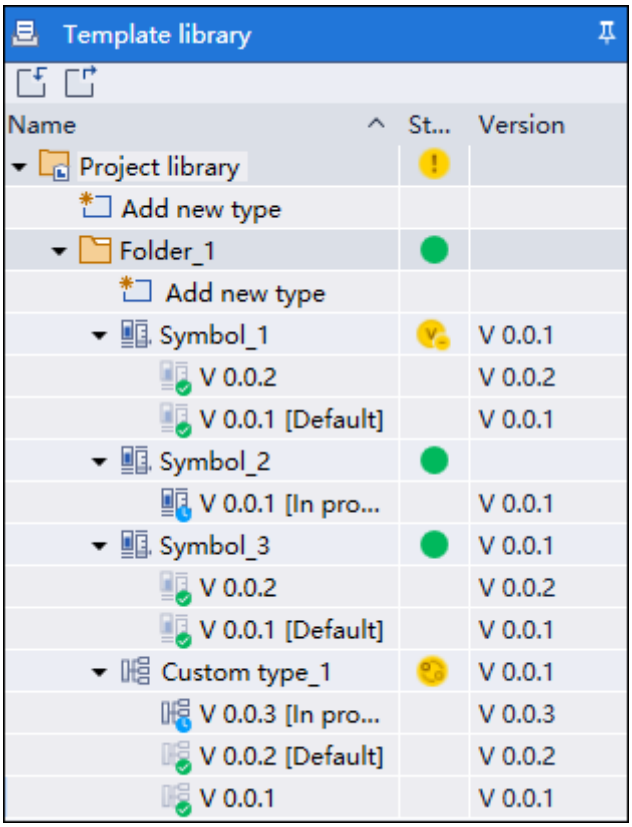
The user-defined structure A has been successfully added to PLC_2, with the corresponding node identifier .

Precautions

- The version of the structure dragged into PLC_2 strictly corresponds to the version in the template library. In the template library, all versions are in a released state (non-editable). Therefore, when a new version is released in the template library, manually synchronize that new version to the PLC_2 device if needed.
- Structure definitions applied in PLC_1 and PLC_2 support editing. After editing, the changes can be updated to the template library using the 13.4.6.11 Synchronizaing PLC Types command.

13.4.5 Template Status Management

Templates and versions in the template library use different symbols to indicate their reference state and release state, helping you quickly identify their current state.



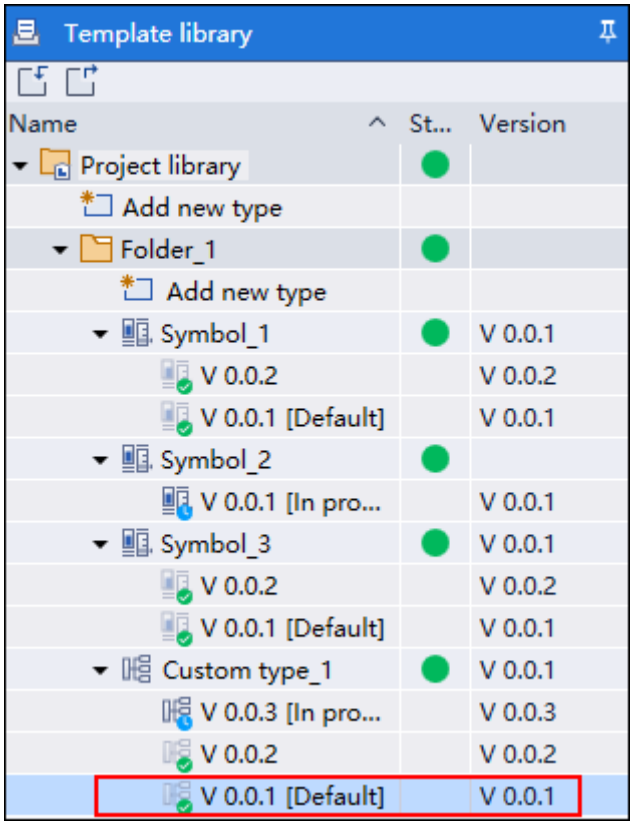


Table13-4-5-1 Description

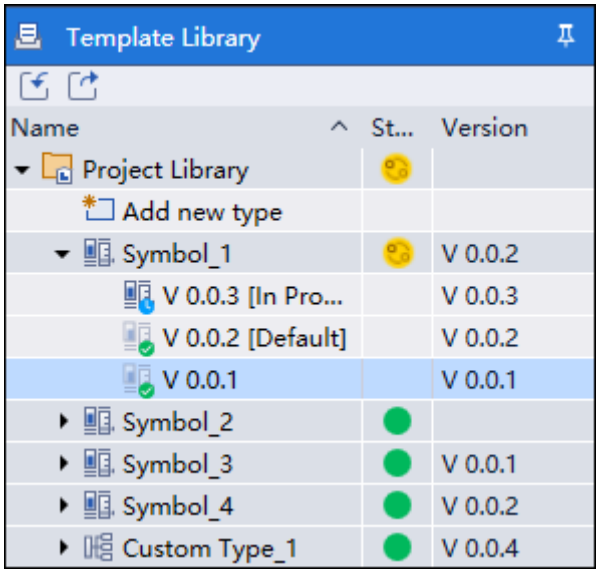
Category	Label	Description
Project/Template node		The default version pf current template references other templates, but the referenced versions are not the default versions of those templates.
		Does not reference other templates, or References the default versions of other templates
		Non-default version is referenced or instantiated
		Multiple inconsistencies

Category	Label	Description
Version node		Version content is being edited and not yet released. Version number ends with [In Progress].
		Version content has been released. Version number ends without any label or with [Default].

Since the default version can be specified using the command "Set as default", the state of the template node changes along with the default version settings, even if the content remains unchanged. For example, in the figure below, when the default version of "Custom type_1" is changed from V 0.0.2 to V0.0.1, the state of the template node changes.



13.4.6 Common Operations on Template

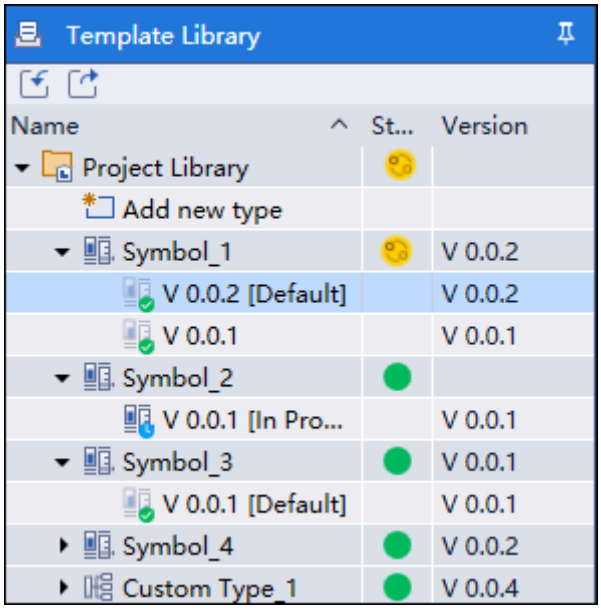
Templates refer generally to symbols and user-defined types in the template library. The operation commands and their results mentioned in the following sections apply to these symbols and user-defined types.

13.4.6.1 Opening a Template

When different nodes are selected in the template, using the "Open" command from the right-click menu produces different results:

Select symbol node

Executing "Open" on a symbol node automatically opens the content of the [Default] version. If there is no default version, the [In Progress] version will be opened. For example, selecting the "Symbol_1" node will open the content of version V 0.0.2 when using the "Open" command.

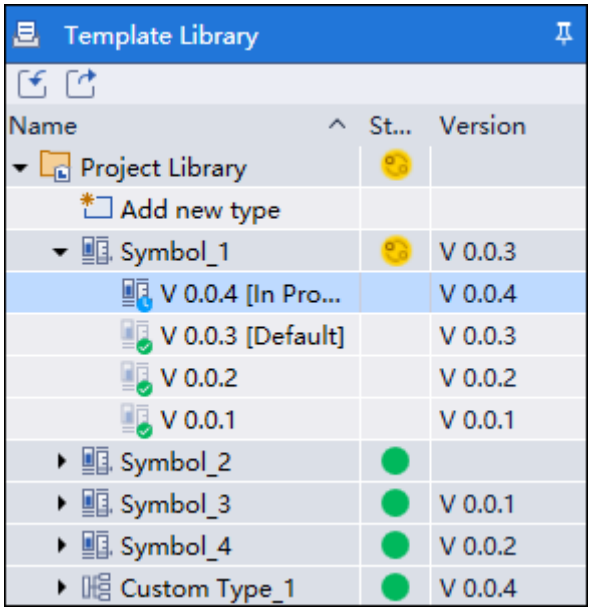


Select symbol version

- No state indicator: For example, for the "V 0.0.1" version of "Symbol_1", the "Open" command will open its content, allowing only viewing, not editing.
- [Default] indicator: For example, for the "V 0.0.2" version of "Symbol_1", the "Open" command will open its content, allowing only viewing, not editing.
- [In Progress] indicator: For example, for the "V 0.0.3" version of "Symbol_1", the "Open" command will open its content and support editing.

13.4.6.2 Modifying a Template

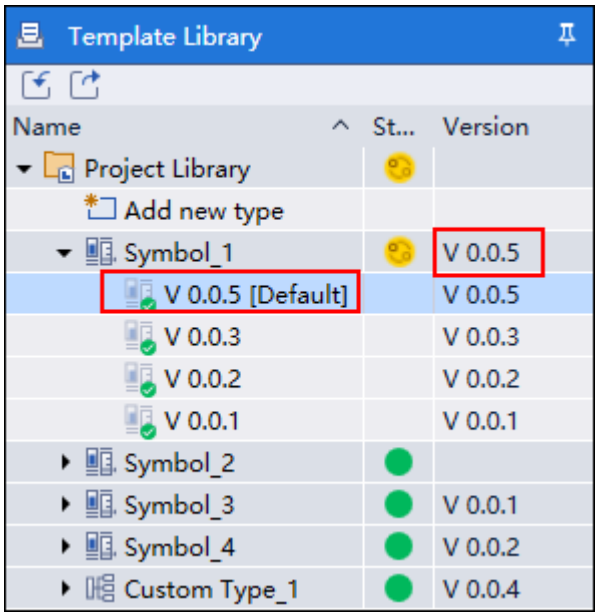
The "Edit" command puts the template into an editable state, to meet the need to modify the template content.



The availability of the "Edit" command in the right-click menu varies depending on the current state of template:

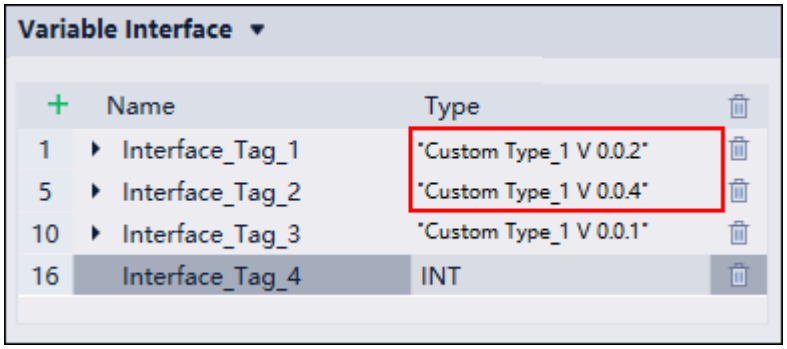
- Template has an [In Progress] version: the Edit command is unavailable. For example, the "V 0.0.1" version of "Symbol_2" is in [In Progress] state, so the Edit command is unavailable.
- Template does not have an [In Progress] version: the Edit command is effective, and you can modify the template content. For example, all versions of "Symbol_1" and "Symbol_3" support editing.
  A new version is automatically generated for the template when using the "Edit" command. The version number of the new version is incremented by 1 from the current version number, and the state indicator is set to [In Progress]. This new version automatically copies the content of the selected version for editing.

13.4.6.3 Publishing a Template



The "Release Template" command verifies the compliance of content in a specific version of a template. Successful verification is considered a successful release. After a template is successfully released, instances can be created in the user interface.

Procedure



1. Select the version identified as [In Progress].
   For example, select the "V 0.0.4" node of "Symbol_1", identified by .
2. In the right-click menu, select "Publish template".

3. Confirm the symbol name and version number
   In the pop-up window, confirm the symbol name and version number. For example, change the version number to 0.0.5 and confirm.
   The identifier and version number of node have been automatically updated, and the state is identified as [Default].

Results

- Only one version of each symbol can be identified as [Default]. This version is not fixed. You can re-designate from historical versions.
- The default version is synchronized to the parent node version. If instantiation is achieved by dragging the parent node, the default version will be instantiated.
- If the variable type of **variable interface** in the symbol template uses user-defined types from the template library, the number of types is unlimited, but only one version of each type can be used. Multiple versions cannot be used simultaneously. For example, using two versions of "Custom type_1" as shown in the figure below is an incorrect operation.

13.4.6.4 Updating a Template

The "Update template" feature synchronizes the default version from the template library to various instances in devices or projects, ensuring consistency and version control.

The specific logic for the update operation varies depending on the object type in the template library:

Update operation for user-defined symbols

Assume a symbol named Cust_symbol has been created in the template library and two versions, V 0.0.1 and V 0.0.2, have been released. The referenced version of the current instance is V 0.0.2, while the default version set in the template library is V 0.0.1.

- Execute operation
  Select the Cust_symbol node and execute the "Update template" command from the right-click menu.
- Update result
  The referenced version of instance is automatically updated to "Cust_symbol V 0.0.1".

NOTE

When the template version referenced by the symbol instance is updated:

- The display area size of the symbol instance in the screen remains the same as before the update and does not automatically adjust to the new version.
- If the number or size of elements in the new version differs from the original, the instance may be partially cut off or displayed incorrectly. You need to manually adjust the display area to ensure proper display.

Update operation for HMI user-defined types

Assume a user-defined type named Cust_type has been created in the template library, with multiple versions released, including V 0.0.1, V 0.0.2, and V 0.0.3. The variable Var1 in the project currently uses data type V 0.0.1, while the default version set in the template library is V 0.0.2.

- Execute operation
  Select the Cust_type node and execute the "Update template" command from the right-click menu.
- Update result
  The data type of variable Var1 is automatically updated to "Cust_type V 0.0.2".

Update operation for PLC user-defined types

Assume a structure named PLC_1_Stru has been created in the PLC_1 device and is already associated with version V 0.0.2 in the template library. If the members of this structure are edited on the PLC side (e.g., added or removed), and version V 0.0.2 is designated as the default version in the template library.

CAUTION

Since the structure instance in the PLC device is bound to version V 0.0.2 of the template library, the update operation will only take effect when V 0.0.2 is set as the default version. Setting any other version as default will have no effect on this instance.

- Execute operation
  Select the Cust_type node and execute the "Update template" command from the right-click menu.
- Update result
  The member information of the structure PLC_1_Stru in the PLC_1 device is updated to match the content of version V 0.0.2 in the template library.

The above operation ensures that the structure definition in the device remains consistently aligned with the corresponding version in the template library, applicable to scenarios such as rapid version rollback or consistent configuration.

NOTE

When modifying structure member information, ensure that the prerequisite conditions for 13.4.4.1 Adding a User-Defined Typeare met.

13.4.6.5 Deleting a Template

Deleting a template removes all related content of the template from the current project. The delete command varies depending on the state of template.

Delete a released version

For a released version, click the "Delete" command from the right-click menu to remove it.

	Delete a Single Version	Delete the Entire Template
Symbol	Condition: Version is in released state with node identifier . Result: Deletes the version node in the template library and removes the instance from the user interface.	Condition: All versions under the symbol node are in released state with node identifier. Result: Deletes the symbol node in the template library and removes all version instances from the interface.
User-defined type	Condition: Version is in released state with node identifier. AND This version is not used in the symbol. Result: • PLC user-defined type: Deleting a specified version severs the connection with the node in PLCs. The identifier in the PLC  changes to . • HMI user-defined type: Deleting a specified version also removes the corresponding variable instance from the HMI variable table (if involved).	Condition: Version is in released state with node identifier . AND This type is not used in the symbol. Result: • PLC user-defined type: Deleting the entire type node severs the connection with the node in the PLCs. The identifier in the PLC  changes to . • HMI user-defined type: Deleting the entire type node also removes the corresponding variable instance from the HMI variable table (if involved).

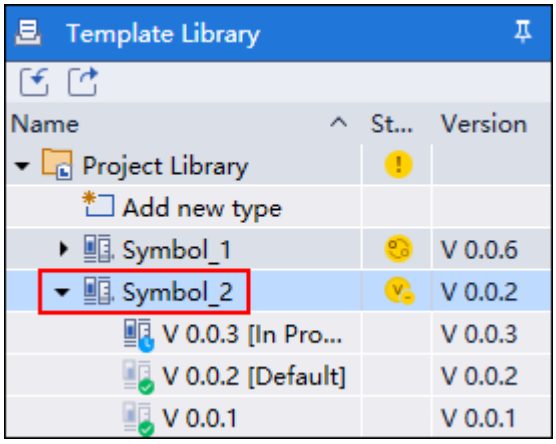
Delete a version in editing

For a version in editing, identified by [In Progress], click the "Discard changes" command from the right-click menu to remove it.

13.4.6.6 Renaming a Template

The name of a template node can be changed, for example, the collapsed node shown in the figure below.

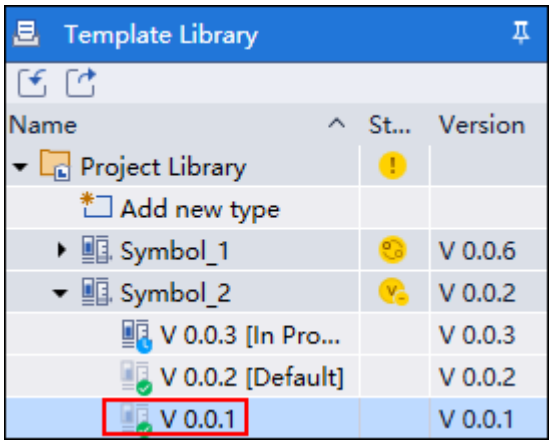
Naming rules:



- It is composed of letters, numbers, Chinese characters, or spaces. It cannot start or end with a space.
- English is case-insensitive, for example, Aa and AA, aa and aA are considered the same name.
- The maximum name length is 128 characters.
- Unsupported special characters include \ , / , : , * , ?, " , < , > , and |.
- It cannot be the same as existing symbol and custom type node names in the template library, but can be the same as folder names.

13.4.6.7 Copying a Template

The "Copy template" feature quickly copies the content of a specific version within a template in the same project.



The "Copy template" command is effective in two locations:

- Template node
  1. Execute the "Copy template" command on a template node, such as the "Symbol_2" node shown in the figure.

2. Enter the new template name and version number in the pop-up window.
3. The default version V 0.0.2 of "Symbol_2" will appear in the template library with the new name and version number.

- Version node
  1. Execute the "Copy template" command on a version node, such as the V 0.0.1 version of "Symbol_2" shown in the figure.

  2. Enter the new template name and version number in the pop-up window.
  3. The default version V 0.0.1 of "Symbol_2" will appear in the template library with the new name and version number.

13.4.6.8 Exporting a Template

Templates in the iFA project export objects from the template library into **.fatpl** file format via the export function. This facilitates flexible management and sharing of released objects in the library.

Export scope

- Released versions of templates are supported for export, indicated by an icon in the lower right corner of the version node .
- If the target version references other templates, they will be exported together.

Procedure

1. In the template library, select the version node to export.
   If not selected, all released versions will be exported by default.
2. Right-click the node and select the "Export" command, or the icon.

3. Specify the file path for the exported file.
   The exported file has a **.fatpl** extension, with the default name **Library.fatpl**.

13.4.6.9 Importing a Template

The template library in iFA projects supports importing existing templates, which is applicable for importing templates from other projects into the current project, or for restoring templates that have been deleted from the project.

Import type

- Template import: Import standard templates from other projects for quick reuse.
- Version restore: Restore the project to a previous state by importing an older version file.
- During import, the software determines whether to import based on the template GUID.
  GUID information can be viewed in the properties of each node.

Import rules

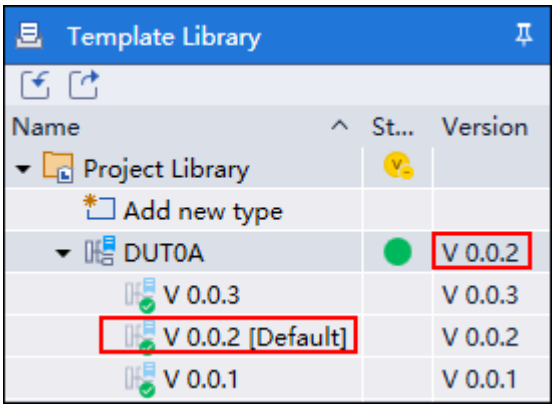
- GUID and name match: If the GUID and name of the imported object exactly match those of an existing object, the software will prevent the import of that object.
- GUID matches but name differs: If the GUID matches but the name differs, the name of the imported object will be changed to match the name in the imported file.
- GUID mismatch: If the GUID does not match, the object will be imported. If a name conflict occurs, the software will automatically rename the imported object to avoid conflicts.

Procedure

1. In the template library, select the root node (project library).
2. Right-click the node and select the "Import" command, or the icon .
3. Load the import file.
   The import file has a **.fatpl extension,** with the default name **Library.fatpl**.
4. Click "OK" to complete the import operation.

Precautions

It is recommended to export and back up the current library content before importing.



13.4.6.10 Setting as Default

The default version is the version automatically selected by the software when a template node is selected. Quick access to versions without manual selection each time is available.

When a template has multiple released versions, you can specify one of them as the default version. By default, the software automatically sets the most recently released version as the default version.

Procedure

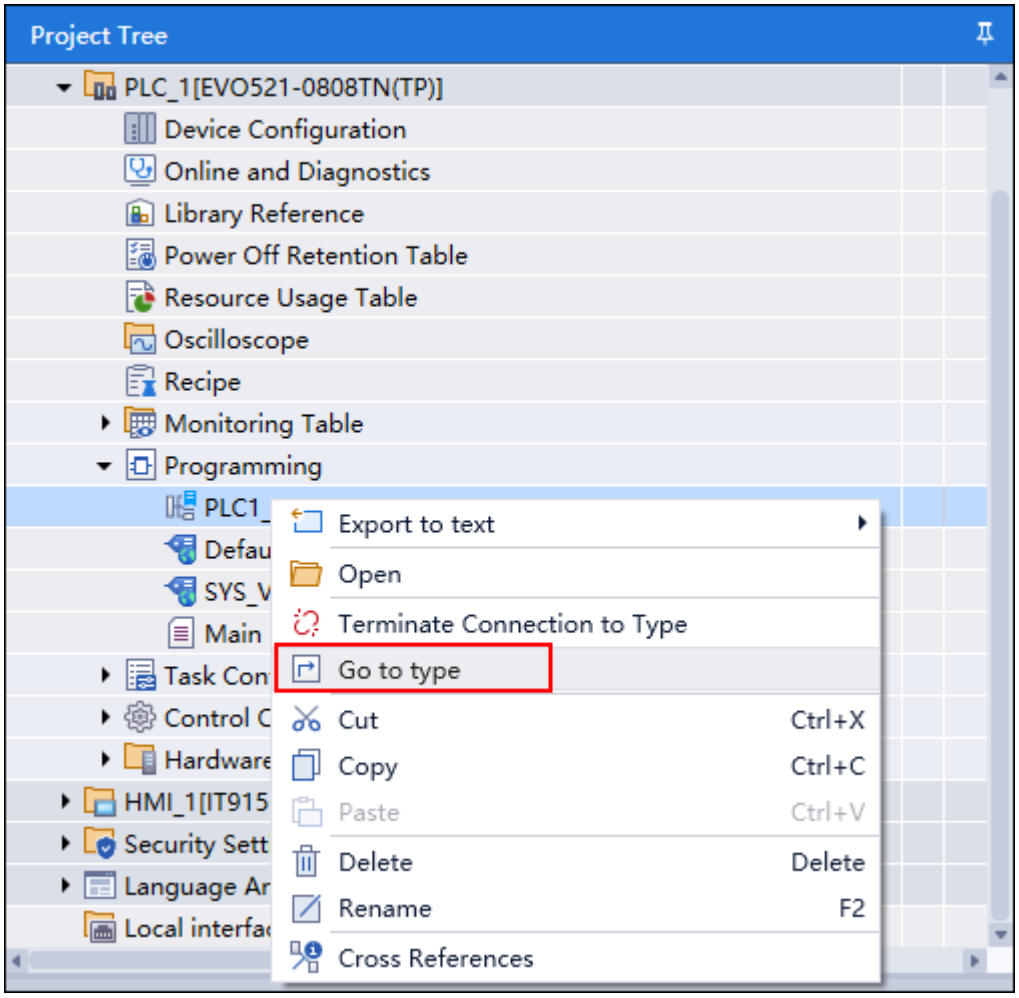
1. Select a released version node of a template that is not identified with [Default].
2. Right-click the node and select "Set as default".
3. The current node is identified with [Default], and the template node also displays the default version number.

13.4.6.11 Synchronizing PLC Types

Synchronizing PLC type refers to synchronizing changes in structure definitions on the PLCs to the template library, enabling templating of the latest definitions.

Any of the following member changes related to structure definitions will trigger a synchronization flag.

- Name
- Data type
- Initial value
- Network public property
- Comment
- Properties
- Quantity



When the definition type of the PLC's structure changes, the corresponding node in the template library will be automatically marked with .

Procedure

1. Select a template version.

   In the template library, select the node version marked with .

   If there are multiple versions marked with , use the "Go to type" command in the PLC to locate the corresponding template version.

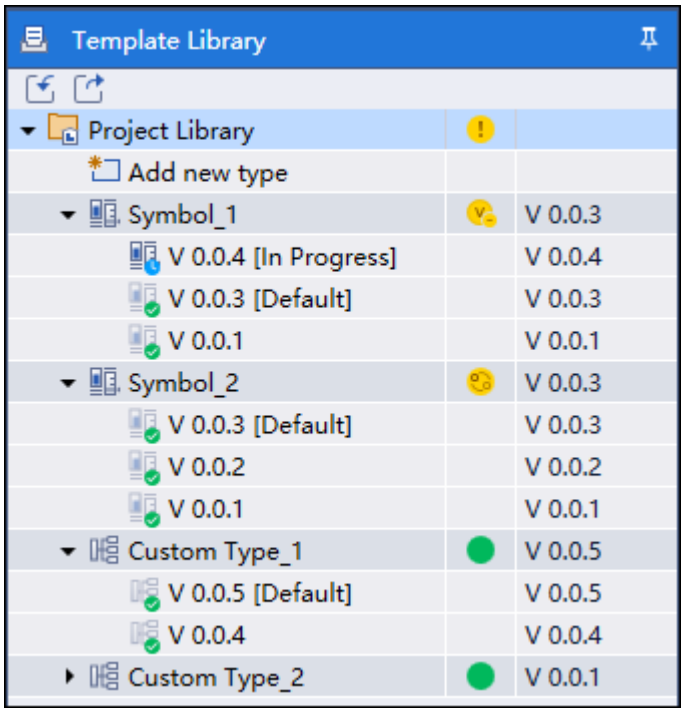
2. Initiate the synchronization command.
   Right-click the selected version and select "Sync PLC type".
3. Determine synchronization scope.
   - Select the PLC devices.
     Check the PLC(s) to sync from the list.
     If a version is applied to multiple PLCs, ensure the correct PLCs are selected.
   - Select synchronization mode.
     If the structure type has nested relationships, you can update all related templates or only update the current template.
4. Auto-update.
   After confirming the settings, the system automatically completes the synchronization.

Result

If the changes meet the prerequisites for templatization, the version will automatically be upgraded by one version; otherwise, the upgrade fails.

13.4.7 Copying and Pasting a Template Across Projects

Templates can not only be used within a single project, but also reused across projects. Whether it is an entire template library, a single template type, or a specific version (such as V 0.0.2), they can all be copied and pasted for use in different projects.



Copy

- Prerequisite
  The copy operation is limited to released templates only, excluding any template instances.

- Procedures

  Take the entire template library as an example to illustrate steps.

  1. Select the root node of the project library

  2. Right-click and select the "Copy" command

Paste

- Procedure

  1. In the template library of the target project, select the root node "Project library".

  2. Right-click and select the "Paste" command.

     First paste of the template

     The software will follow these rules:

     a. First, check whether the GUID of the copied object (viewed in the "Property" window of the type node) is the same as that of an existing type in the target project. If they are different, the paste operation is performed.

     b. Second, check for naming conflicts. If a name conflict occurs, the new type will be renamed during pasting; if no conflict exists, paste directly.

     c. Finally, check whether the property GUIDs of each version of the type are identical. If they differ, paste operation will be performed even if the version numbers (e.g. V0.0.3) are the same, which may result in two identical versions coexisting.

     If the copied type contains nested structures, all related types and versions will be pasted together during the paste operation.

     After the template is pasted, the status related to instance references changes to , while other statuses remain unchanged.

     Subsequent multiple pastes of the same template

     After a template is pasted into the target project, if the template in the source project is updated (for example, a new version is added) and copied to the target project again, you need to specify the update method when the hierarchy of the paste location is different from the node hierarchy in the source project.

     A settings dialog will pop up during pasting

Update the structure of target library: Maintain the node hierarchy of the template consistent with that in the source project.
Keep the structure of target library : Maintain the current node hierarchy of the pasted object within the target library without adjustment.

13.4.8 Copying and Pasting a Template Instance Across Projects

In practical applications, template instances support cross-project copy and paste, which is a key operation for rapid device configuration. During the copy and paste process, the software automatically synchronizes and pastes related templates based on instance dependencies. However, due to differences in template application scope within projects, there are limitations on the templates that can be associated during instance pasting.

Template type and application location

- PLC structure type (template): Used for PLC variable tables to define standardized data types.
- HMI structure data type: Used for HMI variable tables and dynamically bound to screens.
- Symbol template: Used as a visual unit in user screens, forming a unified style for monitoring interfaces.

Copy

1. Select the instance node in the source project tree.
2. Right-click and select the "Copy" command.

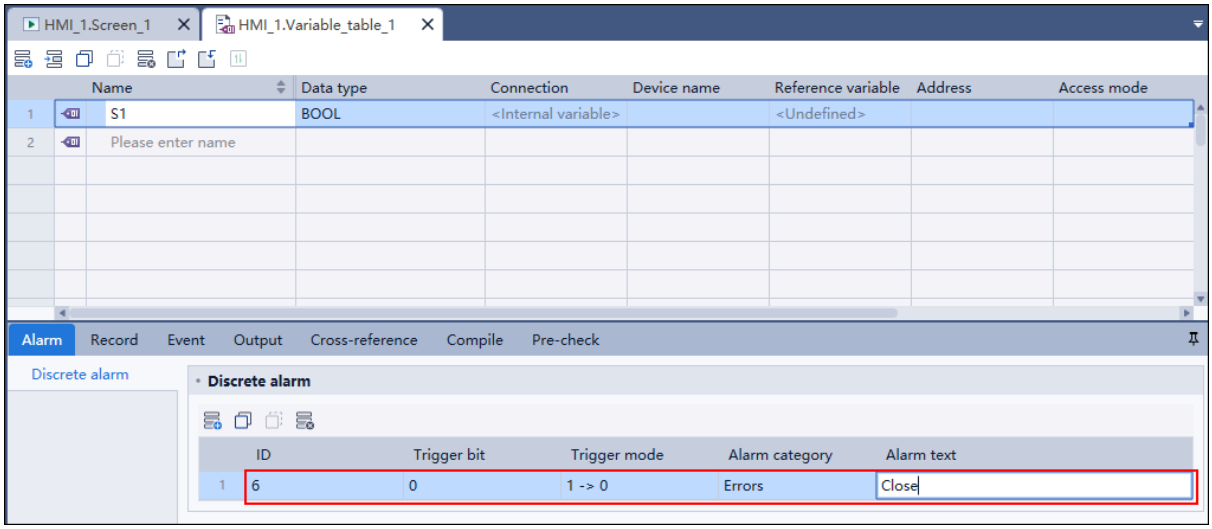
Paste

1. On the target project tree, select the node where you want to paste (e.g., the "Screen" node or the "Variable" node under the HMI device).
2. Right-click and select the "Paste" command.

Table13-4-8-1 Differences in paste results

Copied Object	Pasted Result	Remarks
HMI variable table	The referenced types in the variable table and template library will be pasted together.	If external variables are associated with public PLC variables, the association relationships in the variable table need to be manually restored after pasting.

Copied Object	Pasted Result	Remarks
HMI screen	The screen and the associated symbol templates in the template library (including the versions used), as well as the reference types they depend on, will be pasted together.	If the interface variables of the symbol template reference a template type of a PLC structure, they will be pasted together.
PLC variable table	Variable information	Before pasting the variable table, complete the copy-paste of the structure type first. Otherwise, the data type of the variable instance will cause an error, and the "Network public" status will change from "Public" to "Private".



13.5 Alarm Usage

- 13.5.1 Discrete Alarm Configuration
- 13.5.2 Analog Alarm Configuration
- 13.5.3 System Event Configuration
- 13.5.4 Alarm Category Configuration
- 13.5.5 Alarm Group Configuration
- 13.5.6 Historical Alarm Records
- 13.5.8 Alarm Runtime Configuration
- 13.5.9 Alarm Application Example

13.5.1 Discrete Alarm Configuration

Discrete alarms are triggered by changes in the switch state of a variable.
To create a discrete alarm, follow these steps:

1. Double-click the variable table in the project tree to open the variable table editor.
2. Select the boolean or integer variables created in the variable table.
3. Configure the alarm under "Alarm" in the monitoring area.

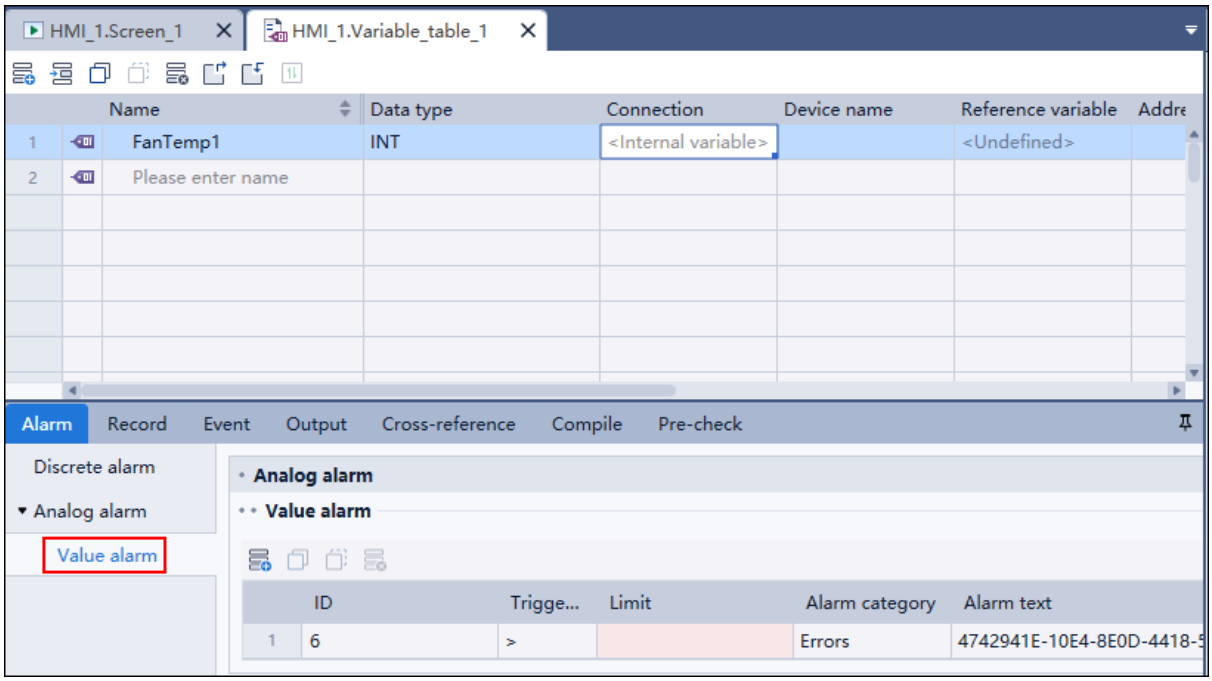
Property	Description	Restriction
ID	Unique identifier for the alarm.	IDs of discrete and analog alarms must not duplicate within the same HMI device. Supports manual settings. Range: 1 to 2,147,483,647.
Trigger bit	Variable bit that triggers the alarm.	For Boolean variables, the bit number must be 0. For integer variables, the bit number must be within the allowed range of the data type. For example, the bit number can only be set to 0 to 7 for a SINT type variable.
Trigger mode	Alarm trigger mode.	Supports 0->1, 1->0, ==0, and ==1. ◦ 0->1: Rising edge alarm. ◦ 1->0: Falling edge alarm. ◦ ==1: Alarm when the value is 1. ◦ ==0: Alarm when the value is 0.
Alarm category	Categorizes alarms into different types.	Range: "Error", "Alarm", and user-defined alarm types.
Alarm Text	The message displayed when the alarm is triggered	Max. length: 256 English characters.

One variable can have multiple alarm conditions. Each HMI device supports a maximum of 5000 alarm conditions (combined total for discrete and analog alarms).

13.5.2 Analog Alarm Configuration

Users can configure alarms via the "Value alarm" tab. In the variable alarm editor, you can view the configured variable alarms.

Value alarm is used to trigger an alarm when a variable value meets certain conditions.

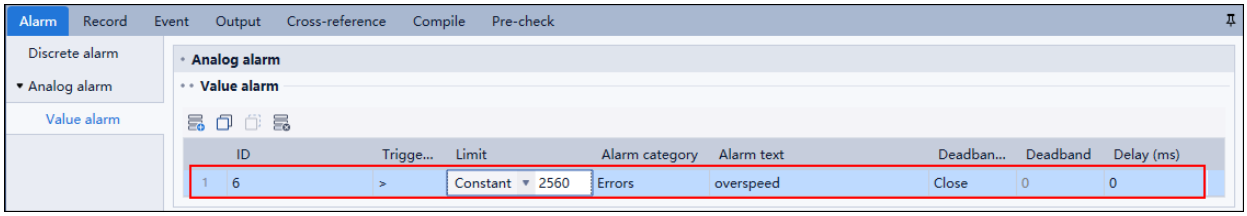


Creating value alarms

Prerequisites

- A project has been created.
- An HMI device has been added.

Procedure



1. Expand "Variable" in the left project tree and double-click "Add" to add a variable table.
2. Add variables in the variable table.
3. Go to "Alarm > Value alarm" in the monitoring area.

4. Add rows to add value alarms.
   One variable can have multiple alarm conditions. Each HMI device supports a maximum of 5000 alarm conditions (combined total for discrete and analog alarms).

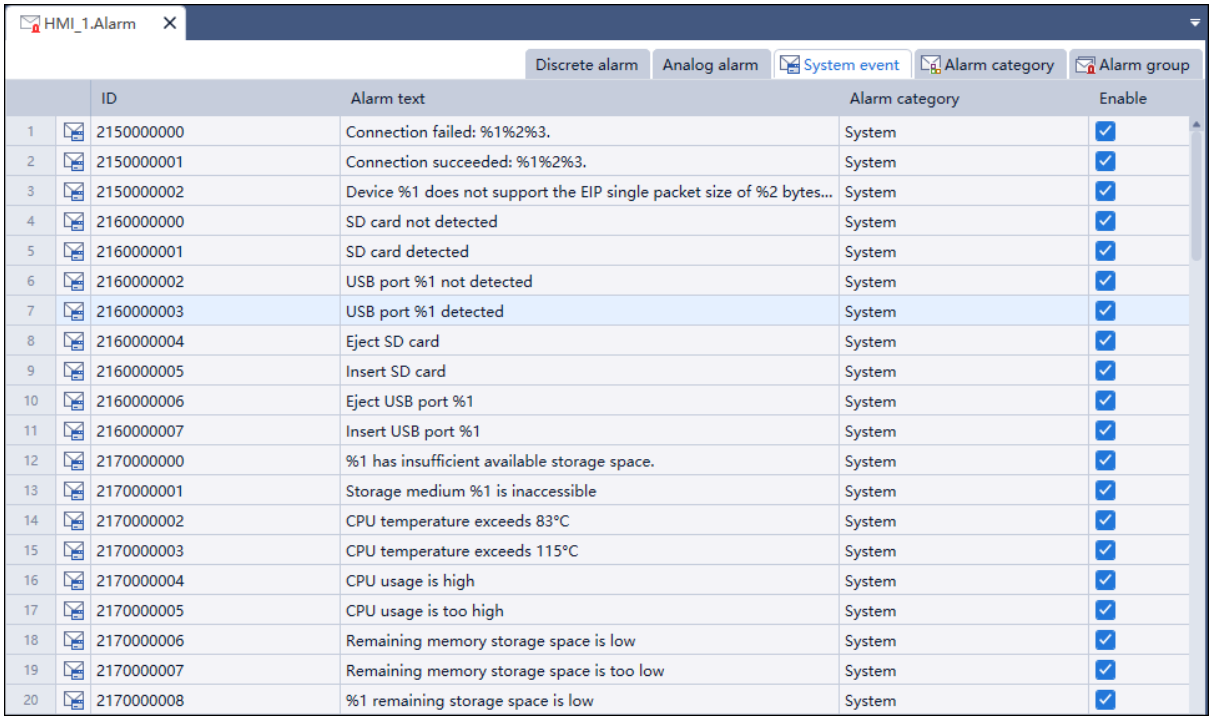
Editing value alarms

In the value alarm editor, alarm conditions can be specified.

Add or delete alarm conditions by adding or deleting rows.

The table below lists the properties of value alarms and their related explanations.

Property	Description	Restriction
ID	Unique identifier for the alarm.	IDs of discrete and analog alarms must not duplicate within the same HMI device. Supports manual settings. Range: 1 to 2,147,483,647.



Property	Description	Restriction
Trigger mode	The condition used to compare the variable trigger value with the limit value.	Supports <, > (default), ==, !=, <=, and >=.
Limits	Value to compare against the variable trigger value to determine whether to trigger an alarm.	Default is an empty constant. It can be a constant or a variable. • Constant: The constant must not exceed the range of the data type of the variable configured for the alarm (e.g., if the variable is of type SINT, the limit range is -128 to 127). • Variable: Only integer and floating-point variables are supported, but the variable itself cannot be selected as the limit.
Alarm category	Categorizes alarms into different types.	Synchronizes with the configured alarm categories (excluding system and user-defined alarm categories).
Alarm Text	The message displayed when the alarm is triggered	Max. length: 256 English characters.
Deadband mode	Sets a variable range. If the variable value fluctuates but stays within this range, no alarm is generated.	Options: Disabled (default), "When activated", "When restored", "When activated/restored". The dead zone mode is grayed out when the trigger mode is set to == or !=.
Deadband	Variable range of the deadband.	The maximum value cannot exceed the range of the data type.
Delay (ms)	When the variable meets the alarm condition, the trigger condition is re-evaluated after the delay time. • If the condition is still met, the alarm is triggered. • If the variable value changes and the alarm would recover, the timer stops.	The default value is 0 ms, with a range of 0 to 600000.

13.5.3 System Event Configuration

The HMI project supports system event configuration. System events refer to alarms or status information generated by internal system modules (such as VNC, resources, and scripts). They can also be regarded as system alarms triggered when runtime behavior deviates from expectations.

Double-click "Alarm" under an HMI device in the project tree. On the "System event" tab, check the event types to be monitored and recorded. Only checked events will be monitored and recorded by the system.

1.

	ID	Alarm text	Alarm category	Enable
1	2150000000	Connection failed: %1%2%3.	System	☑
2	2150000001	Connection succeeded: %1%2%3.	System	☑
3	2150000002	Device %1 does not support the EIP single packet size of %2 bytes...	System	☑
4	2160000000	SD card not detected	System	☑
5	2160000001	SD card detected	System	☑
6	2160000002	USB port %1 not detected	System	☑
7	2160000003	USB port %1 detected	System	☑
8	2160000004	Eject SD card	System	☑
9	2160000005	Insert SD card	System	☑
10	2160000006	Eject USB port %1	System	☑
11	2160000007	Insert USB port %1	System	☑
12	2170000000	%1 has insufficient available storage space.	System	☑
13	2170000001	Storage medium %1 is inaccessible	System	☑
14	2170000002	CPU temperature exceeds 83°C	System	☑
15	2170000003	CPU temperature exceeds 115°C	System	☑
16	2170000004	CPU usage is high	System	☑
17	2170000005	CPU usage is too high	System	☑
18	2170000006	Remaining memory storage space is low	System	☑
19	2170000007	Remaining memory storage space is too low	System	☑
20	2170000008	%1 remaining storage space is low	System	☑

The following describes each type of configurable system event. The system event ID consists of 10 digits, with the following encoding rules:

- First three digits: Represent the event category. The specific correspondence is as follows:
  - 215: Communication events
  - 216: External device events
  - 217: System resource events
  - 218: Alarm events
  - 219: Variable events
  - 220: Recording events
  - 221: User management events
  - 222: Script events
  - 223: System events
  - 224: Recipe events
- Last seven digits: Represent specific events within each category.

Communication events (215)

Alarm ID	Alarm Text	Description
2150000000	Connection failed: %1%2%3	Triggered when a connection to another device fails. The first field is the connection name, the second is the device name, and the third is the link information. If the device name is empty, it is omitted. For USB devices, link information is not displayed. **Ethernet port example** Connection failed: Connection_1, PLC_1, 192.168.0.1. Connection failed: Connection_1, 192.168.0.1. **Serial port example** Connection failed: Connection_1, PLC_1, COM1. Connection failed: Connection_1, COM1. **USB example** Connection failed: Reader 1, PLC_1. Connection failed: Reader 1.
2150000001	Connection succeeded: %1%2%3	Triggered when a connection to another device succeeds.
2150000002	Device %1 does not support the EIP packet length (%2 bytes) set by FA. The maximum supported length is %3 bytes.	For Inovance EIP protocol, if the configured maximum packet length exceeds the PLC's supported limit, it is automatically adjusted to the supported range. Example: The maximum packet length for Connection_1 is automatically adjusted to 1994 bytes.

External device events (216)

Alarm ID	Alarm Text	Description
2160000000	SD card not detected	This event is sent at device startup.
2160000001	SD card detected	
2160000002	USB port %1 not detected	This event is sent at device startup. Example: USB interface USB1 not detected.
2160000003	USB port %1 detected	
2160000004	SD card removed	This event is sent when an SD card is removed/inserted during runtime.
2160000005	SD card inserted	
2160000006	USB port %1 removed	This event is sent when a USB storage device is removed/inserted during runtime. Example: USB port USB1 removed.
2160000007	USB port %1 inserted	

System resource events (217)

Alarm ID	Alarm Text	Description
2170000000	%1 has insufficient available storage space	Triggered when there is not enough storage space for data storage operations. Example: The SD card has insufficient available storage space.
2170000001	%1 storage medium is inaccessible	Triggered when the storage medium cannot be accessed. Example: The SD card storage medium is inaccessible.
2170000002	CPU temperature exceeds 83°C	Triggered when the HMI device CPU temperature exceeds 83°C.
2170000003	CPU temperature exceeds 115°C	Triggered when the HMI device CPU temperature exceeds 115°C.
2170000004	CPU usage is high	Triggered when CPU usage is ≥ 80%.
2170000005	CPU usage is too high	Triggered when CPU usage is ≥ 90%.
2170000006	Remaining memory space is low	Triggered when memory usage is ≥ 80%. The meaning of memory space is consistent with the system variable.
2170000007	Remaining memory space is too low	Triggered when memory usage is ≥ 90%.
2170000008	%1 remaining storage space is low	Triggered when storage usage on the runtime data path or recording path is ≥ 80%.
2170000009	%1 remaining storage space is too low	Triggered when storage usage on the runtime data path or recording path is ≥ 90%.

Alarm events (218)

Alarm ID	Alarm Text	Description
2180000000	Overflow, pending alarms will be discarded	Triggered when too many alarms are triggered in a short time. When more than 10,000 alarms are queued for processing, the real-time alarm view will not display all alarms, and alarm data will not be written to the log file. The upper limit varies by specific device.
2180001000	%1 unlocked successfully	-
2180001001	All installments unlocked successfully	All installments unlocked successfully.
2180001002	%1 unlock failed	-
2180001003	System time modification failed	System time modification failed.

Alarm ID	Alarm Text	Description
2180001004	Trusted time recovery succeeded after RTC failure; restored to %1	When the device's internal clock (RTC) resets to its initial value (e.g., 1970) due to battery depletion or other reasons, the system will automatically detect this anomaly. It then uses the last saved trusted time record to restore the current time and generates this alarm. The "%1" in the alarm will be automatically replaced with the actual date and time restored to.

Recording events (220)

Alarm ID	Alarm Text	Description
2200000000	Record: %1, full	Triggered when a data record or alarm record becomes full. Example: Record: Data record_1, full.
2200000001	Record: %1, fill level has reached %2%	Triggered when a data record or alarm record reaches its fill threshold. Example: Record: %1, fill level has reached %2%
2200000002	Storage log task backlog of %1 entries, backlogged data discarded	Example: Storage log task backlog of 1 entry, backlogged data discarded
2200000003	Data record %1 cleared	Example: Data record 1 from the operation record cleared.
2200000004	Failed to clear data record %1	Example: Failed to clear data record 1 from the operation record.
2200000005	Alarm record %1 cleared	Example: Alarm record 1 from the operation record cleared.
2200000006	Failed to clear alarm record %1	Example: Failed to clear alarm record 1 from the operation record.
2200000007	Operation record %1 cleared	Example: Operation record 1 from the operation record cleared.
2200000008	Failed to clear operation record %1	Example: Failed to clear operation record 1 from the operation record.
2200000009	All data records deleted before loading project	-
2200000010	All alarm records deleted before loading project	-
2200000011	All operation records deleted before loading project	-

User management events (221)

Alarm ID	Alarm Text	Description
2210000000	User %1 has logged in	One login event and one logout event are recorded when switching users.
2210000001	User %1 has logged out	
2210000002	Login failed: Invalid user or password	-
2210000003	Login failed: User is locked	-
2210000005	Logout failed	-
2210000006	Password for user %1 has been changed	Example: Password for user User1 has been changed.
2210000007	Role of user %1 has been changed from %2 to %3	Example: Role of user User1 has been changed from monitoring observer to monitoring observer/ monitoring operator.
2210000008	Logout time for user %1 has been changed from %2 to %3	Example: Logout time for user User1 has been changed from 5 minutes to 10 minutes.
2210000009	User %1 has been renamed to %2	Example: User User1 has been renamed to User2.
2210000010	Comment for user %1 has been changed from %2 to %3	Example: Comment for user User1 has been changed from Comment1 to Comment2.
2210000011	User %1 added	Example: User User1 added.
2210000012	User %1 deleted	Example: User User1 deleted.
2210000013	Export users failed	Example: Export users failed.
2210000014	Export users succeeded	Example: Export users succeeded.
2210000018	Import users failed	Example: Import users failed.
2210000019	Import users succeeded	Example: Import users succeeded.
2210000025	User %1 locked for %2	Manual lock. Example: User User1 locked for 1 minute.
2210000026	User %1 unlocked	Manual unlock. Example: User User1 unlocked.
2210000027	User %1 has made %2 consecutive failed login attempts and the account has been automatically locked	Example: User User1 has made 1 consecutive failed login attempt and the account has been automatically locked.
2210000028	Lock time for user %1 has expired, and the account has been automatically unlocked	Example: Lock time for user User1 has expired, and the account has been automatically unlocked.
2210000029	Failed to get current user login information: %1	-

Alarm ID	Alarm Text	Description
2210000030	User management data cleared before loading project	-

Script events (222)

Alarm ID	Alarm Text	Description
2220000000	Overloaded, script <%1> is rejected	Triggered when too many scripts are triggered in a short time. When more than 128 scripts are queued for processing, all subsequent scripts will be rejected. The upper limit varies by specific device. Example: Overloaded, script <script1> is rejected.
2220000001	Error at line %2 in script <%1>, %3	Triggered when an error occurred in the script, and script execution will be aborted. Example: Error at line 10 of script <script1>, division by zero.

System events (223)

Alarm ID	Alarm Text	Description
2230000000	Start runtime system	Recorded when the runtime system starts.
2230000001	Stop runtime system	Recorded when the runtime system stops. This event can be recorded when manually stopped, but cannot be recorded during power failure.
2230000002	Project downloaded from USB %1 succeeded	Example: Project downloaded from USB1 succeeded.
2230000003	Project downloaded from USB %1 failed	Example: Project downloaded from USB1 failed
2230000004	Project downloaded from SD card succeeded	Example: Project downloaded from SD card succeeded.
2230000005	Project downloaded from SD card failed	Example: Project downloaded from SD card failed.
2230000006	Project downloaded from software %1 succeeded	Example: Project downloaded from IDE succeeded.
2230000007	Project downloaded from software %1 failed	Example: Project downloaded from IDE failed.
2230000008	Project uploaded to software %1 succeeded	Example: Project uploaded to IDE succeeded.
2230000009	Project uploaded to software %1 failed	Example: Project uploaded to IDE failed.
2230000010	Firmware updated from USB %1 succeeded	Example: Firmware updated from USB1 succeeded.

Alarm ID	Alarm Text	Description
2230000011	Firmware updated from USB %1 failed	Example: Firmware updated from USB1 failed.
2230000012	Firmware updated from SD card succeeded	Example: Firmware updated from SD card succeeded.
2230000013	Firmware updated from SD card failed	Example: Firmware updated from SD card failed.
2230000014	Firmware updated from software %1 succeeded	Example: Firmware updated from IDE succeeded.
2230000015	Firmware updated from software %1 failed	Example: Firmware updated from IDE failed.
2230000016	Factory reset succeeded (excluding physical keys)	-
2230000017	Factory reset failed (excluding physical keys)	-
2230000018	Device IP changed from %1 to %2	Recorded when the IP address changes. Example: Device IP changed from 192.0.0.1 to 192.0.0.2.
2230000019	Device IP changed from %1 to %2 failed: Invalid IP address	Example: Device IP changed from 192.0.0.1 to 192.0.0.2 failed: Invalid IP address
2230000020	System time changed from %1 to %2	Recorded when the system time changes. Example: System time changed from 2025/08/19 16:00:00 to 2025/08/22 16:00:00.
2230000021	System time changed from %1 to %2 failed: Invalid time	Triggered when the user attempts to change the device time to a non-existent or invalid time value. "%1" represents the original time, and "%2" represents the target time that failed. Example: Failed to change system time from August 1 to August 32 (non-existent).
2230000022	Failed to change system time from %1 to %2: Installment plan or non-permanently locked user exists	Example: Failed to change system time from 2025/08/19 16:00:00 to 2025/08/22 16:00:00: Installment plan or non-permanently locked user exists.

Recipe events (224)

Alarm ID	Alarm Text	Description
2240000000	Recipe %1 import succeeded	Example: Recipe Recipe1 import succeeded.
2240000001	Recipe %1 import failed	Example: Recipe Recipe1 import failed.
2240000002	Recipe data record %1 cleared	Example: Recipe data record Recipe1: Data record1 cleared.

Alarm ID	Alarm Text	Description
2240000003	Failed to clear recipe data record %1	Example: Failed to clear recipe data record Recipe1: Data record1.
2240000004	All recipe records deleted before loading project	-

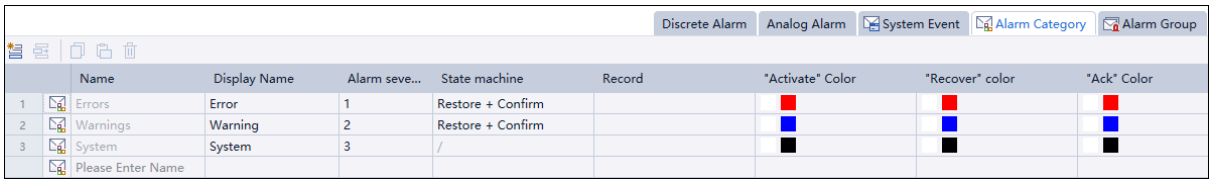
Steps

1. Double-click "Alarm" in the left project tree to open the alarm editor.
2. Click the "System event" tab.
3. Configure system events according to project requirements.
   By default, all system events are enabled. Users can check/uncheck to modify the enabled status.

13.5.4 Alarm Category Configuration

The alarm category editor supports viewing and editing predefined alarm categories. It also supports creating user-defined alarm categories and configuring properties.

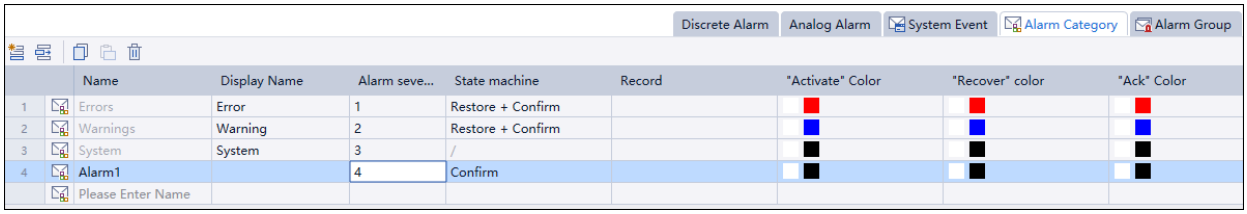
- Predefined alarm categories
  Predefined alarm classes cannot be deleted; they can only be edited within limited scope. There are predefined alarm categories created by the system for each device (in "Alarm > Alarm category").
- User-defined alarm categories
  Users can create new alarm classes in "Alarm > Alarm category" and configure how alarms are displayed.



Creating an alarm category

In the "Alarm category" table editor, you can create user-defined alarm categories and configure their properties. A maximum of 32 alarm categories can be created in total.

Procedure



To create an alarm category, follow these steps:

1. Double-click "Alarm" in the left project tree to open the alarm editor.
2. Click the "Alarm category" tab to display predefined alarm categories and existing user-defined alarm categories. The table below lists the predefined alarm categories.

3. Create a new alarm class using the following three methods:
   - Click the "Add row" icon in the toolbar above the table header.
   - Enter a name in the virtual row, then click elsewhere.
   - Right-click and select "Add row".

All of the above methods will automatically create a default alarm category.

Editing an alarm category

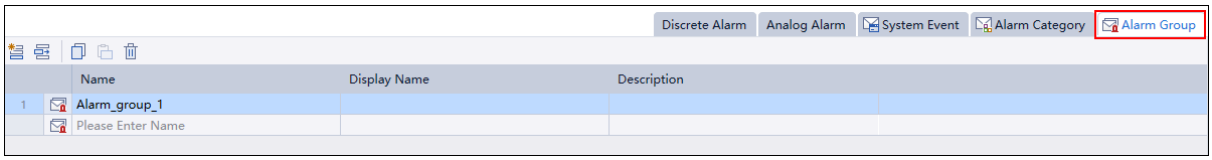
In the alarm category editor, you can edit the properties of each category. The properties are described in the following table.

Item	Description
Name	Alarm category name is unique. The name can contain Chinese and English characters, numbers, underscores ("_"), and hyphens ("-"), with a maximum length of 128 characters and cannot be empty. The names of the predefined alarm categories are respectively "Error", "Alarm", and "System". They cannot be modified.
Display name	Descriptive text for the alarm category. Max. length: 128 characters. Default is empty. For predefined categories, the display name defaults to the same value as the name ("Error", "Alarm", and "System").
Alarm level	Used by operators to distinguish the urgency of alarms. The configurable range is 1 to 999, with smaller numbers indicating higher urgency. Default emergency order: Error > Alarm > System.
Alarm reset method	Options include "Restore + Confirm" (default), "Restore", "Confirm", and "None". Restore + Confirm: The alarm is removed from the real-time alarm list only after both the restore condition is met and the user confirms it. Confirm: The alarm is removed from the real-time alarm list only after the user confirms it. Restore: The alarm is automatically removed from the real-time alarm list after the restore condition is met. None: The alarm does not appear in the real-time alarm list; this is used only for "System" alarms.
Record	You can select from the configured alarm records. Different alarm categories can use the same record or different records.
Activated color	Sets the background color, font color, and whether the alarm flashes when it is activated. By default, the background color is white, the font color is black, and the alarm does not flash. The font color for error categories defaults to red, alarm categories defaults to blue, and system categories defaults to black. The background color for all three categories defaults to white, with no flashing.

Item	Description
Restored color	Sets the background color, font color, and whether the alarm flashes when it is restored. The configuration method and default colors are the same as for the activated color. When the alarm reset method is "Restore" or "Restore + Confirm", the restored color can be modified; otherwise, modification is disabled.
Acknowledged color	Sets the background color, font color, and whether the alarm flashes when it is confirmed. The configuration method and default colors are the same as for the activated color. When the alarm reset method is "Restore" or "Restore + Confirm", the acknowledged color can be modified; otherwise, modification is disabled.

The alarm category editor also supports copy, paste, insert, delete, undo/redo, and find/replace functions.

13.5.5 Alarm Group Configuration



To facilitate viewing, recording, and differentiation, alarm information generated by variables can be divided into different groups.

Assign alarms to various alarm groups based on the actual relationship between alarms. For example, group alarms based on error cause (e.g., "power-off") or error source (e.g., "Motor 1"). Each variable can be configured with one alarm group, and alarm information can be assigned to that alarm group.

Creating an alarm group

Create an alarm group by following these steps:

1. Double-click "Alarm" in the left project tree to open the alarm editor.
2. Click the "Alarm group" tab.

3. There are three ways to create an alarm group.
   - Click the "Add row" icon in the toolbar above the table header.
   - Enter the name in the virtual row (i.e., the last row), then click elsewhere or press the Enter key.
   - Right-click the menu row and select "Add row".

Editing an alarm group

In the alarm group editor, you can edit the properties of the alarm group. The properties are described in the following table.

Item	Description
Name	The name of the alarm group. The name must be unique and cannot be empty. The name can contain Chinese and English characters, numbers, underscores ("_"), and hyphens ("-"), with a maximum length of 128 characters.
Description	Description of the alarm group. The maximum length is 128 characters.

The alarm group editing table also supports copy, paste, insert, and delete operations.

13.5.6 Historical Alarm Records

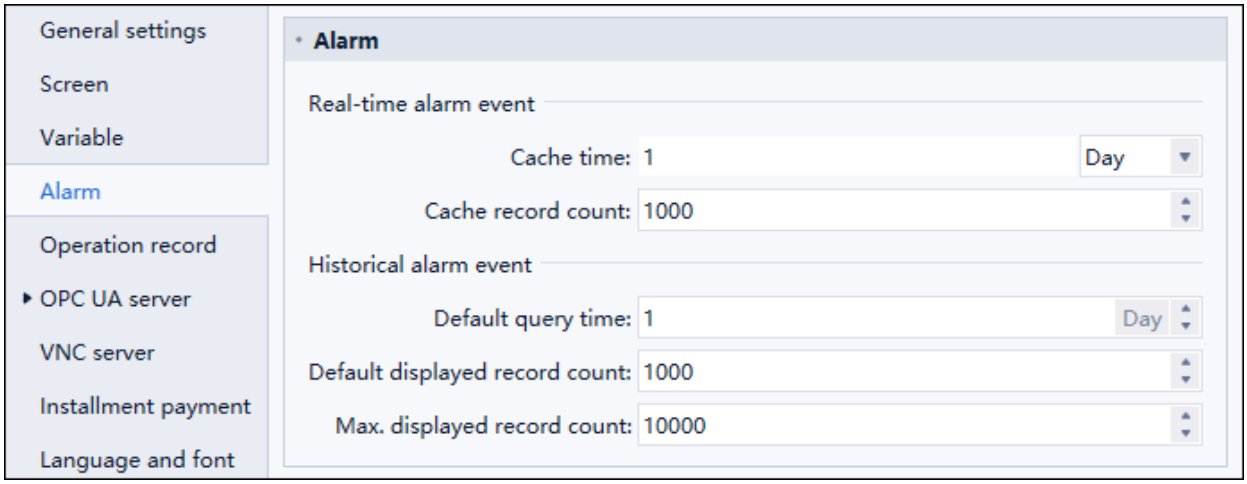
The alarm records store the alarm information generated during project operation, providing data for problem analysis and troubleshooting of project and device issues.

In "Record > Alarm record", you can create and edit the properties of alarm records.

Record content

The alarm to be recorded is assigned to the alarm record by alarm class. When the alarm status changes, the alarm record will hold the following information for the corresponding alarm:

- Alarm number
- Device name
- Alarm variable name
- Date and time the alarm occurred
- Alarm type
- Alarm level
- Alarm information
- Username
- Alarm value
- Data type of the alarm value
- Alarm group
- Alarm status
- Alarm activation time
- Alarm acknowledge time



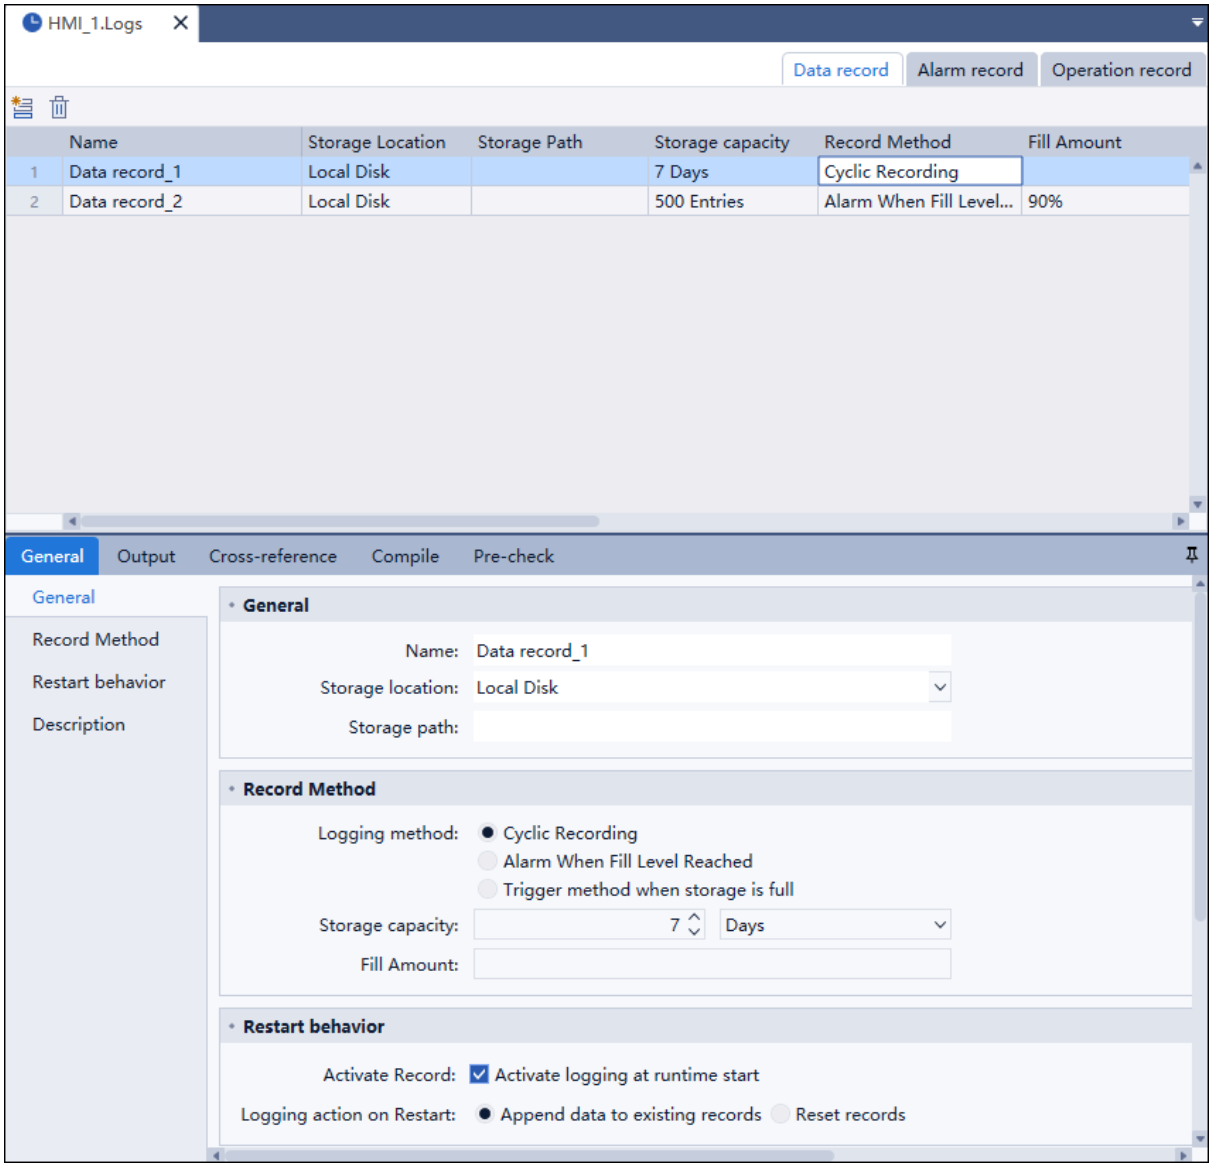
Recording timing

An alarm record will be generated when the alarm occurs, is confirmed and is restored.

Alarm records can be filtered, have their storage content controlled, and be displayed using controls. For details, see 13.3.5.4.1 Alarm View.

Controlling record storage size

Double-click "Runtime setting" in the project tree. On the "Alarm" tab, set "Real-time alarm event" and "Historical alarm event" to save records based on retention time or number of entries.



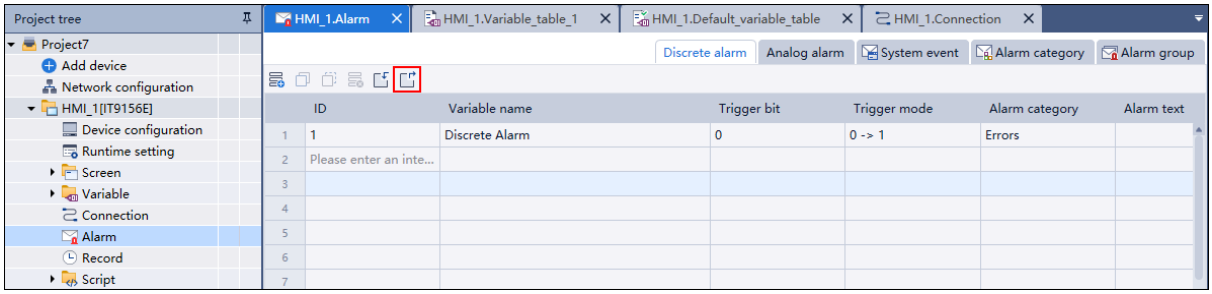
Record setting

1. Add an alarm record

   Double-click the "Record" node in the project tree and select the "Alarm record" tab.

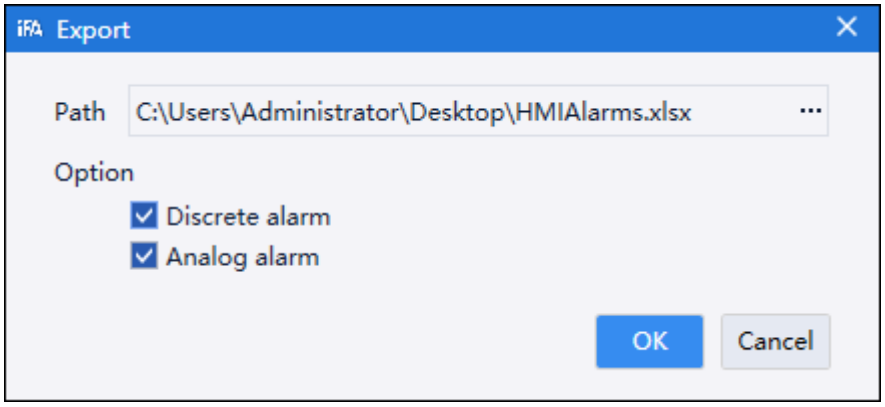
   Click  to add an alarm record.

   The property items of an alarm record are the same as those of a data record. For details, see 13.2.5.6.1 Setting Recording Rules for Data.



2. Associate alarm records in the alarm category
   Double-click the "Alarm" node, select the "Alarm category" tab, and associate alarm records in the "Record" column.

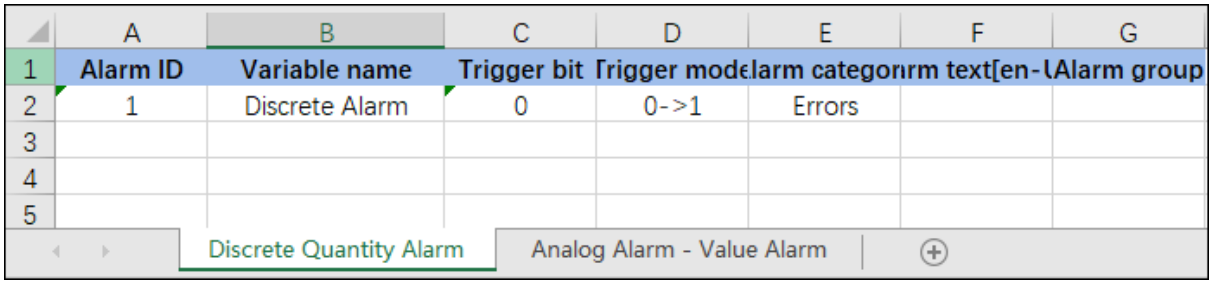
   After an alarm record is associated with a specific category, the system displays the corresponding alarm information based on the category's level and color. This enables users to quickly identify the urgency or priority of the alarm.



13.5.7 Alarm Import/Export

Exporting alarms

1. Select an HMI device in the left project tree and double-click "Alarm".
2. Click the export icon .



3. Select the file export path and check the alarm categories to export, then click "OK".

Parameter	Description	Additional information
Path	◦ The export path defaults to "C:\Users\Your Username\Desktop". ◦ The file name defaults to "HMIAlarms.xlsx".	◦ Export path and filename allow users to modify. ◦ The export file format is xlsx.
Option	◦ Discrete alarm ◦ Analog alarm	Both types can be exported simultaneously.

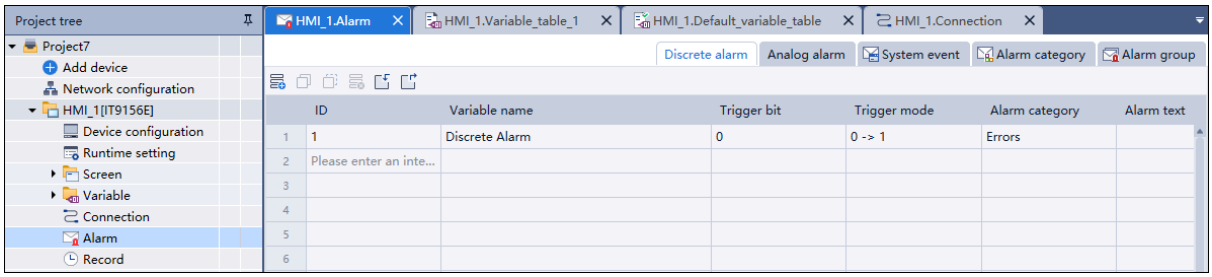
4. Wait until the system prompts "Export completed", then click "OK".
5. Open HMIAlarms.xlsx. Users can view the relevant information for each alarm ID in the "Discrete alarm" and "Analog alarm - value alarm" tables respectively. The exported content is as follows:

	A	B	C	D	E	F	G
1	Alarm ID	Variable name	Trigger bit	Trigger mode	Alarm categor	rm text[en-U	Alarm group
2	1	Discrete Alarm	0	0->1	Errors		
3							
4							
5							

Discrete Quantity Alarm | Analog Alarm - Value Alarm

Importing alarms

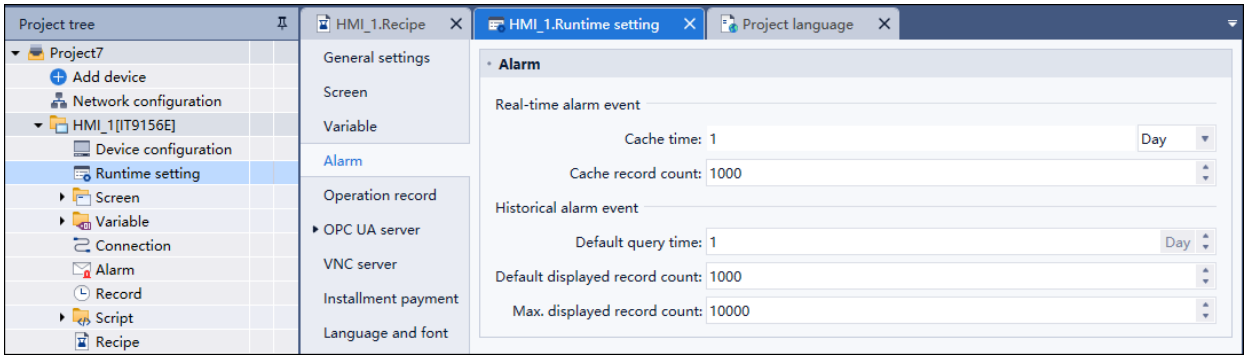
1. Select an HMI device in the left project tree and double-click "Alarm".
2. Click the import icon .



3. Select the xlsx format file to import and click "Open".

> **NOTE**
>
> - Alarm IDs to import must be unique. If the same ID exists, the new alarm will overwrite the old one.
> - The system does not delete existing data; it only performs add or overwrite operations.
> - If an alarm ID is invalid (empty, out of range, or non-numeric), that alarm row will not be imported.

4. Wait until the system prompts "Import completed", then click "OK".
5. (Optional) If there are exceptions during data import, click "Log file" to view the exception log and handle the exceptions as indicated.



6. The imported content is as follows:

13.5.8 Alarm Runtime Configuration

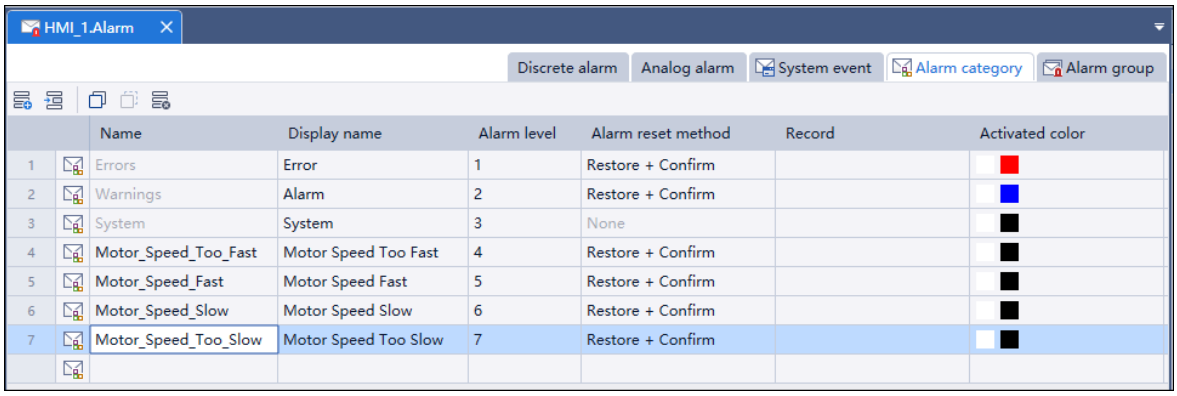
During online operation of the alarm view, the display settings related to the real-time and historical alarm events are configured on the "Alarm" tab of the "Runtime setting" node.

- Real-time alarm events
  Users can configure the alarm cache duration and the number of events displayed on "Real-time alarm event" tab in the alarm view. This allows users to review the latest alarm events within a certain time.
  Cache time: The duration during which any real-time alarm event is recorded from the moment it is generated. Range: 1 hour to 30 days.
  Cached record count: The maximum number of latest real-time alarm events cached. When the limit is reached, the system overwrites the oldest events with the newest ones. Range: 100 to 10,000.
  Downloading a project clears the real-time alarm event cache, and the cache count and duration for existing events will be reset.
- Historical alarm events
  Users can configure the alarm cache duration, and the default and maximum number of events displayed on "Historical alarm event" tab in the alarm view.
  Default query time: The duration (in days) used to query historical alarm data. This is calculated backwards from the moment the "Historical alarm event" page is opened. Range: 1 to 30.
  Default displayed record count: The number of alarm events displayed on the "Historical alarm event" page when no filter is applied. Range: 100 to 10,000.
  Max. displayed record count: The maximum number of filtered historical alarm events that can be displayed on the page. Range: 10,000 to 1,000,000.

13.5.9 Alarm Application Example

This section demonstrates how to use the alarm function to monitor the rotational speed states of an MS1 servo motor during production.

Assume the variable "rotor_speed" (type: UINT; unit: rpm) monitors the motor's rotational speed. In this case, value alarm and discrete alarm are adopted to provide notifications for abnormal speed states of the motor. First, the value alarm sets the minimum and maximum speed for the motor. When the actual speed exceeds the set range, an alarm is issued. If the motor speed is too slow, slightly slow, too fast, or slightly fast, it will trigger the corresponding value alarm. Second, the discrete alarm detects excessive acceleration based on speed rate levels. If the acceleration exceeds the acceptable limit, a discrete alarm is issued.

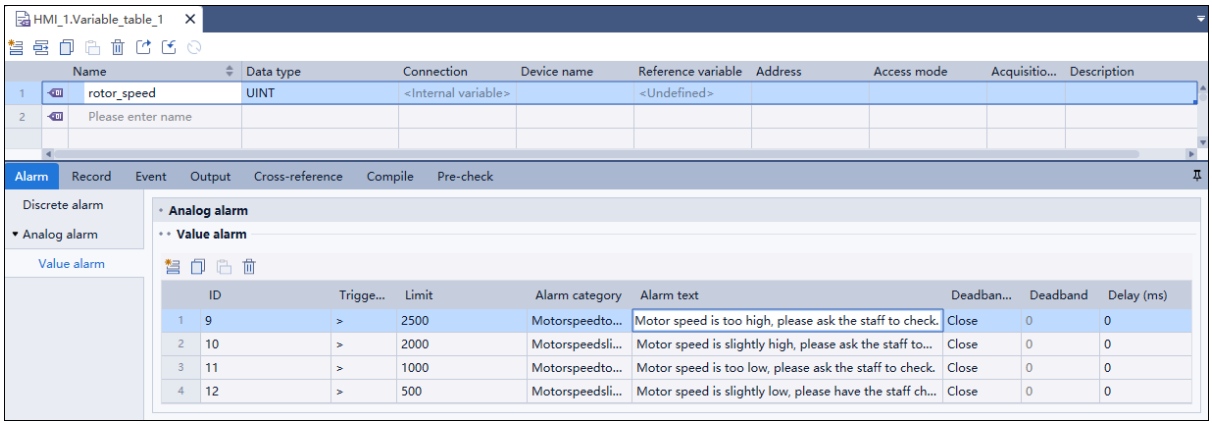


Configure alarms to monitor abnormal states of rotor_speed and use an alarm view control to display alarm information.

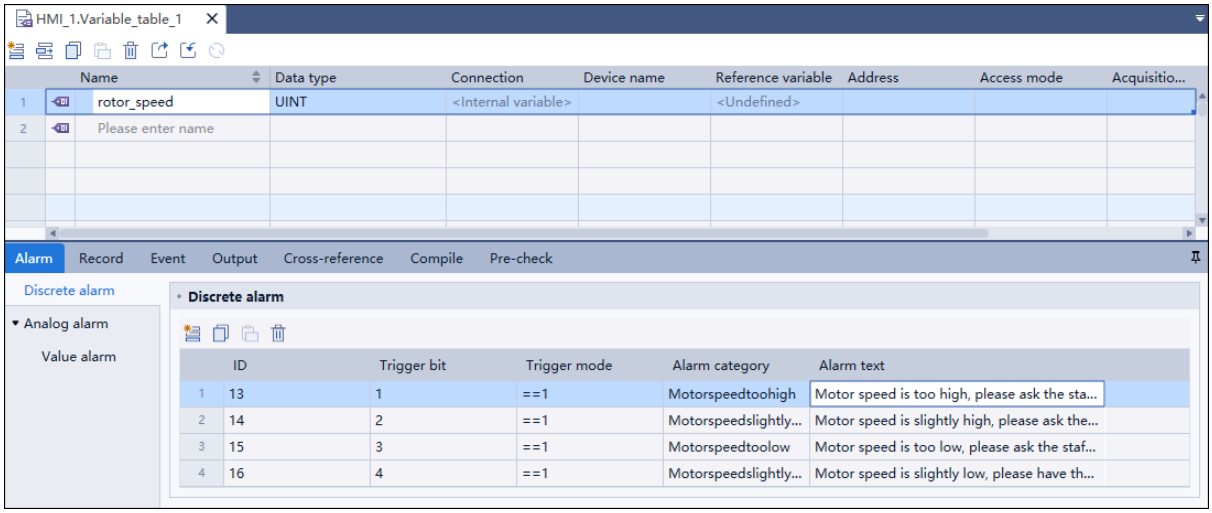
Prerequisites

- A variable of type UINT named "rotor_speed" has been created.

Procedure

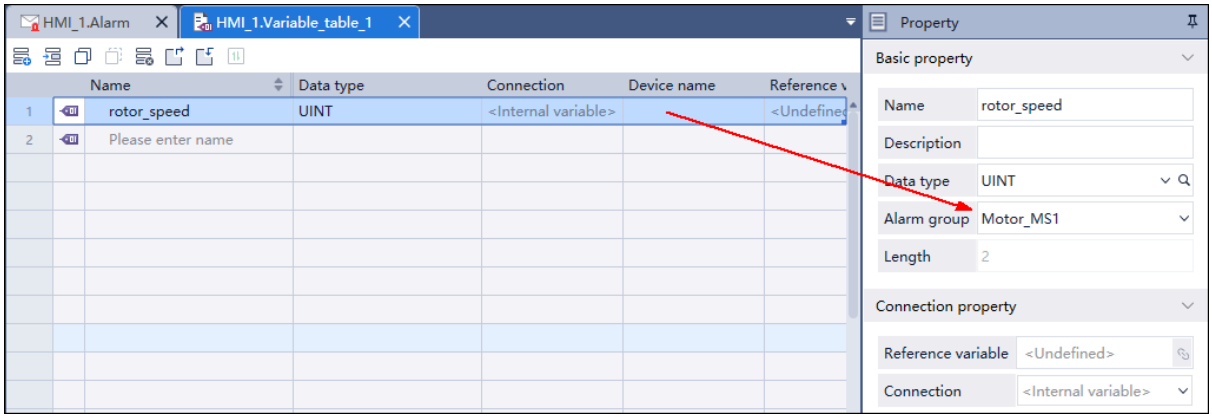


1. Define the alarm category.
   a. Click "Alarm" in the left project tree to open the alarm editor and select the "Alarm category" tab.
   b. Add the following user-defined alarm categories: "Motor speed too fast", "Motor speed fast", "Motor speed slow", and "Motor speed too slow".

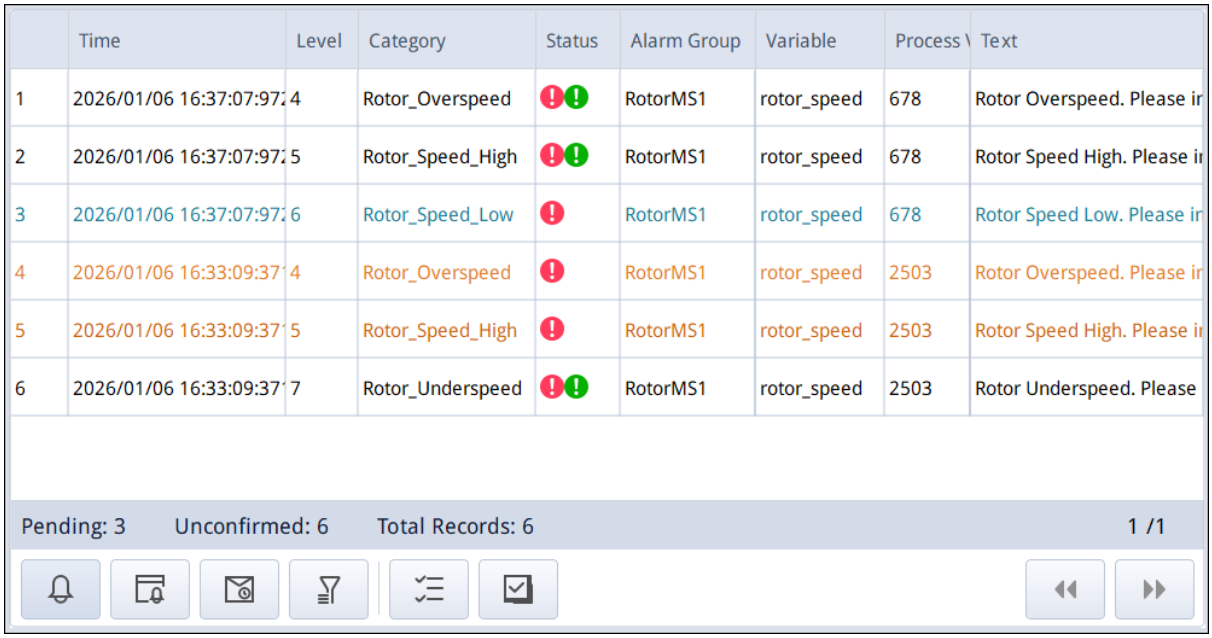


2. Add an alarm group
   On the "Alarm group" tab in the alarm editor, create a new alarm group named "Motor MS1", and add descriptive information based on the specific application scenario.

3. Configure the value alarm
   Open the variable editor for "rotor_speed". In the monitoring area, select "Alarm > Value alarm" and set the value alarm.



4. Configure the discrete alarm
   In the monitoring area, select "Alarm > Discrete alarm" and set the discrete alarm.



5. Configure the alarm group

   In the right property box of the variable "rotor_speed", set the alarm group to "Motor MS1".

6. Use the alarm control

   Create a new screen and configure the alarm view control during configuration. In runtime, the alarm view control will display abnormal information of variables. Simulate the abnormal condition of the motor speed by modifying the value of the variable "rotor_speed". The figure below shows the process by which the alarm control detects a variable's abnormal state in real time.

13.6 Recipe Usage

This chapter introduces the basic concepts of the recipe function and the offline configuration function.

- 13.6.1 Function Overview
- 13.6.2 Adding a Recipe
- 13.6.3 Modifying a Recipe
- 13.6.4 Deleting a Recipe
- 13.6.5 Copying and Pasting a Recipe
- 13.6.6 Importing and Exporting a Recipe

13.6.1 Function Overview

In the manufacturing field, a recipe refers to the proportional relationship between different raw materials used for production. Essentially, a recipe is a set of parameter values that determine the variables in the production process.

For example, a beverage plant will have a basic recipe for beverage production. This recipe lists all the necessary raw materials and their amounts, such as water, white sugar, fruit juice concentrate, edible flavors, and honey. It will also list a series of optional elements and their amounts, such as high fructose corn syrup and vitamins. These optional elements can be flexibly added to the base recipe according to market demand and product positioning, enabling the production of a variety of different flavored and functional beverages.

The table below illustrates the raw material types and their amounts for different beverages. The data is for example only and is intended to help users understand the meaning and relationships of the terms used in the recipe function. The data has not been scientifically validated and shall not be regarded as the actual content of real product elements.

Table13-6-1-1 Beverage recipe example

Element	Reconstituted Juice	Fruit Drink	Honey Water	Energy Drink
Water	300 g	350 g	360 g	340 g
White sugar	0	80 g	40 g	60 g
Fruit juice concentrate	200 g	50 g	0	30 g
Honey	0	10 g	50 g	0
Edible flavor	0	12 mg	15 mg	0
High fructose corn syrup	0	8 g	40 g	50 g
Vitamin	0	30 mg	0	80 mg

The iFA software provides recipe-related editors and visual controls, enabling recipe management and object configuration within the editor. The following explains the terms involved in the recipe configuration:
Recipe: A collection of elements and their amounts for similar products (beverages). These products share the same elements but differ in amounts. Individual products (beverages) are distinguished by their names. The table above is an overall recipe.

Element: The raw materials contained in the product, such as the first column of the table above (e.g., water, white sugar, etc.).

Data record: Data members in a recipe. A recipe contains multiple data records. These data records have the same structure but different values. In the table above, column 2/3/4 each represents a data record.

13.6.2 Adding a Recipe

Addition of the recipe:

1. Double-click "Recipe" in the project tree to open the recipe editing interface.

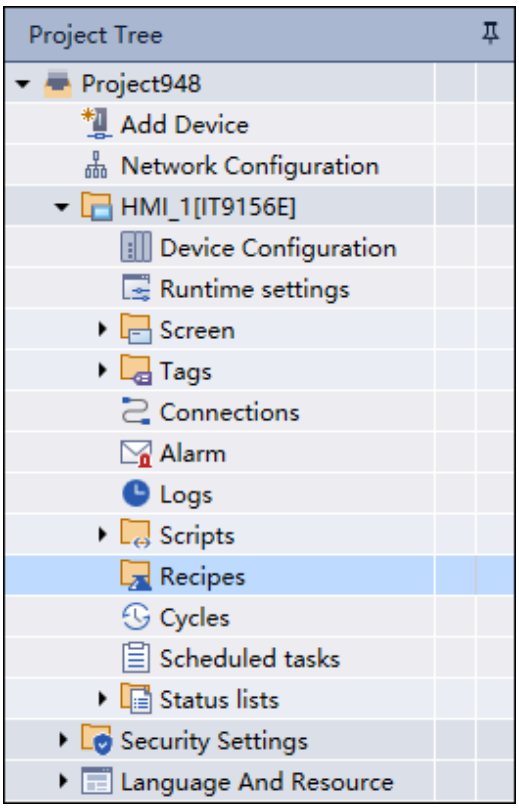


Figure 13-6-2-1 Recipe node

2. Add a recipe.

   Right-click the upper half of the editing interface and select "Add row". You can also enter text in an empty cell to add a recipe.

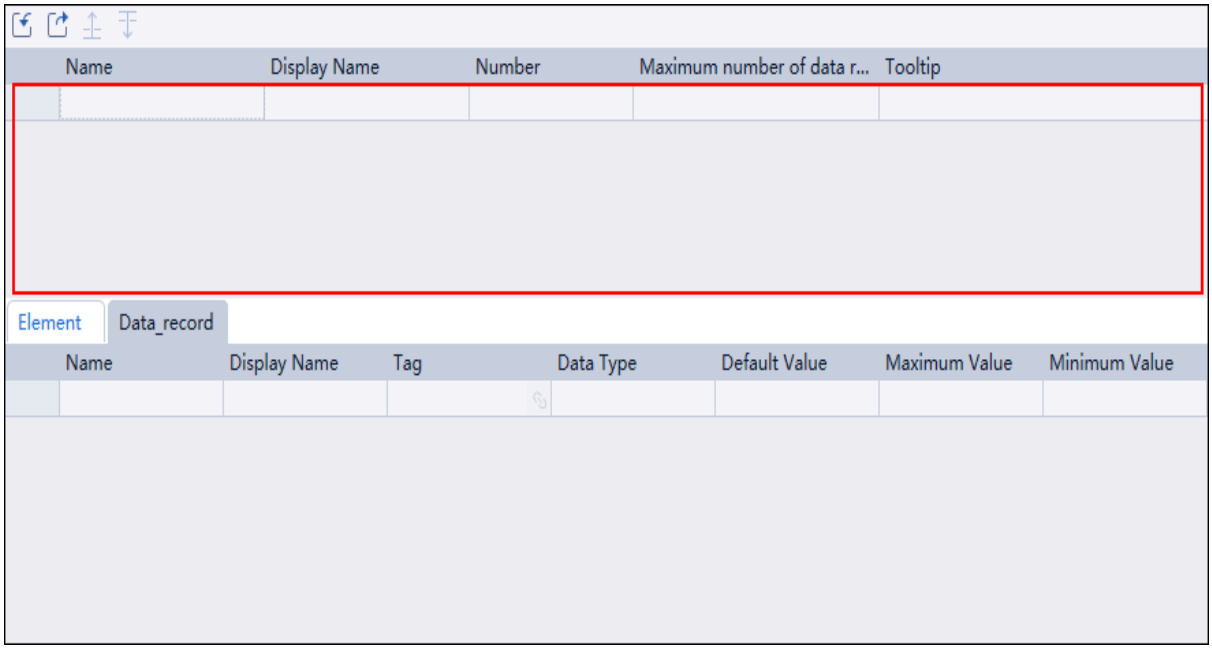

Figure 13-6-2-2 Recipe addition area

A device supports 100 recipes. The following figure shows the result of adding two recipes.

	Name	Display Name	Number	Maximum number of data records	Tooltip
1	Formula_1	Formula_1	1	1000	
2	Formula_2	Formula_2	2	1000	

Figure 13-6-2-3 Recipe addition result

Property	Description
Name	The identifier of a recipe in the software. The name supports Chinese and English characters, numbers, underscores (_), and middle hyphens (-), with a maximum length of 64 characters. Default name is "recipe_n", where n increments starting from 1. Duplicate names are not allowed.
Display name	The name displayed in the recipe control. It supports Chinese and English characters, numbers, underscores (_), and middle hyphens (-), with a maximum length of 64 characters.
ID	Range: 1 to 100.
Max. number of data records	Number of data records in the recipe, with a range from 0 to 1000.
Info text	The description of the recipe. Supports a maximum of 256 characters.

3. Add elements.

   Set the elements in the recipe. A recipe can contain up to 1000 elements.

   On the "Element" tab, select "Add row" from the right-click menu or enter text in an empty cell to add an element.

Element | Data_record

	Name	Display Name	Tag	Data Type	Default Value	Maximum Value	Minimum Value	Decimal Places	Tooltip
1	Water	Water	Water	INT	0	900	0	0	
2	Lemon	Lemon	Lemon	INT	0	50	0	0	
3	Tea	Tea	Tea	INT	0	50	0	0	
4	Syrup	Syrup	Syrup	INT	0	200	0	2	
5	PassionFruit	PassionFruit	PassionFruit	INT	0	50	0	1	

Figure 13-6-2-4 Element addition result

Property	Description
Name	The identifier of an element in the software. The name supports Chinese and English characters, numbers, underscores (_), and middle hyphens (-), with a maximum length of 64 characters. Default name is "Element_n", where n increments starting from 1. Duplicate names are not allowed.
Display name	The name displayed in the recipe control. It supports Chinese and English characters, numbers, underscores (_), and middle hyphens (-), with a maximum length of 64 characters.
Associated variable name	The variable associated with the element. Supports single variables and array variables, with data types BOOL, INT, UINT, REAL, LREAL, STRING, and WSTRING.
Data type	The data type of the associated variable.
Default value	When the values of the elements are set to default in the data record, the recipe control will display this value when it is online.
Maximum value	Range limits of the associated variables.
Minimum value	
Decimal points	Applicable to variable of types INT, UINT, DINT, UDINT, LINT, ULINT, SINT, USINT, REAL, and LREAL. Where: For REAL and LREAL types: Indicates the number of decimal places retained, enhancing numeric precision. For other variable types: Values of data records are displayed according to the number of decimal places. For example, if the configured value of a data record is 400 and the number of decimal places is 1, the data record will be displayed as 40.0 when it is online.
Info text	The description of the element. Supports a maximum of 256 characters.

4. Add data records.
   A recipe can contain a maximum of 1000 data records.
   On the "Data record" tab, select "Add row" from the right-click menu or enter text in an empty cell to add a data record.

Element | Data_record

	Name	Display Name	Number	Water	Lemon	Tea	Syrup	PassionFruit	Tooltip
1	Beverage1	Regular Tea	1	300	0	25	0	0	
2	Beverage2	Passion Fruit Tea	2	300	40	20	50	5	
3	Beverage3	Lemon Tea	3	300	10	28	55	40	
4	Beverage4	Sweet Soup	4	300	0	0	80	0	

Figure 13-6-2-5 Data record addition result

Property	Description
Name	The identifier of a data record in the software. The name supports Chinese and English characters, numbers, underscores (_), and middle hyphens (-), with a maximum length of 64 characters. Default name "Data_record_n", where n increments starting from 1. Duplicate names are not allowed.
Display name	The name displayed in the recipe control. It supports Chinese and English characters, numbers, underscores (_), and middle hyphens (-), with a maximum length of 64 characters.
ID	Range: 1 to 1000.
Element value	Values of each element in different data records.
Info text	The description of the data record. Supports a maximum of 256 characters.

After adding data records, a complete recipe is successfully added.

13.6.3 Modifying a Recipe

After a recipe is created, it may change according to on-site control requirements. Typical changes include:

Adding a recipe/element/data record

Use the "Insert row" or "Add row" command to add a recipe/element/data record.

Insert row: Insert new content above the selected row.

Add row: Add new content to the end of the current table.

Modifying recipe/data record number

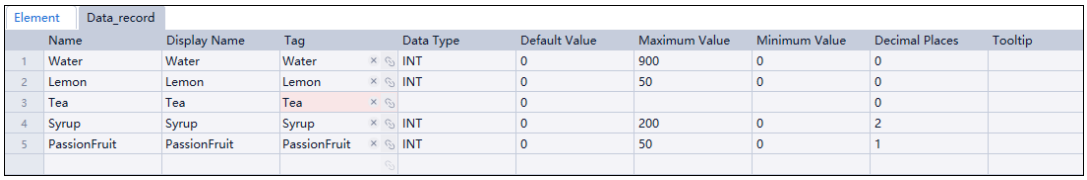
During the online operation of the recipe (controller), users can quickly access relevant information through the recipe and data recording numbers.

The numbers support user customization. Duplicates are not allowed within the associated table.

Double-click the number cell, enter the new number, and press the **Enter** key.

Reordering elements

Elements are initially sorted by the order in which they were added. Manual sorting is supported:

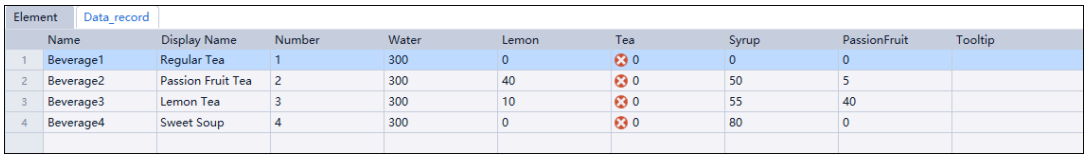


Move up: Click  to move the selected element up by one row.

Move down: Click  to move the selected element down by one row.

Modifying the element-associated variable

If the variable name or data type of an associated variable is changed in the variable table, the element will automatically synchronize the update, requiring no manual modification.



If the changed data type no longer meets the element requirements, the variable will be marked as abnormal on both the "Element" and "Data record" tabs. For example, the data type of the variable "**tea**" associated with the element **green tea** does not meet the constraints, so "**tea**" is marked as abnormal on both the "Element" and "Data record" tabs, as shown below.

Element | Data_record

	Name	Display Name	Tag	Data Type	Default Value	Maximum Value	Minimum Value	Decimal Places	Tooltip
1	Water	Water	Water	INT	0	900	0	0	
2	Lemon	Lemon	Lemon	INT	0	50	0	0	
3	Tea	Tea	Tea		0			0	
4	Syrup	Syrup	Syrup	INT	0	200	0	2	
5	PassionFruit	PassionFruit	PassionFruit	INT	0	50	0	1	

Figure 13-6-3-1 Variable abnormal mark on "Element" tab

Element | Data_record

	Name	Display Name	Number	Water	Lemon	Tea	Syrup	PassionFruit	Tooltip
1	Beverage1	Regular Tea	1	300	0	0	0	0	
2	Beverage2	Passion Fruit Tea	2	300	40	0	50	5	
3	Beverage3	Lemon Tea	3	300	10	0	55	40	
4	Beverage4	Sweet Soup	4	300	0	0	80	0	

Figure 13-6-3-2 Variable abnormal mark on "Data record" tab

13.6.4 Deleting a Recipe

Deleting a recipe will also delete its related elements and data records. Recipes support single deletion and batch deletion (using the Ctrl/Shift keys).

Delete a recipe through the right-click menu or the **Delete** key.

13.6.5 Copying and Pasting a Recipe

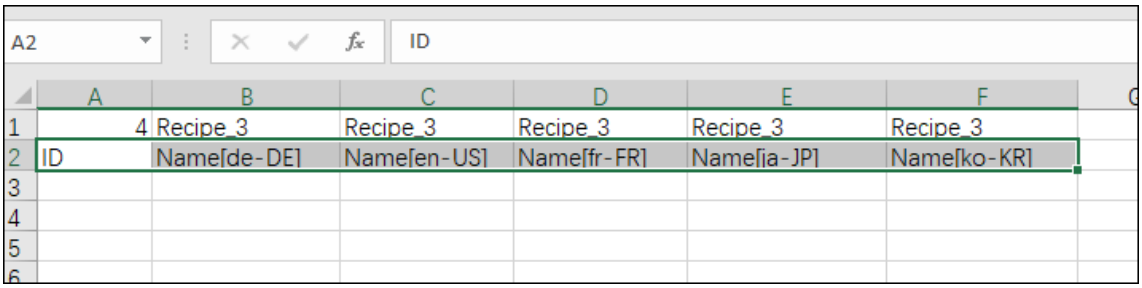
Recipes support copy and paste operations within a device.

Both single and batch copy are supported. The pasted name defaults to the original name with a "_n" suffix.

13.6.6 Importing and Exporting a Recipe

Importing recipes

Import recipes to enable cross-device recipe reuse and reduce configuration time.



Recipe data is imported into iFA software as in .csv format.

- Prepare the file to be imported. Edit the CSV file in a text editor, ensuring the content meets the following three requirements to avoid import failures.

  - When preparing content for import, it is recommended to first export a recipe file and then add new content to it.
  - Recipe export only supports exporting the multilingual content of the current device. To export other languages, enable them in "Runtime setting > Language and font" for the device before exporting.

- The key fields of a recipe must include the Recipe ID and at least one Language ID. These fields cannot be changed or deleted, as indicated by the blue text in the figure.
  - When importing a recipe file into a new project, the "Name[Language ID]" field will be imported into the corresponding language:

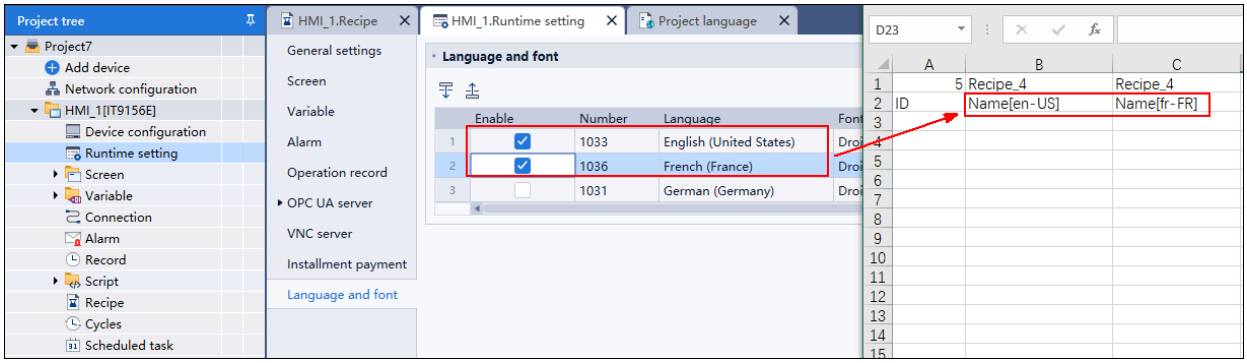
	A	B	C	D	E	F
1	4	Recipe_3	Recipe_3	Recipe_3	Recipe_3	Recipe_3
2	ID	Name[de-DE]	Name[en-US]	Name[fr-FR]	Name[ja-JP]	Name[ko-KR]
3						
4						
5						
6						

  - When importing a recipe file into an existing project, the "Name" field will be imported into all languages activated in the current project:

	1	Recipe_1				
ID		Name	water	lemon	tea	suger	Passion fruit
	1	Ordinary tea	300	0	25	0	0
	2	Passion fruit tea	300	40	20	50	5
	3	Lemon tea	300	10	28	55	40
	4	tea water	350	0	0	80	0

- The Recipe ID must be valid and unique.
- The order and quantity of element data must exactly match those in the data records.
  As shown in the figure above, the order of the five elements (water, lemon, etc.) must exactly match the order in the data records.

- Import the file.
  Click the import icon and select the file to be imported. Only one recipe can be imported at a time. A result prompt appears upon completion. The following table lists common failure prompts and their causes.



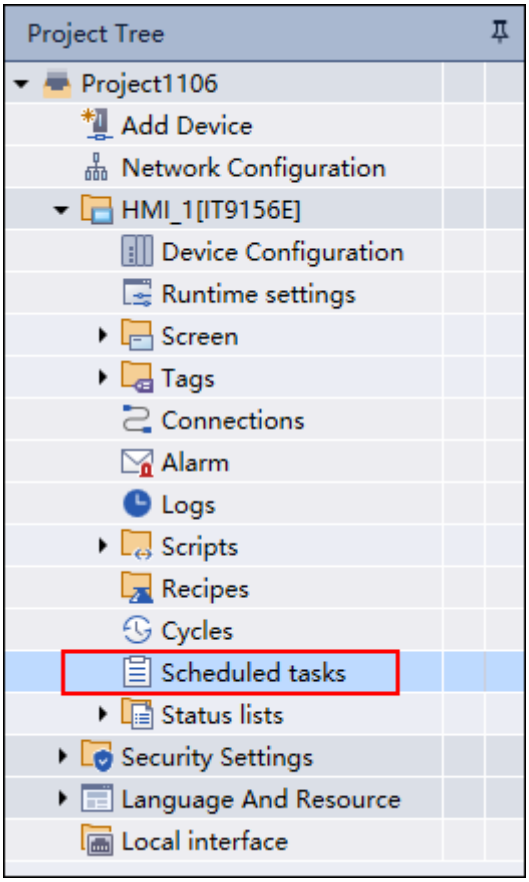
No.	Prompt	Cause
1	Failed to read the file. Please check the modifications made to the import file.	The key fields were modified, deleted, reordered, or the file format was changed.
2	The Recipe ID and Language ID cannot be empty.	The file contains invalid data. See 13.6.2 Adding a Recipe to check the property descriptions.
3	The element data in the data record does not match the data in element management.	The quantity or order of element data in the data record does not match that in element management.

Exporting recipes

Select a recipe and click the export icon to perform the export operation. Only one recipe can be exported at a time.

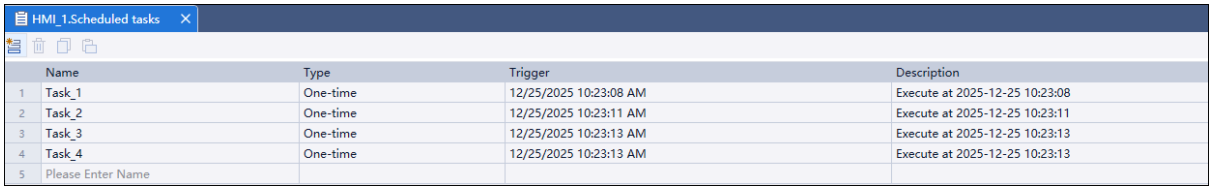
The exported recipe file (.csv) is named after the recipe and is stored by default in **C:\Users\Administrator\Documents**.

Recipe export only supports exporting the multilingual content of the current device. To export other languages, enable them in "Runtime setting > Language and font" for the device before exporting.



13.7 Scheduled Task

- 13.7.1 Adding a Task
- 13.7.2 Editing a Task
- 13.7.3 Task Properties
- 13.7.4 Event Configuration for Tasks
- 13.7.5 Copying and Pasting a Task
- 13.7.6 Deleting a Task

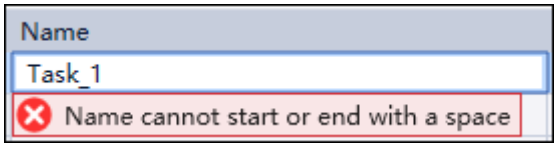


13.7.1 Adding a Task

The visualization platform supports executing tasks based on schedules. The "Scheduled task" window displays all task information in a table format. Different scheduled tasks can use the same configuration parameters. A maximum of 128 tasks can be created. Add a scheduled task as follows:

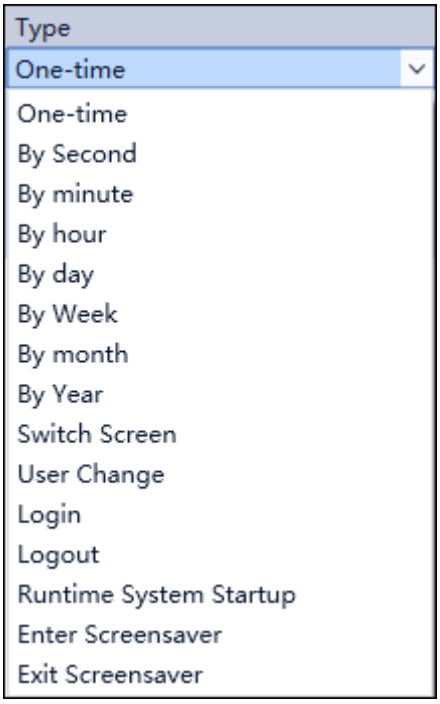
1. Double-click "Scheduled task" in the project tree to open the "Scheduled task" window.

2. Add a scheduled task in the following three ways:
   - Double-click the "Name" cell in the last blank row to enter the edit mode. Enter the name for the new scheduled task, then click elsewhere or press the Enter key to complete the addition.
   - Click  above the table to automatically add a new scheduled task.
   - Right-click the schedule task table and select "Add row" to automatically add a schedule task.
3. The addition result is shown in the figure below.



13.7.2 Editing a Task

The scheduled task supports modifications to its name, type, and trigger.



Name modification

Double-click the task name cell to modify to enter the edit mode. Enter the new name, then click elsewhere or press the Enter key. The software automatically checks the validity of the entered content. If the name is invalid, the software displays an error prompt as shown in the figure below, and discards the input.

Type modification

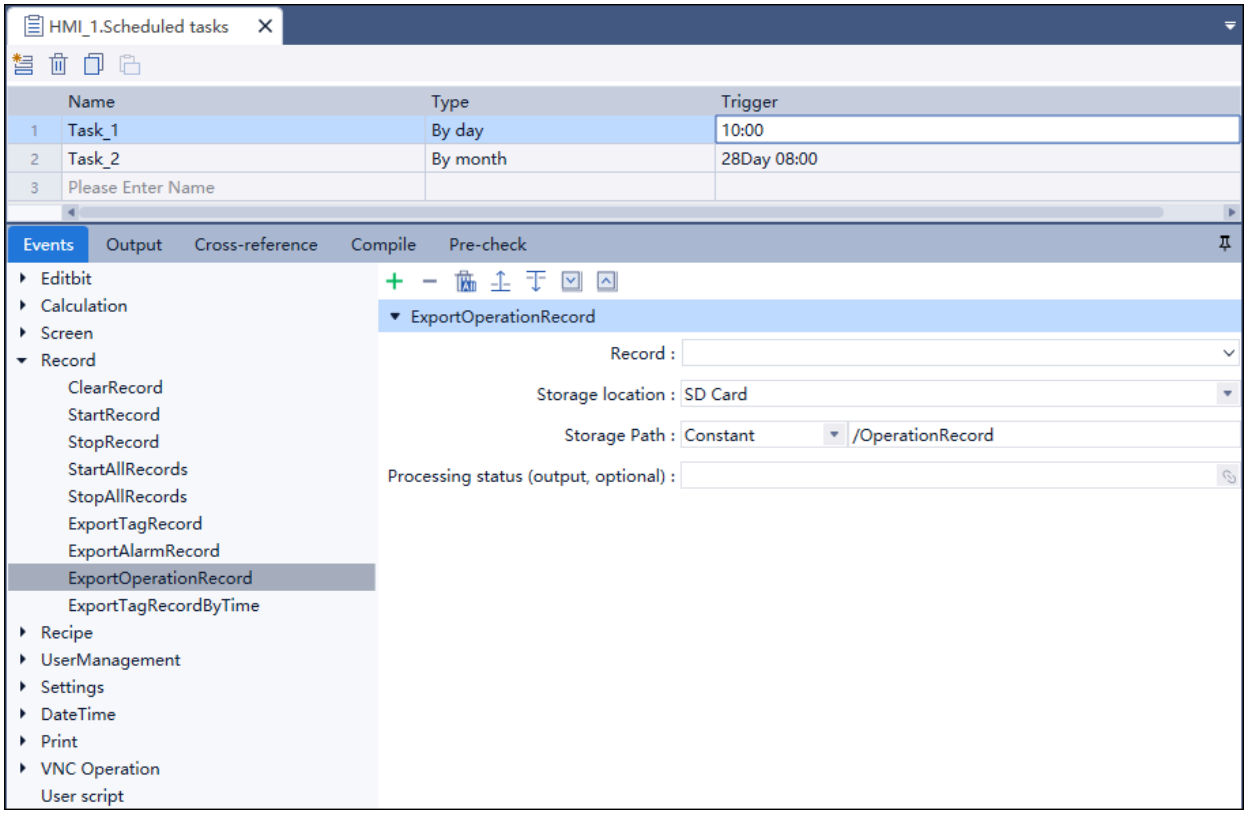
Select the task row to modify, and click  to the right of the cell or double-click the "Type" cell of the task to modify to enter the edit mode. The drop-down list is displayed, as shown below. The current type is selected by default. Select the required type from the drop-down list to complete the modification.

Trigger modification

Select the task row to modify, and click to the right of the cell or double-click the "Type" cell of the task to modify to enter the edit mode. The modification window corresponding to the configured trigger pops up. Enter the new configuration parameters in the window, click elsewhere or press the Enter key.

13.7.3 Task Properties

The basic properties and descriptions of the scheduled tasks are shown in the table below:



Property	Description
Name	Task name. • Supports letters (case-insensitive), numbers, Chinese characters, and spaces • Supported special characters: ~`!@#$%^&*()-_=+[]{}|\;:,.<>/?! （）、：；“”，。？ • Max length: 128 characters. • Name cannot start or end with a space. The default name is "Task_N", where "N" is an incremental sequence number starting from 1. If there is a gap in the existing name numbers, the smallest available number is used.
Type	Only options within the system's supported range can be selected. Default is "Once".
Flip-flop	Only options within the system's supported range can be selected. Default is the current time.
Description	Description information is automatically generated based on the configured trigger, which does not support manual modification. Default is "Execute at the current time".

The types supported by the visualization platform and their descriptions are shown in the table below. In all descriptions automatically generated by the configuration, the default date and time refer to the current date and time.

Property	Description
Once	Users can configure the date and time for task execution. Example of automatically generated description: Execute on 2024-11-19 15:00:00.
By second	Users can configure the number of seconds, ranging from 1 to 59. Example of automatically generated description: Execute every 1 second.
By minute	Users can configure the number of minutes, ranging from 1 to 59. Example of automatically generated description: Execute every 1 minute.
By hour	Users can configure the minute of the hour, ranging from 0 to 59. Example of automatically generated description: Execute once at minute 5 each hour.
By day	Users can configure the time. Example of automatically generated description: Execute at 15:00 daily.
By week	Users can configure the day of the week and time. Example of automatically generated description: Execute at 15:00 every Tuesday.
By month	Users can configure the date and time. Example of automatically generated description: Execute on day 19 at 15:00 each month.
By year	Users can configure the date and time. Example of automatically generated description: Execute at 15:00 on 11-19 each year.
Switch screen	Triggered once when switching screens.
User change	Triggered once when the user changes.
Login	Triggered once when the user logs in.
Logout	Triggered once when the user logs out.
Runtime system startup	Trigger once when the graphical runtime system starts.
Enter screensaver	Triggered once when the touchscreen enters screensaver mode.
Exit screensaver	Triggered once when the touchscreen exits screensaver mode.

13.7.4 Event Configuration for Tasks

Scheduled task supports event configuration. A scheduled task can be configured with up to 32 functions.

The actions of scheduled task execution events will be recorded in the operation log. The results can be viewed through the 13.15.6 Online Operation Record Operations control.

13.7.5 Copying and Pasting a Task

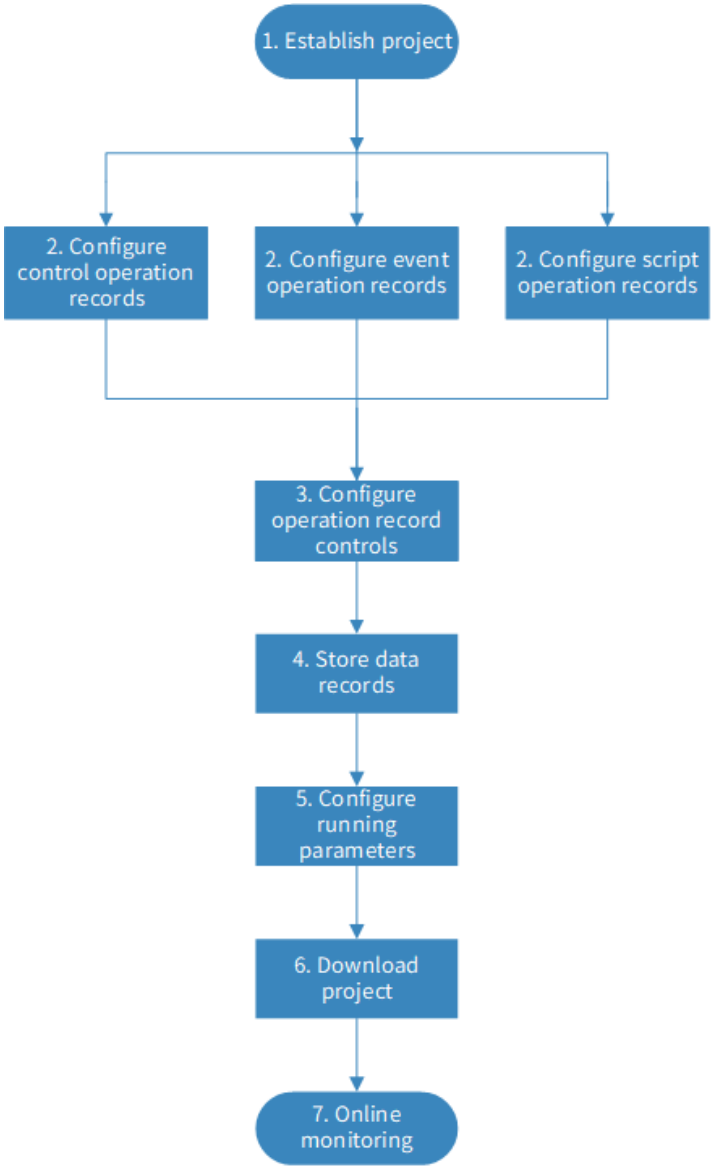
The scheduled task supports single or batch copy/paste. For batch selection, use the Ctrl or Shift key.

Select the scheduled task row to copy, and click or select "Copy" from the right-click menu to copy the selected task. The copied scheduled task can be pasted by clicking above the table, or by selecting "Copy" from the right-click menu.

13.7.6 Deleting a Task

Scheduled tasks can be deleted individually or in batches. For batch deletion, use the Ctrl or Shift key. Select the scheduled task row to delete, and click or select "Delete" from the right-click menu to delete the selected task.

13.8 Operation Record Usage



- 13.8.1 Operation Record Configuration Process
- 13.8.2 Operation Records for Stored Projects
- 13.8.3 Operation Record Runtime Configuration

13.8.1 Operation Record Configuration Process

The operation record function displays each step of the user's operations in real time. When an exception occurs, these records can help analyze whether the operation process conforms to the established workflow, and further evaluate and improve the issue.

In the project, changes to variables, screens, controls, events, and other content will generate corresponding operation records. These records are displayed through dedicated controls for user access. Since the configuration process of operation records involves many aspects, see the following flowchart to understand the configuration sequence.

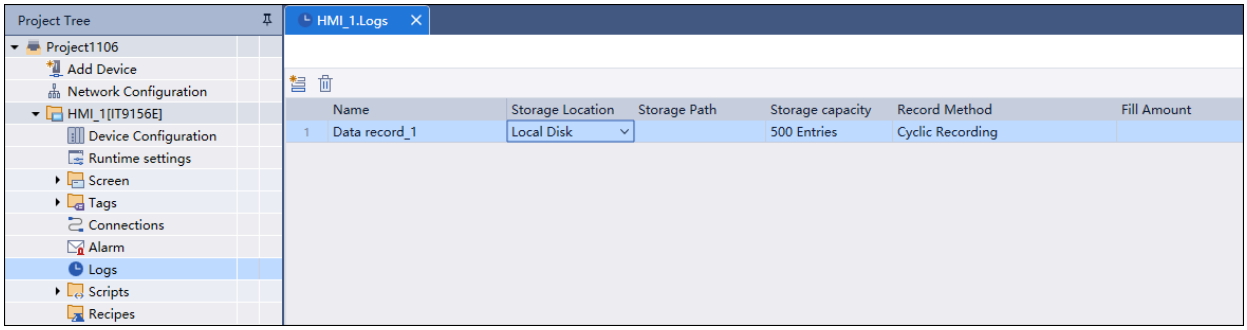


Table13-8-1-1 Operation record configuration process

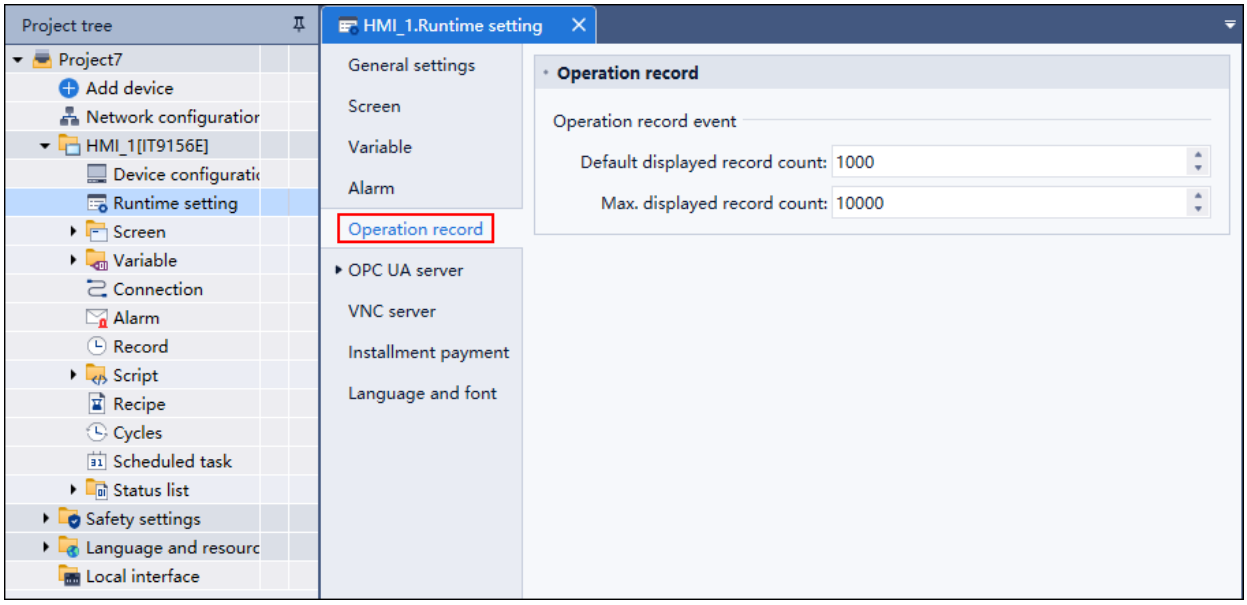
Key Activity	Description
	1. Add user variables, screens, and other information in the project. 2. Set the storage method and path for log information; see 13.8.2 Operation Records for Stored Projects for details. 3. Configure controls, events, or scripts to record runtime change logs. The configuration scope depends on project requirements; one or more of the following can be configured. • The following controls can be configured with the "Record" property: 13.3.5.2.1 Numeric I/O Field, 13.3.5.2.2 Character I/O Field, 13.3.5.2.4 Button, 13.3.5.2.6 Text Button, 13.3.5.2.5 Bit Button, 13.3.5.2.13 Radio Button, 13.3.5.2.10 Combo Box, 13.3.5.2.11 List Box, 13.3.5.2.14 Checkbox, and 13.3.5.2.12 Text Switch. • Specific system functions in events contain the "Operation record" property. These system functions include: 19.3.1 Increasing Variable Value, 19.3.2 Decreasing Variable Value, 19.3.3 Setting Variable Value, 19.2 Inversion, 19.2 Inverting Bit in Variable, 19.2 Setting, 19.2 Setting Bit in Variable, 19.2 Resetting, and 19.2 Resetting Bit in Variable. • User scripts called in events can be configured with the "Operation record" property.

Key Activity	Description
	4. Add an operation record control on the screen to display the recorded content. For configuration details, see 13.3.5.4.8 Operation Records.
	5. Set the maximum number of logs that the operation record control can display at runtime. See 13.8.3 Operation Record Runtime Configuration for details.
	6. Download the configuration content to the touchscreen to make it effective. See 13.14 Project Download for details.
	7. View the operation logs recorded at runtime. See 13.15.6 Online Operation Record Operations for details.



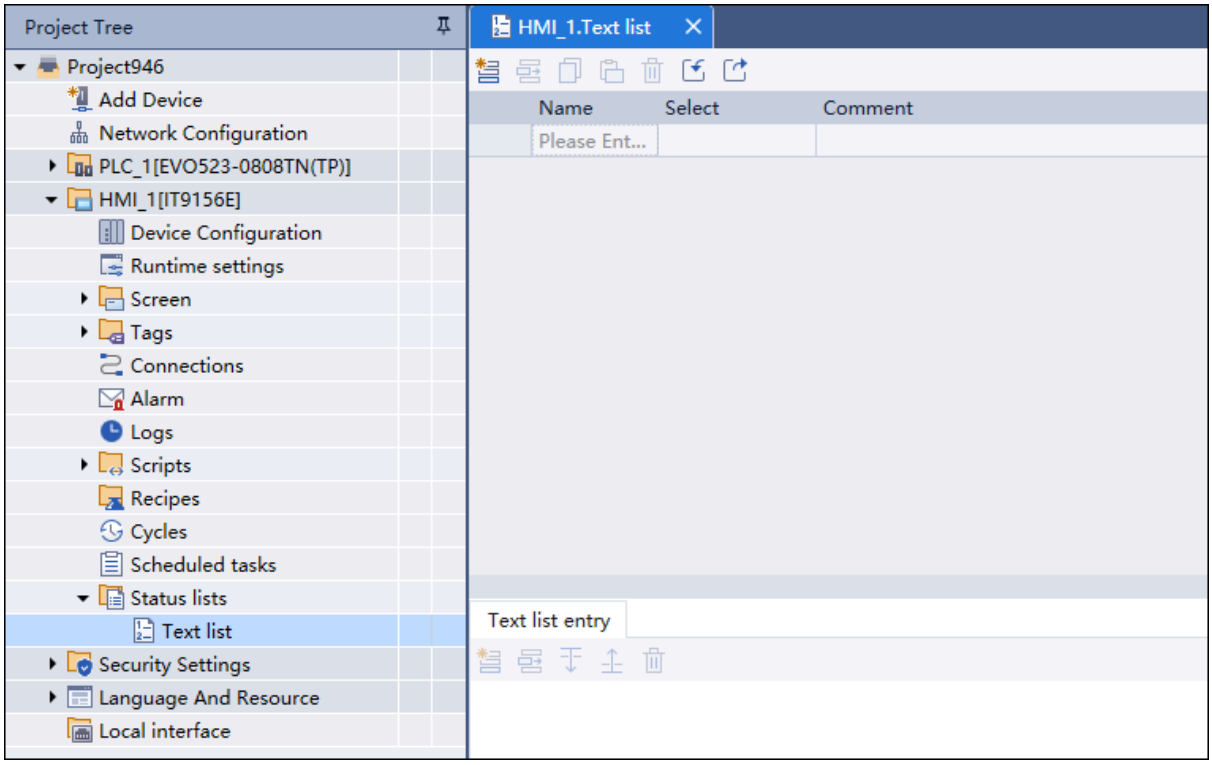
13.8.2 Operation Records for Stored Projects

Each project is automatically configured with an operation record upon creation. One project is configured with one operation record. Adding or deleting records is not supported.

The property items of an operation record are the same as those of a data record. For details, see 13.2.5.6.1 Setting Recording Rules for Data.

13.8.3 Operation Record Runtime Configuration

- Default displayed record count: The number of records displayed in the "Operation record" view with no filter. Range: 100 to 10,000.
- Max. displayed record count: The maximum number of records displayed after filtering according to specified conditions. Range: 10,000 to 1,000,000.



13.9 Text List Usage

- 13.9.1 Adding a Text List
- 13.9.2 Modifying a Text List
- 13.9.3 Deleting a Text List
- 13.9.4 Copying/Pasting a Text List
- 13.9.5 Exporting a Text List
- 13.9.6 Importing a Text List

13.9.1 Adding a Text List

Text lists are used to store specific text. Associate variables with the 13.3.5.2.9 text list control on the screen to monitor data.

1. Open the "Text list" directory in the project tree.
2. Double-click the "Text list" node to open the text list configuration page.

3. Add a text list row.
   - **Add row**

     Click the icon  or select "Add row" in the right-click menu to add a text list entry.
   - **Insert row**

     Select a row, click the icon  or select "Insert row" in the right-click menu to insert a new row above the selected row with default information configured.

A text list supports a maximum of 256 entries.

13.9.2 Modifying a Text List

The modification of a text list consists of two parts: text (rows) and corresponding entries.

Text row

The properties of a text row are determined according to the data types and value ranges of the target variables.

Item	Description
Property	Consists of Chinese characters, English letters, numbers, underscores (_), and hyphens (-), with a maximum of 64 characters.
Select	Value/Range: Supports 2000 entries. Bit number (0 to 31): Supports 32 entries. Bit (0,1): Supports 2 entries.
Comment	Description for the text (row), consisting of 0 to 256 arbitrary characters.

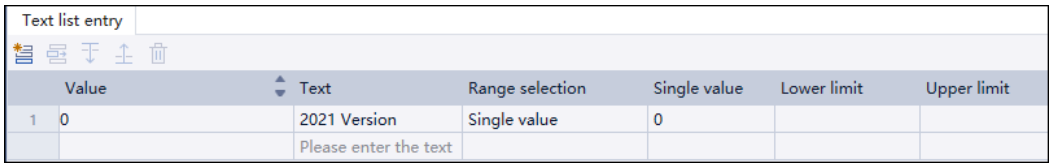
After the name of the text list is modified, if a text list control is associated with this text list, the "Text list" property of the control will automatically update to the new name.

Entry

Select a text (row), and its corresponding entries can be modified on the "Text list entry" tab. The display of the "Text list entry" tab varies according to the settings of the text (row).

- Adding an entry

  Click the icon  or select "Add row" in the right-click menu to add an entry.



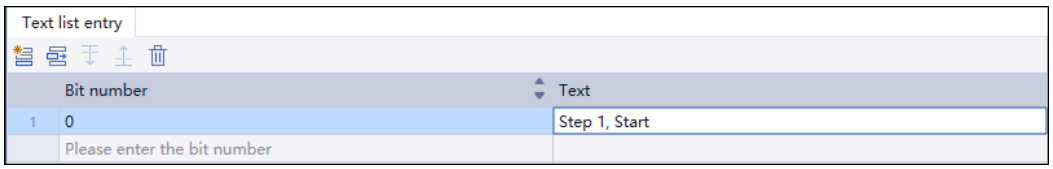


Figure 13-9-2-1 Entry display for "Value/Range" text

Entry display for "Bit number (0 to 31)" text

- Modifying an entry

  The following introduces all properties. Users can selectively view them.

Property Category	Property	Description
Applicable when "Select" = "Value/Range"	Value	The value of the variable. Supports a single numerical value (e.g., 5) or a range (e.g., 2 to 6).
	Range selection	The variable's value is a numerical range, set via upper/lower limits.

Property Category	Property	Description
	Single value	The numerical value corresponding to the entry, within the integer data type range (-2147483648 to 2147483647). Single value: A single numerical value. Upper/Lower limit: Value range.
	Upper/Lower limit	
Applicable when "Select" = "Bit number (0 to 31)"	Bit number	The value of the variable; supports a single numeric value.
Common item	Text	Description of the value or bit number.

- Inserting an entry

  Click the icon  or select "Insert row" in the right-click menu to insert an entry.
  The value or bit number of the new item is automatically filled in based on the current value.

- Reordering entries

  Reorder entries using icons  or . Reordering do not affect the parameter values of the entries.

- Copying/Pasting an entry
  Entries can be copied one by one.
  Pasting entries supports cross-text operations, provided that the "Select" values of the two text rows are the same.

- Deleting an entry

  Select an entry and click the icon  or select "Delete" in the right-click menu to delete the selected entry.

13.9.3 Deleting a Text List

- Select the row containing the single text list, and select the "Delete" icon from the toolbar or select "Delete" from the right-click menu to delete the selected text list.
- Select multiple text list rows, and select the "Delete" icon from the toolbar or select "Delete" from the right-click menu to delete the selected text lists.
- After deletion, all data entries within that text list will be deleted.
- When a text list control is associated with a specific text list, after that text list is deleted, the "Text list" property of the control will be displayed in red.

13.9.4 Copying/Pasting a Text List

Text list supports copy and paste operations within the device.

The copy range includes the text list information and the corresponding entries. Entries can be copied independently.

Before batch copying, select objects using the **Ctrl** or **Shift** keys, then perform the copy operation using **Ctrl + C** or the right-click menu.

Based on the copied content, perform the paste operation at the target location using **Ctrl + V** or the right-click menu. During pasting, duplicate name will be checked and handled automatically.

13.9.5 Exporting a Text List

Text list can be exported.

Method

You can export text information and related entries from the text list one by one using the  icon. Batch export operations are not supported.

Exported file

The **.xlsx** exported file is named after the text list is saved in the C:\Users\Username\Documents directory by default.
The exported content and structure correspond exactly to those on the software interface.

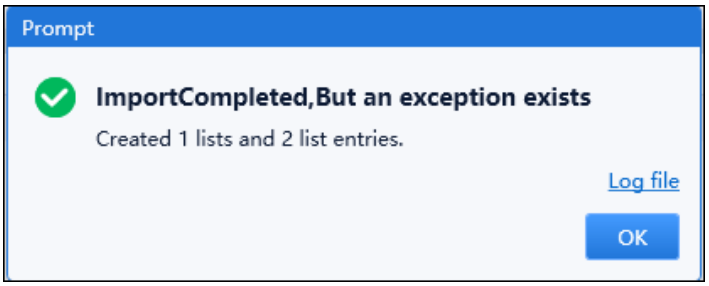
Multilingual support

When exporting, the system automatically includes translations for the corresponding languages based on the languages enabled in the current project.
For example, if the project has enabled German (Switzerland), English (United States), and Chinese (Simplified China), the exported information will by default include translations in these three languages.

Ensure that complete translations for the relevant entries have been added to the project before exporting. If the translation for a certain language of an entry is empty, the corresponding position in the exported file will also be empty.

13.9.6 Importing a Text List

Modify the exported **.xlsx** file and import it to update or create text list entries.



File requirements

- Consistent naming: The file name must exactly match the name of the target text list.
- Valid format: The file structure must match the exported template. The values entered for "Select" fields must be correct, and the number of entries must be within the valid range.
  For example, if "Select" is set to bit numbers (0,1), but the entries contain big numbers other than 0 and 1, it will be considered invalid.

Method

Select an empty row in the text list, then click and select the file to create or update the corresponding entry information in the text list.

Entry information and relevant details regarding import failures will be recorded in the import log.

Multilingual processing

- The system only imports language columns from the file that match the enabled languages for the current project.
- Language columns that do not match will be ignored, and relevant details will be recorded in the import log.

13.10 System Function and Script Usage

- 13.10.1 System Functions
- 13.10.2 User Script

13.10.1 System Functions

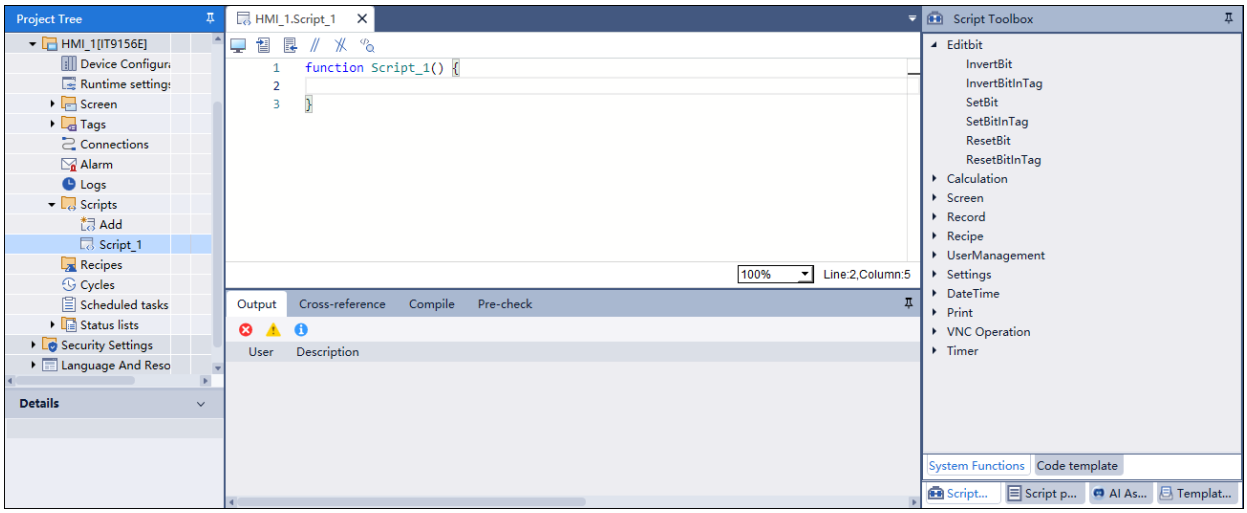
Predefined system functions support routine configuration tasks. Users can use these system functions to configure custom functions for various tasks. The main system functions include:

- 19.2 Bit Operations: Performs operations on variable bits.
- 19.3 Calculation: Performs basic calculations on variables.
- 19.4 Screen: Enables switching, displaying, or hiding user screens.
- 19.5 Alarm: Performs alarm-related tasks.
- 19.6 Record: Performs tasks related to data recording and alarm recording.
- 19.7 Recipe: Performs recipe-related tasks.
- 19.8 User Management: Performs permission management for project content.
- 19.9 Configuration: Configures application parameters related to the HMI device, such as backlight duration and screen light on/off.
- 19.10 Date and Time: Sets and reads the HMI device time.
- 19.11.1 Screenshot: Performs the screen capture function during project operation.
- 19.13 Timer: Creates periodic or scheduled tasks.

Users can configure system functions on all graphic objects that are capable of responding to events. System functions are primarily used in screen events, graphic object events, variable events, scheduled tasks, and custom scripts.

13.10.2 User Script

13.10.2.1 Adding a Script



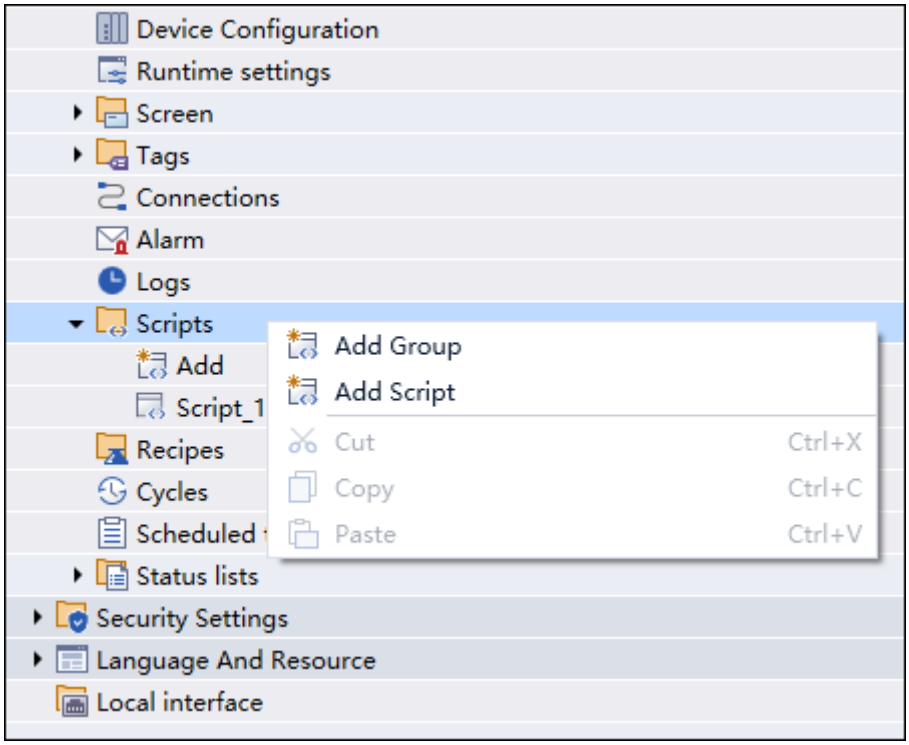
Add a script using the following methods:

- Double-click "Add" under "Script" in the project tree.
- Right-click "Script" in the project tree and select "Add script".

The script name is a combination of English letters, digits, and underscores ("_"). It starts with an English letter, and has a maximum length of 64 characters. Multiple script functions under a single script node cannot have duplicate names.

A maximum of 128 scripts can be created per HMI device.

The initial state of the script after addition is shown in the figure below.



13.10.2.2 Grouping Scripts

User scripts can be grouped and managed based on certain features, such as the controlled object or the implemented control function.

Adding a group

Create a first-level script group under the "Script" node, which supports expanding multiple levels of subgroups.

Right-click "Script" in the project tree and select "Add group" to create a new script group with the node identifier .

Script group names support combinations of Chinese, English, numbers, "_", and "-", with a maximum length of 64 characters. The default name is "Script_Group_n", with the sequence number incrementing automatically.
Script group name must be unique within the same device.

Copying/Pasting

An entire group under the same device supports copy/paste operations, with the content of its scripts unchanged.

Scripts within a group and other scripts outside the group can also be copied and pasted.

Deleting

Delete a group will delete all scripts within it.

13.10.2.3 Modifying a Script

Editing area

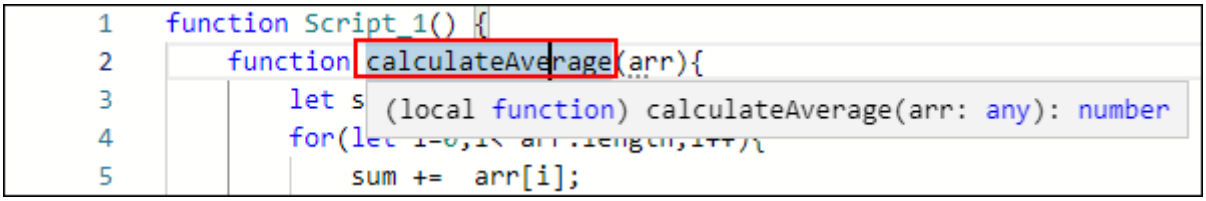
Double-click the newly created script, or right-click it and select "Open" to open the script editing area.

```
function Script_1() {
    function calculateAverage(arr) {
        let sum=0;
        for(let i=0;i< arr.length;i++){
            sum +=  arr[i];
        }
        return sum / arr.length;
    }

    // Define an array
    let numbers = [1, 2, 3, 4, 5];

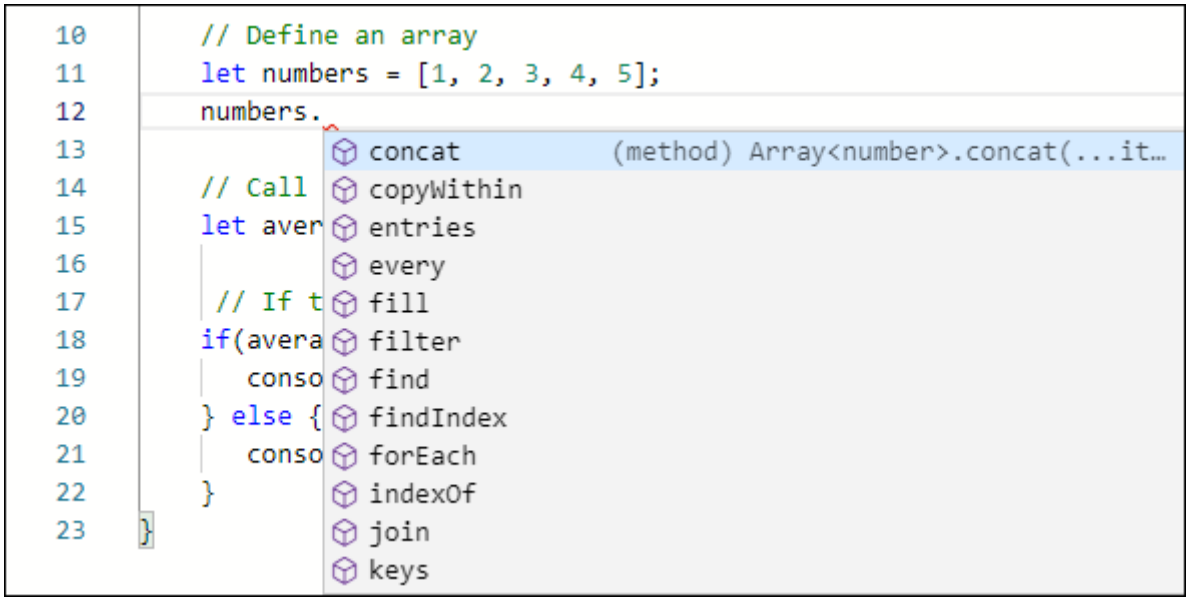
    // Call the function to calculate the average of the array
    let average = calculateAverage(numbers);

     // If the average value is greater than 3, output the corresponding message
    if(average>3){
        console.log("The average value is greater than 3.") ;
    } else {
        console.log("The average value is not greater than3.");
    }
}
```



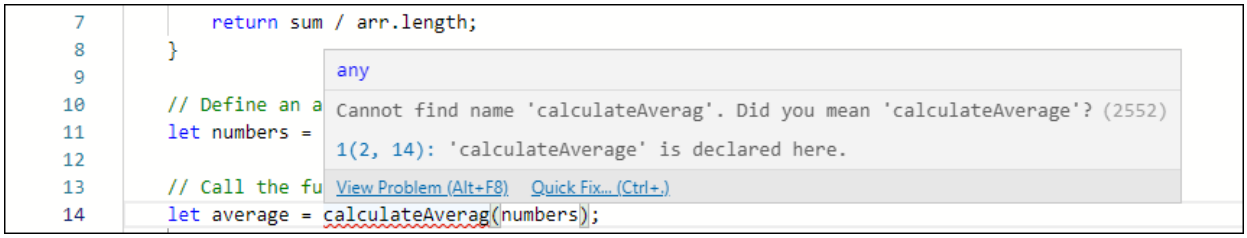
Syntax highlighting distinguishes different parts of the code syntax using different colors, such as keywords, strings, numbers, and comments. These colors are customizable. For details, see Script/text editor.

Intelligent prompt and autocomplete



Autocomplete automatically lists all matching system functions in JavaScript object model while you are typing.

When the mouse hovers over a function, a tooltip displays the function signature.



When a user types a "." after a variable, all public properties and methods of that variable are automatically listed, as shown in the figure below.

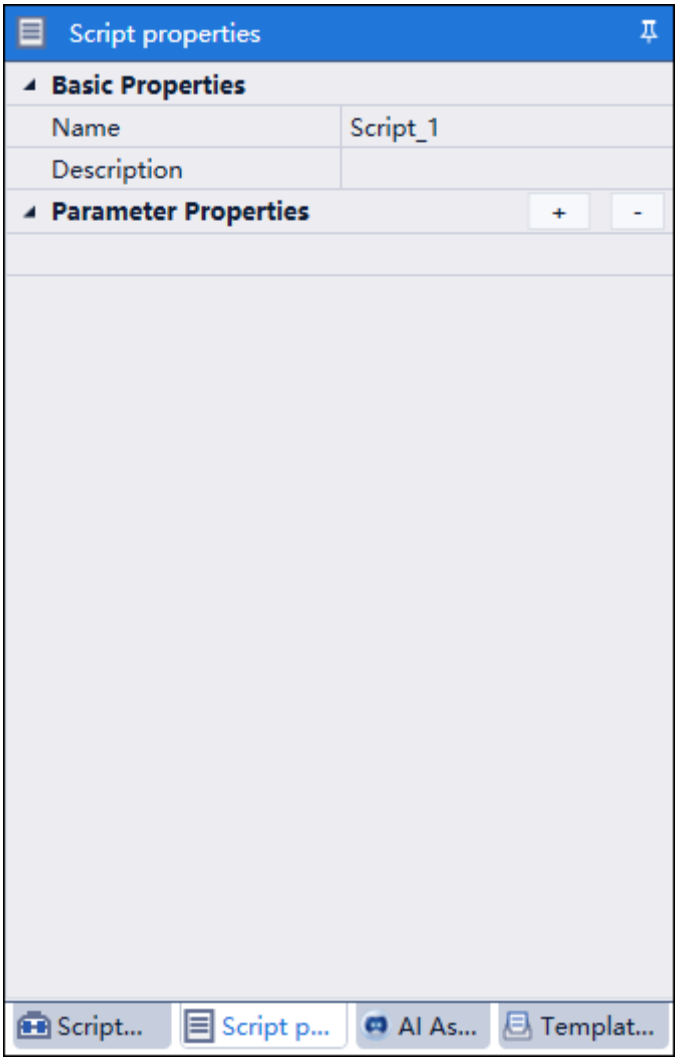
Syntax and semantic checking

The editor provides real-time syntax and semantic checking.

Toolbar

The toolbar provides commonly used convenient operation commands.

Icon	Command	Description
	System	Enables quick access to system variables. Users can select variable tables for all devices in the current project, including the current device and other devices, as well as built-in system variables. The selected variable is added to the cursor position in the form of smartTags('VariableName'). This has the same effect as function 19.1 Variables.
	Indent +	Increases the leading indentation for one or more selected rows of text.
	Indent -	Decreases the leading indentation for one or more selected lines of text.
	Comment	Adds single-line comments to one or more selected lines of text. Single-line comments are created by adding the comment symbol "//" at the beginning of a text line.
	Uncomment	Removes the comment from a text line.
	Error detection	Checks the syntax and semantics of the script. Error messages are output in the information window of the monitoring area.



Shortcut

The script editor provides shortcuts almost identical to those in VS Code, greatly improving the efficiency of script developers. Below are some commonly used shortcuts in programming.

Common Command	Shortcut
Formatting	Shift + Alt + F
Error detection	Ctrl + E
Search	Ctrl + F
Replace	Ctrl + F
Indent	Ctrl +]
Outdent	Ctrl + [
Single-line comment	Ctrl + /
Uncomment	Alt + /
Go to line	Ctrl + G
Go to definition	Ctrl + F12
Delete line	Ctrl + Shift + K
Copy line down	Shift + Alt + DownArrow
Move line down	Alt + DownArrow
Insert line below	Ctrl + Enter

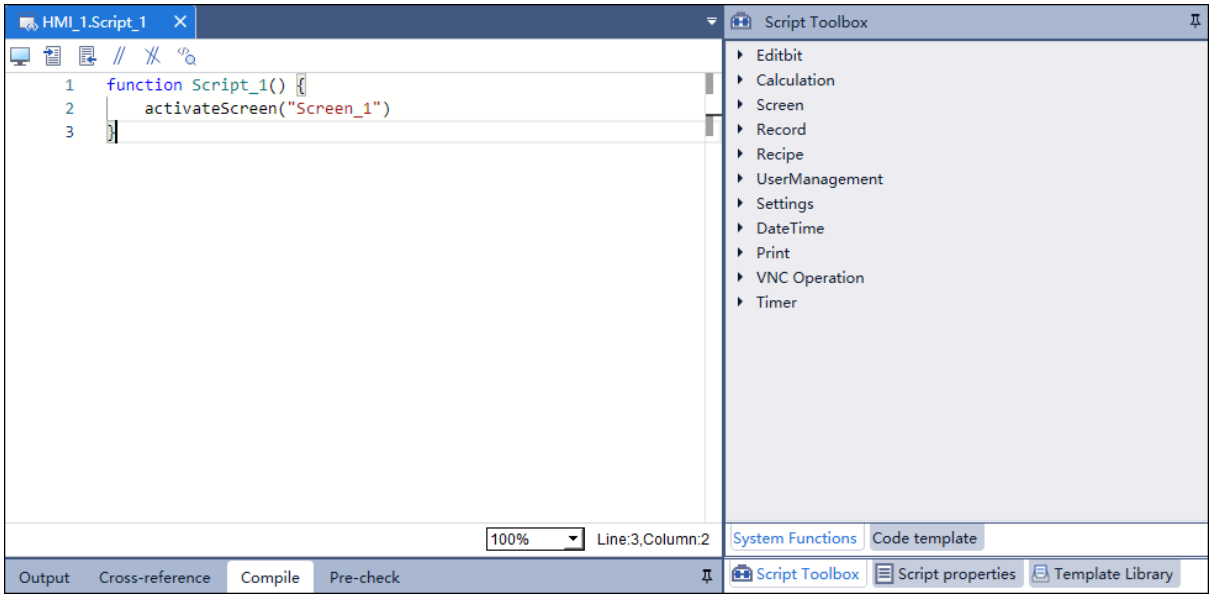
13.10.2.4 Script Properties

Script properties include basic properties and parameter properties. They are used to set the function name and parameters of the current script. Script properties can be set through the "Script property" tab of the toolbox on the right, as shown in the figure below.

- Basic property

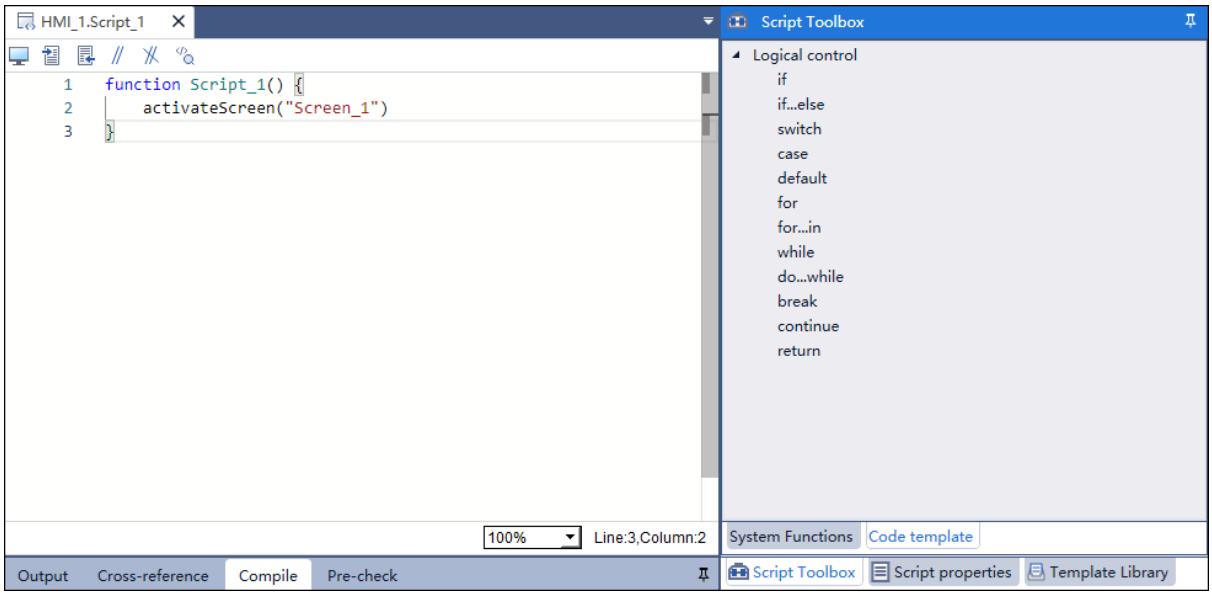
Name	Description
Name	The name of the script function. The name is a combination of English letters, digits, and underscores ("_"). It starts with an English letter, and has a maximum length of 64 characters.
Description	The description of the script function, which is optional. The description is a combination of Chinese characters, English letters, numbers, "-", and "_". The maximum number of characters is 128.

- Parameter property



Click "+" and "-" to add or delete a script function parameter.

Property	Description
Parameter	The parameter name of the script function. The name is a combination of English letters, digits, and underscores ("_"). It starts with an English letter, and has a maximum length of 64 characters. Parameter names within the same script function cannot be duplicated.



13.10.2.5 Script Toolbox

The script toolbox provides system functions and keywords for use.

- System functions
  The script toolbox contains commonly used functions supported by the script editor, including 12 categories of functions such as bit operations, calculation, and word operations. Detailed usage of these functions is explained in the 19 HMI System Functions chapter.
  Users can double-click a function from the "System function" tab in the script toolbox to insert it at the cursor position.

- Code templates
  The "Code template" tab contains commonly used keywords supported by the script editor, as shown in the figure below. Users can double-click a keyword to insert it at the cursor position.

13.10.2.6 JavaScript Syntax Basics

13.10.2.6.1 Language Overview

The script uses TypeScript as its programming language, with a version of ES6 (ES2015). This allows developers to use modern JavaScript features, including classes, block-scoped variables (let and const), arrow functions, and so on. These features not only enhance code readability and structure but also improve programming flexibility and efficiency. Additionally, the software adopts strict mode specifications to ensure code quality and security. For example, it prohibits undeclared variables and restricts the scope of the eval function to reduce potential risks and errors. At the same time, the software disables alarms for unused function parameters and local variables to help developers keep their code clean and avoid unnecessary distractions. These features and specifications make script development more reliable and efficient.

13.10.2.6.2 Common Operators

The common operators and keywords of JavaScript are managed on the "Code template" tab of the "Script toolbox". The table below lists the common operators, excluding the "Constants" and "Control keywords" nodes.

The sorting of the table remains consistent with the software nodes.

Table13-10-2-6-2-1

Operator		Description	Syntax	Example

Arithmetic	%	Remainder: Returns the remainder when the left operand is divided by the right operand.
		The sign of the result always matches the dividend, and its value is the integer closest to zero.
			a % b	`-13 % 5;  // -3`
				`-9 % 2;  // -1`
				`9 % -2;  // 1`
				`1 % -2;  // 1`
				`Infinity % 2;  // NaN`
				`2 % Infinity;  // 2`

	*	Multiplication: Computes the product of the operands.	a * b	`// Number - Number ->Multiplication`
				`2 * 2; //4`
				`-2 * 2; //4`
				`Infinity * 0; //NaN`
				`Infinity * Infinity //Infinity`

	+	Addition: The operator is overloaded for two different operations: numeric addition and string concatenation.
		Supports:
		• Numeric addition
		• String concatenation
		• Concatenation of a number and a string
		• Concatenation of a string and a boolean value
			a + b	`// Number - Number ->Multiplication`
				`2 * 2; //4`
				`-2 * 2; //4`
				`Infinity * 0; //NaN`
				`Infinity * Infinity //Infinity`
				
				`// Number + Number ->Addition;`
				`1 + 2; //3`
				
				`// Number + string -> Connect`
				`5 + 'foo'; //'5foo'`
				
				`// string + string -> Connect`
				`'foot' + 'ball'; //'football'`
				
				`// string + Boolean -> Connect`
				`'a' + false; //'foofalse'`
				
				`// string + Number -> Connect`
				`'3' + 2; //'32'`

	++	Increment: Increments its operand by one, and returns the value before or after the increment depending on the position of the operator.
		When placed after the operand (e.g., a++), the operand is incremented and the original value is returned.
		When placed before the operand (e.g., ++a), the operand is incremented and the new value is returned.
			a ++
			++ a
				`let x=3;`
				`const y=x++;`
				
				`//x=4`
				`//y=3`
				
				`let x=3;`
				`const y=++x;`
				
				`//x=4`
				`//y=4`

Operator		Description	Syntax	Example

	-	Subtraction: Subtracts the right operand from the left operand and returns the difference.	a - b	`// Number - Number ->Subtraction`
				`5 - 3; // 2`
				`3 - 5; // -2`

	--	Decrement: Decrements its operand by one, and returns the value before or after the decrement depending on the position of the operator.
		When placed after the operand (e.g., a--), the operand is decremented and the original value is returned.
		When placed before the operand (e.g., --a), the operand is decremented and the new value is returned.
			a --
			-- a
				`let x=3;`
				`const y=x--;`
				`//x=2`
				`//y=3`
				`let x=3;`
				`const y=--x;`
				`//x=2`
				`//y=2`

	/	Division: Computes the quotient of the operands, where the left operand is the dividend and the right operand is the divisor.	a / b	`1 / 2; // 0.5`
				`let a = floor (3 / 2); // 1`
				`1.0 / 2.0 ; // 0.5`
				`2.0 / 0; // Infinity`
				`2.0 / 0.0; // Infinity`
				`2.0 / -0.0; // -Infinity`

Assignment	%=	Remainder assignment: Divides the variable by the right operand and assigns the remainder to the variable.	a %= b	`let VAR1 = 23;`
				`VAR1 %= 16; // 7`
				`VAR1 %= 0; // NaN`

	*=	Multiplication assignment: Multiplies the variable by the right operand and assigns the result to the variable.	a *= b	`let VAR1 = 2;`
				`VAR1 *= 6; // 12`
				`VAR1 *= 0; // 0`

	+=	Addition assignment: Adds the right operand value to the variable and assigns the result to the variable. The behavior is determined by the types of the two operands, and may be addition or concatenation.	a += b	`let VAR1 = 5;`
				`VAR1 += 3; // 8`
				`let text = "an";`
				`text += "swer"; // answer`
				`text += true; // antrue`
				`text += 5; // an5`

	-=	Subtraction assignment: Subtracts the right operand value from the variable and assigns the result to the variable.	a -= b	`let VAR1 = 7;`
				`VAR1 -= 2 ; // 5`
				`VAR1 -= -12 ; // -5`

Operator		Description	Syntax	Example

	/=	Division assignment: Divides the variable by the right operand value and assigns the result to the variable.	a /= b	`let VAR1 = 7;`
				`VAR1 /= 2 ;  // 3.5`
				`VAR1 /= 2 ;  // 1.4`
				`VAR1 /= 0;  // Infinity`

	=	Assignment: Assigns a value to a variable.	a = b	`let VAR1 = 7;`
				`let VAR2 = 12;`
				`let VAR3 = 18;`
				
				`VAR1 = 12 ;  //VAR1 is 12`
				`VAR1 = VAR2 = VAR3 ;  //Both VAR1 and VAR2 are 18`

Object	delete	Deletes a property from an object. If the property value is an object and there are no further references to it, the object held by the property will eventually be automatically released.	delete object.property
			delete object[property]
				`//Array`
				`const colors = ["red", "yellow", "green", "black","pink"]`
				`delete colors[3];  // Delete the element with index 3 and return true`
				
				`//Custom Object`
				`let paper ={`
				`size:"A4",`
				`color:"White",`
				`weight:"80g",`
				`};`
				
				`delete paper.size; //Remove the size attribute and return true`

	in	Returns true if the specified property exists in the specified object or its prototype chain.
		The right operand must be an object value.
			prop in object
			prop: String or array index.
			object: Property object.
				`//Array`
				`var colors = ["red", "yellow", "green", "black", "pink"];`
				`2 in colors;  //Returns true`
				`6 in colors;  //Returns flase`
				
				`//Custom Object`
				`let paper = {`
				`size: "A4",`
				`color: "White",`
				`weight: "80g",`
				`};`
				
				`"size" in paper;  //Returns true`
				`delete paper.size;  //Returns true`
				`"size" in paper;  //Returns flase`

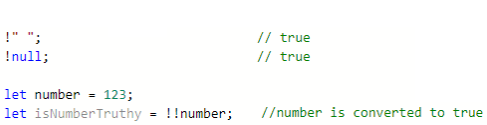
	instanceof	Tests whether the prototype property of a constructor appears in the prototype chain of an instance object.	object instanceof constructor
			object: Instance object.
			constructor: Cconstructor function.
				`class Paper {`
				`constructor(size,color){`
				`this.size = size;`
				`this.color = color;`
				
				`}`
				`}`
				`let Notebook = new Paper("A5","blue");`
				`Notebook instanceof Paper;  // true`
				`Notebook instanceof Object;  // true`

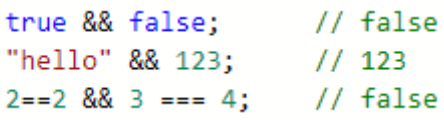
Relation	!=	Inequality: Checks whether two operands are not equal and returns a boolean result. Unlike the strict inequality operator (**!==**), it attempts to convert operands of different types before comparison.	a != b	`NaN != NaN;  // true`
				`null != undefined;  // false`
				`true != "1";  // false`
				`7 != "7";  // false`

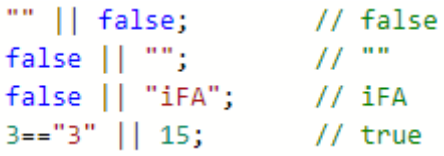
	!==	Strict inequality: Returns true if the operands are not equal in either value or type.	a !== b	`NaN !== NaN;  // true`
				`null !== undefined;  // true`
				`true !== "1";  // true`
				`7 !== "7";  // true`
				`"an" !== "an";  // false`

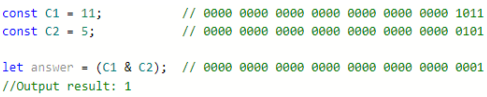
Operator	Description	Syntax	Example

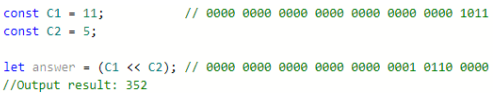
<	Less than: Returns true if the left operand is less than the right operand; otherwise returns false.	a < b	`"a" < "b";  // true`
			`true < false;  // false`
			`5 < 3;  // false`
			`NaN < 3;  // false`
			`5 < Infinity;  // true`

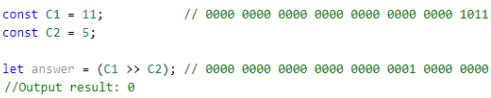












<=	Less than or equal to: Returns true if the left operand is less than or equal to the right operand; otherwise returns false.	a <= b	`"a" <= "b";  // true`
			`true <= false;  // false`
			`5 <= 3;  // false`
			`NaN <= 3;  // false`
			`5 <= Infinity;  // true`

==	Loose equality: Checks whether two operands are equal and returns a boolean result. Unlike the strict equality operator (===), it attempts to convert operands of different types before comparison.	a == b	`NaN == NaN;  //  false`
			`null == undefined;  //  true`
			`true == "1";  //  true`
			`7 == "7";  //  true`

===	Strict equality: Checks whether two operands are equal and returns a boolean result. Operands of different types are always considered unequal.	a === b	`NaN === NaN;  //  false`
			`null === undefined;  //  false`
			`true === "1";  //  false`
			`7 === "7";  //  false`
			`"an" === "an";  //  true`

>	Greater than: Returns true if the left operand is greater than the right operand; otherwise returns false.	a > b	`"a" > "b";  // false`
			`true > false;  // true`
			`5 > 13;  // false`
			`NaN > 3;  // false`
			`3 > NaN;  // false`
			`5 > Infinity;  // false`

>=	Greater than or equal to: Returns true if the left operand is greater than or equal to the right operand; otherwise returns false.	a >= b	`"ab" >= "aa";  // true`
			`"a" >= "3";  // true`
			`true >= 1;  // true`
			`15 >= 13;  // true`
			`NaN >= 3;  // false`
			`3 >= NaN;  // false`
			`5 >= Infinity;  // false`

Operator		Description	Syntax	Example
Logic	!	Logical NOT: Converts true values to false and false values to true, which is often used with boolean values. When used with non-boolean values, returns false if the operand can be converted to true; otherwise returns true.	!expr	
	&&	Logical AND: Returns true if and only if all operands are true; otherwise returns false. Evaluates operands from left to right, returning immediately upon encountering the first false value; if all operands are true, returns the value of the last operand.	expr1 && expr2	
	‖	Logical OR: Returns true if one or more of its operands are true. When used with non-boolean values, returns a non-boolean value. If expr1 can be converted to true, returns expr1; otherwise returns expr2.	expr1 ‖ expr2	
Bit	&	Bitwise AND: The result bit is 1 only if both corresponding bits of the two operands are 1.	a & b	
	<<	Left shift: Shifts the first operand left by the specified number of bits. Bits shifted beyond the left are discarded, and zeros are filled in on the right. Returns a 32-bit integer.	a << b	
	>>	Right shift: Shifts the first operand right by the specified number of bits. Bits shifted beyond the right are discarded, and the leftmost empty bits are filled with the sign bit (the leftmost bit before the shift). Returns a 32-bit integer.	a >> b	

Operator		Description	Syntax	Example

	^	Bitwise XOR: The result bit is 1 if and only if exactly one of the corresponding bits of the two operands is 1.	a ^ b	`const C1 = 11; // 0000 0000 0000 0000 0000 0000 0000 1011`
				`const C2 = 5; // 0000 0000 0000 0000 0000 0000 0000 0101`
				
				`let answer = (C1 ^ C2); // 0000 0000 0000 0000 0000 0000 0000 1110`
				`//Output result: 14`

	|	Bitwise OR: The result bit is 1 if one or both corresponding bits of the two operands are 1.	a | b	`const C1 = 11; // 0000 0000 0000 0000 0000 0000 0000 1011`
				`const C2 = 5; // 0000 0000 0000 0000 0000 0000 0000 0101`
				
				`let answer = (C1 | C2); // 0000 0000 0000 0000 0000 0000 0000 1111`
				`//Output result: 15`

	~	Bitwise NOT: Inverts all bits of the operand.	a ~ b	`const C1 = 11; // 0000 0000 0000 0000 0000 0000 0000 1011`
				`const C2 = 5; // 0000 0000 0000 0000 0000 0000 0000 0101`
				
				`let C3= (~ C1); // 1111 1111 1111 1111 1111 1111 1111 0100`
				`//Output result: -12`
				
				`let C4 = (~ C2); // 1111 1111 1111 1111 1111 1111 1111 1010`
				`//Output result: -6`

13.10.2.6.3 Operator Precedence

The precedence of operators determines the order in which operations are executed in an expression. Operators with higher precedence are executed first.

The table below lists common operators ordered by precedence, from highest (19) to lowest (1).

Precedence	Operator Type	Associativity	Operator
19	Grouping	N/A (Not applicable)	(...)
18	Member access	Left to right	... .
	new (with argument list)	N/A	new ... (...)
	Function call	From left to right	... (...)
17	new (without argument list)	Right to left	new ...
16	Post-increment	N/A	... ++
	Post-decrement		... --
15	Logical NOT (!)	From right to left	! ...
	Bitwise NOT (~)		~ ...
	Pre-increment		++ ...
	Pre-decrement		-- ...
	type of		typeof ...
	void		void ...
	delete		delete ...
	await		await ...
14	Exponentiation (**)	From right to left	... ** ...
13	Multiplication (*)	From left to right	... * ...
	Division (/)		... / ...
	Modulo (%)		... % ...

Precedence	Operator Type	Associativity	Operator
12	Addition (+)	From left to right	... + ...
	Subtraction (-)		... - ...
11	Bitwise left shift (<<)	From left to right	... << ...
	Bitwise right shift (>>)		... >> ...
10	Less than (<)	From left to right	... < ...
	Less than or equal to (<=)		... <= ...
	Greater than (>)		... > ...
	Greater than or equal to (>=)		... >= ...
	in		... in ...
	instanceof		... instanceof ...
9	Equal (==)	From left to right	... == ...
	Not equal (!==)		... != ...
	Strict equality (===)		... === ...
	Strict inequality (!==)		... !== ...
8	Bitwise AND (&)	From left to right	... & ...
7	Bitwise XOR (^)	From left to right	... ^ ...
6	Bitwise OR (|)	From left to right	... | ...
5	Logical AND (&&)	From left to right	... && ...
4	Logical OR (||)	From left to right	... || ...
3	Conditional (ternary) operator	From right to left	... ? ... : ...
2	Assignment	From right to left	... = ...
			... += ...
			... -= ...
			... **= ...
			... *= ...
			... /= ...
			... %= ...
			... <<= ...
			... >>= ...
			... >>>= ...

Precedence	Operator Type	Associativity	Operator
			… &= …
			… ^= …
			… |= …
			… &&= …
			… ||= …
			… ??= …
1	Comma / Sequence	From left to right	… , …

Relationship between expression operator precedence and associativity:

- When an expression contains only operators of different precedence levels, precedence takes priority over associativity and does not affect the output.
- When an expression contains multiple operators with the same precedence level, associativity determines the order of execution;
  For example, the exponentiation operator is right-associative, so **4 ** 2 ** 3** and **4 ** (2 ** 3)** have the same execution order and result, but **(4 ** 2) ** 3** changes the order and yields a different result.

```
4 ** 2 ** 3;     //  65536

4 ** (2 ** 3);   //  65536

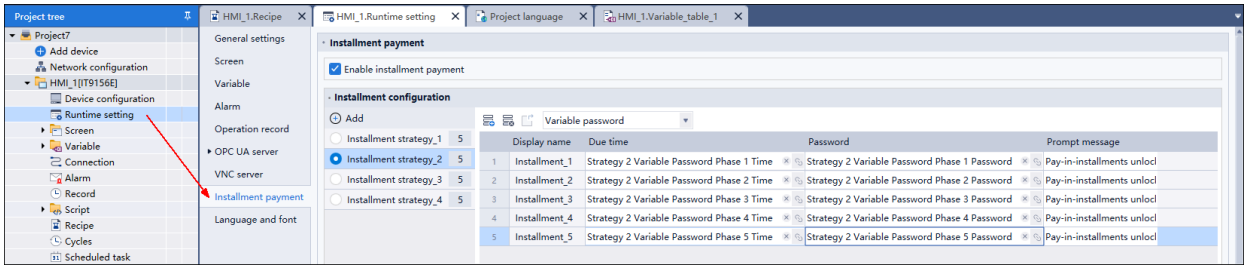
(2 ** 2) ** 3;   //  4096
```

13.11 Installment Payment

- 13.11.1 Function Overview
- 13.11.2 Enabling Installment Payment
- 13.11.3 Selecting an Installment Strategy
- 13.11.4 Installment Unlocking Modes
- 13.11.5 Configuring Pre-Due Reminder
- 13.11.6 Configuring Lock Screen
- 13.11.7 Impact of Installment Payment on Other Functions

13.11.1 Function Overview

The installment payment feature provides an embedded payment guarantee solution for equipment sales. You can divide the total price of the equipment into multiple stages, with each stage's payment due dates directly associated with the device's usage permissions, thereby safeguarding the supplier's payment rights at the software level.



Operation strategy

1. During the project configuration phase, the equipment supplier or owner pre-defines the installment payment strategy, including: the total number of installments, the due date corresponding to each installment, the amount payable, and the unique authorization password for that installment.
2. After the project is put into operation, the device follows the pre-defined installment schedule. When each installment reaches its due date, the system automatically triggers a control mechanism that locks the device's normal functions and forces it into a pending-authorization state.
3. After the user fulfills the current payment obligation, they obtain the activation password for that installment from the supplier. Upon entering the correct password in the device prompt interface, the device is unlocked, full usage rights are restored, and the system proceeds to the next payment cycle.

13.11.2 Enabling Installment Payment

Enabling

The installment payment function is controlled by a master switch. In the device's runtime configuration, there is a top-level "Enable" checkbox, which has the highest priority:

Unchecked: The entire function is disabled. All related settings are invalid, and the device will not perform any expiration checks or locking.

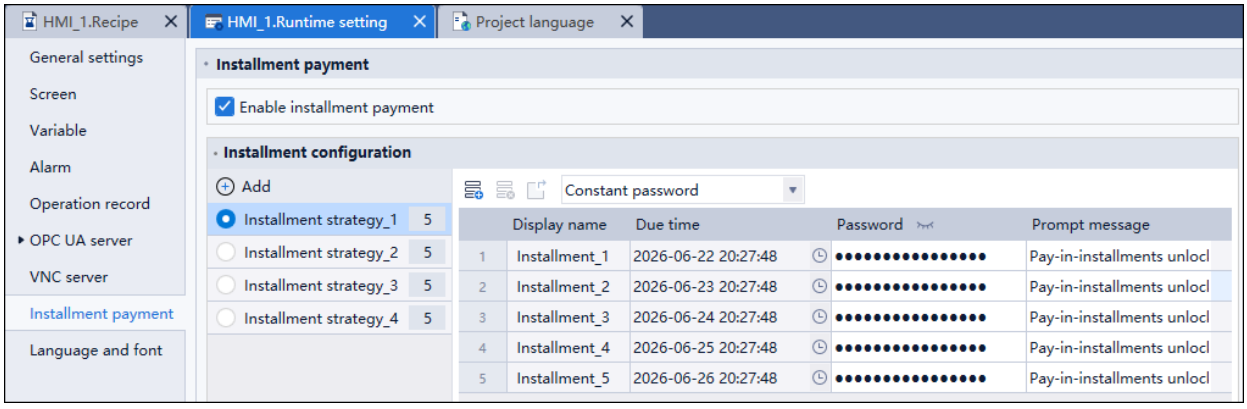
Checked: The function is enabled, and all installment-related options can be configured.

Procedure

After enabling the installment payment function, follow the steps below to ensure proper operation:

1. Configure the installment strategy and term
   Specify the installment strategy, the number of installments, and the due date for each installment. For related instructions, see 13.11.3 Selecting an Installment Strategy.
2. Configure the installment unlocking mode
   There are two installment unlocking modes. For related instructions, see 13.11.4 Installment Unlocking Modes.
3. Configure the pre-due reminder
   Set the time period and reminder frequency for advance notifications. For related instructions, see 13.11.5 Configuring Pre-Due Reminder.
4. Configure the unlocking interface
   Set the lock screen style displayed after the device expires. For related instructions, see 13.11.6 Configuring Lock Screen.
5. Compile and download project
   Compile the project and download it to the HMI device.

6. Function activation and expiration unlock
   After the device is running, the system monitors the time automatically. Upon expiration, the screen will be locked as configured. You must enter or import the correct password to unlock the device.
   When dynamic password or dynamic numeric password are enabled, a periodically changing dynamic code generated by the system will be displayed on the lock screen. The device owner needs to use this dynamic code to generate the corresponding password before unlocking.

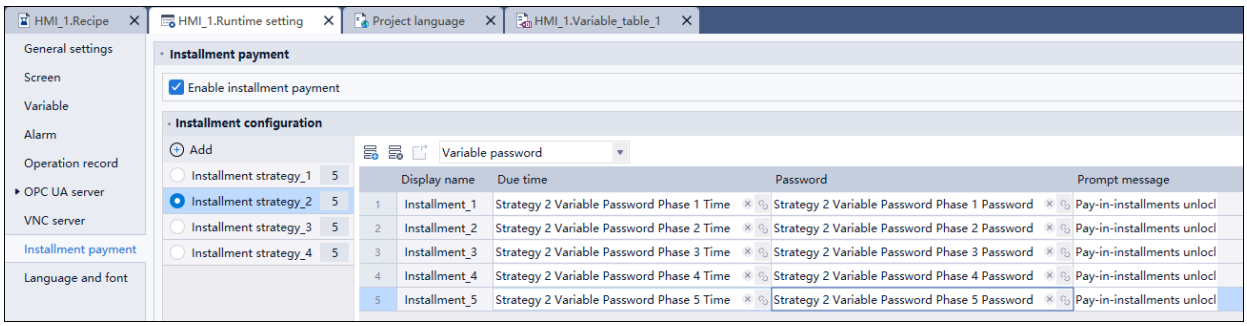


13.11.3 Selecting an Installment Strategy

A device supports configuring up to 10 different installment strategies. Each strategy allows a maximum of 48 installments. Four strategies are supported for installment payments, and their characteristics are compared as follows:

Strategy	Unlock Credential	Feature	Applicable Scenario	Security
Constant password	Pre-set static password	Easy to set up and convenient for users to remember. Once leaked, the entire project must be modified.	Suitable for internal trials or short-term installments with low security requirements.	low
Variable password	Value stored in a specified variable	The password can be modified dynamically without modifying the project. It is convenient and flexible.	Scenarios requiring remote or automatic password changes.	Mid
Dynamic password	Dynamic code generated by the server, consisting of numbers and letters.	The password is valid for one-time use and cannot be reused. It is highly secure.	Scenarios requiring strict control and after-sales service.	Highest
Dynamic numeric password	Dynamic code generated by the server, consisting only of numbers.			high

Constant password

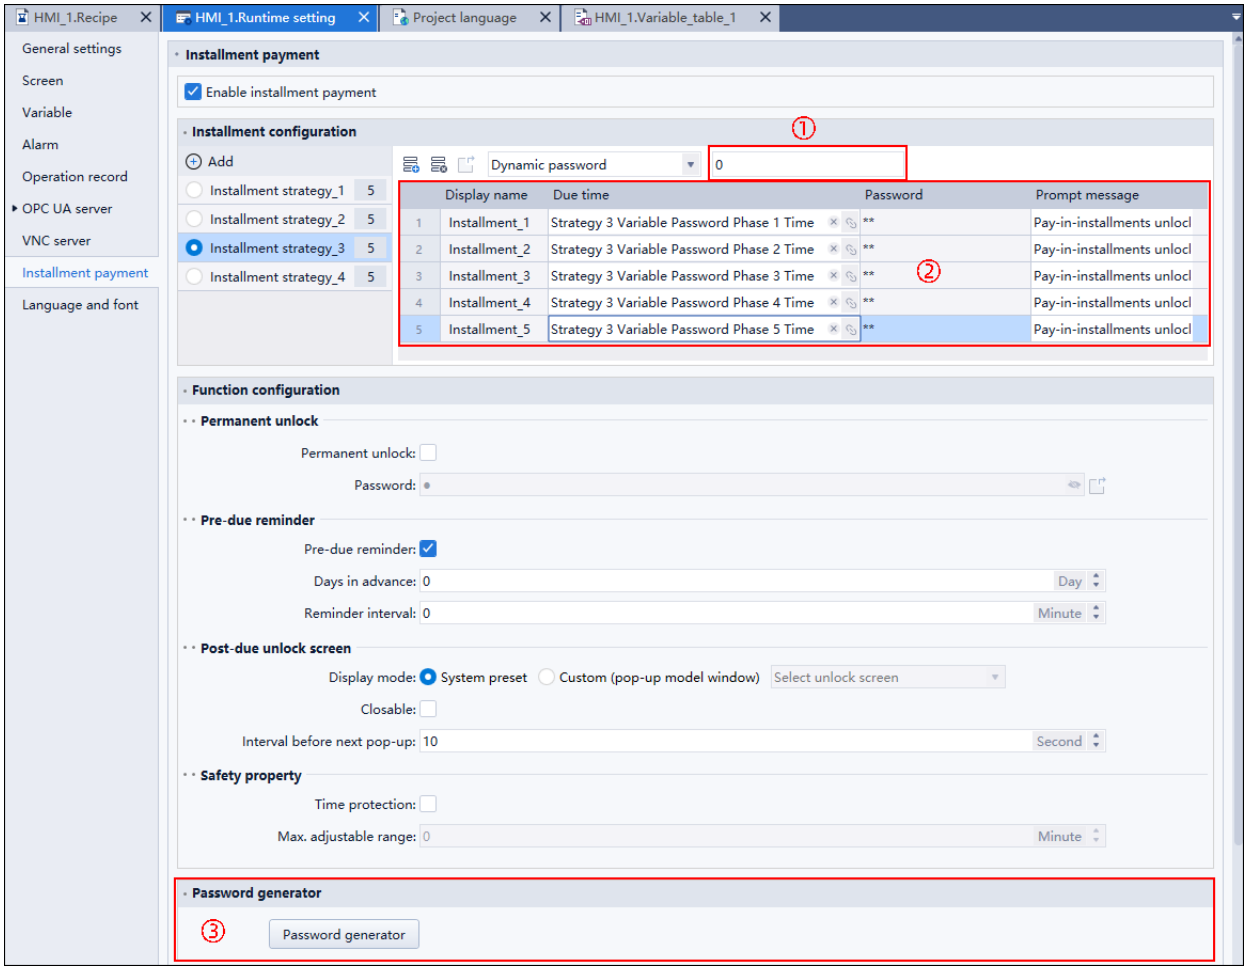


Each installment is configured with a fixed due time and password.

Password: Consists of numbers and letters, with a maximum length of 32 characters.

Variable password

The due time and password are dynamically provided by variables.



- Due time: Specify a DateTime-type variable to store the authorized due time.
  It is recommended to set the initial value of the variable to a future time later than the project download time.
  If the initial value of this variable is empty, the system automatically uses the default value 1970/01/01 08:00:00. Since this time is far earlier than the current time, the device will be immediately marked as expired upon downloading the project, triggering a lockout.
- Password: Specify a String or WString variable.

> NOTE
>
> A password written online is valid only if it is written before the due time.

Dynamic password

When the device authorization expires, the system automatically generates and displays a dynamic code consisting of numbers and letters on the lock screen. The device vendor or authorized service personnel use a dedicated password generator to obtain a unique, one-time unlock password corresponding to the dynamic code.

The device user unlocks the device interface using this password to restore normal operation.

- Installment configuration

  At Position 1, configure the static passphrase - a preset passphrase managed by the device owner, used to verify the operator's permission.

  The passphrase consists of 1 to 9 digits and cannot be empty.

  At Position 2, configure the time variable. For variable requirements, see the Variable password section above.

> NOTE
>
> Each installment must be bound to a different DateTime variable. Initial values must be distinct, and each subsequent due time must be later than the previous one.

- Password generator

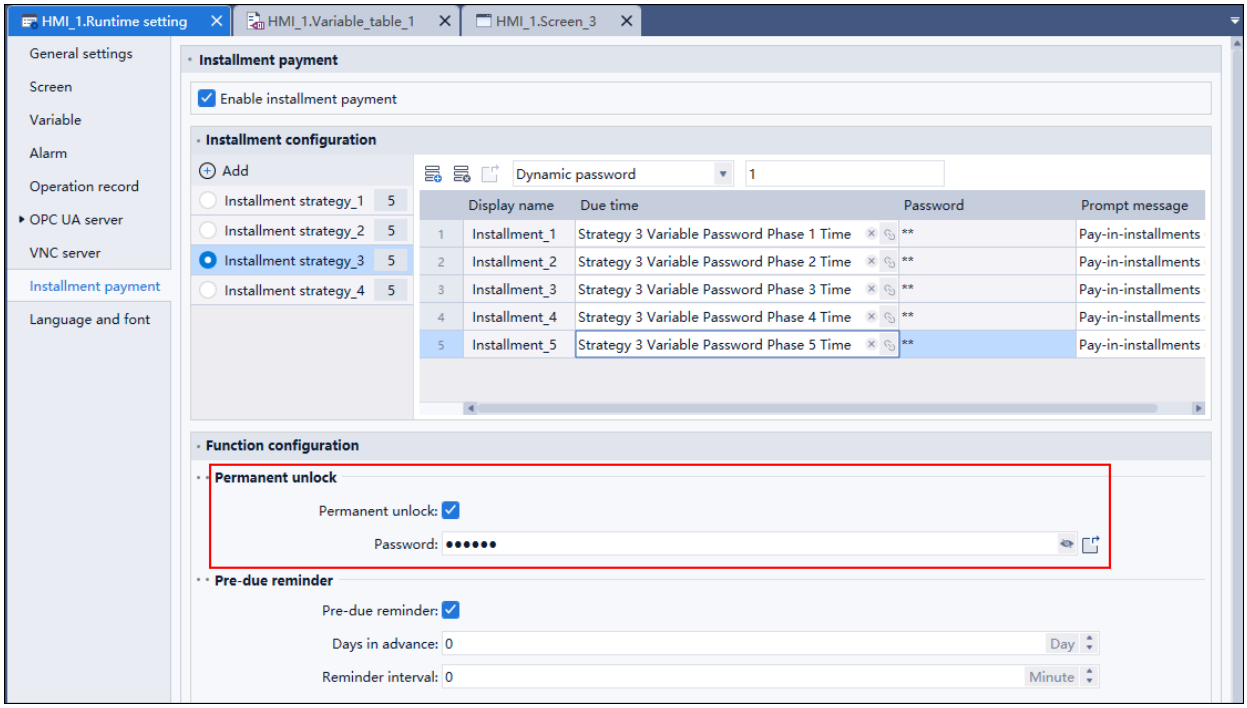
  At Position 3, open the password generator. The window is shown in the figure below.

Password generator contains the following configuration items:

Parameter	Description
Password type	Select the corresponding installment strategy.
Dynamic check password	Enter the pre-set passphrase from Position 1.
Dynamic code	Enter the dynamic code displayed on the installment lock screen.
Delay	Extend the current installment authorization period.
Days to extend	
Generate password	Generate the unlock password.
	Copy the unlock password to clipboard.
	Export the unlock password to a txt file. File naming: DynamicPasswordPolicy_InovanceExpiryKey.

Dynamic numeric password

Dynamic numeric password is a specific form of dynamic password, and it works exactly the same. There are two differences:

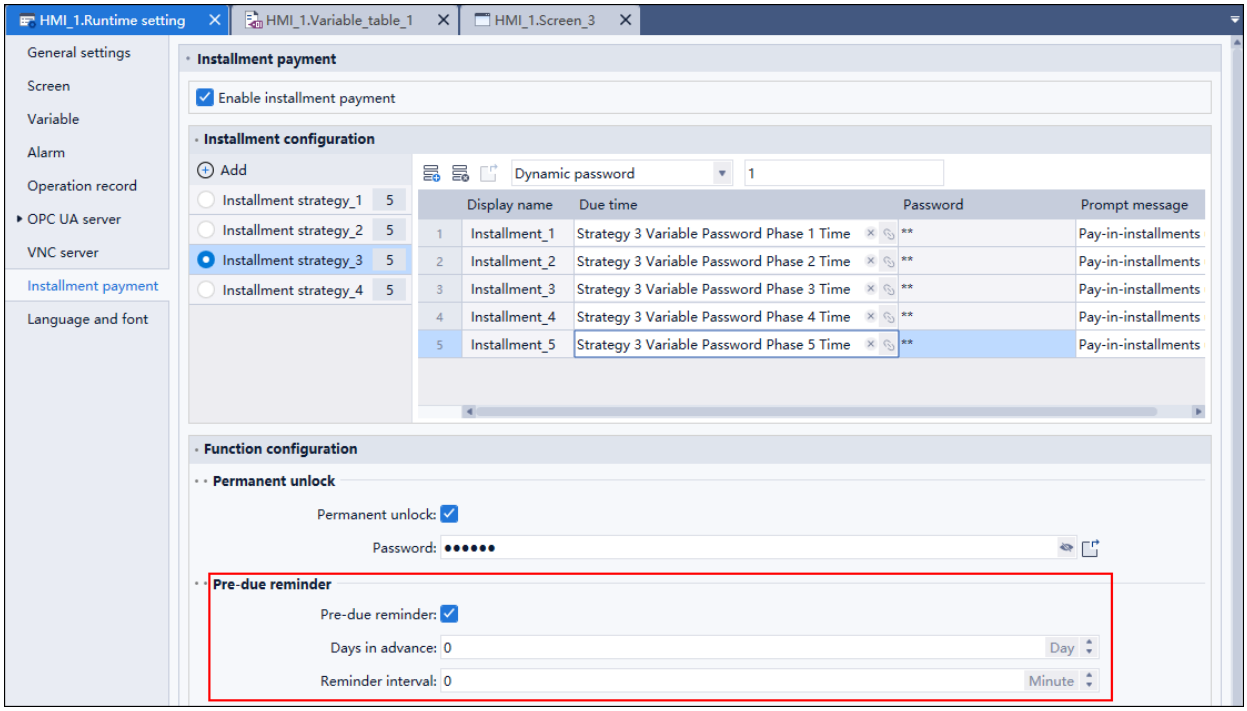


- The dynamic code consists of numeric digits only (no letters).
- The exported txt file is named: DynamicNumericPasswordStrategy_InovanceExpiryKey.

13.11.4 Installment Unlocking Modes

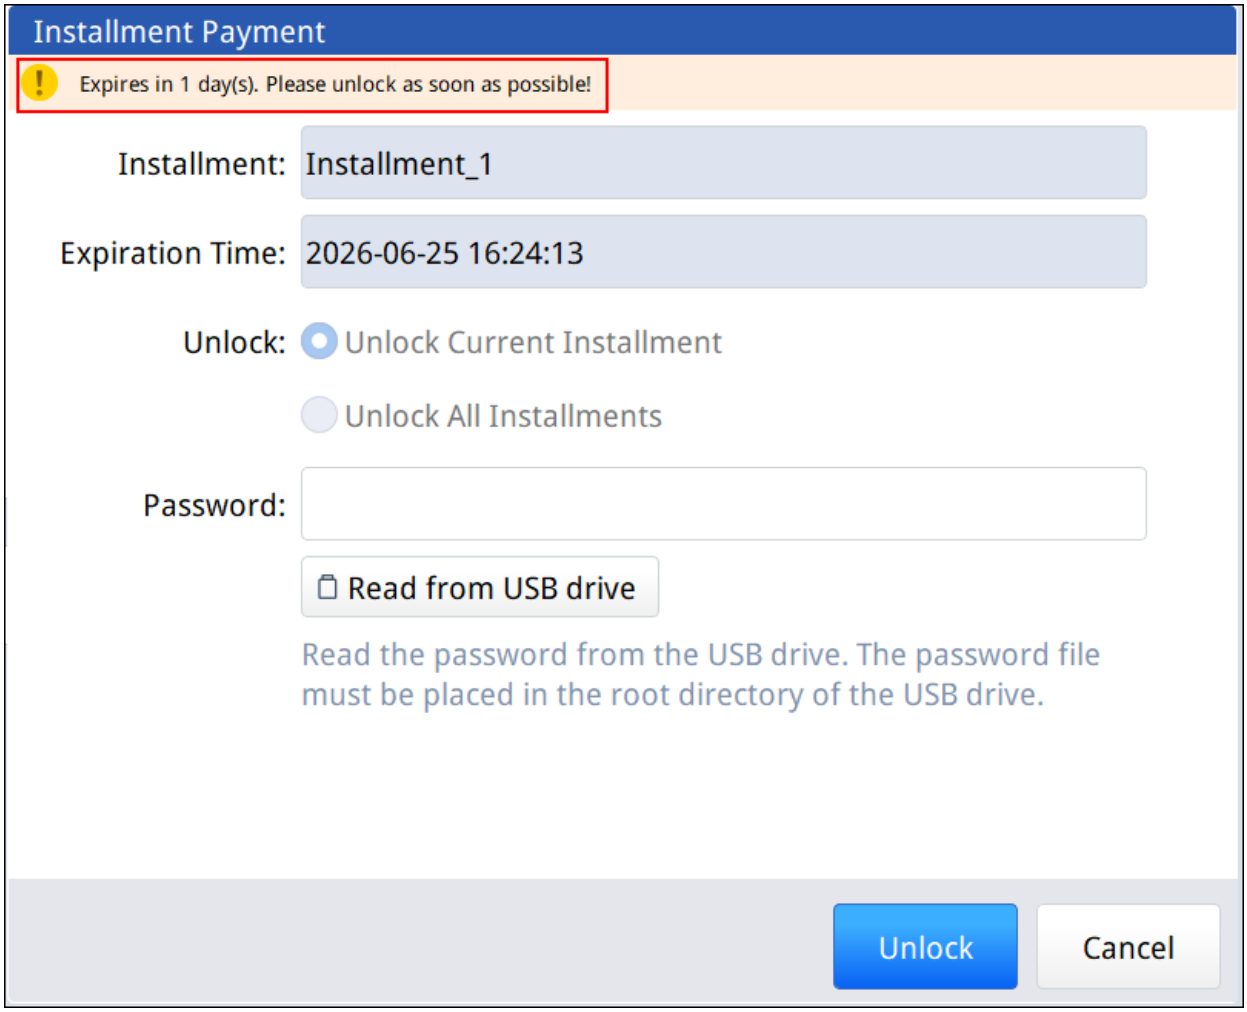
The system provides two authorization modes to conveniently adapt to different authorization delivery and maintenance scenarios. The default is **unlocking the current installment**.

Mode	Trigger Mode	Password Rule	Description
Unlock the current installment	Enter the password for the corresponding installment to unlock.	The password is pre-defined in the installment strategy. The password requirements vary depending on the strategy. For details, see 13.11.3 Selecting an Installment Strategy.	Unlock sequentially in installment order (Installment 1 → Installment 2). The password for each installment is valid only for that specific installment and becomes invalid after unlocking.
Unlock all installments	Enter a global unlock password.	The password consists of 32 digits.	Activate all remaining authorized installments at once.



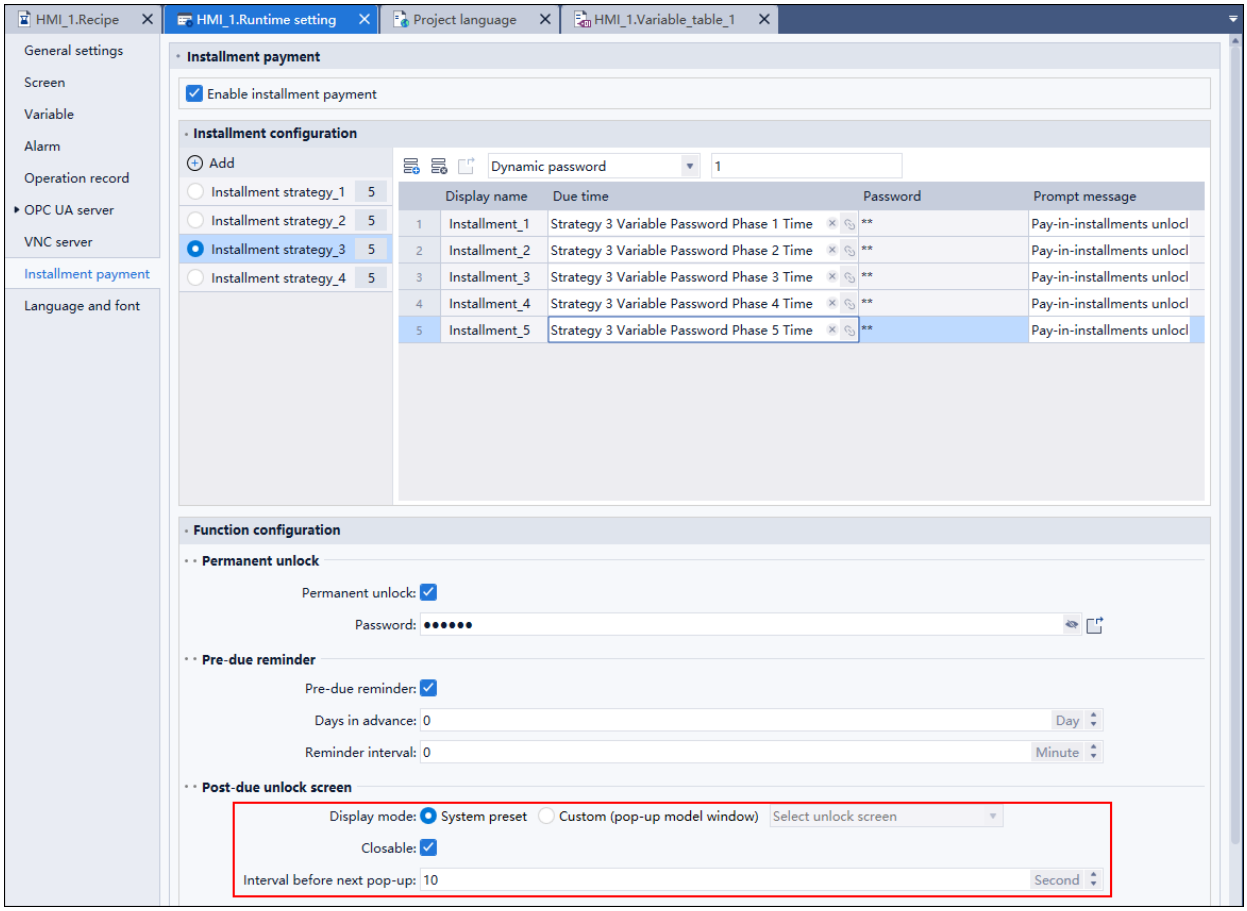
If there is a possibility to unlock all installments later, it is recommended to pre-configure the corresponding passwords in the project as shown in the figure below.

13.11.5 Configuring Pre-Due Reminder



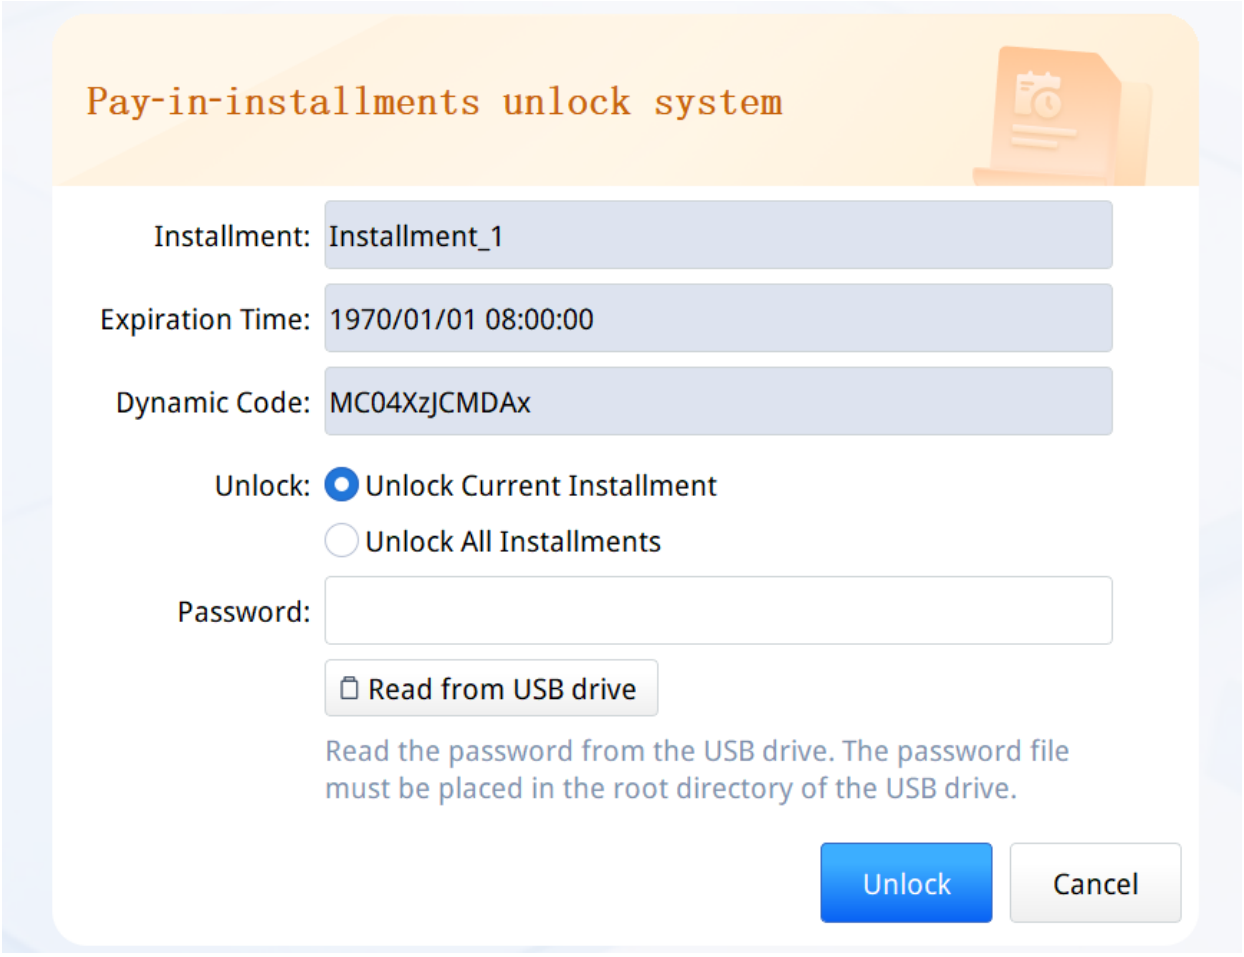
The pre-due reminder is an alarm sent by the system to the user before the authorized due date of each installment. The advance notice period can be flexibly configured, such as one day in advance or two days in advance.

The following figure shows the configuration.



- Days in advance: Ranges from 0 to 20.
- Reminder interval: The time interval between two consecutive reminders within the configured advance days. Range (minutes): 0 to 4320. 0 indicates that only one reminder is sent when the advance days condition is first met.

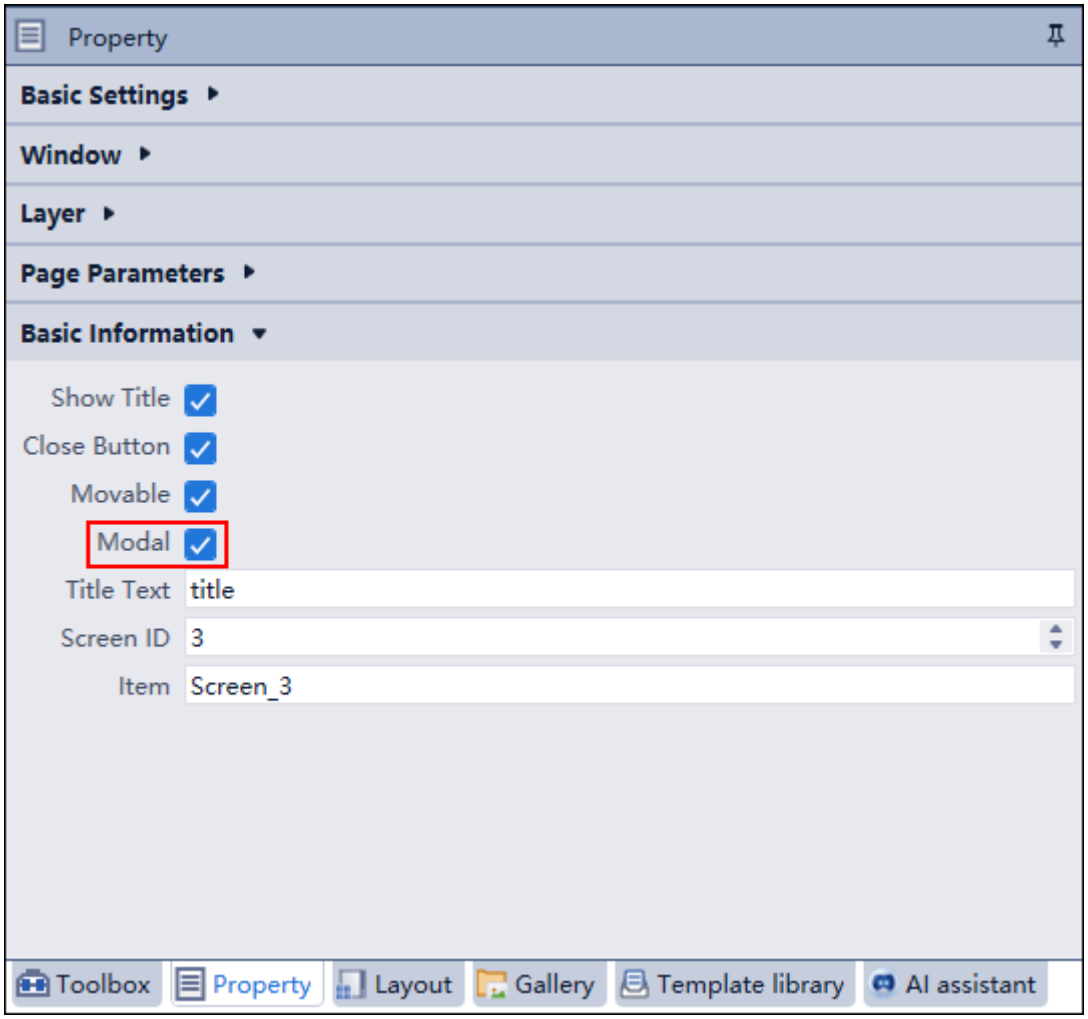
The reminder position and content in the default system pop-up dialog are shown in the figure below.



13.11.6 Configuring Lock Screen

After the device authorization expires, the lock screen mechanism will be triggered. You must enter the unlock password to continue using the device. The lock screen is divided into two types: system preset lock screen templates and user-defined screens.

System preset lock screen



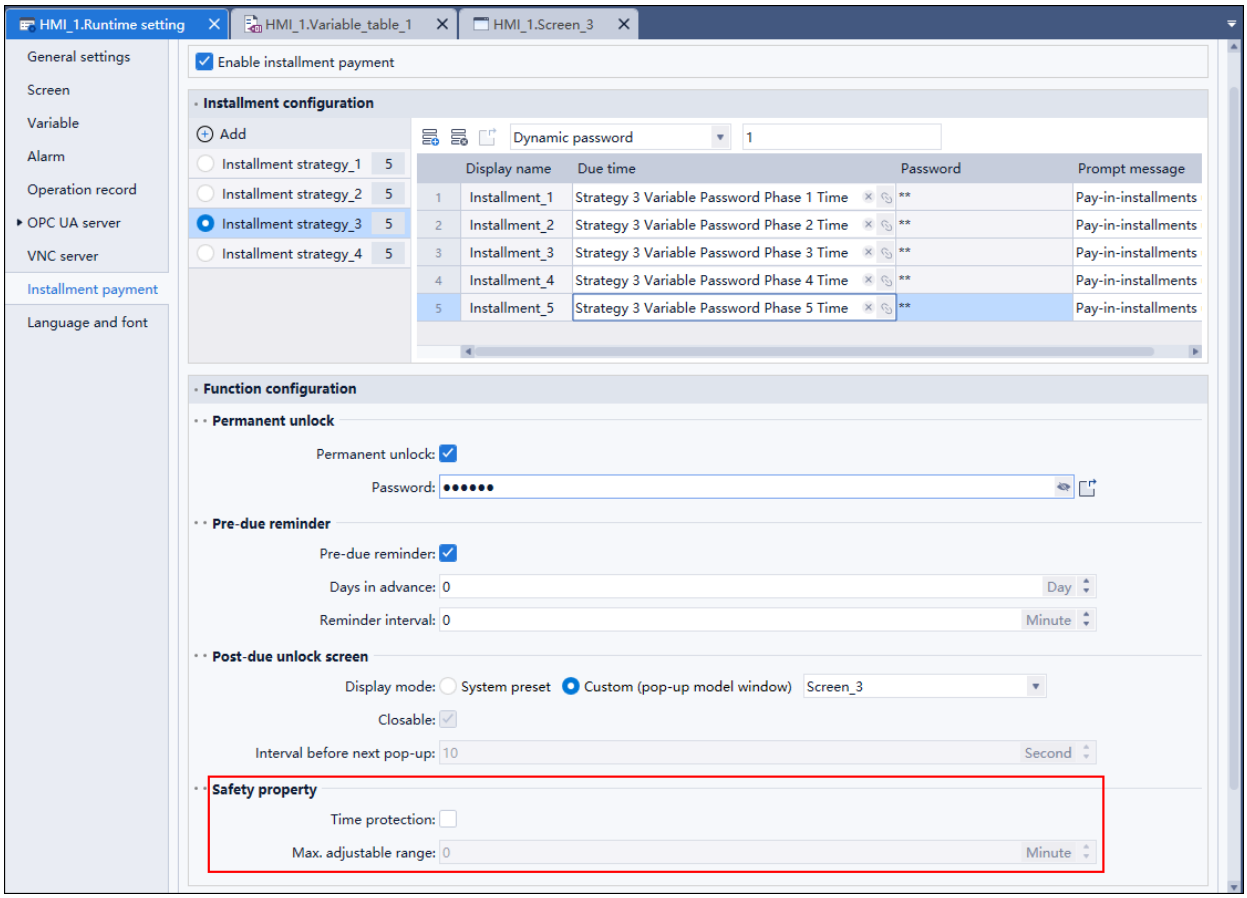
The figure below shows an example of the lock screen for the dynamic password strategy.

The "Cancel" button is only displayed when "Closable" is checked.

User-defined screen

User-defined screens are displayed via a modal pop-up, allowing users to customize the displayed content. The pop-up requires specific properties to be checked.

The pop-up can manage installment payments by monitoring system variables and configuring related system functions.



Item		Description
System Variables	$InstallMentLockState	Installment lock status. 1: Device locked (waiting for password input); 0: Device unlocked
	$InstallMentLockRemain Time	Remaining time until next installment unlock (in minutes). Value is 0 when all installments are unlocked.
	$InstallMentRemainPeriod	Total number of remaining unlocked installments in the current strategy.
	$InstallMentLockTrigger	Trigger flag for the next installment.
	$InstallmentFunctionExists	Installment function existence flag. Value is 1 when a valid installment strategy is configured in the project; otherwise, it is 0.
	$DynamicCode	Dynamic code (32 characters). The dynamic code is displayed only after expiration. When the device is unlocked, this value is empty.

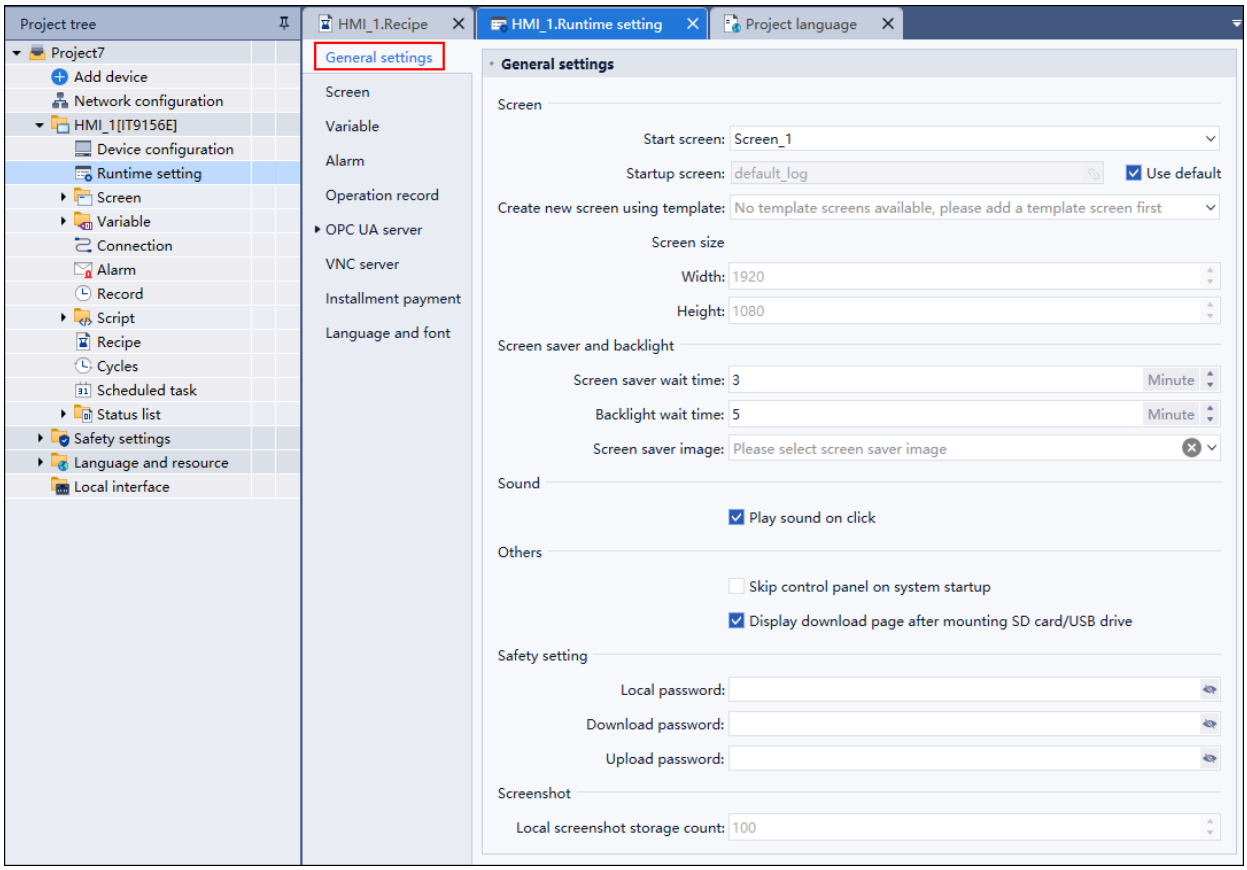
Item		Description
	$InstallmentVariableName	Installment name output, supports up to 128 characters. This value is empty when there are no installments.
	$InstallmentDueDate	Installment due time. This value is set to 1970-01-01 00:00:00 when there is no installment.
System Functions	19.9.13 Unlocking Installments	This function is used to manage the installment unlocking options and verify the installment unlocking password in the active installment payment strategy of a device.
	19.9.14 Triggering Installments in Advance	This function is used to unlock operation restrictions before the installment due time. Used to unlock upcoming installments or all remaining installments in advance.

13.11.7 Impact of Installment Payment on Other Functions

During the authorized installment period, the device date and time cannot be modified.

Time protection: When checked, time modification is allowed, but the maximum allowable change must not exceed one day; when unchecked, modification is prohibited.

13.12 Monitoring Runtime Configuration



- 13.12.1 Screen Display Configuration
- 13.12.2 Preload Screen Configuration

- 13.12.3 OPC UA Server Configuration
- 13.12.4 VNC Server Configuration

13.12.1 Screen Display Configuration

Before downloading a screen to the monitoring device, certain common properties must be configured, such as the screen saver wait time and the startup screen.

These properties are displayed on the "General settings" tab of the "Runtime setting" node in the project tree.

Category	Item	Description
Screen	Start screen	The first screen displayed when the project is running. The start screen node is identified as . The start screen can also be set through the right-click menu of the screen node.
	Startup screen	The screen displayed on the HMI during startup. The default is the Inovance logo. Supports 8-bit and 24-bit BMP format images, with a maximum image size of 3 MB. The image set here depends on the project gallery. If this image is deleted from the project gallery, a fault will be reported.

Category	Item	Description
	Create new screen using template	Newly created screens will automatically reference the specified template. Only screens created after this setting will use the template.
	Screen size	The screen size of the PC device, in pixels. The range for both width and height is 1 to 10000. Not supported by HMIs.
Screen saver and backlight	Screen saver wait time	The time the HMI waits before automatically starting the screen saver after detecting no user activity. Range: 0 to 255. Value 0 means the screen saver is disabled.
	Backlight wait time	The time after which the HMI turns off the backlight when no user activity is detected. Range: 0 to 255. Value 0 means the backlight is not turned off.
	Screen saver image	The screen displayed when the HMI enters screen saver mode.
Sound	Play sound on click	When a graphic element with a configured event is clicked on the screen, the HMI emits a sound.
Others	Skip control panel on system startup	Controls whether the control panel entry prompt is displayed during HMI startup. Checked: not displayed; unchecked: displayed. This setting takes effect when the project is downloaded to the HMI and remains active until the next download.
	Display download page after mounting SD card/ USB drive	Controls whether the HMI upload/download page of the system control panel is triggered when an SD card or USB drive is inserted. Checked: triggered; unchecked: not triggered.
Safety settings	Local password	Password for accessing the HMI control panel. The password must meet the complexity rules defined in "Safety settings > Settings". For details, see 9.5 Setting Password Policies. Password validation rules are also defined in "Safety settings > Settings". For details, see 9.6 HMI Security Authentication Policy.
	Download password	Password for downloading project data to the monitoring device. The password consists of letters, numbers, and special characters, with a maximum length of 32 characters.
	Upload password	Password for reading project data from the monitoring device. The password consists of letters, numbers, and special characters, with a maximum length of 32 characters.

Category	Item	Description
Screenshot	Local screenshot storage count	The maximum number of online screenshot files that can be stored on the local disk of the HMI. Default is 100; modification is not supported. When the limit is exceeded, the system automatically deletes the oldest historical screenshots in chronological order to free up space.

13.12.2 Preload Screen Configuration

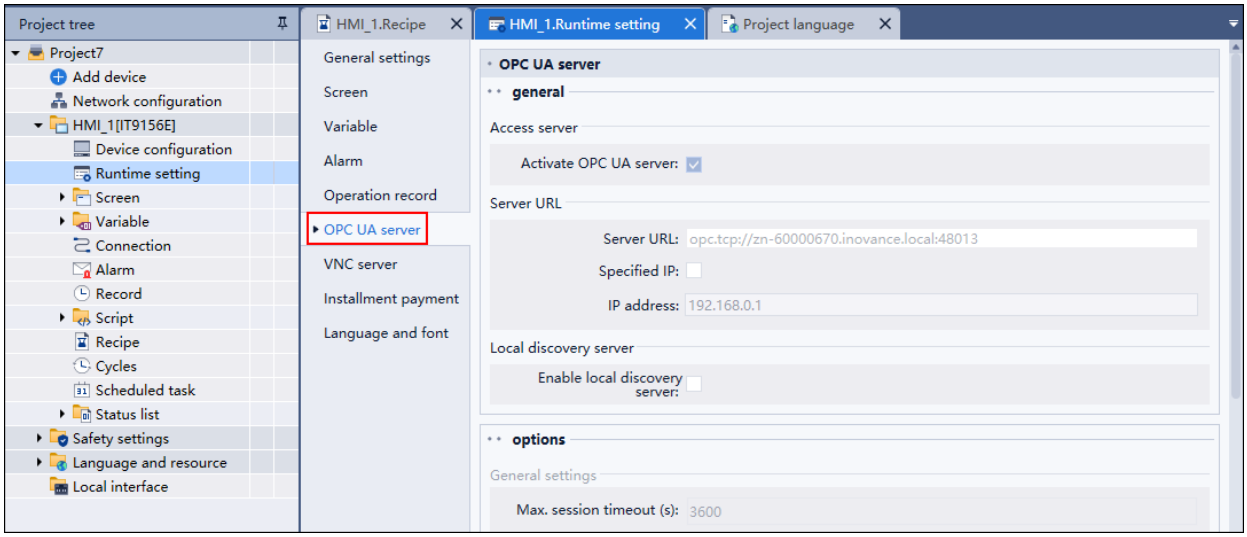
The preload function loads frequently used complex screens into memory during system startup and retains them, improving screen switching responsiveness at runtime.

Use restrictions

- Supports standard screens.
- Does not support pop-up screens, picture-in-picture, and template screens.
- Supports preloading up to 64 screens.

Procedure

1. In the project tree, double-click the "Runtime setting" node of the target device.
2. In the opened window, switch to the "Screen preloading" tab.
3. In the screen list, configure the target screens for preloading.



Configuration rules

- The system loads screens in the order listed. Use the shortcut tools above the list to adjust the loading order.
- Items that do not comply with the screen type rules or have duplicate screen names are marked in red.

13.12.3 OPC UA Server Configuration

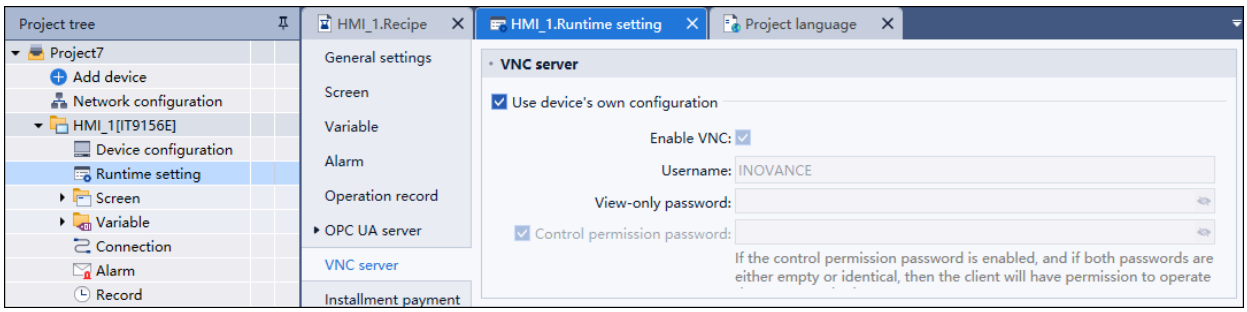
The monitoring application supports the OPC UA protocol, and the monitoring device acts as a server to expose data to external clients.

Configure the OPC UA server under "Runtime setting > OPC UA server".

Category	Item	Description
General settings	Access server	The OPC UA server is activated by default and cannot be modified.
	Server URL	The URL supports access using the server's PC name or IP address.
	Local discovery server	Whether to discover local or remote OPC UA servers.
Option	General mode	Not modifiable
	Subscription mode	Not modifiable The maximum number of monitored items per subscription is 0, meaning no limit on the item count.
Safety policy	No safety settings	Data transmission does not require encryption.
	Aes128Sha256RsaOaep - Sign	Select the corresponding options based on the certificate and safety mode; multiple selections are supported.
	Aes128Sha256RsaOaep - Sign and encryption	
	Aes256Sha256RsaPss - Sign	
	Aes256Sha256RsaPss - Sign and encryption	
	Basic256Sha256 - Sign	
	Basic256Sha256 - Sign and encryption	
Authentication	Anonymous login	No authentication is required for client access.
	Username and password authentication	Client access requires identity authentication.
	User Management	Add authentication credentials. Username: Consists of letters (case-sensitive), numbers, Chinese characters, and special characters. Maximum length: 128 characters. Password: Consists of letters (case-sensitive), numbers, and special characters. Length range: 8 to 32 characters.

13.12.4 VNC Server Configuration

In remote access to the HMI, the VNC (Virtual Network Computing) server is a software component running on the HMI device. It allows authorized external devices (such as computers and tablets) to access and control the HMI interface remotely via a network connection.



Access management configuration

Access management for the VNC server can be configured through the following three methods:

- Software interface: Configure directly in the project software.
- Hardware control panel: Configure on the HMI control panel, consistent with the software interface settings. For details, see 20.3.1 IT9000 Series Human Machine Interface User Guide.

- System functions in software configuration: Set VNC parameters by calling events. For details, see 19.12 VNC Operations.

This section focuses on configuring VNC server access permissions through the software interface.

Item	Description
Use device's own configuration	Determines whether the current configuration or the HMI control panel configuration take effect. Checked: HMI control panel configuration takes effect. Unchecked: Current software configuration takes effect.
Enable VNC	Enables or disables remote access to the HMI. Same as the function "19.12.1 Setting the VNC Enable". Checked: Remote access allowed. Unchecked: Remote access prohibited.
Username	Specifies the username for remote access to the HMI. Max length: 32 English characters. Same as the function 19.12.2 Setting the VNC Username.
View-only password	Sets the password for remote monitoring access. Password rules: • Maximum length is 32 characters. • Supports letters, numbers, special characters, and punctuation marks. Same as the function 19.12.3 Setting the VNC View-Only Password.
Control permission password	Sets the password for full remote operation access. Password rules: • Maximum length is 32 characters. • Supports letters, numbers, special characters, and punctuation marks. Its permission management is the same as the function 19.12.5 Setting the VNC Control Permission. Its password configuration is the same as the function 19.12.4 Setting the VNC Control Password.

> NOTE
>
> The storage of view-only passwords and control permission passwords uses AES-128 encryption, ensuring secure, reliable, and efficient protection of stored passwords.

13.12.5 VNC Client Configuration

The VNC client must be installed on the current operating device to connect to and control the remote device (HMI). To ensure compatibility and optimal performance, the following clients are recommended:

PC

- TigerVNC version 1.15.80 or later (https://tigervnc.org)
- RealVNC version 6.22 or later (https://www.realvnc.com)

Mobile

- AVNC version 2.7.0 or later (for Android systems)
  AVNC may not be available in some Android app stores. If not found, search for "AVNC APK" via a web browser.

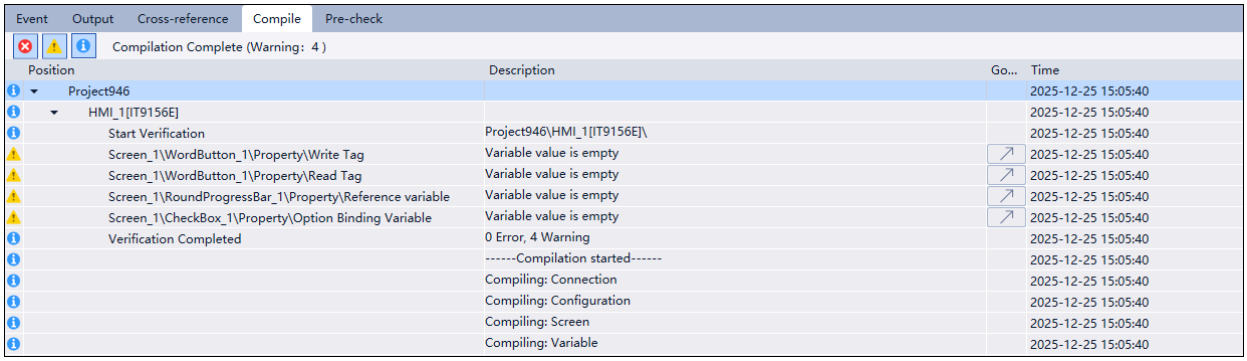
Before use, ensure the following:

1. The VNC server on the HMI is enabled. For details, see the hardware device user guide.
2. The HMI is connected to the network and has obtained a corresponding IP address.

13.13 Compilation Configuration

- 13.13.1 Compiling/Clearing
- 13.13.2 Saving a Compiled File As

13.13.1 Compiling/Clearing



Compiling

After you have designed a project, you need to compile the project before running it.

To use the compile function, select "Compile (C) > Compile" from the menu bar. You can also click the corresponding icon on the toolbar, or use the shortcut key Ctrl + B to compile the configuration project.

During compilation, the correctness, boundary conditions, and associations of the configuration project data are verified.

After compilation, the results are displayed in the output view.

The icons in the upper-left corner of the figure below represent the three types of compilation output: fault, alarm, and info. Users can click the icons to hide or show the corresponding output.

If some control properties are set incorrectly in the configuration, alarms or faults will be reported during compilation. You can locate the specific issue by double-clicking the corresponding prompt in the output view. After modifying the configuration project to resolve alarms and faults, the project can be compiled and downloaded normally.

If the project files are locked, causing abnormal compilation file generation and preventing download, the clear function can be used. Select "Compile (C) > Clear/Clear all" from the menu bar, and a dialog box will pop up.

Clearing

After the user confirms in the dialog box, the compilation information will be cleared. Download can proceed after manually recompiling.

Clear: Clears the compilation information for the current device.

Clear all: Clears the compilation information for all devices in the current project, which may prevent devices from going online directly.

When the scope of project modifications is large, or when the user intends to perform a full compilation, the user can select "Compile (C) > Recompile". This automatically clears the previous compilation information and performs a new compilation. Recompile is a combined operation of clear and compile. Standard compilation is incremental, with only changed parts compiled. Recompilation compiles the entire project completely.

13.13.2 Saving a Compiled File As

Configuration files (project source code) and compiled files for HMI and PC projects can compressed. The compressed file can be copied to the monitoring device for running, replacing the standard project download process.

File packaging

Select "Compile > Save target file as" from menu bar to open the configuration window and specify the scope of the packaged files.

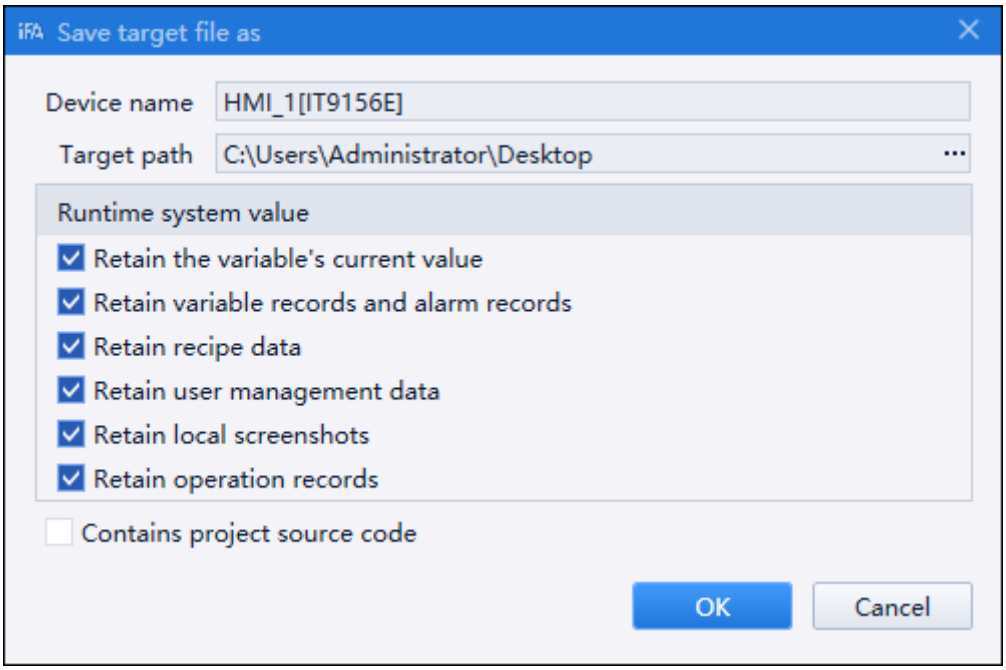


Figure 13-13-2-1 "Save target file as" window

- Device name: The device to be compiled is selected by default.
- Target path: The default path is "C:\Users\Username\Desktop". Users can modify the path.
- Runtime system value
  Refers to the data generated during runtime on the monitoring device due to online operations and variable value changes. Examples are recipe view data records added online and data records generated by variable value storage.
  When these project data are inconsistent with the offline configuration data, the user needs to determine the baseline data to be used when the project's compiled files are running on the monitoring device.
  - Retain the variable's current value: Sets the initial values for internal variables at runtime. Checked: use the last online values. Unchecked: use the initial values.
    This setting takes effect only when the internal variable's Retain property is set to .
  - Retain variable records and alarm records: Determines whether to clear historical variable data and alarm data. Checked: data is retained. Unchecked: data is cleared.

    > CAUTION
    >
    > If variable names or data types have changed, related historical data will still be cleared even if this option is checked.

  - Retain recipe data: Determines whether to retain online values and translated display names in multiple languages for recipe data records.

Object	Checked		Unchecked
Online values of data records	Retains current data and perform only incremental updates.	When an element variable is deleted, the data record corresponding to that variable will be cleared.	Clears all online values and run/display using offline configuration values.
		When an element variable is added or its name is changed, the data record for the new name will be displayed according to the element's default value.	
		When the data type of an element variable is changed, the data record for that variable will be displayed according to the element's default value.	
Multilingual translations of data record display names	Retains all current translations.	For the same recipe, data records with the same ID retain their original display names.	Uses new translations for display names.

◦ Retain user management data:

Object	Checked	Unchecked
13.3.5.4.5 User view control	Retains and applies all user account information and states that were added or edited online.	Does not retain any online changes; the control reverts to the user data defined during project configuration.
9.6 Account lockout information	Retains current failed login counts and remaining lock durations; the locked state remains active.	Resets the failed login count and lock durations; all accounts are unlocked.

◦ Retain local screenshots: Sets whether to retain screenshot files stored in the local disk directory (/**inodata/screenshot**). These files are captured online via the 19.11.1 screenshot command or the screenshot button in the trend view. Checked: retain files. Unchecked: clear files.

◦ Retain operation records: Sets whether to retain historical data of operation records. Checked: retain. Unchecked: clear.

- Include project source code
  Project source code refers to the project's offline configuration files. These files are downloaded with the project to the monitoring device as a backup for future reference and recovery.

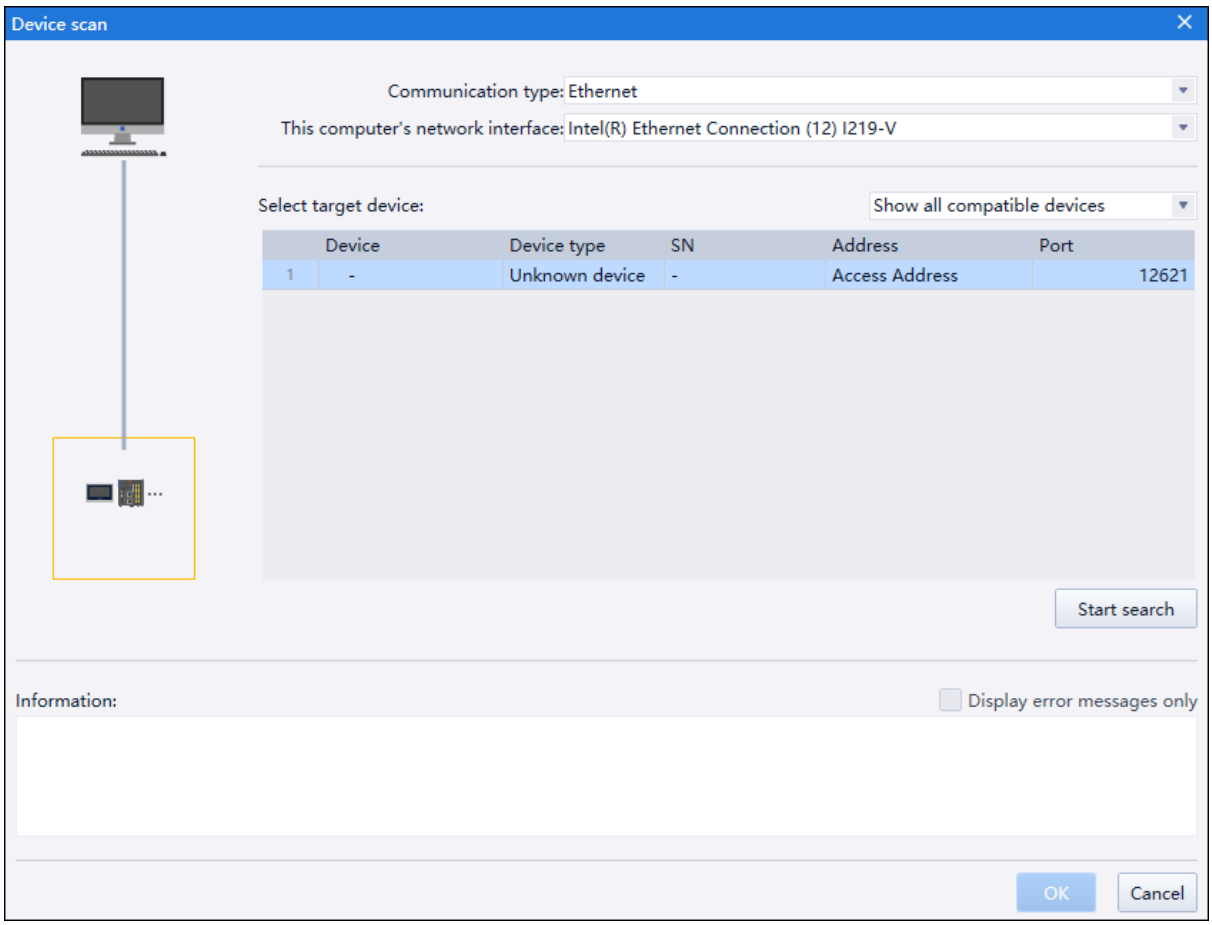
File usage

The compressed package is named project.inovp.

It does not need to be renamed or decompressed, and can be loaded directly.

- PC device
  Copy the file to the runtime software's designated installation path: Installation directory:\Inovance View\View\Datas\ProjectData\HMI\Download. The runtime software loads the data automatically upon startup.

- HMI device
  Use the AutoRun application on the device to update the project package.
  After loading project.inovp via the HMI control panel (HMI upload/download > Download project), it is automatically copied to the project path.



13.14 Project Download/Upload

- 13.14.1 Monitoring Device Connection
- 13.14.2 Project Download
- 13.14.3 Project Upload

13.14.1 Monitoring Device Connection

Before downloading to the monitoring device (HMI or PC), you need to establish a connection between the computer and the monitoring device, and set the IP address and other communication parameters. For HMI settings, see 7.3.1 HMI Ethernet Settings.

1. Select the "Download" command.
   The "Device scan" window pops up.

2. Set the communication parameters.
   Select the **Communication type** and the network interface of this computer, then click "Start search".
   Communication type supports both **Ethernet** and **USB** methods; choose based on the physical connection.

3. Check target device information.
   Check the target device's name, SN code, IP address, and port information, ensuring correct connection.

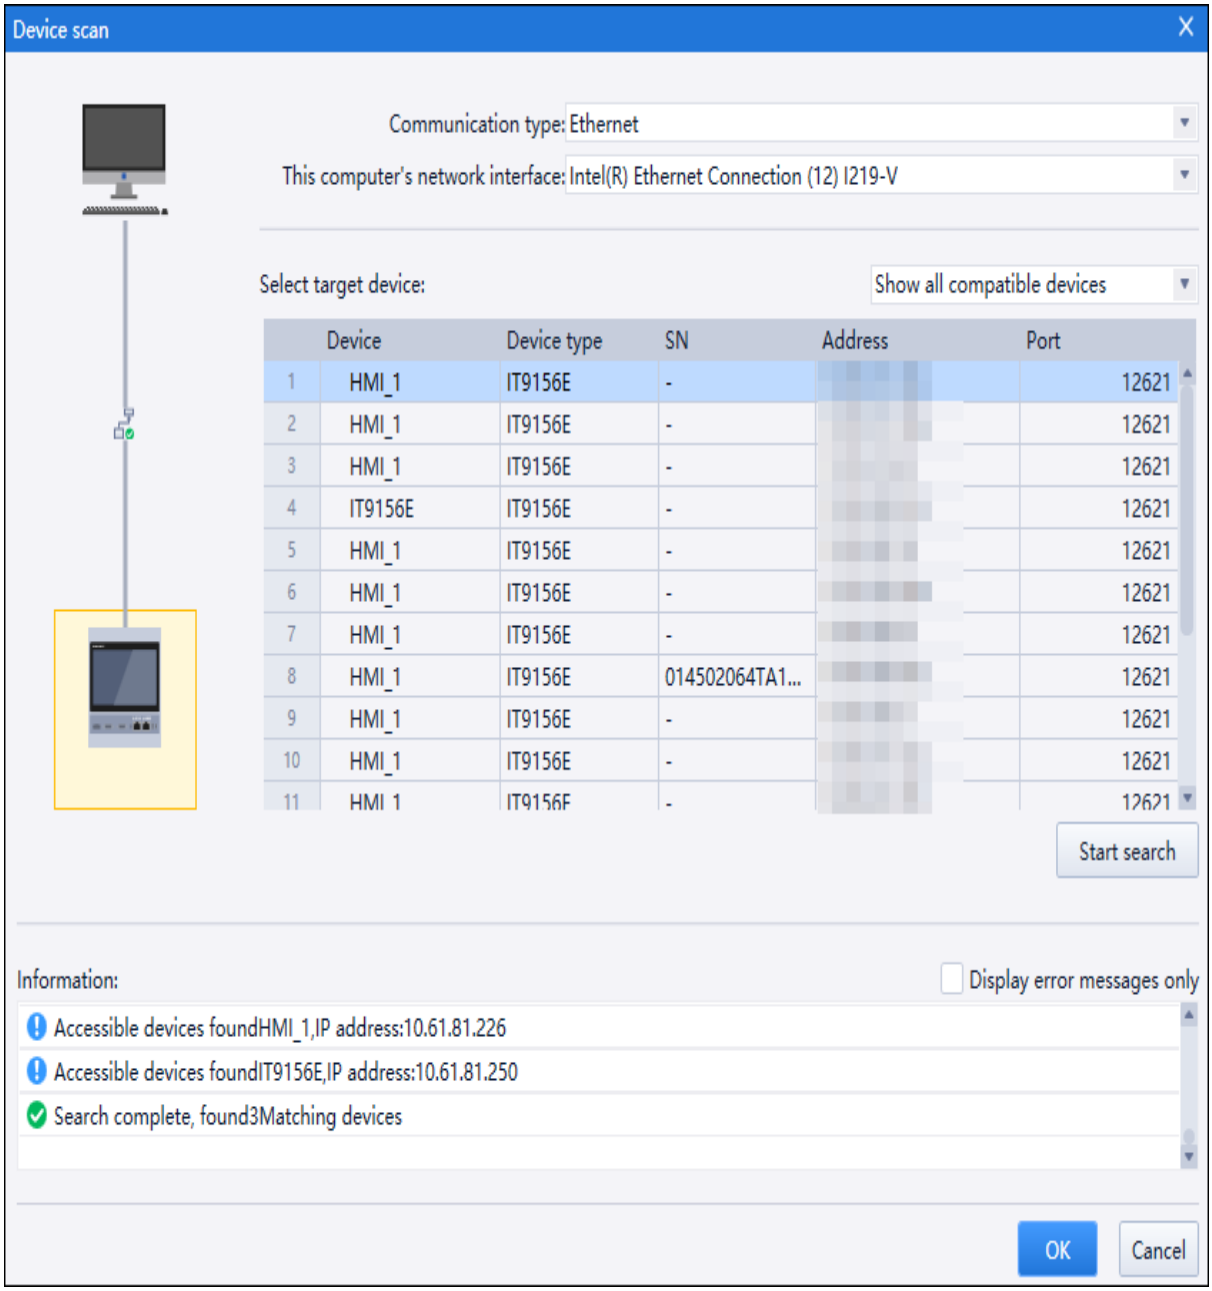


Figure 13-14-1-1 HMI search results

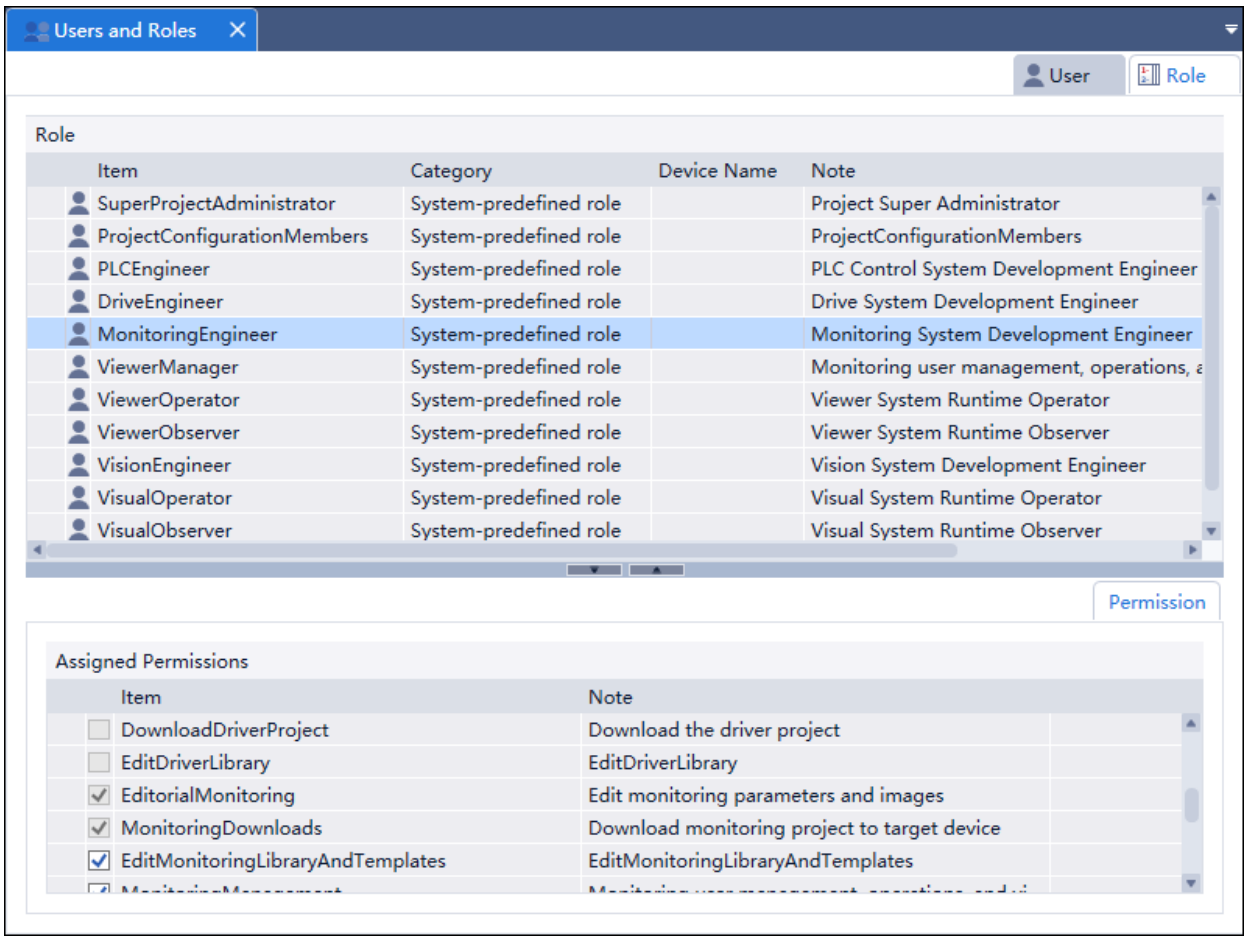
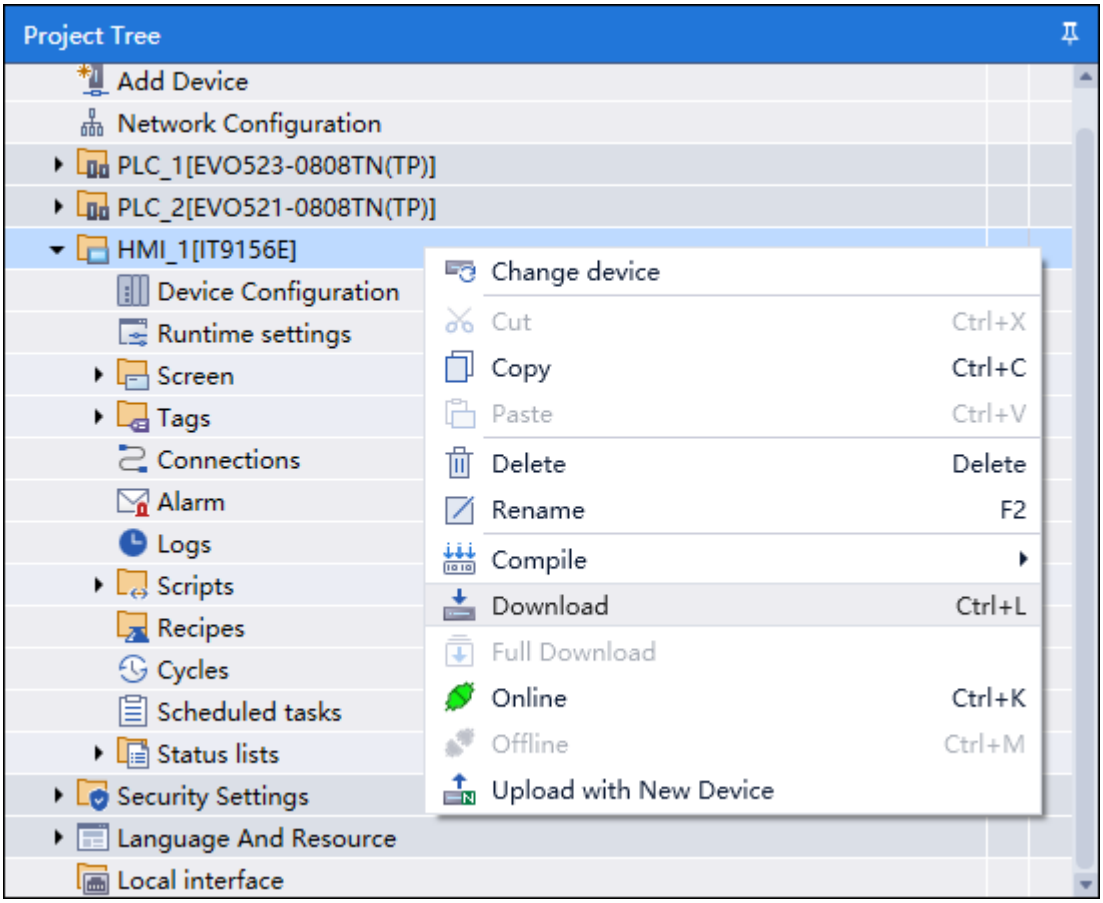


When scanning devices via USB, note that only one device can be identified at a time. Even if multiple devices are connected simultaneously, the system will randomly select one for scanning.

4. Confirm the connection object.
   Select the target device and click "OK" to establish the connection between the computer and the target device.

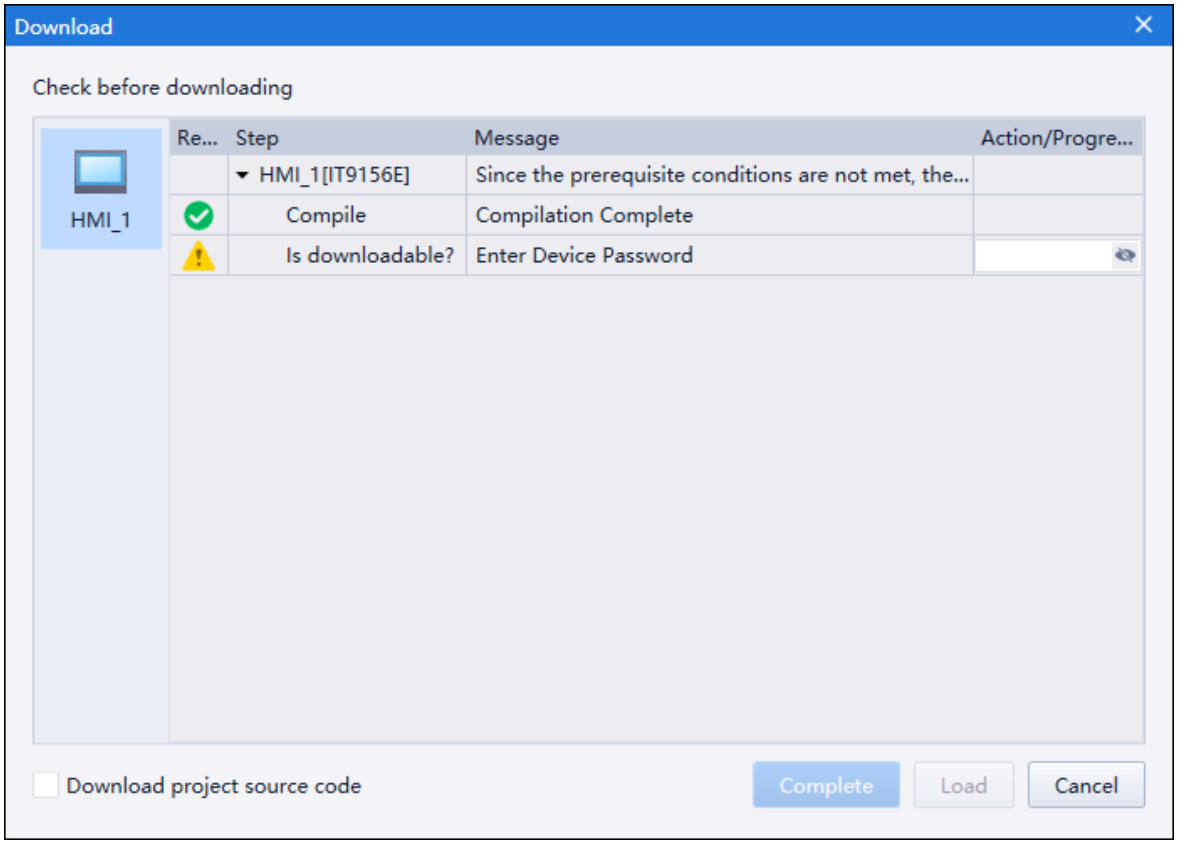
13.14.2 Project Download



Before downloading the project to the monitoring device, ensure that the engineer has download permissions and knows the download password for the monitoring device.

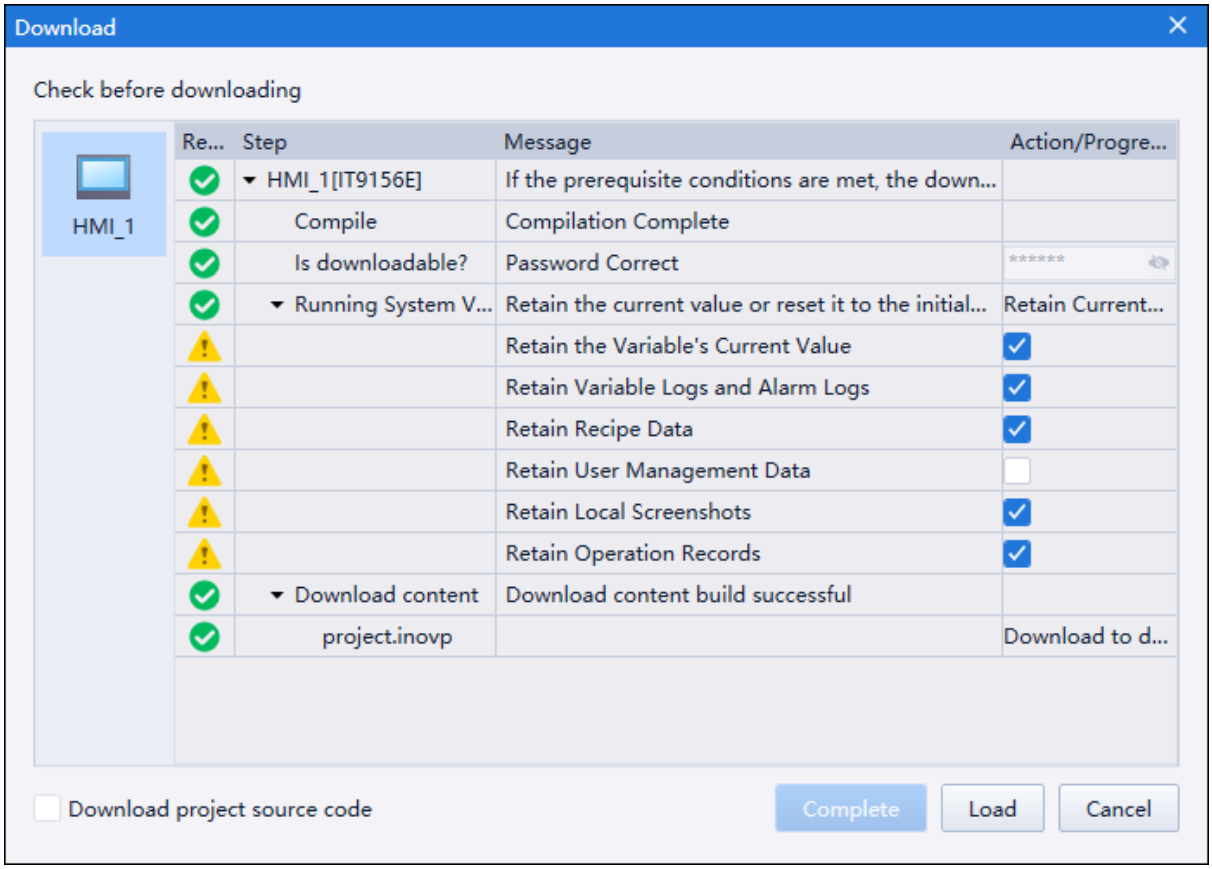
Under the "User and role" node in the project tree, enable the **monitoring download** permission for the engineer. For details, see 9.7 Managing Users.

The download procedure is as follows:



1. Select the "Download" command.
   The download command is available in three locations:
   a. Right-click the monitoring device in the project tree and select "Download".

b. Select "Online > Download" from the menu bar.



c. Select the download icon  from the toolbar.

After the project configuration is compiled, the "Download" window appears. The content of this window varies depending on whether the monitoring device has a download password set.

The download password is set in the device's general properties. For details, see 13.12.1 Screen Display Configuration.

2. Set the download scope.
   If a device password is required, enter the valid password and click anywhere in the window to complete password verification. Below is an example of a window after successful verification.

   The impact of downloading offline project content on the running data in the device, as well as whether the downloaded files include source code, need to be set in the "Download" window.

   Runtime system value

   If a project is already running on the monitoring device, the user needs to check the data items under **Runtime system value** to set whether to retain them. For descriptions of each item, see Runtime system value in 13.13.2 Saving a Compiled File As.

   Download project source code

   Project source code refers to the original configuration files of the currently downloaded project, including code, configuration files, and so on. It serves as a project backup and can be used to restore a specific version of the project during upload.

   Project source code is not mandatory for download. It is transmitted to the monitoring device as a backup only when this option is checked. These files are read and used only during project upload.

   Each download operation clears the previous download information from the monitoring device. If this option remains checked, the latest source code version is retained on the device.

   Click "Load" to start the project download.

3. Complete the download.
   When the download progress reaches 100%, the current project configuration has been successfully downloaded to the monitoring device.
   Click "OK" to end the download operation.

13.14.3 Project Upload

Project upload is a reverse-read function provided by iFA. It reads the complete project data (including screens, variables, communication parameters, scripts, alarms, recipes, and other configuration content) currently running on the HMI via a communication cable or network connection. It then synchronizes the data to the iFA project, and generates a viewable and editable project file, enabling backup and recovery of the on-site project.

Applicable Scenario

This function is suitable for scenarios such as loss of the local source project file, inconsistency between the on-site project and the local file, device replacement, and project archiving/backup. It can be used for quick retrieval of the complete program in use on-site.

Restrictions

The following conditions must be met to upload an HMI project:

- The HMI project source code must have been downloaded to the device with the "Download project source code" option checked. See 13.14.2 Project Download for details.
- If an upload password is set in the source project, please be aware of it.
- The device ID of the upload device must not duplicate any existing device ID in the current project (the software automatically detects and prompts accordingly).
- The software version running on the device must exactly match the iFA software version.
- The device model added in the iFA project must match the physical device model.

Upload scope

Uploaded data is limited to the device's own configuration content, including hardware parameter settings, scripts, internal/external variables, and screens.

For the following global functional modules, only the parts instantiated in the device will be uploaded:

- Template library
  Only symbols or custom type versions that are instantiated on the device are uploaded. For example, if a symbol has five versions but only two are used in the device, only these two versions are uploaded.
- Connections
  Only manually created PLC-HMI connections (with connection identifier ) are uploaded. Automatically created connections (with connection identifier ) are not uploaded.
- Device permissions
  If a permission configured in the source project does not exist under the same name in the current project, the permission configuration location is marked as abnormal.
- Image resources
  If local images are used in the project, they are uploaded along with the project data. If duplicate image names are encountered, the system automatically renames them.

Upload procedure

1. Open the target project in the iFA software.
2. Select the upload command.
   Select "Online > Upload with new device" from the menu.
3. Scan and select the target device.
   Scan devices via Ethernet or USB, then select the target device from the scan list.
   - USB connection: Scans and selects the connected device directly;
   - Ethernet connection: The PC and device IP addresses must be on the same subnet; otherwise, the device cannot be detected.
4. Verify the upload password.
   If an upload password was set during the download of the source project, enter the password. If no password was set, this step is skipped.
5. Execute project upload.
   Begin uploading the source project data. Monitor the prompts during the process. If a device ID conflict is detected, the upload operation will be terminated.
6. Verify and correct after upload.
   After the upload is complete, verify the result and manually adjust any anomalies.

13.15 Screen Operation

- 13.15.1 Real-time Variable Value Monitoring
- 13.15.2 Online Recipe View Operations
- 13.15.3 Online Historical Data Viewing
- 13.15.4 Online Alarm View Operations
- 13.15.6 Online Operation Record Operations
- 13.15.7 Online System Diagnostics
- 13.15.8 Online PLC Program Viewing

13.15.1 Real-time Variable Value Monitoring

When a user-designed process screen is running on the monitoring device, variable values on the screen are updated according to the following rules:

- System variables: Updated every 1s.
- User variables:
  - Updated according to the set 13.2.5.3 acquisition cycle if recording or alarm properties are configured.
  - If recording or alarm properties are not configured, variable values are updated according to the set 13.2.5.3 acquisition cycle only when the screen containing them is open. Updates stop when the screen is closed.

For objects configured on the screen, the display of numeric I/O field and character I/O field values differs under normal and abnormal communication conditions:

Control	Normal Communication		Communication Interrupted
/	Displayed in plain text	Displayed in cipher text	/
Numeric I/O field	56.30 ℃ 55 6688	***** ℃ **	0 ℃ 0 0
Character I/O field	INOVANCE	********	

CAUTION

When an IT9000 series device communicates with an EVO1000 series PLC, if the acquisition cycle of the communication variable is set to less than 500 ms, the new value may flicker after being written via the screen (symptom: the new value briefly jumps back to the old value before being written, and then returns to the new value). To avoid this phenomenon, it is recommended to set the acquisition cycle to 500 ms or longer.

13.15.2 Online Recipe View Operations

The recipe configuration data is monitored online through the 13.3.5.4.3 Recipe View.

The following shows the online operation interface of the recipe view after associating variables.

Figure 13-15-2-1 Online operation interface of the recipe view

The display effect in the recipe view can be configured on the "Property" tab on the right.

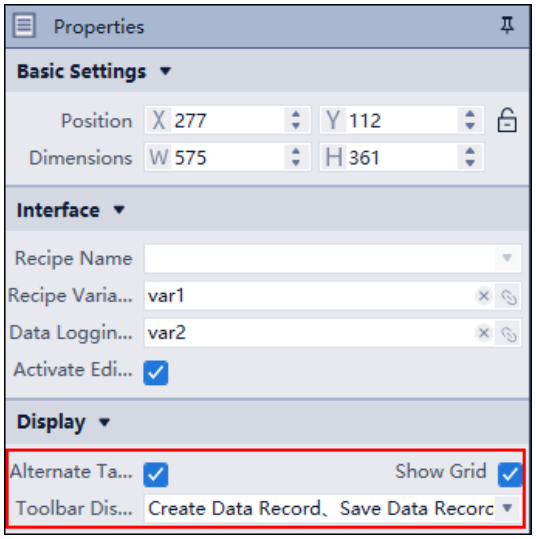


Figure 13-15-2-2 Online display properties of the recipe

The properties are described as follows:

- Recipe name: Selects the recipe to monitor by name.
- Recipe number: Selects the recipe to monitor by number.
- Data record name: Locates the corresponding row in the selected recipe by data record name and highlights it in blue, as shown in row 2 of the figure above.
- Data record number: Same function as data record name; locates the data record by ID.
- Create data record: Creates a new data record online. For naming requirements of the display name, see 13.6.2 Adding a Recipe.
  In multilingual environments, the name entered is used as the default name for all enabled languages.
- Rename data record: Modifies the display name of an existing data record. In multilingual environments, only the translation for the current UI language is changed; other language versions remain unchanged. To change other languages, switch to the corresponding language and rename again.
- Save data record: Saves the values of the selected data record to the monitoring device's data cache. When "Retain recipe data" is enabled in the download settings, saved values remain effective.
- Delete data record: Deletes the selected data record.
- Export recipe: Exports the current recipe information and data and saves it in CSV format.
  Connect an external storage device (e.g., USB drive, SD card), then select a folder and enter a file name.

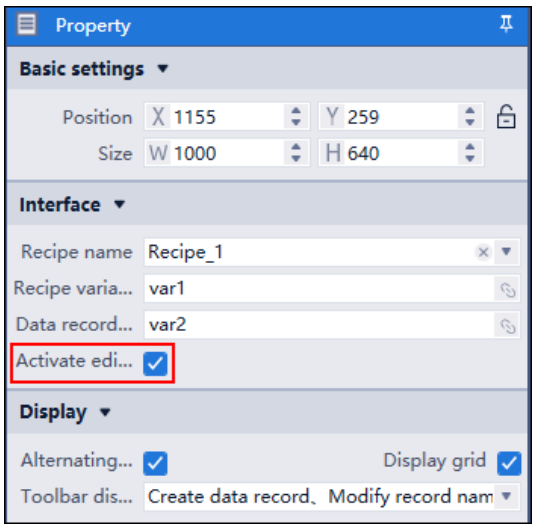
  - Exported files cannot be saved in the root directory.
  - Recipe export only supports exporting the multilingual content of the current device. To export other languages, enable them in "Runtime setting > Language and font" for the device before exporting.

  After confirmation, the current recipe data is exported to the specified location in CSV format, and a confirmation message appears in the recipe view.
- Read from PLC: Reads real-time element values from the PLC and updates them into the selected data record.
- Write to PLC: Writes the values of the selected data record to the PLC to make them effective.

Operations supported by the recipe view during online operation, such as modifying data or adding/deleting data records, do not affect the offline configuration of the recipe.

Modifying data records

Modifying data records is allowed only when **Activate edit mode** is checked, as shown below.



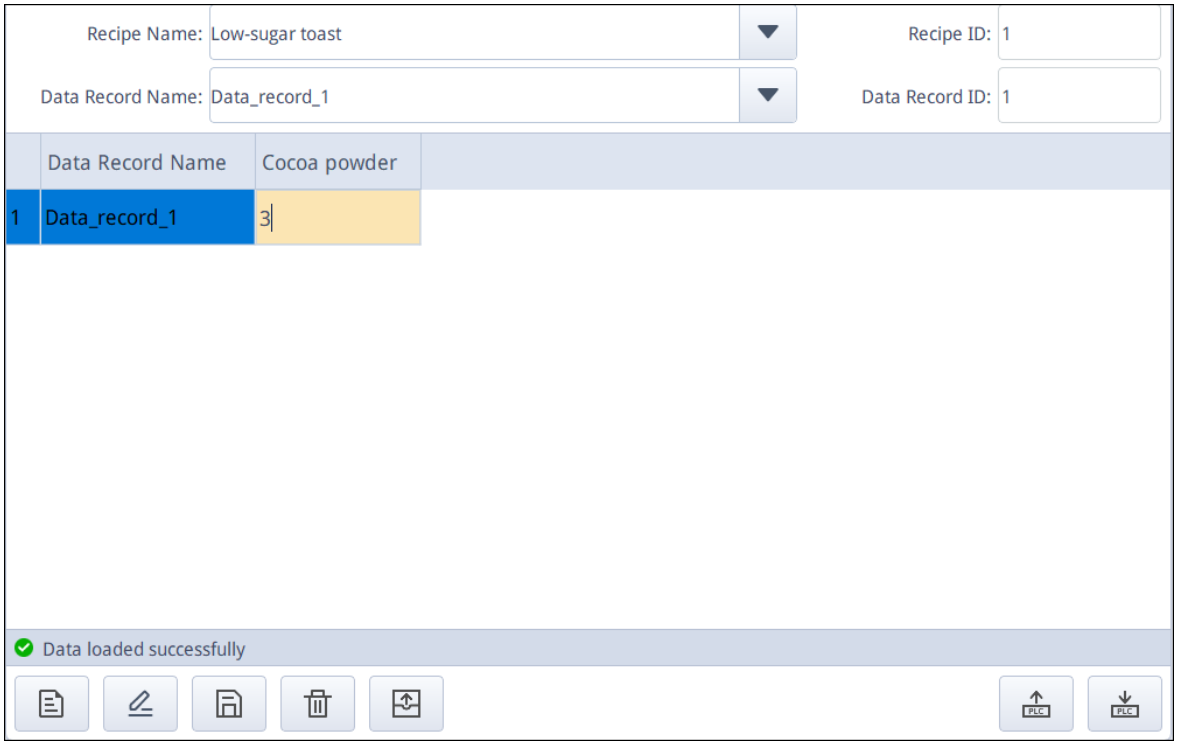


Figure 13-15-2-3 "Activate edit mode" property of a recipe

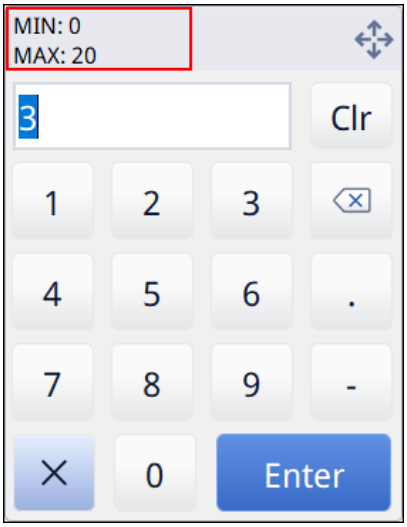


- Modifying element values

  1. Click the target cell and the cell background turns yellow, such as the **cocoa powder** content cell in the figure below.

  2. Write a new value.

     Enter the new value (within the allowed range) in the dialog box.

If the input value exceeds the limit, a red alarm is displayed.

When the input value is valid, the cell background turns green.

3. Click  to save data.
4. Click  to write the new value to the PLC.

Adding a data record

Click  to add a data record. A recipe supports up to 1000 data records.

Click  to save the added data records and click  to write them to the PLC to take effect.

Deleting a data record

Delete the selected data record.

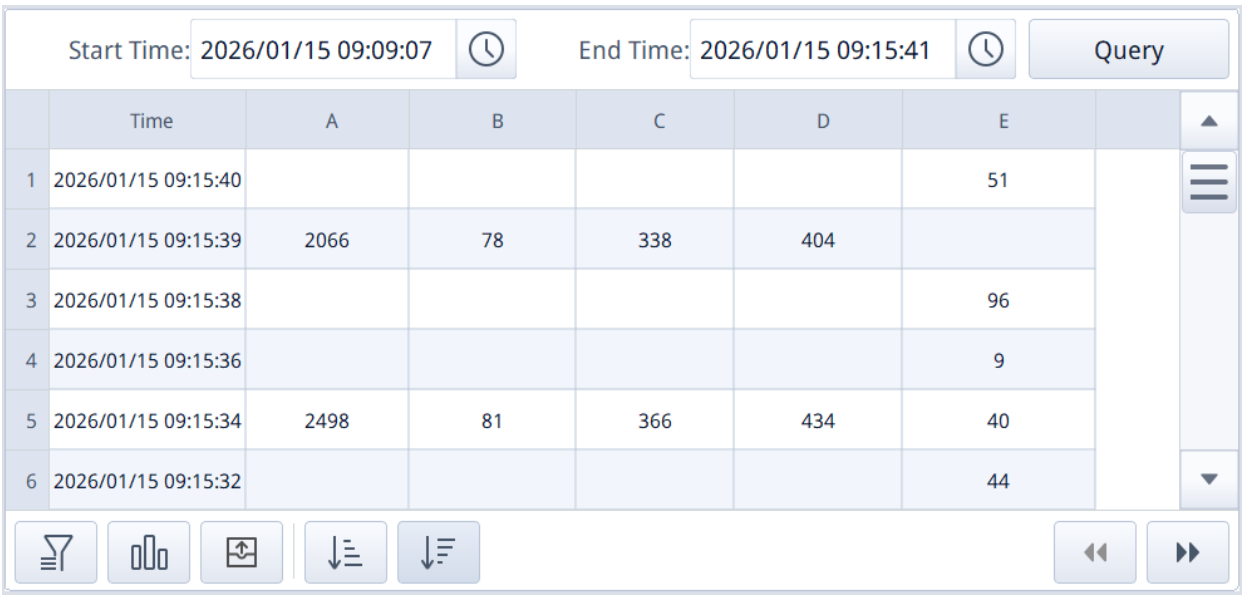
Importing/Exporting recipe data

Recipe data export: Recipe data can be exported via the  icon or the script instruction (see 19.7.6 Exporting Recipe Data Records).

Ensure that element data has been saved. Values that have been modified but not yet saved (indicated by a green cell background) will be exported based on the pre-modification values.

Recipe export only supports exporting the multilingual content of the current device. To export other languages, enable them in "Runtime setting > Language and font" for the device before exporting.

Recipe data import: Imports the exported data to overwrite the current recipe content using the script instruction (see 19.7.7 Importing Recipe Data Records).

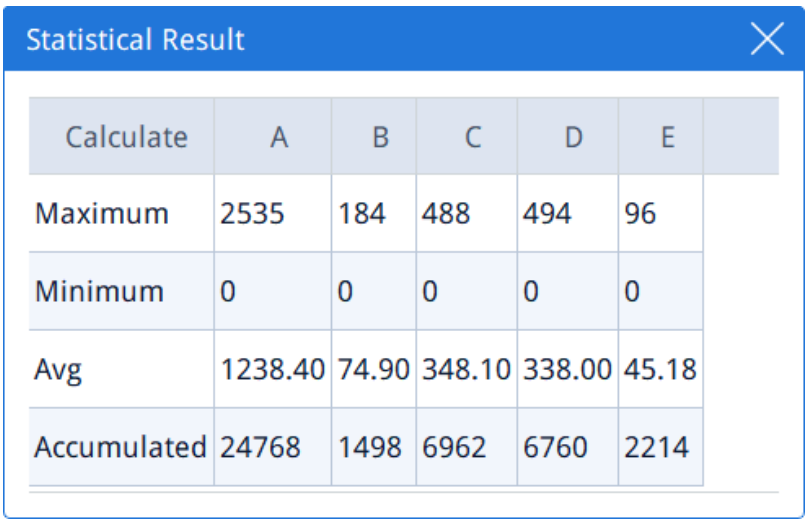


13.15.3 Online Historical Data Viewing

Users can view historical variable data online through controls 13.3.5.4.6 variable log view, 13.3.5.3.6 F(t) trend curve, and 13.3.5.3.7 F(x) trend curve. For details on their features and configuration, see the related sections. This section focuses on their online usage.

Variable log view

Variable log view displays detailed values of specified variables within a selected time period from the data record. For example, the figure below displays the values of variables A to E between 15:57 and 15:58 on November 22, 2024.



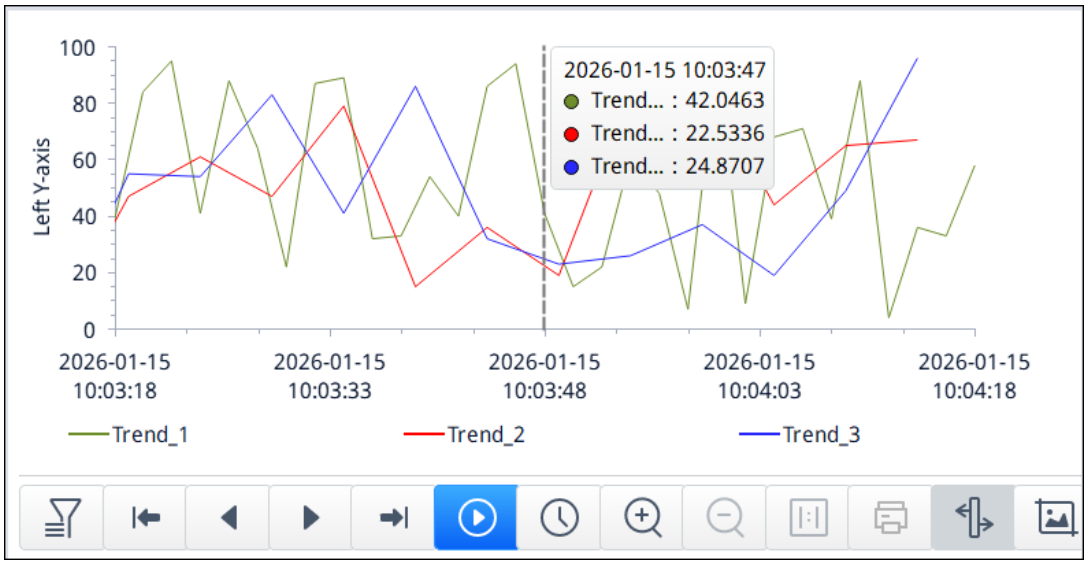
Variables A to D have a 5-second recording cycle, while E has a 2-second cycle. Since the table rows are organized by logging cycle, some cells may be blank, as shown in the figure below:

	Time	A	B	C	D	E
1	2026/01/15 09:15:40					51
2	2026/01/15 09:15:39	2066	78	338	404	
3	2026/01/15 09:15:38					96
4	2026/01/15 09:15:36					9
5	2026/01/15 09:15:34	2498	81	366	434	40
6	2026/01/15 09:15:32					44

: Filters the variables displayed in the view.

: Calculates the maximum/minimum, average, and cumulative values for integer and floating-point variables over the selected period (floating-point values default to two decimal places).

Calculate	A	B	C	D	E
Maximum	2535	184	488	494	96
Minimum	0	0	0	0	0
Avg	1238.40	74.90	348.10	338.00	45.18
Accumulated	24768	1498	6962	6760	2214



: Exports the current table data and statistics in CSV format. For related operations, refer to the data record file export in the recipe view.

: Sorts time from newest to oldest.

: Sorts time from oldest to newest.

F(t) trend curve

The F(t) trend curve displays the relationship between variable values and time. The figure below shows the trend of three variables between 17:11 and 17:12 on March 10, 2025.

F(t) trend curve example

: Filters the variables displayed; supports up to 16 trends.

: Moves the trend time to the first recorded value.

: Moves the trend time backward by one time period (set in view properties).

: Moves the trend time forward by one time period (set in view properties).

: Moves the trend time to the last recorded value.

: Activates real-time data display.

For example, click this icon and the view displays the real-time value of the variable. If the communication between the HMI and the PLC is interrupted, the real-time value acquisition fails, causing the X-axis time of the curve to stop refreshing. It resumes when communication and real-time value acquisition returns to normal.

: Sets the number of values or the time interval displayed in the view. Supports three configuration methods:

- Time range: Queries values within a specified duration from the start time. Range: 1 to 32767.
- Number of measuring points: Queries a specified number of data points from the start time. Range: 0 to 86400.
  For example, the figure below displays 20 measuring points backward from 17:11:41:

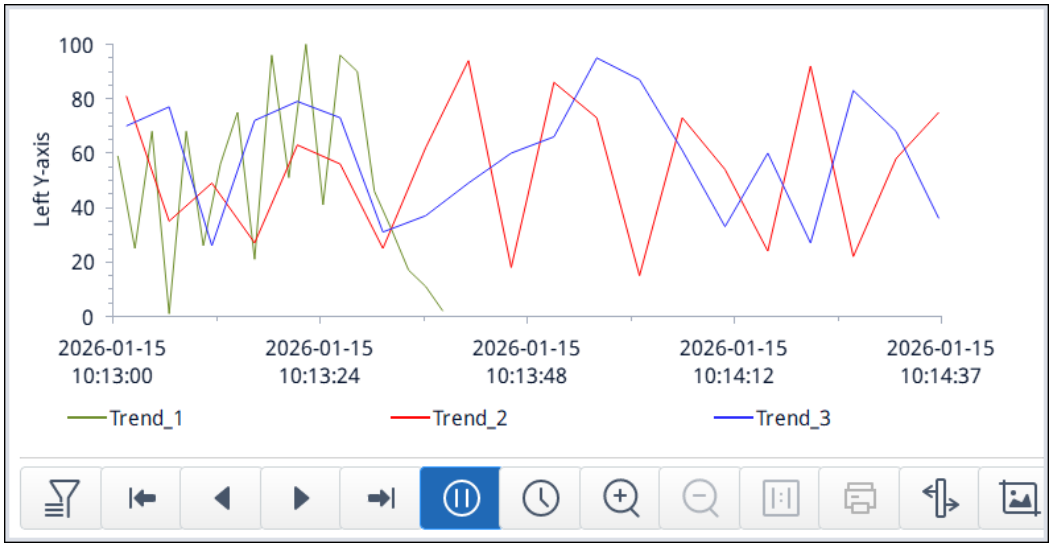


Figure 13-15-3-2 Displaying 20 measuring points

- Start and end time: Queries values within a custom time range.

: Zooms in the curve display area, with a maximum scale of 500%.

: Zooms out the curve display area, with a minimum scale of 100%.

: Returns the curve display area to normal.

: Visible only after offline configuration. Sets the visibility of scales in the view, such as the dashed line in the **F(t) trend curve example**.

The curve displays both real-time values and interpolated values. Interpolated values are calculated from adjacent two real-time values to ensure data continuity. For example, the interpolated value for Trend_3 lies on the line connecting the two points, as shown below.

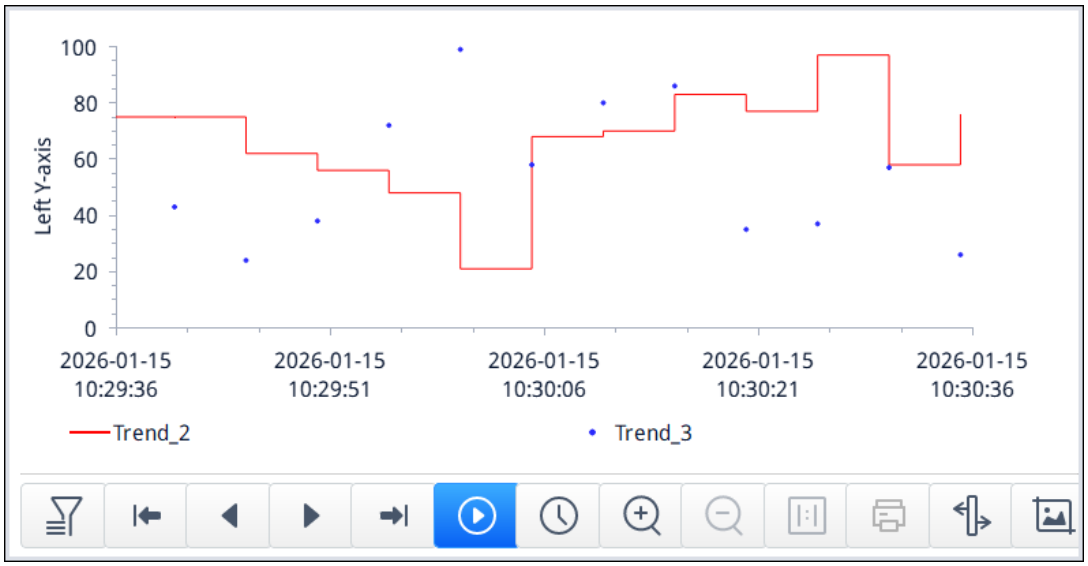

Figure 13-15-3-3 Interpolated value for Trend_3

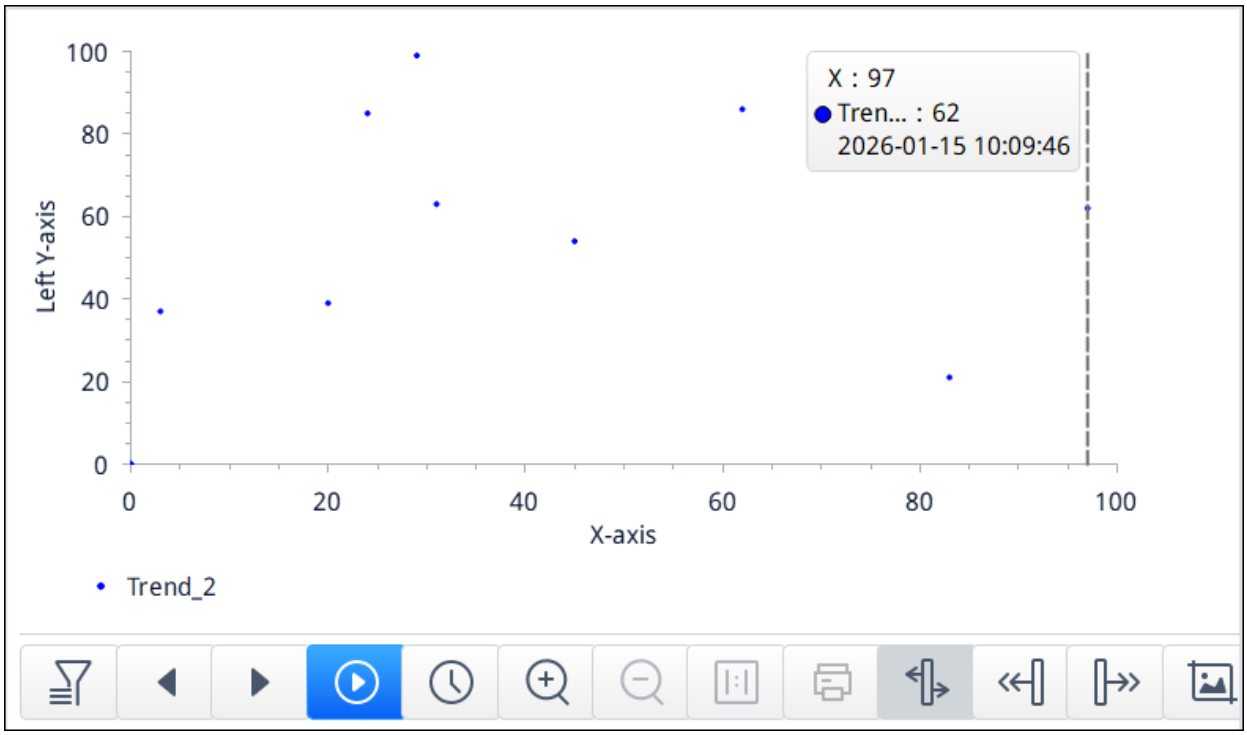


: Captures the current view and saves it as a PNG file named [screenshot_YYYY-MM-DD_HH-MM-SS-ms].png to the specified path. For detailed settings, see the **screenshot** property description of the 13.3.5.3.6 F(t) trend curve.

If stored on an SD card or USB device with full storage, the operation will fail.

F(x) trend curve

The F(x) trend curve displays data points on a Cartesian coordinate plane, showing the correlation between variables. Each point's position is determined by variable values.

The figure below shows the real-time trend of a group of variable values.

: Filters the trends displayed; supports up to 16 trends.

: Moves the trend time backward by one time period (set in view properties).

: Moves the trend time forward by one time period (set in view properties).

: Stops or starts updating data records.

: Sets the number of values or time intervals displayed in the view. For details, see above-mentioned descriptions of the **F(t) trend curve**.

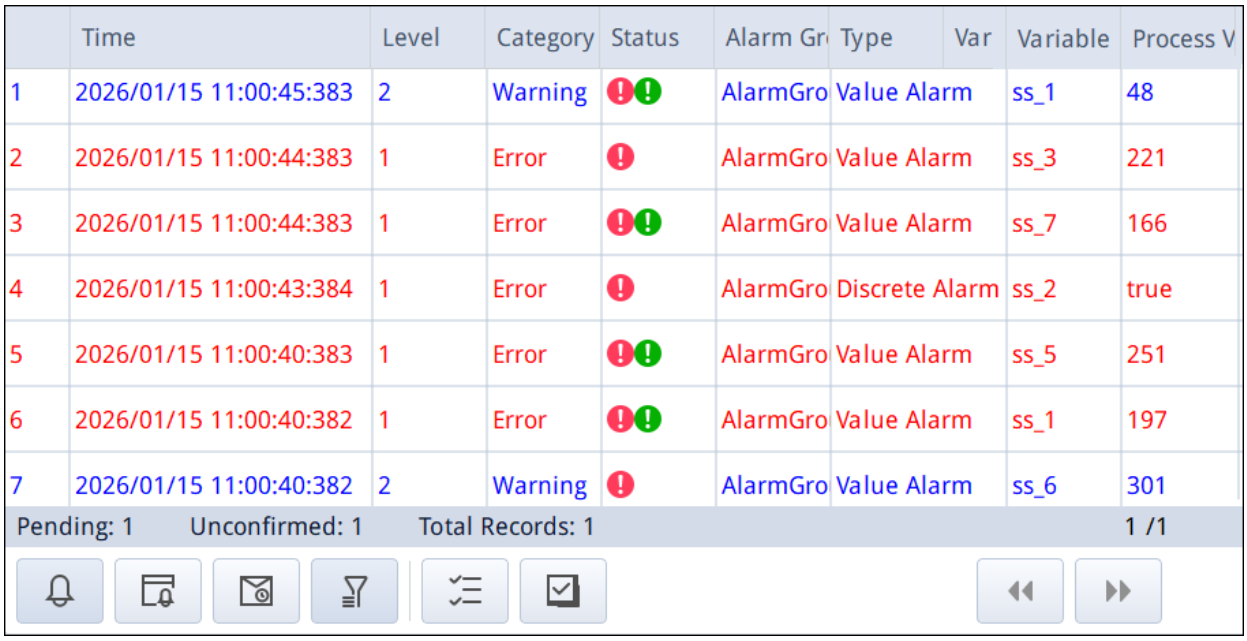
: Zooms in the curve display area, with a maximum scale of 500%.

: Zooms out the curve display area, with a minimum scale of 100%.

: Returns the curve display area to normal.

: Shows or hides the ruler, such as the gray dashed line in the figure above. The ruler displays the value at the current position. For details, see above-mentioned descriptions of the **F(t) trend curve**.

: Moves the ruler to the left.



: Moves the ruler to the right.

: Captures the current view and saves it as a PNG file named [screenshot_YYYY-MM-DD_HH-MM-SS-ms].png to the specified path. For detailed settings, see the **screenshot** property description of the 13.3.5.3.6 F(t) Trend Curve.

If stored on an SD card or USB device with full storage, the operation will fail.

13.15.4 Online Alarm View Operations

The 13.3.5.4.1 alarm view configured on the screen is sent to the monitoring device via project download. The system displays generated alarms in the alarm view window, organizing them into different pages based on alarm time and category for easy access.

This section focuses on the online operations of the alarm view. For offline configuration, see 13.3.5.4.3 Recipe View.

The alarm view automatically displays the preset page during online operation. Preset values can be modified in the **"Data"** section on the **"Property"** tab.

The alarm view consists of three parts from top to bottom: alarm table, status bar, and buttons.

- Alarm table

  The alarm table is a collection of information that displays all generated alarms.

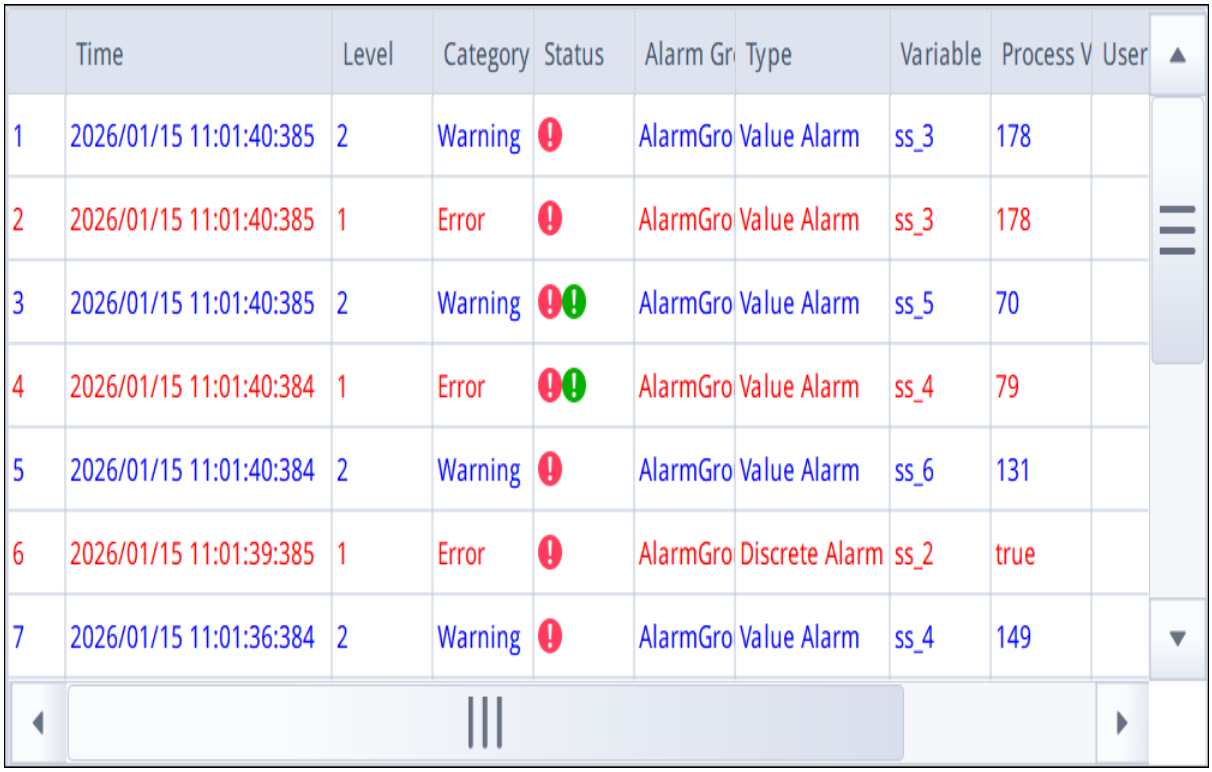


Figure 13-15-4-1 Alarm table

The alarm table header row can be configured in the "**Data**" section on the "**Property**" tab.
Time: Time when the alarm was triggered or the alarm event occurred. Events include alarm acknowledgment, alarm recovery, and user operations.
Level: Importance level of the alarm category. Lower numbers indicate higher priority. See 13.5.4 Alarm Category Configuration for offline settings.

Alarm category: There are four default categories, namely Error, Warning, User operation, and System. Users can rename category names and add types. See 13.5.4 Alarm Category Configuration for offline settings.

Alarm status: Status of Error and Alarm, including Active, Restored, and Confirmed.
Alarm group: Alarm group of the variable. For offline settings, see 13.2.5.3 Setting Variable Properties.
Type: Alarm type of the variable. For offline settings, see 13.5.1 Discrete Alarm Configuration and 13.5.2 Analog Alarm Configuration.
Variable: The variable that triggered the alarm.
Process value: The value at the moment of alarm triggering or event occurrence.
Username: Operator who triggered the "User operation" type alarm.
Text: Description of system alarms and user operations.

- Status bar
  Displays the current number of alarms and the total number of pages available.

- Buttons
  Buttons are displayed at the bottom of the alarm view window. A dark gray button indicates the corresponding operation is in progress.

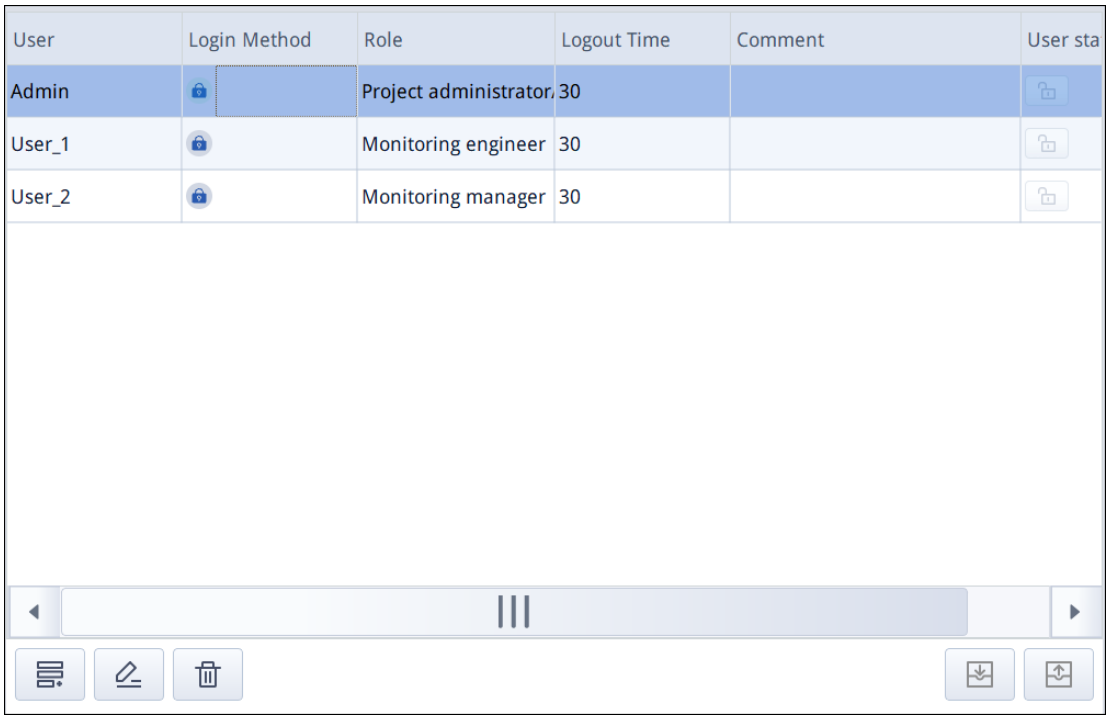
: Real-time alarms. Displays errors and warnings triggered when variables meet preset alarm conditions. When a variable meets the preset conditions, an alarm of the corresponding category is triggered. The alarm remains in the real-time alarm page until it is both confirmed and restored. Supports filtering and acknowledgment.
: Real-time alarm events. Displays system alarms, user operations, and real-time alarm action events. The maximum display count is set in 13.5.8 Alarm Runtime Configuration.

Event recording rules:

- Each trigger of a system alarm or user operation generates a corresponding alarm event.
- Each status change of a real-time alarm generates a corresponding event.
- Each project download causes current alarms to be recorded again, even if previously recorded.

: Historical alarm events. Displays stored records for all alarm categories. Supports filtering. The maximum display count is set in 13.5.8 Alarm Runtime Configuration.
: Filters alarms by specified conditions for real-time alarms, real-time alarm events, and historical alarm events. For historical alarm events, the default filter time is set in 13.5.8 Alarm Runtime Configuration and can be customized in the filter dialog.

Once set, the filter only resets to default after a project download or system restart.
When the filter button is executed simultaneously with other buttons, it indicates that the displayed alarms are filtered results. For example, indicates that the content displayed on the

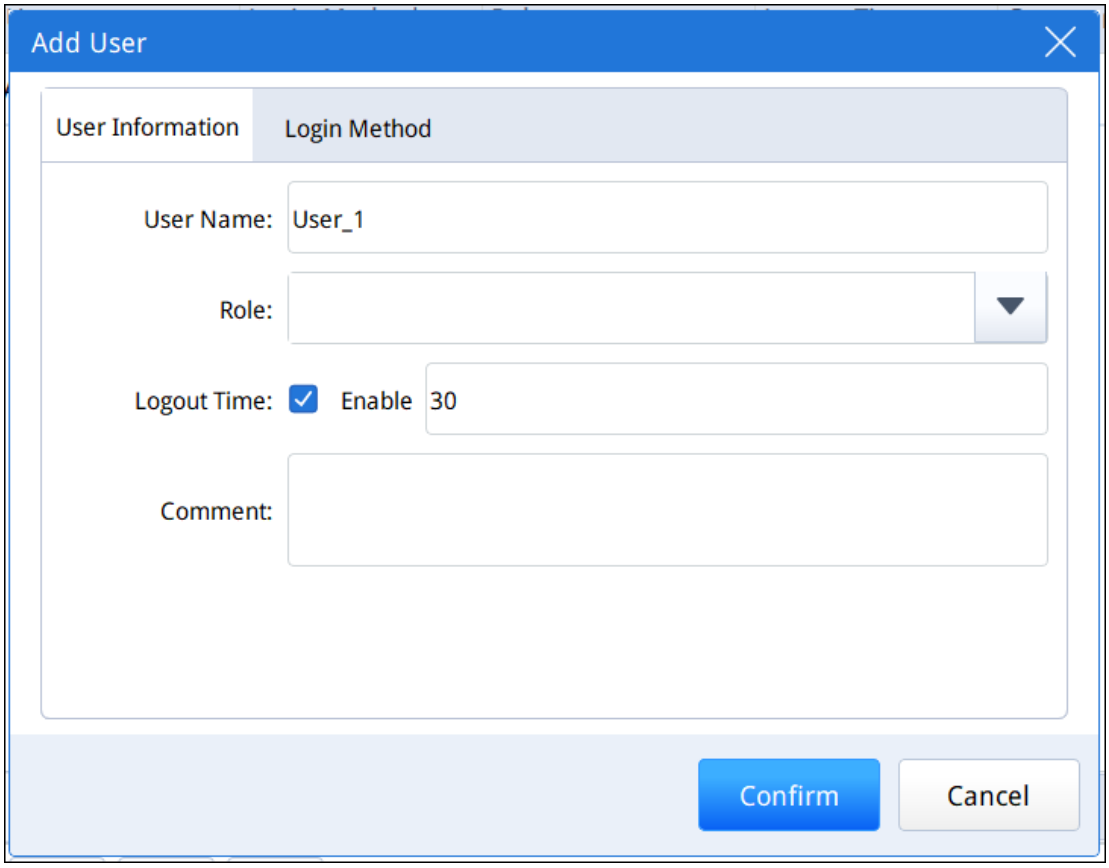


real-time alarm page is the result filtered according to the specified conditions.

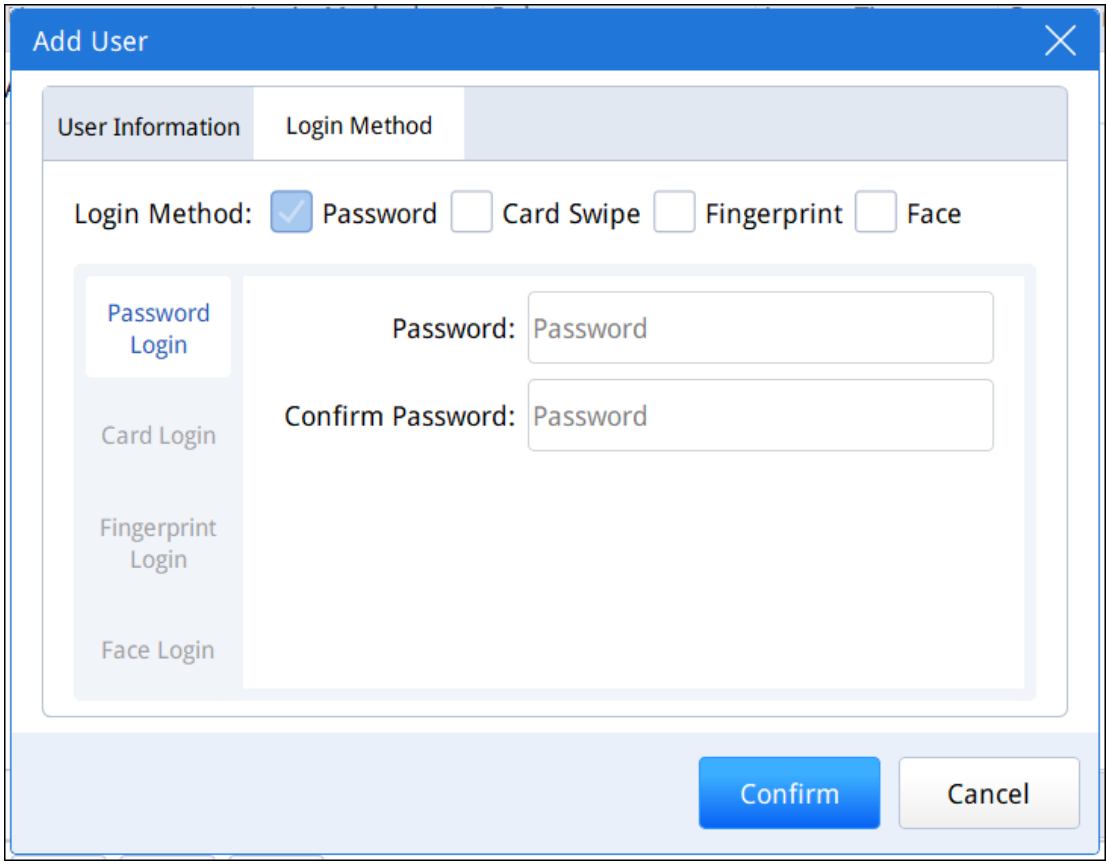
: Confirms real-time alarm statuses one by one.

: Confirms all current real-time alarm statuses.

13.15.5 Online User View Operations



When the HMI device is running, administrators can add, delete, modify, and lock/unlock user accounts in the user view. For offline configuration, see 13.3.5.4.5 User View. It must be used in conjunction with the 13.3.5.4.4 User Login control to manage access permissions.



Adding a user

Administrators can create user accounts by clicking and configuring in the pop-up dialog.

- Configure user information.

  - Username: Displays the name of the new user. By default, it starts from User_1 and allows users to rename it. The maximum number of users per device is 50.
  - Role: Displays the role name assigned to the current device during offline configuration.
  - Logout time: Sets whether the logout function is enabled and sets the logout time. The default unit is minutes, with a default value of 30.
  - Comment: Displays user comment information.
- Configure login method.

- Password login: After selecting password login, the user password shall be set for login.
  Password storage uses AES-128 encryption, ensuring secure, reliable, and efficient protection of stored passwords.
- Card login: After selecting card login, swipe the card to input login information.
  To input card information, the card reader connection must be created, and the corresponding variable must be associated during offline configuration. Then, swipe the card to input the information.
- Fingerprint login: Not enabled.
- Face login: Not enabled.

Modifying a user

After logging in, administrators can edit all information of non-administrator users via . For administrator accounts, only limited fields such as comment and logout time can be edited.

Setting user status

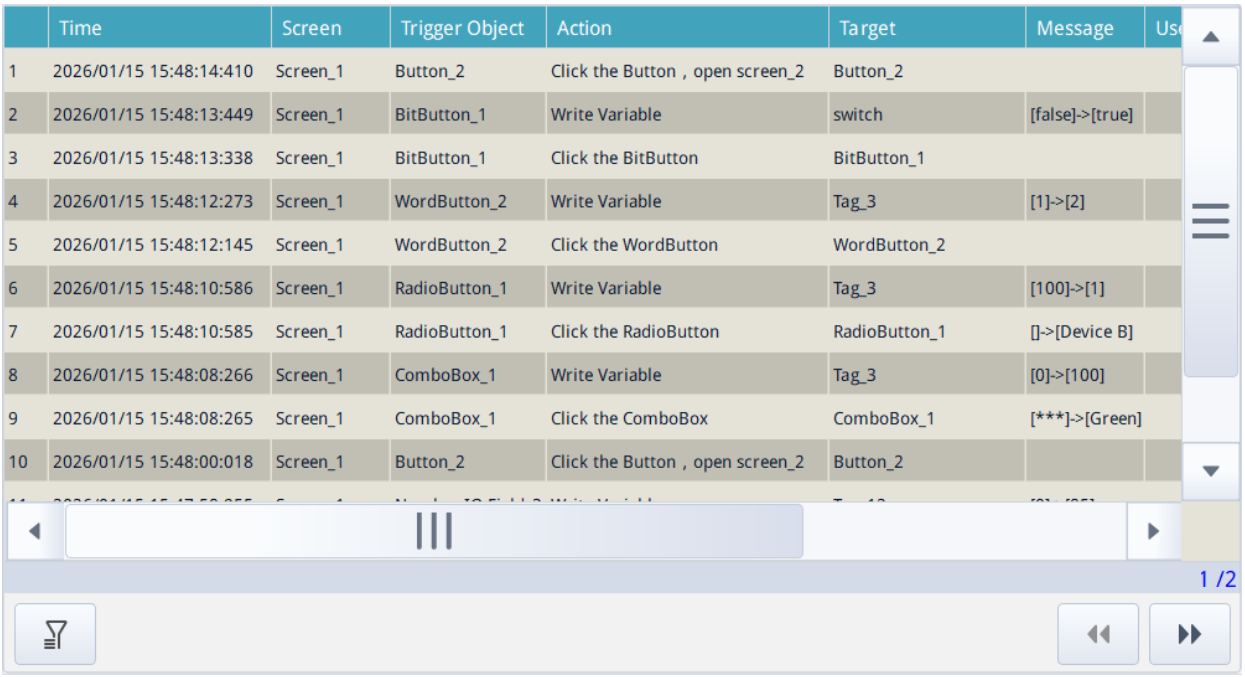
Administrators can manually lock or unlock user accounts in the user view to control system access permissions.

- Operation scope
  - Administrators can lock or unlock non-administrator users.
  - Administrators can unlock each other but cannot lock each other.
- Lock duration setting

  Click the lock icon  in the user status column and specify the lock duration. Range: 0 to 3600s. 0s means permanently locked until manually unlocked by an administrator.

> **NOTE**
>
> To retain the lock status and remaining duration after a project download, ensure that "Retain user management data" is checked during download.

Deleting a user



After logging in, administrators can delete non-administrator users by clicking .

13.15.6 Online Operation Record Operations

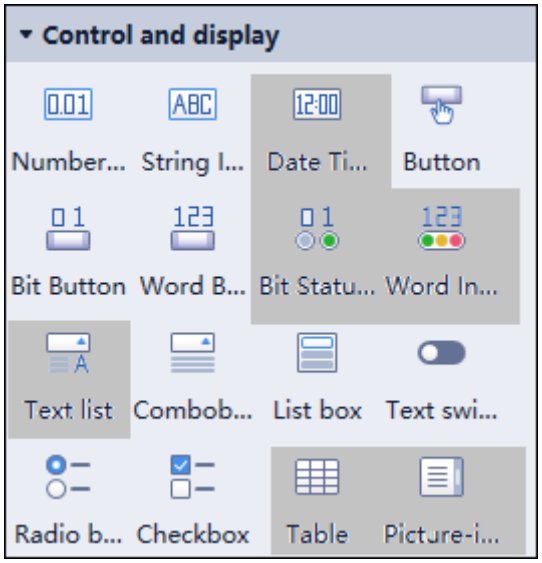
After the 13.3.5.4.8 Operation Records control is configured on the screen, recorded data is displayed in real time when specific operations occur during project runtime.

By default, recorded data is not automatically displayed when the control is online. It can be viewed by applying filters via  or by switching screens.

The control refreshes data every 2s by default. To change the refresh rate, adjust the "Refresh interval" parameter in the offline project.

	Time	Screen	Trigger Object	Action	Target	Message	Use
1	2026/01/15 15:48:14:410	Screen_1	Button_2	Click the Button , open screen_2	Button_2		
2	2026/01/15 15:48:13:449	Screen_1	BitButton_1	Write Variable	switch	[false]->[true]	
3	2026/01/15 15:48:13:338	Screen_1	BitButton_1	Click the BitButton	BitButton_1		
4	2026/01/15 15:48:12:273	Screen_1	WordButton_2	Write Variable	Tag_3	[1]->[2]	
5	2026/01/15 15:48:12:145	Screen_1	WordButton_2	Click the WordButton	WordButton_2		
6	2026/01/15 15:48:10:586	Screen_1	RadioButton_1	Write Variable	Tag_3	[100]->[1]	
7	2026/01/15 15:48:10:585	Screen_1	RadioButton_1	Click the RadioButton	RadioButton_1	[]->[Device B]	
8	2026/01/15 15:48:08:266	Screen_1	ComboBox_1	Write Variable	Tag_3	[0]->[100]	
9	2026/01/15 15:48:08:265	Screen_1	ComboBox_1	Click the ComboBox	ComboBox_1	[***]->[Green]	
10	2026/01/15 15:48:00:018	Screen_1	Button_2	Click the Button , open screen_2	Button_2		

1 /2



The number of columns and their titles can be customized. By default, the table contains 11 columns, as described below.

Time: Timestamp when the operation occurred. The default precision is millisecond level, which can be configured to second level.

Depending on the target object, the timestamp may refer to the time the control was operated, the function was executed, or the event was triggered.

Screen: Name of the screen containing the operated object.

Trigger object: Name of the operated object. Supported object types include task lists, scripts, controls (10 types shown in the figure below), records, and screens.

Action description: Description of the action, such as writing a variable, storage overflow, function execution, or exceeding a limit.

Action object: Target object of the action, such as a variable name or script name.

Information: Result of the action. For example, if a variable changes from 20 to 25, it is recorded as [20] -> [25]; if the setValue function changes from 1 to 3, it is recorded as setValue: [1] -> [3].

This field is recorded even if the value remains unchanged before and after the action.

Username: Name of the operator.

Device name: Name of the operating device.

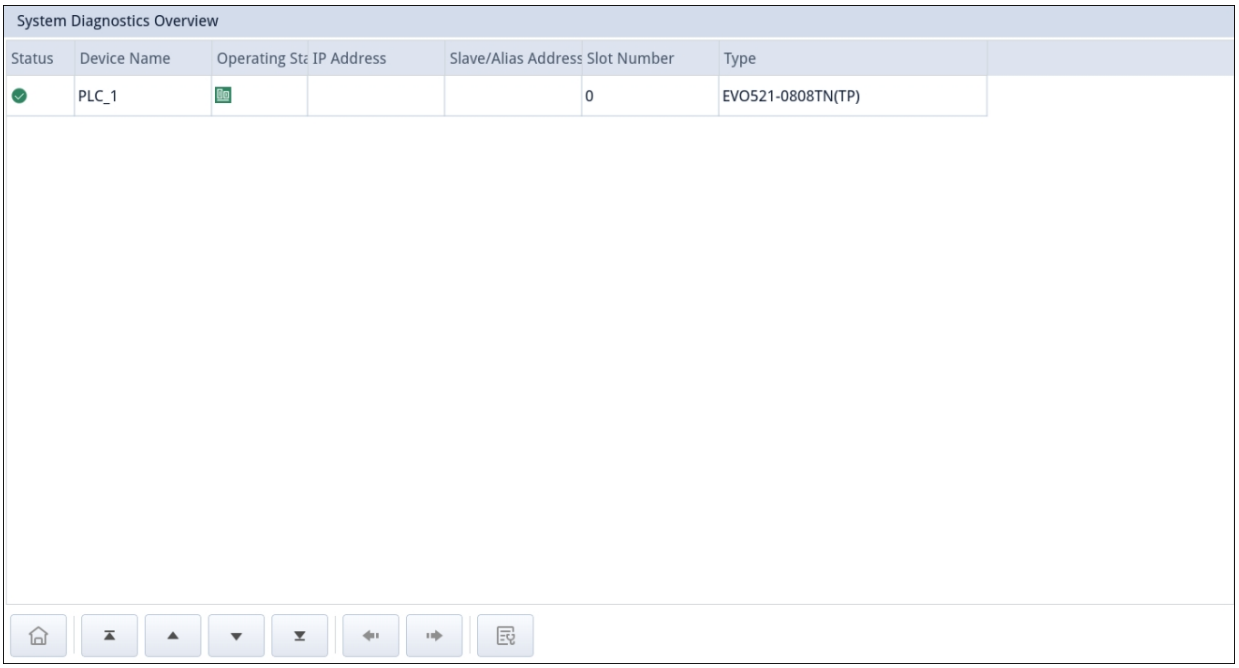
Connection: When the action object is an external variable, displays the corresponding connection name.

Address: Storage address of the variable.

CAUTION

There is a 1s to 2s delay in saving operation records. Data is only saved after it appears in the control list. If the device is powered off before the data is displayed, the corresponding records will be lost.

13.15.7 Online System Diagnostics



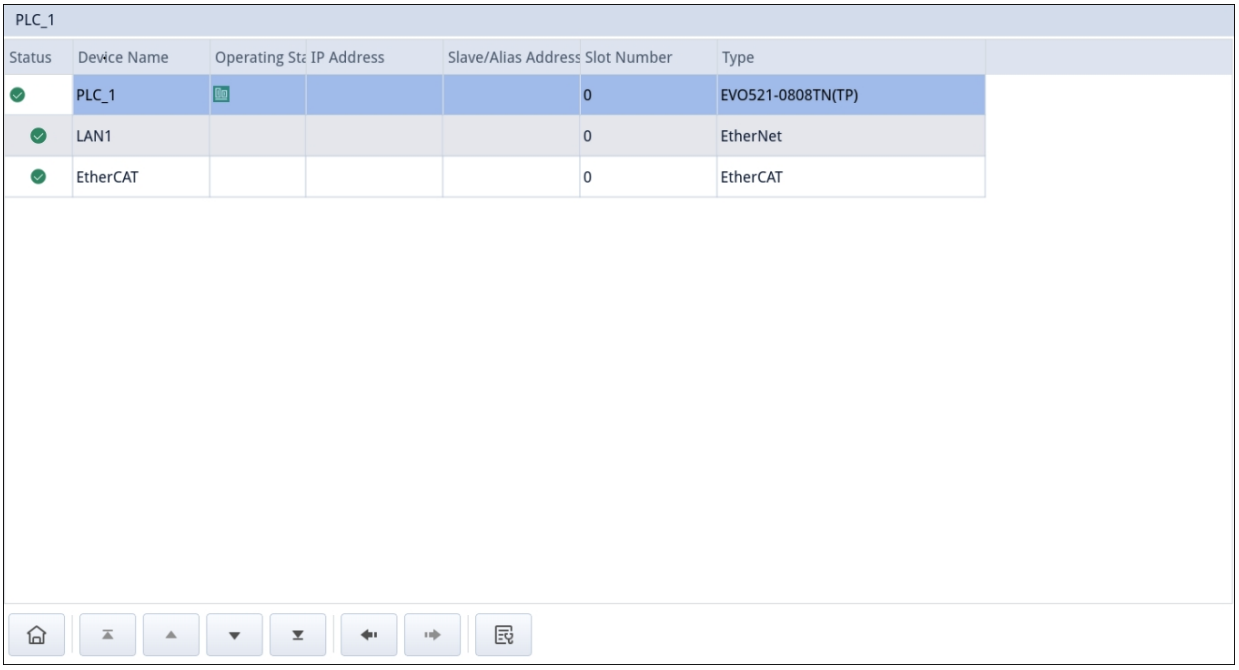
Prerequisites

- The PLC and HMI are in the same project in iFA software.
- "Inovance Technology, Ethernet/IP Tags protocol" is used for communication.
- The system diagnostics control can only run on physical devices and does not support simulation.

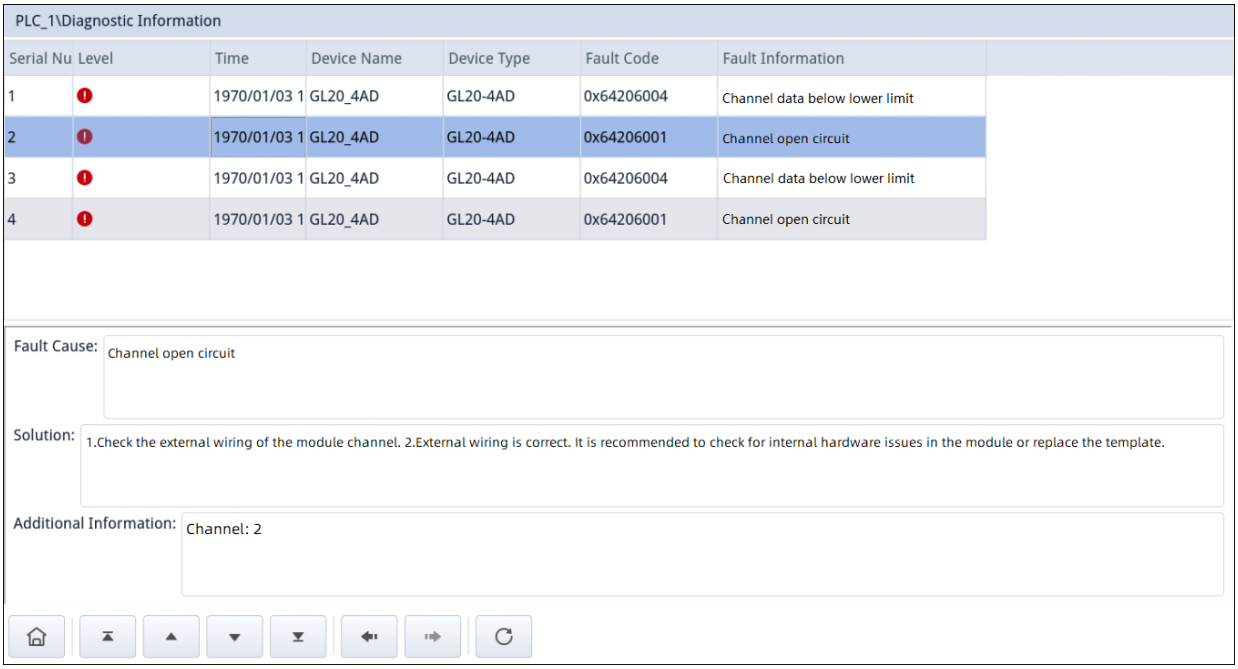
Online monitoring

When the screen containing the "System diagnostics" control is active, the control displays the system

diagnostic overview interface by default.



Item	Description
Control header	Displays the hierarchy of the device based on the current level and selected object. The hierarchy text is identical to the path name in the software.
Status	Displays the current device running status or the connection status between PLC and HMI. PLC statuses include: Normal, Fault, and Lower-level device fault.
Device name	Displays the name of the device as shown in the project tree.
Operation status	Displays the four PLC statuses: Operational: Stopped: Paused: Forced: This column is empty for other modules.
IP address	Displays the IP address or port connected between the PLC and the current HMI.
Slave/alias address	Displays the slave number or alias address of EtherCAT slave devices. Empty for non-EtherCAT slaves.
Slot number	Displays the slot number of the current module in the rack.
Type	Displays the device model.

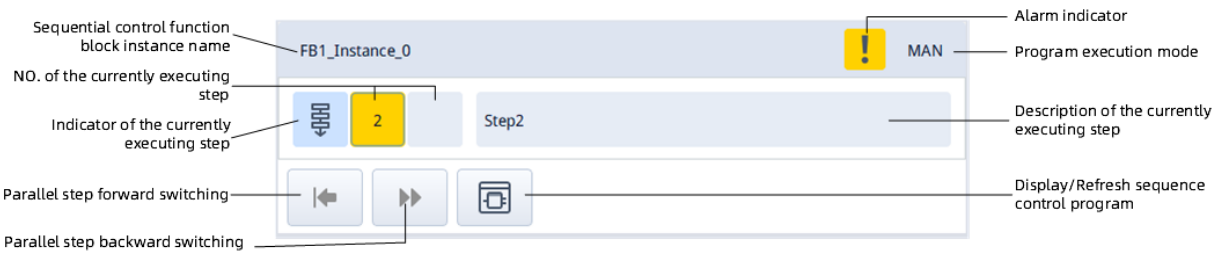


Button	Description
	Returns to the system diagnostics overview interface.

Button	Description
	Selects the first row.
	Selects the previous row.
	Selects the next row.
	Selects the last row.
	Returns to the previous interface.
	Moves to the next level interface. Available only when the PLC and HMI are well connected.
	Open PLC diagnostics

Select a PLC device row and click . View the connection status of the PLC device's LAN port and EtherCAT port.

Select a PLC device row and click . View the I/O channel diagnostic information of the PLC device.



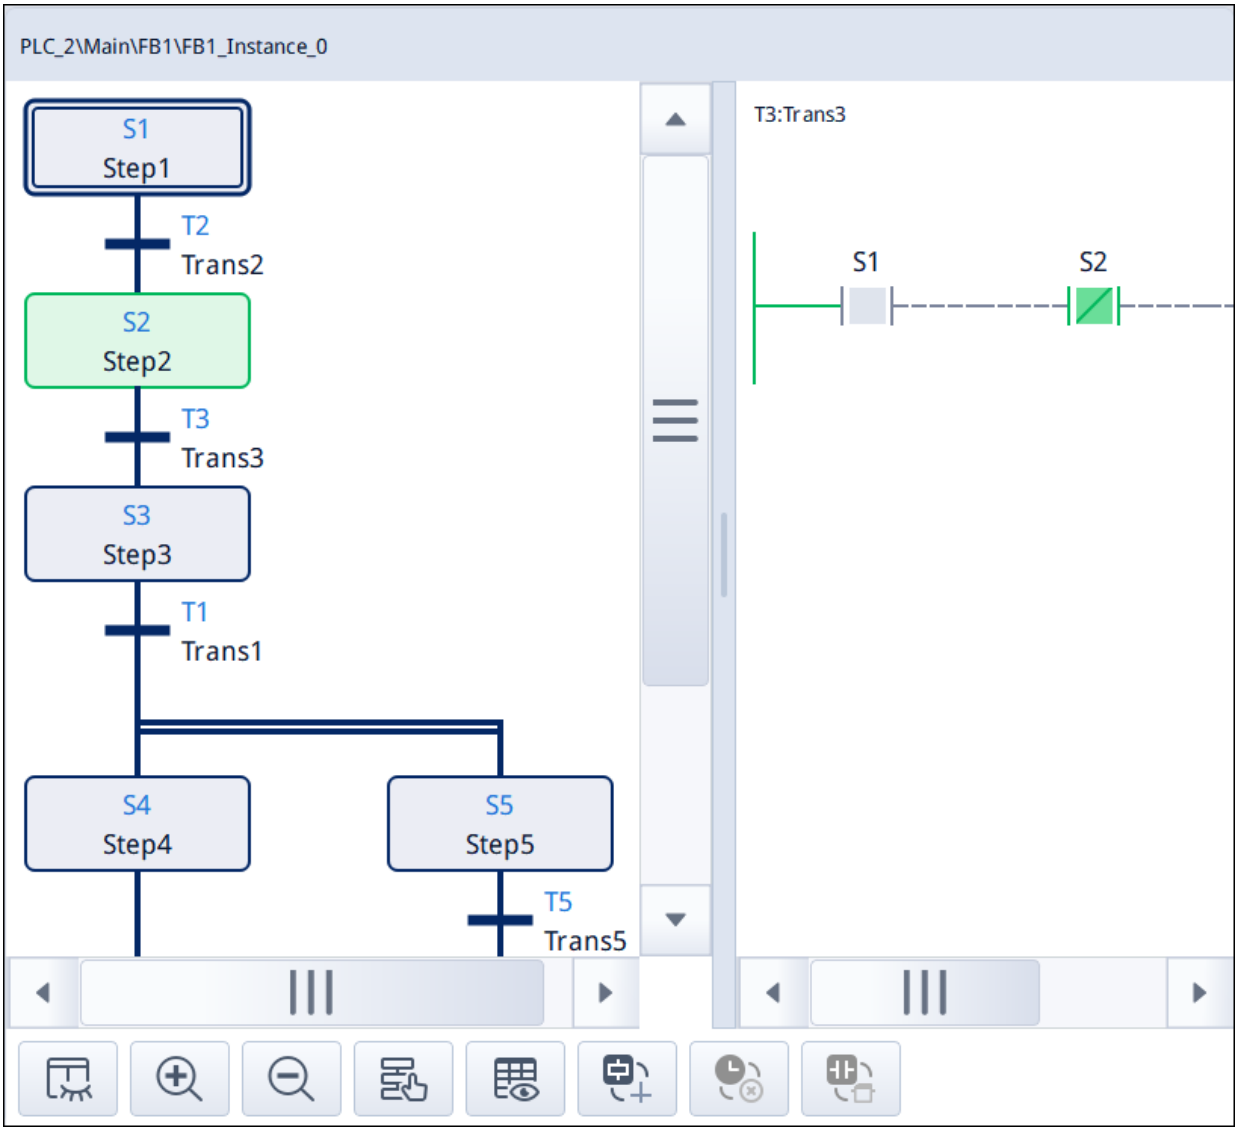
13.15.8 Online PLC Program Viewing

Sequential control programs can be displayed or hided on the interface, and the dynamic execution progress can be viewed in real time.

Prerequisites

- The SFC program has been compiled successfully.
- The 13.3.5.4.9 SFC view control and 13.3.5.4.10 code view control have been configured.

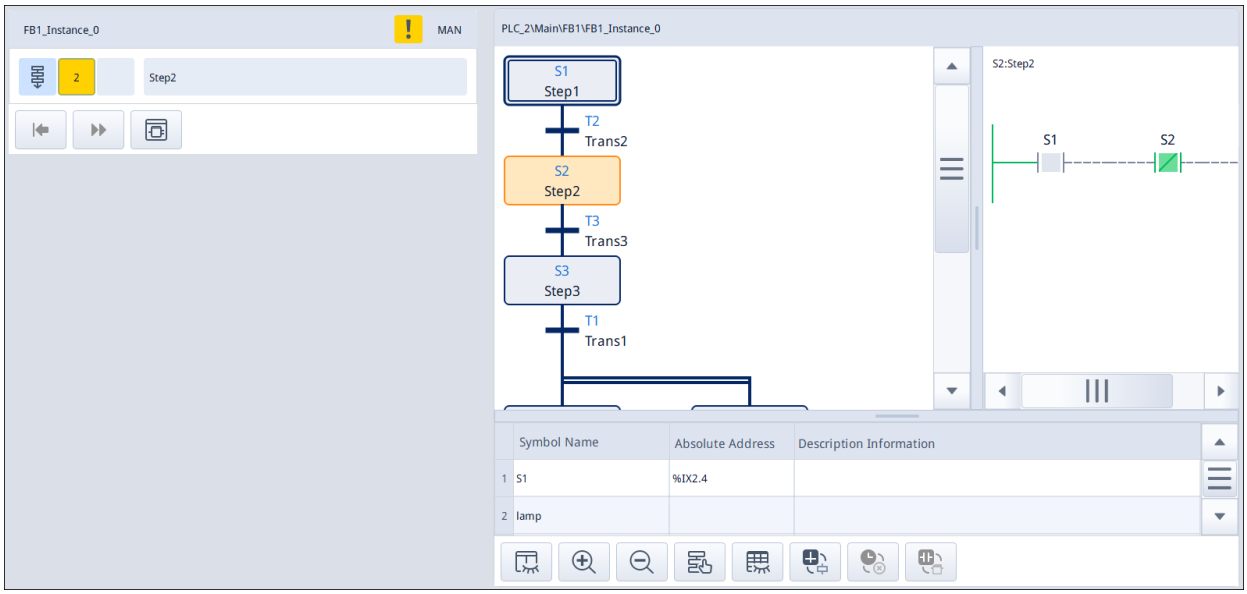
SFC view control interface



The interface is introduced below from top to bottom and left to right.

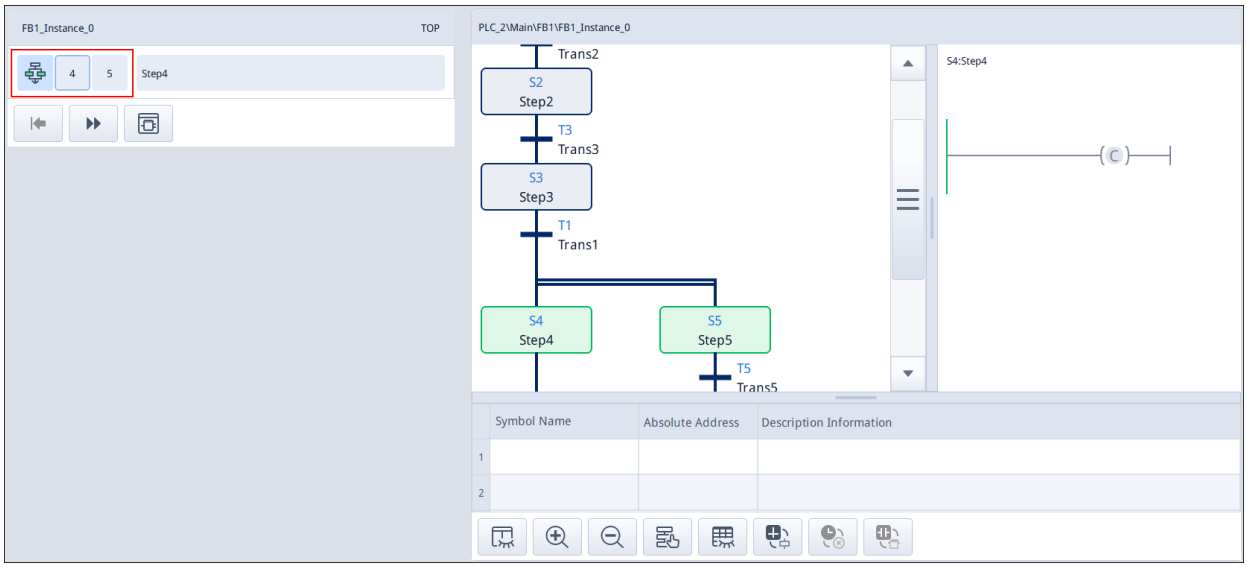
Item	Note
Sequential control function block instance name	An SFC view can display only one instance program.
Number of the currently executing step	Displays the number of the step being executed. If the interlock or monitor condition of the executing step is not satisfied, the number is highlighted in yellow. • In single-step mode, the corresponding step number is displayed in the second box. • In parallel branch mode, two step numbers are displayed in the second and third boxes. You can use the forward/backward icons to switch the displayed step numbers.

Item	Note
Indicator of the currently executing step	 : Initial step is being executed.  : Single process step is being executed.  : Parallel branch is being executed.
Parallel step forward/ backward switching	Switches the displayed step number during parallel branch execution.
Alarm indicator	Displayed when the interlock or monitor condition of the current step is satisfied.
Program execution mode	MAN: Steps are executed via the commissioning panel, independent of transition conditions. AUTO (default): Automatically moves to the next step when the transition condition is satisfied. TOP (Semi-auto - transition conditions ignored): Moves to the next step when the transition condition is satisfied or a rising edge of the T_PUSH parameter is triggered. TAP (Semi-auto - transition condition-based): Moves to the next step when the transition condition is satisfied and a rising edge of the T_PUSH parameter is triggered.
Description of the currently executing step	Description of the active step.
Display/Refresh sequence control program	Displays or refreshes the sequential program in the code view control.



Code view control interface

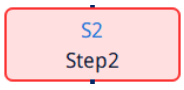
Item	Description
	Opens the action of the current step or transition.
	Zooms in the program display scale.
	Zooms out the program display scale.
	Manual/Automatic switching: In manual mode, users can view the internal logic of each step/transition regardless of whether the step is active. This does not affect PLC operations.
	Displays or hides the symbol table. Click to display internal variable information of the currently executing transitions in a tabular format.
	In manual mode, the displayed content switches between steps and transitions.
	Reserved, not enabled.
	Reserved, not enabled.



Combined usage of SFC view and code view

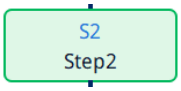
Click  in the SFC view to open the sequence control program in code view. The SFC view displays the overall execution status of the sequential program, while the code view displays its internal logics.

The SFC view connects to the PLC via an instance variable. Once connected, it displays the real-time execution status of the sequential program, including the number of currently executing step, step description, and commissioning mode. The code view is used to view the execution status of each step/transition and the program execution process, facilitating program commissioning and diagnosis.



When executing parallel branches, the SFC view displays information for up to two parallel steps simultaneously. The effect is shown below:

Step status in the sequence control program:



: Inactive status.

: Monitoring alarm status. An alarm is generated when the monitoring condition is met.

: Alarm status. The step enters an interlock alarm status when the interlock condition is not met, or when both interlock and monitoring alarms occur simultaneously.

: Active status.

13.16 Monitoring Simulation Commissioning

- 13.16.1 Simulation Data Storage
- 13.16.2 Simulating an HMI
- 13.16.3 Simulating a Variable
- 13.16.4 Co-simulation Between PLC and HMI

13.16.1 Simulation Data Storage

During simulation, certain scripts, controls (such as data import/export functions and dedicated controls), and external files required for control operation (such as video files) must be placed in the designated simulation resource folder. Only then can the simulator successfully recognize and call them, ensuring proper functionality of the related features.

Storage location

Root directory: The simulation resource folder named HMISimulation is stored in root directory of the iFA Evolution installation.

For example, if iFA Evolution is installed on the D drive, the simulation resource folder storage path is D:\HMISimulation.

HMISimulation folder structure

This folder contains four subfolders, each corresponding to a different storage location. The stored data objects are listed in the table below.

Subfolder	Storage	Script	Control	Data Record	Alarm Record	Operation Record
Local	Local disk	Functions for data import/ export only	File reading: such as multimedia and PDF Screenshots: F(t) trends and F(x) trends	Supported	Supported	Supported
SD	SD card					
USB1	USB equipment					
USB2						

13.16.2 Simulating an HMI

Single HMI simulation is suitable for initial HMI screen commissioning and testing. It focuses on verifying whether controls on the screen correctly display variable values and respond to interactions. It does not

require connection to a physical device, and simulation data is sourced from the 13.16.3 Simulating a Variable.

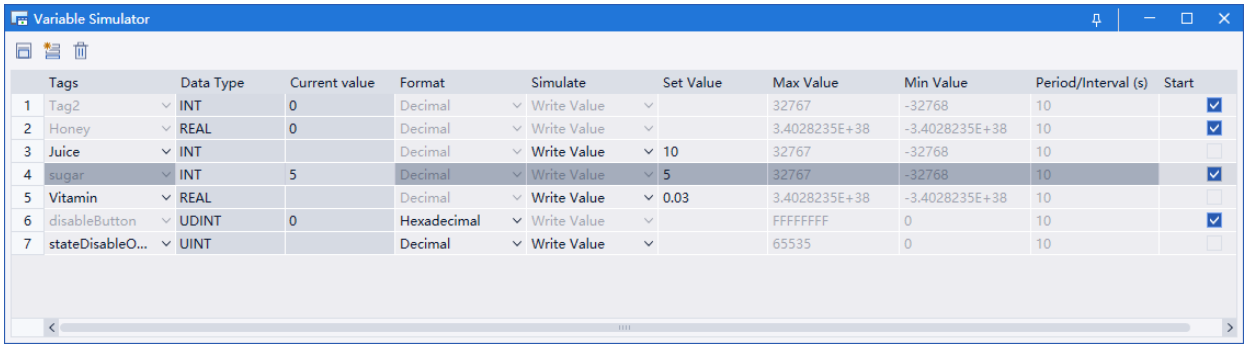
Limits

- Historical data and historical alarm-related functions are not supported in simulation.
- The maximum continuous runtime for each simulation is two hours.

Requirements

- Ensure that controls on the screen are correctly associated with variables.
- Ensure that the project compiles without errors.
- Each simulation supports only one device.

Procedure



1. Start simulation.
   Click the simulation icon and it automatically changes to . In the meantime, the variable simulator and the graphical runtime system are opened. The window size of the graphical runtime system adjusts to the actual HMI screen size and displays the startup screen by default.
2. Simulate variables.
   Add the required variables in the variable simulator and set the simulation type and value range for each variable.
3. Adjust the screen.
   Check the values and interaction effects on the screen to verify normal functionality.
4. Exit simulation.
   Click to exit the current simulation. The configuration settings in the variable simulator can be saved for reuse in subsequent simulations.

13.16.3 Simulating a Variable

Use the variable simulator to simulate a variable. It is a tool for simulating the real-time values of internal and external variables. It synchronizes variable values to the screen in real time and retains runtime values when specific conditions are met.

Start

The variable simulator cannot be started independently; it must be launched via the simulation command .

- Variable: Simulation objects. A maximum of 500 variables can be added.
  Variables are displayed in a tiled layout, without using a tree structure to represent structures or arrays. Only data that exists in the variable table at the time the simulator is started can be selected; new data in the variable table is not synchronized after the simulator starts.
- Data type: The data type of the variable. This field cannot be edited.
- Current value: The current simulated value. This field cannot be edited.
- Format: The variable value is simulated in the specified format. Note:
  - BCD code (8421 BCD): A binary encoding used to represent decimal numbers.
  - Data types supporting BCD format: UINT, UDINT, ULINT, and USINT.
  - Data types for which the format cannot be modified: STRING, WSTRING, BOOL, REAL, LREAL, DATETIME, INT, DINT, LINT, and SINT.
- Simulate: Sets the simulation type for the value.
  - Write value: Manually sets the simulated value of the variable.
  - Random: Randomly changes the value between a defined minimum and maximum.
  - Increment: Automatically increases from the set minimum to the maximum; the step size can be configured.
  - Decrement: Automatically decreases from the set maximum to the minimum; the step size can be configured.
  - Shift: Applicable to unsigned integer data types. Shifts bit by bit upward from bit 0, cycling repeatedly.
  - Sine: Generates a periodic sine-wave variation between the maximum and minimum values.
- Set value: Sets the corresponding value based on the selected simulation type.
- Max./Min. value: Sets the value range for the variable.
- Period/Interval: Sets the period for value changes. The unit is seconds, with precision up to three decimal places.
- Start: Enables or disables the simulation for the current variable. Once enabled, the variable cannot be changed.

Simulation data processing

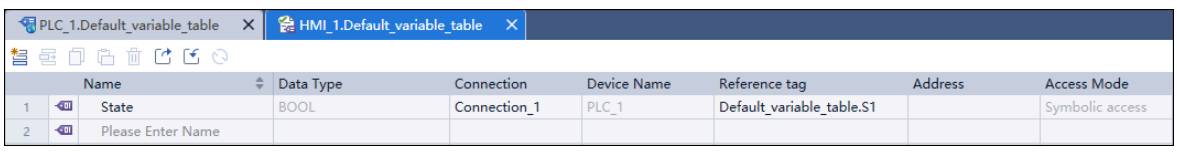
When simulating the same device (even after disconnecting), as long as the device has not been replaced, the system retains and handles data as follows:

- Data retention at power failure
  When the simulation restarts, the system retains the power failure data of variables defined in the previous simulation, ensuring continuity and consistency.

- Retention of data/alarm records
  All data/alarm records from previous simulations are retained.
- Recipe configuration data management
  If the recipe configuration data has not been modified, the data records from the previous simulation are retained.
  If the recipe configuration data has been modified, the system updates and displays the latest configuration data.
- User permission data management
  If the user permission data for the device has not been modified, the user permission data from the previous simulation is retained.
  If the user permission data has been modified, the system updates and displays the latest user permission information.

13.16.4 Co-simulation Between PLC and HMI

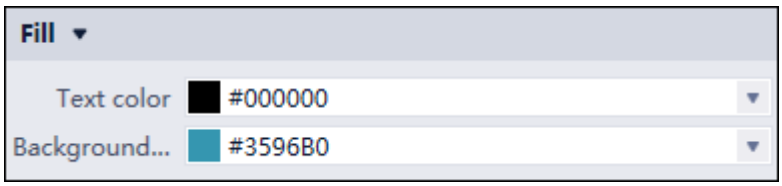
Co-simulation between PLC and HMI uses the PLCSIM tool and HMI simulation components for communication function commissioning between HMI and PLC without physical device connections. It focuses on verifying variable interaction and control logic between the two. The following are the steps to set the combined application simulation:



Requirements

- Ensure that the simulation commissioning component for HMI and PLC are installed in the iFA software.
- Configure the PLC and HMI devices within the same project.

Procedure

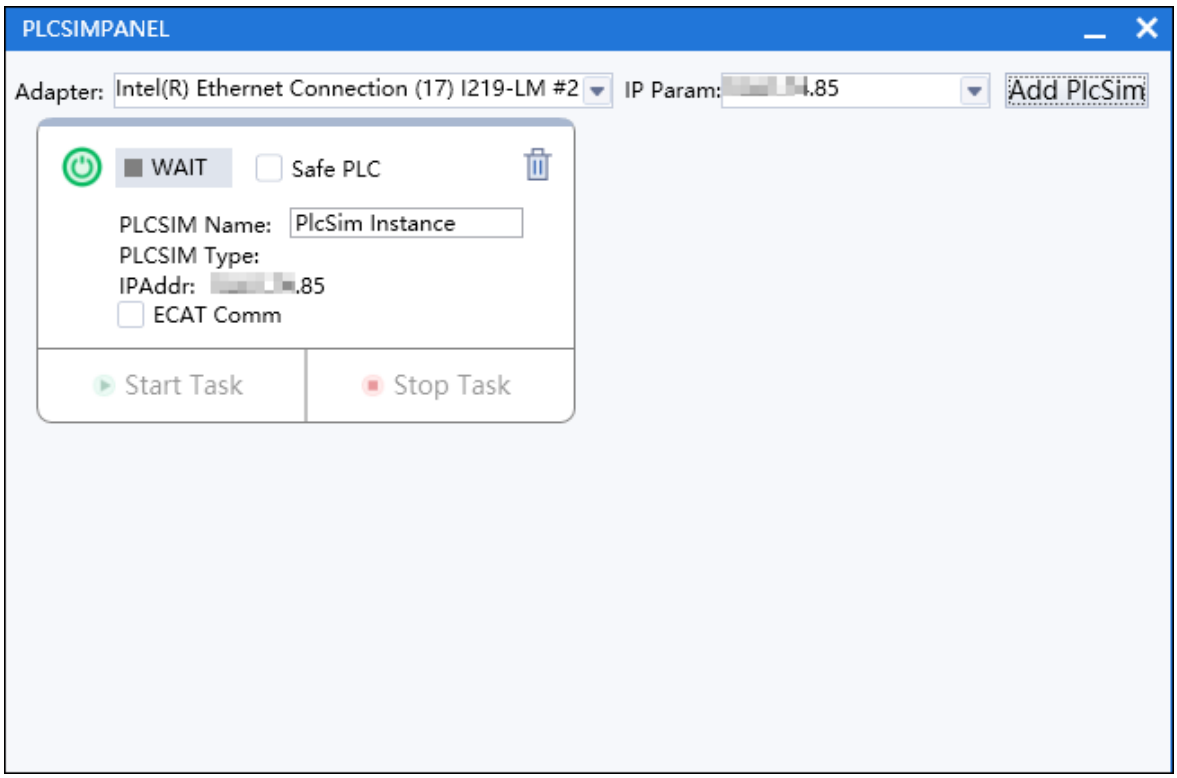


The following steps use one variable communicating and being written between the PLC and HMI to illustrate the simulation procedure:

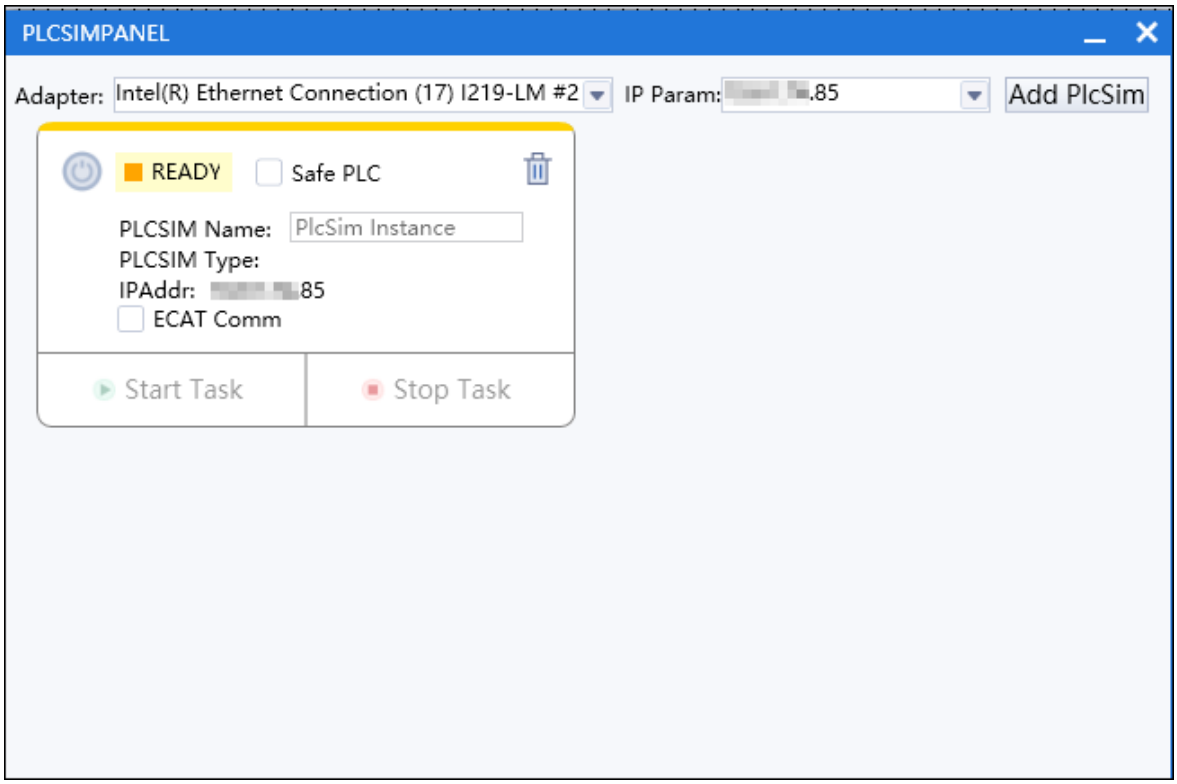
1. Configure communication variables.
   a. Add a variable to the PLC device. For example, add S1 to the default variable table with a BOOL type.
   b. Set variable S1 as a public variable. For example, set the "Network public" property to "Read/Write."
   c. Add a variable to the HMI device. For example, add State to the default variable table with a BOOL type.
   d. Establish communication connection.
      Associate variable State with S1, and a connection between PLC and HMI is automatically established, named Connection_1.

   e. Configure HMI screen.
      Add controls to the HMI screen and associate them with variable State. For example, add a text switch.

      To facilitate identification, you can set a new style for the ON state, as shown in the following figure.



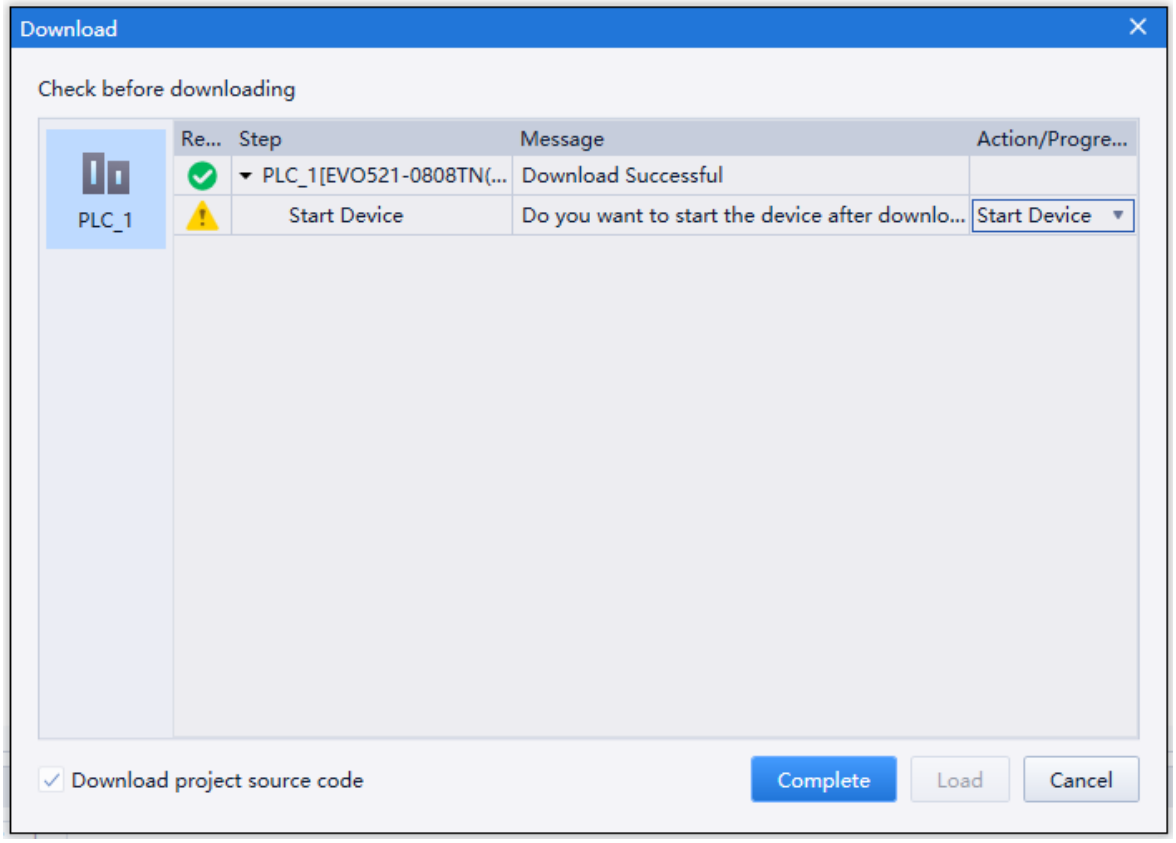
f. Compile the project.
Compile the PLC and the HMI project, and ensure there are no errors.



2. Start PLC device simulation.

a. Double-click the PLC device node in the project tree, then click . The button status is displayed as , and the PLCSIM control operation panel pops up.

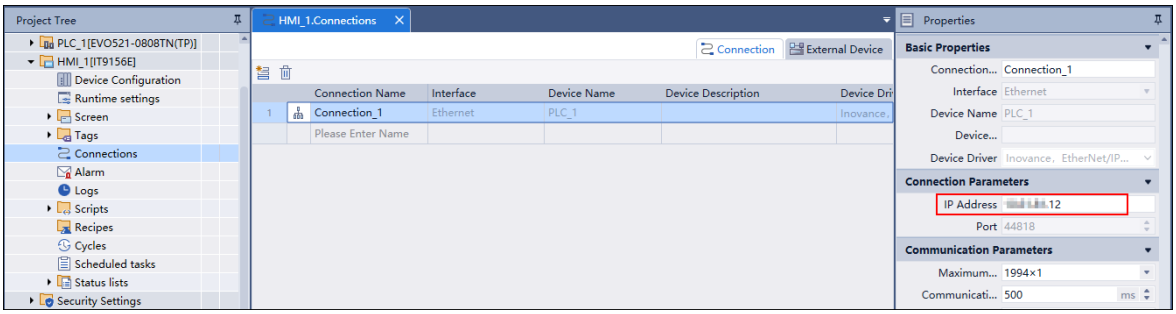
b. Enter the current computer's IP address, select "Add Plcsimulation," and create a simulation instance for the PLC device.



c. Click to activate the PLC simulation environment.

d. Click Online, and select the PLCSIM device with the same IP in the scan results.

e. Download and start the PLC device.

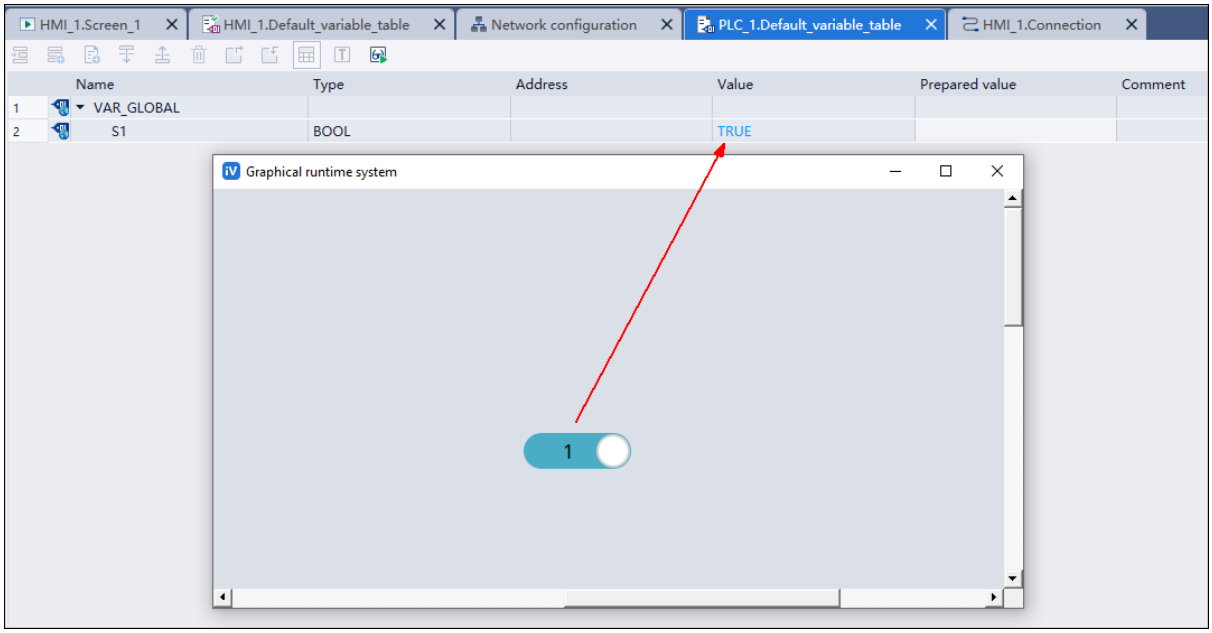


At this point, the PLC device enters simulation mode and starts running.

3. Start HMI device simulation.

a. Set the HMI communication connection address.

Double-click the HMI device's connection node in the project tree, and ensure the connection IP matches the IP in the PLCSIM control panel (the IP set in step 7).



b. Start HMI simulation mode.

Click . The button is displayed as , and the "Graphical runtime system" window opens.

4. Perform co-simulation commissioning.

Change the switch status in the "Graphical runtime system" window and observe the value change of variable S1 in the PLC device.

5. Exit co-simulation mode.

   HMI device: Right-click the blank area of the "Graphical runtime system" window, select "Exit", and then click  to exit the simulation mode.

   PLC device: Select sequentially 

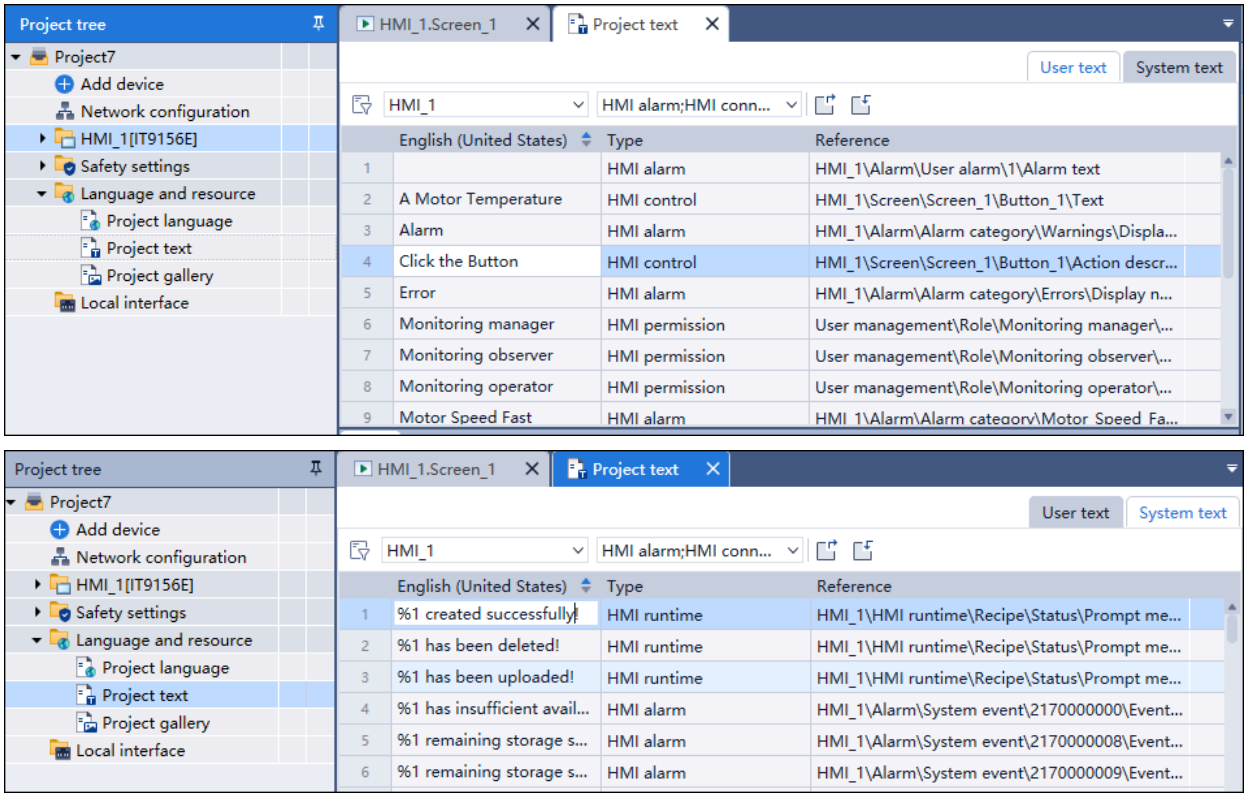
and  to exit the simulation mode.

13.17 Multilingual Settings

13.17.1 Multilingual Overview

Project language

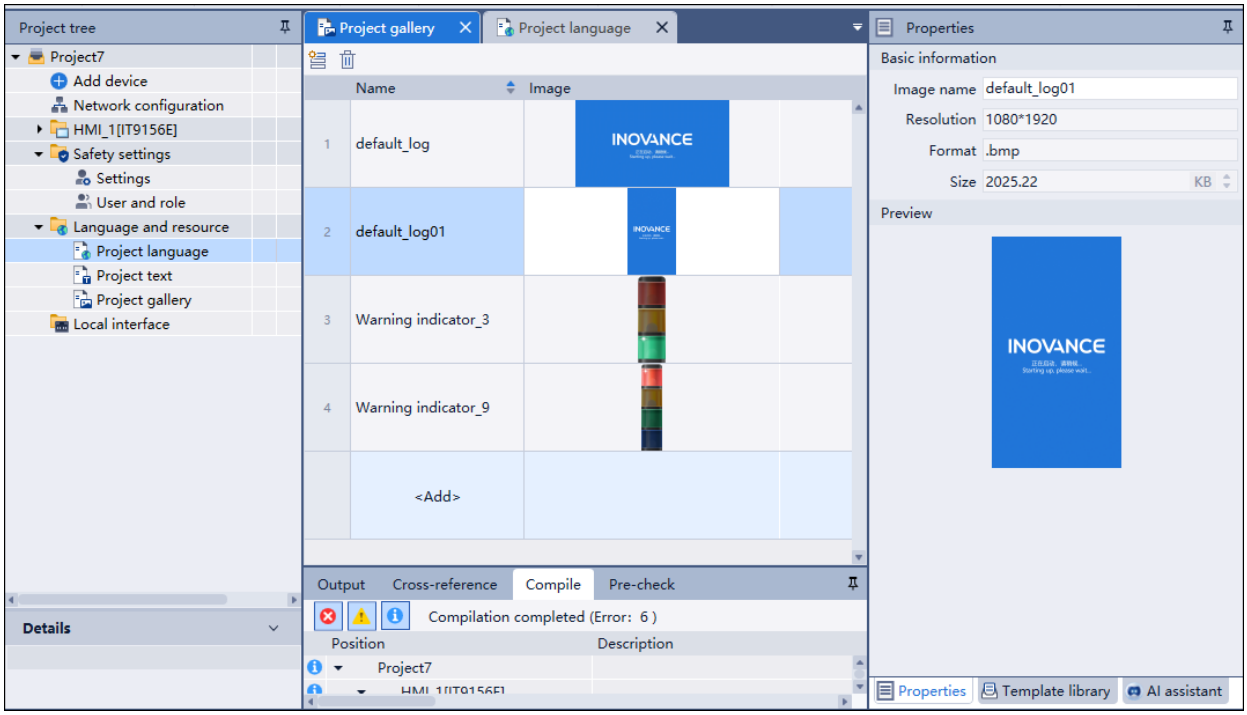
- Edit language: Select the language used for the currently edited object. When entering text, it is always created in the edit language.



- Reference language: Select the base language used as a reference for translating other languages. Its default value is the default language.

Project text

After selecting a project language, the reference language serves as the base for translating other languages. Users can right-click an information text to jump to the corresponding text object, or locate it using the "Reference" column. Then edit the text objects in other languages.

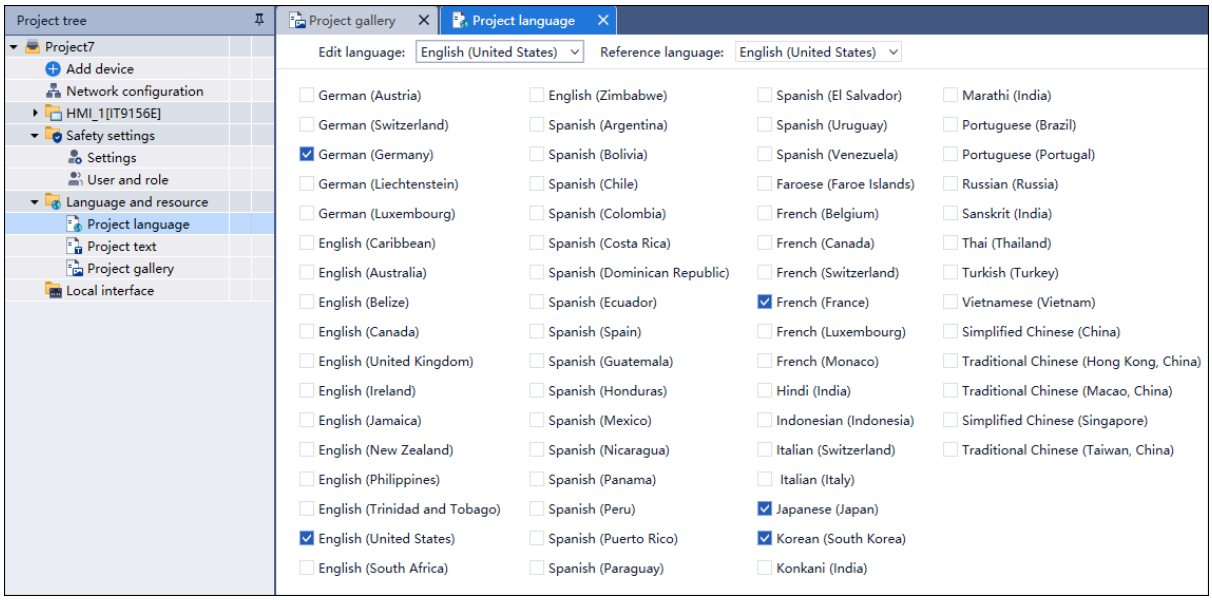


Project text is divided into user text and system text.

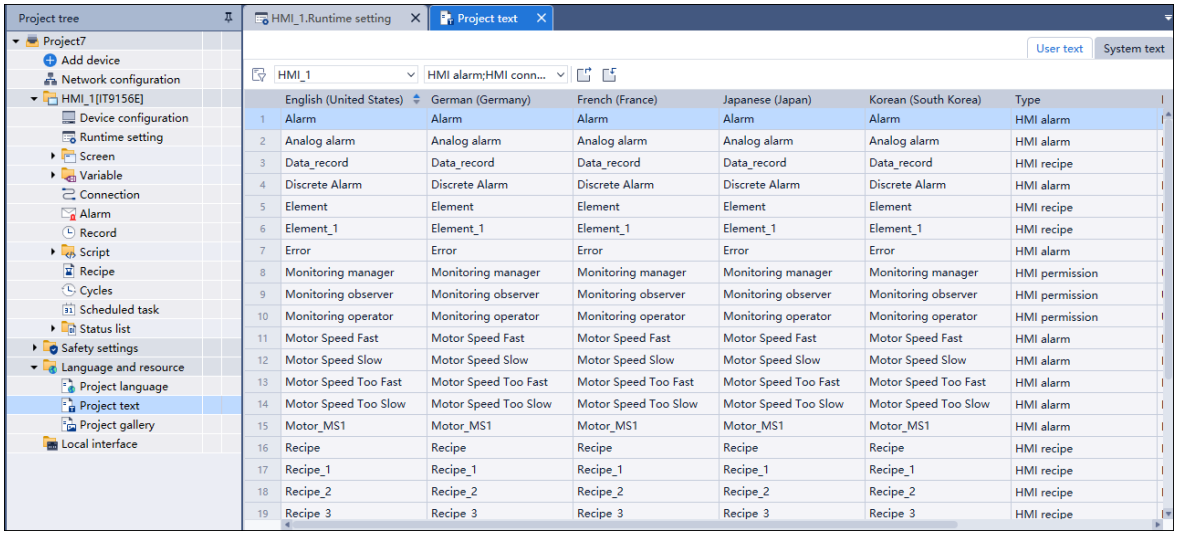
- User text: After user-defined information text objects are configured in 12 scenarios (such as HMI alarms, HMI variables, and HMI screens), they are automatically added to the user text list in the project texts.
- System text: Built-in information text objects of the system.

Project gallery

Graphics used within a project are automatically added to the project gallery for unified management. The project gallery can be used across all HMI devices in the current project.



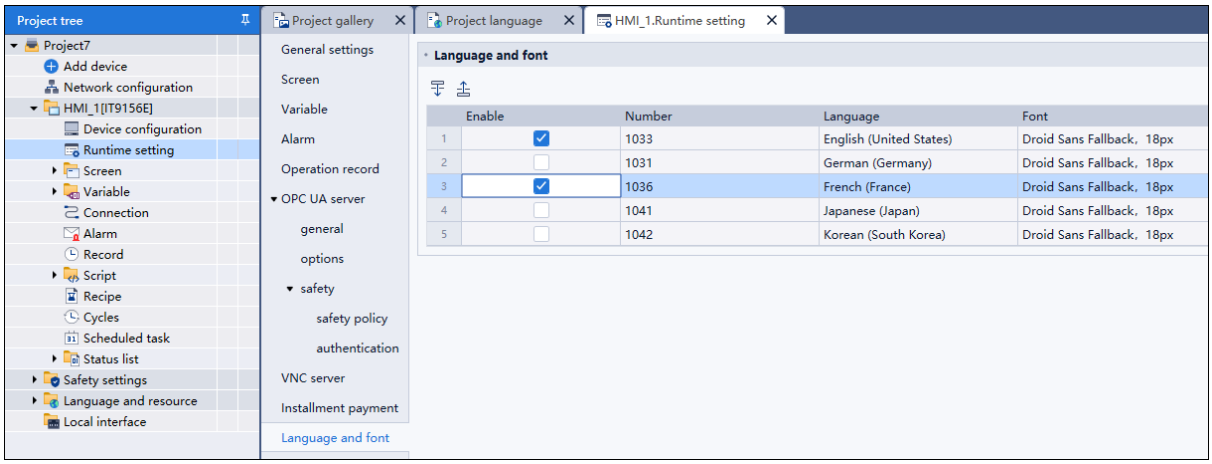
13.17.2 Multilingual Configuration and Modification



The project language page is used to specify the range of switchable languages. Only enabled languages can be dynamically switched on the HMI during operation. Disabled languages do not support switching.

Procedure

1. On the "Project language" page, check the required languages and select the edit language and reference language.



2. After adding an object that contains multilingual text information, the system simultaneously adds the corresponding project text information to the project text. Objects such as symbols, screens, alarms, and text lists support multilingual text information. For details, see 13.17.3 Multilingual Translation Scope.
   Example:
   a. Add a button control to the screen and edit the text information.
   b. In the project tree, double-click "Project text" under "Language and resource" to edit the text information for each language.

c. Switch the edit language of the screen; the language of the information text will change accordingly.

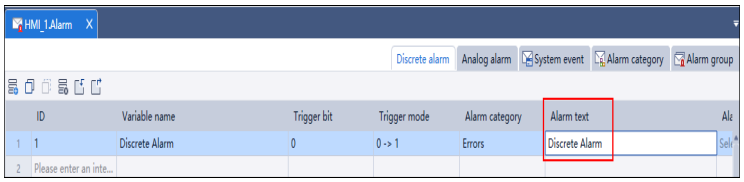
> **NOTE**
>
> - If an information text object is deleted, the corresponding information in the project texts will also be deleted.
> - When undoing or restoring objects containing multilingual text information, the system will synchronously undo or restore the project text information.
> - When copying objects containing multilingual text information within the device, across devices, or across projects, the system will synchronously copy the multilingual text information to the project texts. During pasting, all language texts that have been activated in the project for the selected content must be pasted together.

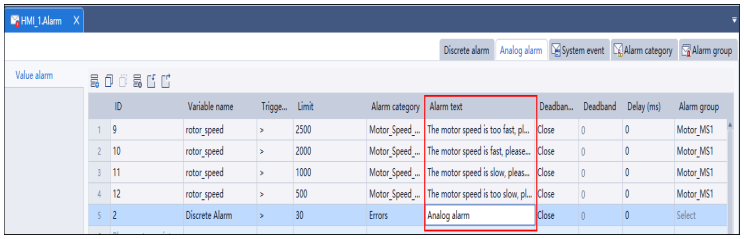
3. In the "Runtime setting" of the HMI device, activate the target language.

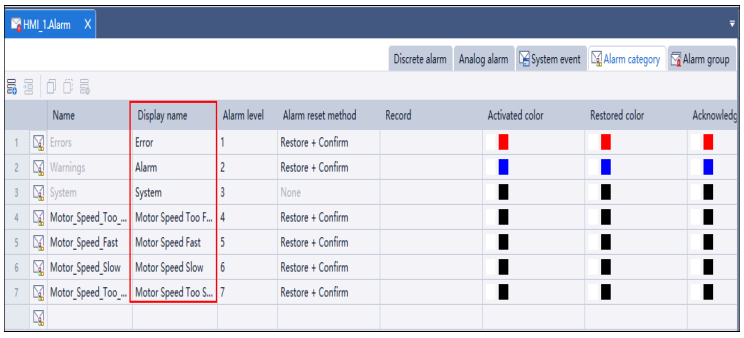
The order of languages can be adjusted.

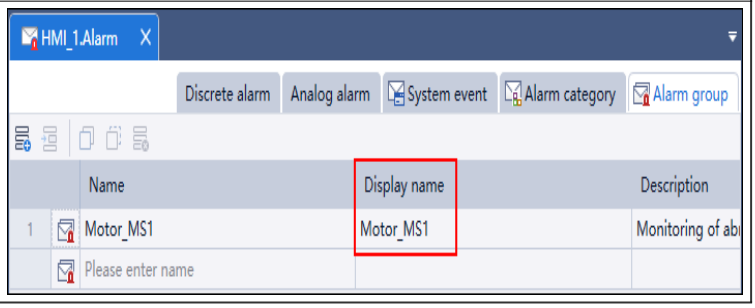
Each language corresponds to a unique ID, which is used when configuring 19.9.12 language functions.

13.17.3 Multilingual Translation Scope

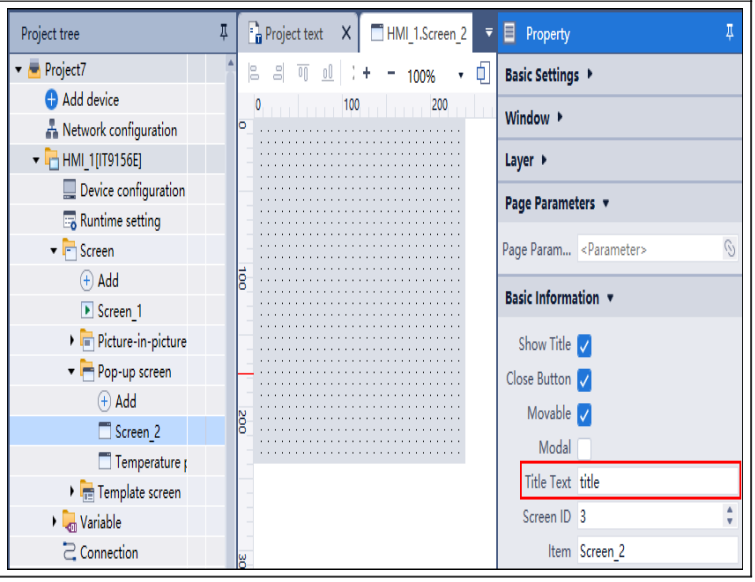




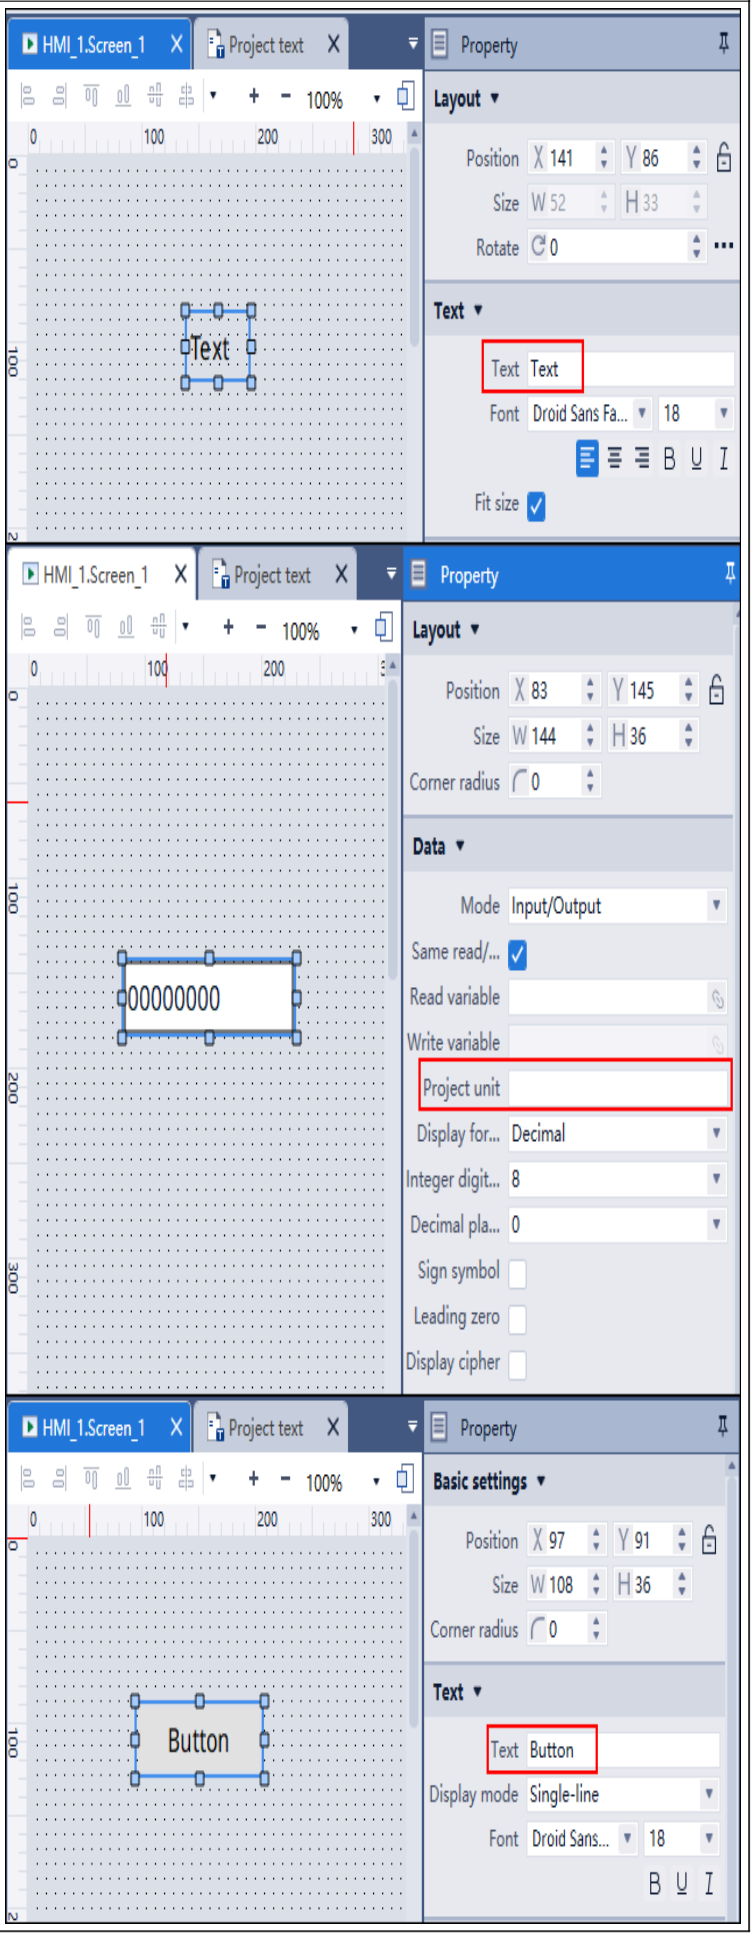




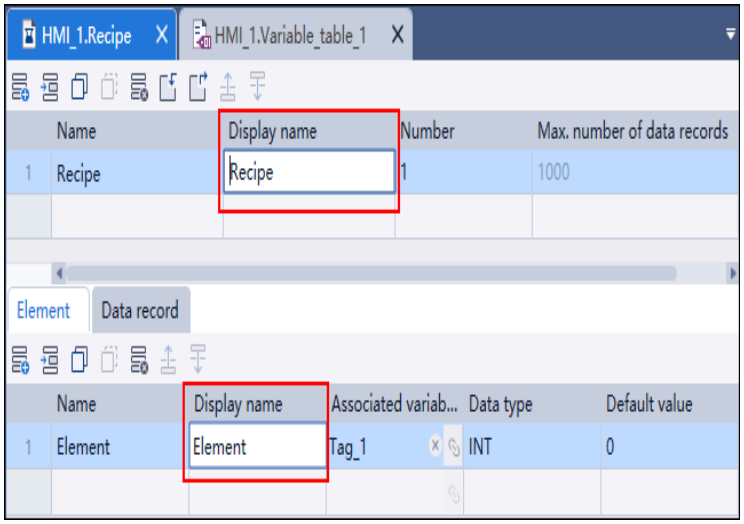
Multilingual translation scope

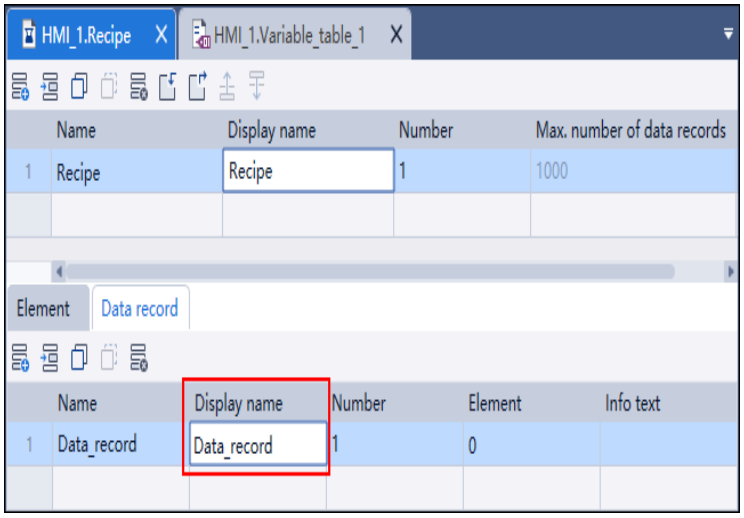


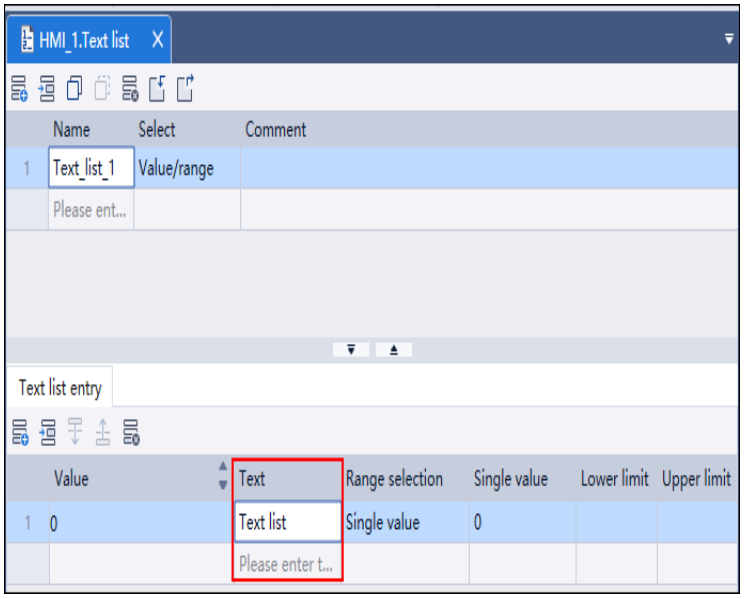
Project text is divided into user text and system text.



- User text refers to user-defined information text objects in 12 scenarios, including HMI alarm, HMI variable, HMI screen, etc.
- System text refers to built-in information text objects of the system.







The table below lists the sources and scope of various types in user text, making it convenient for users to check and translate.

Users can right-click an information text on the project text page and select "Jump to text properties" to jump to the information text object. They can also locate the information text object based on the corresponding reference column, and edit the text object in other languages in both user text and system text.

Category	Scope	Editing Method
HMI alarm	"Alarm text" for discrete alarms.	
	"Alarm text" for analog alarms.	
	"Display name" for alarm categories.	
	"Display name" for alarm groups.	

Category	Scope	Editing Method
HMI screen	"Title text" for pop-up screens.	

Category	Scope	Editing Method
HMI control	Text supported for editing in controls, such as "Text content" and "Text" of the control, as illustrated below: • "Text content" of text controls. • "Project unit" of numeric I/O field controls. • "Text content" of button controls. Unsupported controls: SFC view and code view.	

Category	Scope	Editing Method
HMI recipe	"Display name" of recipes.	
	"Display name" of elements.	
	"Display name" of data records.	
HMI text list	"Text" of list items.	

13.18 HMI Program Reuse Across Projects

Cross-project HMI program reuse allows the process program of one HMI device to be reused in another device of the same model, reducing redundant configuration work and improving configuration efficiency.

Usage limits

Both of the following conditions must be met:

- Same device model: The source HMI and the target HMI must be of the same model.
- Same software version: The iFA software version on the PC must be consistent with the runtime program version running on the HMI device.

Reuse limits

Not all device information can be reused across projects via copy-paste or upload operations. The scope of reusable content via copy-paste is exactly the same as that supported by upload. For details, see Upload scope.

Program reuse procedure

- Method 1: Local source project exists – copy and paste directly within the software
  . Applicable scenario: The source project containing the device program already exists in iFA.
  1. Open the iFA software on the same computer;
  2. Open two windows and load the source project (containing the device program to be copied) and the target project;
  3. Select the HMI device program in the source project, then use Copy and Paste commands to complete cross-project reuse.

- Method 2: No local source project – upload the device program first, then copy and paste
  . Applicable scenario: The source project does not exist in iFA; the program is stored only on the physical HMI device.
  1. Connect the device and computer through one of the following:
     Ethernet connection: Configure the computer IP address to ensure it is on the same subnet as the HMI device.;
     USB connection: Connect the device and computer directly using a USB cable;
  2. Upload the program: Open iFA and perform the 13.14.3 upload operation to read the program from the device and generate a local source project;
  3. Cross-project copy: Follow the steps in Method 1 to copy the uploaded device program to other target projects.

13.19 Migrating InoTouchPad Project to iFA Evolution

- 13.19.1 InoTouchPad Project Migration
- 13.19.2 Communication Protocol Conversion During Project Migration

13.19.1 InoTouchPad Project Migration

InoTouchPad projects support migration to iFA Evolution projects.

Migration restrictions

Before migration, confirm that the software versions and device models meet the following requirements:

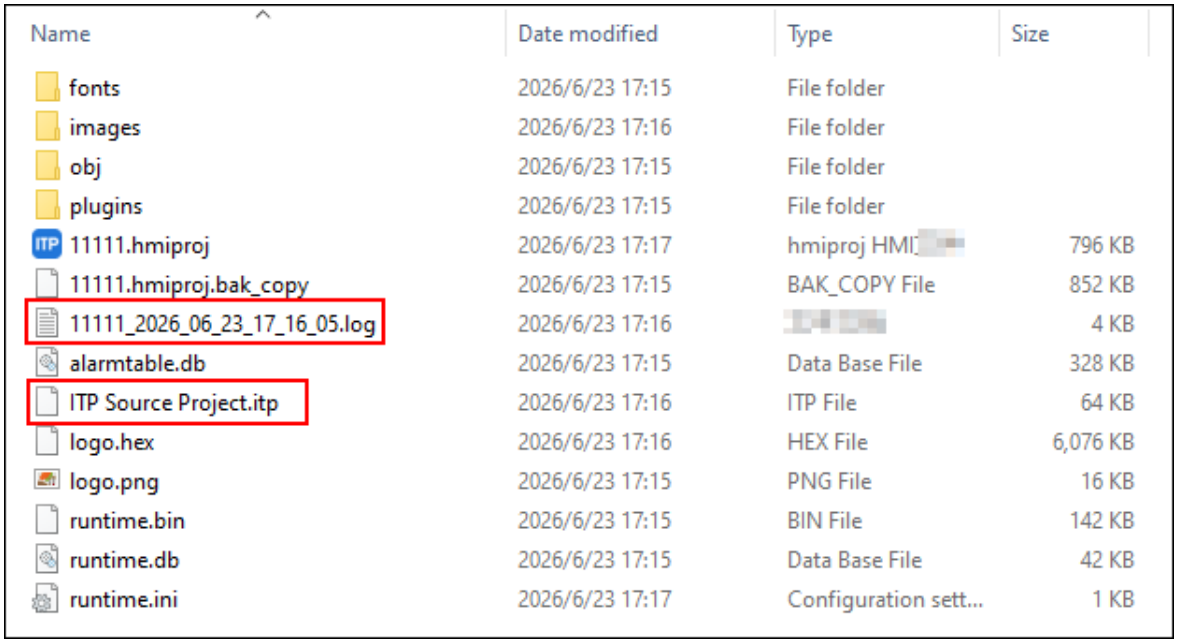
Item	InoTouchPad	iFA Evolution
Software version	V1R7C02SPC1Beta and above	iFA Evolution V1.4.4.5 and above
Device model	ITS7156E (1920*1080)	IT9156E (1920*1080)

Precautions before migration

Project backup: Make a complete backup of the InoTouchPad project and the iFA Evolution project.

Environment check: Ensure that the software versions on both sides meet the requirements and are running normally.

Function compatibility check: The current specified versions of InoTouchPad and iFA Evolution are not fully compatible. Please pre-check whether the InoTouchPad project involves the items listed in the following table and evaluate the impact.



Module	Incompatible Item	Solution after Migration
Connection	Some communication protocols are supported by InoTouchPad but not by iFA Evolution.	Related connection data is not imported, and communication variables are automatically converted to internal variables. Equivalent protocols must be manually created and variables re-associated. For the correspondence of communication protocols, see 13.19.2 Communication Protocol Conversion During Project Migration.
Index tag	Index variables associated with absolute address protocols and internal connections.	Not imported.
	Index variables associated with non-array type variables under tag protocols.	Not imported.
	Different index logic.	index variable takes effect: Sub-index = index value
Style sheet	Some advanced fill style properties are not compatible, such as complex gradients and path brushes.	Only basic properties are imported; other appearance styles need to be manually adjusted.
Script	Function name and syntax are incompatible.	Refer to the error log and perform equivalent conversion item by item.
System variable	Some system variables are incompatible.	There is an alarm during import.
System function	Some functions are supported in InoTouchPad but not in iFA Evolution.	Related function data is not imported; please pay attention to the prompt information during import.

Module	Incompatible Item	Solution after Migration
Data record	When the variable recording mode is based on command, it is incompatible.	It needs to be manually configured to demand-based storage.
Event	Some events are supported in InoTouchPad but not in iFA Evolution.	Related event data is not imported; please pay attention to the prompt information during import.
Alarm	Some alarm properties are incompatible.	Alarm categories, groups, and properties are not imported; please pay attention to the prompt information during import.
Structure	Structure variables are incompatible.	Create the corresponding structure definition in the template library; naming rule: HMI instance name_structure name. Structure definitions with the same name are not imported repeatedly.
Timer control	Timer control is incompatible.	After migration, a timer control instance corresponds to the timer event on the screen. If a screen contains multiple timer controls, only the data of the control with the smallest ID is matched to the screen timer event after migration. Data of other controls is not imported.
Layer	Layer is incompatible.	After import, the contents of all visible layers in the InoTouchPad project (regardless of their original layer numbers) are merged into Layer 0. The contents of all invisible layers in the InoTouchPad project (regardless of their original layer numbers) are merged into Layer 1 after import.
Recipe	Recipe properties (synchronized variables and offline variables) are incompatible.	Properties are not imported. Element variables are automatically created.
Control	Alarm records, alarm bars, recipe views, user views, and operation records are incompatible.	The control's initial state is retained at its original position on the screen after import.
Animation	Some animation types are incompatible.	The flashing property of appearance change animations is converted to fill flashing animation. After import, pipe elements are automatically matched with pipe flow animation, and a Boolean variable "PipeFlow" with a default value of 1 is automatically created. The flow speed is matched to the closest available option based on the original value.

Module	Incompatible Item	Solution after Migration
Special character	Special characters in names (such as screens or variables) are incompatible.	Replaced with an underscore "_".
Name length	Name length is incompatible.	Names are truncated; exceeding parts are not imported. Prompts are output in the monitoring area.

Migration procedure

1. Export the InoTouchPad project.
   a. Open the source project to be migrated in InoTouchPad software.
   b. Export the project file from InoTouchPad.
   Select "Project > Export migration project" to export the project file.
   Two key files are exported: one is the migration project file (*.itp), the main file of the project data, which can be imported to iFA Evolution; the other is the export log file (*.log), which records the export process and content list in detail for verification and troubleshooting during migration. The file format is shown in the figure below.

2. Import the project to iFA Evolution.
   a. Open an existing project or create a project in iFA Evolution.
   b. Import the migration project file.
   Select "Project > Project migration" and select the target project file (with the suffix .itp).
   c. Start the migration.
   Click "Start", and the software automatically performs data conversion and device creation.
   Device names start from "HMI_1" and increment sequentially.

3. Check and adjust.
   After the migration, check and adjust each item according to the prompt information in the output area to ensure the integrity and accuracy of the data.

13.19.2 Communication Protocol Conversion During Project Migration

Ethernet

Category	InoTouchPad	iFA Evolution
Inovance	AM600 Modbus TCP protocol	Modbus TCP protocol (AM400/600 series)
	AM600 Qlink TCP protocol	Qlink TCP protocol (AM400/600 series)
	AM700 Qlink TCP protocol	Modbus TCP Protocol (AM300/500, AC700/800 series)
	AC810 Qlink TCP protocol	
	H5U TCP monitoring protocol	TCP monitoring protocol (H5U/Easy series)
	Easy TCP monitoring protocol

	MelSec-Q\L (Binary)	MelSec-Q\L (Binary) protocol (Q series)

Serial interface

Category	InoTouchPad	iFA Evolution
Inovance	AM600 Modbus protocol	Modbus RTU protocol (AM400/600 series)
	H5U Qlink protocol	Qlink RTU protocol (H5U series)
	MD series AC drive Modbus protocol	Modbus RTU protocol (MD series)
Modbus IDA	Modbus RTU protocol	Modbus RTU master
	Modbus slave	Modbus RTU slave

14 Maintenance Upgrade

14.1 PLC Firmware and Project Upgrade

14.1.1 Firmware Upgrade

14.1.1.1 Upgrading Firmware via SD Card

The PLC firmware upgrade package provides all required software data for the upgrade.

> NOTE
>
> Only EVO400, EVO500 and EVO800 series PLCs support firmware upgrade through SD card.

Prerequisites

- The device supports upgrade through SD card.
- A bootable SD card is ready (firmware can be downloaded from the Inovance website).

Procedure

1. Power off the device, and then insert the bootable SD card into the device.
2. Power on the device, and then the system begins the firmware upgrade. The device indicator flashes quickly for 3s.

   > NOTE
   >
   > The upgrade lasts about two minutes. Do not power off the device during the upgrade; otherwise, unrecoverable system faults may occur.

3. After the upgrade, power off the device and remove the SD card.
4. Power on the device to resume normal operation.

Device indicator states

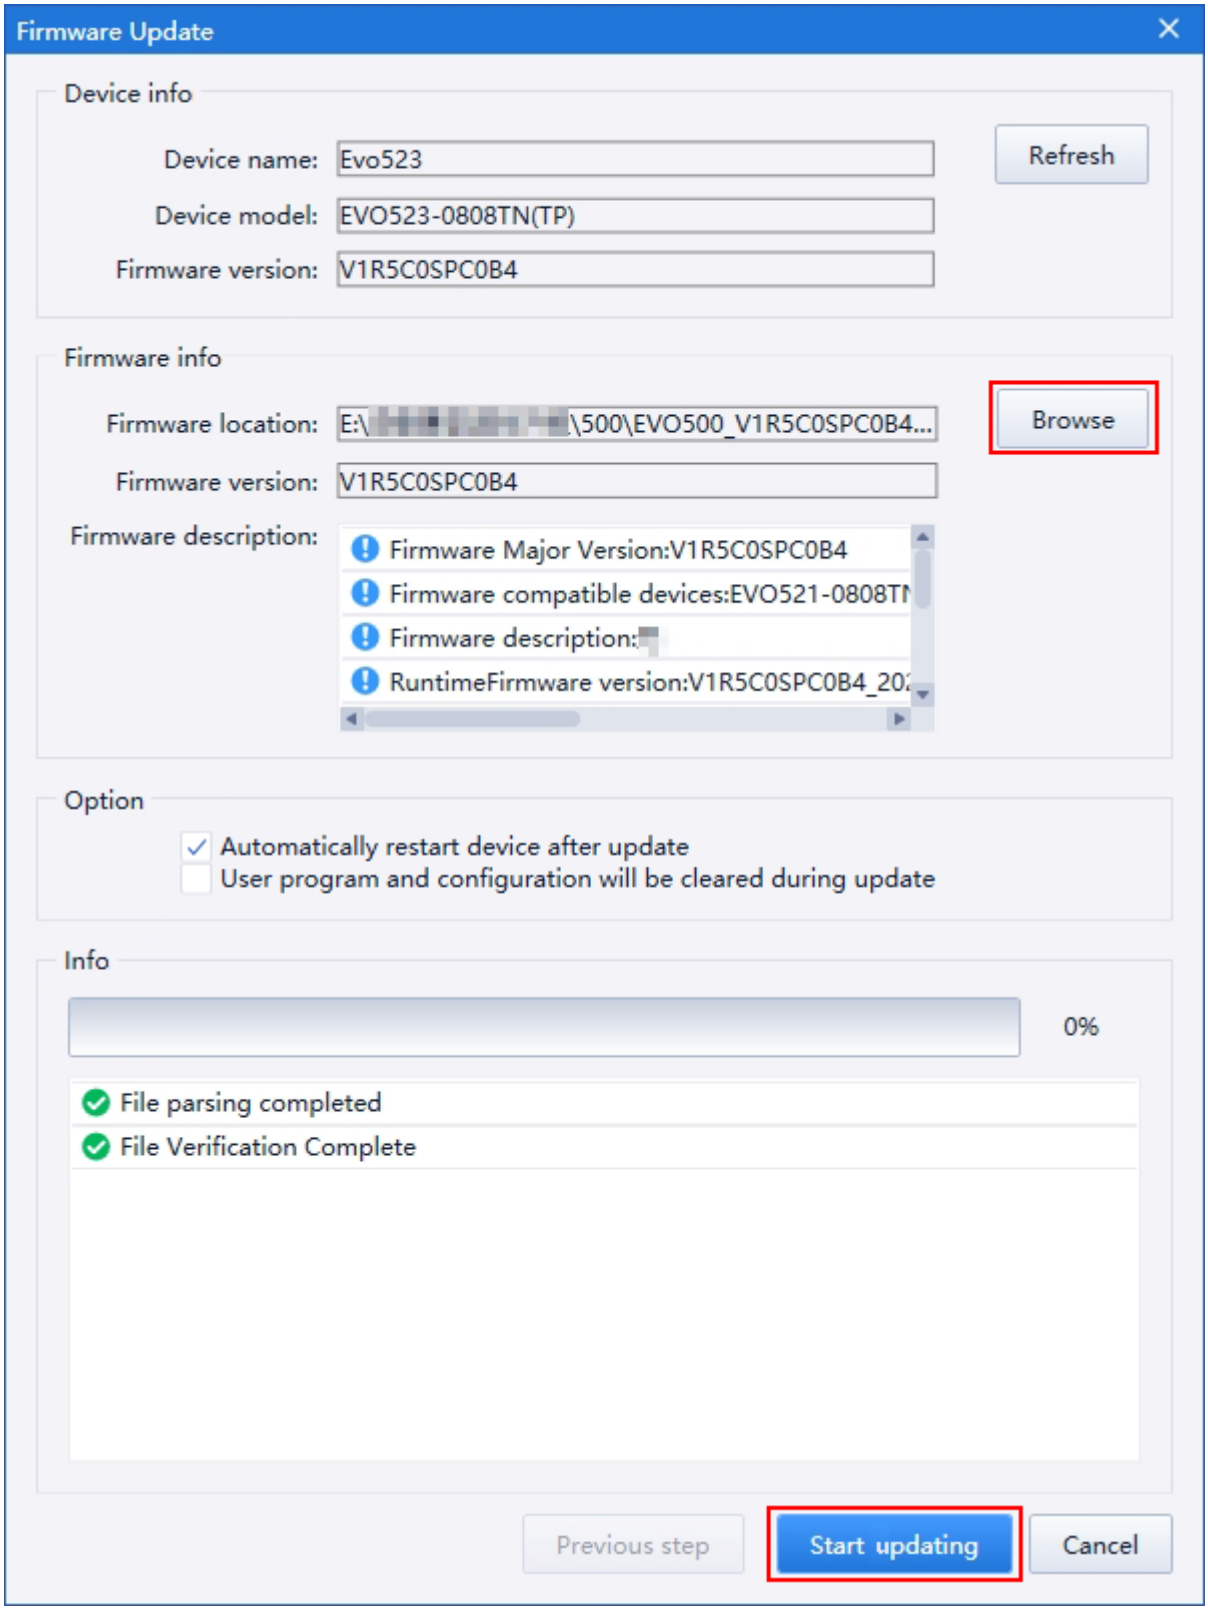
Item	State
Firmware upgrade start	RUN + ERR: flashing quickly (3s)
Upgrade process	RUN + ERR: steady on
Upgrade success	RUN + ERR: flashing slowly
Upgrade failure	ERR: flashing slowly

14.1.1.2 Upgrading Firmware via Ethernet

The upgrade page is used for PLC firmware upgrade. The PLC firmware upgrade package contains all required software data for the upgrade.

Background

The EVO800 series firmware upgrade through Ethernet includes two methods: Direct connection between the PC and EVO800 series control module, and direct connection between the PC and EVO800-CM-EN Ethernet expansion module. The firmware upgrade description is shown in the table below.



Ethernet connection method	Firmware upgrade description
Direct connection between the PC and EVO800 series control module	The following types of modules support firmware upgrades: • Directly connected control modules • EVO800-CM-EN Ethernet expansion module directly connected to the PLC • EVO800-CM-PN master expansion module directly connected to the PLC • EVO800-CM-DP master expansion module directly connected to the PLC
Direct connection between the PC and EVO800-CM-EN Ethernet expansion module	Only supports firmware upgrade for the directly connected EVO800-CM-EN Ethernet expansion module.

Prerequisites

The firmware file is obtained by downloading it from the Inovance website or contacting the Inovance service engineer.

Procedure

1. Choose "Online > Firmware update > PLC and HMI" from the menu bar.
2. On the opened "Device scanning" interface, select "Ethernet" for the "Communication type," and then click "Start search."
3. Select the target device, click "OK", and then the system automatically opens the "Firmware update" interface.
4. On the opened "Firmware update" interface, click "Browse" to select the firmware file to be upgraded, select the upgrade method under the "Options", and then click "Start updating".

Parameter		Description
Device information	Device name	Current device name.
	Device model	Current device model.
	Firmware version	Current firmware version of the device.
Firmware information	Firmware location	The location where the firmware is stored.
	Firmware version	The firmware version to be upgraded.
	Firmware description	Detailed information about the firmware upgrade package.

Parameter		Description
Options	Restart device after update	Automatically restart the current device after firmware update.
	Clear user program and configuration during the update	User projects, data, IP configuration, and other properties in the PLC will be cleared during the upgrade.

5. Click "OK" on the opened dialog box to start the firmware upgrade.

NOTE

- Do not power off the device during the upgrade; otherwise, unrecoverable system faults may occur.
- The upgrade lasts about two minutes. After the upgrade, the device automatically restarts.
- After the device restart (or the upgrade), the device's display shows "00" or changing numbers.

6. After the upgrade, check the device information and version information for consistency with the firmware version and details.

Device indicator states

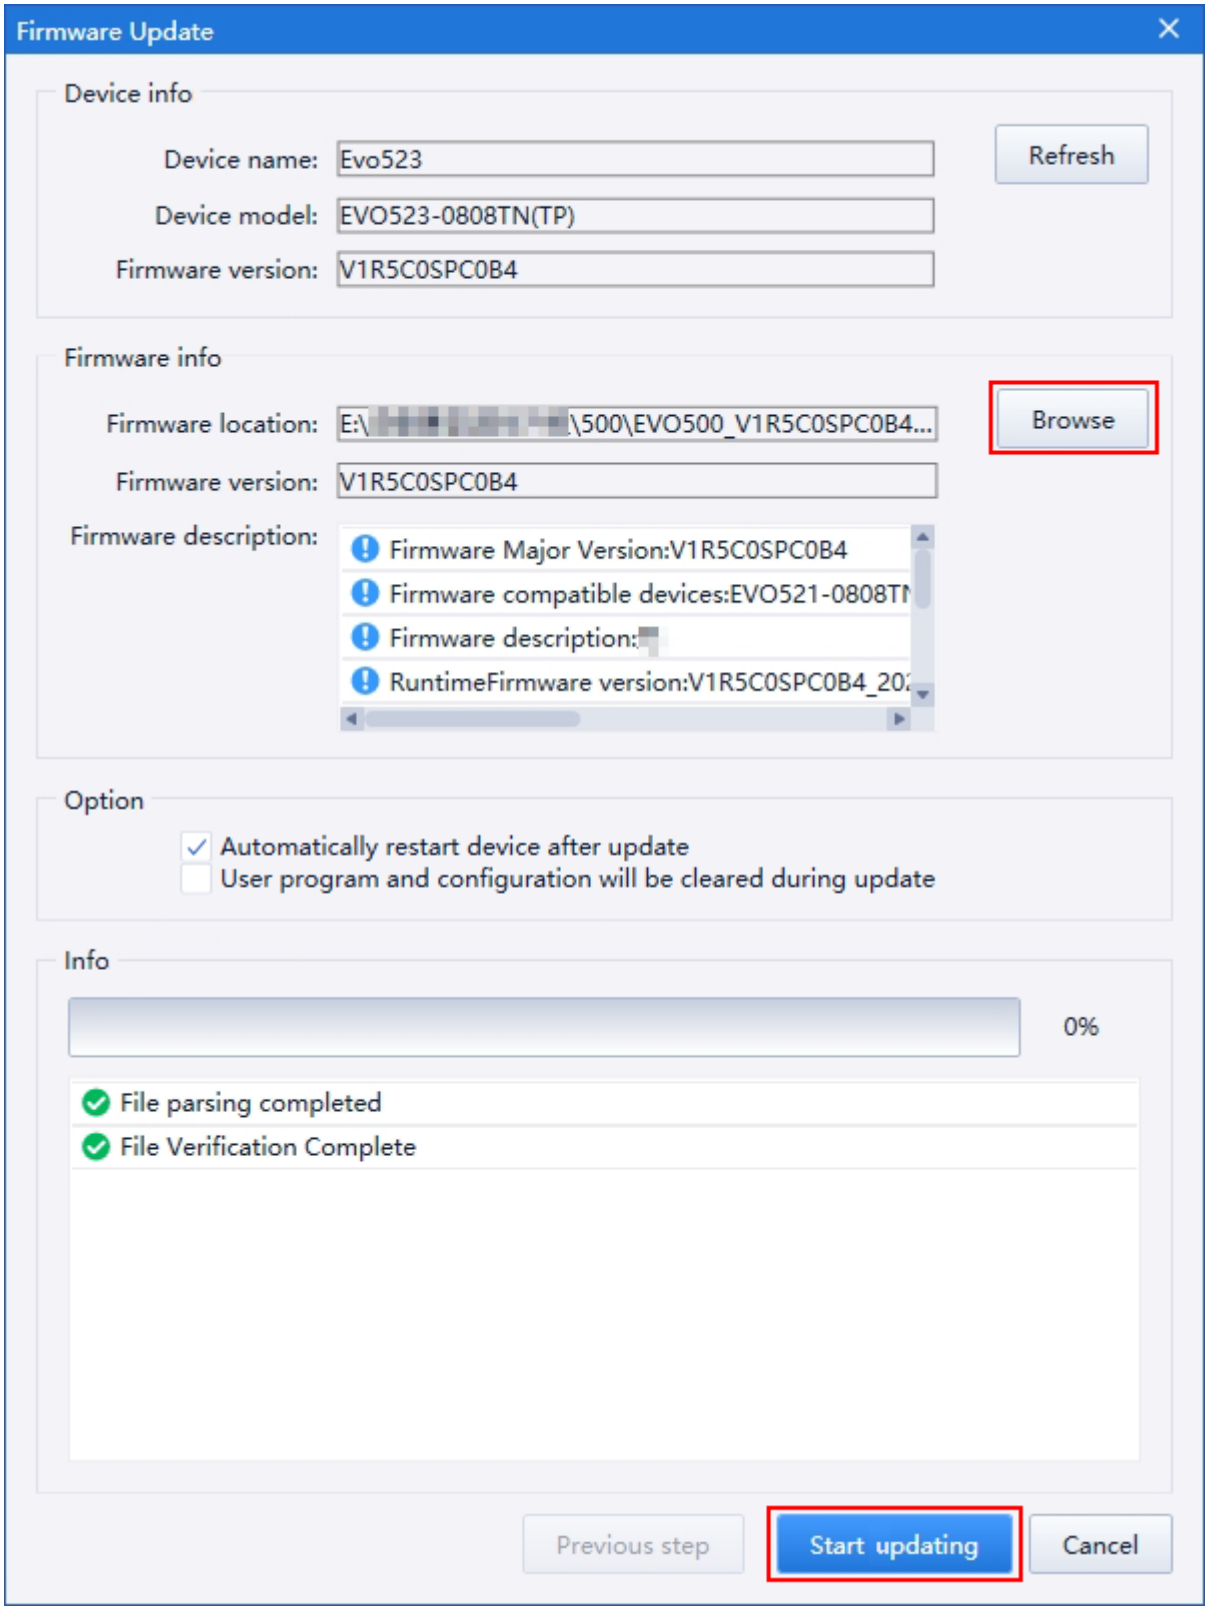
Item	State
Firmware upgrade start	RUN + ERR: flashing quickly (3s)
Upgrade process	RUN + ERR: steady on
Upgrade success	RUN + ERR: flashing slowly
Upgrade failure	ERR: flashing slowly

14.1.1.3 Upgrading Firmware via Type C

The PLC firmware upgrade package provides all required software data for the upgrade.

NOTE

Only EVO400, EVO500, and EVO700 series PLCs support firmware updates through Type-C interface.



Prerequisites

- The PLC is connected to a Type-C interface.
- The firmware file is obtained by downloading it from the Inovance website or contacting the Inovance engineer.

Procedure

1. Choose "Online -> Firmware update -> PLC and HMI" from the menu bar.

2. On the opened "Device scanning" interface, select "USB" for the "Communication type," and then click "Start search."
3. Select the target device, click "OK", and then the system automatically opens the "Firmware update" interface.
4. On the opened "Firmware update" interface, click "Browse" to select the firmware file to be upgraded, select the upgrade method under the "Options", and then click "Start updating".

Parameter		Description
Device information	Device name	Current device name.

Parameter		Description
	Device model	Current device model.
	Firmware version	Current firmware version of the device.
Firmware information	Firmware location	The location where the firmware is stored.
	Firmware version	The firmware version to be upgraded.
	Firmware description	Detailed information about the firmware upgrade package.
Options	Restart device after update	Automatically restart the current device after firmware update.
	Clear user program and configuration during the update	User projects, data, IP configuration, and other properties in the device will be cleared during the upgrade.

5. Click "OK" on the opened dialog box to start the firmware upgrade.

NOTE

- Do not power off the device during the upgrade; otherwise, unrecoverable system faults may occur.
- The upgrade lasts about two minutes. After the upgrade, the device automatically restarts.
- After the device restart (or the upgrade), the device's display shows "00" or changing numbers.

6. After the upgrade, check the device information and version information for consistency with the firmware version and details.

Device indicator states

Item	State
Firmware upgrade start	RUN + ERR: flashing quickly (3s)
Upgrade process	RUN + ERR: steady on
Upgrade success	RUN + ERR: flashing slowly
Upgrade failure	ERR: flashing slowly

14.1.1.4 Upgrading Firmware via USB Flash Disk (EVO700)

EVO700 series PLCs support firmware upgrade through USB flash disk.

Prerequisites

- A USB flash disk with a capacity of not more than 32 G and using the FAT32 file system is ready.
- A bootable USB flash disk is created with the support of the Inovance engineer.

Procedure

1. Power off the device, and then insert the USB flash disk into the device's USB port.

2. Power on the device, and then the system begins the firmware upgrade.
3. During the upgrade, the segment display icon 888shows "UUU" and the icon ▬▬▬▬indicates the progress.
4. After the upgrade, the buzzer beeps three times, and the segment display icon 888shows "UUU" and flashes or shows "00".
5. Power off the device, remove the USB flash disk, and then power on the device to resume normal operation.

14.1.1.5 Upgrading Redundant System Firmware (EVO800)

14.1.1.5.1 Upgrading via SD Card

The EVO800 series PLC system supports dual-rack redundant mode with a primary-backup switchover in 20 ms. When upgrading the redundant system firmware, upgrade the primary and backup PLCs and redundant systems separately.

The methods for upgrading primary and backup devices are the same. The following describes the method for upgrading the primary device.

Prerequisites

- The dual-rack redundant system, consisting of primary and backup PLCs, power supply modules, racks, and redundant modules, has been installed and powered on, and the devices are operating normally.
- An SD card with a capacity of 8GB to 32GB is ready, and a bootable SD card is created with the support of the Inovance engineer.

Procedure

1. Power off the device, and then insert the bootable SD card into the SD card slot of the primary PLC.
2. Power on the device and wait for 30s (the power indicator being steady on indicates normal power supply). The system automatically starts the firmware upgrade. For the indicator states during the upgrade, see the "Device indicator states" table.
3. After the firmware upgrade, remove the SD card and power off the device.
4. Power on the device to resume normal operation.
5. Follow the preceding steps to upgrade the backup device firmware.

After the primary device firmware is upgraded, the firmware will not be automatically synchronized to the backup device. Therefore, you must manually upgrade the backup device using the same version of the firmware package to ensure the same firmware versions of the primary and backup devices.

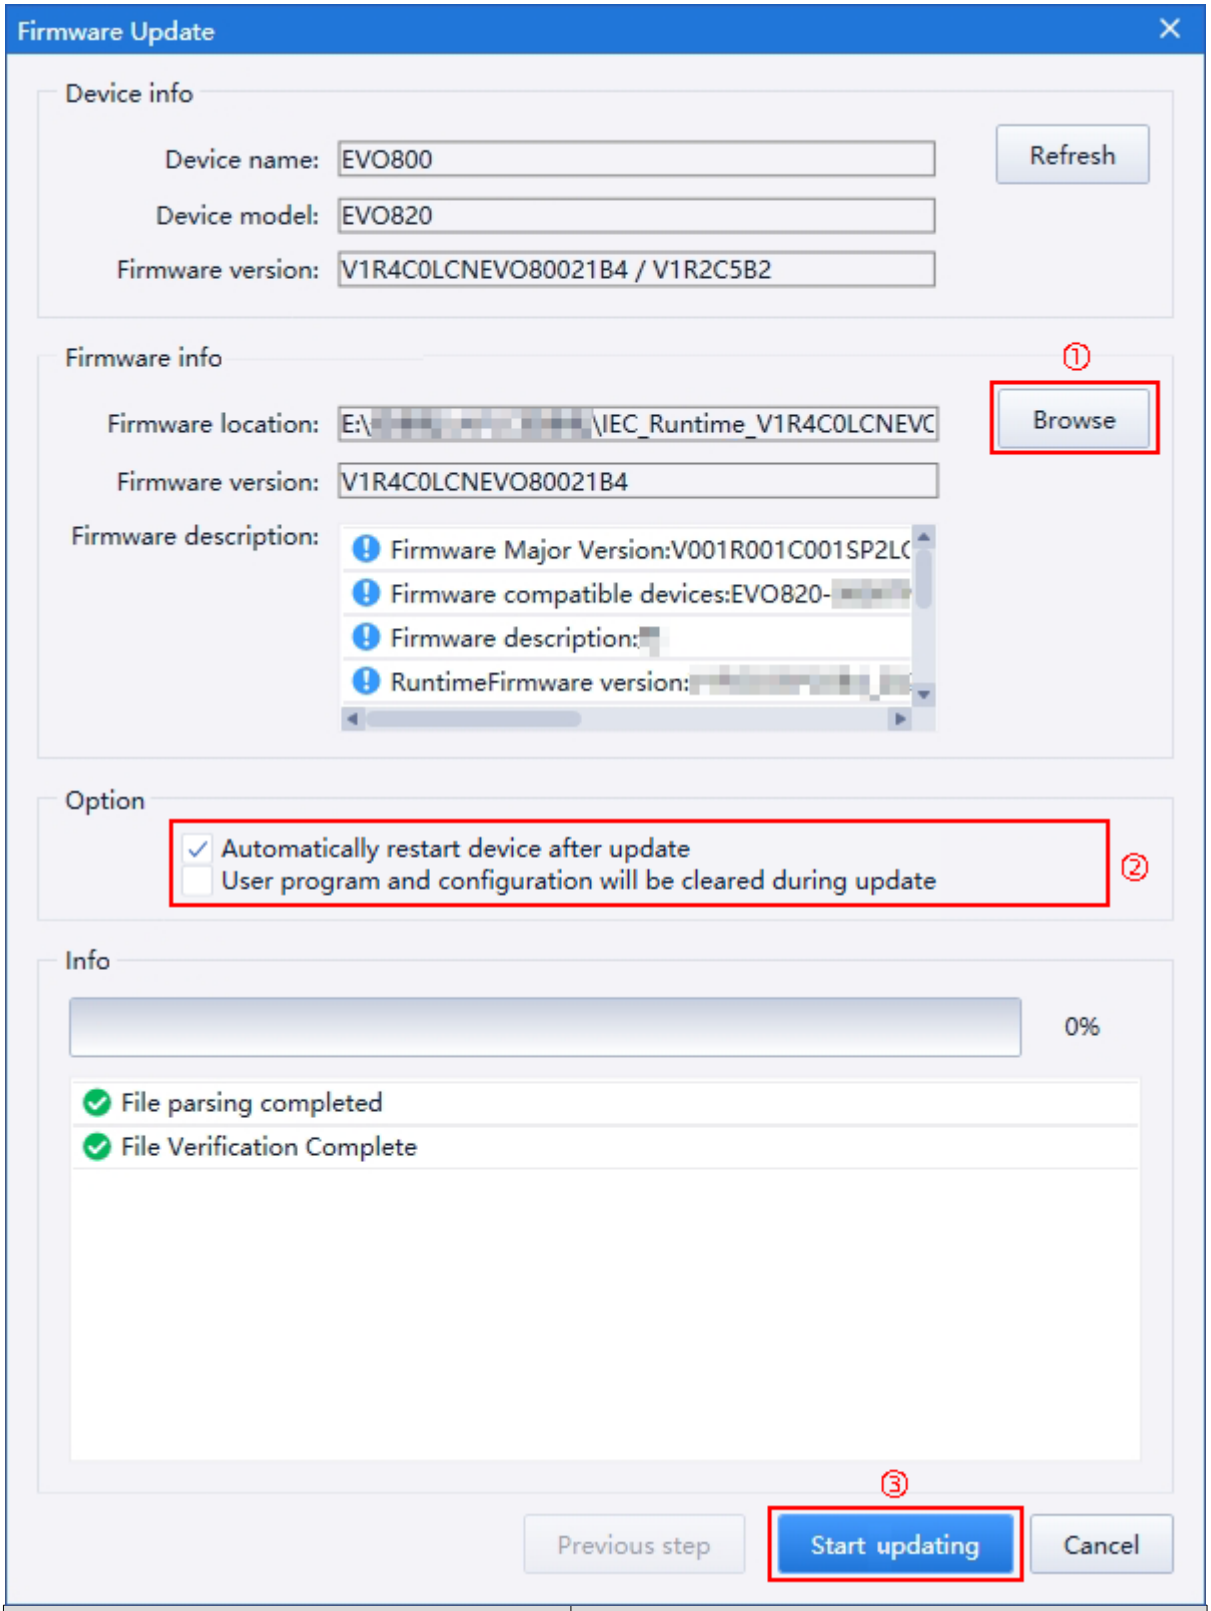
The PLC firmware upgrade package includes the redundant module firmware package. As a result, the primary and backup redundant modules will be upgraded synchronously during the upgrade of the primary and backup PLCs.

Device indicator states

Item	State
Upgrade start	The SD card indicator on the display is lit (card inserted), and the digital display flashes slowly at 000 for 3s.
Upgrade process	The SD card indicator on the display flashes (data reading/writing in progress), and the digital display shows 1 to 100.
Upgrade success	The SD card indicator on the display is lit; the digital display shows 100, and the yellow exclamation mark flashes continuously, prompting the user to remove the card.
Upgrade failure	The red exclamation mark flashes, and the SD card indicator is lit; the digital display shows a fault code greater than 100.

14.1.1.5.2 Upgrading via Ethernet

The EVO800 series PLC system supports dual-rack redundant mode with a primary-backup switchover in 20 ms. When upgrading the redundant system firmware, upgrade the primary and backup PLCs and redundant systems separately.



The methods for upgrading primary and backup devices are the same. The following describes the method for upgrading the primary device.

Prerequisites

- The dual-rack redundant system, consisting of primary and backup PLCs, power supply modules, racks, and redundant modules, has been installed and powered on, and the devices are operating normally.
- The primary and backup PLCs have been connected to the Ethernet via network cables.
- The optical fiber cable connecting the redundant racks has been disconnected; otherwise, the message "Firmware upgrade is prohibited in redundant mode" will appear.
- The PLC firmware upgrade package (such as EVO800-RM_V1R4C0LCNEVO80021B4_20250408_5053.zip) has been obtained by downloading it from the Inovance website or contacting the Inovance engineer.

Procedure

1. Choose "Online -> Firmware update -> PLC and HMI" from the menu bar.
2. On the opened "Device scan" interface, select "Ethernet" for the "Communication type," and then click "Start search."
3. Select the target device, click "OK", and then the system automatically opens the "Firmware Update" interface.
4. On the opened "Firmware update" interface, click "Browse" to select the firmware file to be upgraded, select the upgrade method under the "Options", and then click "Start updating".

Parameter		Description
Device information	Device name	Current device name, such as EVO800.
	Device model	Current device model, such as EVO820.
	Firmware Version	Current firmware version of the device, such as V1R4C0LCNEVO80021B4.
Firmware information	Firmware location	The location where the firmware is stored.
	Firmware version	The firmware version to be upgraded.

Parameter		Description
	Firmware description	Detailed information about the firmware upgrade package.
Options	Restart device after update	Automatically restart the current device after firmware update. It is recommended to check this option to ensure a successful firmware update.
	Clear user program and configuration during the update	User projects, data, IP configuration, and other properties in the device will be cleared during the upgrade.

5. When the upgrade progress under the "Information" bar shows 100% and the device begins to restart, the firmware is updated successfully. Wait for the device to restart.

NOTE

- Do not power off the device during the upgrade; otherwise, unrecoverable system faults may occur.
- The upgrade takes approximately two minutes, and the device automatically restarts after upgrade (if the option "Automatically restart the device after upgrade" is checked); otherwise, the device must be restarted manually.
- After the device restart (or the upgrade), the device's display shows "00" or changing numbers.

6. Follow the preceding steps to upgrade the firmware for the backup PLC and redundant module.
After the primary device firmware is upgraded, the firmware will not be automatically synchronized to the backup device. Therefore, you must manually upgrade the backup device using the same version of the firmware package to ensure the same firmware versions of the primary and backup devices.

NOTE

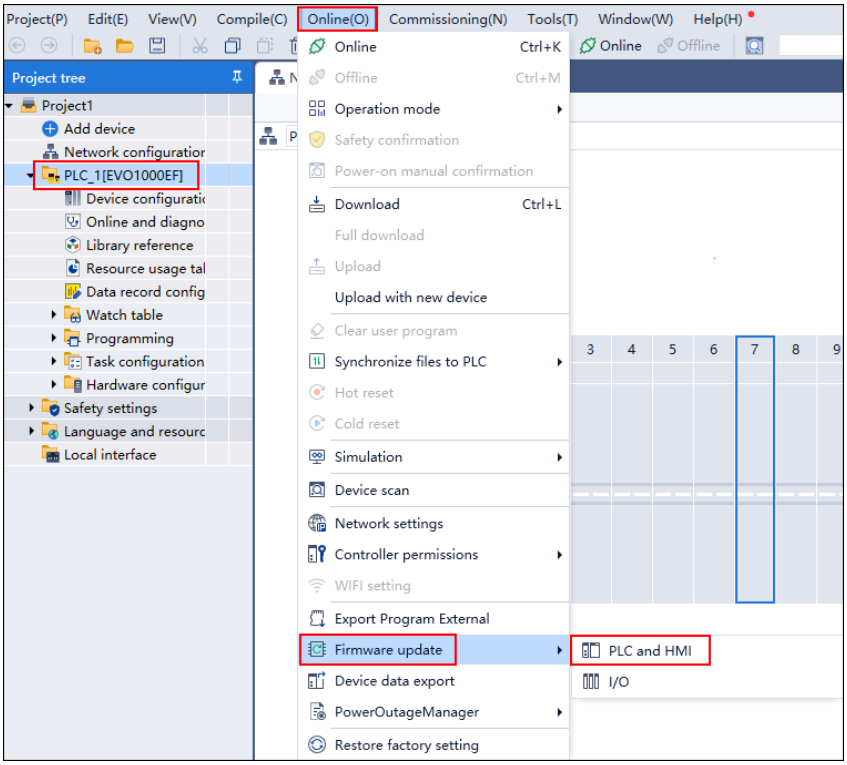
- The PLC firmware upgrade package includes the redundant module firmware package. As a result, the primary and backup redundant modules will be upgraded synchronously during the upgrade of the primary and backup PLCs.
- The redundant module cannot be automatically restarted. You must manually power off and then power on the redundant module to ensure a successful firmware upgrade.

14.1.1.6 Upgrading Safety PLC Firmware (EVO1000)

The EVO1000EF safety PLC module and the communication unit are combined into a firmware package. When a firmware update is performed, both devices are upgraded simultaneously.

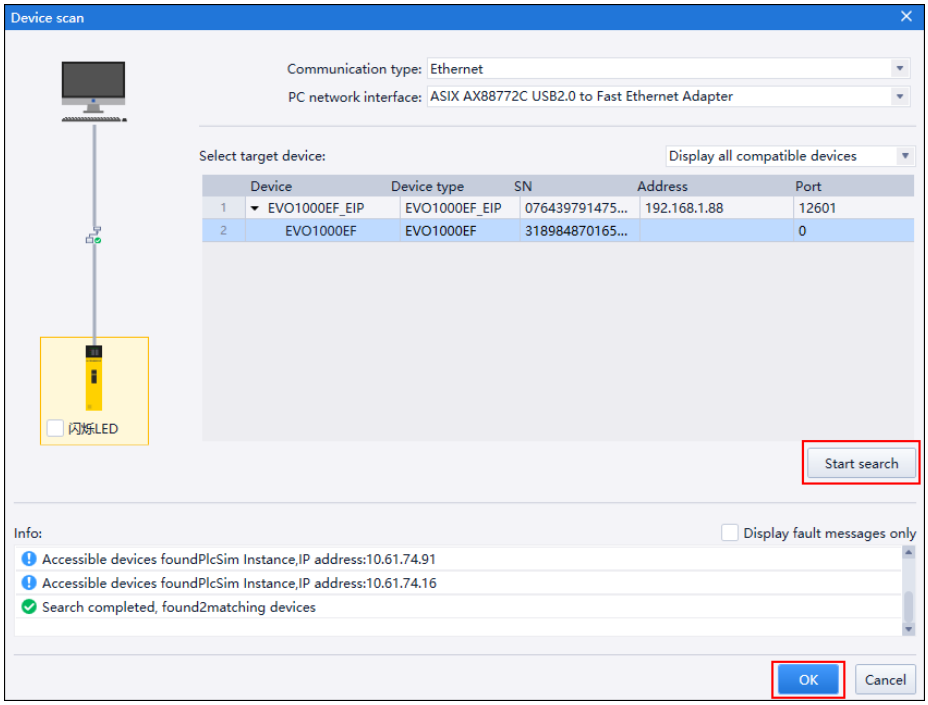
- Downgrade: The version to be upgraded to is lower than the current firmware version.
- Same version: The version to be upgraded to is the same as the current firmware version.
- Upgrade: The version to be upgraded to is higher than the current firmware version.

> **NOTE**
>
> The firmware package must match the device model.



The following uses a firmware package created by combining the EVO1000EF safety PLC module firmware and the EVO1000EF EIP communication unit firmware as an example.

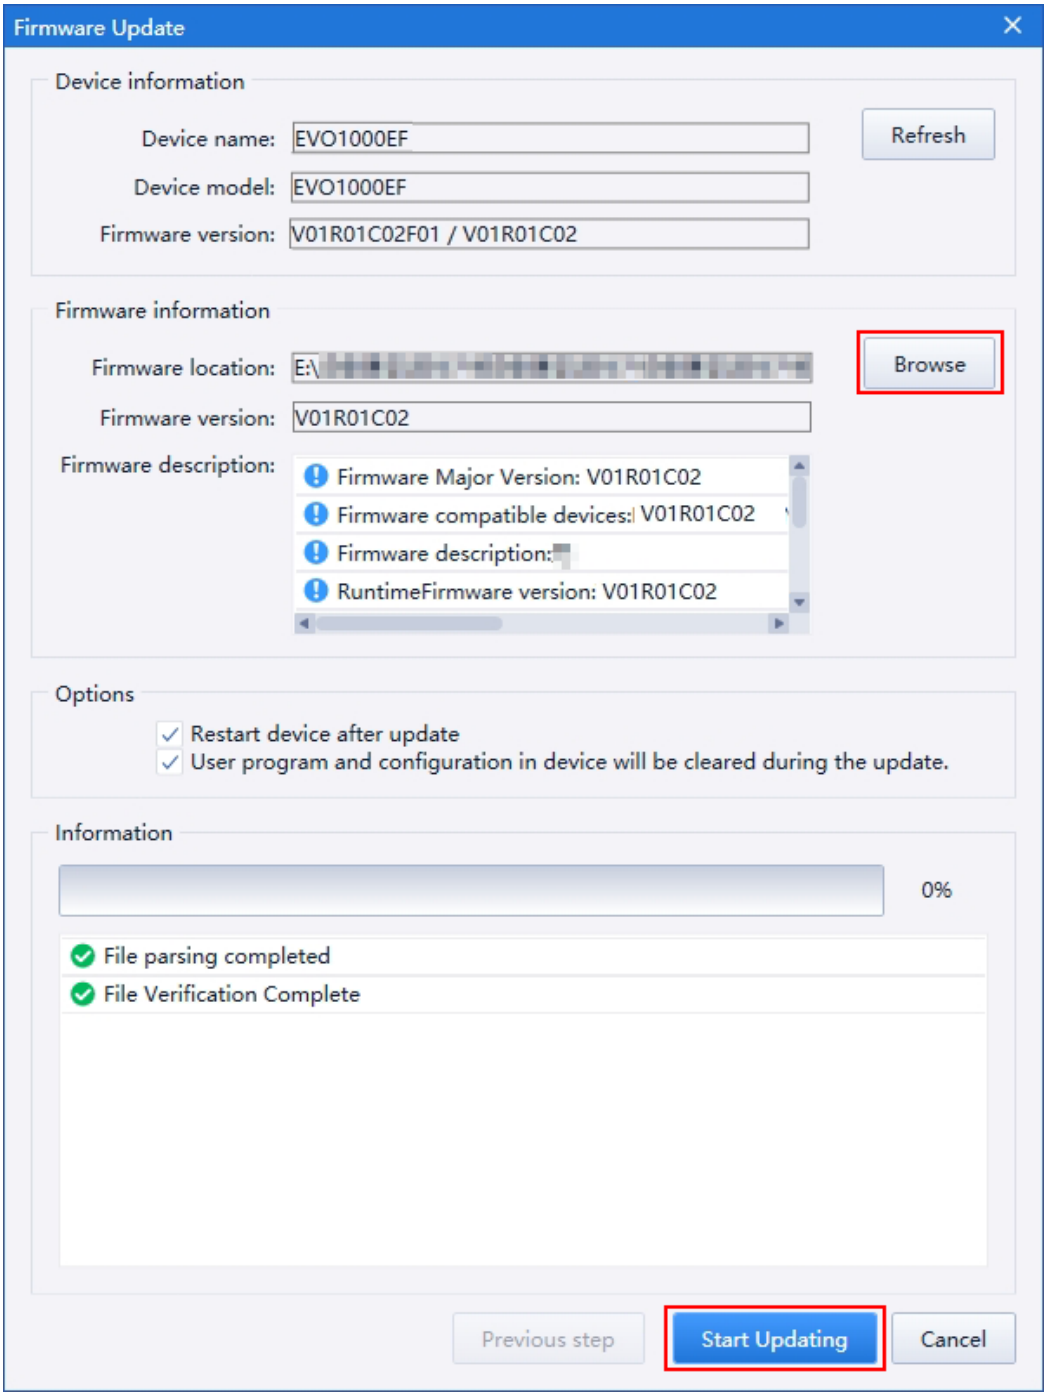
Prerequisites



The firmware upgrade package has been obtained from the Inovance technical support.

Procedure

1. Open the iFA Evolution software, and select "Online > Firmware update > PLC and HMI" from the menu bar.



2. In the "Device scanning" window, click "Start search". Then, select the device to be upgraded and click "OK".

3. In the pop-up "Firmware update" window, click "Browse", locate the corresponding version of the firmware upgrade package on local PC, and click "OK".

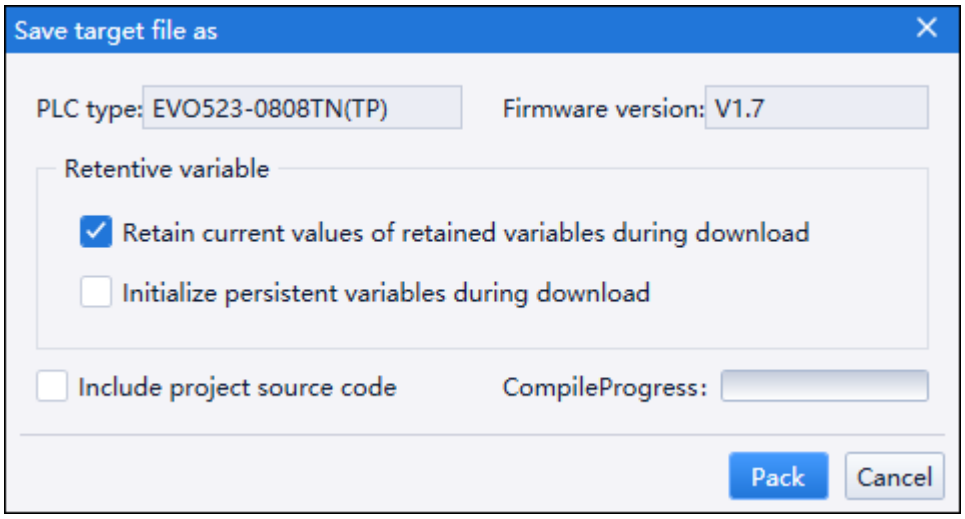
4. After the firmware upgrade package is successfully opened, ensure the firmware version information is accurate, and click "Start update".

5. In the pop-up "Firmware update" window, click "OK" to start the firmware update.

   The "Firmware update" interface will display the firmware update progress. When the progress bar reaches 100%, it indicates that the firmware update is complete.

> **CAUTION**
>
> After the firmware update, the device will restart. The firmware update of the main partition during the device's boot phase will take several minutes. Wait until the CUS indicator on the safety PLC module becomes steady green before operating the device.

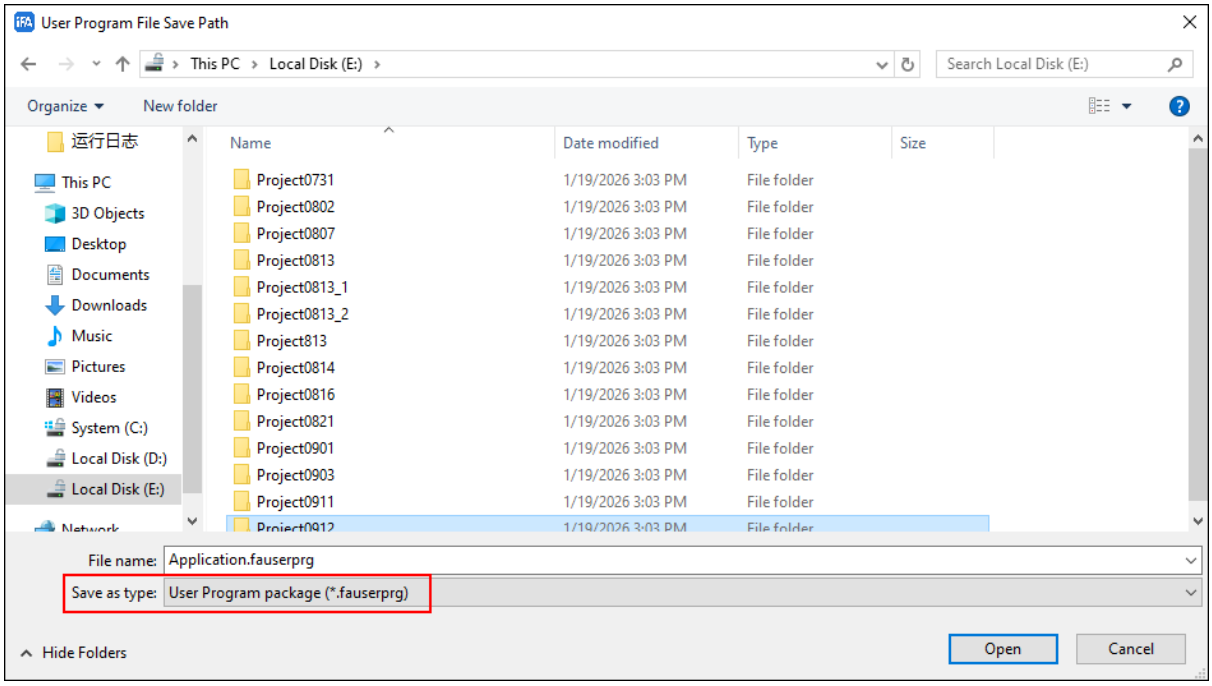
14.1.2 PLC User Program Upgrade



14.1.2.1 Saving a PLC User Program As

The software supports saving the successfully compiled user program as a target file, which can be used to upgrade the user program through SD card or USB flash disk.

> NOTE
>
> The saved target file contains only the device's general file: user project package information file (including device type, firmware version, whether to initialize at startup).



Procedure

1. Choose "Compile -> Save target file as" from the menu bar to access the "Save target file as" window.

   - PLC Type: Displays the current PLC type.
   - Firmware Version: Displays the current device's firmware version.
   - Retained Variables: Allows selecting whether to clear retentive variables during the download. The option "Retain current values of retained variables during download" is checked by default.
   - Include Project Source Code: Allows selecting whether to include the project source code in the package. This option is not checked by default. When checked, the project source code will be included in the package.
   - Compilation Progress: The interface displays the compilation progress by default. The packaging progress is displayed after the compilation is complete and the save path is selected.

2. Click "Package". A full compilation is performed by default. After successful compilation, a window for selecting the save path appears, allowing you to select a path to save the file. The save format is .fauserprg.

3. Click "Open" and follow the prompts to proceed.

> **CAUTION**
>
> Packaging is not supported in simulation mode or online mode.

14.1.2.2 Upgrading a User Program via SD Card/USB Flash Disk

EVO400, EVO500, and EVO800 series PLCs support user program upgrade through SD card, while EVO700 and EVO700C series PLCs support user program upgrade through USB flash disk.

Prerequisites

- A SD card or USB flash disk with a capacity of not more than 32 G and using the FAT32 file system is ready.
- A "PLCprogram" directory is created in the root directory of the SD card or USB flash disk, and the packaged user program is copied to this directory. For the steps to package the user program, see "14.1.2.1 Saving a PLC User Program As".

Procedure

The steps for upgrading user programs through SD card and USB flash disk are similar. The following describes the steps for upgrading user programs through SD card:

1. Disconnect both 5 V and 24 V power supplies from the PLC.
2. Insert the SD card containing the project file into the GE20-TF storage expansion card, and then insert the expansion card into the PLC.
3. Set the PLC's DIP switch to Stop state.

CAUTION

- If the controller is not in Stop state, the user program cannot be upgraded after re-power in step 4, resulting in a failed upgrade.
- After a failed upgrade, the original project in the controller will not be loaded. To restore and load it, power off the controller, remove the SD card, and then power on again.

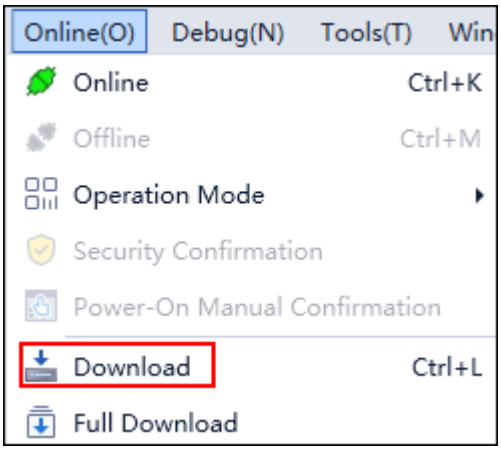
4. Power on the PLC to automatically upgrade the user program.
   The device model, firmware version, and device permissions are verified during the upgrade. Any inconsistency in these items will cause the upgrade to fail.

   The indicator states during the upgrade are as follows:

Item	Indicator State
Upgrade process	RUN: flashing quickly (4Hz)
Upgrade success	RUN: off
Upgrade failure	ERR: flashing slowly
Program running	RUN: steady on

5. Set the DIP switch to Run state, load and run the user program, and then remove the SD card.

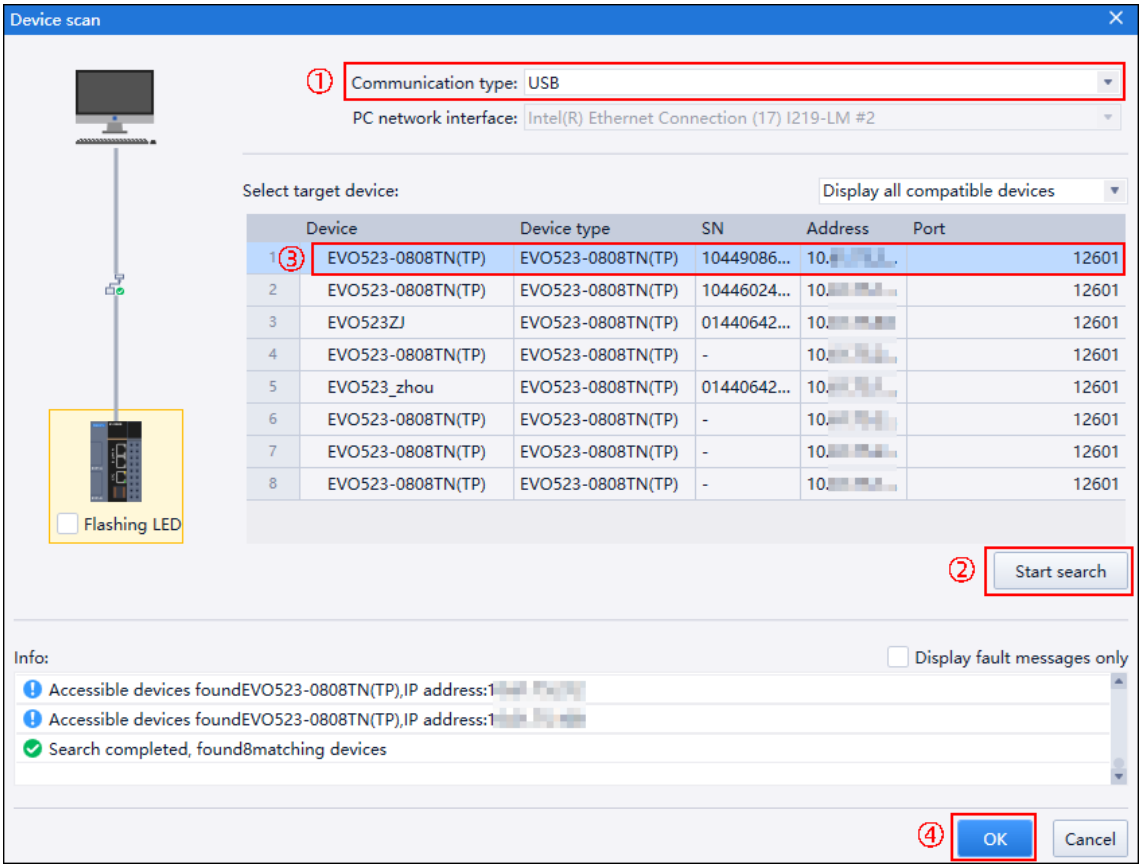
NOTE



To upgrade the user program on the EVO760 series PLC using USB flash disk, insert the USB flash disk into the PLC's USB port, and then follow the steps described above.

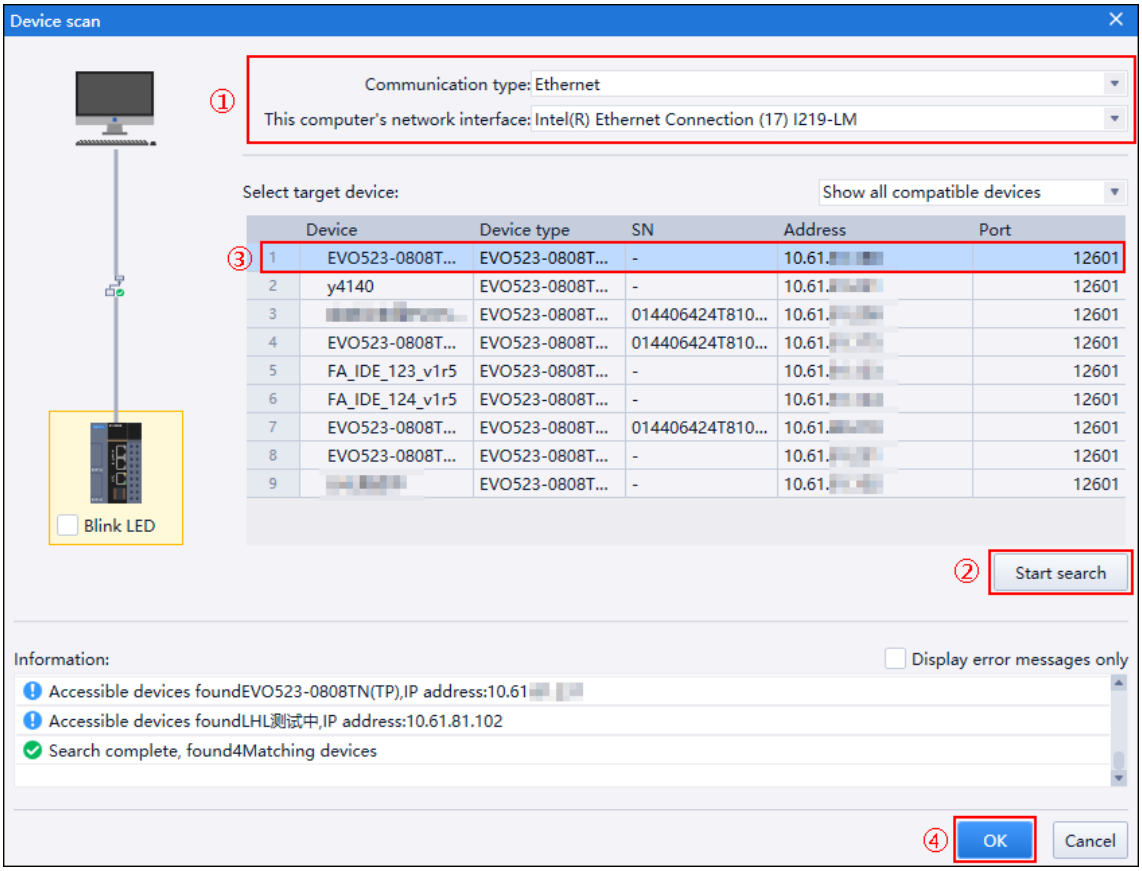
14.1.2.3 Upgrading a User Program via Type-C/Ethernet

Only EVO400/EVO500 series PLCs support user program upgrade through Type-C and Ethernet.



Procedure

1. Open a compiled project using the iFA Evolution.
2. Choose "Online -> Download" from the menu bar.

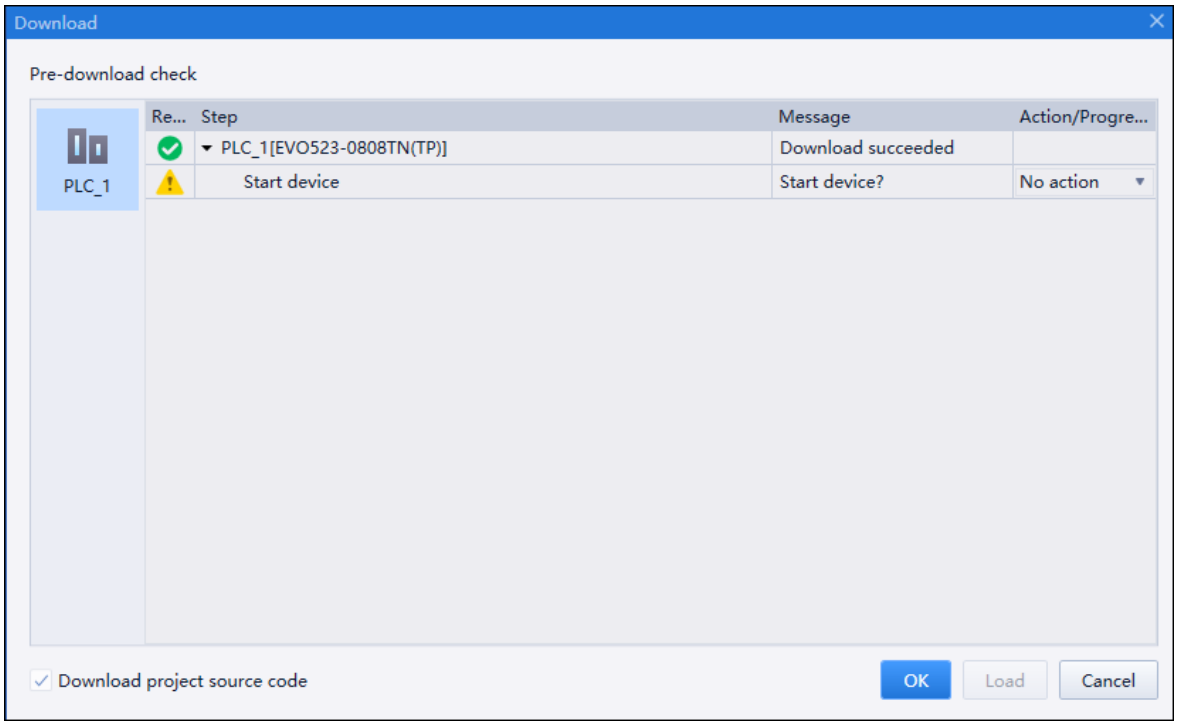


3. Scan for devices.
   - Through Type-C
     a. On the opened "Device scanning" interface, select "USB" for the "Communication type," and then click "Start search."

     b. Select the device to upgrade, and then click "OK".

   - Through Ethernet
     a. On the opened "Device scanning" interface, select "Ethernet" for the "Communication type" and the network interface connected to the device for the "This computer's network interface," and then click "Start search."

     b. Select the device to upgrade, and then click "OK".



4. Download the project.

a. On the opened "Download" interface, click "Load" to download the project.

> **NOTE**
>
> The option "Download project source code" is checked by default, which means that the project source code will be downloaded to the device; if this option is not checked, the project source code will not be downloaded.

b. After successful download, select whether to start the device, and then click "OK."

14.1.2.4 Upgrading a User Program via SFTP

EVO500, EVO700, EVO760C, EVO780C, and APC series PLCs with firmware version V1.6 or later support user program upgrades via SFTP. Two upgrade methods are available; choose the appropriate one based on the actual situation:

- Immediate upgrade: The program takes effect immediately after the transfer is completed.
- Upgrade upon restart: After the program transfer is completed, manually restart the PLC for the changes to take effect.

Prerequisites

- The SFTP server function has been enabled. For specific operations, see 10.6.14.6 SFTP Server Configuration.
- The user program has been packaged. For specific operations, see 14.1.2.1 Saving a PLC User Program As.

Procedure

- Immediate upgrade

1. Upload the packaged user program to the /ssh_update directory on the PLC via SFTP.
2. After the file transfer is completed, the upgrade process is automatically triggered. The system updates the program and automatically restarts the PLC.

- Upgrade upon restart

1. Upload the packaged user program to the /ssh_update/manual_update directory on the PLC via SFTP.
2. After the file transfer is completed, manually restart the PLC. Upon power-up, the system automatically detects and completes the program upgrade.

Precautions

- The immediate upgrade automatically restarts the controller.

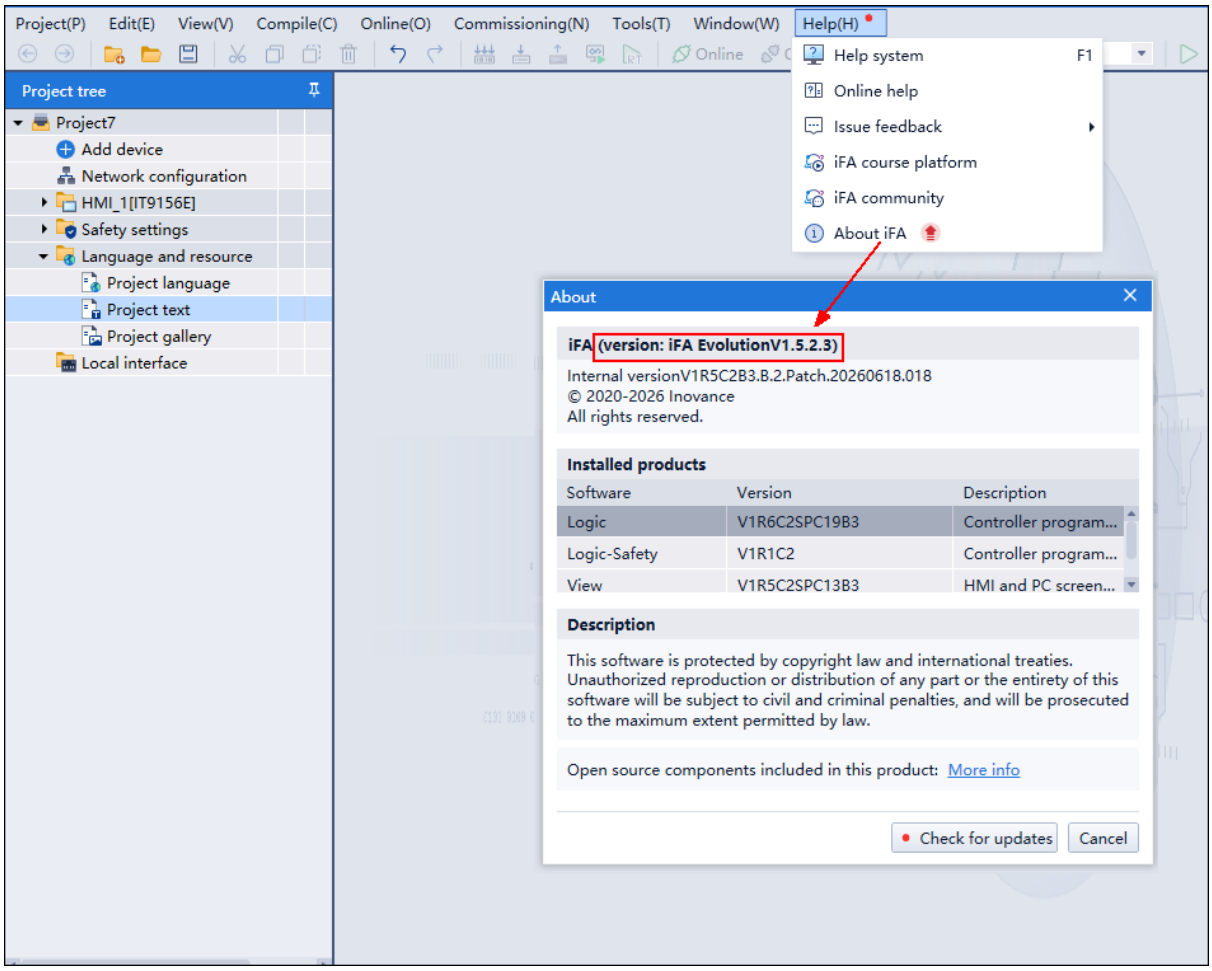
- For upgrade upon restart, it is recommended to wait one minute after the file transfer before restarting, to ensure the files are fully written to disk and to avoid upgrade failure.
- Regardless of the upgrade method, wait approximately one minute after the controller restarts to ensure system stability before attempting to reconnect.
- User files are not retained after either a successful or failed upgrade.
- The device status after the upgrade is determined by the DIP switch status.
- The indicator status during the upgrade is consistent with upgrading user programs via an SD card. For details, see 14.1.2.2 Upgrading a User Program via SD Card/USB Flash Disk.

14.2 HMI Firmware and Project Upgrade

14.2.1 Upgrading HMI Firmware

The firmware version of the HMI device is closely related to the version of the iFA software. The HMI firmware may need to be upgraded synchronously during software upgrade to ensure compatibility and functional integrity. The firmware upgrade requires a dedicated firmware package, so it is essential to obtain and use the correct version.

Requirements



Back up the project data before upgrading the touchscreen firmware.

Obtaining the firmware package

- Firmware package format
  The firmware package format is changed as follows from iFA Evolution V1.4.4.5:
  - Before V1.4.4.5: The firmware packages are provided as .zip files.
  - V1.4.4.5 and later: The firmware packages are provided as .upgrade files.
- How to obtain

1. Check the iFA version number

Select "Help > About iFA".

2. Download the firmware package

   Access the website https://forum.inovance.com/forum?id=562, and then download the firmware package based on the iFA version number.

Installing the firmware package

1. Enable the HMI firmware upgrade command.

   Select "Online > Firmware update > PLC and HMI" from the menu bar.

2. Scan for devices.

   On the opened "Device scanning" interface, specify the communication type and then complete the scan.

   - Ethernet: All devices on the network segment can be identified.
   - USB: Only one device can be identified at a time. Even if multiple devices are connected simultaneously, the system will randomly select one for scanning.

3. Select the target device, click "OK", and then the system automatically opens the "Firmware Update" interface.

4. Configure the upgrade object and method

   a. Load the downloaded firmware package

b. Set the upgrade method

- Restart device after update: The system automatically restarts the device after successful update. This process does not affect the user project data.
- Clear user program and configuration during update: The user projects and data on the device are cleared during the update, and the control panel configuration is restored to factory settings.

5. Start updating

6. Check the version information

   Repeat Steps 1 to 3 to obtain the device information and check whether the firmware version is updated.

CAUTION

- Downgrading the firmware will erase user projects and settings on the device. Ensure all important information is backed up before the operation to prevent data loss.
- Ensure that the HMI device remains powered on during the firmware update and device restart.

Recovery after firmware update failure

In case of unexpected power failure or disconnected interface (USB/network port) during firmware update, the touchscreen may fail to start.

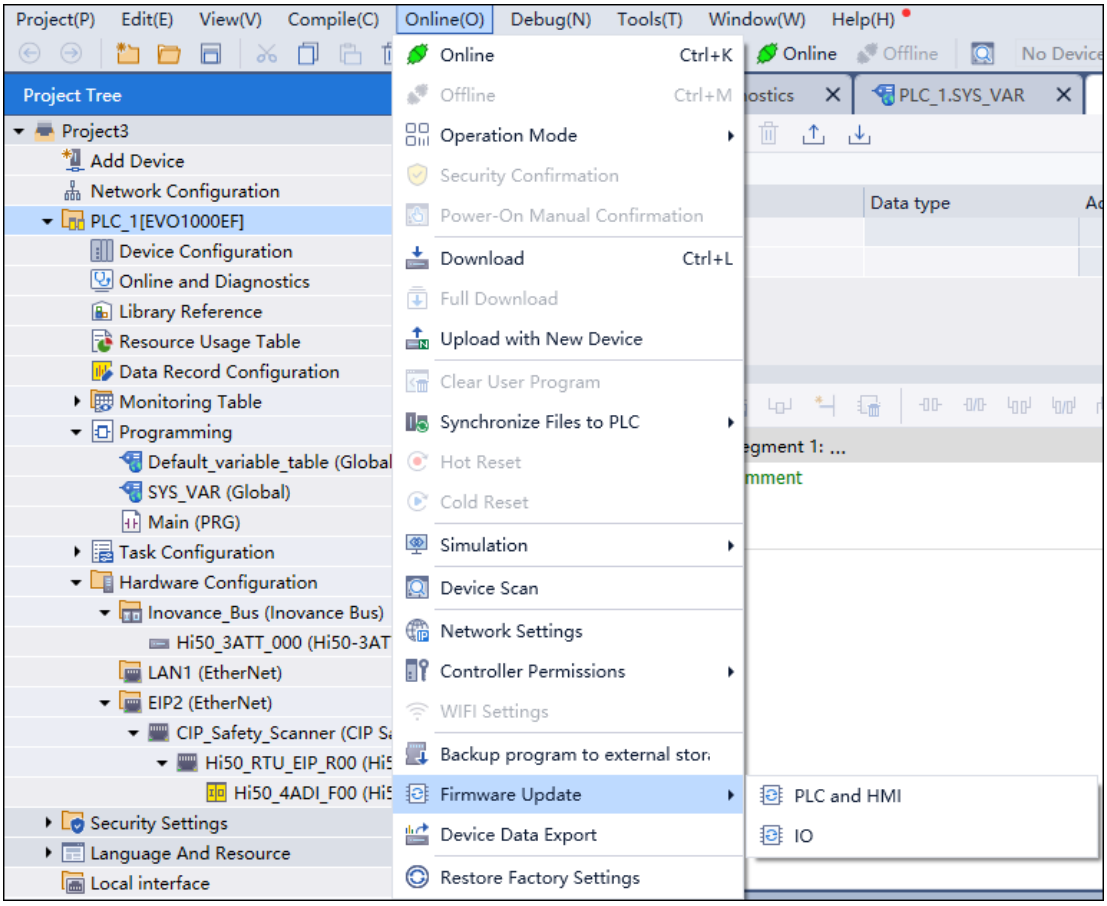
Follow these steps to recover the firmware update:

1. Press the RST button on the touchscreen to restore the touchscreen to factory settings.
2. After the HMI starts up normally, repeat the firmware upgrade process.

Risk warning: Restoring to factory settings will erase all projects and data on the touchscreen. To prevent data loss, back up data before the firmware upgrade.

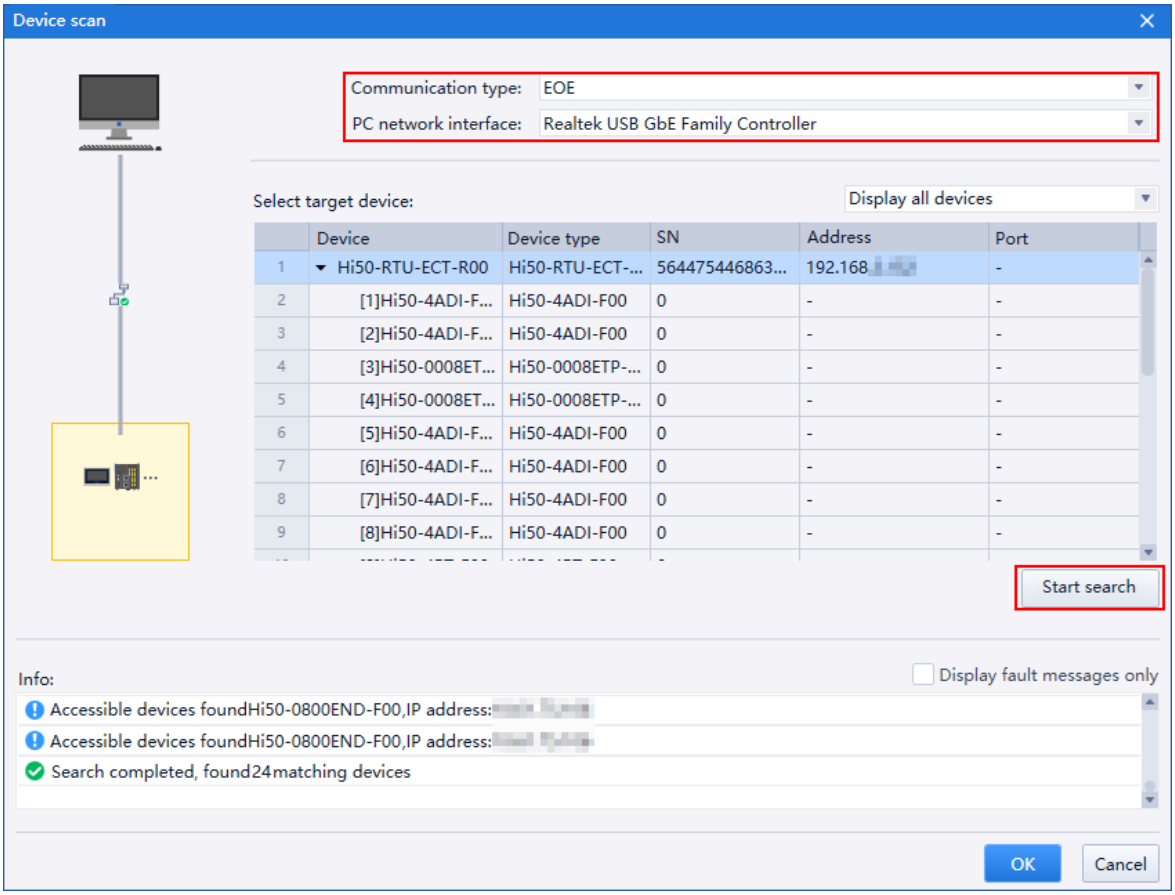
14.3 I/O Firmware Upgrade

14.3.1 Upgrading Hi50 Series Safety I/O Module Firmware



The combined application of the iFA Evolution software and the EVO1000EF series PLC system introduces the firmware upgrade procedure which is the same for the Hi50-RTU-ECT-R00 and Hi50-RTU-EIP-R00 modules. This section takes Hi50-RTU-ECT-R00 as an example.

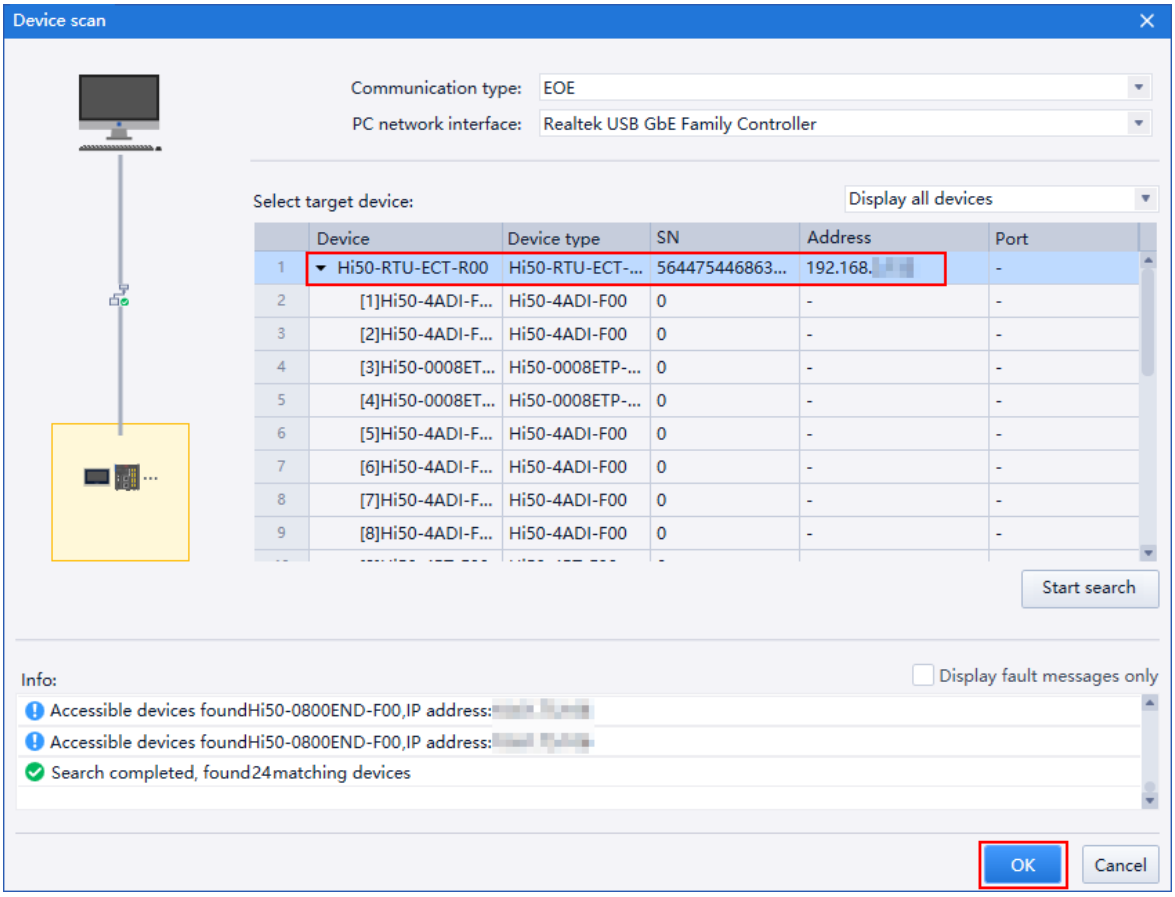
Prerequisites



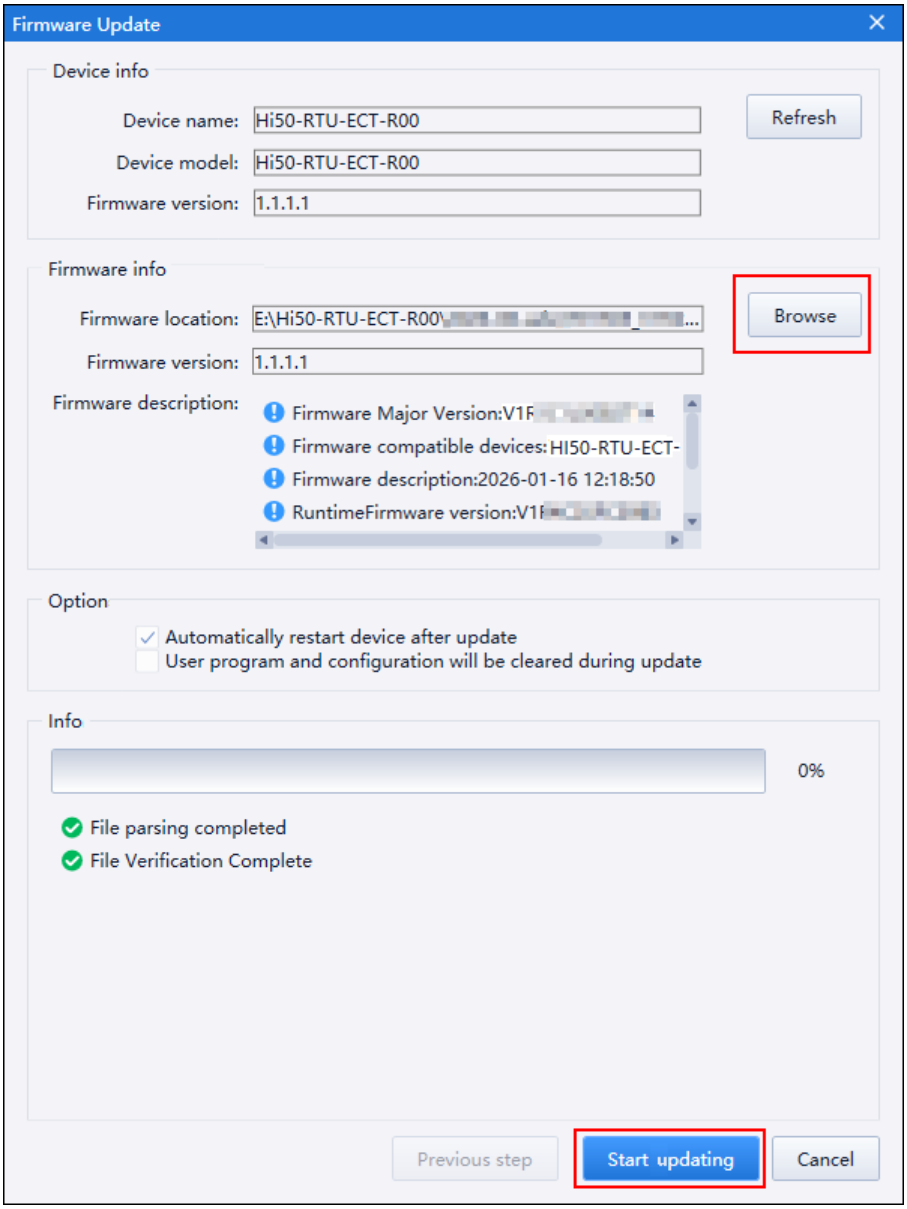
- The hardware installation and wiring in the configuration example is complete.
- All the devices in the configuration example are powered on and started.
- The PC installed with iFA programming software (V1R4C2B3.R.4 or later) is connected via network cable to the EIP port of the EVO1000EF.
- The IN port of the Hi50-RTU-ECT-R00 module is connected to the PC via a network cable.

Procedure

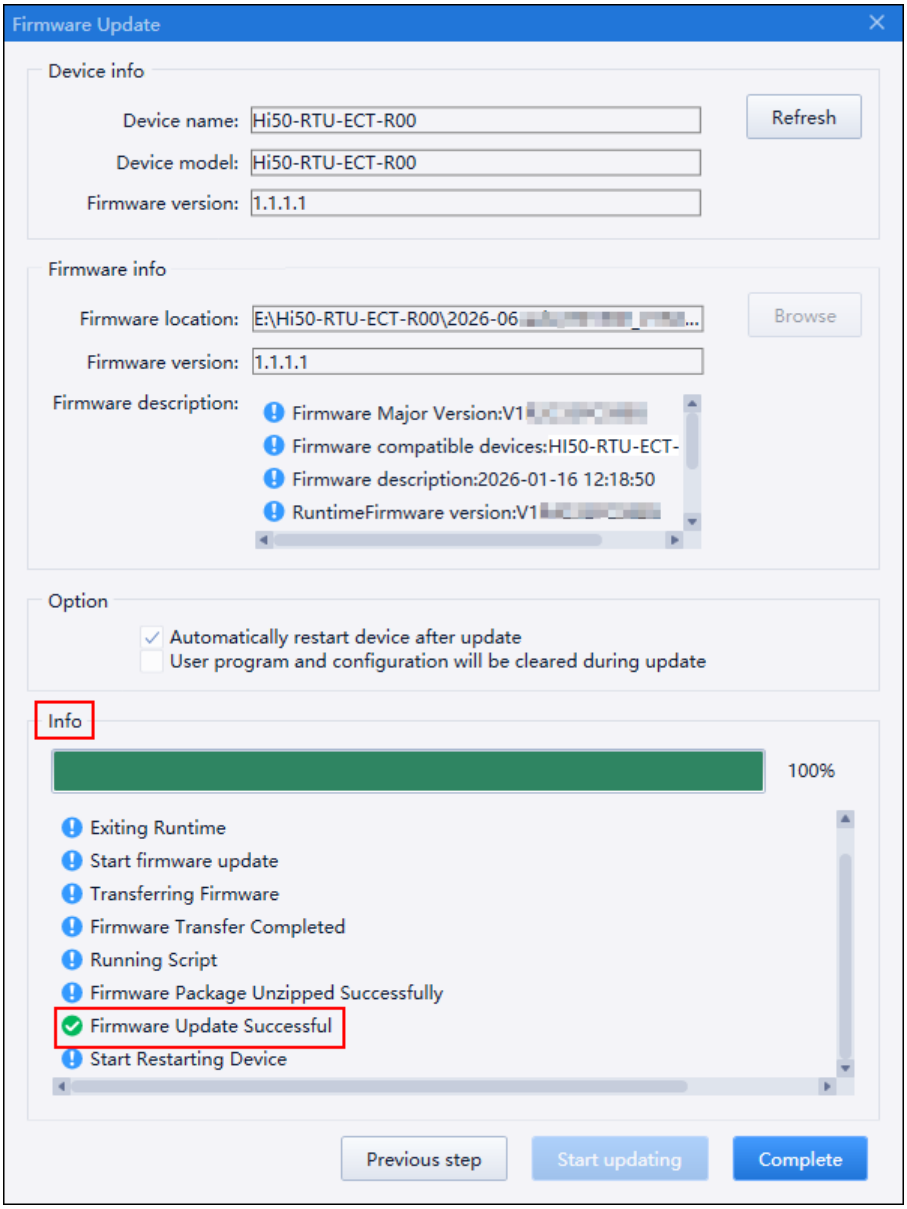
1. Choose "Online > Firmware Update > IO".



2. Select "Communication type" and "This computer's network interface", and then click "Start search".



> **NOTE**
>
> For the Hi50-RTU-EIP-R00 module, set the "Communication type" to "Ethernet".



3. Select the module to be upgraded, and then click "OK."

4. Click the "Browse" button after the "Firmware location", select the firmware path for the module, and then click "Start updating".

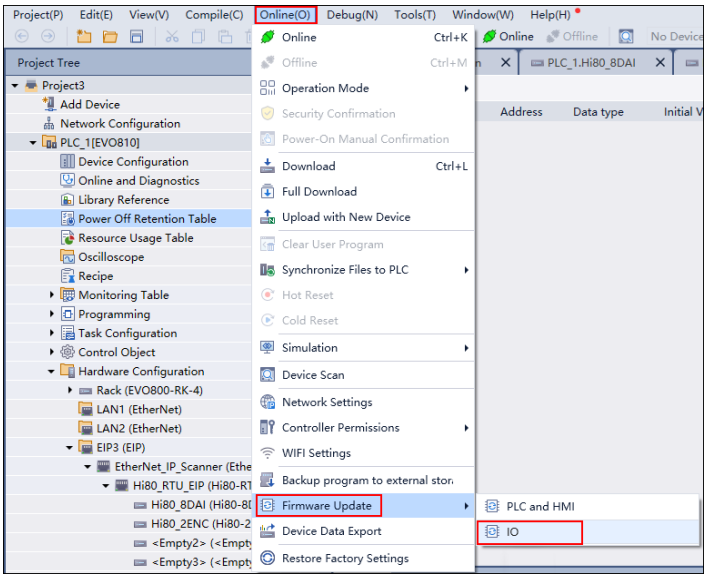
5. When the firmware upgrade progress under "Information" shows 100% and the message "Firmware update successful" appears, click "Complete."

6. Power on the entire configuration system.

14.3.2 Upgrading Hi80 Series I/O Firmware

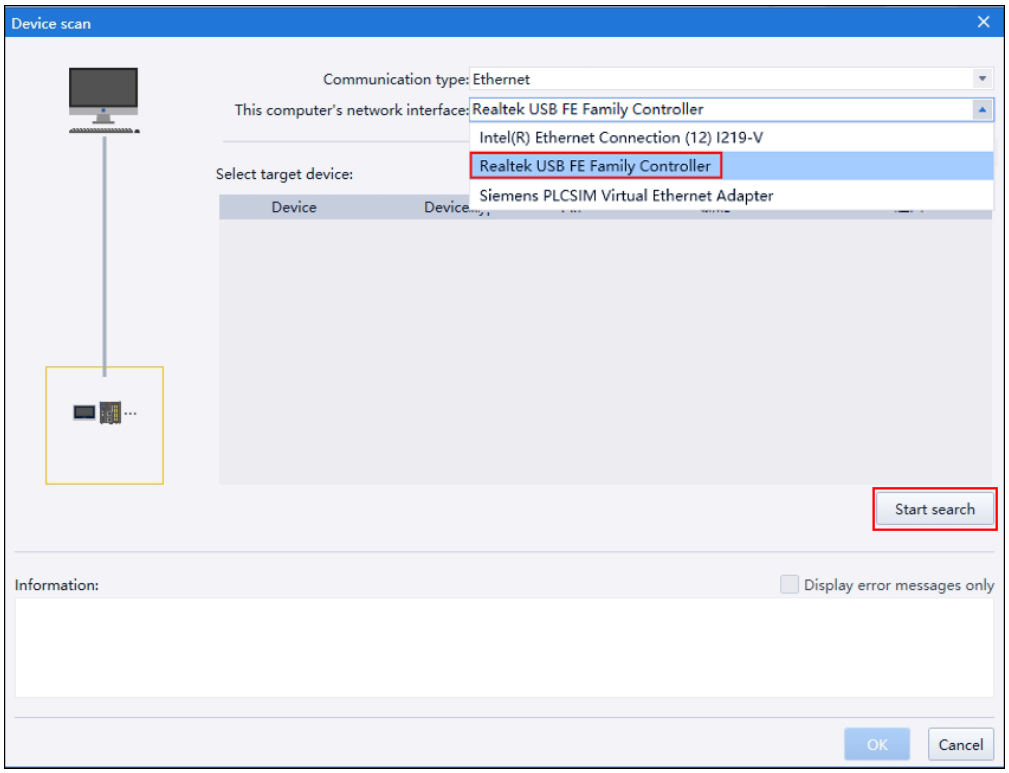
Introduction

The EIP communication interface module and the I/O module share the same firmware upgrade method. This section describes the firmware upgrade of the EIP communication interface module.



Prerequisites

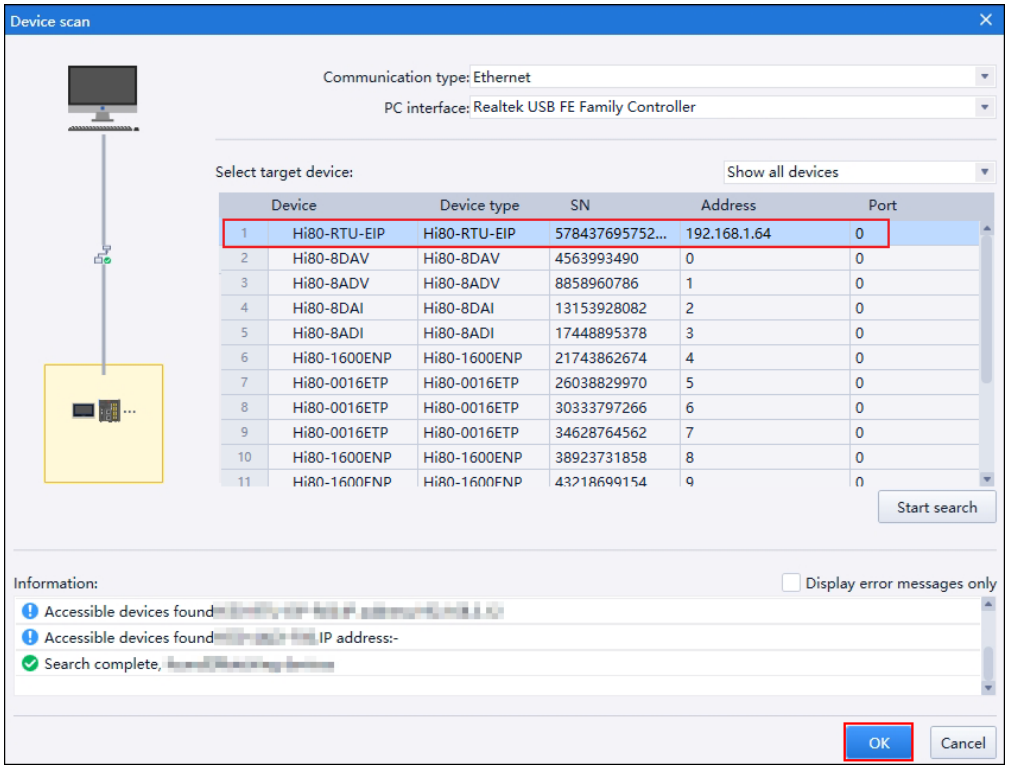
- The firmware to be upgraded (Hi80-RTU-EIP_VxxRxxBxxTxx.upgrade or Hi80-RTU-EIP_VxxRxxBxxTxx.bin) has been obtained from the technical service personnel of Inovance.
- The PC installed with the iFA Evolution programming software is connected via network cable to the EIP communication interface module.
- The device is powered on and started.



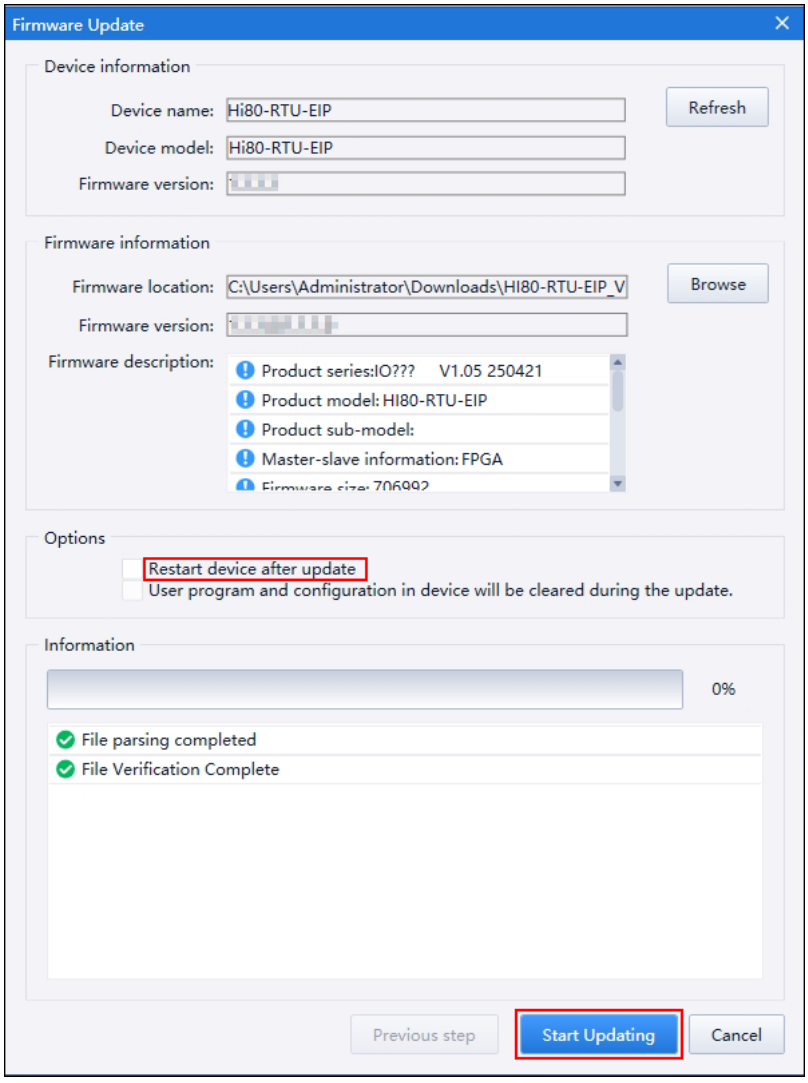
Procedure

1. Open the iFA Evolution programming software on the PC desktop and open the project.

2. Click "Online" and then choose "Firmware Update > IO".



3. Select "This computer's network interface," and then click "Start search".

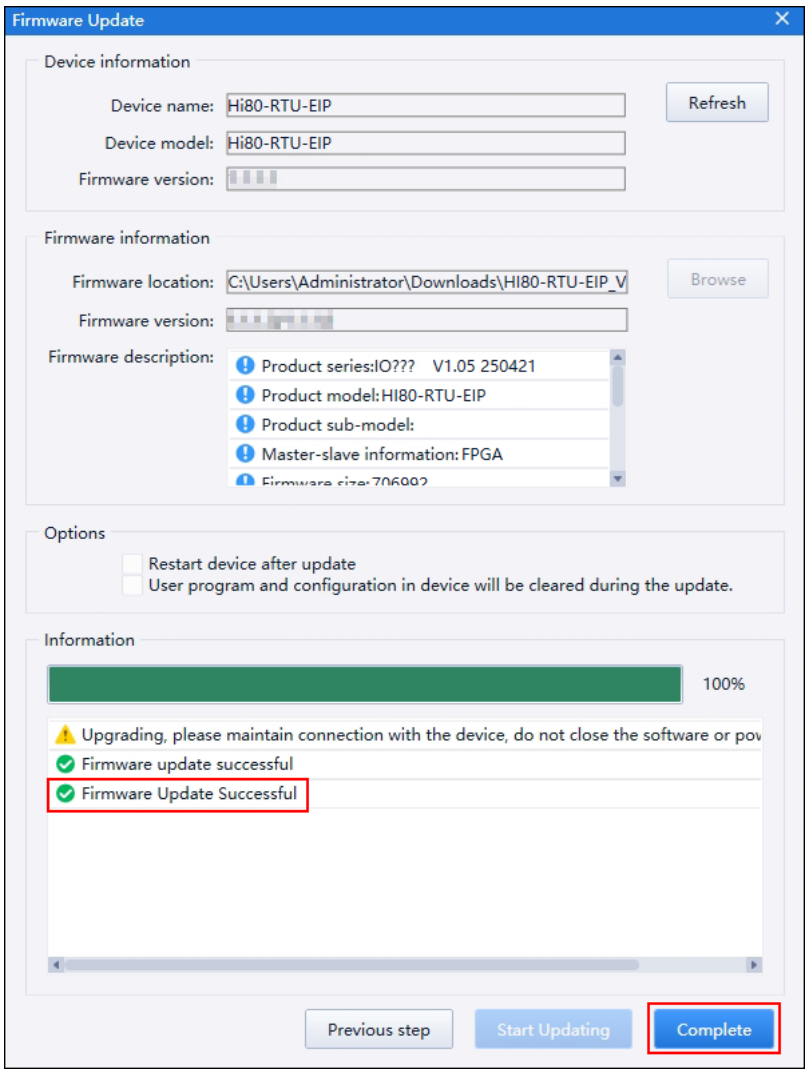


CAUTION

The network interface must be configured in the same network segment as the Hi80-RTU-EIP communication interface module.

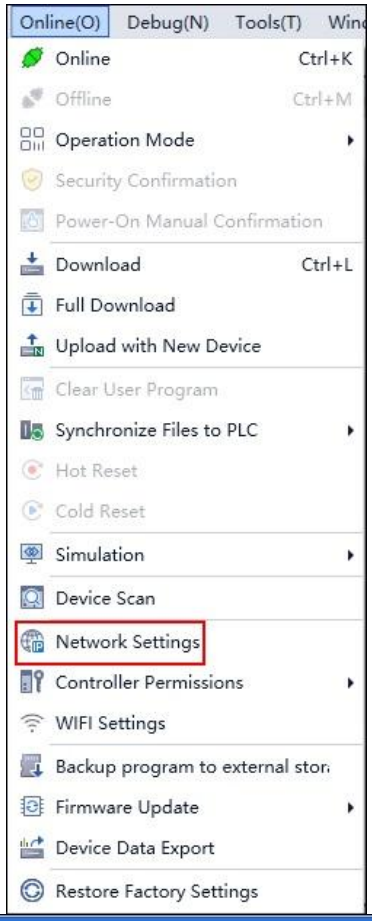
4. Select the target device, and then click "OK."

5. Select the upgrade file, and then click "Start updating". If you want the upgrade to take effect immediately after completion, check the option "Restart device after update," as shown in the figure below.

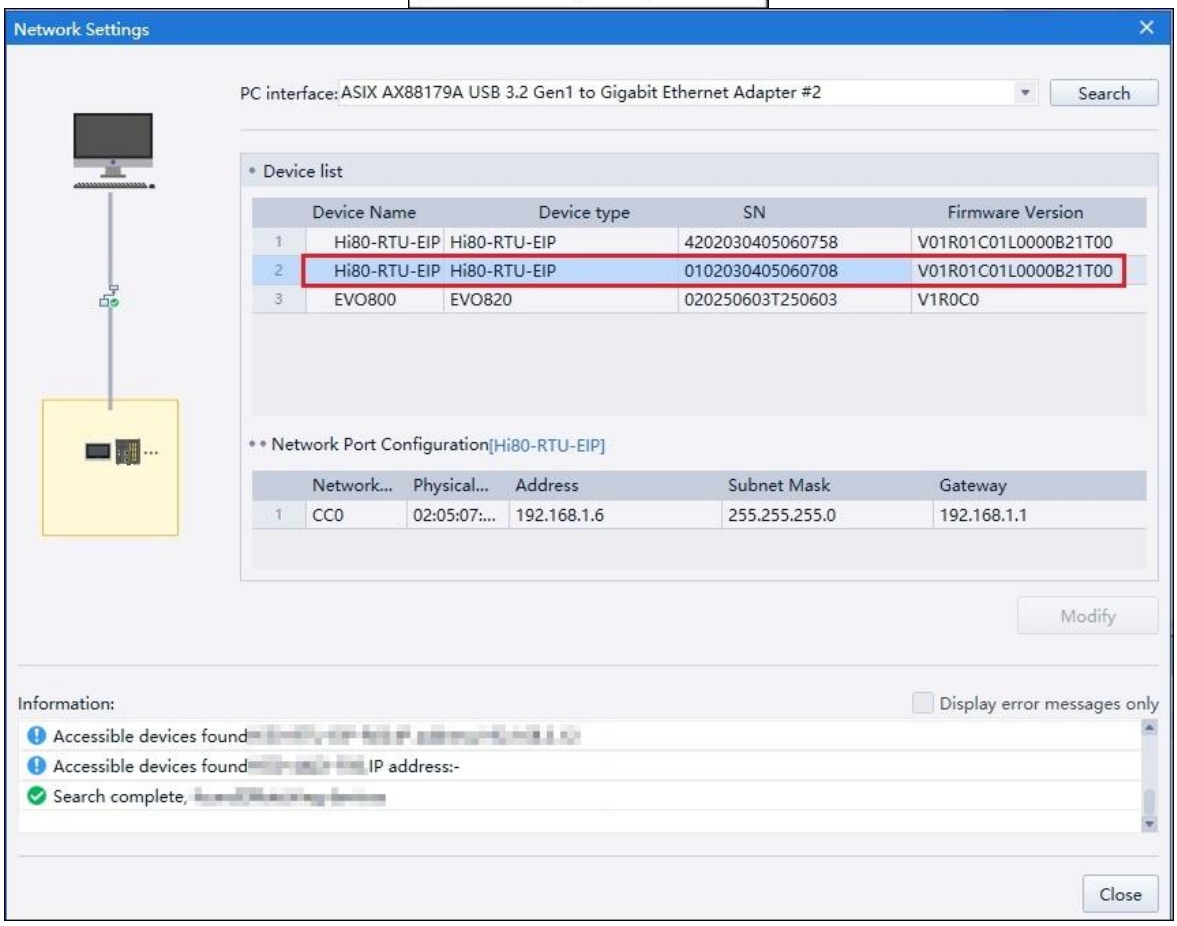


NOTE

- Firmware version: V1.1.25.0 and later
- If the option "Restart device after update" is not checked, the upgrade will take effect only after a power cycle on the system side.
- During firmware upgrade, the option "Clear user program and configuration during the update" cannot be checked.

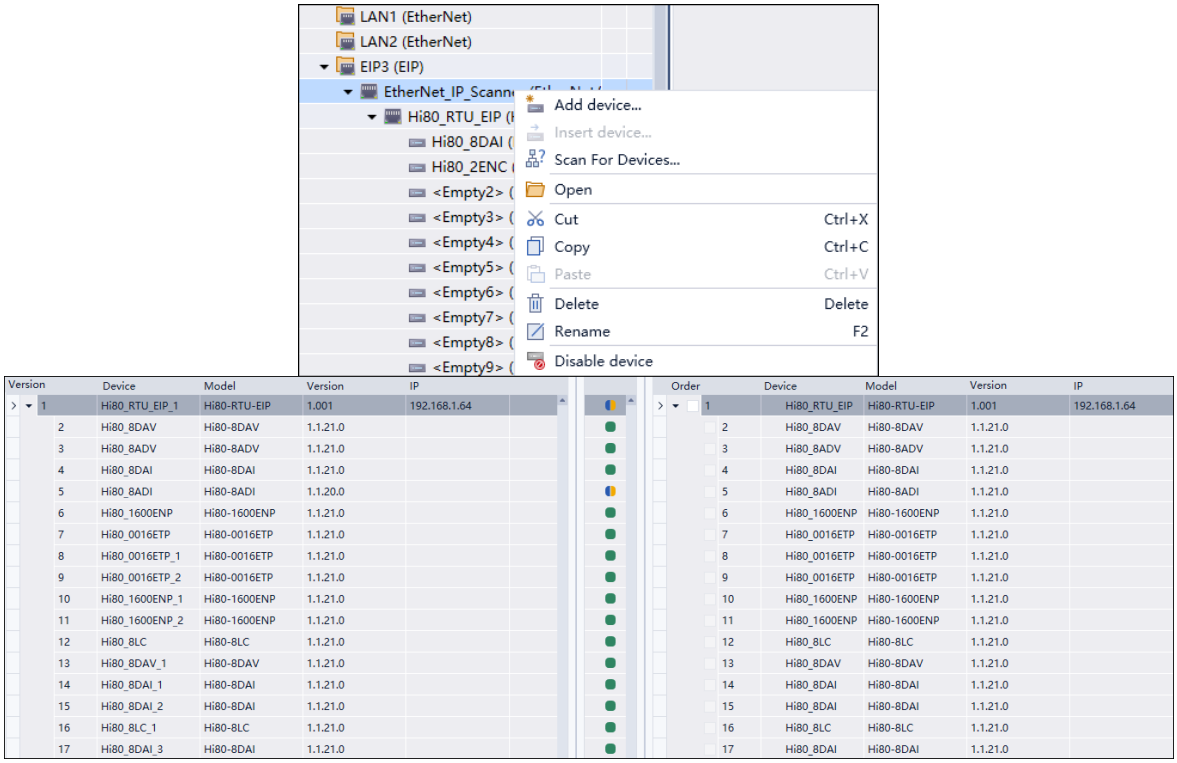


CAUTION



- LED indicator status during EIP communication interface module firmware upgrade: PWR - steady on; NET - flashing; MOD, SF, and A/B - steady off.
- LED indicator status during I/O module firmware upgrade: PWR - steady on; RUN - flashing; ERR - steady off.

6. Click "Complete" after "Firmware update successful" is displayed.



7. After the upgrade, check that the version information matches the expected version.
   - View the communication interface module version.
     Choose "Online (O) > Network setting".

◦ View the I/O module version.

Right-click "EtherNet_IP_Scanner" and select "Scan for devices" to view the version information.

Version	Device	Model	Version	IP
1	Hi80_RTU_EIP_1	Hi80-RTU-EIP	1.001	192.168.1.64
2	Hi80_8DAV	Hi80-8DAV	1.1.21.0	
3	Hi80_8ADV	Hi80-8ADV	1.1.21.0	
4	Hi80_8DAI	Hi80-8DAI	1.1.21.0	
5	Hi80_8ADI	Hi80-8ADI	1.1.20.0	
6	Hi80_1600ENP	Hi80-1600ENP	1.1.21.0	
7	Hi80_0016ETP	Hi80-0016ETP	1.1.21.0	
8	Hi80_0016ETP_1	Hi80-0016ETP	1.1.21.0	
9	Hi80_0016ETP_2	Hi80-0016ETP	1.1.21.0	
10	Hi80_1600ENP_1	Hi80-1600ENP	1.1.21.0	
11	Hi80_1600ENP_2	Hi80-1600ENP	1.1.21.0	
12	Hi80_8LC	Hi80-8LC	1.1.21.0	
13	Hi80_8DAV_1	Hi80-8DAV	1.1.21.0	
14	Hi80_8DAI_1	Hi80-8DAI	1.1.21.0	
15	Hi80_8DAI_2	Hi80-8DAI	1.1.21.0	
16	Hi80_8LC_1	Hi80-8LC	1.1.21.0	
17	Hi80_8DAI_3	Hi80-8DAI	1.1.21.0	

Order	Device	Model	Version	IP
1	Hi80_RTU_EIP	Hi80-RTU-EIP	1.001	192.168.1.64
2	Hi80_8DAV	Hi80-8DAV	1.1.21.0	
3	Hi80_8ADV	Hi80-8ADV	1.1.21.0	
4	Hi80_8DAI	Hi80-8DAI	1.1.21.0	
5	Hi80_8ADI	Hi80-8ADI	1.1.21.0	
6	Hi80_1600ENP	Hi80-1600ENP	1.1.21.0	
7	Hi80_0016ETP	Hi80-0016ETP	1.1.21.0	
8	Hi80_0016ETP	Hi80-0016ETP	1.1.21.0	
9	Hi80_0016ETP	Hi80-0016ETP	1.1.21.0	
10	Hi80_1600ENP	Hi80-1600ENP	1.1.21.0	
11	Hi80_1600ENP	Hi80-1600ENP	1.1.21.0	
12	Hi80_8LC	Hi80-8LC	1.1.21.0	
13	Hi80_8DAV	Hi80-8DAV	1.1.21.0	
14	Hi80_8DAI	Hi80-8DAI	1.1.21.0	
15	Hi80_8DAI	Hi80-8DAI	1.1.21.0	
16	Hi80_8LC	Hi80-8LC	1.1.21.0	
17	Hi80_8DAI	Hi80-8DAI	1.1.21.0	

15 Diagnostics

15.1 Overview

The diagnostics function is primarily used to quickly locate various errors that occur during the operation of PLCs and other devices. By parsing error information and equipment operating status, it helps users identify and implement corresponding solutions.

All PLC devices have built-in diagnostics functions to detect system faults in real time and assist in troubleshooting. This function can automatically identify anomalies that may occur during operation and provide detailed fault-related information.

Diagnostics features

- The programming system supports diagnostics for various communication devices, and can generate fault and other information based on the actual operating status of each device.
- The diagnostic range mainly involves CPU modules and other types of device modules.
- Fault causes and corresponding solutions are output in text format.
- Supports archiving and recording of alarm information.

15.2 Quick Guide

15.2.1 Diagnostics via Segment Code Screen

The segment code screen allows quick and direct reading of fault codes and other information. Only PLC devices with a segment code screen support this diagnostic method.

Prerequisites

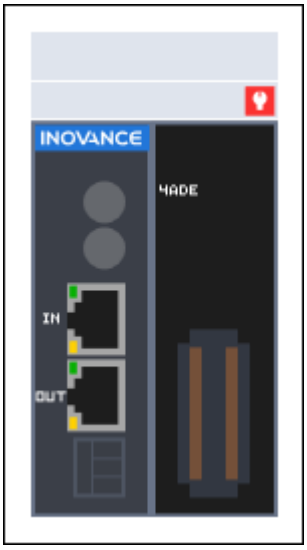
- A project has been created.
- The project has been downloaded to the PLC device.

Procedure

Take the EVO800 series as an example, follow the steps below to determine the diagnostic information using the segment code screen:

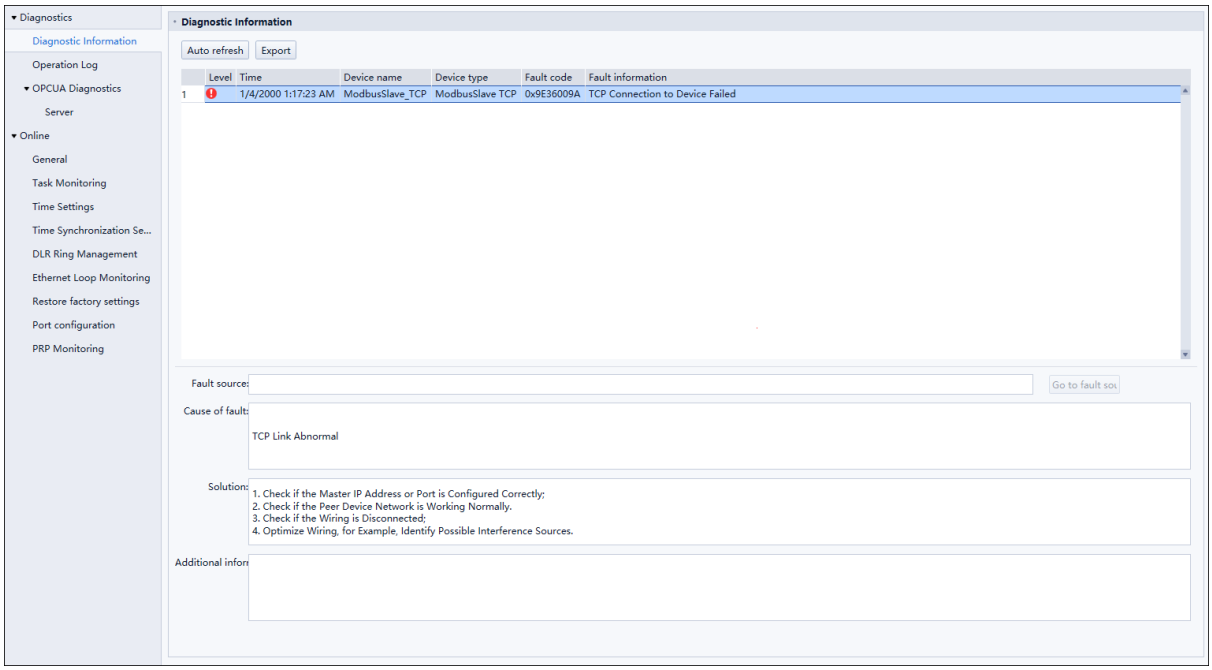
1. Observe the status and fault code values displayed on the segment code screen.
2. Look up the corresponding fault code solutions in the software or documentation.

15.2.2 Diagnostics via iFA Software



Detailed diagnostic information can be quickly accessed via iFA Evolution.

Prerequisites



- A project has been created.
- The project has been downloaded to the PLC device.
- A fault has occurred.
- The programming device can be connected to the PLC device via the interface.
- The device has been switched to online.

Procedure

1. Double-click "Device configuration" in the left project tree and go to the "Network configuration" tab.
2. On the "Device configuration" page, view the device fault info.

3. In the "Diagnostic info" section, all diagnostic events are displayed in the order in which the events occurred.

15.3 Display of System Diagnostics

15.3.1 Viewing Diagnostic Information via Hardware Interface

15.3.1.1 Device Indicators

LED indicators on PLC devices and their expansion modules serve as critical diagnostic tools. They convey device operating status, fault information, and external communication conditions through different colors and flashing frequencies.

The meaning, combination, and fault resolution measures of LED indicators vary across different device models. The following describes the indicator meanings for some common models. For details on other devices or modules, see their respective device guides.

Indicators of the EVO500 series

Name	Label	Status	Note
Power supply indicator	Power	Steady green	Power supply normal
		Steady off	Power supply fault
Operation indicator	RUN	Steady green	The module operation is normal.
		Flashing	Firmware or SD card program upgrade
		Steady off	The module operation is faulty.
Fault indicator	ERR	Steady red	Module fault
		Steady off	The module is in normal state.
Network port indicator 1A	LAN1A	Steady green	Connection established successfully
		Flashing	Communicating
		Steady off	Connection not established

Name	Label	Status	Note
Network port indicator 1B	LAN1B	Steady green	Connection established successfully
		Flashing	Communicating
		Steady off	Connection not established

Indicators of the EVO800 series redundant module

Name	Label	Status	Note
Power supply indicator	Power	Steady green	Module power supply normal
		Steady off	The module power supply is faulty.
Operation indicator	RUN	Steady green	The module operation is normal.
		Steady off	The module operation is faulty.
Fault indicator	ERR	Steady red	Module fault
		Steady off	The module is in normal state.
Redundancy status indicator	OK	Steady green	Rack redundancy status normal
		Steady off	Rack redundancy status abnormal
Fiber 1 indicator	SFP1	Steady yellow	SFP1 connection normal
		Steady off	SFP1 connection abnormal
Fiber 2 indicator	SFP2	Steady yellow	SFP2 connection normal
		Steady off	SFP2 connection abnormal
Rack A indicator	A	Steady green	The rack setting switch is set to A, indicating that this is Rack A.
		Steady off	The rack setting switch is set to B.
Rack B indicator	B	Steady green	The rack setting switch is set to B, indicating that this is Rack B.
		Steady off	The rack setting switch is set to A.

15.3.1.2 Segment Code Screen

For devices equipped with a segment code display (such as the EVO700 and EVO800 series), users can directly read the device's operating status and fault codes from the screen. By referencing these fault codes, users can quickly look up the corresponding troubleshooting steps to efficiently identify and resolve issues.

The content displayed, icon meanings, and troubleshooting steps associated with fault codes on the segment code display vary by device model. See the specific device guide for accurate information. This section uses the EVO800 series as an example to illustrate the segment code display. For details on icon meanings and fault codes, see the device guide.

Figure 15-3-1-2-1 EVO800 series segment code display

15.3.2 Viewing Diagnostic Information via iFA Software

15.3.2.1 Diagnostic Symbol Description

Diagnostic symbols for devices and modules

When establishing an online connection to a device in the iFA software, users can view the diagnostic status of the device and its downstream devices, as well as the device's operating mode. The following table lists the related symbols and their meanings.

Operator	Description
	Connection to the module or device is being established.
	The device cannot be accessed via the configured address.
	The password dialog box was terminated without entering the correct password during the online connection to a protected device.
	No fault
	Fault/Error on downstream component
	Fault
	Diagnosis cannot be performed or can only be partially performed.
	The module or device (below the CPU) cannot be accessed from the CPU.
	The functionality of this module or submodule is no longer available (such as input and output data).
	Connection established, but module status is undetermined or unknown (common with third-party IO-Link devices or coupler modules).
	The configured module does not support displaying the diagnostic status.

Operator	Description
	The module or device is disabled.
	Hardware error on downstream component: at least one downstream hardware component is faulty.
	The library has been uninstalled.

Status comparison symbols

Diagnostic symbols can be used in combination with small symbols indicating online/offline comparison results. The following table lists the available comparison symbols and their meanings.

Operator	Description
	Online and offline programs are inconsistent.
	Show differences only
	Differences in subnodes
	Exists online only
	Exists offline only
	Online and offline programs are consistent.
	Show matches and differences
	Show all results
	Show online only

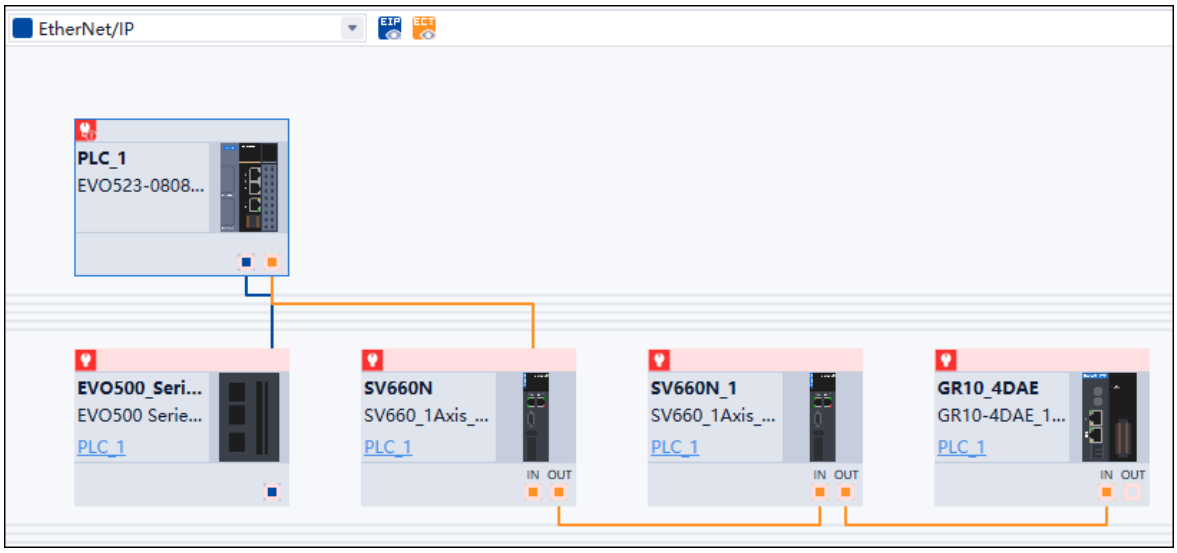
Symbols for device operation mode

To quickly identify the device's current operating status, the table below lists symbols related to device operating modes and their meanings.

Operator	Description
	Initial status
	Run
	Stop

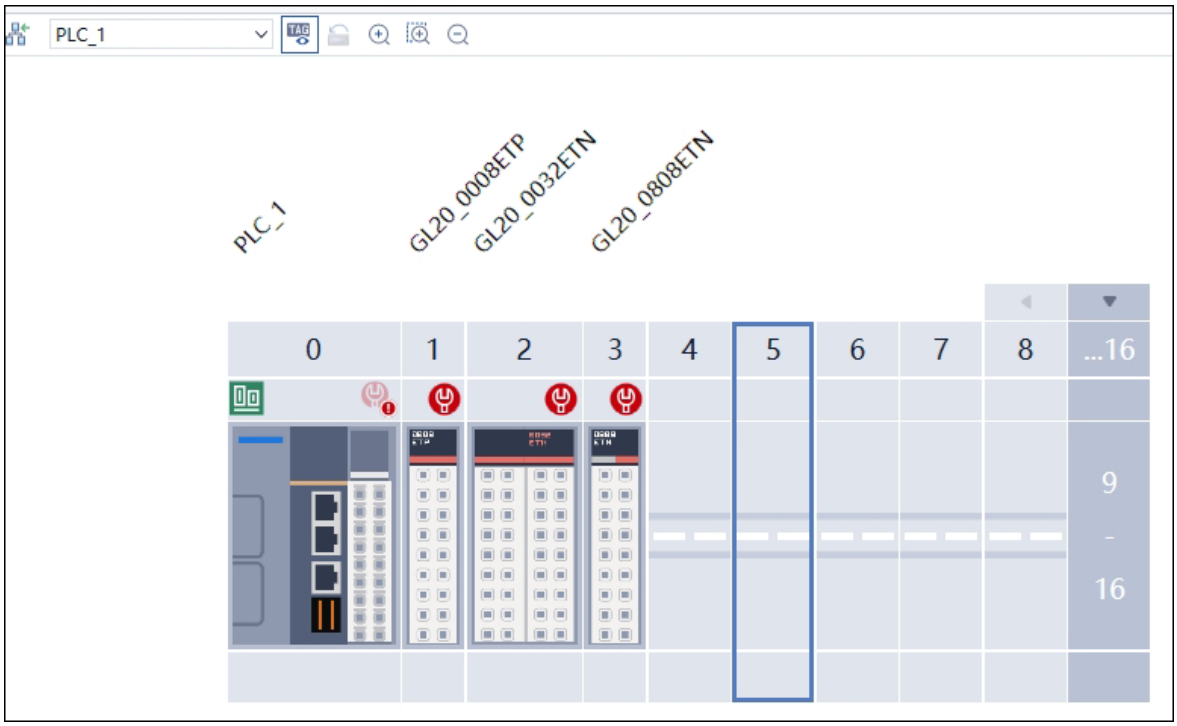
15.3.2.2 Device View and Network View

After the device goes online, current status information of the device can be viewed in either device configuration or network configuration.



Prerequisites

The device has been switched to online.



Procedure

1. Double-click "Network configuration" or "Device configuration" in the project tree to open the corresponding page.

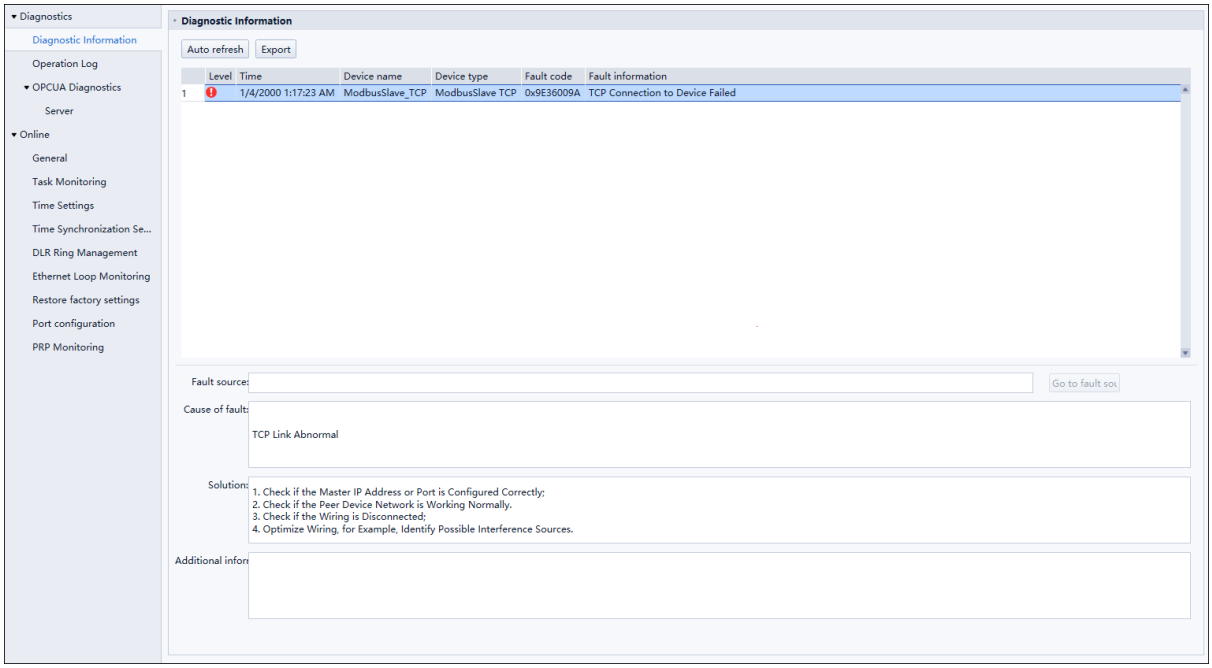
2. View diagnostic information. For the meaning of each symbol, see 15.3.2.1 Diagnostic Symbol Description.
   - Network configuration: Displays diagnostic information for all connected devices. Double-click a device to navigate to its "Device configuration" view for its diagnostic information.

   - Device configuration: Displays diagnostic information only for the current device and its subordinate devices. Users can directly view the device's current status information.

NOTE

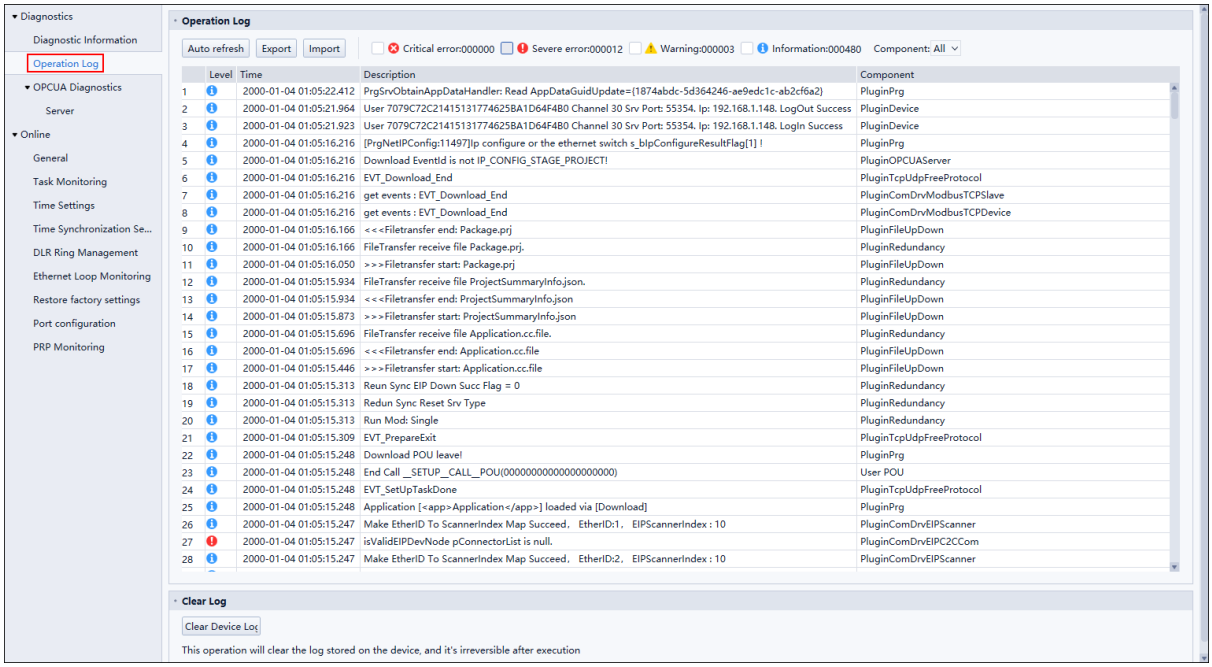
Through the network configuration or device configuration, users can view only the current status information of the device. To view detailed diagnostic information for each device, double-click the diagnostic symbol on the device directly. The system will automatically navigate to the "Online and diagnostics" page for more information.

15.3.2.3 Online and Diagnostics



The "Online and diagnostics" interface provides a centralized view of device operating status, diagnostics information, and logs. It integrates status monitoring, fault localization, and data traceability to help users quickly assess device status, detect and address potential issues, and improve system reliability and maintenance efficiency.

Prerequisites



The device has been switched to online.

Procedure

1. Double-click "Online and diagnostics" in the project tree.
2. On "Diagnostic info" tab, view device diagnostic information, including fault level, time, device name, device type, fault code, and fault information. Select a fault entry to display the fault source, cause, and solution.

3. On "Operation log" tab, view relevant log information for the device during operation. Click "Freeze display" to filter by fault level, component, etc.

NOTE

For details about diagnostic information and operation logs, see 10.11.20 Diagnostic Information and 10.11.21 Operation Log.

15.3.3 Viewing Diagnostic Information via Web Server

After enabling the Web server, users can access module data, user program data, and diagnostic data from the device via an Internet browser on any terminal device (such as a PC or smartphone) without installing iFA.

Restrictions

The Web server supports the following browsers and versions:

Category	Browser and Version
PC	• Google Chrome 63.0 or later • Mozilla Firefox 67.0 or later • Microsoft Edge 18.0 or later • MacOS Safari 12.0 or later
Mobile	• iOS Safari 13.0 or later • Android Chrome 80.0 or later • Android Firefox 68.0 or later

Prerequisites

- The device has been switched to online.
- The Web server configuration is complete. For details, see 10.6.14.7 Web Server Configuration.

Logging in to the Web server

1. Enter "http://device_IP_address" in the browser, enter the username and password (configured during Web server setup), and click "Login".
2. On the "Web diagnostics and monitoring" page, users can view module data, user program data, and diagnostic data from the device.

Diagnostic items

- Main interface: Displays device system status, device information, and basic device details.

Item		Description
Product information		Specific model information of the product, and the current RTC time/time zone of the controller.
System State		Device operating status.
CPU operation		The device flashes based on online PLC. Click the "Device flashing" button once and the device will flash for 5s.
Device information (in EVO800 series redundant mode, the main/backup device status will be displayed; in single mode of EVO700 series and other devices, device information will not be displayed)		Displays the optical fiber status information of the main/backup devices.
Device image		Displays the device image.
Basic information	Project name	Name of the project created by the user.
	Controller version	Controller firmware version.
	Product model	Specific product model, such as EVO800.
	SN code	PLC hardware serial number.
	Main control module (Displayed in EVO800 redundant mode)	For redundant control modules, the model of the main control module is displayed, such as EVO820.
	Redundant synchronization module (Displayed in EVO800 redundant mode)	For redundant control modules, the model of redundant module is displayed, such as EVO800-RM.
	Last compilation time	The last project compilation time in the controller (including incremental compilation).
	Last download time	The last project download time in the controller (including online modifications).

- Online and diagnostics: Displays diagnostic information for the current device, including fault level, time, device name, fault code, and fault message.

NOTE

When the online diagnostic information section shows blank content, manually clear the browser cache and refresh the web server to retrieve the latest online diagnostic information.

Function	Description
Search	Enter a fault code in the search box to filter matching information.
Advanced filter	Select a fault level (Fatal, Critical, Alarm, Info, Unknown) to filter faults by level.
Sort	Sorting can be performed by level, time, or in ascending/descending order.
Freeze display	Click "Freeze display" to stop real-time refreshing of diagnostic information.
Export controller log	Click "Export controller log" to save device diagnostic information locally.
View fault details	Click the fault level to display detailed fault information, including the cause of the fault code and recommended solutions.

- Network communication: Displays network port communication information for the current device. All network information is read-only, not editable, and refreshes every second.

Parameter	Description
Port	The port refers to the actual physical port of the device.
Port IP	The IP address of the port.
Subnet mask	The subnet mask of the port.
Connected device information	The IP address of the connected device. If connected via a personal PC, the PC's IP address is displayed.
Communication type	The protocol type used by the device. Currently supports communication protocols such as EIP/OPCUA/WEB/Modbus TCP.
Connection status	Displays whether the device's connection status is normal or faulty. • For active connection, the slave status matches the project tree status, and the PLC acts as the master (such as EIP master and Modbus TCP/RTU master). • For passive connection, the connection status displays "Connected", and the PLC acts as a slave (such as EIP slave, Modbus TCP/RTU slave, WEB, OPCUA server, or HMI-CLASS3 connection).

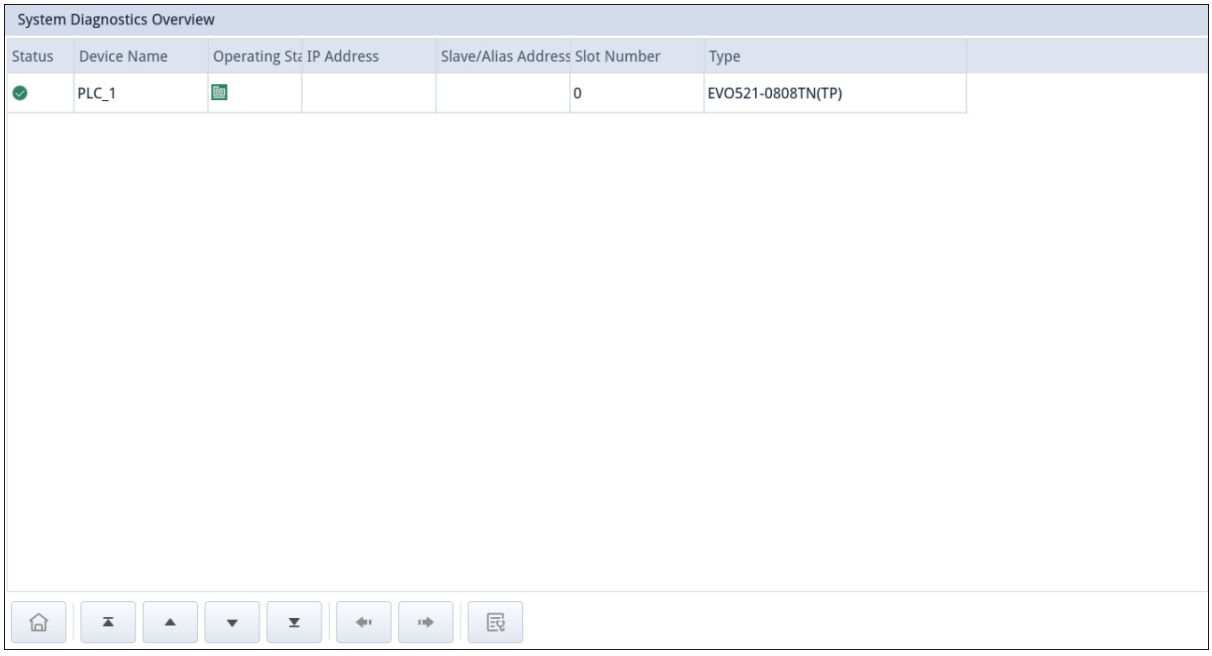
NOTE

For details about the Web server, see 10.11.12 Web Diagnostics and Monitoring.

15.3.4 Viewing Diagnostic Information via HMI Device

The HMI provides a centralized diagnostics display function, allowing real-time monitoring of PLC operating status and viewing of diagnostic data from I/O modules and coupler modules. All HMI diagnostic data is synchronized in real time from the content under the PLC device's "Online and diagnostics" node.

Restrictions

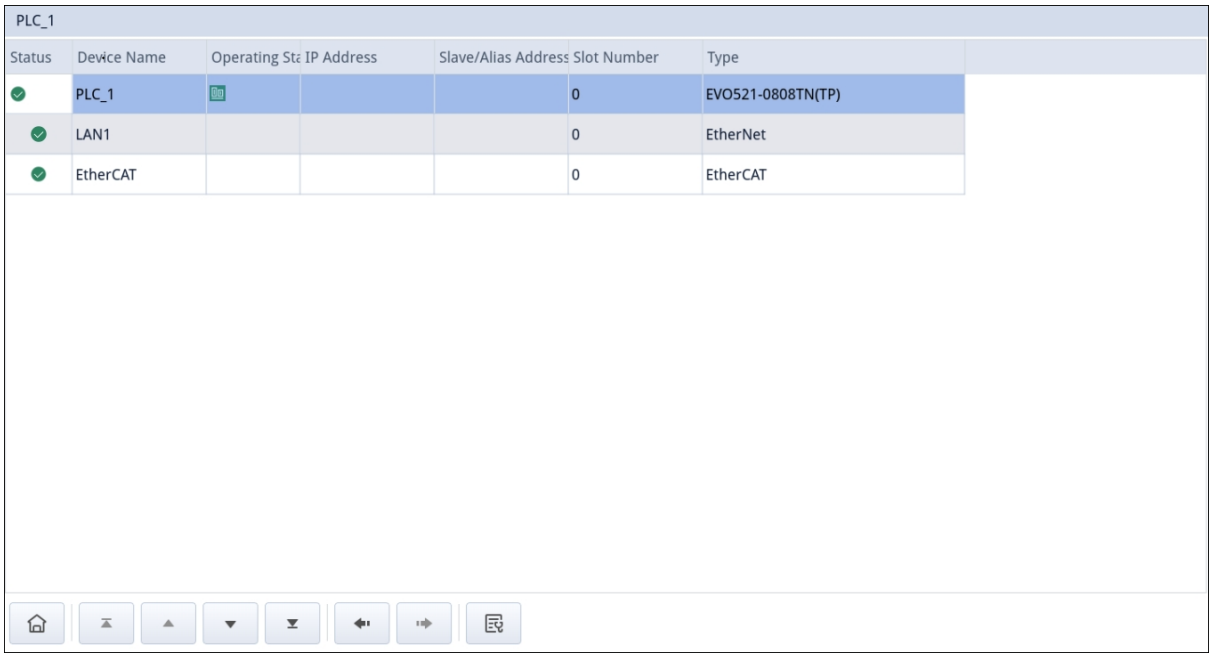


The HMI diagnostic display is implemented through the system diagnostic control. This control must run in a physical hardware environment and is not supported in a simulation environment.

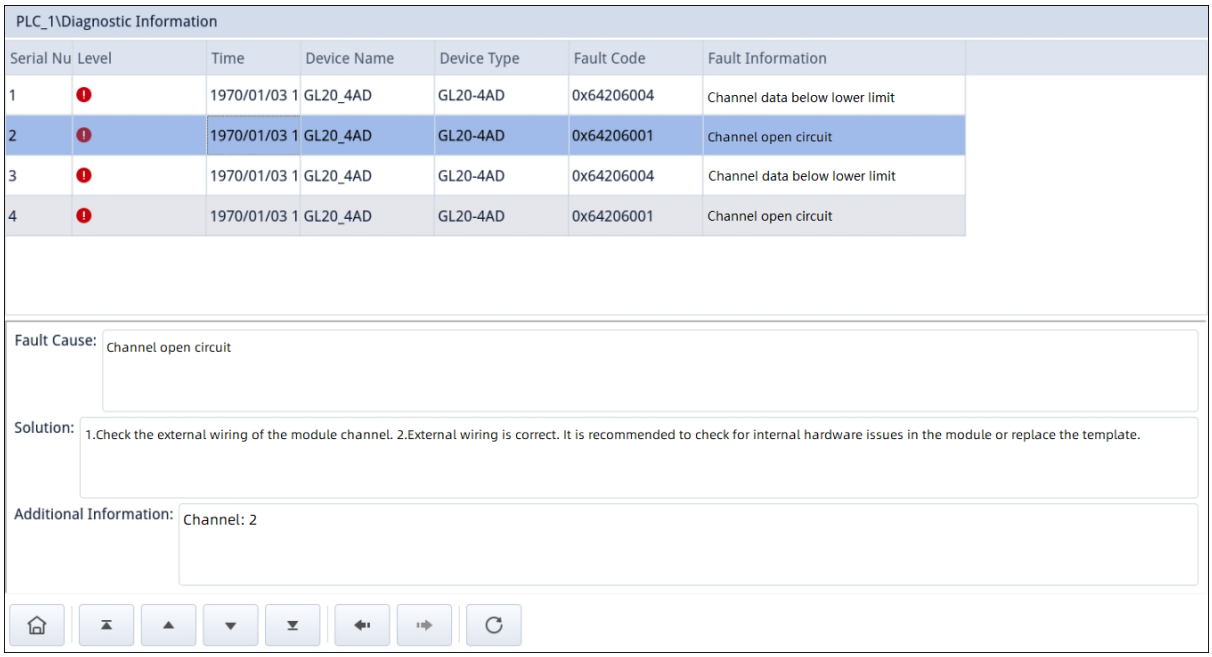
Prerequisites

- The PLC and HMI are in the same project in iFA software.
- "Inovance Technology, Ethernet/IP Tags protocol" is used for communication.
- The HMI's system diagnostic control must run in a physical hardware environment and is not supported in a simulation environment.
- A screen has been added in the HMI.

Procedure



1. In the iFA project tree on the left, double-click the screen.
2. Select the "System diagnostics" object from the "Toolbox" on the right and drag it to the screen area.
3. On the "Property" tab on the right, configure the properties. For details, see System diagnostics control properties.
4. Download the project. For details, see 13.14 Project Download.
5. When the screen containing the "System diagnostics" control is active, the control displays the system diagnostic overview interface by default.



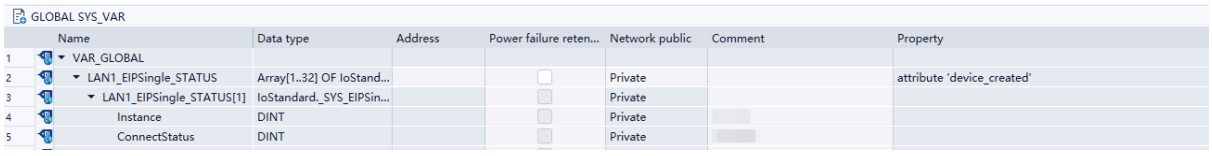
Item	Description
Control header	Displays the hierarchy of the device based on the current level and selected object. The hierarchy text is identical to the path name in the software.

Item	Description
Status	Displays the current device running status or the connection status between PLC and HMI. PLC statuses include: Normal, Fault, and Lower-level device fault.
Device name	Displays the name of the device as shown in the project tree.
Operation status	Displays the four PLC statuses: Operational: Stopped: Paused: Forced: This column is empty for other modules.
IP address	Displays the IP address or port connected between the PLC and the current HMI.
Slave/alias address	Displays the slave number or alias address of EtherCAT slave devices. Empty for non-EtherCAT slaves.
Slot number	Displays the slot number of the current module in the rack.
Type	Displays the device model.

6. Select a PLC device row and click . View the connection status of the PLC device's LAN port and EtherCAT port.

7. Select a PLC device row and click . View the I/O channel diagnostic information of the PLC device.

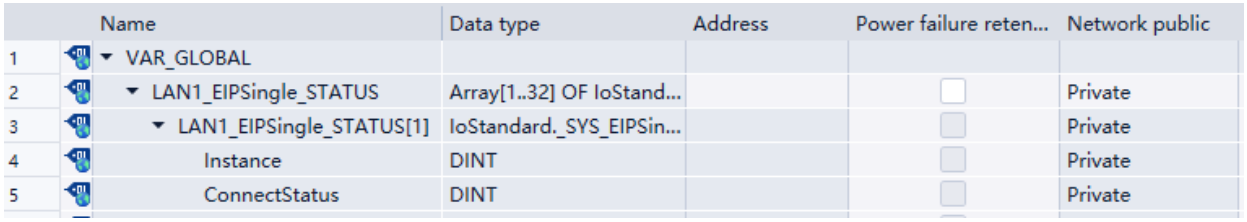
15.4 System Variable Diagnostics



The platform provides a series of predefined system variables for real-time monitoring and diagnostics of system operating status. These system variables cover key aspects such as devices, fieldbuses, and remote communication. Users can quickly locate faults by directly reading these variables without writing complex diagnostic logic.

Prerequisites

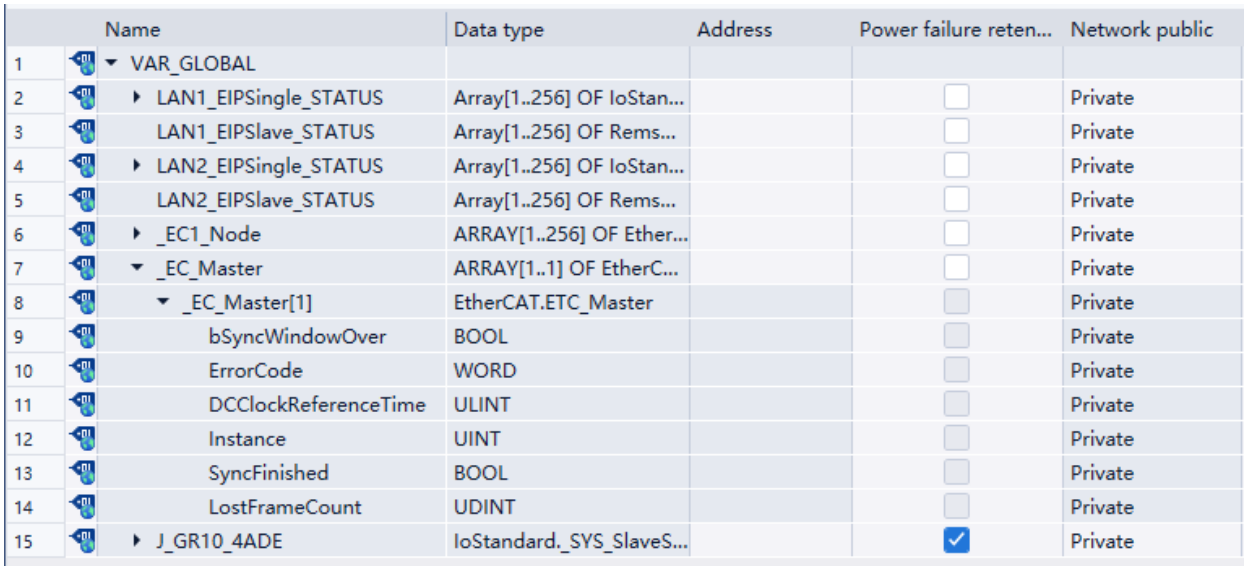
- Devices and corresponding modules have been added, such as EtherCAT masters/slaves and EtherNet/IP adapters.
- The device has been switched to online.



Procedure

1. Under the "Programming" node in the left project tree, double-click "SYS_VAR(Global)" to open the system variable table.
2. View diagnostic information in the list. For details about various faults, see System variable diagnostic categories.

System variable diagnostic categories



- Device diagnostic status variables Device diagnostic status variables are related to EtherNet/IP device configuration. When adding a PLC device, corresponding variables are automatically created in the system variable table. Variable name: Device network port number_EIPSingle_STATUS.
  These variables are used to display connection information of the master. The specific structure details are shown in the table below.

	Name	Data type	Address	Power failure reten...	Network public
1	VAR_GLOBAL				
2	LAN1_EIPSingle_STATUS	Array[1..32] OF IoStand...		☐	Private
3	LAN1_EIPSingle_STATUS[1]	IoStandard._SYS_EIPSin...		☐	Private
4	Instance	DINT		☐	Private
5	ConnectStatus	DINT		☐	Private

Variable	Definition	Function description
Instance	Instance number	-
ConnectStatus	Connection Status	0: Connection is closed. 1: Connection is abnormal. 3: Connection is normal.

- EtherCAT master system variables EtherCAT master system variables are related to EtherCAT device configuration and are automatically created in the system variable table when adding an EtherCAT device, with the variable name: _EC_Master.
  EtherCAT master system variables are used to display information about the EtherCAT master. The specific structure is described in the table below.

	Name	Data type	Address	Power failure reten...	Network public
1	VAR_GLOBAL				
2	LAN1_EIPSingle_STATUS	Array[1..256] OF IoStan...		☐	Private
3	LAN1_EIPSlave_STATUS	Array[1..256] OF Rems...		☐	Private
4	LAN2_EIPSingle_STATUS	Array[1..256] OF IoStan...		☐	Private
5	LAN2_EIPSlave_STATUS	Array[1..256] OF Rems...		☐	Private
6	_EC1_Node	ARRAY[1..256] OF Ether...		☐	Private
7	_EC_Master	ARRAY[1..1] OF EtherC...		☐	Private
8	_EC_Master[1]	EtherCAT.ETC_Master		☐	Private
9	bSyncWindowOver	BOOL		☐	Private
10	ErrorCode	WORD		☐	Private
11	DCClockReferenceTime	ULINT		☐	Private
12	Instance	UINT		☐	Private
13	SyncFinished	BOOL		☐	Private
14	LostFrameCount	UDINT		☐	Private
15	J_GR10_4ADE	IoStandard._SYS_SlaveS...		☑	Private

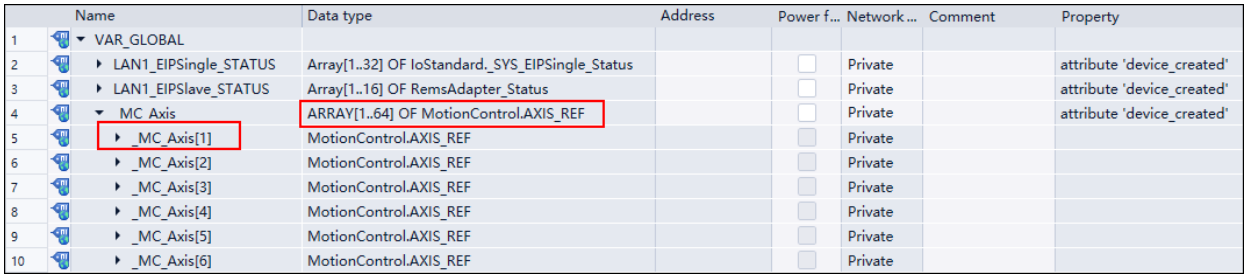
Variable	Definition	Function description
bSyncWindowOver	Synchronization window deviation	The default value is FALSE. bSyncWindowOver is set to TRUE when the "Sync window" value (μs) is greater than 0 and is no less than the current bus's "Max. sync window deviation".
ErrorCode	Master fault code	0x0001: Configured slave count < scanned slave count 0x0002: Slave alias conflict 0x0004: Slave fault detected 0x0008: Continuous frame loss 0x0010: Slave CRC fault 0x0020: Main network card not connected 0x0040: Redundant network card not connected 0x0080: Slave alias is 0 0x0100: Network card not connected
DCClockReferenceTime	DC reference clock	DC reference clock real-time value (read-only).

Variable	Definition	Function description
Instance	Master instance address	-
SyncFinished	Master synchronization status	SyncFinished is set to TRUE after master startup completes, regardless of whether slaves are in OP (Operational) status.
LostFrameCount	Lost frame count	Consistent with the "Lost frames" displayed on the "Online" configuration page of the EtherCAT master.

- EtherCAT slave system variables EtherCAT slave system variables are related to EtherCAT device configuration and are automatically created in the system variable table when adding an EtherCAT device, with the variable name: _EC1_Node.
  EtherCAT slave system variables are used to display information about the EtherCAT slaves. The specific structure is described in the table below.

	Name	Data type	Address	Power failure reten...	Network public
1	VAR_GLOBAL				
2	LAN1_EIPSingle_STATUS	Array[1..256] OF IoStan...			Private
3	LAN1_EIPSlave_STATUS	Array[1..256] OF Rems...			Private
4	LAN2_EIPSingle_STATUS	Array[1..256] OF IoStan...			Private
5	LAN2_EIPSlave_STATUS	Array[1..256] OF Rems...			Private
6	_EC1_Node	ARRAY[1..256] OF Ether...			Private
7	_EC1_Node[1]	EtherCAT.ETC_Slave			Private
8	wState	WORD			Private
9	ErrorCode	WORD			Private
10	ActualAliasSlaveAddr	DWORD			Private
11	PhysSlaveAddr	DWORD			Private
12	IsConfigAsOptional	BOOL			Private
13	DisableState	BOOL			Private
14	ConfigProductID	DWORD			Private
15	ProductID	DWORD			Private
16	Name	STRING(257)			Private
17	_EC1_Node[2]	EtherCAT.ETC_Slave			Private

Variable	Definition	Function description
wState	Slave connection status	1: Initialized 2: Pre-operational 3: Boot-operational 4: Safe-operational 8: Run 17: Initialization fault 18: Pre-operational fault 19: Boot-operational fault 20: Safe-operational fault 24: Operational fault



Variable	Definition	Function description
ErrorCode	Slave fault code	0x0001: Slave device offline 0x0002: Slave device vendor ID mismatch 0x0004: Slave device product code mismatch 0x0008: Slave device version number mismatch 0x0010: Slave device fault flag 0x0020: Slave device reverse connection 0x0040: Slave device port closed 0x0080: Slave device status fault 0x0100: Slave device SDO configuration failed 0x0200: Slave device status transition timeout 0x0400: Slave device SDO download timeout 0x0800: Slave device EEPROM fault Note: When multiple faults exist simultaneously, the slave fault codes will be displayed in an accumulated manner.
ActualAliasSlaveAddr	Slave alias address	-
PhysSlaveAddr	Slave physical address	Slave address 1001
IsConfigAsOptional	Whether the slave is configured with an alias	TRUE: The slave is configured with an alias. FALSE: The slave is not configured with an alias.
DisableState	Whether the slave is disabled	TRUE: The slave is disabled. FALSE: The slave is enabled.
ConfigProductID	Configured product ID	-
ProductID	Actual slave product ID	-
Name	Slave name	-

- Remote adapter status variables Remote adapter status variables are related to EtherNet/IP device configuration. When adding an EtherNet/IP device, corresponding variables are automatically created in the system variable table. Variable name: Device network port number_EIPSlave_STATUS. These variables are used to display the operation status of the remote adapter. The specific structure details are shown in the table below.

Variable	Definition	Function description
DevName	Remote adapter name	-
wState	Remote adapter connection status	0: Connection is closed. 1: Remote adapter is disabled. 2: Connection is abnormal. 3: Connection is normal.
ErrorCode	Remote adapter fault code	See 21.1 Appendix 1: List of Fault Codes.
CfgIP	Remote adapter configured IP	-
ActualIP	Remote adapter actual IP	-
DisableStatus	Remote adapter disabled status	TRUE: The slave is disabled. FALSE: The slave is enabled.
DevAliasID	Remote adapter alias ID	-

- Axis array variables Axis array variables are related to axis device configuration. When an axis device is added, the corresponding variables are automatically created in the system variable table. Variable name: _MC_Axis. These variables are used to manage all real axes and virtual axes under all EtherCAT masters in a centralized way, and store system variable information for these axes. For detailed structure description, refer to 18.3.3.2.2.1 AXIS_REF: Axis Structure.

Axis array variables	Description
Array name	_MC_Axis
Array length	Total number of EtherCAT axes supported by this PLC
Array mapping	Axis array subscript represents the axis number. For example, the array element corresponding to "Axis" is _MC_Axis[1].
Variables accessible in the array	Refer to 18.3.3.2.2.1 AXIS_REF: Axis Structure.

Axis array variables	Description
Axis array subscript corresponding to the axis	The subscript of the axis in the axis array is displayed under the project tree "PLC_X node > Control object > Axis". The subscript can be manually adjusted in the 16.1.3 Axis basic settings interface. Note: Axis numbers must not be duplicated and must not exceed the maximum number of axes supported by the PLC.

For more information on diagnostic system variables, see 10.1.1.9.6 System Variable Table.

15.5 Instruction Diagnostics

Instruction diagnostics enable real-time retrieval of device diagnostic information within user programs. By calling diagnostic instructions, users can query the current device operating status, fault information, and alarm details, enabling real-time monitoring of system status and rapid fault localization. The following lists all diagnostic instructions supported by the platform.

- System information

Instruction	Functions
SysHC_HWInfo	Obtain hardware Information
GetDeviceDiag	Obtain device diagnostic information
GetDeviceStatus	Obtain device state
SysHC_CPUInfo	Obtain CPU information such as memory, frequency, and temperature
SysHC_FaultRecord	Get fault data recording by calling instruction

- Redundancy information

Instruction	Functions
GetControllerModuleDiagnosisInformation	Obtain basic diagnostic information of the controller module
GetRedundancyModuleDiagnosisInformation	This instruction obtains the basic diagnostic information of the redundancy module.

- EtherNetIP

Instruction	Functions
GetEIPSystemstats	Retrieve EIP system diagnostic information
GetEIPConnectstats	Get diagnostic information of EIP connection
SysHC_EthernetIPDeviceDiagnose	Obtain the fault diagnostics of the EIP slave
SysHC_EthernetIPSlaveDiagnose	Obtain the fault diagnostics of the EIP master

- Local bus

Instruction	Functions
SysHC_CPU_IOMODULE_Diagnose	Get the diagnostic state of local IO module
LBus_GetDiagMailBoxData	Get diagnostic mailbox information of the specified module on the local bus
LBus_GetModuleInfo	Get all information about the local bus and local I/O
SysHC_GetAllGL20ModuleInfo	This instruction gets basic information about all modules on the local bus.
SysHC_GetGL20ModuleInfo	Get basic information about a specified module on the local bus

- ModbusRTU

Instruction	Functions
SysHC_ModbusRtuSlaveDiagnose	Get the diagnostic status from the Modbus-RTU master

- ModbusTCP

Instruction	Functions
SysHC_ModbusTcpSlaveDiagnose	Obatin Modbus-TCP master diagnostic status information
SysHC_ModbusTcpDeviceDiagnose	Get Modbus-TCP as slave diagnostic status information

- EtherCAT

Instruction	Functions
ETC_GetCouplerInfo	Read EtherCAT coupler information
ETC_GetMasterinfo	Get EtherCAT master information
ETC_GetSlaveInfo	Get EtherCAT slave information
ETC_MasterDiagnose	Get EtherCAT master diagnosis information

- CANBus

Instruction	Functions
CANBus_GetDevDiagInfo	Get device diagnostic information

- CIA405

Instruction	Functions
CIA405_GET_STATE	Obtain the status of the CANopen device

- Free TCP

Instruction	Functions
SktTCPGetStatus	This instruction gets TCP connection status.

- FINS communication

Instruction	Functions
FINS_ServerDiag	Get the diagnostic information of FINS server

- Melsec communication

Instruction	Functions
MELSEC_ServerDiag	Get the diagnostic information of Melsec server

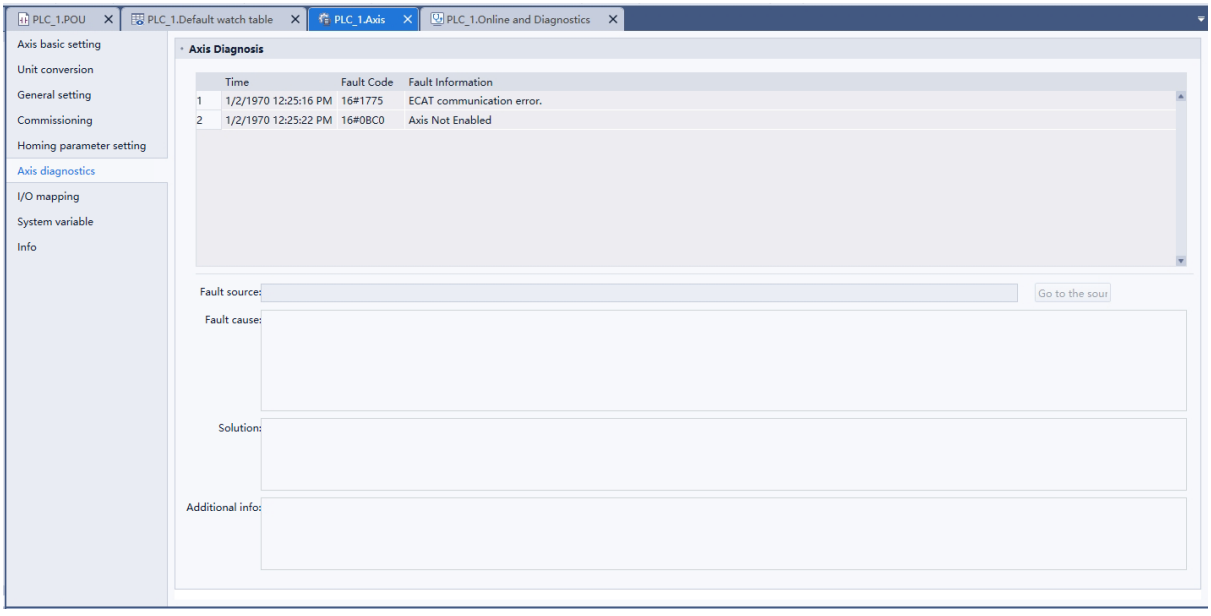
NOTE

For detailed parameters, programming examples, and complete usage instructions for each instruction, see 18.4 Communications and Diagnostics in the "Common Instructions" chapter.

15.6 Axis Control Diagnostics

Axis control diagnostics are a critical component for ensuring stable operation of automation equipment and improving system reliability. They enable fast and accurate fault localization and allow users to trace the root cause of issues based on diagnostic information, so that corrective measures can be taken.

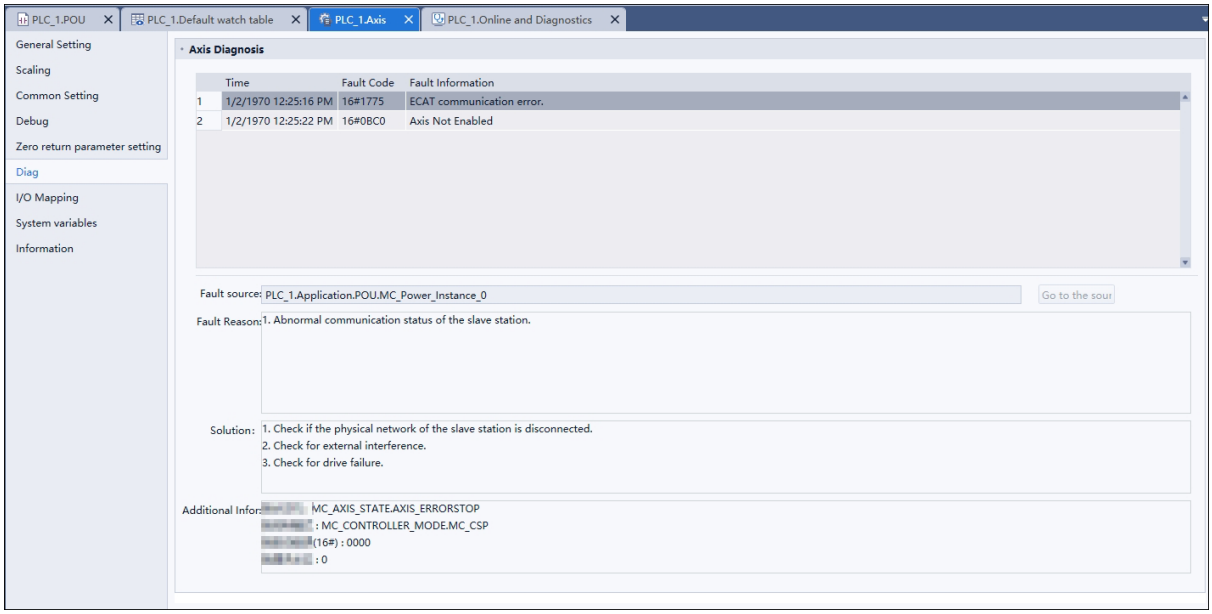
The platform provides two diagnostic approaches for viewing and analyzing axis-related diagnostics, helping users efficiently troubleshoot and resolve axis operation anomalies.



Diagnosing via the axis configuration interface

Prerequisites

- An axis has been added.
- The device has been switched to online.



Procedure

1. In the project tree on the left, select "Control object > Axis". Double-click the added axis to open the axis configuration interface.
2. On the "Axis diagnostics" tab, view the occurrence time, fault code, and fault information of all faults in the list.

Parameter	Description
Time	The time when the fault occurred.
Fault code	Displayed in hexadecimal by default. For details, see 18.3.3.8 Fault Codes for all fault codes, corresponding information, causes, and solutions.
Fault information	Brief information about the fault.

3. In the axis diagnostics list, select a fault to view its source, cause, solution, and additional information.

Parameter	Description
Fault source	Displays the root cause of the fault.
Cause	The cause corresponding to the fault information.
Solution	The corrective action corresponding to the fault information.
Additional info	Additional details, including axis state machine, axis control mode, axis drive fault, and axis communication status.

Diagnosing via axis structure variables

The axis structure parameter fbeFBError records fault information for motion control instructions, including fault code, source, occurrence time, and communication status upon fault. When viewing diagnostic information through axis structure variables, the software provides the following two entries.

- System variable table
  The system variable table provides variables related to axis device configuration. When an axis device is added, the corresponding variable (variable name: _MC_Axis) is automatically created in the table. You can directly locate the axis structure variable Axis.fbeFBError and view diagnostic information here.
- Watch table
  The watch table supports real-time monitoring of specified variables. You can add the axis structure variable Axis.fbeFBError to the watch table to directly view diagnostic information.

NOTE

For details about the fbeFBError parameter, see FB fault message display and 18.3.3.2.2.4 MC_FBERROR_REF: Fault Record Structure.

16 Motion Control

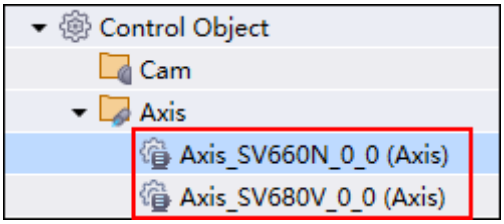
16.1 Axis Configuration

16.1.1 Overview

In motion control systems, the object of motion control is referred to as an axis. The axis serves as a bridge connecting the drive and the PLC. When used as an output device, the axis can control EtherCAT bus drives compliant with the 402 protocol or local high-speed pulse outputs. When used as an input device, the axis can implement functions such as counting and frequency measurement for EtherCAT bus modules compliant with the 402 protocol or local high-speed pulse inputs.

16.1.2 Adding an Axis

Prerequisites



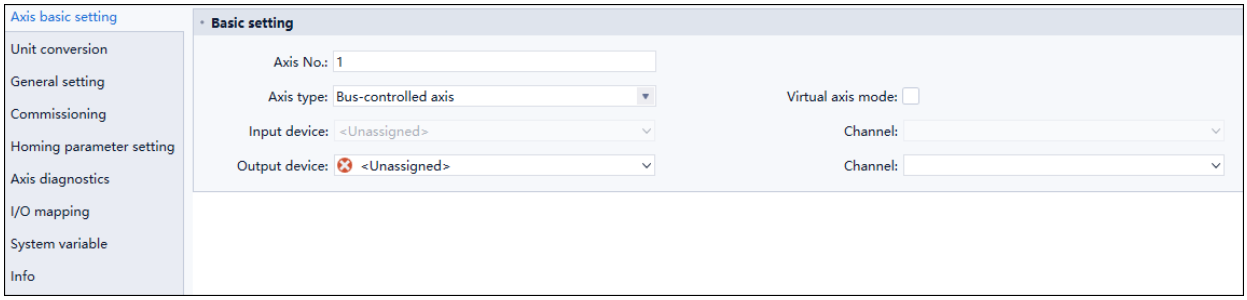
The selected controller supports the motion control function.

Procedure

1. Select "Control Object > Axis" in the left project tree.
2. Right-click the "Axis" node and select "Add axis".
3. In the pop-up dialogue box, enter the axis name and click "OK".

Result

The newly created axis is displayed under the "Axis" directory.



You can also assign axes in batches to added servo devices. For details, refer to 16.1.4 Batch Servo Assignment.

16.1.3 Basic Axis Settings

Double-click an added axis in the left project tree to open the axis configuration interface and set basic axis parameters.

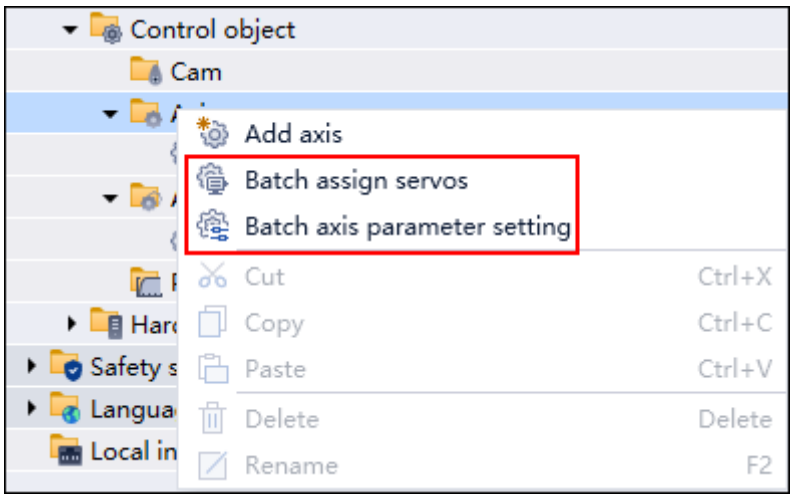
Basic axis configuration includes "Axis number", "Axis type", "Input device", "Output device", and "Probe setting".

- Axis number: The axis identifier. When adding an axis device, a unique axis number is automatically assigned, which can be viewed and modified.
- Axis type: Options include bus-controlled axis, bus encoder axis, local encoder axis, and local pulse axis.

ID	Axis Type	Note	Category
①	Bus-controlled axis	Controls EtherCAT bus drives compliant with the CiA402 protocol. Supports basic control modes including torque, position, speed, and homing.	Real axis
②	Bus encoder axis	Controls EtherCAT bus expansion modules compliant with the CiA402 protocol. Combined with the module's input/output interfaces, it enables functions such as position preset, probe, gate control, and comparison output.	
③	Local Encoder Axis	Integrated with local high-speed I/O counters, it enables 4-axis 32-bit high-speed counting, frequency measurement, latch, and preset functions.	

ID	Axis Type	Note	Category
④	Local pulse axis	Controls pulse drives via local high-speed I/O. It supports up to four local pulse axes if configured as dual-channel mode. Supports basic control modes including position, speed, and homing. Torque mode is not supported.	

- Input device: EtherCAT-compliant expansion modules or high-speed counters.
- Output device: EtherCAT-compliant servo drives, expansion modules, or high-speed I/O terminals.
- Virtual axis mode: Effective only for bus-controlled axes and local pulse axes. After enabling virtual axis mode, no output device needs to be selected to use motion control instructions.
- Virtual axis probe setting: A controller supports two channels of virtual axis probe signals, triggered by local high-speed I/O terminals. It can be used with MC_TouchProbe to capture probe positions.



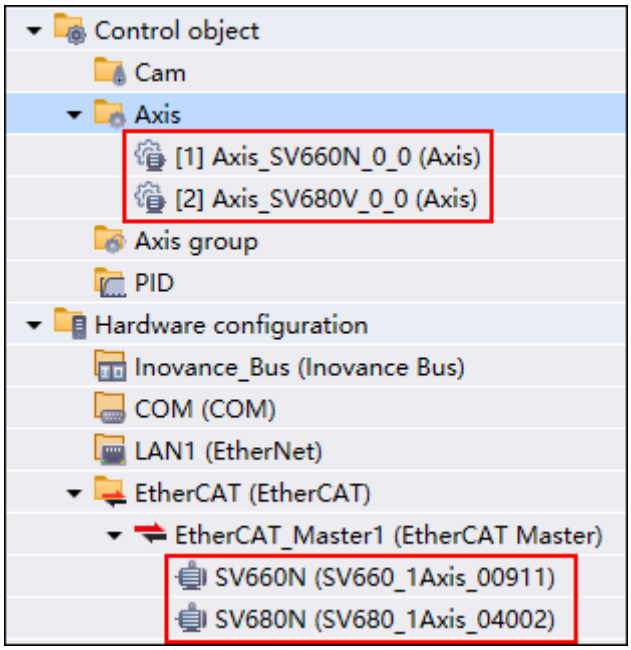
For multiple axes, axis parameters can be set in batches. For details, see 16.1.4 Batch Axis Parameter Settings.

16.1.4 Batch Servo Assignment and Axis Parameter Settings

When the device has multiple axes (such as servo motors and stepper motors), configuration parameters for different axes can be compared, copied, and pasted, reducing repetitive operations and improving configuration efficiency.

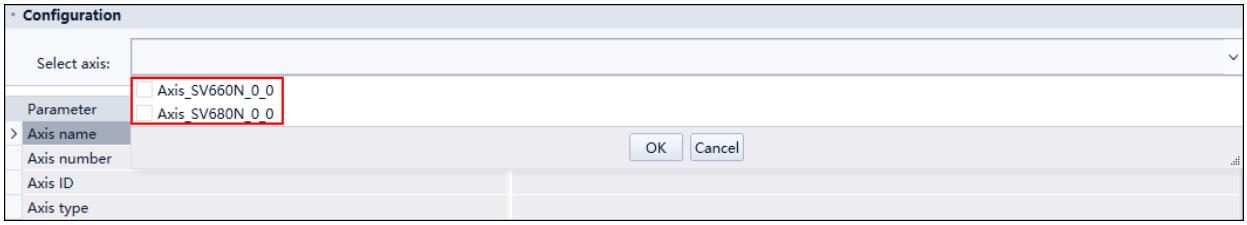
Procedure:

1. Right-click "Axis" under "Control object" in the left project tree.
2. Select "Batch assign servos" or "Batch axis parameter setting".



Batch servo assignment

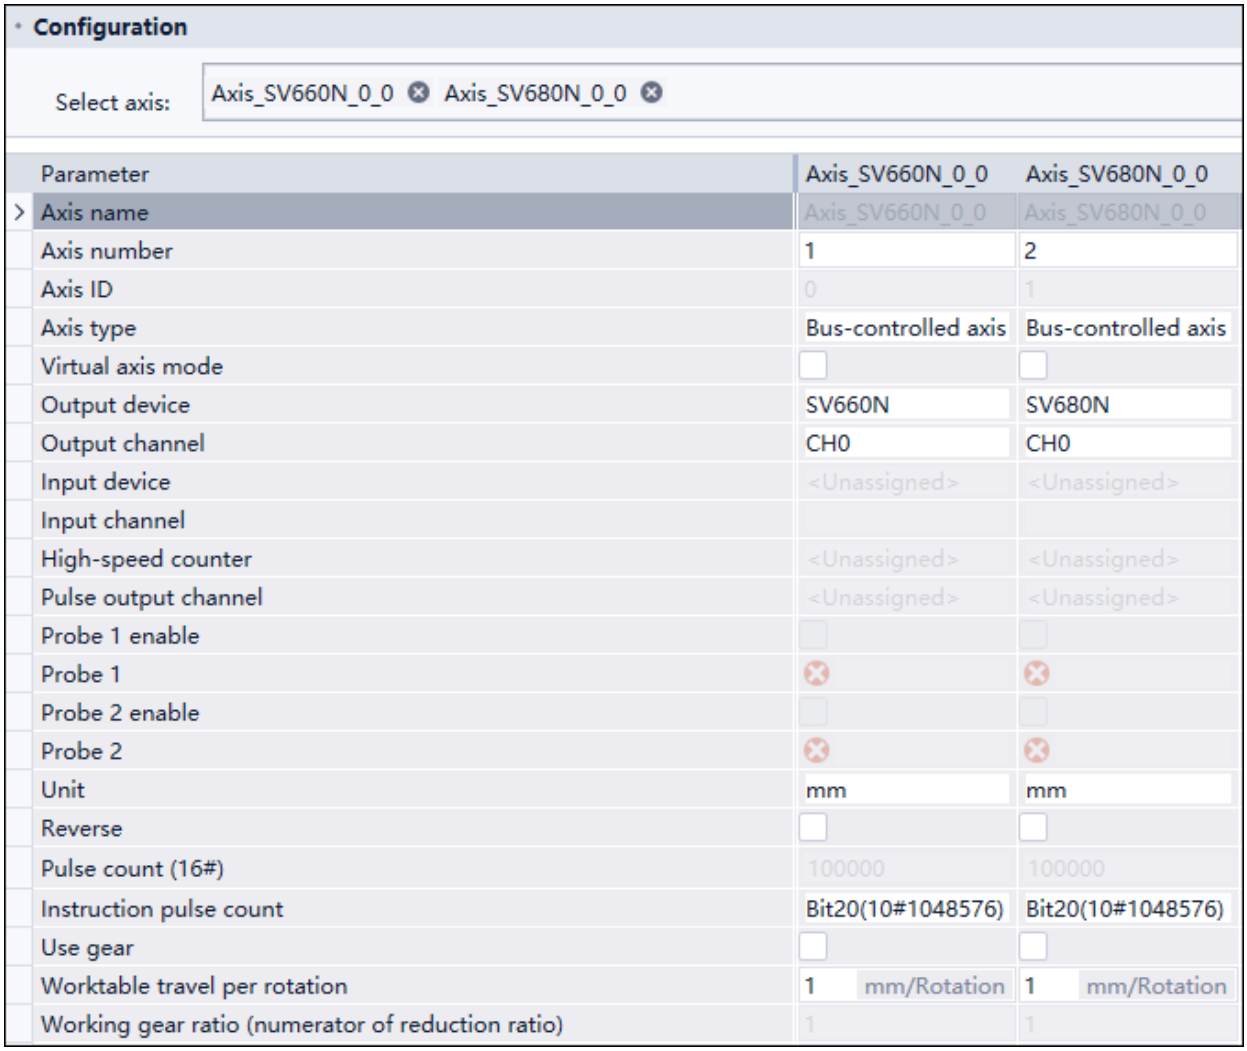
The batch servo assignment supports the following operations:



- Batch axis creation: Generates corresponding control axes for all servo drives without assigned axes.

- Auto mapping: Automatically completes the association settings between drives and axes.
- Multi-axis devices: If the drive supports multiple axes (such as a dual-axis servo), the system automatically creates the corresponding number of axes based on actual axis count.
- Third-party devices: Third-party devices are processed as single-axis drives by default, with only one axis created.

After adding servo devices, right-click "Axis" and select "Batch assign servos" to automatically create control axes corresponding to the servo devices, as shown in the figure below.



Batch axis parameter settings

After selecting the batch axis parameter settings function, you can select added axes for the following operations:

- Support viewing and modifying parameters of multiple axes simultaneously.
- Applicable to single-axis and IO modules of the same model.
- The parameters of up to eight axes can be compared simultaneously.

Multi-axis parameter comparison

- The parameters of multiple axes are displayed simultaneously for intuitive comparison.
- Different axes can be selected for parameter comparison (e.g., Axis 1 vs Axis 3 vs Axis 5).

Parameter modification method

- All parameters can be entered using drop-down options.
- Copying (Ctrl + C) and pasting (Ctrl + V) are supported for quick batch parameter modification.
- Parameter values can be dragged left or right to overwrite parameters on other axes.

Parameters available for batch settings

The following parameters support batch settings:

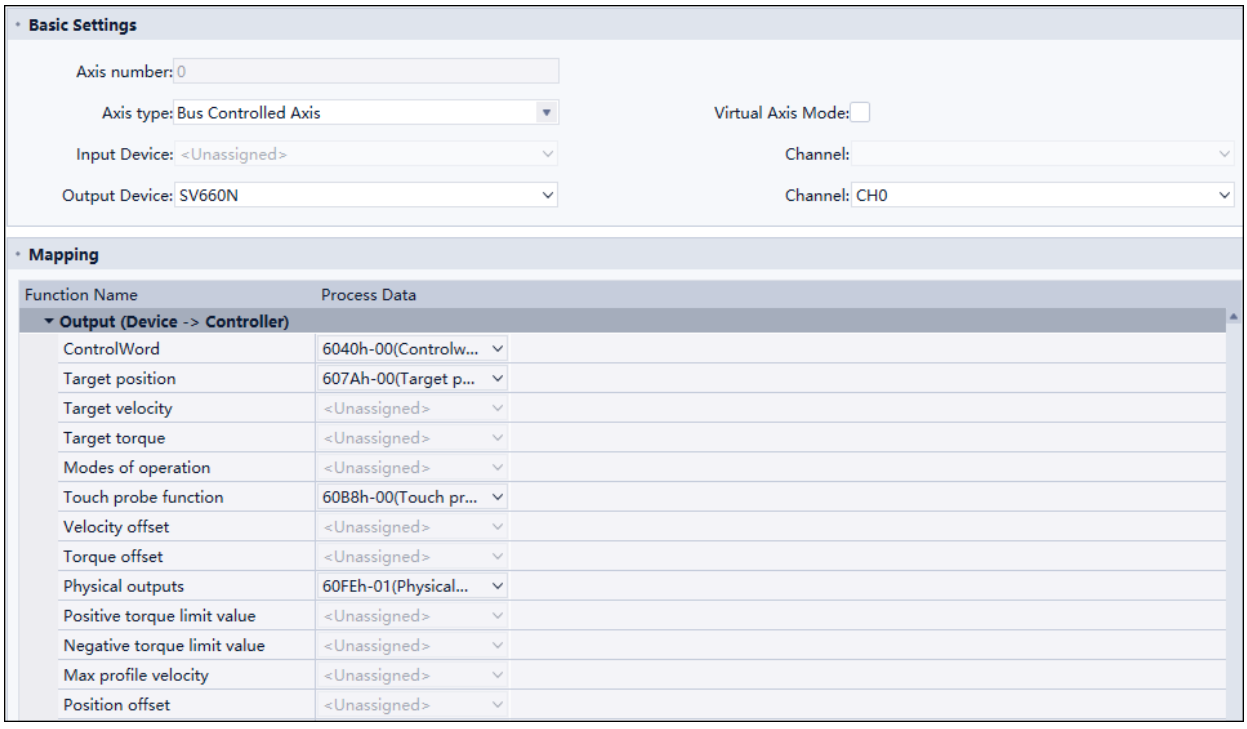
- Basic axis settings (e.g., axis type, control mode)
- Unit conversion (e.g., pulses/mm, speed unit)
- General settings (e.g., limit, alarm parameters)
- Homing parameters (e.g., homing method, speed)
- Bus cycle task (e.g., communication synchronization settings)

Use case 1: To adjust the homing speed of five servo motors, users can directly modify them in the table in batch, without setting each axis individually.

Use case 2: To copy the unit conversion parameters from axis 2 to axis 4 and axis 6, users only need to copy the parameter and paste it.

Use case 3: Users can compare the configuration differences between axis 1 and axis 3 to quickly identify inconsistent parameters, and adjust them.

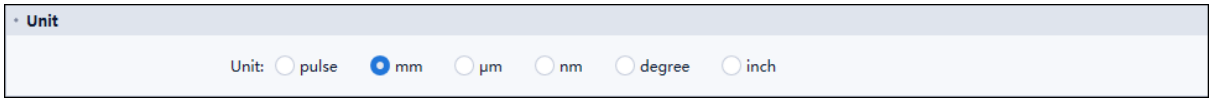
16.1.5 Bus-Controlled Axis



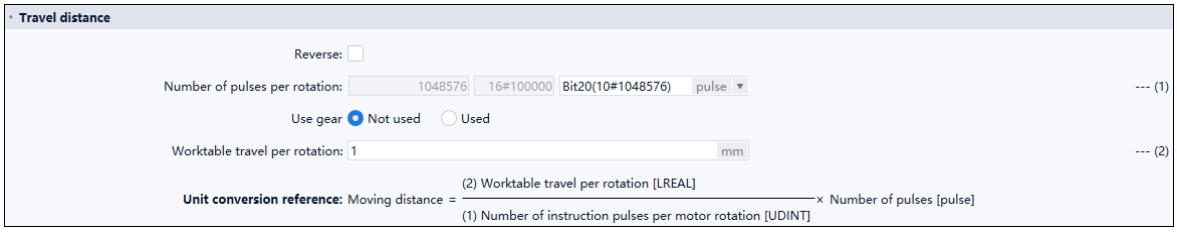
16.1.5.1 Basic Axis Settings

After selecting "Bus-controlled axis" as the axis type, the "Output device" option is activated.

- If device configuration has been completed in the device and network, you can select the corresponding device as the output.
- If the device and network configuration have not been performed, you can scan for devices under the EtherCAT_Master node.



After completion, the PDOs selected on the servo side will be automatically mapped to the axis side:



16.1.5.2 Unit Conversion

- Unit: Conversion between six units, including pulse, millimeter (default), micron, nanometer, degree, and inch. The unit can be configured as needed.

- Travel distance: Conversion between user unit and pulse unit.
  For bus-controlled axes or local pulse axes, the user unit (such as pulse, millimeter, or micron) is used on the instruction side, while the pulse unit is used for actual control of the physical motor. Gear ratio coefficient needs to be configured for unit conversion. The conversion modes are divided into the following scenarios:
  - Gears not used
    When gears are not used, the conversion formula from user unit to pulse unit is as follows:

    Taking the Inovance 20-bit encoder as an example, set the parameters as follows:

    The number of pulses per motor revolution is default to 10#1048576. Number of bits for common encoders can be directly selected, which currently supports 14-bit, 18-bit, 20-bit, 23-bit, and 26-bit encoders. The number of pulses per motor revolution can also be customized, supporting both decimal and hexadecimal input formats. Hexadecimal input requires the "16#" prefix; otherwise, the system will automatically process the value as decimal.

    The working stroke per revolution of the worktable is 1.

    Based on the above parameters, if the target distance input on the relative motion instruction side is 100, the control axis will output an actual pulse count of 104857600, causing the motor to rotate 100 revolutions. Without a reducer, the worktable moves 100 user units.

  - Gears used
    The typical scenario for linear mode is shown in the following figure:

    (1) is the motor, (3) is the workpiece, (4) is the work gear ratio, and (5) is the motor gear ratio.

    The typical scenario for rotary mode is shown in the following figure:

Rotation mode: Moving distance = $\frac{\text{(3) Worktable travel per rotation [LREAL]} \times \text{(5) Motor gear ratio [UDINT]}}{\text{(1) Number of instruction pulses per motor rotation [UDINT]} \times \text{(4) Working gear ratio [UDINT]}} \times$ Number of pulses [pulse]

M: Motor, W: Worktable

(1) is the motor, (3) is the workpiece, (4) is the work gear ratio, and (5) is the motor gear ratio.

16.1.5.3 General Settings

- Basic settings

  - Axis type: Supports rotary mode and linear mode. The linear mode is suitable for motor scenarios involving reciprocating motion, such as lead screws and linear motors. The rotational mode is suitable for motor scenarios involving unidirectional rotation where cumulative position tracking is not required.
  - Encoder type: Supports incremental encoder and absolute encoder.
  - Ramp velocity: Supports trapezoidal and S-type motion planning. Trapezoidal (T-type) motion planning does not involve jerk parameter. S-type motion planning requires input of jerk parameter. $\sin^2$: The jerk parameter is only valid when the breakpoint acceleration drops to 0. If the initial acceleration is 0, the jerk parameter is invalid.
  - Data storage location: Applicable when the encoder type is set to absolute encoder; data can be saved on the servo side or the PLC side.
  - Position hysteresis management: Select "Disable" to turn off the excessive position deviation alarm. Select "Effective" to periodically check whether the deviation exceeds the set hysteresis limit.
- Period setting: Used in rotary mode to limit the rotation period.

- Software limit: Applicable in linear mode. When enabled, it limits the positive and negative positions of the axis.

- Software limit prediction parameter setting: Configures the axis limit protection by determining the risk between the current position and the limit position.

- Motion parameter limit: The figure below shows the upper limits for single-axis motion parameters. If the parameters in the motion instruction block exceed these limits, the function block will report a fault.

- Commissioning parameter limit: The figure below shows the limits for single-axis commissioning parameters. These limits only apply to MC_Jog and MC_Inch instructions, as well as the maximum speeds and acceleration/deceleration of the forward/reverse operations in the "Axis commissioning" function. If the set value exceeds the limit value, the system will operate at the limit value.

- Other settings

  - Positive torque maximum: The upper limit value of positive torque. The set parameter will be directly written to the 60E0 object via the SDO object.
  - Negative torque maximum: The upper limit value of negative torque. The set parameter will be directly written to the 60E1 object via the SDO object.
  - Maximum velocity: The upper limit speed. The set parameter will be multiplied by the gear ratio and then directly written to the 607F object via the SDO object.

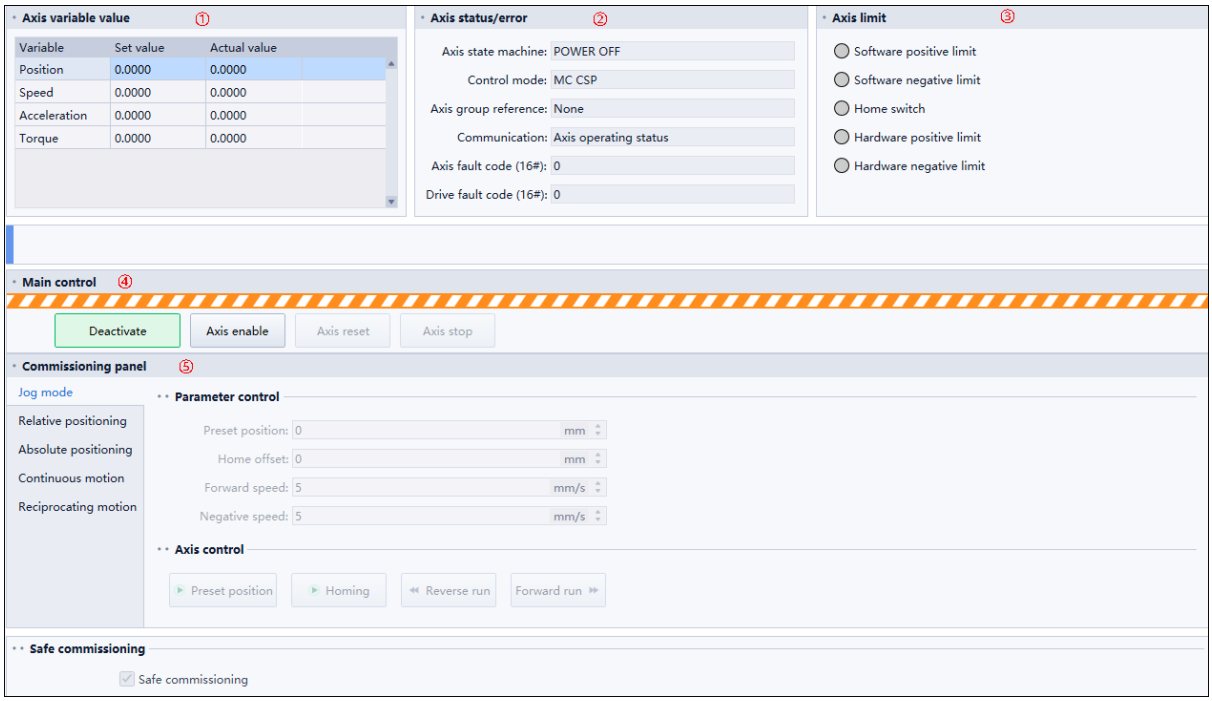
- The maximum values of positive/negative torque and speed should be set appropriately. Excessively high settings will render the protection and restriction function ineffective.
- If the set maximum speed is lower than the homing speed, the homing speed of MC_Home will be executed according to the maximum speed set on the interface. When executing a torque control instruction, the speed parameter of the torque control instruction will be converted into pulse units and written to the 607F object internally via SDO.

- Monitor parameter setting

  - Positioning range: Used to set the positioning completion width, in reference units. The value is 0 or a real integer, with a default of 10.
  - Positioning check time: Used to set the positioning completion check time, in ms. The value range is 0 to 10000, with a default of 0. When set to 0, it indicates that the arrival check function is disabled.

- Option: If enabled, the axis status will not switch to ERRORSTOP upon limit hit or abnormal parameters. Use this option with caution.

16.1.5.4 Commissioning



Basic functions such as enabling, positioning, reciprocation, homing, and stopping can be achieved through online commissioning. If the axis is connected to a bus stepper drive, the drive must support the relevant functions to perform homing or torque control. After confirming that basic motions are normal, complex motion control can be achieved using motion control function blocks.

NOTE

Axis commissioning and program motion control function blocks cannot be used simultaneously. Axis commissioning has the highest priority. After clicking "Activate commissioning", any execution of motion control function blocks will trigger a fault, and the motion control functions will be invalid. The functions can be used normally again after commissioning is disabled, and the function block is reset and triggered again.

Supported axis types: bus-controlled axes, local pulse axes, and virtual axes.

1. When the device is online and switched to the operational status, the "Activate commissioning" button can be clicked to activate axis commissioning. The interface will be as shown in the figure below.

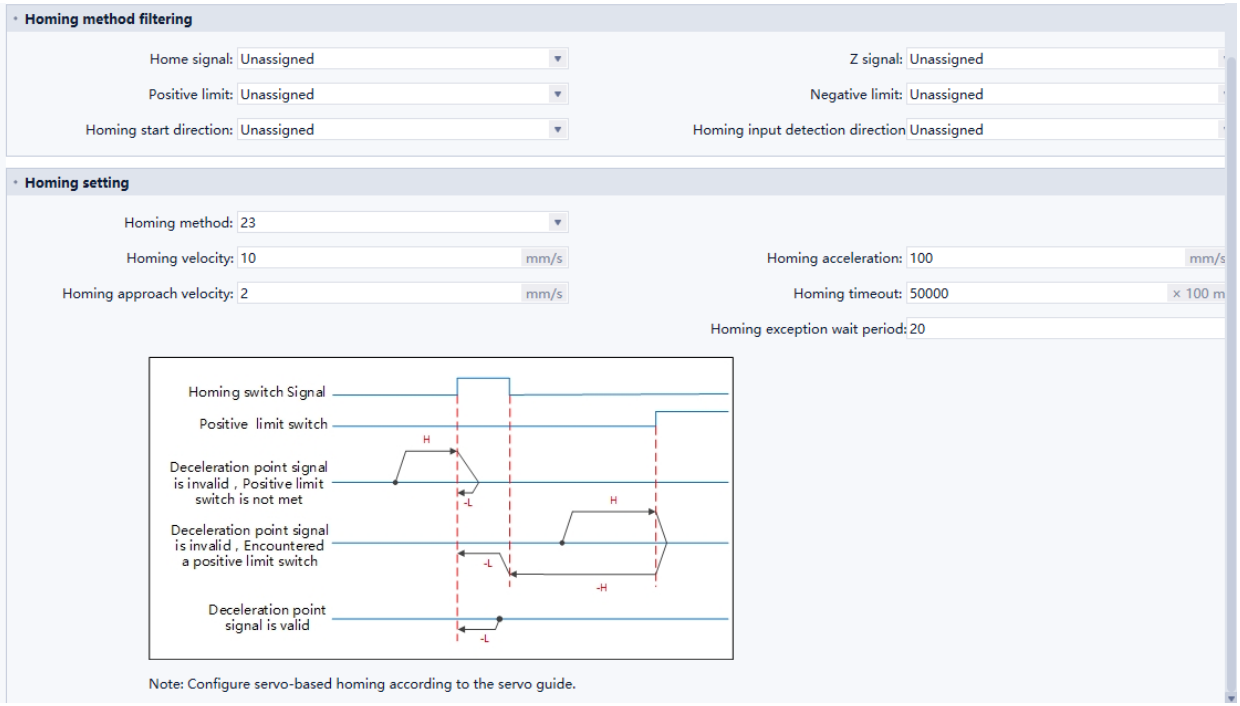
No.	Description
①	Axis-end information including position, speed, acceleration, and so on.
②	Axis status and drive fault information
③	Axis-end limit terminal status
④	Buttons for activating/deactivating commissioning, enabling axis, resetting axis and stopping axis.
⑤	Jog or other motion mode options

2. Click the "Axis enable" button to enable the axis. You can then view the axis information including the current position, speed, status, and so on.
3. By setting different motion modes and motion parameters, the overall operational status of the servo can be viewed.
4. Safe commissioning: Enabled by default. When axis commissioning is activated, switching pages or closing the commissioning page will force the axis to stop.
   The axis must be stopped in the following cases:
   - The current commissioning page is switched.
   - The current commissioning page is closed.
   - The iFA software is closed.

   The axis will not be stopped in the following cases:
   - The axis commissioning page remains unchanged in multi-view mode.
   - The commissioning page is minimized.
5. Additional notes
   - The commissioning mode is used for axis commissioning. Motion control function blocks in this mode will report a fault.
   - In commissioning mode, the axis will be stopped automatically if the software is closed, the project is switched, or the PLC is re-downloaded and installed.
   - In commissioning mode, the oscilloscope can be used normally.
   - In commissioning mode, the I/O mapping data of all slave modules remain unaffected.
   - During single-axis commissioning, enabling servo commissioning will cause an enabling conflict. The servo commissioning must be disabled before using axis commissioning.
   - In commissioning mode, parameter anomalies and other faults will cause the axis to enter the ERRORSTOP status.
6. Common functions on this interface

Option	Note
Axis variable value	Supports monitoring of set and actual values of axis position, speed, acceleration, and torque.
Axis limit	Displays software positive limit, software negative limit, home switch, hardware positive limit, and hardware negative limit.
Activate commissioning	After the software is online, all parameters on the commissioning interface will be ineffective if this button is not clicked. Once clicked, the "Axis enable" button becomes operable. During axis operation, deactivating commissioning will switch the axis to the power-off status.
Enable axis	Once clicked, the axis status will be switched to StandStill; the jog mode parameters and other mode parameters on the commissioning interface become editable.
Axis reset	If a fault occurs after the axis is enabled, this button can be used to reset the axis.
Axis stop	This button is effective regardless of the motion mode of the axis.

Option	Note
Jog mode	◦ Sets the speed for forward and reverse jogging. The unit is converted according to the settings on the unit conversion interface. ◦ Supports preset value configuration. Input the preset value and click "Settings" to apply it. The unit is converted according to the settings on the unit conversion interface. ◦ Control the jogging direction of the motor by clicking "Jog backward"/"Job forward". ◦ The running parameter for jog mode serves as both the speed parameter and the acceleration parameter.
Other modes	Relative positioning: Parameters include target distance, speed, acceleration, deceleration, and jerk. Absolute positioning: Parameters include target distance, speed, acceleration, deceleration, and jerk. Continuous motion: Parameters include target speed, acceleration, deceleration, and jerk. Reciprocating motion: Parameters include two sets of target positions. Torque control: Parameters include target torque, torque ramp, and limited speed.



16.1.5.5 Homing Parameter Settings

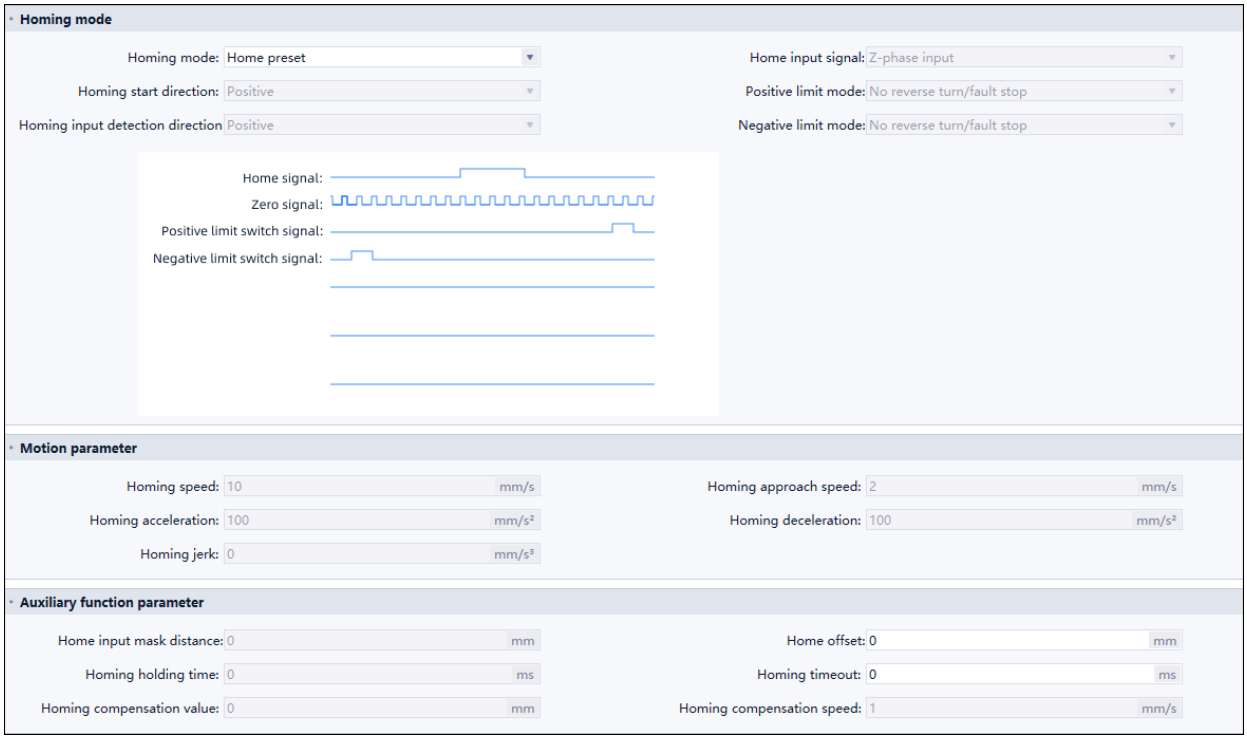
On the homing parameter setting interface, two homing modes can be configured, namely servo-based homing and controller-based homing.

Servo-based homing

The parameters of servo-based homing involve homing method filtering and homing settings. Homing method filtering is used only to filter the options in the homing list and does not require PLC program download. Homing setting parameters are primarily used for graphical parameter configuration of axis-end servo homing. Graphical configuration guidelines are provided at the bottom of the interface. Follow the guidelines to select the homing method from the drop-down menu and complete the corresponding parameter configuration. It supports homing methods 1 to 35 and -1, -2, -3 as defined by the CiA402 protocol. For axes bound to bus expansion modules (e.g., 4PME), only homing methods 17 to 35 are supported.

Parameter		Description
Homing method filtering	Home signal	Used to select whether to use the home signal. • When "Unassigned" is selected, it is not used as a mandatory filter condition. • When "Used" is selected, homing methods that do not support the home signal will be excluded. • When "Not used" is selected, homing methods that require the home signal will be excluded.
	Z signal	Used to select whether to use the motor Z signal. • When "Unassigned" is selected, it is not used as a mandatory filter condition. • When "Used" is selected, homing methods that do not support the Z signal will be excluded. • When "Not used" is selected, homing methods that require the Z signal will be excluded.
	Positive limit	Used to select whether to use the hardware right limit signal. • When "Unassigned" is selected, it is not used as a mandatory filter condition. • When "Used" is selected, homing methods that do not support the positive limit signal will be excluded. • When "Not used" is selected, the homing modes that require the positive limit signal will be excluded.

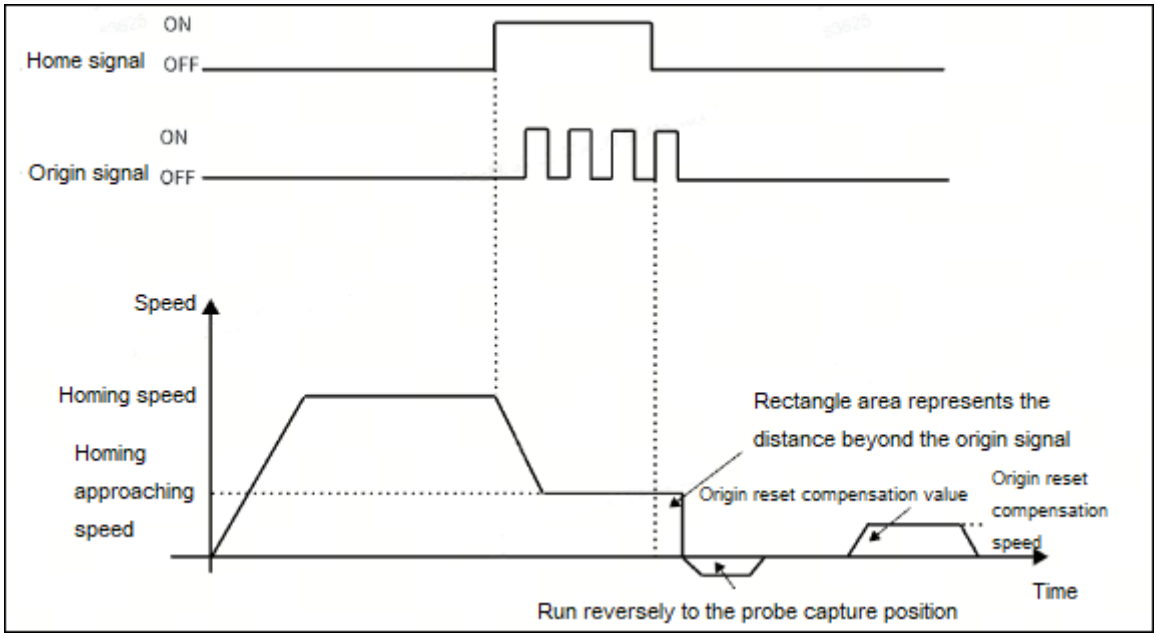
Parameter		Description
	Negative limit	Used to select whether to use the hardware left limit signal. • When "Unassigned" is selected, it is not used as a mandatory filter condition. • When "Used" is selected, homing methods that do not support the negative limit signal will be excluded. • When "Not used" is selected, homing methods that require the negative limit signal will be excluded.
	Homing direction	Used to set the direction of motion at the beginning of homing. • Positive: The direction of motion is forward when the limit (home) signal input is inactive, otherwise it is the opposite. • Negative: The direction of motion is reverse when the limit (home) signal input is inactive, otherwise it is the opposite.
	Homing input detection direction	The direction of motion when the home signal is reached. • Positive: Stops at the edge of the home signal during forward motion. • Negative: Stops at the edge of the home signal during reverse motion.
Homing Settings	Homing method	The range is -3, -2, -1, and 1 to 35. It is written to object 0x6098 via startup parameters.
	Homing velocity	The homing velocity is written into the sub-index No. 1 of the object dictionary 0x6099 in the form of startup parameters after the user units are converted into pulse units.
	Approach velocity	Indicates the homing approach velocity. It is written into the sub-index No. 2 of the object dictionary 0x6099 in the form of startup parameters after the user units are converted into pulse units.
	Homing acceleration	The homing acceleration is written into the object dictionary 0x609A in the form of startup parameters after the user units are converted into pulse units.
	Homing timeout	This parameter is exclusive to Inovance drives.
	Homing exception wait time	Number of cycles to wait from a homing exception to the reporting of a homing error. Default: 20 cycles.



Parameter settings for servo-based homing are effective for the MC_Home instruction.

Associated parameter limits

Parameter	Affected Parameters
Positive limit	When using positive limit: • Negative limit: Not used. • Homing direction: Positive.
Negative limit	When using negative limit: • Positive limit: Used. • Homing direction: Negative.
Home input/output direction	When the home input/output direction is positive or negative, the home signal is used.



Controller-based homing

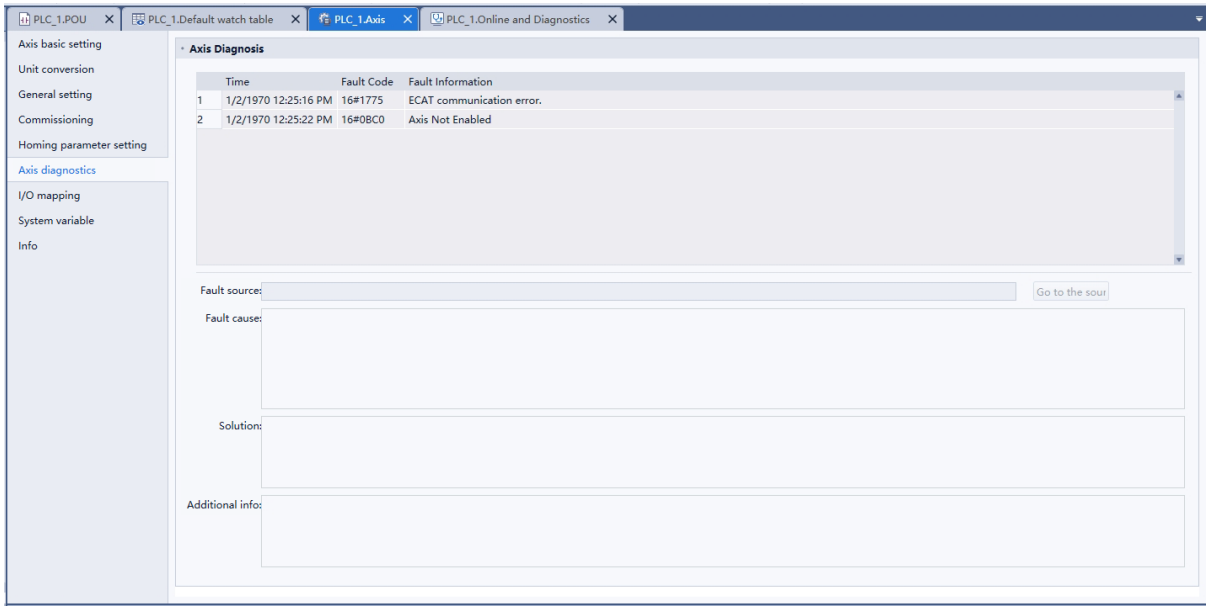
The following figure shows the controller-based homing interface. This function must be used with the MC_Homing instruction for homing. In this mode, the controller independently plans the homing trajectory and determines the final mechanical home using limit sensors, home switches, and probe signals. The controller-based homing interface mainly includes the settings of homing mode, motion parameters, and auxiliary function parameters.

- Homing mode: Includes selection of homing method, home input signal, homing direction, homing input detection direction, positive limit mode, negative limit mode, and homing trajectory preview.
- Motion parameters: Includes settings for homing speed, homing approach speed, homing acceleration, homing deceleration, and homing jerk.
- Auxiliary function parameters: Includes settings for home input mask distance, homing holding time, homing compensation value, homing compensation speed, homing offset, and homing timeout.

Introduction to controller-based homing:

After the homing instruction is initiated, the motor accelerates to the homing speed at the set homing acceleration, and runs at a constant speed to search for the home switch signal. Upon detecting the rising edge of the home switch signal, the motor decelerates at the set homing deceleration to the approach speed and continues running at this speed. When the rising edge of the first zero signal is detected after the home switch drops to a low level, the home is considered found. The motor then performs an emergency stop at the software maximum deceleration and latches the position of the rising edge of the current zero signal. After the motor stops, it moves in reverse to the position where the zero signal was latched. If a compensation value is set, the motor pauses for 500 ms and then moves the distance specified by the homing compensation value at the homing compensation speed before stopping. The entire homing process is then complete.

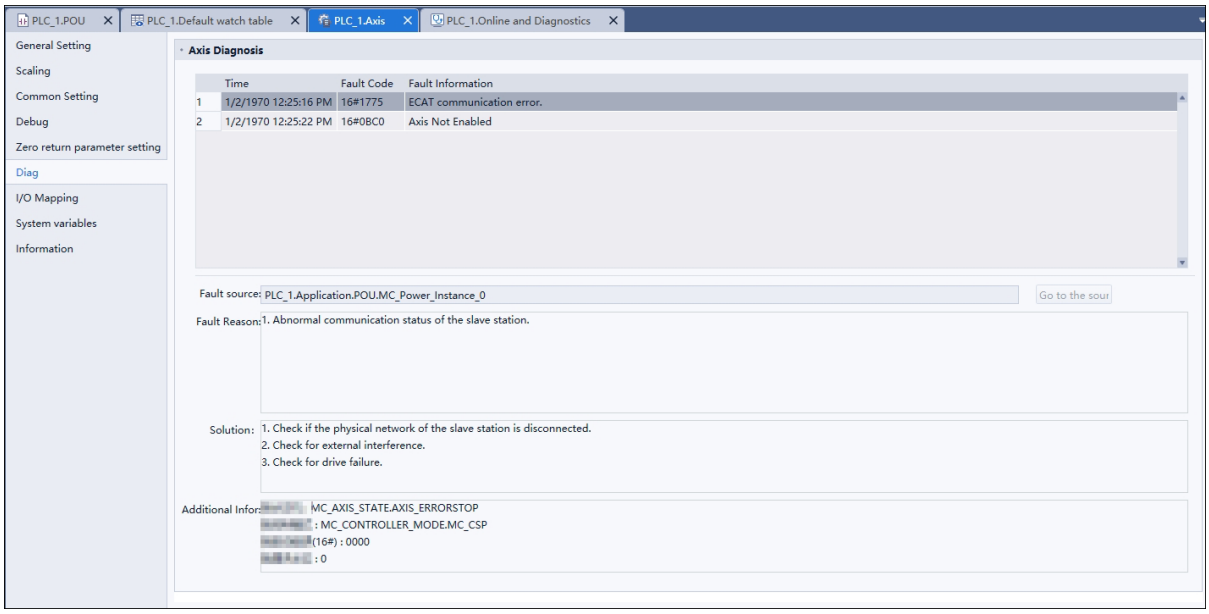
For detailed functionality, see 18.3.3.3.53 MC_Homing.



NOTE

Controller-based homing only modifies the position system of the controller and does not modify the position system of the servo drive.

16.1.5.6 Axis Diagnostics



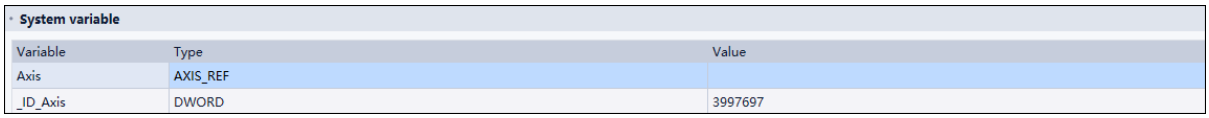
Axis diagnostics are a critical component for ensuring stable operation of automation equipment and improving overall system reliability. Through axis diagnostics, issues can be quickly and accurately identified and solved, reducing equipment downtime, increasing production efficiency, and ensuring continuous operation. Users can locate and track axis faults based on axis diagnostic information and resolve issues according to the provided solutions.

The axis diagnostic list is shown in the figure below.

- Time: The time when the fault occurred.
- Fault code: Displayed in hexadecimal by default. For details, see 18.3.3.8 Fault Codes for all fault codes, corresponding information, causes, and solutions.
- Fault message: A brief summary of the fault.

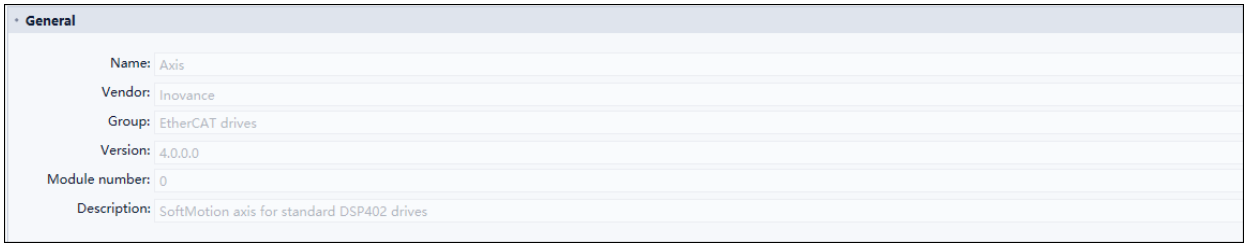
Click a fault entry in the axis diagnostic list to view the fault source, cause, solution, and additional information.

- Fault source: Displays the root cause of the fault.
- Fault cause: The cause corresponding to the fault information.
- Solution: The corrective action corresponding to the fault information.
- Additional information: Additional details, including axis state machine, axis control mode, axis drive fault, and axis communication status.



16.1.5.7 I/O Mapping

All task names and bus cycle settings will be displayed in the bus cycle options. For axis objects (including control axes and encoder axes), it is recommended to prioritize the EtherCATMaster_Task**.** Selecting other tasks may result in abnormal conditions such as planned speed jump.

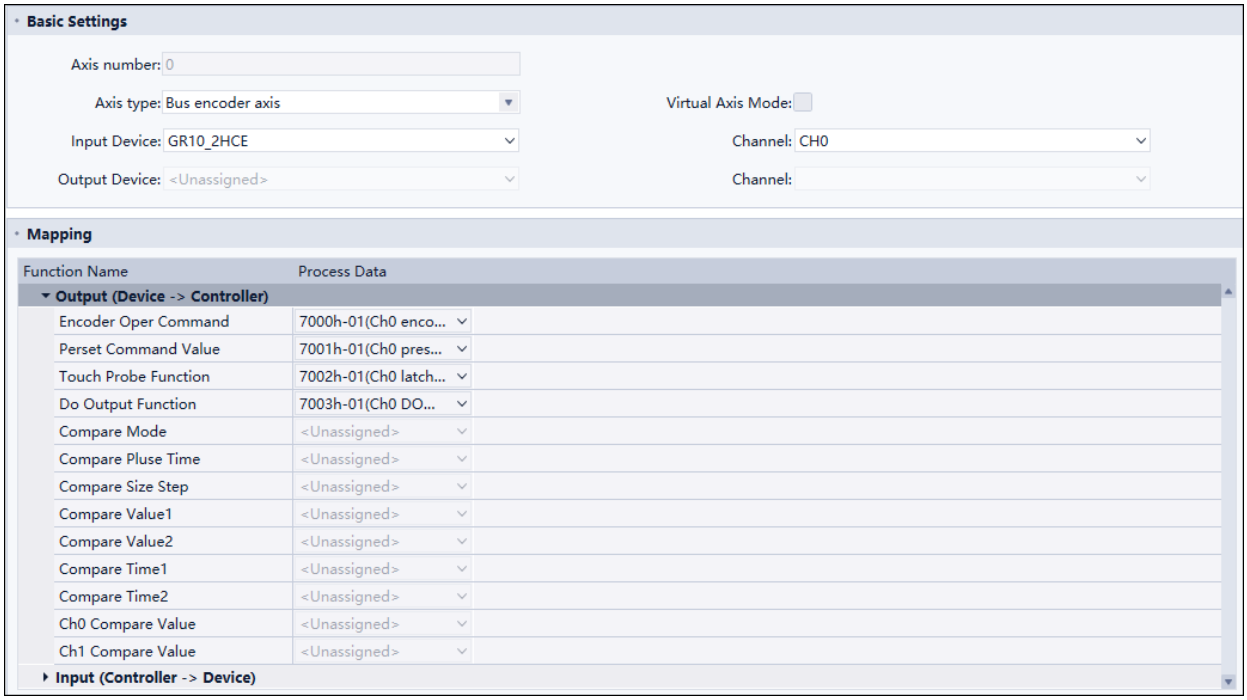


16.1.5.8 System Variables

The "System variable" tab displays the data structure and device ID of the axis.

16.1.5.9 Information

This interface displays basic information about the axis, including name, vendor, group, version, module number, and description.



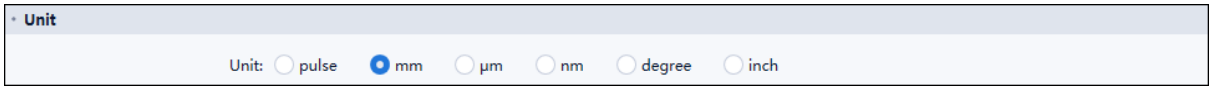
16.1.6 Bus Encoder Axis

16.1.6.1 Overview

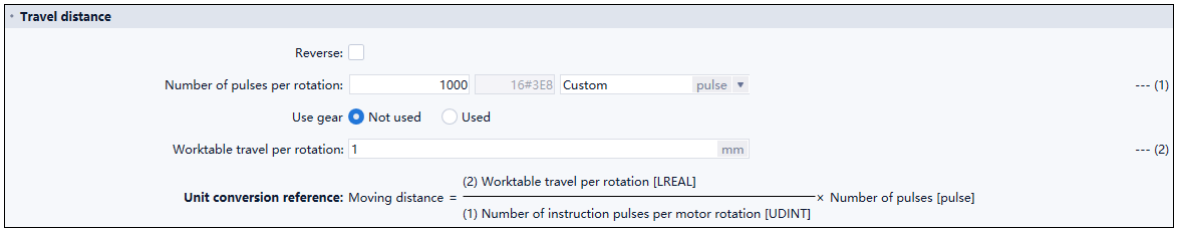
The bus encoder axis supports a maximum input pulse frequency of 200 kHz. Taking the GR10-2HCE module as the input device for illustration, the bus encoder axis can count three forms of pulses: phase A/B, pulse+direction, and CW/CCW. One GR10-2HCE module has two channels, each of which can be assigned for one axis. Bus encoder axes can also work with the DI and DO terminals of the GR10-2HCE module to implement position presetting, probe, gating, and comparison output. The feedback position of the GR10-2HCE module in pulses is sent to the PLC through PDOs, and the feedback position within the PLC is finally provided to users in the form of LREAL data type through the conversion of gear ratios, which can also be used as the master axis of a cam or gear.

16.1.6.2 Basic Axis Settings

The EtherCAT bus expansion module must be configured in the device and network before selecting the bus encoder axis. After selecting the input device, the channel will be automatically configured by default.



NOTE



The input device for the bus encoder axis currently only supports Inovance's encoder modules.

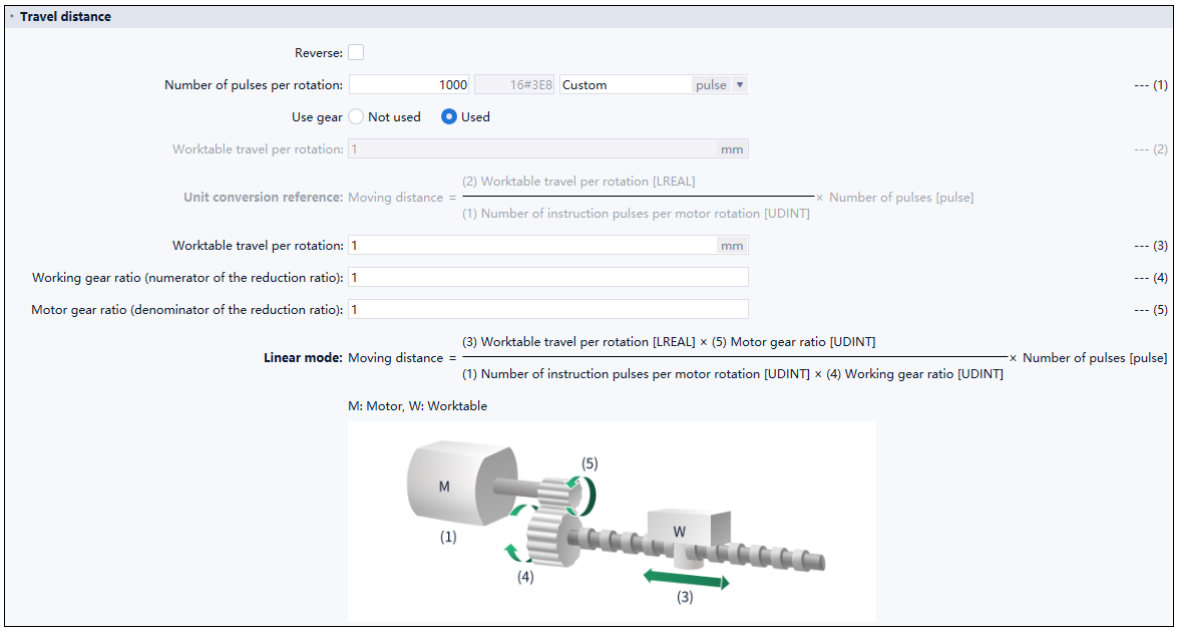
16.1.6.3 Unit Conversion

- Unit: Conversion between six units, including pulse, millimeter (default), micron, nanometer, degree, and inch. The unit can be configured as needed.

- Travel distance: Conversion between user unit and pulse unit.
  For bus-controlled axes or local pulse axes, the user unit (such as pulse, millimeter, or micron) is used on the instruction side, while the pulse unit is used for actual control of the physical motor. Gear ratio coefficient needs to be configured for unit conversion. The conversion modes are divided into the following scenarios:
  - Gears not used
    When gears are not used, the conversion formula from user unit to pulse unit is as follows:

> **NOTE**
>
> The maximum input pulse frequency for the bus encoder axis GR10-2HCE is 200 kHz, so the default number of instruction pulses per motor revolution for the bus encoder axis is 16#3E8, which is 1000 in decimal.

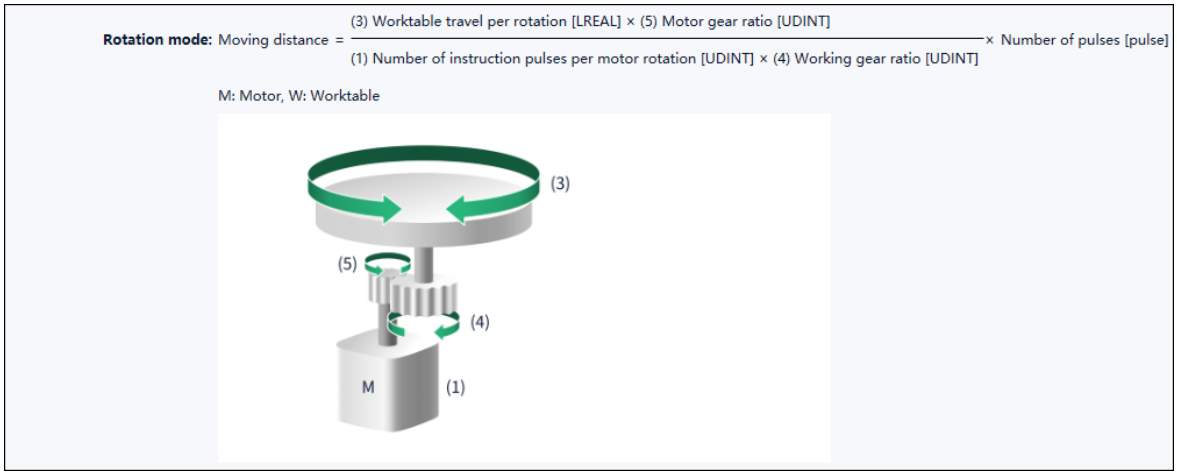
Taking the Inovance 20-bit encoder as an example, set the parameters as follows:



The number of pulses per motor revolution is default to 10#1048576. Number of bits for common encoders can be directly selected, which currently supports 14-bit, 18-bit, 20-bit, 23-bit, and 26-bit encoders. The number of pulses per motor revolution can also be customized, supporting both decimal and hexadecimal input formats. Hexadecimal input requires the "16#" prefix; otherwise, the system will automatically process the value as decimal.

The working stroke per revolution of the worktable is 1.

Based on the above parameters, if the target distance input on the relative motion instruction side is 100, the control axis will output an actual pulse count of 104857600, causing the motor to rotate 100 revolutions. Without a reducer, the worktable moves 100 user units.



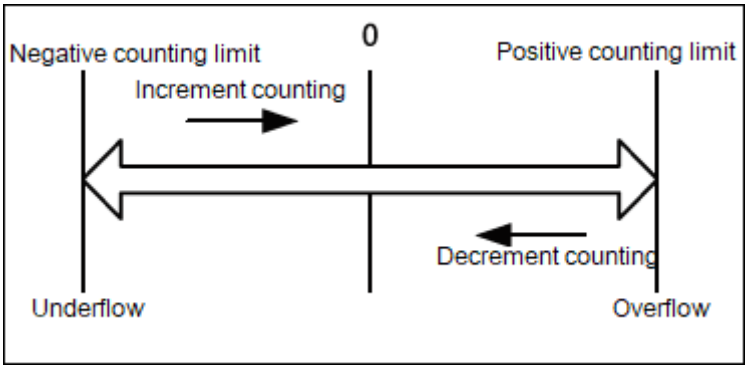
- Gears used

  The typical scenario for linear mode is shown in the following figure:

(1) is the motor, (3) is the workpiece, (4) is the work gear ratio, and (5) is the motor gear ratio.

The typical scenario for rotary mode is shown in the following figure:

(1) is the motor, (3) is the workpiece, (4) is the work gear ratio, and (5) is the motor gear ratio.



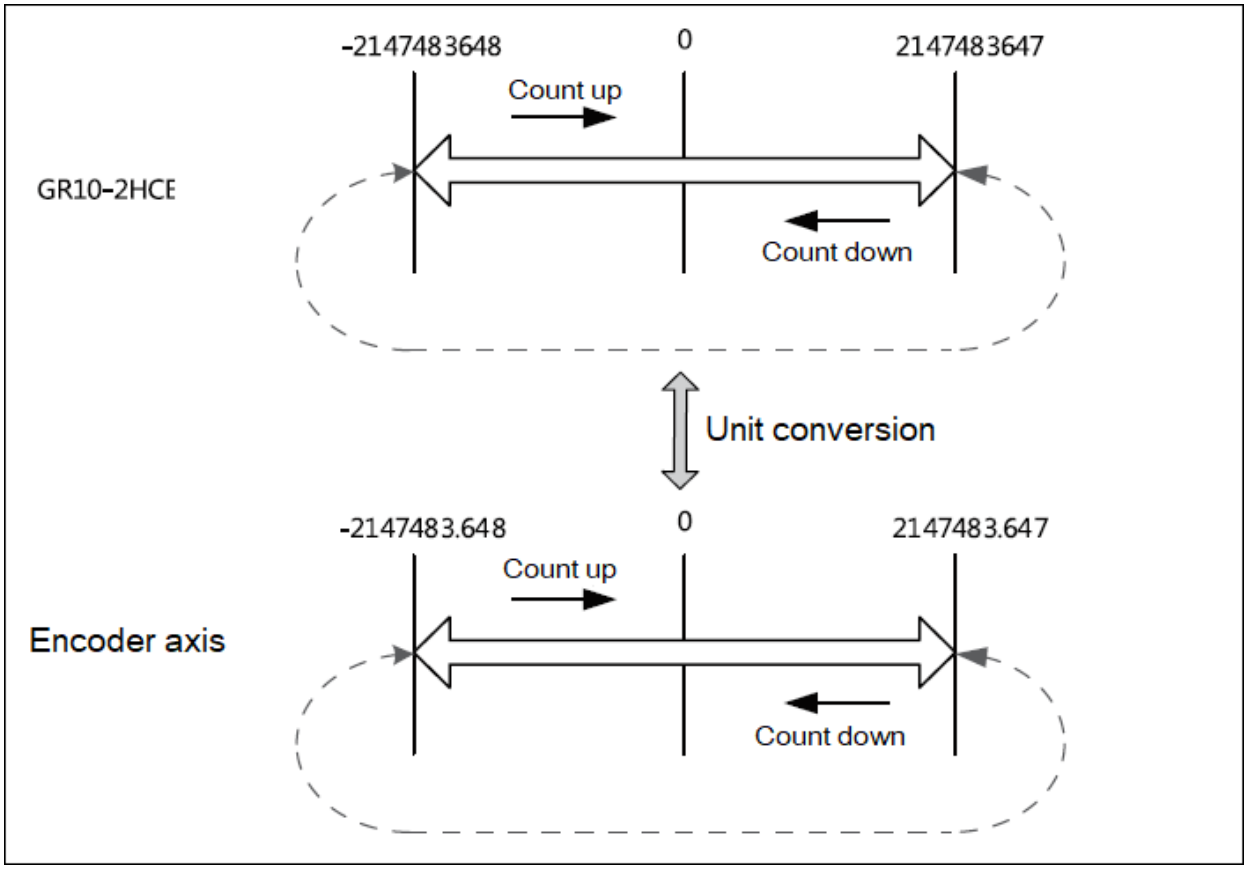
16.1.6.4 Counter Settings

1. Mode

- Linear mode

  In linear mode, the software limit can be enabled or disabled. After enabling the software limit, the positive limit value and negative limit value can be set. When the counter reaches the limit value, counting stops, and the PostiveLimit or NegativeLimit flag in the ENC_Counter instruction is set.

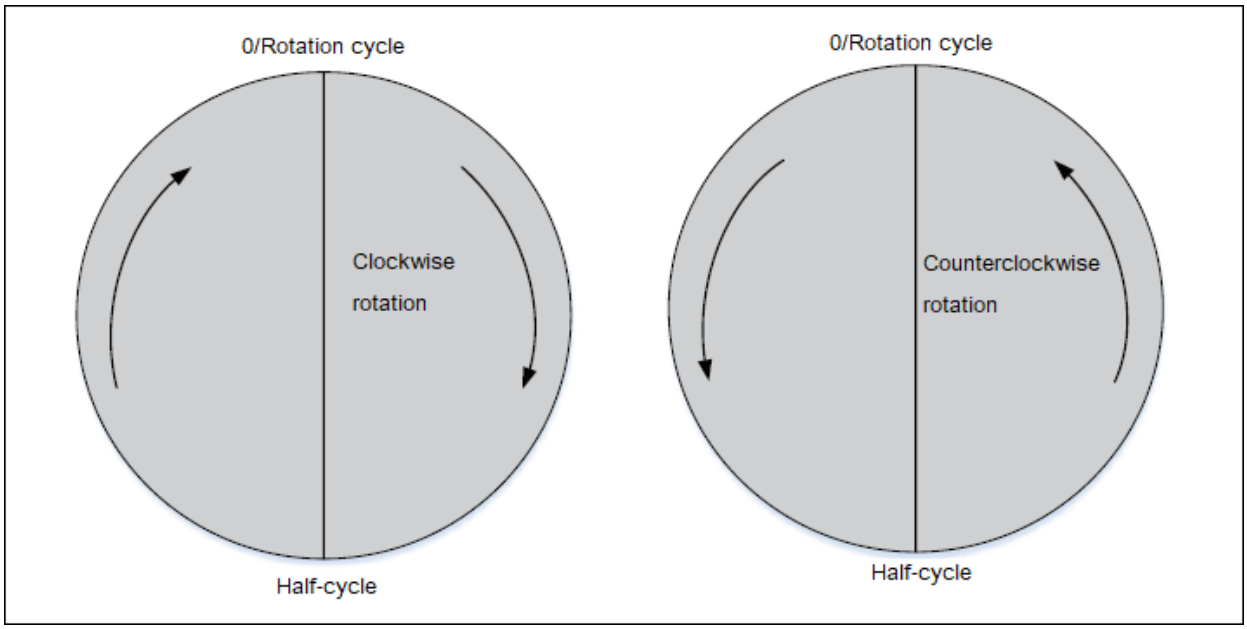
When software limit is disabled, the module's count value cycles within the range of -2147483648 to 2147483647. When forward counting reaches the maximum positive value, it directly jumps to the maximum negative value and continues counting. The reverse is the same.



Example:

The actual position of the bus encoder axis is related to the gear ratio.

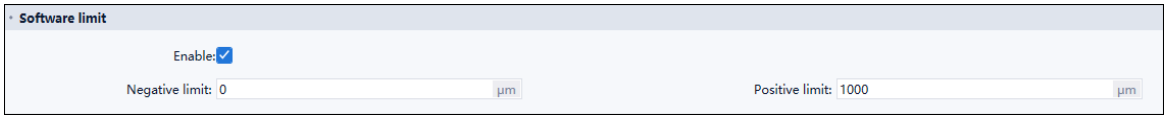
Number of pulses per motor revolution = 1000.



Working stroke per worktable revolution = 1.

All counting units in the module's PDO objects are in pulse units, while the counting units displayed at the axis end are in user units.

◦ Rotary mode

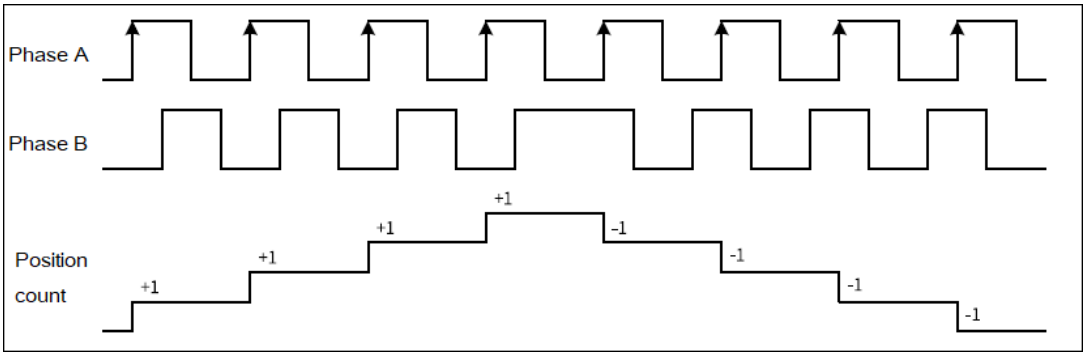


In rotary mode, the rotation period can be set. The counter will count reciprocally between 0 and the rotation period.

2. Period: Used in rotary mode to limit the rotation period.

3. Software limit: Used in linear mode. When enabled, it limits the positive and negative positions of the axis.

4. Counter parameters



- Counting mode

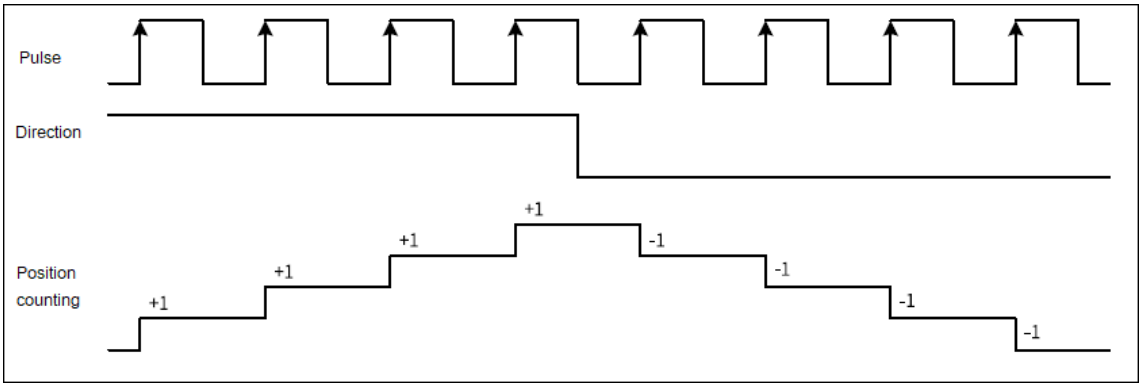
  Five count modes are supported: phase A/B 1-frequency multiplication, phase A/B 2-frequency multiplication, phase A/B 4-frequency multiplication, pulse+direction, and CW/CCW.

  - Phase A/B pulse

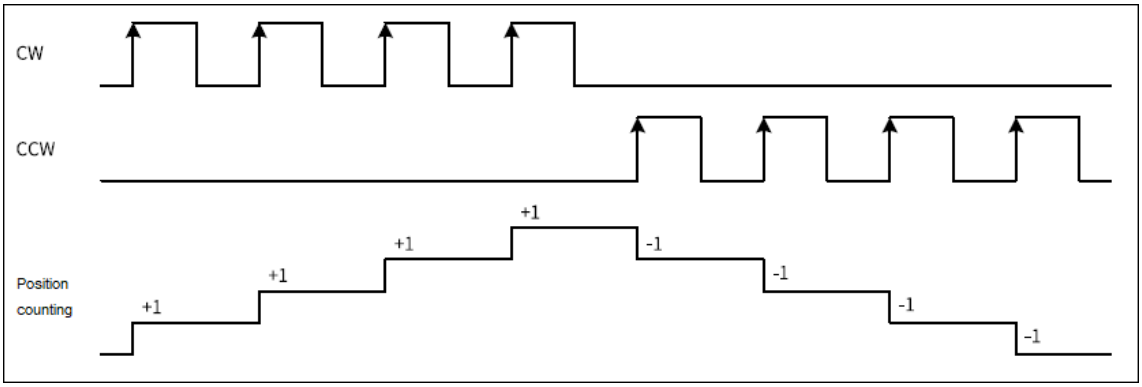
    In phase A/B mode, the encoder generates two orthogonal phase pulse signals with a phase difference of 90°, that is, phase A signal and phase B signal. When the phase A signal leads the phase B signal, the counter counts up; when the phase B signal leads the phase A signal, the counter counts down. The phase A/B pulse can be set to operate in frequency multiplication by 1, 2, or 4.

    When set to phase A/B 1-frequency multiplication, counting is performed only on the rising edge of the A-phase pulse, as shown in the figure below.

When set to A/B phase 2-frequency multiplication, counting is performed on both the rising and falling edges of the A-phase pulse, as shown in the figure below.



When set to A/B phase 4-frequency multiplication, counting is performed on the rising and falling edges of both the A-phase and B-phase pulses, as shown in the figure below.



- Pulse + direction

  Phase A serves as the pulse input for the counter, and phase B serves as the direction control input for the counter. When the B-phase signal is at high level, the counter increments; when it is at low level, the counter decrements.

- CW/CCW mode

  Clock Wise (CW) is the forward pulse signal, and Counter Clock Wise (CCW) is the reverse pulse signal. When the encoder is forward running, CW pulse signals are output; when the encoder is reverse running, CCW pulse signals are output.

◦ Counting logic

Used to set the logic of counting direction as follows:

Table16-1-6-4-1 Counting logic description

Counting Mode	Positive Logic	Negative Logical
Phase A/B	Incremental count if phase A leads phase B. Decremental count if phase B leads phase A.	Decremental count if phase A leads phase B. Incremental count if phase B leads phase A.
Pulse + direction	Incremental count if phase B is at a high level. Decremental count if phase B is at a low level.	Decremental count if phase B is at a high level. Incremental count if phase B is at a low level.
CW/CCW	Incremental count if it is phase A pulse input. Decremental count if it is phase B pulse input.	Decremental count if it is phase A pulse input. Incremental count if it is phase B pulse input.

- Frequency sampling period
  Used to set the pulse frequency calculation period.
- Input filter time
  Used to set the filter time for input terminal signals. The default is 2 μs, indicating that waveforms below 2 μs are filtered out.

5. External input

Each counter channel can independently configure four digital input terminals. The functions of each terminal are as shown in the table below, where n represents the channel number.

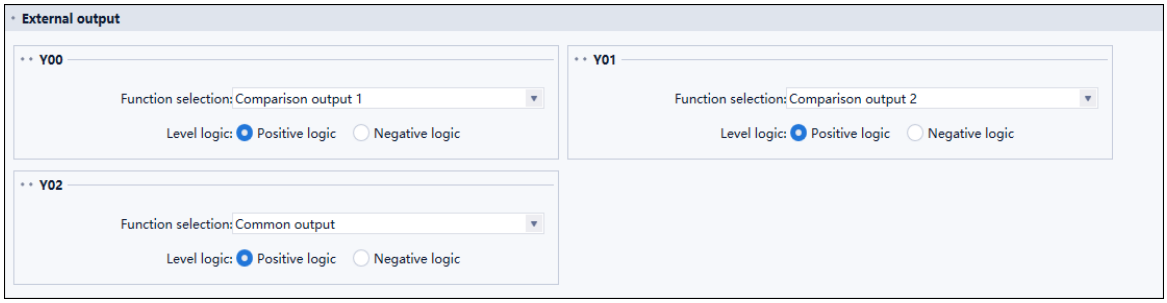


Table16-1-6-4-2 Input terminal function selection

Terminal	Optional Function	Default
Xn0	0: Common input 1: Probe function 1 3: Reset 4: Preset 5: Gating	Probe function 1

Terminal	Optional Function	Default
Xn1	0: Common input 2: Probe function 2 3: Reset 4: Preset 5: Gating	Probe function 2
Xn2	0: Common input 3: Reset 4: Preset 5: Gating	Common input
Xn3	0: Common input 3: Reset 4: Preset 5: Gating	Common input

- Common input
  When the terminal is configured as a common input, the terminal status can be obtained via module I/O mapping or the ENC_ReadStatus instruction.
- Probe function
  When the probe function is configured, the ENC_TouchProbe instruction must be called to latch the position. For details, see the ENC_TouchProbe instruction description.
- Reset function
  When the reset function is configured, the counter value will be cleared upon a valid input signal at the digital input terminal.
- Preset function
  When the preset function is configured, the ENC_Preset instruction must be called to preset the counter. When the input signal of the digital input terminal is active, the counter value will be set to the preset value specified by the Position parameter in the ENC_Preset instruction. If multiple terminals are configured as preset functions, only one terminal signal needs to be active for the preset function to be executed. Digital terminals can be set using the ENC_DigitalOutput instruction.
- Gating function
  When the gating function is configured, the counter starts only when the Enable pin of ENC_Counter is ON and the gating signal is active. If no terminal is configured for gating function, the counter starts as long as the Enable pin of ENC_Counter is set to ON. If multiple terminals configured for gating function, the counter starts only when all gating signals are active simultaneously.

6. External output

- Output terminal function selection

  Output terminal function description (n represents channel number)

Terminal	Optional Function	Default
Yn0	0: Common output 3: One-dimensional comparison output 4: Two-dimensional comparison output (currently not supported)	One-dimensional comparison output
Yn1	Common output	Common output
Yn2	Common output	Common output

- Common output

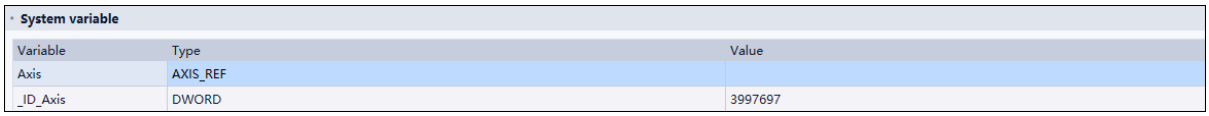
  When the terminal is configured as a common output, the status of the digital output terminal can be controlled via the ENC_DigitalOutput instruction. For specific usage, see 18.3.3.6.9 ENC_DigitalOutput.

- One-dimensional comparison output

  When one-dimensional comparison output is configured, the step comparison output or array comparison output functions can be performed. For specific usage, see 18.3.3.6.10 ENC_Compare, 18.3.3.6.7 ENC_StepCompare, and 18.3.3.6.6 ENC_ArrayCompare.

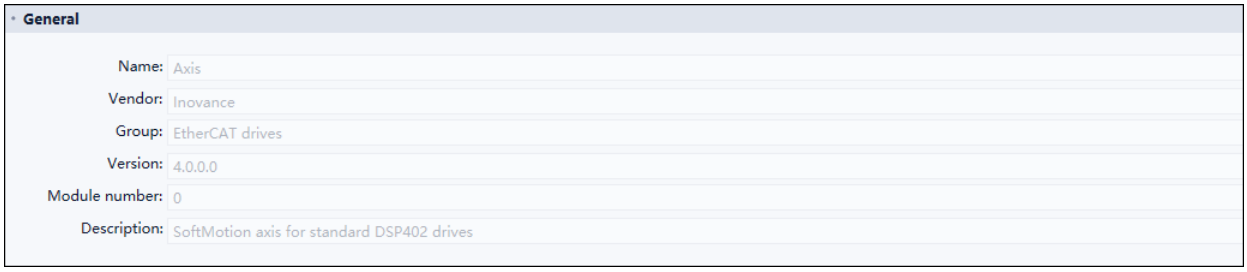
16.1.6.5 Axis Diagnostics

For details, see 16.1.5.6 Axis Diagnostics.



16.1.6.6 I/O Mapping

All task names and bus cycle settings will be displayed in the bus cycle options. For axis objects (including control axes and encoder axes), it is recommended to prioritize the EtherCATMaster_Task**.** Selecting other tasks may result in abnormal conditions such as planned speed jump.

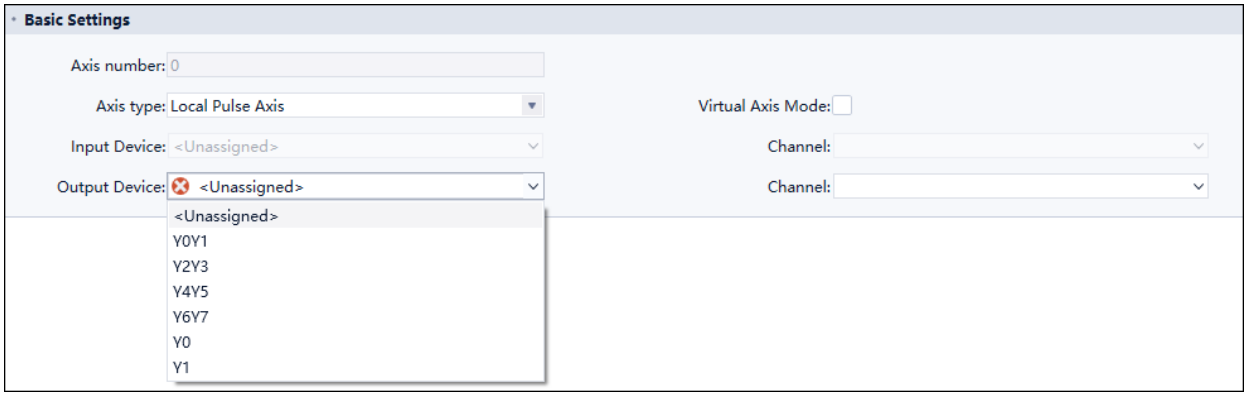


16.1.6.7 System Variables

The "System variable" tab displays the data structure and device ID of the axis.

16.1.6.8 Information

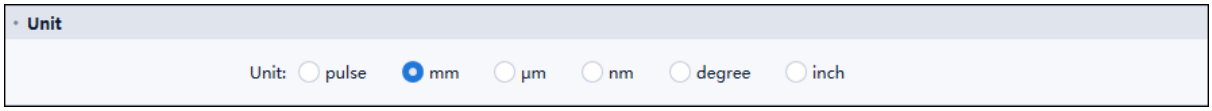
This interface displays basic information about the axis, including name, vendor, group, version, module number, and description.



16.1.7 Local Pulse Axis

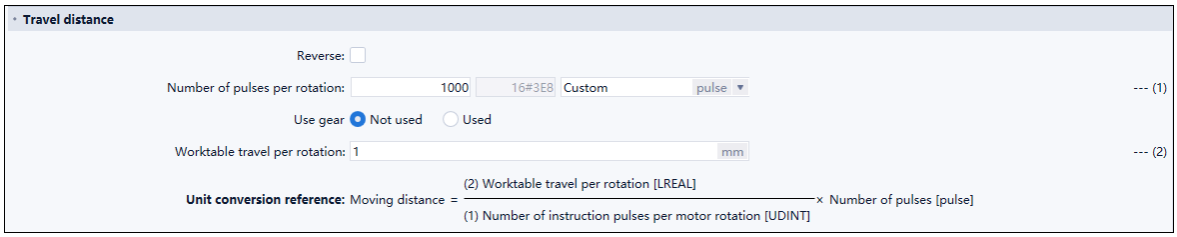
16.1.7.1 Overview

Local pulse axis is controlled using a pulse drive controlled by local high-speed I/O. For dual-end configuration, up to four local pulse axes can be configured: Y0/Y1, Y2/Y3, Y4/Y5, and Y6/Y7. Each pulse output channel can be configured as A/B phase (default to 4-frequency multiplication), pulse + direction, or CW/CCW. Up to two probe terminals can be set per pulse output channel. The local pulse axis supports control in several basic modes such as point, speed, and homing modes. Torque mode is not supported. The parameter configuration and instruction usage of local pulse axes are largely consistent with bus-controlled axes.



16.1.7.2 Basic Axis Settings

After selecting "Local pulse axis" as the axis type, the "Output device" option is activated. Corresponding high-speed I/O terminals can be selected for the output device. Y0 and Y1 can be used as single-ended outputs. The local pulse axis supports a maximum output frequency of 200 kHz. When setting the gear ratio and speed parameters, ensure that the calculated output frequency does not exceed this upper limit.



16.1.7.3 Unit Conversion

- Unit: Conversion between six units, including pulse, millimeter (default), micron, nanometer, degree, and inch. The unit can be configured as needed.

- Travel distance: Conversion between user unit and pulse unit.
  For bus-controlled axes or local pulse axes, the user unit (such as pulse, millimeter, or micron) is used on the instruction side, while the pulse unit is used for actual control of the physical motor. Gear ratio coefficient needs to be configured for unit conversion. The conversion modes are divided into the following scenarios:
  - Gears not used
    When gears are not used, the conversion formula from user unit to pulse unit is as follows:

    Taking the Inovance 20-bit encoder as an example, set the parameters as follows:

    The number of pulses per motor revolution is default to 10#1048576. Number of bits for common encoders can be directly selected, which currently supports 14-bit, 18-bit, 20-bit, 23-bit, and 26-bit encoders. The number of pulses per motor revolution can also be customized, supporting both decimal and hexadecimal input formats. Hexadecimal input requires the "16#" prefix; otherwise, the system will automatically process the value as decimal.

    The working stroke per revolution of the worktable is 1.

    Based on the above parameters, if the target distance input on the relative motion instruction side is 100, the control axis will output an actual pulse count of 104857600, causing the motor to rotate 100 revolutions. Without a reducer, the worktable moves 100 user units.

  - Gears used

    The typical scenario for linear mode is shown in the following figure:

    (1) is the motor, (3) is the workpiece, (4) is the work gear ratio, and (5) is the motor gear ratio.

    The typical scenario for rotary mode is shown in the following figure:

(1) is the motor, (3) is the workpiece, (4) is the work gear ratio, and (5) is the motor gear ratio.

16.1.7.4 Mode/Parameter Settings

1. Basic settings

   - Axis type: Supports rotary mode and linear mode. The linear mode is suitable for motor scenarios involving reciprocating motion, such as lead screws and linear motors. The rotational mode is suitable for motor scenarios involving unidirectional rotation where cumulative position tracking is not required.
   - Ramp velocity: Supports trapezoidal and S-type motion planning. Trapezoidal (T-type) motion planning does not involve jerk parameter. S-type motion planning requires input of jerk parameter.
   - Position hysteresis management: Select "Disable" to turn off the excessive position deviation alarm. Select "Effective" to periodically check whether the deviation exceeds the set hysteresis limit.

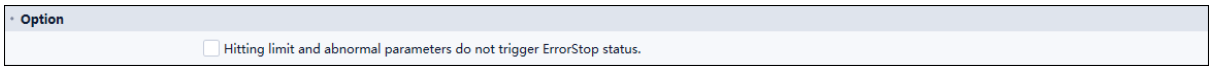
2. Period setting: Used in rotary mode to limit the rotation period.

3. Software limit: Applicable in linear mode. When enabled, it limits the positive and negative positions of the axis.

4. Software limit prediction parameter setting: Configures the axis limit protection by determining the risk between the current position and the limit position.

5. Motion parameter limit: The figure below shows the upper limits for single-axis motion parameters. If the parameters in the motion instruction block exceed these limits, the function block will report a fault.

6. Commissioning parameter limit: The figure below shows the limits for single-axis commissioning parameters. These limits only apply to MC_Jog and MC_Inch instructions, as well as the maximum speeds and acceleration/deceleration of the forward/reverse operations in the "Axis commissioning" function. If the set value exceeds the limit value, the system will operate at the limit value.

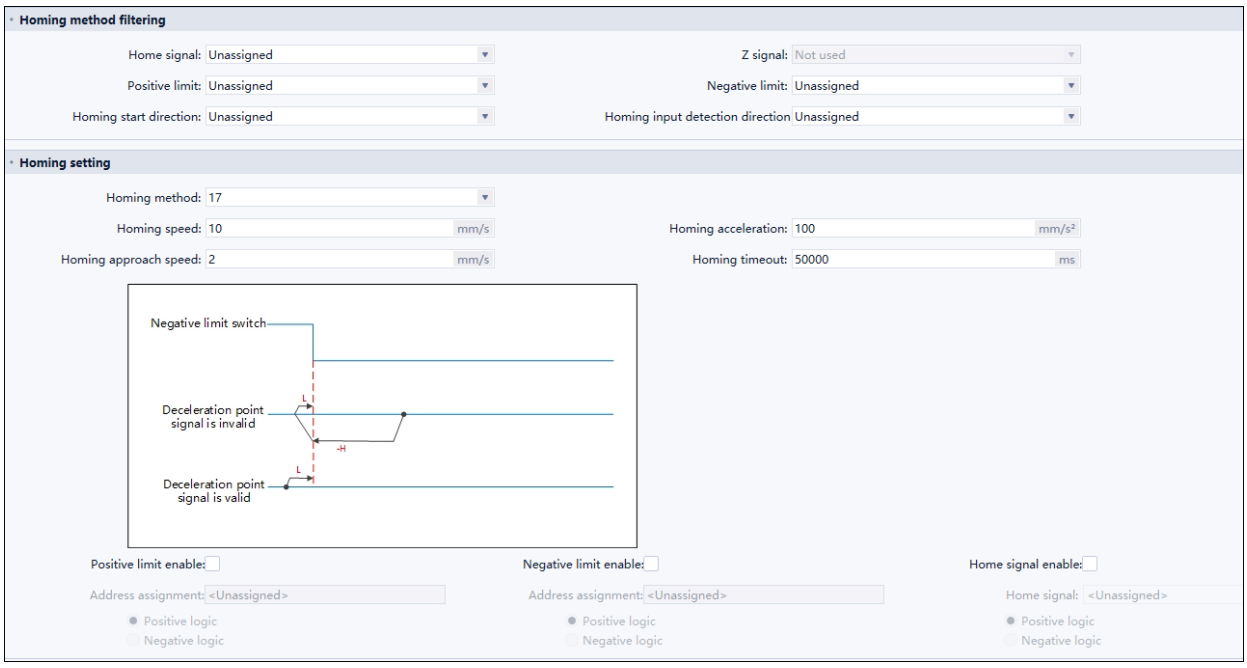


7. Monitor parameter setting

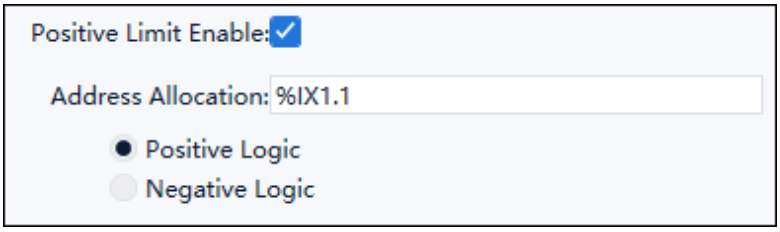
   - Positioning range: Used to set the positioning completion width, in reference units. The value is 0 or a real integer, with a default of 10.
   - Positioning check time: Used to set the positioning completion check time, in ms. The value range is 0 to 10000, with a default of 0. When set to 0, it indicates that the arrival check function is disabled.

8. Option: If enabled, the axis status will not switch to ERRORSTOP upon limit hit or abnormal parameters. Use this option with caution.

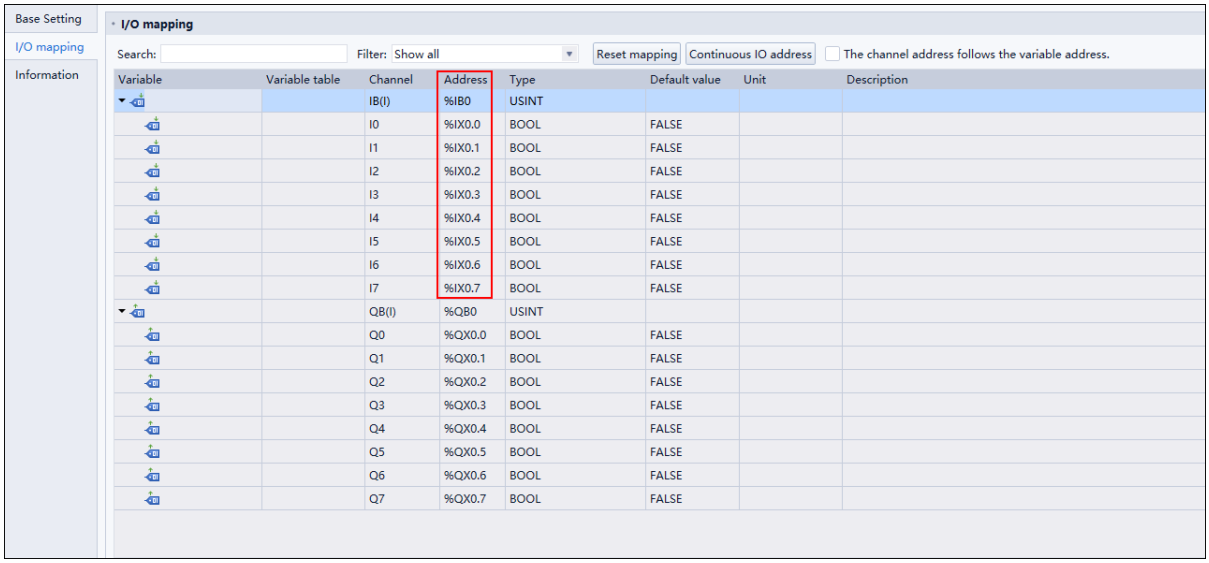
9. Probe setting: After enabling the probe function, select a digital input terminal to work with the MC_TouchProbe instruction for position latching. For detailed usage, see 18.3.3.3.10 MC_TouchProbe.



10. Output setting: Sets pulse output mode. The direction reversal delay time is ineffective.



16.1.7.5 Homing Settings



Homing settings are mainly used for graphical parameter configuration of homing for local pulse axes (as shown in the figure below). Follow the graphical configuration guidance to select the homing mode from the drop-down menu and complete the corresponding parameter configuration. The homing for local pulse axes adopts the method specified in the CiA402 protocol, and supports homing without Z-phase signal.

Since the input signals of local pulse axes are not assigned fixed functions, positive and negative limit signals and home signals need to be bound and enabled through configuration. The configuration is shown in the figure below.

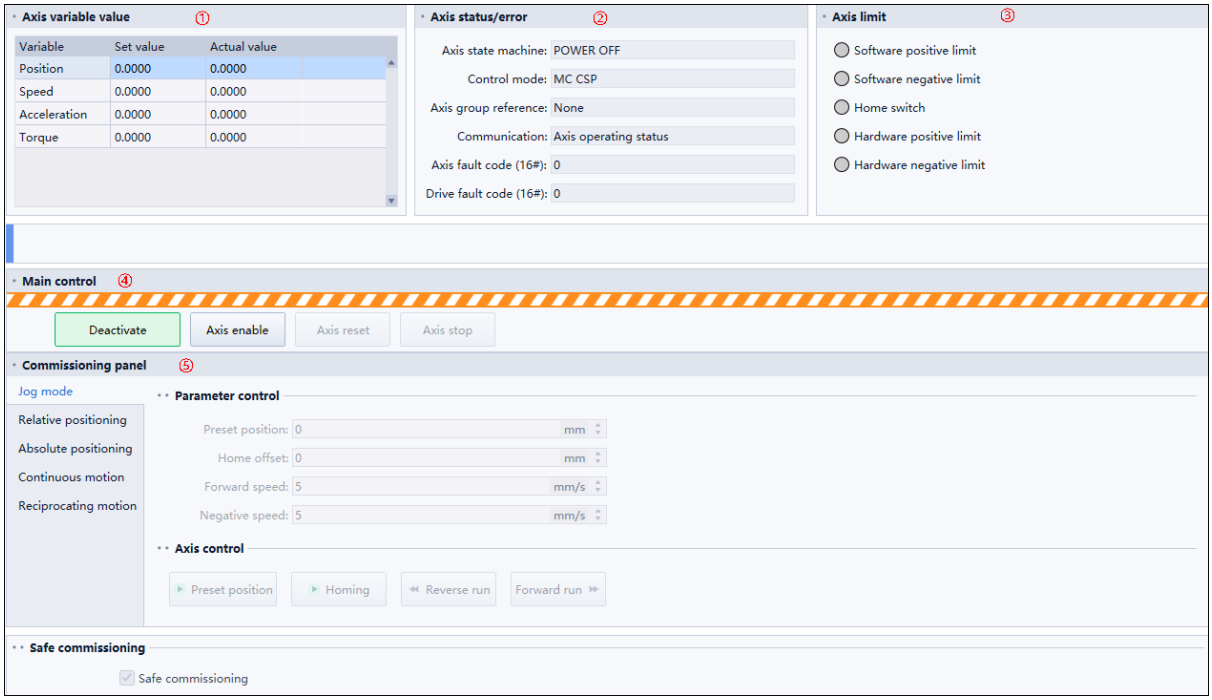
Address allocation can be obtained through device I/O mapping in hardware configuration. As shown in the figure below, for local high-speed I/O, the mapped address of the input can be obtained according to the terminal to be connected.

Variable	Variable table	Channel	Address	Type	Default value	Unit	Description
		IB(I)	%IB0	USINT			
		I0	%IX0.0	BOOL	FALSE		
		I1	%IX0.1	BOOL	FALSE		
		I2	%IX0.2	BOOL	FALSE		
		I3	%IX0.3	BOOL	FALSE		
		I4	%IX0.4	BOOL	FALSE		
		I5	%IX0.5	BOOL	FALSE		
		I6	%IX0.6	BOOL	FALSE		
		I7	%IX0.7	BOOL	FALSE		
		QB(I)	%QB0	USINT			
		Q0	%QX0.0	BOOL	FALSE		
		Q1	%QX0.1	BOOL	FALSE		
		Q2	%QX0.2	BOOL	FALSE		
		Q3	%QX0.3	BOOL	FALSE		
		Q4	%QX0.4	BOOL	FALSE		
		Q5	%QX0.5	BOOL	FALSE		
		Q6	%QX0.6	BOOL	FALSE		
		Q7	%QX0.7	BOOL	FALSE		

NOTE

Controller-based homing is adopted for local pulse axes.

16.1.7.6 Commissioning



Basic functions such as enabling, positioning, reciprocation, homing, and stopping can be achieved through online commissioning. If the axis is connected to a bus stepper drive, the drive must support the relevant functions to perform homing or torque control. After confirming that basic motions are normal, complex motion control can be achieved using motion control function blocks.

NOTE

Axis commissioning and program motion control function blocks cannot be used simultaneously. Axis commissioning has the highest priority. After clicking "Activate commissioning", any execution of motion control function blocks will trigger a fault, and the motion control functions will be invalid. The functions can be used normally again after commissioning is disabled, and the function block is reset and triggered again.

Supported axis types: bus-controlled axes, local pulse axes, and virtual axes.

1. When the device is online and switched to the operational status, the "Activate commissioning" button can be clicked to activate axis commissioning. The interface will be as shown in the figure below.

No.	Description
①	Axis-end information including position, speed, acceleration, and so on.
②	Axis status and drive fault information
③	Axis-end limit terminal status
④	Buttons for activating/deactivating commissioning, enabling axis, resetting axis and stopping axis.
⑤	Jog or other motion mode options

2. Click the "Axis enable" button to enable the axis. You can then view the axis information including the current position, speed, status, and so on.
3. By setting different motion modes and motion parameters, the overall operational status of the servo can be viewed.
4. Safe commissioning: Enabled by default. When axis commissioning is activated, switching pages or closing the commissioning page will force the axis to stop.
   The axis must be stopped in the following cases:
   - The current commissioning page is switched.
   - The current commissioning page is closed.
   - The iFA software is closed.

   The axis will not be stopped in the following cases:
   - The axis commissioning page remains unchanged in multi-view mode.
   - The commissioning page is minimized.

5. Additional notes
   - The commissioning mode is used for axis commissioning. Motion control function blocks in this mode will report a fault.
   - In commissioning mode, the axis will be stopped automatically if the software is closed, the project is switched, or the PLC is re-downloaded and installed.
   - In commissioning mode, the oscilloscope can be used normally.
   - In commissioning mode, the I/O mapping data of all slave modules remain unaffected.
   - During single-axis commissioning, enabling servo commissioning will cause an enabling conflict. The servo commissioning must be disabled before using axis commissioning.
   - In commissioning mode, parameter anomalies and other faults will cause the axis to enter the ERRORSTOP status.

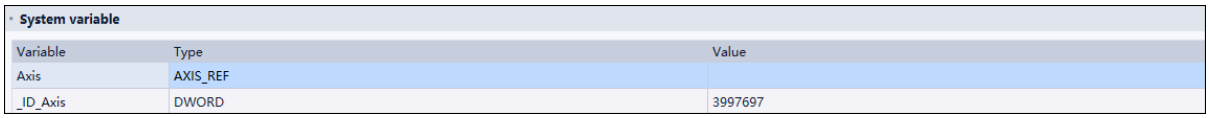
6. Common functions on this interface

Option	Note
Axis variable value	Supports monitoring of set and actual values of axis position, speed, acceleration, and torque.
Axis limit	Displays software positive limit, software negative limit, home switch, hardware positive limit, and hardware negative limit.
Activate commissioning	After the software is online, all parameters on the commissioning interface will be ineffective if this button is not clicked. Once clicked, the "Axis enable" button becomes operable. During axis operation, deactivating commissioning will switch the axis to the power-off status.
Enable axis	Once clicked, the axis status will be switched to StandStill; the jog mode parameters and other mode parameters on the commissioning interface become editable.
Axis reset	If a fault occurs after the axis is enabled, this button can be used to reset the axis.
Axis stop	This button is effective regardless of the motion mode of the axis.
Jog mode	◦ Sets the speed for forward and reverse jogging. The unit is converted according to the settings on the unit conversion interface. ◦ Supports preset value configuration. Input the preset value and click "Settings" to apply it. The unit is converted according to the settings on the unit conversion interface. ◦ Control the jogging direction of the motor by clicking "Jog backward"/"Job forward". ◦ The running parameter for jog mode serves as both the speed parameter and the acceleration parameter.

Option	Note
Other modes	Relative positioning: Parameters include target distance, speed, acceleration, deceleration, and jerk. Absolute positioning: Parameters include target distance, speed, acceleration, deceleration, and jerk. Continuous motion: Parameters include target speed, acceleration, deceleration, and jerk. Reciprocating motion: Parameters include two sets of target positions. Torque control: Parameters include target torque, torque ramp, and limited speed.

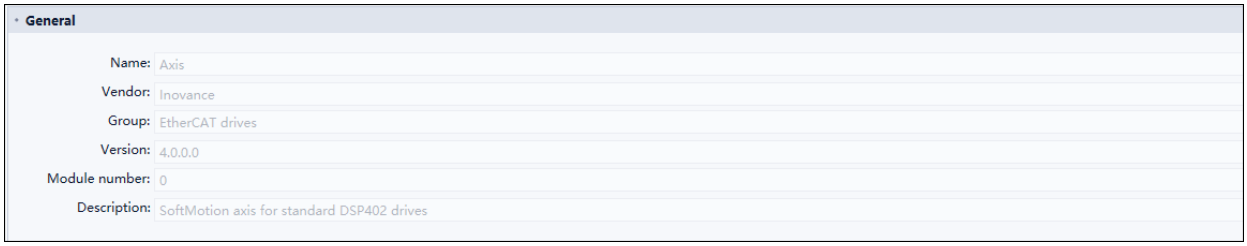
16.1.7.7 Axis Diagnostics

For details, see 16.1.5.6 Axis Diagnostics.



16.1.7.8 I/O Mapping

All task names and bus cycle settings will be displayed in the bus cycle options. For axis objects (including control axes and encoder axes), it is recommended to prioritize the EtherCATMaster_Task**.** Selecting other tasks may result in abnormal conditions such as planned speed jump.

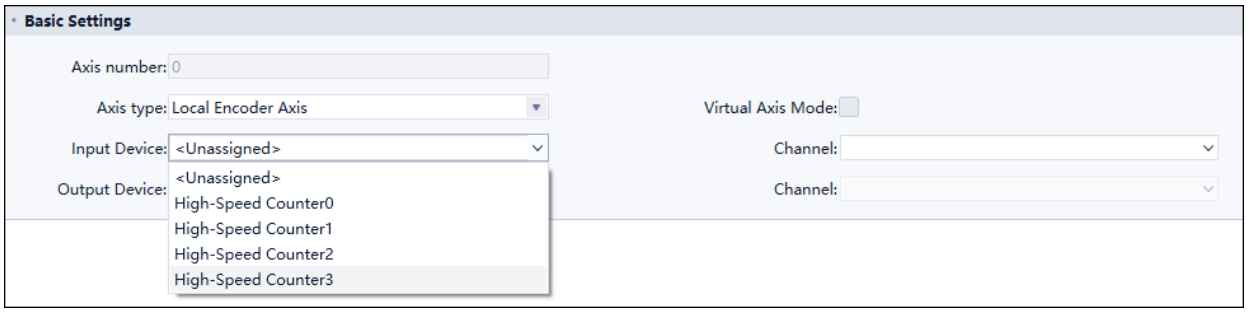


16.1.7.9 System Variables

The "System variable" tab displays the data structure and device ID of the axis.

16.1.7.10 Information

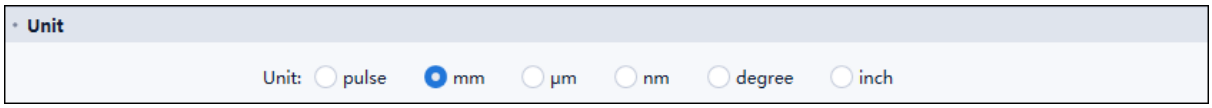
This interface displays basic information about the axis, including name, vendor, group, version, module number, and description.



16.1.8 Local Encoder Axis

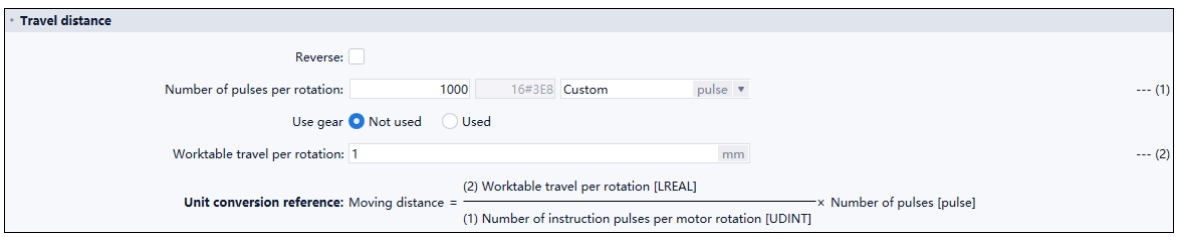
16.1.8.1 Overview

Axes associated with counters are referred to as counter axes. The system supports 4-axis 32-bit high-speed counters, which can realize phase A/B frequency multiplication by 1/2/4, CW/CCW, pulse + direction, and single-phase counting. Counting signal sources are external pulse input or internal 1 ms/1 μs clock counting, which can be used to preset and latch the counter in combination with other input signals.



16.1.8.2 Basic Axis Settings

After selecting "Local encoder axis" as the axis type, the "Input device" option is activated. The input device can be selected as 4-channel high-speed counters. After selecting the high-speed counter, set "Signal source" to the I/O terminal corresponding to the A/B phase on the "Mode/Parameter setting" tab page.

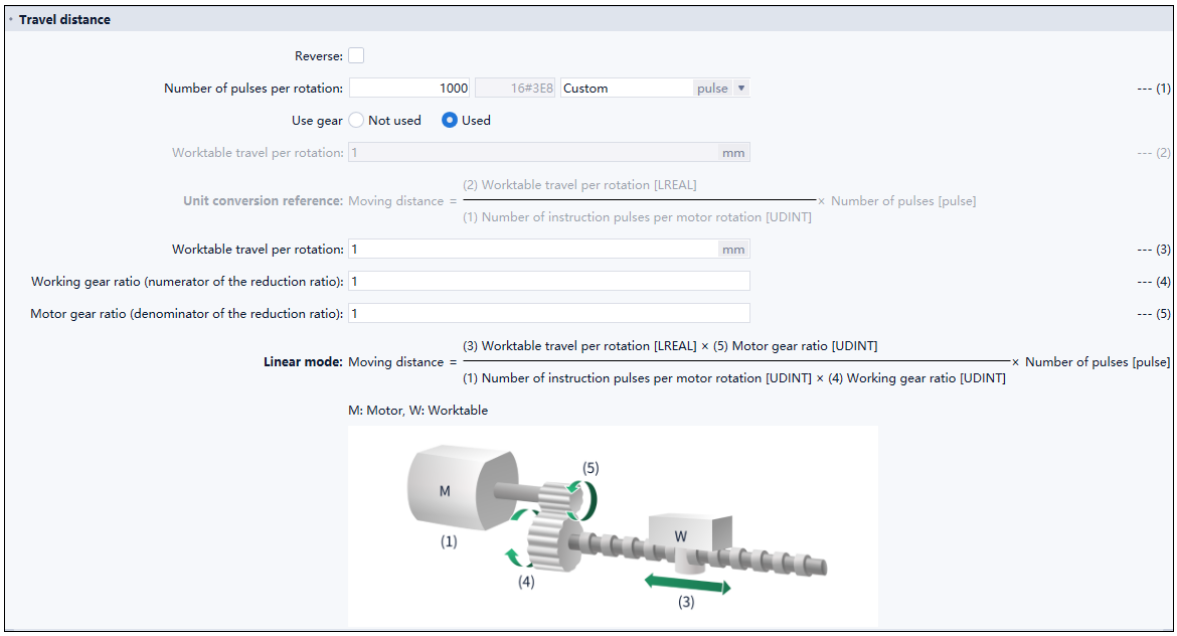


16.1.8.3 Unit Conversion

- Unit: Conversion between six units, including pulse, millimeter (default), micron, nanometer, degree, and inch. The unit can be configured as needed.

- Travel distance: Conversion between user unit and pulse unit.
  For bus-controlled axes or local pulse axes, the user unit (such as pulse, millimeter, or micron) is used on the instruction side, while the pulse unit is used for actual control of the physical motor. Gear ratio coefficient needs to be configured for unit conversion. The conversion modes are divided into the following scenarios:
  - Gears not used
    When gears are not used, the conversion formula from user unit to pulse unit is as follows:

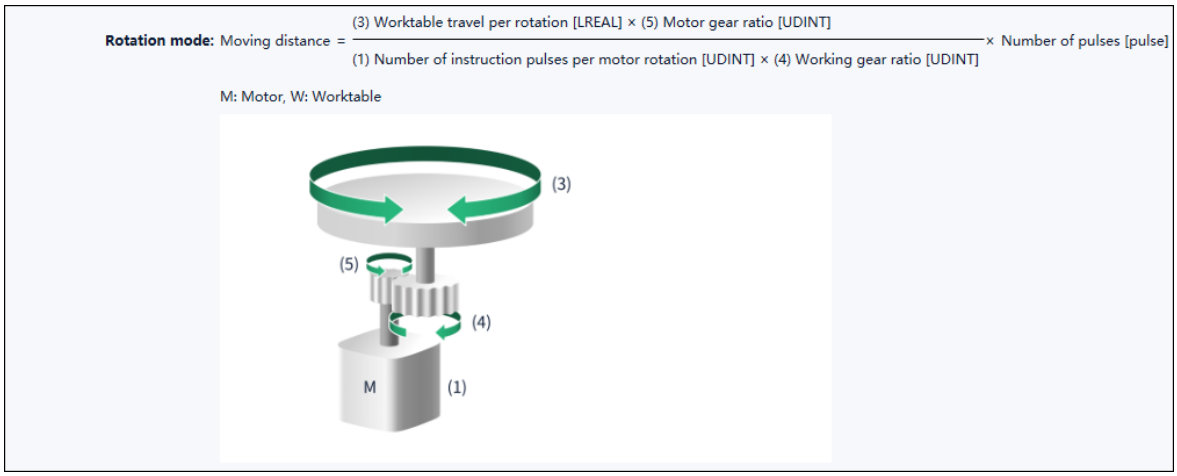
    Taking the Inovance 20-bit encoder as an example, set the parameters as follows:



The number of pulses per motor revolution is default to 10#1048576. Number of bits for common encoders can be directly selected, which currently supports 14-bit, 18-bit, 20-bit, 23-bit, and 26-bit encoders. The number of pulses per motor revolution can also be customized, supporting both decimal and hexadecimal input formats. Hexadecimal input requires the "16#" prefix; otherwise, the system will automatically process the value as decimal.

The working stroke per revolution of the worktable is 1.

Based on the above parameters, if the target distance input on the relative motion instruction side is 100, the control axis will output an actual pulse count of 104857600, causing the motor to rotate 100 revolutions. Without a reducer, the worktable moves 100 user units.

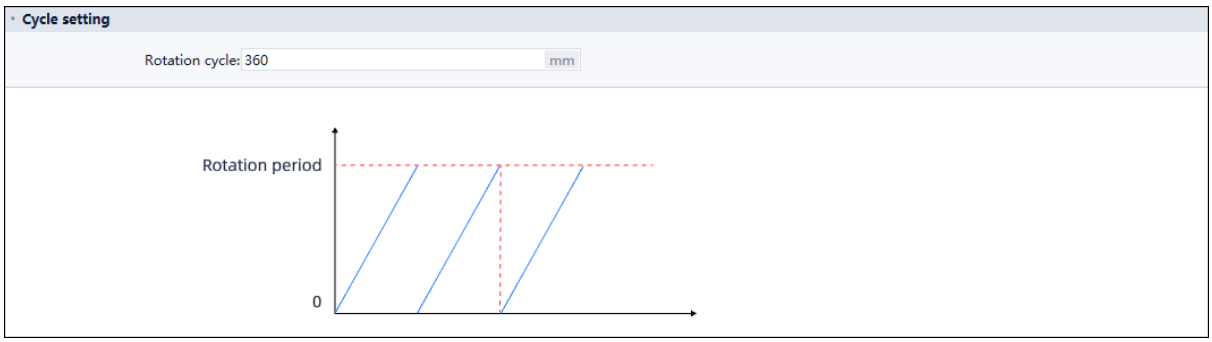


- Gears used

  The typical scenario for linear mode is shown in the following figure:

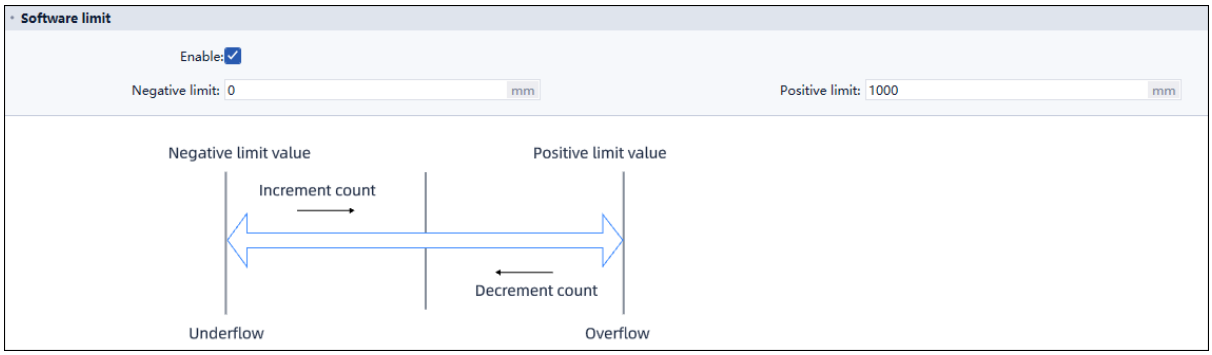
(1) is the motor, (3) is the workpiece, (4) is the work gear ratio, and (5) is the motor gear ratio.

The typical scenario for rotary mode is shown in the following figure:



(1) is the motor, (3) is the workpiece, (4) is the work gear ratio, and (5) is the motor gear ratio.

16.1.8.4 Mode/Parameter Settings



1. Mode setting

2. Period setting: Used in rotary mode to limit the rotation period. The counter counts reciprocally between 0 and the rotation period.

3. Software limit: Used to set whether to enable software limits in linear mode. After enabling the software limit, the positive limit value and negative limit value can be set. When the counter reaches the limit value, counting stops, and the PostiveLimit or NegativeLimit flag in the ENC_Counter instruction is set. When software limit is disabled, the module's count value cycles within the range of -2147483648 to 2147483647. When forward counting reaches the maximum positive value, it directly jumps to the maximum negative value and continues counting. The reverse is the same.

4. Counter mode setting

   - Counting mode

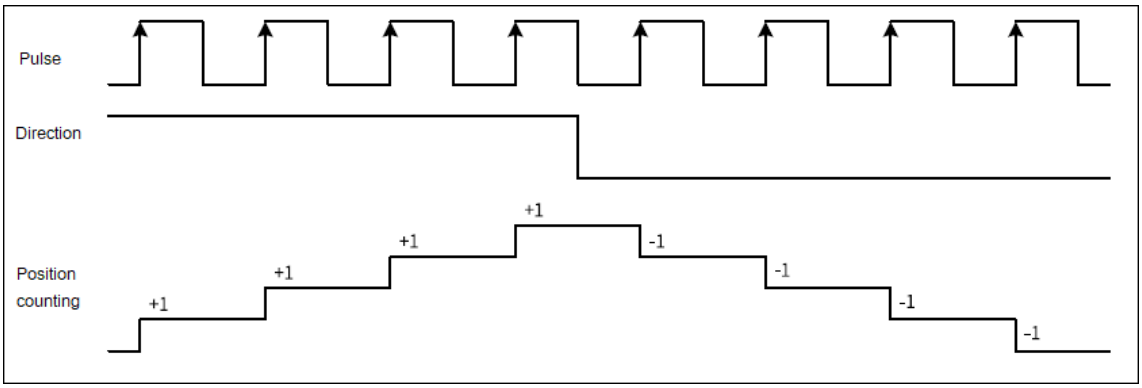
     Six count modes are supported: phase A/B 1-frequency multiplication, phase A/B 2-frequency multiplication, phase A/B 4-frequency multiplication, pulse+direction, CW/CCW, and single-phase counting.

     - Phase A/B pulse

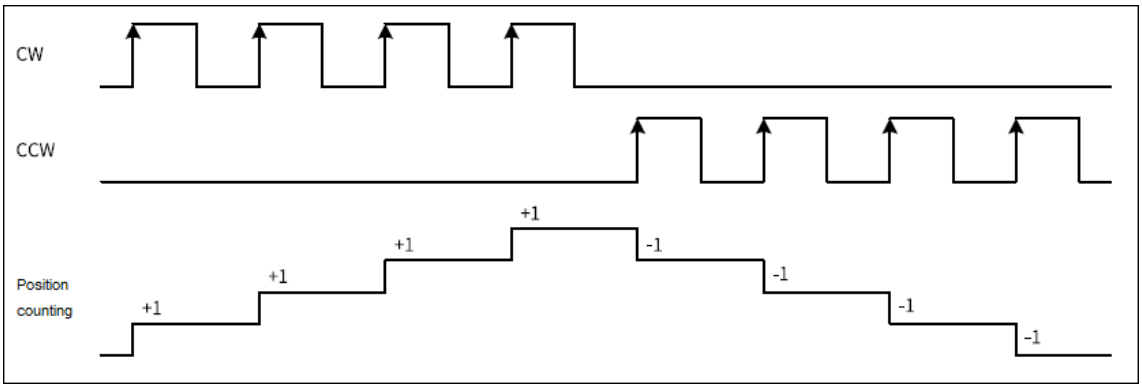
       In phase A/B mode, the encoder generates two orthogonal phase pulse signals with a phase difference of 90°, that is, phase A signal and phase B signal. When the phase A signal leads the phase B signal, the counter counts up; when the phase B signal leads the phase A signal, the counter counts down. The phase A/B pulse can be set to operate in frequency multiplication by 1, 2, or 4.

       In the mode of phase A/B frequency multiplication by 1, only the rising edge of phase A pulse is counted as shown in the following figure.

In the mode of phase A/B frequency multiplication by 2, the rising and falling edges of phase A pulse are counted as shown in the following figure.

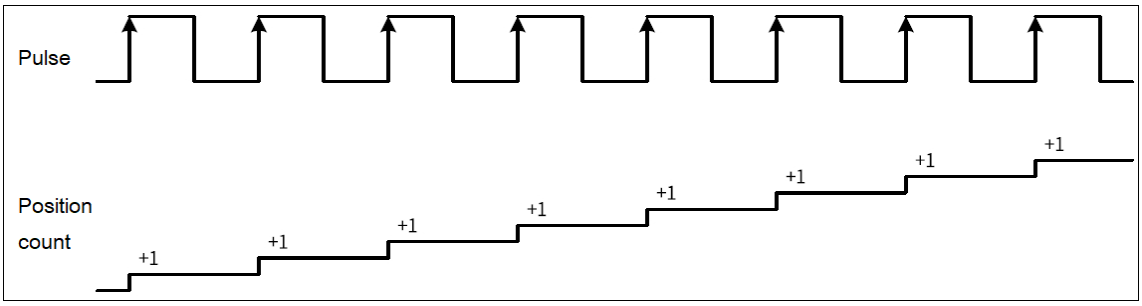


When set to A/B phase 4-frequency multiplication, counting is performed on the rising and falling edges of both the A-phase and B-phase pulses, as shown in the figure below.



- Pulse + direction

  Phase A serves as the pulse input for the counter, and phase B serves as the direction control input for the counter. When the B-phase signal is at high level, the counter increments; when it is at low level, the counter decrements.



- CW/CCW mode

  Clock Wise (CW) is the forward pulse signal, and Counter Clock Wise (CCW) is the reverse pulse signal. When the encoder is forward running, CW pulse signals are output; when the encoder is reverse running, CCW pulse signals are output.

- Single-phase counting

  In this mode, the high-speed counter counts up the pulse signals. The position count is added with 1 when the rising edge of a pulse is input.

◦ Signal source

Different signal sources can be selected depending on the counting mode. The supported input/output terminals of signal sources in various counting modes are shown in the following table.

Table16-1-8-4-1 Signal source and counting mode

Counting Mode	X0	X1	X2	X3	X4	X5	X6	X7	Internal 1 ms	Internal 1 μs
Phase A/B	Phase A	Phase B	Phase A	Phase B	Phase A	Phase B	Phase A	Phase B	x	x
CW/CCW	CW	CCW	CW	CCW	CW	CCW	CW	CCW	x	x
Pulse + direction	Pulse	Direction	Pulse	Direction	Pulse	Direction	Pulse	Direction	x	x
Single-phase counting	Pulse	Pulse	Pulse	Pulse	Pulse	Pulse	Pulse	Pulse	Pulse	Pulse

5. Reset setting

When the reset function is configured, the counter value will be cleared upon a valid input signal at the digital input terminal.

6. Probe setting

For local encoder axes, each axis supports one channel of probe signal. It must be used in conjunction with the ENC_TouchProbe instruction for position latching.

7. Preset setting

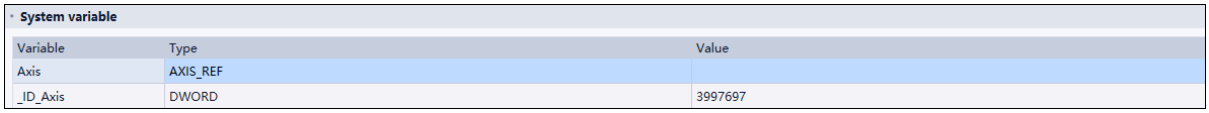
When a terminal is allocated with the preset function, you need to call the instruction ENC_Preset to implement the counter preset function. When the input signal of the DI terminal is active, the value of the counter will be set to the preset value of parameter Position of the instruction ENC_Preset.

8. Compare output setting

The comparison output function provides high real-time performance with output response reaching the millisecond level. Output terminals Y0 to Y3 all support the comparison output function. Each encoder axis can be configured with one channel of comparison output function. The comparison output function can be used in conjunction with the ENC_Compare, ENC_ArrayCompare, or ENC_StepCompare instructions. The duration of the output terminal can be set in either pulse units or time units. When the time unit is set to ms, the configurable range is 0.1 to 6553.5 ms. When the time unit is set to Unit, the configurable range is 1 to 65535 Unit.

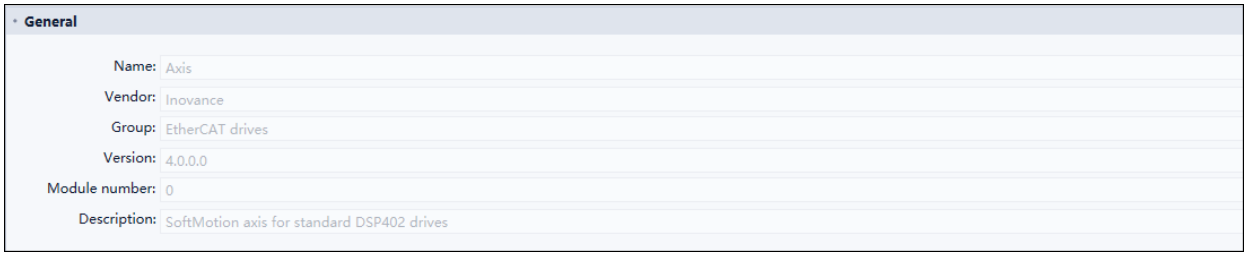
16.1.8.5 Axis Diagnostics

For details, see 16.1.5.6 Axis Diagnostics.



16.1.8.6 I/O Mapping

All task names and bus cycle settings will be displayed in the bus cycle options. For axis objects (including control axes and encoder axes), it is recommended to prioritize the EtherCATMaster_Task**.** Selecting other tasks may result in abnormal conditions such as planned speed jump.



16.1.8.7 System Variables

The "System variable" tab displays the data structure and device ID of the axis.

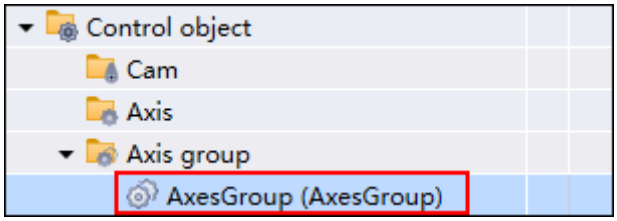
16.1.8.8 Information

This interface displays basic information about the axis, including name, vendor, group, version, module number, and description.

16.2 Axis Group Configuration

16.2.1 Adding an Axis Group

Prerequisites

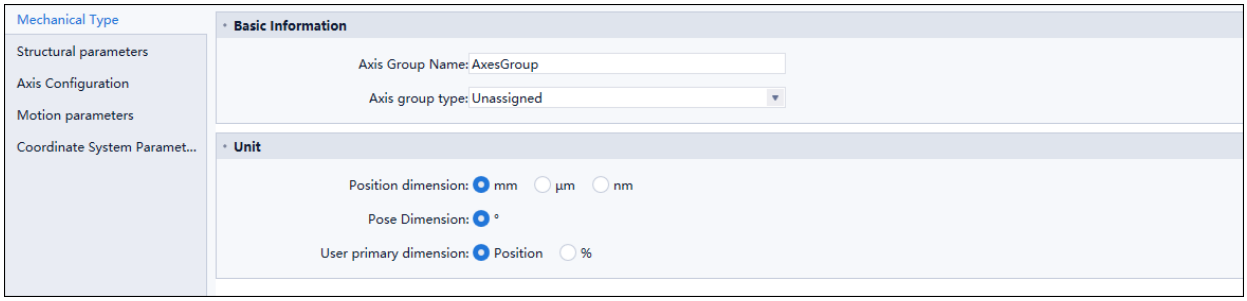


- Hardware configuration has been set up.
- Corresponding drives and axes have been added.

Procedure

1. Click "Control object" in the left project tree to expand the control object list.
2. Right-click "Axis group" and select "Add axis group". The "Add axis group" dialog box appears.
3. Enter the name of the axis group and click "OK".

Result



The newly created axis group can be seen under the axis group directory.

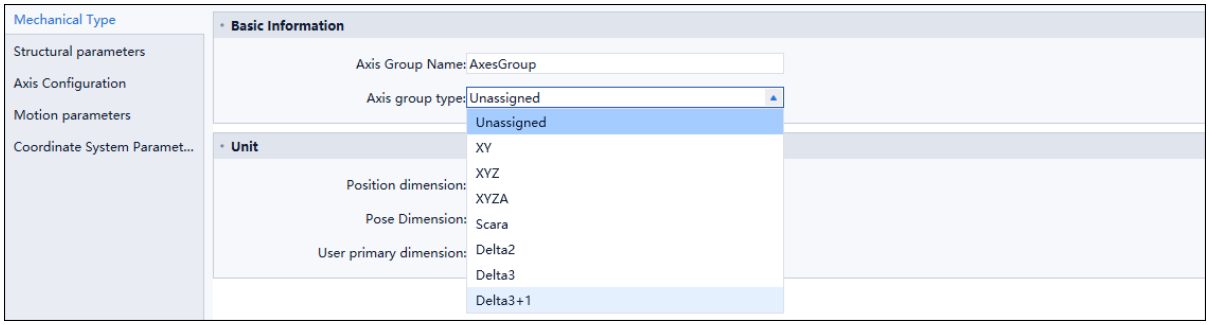
16.2.2 Axis Group Parameter Settings

16.2.2.1 Mechanical Types

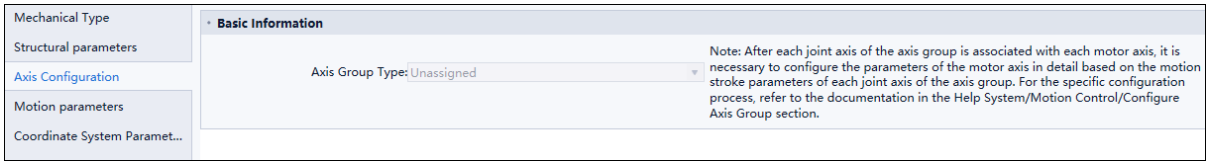
Double-click the axis group added in the left project tree to open the configuration interface.

Axis group type description

Axis Group Type	Motion Position Parameter				Coordinate System Type (CoordSystem)	
	Absolute Position (ACS/PCS)	Relative Position (ACS/PCS)	Auxiliary Point (PCS)	End Point (PCS)	ACS	PCS
Planar XY	Position/ Velocity/ Acceleration[1] Position/ Velocity/ Acceleration[2]	Distance[1] Distance[2]	AuxPoint[1] AuxPoint[2]	EndPoint[1] EndPoint[2]	A1 A2	X Y
Cartesian XYZ	Position/ Velocity/ Acceleration[1] Position/ Velocity/ Acceleration[2] Position/ Velocity/ Acceleration[3]	Distance[1] Distance[2] Distance[3]	AuxPoint[1] AuxPoint[2] AuxPoint[3]	EndPoint[1] EndPoint[2] EndPoint[3]	A1 A2 A3	X Y Z



Cartesian XYZA	Position/ Velocity/ Acceleration[1] Position/ Velocity/ Acceleration[2] Position/ Velocity/ Acceleration[3] Position/ Velocity/ Acceleration[4]	Distance[1] Distance[2] Distance[3] Distance[4]	AuxPoint[1] AuxPoint[2] AuxPoint[3] AuxPoint[4]	EndPoint[1] EndPoint[2] EndPoint[3] EndPoint[4]	A1 A2 A3 A4	X Y Z A
SCARA	Position/ Velocity/ Acceleration[1] Position/ Velocity/ Acceleration[2] Position/ Velocity/ Acceleration[3] Position/ Velocity/ Acceleration[4]	Distance[1] Distance[2] Distance[3] Distance[4]	AuxPoint[1] AuxPoint[2] AuxPoint[3] AuxPoint[4]	EndPoint[1] EndPoint[2] EndPoint[3] EndPoint[4]	A1 A2 A3 A4	X Y Z A
Delta2	Position/ Velocity/ Acceleration[1] Position/ Velocity/ Acceleration[2]	Distance[1] Distance[2]	AuxPoint[1] AuxPoint[2]	EndPoint[1] EndPoint[2]	A1 A2	X Y

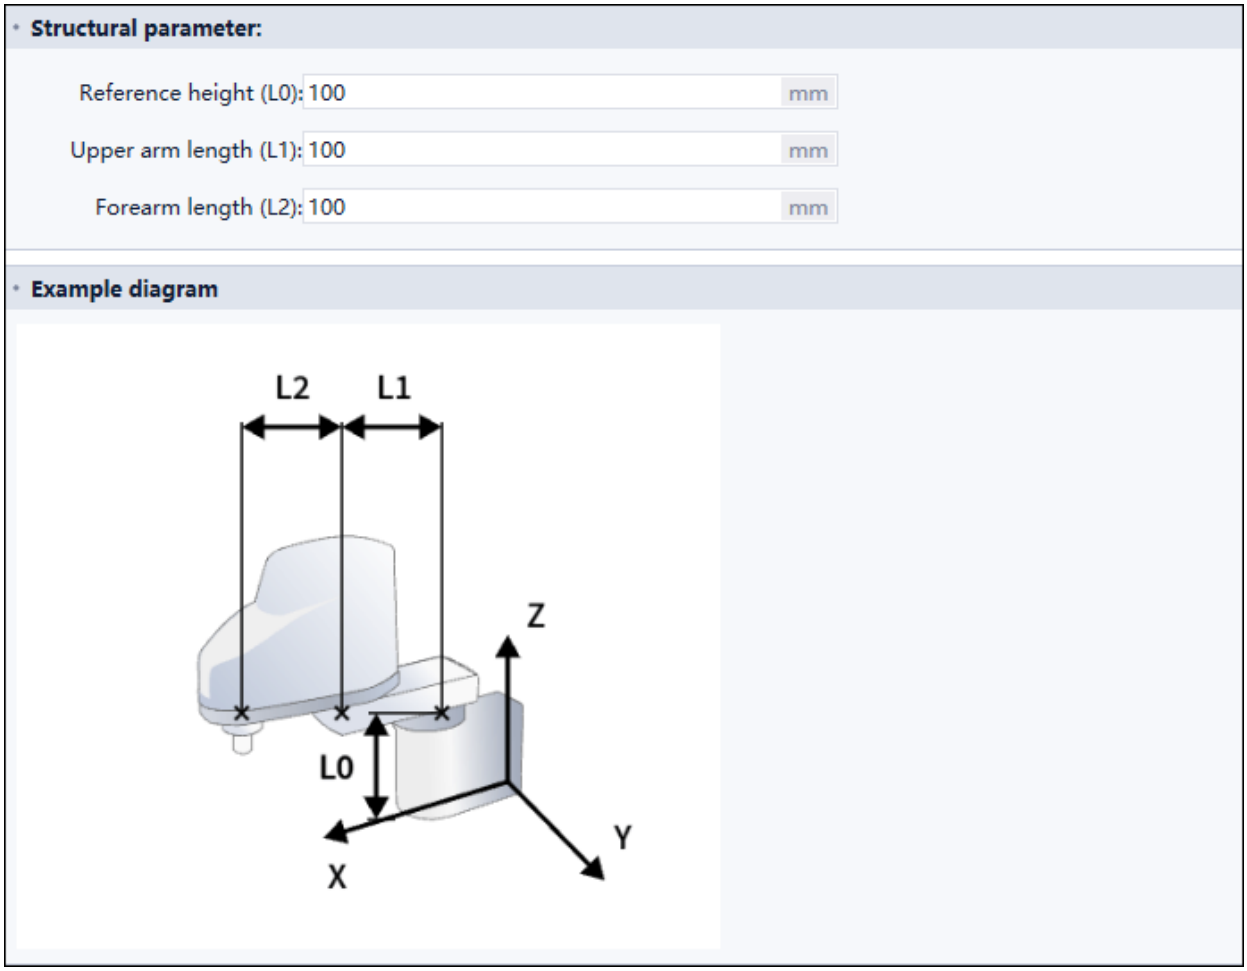


Delta3	Position/ Velocity/ Acceleration[1] Position/ Velocity/ Acceleration[2] Position/ Velocity/ Acceleration[3]	Distance[1] Distance[2] Distance[3]	AuxPoint[1] AuxPoint[2] AuxPoint[3]	EndPoint[1] EndPoint[2] EndPoint[3]	A1 A2 A3	X Y Z
Delta3+1	Position/ Velocity/ Acceleration[1] Position/ Velocity/ Acceleration[2] Position/ Velocity/ Acceleration[3] Position/ Velocity/ Acceleration[4]	Distance[1] Distance[2] Distance[3] Distance[4]	AuxPoint[1] AuxPoint[2] AuxPoint[3] AuxPoint[4]	EndPoint[1] EndPoint[2] EndPoint[3] EndPoint[4]	A1 A2 A3 A4	X Y Z A

NOTE

- The A-axis motion parameter values set for AuxPoint[4] do not participate in pose planning.
- The motion parameters of each joint axis set in the ACS space must be within the corresponding software limit range.
- The A-axis motion parameters set in the PCS space must be within ±180°.
- The HIC configuration is user-defined that supports axis groups consisting of 2 to 6 axes. It is recommended to use it with the "CmpHCInterpolator" library. Users can also call this axis group to control the motion of individual axes within the group based on the forward and inverse kinematics of the user-defined axis group.

Note: The "Axis group type" must be set; otherwise, the axes in the axis group cannot be configured. If the "Axis group type" is SCARA, Delta2, Delta3, or Delta3+1, the MC_SetPosition or MC_Home instruction must be used before executing the MC_GroupEnable instruction to set the position of each joint axis within the selected configuration range.

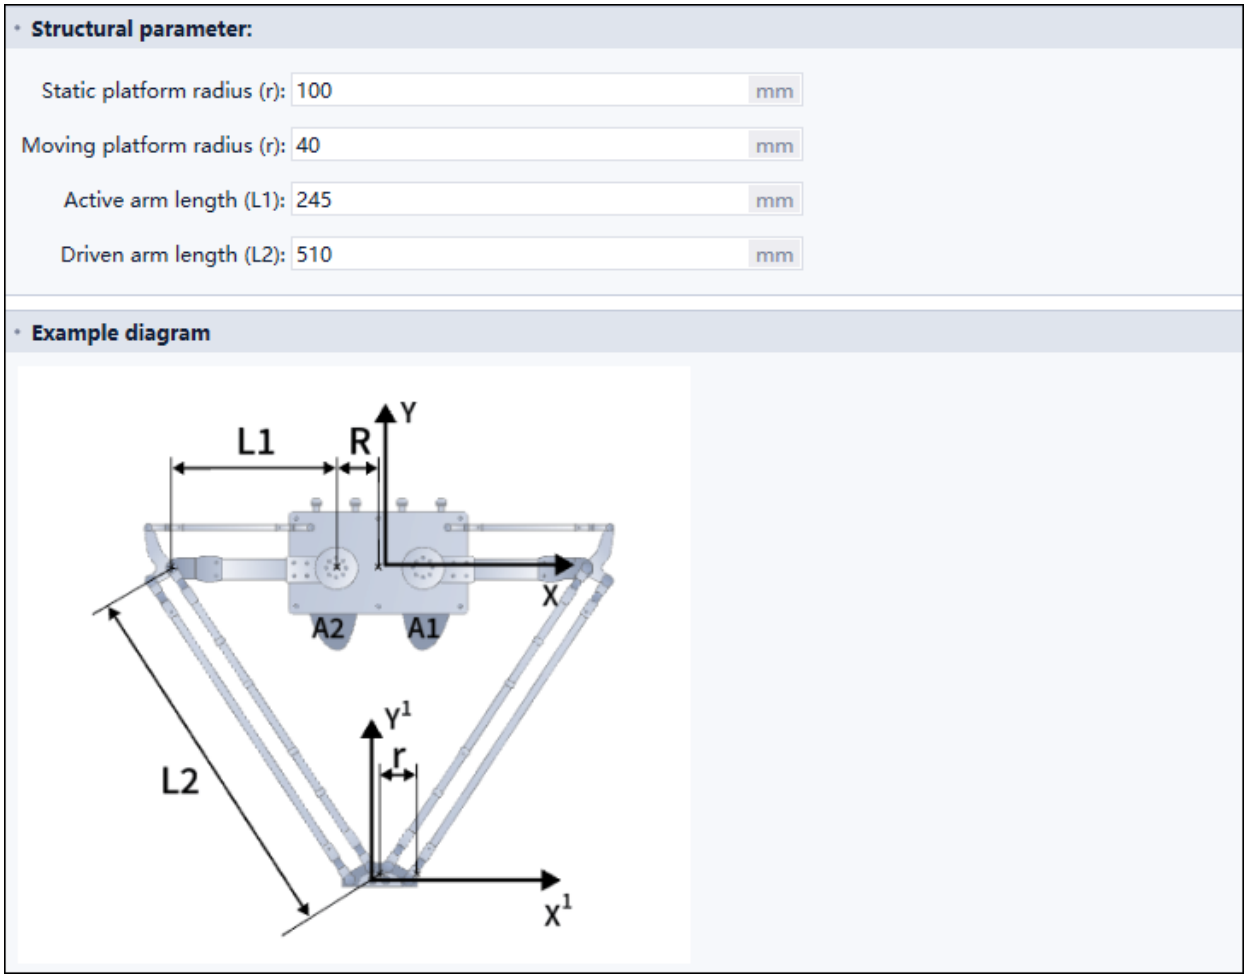


Option	Note
Axis group name	The set axis group name is displayed in the project tree.
Axis group type	Includes Planar XY, Cartesian XYZ, Cartesian XYZA, SCARA, Delta2, Delta3, and Delta3+1.
Unit	• Position dimension: Units include millimeters (default), micrometers, and nanometers. • Pose dimension: Unit is degrees. • User primary dimension: Units include position (default) and percentage. When set to "Position", the parameters (such as speed and acceleration) in the axis group motion instructions are input in the unit of position/ms. When set to "%", the parameters in the motion instructions are input as the product of the maximum parameter value set in the axis group and the input percentage.

16.2.2.2 Structural Parameters

- When the axis group type is set to SCARA, the following structural parameters shall be configured: reference height (L0), active arm length (L1), and driven arm length (L2).

- When the axis group type is set to Delta2, the following structural parameters shall be configured: static platform radius (R), moving platform radius (r), active arm length (L1), and driven arm length (L2). The structural parameters of Delta2 must satisfy the following constraints:
  - Structural parameters must be greater than 0.



$$R>0, r>0, L_1>0, L_2>0$$

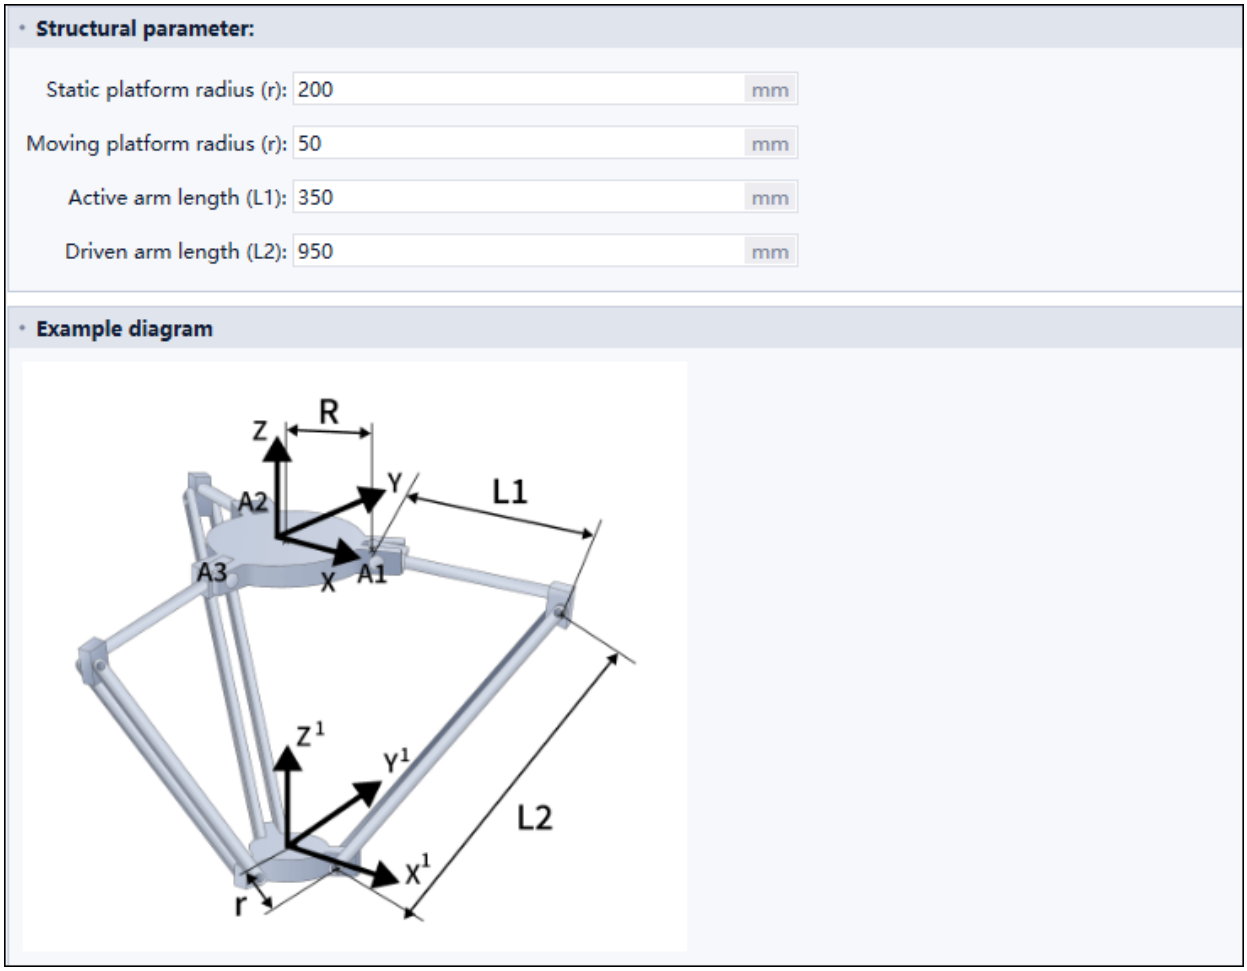
  - The static platform radius must be greater than the moving platform radius.

$$R>r$$

  - The difference between the driven arm length and the active arm length must be greater than the difference between the static platform radius and the moving platform radius.

$$L_2>(L_1+R-r)$$

- When the axis group type is set to Delta3, the following structural parameters shall be configured: static platform radius (R), moving platform radius (r), active arm length (L1), and driven arm length (L2). The structural parameters of Delta3 must satisfy the following constraints:
  - Structural parameters must be greater than 0.



$$R>0, r>0, L_1>0, L_2>0$$

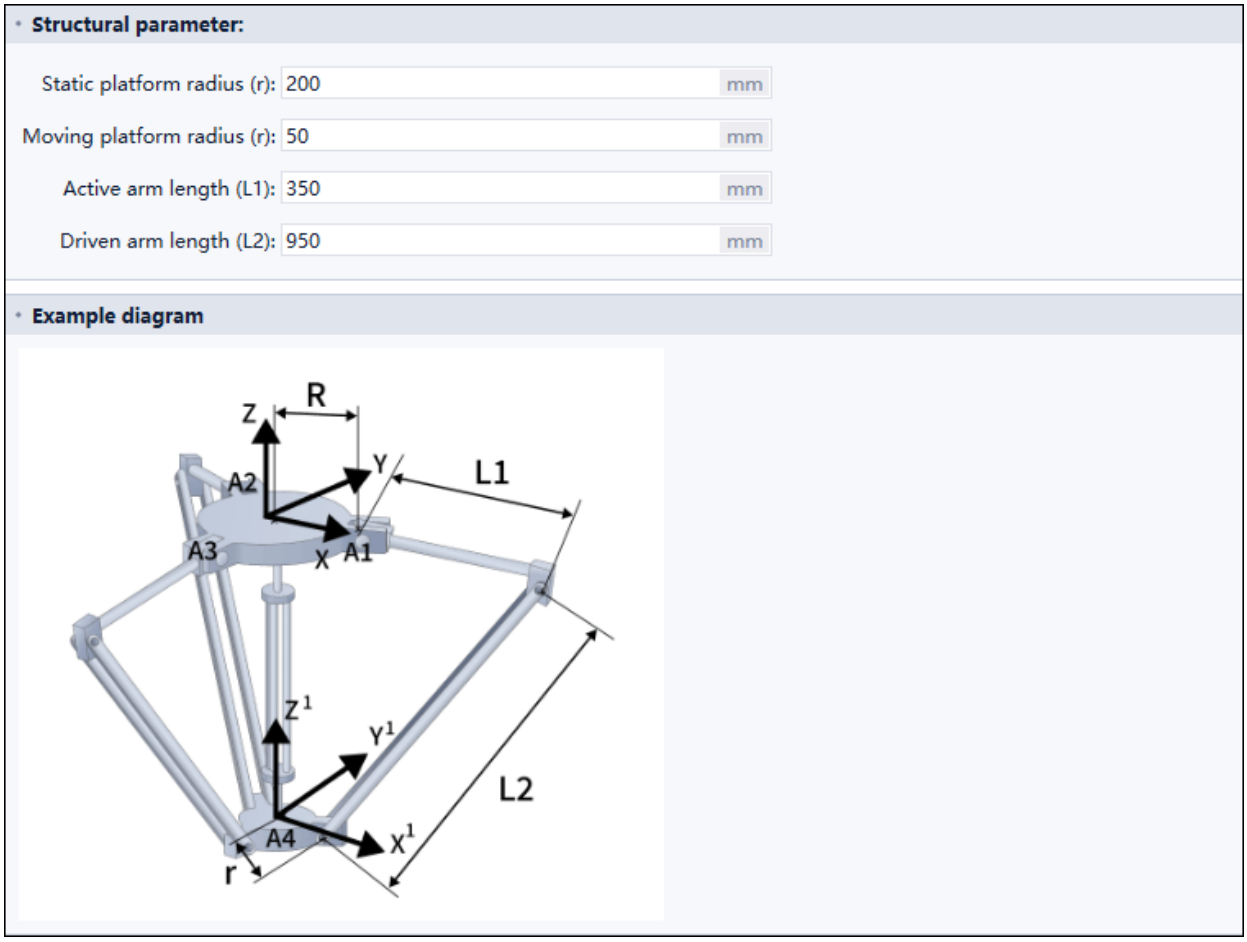
  - The static platform radius must be greater than the moving platform radius.

$$R>r$$

  - The difference between the driven arm length and the active arm length must be greater than the difference between the static platform radius and the moving platform radius.

$$L_2>(L_1+R-r)$$

- When the axis group type is set to Delta3+1, the following structural parameters shall be configured: static platform radius (R), moving platform radius (r), active arm length (L1), and driven arm length (L2). The structural parameters of Delta3+1 must satisfy the following constraints:
  - Structural parameters must be greater than 0.



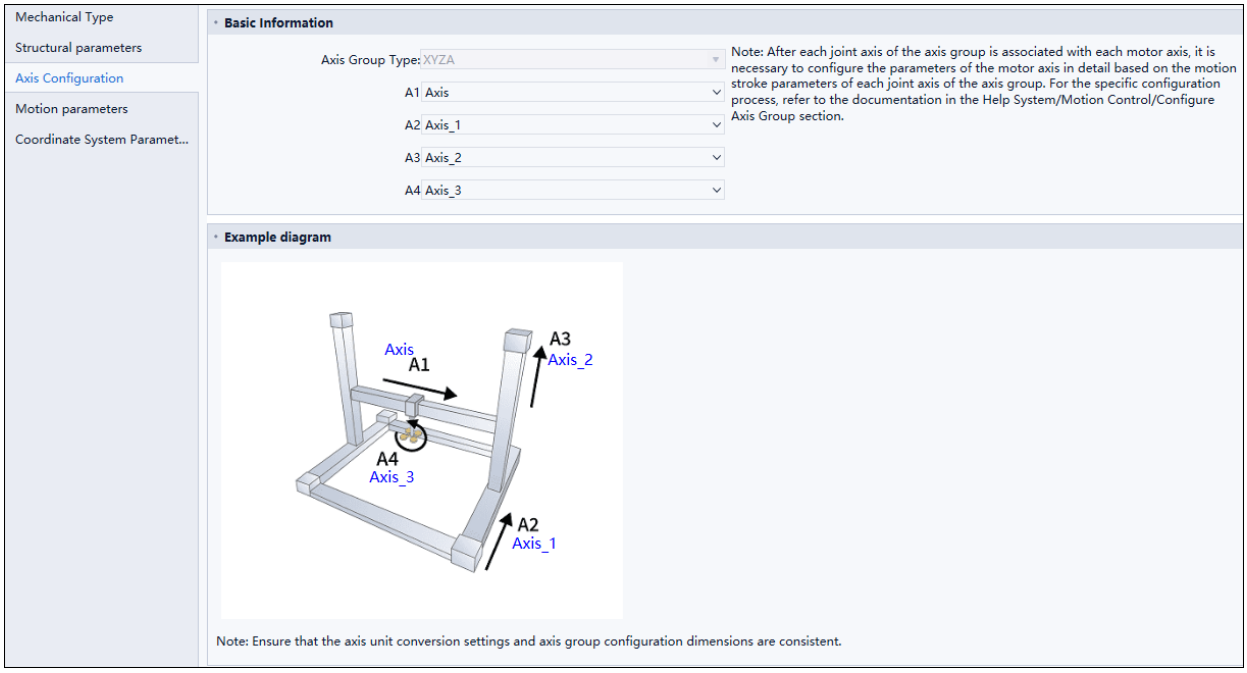
$$R>0, r>0, L_1>0, L_2>0$$

  - The static platform radius must be greater than the moving platform radius.

$$R>r$$

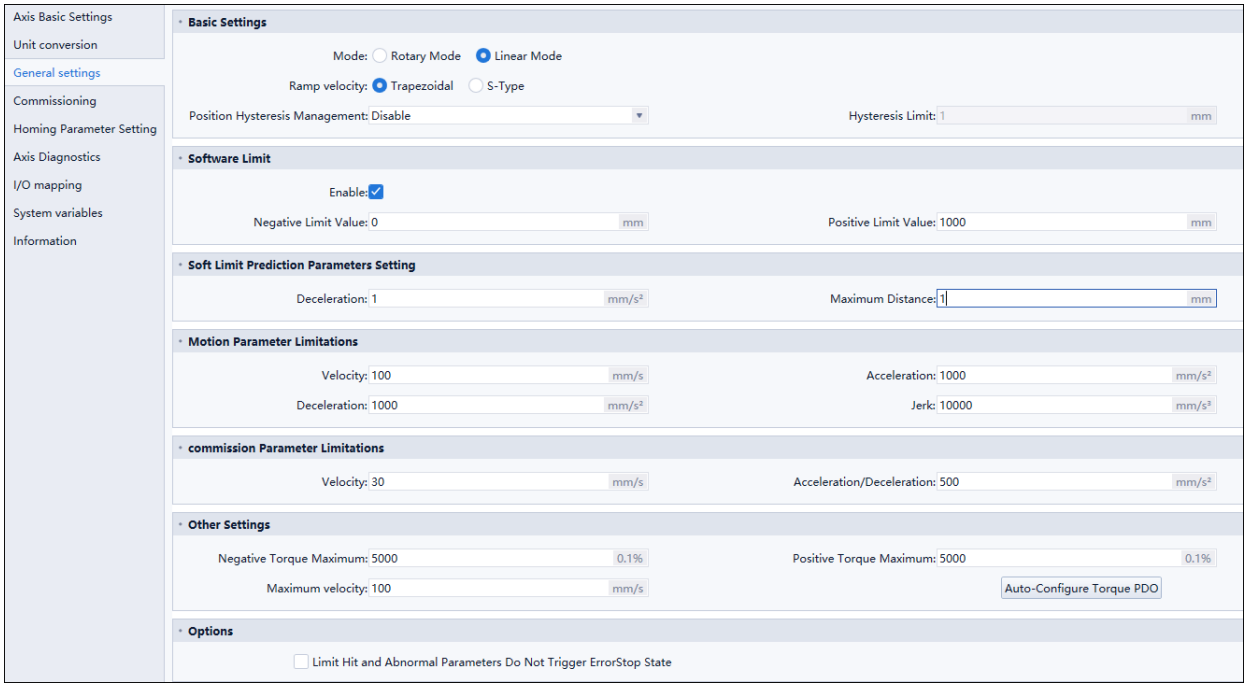
  - The difference between the driven arm length and the active arm length must be greater than the difference between the static platform radius and the moving platform radius.

$$L_2>(L_1+R-r)$$



16.2.2.3 Axis Configuration

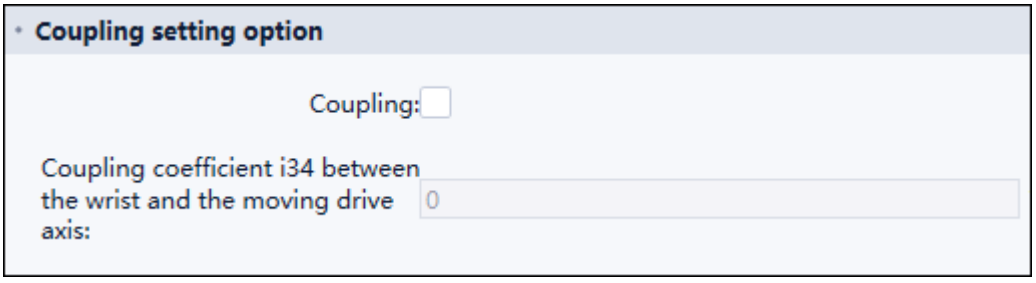
Before configuring the axes on the "Axis configuration" tab page, select the appropriate axis group type on the "Mechanical type" tab page.



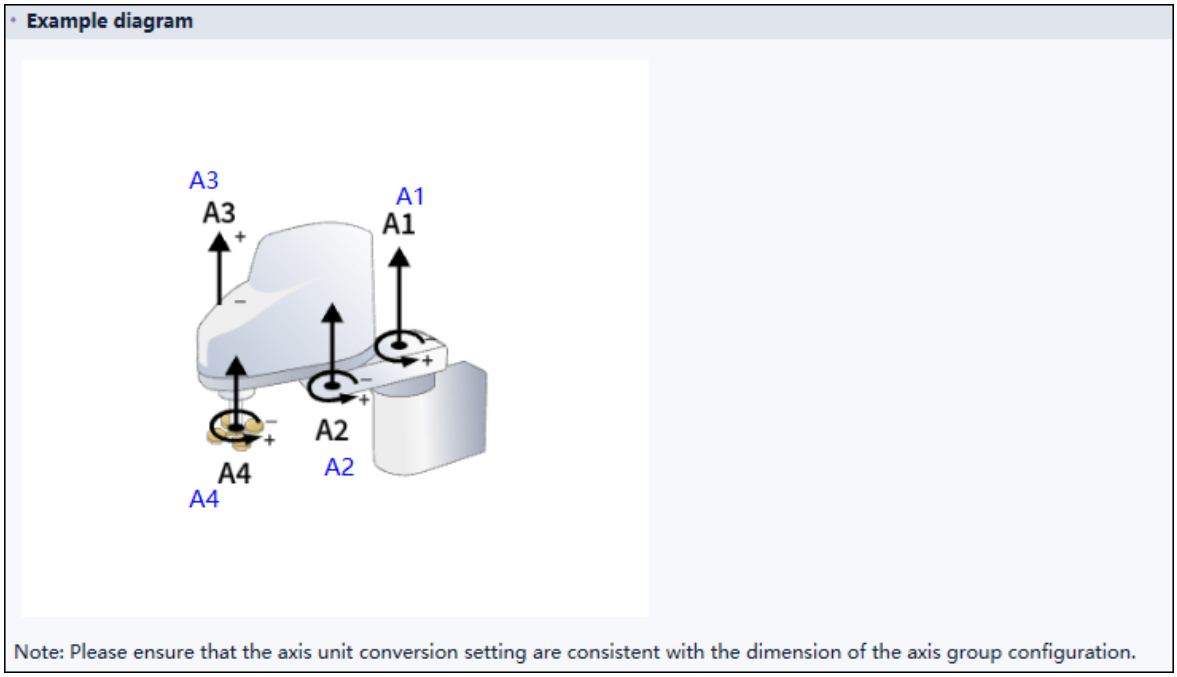
After selecting the axis group type, configure the axes within the axis group on the "Axis configuration" tab page. The axis group is associated with individual axes.

NOTE

- To limit the operating conditions of individual axes during axis group operation (such as motion parameter limits and software limits), configure the corresponding settings in the "General setting" interface of the respective axis as needed.
- If the axis group type is SCARA, Delta2, Delta3, or Delta3+1, you need to determine its motion range within the workspace and the motion range of each joint based on the structural parameters of the axis group. Set the software limits of individual axes based on the joint motion range to prevent the joint angle from exceeding the reachable limit during axis group motion; otherwise, the axis group motion will report a fault.
- The speed ramp mode, software limit prediction parameter settings, and commissioning parameter limits of individual axes do not take effect in the axis group.



- Axes added in the left project tree must be associated consistently when configuring the axis group type.
  - The axis group type cannot be modified, and it must match the type selected in the "Mechanical type" tab page.
  - Configuration of bus-controlled axes, local pulse axes, and virtual axes is supported.
  - Only the linear mode is supported.
  - The example diagram shows the specific motion position and positive motion direction of each axis.



CAUTION

The motion units and transmission relationships of each joint must be correctly set in the interface of the bound axis.

- If the axis group type is set to the **Scara** mechanical model, the axis configuration interface will display the coupling setting options, as shown in the figure below.

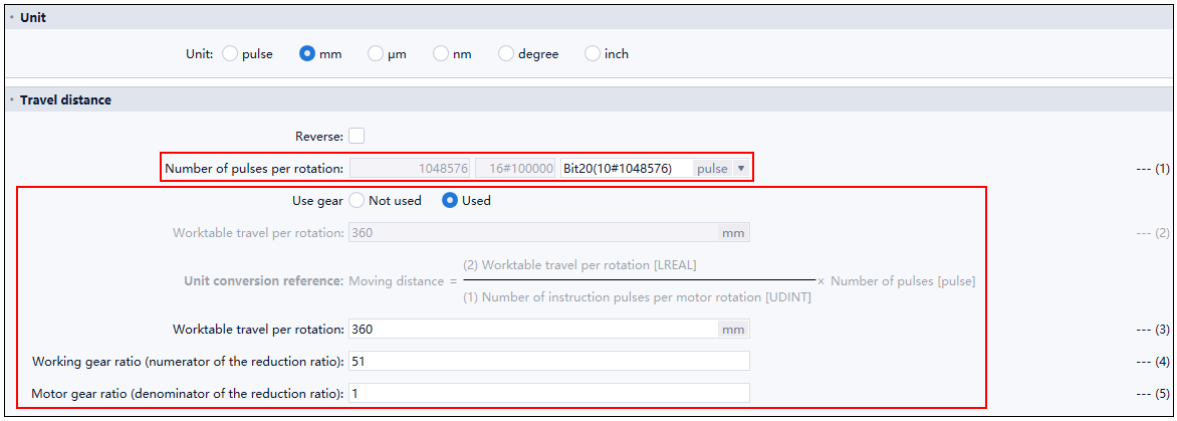
  - The parameter will only take effect after checking "Coupling".
    Wrist and mobile drive shaft coupling coefficient i34: The rotation amount of A4 is added to A3 with a proportional coefficient. The unit used here is radians.
  - The example diagram of the SCARA model is as follows:

The meanings of A1 to A4 are as follows:

A1: Main arm drive axis.

A2: Forearm drive axis.

A3: Moving drive axis.



A4: Wrist drive axis.

- The position dimensions of **each joint are automatically synchronized with the corresponding settings of the axis.**
  If joints 1, 2, and 4 are rotary joints, set the axis unit to degrees, and settings shall be based on the reducer ratio and motor encoder bit count of each joint.

  If joint 3 is a linear joint, set the axis unit to mm, and settings shall be based on the mechanical transmission ratio of joint 3 and the pitch of the lead screw.

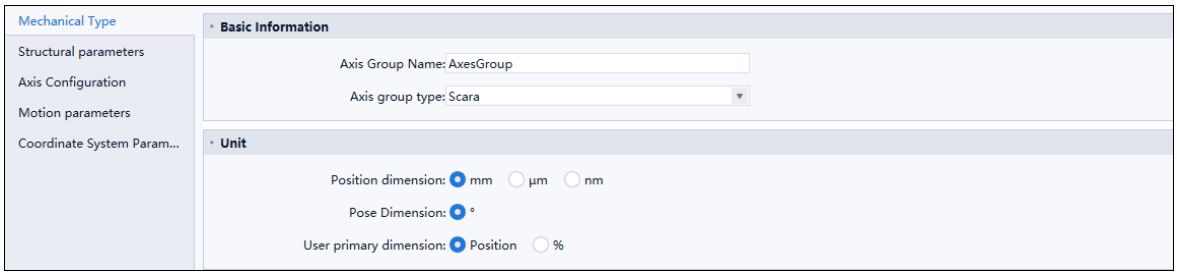
  Set parameters such as work gear ratio and motor gear ratio in the "Unit conversion" interface of each joint's bound axis.

  For a SCARA mechanical arm with the gear ratio parameter "dRatio":[51,51,2,12,0,0,0,0], if the joint motor encoder has 20 bits, set the **number of pulses per motor revolution** to 16#100000, i.e., 2^{20}.

Based on the gear ratio parameters, on the "**Unit conversion**" interface for Axis_1 corresponding to joint 2, select "Used" for the gear, set the "Worktable travel per revolution", and set the "Working gear ratio" to 51 and the "Motor gear ratio" to 1 according to the gear ratio parameters.

The settings for other joint axes are similar. Configure them individually based on the gear ratio parameters of each joint.

If joints 3 and 4 are coupled, the rotary motion of joint 4 causes displacement in joint 3, which can be offset by setting the **"Coupling coefficient i34 between the wrist and the moving drive axis"**.



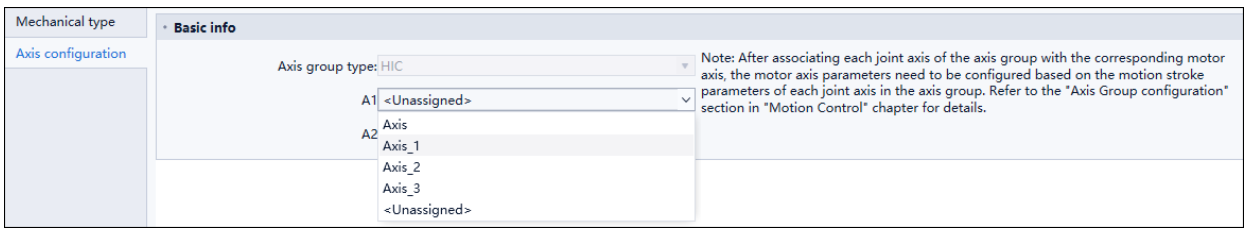
Calculation example of the "Coupling coefficient i34 between the wrist and the moving drive axis":

① Determine the relationship between the rotation angle and displacement: Manually rotate joint 4 by one revolution (2π, in radians) and measure the displacement of joint 3. Typically, it is the ratio of N-pitch displacement to one revolution radians, i.e., N × pitch / (2π).

② Determine the sign of the coupling coefficient: Manually rotate the rotary joint 4 and observe the motion direction of joint 3. If the direction of joint 3 is the same as the rotation direction of joint 4, the coupling coefficient is negative; otherwise, it is positive.

③ If the pitch of joint 3 is 16 mm, and joint 3 moves upward by one pitch when joint 4 completes one revolution, the coupling coefficient is: 16 / (2π) × (-1) = -2.55.

④ When calculating the coupling coefficient, the default "Unit" on the "Mechanical type" interface is mm. If the unit is changed to μm or nm, the calculated result must be scaled down proportionally based on step ③.



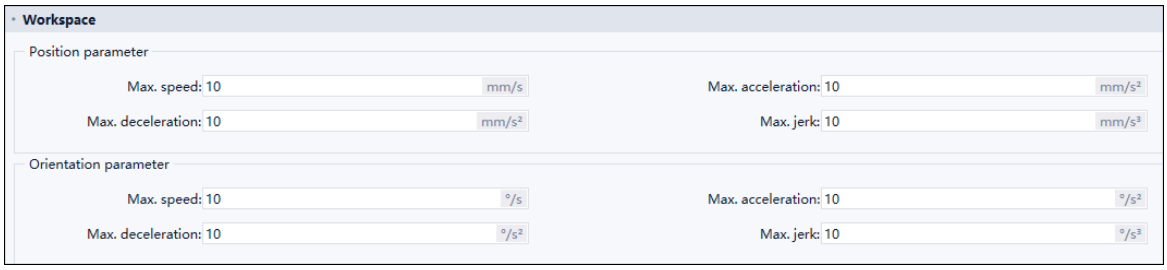
For example:

- If "Unit" is set to μm, the coupling coefficient calculated in step ③ must be scaled down by the conversion factor between mm and μm – since 1 mm = 1000 μm, the coefficient needs to be divided by 1000. Thus, -2.55/1000 equals -0.00255.
- If "Unit" is set to nm, the coupling coefficient calculated in step ③ must be scaled down by the conversion factor between mm and nm – since 1 mm = 1000000 nm, the coefficient needs to be divided by 1000000. Thus, -2.55/1000000 equals -0.00000255.

- If the axis group type is set to the "**HIC**" mechanical model, the configuration interface only supports setting the "Mechanical type" and "Axis configuration" panels, as shown in the figure below.

  - In the "Mechanical type" panel, you can set the number of axes in the custom axis group, with a range of [2,6].

- In the "Axis configuration" panel, you can set the axes corresponding to each joint of the custom axis group.

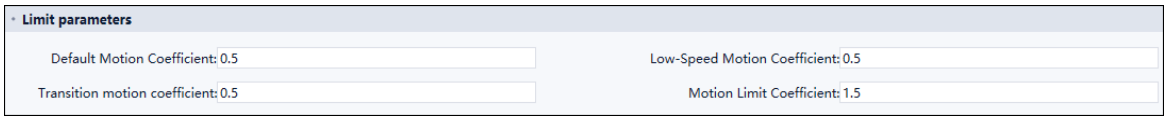


16.2.2.4 Motion Parameters

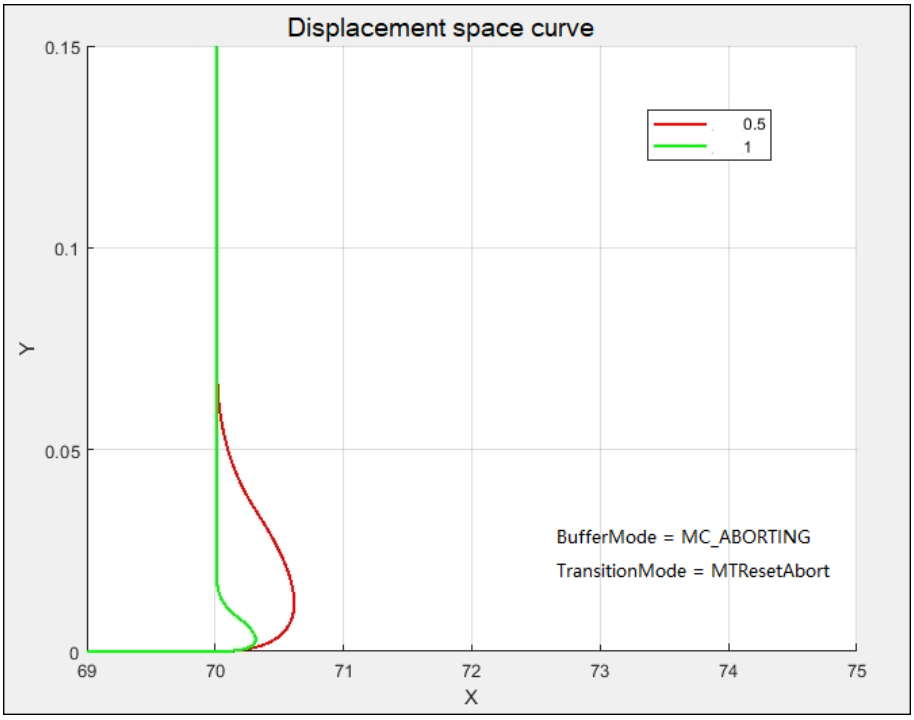
1. Curve type

Supports T-type (default), S-type (3rd order 7 segments), S-type (7th order 7 segments). This defines the planning method for the synthesized trajectory, which has no direct relation to single-axis planning methods.

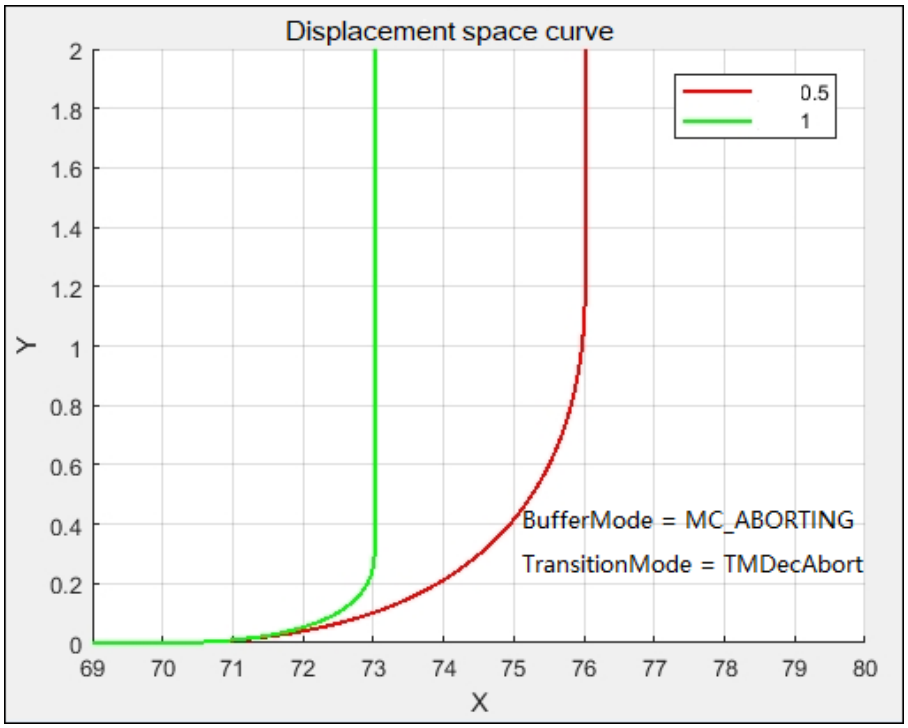
2. Workspace



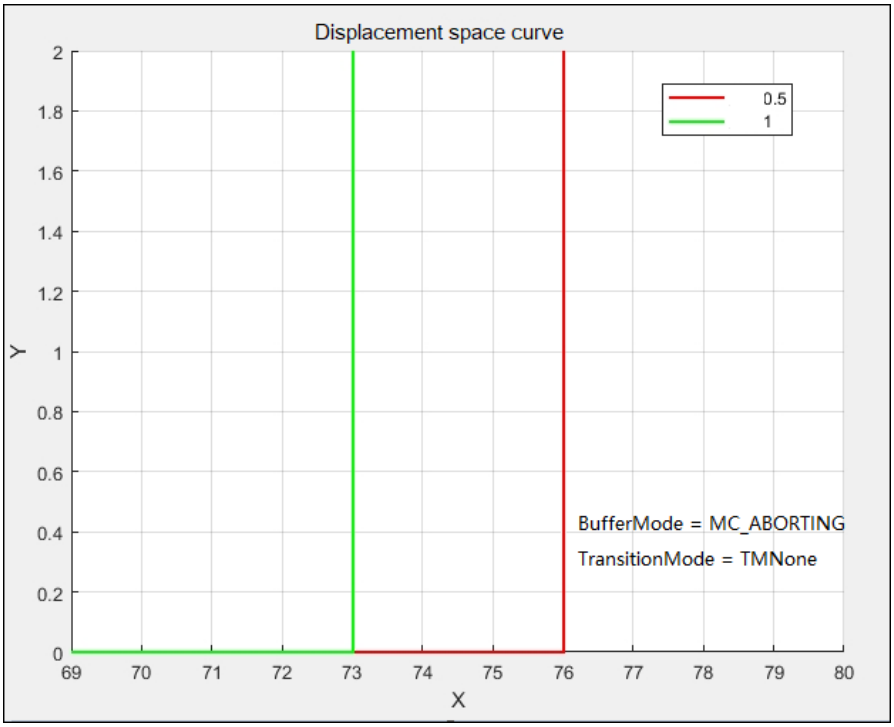
- The maximum values set for "Position parameter" apply to the position space, which limit the synthesized trajectory for position.
- The maximum values set for "Orientation parameter" apply to the pose space, which limit the synthesized trajectory within the pose space of axis groups including pose settings.



NOTE



- The above are the maximum motion parameters in Cartesian space. The maximum motion parameters of individual joints shall be configured in the associated axis settings.
- When the axis group type is set to "SCARA" or "XYZA", the workspace support settings for "Orientation parameter"; for other axis group types, only "Position parameter" can be set.
- For EVO500 series PLC V1.2 version, "Orientation parameter" cannot be set for "XYZA" axis group type.



3. Limit parameters

- Default motion coefficient: Used to set the default speed for continuous trajectories. The continuous trajectory function is currently not available, so this parameter is ineffective.
- Low-speed motion coefficient: Used in the MC_GroupJog instruction for ratio settings. The MC_GroupJog instruction is currently not available, so this parameter is ineffective.
- Transition motion coefficient: Used when motion instructions are executed in Abort mode to construct transition trajectories. The higher the coefficient, the shorter the transition trajectory and the faster the transition is completed. The figure below shows the effect of different transition modes with different coefficients.

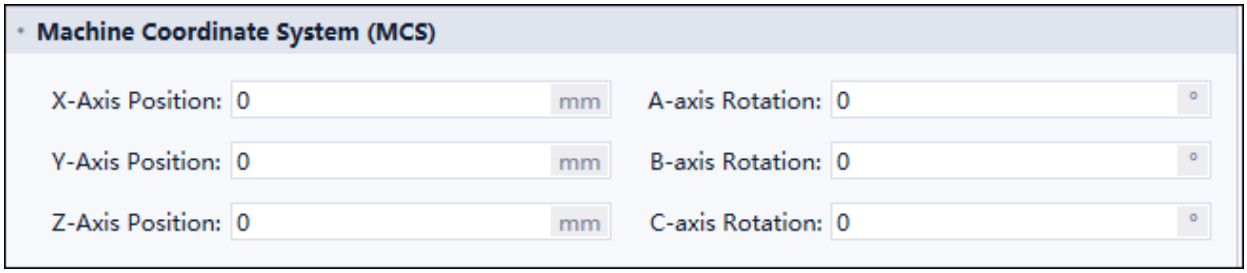
◦ Motion limit coefficient: Used to limit virtual axis speed in ACS space (i.e., axis space). During interpolation, the speed of each virtual axis must not exceed the product of the motion limit coefficient and the single-axis speed limit; otherwise, a fault will be reported.

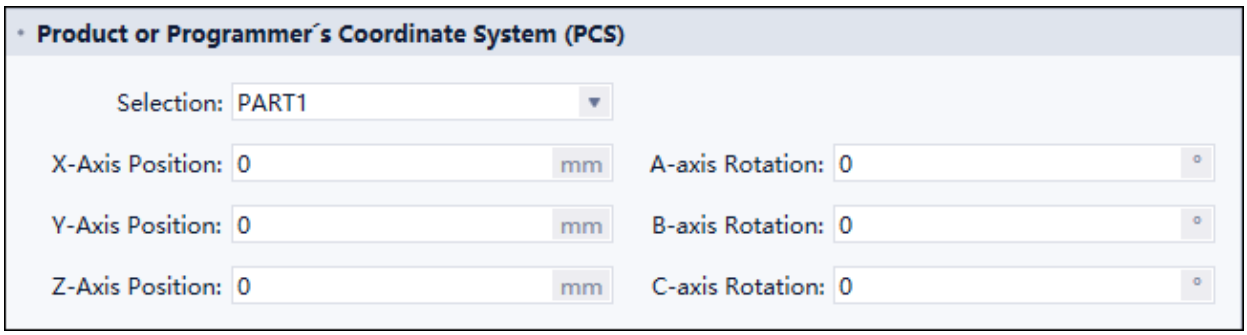
4. Home settings



The defined homing sequence of single axes shall not contain descending order, and the homing sequence number of the first axis must be 1. Take the **Cartesian XYZA axis group type** as an example. Valid homing sequences include [1, 1, 1, 1;], [1, 2, 3, 4;], [1, 2, 2, 2;], [1, 2, 2, 3;], [1, 2, 3, 3;], etc. Axes assigned the same sequence number will perform homing simultaneously.

NOTE

The configuration of homing parameters must be completed in the bound associated joint axes.

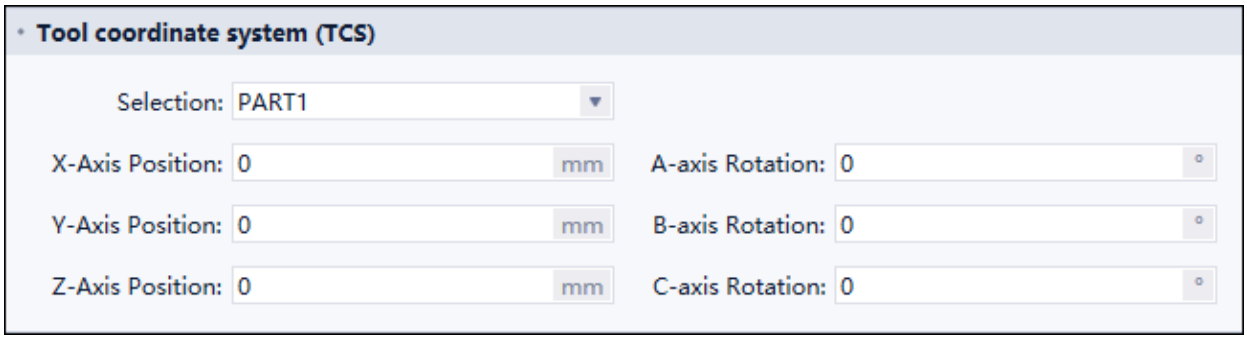


16.2.2.5 Coordinate System Parameters

1. Machine coordinate system (MCS)

Used to set the base coordinate system of the machine (MCS is currently not enabled, so default parameters can be kept).

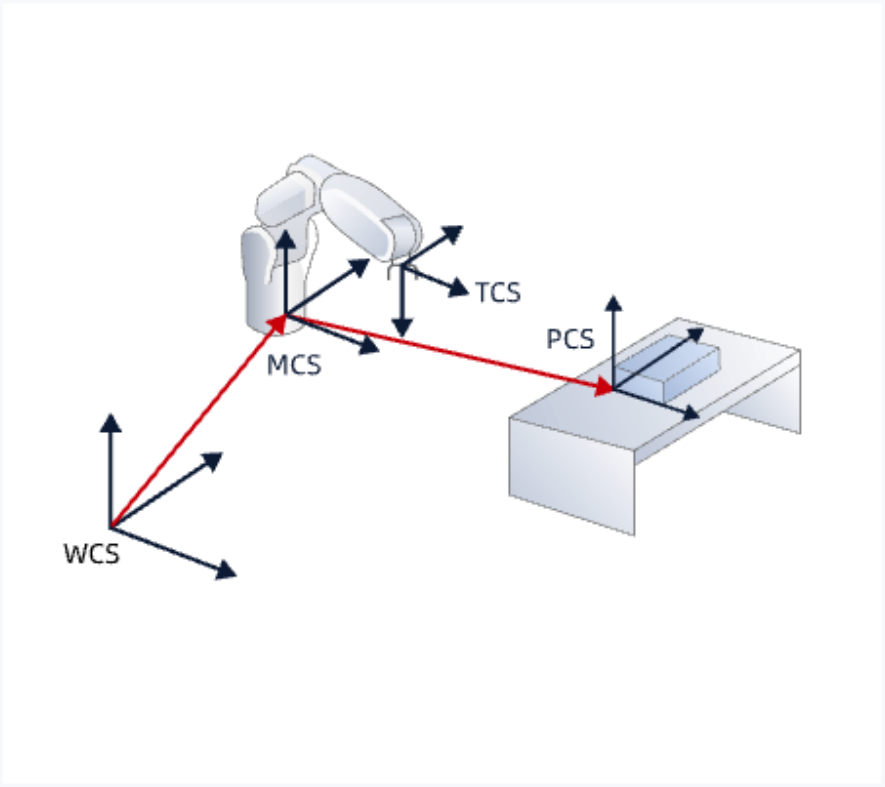
2. Product or programmer's coordinate system (PCS)



Used to store workpiece coordinate systems, a total of 10 sets can be stored.

NOTE

After the product coordinate system IDE is set, it is stored in the axis group object. To activate it, select the corresponding coordinate system for configuration via the MC_SetCartesianTransform instruction.



3. Tool coordinate system (TCS)

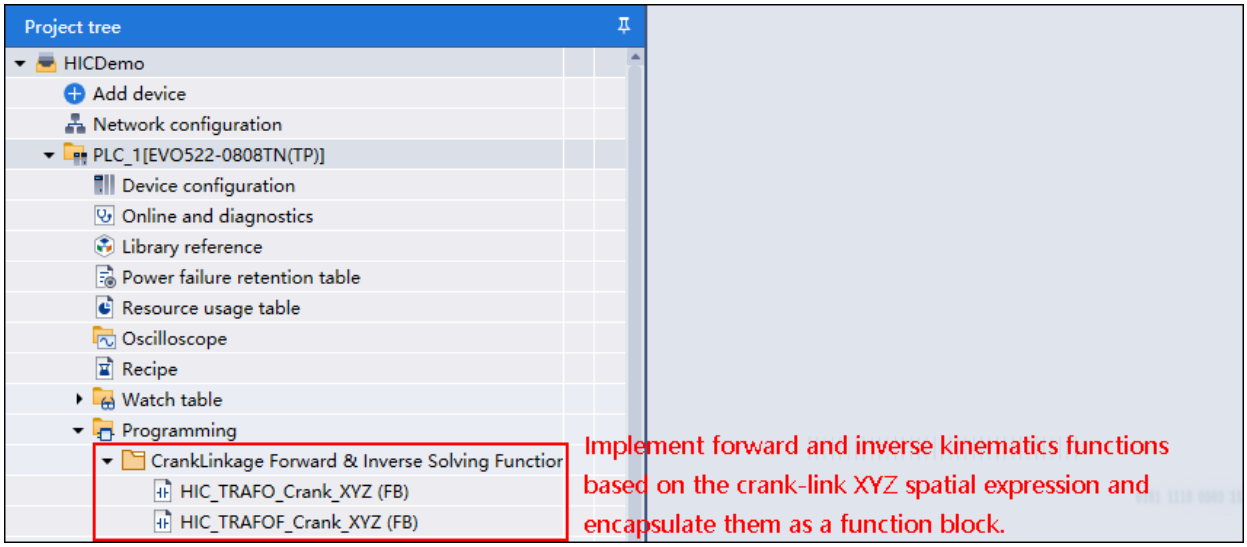
Used to store tool coordinate systems, a total of 10 sets can be stored (this function is currently not enabled).

4. Coordinate system diagram

Coordinate System Diagram

Note: The rotation angles of the coordinate system ABC correspond sequentially to the ZYX Euler angles.

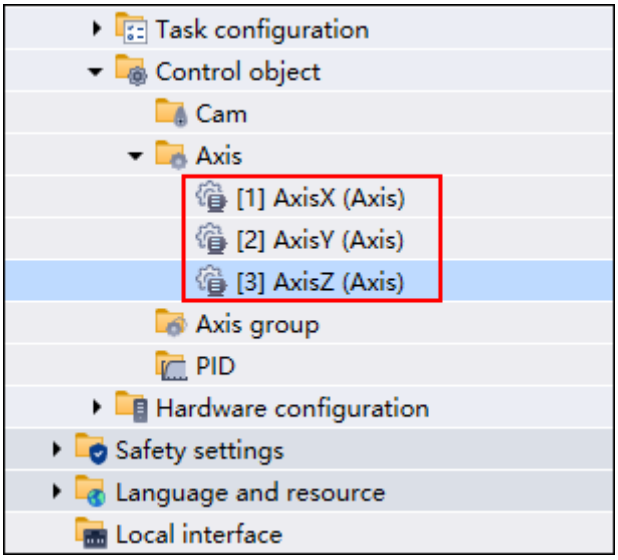
16.2.2.6 HIC Configuration Example



Taking a crank-link mechanism with three axes as an example: one rotational axis and two linear translational axes. Assuming its crank length is L_1 and the crank rotation angle is Θ_A, its end point in space can be expressed by the following formula.

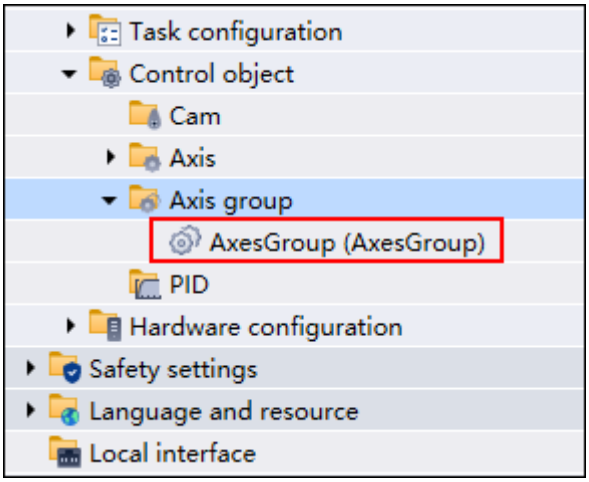
$$\begin{cases} X = L_1 \cdot \cos\theta_A \\ Y = Y_{axis} \\ Z = Z_{axis} \end{cases}$$

Based on this formula, its forward kinematics function and inverse kinematics function can be derived. The example omits the specific implementation of the kinematics functions.



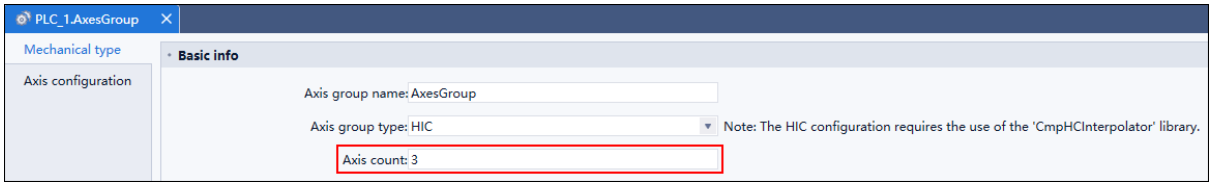
Kinematics function implementation

Encapsulate the implemented forward kinematics and inverse kinematics functions as function blocks, enabling forward and inverse kinematics calculations for the crank-link configuration.

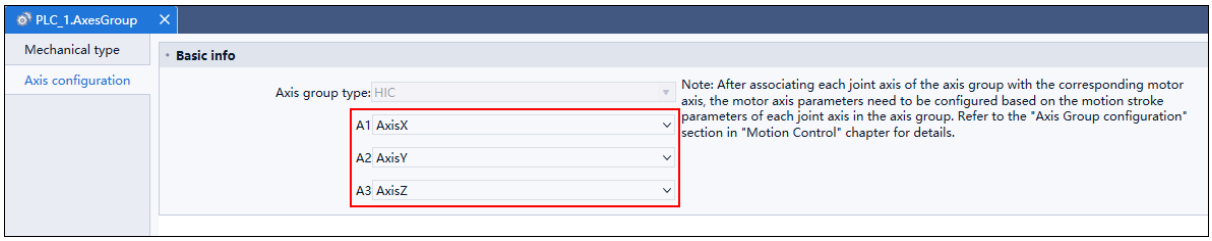


Axis addition

Right-click an axis under "Control object" in the left project tree, select "Add axis" to add the axes corresponding to the crank-link mechanism, and bind them to the servo. A virtual axis is used as an example here.

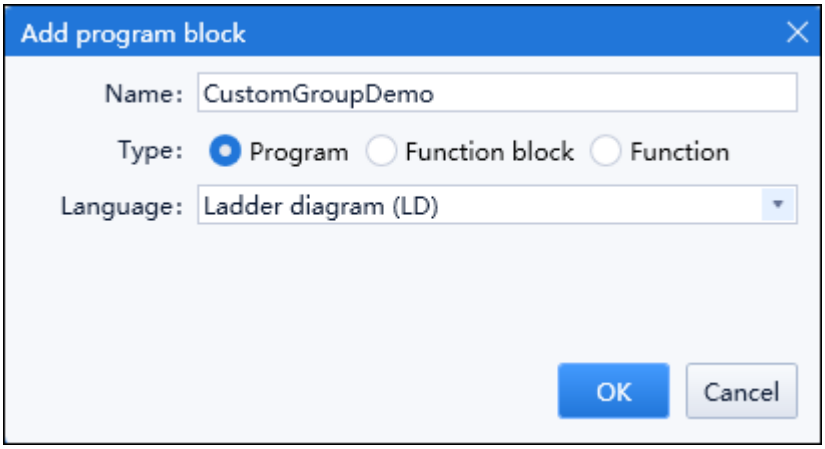


Axis group addition

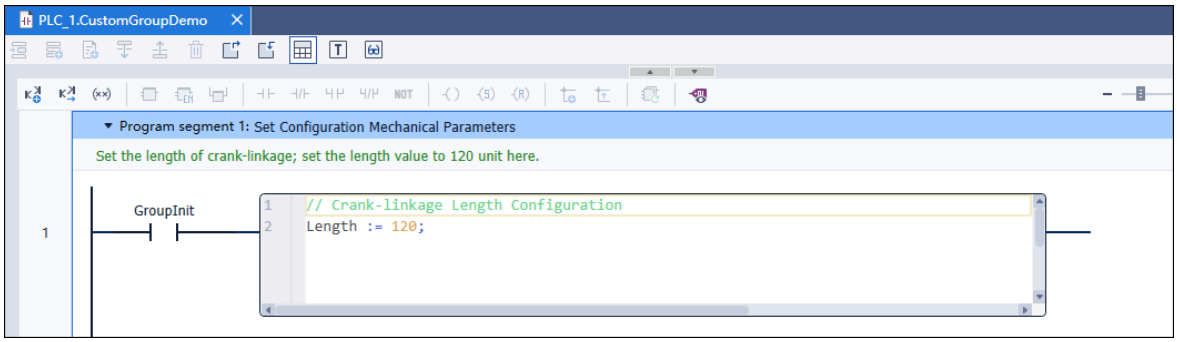


1. Right-click an axis under "Control object" in the left project tree, and select "Add axis group".

2. Set the "Axis count" according to the configuration (range: 2 to 6). In this example, it is set to 3.

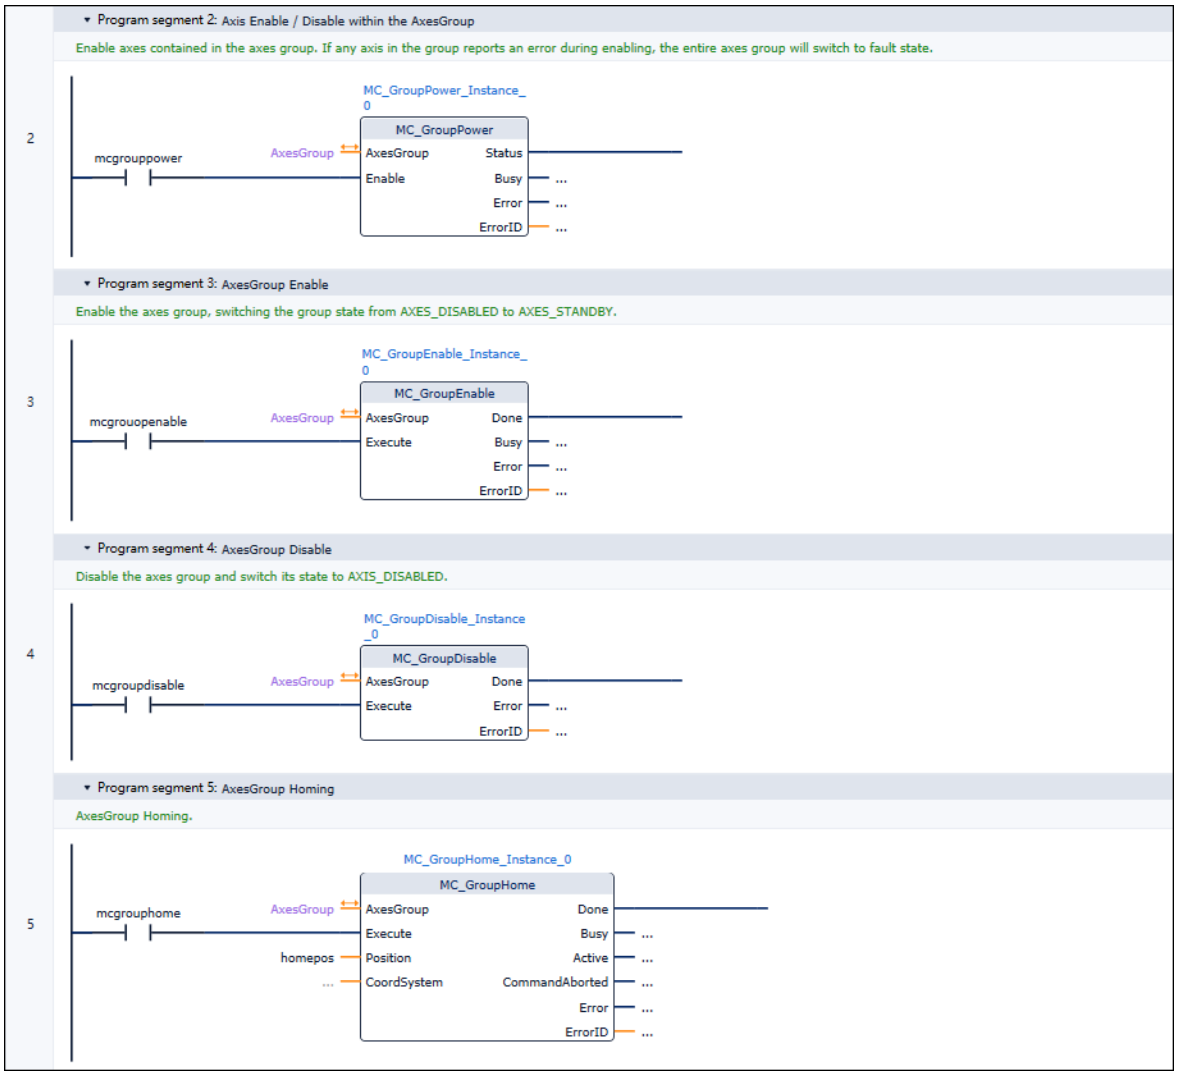


3. Assign axes to the axis group based on the joint-to-axis correspondence.



Program example

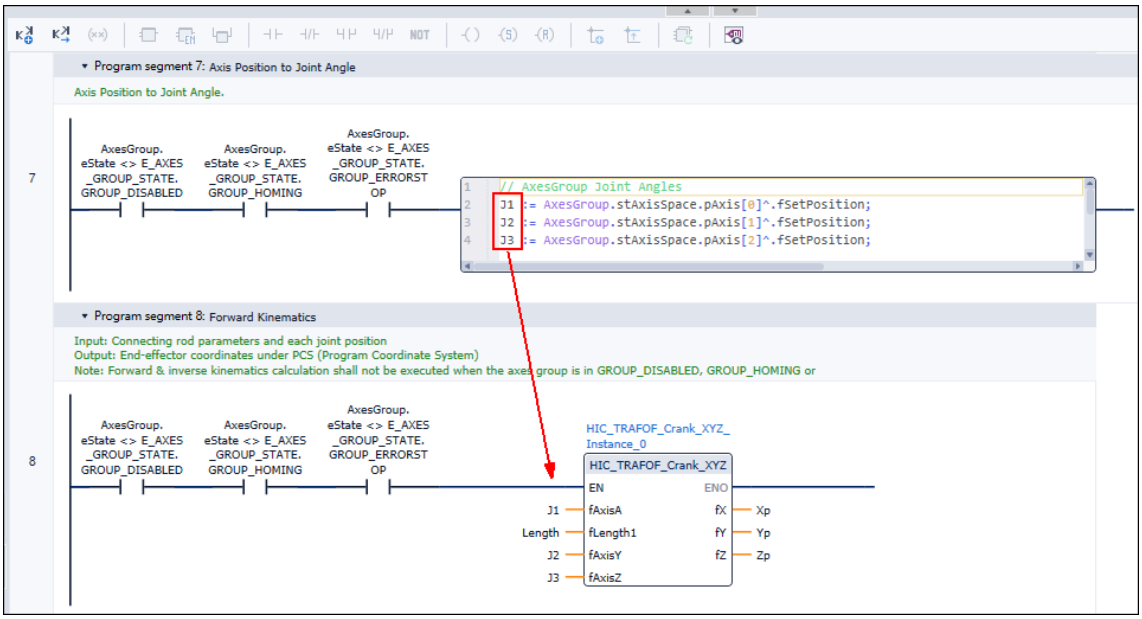
1. Right-click "Programming" in the project tree and select "Add program block".



2. Follow the steps below to implement position control for the crank-link mechanism.

   a. Set the mechanical parameters of the configuration for forward/inverse kinematics functions.

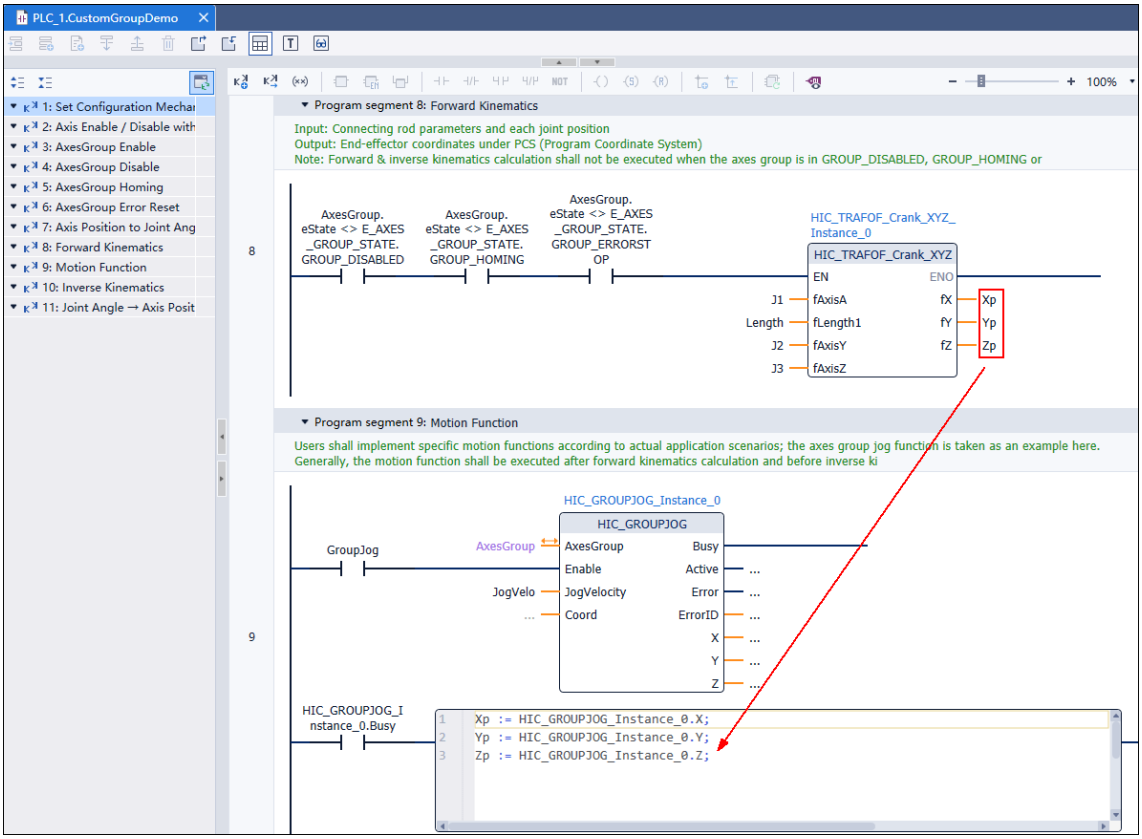
b. Add axis group-related instructions.



NOTE

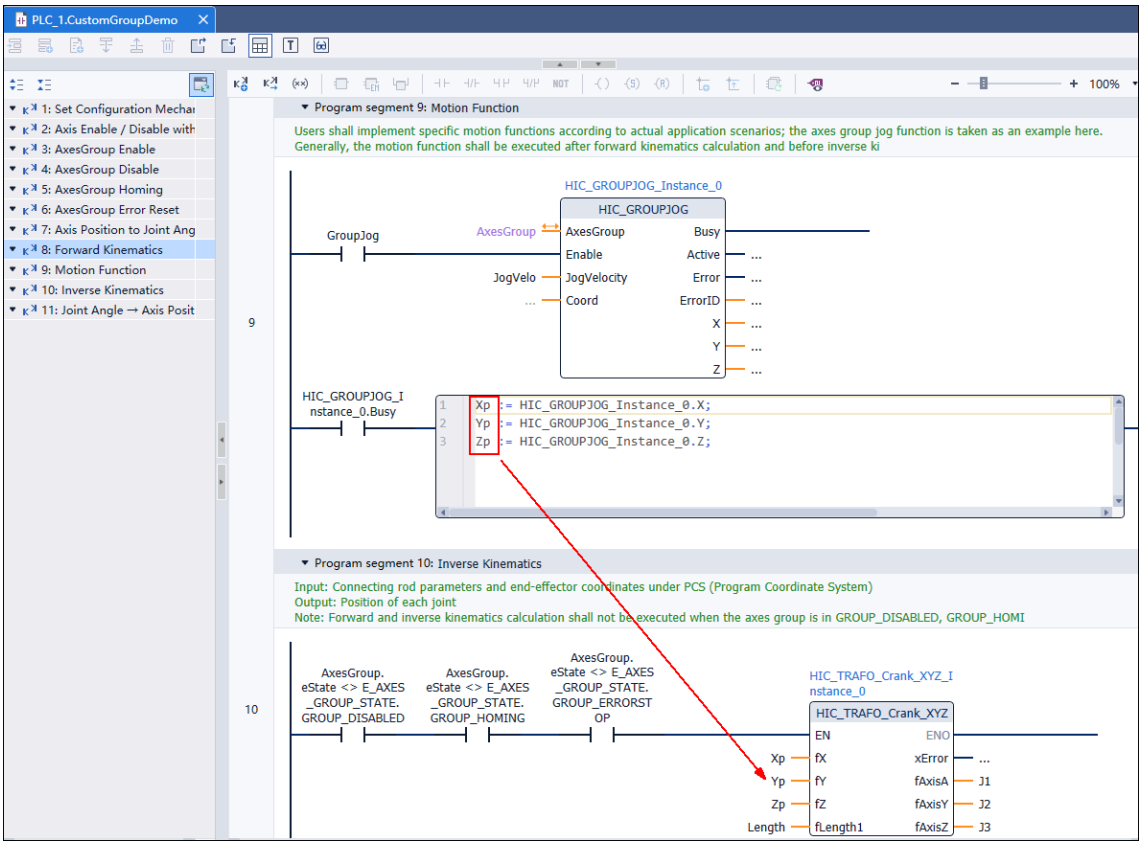
The HIC configuration only supports instructions from the "MotionControl" library, such as MC_GroupPower, MC_GroupEnable, MC_GroupDisabled, MC_GroupHome, and MC_GroupReset. When calling other axis group motion instructions from the library (e.g., MC_MoveLinearAbsolute), the Done output parameter is set immediately after triggering, but no position output is generated on the axes in the group.

c. Place the implemented forward kinematics and inverse kinematics functions in the program. The placement order can be adjusted according to different scenario requirements. In this example, forward kinematics function is placed above inverse kinematics.



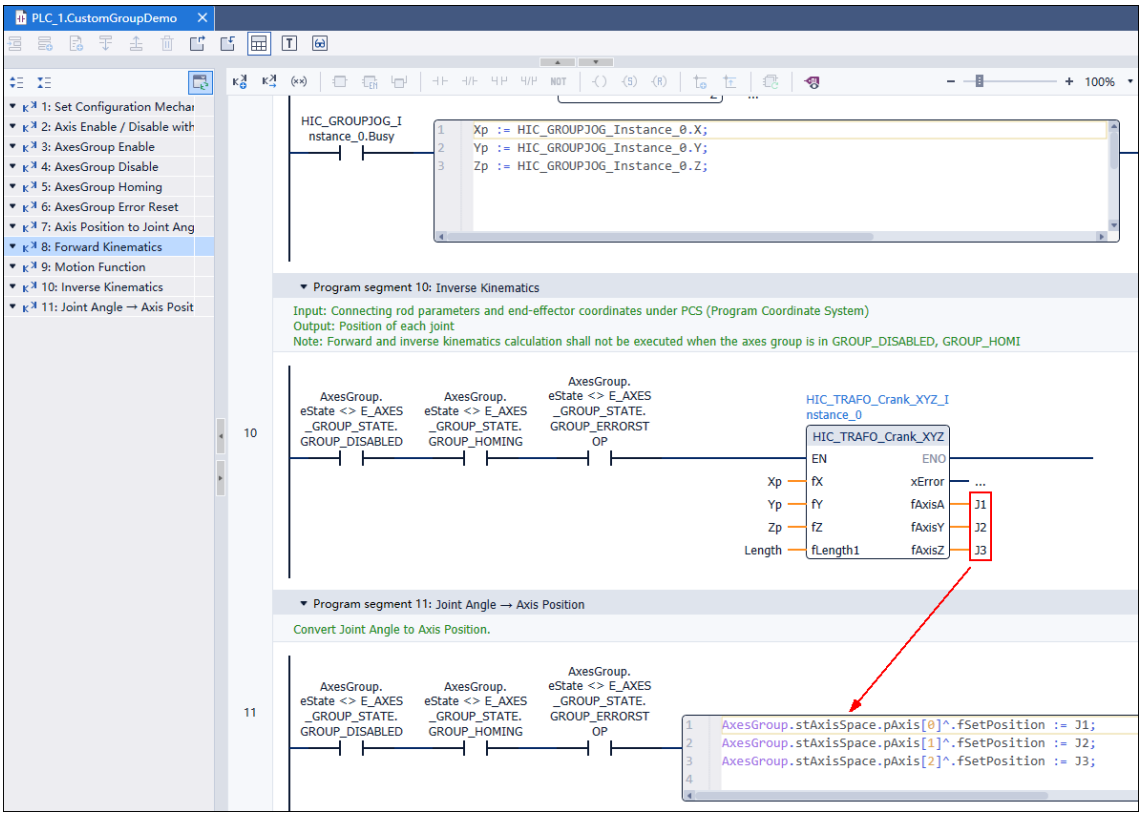
α. Forward kinematics (ACS -> PCS): Converts the joint angles of each axis in the axis group to spatial positions. Obtain each joint angle, combine with link parameters, and pass them to the forward kinematics function. In this example, kinematics solving is skipped when the axis group is in

GROUP_DISABLED, GROUP_HOMING, or GROUP_ERRORSTOP.



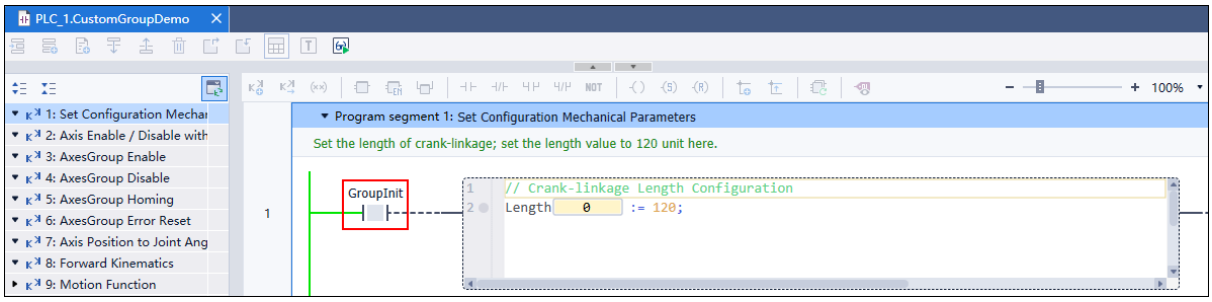
β. Motion function: The user implements specific motion functions based on application requirements. This example uses axis group jogging function. Generally, the motion function is placed after forward kinematics and before inverse kinematics.

γ.

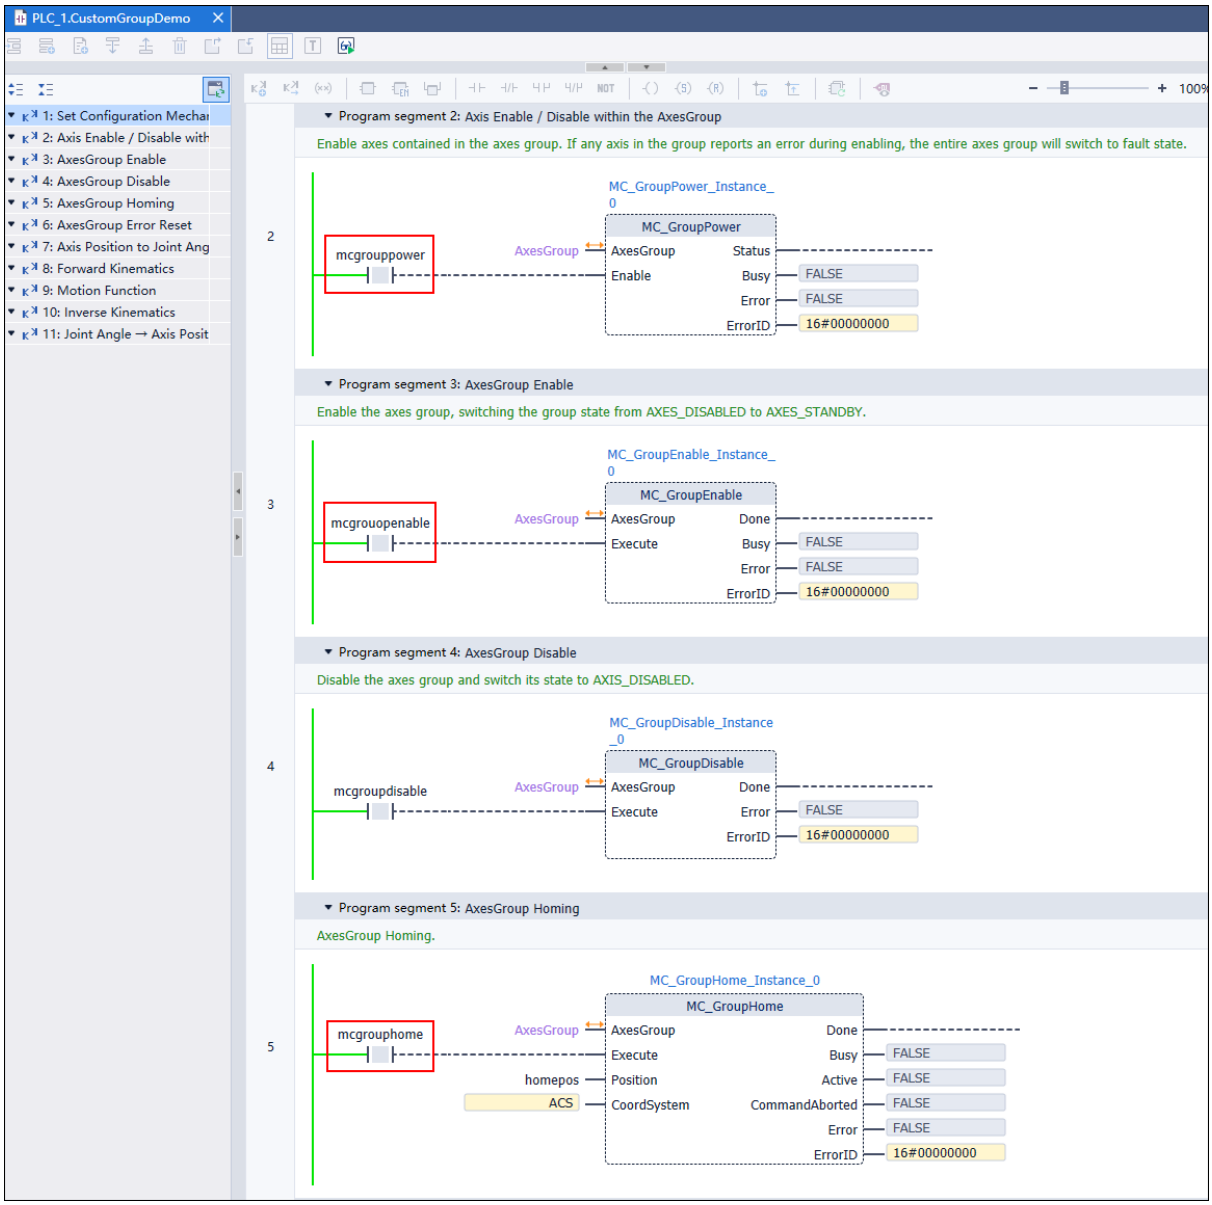


Inverse kinematics (PCS -> ACS.): Converts configuration spacial position to each axis joint angle. Pass the XYZ spatial positions output from the motion function, combined with link parameters, to the inverse kinematics function. In this example, kinematics solving is skipped when the axis group

is in GROUP_DISABLED, GROUP_HOMING, or GROUP_ERRORSTOP.

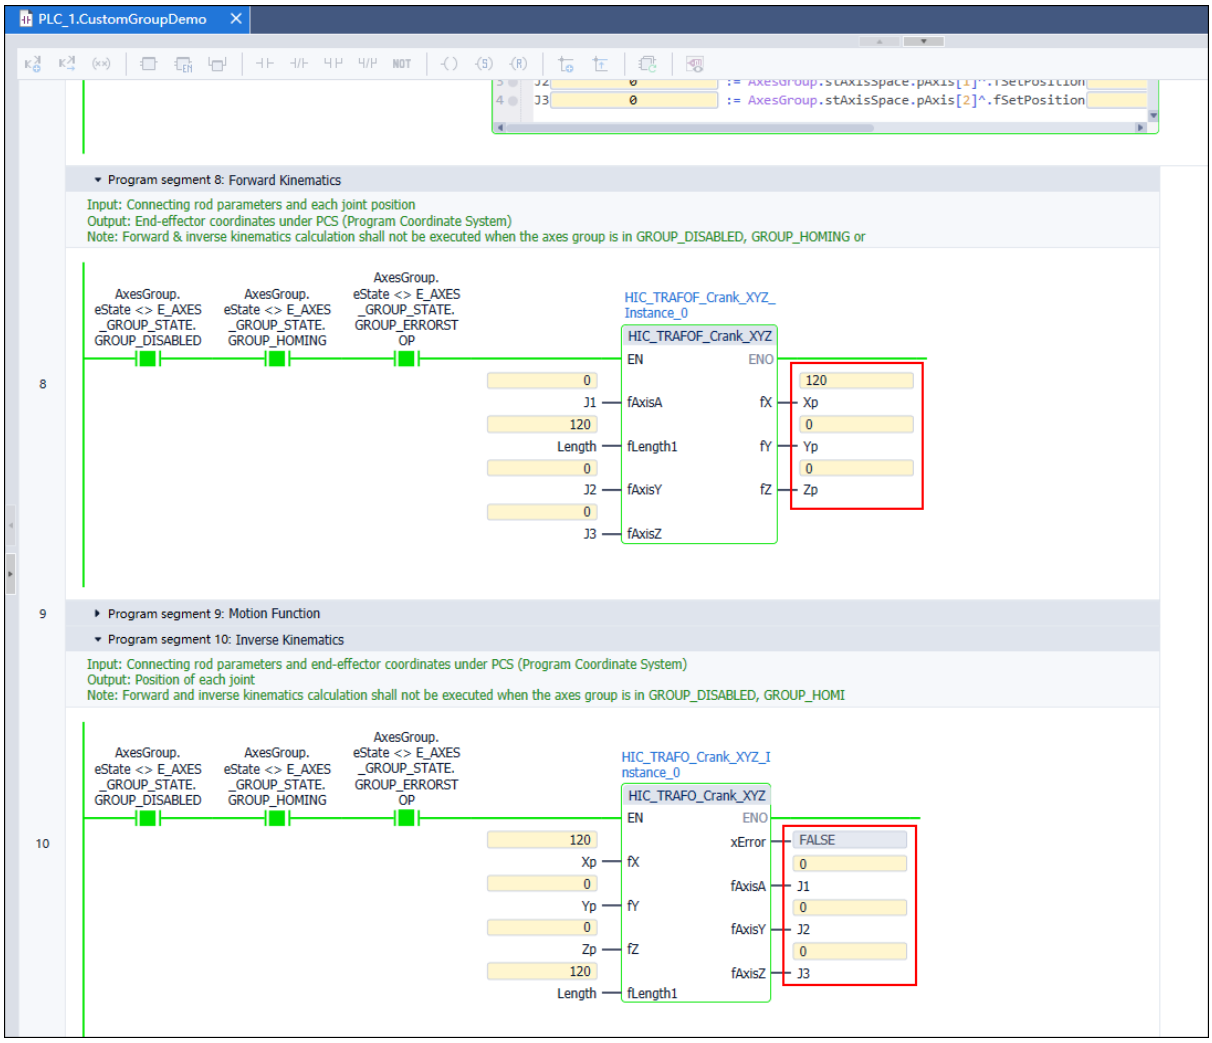


δ. The joint angles solved by the inverse kinematics function are assigned to the corresponding axes in the axis group to control its motion.

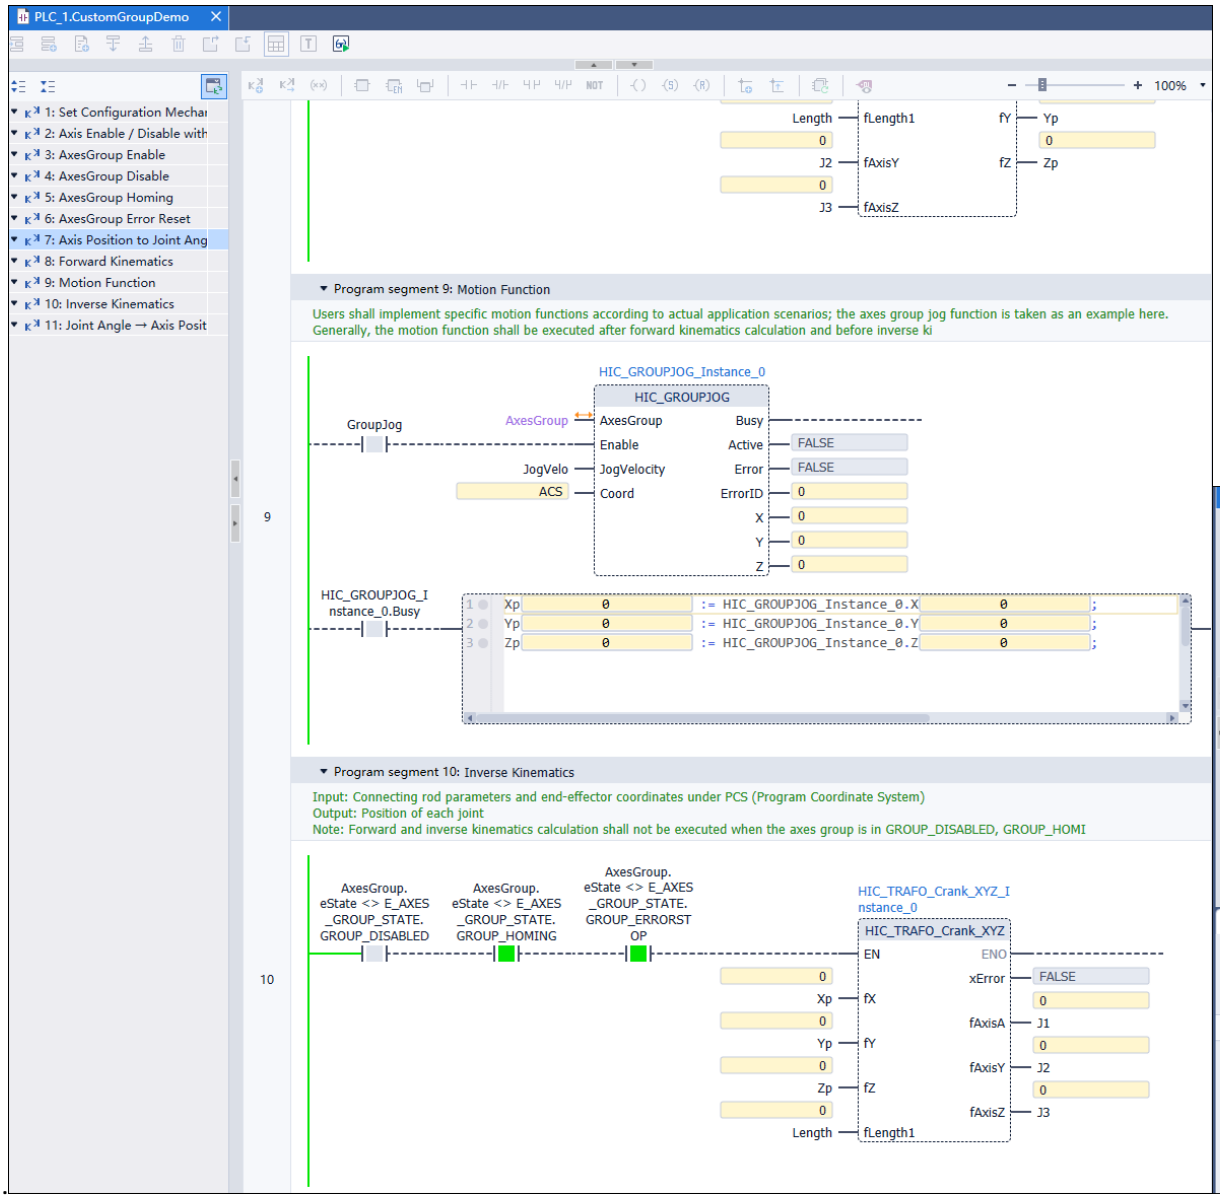


Examples

1. Set configuration parameters.



2. Execute MC_GroupPower (enable axes in the axis group), MC_GroupEnable (enable the axis group), and MC_GroupHome (home the axis group). If the axis group is in GROUP_ERRORSTOP or an axis in the axis group is in AXIS_ERRORSTOP, execute MC_GroupReset. If axis group motion is complete and no further control is needed, execute MC_GroupDisabled to disable the axis group.



3. After the axis group completes MC_GroupHome, each axis joint is at 0. The forward kinematics function returns XYZ spatial position (120, 0, 0), which matches the configuration. The joint angles solved by the

inverse kinematics function also match the axis group joints.

4. Start the motion function HIC_GroupJog, which outputs XYZ spatial positions. The inverse kinematics function then calculates the corresponding joint angles and passes them to the joints in the axis group to

control the group's

motion.

16.3 Cam Configuration

16.3.1 Overview

- Overview of cam motion

  Cam motion adopts the relative motion characteristics between a mechanical cam and a tappet. It refers to a continuous synchronous motion where a slave servo axis follows a master axis according to a predefined nonlinear position relationship, to fulfill equipment motion requirements. It is widely used in applications requiring synchronization, such as fixed-length cutting, chasing shear control, flying shear control, and multi-color overprinting.

  The position relationship between the master and slave axes in an electronic cam curve is shown in the following figure, with the horizontal axis representing the master axis position and the vertical axis representing the slave axis position:

- The cam motion control function can be realized via software, which means using a software-based "cam table" to replace a mechanical cam. Therefore, this function is also called electronic cam control. Compared to mechanical cams, it has the following features:
  - Cam profile creation: Supports drawing various cam curves to create cam profiles;
  - Diverse cam profiles: Supports selecting multiple cam tables, which can be dynamically switched during operation through the MC_GenerateCamTable instruction;
  - Cam profile modification: Supports dynamic modification of key points or dense points in the cam table during operation;
  - Multiple cam slave axes: Supports multiple cam slave axes;
  - Cam clutch: Supports enabling or exiting cam motion during operation through the MC_CamIn or MC_CamOut instructions;
  - Unique functions of electronic cams: Supports virtual master axes, phase superposition, and other features.
- Technical terms
  - Master axis: The reference axis used for synchronous control;
  - Slave axis: The servo axis that follows the master axis position according to the required nonlinear characteristics;
  - Cam table: A data table or cam curve describing the relative position, range, and periodicity between the master and slave axes.
  - Phase: The relative value of the master axis from the starting position of the cam table.
  - Displacement: The relative value of the slave axis from the starting position of the master axis tracking.

16.3.2 Introduction to Cam Table

Cam data refers to a set of data composed of the master axis phase and the slave axis displacement. A cam table refers to a combination of multiple cam data sets. Phase and displacement values of cam data in a cam table are relative quantities expressed in relation to the start point "0.0". The phase values of the cam data in the cam table need to be arranged in ascending order.

There are two types of cam table data:

- "Key point" type: Each cam point of this type contains the positions, speed ratio, acceleration ratio, jerk ratio and curve type of master and slave axes. Currently supported curve types include: straight line, parabola, cubic curve, quintic curve, septic curve, cosine acceleration curve, sine acceleration curve, modified T-type acceleration curve. Due to the large amount of data contained in each key point, the maximum number of points supported per table is 20000.
- "Dense point" type: This type only contains the position of master and slave axes, and each cam point is linearly connected. This type of cam table can support up to 65535 points.

16.3.3 Cam Table Data Structure

The cam table data structure supports both key points and dense points. Each cam table is divided into two parts: One part describes the key information of the cam table, and the other describes the specific data stored in the table.

Number of cam table points: Up to 20000 key points and up to 65535 dense points are supported.

The MC_CAM_TABLE_REF data structure is defined as follows:

Table16-3-3-1 Cam table data structure

Variable Name	Data Type	Description
strCamTableName	STRING	Cam table name
iNodeType	INT	Node type: 1: Key node. 2: Dense node.
iNodeNumber	UINT	Number of points
pNodePtr	POINTER TO BYTE	Pointer to the cam table point array

In the cam table point array, key point or dense point arrays need to be bound, with the following data types:

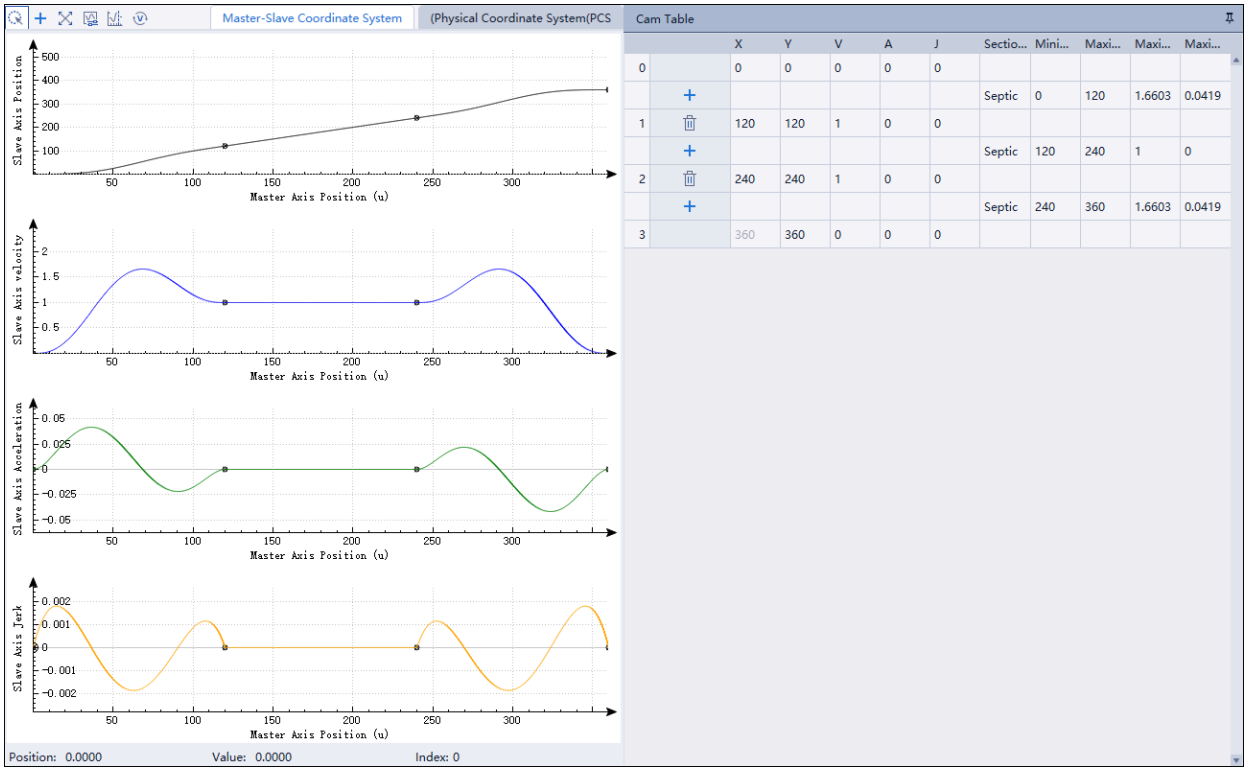
The MC_CAM_KEY_NODE_REF data structure is defined as follows:

Table16-3-3-2 Key point definition

Variable Name	Data Type	Description
fPhase	LREAL	Phase (of the master axis) at the node.
fDistance	LREAL	Displacement (of the slave axis position) at the node.
fVel	LREAL	Velocity at the node.
fAcc	LREAL	Acceleration at the node.
fJerk	LREAL	Jerk at the point.
iCurveType	INT	Curve type: 1: Straight line. 2: Parabolic curve. 3: Cubic curve. 4: Quintic curve. 5: Septic curve. 6: Cosine acceleration curve. 7: Sine acceleration curve. 8: Modified T-type acceleration curve.

MC_CAM_FITTING_NODE_REF data structure definition:

Table16-3-3-3 Dense point definition



Variable Name	Data Type	Description
fPhase	LREAL	Phase (of the master axis) at the node.
fDistance	LREAL	Displacement (of the slave axis position) at the node.

16.3.4 Creating a Cam Table

1. Click the "Control object" in the left project tree to expand the control object list.
2. Right-click "Cam" and select "Add cam".
3. In the pop-up dialogue box, enter the cam name and click "OK".

By default, the added cam table is of "key point" type, which can be modified through cam table properties.

In general, a cam table of "dense point" type contains more cam points, which need to be added through the following steps:

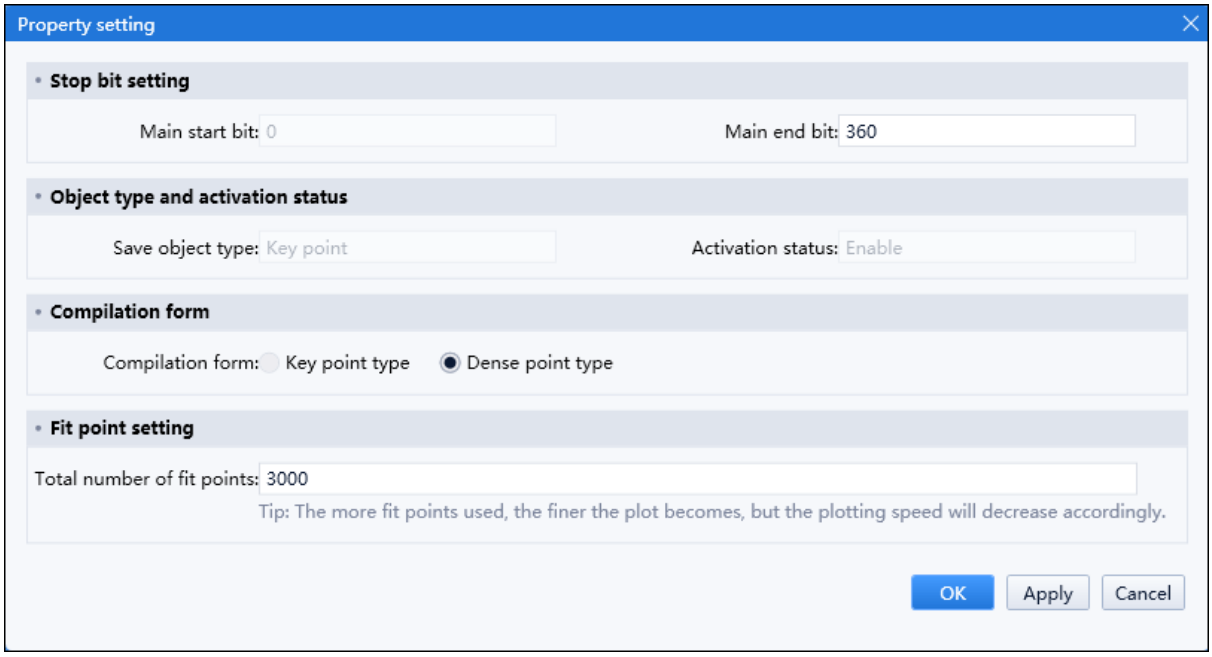
Method 1:

1. Create a CSV file with the following content:

1	CamObjectName:	Cam_0	Cam table name
2	CAMModelTypeEnum:	2	Cam table type; 2 means dense point
3			
4	NumberOfCamPoints:	4	Number of cam points
5	X	Y	
6	0	0	
7	120	120	
8	240	240	Dense point data
9	360	360	

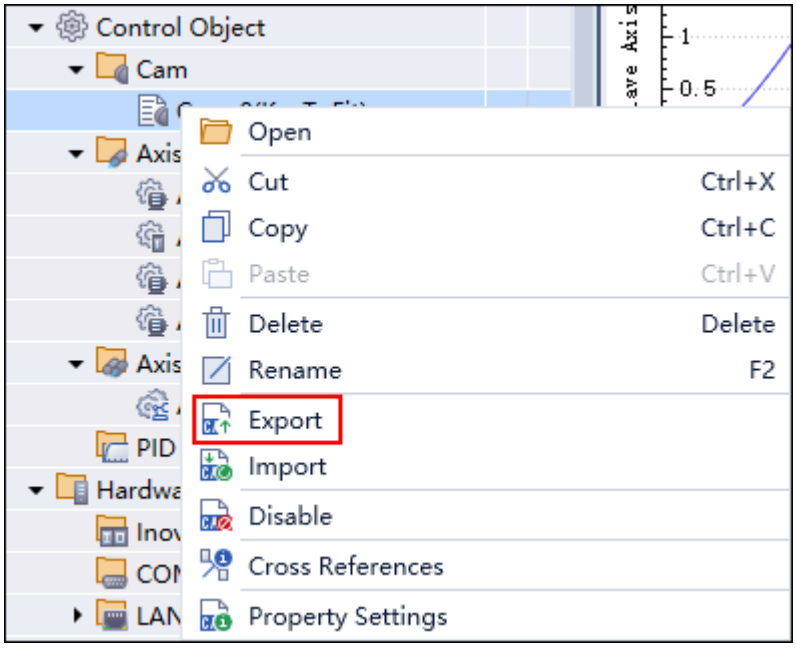
Note: The keywords "CamObjectName:", "CAMamModelTypeEnum:", "NumberOfCamPoints:", "X", and "Y" in the table must be exactly the same as those in the figure; otherwise, the CSV file cannot be imported.

The cam table name, number of cam points, and dense point data can be modified, but the cam table type (2) cannot be modified.



2. Based on specific process requirements, write the dense point data (X: phase, Y: displacement) into the CSV file.

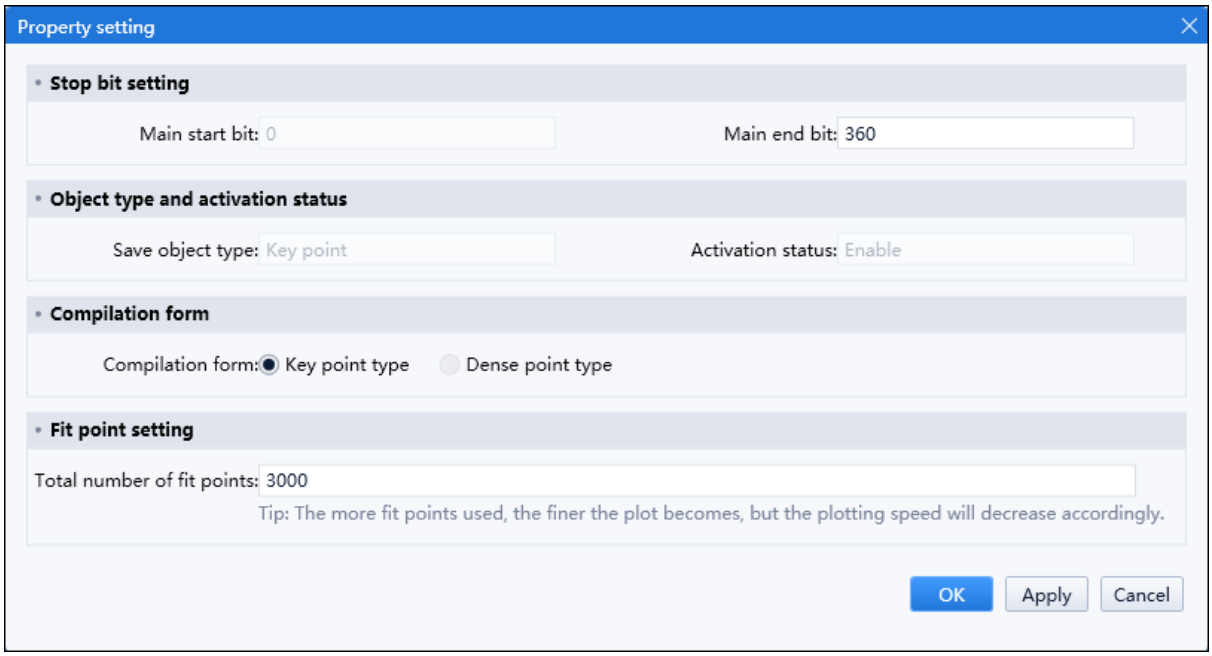
NOTE



- The keywords "CamObjectName:", "CAMamModelTypeEnum:", "NumberOfCamPoints:", "X", and "Y" in the table must be exactly the same as those in the figure; otherwise, the CSV file cannot be imported.
- The cam table name, number of cam points, and dense point data can be modified, but the cam table type cannot be modified.
- The number of cam points can be less than the actual number of dense point data; otherwise, the CSV file cannot be imported.

Method 2:

1. Create a cam table in iFA, right-click the cam table and select "Property setting". In the pop-up window, modify the compilation form of the cam table to "Dense point type", as shown in the figure below:

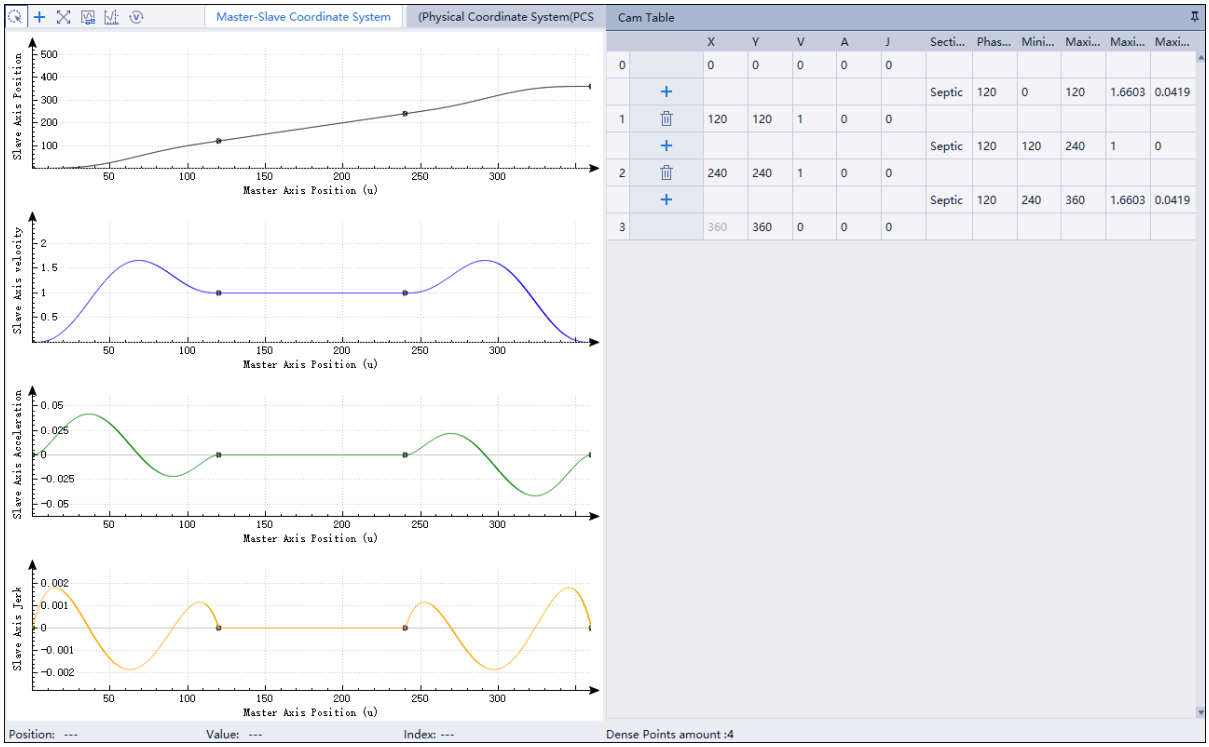


2. After modification, right-click the cam table and select "Export" to export the data to a CSV file, as shown in the figure below:

The exported file has the same format as the file created in method 1, and dense point data can be added in the table.

16.3.5 Cam Table Properties

1. Right-click the Cam_0 table and select "Property setting".
2. Set the corresponding properties in the pop-up window.



- The "Main start bit" is default to 0 and cannot be modified.
- The "Main end bit:" is the end position of the master axis and can be set according to the process scenario.
- The object type and activation status show the point type of the current cam table and whether it is disabled.
- The compilation form sets whether the point type of the current cam table is downloaded as key points or dense points, allowing switching between two types of data.
- The fit point setting adjusts the drawing precision; the more fit points, the more precise the drawing, but the drawing speed will decrease.

16.3.6 Cam Chart

16.3.6.1 Cam Table Configuration Interface

Double-click the added cam table in the project tree to open the cam table configuration interface. The interface is shown in the following figure.

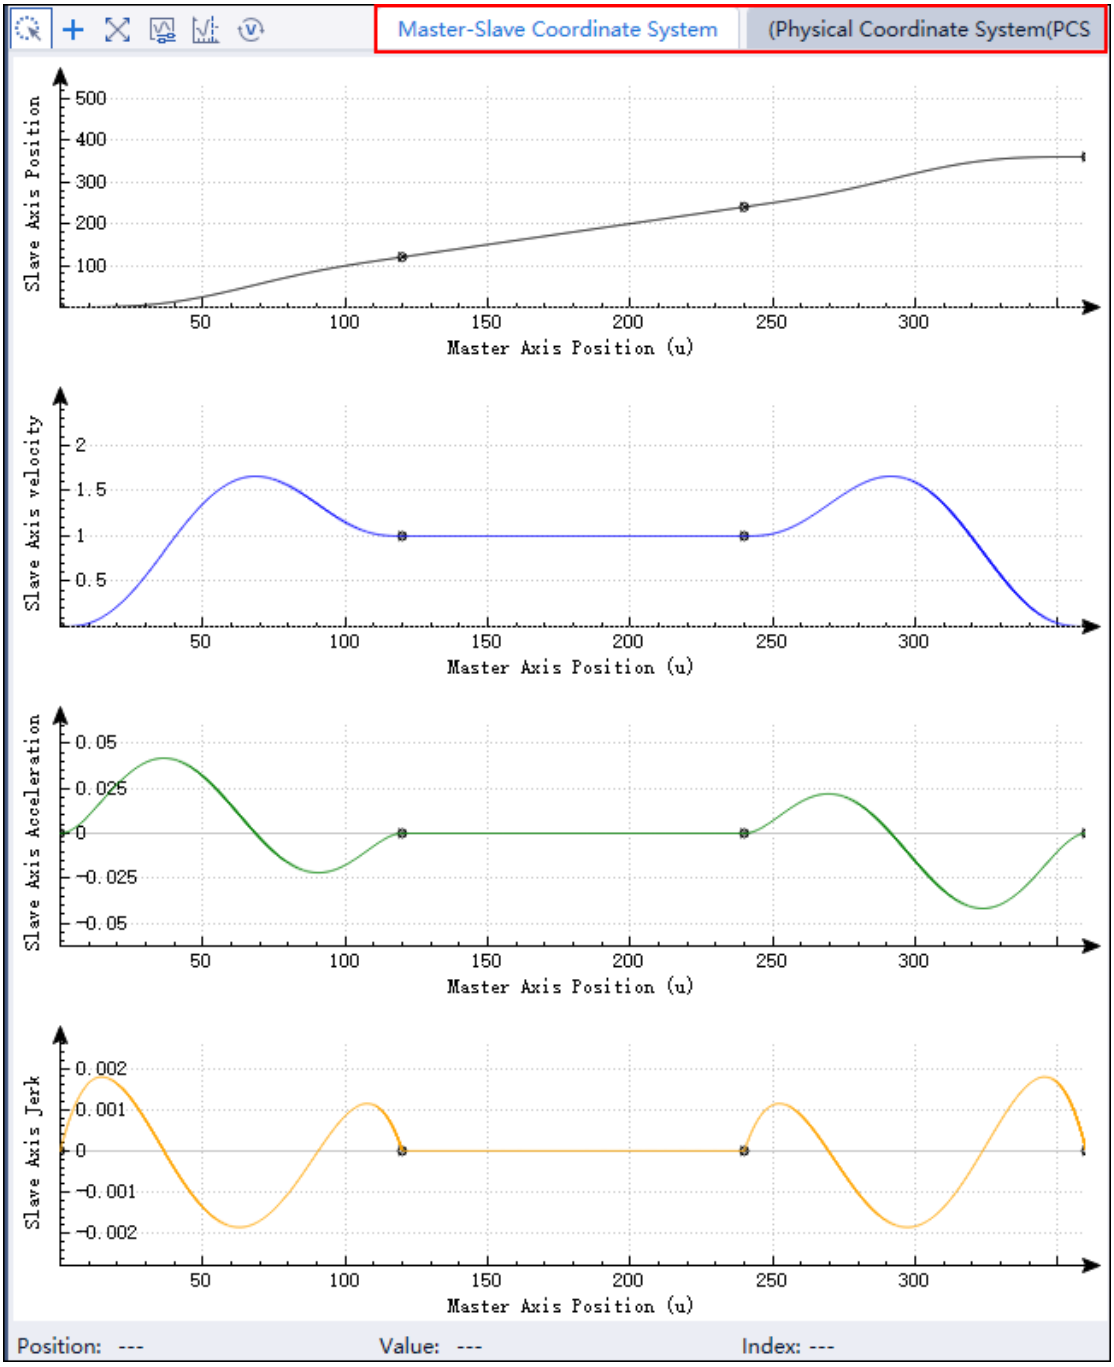
16.3.6.2 Cam Diagram

The left view of the cam chart is the cam diagram view, which includes four commonly used diagrams and the following functions:

ID	Function	Description
①	Select point	This option is activated by default, allowing to select and drag any key point in a diagram.
②	Add point	Click the "Add point" icon and click a position in a diagram to add a key point at the position.
③	Adaptive	Based on the current screen size, the X and Y coordinates are automatically adjusted to fit the position curve, velocity curve, acceleration curve, and jerk curve into the screen.
④	Profile configuration	Used to set the content displayed in the diagrams, with all content displayed by default. You can set the point shape, point size, and curve color for each diagram.

ID	Function	Description
⑤	Add cursor	After adding a cursor and inputting the phase of the X master axis, click "Apply" to view the displacement and velocity/ acceleration data of the slave axis.
⑥	Switch coordinate	Used to switch between master-slave coordinate system and physical coordinate system.

Cam diagram description:



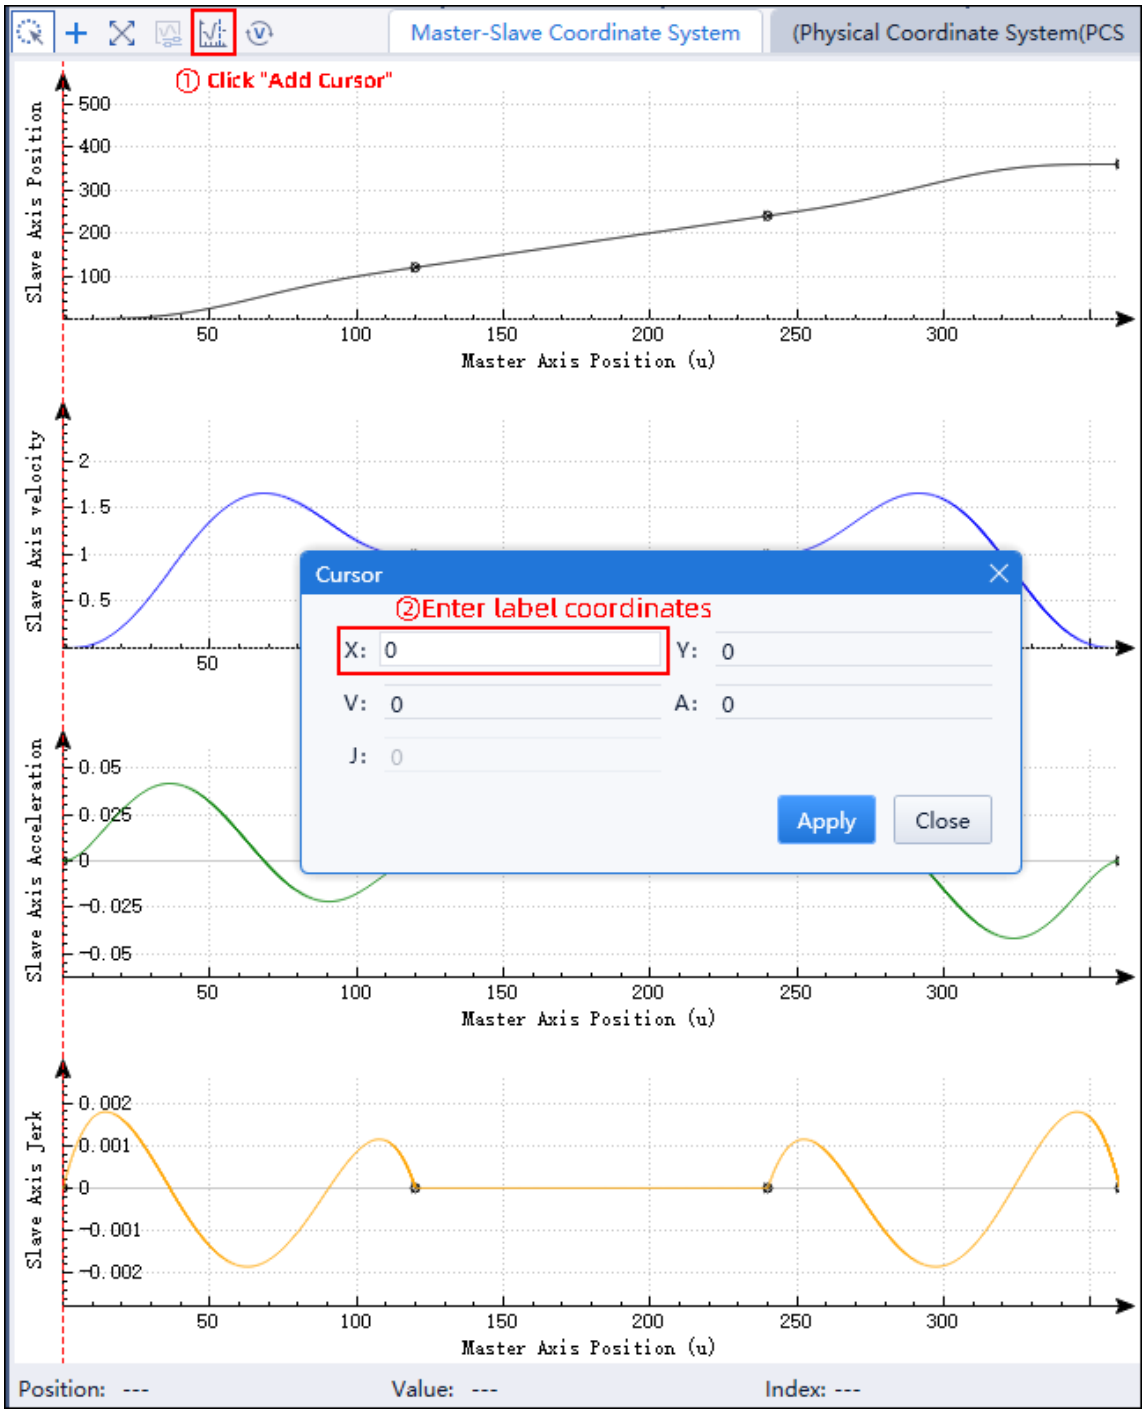
- The cam diagram supports inserting and deleting key points, editing coordinate, and selecting interpolation types.
- The cam diagram supports pitch editing, and the total number of cam interpolation points cannot exceed 65536.
- Whether the cam diagram is of dense point type or key point type, it can display position, velocity, acceleration, and jerk coordinates. Key points can be dragged and dense points cannot.
- The cam diagram supports zooming in on the selected area by dragging the mouse (zooming includes three modes: X-axis, Y-axis, and overall zoom). Adaptive zooming is also supported to automatically fit the entire cam curve to the diagram.
- When the mouse hovers over a key point on the cam diagram, the motion parameter data of the table will be displayed, and the selected key point will be marked with a bright spot. (The motion parameter data can be displayed in one table or multiple tables, and displaying in multiple tables requires selecting the curve).
- The cam diagram supports adding horizontal and vertical cursors, where the horizontal cursor can set the Y-axis position, and the vertical cursor can set the X-axis position. Precise values cannot be obtained by dragging the cursor.
- The cam diagram supports selection of graphical interfaces for velocity, acceleration, and jerk (multiple selections are supported; all interfaces are displayed by default). It also supports setting the point shape, point size, and curve color for each diagram.

Master-slave coordinate system and physical coordinate system

Overview

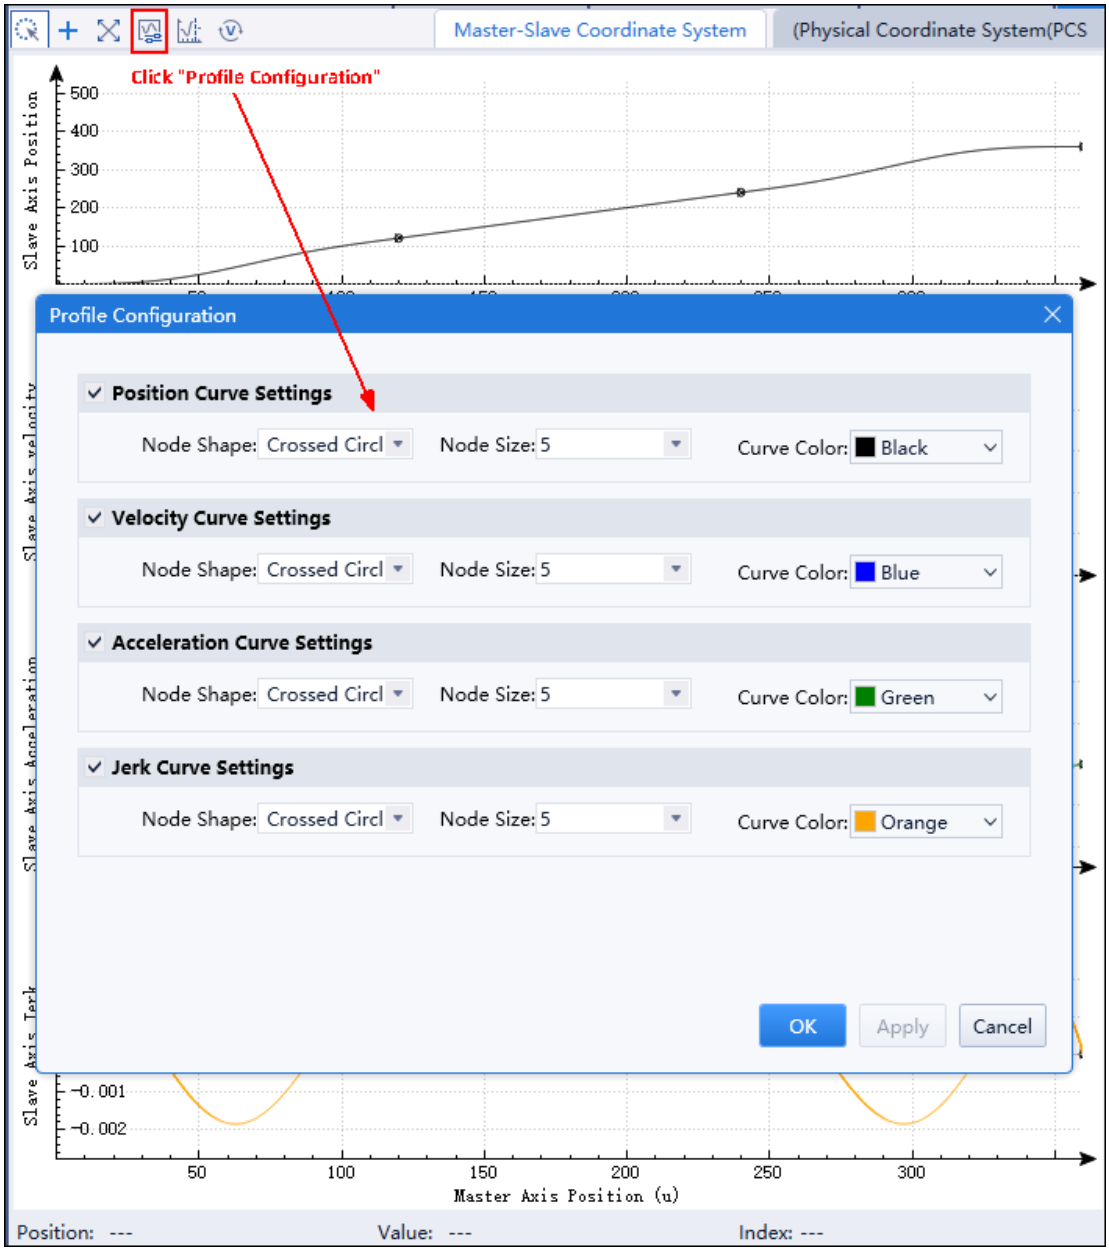
The master-slave coordinate system displays the relationship between the position, velocity, acceleration, and jerk of master axis and slave axis. The physical coordinate system displays the relationship between the cam cycle time and the slave axis position, velocity, and acceleration.

By default, the master-slave coordinate system is displayed. The coordinate system can be switched through the tabs in the upper right corner of the diagram view area.



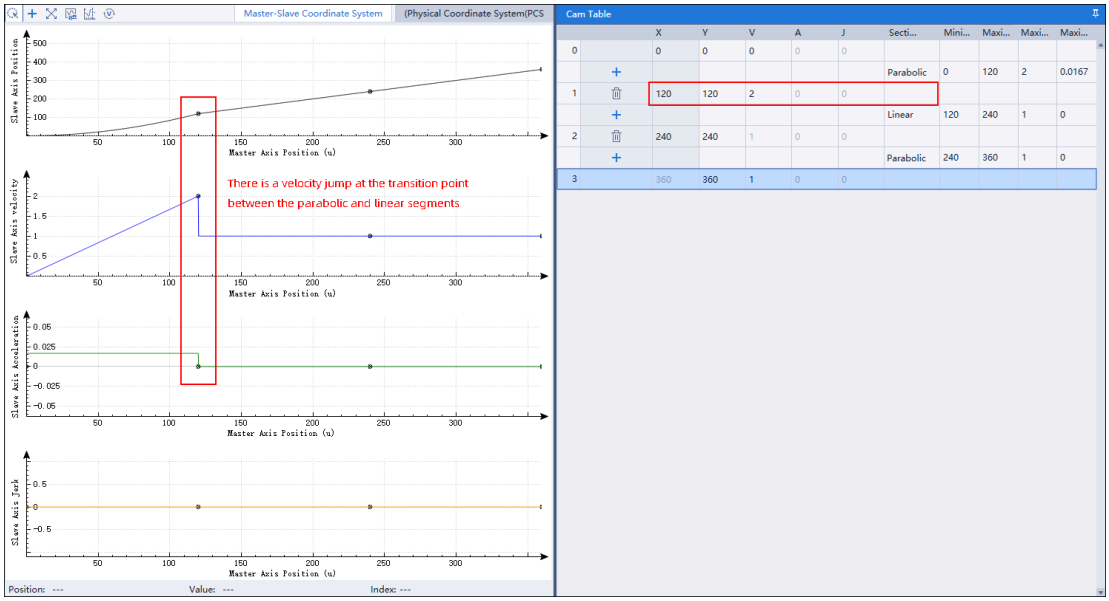
- In the physical coordinate system, click the "Set cam cycle time" icon, modify the cycle time of the cam in the pop-up window, and click "OK" to apply the changes and refresh the physical coordinate system.
- In the physical coordinate system, the jerk column in the cam table is not displayed.
- In the physical coordinate system, the jerk diagram is not displayed. You can choose to display the position, velocity, and acceleration diagrams as needed.
- In the physical coordinate system, points can only be added and moved on the master/slave axis position diagram.
- After a cursor is added, the "Graphic configuration" icon is unavailable in the master-slave coordinate system, and both the "Graphic configuration" icon and the "Set cam cycle time" icon are unavailable in the physical coordinate system.
- In the physical coordinate system, selecting or deselecting "Jerk curve setting" in the "Graphic configuration" window only affects the master-slave coordinate system.

- In the physical coordinate system, a cursor can be added to the position diagram, which can be dragged to display the X/Y/V/A data in the physical coordinate system in the pop-up "Cursor" window.
- In the physical coordinate system, key points in each diagram can be moved by mouse.
- The cam comparison function does not distinguish between coordinate system types and compares data in the master-slave coordinate system.



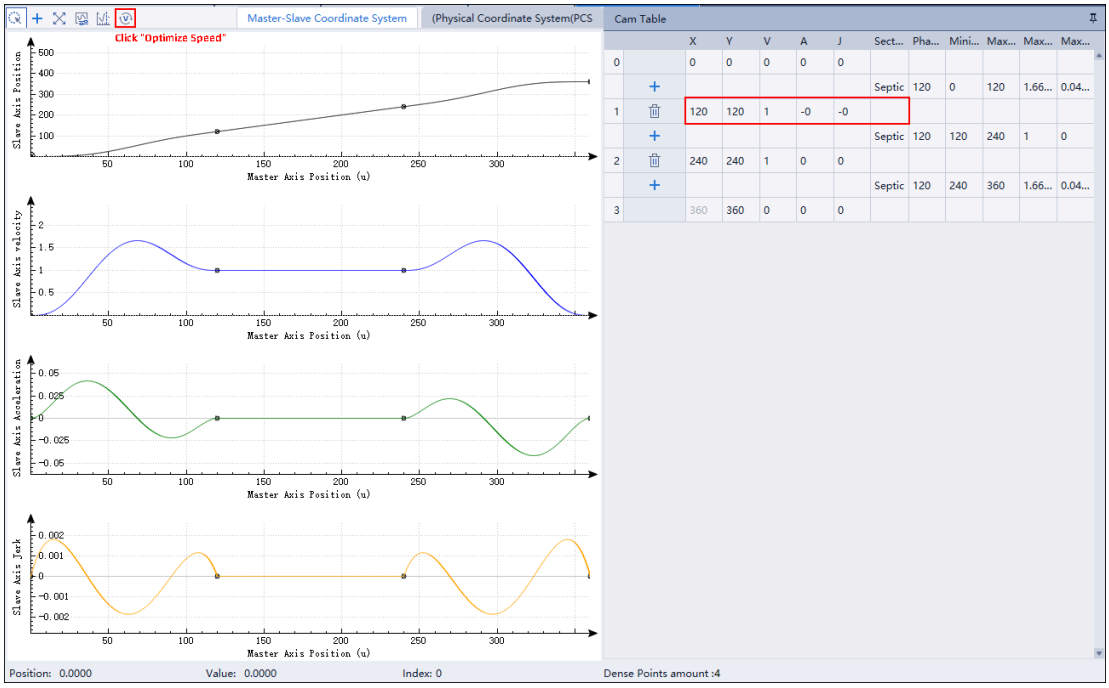
Cursor

The cursor can be displayed on the cam diagram for easier observation.



Profile configuration

Used to set the point shape, point size, and curve color for each diagram.



Optimize speed

Used to adjust the sudden changes in velocity during point transitions in the cam table.

If the system is sensitive to sudden changes in velocity, click the "Optimize speed" icon to optimize the motion parameters between points, such as velocity, acceleration, and jerk, eliminating sudden changes.

Currently, you can optimize sudden velocity changes due to the following two scenarios. The optimization is performed for the velocity of the entire cam table, rather than the velocity between two nodes.

- When a parabolic, cubic, quintic, or septic curve is followed by a linear curve, the velocity of the current node and subsequent nodes is adjusted to match the velocity of the linear curve.
- When a parabolic, cubic, quintic, or septic curve is followed by a cosine acceleration curve, a sine acceleration curve, or a modified trapezoidal acceleration curve, the velocity at the current node and the next node is set to 0.

  The acceleration and jerk are adjusted based on the optimized velocity.

NOTE

The MC_GenerateCamTable instruction can also be used to optimize sudden velocity changes in user-created cam points. For details, see 18.3.3.4.10 MC_GenerateCamTable.

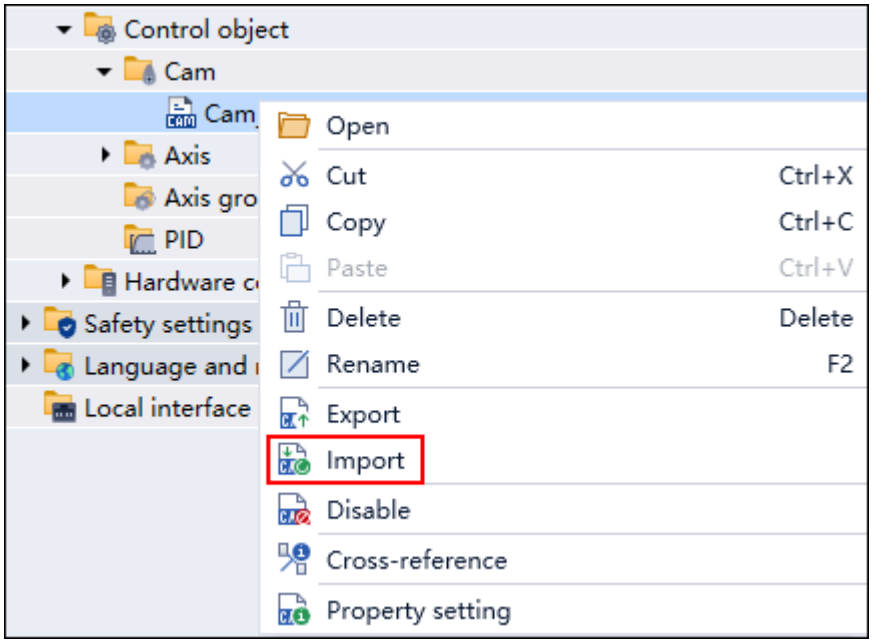
16.3.6.3 Cam Table

The right side of the cam chart is the cam table view, which contains more detailed information.

Cam table description:

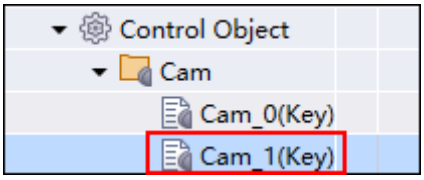
- The starting point of the cam table is (0,0) and cannot be modified, but the velocity ratio at the starting point can be modified (for both the cam table and cam diagram).
- The velocity ratio of linear segments in the cam table cannot be modified. Additionally, for certain curve types, the speed ratio cannot be adjusted when they are connected, such as curve segments following cosine acceleration curves, modified T-type acceleration curves, and sine acceleration curves.
- The velocity ratios at the start and end points can be different (for both the cam table and cam diagram).
- The maximum length of the cam table is 65535, and the minimum pitch is 0.0001 (for both the cam table and cam diagram).
- The minimum precision of the cam table is to six decimal places.
- When changing the curve type of the cam table, parameters such as velocity, acceleration and jerk remain unchanged, unless the curve type is switched to linear.
- The supported curve types include linear, parabolic, cubic, quintic, septic, cosine acceleration, sine acceleration, and modified T-type curves.

ID	Curve Type	Note	Applicable Scenario
①	Linear curve	A linear acceleration curve typically refers to a trajectory where the following axis moves with constant acceleration along a straight line during the motion. This acceleration mode is characterized by a linear increase in velocity over time, hence its velocity-time diagram is a straight line with a positive slope.	Scenarios insensitive to impact
②	Parabolic curve	For motions with constant acceleration or constant deceleration, the displacement of the follower is proportional to the square of the cam rotation angle, and the displacement curve is a parabola, also known as the parabolic motion law. The velocity diagram of this motion law is continuous and will not cause rigid impact. However, there are sudden changes in acceleration at the start point, midpoint and end point, causing sudden changes in the inertial force of the push rod. These sudden changes are finite values and will cause flexible impacts in cam mechanisms.	Medium-speed and light-load scenarios



ID	Curve Type	Note	Applicable Scenario
③	Cubic curve	A cubic polynomial cam curve is a cam profile design method based on cubic polynomial functions, commonly used in mechanical processing and motion control fields. It constructs a smooth cam profile by fitting discrete data points, achieving precise motion control. In cubic curves, displacement and velocity are continuous, but acceleration is discontinuous.	High-speed and medium-load scenarios
④	Quintic curve	This motion law has neither rigid impact nor flexible impact, and features stable motions. This mode is applicable to high-speed scenarios.	High-speed and medium-load scenarios
⑤	Septic curve	The septic polynomial cam curve can meet the setting requirements of position, velocity, acceleration, and jerk at the start and end cam points. It achieves excellent motion performance in scenarios with strict requirements on rigid and flexible impacts.	High-speed and medium-load scenarios
⑥	Cosine acceleration curve	The cosine acceleration motion curve belongs to the trigonometric function-based motion law, also known as the simple harmonic cam curve. It has a flexible impact at the start and end of the motion. If the simple harmonic motion law is adopted for both the outstroke and return stroke periods, the non-impact condition can be satisfied The cosine acceleration curve can only meet the position requirements at the start and end cam points.	High-speed scenarios
⑦	Sine acceleration curve	The sine acceleration motion curve belongs to the trigonometric function-based motion law, also known as the cycloidal cam curve. It has no flexible impact at the start and end of the motion. The sine acceleration curve can only meet the position requirements at the start and end cam points.	High-speed scenarios
⑧	Modified T-type acceleration curve	The modified T-type acceleration cam curve has the advantages of smaller quasi-velocity and quasi-acceleration amplitude, and there is no flexible or rigid impact. This cam curve can only meet the position requirements at the start and end cam points.	Medium-high speed and heavy-load scenarios

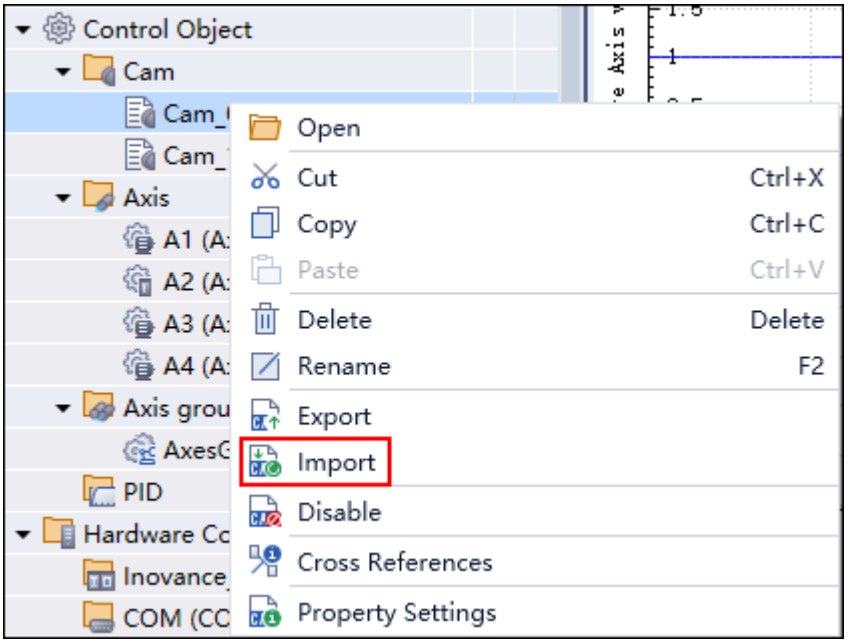
- The cam table has "Add" and "Delete" icons. Click the "Add" icon to quickly insert an intermediate point between two points. Click the "Delete" icon to quickly delete a certain point.



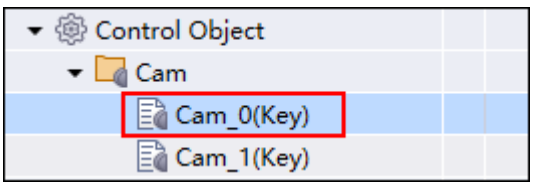
Importing a cam table

Normal import

1. Right-click "Cam" in the left project tree and select "Import cam table".



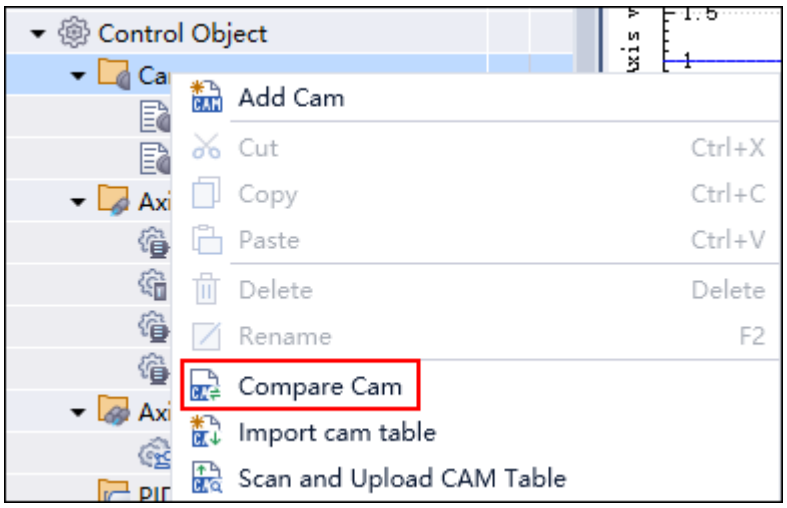
2. Select the file to import. After a successful import, a new cam table will be added under the "Cam" node.



Overwrite import

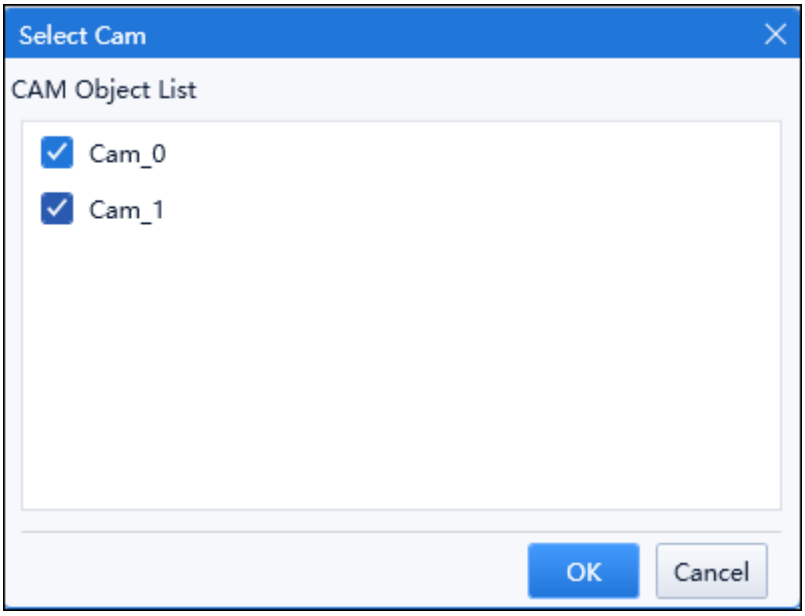
1. Right-click an existing cam table in the left project tree and select "Import".

2. Select the file to import. After a successful import, the new cam table will overwrite the charts in the selected cam table.



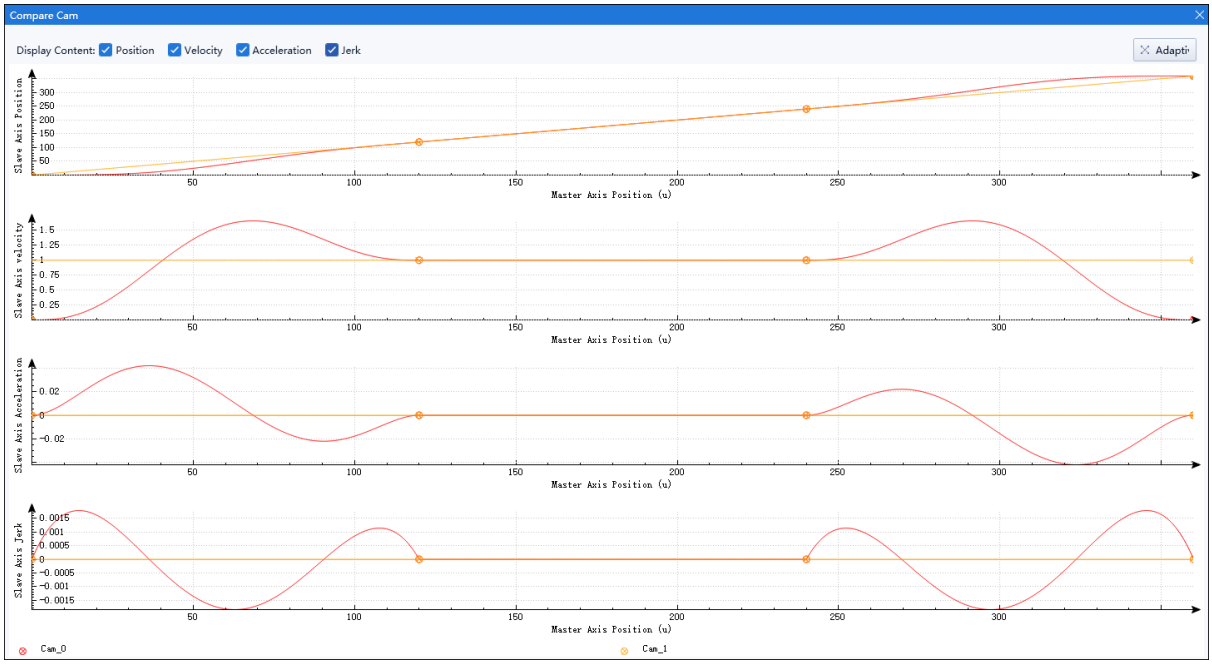
Comparing cam tables

Prerequisites



There are multiple cam tables.

Procedure

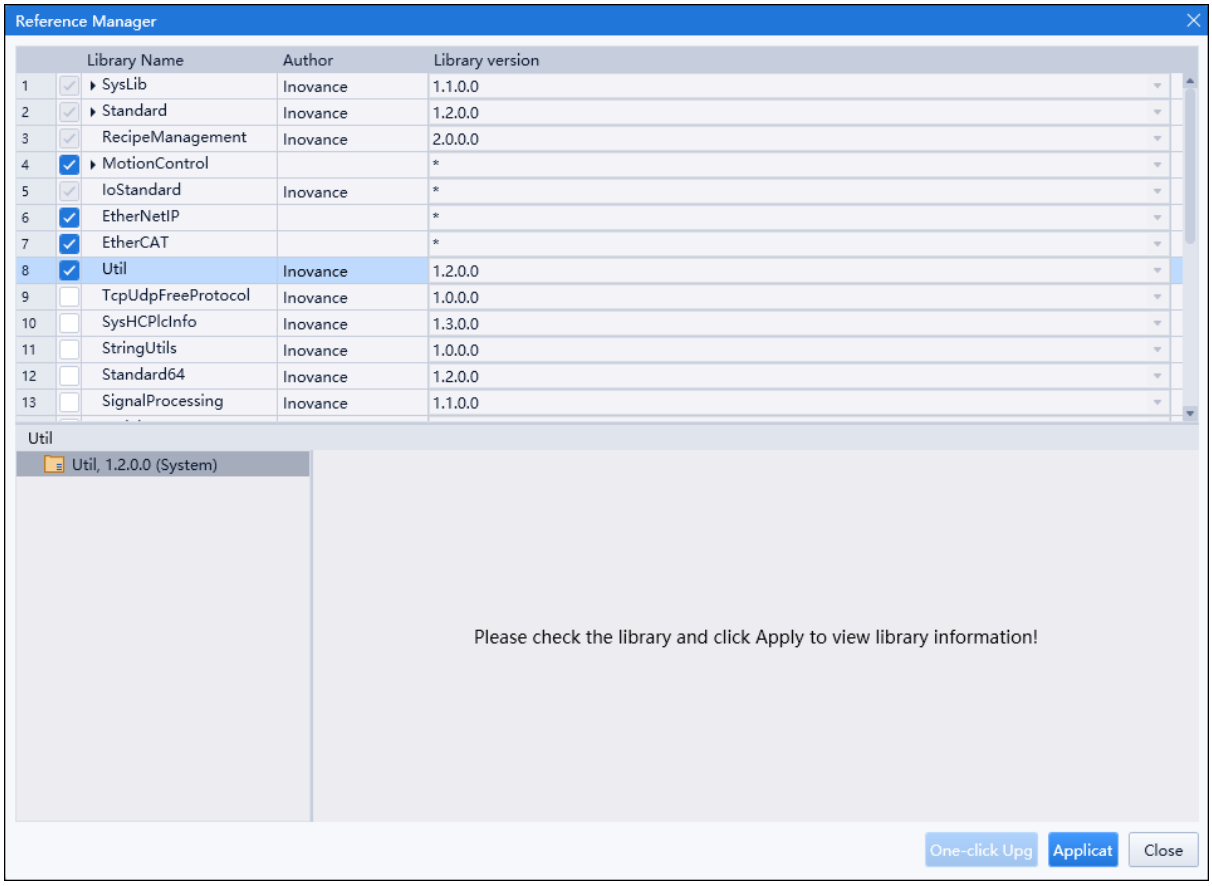


1. Right-click "Cam" in the left project tree and select "Compare cam".

2. In the pop-up "Select cam" window, check the cam tables to compare, and click "OK".

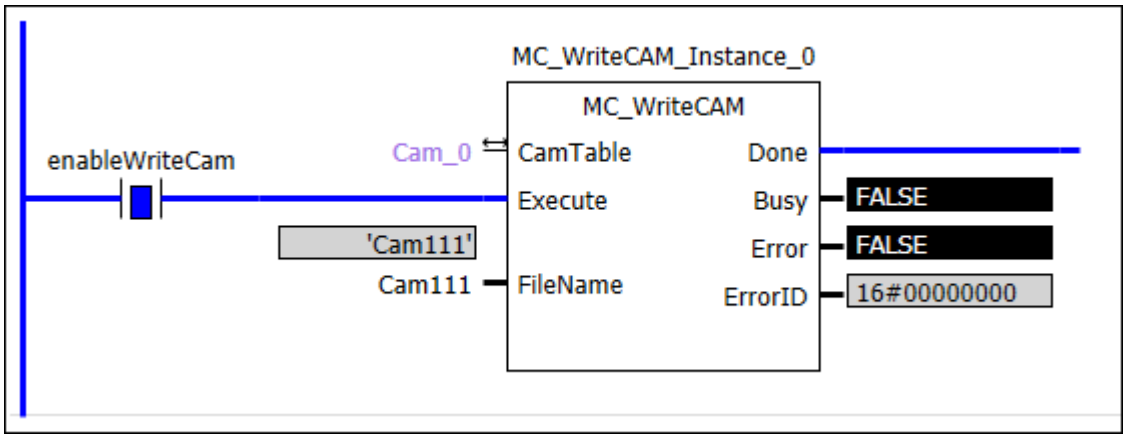
3. The comparison results of different cam tables are shown in the following figure.

Uploading a cam table



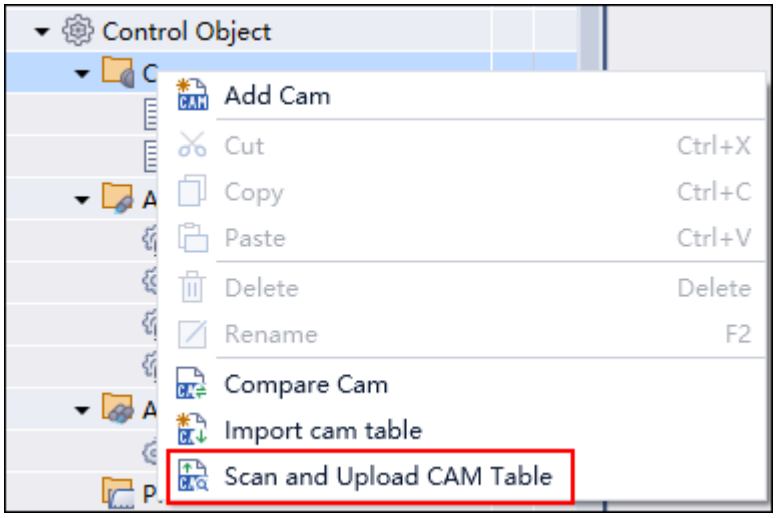
The MC_WriteCam instruction can be used to write custom cam tables or system-created cam tables into the controller. After the device goes offline, the cam tables in the controller can be uploaded to the "Cam" node.

Prerequisites

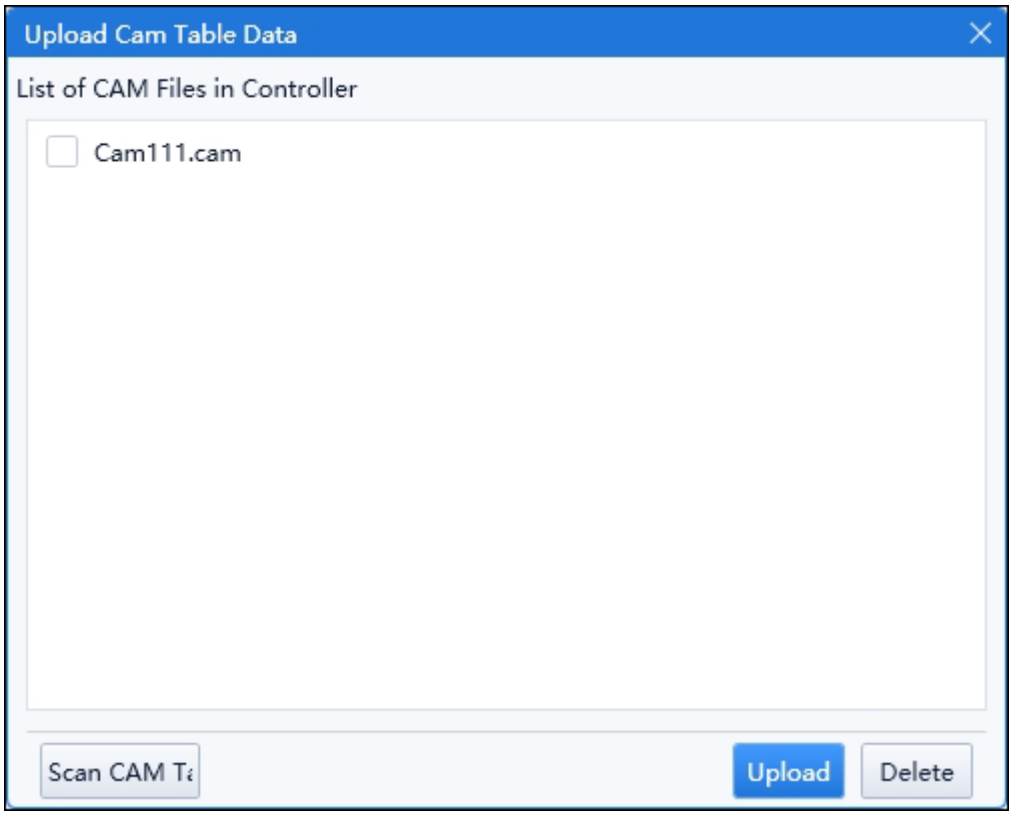


The relevant library references have been added.

Procedure

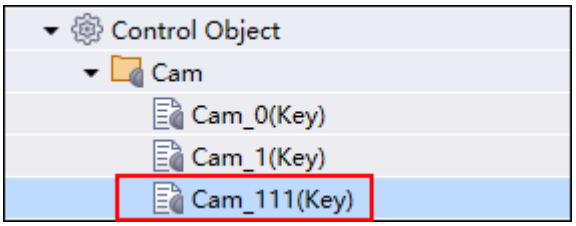


1. Double-click "Library reference" in the left project tree to open the "Reference manager" window.
2. Check the "MotionControl" library.



3. Select the upload and download functions for the cam table in the toolbox.

4. After a successful execution, click the "Offline" icon, right-click "Cam" in the project tree, and select "Scan and upload cam table".



5. The cam files in the controller will be displayed in the pop-up window. Select a cam file and click "Upload".

6. A success prompt for the cam table upload will appear.

7. The uploaded cam table will be added under the "Cam" node in the project tree.

17 Drive Settings

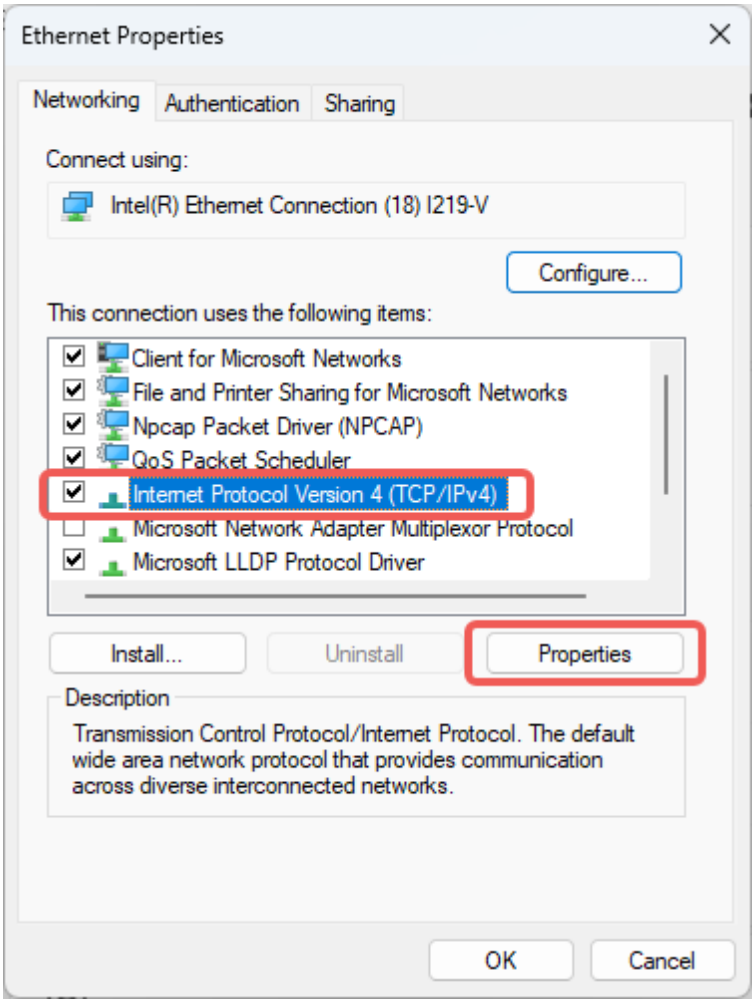
17.1 EtherCAT Configuration

17.1.1 EOE Connection

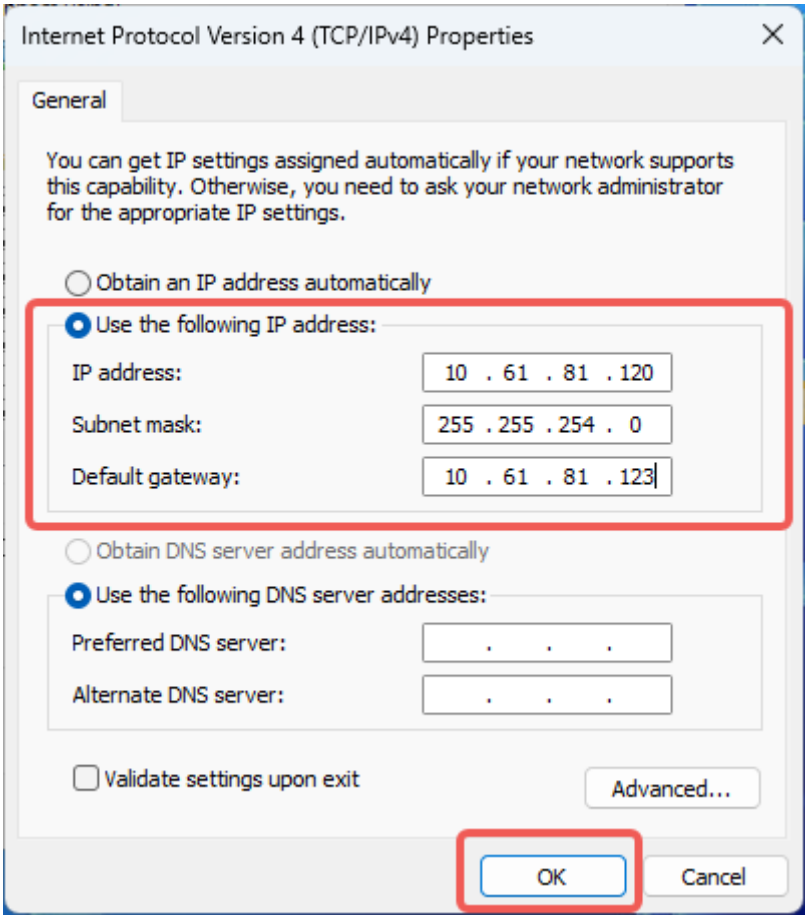
Before commissioning the servo and performing operations, an EOE connection must be established first through the following steps:

1. Perform network settings and configure the computer IP address. For details, see 17.1.2 Network Settings.
2. Create a master station and add an EtherCAT master node. For details, see 17.1.3 Master Station Creation and Configuration.
3. Add the servo drive device. For details, see 17.1.4 Adding a Device.
4. Set the EOE parameters for the servo drive. For details, see 17.1.7.6 EoE Settings.
5. Switch to online mode.
6. Connect the servo drive. For details, see 17.1.8 Device Connection.

17.1.2 Network Settings



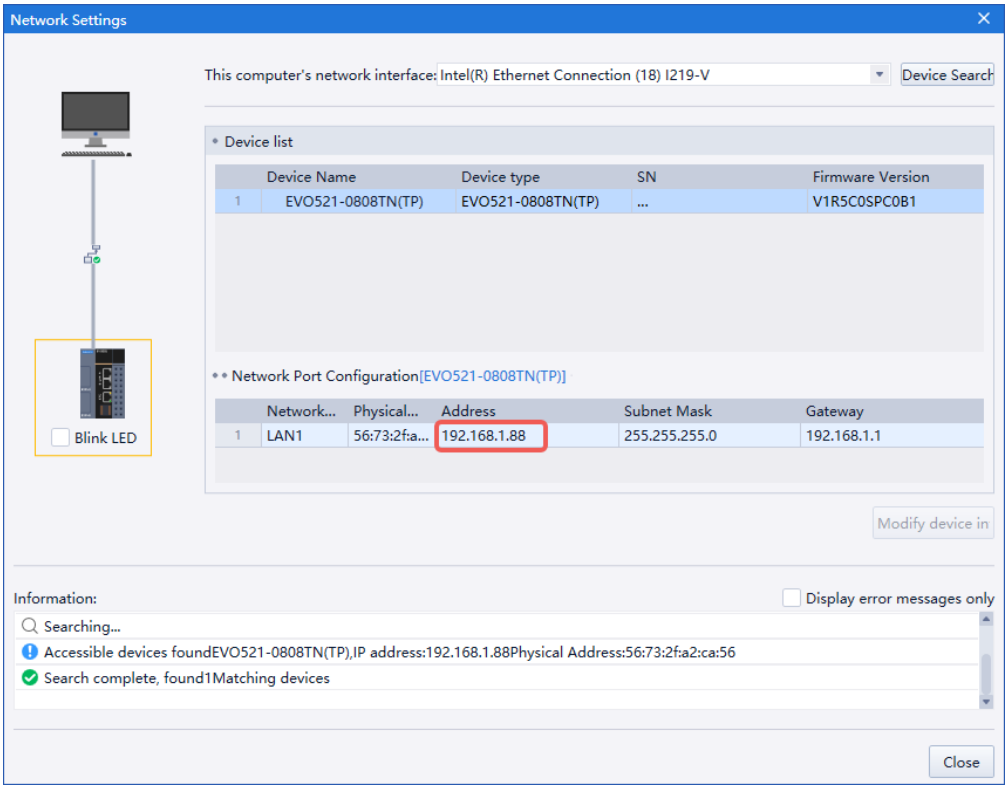
When communicating with the drive using the EOE method, the IP address of the local computer shall be modified to ensure that the computer and the device are in the same subnet.



Manual network configuration is required for EVO500 series PLCs with a device version lower than V1.4 or a firmware version lower than 1.4.0.0. Other models or newer versions have achieved automatic adaptation and do not require additional operations.

The method for setting the computer's IP address is as follows:

1. In the "Ethernet properties -> Networking" window, select "Internet Protocol Version 4 (TCP/IPv4)" and click "Properties".



2. Select "Use the following IP address", then enter the correct IP address, subnet mask, and default gateway, and click "OK" to complete the settings.

NOTE

Set the default gateway to the IP address of the PLC, which can be obtained through software, as follows:

In the menu bar, select "Online > Network setting". In the pop-up window, click "Device search" to obtain the device IP.

17.1.3 Master Creation and Configuration

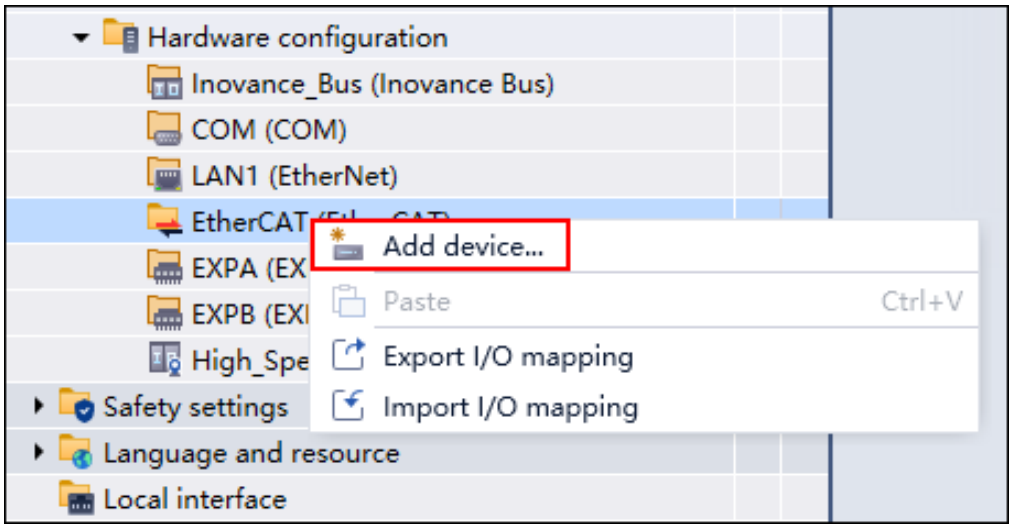
This section introduces the precautions for master station creation and configuration:

- Before creating the master, add a PLC device; otherwise, the drive cannot be added or configured.
- Before operating the device, switch the PLC to offline mode; otherwise, operations fail. When switching the device to offline mode, the "Online" icon in the toolbar becomes highlighted, and the "Offline" icon becomes grayed out.
- The EtherCAT configuration mainly involves device operations. For details, see 17.1.4 Adding a Device.
- For details about disabling/enabling devices, see 17.1.5 Disabling/Enabling a Device.

17.1.4 Adding a Device

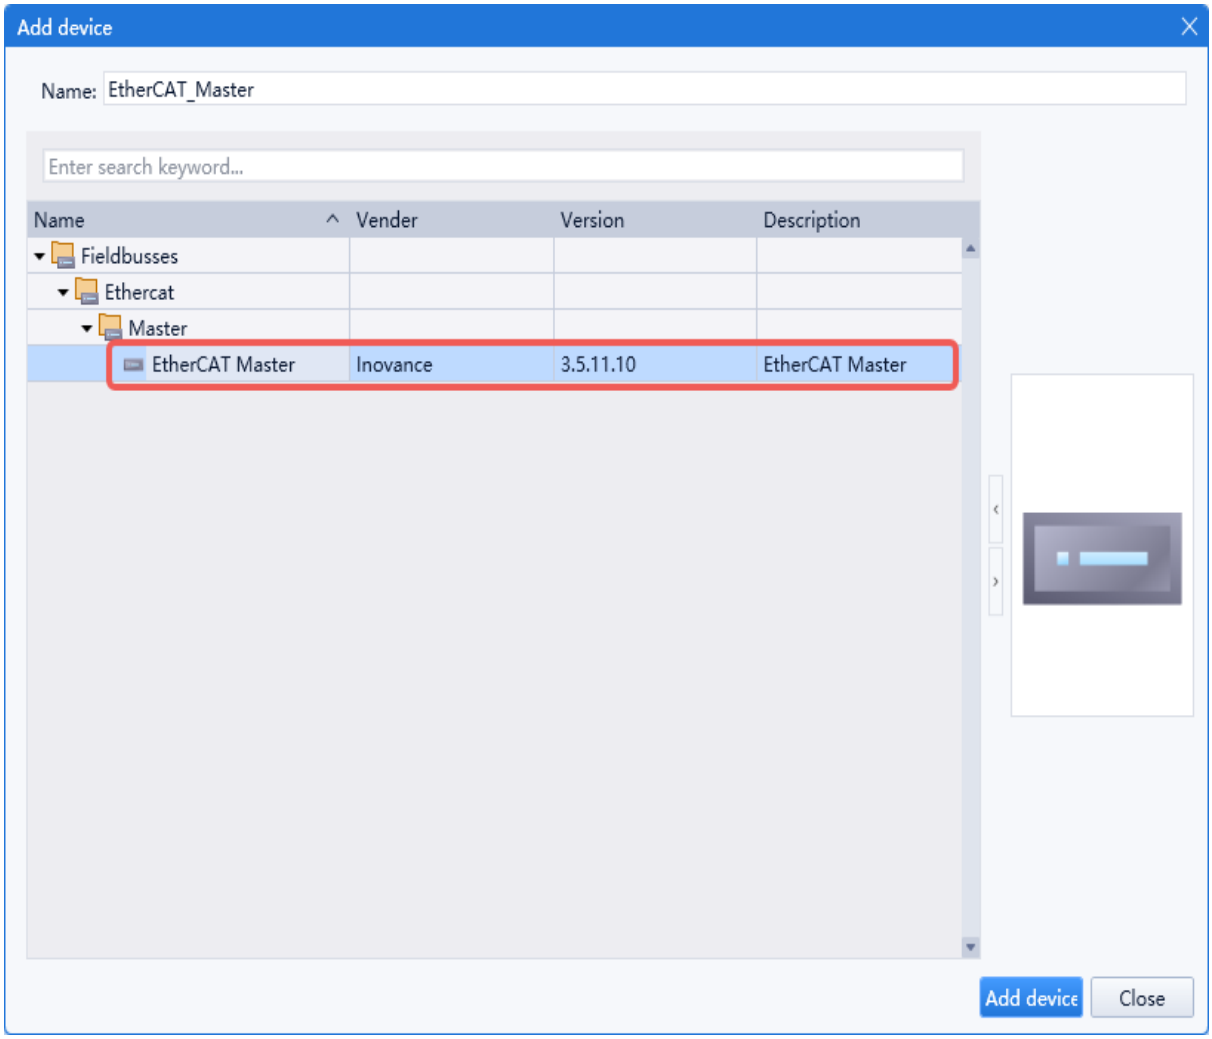
During EtherCAT configuration, right-click the "EtherCAT (EtherCAT)" node under "Hardware configuration" of the PLC node to add an EtherCAT master; then add slaves (drive devices) under the master through the "Add device" and "Scan for devices" functions.

17.1.4.1 Adding a Device



The "Add device" function can be used to add EtherCAT master and slaves.

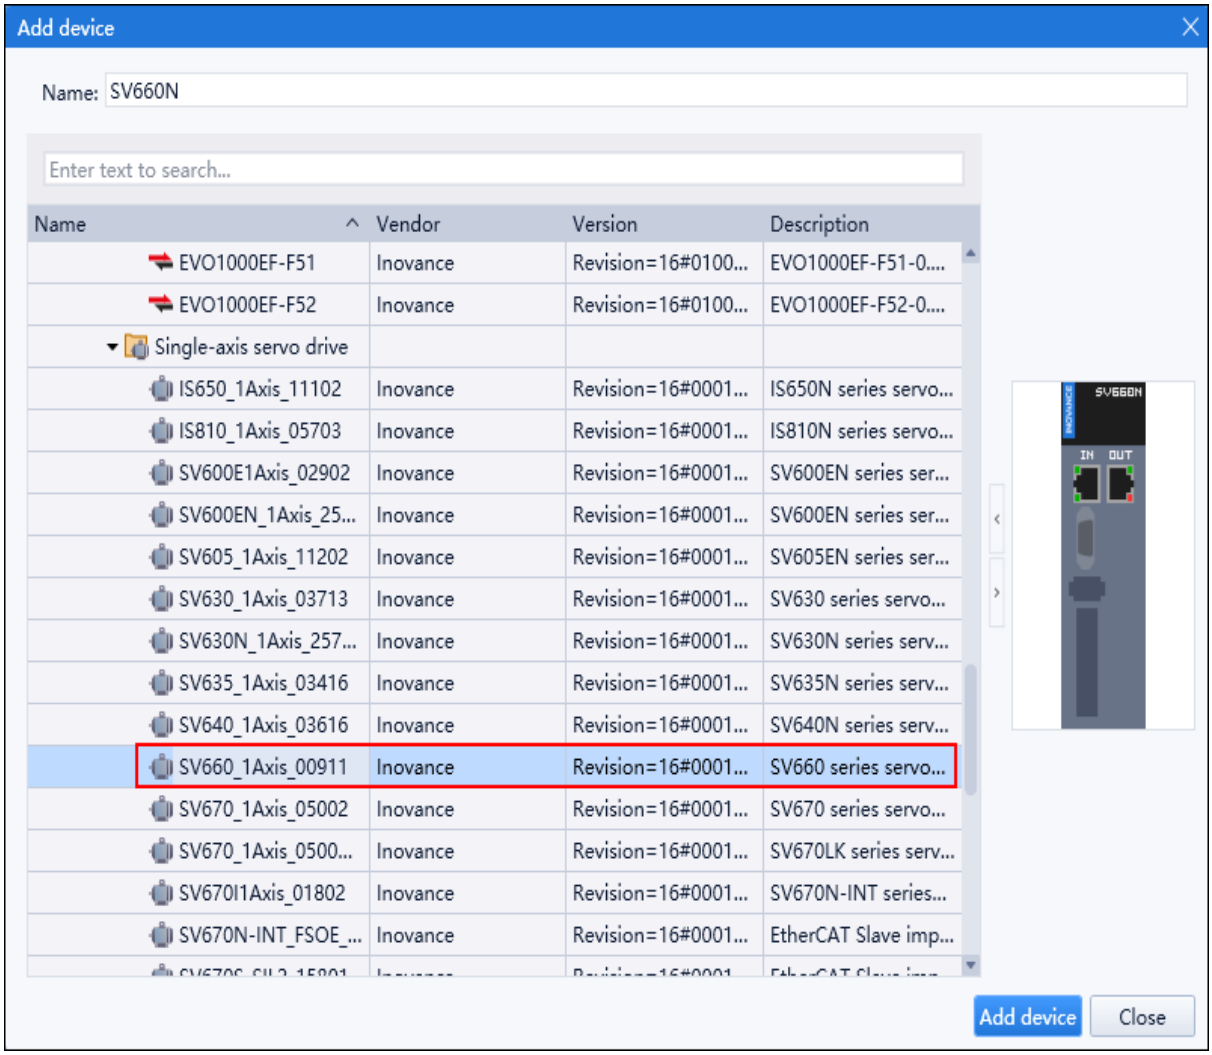
Prerequisites



- A PLC device has been added.
- The drive device has been correctly connected.
- The PLC device is in an offline status.

Procedure

1. Right-click "Hardware configuration > EtherCAT (EtherCAT)" in the project tree, and select "Add device".



2. In the pop-up window, double-click "EtherCAT Master", or select it and click "Add device".

3. After adding, right-click "EtherCAT (EtherCAT) > EtherCAT_Master (EtherCAT Master)" in the project tree, and select "Add device".

4. In the pop-up "Add device" interface, select the actual drive model that is connected, then click "Add device" or double-click the device model to add the drive.

NOTE

Only one master can be added under the "EtherCAT (EtherCAT)" node; multiple servo drive devices can be added under "EtherCAT_Master (EtherCAT Master)".

17.1.4.2 Scanning for Devices

The "Scan for devices" function can be used to add servo drives.

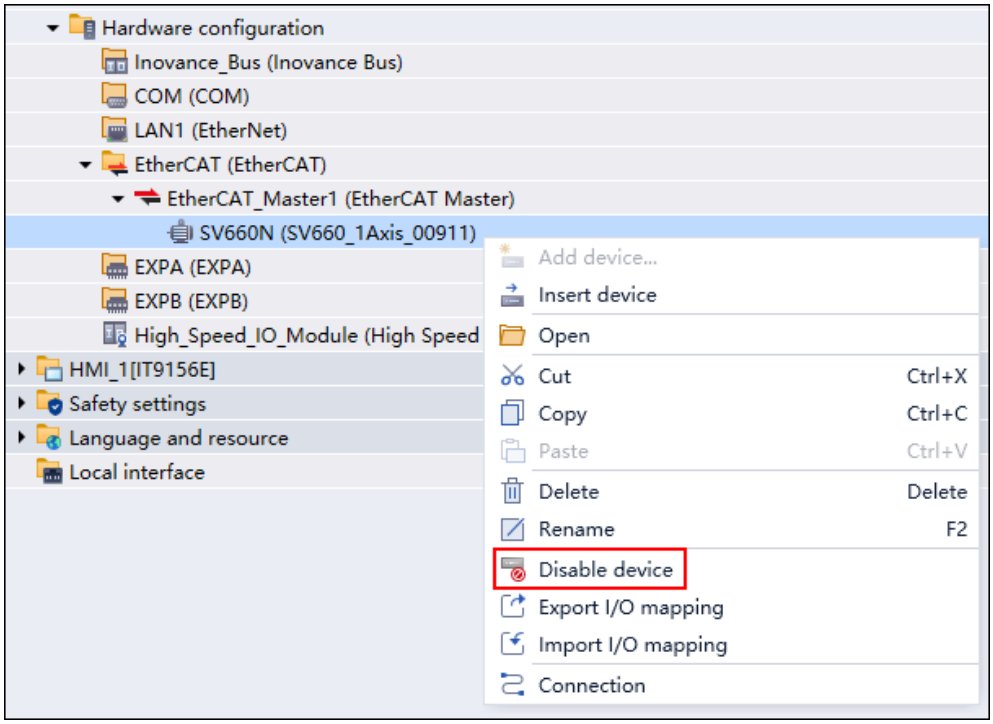
Prerequisites

- The drive device has been correctly connected.
- The "EtherCAT_Master (EtherCAT Master)" node has been created.
- The PLC has been compiled and downloaded.

Procedure

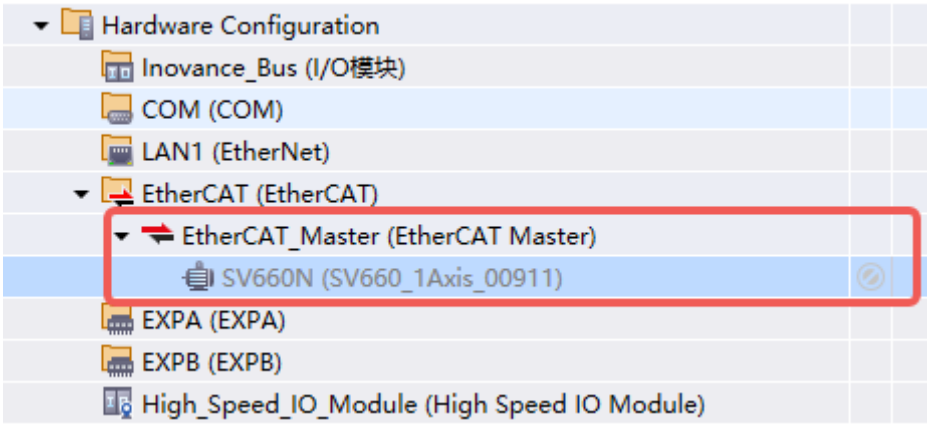
1. Right-click the "EtherCAT_Master (EtherCAT Master)" node in the project tree and select "Scan for devices".
2. In the pop-up window, click "Device scanning" and wait for the scan results.
3. Select the scanned device, click "Copy all devices to project" to add the selected device.

17.1.5 Disabling/Enabling a Device



When "Virtual axis mode" is selected for a motion control axis, even if you disable the EtherCAT master (along with all the master and slave stations under this bus), you can still control the motion control axis through the program. When the EtherCAT master is disabled, all EtherCAT slaves are disabled and the bus servo axes associated with the slaves stop running. Similarly, when the EtherCAT master is enabled, all EtherCAT slaves will be enabled.

Prerequisites



Devices have been added to the master.

Procedure

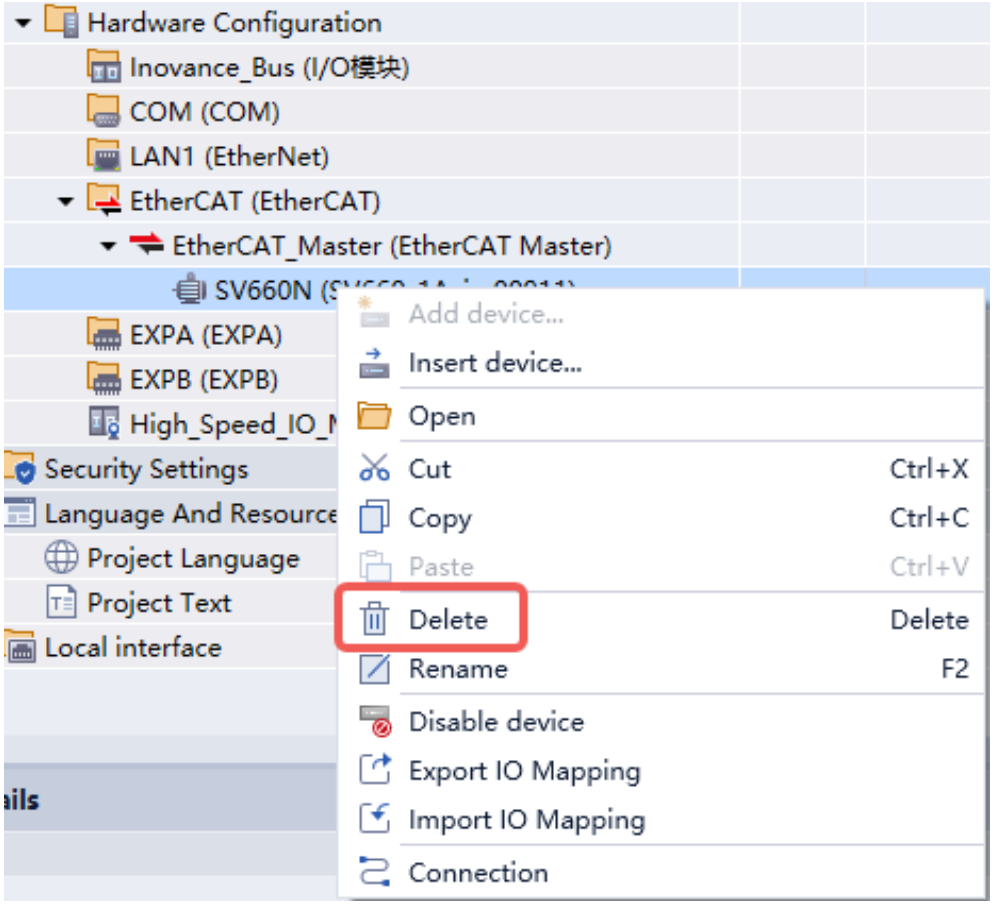
Right-click the device node in the project tree and select "Disable device" to disable the selected device and all devices under it (a single device can also be enabled or disabled using the same method).

For example, the effect of disabling "EtherCAT_Master" is shown in the following figure:

A disabled a device cannot be connected. To enable a disabled device, right-click the disabled device and select "Enable device".

17.1.6 Deleting a Device

The operation to delete a device is cascaded, meaning that the selected device and all its sub-devices will be deleted.

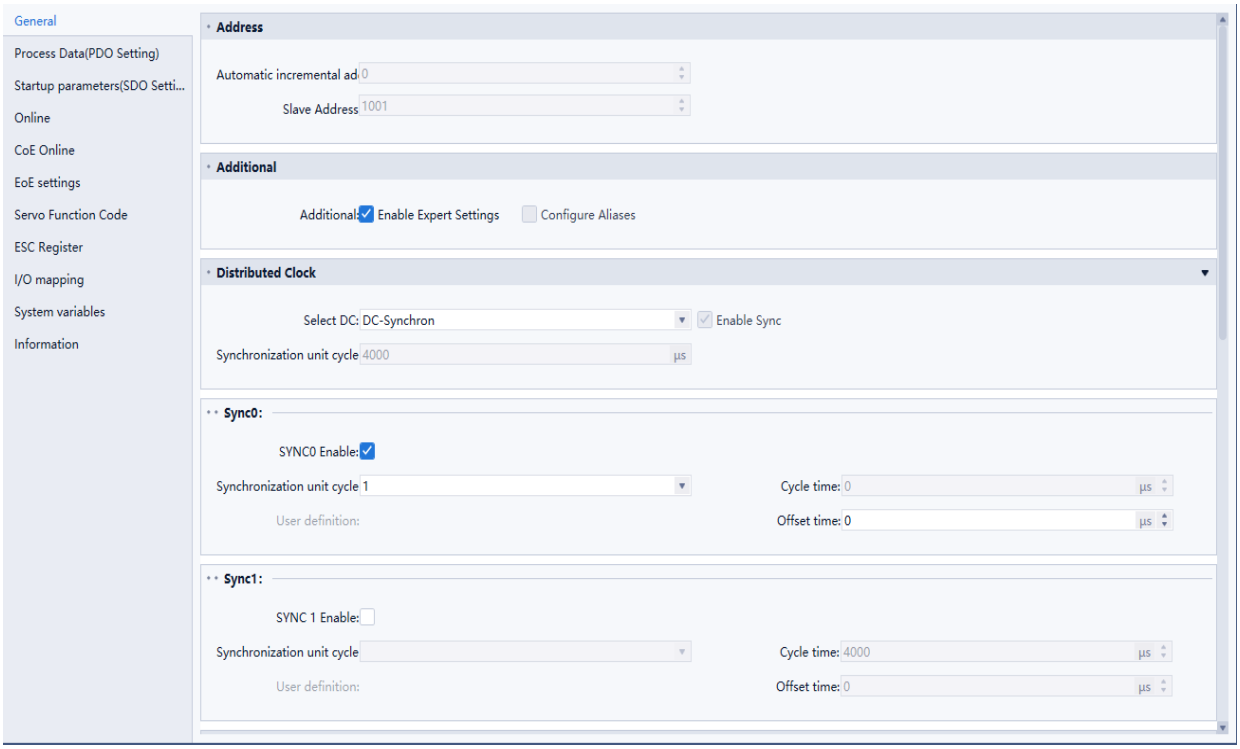


Prerequisites

The PLC has been switched to offline status.

Procedure

Right-click the added device node, select "Delete", and then click "OK" in the confirmation box.



Servo drive devices, EtherCAT masters, or LC devices can all be deleted.

17.1.7 Device Configuration

17.1.7.1 General Settings

Double-click a slave node (servo device) to open the slave configuration window. The "General" interface of the EtherCAT slave provides basic configuration information for the slave, as shown in the figure below.

Address

If the "Auto-configure master/slave" option in the master device editor is not checked, the following options can be configured:

- Automatic incremental address: The automatic incremental address (16-bit) is determined by the physical topology position of the slave in the network. This address is only used when the EtherCAT master starts up. It assigns EtherCAT slave addresses to slaves at corresponding physical topology positions through sequential addressing.

  During sequential addressing, the auto-increment address of the slave is determined by its connection position in the physical topology network, represented by a negative number. Sequential addressing sends data frames containing sub-messages. As each data frame passes through a slave device, the auto-increment address in the sub-message automatically increments by 1. When a physical slave receives the data frame, it addresses its own message by checking whether the auto-increment address in the sub-message is 0. This mechanism of updating internal address variables in the slave through data frames is called "sequential addressing" or "auto-increment addressing".

- Slave address: The configuration address (nominal address) of the slave, assigned by the master during startup. This address is independent of the actual position in the network, and the address of the slave is unrelated to its connection order within the segment. After disabling a slave device in hardware configuration, the address of the slave device is set to 0, and it is reassigned according to the current specifications when the slave is re-enabled.

Additional settings

- Enable expert settings: If this option is checked, you can configure distributed clocks, startup checks, timeouts, DC cycle unit control, watchdogs, and other functions.
- Configure aliases: This reflects the status of the "Enable alias" option in the general settings of the EtherCAT master, and cannot be modified here.

Distributed clock

- Enable sync: If this option is checked, it indicates that the "Distributed clock" function is used.
- Synchronization unit cycle (μs): If the "Distributed clock" function is enabled, the synchronization unit cycle value will default to the same as the EtherCAT master's cycle time.
- Select DC: This drop-down menu provides all settings related to distributed clocks in the device description file, generally including free operation, SM event synchronization, DC synchronization, and so on. The setting items are described in the table below:

ID	Item	Description
1	Free operation mode	In this mode, the local control cycle is generated by a local timer interrupt. The cycle time can be set by the master. This is an optional function for the slave.
2	SM event synchronization	A local cycle is triggered when a data input or output event occurs. The master can write the transmission cycle of the process data frame to the slave. The slave can then check whether the cycle time is supported or perform local optimization of the cycle time. The slave can choose to support this function. Synchronization typically occurs with the data output event. If a slave has only input data, synchronization occurs with the data input event.
3	DC synchronization	A local cycle is triggered by the SYNC event. The master must complete the transmission of the data frame before the SYNC event. Therefore, the master clock must also be synchronized to the reference clock.
4	Sync0 and Sync1	Slave synchronization signals 0 and 1. The distributed clock control unit of the slave (an internal function of the EtherCAT-specific communication chip) can generate two synchronization signals, Sync0 and Sync1. These signals provide interrupt flags to the application layer of the slave or directly trigger the update of output data.
5	Sync0 enablement and Sync1 enablement	Check these options to enable the Sync0 and Sync1 synchronization signals. • Synchronization unit cycle: If this option is checked, slave synchronization cycle time = master cycle time × selected coefficient. • The "Cycle time (μs)" item indicates the current set cycle time of the slave.
6	User-defined DC mode	If this option is selected in the "Select DC" drop-down menu, user-defined synchronization cycle time in microseconds can be entered in the "Offset time" fields for Sync0 and Sync1.

Diagnostics

Visible only in online mode.

Current status: Displays the current status of the slave's communication state machine. Possible values include: Initialization, Pre-operational, Safe-operational, Operational, Boot (not supported by Inovance

servo). If the current status is operational, it indicates that the slave configuration has been correctly completed.

Option

Option: If a slave device is defined as "optional", no fault messages will be generated to prevent the device from not being present in the bus system. To enable this option, a station address must be stored in the slave device, so the "station alias" address must be defined and written into the EEPROM. This option is only valid when the "Auto-configure master/slave" option is checked in the EtherCAT master general settings and the EtherCAT slave supports this function.

Start check

By default, the system automatically checks the identity of the supplier and the product ID at startup based on the current configuration. You can also check the "Check version number" option to check the specified version. If a mismatch is detected, the bus will stop running and no further actions will be performed. This setting is used to prevent the download of incorrect configurations.

Timeout

By default, the following operations are not defined as timeouts. To observe whether these operations exceed a specific time, you can set them here.

- SDO access: Sets the timeout time for SDO (Service Data Object) access from the EtherCAT master protocol to the slave.
- I -> P: Sets the timeout time for the transition of the slave communication state machine from "Initialization" to "Pre-operational".
- P -> S / S-> O: Sets the timeout time for the transition of the slave communication state machine from "Pre-operational" to "Safe-operational", or from "Safe-operational" to "Operational".
- Detect port -> Open port: After the slave is connected, sets the timeout time for detecting and opening the port.

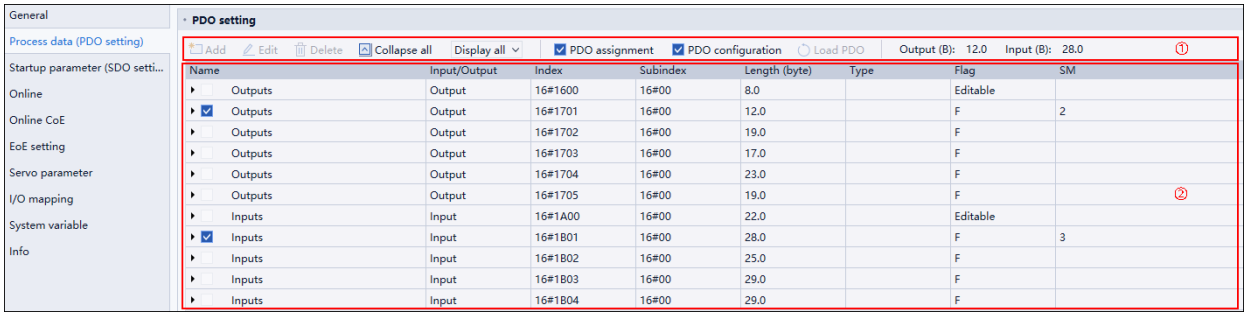
DC cycle unit control

This option is assigned to the local microprocessor to select the options defined by the distributed clock function. The control function is implemented in register 0x980 of the EtherCAT slave, with optional settings being: Periodic unit, Latch 0, and Latch 1.

Watchdog

- Watchdog multiplier: Sets the multiplier of the watchdog timer to determine its minimum timing increment. The default value is 2498. The minimum timing increment of the watchdog timer is 100 μs.
- PDI watchdog: After enabling the PDI watchdog, if the PDI (Physical Device Interface) communication time of the EtherCAT slave exceeds the set value, the watchdog will be triggered.
- PD watchdog: Sets the PD watchdog.

Slave alias



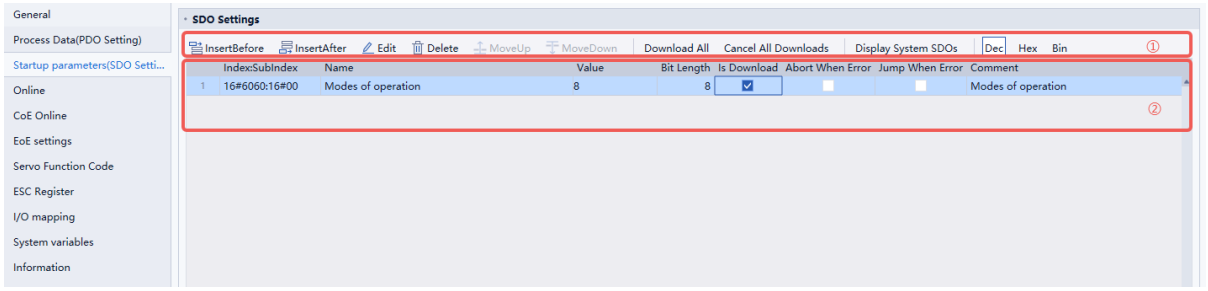
The settings of slave alias are only valid when "Option" is checked and the slave device supports alias addresses (defined by the device description file). If the corresponding alias address of the slave is configured, there is no need to change the configuration in the user program when adjusting its position in

the physical topology network, and the slave can still operate normally. Note: After modifying the alias address of the slave, the user program must be re-downloaded for the alias to take effect. Additionally, some slaves must be powered off and restarted for the alias to take effect. For details, see the user guides of relevant slave devices.

- Disable: If this option is checked, the slave will not detect the alias address.
- Configure site alias (ADO 0x0012): When the slave device supports alias addresses and "Option" is checked, writing the alias address is supported only in online operation mode.
- Write EEPROM: This command is visible only in online mode. It allows the defined address to be written to the EEPROM of the slave. If the slave does not support the written address, this command is invalid and the slave cannot operate in site alias form.
- Actual address: This field is visible only in online mode. The actual address of the slave is displayed, which can be used to check whether the "Write EEPROM" command is successful.
- Display device identification (ADO 0x0134): Reserved.
- Data word (2 bytes): Reserved.

17.1.7.2 Process Data (PDO Settings)

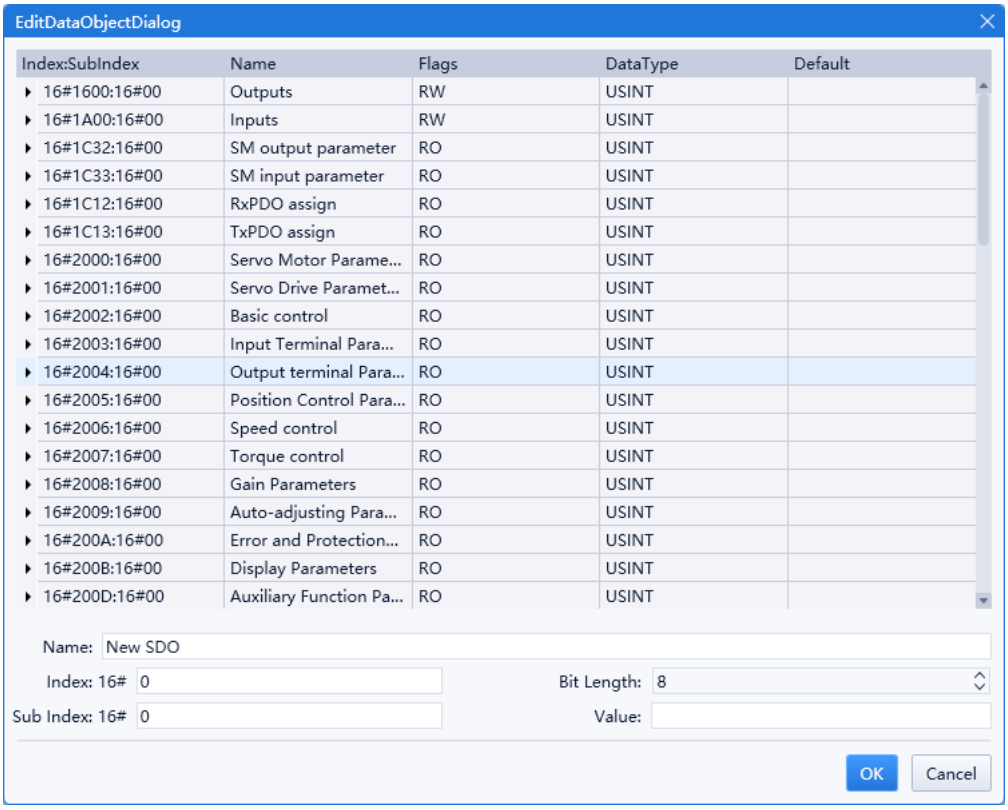
In actual automated control systems, there are normally two forms of data exchange between application programs: time-critical and non-time-critical. Time-critical indicates that specific actions must be completed within a designated time window; if not, it may lead to control failure. The process of periodically sending time-critical data is called periodic process data communication. Non-time-critical data can be sent non-periodically using MailBox data communication in EtherCAT.



No.	Function	Description
①	Toolbar	Supports adding, editing, deleting, and filtering PDO entries.
②	PDO display area	Displays detailed information about PDO.

- Adding: Adds PDO items based on the properties of the current PDO group (editable properties only). Users can choose to add one set or multiple sets of data.
- Edit: Edits the selected PDO item based on the properties of the current PDO group (editable properties only).
- Delete: Deletes the selected PDO item based on the properties of the current PDO group (editable properties only).
- Collapse all: Collapses all entries in the PDO display area with one click.
- Filter box: Filters the PDO display area to display all, display output PDO entries, or display input PDO entries.

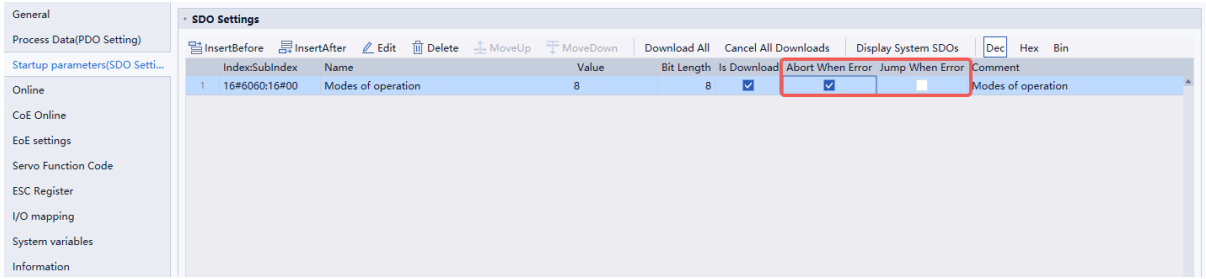
- PDO allocation/PDO configuration: In the configuration of the GR10_4ADE module, PDO allocation and configuration refer to assigning PDO objects to the corresponding input/output channels and setting PDO parameters to ensure correct communication between the module and the CANopen network.
- Load PDO: When the slave is in operation, the current PDO group data of the slave can be uploaded to the backend.



17.1.7.3 Startup Parameter (SDO Settings)

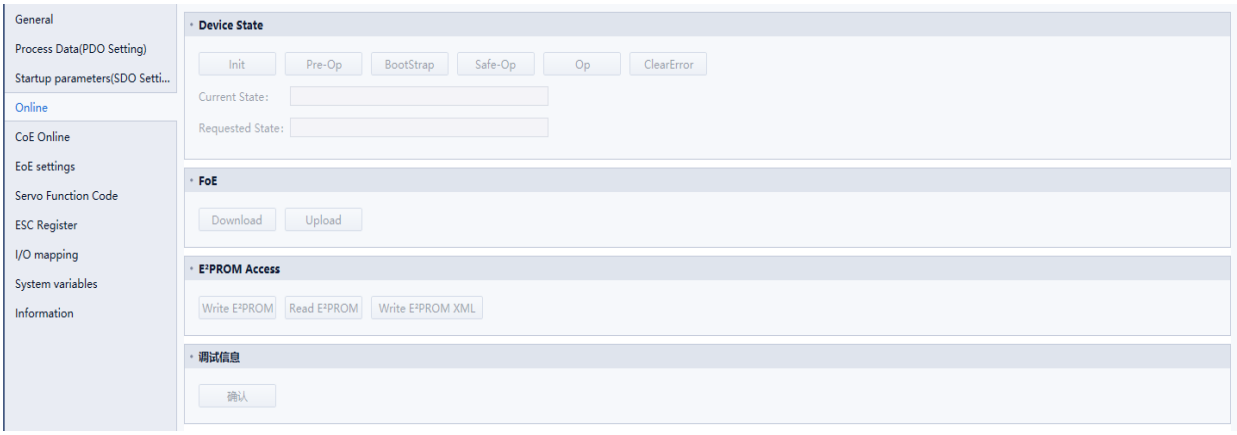
Startup parameters can be transmitted to the slave through SDO (Service Data Object) when the system starts. They include basic configuration parameters required for the slave startup, as shown in the following figure.

No.	Function	Description
①	Toolbar	Supports inserting, editing, deleting, downloading, canceling download, and setting display mode for SDO entries.
②	SDO entry display area	Displays detailed information of SDO entries.



- Insert before: Adds an SDO entry to the startup parameter list before the currently selected entry. The object dictionary selection box that pops up is shown below. After selecting the SDO to add, you can modify its name, index, sub-index, bit length, and value in the edit bars below, then click "OK" to create a new startup parameter.

- Insert after: Adds an SDO entry to the startup parameter list after the currently selected entry.
- Edit: Edits the parameters of the currently selected entry. Read-only parameters cannot be edited, such as system parameters.
- Delete: Deletes the currently selected entry.
- Move up/Move down: The order of the SDO list (from top to bottom) represents the order in which startup parameters are transmitted to the module. The "Move up" and "Move down" buttons can change the transmission order.
- Download all (SDO)/Cancel all downloads (SDO): Click "Cancel all downloads" to deselect the download property of all entries. Click "Download all" to select the download property of all entries. You can also select the download property of some entries for partial download.
- Display system parameters: Displays the parameters added to the SDO after PDO allocation and PDO configuration are checked, for comparison only.
- Value display mode: The values in the "Value" column of the SDO entry display area can be displayed in decimal, hexadecimal, or binary.



Note: When a fault occurs during the SDO transmission process, it can be resolved through the following options:

- Exit on error: If this option is selected, the SDO transmission will exit if an error is detected.
- Skip on error: If this option is selected, the SDO transmission will skip to the next line and continue if an error is detected.

17.1.7.4 Online

The slave online configuration editor can only be used after logging into the device. The related functions and interface are as follows.

- **Device state**

The EtherCAT state machine coordinates the status relationships between the master and slave applications during initialization and operation, as shown in the following figure. The EtherCAT operation transition sequence is: Initialization -> Pre-operational -> Safe-operational -> Operational. The following table introduces each status transition relationship.

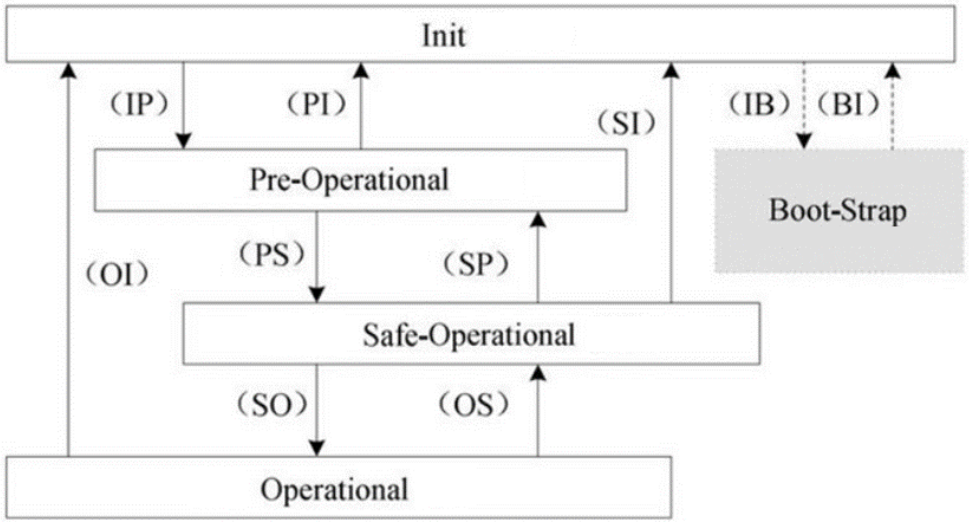


Figure 17-1-7-4-1 EtherCAT status transition relationship

No.	Status Transition	Local Management Service
①	IP	Starts mailbox communication.
②	PI	Stops mailbox communication.
③	PS	Starts input updating.
④	SP	Stops input updating.
⑤	SO	Starts output updating.
⑥	OS	Stops output updating.

No.	Status Transition	Local Management Service
⑦	OP	Stops output/input updating.
⑧	SI	Stops output updating and mailbox communication.
⑨	OI	Stops output/input updating and mailbox communication.
⑩	IB	Starts boot mode.
⑪	BI	Restart the device

  - Clear error: Click this button to clear the error in the current status.
  - Current status: Displays the current operating status of the device.
  - Request status: Displays the currently requested status. When selecting another status and the transition has not been completed, this bar will display the requested but uncompleted status.

- FoE

  Used to transmit firmware files to the slave for firmware upgrades.

  Click the "Boot status" button to transit the slave to boot mode. Click "Download"/"Upload" to download or upload firmware files and a dialog box pops up. Enter a string and password to execute the file transfer. This information is provided by the slave device and recorded in the slave's data table. Avoid power outages or status switches during firmware upgrades.

- ^{E2}PROM interface

  The configuration of the slave can be read from or written to the E2PROM.

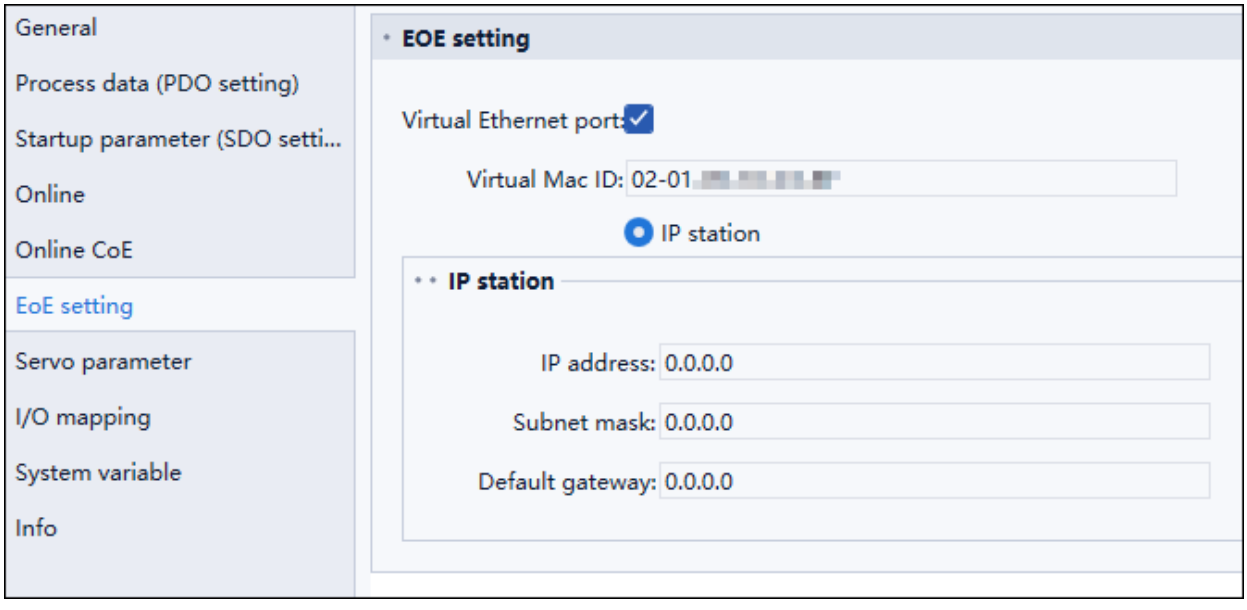
  Similar to firmware file transfer, this operation will also pop up a dialog box to open or save the file. Users can use the "Write E2PROMXML" command to directly write the slave configuration from an XML file to the device. This command is only valid if there is configuration data in the XML file (in the <configuration data> section).

- Commissioning

  Click "Clear" to clear all fault codes from the slave.

17.1.7.5 Online CoE

The values of online CoE can only be read when the bus is operating normally and the PLC is logged in, as shown in the following figure.



- The interface displays the index, item, flag, type, and value information of the data.
- The flags include RO (read-only) and RW (read-write).
- Click "Read this page" to read the values of the parameters on the current page.
- Click "Auto upload" to automatically read the values of the parameters from the device.
- Select "Offline files from ESI" or "Online device" to switch the source of the data in the list.

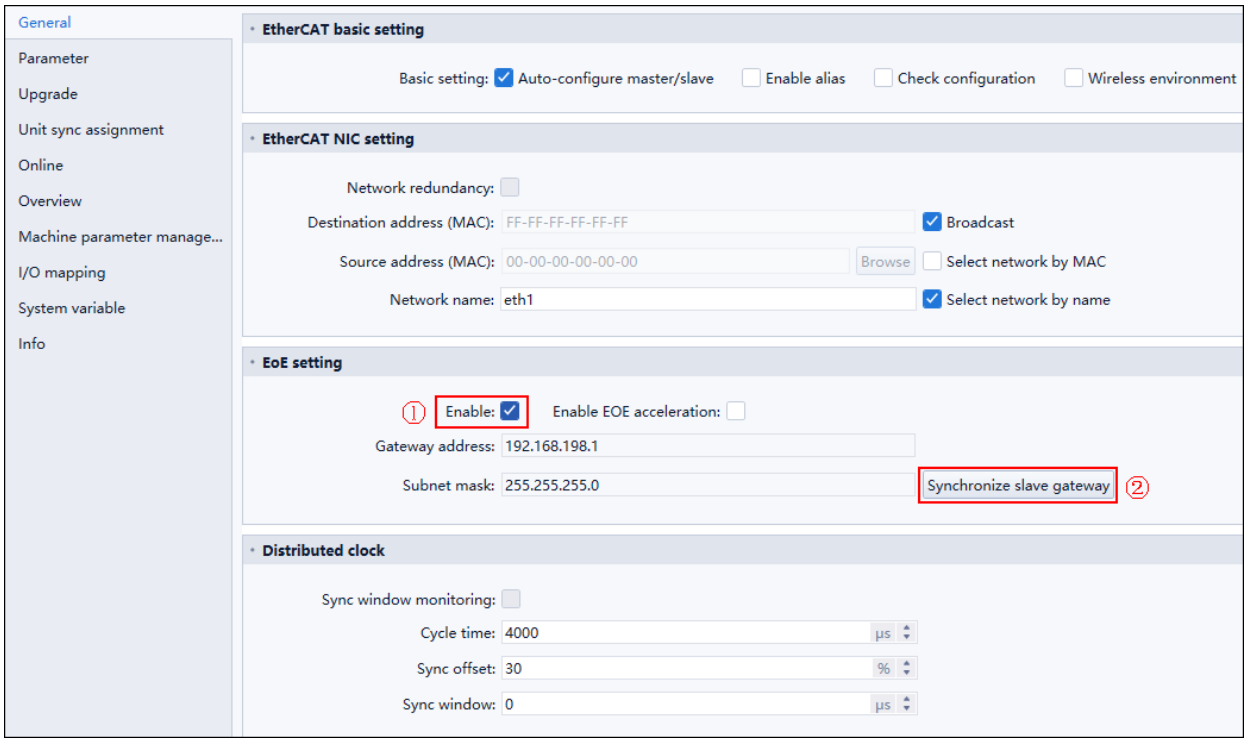
17.1.7.6 EoE Settings

This function is currently not supported for the MD800 and MD810 series products.

EtherNET over EtherCAT (EoE) allows any EtherNET device to be connected to EtherCAT via a conversion terminal without affecting the real-time performance of EtherCAT. Similar to well-known Internet protocols, such as TCP/IP, VPN, PPPoE (DSL), Ethernet frames are transmitted via the EtherCAT protocol.

- This setting allows standard network devices to be connected to end devices (such as printers, PCs) via a switch by enabling "Virtual Ethernet port" and set the "IP station".

For special slave devices that support EoE, communication can be set. The following dialog box will only pop up when the device supports EoE.



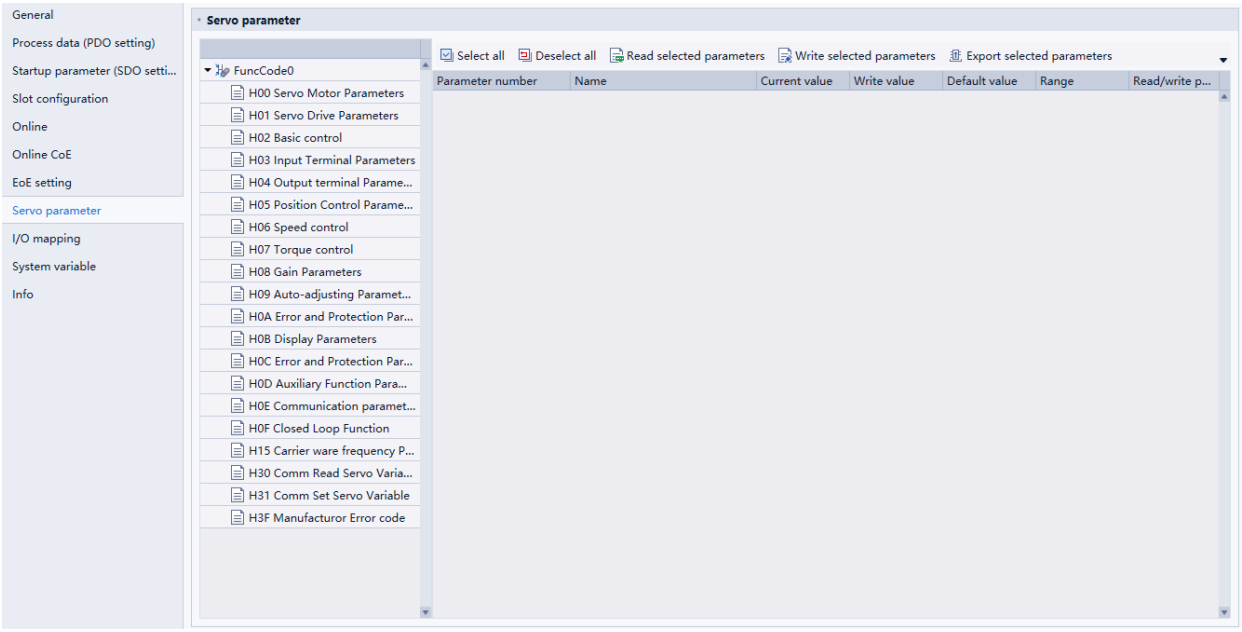
- Virtual Ethernet port: Enables the EoE function of the slave device. If this option is checked, a special "Virtual Mac ID" must be defined.
- Virtual MacID: Automatically assigned by the system, which can be manually modified by users. If a MacID duplication occurs, a compilation fault will occur.
- IP station: Configures the device as an IP interface. When this option is selected, the Ethernet communication parameters must be set.

  Ethernet communication parameters must be set based on the parameters of the virtual Ethernet adapter. The entries for IP address, subnet mask, and default gateway are each allocated four bytes to identify the slave in the network and support modifications to the default settings.

NOTE

The IP address must be in the same subnet as the virtual Ethernet adapter. For example, if the Ethernet adapter's address is 192.168.1.1 and the subnet mask is 255.255.255.0, then the IP address must be within the range of 192.168.1.2 to 192.168.1.254.

- After configuring the EoE settings of the slave, double-click the master node "EtherCAT_Master (EtherCAT Master)", check "Enable" in the "EoE settings" section of the general settings, and then click "Synchronize slave gateway" to complete the EtherCAT configuration, as shown in the figure below:



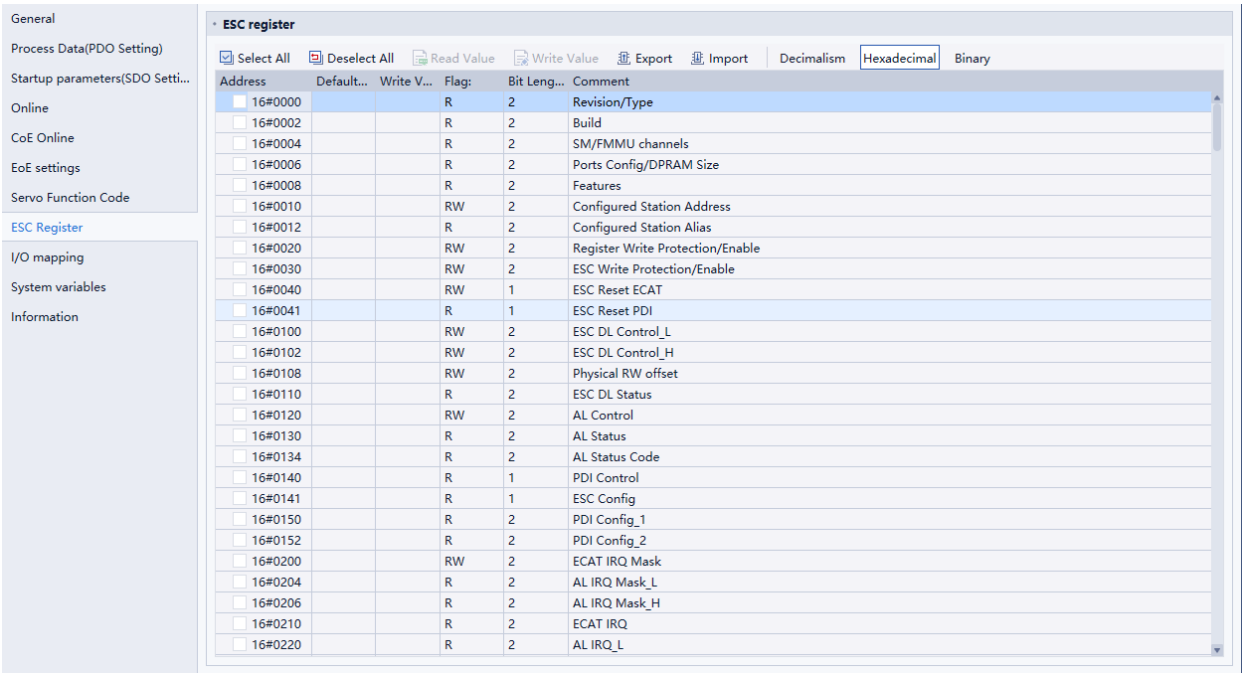
NOTE

The gateway address cannot be in the same subnet as the PLC's IP address. If they are in the same subnet, it is recommended to modify it manually.

Only devices that support the EoE function can be configured.

17.1.7.7 Servo Parameters

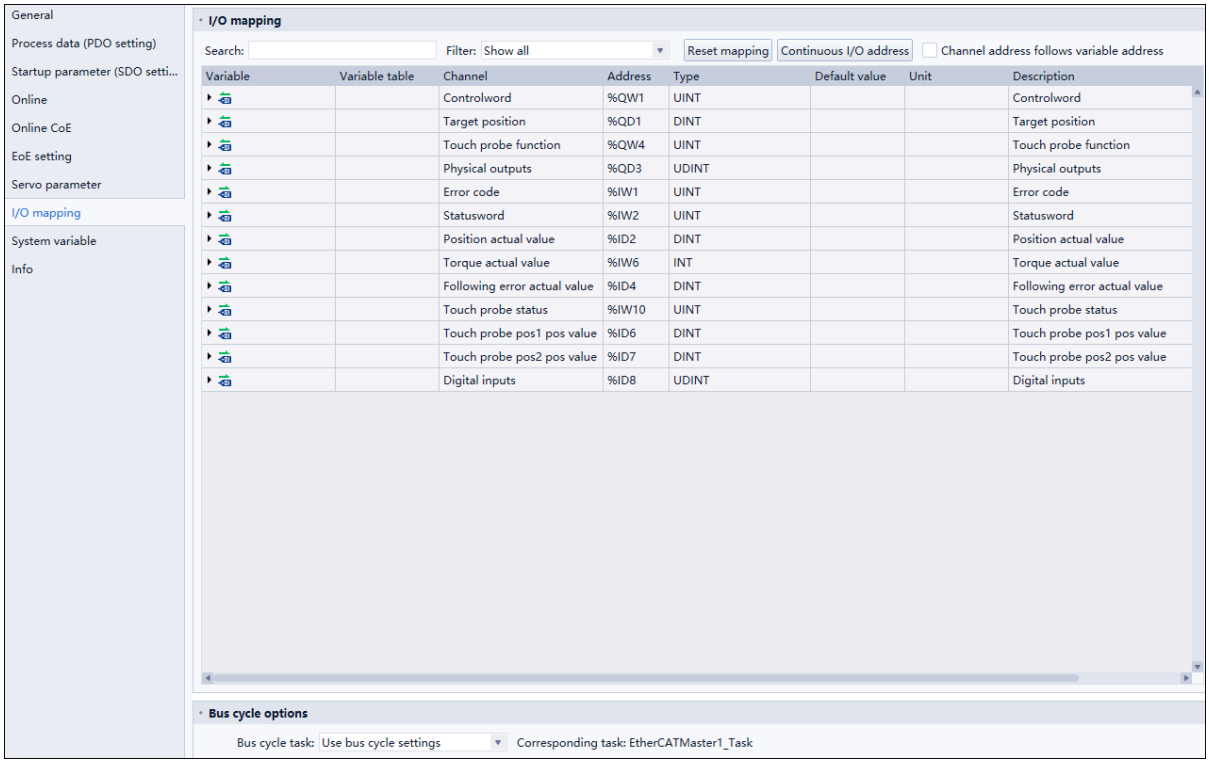
Servo function codes refer to the manufacturer parameters defined for Inovance servo products. Under the "Servo parameter" tab of slave configuration, the manufacturer parameters of multiple product can be read and written in batches, imported, and exported, facilitating commissioning and maintenance.



- Select all: Selects all slaves and axes, as well as the servo function codes under the axes.
- Deselect all: Cancels all selected items.
- Read selected parameters: In the servo operation status, reads the servo function codes with RO, RW, or R properties.
- Write selected parameters: In the servo operation status, writes the servo function codes with W or RW properties.
- Export selected parameters: Exports the selected servo parameters in an Excel file.
- Import parameters: Imports the parameters of all slaves from an external Excel file. If the configuration does not match the file, a fault will be reported.

17.1.7.8 ESC Register

The ESC register is used to read the values of the ESC chip register addresses in advanced commissioning, as shown in the figure below. For descriptions of each function and parameter, see the table below.

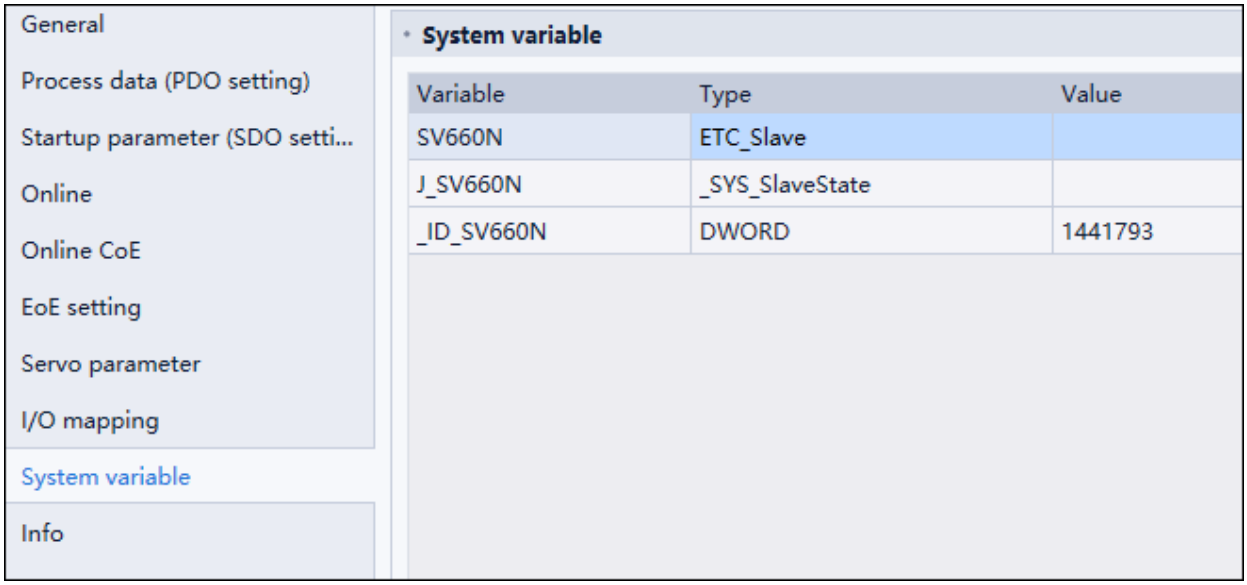


Currently, only the SV680N series device supports this feature.

Parameter	Description
Select all	Selects all parameters in the list.
Deselect all	Deselects all parameters in the list.
Read value	Reads the values of the selected items in operation status.
Writing a Value	Writes the values with write property in operation status.
Export	Exports the selected items as an .xml file and save it to the local disk.
Import	Imports an .xml file from the local disk that meets the format requirements.
Display format	Switches the display format to decimal, hexadecimal, or binary.

17.1.7.9 I/O Mapping

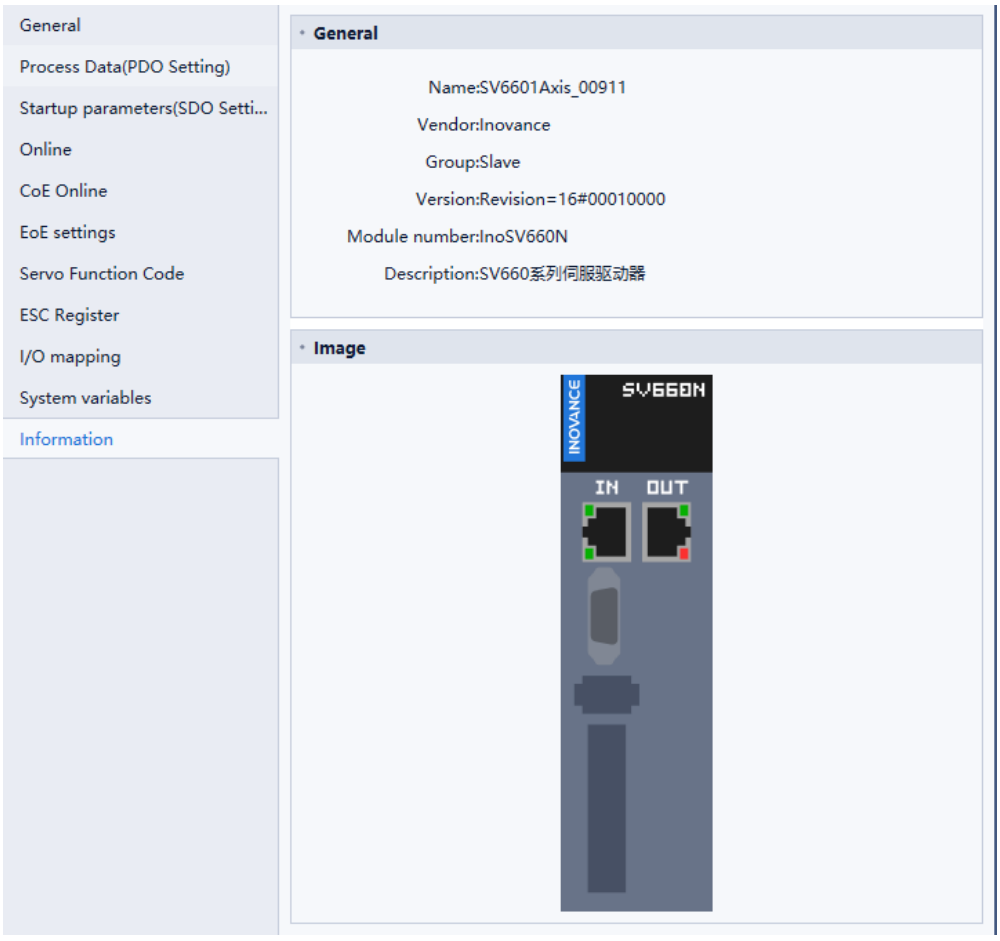
The "I/O mapping" interface is shown in the figure below, and detailed explanations of the parameters are provided in the table below.



Parameter	Description
Search	Searches for the corresponding I/O mapping channel based on keywords.
Filter	Displays the corresponding variables based on the filtering option.
Reset mapping	Clears the mapped variable information.
Continuous I/O address	Clears the device's I/O address and reassign it to a continuous address.
Channel address follows variable address	This option is not checked by default. If "Channel address follows variable address" is not selected: The I/O mapping channel address is fixed, and the variable type must strictly match the channel type. This mode only supports binding standard data types. After the variable is bound to the channel, the channel address will be automatically assigned to the variable. If "Channel address follows variable address" is selected: Binding can be completed when the channel byte size matches the variable byte size. This mode supports binding standard data types, structures, unions, and enumerations as custom types. After the variable is bound to the channel, the I/O mapping channel address will be removed, and the channel address will automatically follow the variable address.

Parameter	Description
Variable	Configures the variables for I/O mapping, which can be performed in the following two ways: • Mapping the I/O mapping channel to an existing variable (standard data type) Double-click the cell in the "Variable" column, and click "...". Select the existing variable to be mapped in the pop-up "Input assistant" interface and click "OK". • Mapping the I/O mapping channel to an existing variable (struct/union/array) 1. Select "Channel address follows variable address". 2. Double-click the cell in the "Variable" column, and click "...". Select the user-defined instance to be mapped in the pop-up "Input assistant" interface and click "OK". 3. When binding a user-defined type to the first channel, select the binding method in the dialog box. ▪ Bind the structure directly to this channel: After selected, the variable is bound only to this channel. ▪ Bind the elements in the structure sequentially to all channels of this device: After selected, the variables in the struct are automatically bound to all channels of the device in order; when the struct variable has multiple levels of nesting, only the first-level variables are bound sequentially. • Mapping the I/O mapping channel to a new variable Double-click the cell in the "Variable" column, enter the name of the new variable, and press the Enter key. The new variable will be synchronized to the default variable table. The name of the new variable must comply with IEC programming standards, otherwise it will result in a compilation fault.
Variable table	Identifies the type of variable table for I/O mapping variables.
Channel	Indicates the bit number of the current I/O mapping channel.

Parameter	Description
Address	Indicates the address assigned to the current I/O mapping variable. To customize the I/O address, double-click the cell in the "Address" column to modify it.
Type	Indicates the data type of the current I/O mapping variable.
Default value	Indicates the default value of the current I/O mapping variable.
Unit	Indicates the unit of the current I/O mapping variable.
Description	Indicates the description information of the current I/O mapping variable.
Prepared value	Indicates the value pre-written or forced for the current I/O mapping variable. Double-clicking the cell in the "Prepared value" column for modification. After modification, use "Ctrl+F7" or "F7" to write the value or force it to be uploaded to the I/O mapping variable.
Bus cycle task	This function is applicable to virtual axes. The "Bus cycle task" must be bound to the called EtherCAT task (default is "Use bus cycle settings", which is applicable to a single master). It is prohibited to call the same virtual axis under multiple EtherCAT tasks.



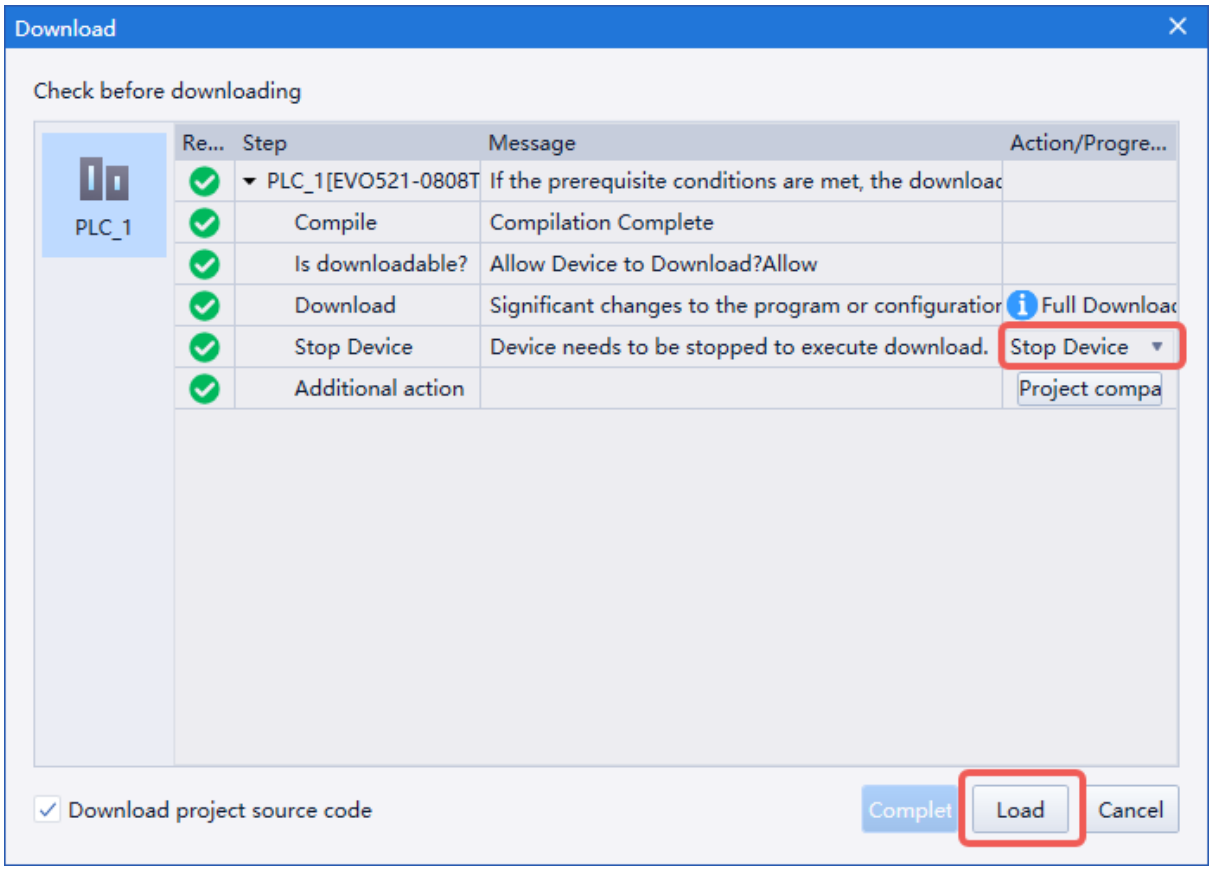
17.1.7.10 System Variables

In the "System variable" tab of the EtherCAT slave, instances (variables) of type ETC_Slave and _SYS_SlaveState are specified for servo slaves I/O, supporting control of devices connected to the EtherCAT slave via user programs, and displaying the device ID value of this slave.

17.1.7.11 Information

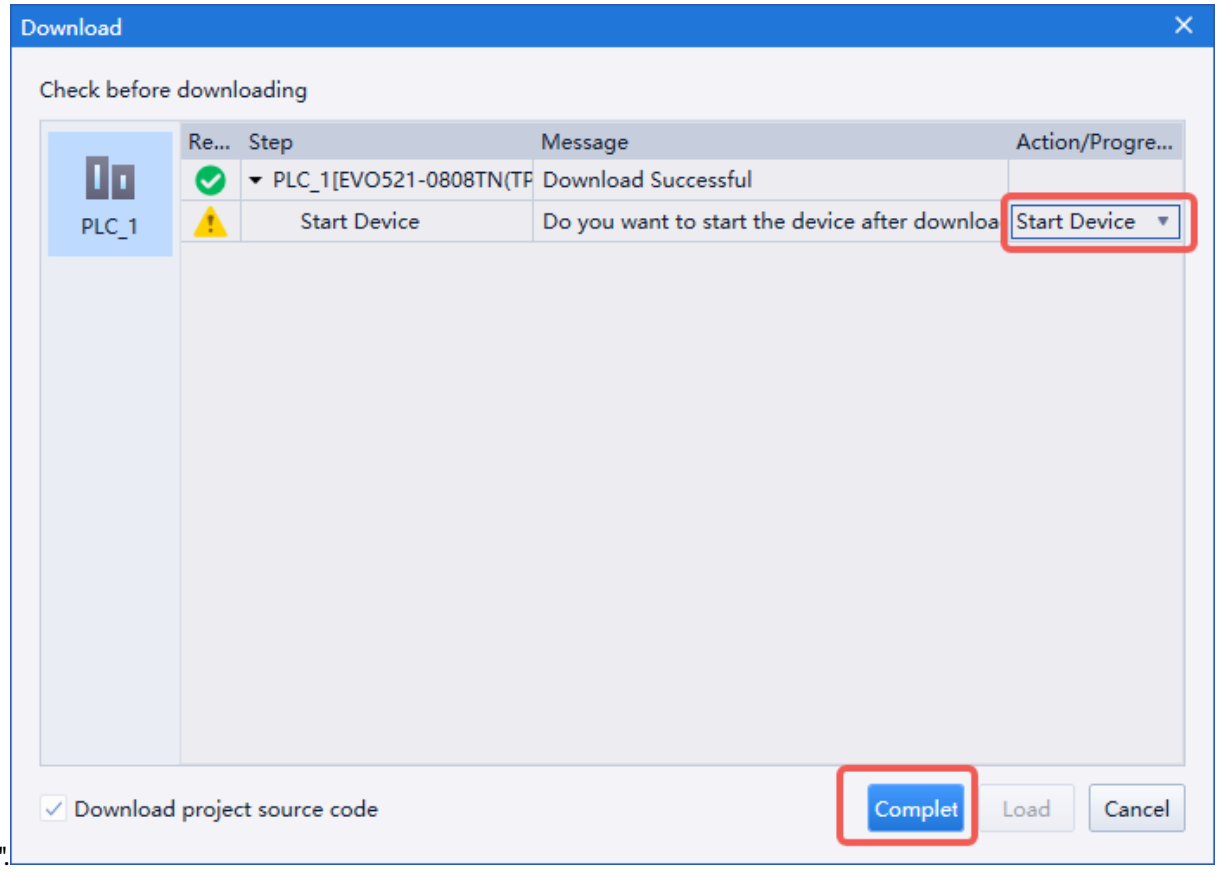
This interface displays the general information and image of the device, as shown in the following figure:

17.1.8 Drive Connection



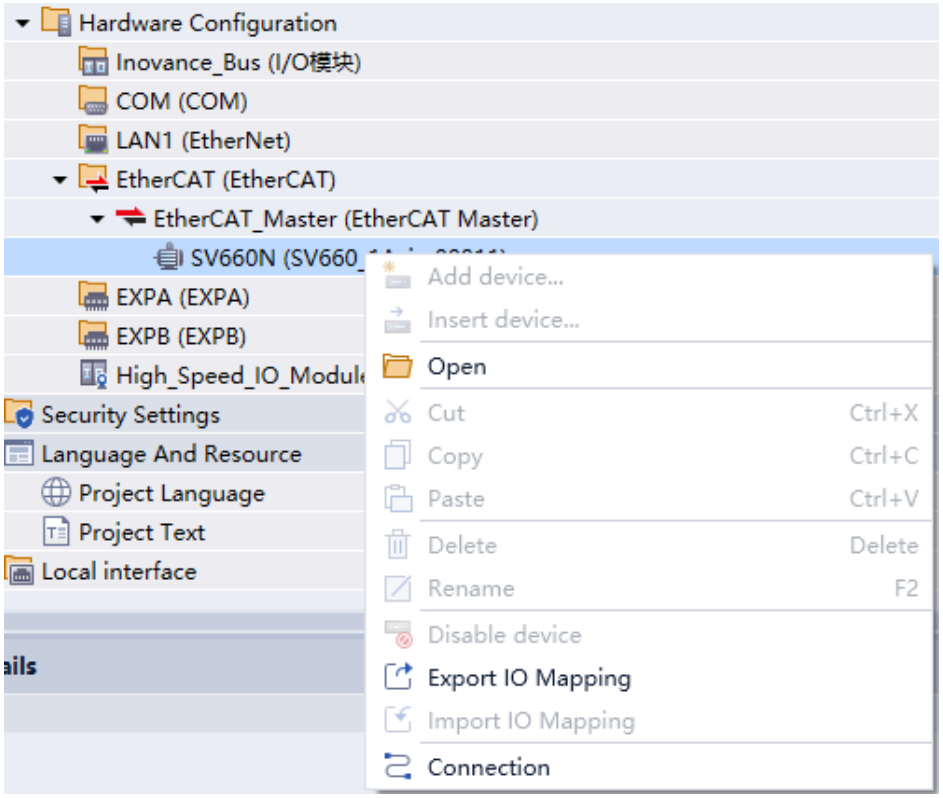
After the EtherCAT and drive device are configured, you can connect the drive.

Prerequisites



The PLC has been switched to online mode.

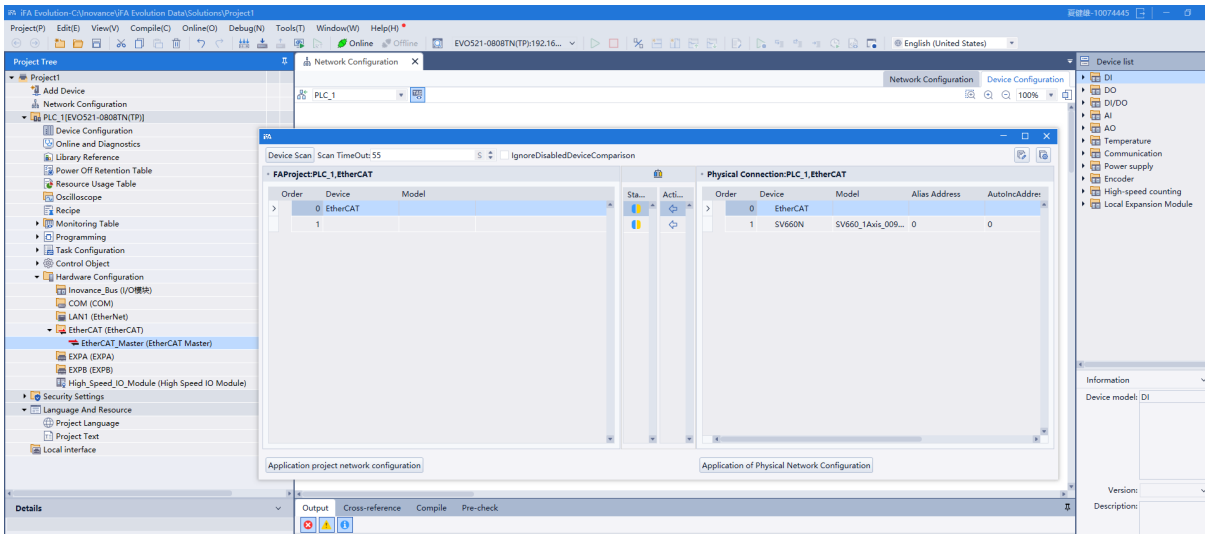
Procedure



1. Click the "Online" icon on the toolbar. In the pop-up window, switch "No action" to "Stop device", and then click "Load".

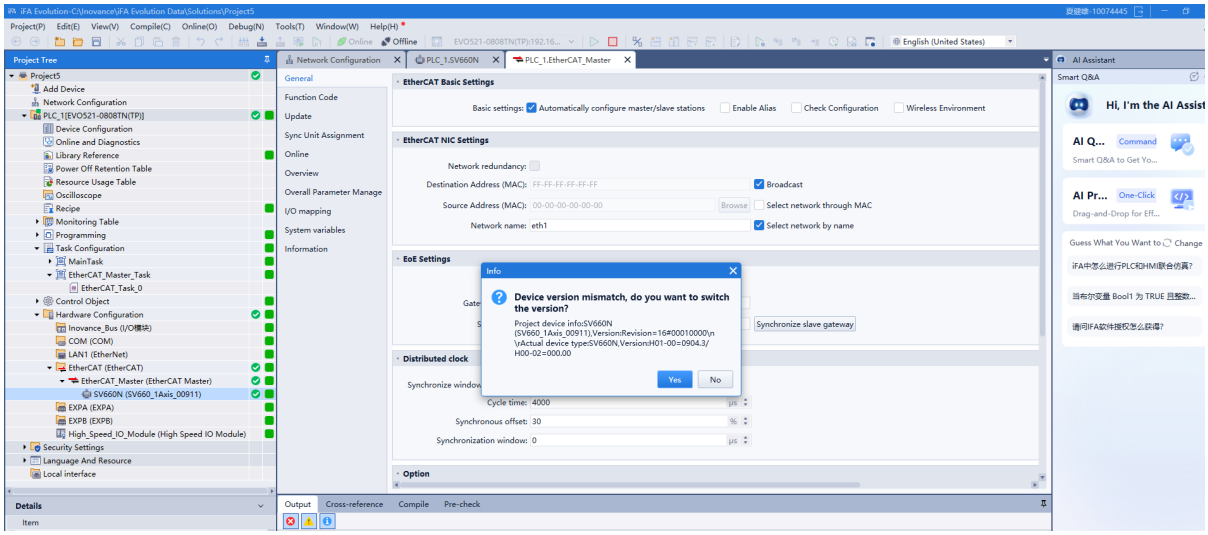
2. After successful loading, switch "No action" to "Start device" in the pop-up window, then click "OK".

3. Right-click the servo drive node and select "Connect" to connect the drive.



Note: If a device is faulty, a corresponding prompt will appear when connecting the device; if the PLC has not been switched to online mode, a corresponding prompt box will also appear.

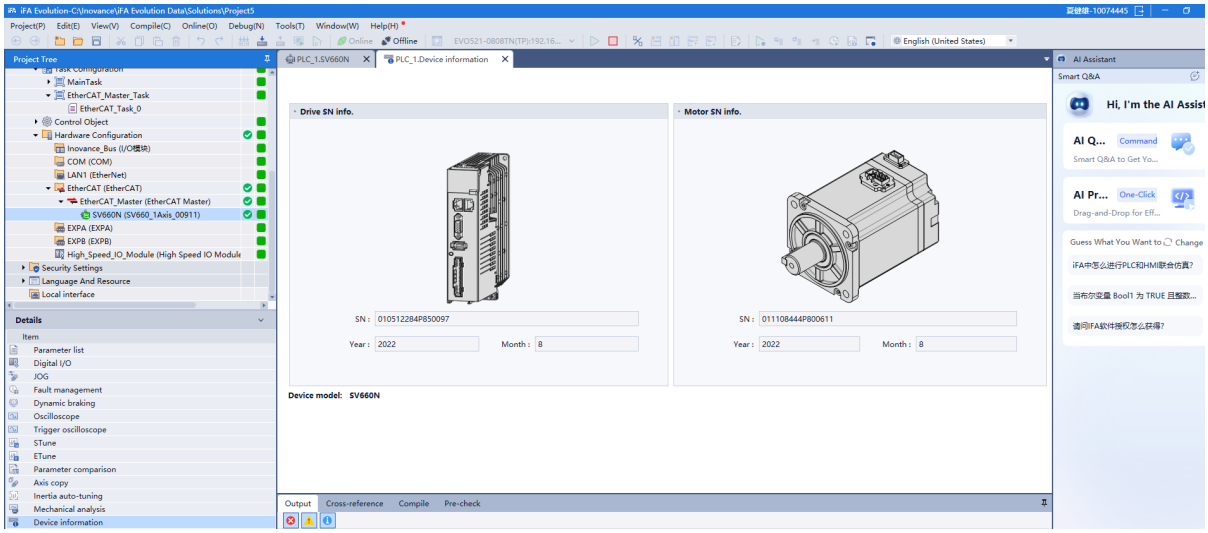
17.1.9 Version Switching



When the version of the device created in the project is inconsistent with that of the actual connected hardware device, version switching is required for device connection.

Procedure

1. After IEC scans the device, click "Connect" to check if the version added offline matches that of the actually connected device.
   Note: IEC scanning does not distinguish between device versions; for example, whether SV660NC or SV660NS is connected, the scanning result will all be SV660N.



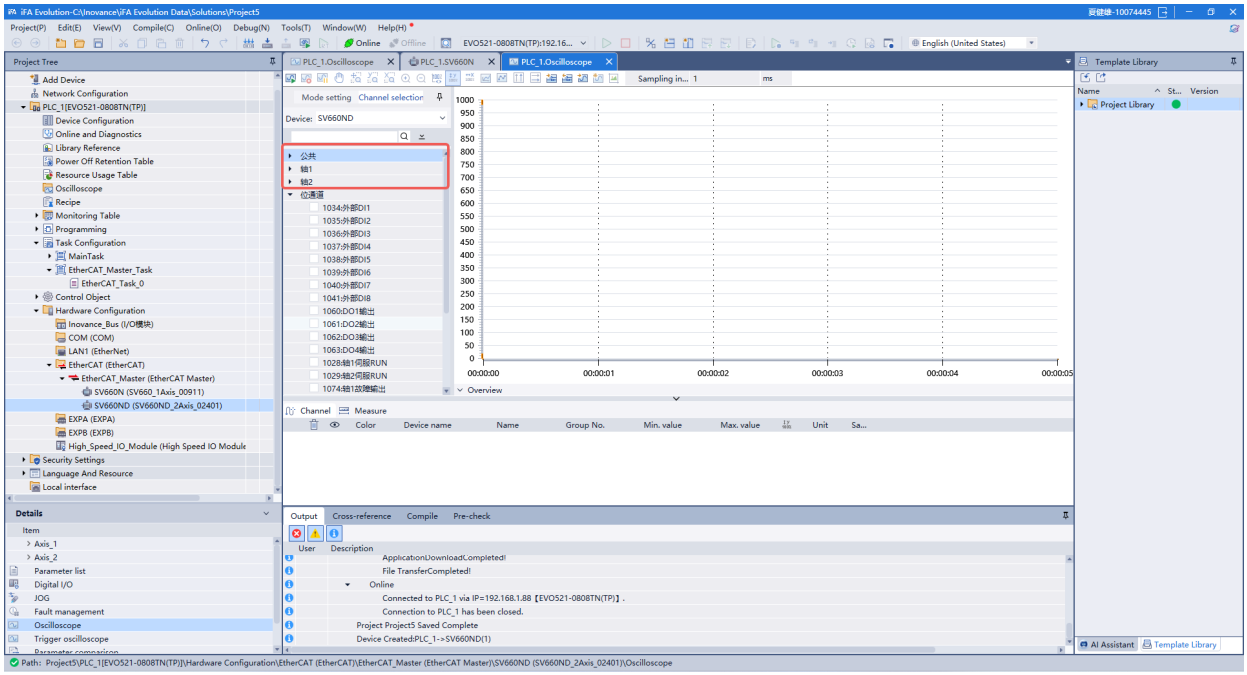
2. If the device versions are inconsistent, a version switching prompt will appear.

3. Version switching will delete the function nodes under the servo and their corresponding views, and refresh the commissioning function nodes in the detailed view.

4. After the version switching, the specific device type will be displayed in the device information interface.

Note:

- After reconnecting the device after disconnection, the version switching prompt will no longer appear.
- When opening a historical project and connecting the device, the version switching prompt will not appear.



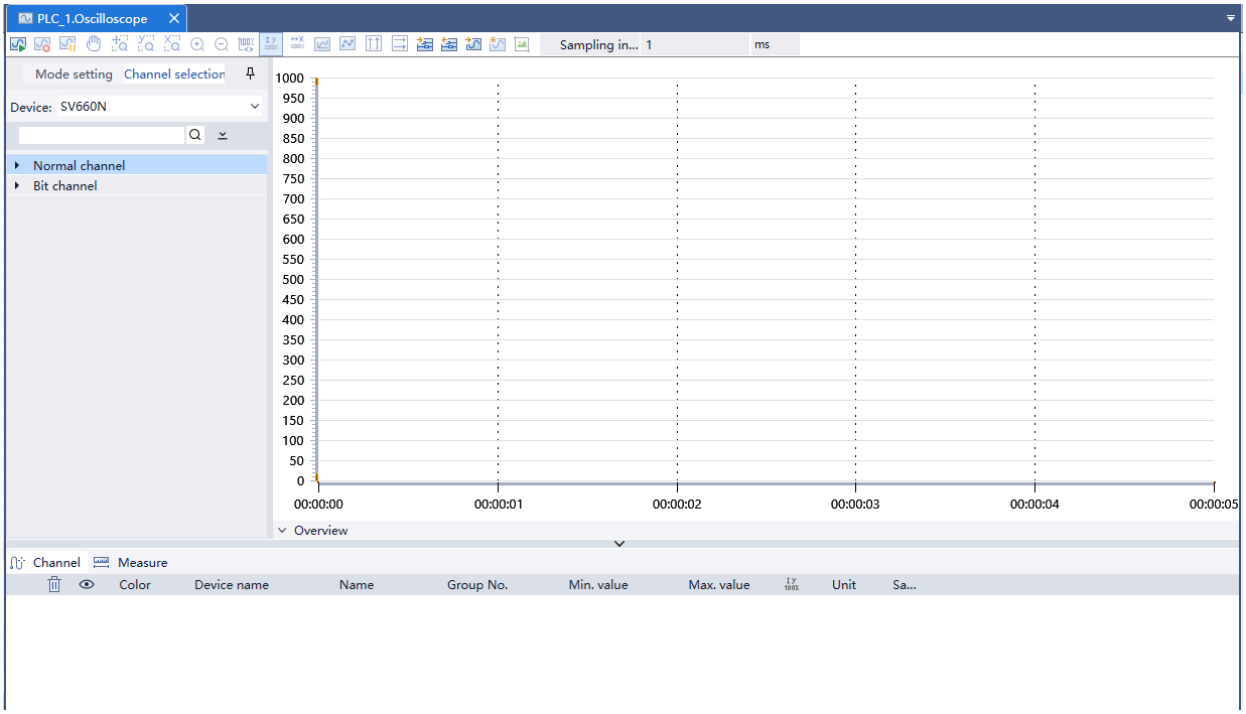
17.2 General Functions

17.2.1 Oscilloscope

17.2.1.1 Overview

This function is not supported by the STD60N series products.

Axis 1 and Axis 2 functions are available for dual-axis device.



Oscilloscope mode is divided into continuous oscilloscope and trigger oscilloscope.

- Continuous oscilloscope: During on-site commissioning, the oscilloscope is typically used to monitor the operational status of device in real time. It continuously samples signals from selected parameter channels, and analyzes the device's operational status by observing waveform changes in the channel data.
- Trigger oscilloscope: The trigger conditions of the trigger object are configured. When the trigger conditions are met, save the channel values to be monitored to the cache of the drive. Then you can read the channel values which are displayed as a curve. This mode enables you to perform commissioning according to the field conditions and observe the change of variables after certain conditions are met.

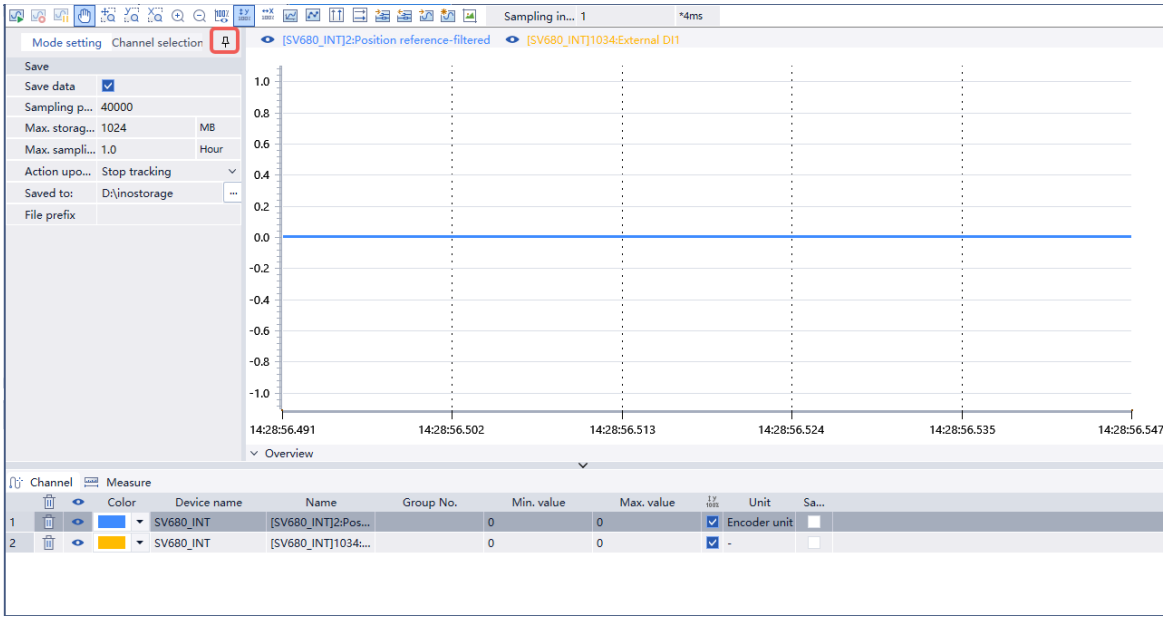
The sampling modes of the oscilloscope are as follows:

Sampling Mode	Description
Continuous	Samples in a continuous and uninterrupted way.
Single trigger	Samples once when specific trigger conditions are met.

Note:

- Under the same project, any two consecutive oscilloscopes cannot run simultaneously.
- Servo hardware devices do not support multiple oscilloscopes (including trigger oscilloscopes and continuous oscilloscopes) collecting data simultaneously.
- The oscilloscope can acquire data from multiple servos under the same PLC.
- One drive does not allow simultaneous acquisition of multiple trigger oscilloscopes.

17.2.1.2 Functions



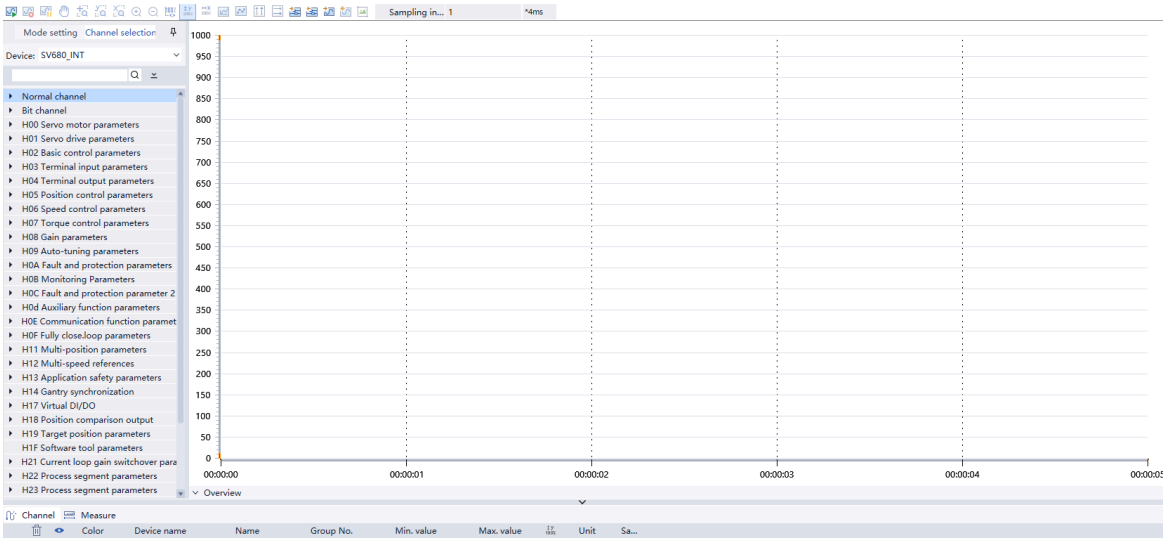
The functions of the oscilloscope are as follows:

- **Toolbar**

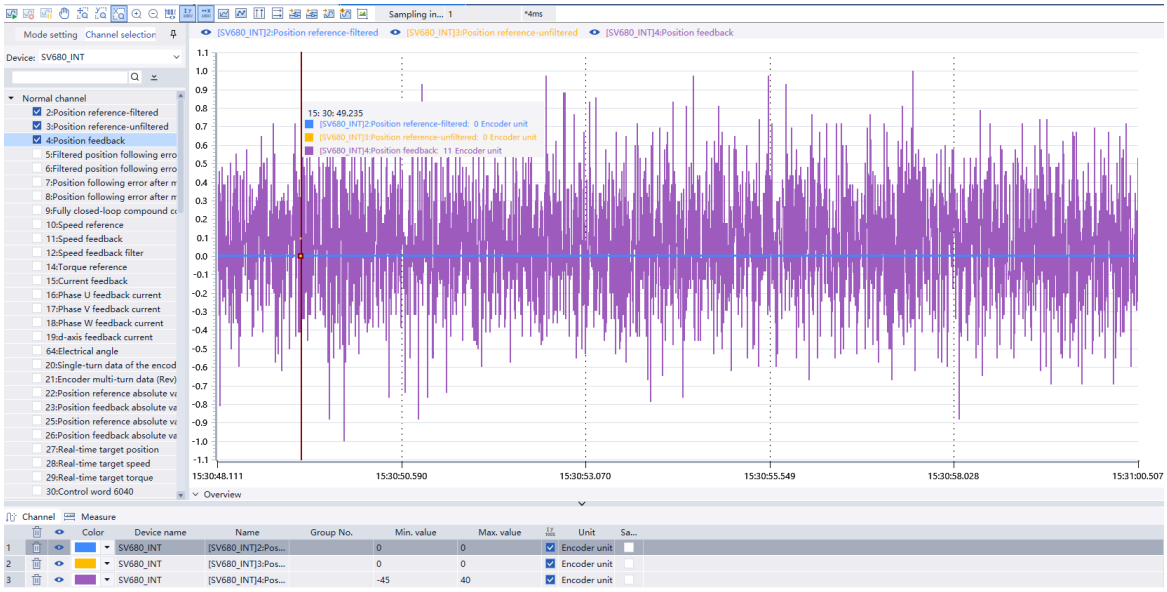
  For detailed descriptions of each function button in the auxiliary toolbar for operating the oscilloscope, see "Analysis Auxiliary Function".

- **Overview**

  The overview diagram includes a collapse button and area viewing function (viewing a specific area's waveform by dragging with the mouse).

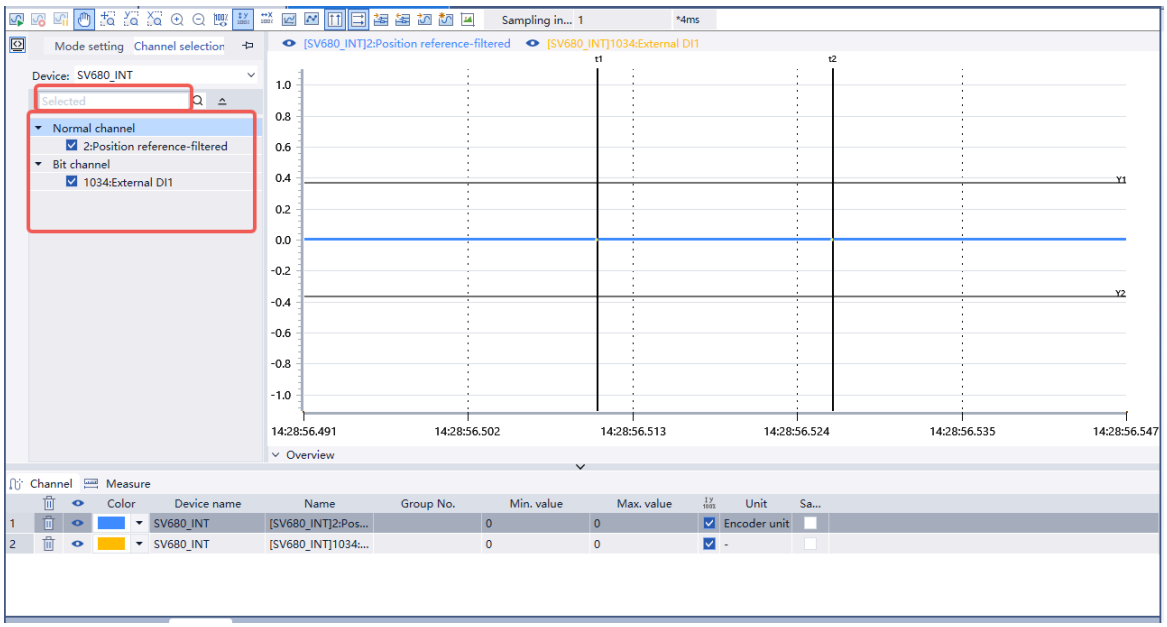


Click the collapse button to collapse the left-side menu bar.



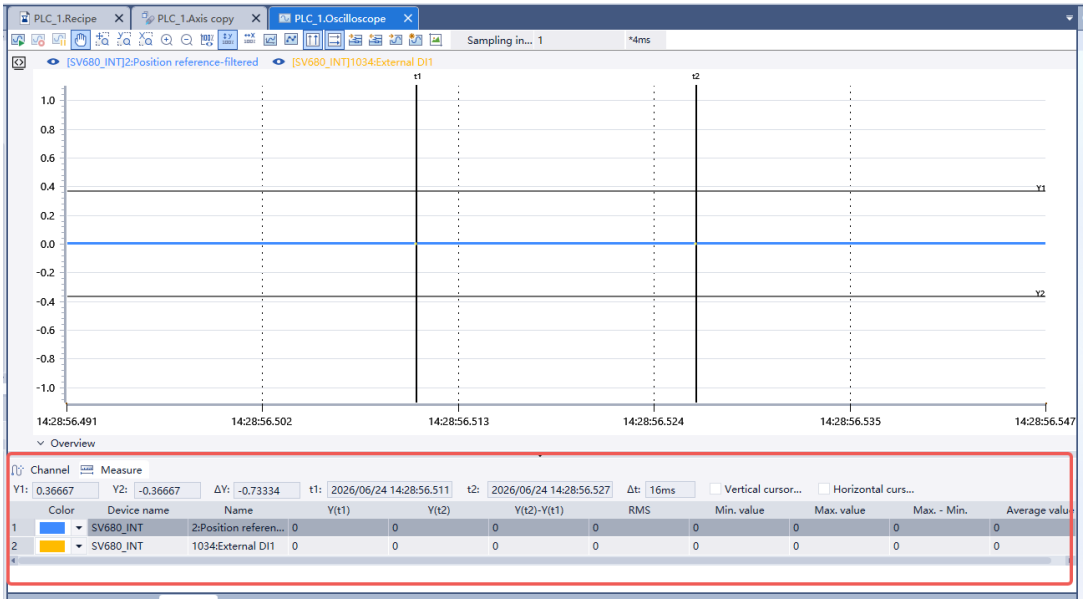
- **Detailed area**

  The detailed area is the main display area (waveform area).

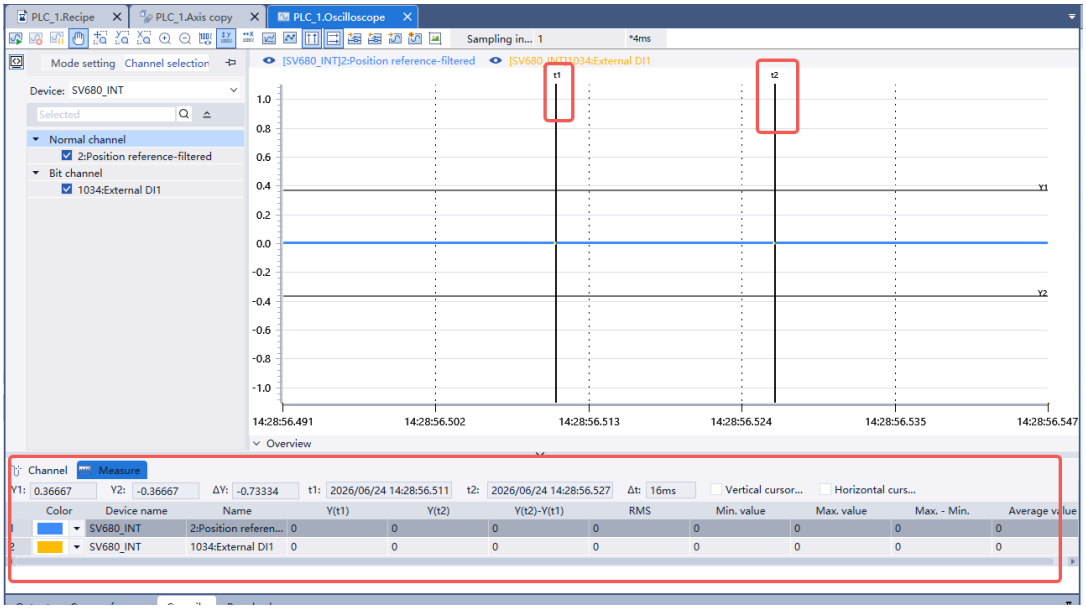


- **Channel**
  - The channel table mainly includes signal display/hide, color settings, and grouping functions.
    - Delete
      - Deletes the channel information of an entire row.
    - Show/Hide column: This column contains a toggle icon, which allows you to show or hide the signal in the detailed area.
      - The toggle icon in the column header applies to all signals.
      - The icon remains visible as long as at least one signal is visible. It only becomes hidden when all signals are invisible.
      - When hiding the currently viewed signal, the next visible signal in the current group becomes the current viewed signal; if no other visible signal exists in the current group, the next visible signal among all signals becomes the current viewed signal; if all signals are hidden, the button in the column header becomes hidden, and the detailed area reverts to default style.
      - When hiding a signal, if this signal is the last visible signal in the current group, the entire group is hidden in the detailed area.
    - Color setting column: The set signal color remains consistent in the Y-axis title, curve, and legend of the detailed chart.

- Group number column: Signals with the same group number are displayed in the same group.
  - Grouping is not supported in single-channel mode (group numbers do not take effect).
  - Signals without a group number form their own separate group.
  - When no visible signal exists in a group, the group is hidden.



◦ Selected channels



- **Measurement**

  X-axis and Y-axis cursor measurement.

  - Y-axis cursor: Click the "Horizontal cursor" icon button on the toolbar to display it.

- The measurement table is used in conjunction with the X-axis cursor to display statistical results within the X-axis cursor area; click the "Vertical cursor" icon button on the toolbar to display it.

17.2.1.3 Configuration

Prerequisites

- The project has been created.
- The servo device has been added.
- The servo device is online.

Steps

1. Click an added servo device in the project tree.
2. Double-click "Oscilloscope" in the detailed view to open the interface.
3. Se the sampling mode to the continuous trigger mode or single trigger mode, and set corresponding parameters.

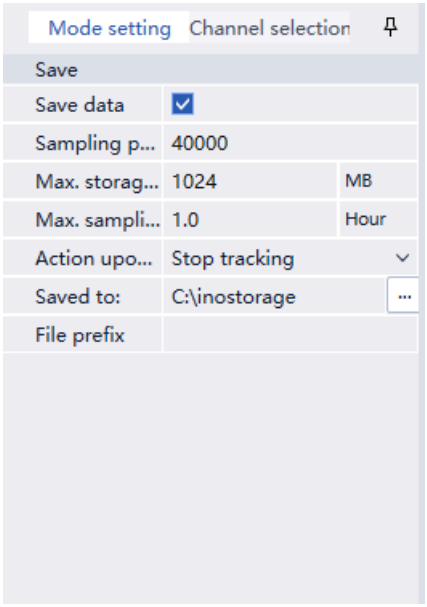
4. Select channel parameters.

5. Start the oscilloscope.

17.2.1.4 Continuous Oscilloscope

Sampling settings

1. Set the sampling mode to "Continuous".



2. Set the sampling interval, which ranges from 1 to 200, with a default value of 1.

   After activating logging, the minimum sampling interval is calculated based on the selected signals. If the set value is smaller than the calculated minimum sampling interval, the set value will be overridden by the minimum value.

   The EoE network calculates the minimum sampling interval based on the controller's communication cycle and the number of channels, using the following formula:

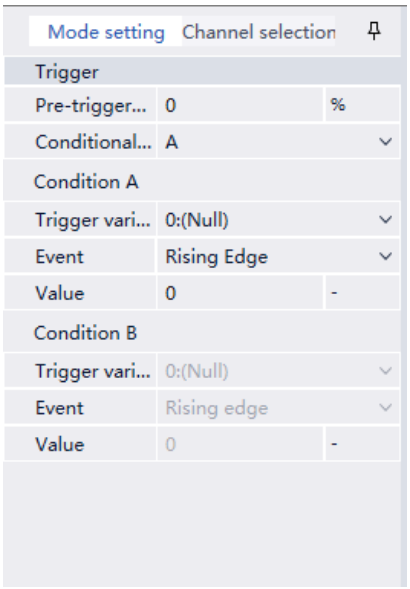
Minimum sampling interval = Communication cycle * Transmission cycle * Bandwidth occupancy rate / (Oscilloscope data frame bytes / (Channel width * Number of channels))

The transmission cycle is 2, the oscilloscope bandwidth occupancy in normal mode is 25%, the number of data frame bytes is 120, and the channel width is default to 4.

Storage settings

The following table shows the functions and detailed descriptions of the storage settings:

Function	Description
Store continuous data	Not enabled by default. You can set the related parameters only when this option is checked.
Sampling per file	Default: 10000; range: 10000 to 30000
Max. storage data	Default: 1; range: 1 to 1000000; unit: MB. Provided that the storage capacity requirement is met, an error margin of 0 to 3 MB is permitted during actual data sampling.



Function	Description
Max. sampling time	Default: 1 hour; range: 1.0 to 24000; unit: hour
Action upon max. data or time	When sampling data size or sampling time reaches the limit, you can choose to stop tracking (default) or delete old files.
Save to	Select the local directory for saving oscilloscope data.
File prefix	Set the prefix for oscilloscope data saving file. The default prefix is empty.

17.2.1.5 Trigger Oscilloscope

Currently, the trigger oscilloscope is not supported by the MD810 and MD800 series products.

Axis 1 and Axis 2 functions are available for dual-axis device.

Configure the trigger condition for the servo drive and poll the trigger results. If the trigger is successful, the data is read and displayed.

Sampling settings

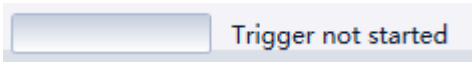
The trigger mode only supports single device (current device) sampling. The triggered sampling mode supports single trigger.

The default unit for sampling interval is 62.5 μs (unit value is refreshed when the device is online). If the device is online, the unit value is read from the device. The sampling interval ranges from 1 to 1000×62.5 μs.

Triggering

1. Configure the data ratio set by pre-trigger. Unit: %; range: 0 to 100.
2. Configure the relationship between conditions. You can select the relationship between trigger condition A and trigger condition B.

Option	Description
A	Trigger the data recording when condition A is met.



Option	Description
B	Trigger the data recording when condition B is met.
A and B	Trigger the data recording when conditions A and B are met.
A or B	Trigger the data recording when condition A or B is met.

3. Configure the trigger condition parameters.

Function	Description
Trigger variable	Select the trigger variable in the drop-down box. The content is provided by the device file.
Event	Select the trigger event from the drop-down box. Options: rising edge, equal to, falling edge, and edge change
Value	Enter the trigger value in the text box. Limit the input range according to the value range.
Value range	Displays the range of the currently selected trigger variable, which cannot be edited.

Trigger process

1. Indicates the trigger progress.
   - Initially, prompts "Trigger not started".

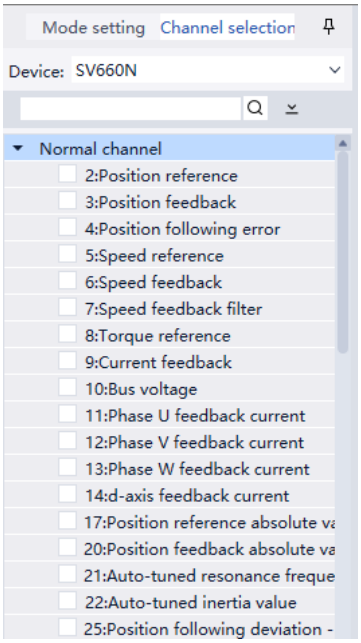
   - After you click "Start", it prompts "Data in preparation".

   - Displays the percentage of data reception progress.

   - When the data reception is stopped, prompts "Error: stop trigger".

   - After the trigger data is received, it prompts "Trigger completed".

2. Trigger result
   - Single trigger



17.2.1.6 Channel Selection

Channel selection

1. Select a configured device.
2. Expand the list of normal channels or bit channels, and check one or more channels. The added channel is displayed in the lower information panel.
   - A corresponding signal is also added to the lower channel and measurement list, and a color is generated randomly.
   - If it is the first visible signal, it is set as the currently viewed signal.
   - In the channel table, after the newly added signal is selected, the Y-axis title of the corresponding color will be displayed in the detailed chart.
   - The corresponding signal will be displayed in the illustration and indicated in color.

   Channel selection limitations:

   - Up to 6 normal channels and 8 bit channels can be selected.
   - If the bit channel is selected, the quota of one normal channel will be occupied. For example, if you select 1 to 8 bit channels, you can only select 5 normal channels at most.

Signal removal

Unselect the selected a signal to remove it. At the same time, the contents related to the signal on the diagram interface are also removed.

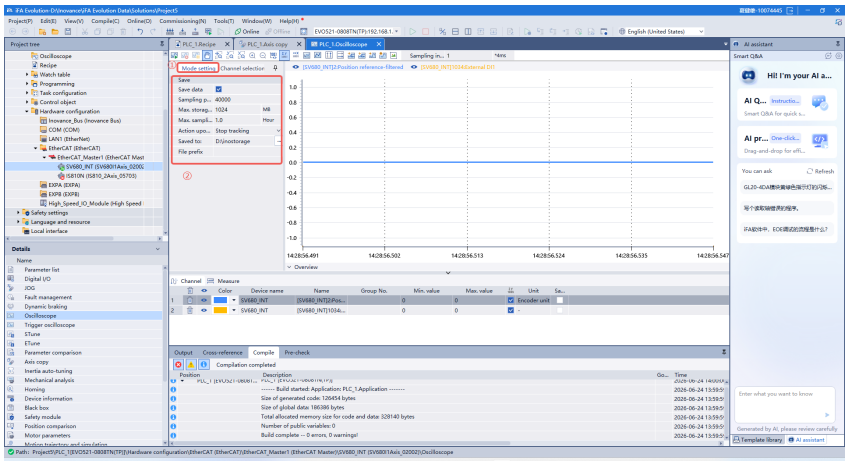
- The signal is also removed from the channel and measurement list.
- The Y axis and curve of the signal are removed.
- The signal is removed from the illustration.

17.2.1.7 Waveform File Import/Export

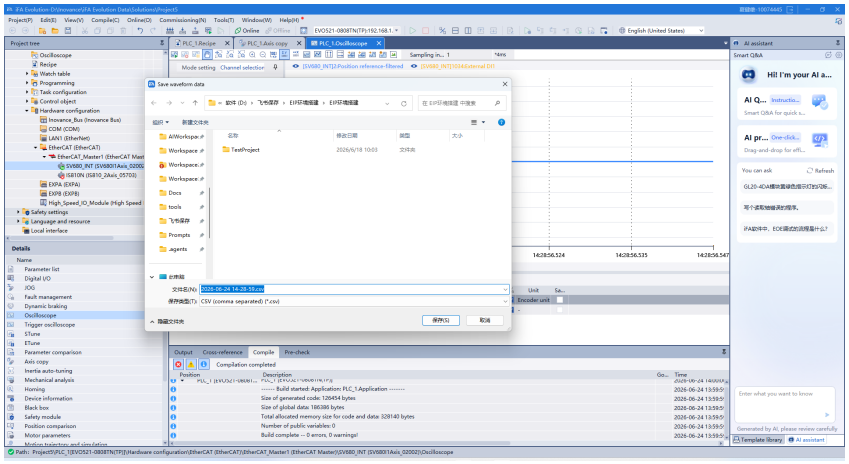
Export

After the oscilloscope stops running, click the data export icon on the toolbar to export the oscilloscope data. The oscilloscope waveform file is named automatically in the following format: file prefix time stamp_serial number.csv. Click "Save" to export the file to the specified location.

Import



Click the data import icon on the toolbar to import oscilloscope data. Select a CSV data file to display the import result.

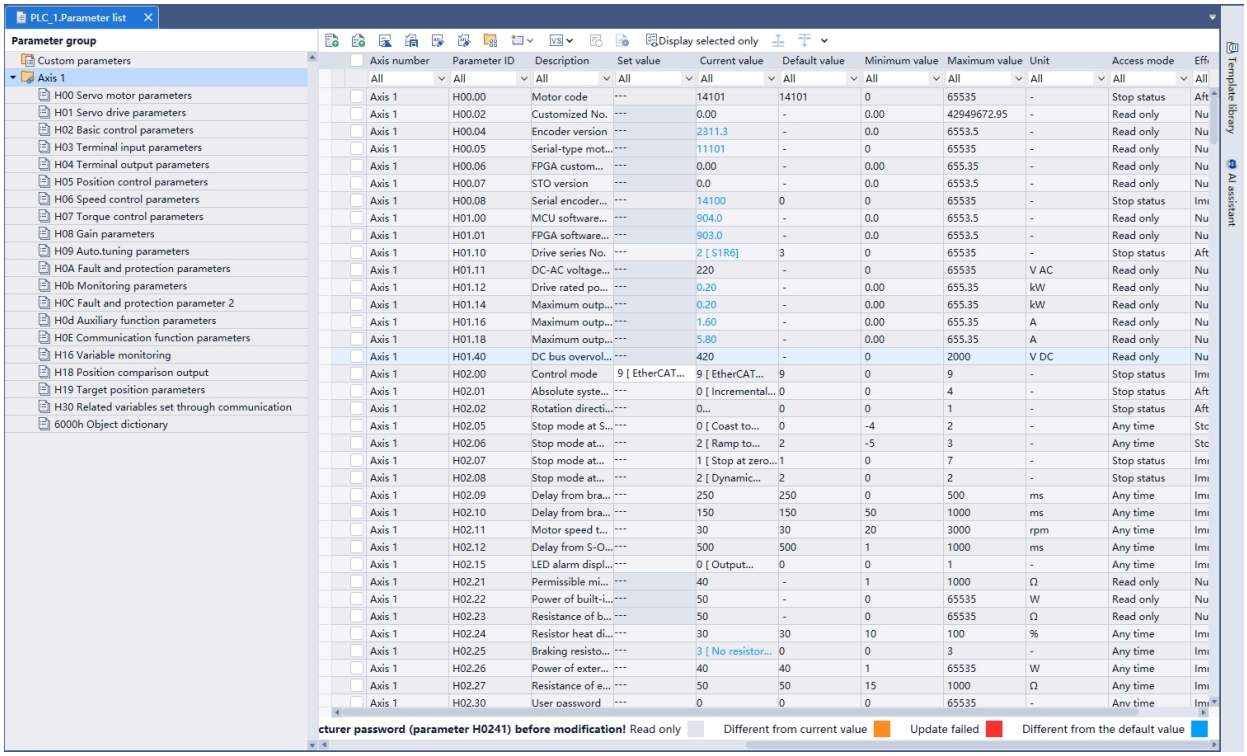


17.2.1.8 Analysis Auxiliary Function

See the following table for descriptions of the icons of the oscilloscope toolbar.

Function		Description
	Start	Starts the oscilloscope to acquire data and draw curves. Restrictions: • The drive must be online. • When a fault occurs on the parameter configuration interface, this process fails.
	Stop	Stops data acquisition.
	Halt	The oscilloscope waveform stops moving and pauses at the current position.
	Move view	When the function is enabled, you can drag the curve in the view, which is mutually exclusive with the zoom function. Restrictions: This function is disabled by default, selected and enabled at continuous acquisition, and disabled at triggered acquisition.
	Zoom	Zooms in or zooms out the curve. When the function is enabled, you can select a waveform segment from the X axis and Y axis for observation. It is mutually exclusive with the drag function. Drag the mouse from the left to right to zoom in the curve. Drag the mouse from right to left to zoom out. Restrictions: This function is disabled by default, unselected but enabled at continuous acquisition, and unselected and disabled at triggered acquisition.
	Vertical zoom	Zooms in or zooms out only on the Y axis Restrictions: This function is disabled by default, unselected but enabled at continuous acquisition, and unselected and disabled at triggered acquisition.
	Horizontal zoom	Zooms in or zooms out only on the X axis Restrictions: This function is disabled by default, unselected but enabled at continuous acquisition, and unselected and disabled at triggered acquisition.
	Zoom in	Zooms in on the entire curve. Restrictions: This function is disabled by default, enabled at continuous acquisition, and disabled at triggered acquisition.
	Zoom out	Zooms out on the entire curve. Restrictions: This function is disabled by default, enabled at continuous acquisition, and disabled at triggered acquisition.

Function		Description
	Show all	Displays 100% of the X and Y axes. When this function is enabled, the icons buttons for displaying all on Y-axis and X-axis are selected.
	Y axis display	Only the Y axis is 100% displayed.
	X axis display	Only the X axis is 100% displayed.
	Channel switchover	Switches between single-channel and multi-channel. Single-channel is displayed by default when the oscilloscope is turned on.
	Discrete diagram	Displays the data sampling points as small dots on the curve. Restrictions: This function is disabled by default and enabled after successful acquisition.
	Vertical measurement cursor	Displays a group of cursors (t1, t2) in horizontal direction, and the statistical data of the sampled data between cursor (t1, t2) in the measurement table. Restrictions: This function is disabled by default, and disabled upon acquisition and enabled after successful acquisition.
	Horizontal measurement cursor	Displays a group of cursors (Y1, Y2) in vertical direction, and displays the cursor values in the measurement window. Restrictions: • The Y axis cursor is displayed in the channel where the current viewing signal is located. Switching the current viewing signal also switches the Y axis cursor. • This function is disabled upon acquisition and enabled after successful acquisition.
	Mode setting	
	Import configuration	Imports the oscilloscope configuration file (JSON format). Restrictions: This function is disabled when acquisition starts.
	Import configuration	Exports the oscilloscope configuration file (JSON format). Restrictions: This function is disabled when acquisition starts.



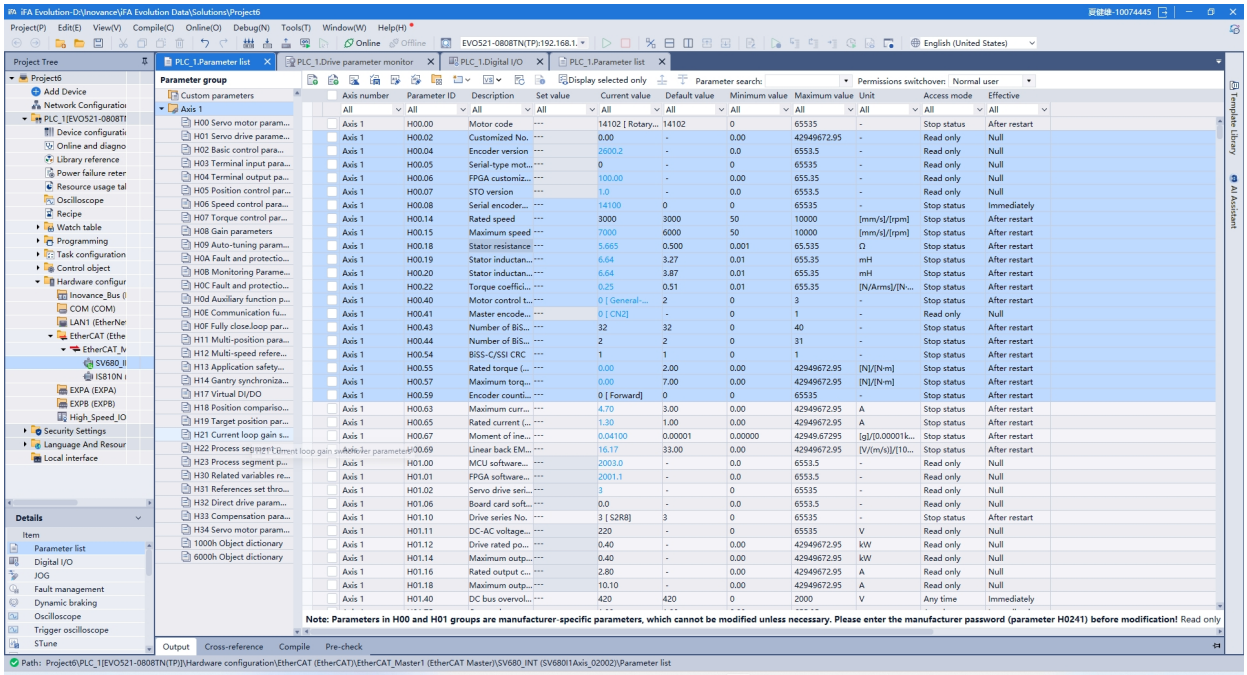
Function		Description
	Export data	Exports the oscilloscope data file (CSV format). Restrictions: This function is disabled when acquisition starts. Saves the current interface waveform. 
	Screenshot	Takes a screenshot of the waveform on the current interface.

The waveform area also includes the following functions:

- When the zoom function is enabled, drag the mouse from left to right for zooming. Dragging the mouse from right to left will display all the data in the overview area.
- Click to zoom:
  - X axis direction: Press and hold the Shift key. The horizontal zooming cursor appears. Click the left mouse button to zoom in, and the right mouse button to zoom out.
  - Y axis direction: Press and hold the Ctrl key. The vertical zooming cursor appears. Click the left mouse button to zoom out, and the right mouse button to zoom in.
- Scroll to zoom.

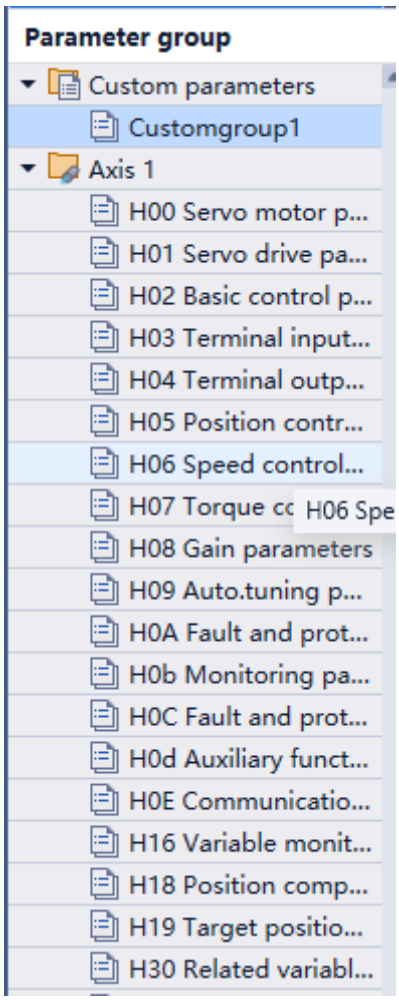
17.2.2 Parameter List

The parameter list displays and manages parameters, including information display, upload/download, comparison, property update, parameter customization and recipe management. The following figure shows the parameter list interface:



Note: The parameter list interface of the MD630 series differs from other servos and AC drives. For details, see 17.2.2.6 Parameter List (MD6X0 Series).

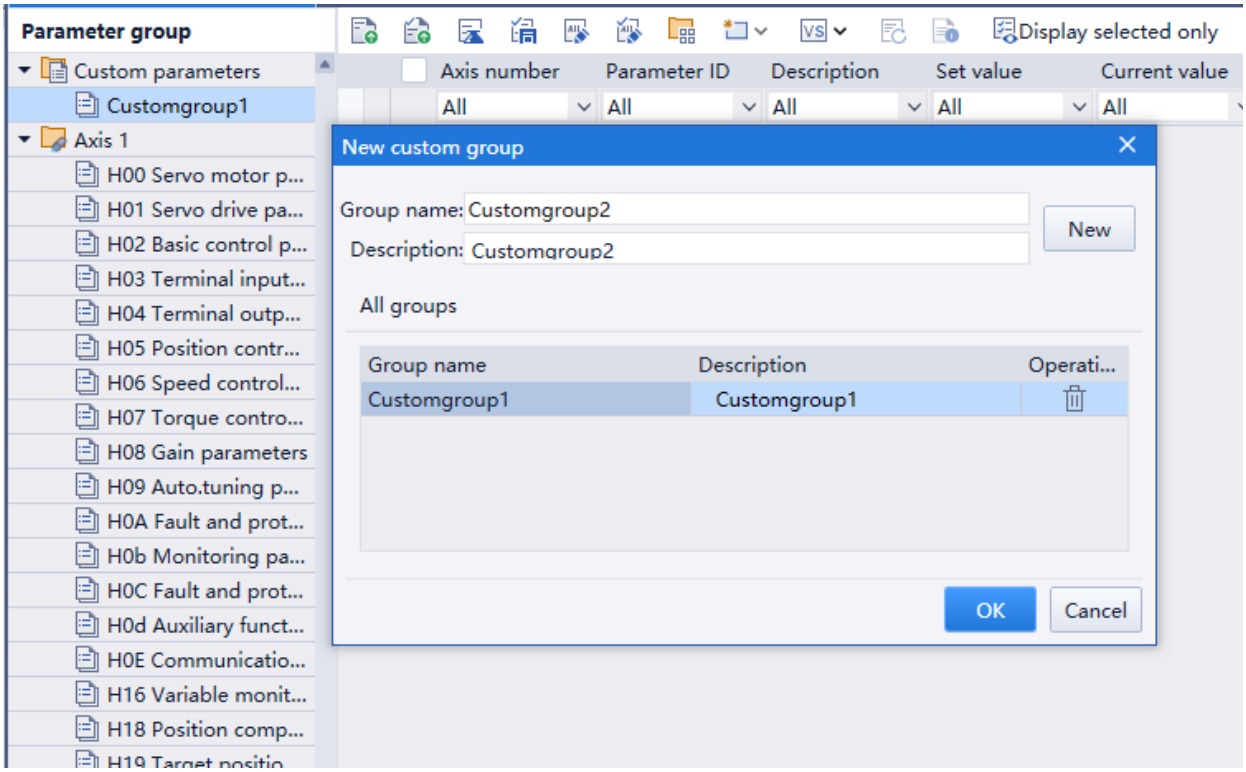
17.2.2.1 Parameter Viewing



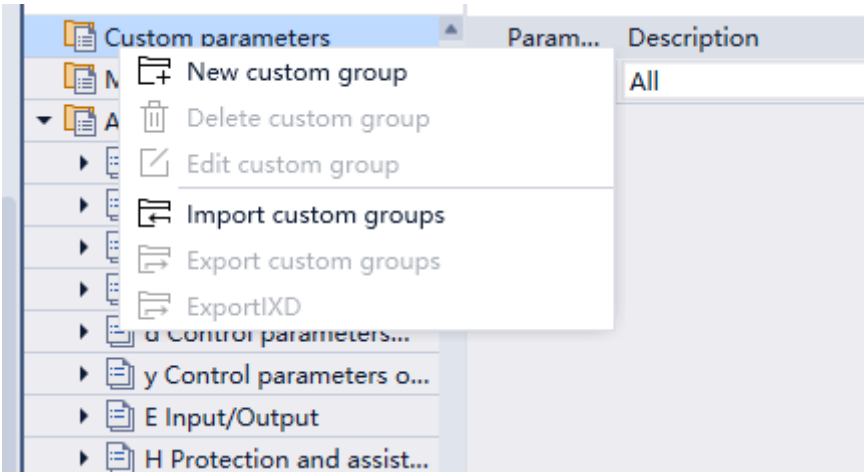
Select a servo drive in the project tree, and double-click "Parameter list" in the detailed view to open the interface.

- Axis 1 and Axis 2 functions are available for dual-axis device.

You can collapse or expand parameter groups via the right-click menu of the top-level node of the default group. For multi-axis devices, the top-level node of the default group is "All parameters"
; for single-axis devices, it is "Axis 1".



- Select "Custom parameters", and view the parameters by clicking the axis node in the custom parameter list or the default group node under the axis, as shown in the figure below:



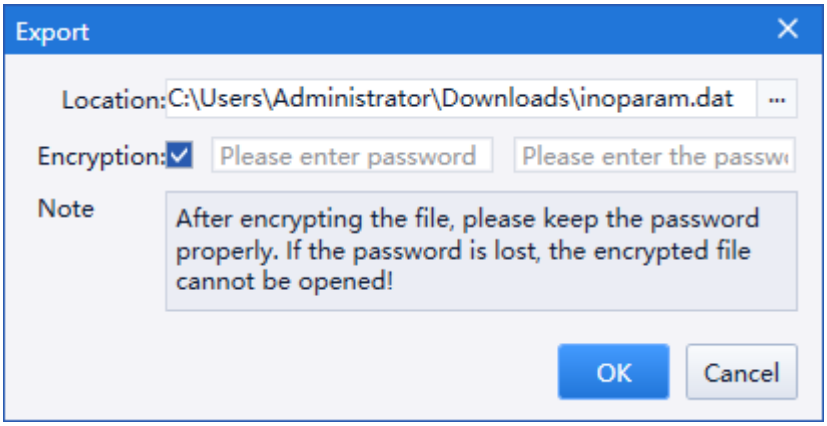
17.2.2.2 Custom Group

Currently, you can create up to 20 custom groups. The specific steps are as follows:

1. Right-click "Custom parameters" on the left side of the parameter list interface and select "New custom group".
2. Enter the group name and description, then click "New". The custom group will appear in the list below. Click "OK" to complete the creation. Multiple custom groups can be created in batch.

3. Right-click the new custom group to perform the following operations.

Function	Description
New custom group	Creates a custom group, with function identical to Step 2. Restrictions: • Up to 20 custom groups can be created. • Multi-level nesting is not supported. • The group name can contain up to 50 characters.
Delete custom group	Deletes the currently selected custom group.
Edit custom group	Modifies the name and description of an existing custom group.



Function	Description
Import custom groups	Imports custom group from the local disk. Restrictions: • Only DAT format file is supported for import. • When the number of custom groups reaches 20, no further custom groups can be imported. • The imported custom group name is the parameter file name. If the file name exceeds 50 characters, the first 50 characters will be used as the group name. • The description of the imported custom group is blank by default.
Export custom groups	Exports the currently selected custom group to the local disk. Restrictions: Only DAT and CSV format files are supported for export.

17.2.2.3 Toolbar

The toolbar for the parameter list is shown in the figure below. For detailed descriptions of the functions, see the table below.

Description		Description
	Upload and save (current page)	Uploads the current values of all parameters on the current page and save them locally. • After the upload is complete, the upload result is displayed, including a list of parameters failed to be uploaded and the reasons for their failure. • You can retry uploading failed parameters.

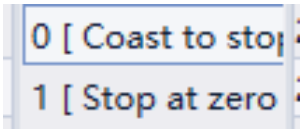
Description		Description
	Upload and save all selected	Uploads the current values of all selected parameters and save them locally. • After the upload is complete, the upload result is displayed, including a list of parameters failed to be uploaded and the reasons for their failure. • You can retry uploading these parameters. • When exporting files, you can apply encryption settings as needed. 
	Import data	Opens a recipe saved on the local disk. After successfully opening a recipe, its variable values will be linked to the parameters of the current device, serving as the new setting values to be downloaded to the device. Restrictions: • Only DAT format recipe files are supported for opening. • A recipe can only be opened successfully if the device in the recipe matches the current device model being commissioned.
	Save set values of all selected	Saves the values of all selected parameters as data records in a file. The file contains basic information required for verification when using the recipe. Restrictions: Only DAT and CSV format files are supported for saving.
	Download all parameters except H00/H01 group	Writes the setting values of all parameters, excluding the H00 and H01 groups, into the device. • After downloading, the download result is displayed, and any parameters that failed to download, along with the reasons for failure, are shown in a list. • You can retry downloading failed parameters.

Description		Description
	Download checked options (current page)	Writes the setting values of all selected parameters on the current page into the device. • After downloading, the download result is displayed, and any parameters that failed to download, along with the reasons for failure, are shown in a list. • You can retry downloading failed parameters.
	Custom parameters	In the "Custom parameters" interface, you can add or remove parameters from custom groups. Parameters within custom groups are used in the same way as native device parameters. **Steps:** 1. In the drop-down list in the upper right corner, select the custom group where you want to add or remove parameters. 2. Check the required parameters in the left parameter list. 3. Click "Add to custom group" to add the selected parameters to the current group. 4. Click "OK" to complete the parameter addition. **Other functions:** • Right-click menu: ◦ The right-click menu on the left side includes: "Select all", "Deselect all", "Check selected", and "Uncheck selected". ◦ The right-click menu on the right side includes: "Select all", "Deselect all", "Check selected", "Uncheck selected", and "Add to". • New group: Opens the new custom group interface and returns to the custom parameter interface after the interface is closed. Any changes made in the "New custom group" interface will be synchronized to the custom parameters in the right-side parameter list when you click "OK". This synchronization applies to the custom group itself, not to the parameters within it. • Select all: Selects all parameter items in the list. • Delete: Deletes the selected parameters from the current group.
	Add to (selected)	Copies the currently selected parameters to a new or existing custom group. Restriction: Addition is not allowed if no parameters are currently selected.

Description		Description
	Parameter Comparison	Displays the changes of the parameter values. • You can compare the setpoint of a device parameter with its current value and display the comparison result. • You can compare the setpoint of a device parameter with its factory value and display the comparison result. • You can compare the current values with the set values of device parameters, and view the comparison result.
	Change property	Ensures that the parameter properties in the host controller match those in the physical device. Properties include default values, parameter lower/upper limits, and accuracy, and support both manual and automatic updates. Restrictions: • If the device supports automatic updates, its properties will be updated automatically upon device connection, and the update process cannot be canceled. • Cancellation is supported during manual attribute updates.
	Parameter description	Displays detailed information about the parameter.
	Display selected only	Displays only the selected items in the parameter list.
	Move up	Moves the parameter up in the custom parameter group.
	Move down	Moves the parameter down in the custom parameter group.
	Parameter search	Searches for parameters matching the keyword. Restrictions: • The search scope includes parameter ID, address, description, unit name, parameter upper limit, parameter lower limit, and access mode. • It offers a selection of previously searched keywords, allowing you to easily choose a historical keyword for your search.

Description		Description
	Permissions switchover	Limits the user's access range to parameters. The drop-down list supports two permission options: "Normal user" and "Super administrator". Restrictions: • When switching the permission from "Super administrator" to "Normal user", the permissions for all drive devices in the current project will be changed to "Normal user". • When "Super administrator" is selected, a pop-up window will prompt you to enter the password and ask whether to apply the permission setting to all drive devices in the project. If "Apply to all drive devices in the project" is selected and the password is correct, the permissions for all drive devices in the current project will be changed to "Super administrator". If not selected, only the current device will be set to "Super administrator". • The scope of permission includes viewing and operating parameters related to parameter list, custom parameters, parameter comparison, axis copy, and other functions.

17.2.2.4 Parameter Modification



The access modes for editing parameters in the parameter list are classified as "Read only", "Stop status", and "Any time".

Parameters with access modes of "Stop status" and "Any time" can be edited by clicking the value in the "Set value" column. The editable types include the following:

1. General type: Simple types such as integers can be directly entered in the input box.

2. Drop-down box

3. Bit field

Index	Current value	Set value
bit0: Output DO active signal if current position changes from "les...	1	0
bit1: Output DO active signal if current position changes from "mo...	0	0

4. Bit field drop-down box

Index	Current value	Set value
bit0 to bit3: E234.0 fault level setting	0 [Default level]	0 [Default level]

5. 5-segment code drop-down box (exists in AC drive parameter list)

Index	Current value	Set value
Ones: 位置指令符号	0 [正]	0 [正]
Tens: 加减速时间选择	1 [位置控制加减速时间1]	1 [位置控制加减速时间1]

6. 5-segment code bit (not currently available)
7. 5-segment code bit drop-down box (not currently available)

Note: When editing a parameter, if the setting value is invalid, it will be reset to the previous data.

Right-clicking the parameter list editing area will display the following menu for parameter operations. For details, see the following table.

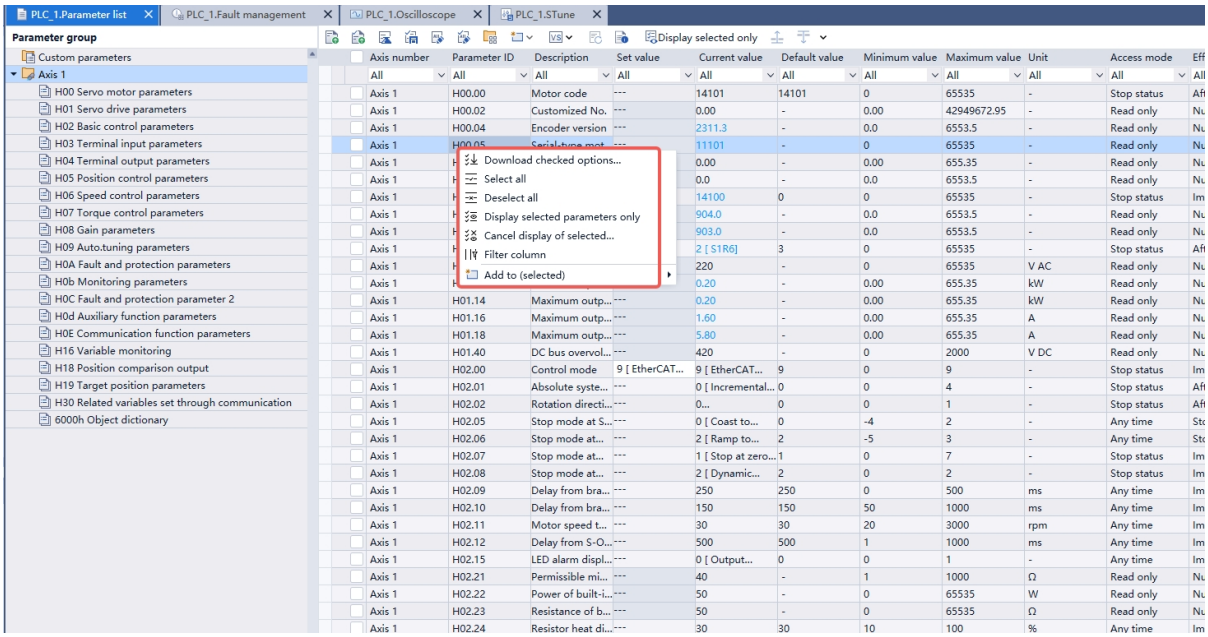


Figure 17-2-2-4-1 Default parameters

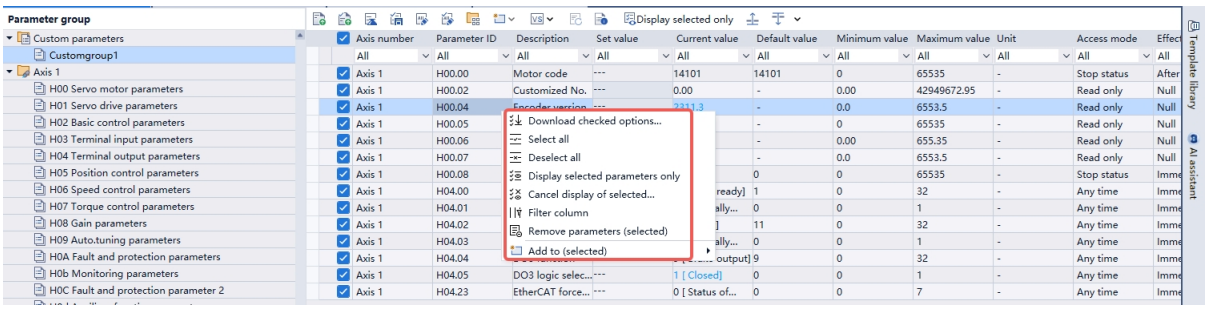

Figure 17-2-2-4-2 Custom parameters

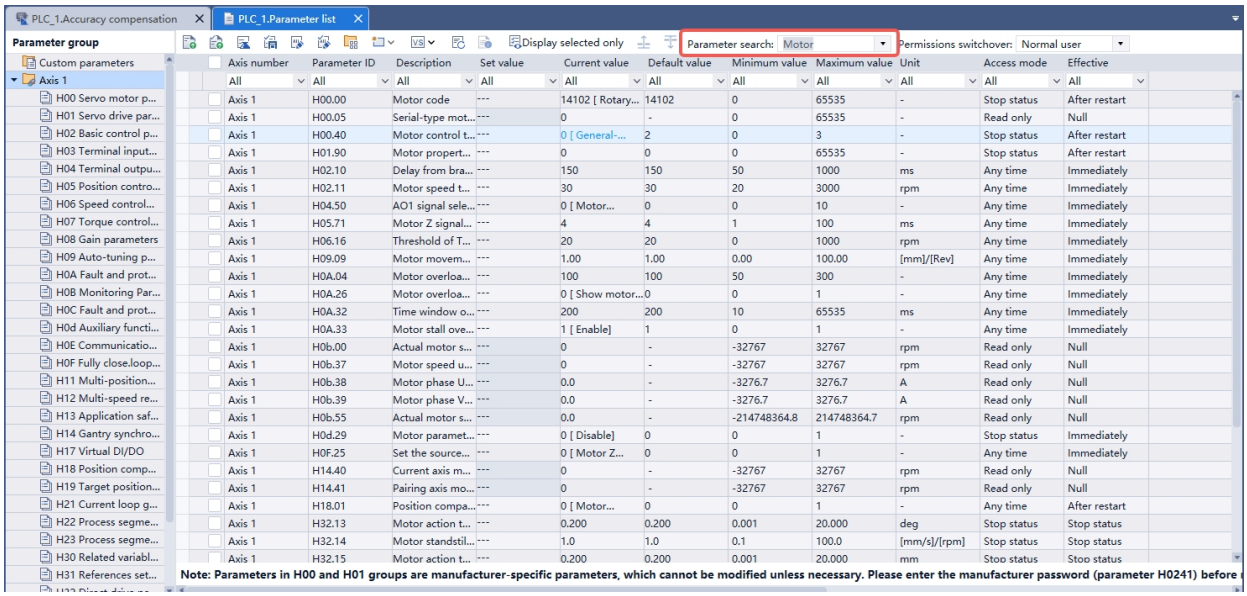


Function	Description
Download checked options (current page)	Writes the setting values of the selected parameters on the current page into the device. • After downloading, the download result is displayed, and any parameters that failed to download, along with the reasons for failure, are shown in a list. • You can retry downloading failed parameters.
Add the selected to the drive monitoring table (current page)	Adds the selected parameters on the current page to the drive monitoring table.
Select all	Selects all parameters on the current page.
Deselect all	Deselects all parameters on the current page.
Display selected parameters only	Displays only the selected parameters on the current page, hiding those that are not selected.
Cancel display of selected parameters only	Cancels the display of only the selected parameters on the current page, i.e., displays all parameters on the current page.

Function	Description
Filter column	Filters the columns displayed in the parameter list based on the filter conditions set in the pop-up "Filter column" dialog box.
Remove parameters (selected)	Removes the selected parameters from the current custom group. Restriction: This function is supported only in the parameter list of a custom group.
Add to (selected)	Copies the currently selected parameters to a new or existing custom group.

17.2.2.5 Parameter Search

The "Parameter search" function in the toolbar is used to search for target parameters. Note the following instructions:

- Except for the "Effective" parameter, you can search for other parameters by entering relevant keywords in the input box.
- The "Parameter search" drop-down box offers a selection of previously searched keywords for quick search.
- To cancel the filter after searching, select "All" from the drop-down list to revert to displaying all parameters.
- Keyword search uses fuzzy matching and is case-insensitive. For example, entering the keyword "Motor" will return the related parameters, as shown in the figure below.

- The search scope is limited to the currently selected node only. For example, if an axis node is selected, the search will cover all parameters within that axis. If a parameter group node is selected, the search will cover all parameters within that group.

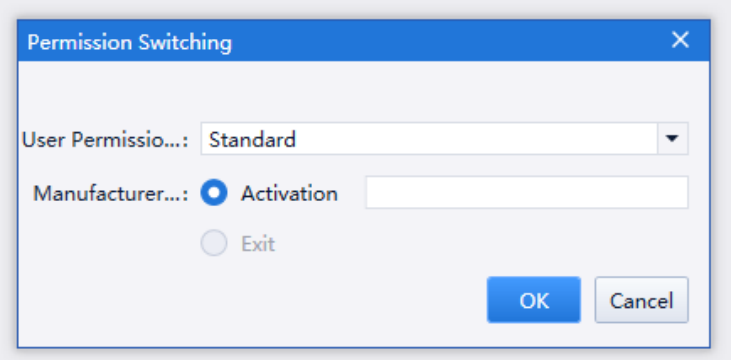
17.2.2.6 Parameter List (MD6X0 Series)

The parameter list function of the MD630 series displays and manages parameters, which include information display, upload/download, property update, description, and custom parameter management.

Parameter viewing

Select a parameter node on the left to display its information on the right. The node contains the parameter information of all subnodes.

- Parameters under the "All parameters" node and its subnodes are system default parameters.
- Parameters under the "Modified parameters" node are parameters whose current values differ from the default values.
- Parameters under the "Custom parameters" node are parameters added by the user.



Custom parameters

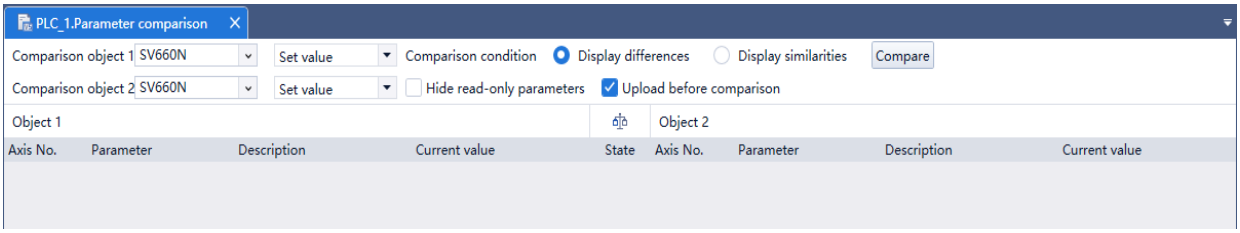
See "Custom Group" for details.

Toolbar

- Displayed in Workspace

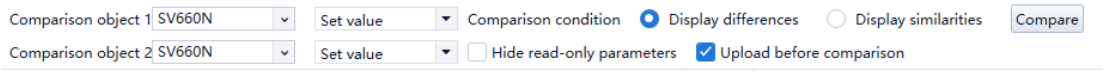
Description	Icon	Description
Upload and save (current page)		Upload and save all parameters included in the selected node and visible to all users. Retry is allowed upon a failure.
Upload and save (all parameters)		Upload and save all parameters included in the current device and visible to all users. Retry is allowed upon a failure.
Open and download parameter file		Open a .dat parameter file and download it to the device. Retry is allowed upon a failure.
Custom parameters		Used to edit parameter information in the custom parameter group.
Parameter Comparison		Used to check the change of the parameter values. You can compare the current values with the set values of device parameters, and view the comparison result.
Change property		Used to update the property of current device. If failed, check whether property update is already in progress.
Parameter description		Provides additional description for the selected parameter.
Move up/down		Move parameters in the customized group. You can select multiple parameters and then click "Move up" or "Move down".

Description	Icon	Description
Permissions switchover	Current permissions Standard	To limit the scope of users' access to parameters, you can set user permissions from the drop-down list, which provides three options: "Standard", "Extended", and "Expert". Restrictions: 1. When you switch "Standard" to "Expert", user permissions on all the drives in the current project will be switched to "Expert". The same rule applies to other user permission switchover cases. 2. Manufacturer permissions include "Activate" and "Exit".  3. General-purpose AC drives (such as MD810) have two permission levels: normal user and super administrator.
Parameter search	Parameter search:	Used to search for parameters in the list of parameter that can be accessed in the current node.

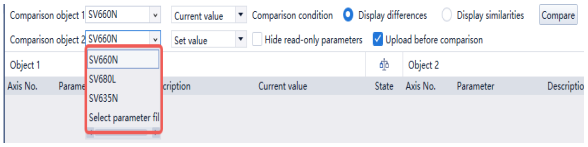


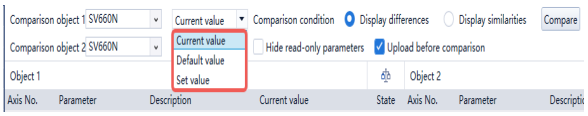
17.2.3 Parameter Comparison

This function is used to compare parameters. It only supports comparing devices of the same model under the same project. For devices with parameter tables that include set values, the comparison types include current values, default values, and set values. For devices with parameter tables that do not include set values, the comparison types include only current values and default values. This enables intuitive identification of differences between parameters, facilitating device commissioning.



Select a device in the project tree and double-click "Parameter comparison" in the detailed view to open the parameter comparison interface.





- **Function interface**

  The parameter comparison interface consists of two parts: the parameter configuration area and the comparison result area. The parameter configuration area allows you to set the parameters of the compared objects. The comparison result area displays the comparison result.

- **Parameter configuration**

Function	Description	Restriction
Comparison object	Select the object to be compared from the drop-down list. • The objects in the list are the root nodes of all devices in the current project (supporting the full series). • Select parameter file: Click "Select parameter file" to select a parameter file from the local disk as the comparison object. A parameter file is exported through software and stores corresponding device parameters. 	• When the information of the device root node in the project tree changes, both the text box and the drop-down list of the comparison object will be updated synchronously. Change types include: rename, delete, and add new devices. • There is no conflict between "Comparison object 1" and "Comparison object 2". Both can be compared with the same object. • Online devices can be compared with offline parameter files for parameters. • Only the parameter file in the DAT format is supported.
Comparison type	Select the parameter type to be compared in the drop-down list. You can select the current value, factory value, and set value. 	Only when the comparison object is set by "Select parameter file", the comparison type is forcibly set to "Set value" and the drop-down list is disabled.
Comparison condition	Select the display mode of the comparison result area. • Display same: The comparison result area displays only parameters without difference. • Display different: The comparison result area displays only parameters with difference.	When the comparison conditions are modified, the comparison results are updated immediately.

Function	Description	Restriction
Hide read-only parameters	Filter the comparison results. • When "Hide read-only parameters" is checked, the comparison result displays only the parameters that can be set. • When it is not checked, all comparison results will be displayed.	The checking and unchecking of "Hide read-only parameters" takes effect in real time and the comparison results are updated immediately.
Upload before comparison	Select whether to refresh the current value of the comparison object before comparison. • Check "Upload before comparison" to read the current value of the object from the drive before comparison. • Uncheck it to use the cached current value of the object for comparison.	It takes effect when at least one "Current value" is present in two comparison types.
Start comparing	Click the "Compare" button to start comparing. • After a successful comparison, a comparison completion window will pop up. • When comparison fails, you will be prompted that the device type does not match, and you need to select a comparison object again.	/

- **Result display**

  Parameter comparison results are displayed in a list. Data of comparison object 1 is displayed on the left, data of comparison object 2 is displayed on the right, and the comparison state is displayed in the middle. The data in the list does not support editing.

  - When the comparison finds no difference, the comparison status is green, and the data table color of comparison object 1 is the same as that of comparison object 2.
  - When the comparison finds any difference, the comparison status is a yellow exclamation mark, and the data table colors of comparison objects 1 and 2 are yellow and blue respectively.

17.2.4 Machine Parameter Management

17.2.4.1 Machine Recipe Management

For details, see Machine Recipe Management.

17.2.4.2 Machine Parameter Management

For details, see Machine Parameter Management.

17.2.4.3 Firmware Batch Update

For details, see 10.6.3.2.7.3 Batch Firmware Upgrade.

17.3 Common Servo Function

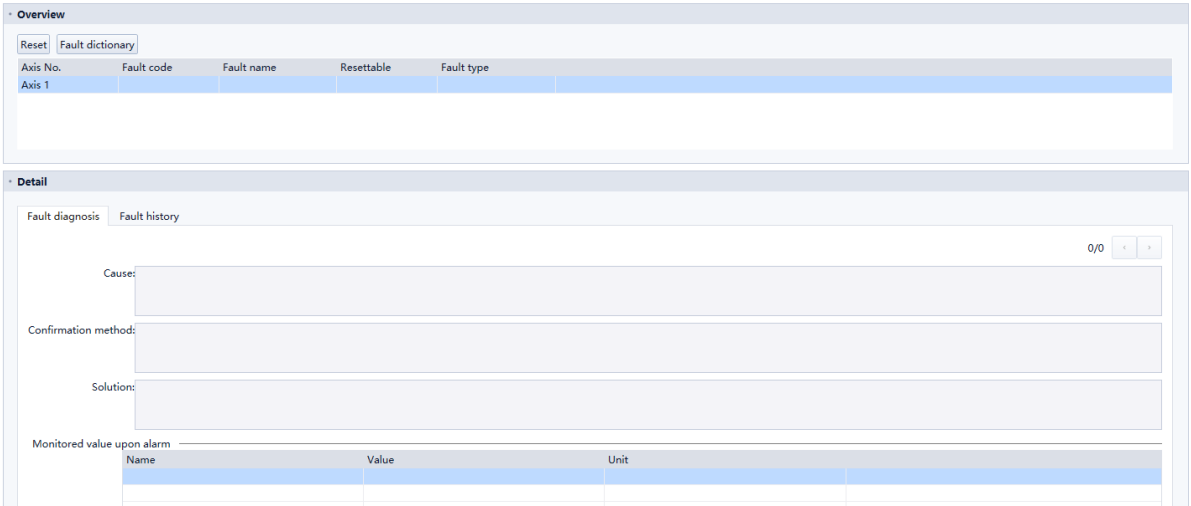
17.3.1 Overview

Before activating the servo commissioning function, an EOE connection needs to be established. For details, see 17.1.1 EOE Connection.

17.3.2 Fault Management

Faults and alarms are classified into three levels based on their severity.

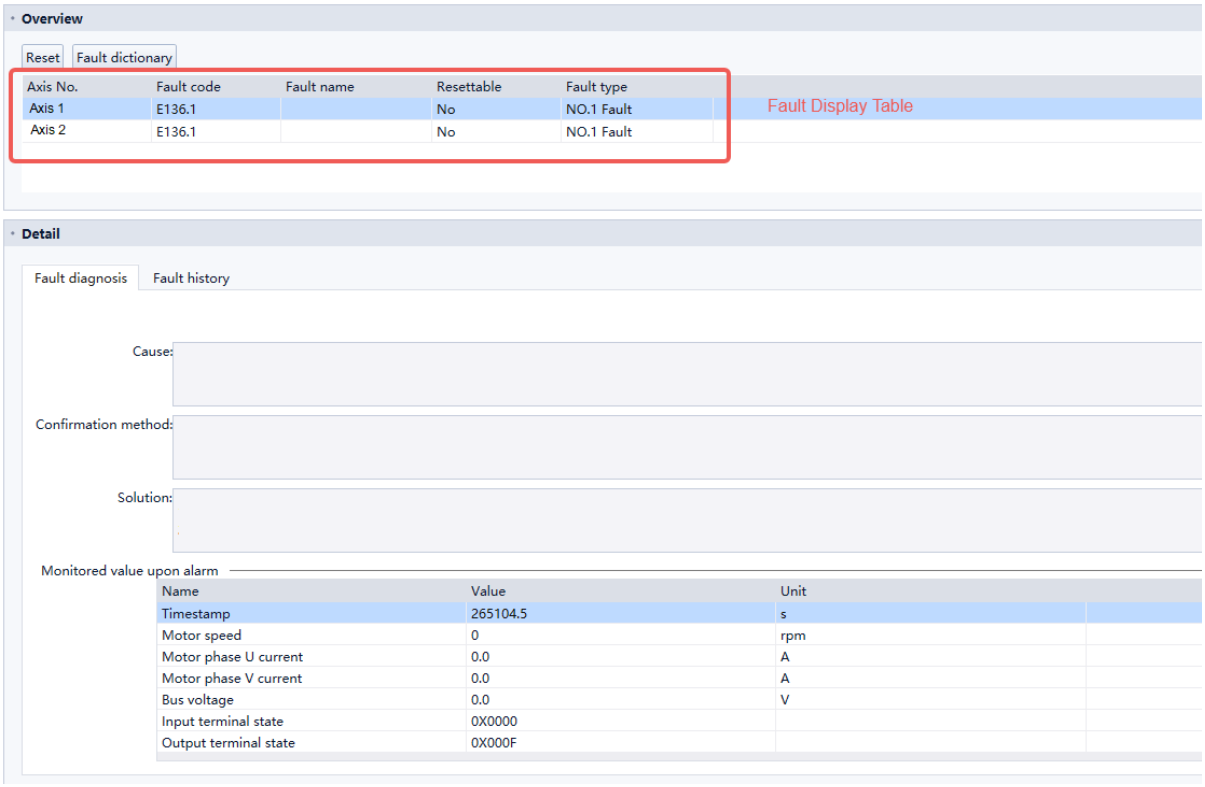
- No. 1 non-resettable fault
- No. 1 resettable fault
- No. 2 resettable fault
- No. 3 resettable alarm



Note: Level of severity is No. 1 > No. 2 > No. 3

17.3.2.1 Servo Fault Management

Select a servo device in the project tree and double-click "Fault management" in the detailed view to display detailed information about the current device faults and their solutions.

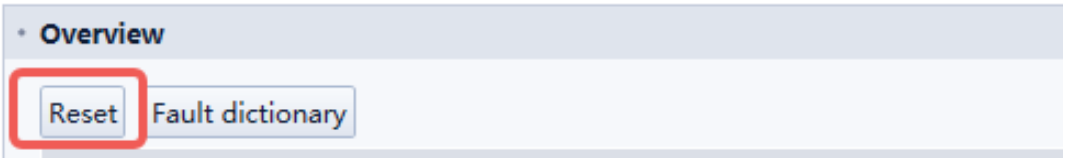


The servo fault management interface is shown in the figure below. It mainly consists of the following three parts:

- The fault overview area displays basic information about all current faults and allows "Reset" operation and access to the "Fault dictionary".
- The fault diagnosis area displays information such as the cause of the fault and its solutions.
- The fault history area displays historical fault information.

17.3.2.2 Fault Overview

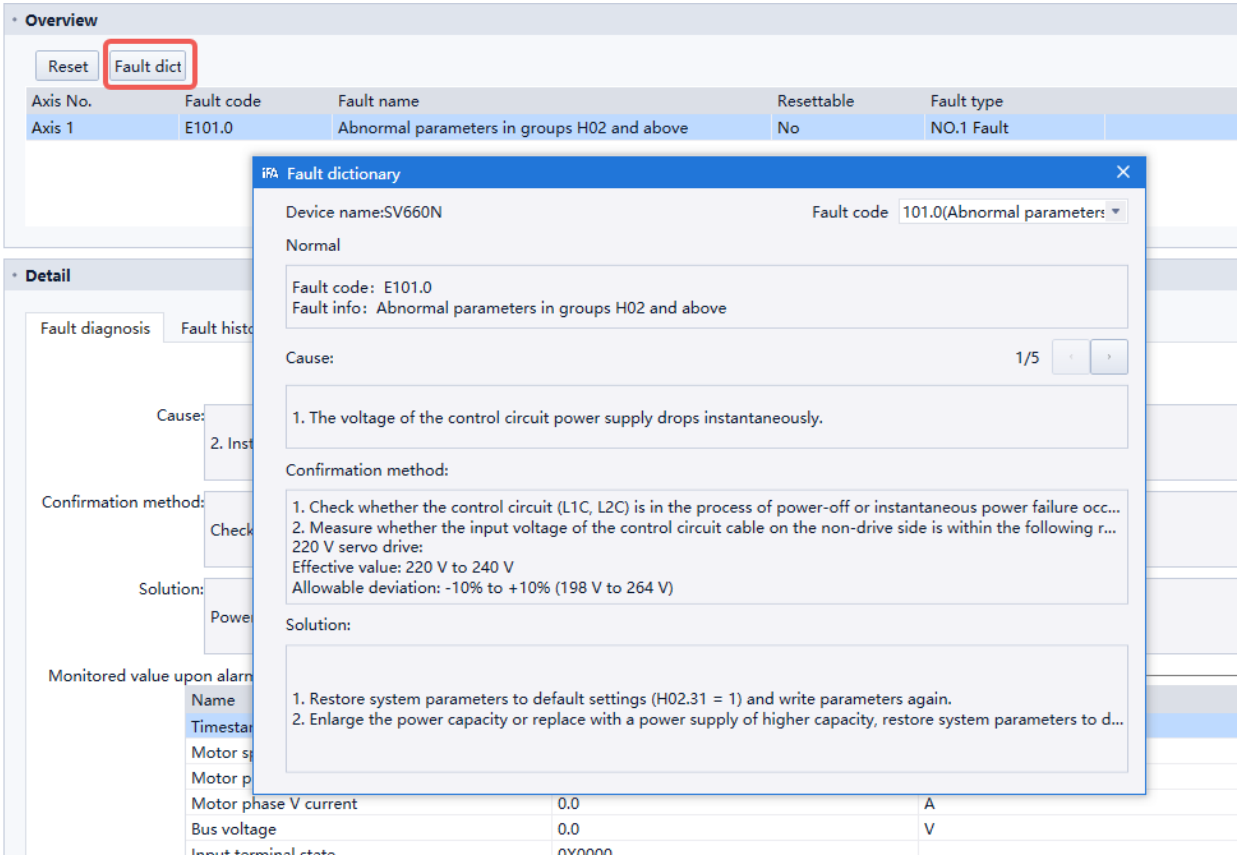
The "Fault management" interface is shown in the following figure.



17.3.2.3 Troubleshooting

The main solution to faults is "Reset". Click "Reset" to reset the faults.

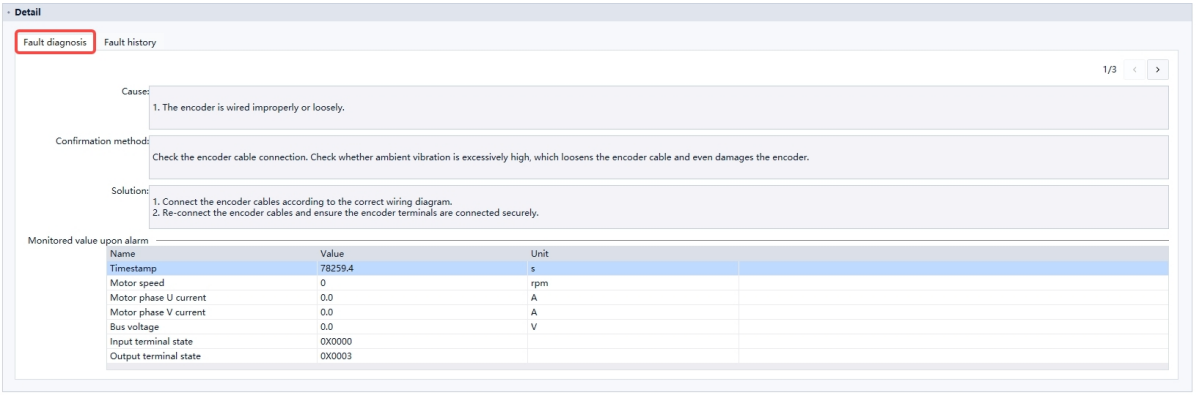
Restrictions:



- Available only for resettable faults.
- Resettable faults can only be reset after the fault has been cleared.

17.3.2.4 Fault Dictionary

The fault dictionary displays detailed information about all faults related to the current device, including fault code, cause, confirmation method, and solution.

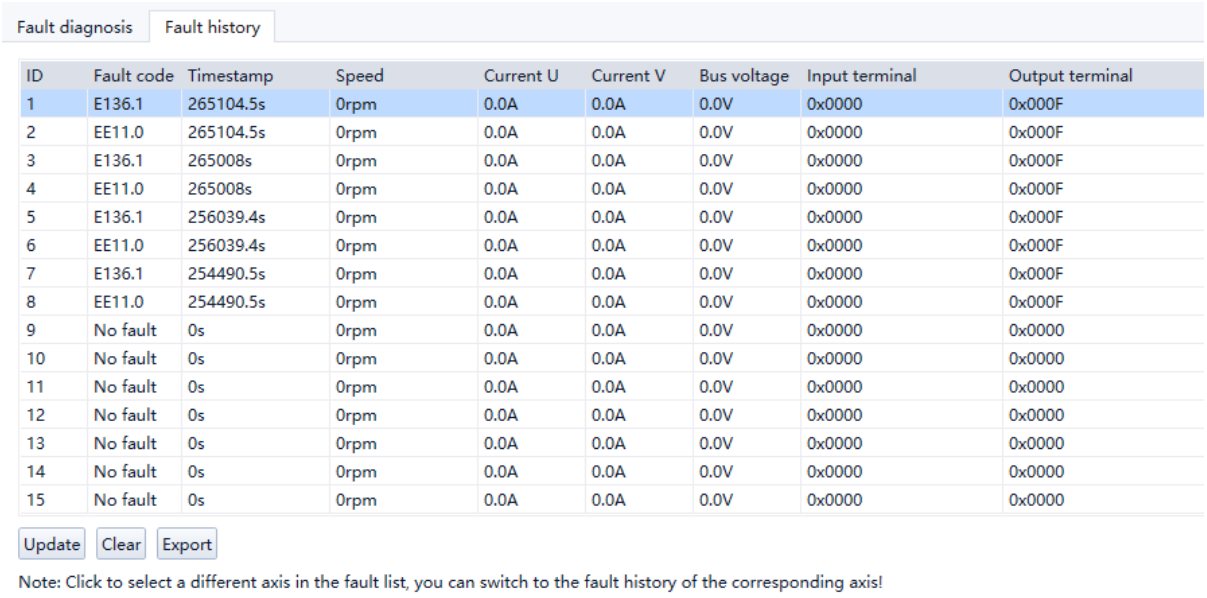


Clicking "Fault dictionary" will pop up the following interface. See the table below for detailed descriptions.

Description	Description
Fault code	The fault code to be viewed is selected from the drop-down box in the upper right corner of the interface. The options are product-specific. After selecting a fault code, the interface will display detailed information about the selected code.
Normal information	Displays the selected fault code and fault name.
Troubleshooting information	Displays the fault cause, confirmation method, and solution of the selected fault code.
Page turning buttons	If there are multiple causes for a fault, you can use these buttons to view different fault diagnosis information.

17.3.2.5 Fault Diagnostics

The fault diagnosis area displays information about the cause, confirmation method, solution of the current fault, and device parameters upon fault. The interface is shown in the figure below. For detailed function descriptions, see the table below.

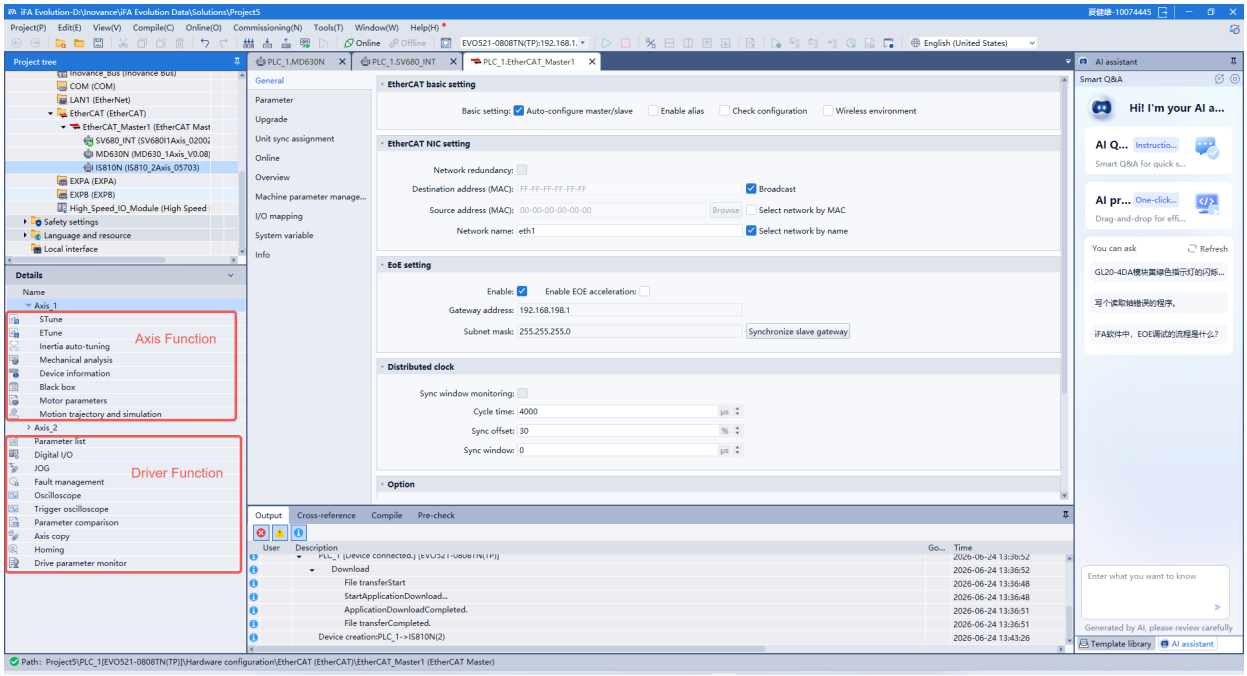


Function	Description
Cause	Displays the cause of the fault.
Confirmation method	Displays the confirmation method for the corresponding fault.
Solution	Displays the solution of the fault.
Monitored value upon alarm	Displays the name, value, and unit of the related parameters being monitored when the fault occurs.
Page turning buttons	If there are multiple causes for a fault, you can use these buttons to view different fault diagnosis information.

17.3.2.6 Fault History

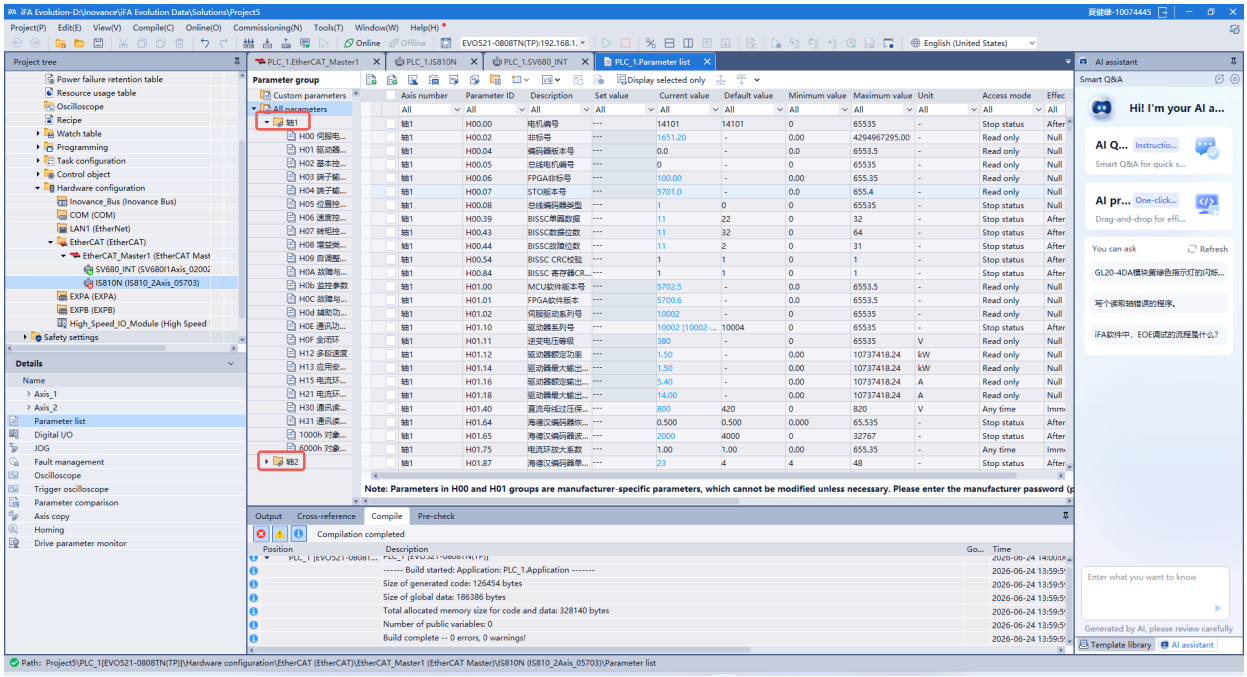
The servo drive can record the latest faults and alarms, and the drive status parameters upon fault/alarm. The number of records varies among different devices.

Click "Fault history" in the "Fault management" interface to display the following interface. For detailed function descriptions, see the table below.



Function	Description
Update	Updates the fault history record of the current servo device.
Clear	Clears all current fault record information.
Export	Exports the current fault record information into a CSV file and save it to the selected local path.

17.3.3 Multi-Axis Device



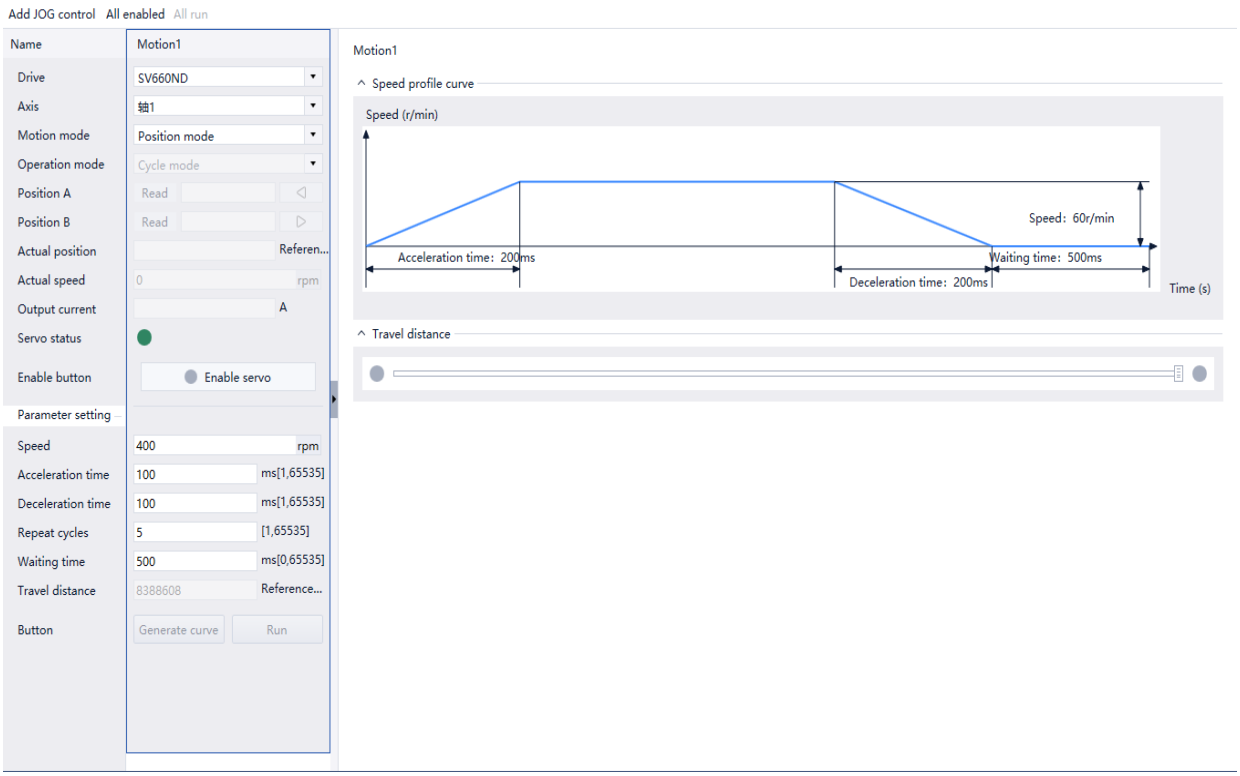
The currently integrated multi-axis devices include: SV660ND, SV630ND, and IS810N series products.

Display format for dual-axis devices

Click the device node in the project tree to display the axis function nodes and drive function nodes in the detailed view. Click the Axis_1/Axis_2 node to expand or collapse the specific axis function commissioning nodes.

Difference between axis functions and drive functions: in the opened commissioning view, drive functions allows simultaneous commissioning of multiple axes, while axis functions only allows commissioning of the corresponding single axis.

17.3.4 JOG Motion Control

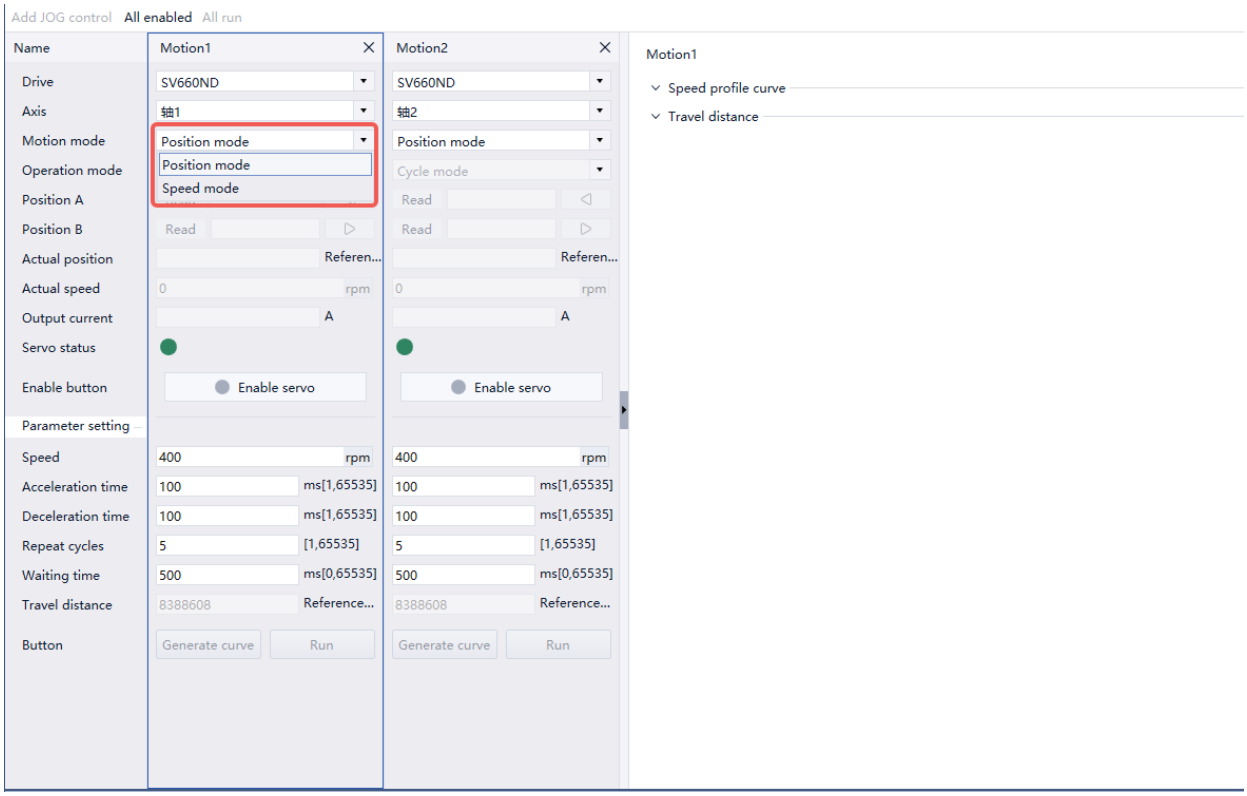


17.3.4.1 Overview

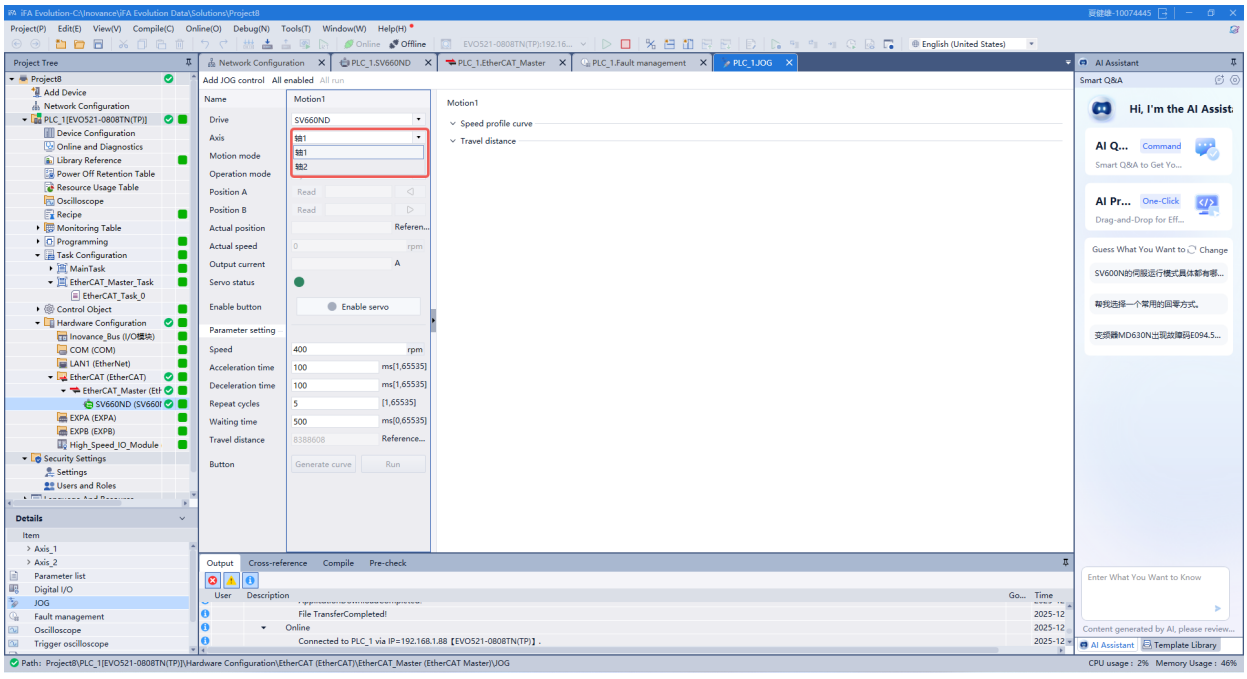
Select a servo device in the project tree and double-click "JOG" in the detailed view to open the following interface.

Jog motion control consists mainly of speed jog and position jog.

- Speed jog: It is mainly used to control the motor in the jog mode, which detects whether the motor can run and rotate properly.
- Position jog: It is mainly used to run the motor in the specified limit at the specified speed reciprocally or in a fixed distance.



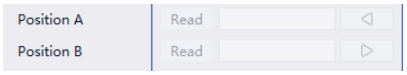
The "JOG" interface consists of the toolbar, parameter description, motion control, and chart.

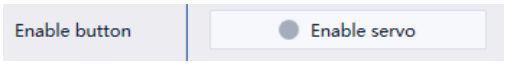


Function	Description
Add JOG control	Adds a jog panel. Restrictions: • If the number of current axes is n, up to n panels can be added. However, n cannot exceed 20. If the number of current axes is 0, no panel can be added. • The "Add JOG control" button is disabled when no jog panel can be added.
All enabled	Enables or disables all devices that have the jog control panel added on the current interface.
All run	Starts or stops all devices that have the jog control panel added on the current interface.

17.3.4.2 Mode Selection

The jog modes include position mode and speed mode.





For dual-axis equipment, axis 1 or axis 2 can be selected.

17.3.4.2.1 Position JOG and Parameter Settings

This function is mainly used to run the motor in the specified limit at the specified speed reciprocally or in a fixed distance.

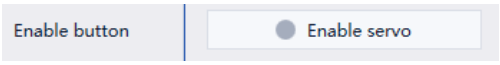
Function	Description
Drive	Selects the drive for position jog in the drop-down list. • The drive cannot be changed in the motion enabled status. • When the drive nodes change (added/deleted/edited) in the project tree, the drive information changes synchronously.
Axis	Selects the axis for position jog in the drop-down list. • The axis cannot be changed in the motion enabled status. • When the selected drive changes, the axis is simultaneously updated to the one currently mounted to the drive.
Motion mode	Selects the desired motion mode from the drop-down list. The motion mode cannot be changed in the motion enabled status.
Operation mode	Selects the required operation mode in the drop-down list. Options includes "Cycle mode" and "Specified distance". • In the cycle mode, the motor reciprocates. • In the specified distance mode, the motor runs at the specified distance. The operation mode cannot be changed in the motion enabled status.
Position A/Position B	 Limits the maximum limit position at both ends of the motor's reciprocating motion. • The "Read" button is used to read the current position as position A/B. • The text box displays the values of position A/B, which can be edited. • The forward/reverse running icons control the forward/reverse rotation of the motor. Restrictions: This function is available only when the motor is enabled and the operational status is not enabled.
Actual position	Displays the actual position of the current axis, which cannot be edited.
Actual speed	Displays the actual speed of the current axis, which cannot be edited.
Output current	Displays the output current, which cannot be edited.
Servo status	Displays the status of the servo drive. The icon is green when the drive is connected, and gray when the drive is disconnected.

Function	Description
Enable button	 Enables or disables the motor. The button is displayed as "Enable servo" in gray by default. Click "Enable serve". If the servo drive is enabled successfully, the button is displayed as "Disable servo" and the servo status icon becomes green. Click "Disable servo" to restore the button to the initial status. Restrictions: • When the servo drive is disconnected, the button is disabled. • When the servo drive is connected, the button is enabled. • When the interface is closed, a prompt indicating whether to stop all drive operations is displayed. If you select yes, the jog interface is closed and servo drives in jog operation will all be stopped. If you select no, the jog interface is closed but jog operations of the servo drives continue.
Speed	Defines the speed of an axis. It cannot be edited in the motion enabled status.
Acceleration time	Defines the acceleration time of an axis. It cannot be edited in the motion enabled status.
Deceleration time	Defines the deceleration time of an axis. It cannot be edited in the motion enabled status.
Repeat cycles	Defines the number of reciprocations for the motor. The parameter is available only when the operation mode is set to "Cycle mode".
Waiting time	Defines the waiting time of the motor. The parameter is available only when the operation mode is set to "Cycle mode".
Travel distance	Sets the motor to run at the specified distance. Range: -2147483648 to 2147483648. The parameter is available only when the operation mode is set to "Specified distance".
Generate curve	Generates a speed curve. Click "Generate curve" or "Run" to update the curve. When the current panel changes, the curve synchronously updates to the last updated data of the panel.
Run	Runs the motor.

Function	Description
Speed profile curve	 Displays a speed curve. • The speed curve is updated only when you click "Generate curve". • When multiple position mode panels are added, they share one speed curve chart. Click "Generate curve" of a specific axis to generate the speed curve for that axis.
Travel distance	 Tracks the motor position. • It is disabled by default. The left and right status indicators are both gray. • The interface will retain the last running status. • The left and right status indicators will be refreshed when operation starts. ◦ If the current position is larger than position A, the status indicator on the left becomes red. When the position point moves to the leftmost, the status indicator on the right becomes green. ◦ If the current position is smaller than position B, the status indicator on the right becomes red. When the position point moves to the rightmost, the status indicator on the left becomes green. ◦ If the current position is between position A and position B, both the left and right status indicators become green. The position point is displayed between position A and position B proportionally according to the current position. • Tracking is performed only when you click "Run". Tracking stops after the operation is disabled.

CAUTION

For specified distance operation in the position mode, the following conditions must be met:



- During startup, the current position must be within the range of position B to position A.
- When you set the distance, the motion of the motor must be within the range of position B to position A. Otherwise, the motor cannot complete the desired operation.

17.3.4.2.2 Speed JOG and Parameter Settings

STD60N series does not support speed jog.

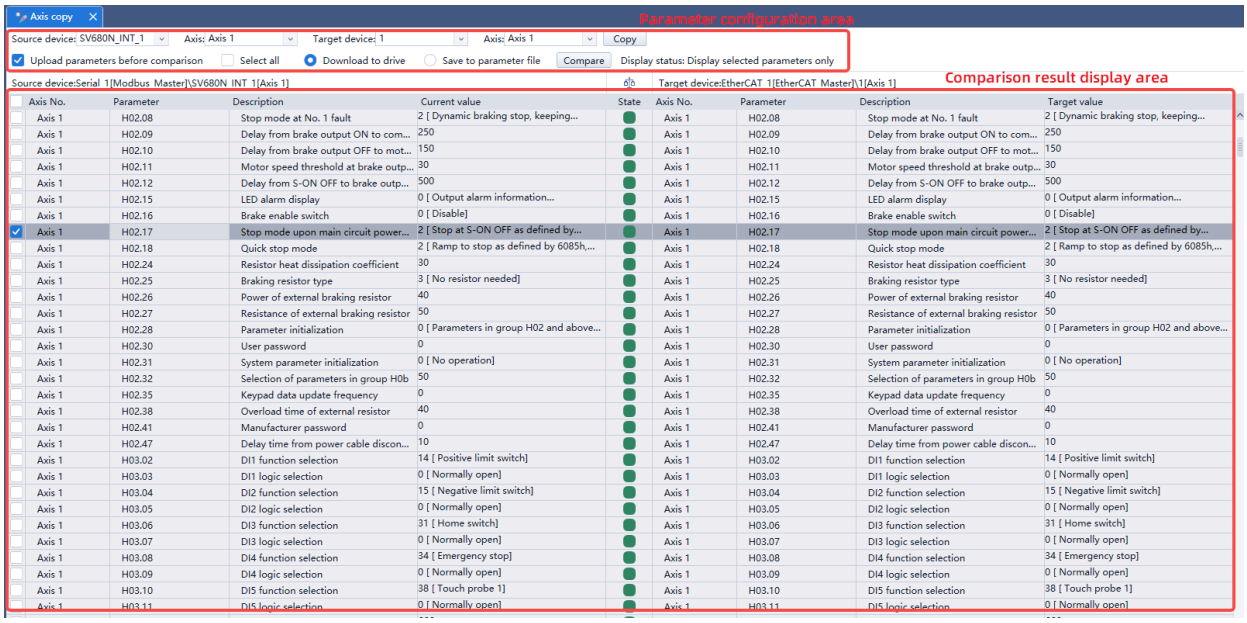
This function is mainly used to control the motor in the jog mode, which detects whether the motor can run and rotate properly.

Function	Description
Drive	Selects the drive for speed jog in the drop-down list. • The drive cannot be changed in the motion enabled status. • When the drive nodes change (added/deleted/edited) in the project, the drive information changes synchronously.
Axis	Selects the axis for speed jog in the drop-down list. • The axis cannot be changed in the motion enabled status. • When the selected drive changes, the axis is simultaneously updated to the one currently mounted to the drive.
Motion mode	Selects the desired motion mode from the drop-down list. The motion mode cannot be changed in the motion enabled status.
Actual position	Displays the actual position of the current axis, which cannot be edited.
Actual speed	Displays the actual speed of the current axis, which cannot be edited.
Output current	Displays the output current, which cannot be edited.
Servo status	Displays the status of the servo drive. The icon is green when the drive is connected, and gray when the drive is disconnected.

Function	Description
Enable button	 Enables or disables the motor. The button is displayed as "Enable servo" in gray by default. Click "Enable serve". If the servo drive is enabled successfully, the button is displayed as "Disable servo" and the servo status icon becomes green. Click "Disable servo" to restore the button to the initial status. Restrictions: • When the servo drive is disconnected, the button is disabled. • When the servo drive is connected, the button is enabled. • When the interface is closed, a prompt indicating whether to stop all drive operations is displayed. If you select yes, the jog interface is closed and servo drives in jog operation will all be stopped. If you select no, the jog interface is closed but jog operations of the servo drives continue.
Speed	Defines the speed of an axis. Modification is prohibited when the servo drive performs forward and reverse running.
Acceleration time	Defines the acceleration time of an axis. Modification is prohibited when the servo drive performs forward and reverse running.
Deceleration time	Defines the deceleration time of an axis. Modification is prohibited when the servo drive performs forward and reverse running.
Forward/ reverse running icons	 Controls forward/reverse running of an axis. Long press the icon to start forward/reverse running and release it to stop. When the servo drive is enabled, the forward/reverse icon is enabled. When the servo drive is disabled, the forward/reverse icon is disabled.

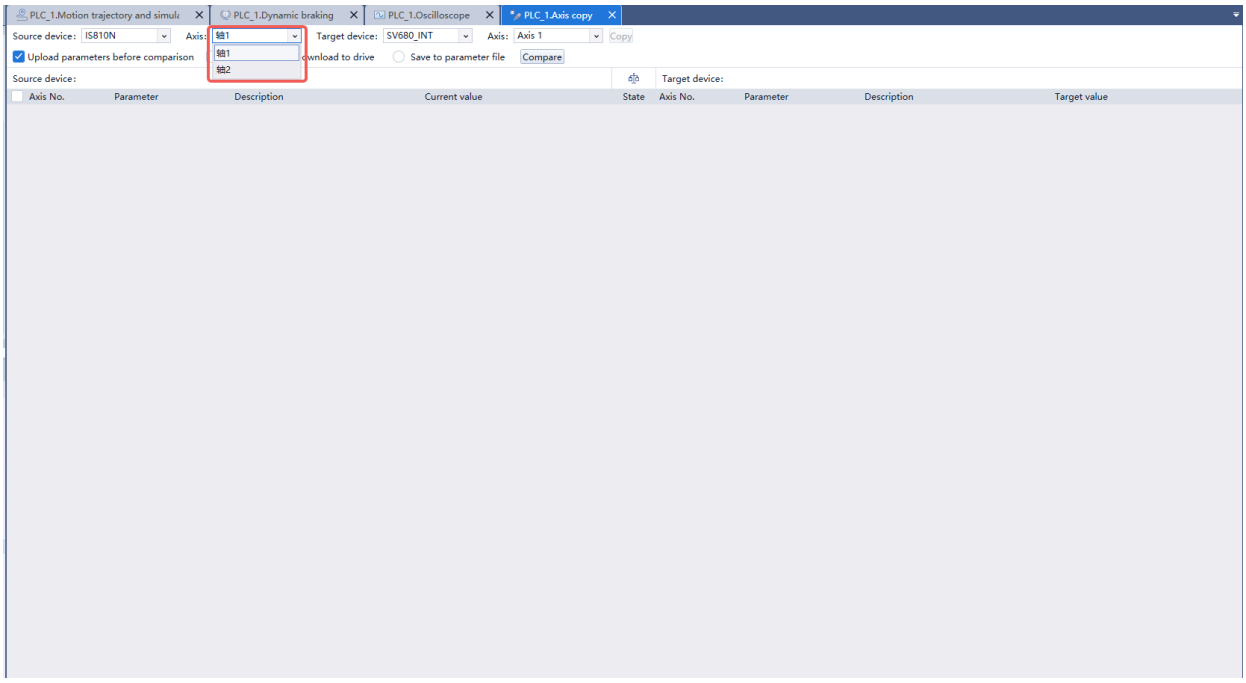
NOTE

The acceleration time of SV680N indicates the time required to accelerate from 0 rpm to 1000 rpm. The deceleration time indicates the time required to decelerate from 1000 rpm to 0 rpm.



17.3.5 Axis Copy

This function is used to copy the current values of related axis parameters of the source device to the target device. Two devices must be of the same series. You can quickly copy the parameters of the source device to the target device through axis copying.

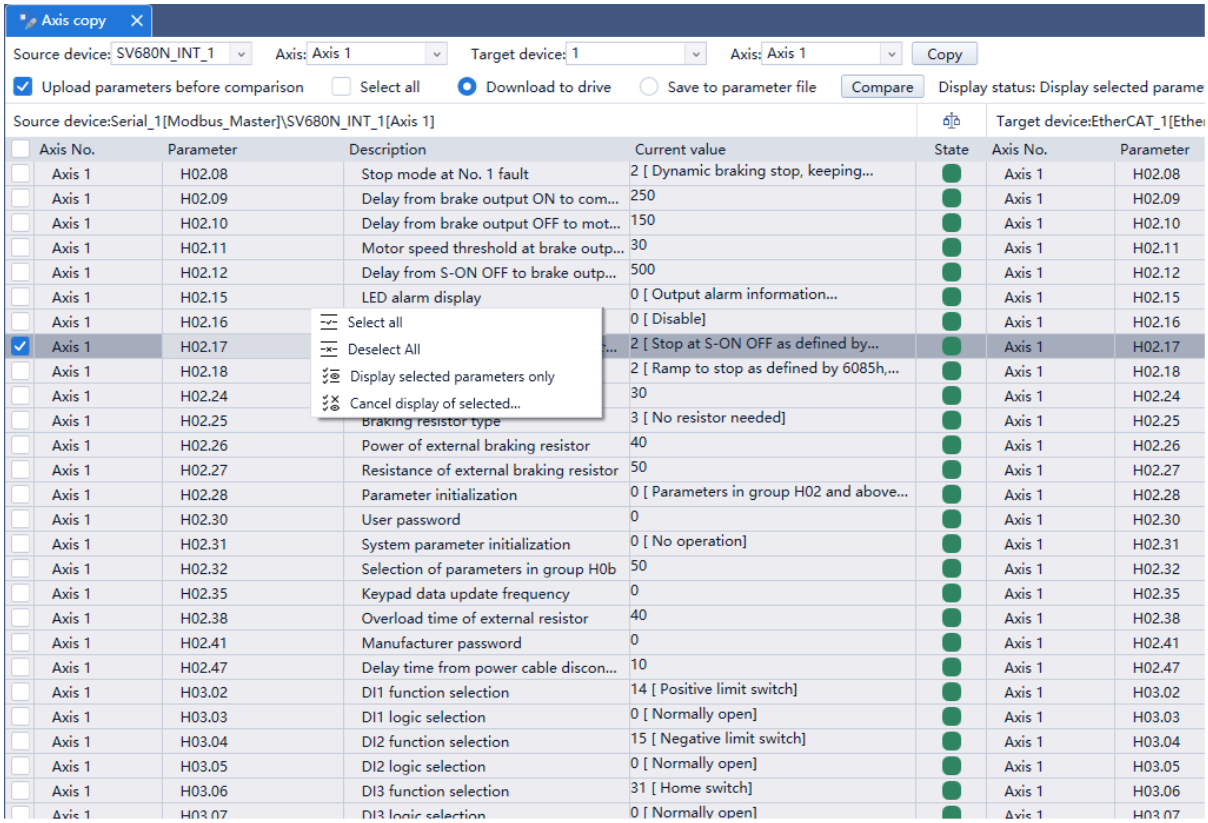


Select a servo drive in the project tree and double-click "Axis copy" in the detailed view to open the interface.

- **Function interface**

  The "Axis copy" interface consists of two parts: parameter configuration area and comparison result area. Before copying the axis parameters, compare the parameters of the two devices and copy the parameters of the source device to the target device based on the comparison results, as shown in the figure below.

Axis 1 and Axis 2 functions are available for dual-axis device.



- **Parameter configuration**

Function	Description	Restriction
Source device	Selects the data source object to be copied in the drop-down list. All servo root nodes in the current project can be selected. It is only applicable to SV660N, SV680N, STD60N, SV630N, SV630NS, SV670N and IS680N-PLUS series products.	• When the information of the servo root node changes (renamed/deleted/added), both the text box and the drop-down list of the comparison object will be updated synchronously. • The "Source device" and "Target device" are independent. Different axes of the same type servo drive can be selected on both devices for comparison and copying.
Axis (source device)	Selects the data source object to be copied. Options include all axes under the source device.	When the "Source device" and "Target device" are the same servo drive and the same axis, comparison and copy cannot be performed.
Target device	Selects the target object to be copied in the drop-down list. All servo root nodes in the current project can be selected. It is only applicable to SV660N, SV680N, STD60N, SV630N, SV630NS, SV670N and IS680N-PLUS series products.	• When the information of the servo root node changes (renamed/deleted/added), both the text box and the drop-down list of the comparison object will be updated synchronously. • The "Source device" and "Target device" are independent. Different axes of the same type servo drive can be selected on both devices for comparison and copying.
Axis (target device)	Selects the target object to be copied. Options include all axes under the target device.	When the "Source device" and "Target device" are the same servo drive and the same axis, comparison and copy cannot be performed.

Function	Description	Restriction
Upload parameters before comparison	Check to refresh the current values of the comparison objects (the source and target devices) before comparison. • If it is checked, the current value of the object from the drive is read before comparison. • If it is unchecked, the cached current value of the object is used for comparison.	/
Compare	Click "Compare" to compare the current values of "Source device" and "Target device".	/
Select all	Selects or deselects all parameters in the comparison results.	/
Download to drive	When "Download to drive" is checked, click "Copy" to download the current values of the parameters checked on the source device directly to the target device.	/
Save to parameter file	When "Save to parameter file" is checked, click "Copy" to save the current values of the parameters checked on the source device to the local disk.	The file can only be in the DAT format.
Copy	After selecting the parameters to be copied in the comparison results, click the "Copy" button to execute the corresponding copy operation. • If "Download to drive" is checked, the current values are copy (downloaded) to the target device. • If "Save to parameter file" is checked, the current values are saved to the local drive.	Copy can only be performed when there are selected parameters in the comparison results.

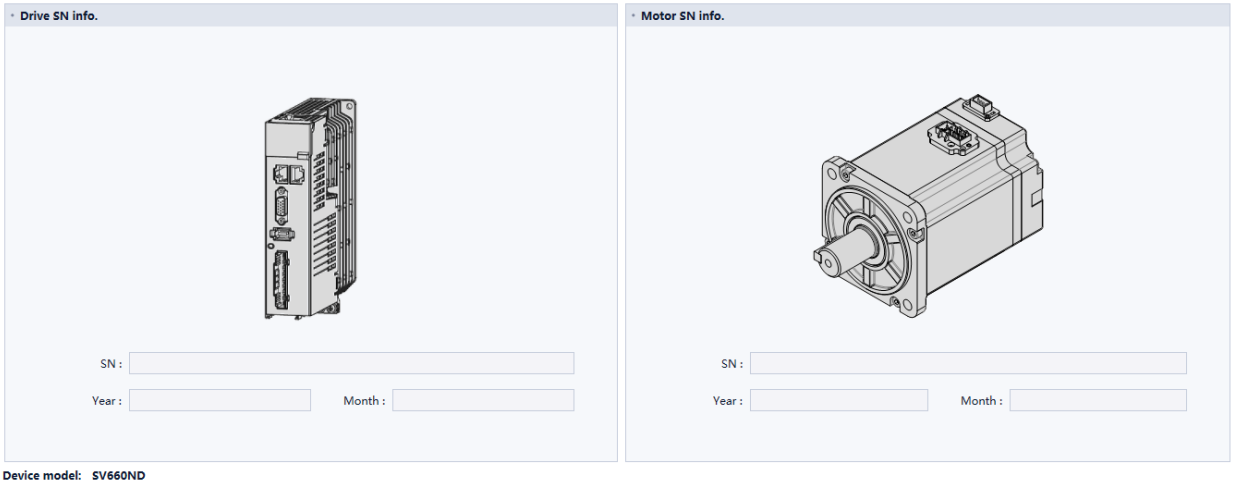
- **Right-click menu**

  Right-click the axis copy result display area to perform the following operations to the list: selecting all, unselecting all, displaying selected parameters, and displaying all, as shown in the figure below.

- **Result display**

  The parameter comparison results are displayed in a list, with source device data on the left, target device data on the right, and the comparison status in the middle. The data in the list does not support editing.

  - When the comparison finds no difference, the comparison status is green, and the data table colors of the source and target devices are the same.
  - When the comparison finds any difference, the comparison status is a yellow exclamation mark, and the data table colors of source and target devices are yellow and blue respectively.



17.3.6 Device Information

This function is currently not supported for IS810N series products.

Select a servo drive in the project tree, and double-click "Device information" in the detailed view to open the interface.

The "Device information" interface consists of the following three parts:

- Axis selection: Selects the axis for the current device and refresh motor information.
- Drive SN info.: Displays the serial number and date of the current drive device.
- Motor SN info.: Displays the serial number and date of the motor connected to the current device.

- **Axis selection**

  If the current device has multiple axes, you can switch between them using the drop-down box.

  After the axis is switched, the motor device information will be synchronized and refreshed if a motor is connected.

- **Drive SN info.**

  Displays the drive illustration, serial number (SN code), and date information (year and month).

  If the current drive device is offline, the serial number and date information will be empty.

- **Motor SN info.**

  Displays the motor illustration, serial number (SN code), and date information (year and month).

  If the current drive device is offline or no motor device is connected, the serial number and date information will be empty.

17.3.7 Drive Parameter Monitoring

This function monitors the real-time values of axis parameters in the operation status of the servo drive. The monitored axis parameter objects are configured by the user.

Select a servo device in the project tree, and double-click "Drive parameter monitor" in the detailed view to open the interface, as shown in the following figure.

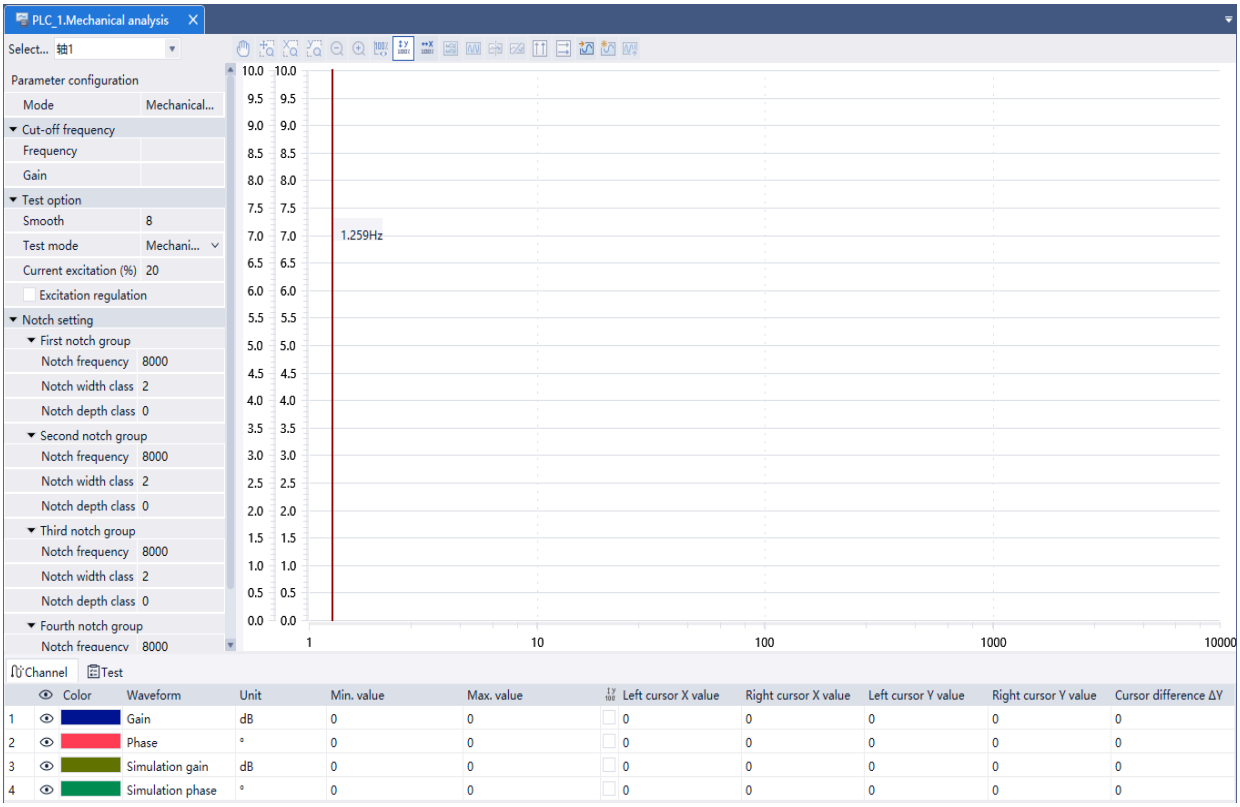
Restrictions:

- The drive monitoring table supports a maximum of 200 parameters, and the number of distributed servo slaves does not exceed 16.

	Device name	Axis name	Parameter	Parameter name	Value
1	SV660N_1	Axis1	H19.45	Target value of position comparison 16	
2	SV660N_1	Axis1	H19.48	Target value of position comparison 17	
3	SV660N_1	Axis1	H19.57	Target value of position comparison 20	
4	SV660N_1	Axis1	H19.59	Attribute value of position comparison 20	
5	SV660N_1	Axis1	H19.60	Target value of position comparison 21	
6	SV660N_1	Axis1	H19.62	Attribute value of position comparison 21	
7	SV660N_1	Axis1	H19.63	Target value of position comparison 22	
8	SV660N_1	Axis1	H19.65	Attribute value of position comparison 22	
9	SV660N_1	Axis1	H19.66	Target value of position comparison 23	
10	SV660N_1	Axis1	H19.68	Attribute value of position comparison 23	
11	SV660N_1	Axis1	H19.69	Target value of position comparison 24	
12	SV660N_1	Axis1	H19.71	Attribute value of position comparison 24	
13	SV660N_1	Axis1	H19.72	Target value of position comparison 25	
14	SV660N_1	Axis1	H19.74	Attribute value of position comparison 25	
15	SV660N_1	Axis1	H19.75	Target value of position comparison 26	
16	SV660N_1	Axis1	H19.77	Attribute value of position comparison 26	

Function	Description
	Moves down the selected row. Multiple rows can be moved simultaneously.
	Moves up the selected row. Multiple rows can be moved simultaneously.
	Deletes the selected row, and the row below will be shifted up.
	Enables monitoring. • Enabled: The PLC reads and displays the real-time values of the slave parameters.
	Disables monitoring. • Disabled: The PLC does not read real-time values.
Device name	The name of the servo slave in the project; if the name changes, it will automatically synchronize here.
Axis name	The axis number configured internally in the servo, independent of the motion control axis name.
Parameter	Parameter format: H00.00.
Parameter name	Description of the parameter.
Value	Indicates the real-time value of an axis parameter, which can only be monitored, but does not support writing. The refreshing period of the value is 1s. Displays the real-time value when the slave communicates with the PLC normally. If the communication is abnormal, it displays "Device not connected".

17.3.8 Mechanical Characteristic Analysis



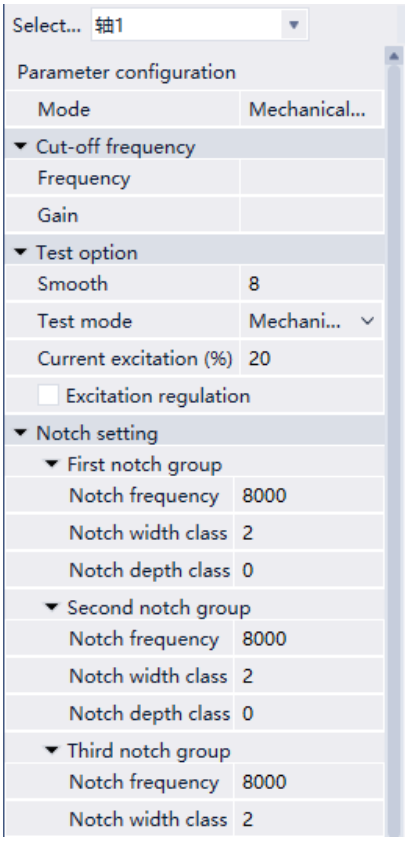
17.3.8.1 Mechanical Characteristics

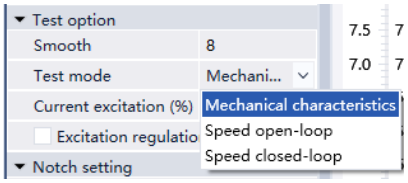
This function determines the mechanical resonance point and system bandwidth. It supports three test modes: mechanical characteristics, speed open loop, and speed closed loop.

Select a servo device in the project tree, and double-click "Mechanical analysis" in the detailed view to open the interface. Select the "Mechanical characteristics" mode, as shown in the figure below.

- **Function interface**

  The mechanical analysis interface consists of three parts: parameter configuration area, Bode diagram display area, and channel/test area.



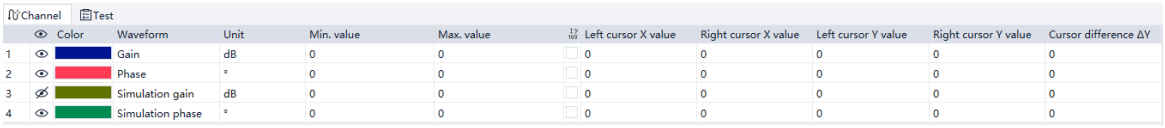


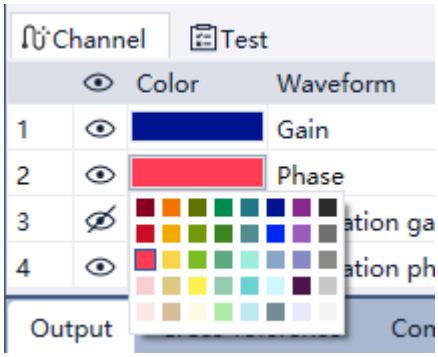
Note: Each servo drive node of the same project has a separate mechanical characteristic analysis view.

- **Basic operating process**

  Configure parameters in the "Parameter configuration" area, click "Start" on the "Test" tab, wait for the test to complete, and view the Bode diagram for analysis.

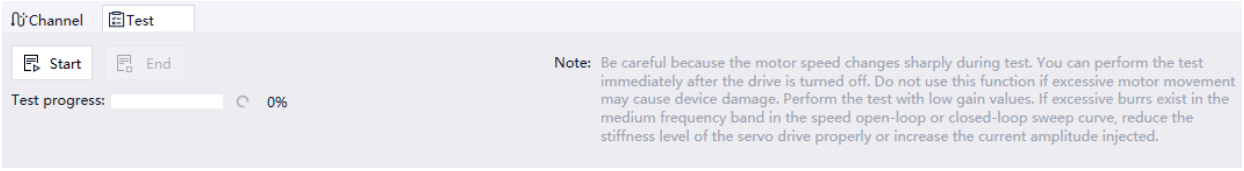
- **Parameter configuration**





Function		Description	Restriction
Selected axis		Selects the axis number required for mechanical characteristic analysis.	/
Mode		Selects "Mechanical characteristics".	/
Cut-off frequency	Frequency	Indicates the cut-off frequency displayed after the mechanical characteristics analysis is done.	Read-only
	Gain	Indicates the gain corresponding to the cut-off frequency displayed after the mechanical characteristics analysis is done.	Read-only
Test option	Smooth	Sets the smoothness of the curve.	Value range: An integer within 0 to 25.
	Test mode	Defines the test mode for mechanical analysis. Options include "Mechanical characteristics", "Speed open-loop", and "Speed closed-loop". 	/
	Current excitation	Sets the current excitation value for mechanical characteristic analysis.	Value range: An integer within 0 to 150.
	Excitation regulation	Enables or disables the excitation regulation for mechanical characteristic analysis.	/

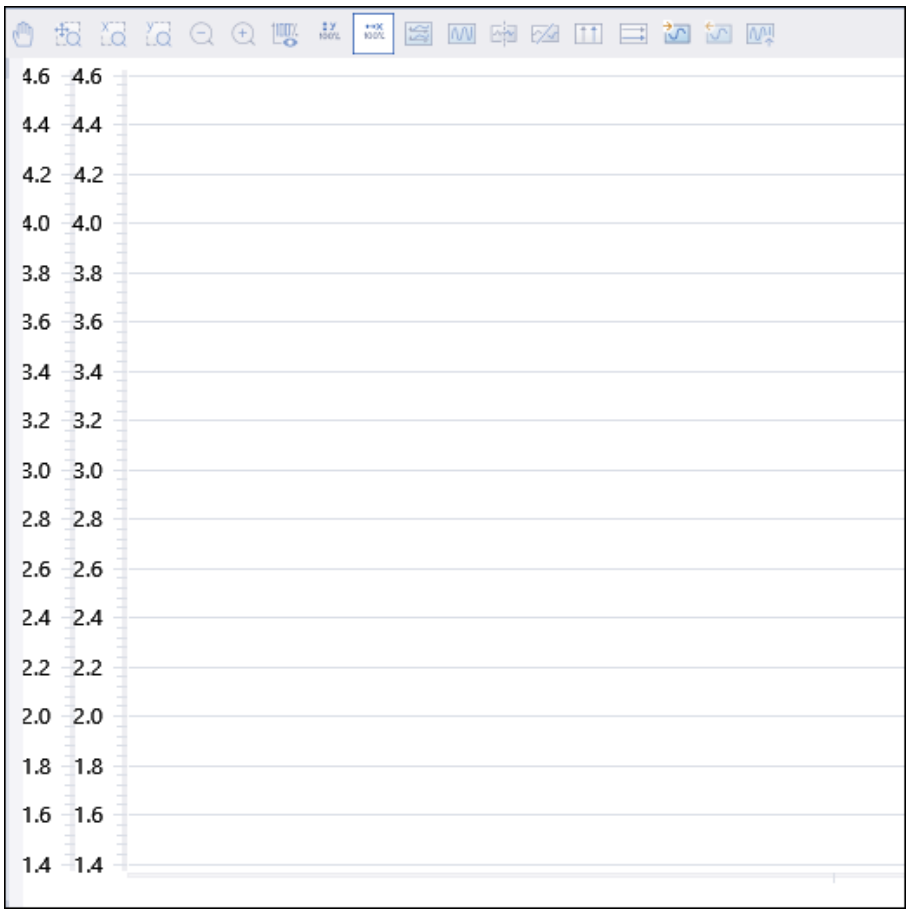
Function		Description	Restriction
Notch setting	Notch parameters	There are parameters of four notch groups, including the notch frequency, width class, and depth class.	• Notch frequency range: 50 to 8000 Hz. • Notch width class range: 0 to 20. • Notch depth class range: 0 to 99. The preceding parameters are all integer values.



- **Channel tab**

The channel tab is used to set the curve display and data display styles in the Bode diagram.

Function	Description	Restriction
Display/hide	Displays or hides the current curve.	/
Color	Sets the color of the channel curve. 	/
Waveform	Displays the variable name of the current channel.	Read-only
Unit	Displays the unit of the current channel.	Read-only
Min. value	Displays the minimum value of the current channel.	Read-only
Max. value	Displays the maximum value of the current channel.	Read-only
Left cursor X/Y value	Displays the X/Y value corresponding to the current channel left cursor.	Read-only
Right cursor X/Y value	Displays the Y value corresponding to the current channel right cursor.	Read-only
Cursor difference ΔY	Displays the difference between the left and right cursor values.	Read-only



- **Test tab**

Function	Description	Restriction
Test mode	Displays the current mode of the drive after the test.	It is not displayed when "Mechanical characteristics" is selected.
Start	Starts the mechanical characteristics analysis and displays the Bode diagram.	/
End	Ends the test.	The button is available during the test and unavailable when the test is not started.
Test progress	Displays the data collection progress of mechanical characteristic analysis.	/
Note	Displays note information during the test.	/

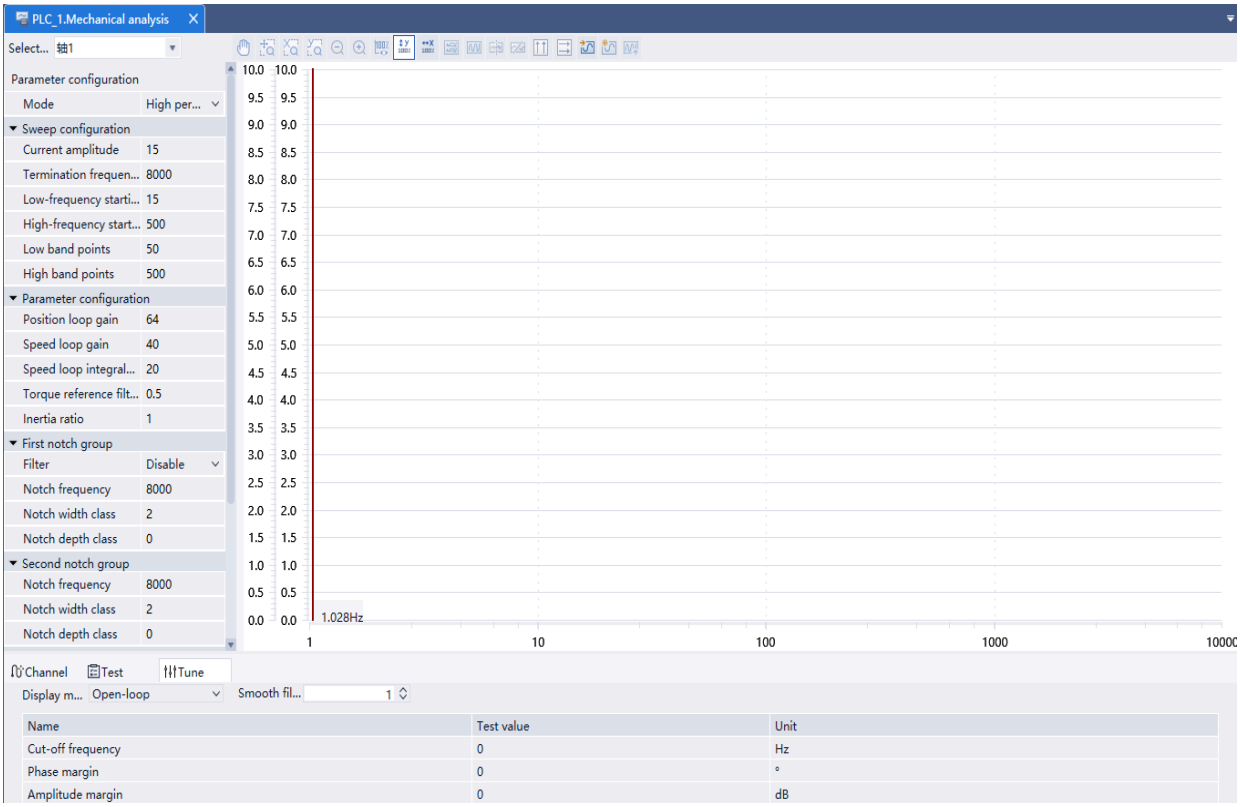
- **Bode diagram**

The test results of mechanical characteristic analysis are displayed as a Bode diagram curve.

The functions of generating analog curve and exporting analog curve data are applicable only to the high-performance auto-tuning. For details, see 17.3.8.2 High-Performance Tuning.

Function		Description	Restriction
	Pan	When it is enabled, you can move and control the view conveniently with the mouse.	• It is mutually exclusive to the zoom function. • It is unavailable when there is no curve.
	Zoom	Zooms in/out the curve in the view. You can select a waveform segment on the X- and Y-axis for observation.	• It is mutually exclusive to the drag function. • It is unavailable when there is no curve.
	Horizontal zoom	Zooms the curve on the X axis.	• It is mutually exclusive to the drag function. • It is unavailable when there is no curve.
	Vertical zoom	Zooms the curve on the Y axis.	• It is mutually exclusive to the drag function. • It is unavailable when there is no curve.
	Zoom -	Zooms out on the entire curve.	It is unavailable when there is no curve.
	Zoom +	Zooms in on the entire curve.	It is unavailable when there is no curve.
	Show all	Displays 100% of the X and Y axes. When this function is enabled, the icons buttons for displaying all on Y-axis and X-axis are selected.	It is unavailable when there is no curve.
	Y-axis auto scale	Displays 100% of only the Y axis.	It is unavailable when there is no curve.
	X-axis auto scale	Displays 100% of only the X axis.	It is unavailable when there is no curve.
	Group display	Displays curves by group.	• This function can only be used when there are four curves. • It is unavailable when there is no curve.

Function		Description	Restriction
	Generate simulation curve	After modifying the configuration parameters for high-performance tuning, click the "Generate simulation curve" icon to generate two simulated curves.	• This is only available after the high-performance auto-tuning test is done. • This button is unavailable in the mechanical characteristic analysis mode.
	Compare waveform	Imports the CSV waveform file, and compares it with the waveform on the current interface.	• This function is only available when a waveform is present on the current interface. • High-performance tuning curves cannot be compared with mechanical characteristic curves. • It is unavailable when there is no curve.
	Cancel comparison	Cancels the waveform comparison and deletes the imported comparison waveform curves.	/
	Vertical cursor	Displays two vertical cursors (left and right); the intersection values of each vertical cursor with the curve can be read in the channel. 	It is unavailable when there is no curve.
	Horizontal cursor	Displays two horizontal cursors (upper and lower); the intersection values of each horizontal cursor with the curve can be read in the channel.	Horizontal cursor measurement is not currently supported.
	Import	Imports the CSV waveform file.	/
	Export	Exports the waveform curve to a CSV file and saves it to the local drive.	It is unavailable when there is no curve.
	Export simulation curve	Exports the simulation curve data to a CSV file and saves it to the local drive.	It cannot be used when there is no simulation curve.



17.3.8.2 High-Performance Tuning

This feature currently supports only certain product series.

In high-performance auto-tuning mode, the characteristic analysis is automatically performed on a servo drive through built-in algorithms to obtain the relative optimal values of related parameters. This function eases the servo drive performance commissioning, precisely suppresses high-frequency resonance, and improves the servo drive stability and responsiveness.

- **Function interface**

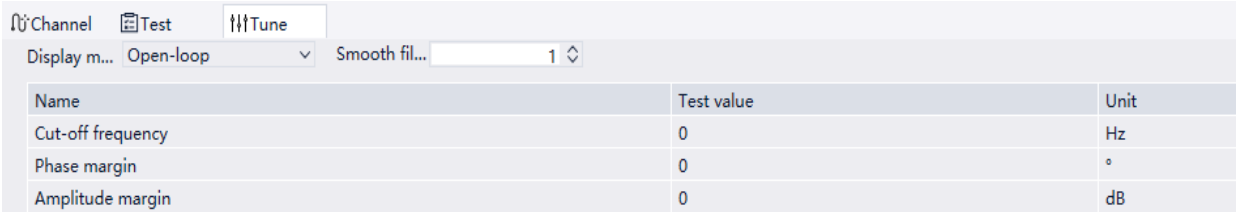
  Select a servo device in the project tree, and double-click "Mechanical analysis" in the detailed view to open the interface. Select the "High performance tuning" mode. The interface consists of three parts: parameter configuration area, Bode diagram display area, and channel/test/tuning tabs, as shown in the following figure.

- **Basic operating process**

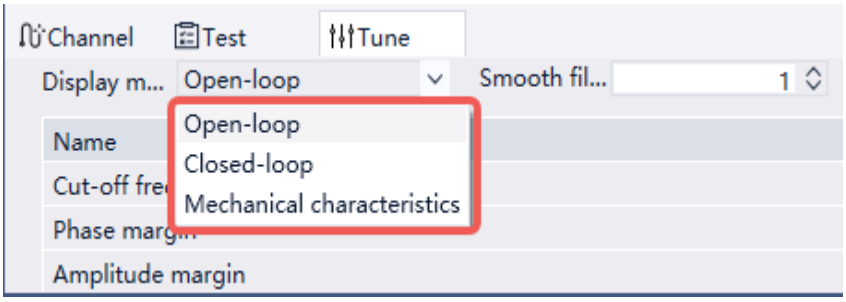
  Configure parameters in the "Parameter configuration" area, and click "Start" on the "Test" tab. Wait for the test to complete, click the "Start" button on the "Tune" tab, and view the Bode diagram for analysis.

- **Parameter configuration**

Function		Description	Restriction
Selected axis		Selects the axis No. to perform high-performance auto-tuning.	/
Mode		Selects "High performance tuning".	/
Sweep configuration	Current amplitude	Defines the current amplitude of the auto-tuned sweep frequency.	• A value with one decimal place • Range: 0.0 to 400.0
	Termination frequency	Sets the stop frequency for tuning.	• Integer • Range: 0 to 8000
	Low-frequency starting frequency	Defines the start frequency of the low-frequency range for auto-tuning.	• Integer • Range: 0 to 8000 • Must be below the high frequency start frequency.



Function		Description	Restriction
	High-frequency starting frequency	Defines the start frequency of the high-frequency range for auto-tuning.	• Integer • Range: 0 to 8000 • Must be above the low frequency start frequency.
	Low band points	Defines the number of sweep frequency points of the low-frequency range for auto-tuning.	• Integer • Range: 0 to 500
	High band points	Defines the number of sweep frequency points of the high-frequency range for auto-tuning.	• Integer • Range: 0 to 1000
Parameter configuration	Position loop gain	Sets the position loop gain.	• A value with one decimal place • Range: 0.1 to 2000.0 Hz
	Speed loop gain	Sets the speed loop gain.	• A value with one decimal place • Range: 0.1 to 2000.0 Hz
	Speed loop integral time	Sets the speed loop integral time.	• A value with two decimal places • Range: 0.15 ms to 512.00 ms
	Torque reference filter time	Defines the torque reference filter time.	• A value with two decimal places • Range: 0.01 ms to 30.00 ms
	Inertia ratio	Sets the inertia ratio.	• A value with two decimal places • Range: 0.00 to 120.00
Notch	Notch parameters	Sets the parameters of the four notch groups. When different filter options are selected for the 1st notch, the configurable parameters of the 1st notch will also be changed. For details, see the following table.	• Notch frequency range: 50 to 8000 Hz. • Notch width class range: 0 to 20. • Notch depth class range: 0 to 99. All three parameters are integers.



Filter	Configurable Parameter	Icon
Disabled	Notch frequency Notch width class Notch depth class	
First-order low-pass	Cut-off frequency	
Second-order low-pass	Cut-off frequency Damping coefficient: A value with three decimal places; range: 0.000 to 10.000.	
Lead-lag	Frequency: An integer; range: 0 to 16000. Gain: A value with one decimal place; range: -336.0 to 336.0.	
Custom	Numerator of cut-off freq.: An integer; range: 0 to 16000. Numerator of damping coef.: A value with three decimal places; range: 0.000 to 10.000. Denom. of cut-off freq.: An integer; range: 0 to 16000. Denom. of damping coef.: A value with three decimal places; range: 0.000 to 10.000.	

- **Channel/Test tab**

  The channel/test tab in the high-performance auto-tuning mode has the same functions as that in the mechanical characteristic analysis mode. For details, see "Mechanical Analysis".

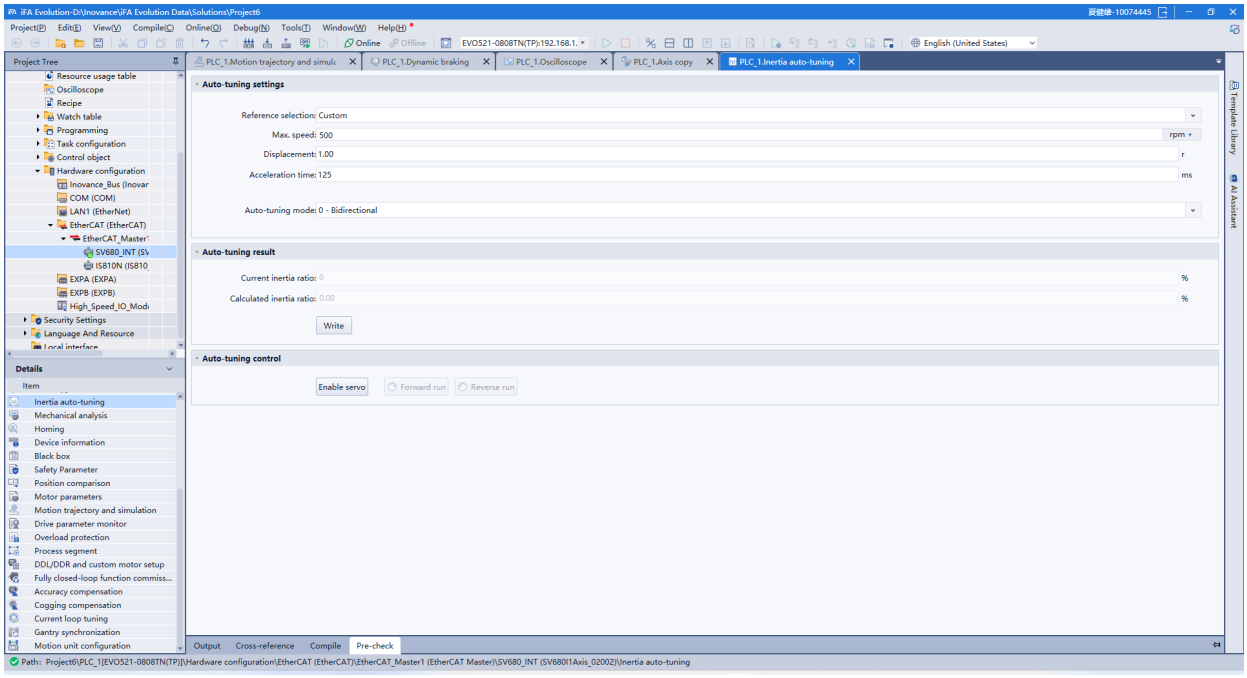
- **Tune tab**

Function	Description
Display mode	The display modes include open-loop, closed-loop, and mechanical characteristics. When you select different display modes, the curve and the parameter list will change accordingly.
Smooth filtering	Defines the smoothness of the curve.
Filter table	Displays the corresponding parameter values after high performance auto-tuning is done.

- **Bode diagram**

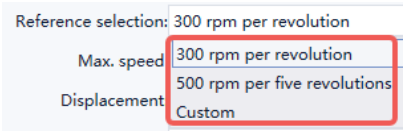
This section only explains the two icons for generating simulation curve and exporting simulation curve. For details on other icons, see "Mechanical Analysis".

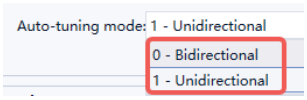
Icon	Function	Description	Restriction
	Generate simulation curve	After modifying the configuration parameters for high-performance tuning, click the "Generate simulation curve" icon to generate two simulated curves.	• This is only available after the high-performance auto-tuning test is done. • This is unavailable in the mechanical characteristic analysis mode.
	Export simulation curve	Exports the simulation curve data to a CSV file and saves it to the local drive.	It cannot be used when there is no simulation curve.



17.3.9 Inertia Auto-Tuning

This function enables automatic parameter settings for the servo drives and is an important part of servo gain auto-tuning. Correct load inertia ratio ensures quick commissioning. The load inertia ratio is an important parameter of the servo system, and its meaning is shown in the following figure.





$$\text{Load inertia ratio} = \frac{\text{Total rotational inertia of mechanical load}}{\text{Motor rotor inertia}}$$

- **Function interface**

  In the project tree, select a servo device and double-click "Inertia auto-tuning" in the detailed view to open the interface. The interface mainly consists of three parts: "Auto-tuning settings", "Auto-tuning result", and "Auto-tuning control", as shown in the figure below.

- **Parameter setting**

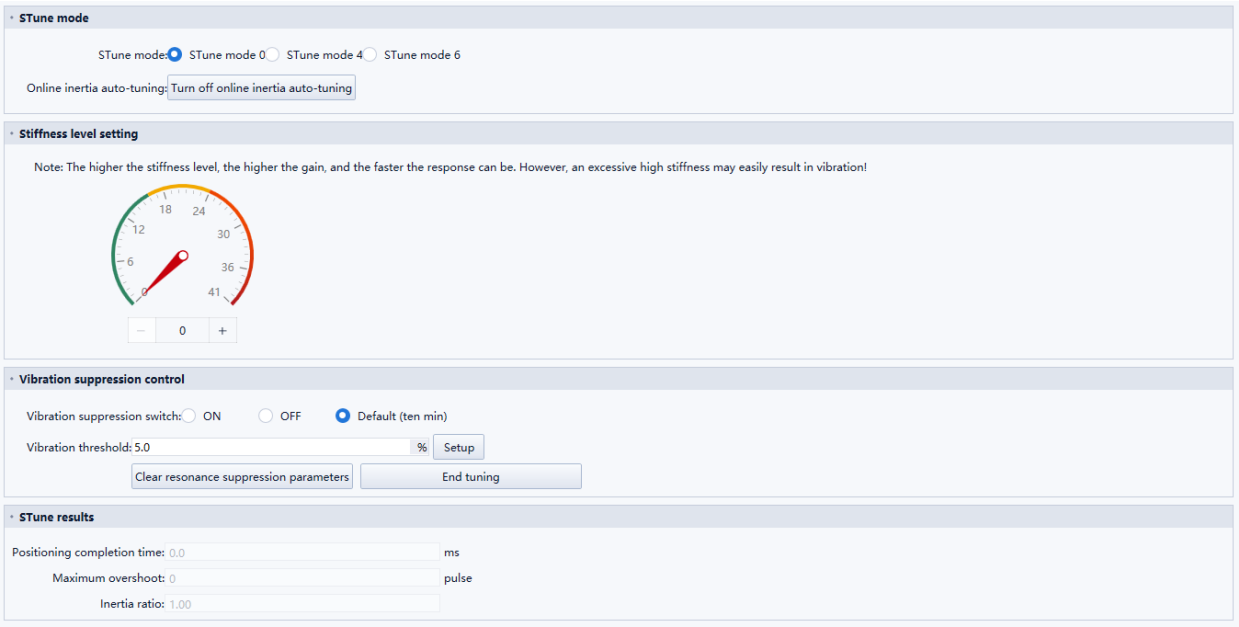
Function	Description
Axis	Selects the axis number of the current device. Restrictions: Unable to configure when the drive is enabled.
Reference selection	Selects a motor reference. Restrictions: Unable to configure when the drive is enabled. 
Maximum velocity	Defines the maximum motor speed. Restrictions: • Editable only when the "Reference selection" is set to "Custom". • Integer; range: 100 to 1000; unit: rpm/min • It will be sent to the drive upon enabling.
Displacement	Defines the motor displacement. Restrictions: • Editable only when the "Reference selection" is set to "Custom". • A value with two decimal places; range: 0.00 to 100.00; unit: r (revolution). • It will be sent to the drive upon enabling.
Acceleration time	Defines the time for accelerating to the maximum speed. Restrictions: • It will be sent to the drive upon enabling. • Integer; range: 20 to 800; unit: ms • It cannot be edited after enabling.
Auto-tuning mode	Selects the inertia auto-tuning mode. Restrictions: • Unable to configure when the drive is enabled. • It will be sent to the drive upon enabling. 

- **Auto-tuning results**

Function	Description
Current inertia ratio	Displays the inertia ratio before presumption, which cannot be edited.
Calculated inertia ratio	Displays the presumed inertia ratio, which cannot be edited.
Write	Downloads the presumed inertia ratio to the drive. Download cannot be performed after enabling.

- **Auto-tuning control**

Function	Description
Enable servo	Enables/disables the drive.
Forward run	Controls the forward rotation of the motor. You can long press the button or click it once. Restrictions: It is available when the drive is enabled, and disabled after the drive is disabled.
Reverse Rotation	Controls the reverse rotation of the motor. You can long press the button or click it once. Restrictions: It is available when the drive is enabled, and disabled after the drive is disabled.



17.3.10 STune Adjustment

STune allows the servo drive to perform automatic parameter auto-tuning based on rigidity level settings for fast and stable gain adjustment.

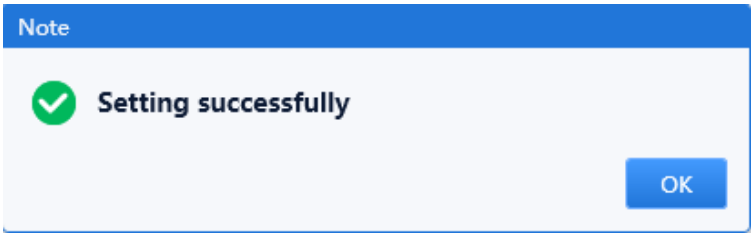
It is applicable to scenarios with small load inertia change and does not support torque control.

- **Function interface**

  Select a servo drive in the project tree, then double-click "STune" in the detailed view to open the interface, as shown in the figure below.

- **ETune mode**
  - STune mode

> **NOTE**
>
> - In STune mode 0, you need to set the inertia ratio before adjusting the stiffness. For unknown inertia, perform inertia tuning manually. If vibration occurs on the machine, decrease the stiffness level before manual inertia tuning. In modes 4 and 6, the inertia ratio can be adjusted through the wizard-type interface, without the need for setting an inertia ratio.
> - Adjust the stiffness level gradually during load operation. The present stiffness level will be written to the drive automatically. Keep monitoring the operating waveform after increasing the stiffness level (increase by one level at a time) until desired performance is achieved.
> - The mode takes effect automatically after you select it.



Mode	Name	Description
STune mode 0	Manual mode + Inertia auto-tuning	The gains need to be adjusted manually.
STune mode 4	Normal mode + Inertia auto-tuning	Automatic gain setting, inertia auto-tuning and vibration suppression based on the set stiffness.
STune mode 6	Quick positioning mode + Inertia auto-tuning	Automatic gain setting, inertia auto-tuning and vibration suppression based on the set stiffness. This mode is applicable to occasions requiring quick positioning.

  - Online inertia auto-tuning: Used to disable online inertia auto-tuning.

- **Stiffness level setting**

Description	Description
Diagram	Graphically displays the set stiffness level.
+	Increments the stiffness level. Restrictions: Click once to increase the stiffness level by 1, and long press is ineffective.
-	Decrements the stiffness level Restrictions: Click once to decrease the stiffness level by 1, and long press is ineffective.
Stiffness level	Displays the set stiffness level. Restrictions: Non-editable; range: 0 to 41.

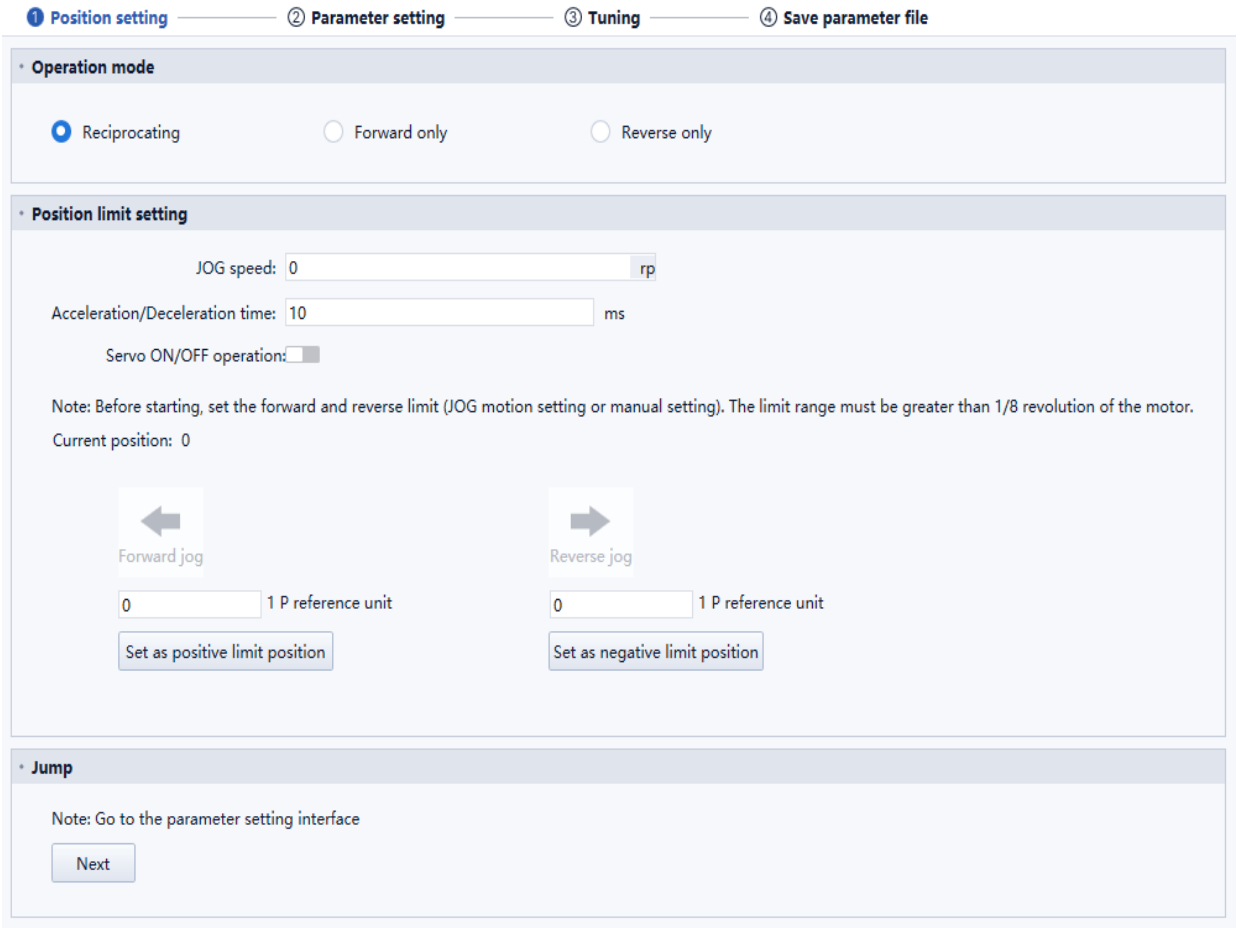
- **Vibration suppression control**

Description	Description
Vibration suppression switch	Enables or disables the vibration suppression function. Options: ON, OFF, and default (10 minutes)
Vibration threshold	• Defines the percentage of the vibration threshold. Range: 0% to 100%. Default is 5.0%. • Write the input vibration threshold into the servo drive via the "Setup" button. If the setting is successful, the following dialog box appears: 
Clear resonance suppression parameters	Clears the resonance suppression parameters.
End tuning	Switches to STune mode 0.

- **STune results**

Description	Description
Positioning completion time	Displays the positioning completion time in real time. It cannot be edited.
Maximum overshoot	Displays the maximum overshoot in real time. It cannot be edited.

Description	Description
Inertia ratio	Displays the inertia ratio in real time. It cannot be edited.



17.3.11 ETune Guided Auto-Tuning

17.3.11.1 Overview

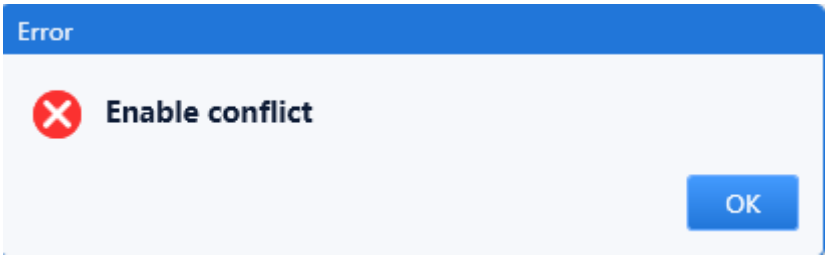
ETune is a wizard-type auto-tuning function used to guide users to set corresponding curve trajectories and response parameters. After settings, the servo drive performs auto-tuning to generate the optimal gain parameters. The auto-tuned parameters can be saved and exported as a recipe for use in other devices of the same model. The ETune function is intended to be used in applications featuring small load inertia changes.

17.3.11.2 Position Settings

Select a servo device in the project tree, and double-click "ETune" in the detailed view to open the interface, as shown in the figure below.

Description of marks at the top of the interface

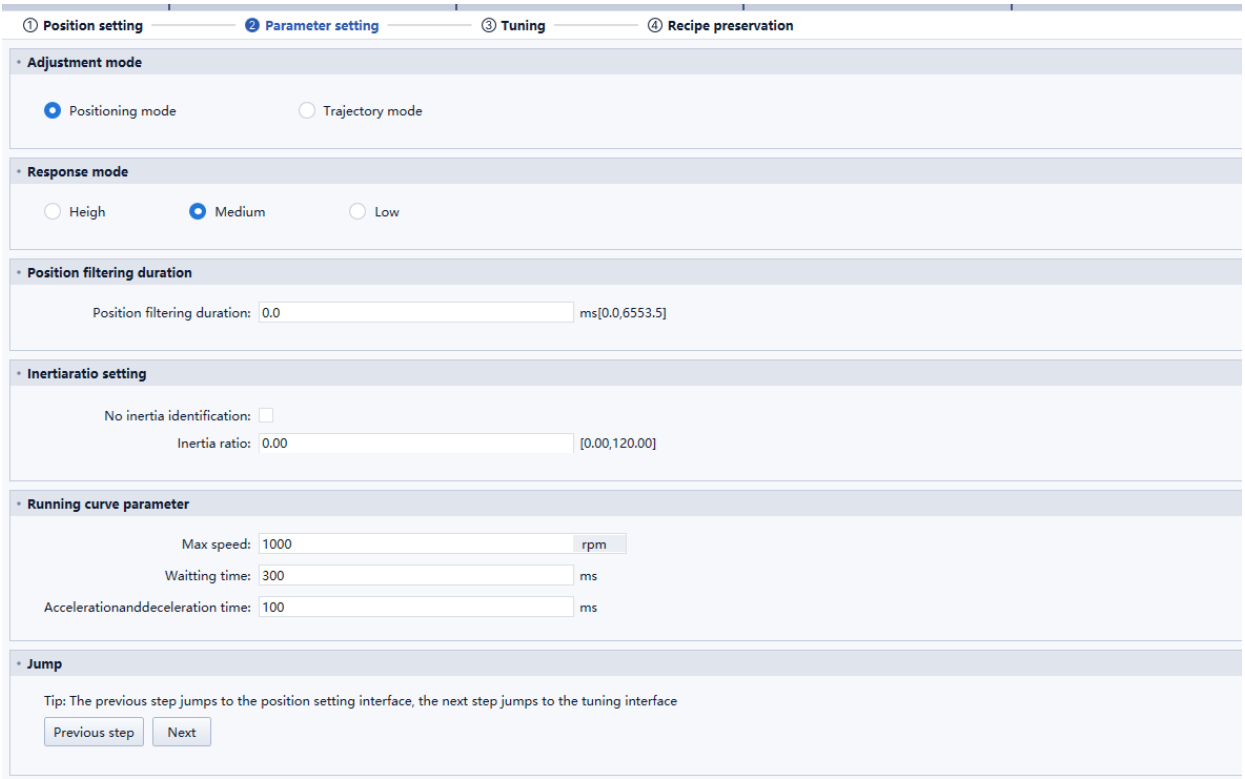
Mark	Description
	Set for the first time.
	Not set.
	Setting failed.
	Setting succeeded.
	Setting is ongoing, and the previous setting failed.
	Setting is ongoing, and the previous setting succeeded.



Function

Function	Sub-Function	Description
Run mode	Reciprocating	The motor reciprocates between positive and negative limit positions.
	Forward only	The motor takes the difference between the positive and negative position limits as the maximum distance per action and keeps running in the forward direction.
	Reverse only	The motor takes the difference between the positive and negative position limits as the maximum distance per action and keeps running in the reverse direction.
Position limit setting	JOG speed	Defines the jog speed. Range: 0 to 1000; unit: rpm
	Acceleration/ Deceleration time	Defines the acceleration/deceleration time during jog. Range: 0 to 65535; unit: ms
	Servo ON/OFF operation	Enables or disables the servo drive. It is displayed according to the enabling status of the servo drive.

Function	Sub-Function	Description
	Current position	Displays the actual feedback position of the motor.
	Forward jog	Controls the forward jog of the servo drive. Click or long press to start.
	Positive limit position (1 P reference unit)	Displays the positive limit position, which can be directly edited, or set by clicking the "Set as positive limit position" button. Restrictions: • Range: -2147483647 to 2147483647 • The positive limit position cannot be smaller than the negative limit position. • The positive limit position cannot be smaller than the current position. • The difference between the positive and negative limits cannot be smaller than 1/8 revolution of the motor (that is, 1/8 of the motor limit threshold).
	Set as positive limit position	Sets the current position to the positive limit position, which is the value of the previous electronic gear ratio. Click this button to set the current position to the input box of the positive limit position.
	Reverse jog	Controls the reverse jog of the servo drive. Click or long press to start.
	Negative limit position (1 P reference unit)	Displays the negative limit position, which can be directly edited, or set by clicking the "Set as negative limit position" button. Restrictions: • Range: -2147483647 to +2147483647 • The negative limit position cannot be greater than the positive limit position. • The negative limit position cannot be greater than the current position. • The difference between the positive and negative limits cannot be smaller than 1/8 revolution of the motor (that is, 1/8 of the motor limit threshold).
	Set as negative limit position	Sets the current position to the negative limit position, which is the value of the previous electronic gear ratio. Click this button to set the current position to the input box of the negative limit position.
Jump	Next	Jumps to the "Parameter setting" interface and writes all the currently configured parameters to the drive.



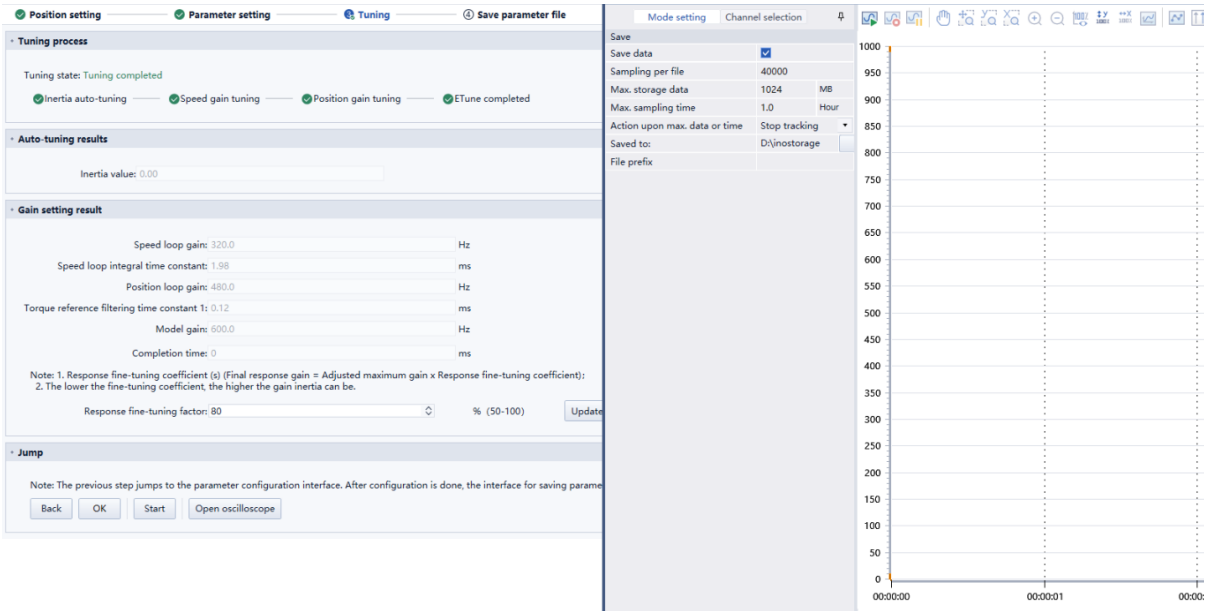
CAUTION

The enable operation in ETune and the servo enable operation in JOG control cannot be executed simultaneously; otherwise, an enable conflict will be prompted.

17.3.11.3 Parameter Settings

The parameter setting interface is shown in the following figure. See the following table for descriptions of functions and parameters.

Description		Description
ETune mode		Selects "Positioning mode" or "Trajectory mode".
Response mode		Selects the response mode from "High", "Medium", and "Low".
Position filtering time constant		Defines the position filter time constant. A value with one decimal place; range: 0.0 to 6553.5; unit: ms
Inertia ratio setting	No inertia auto-tuning	Sets whether inertia ratio is auto-tuned. Inertia auto-tuning is performed by default. Restrictions: When it is enabled, the "Inertia ratio" input box cannot be edited.



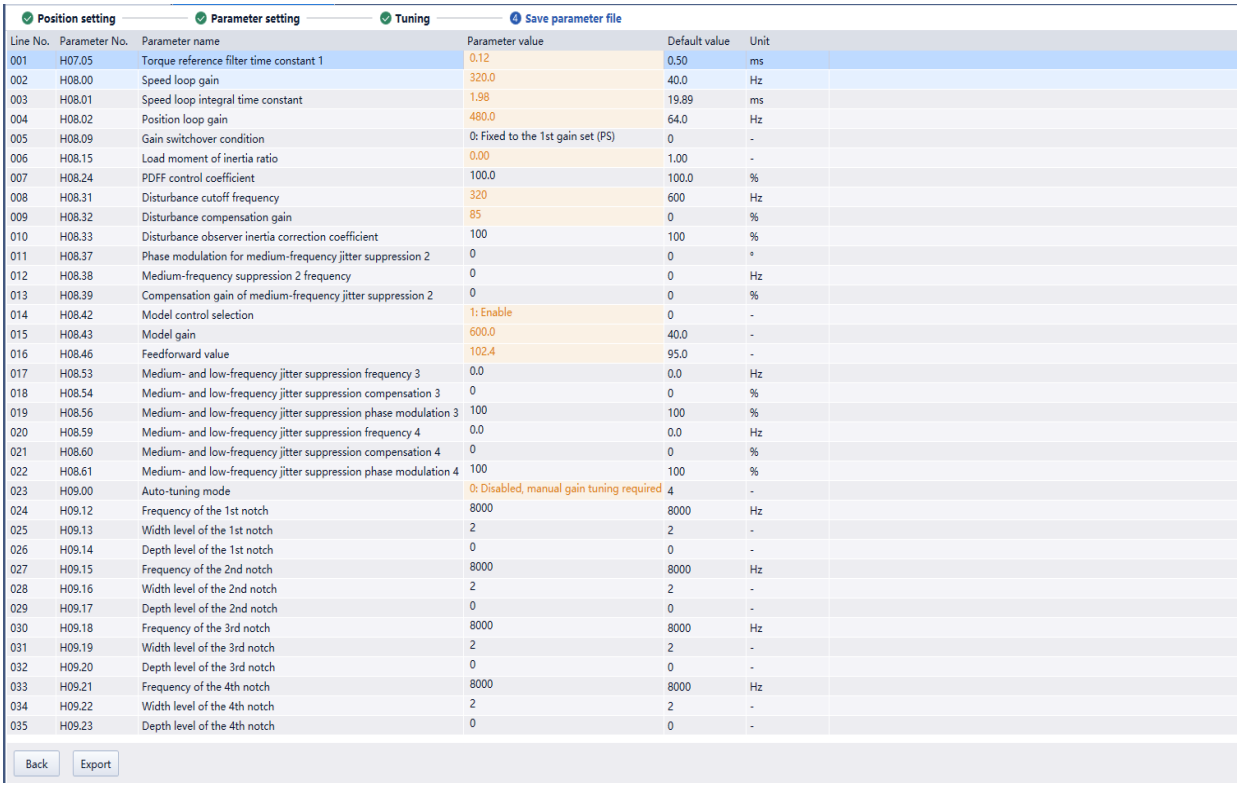
Description		Description
	Inertia ratio	Defines the inertia ratio. A value with two decimal places; range: 0.00 to 120.00
Motion curve parameter	Maximum speed	Defines the maximum auto-tuned speed. Integer; range: 0 to 1000; unit: rpm Restrictions: The maximum motor speed cannot be exceeded.
	Waiting time	Defines the waiting time between two operations. Integer; range: 0 to 65535; unit: ms
	Acceleration/ Deceleration time	Defines the maximum auto-tuned acceleration/deceleration time. Integer; range: 0 to 65535; unit: ms
Jump	Back	Jumps to the "Position setting" tab.
	Next	Jumps to the "Tuning" tab and writes the parameters set in this tab to the drive.

17.3.11.4 Tuning

If inertia auto-tuning is enabled (by default) in the "Parameter setting" tab, the following is displayed under the "Tuning state": ① Inertia auto-tuning, ② Speed gain tuning, ③ Position gain tuning, and ④ ETune completed. After auto-tuning is started, inertia auto-tuning is performed based on the set curve. After auto-tuning is done, the drive automatically enters the gain tuning stage.

If inertia auto-tuning is disabled in the "Parameter setting" tab, the following is displayed under the "Tuning state": ① Speed gain tuning, ② Position gain tuning, and ③ ETune completed. Gain is auto-tuned directly after auto-tuning is started.

The "Tuning" tab is shown in the following figure. See the following table for descriptions of functions and parameters.



During gain auto-tuning, if you modify "Response fine-tuning coefficient" and click "Update", gain auto-tuning will be continued based on the set fine-tuning coefficient. After gain auto-tuning is done, click "OK" to save the parameters to EEPROM and export the parameters as a recipe file.

Function		Description
Tuning process	Tuning state	The number before each status is marked by different colors. • Blue indicates an ongoing process is going on. • No color indicates a process that has not been performed. • Green indicates a completed process with correct content • Red indicates a completed process with incorrect content If inertia auto-tuning is enabled (by default) in the "Parameter setting" tab, the following is displayed under the "Tuning state": ① Inertia auto-tuning, ② Speed gain tuning, ③ Position gain tuning, and ④ ETune completed. After auto-tuning is started, inertia auto-tuning is performed based on the set curve. After auto-tuning is done, the drive automatically enters the gain tuning stage. If inertia auto-tuning is disabled in the "Parameter setting" tab, the following is displayed under the "Tuning state": ① Speed gain tuning, ② Position gain tuning, and ③ ETune completed. Gain is auto-tuned directly after auto-tuning is started.
Auto-tuning results	Inertia value	Displays the inertia value after inertia auto-tuning. It cannot be edited.
Gain setting result	Speed loop gain	Displays the speed loop gain value after auto-gain. It cannot be edited.
	Speed loop integral time constant	Displays the speed loop integral time constant after auto-gain. It cannot be edited.
	Position loop gain	Displays the position loop gain value after auto-gain. It cannot be edited.
	Torque reference filtering time constant 1	Displays the torque reference filter time constant 1 after auto-gain. It cannot be edited.
	Model gain	Displays the model gain value after auto-gain. It cannot be edited.
	Completion Time	Displays the completion time after auto-gain. It cannot be edited.
	Response fine-tuning factor	Defines the response fine-tuning factor. Range: 50% to 100%
	Update	Writes the response fine-tuning coefficient to the servo drive.

Function		Description
Jump	Back	Jumps to the "Parameter setting" tab. If "Back" is clicked during auto-tuning, a dialog box will appear asking you whether to go back. If you confirm to go back, auto-tuning will be terminated. If "Back" is clicked without auto-tuning in progress, the system will directly go back to the previous step.
	Completion	After auto-tuning is completed, a dialog box will appear indicating that gain auto-tuning is completed. Clicking "OK" will jump to the "Save parameter file" interface and save the parameters to EEPROM. Restrictions: The "OK" button is unavailable before auto-tuning is done.
	Start/Stop	Starts or stops auto-tuning. Clicking "Stop" will stop auto-tuning, and restore the related recipe parameters to the status before auto-tuning.

17.3.11.5 Recipe Storage

After auto-tuning is done, the related parameters will be displayed in a list and exported as a recipe file for future reuse. The recipe storage interface is shown in the following figure. See the following table for descriptions of functions and parameters.

Line No.	Parameter No.	Parameter name	Parameter value	Default value	Unit
001	H07.05	Torque reference filter time constant 1	0.12	0.50	ms
002	H08.00	Speed loop gain	320.0	40.0	Hz
003	H08.01	Speed loop integral time constant	1.98	19.89	ms
004	H08.02	Position loop gain	480.0	64.0	Hz
005	H08.09	Gain switchover condition	0: Fixed to the 1st gain set (PS)	0	-
006	H08.15	Load moment of inertia ratio	0.00	1.00	-
007	H08.24	PDFF control coefficient	100.0	100.0	%
008	H08.31	Disturbance cutoff frequency	320	600	Hz
009	H08.32	Disturbance compensation gain	85	0	%
010	H08.33	Disturbance observer inertia correction coefficient	100	100	%
011	H08.37	Phase modulation for medium-frequency jitter suppression 2	0	0	°
012	H08.38	Medium-frequency suppression 2 frequency	0	0	Hz
013	H08.39	Compensation gain of medium-frequency jitter suppression 2	0	0	%
014	H08.42	Model control selection	1: Enable	0	-
015	H08.43	Model gain	600.0	40.0	-
016	H08.46	Feedforward value	102.4	95.0	-
017	H08.53	Medium- and low-frequency jitter suppression frequency 3	0.0	0.0	Hz
018	H08.54	Medium- and low-frequency jitter suppression compensation 3	0	0	%
019	H08.56	Medium- and low-frequency jitter suppression phase modulation 3	100	100	%
020	H08.59	Medium- and low-frequency jitter suppression frequency 4	0.0	0.0	Hz
021	H08.60	Medium- and low-frequency jitter suppression compensation 4	0	0	%
022	H08.61	Medium- and low-frequency jitter suppression phase modulation 4	100	100	%
023	H09.00	Auto-tuning mode	0: Disabled, manual gain tuning required	4	-
024	H09.12	Frequency of the 1st notch	8000	8000	Hz
025	H09.13	Width level of the 1st notch	2	2	-
026	H09.14	Depth level of the 1st notch	0	0	-
027	H09.15	Frequency of the 2nd notch	8000	8000	Hz
028	H09.16	Width level of the 2nd notch	2	2	-
029	H09.17	Depth level of the 2nd notch	0	0	-
030	H09.18	Frequency of the 3rd notch	8000	8000	Hz
031	H09.19	Width level of the 3rd notch	2	2	-
032	H09.20	Depth level of the 3rd notch	0	0	-
033	H09.21	Frequency of the 4th notch	8000	8000	Hz
034	H09.22	Width level of the 4th notch	2	2	-
035	H09.23	Depth level of the 4th notch	0	0	-

Function	Description
Parameter list	Displays information about the parameters. • The parameters are displayed according to the actual status of the servo drive. • If the parameter value is inconsistent with the default value, it will be highlighted. • The value of the offline parameter is highlighted in red.
Export	Exports the auto-tuning result to a recipe file in the CSV or DAT format for future use.
Back	Jumps to the "Tuning" tab.

17.3.12 Homing

This feature is currently not supported for certain product series.

The homing function is used to search for the mechanical home and determine the position relation between the mechanical home and mechanical zero.

- Mechanical home: A fixed position on the machine, which corresponds to a certain home switch or the motor Z signal.
- Mechanical zero: Absolute zero point on the machine. After homing is completed, the motor stops at the mechanical home. The relationship between the mechanical home and the mechanical zero can be set via 607Ch (Home offset): Mechanical home= Mechanical zero + Home offset (0x607C). When the offset is 0, the mechanical home is the same as the mechanical zero.

- **Function interface**

  Select a servo drive in the project tree, and double-click "Homing" in the detailed view to open the interface, as shown in the figure below.

- **Homing curve configuration**

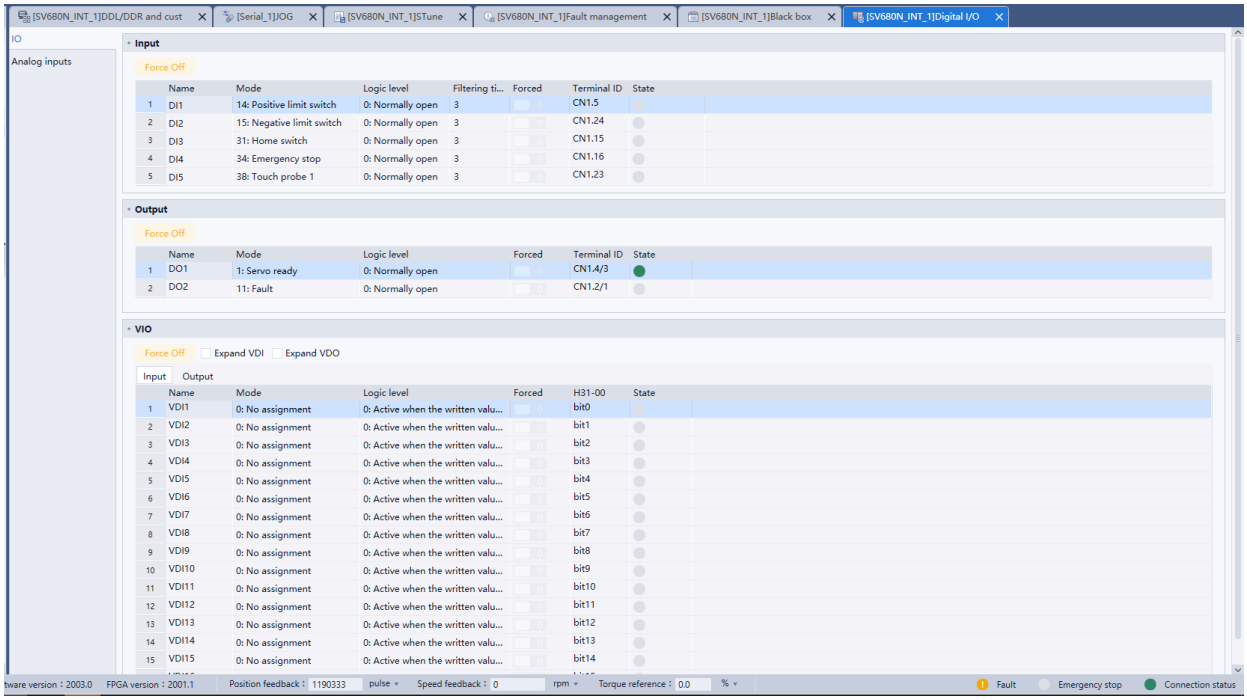
Description	Description
Homing method	Sets the homing method for the servo home. The homing curve diagram corresponding to the selected homing method will be displayed on the right, and other parameters and their settings will also change.
Home signal	Sets the home signal. Corresponding settings will be displayed based on the selected homing method, and the corresponding homing curve diagram will be shown according to the different settings.

Description	Description
Starting direction	Sets the direction for starting the homing process. Corresponding settings will be displayed based on the selected homing method, and the corresponding homing curve diagram will be shown according to the different settings.
Motor action upon positive limit input	Sets the motor action when the positive limit input is triggered. Corresponding settings will be displayed based on the selected homing method, and the corresponding homing curve diagram will be shown according to the different settings.
Motor action upon negative limit input	Sets the motor action when the negative limit input is triggered. Corresponding settings will be displayed based on the selected homing method, and the corresponding homing curve diagram will be shown according to the different settings.
Motor stop position	Sets the position where the motor stops. Corresponding settings will be displayed based on the selected homing method, and the corresponding homing curve diagram will be shown according to the different settings.
Homing curve	Displays curve diagrams for various homing modes. When parameters in the homing curve configuration are changed, the homing curve interface will synchronously display the corresponding curve diagram.

- **Homing parameter configuration**

Description	Description
Speed in high-speed search for dec. home	Sets the speed in high-speed search for deceleration home.
Speed in low-speed search for dec. home	Sets the speed in low-speed search for deceleration home.
Homing time limit	Sets the time limit for home searching.
Homing acceleration time	Sets the homing acceleration time.

Description	Description
Home offset	Sets the home offset.
Mechanical home offset setting	Selects whether the mechanical home offset is the coordinate after homing or the relative offset after homing. The two modes cannot be selected simultaneously.



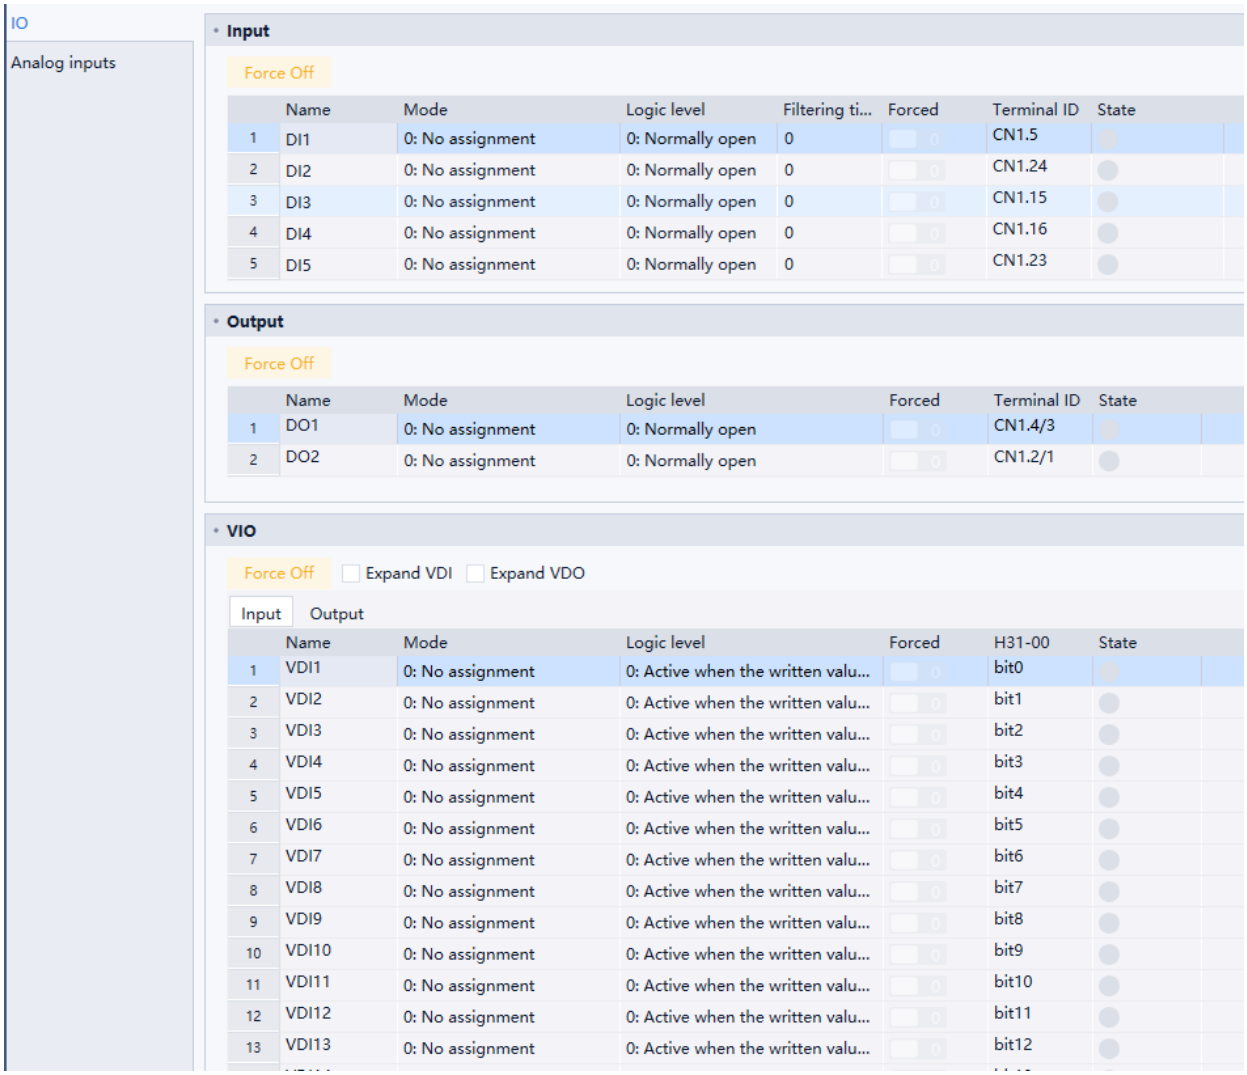
17.3.13 Digital I/O Settings

Digital I/O is used to set and monitor DI and DO functions, as well as virtual I/O functions.

17.3.13.1 I/O Settings and Monitoring

This function monitors and sets the DI/DO function and level polarity of the servo drive, and forcibly switches on or off the DI/DO status.

Select a servo drive in the project tree, and double-click "Digital I/O" in the detailed view to open the interface, as shown in the following figure. See the following table for the description of all functions and parameters.



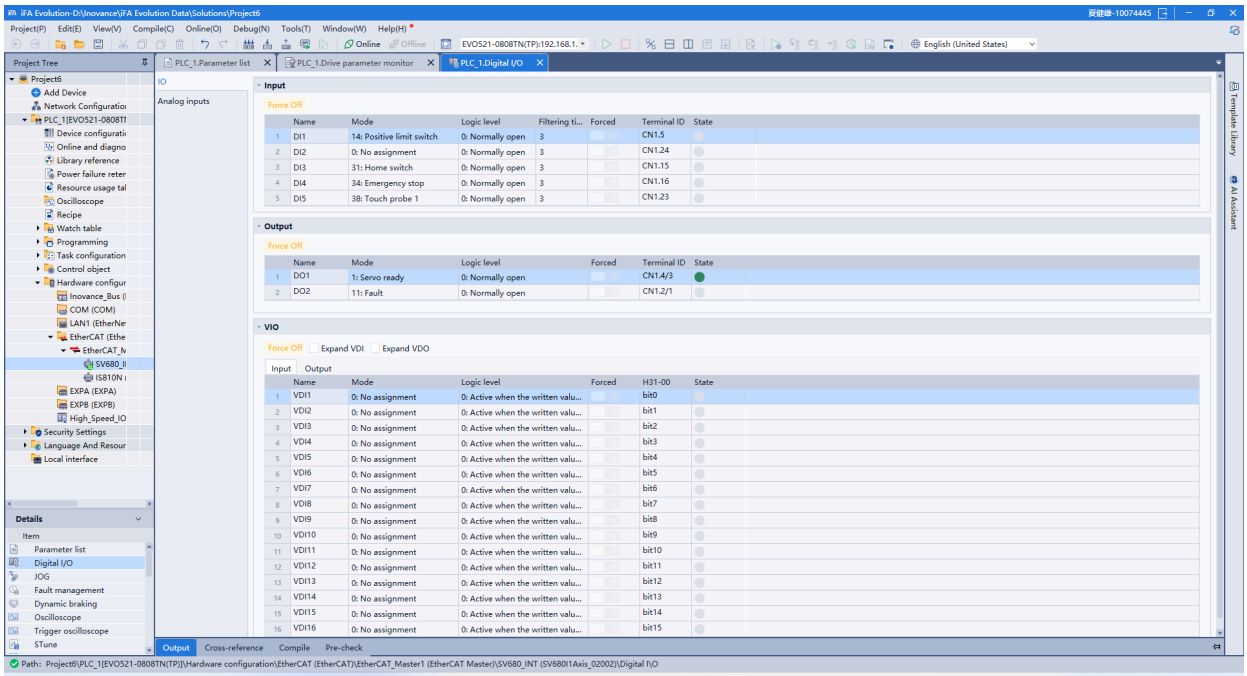
Description	Description
Name	I/O name and actual physical connector pin. It is displayed according to the pins and functions of the servo drive, and cannot be edited.

Description	Description
Mode	Mode setting and monitoring of the I/O terminal. Values can be switched through the drop-down list. The value is updated in real time according to the actual status of the servo drive.
Logic level	Level logic setting and monitoring of the I/O terminal. Values can be switched through the drop-down list. The value is updated in real time according to the actual status of the servo drive.
Filtering time (ms)	Filtering time of the DI terminal. The value is updated in real time according to the actual status of the servo drive and cannot be edited.
Forced	Used to forcibly change the current status of the I/O terminal. It can be set only when "Force on" is displayed. If the I/O interface is closed, the forced enable switch in the current interface will also be turned off.
Terminal ID	Connection sign of the I/O terminal, which cannot be edited.
Status	Used to monitor the actual status of the I/O terminal. The value is updated in real time according to the actual status of the servo drive. It can be manually set only when "Force on" is displayed.
Force off/Force on	Used to enable and disable the forced I/O enable function. The forced input function and the forced output function are mutually exclusive and cannot be enabled simultaneously.

17.3.13.2 Virtual I/O Settings and Monitoring

This function is used to monitor and set the virtual I/O function and logic level of the servo drive, and forcibly turn on or off the real-time VDI status. The forced function of the VDO is currently not supported.

The virtual I/O interface is shown in the following figure. See the following table for descriptions of functions and parameters.

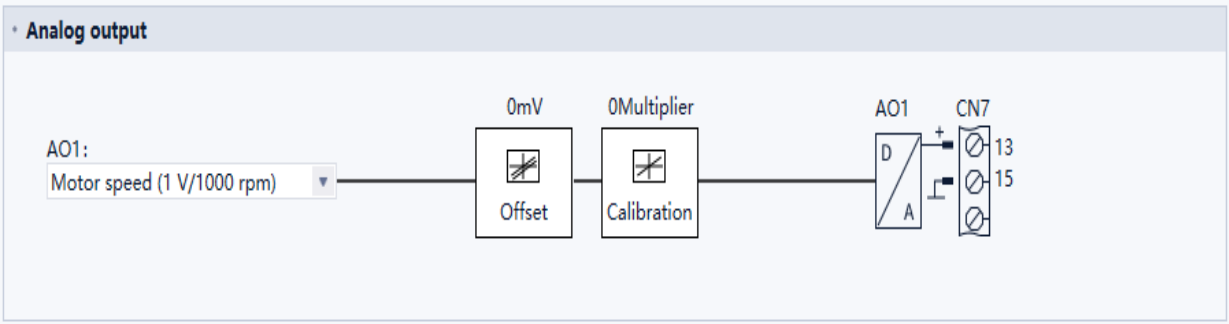


Description	Description
Expand VDI/VDO	Used to enable/disable the input/output communication function of the virtual I/O. Only specific servo drives have virtual I/O functions.
Force off/Force on	Used to enable and disable the forced virtual I/O enable function. Displays the current status of the forced virtual I/O enable function. This button is not displayed in the "Output" tab as the VDO does not support the forced enable function.
Name	Virtual I/O name and actual physical connector pin. It is displayed according to the pins and functions of the servo drive, and cannot be edited.
Mode	Mode setting and monitoring of the virtual I/O terminal. Values can be switched through the drop-down list. The value is updated in real time according to the actual status of the servo drive.

Description	Description
Logic level	Level logic setting and monitoring of the virtual I/O terminal. Values can be switched through the drop-down list. The value is updated in real time according to the actual status of the servo drive.
Forced	Used to forcibly change the current status of the virtual I/O terminal. It can be set only when "Force on" is displayed.
H31-00	Bit 0 to bit 15 of H31.00 represent VDI1 to VDI16, which cannot be edited.
State	Used to monitor the actual status of the virtual I/O terminal. The value is updated in real time according to the actual status of the servo drive. It can be manually set only when "Force on" is displayed.

17.3.13.3 Analog Input Settings

The AI function interface is shown in the following figure. See the following table for descriptions of functions and parameters.



Function	Description
Input mode	Sets the input mode to "Speed mode" or "Torque mode".
Offset	Click "Offset" in the diagram and set the offset value in the pop-up window. Range: -5000 to 5000; unit: mV

Function	Description
Calibration	Click "Calibration" in the diagram and set the calibration value in the pop-up window. • Range in speed mode: 0 to 10000; unit: rpm • Range in torque mode: 0.00 to 8.00; unit: times
Dead zone	Click "Dead zone" in the diagram and set the dead zone value in the pop-up window. Range: 0.0 to 1000.0; unit: mV
Filter	Click "Filter" in the diagram and set the filter value in the pop-up window. Range: 0.00 to 655.35; unit: ms
Zero drift calibration	Click "Zero drift calibration" in the diagram to correct the zero drift.

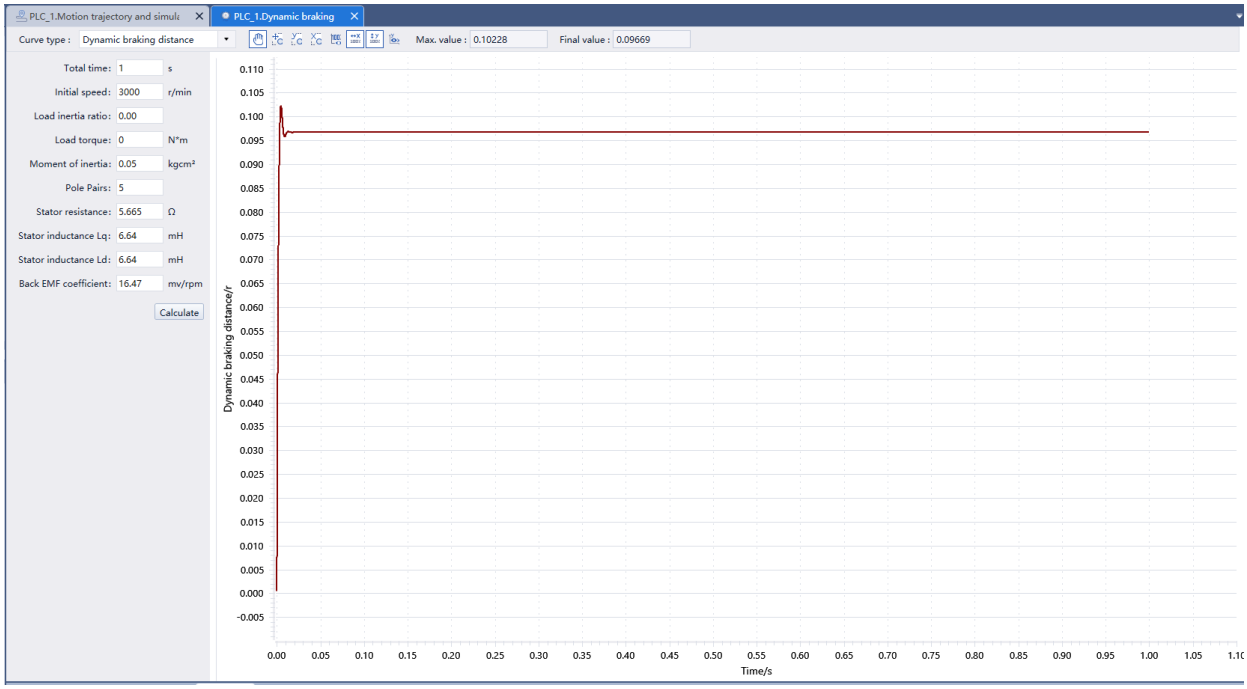
17.3.13.4 Analog Output Settings

Models supporting analog output function: analog SV670N, SV680N, SV680P-INT, SV680N_INT, SV680N_1G, SV680LN, SV670P-INT, SV670N_INT, SV670N_1Axis_05002_LK.

The AO function interface is shown in the following figure. See the following table for descriptions of functions and parameters.

Function	Description
Signal selection	Sets the mode of the output signal.
Offset	Click "Offset" in the diagram and set the offset value in the pop-up window. Range: -10000 to 10000; unit: mV
Calibration	Click "Calibration" in the diagram and set the calibration value in the pop-up window. Range: -99.99 to 99.99; unit: times

17.3.14 Dynamic Braking Calculation



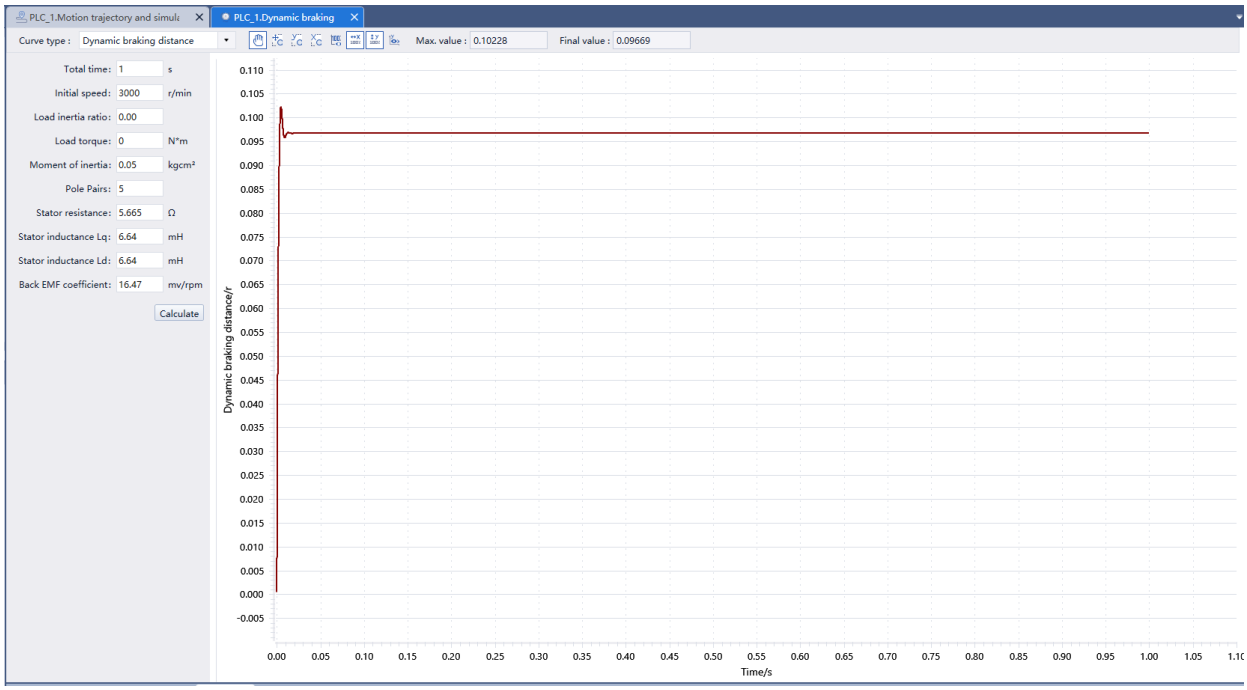
This function is not available for IS810N series products.

This function assesses and analyzes the performance of the dynamic braking system through calculation and simulation. It can be used to determine the correctness of dynamic braking parameters and the system design, and optimize the control policy. Accurate dynamic braking distance can be automatically measured by setting related parameters.

- **Parameter configuration**

  Select a servo device in the project tree, and double-click "Dynamic braking" in the detailed view to open the interface. After configuring the related parameters, click the "Calculate" button to generate the corresponding curve, as shown in the figure below. Refer to the table below for descriptions of each function and parameter.

  When the servo is online, the dynamic braking measurement function reads the corresponding parameters from the servo. If the servo is offline, the function uses automatically filled default parameters.



Function	Description
Total time	Defines the total time. The default value when the servo drive is not online is 1. Range: 0 to 100; unit: s
Initial speed	Defines the initial speed. The default value when the servo drive is not online is 3000. Range: -1000000.00 to 1000000.00; unit: r/min

Function	Description
Load inertia ratio	Defines the load moment of inertia ratio. If the servo drive is online, the parameter in the servo drive is read. The default value when the servo drive is not online is 20. Range: 0.00 to 120.00.
Load torque	Defines the load torque. The default value when the servo drive is not online is 0. Range: -1000000.00 to 1000000.00; unit: N*m
Moment of inertia	Defines the motor moment of inertia. If the servo drive is online, the parameter in the servo drive is read. The default value is 0.01 when the servo drive is not online. Range: 0.01 to 655.35, unit: $kgcm^2$.
Pole pairs	Defines the number of PMSM pole pairs. If the servo drive is online, the parameter in the servo drive is read. The default value when the servo drive is not online is 2. Range: 2 to 65535.
Stator resistance	Defines the stator resistance. If the servo drive is online, the parameter in the servo drive is read. The default value when the servo drive is not online is 0.001. Range: 0.001 to 65.535, unit: Ω.
Stator inductance Lq	Defines the stator inductance Lq. If the servo drive is online, the parameter in the servo drive is read. The default value is 0.01 when the servo drive is not online. Range: 0.01 to 655.35; unit: mH
Stator inductance Ld	Defines the stator inductance Ld. If the servo drive is online, the parameter in the servo drive is read. The default value is 0.01 when the servo drive is not online. Range: 0.01 to 655.35; unit: mH
Back EMF coefficient	Defines the linear back EMF coefficient. If the servo drive is online, the parameter in the servo drive is read. The default value is 0.01 when the servo drive is not online. Range: 0.01 to 655.35; unit: mV/rpm

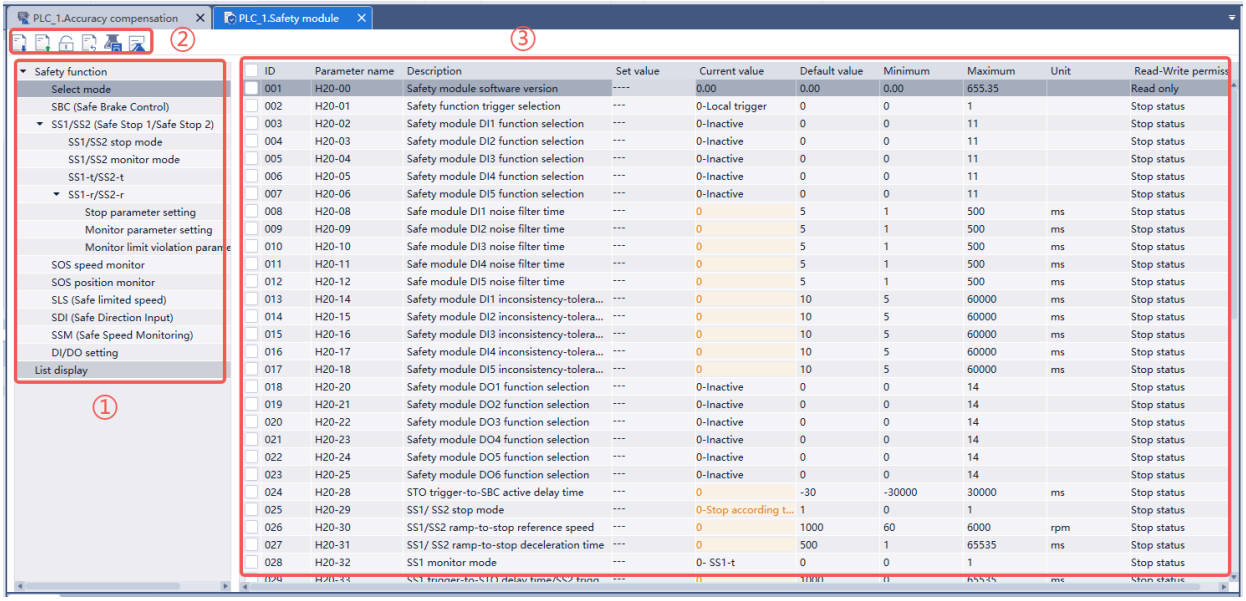
Function	Description
Calculate (button)	Click the "Calculate" button to perform dynamic braking measurement based on the set parameters, then generate the corresponding curve on the right side.

- **Curve operation**

  After the curve is generated, you can perform operations on the curve through the icons above the curve. See the following table for descriptions of functions and parameters.

Function		Description
	Curve type	Selects a curve type that displays certain data, including dynamic braking distance, motor dynamic braking speed and three-phase current amplitude.
	Pan	When it is enabled, you can move and control the view conveniently with the mouse. Restrictions: • It is mutually exclusive with the zoom function. • It is disabled when there is no curve.
	Zoom	When it is enabled, you can select a waveform segment on the X and Y axes for observation. Restrictions: • It is mutually exclusive to the pan function. • It is disabled when there is no curve.

Function		Description
	Vertical zoom	Zooms only on the Y-axis. Restrictions: • It is mutually exclusive to the pan function. • It is disabled when there is no curve.
	Horizontal zoom	Zooms only on the X-axis. Restrictions: • It is mutually exclusive to the pan function. • It is disabled when there is no curve.
	Display whole	Displays 100% of the curve on the X and Y axes. Restrictions: It is disabled when there is no curve.
	X-axis auto scale	Displays 100% of the curve on the X axis. Restrictions: It is disabled when there is no curve.
	Y-axis auto scale	Displays 100% of the curve on the Y axis. Restrictions: It is disabled when there is no curve.
	Display value	Displays the coordinates in the curve. Restrictions: It is disabled when there is no curve.
	Max. value	Displays the maximum value of curve data. Accurate to 5 decimal places.
	Final value	Displays the final value of curve data. Accurate to 5 decimal places.

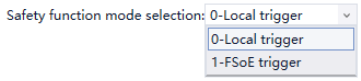


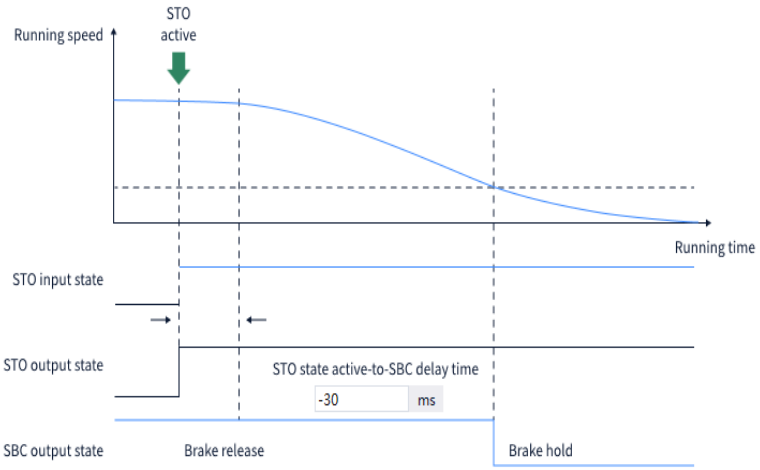
17.3.15 Safety Parameters

This function is currently supported only for the SV680 series function safety models.

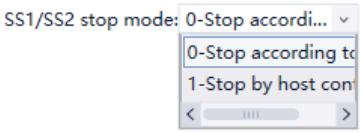
This function is designed for production scenarios that require high safety levels and richer function configurations. It enables users to configure safety functions such as STO, SS1, or SDI through the safety module function. The safety module function allows reading and writing settings for servo safety module parameters through the parameter list, or configuration via graphical interfaces for each function.

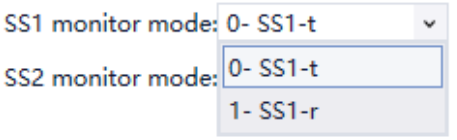
Click and select the servo drive in the project tree, then double-click "Safety module" in the detailed view to open the interface, as shown in the figure below.



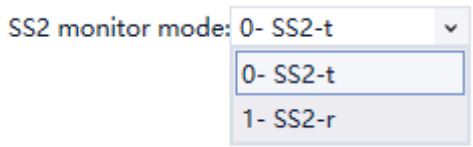


The function interface is divided into three parts: function selection area, toolbar, and parameter editing area.

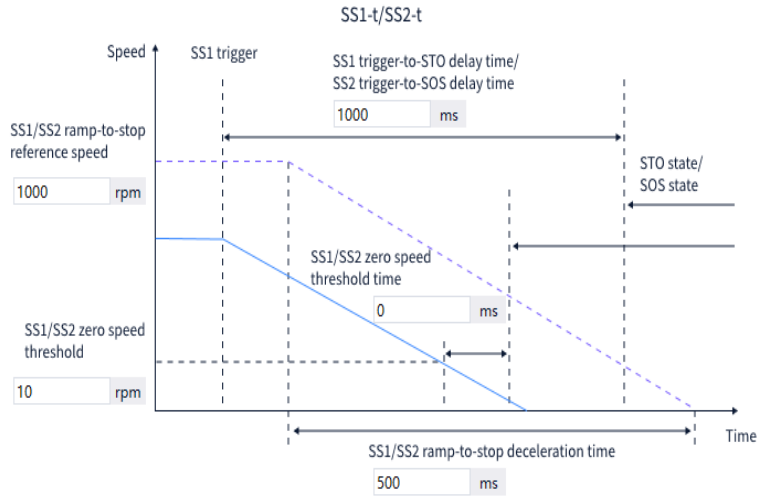




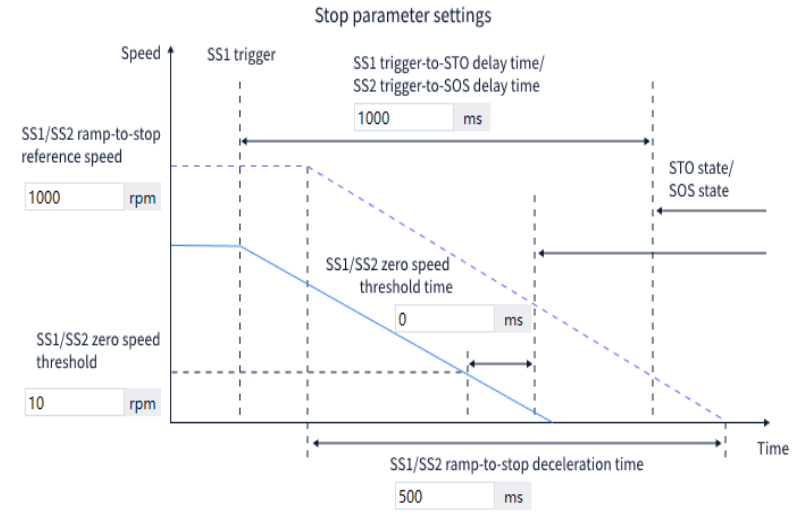
No.	Description	Description
①	Function selection	Selects the corresponding function configuration interface for the safety parameters.
②	Toolbar	Performs relevant operations on the safety parameter list.
③	Parameter editing area	Configures the various functions of the safety parameters, which can be used in conjunction with the toolbar.

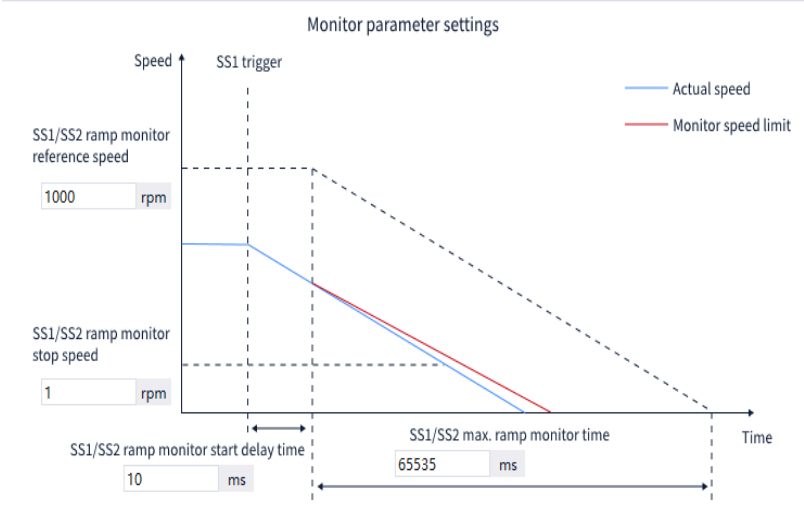


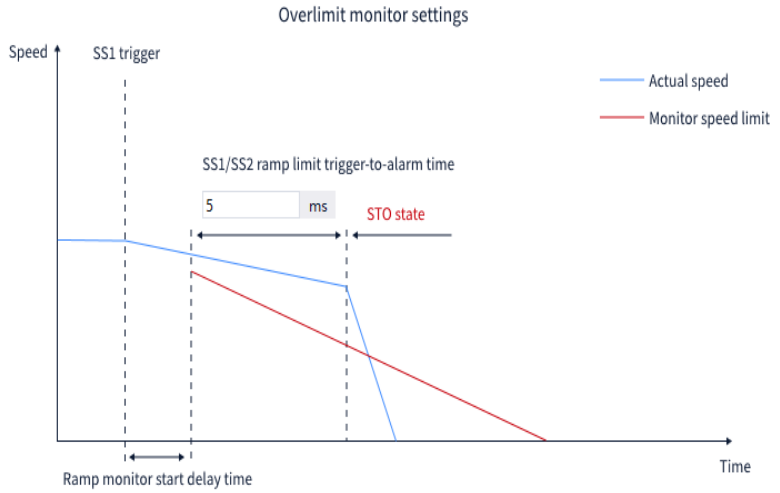
- **Function selection**

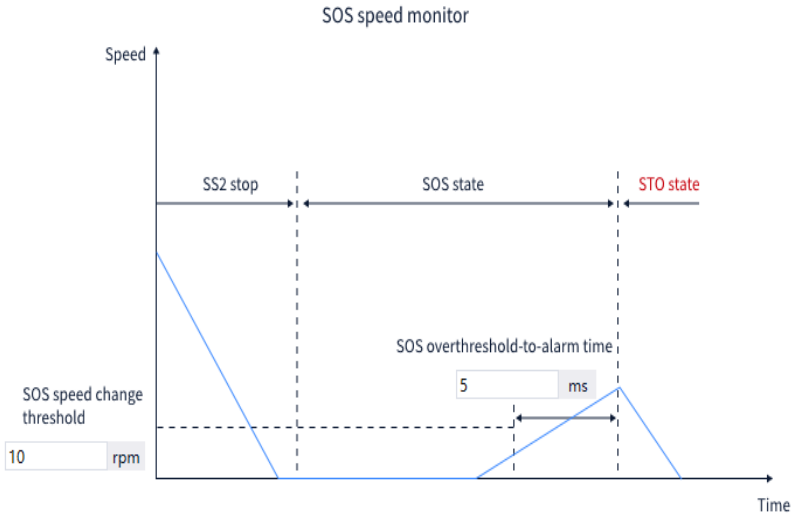


The function selection area displays all safety parameters in a tree structure. Clicking a function node will display its corresponding editing interface. Values set in the function editing interface are synchronized to the parameter editing area. The interface is shown in the figure below. For detailed descriptions of each safety function, see the table below.



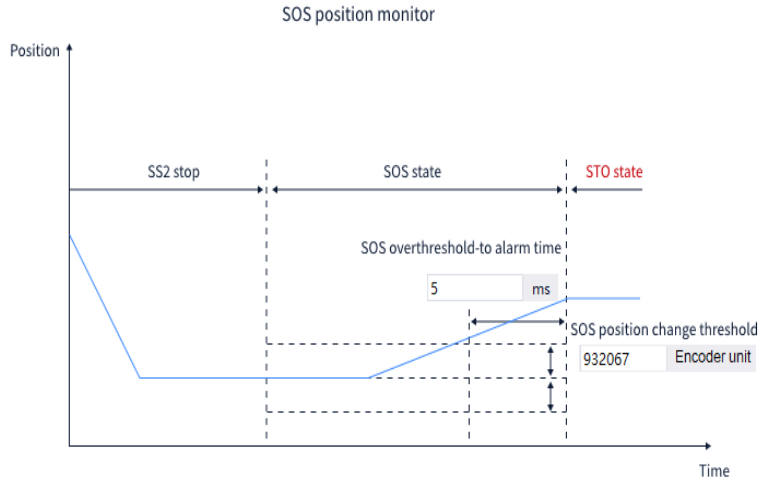


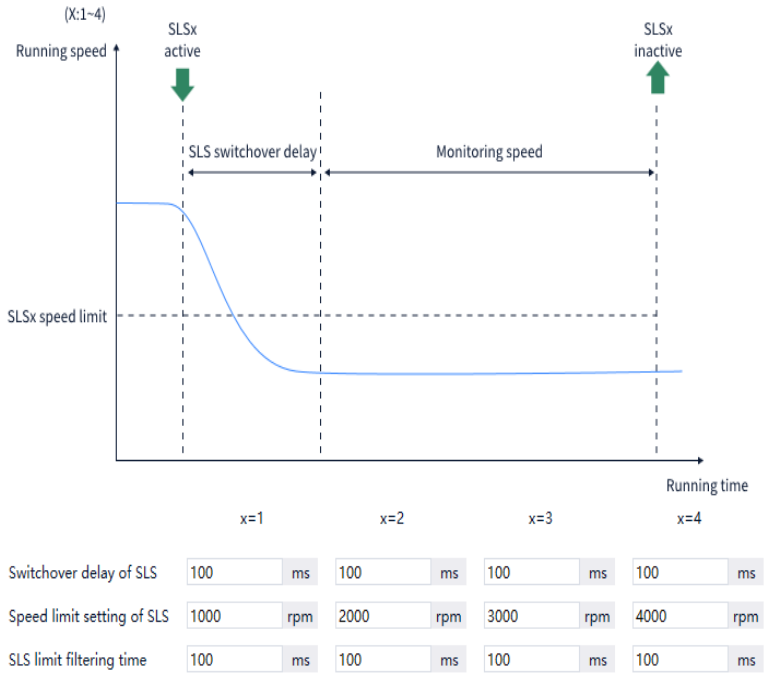




<table>
<tr><th colspan="2">Function</th><th>Configuration</th></tr>
<tr><td colspan="2">Mode selection</td><td>The selectable modes are shown in the figure below:

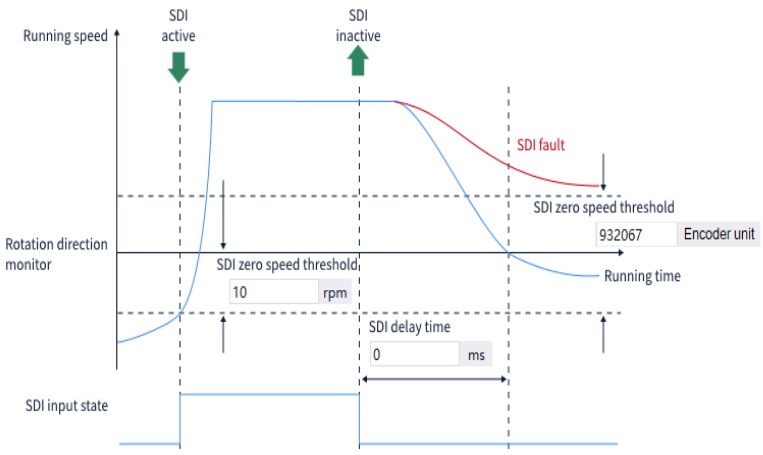
</td></tr>
<tr><td colspan="2">SBC (Safe brake control)</td><td>

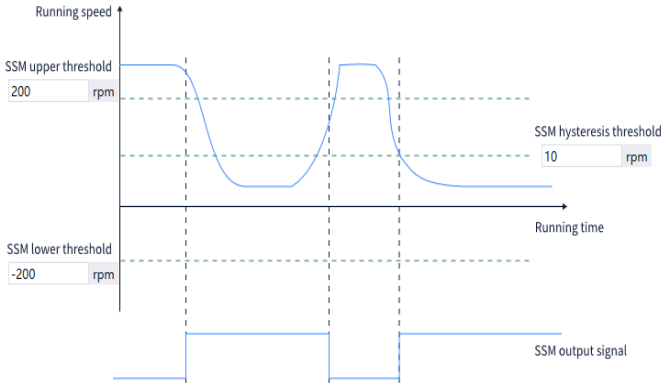




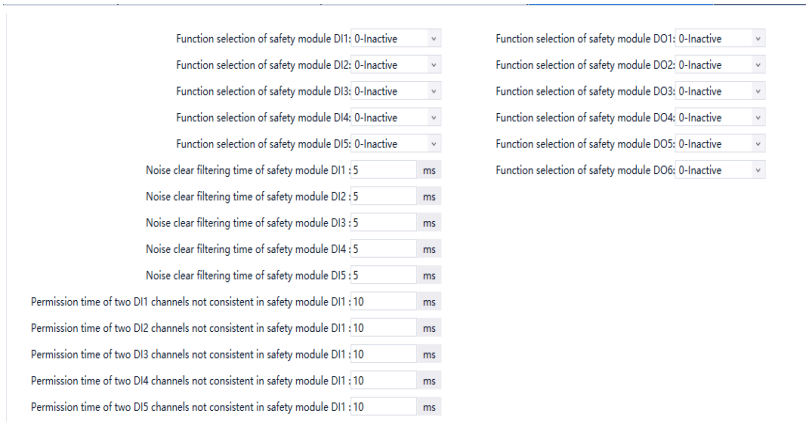
Configurable parameter:
STO state active-to-SBC delay time: Ranges from -30000 to 30000 ms.</td></tr>
<tr><td rowspan="2">SS1/SS2 (Safe stop 1/Safe stop 2)</td><td>SS1/SS2 stop mode</td><td>The selectable modes are shown in the figure below:

</td></tr>
<tr><td>SS1/SS2 monitor mode</td><td>The selectable modes are shown in the figure below:





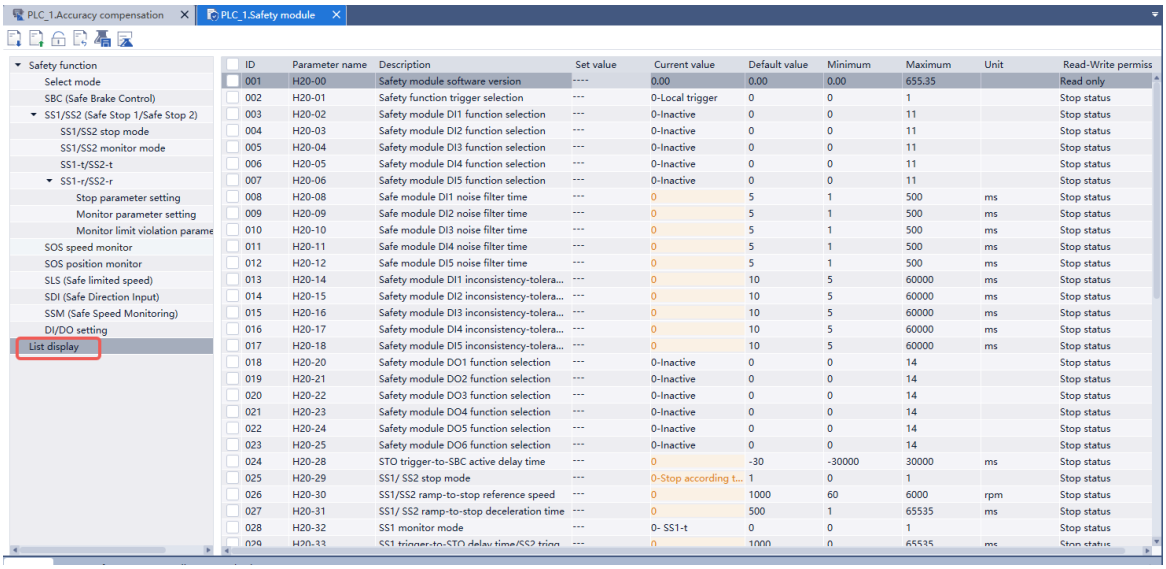
</td></tr>
</table>



Function		Configuration
	SS1-t/SS2-t	 Configurable parameter: • SS1/SS2 ramp-to-stop reference speed: Ranges from 60 to 6000 rpm. • SS1/SS2 zero speed threshold: Ranges from 1 to 6000 rpm. • SS1 trigger-to-STO delay time/SS2 trigger-to-SOS delay time: Ranges from 0 to 65535 ms. • SS1/SS2 zero speed threshold time: Ranges from 0 to 65535 ms. • SS1/SS2 ramp-to-stop deceleration time: Ranges from 1 to 65535 ms.

Function			Configuration
	SS1-r/ SS2-r	Stop parameter setting	 Configurable parameter: • SS1/SS2 ramp-to-stop reference speed: Ranges from 60 to 6000 rpm. • SS1/SS2 zero speed threshold: Ranges from 1 to 6000 rpm. • SS1 trigger-to-STO delay time/SS2 trigger-to-SOS delay time: Ranges from 0 to 65535 ms. • SS1/SS2 zero speed threshold time: Ranges from 0 to 65535 ms. • SS1/SS2 ramp-to-stop deceleration time: Ranges from 1 to 65535 ms.
		Monitor parameter setting	 Configurable parameter: • SS1/SS2 ramp monitor reference speed: Ranges from 60 to 6000 rpm. • SS1/SS2 ramp monitor stop speed: Ranges from 0 to 6000 rpm. • SS1/SS2 ramp monitor start delay time: Ranges from 5 to 65535 ms. • SS1/SS2 max. ramp monitor time: Ranges from 1 to 65535 ms.

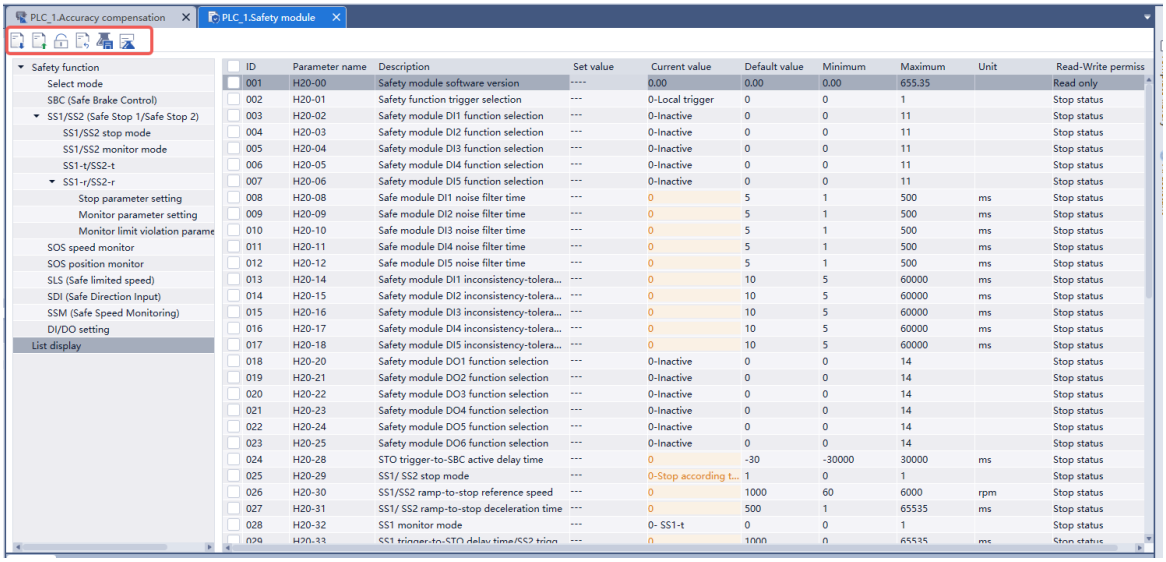
Function			Configuration
		Monitor limit violation parameter setting	 Configurable parameter: SS1/SS2 ramp-limit-trigger-to-alarm time, input range: 0 to 65535 ms
SOS speed monitor			 Configurable parameter: • SOS speed change threshold: Ranges from 1 to 6000 rpm. • SOS overthreshold-to-alarm time: Ranges from 0 to 65535 ms.



Function	Configuration
SOS position monitor	 Configurable parameter: • SOS position change threshold: Ranges from 1 to 536870912 pulses. • SOS overthreshold-to-alarm time: Ranges from 0 to 65535 ms.
SLS (Safe limited speed)	 x=1 x=2 x=3 x=4 Switchover delay of SLS 100 ms 100 ms 100 ms 100 ms Speed limit setting of SLS 1000 rpm 2000 rpm 3000 rpm 4000 rpm SLS limit filtering time 100 ms 100 ms 100 ms 100 ms Configurable parameter: • Switchover delay of SLS: Ranges from 0 to 65535 ms. • Speed limit setting of SLS: Ranges from 0 to 6000 rpm. • SLS limit filtering time: Ranges from 0 to 65535 ms.

Function	Configuration
SDI (Safe direction input)	 Configurable parameter: • SDI zero speed threshold: Ranges from 0 to 3000 rpm. • SDI zero position threshold: Ranges from 1 to 536870912 pulses. • SDI delay time: Ranges from 0 to 65535 ms.
SSM (Safe Speed Monitoring)	 Configurable parameter: • SSM upper threshold: Ranges from -6000 to 6000 rpm. • SSM lower threshold: Ranges from -6000 to 6000 rpm. • SSM hysteresis threshold: Ranges from 0 to 6000 rpm.

Function	Configuration
DI/DO setting	Select the functions of safety module DI/DO from the drop-down lists; set the noise clear filtering time of safety module DI and the permission time of two inconsistent DI channels via the input boxes. • Noise clear filtering time: Ranges from 1 to 500 ms. • Permission time of two inconsistent DI channels: Ranges from 5 to 60000 ms. 



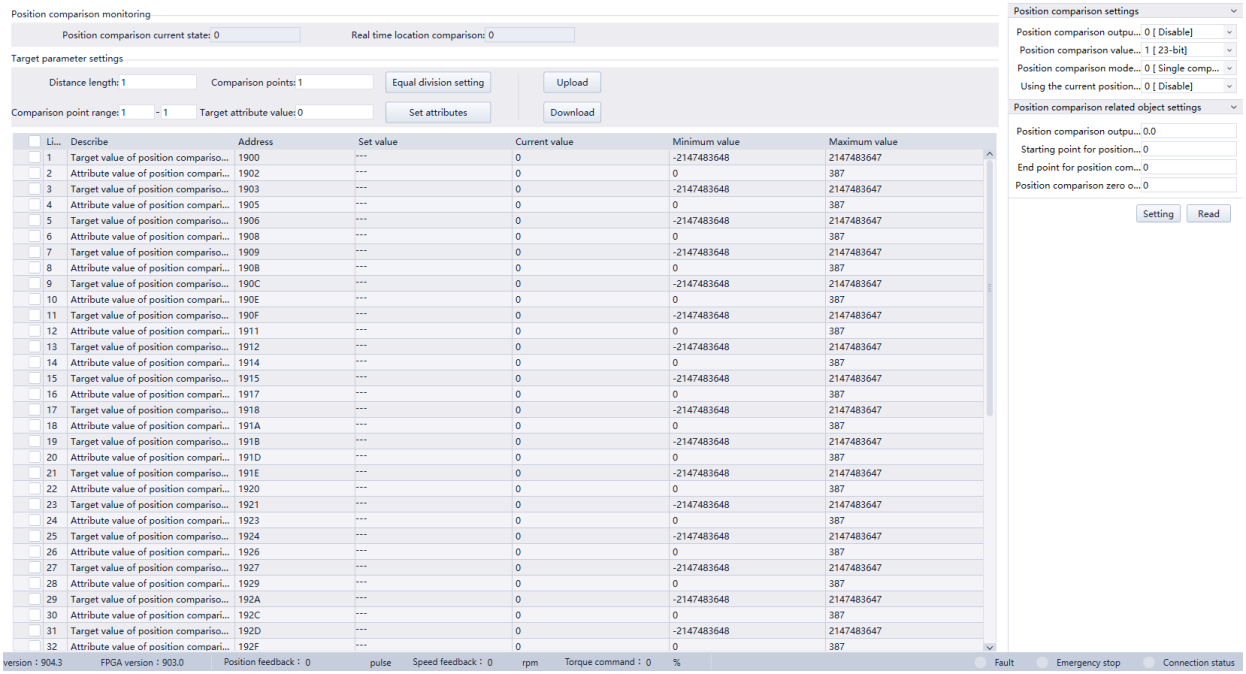
- **Parameter editing**

  The parameter editing area displays all safety function parameters in a list format. You can modify the set values of relevant parameters in the list and perform corresponding operations via the toolbar.

- **Toolbar**

  The toolbar contains the following function buttons as shown in the figure below. See the table below for detailed descriptions of each function button.

Function		Description
	Download	Downloads the selected safety parameters with set values from the parameter editing area to the drive. If password is required, the default password is "11111".
	Upload	Uploads the selected safety parameters from the drive and update them in the parameter editing area. If password is required, the default password is "11111".
	Password modification	Modifies the corresponding password. The default password is "11111".
	Restore default	Restores safety functions to factory settings.
	Export data	Saves the selected recipe parameters to the local disk (file extension: safetyparam).
	Import data	Imports the parameters from a local recipe file to the safety parameter module.



17.3.16 Comparison Output

This function is currently not supported for STD60N, IS650N-PLUS, and IS810N series products.

"Position comparison setting" and "Related object setting for position comparison" are general configurations for all models, while "ABZ output function setting" and "ABZ polarity selection" are supported only for certain products. Refer to the actual interface display for availability.

The position comparison function parameters are configured and monitored using the backend software. This function compares the instantaneous position data fed back from the drive with the data pre-stored in a target position array. When the comparison condition is met, it immediately outputs a DO pulse signal (with configurable DO number and pulse width) for subsequent motion control.

Select a servo drive in the project tree, and double-click "Position comparison" in the detailed view to open the interface, as shown in the figure below.

Steps

1. Configure position comparison settings.
   - Position comparison parameters are written immediately upon setting.
   - The following table shows the supported configuration items and their corresponding relationships for position comparison setting.

ID	Position comparison output enable	Position comparison output feedback source	Position comparison mode selection
1	1 [Enable (rising edge-triggered)]	0 [Motor encoder feedback]	0 [Individual comparison mode]
2	1 [Enable (rising edge-triggered)]	0 [Motor encoder feedback]	1 [Cyclic comparison mode]
3	1 [Enable (rising edge-triggered)]	0 [Motor encoder feedback]	2 [Fixed cyclic comparison mode]
4	1 [Enable (rising edge-triggered)]	1 [Fully closed-loop position feedback]	0 [Individual comparison mode]
5	1 [Enable (rising edge-triggered)]	1 [Fully closed-loop position feedback]	1 [Cyclic comparison mode]
6	1 [Enable (rising edge-triggered)]	1 [Fully closed-loop position feedback]	2 [Fixed cyclic comparison mode]
7	0 (disable)	0 [Motor encoder feedback]	0 [Individual comparison mode]
8	0 (disable)	0 [Motor encoder feedback]	1 [Cyclic comparison mode]
9	0 (disable)	0 [Motor encoder feedback]	2 [Fixed cyclic comparison mode]

ID	Position comparison output enable	Position comparison output feedback source	Position comparison mode selection
10	0 (disable)	1 [Fully closed-loop position feedback]	0 [Individual comparison mode]
11	0 (disable)	1 [Fully closed-loop position feedback]	1 [Cyclic comparison mode]
12	0 (disable)	1 [Fully closed-loop position feedback]	2 [Fixed cyclic comparison mode]

- "Position comparison output feedback source", "Resolution of position comparison value", and "Position comparison mode selection" are effective only when "Position comparison output enable" is set to "1 [Enable (rising edge-triggered)]". You can select the resolution of position comparison value according to actual needs.
- Enable "Current position as zero" only when the comparison status is invalid; otherwise, it may cause abnormal behavior in the comparison logic.

2. Configure "ABZ output function setting" and "ABZ polarity selection".
   - Click "Setting" to write the parameters set in "ABZ output function setting". (This function is not supported for SV660N series product)
   - The following table shows the supported configuration items and their corresponding relationships for ABZ output function settings.

No.	OCZ Port Function	Z Port Function	A/B Port Function	ABZ Output Function Setting
1	Frequency division output	Frequency division output	Frequency division output	0
2	Position comparison	Frequency division output	Frequency division output	1
3	Frequency division output	Position comparison	Frequency division output	2
4	Position comparison	Position comparison	Frequency division output	3
5	Frequency division output	Frequency division output	Position comparison	4
6	Position comparison	Frequency division output	Position comparison	5
7	Frequency division output	Position comparison	Position comparison	6
8	Position comparison	Position comparison	Position comparison	7

- Click "Setting" to write the parameters set in "ABZ polarity setting". (This function is not supported for SV660N series product)
- The following table shows the supported configuration items and their corresponding relationships for ABZ polarity selection.

ID	OCZ Port Output Logic	Z Port Output Logic	A/B Port Output Logic	ABZ Output Polarity Selection
1	Positive polarity, output high level when effective	Positive polarity, output high level when effective	Positive polarity, output high level when effective	0
2	Negative polarity, output low level when effective	Positive polarity, output high level when effective	Positive polarity, output high level when effective	1
3	Positive polarity, output high level when effective	Negative polarity, output low level when effective	Positive polarity, output high level when effective	2
4	Negative polarity, output low level when effective	Negative polarity, output low level when effective	Positive polarity, output high level when effective	3
5	Positive polarity, output high level when effective	Positive polarity, output high level when effective	Negative polarity, output low level when effective	4
6	Negative polarity, output low level when effective	Positive polarity, output high level when effective	Negative polarity, output low level when effective	5
7	Positive polarity, output high level when effective	Negative polarity, output low level when effective	Negative polarity, output low level when effective	6
8	Negative polarity, output low level when effective	Negative polarity, output low level when effective	Negative polarity, output low level when effective	7

3. Configure the parameters in "Related objects setting for position comparison". Click "Setting" to write the parameters set in "Related objects setting for position comparison".

Parameter	Description
Fixed number of cycles	Configures the number of cycles required for completion in the fixed cyclic comparison mode. Range: 1 to 65535.
Output width of position comparison	When the position comparison condition is met, the active level width of the DO can be set. Range: 0.1 to 204.7 ms.
Start point of position comparison	Position of the first comparison point. Range: 0 to 40 pulses.

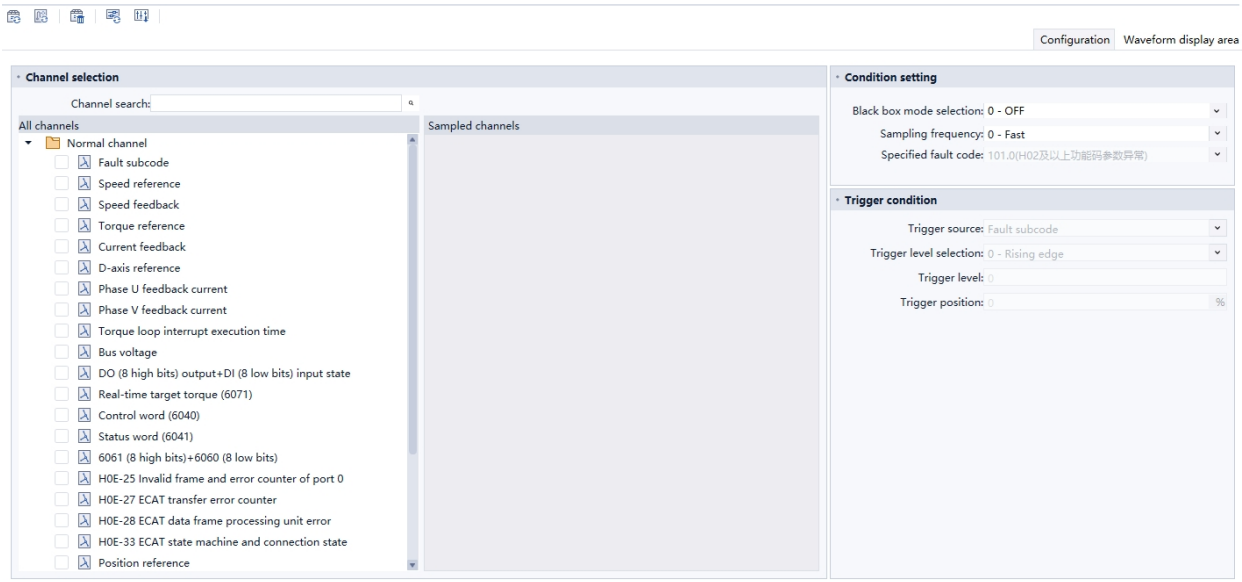
Parameter	Description
End point of position comparison	Position of the last comparison point. Range: 0 to 40 pulses.
Zero offset of position comparison	Offset value after setting the current configured position as the zero point. Range: -2147483648 to 2147483647 pulses.

4. Read and set related parameters.
   - Click the "Setting" button to write related parameters for position comparison.
   - When the view becomes visible from a hidden status, click the "Read" button to read the related object parameters for position comparison from the online device.
5. Configure target parameters, and view position comparison monitoring information, target values, attribute values, etc.
   - Position comparison monitor area: Displays the current statuses and real-time position of the position comparison.
   - See the table below for the descriptions of target parameter setting.

Parameter	Description
Distance length	In individual comparison mode, it indicates the total travel distance of the servo drive; in cyclic or fixed comparison mode, it indicates the travel distance between two adjacent points. Range: -2147483648 to 2147483647 pulses.
Comparison points	In individual comparison mode, it indicates the total number of comparison points for the servo drive; in cyclic or fixed comparison mode, it indicates the number of points to be cyclically compared. Range: 1 to 40 points.
Comparison point range	Sets the number of points to be compared within the range of total comparison point count. Range: 1 to 40 points.
Target property value	Property value of the target position. Range: -2147483648 to 2147483647 pulses.
Equal division setting	Divides the target distance length equally according to the number of comparison points.
Upload	Reads the current values of the relevant position comparison parameters from the current axis of the connected drive and update them to the editing interface.
Download	Writes the set parameters from the current position comparison parameter editing interface to the target axis of the currently connected drive.

Parameter	Description
Setting property	Writes the target property-related parameters from the current target parameter editing interface to the target axis of the currently connected drive.

- List area: Reads and displays related target values and property values during the drive position comparison process.



17.3.17 Black Box

17.3.17.1 Overview

This function analyzes the recorded data, operation statuses, and fault causes of the related devices to improve their maintainability.

Select a servo device in the project tree, and double-click "Black box" in the detailed view to open the interface, which contains two tabs: "Configuration" and "Waveform display area".

17.3.17.2 Configuration

- **Toolbar**

Function		Description
	Read black box	Reads the black box data, and then jumps to the waveform display area.
	Clear black box	Clears the black box data.

Function		Description
	Read configuration	Reads the configuration from the drive and displays it on the current page.
	Reading all channels	Reads all channel information from the black box. NOTE This function is not supported by the SV660N series products.
	Write configuration	Writes the configuration of the current page to the drive.

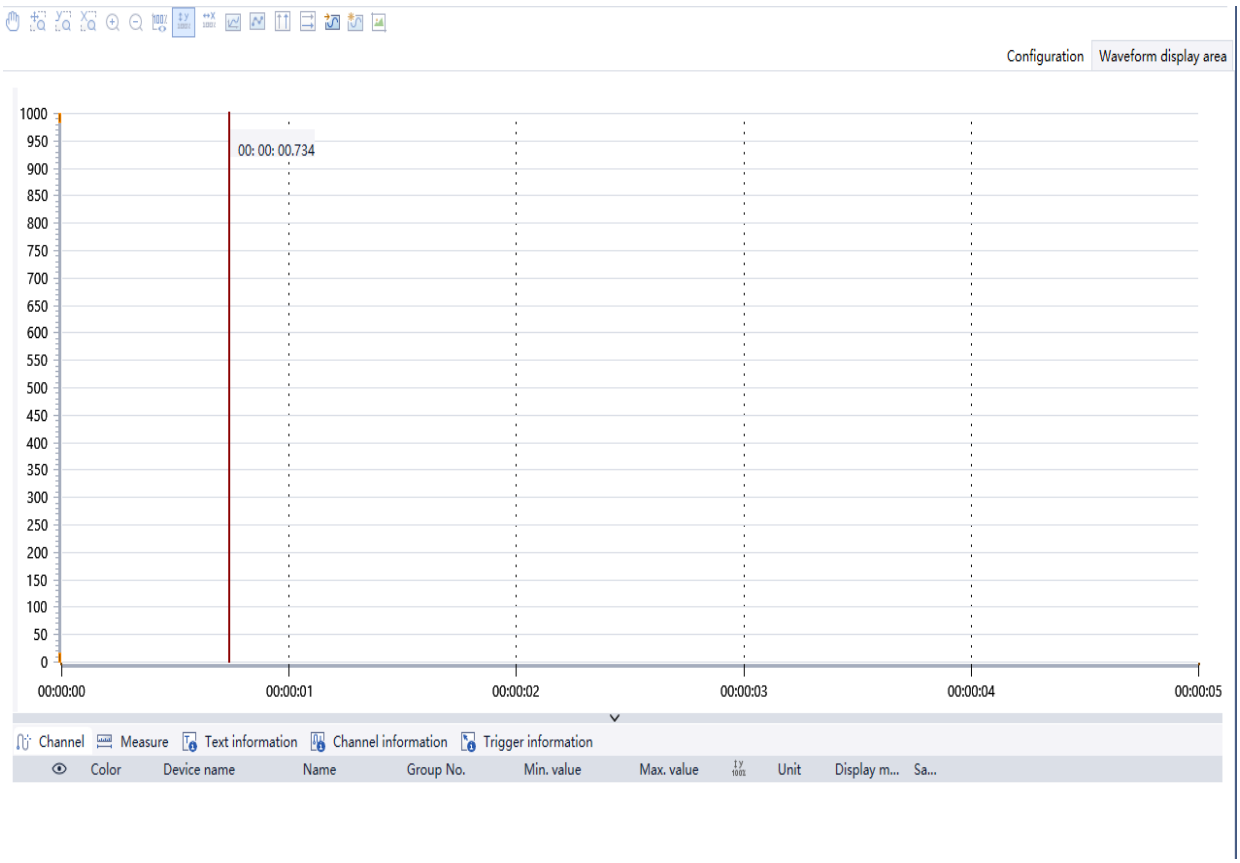
- **Axis selection**

  Selects the corresponding axis of the drive.

- **Channel selection**

  Selects the black box channel for data reading. You can search for the related channels quickly through the "Channel search" box.

- **Trigger condition**



Parameter	Description
Trigger source	Defines the trigger source. It is available only when the black box mode is set to "3 - Triggered by specified condition".
Trigger level	Defines the trigger level. The value ranges from 0 to 65535 pulses. It is available only when the black box mode is set to "3 - Triggered by specified condition".
Trigger level selection	Defines the trigger level selection. It is available only when the black box mode is "3 - Triggered by specified condition".
Trigger position	Defines the trigger position. The value ranges from 0% to 100%.

- **Condition setting**

Parameter	Description
Sampling frequency	Defines the sampling frequency. Options are as follows: • 0 - Fast (16 kHz) • 1 - Normal (4 kHz) • 2 - Slow (1 kHz)

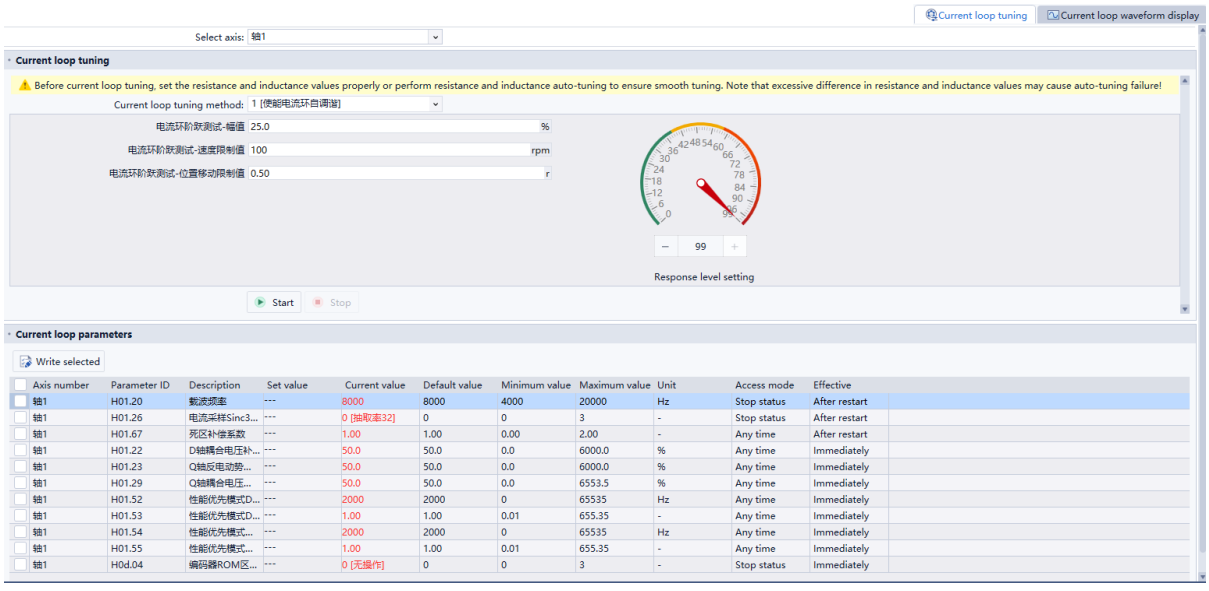
Parameter	Description
Black box mode selection	Selects the black box mode. Options are as follows: • 0 - OFF • 1 - Any fault • 2 - Specified fault • 3 - Triggered by specified condition
Specified fault code	Defines the fault code to trigger the black box function. It is available only when the black box mode is set to "2 - Specified fault".

17.3.17.3 Waveform Display

The toolbar on the "Waveform display area" tab is the same as that on the "Oscilloscope" tab. For details, see 17.2.1.8 Analysis Auxiliary Function. The waveform curve is displayed in the middle area and related information is displayed in the lower area. See the following table for details.

Function	Description
Channel	Displays channel information. You can also set the channel color and group number.
Measurement	Measures the waveform through the cursor, and displays the values of each curve in real time.

Function	Description
Channel information	Displays the sampling frequency, total sampling point count, and sampling point count before trigger of the speed and position references.
Trigger information	Displays the following two trigger messages: • Condition information: Displays the trigger condition based on the actual value. • Fault information: Displays the fault information generated upon triggering. NOTE The trigger information of the current servo drive is displayed as null.
Text information	Displays relevant information about the device.

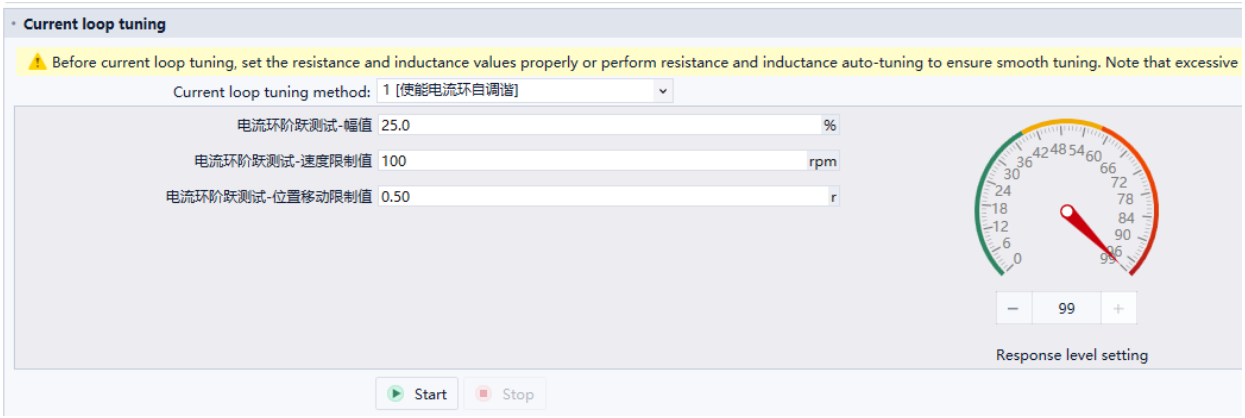


17.3.18 Current Loop Adjustment

This function is supported only by the IS650N-PLUS, SV680N-INT, SV670N-INT, and SV680LN series.

As the innermost loop of a servo control system, the response and stability of the current loop play a vital role in the performance of the system.

17.3.18.1 Function Interface



Select a servo device in the project tree, and double-click "Current loop tuning" in the detailed view to open the interface. The interface mainly consists of three parts: current loop tuning, current loop parameters, and current loop waveform display. The interface is shown in the following figure.

17.3.18.2 Current Loop Tuning

17.3.18.2.1 Current Loop Auto-Tuning

This mode provides a static auto-tuning method for the current loop. After this mode is enabled, the drive executes gain parameter tuning for the current loop automatically. You can set the response level. The higher the response level, the higher the responsiveness and bandwidth of the current loop.

Description	Description
Current loop step test - Amplitude	Sets the amplitude of the excitation signal for the auto-tuning process.
Current loop step test - Speed limit value	Sets the maximum speed at which the current excitation can remain stable.
Current loop step test - Displacement limit value	Sets the maximum distance at which the current excitation can remain stable.
Response level setting	Sets the response level for the current loop.

Description

Excessively high response level may induce current loop control noise. In actual use, users shall set the response level as needed to achieve a balance between current loop responsiveness and noise.

17.3.18.2.2 Static Step Test of Current Loop

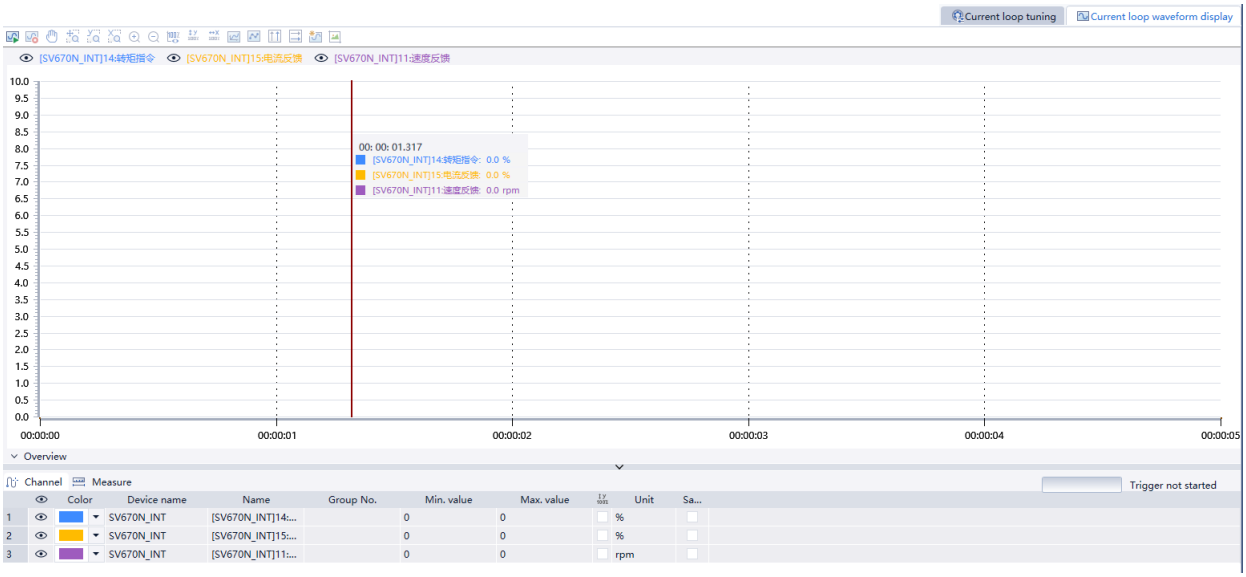
This mode provides a static method for observing the current loop step response. Users can manually adjust the current loop gain parameters to observe and verify the current loop response.

Description	Description
Current loop step test - Amplitude	Sets the amplitude of the step excitation signal.
Current loop step test - Duration	Sets the duration of the step excitation signal.
Current loop step test - Speed limit value	Sets the maximum speed at which the current excitation can remain stable.
Current loop step test - Displacement limit value	Sets the maximum distance at which the current excitation can remain stable.

17.3.18.2.3 Step Test of Current Loop

This mode provides a dynamic method for observing the current loop step response. Its parameter settings are the same as static step test. Users can manually adjust the current loop gain parameters to observe and verify the current loop response.

17.3.18.3 Current Loop Parameters



The current loop parameter interface is used to manually set and monitor current loop gain parameters. The parameter settings in this interface are consistent with those in the parameter list. For details, see 17.2.2 Parameter List.

Axis number	Parameter ID	Description	Set value	Current value	Default value	Minimum value	Maximum value	Unit	Access mode	Effective
轴1	H01.20	载波频率	---	8000	8000	4000	20000	Hz	Stop status	After restart
轴1	H01.26	电流采样Sinc3...	---	0 [抽取率32]	0	0	3	-	Stop status	After restart
轴1	H01.67	死区补偿系数	---	1.00	1.00	0.00	2.00	-	Any time	After restart

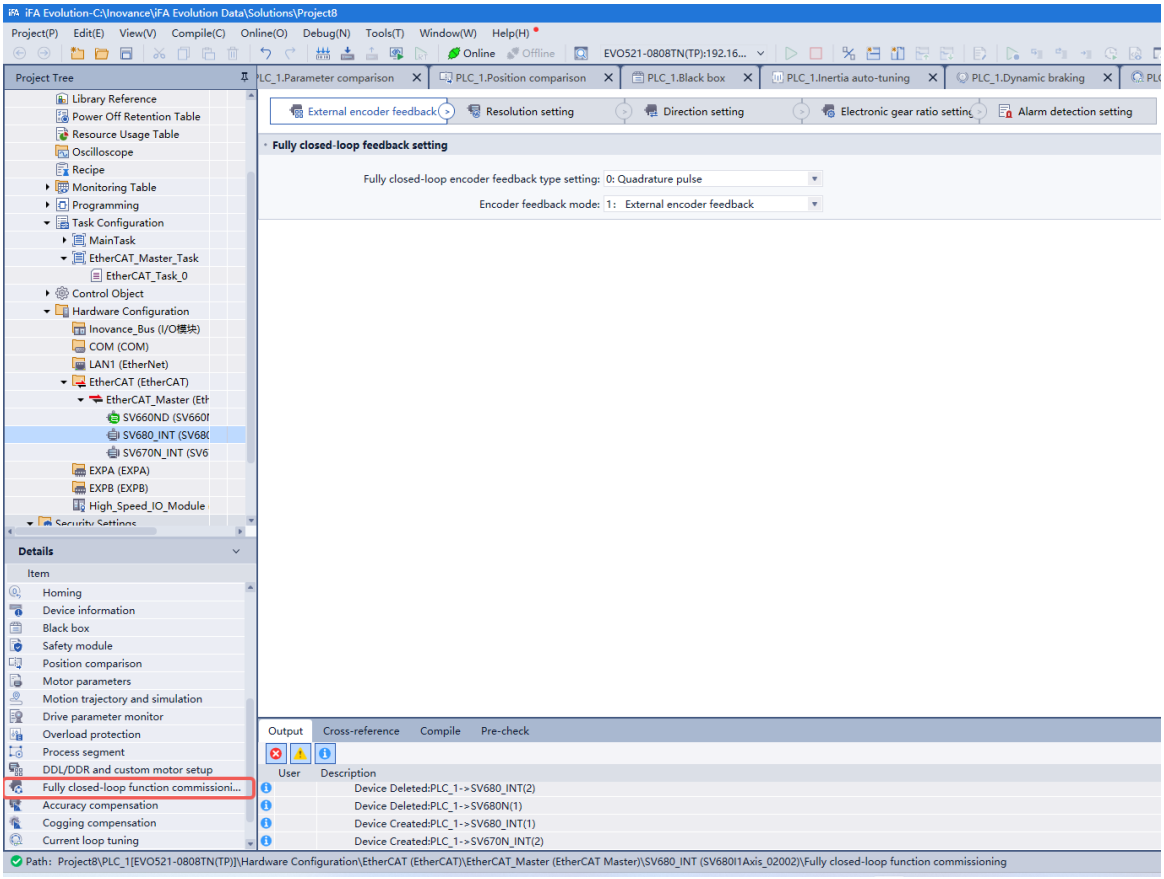
轴1	H01.29	Q轴耦合电压...	---	50.0	50.0	0.0	6553.5	%	Any time	Immediately
轴1	H01.52	性能优先模式D...	---	2000	2000	0	65535	Hz	Any time	Immediately
轴1	H01.53	性能优先模式D...	---	1.00	1.00	0.01	655.35	-	Any time	Immediately
轴1	H01.54	性能优先模式...	---	2000	2000	0	65535	Hz	Any time	Immediately
轴1	H01.55	性能优先模式...	---	1.00	1.00	0.01	655.35	-	Any time	Immediately
轴1	H0d.04	编码器ROM区...	---	0 [无操作]	0	0	3	-	Stop status	Immediately

17.3.18.4 Current Loop Waveform Display

After completing the static step test and step test of the current loop, the system will automatically jump to the current loop waveform display area and trigger the data acquisition of torque reference, current feedback, and speed feedback. Users can observe and verify the current loop response through the waveform.

The toolbar in this interface has the same functions as that in the "Trigger oscilloscope" interface. For details, see 17.2.1.8 Trigger Oscilloscope.



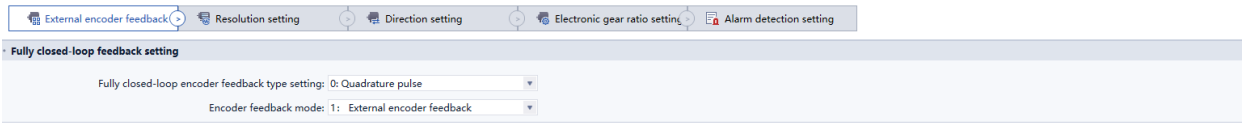
17.3.19 Fully Closed-Loop Functions

This function currently supports only the IS650N-PLUS, SV680-INT, and SV670N-INT product series.

The fully closed-loop control method installs position detection devices (such as linear encoders and encoders) on the moving components to provide real-time feedback on motion status and position information, eliminating the impact of temperature and mechanical errors on control performance and improving motion accuracy. This function is designed to guide users in quickly configuring the fully closed-loop function.

Function entry

Select a servo drive in the project tree and double-click "Fully closed-loop function commissioning" in the detailed view to open the interface.

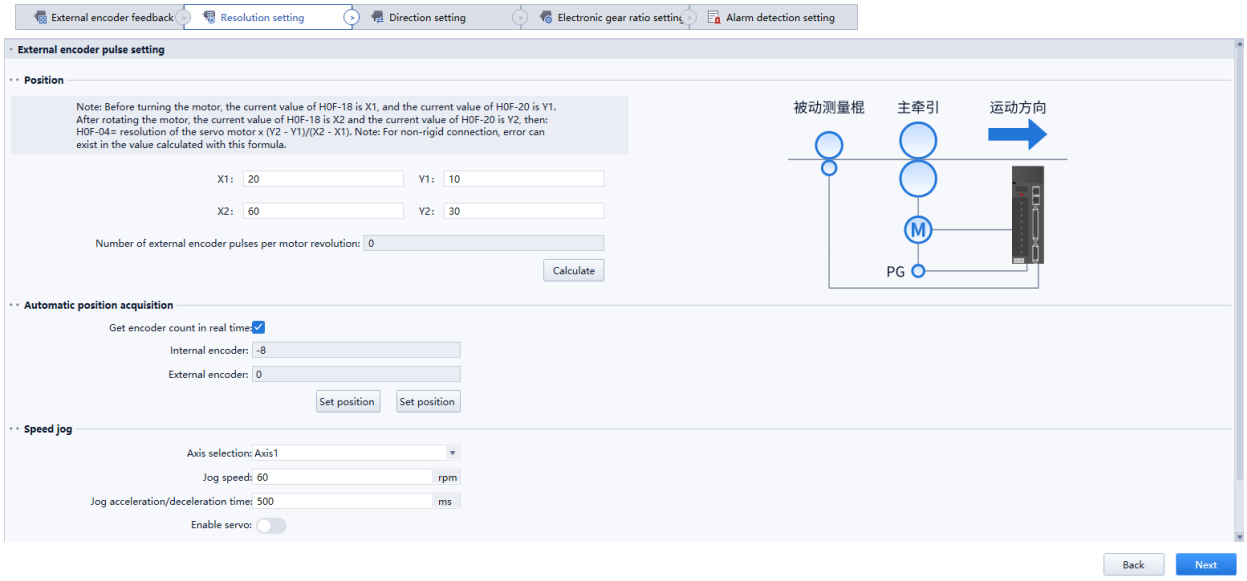


Function description

After setting basic gain parameters, check that the servo drive operates properly without overshoot and stops without generating noise. After the basic operating conditions are met, the fully closed-loop parameters need to be configured, which contains the following steps: external encoder feedback type setting, resolution setting, direction setting, electronic gear ratio setting, and alarm detection setting.

17.3.19.1 External Encoder Feedback Type Settings

The first step is to set the fully closed-loop encoder feedback type and encoder feedback mode. The interface is as follows.



If the encoder is of a third-party type (SSI/ENDAT/BISSC), the system will prompt you to power off and on the device again after parameter configuration. When the encoder feedback mode is set to internal encoder mode, the next step (resolution setting) cannot be performed.

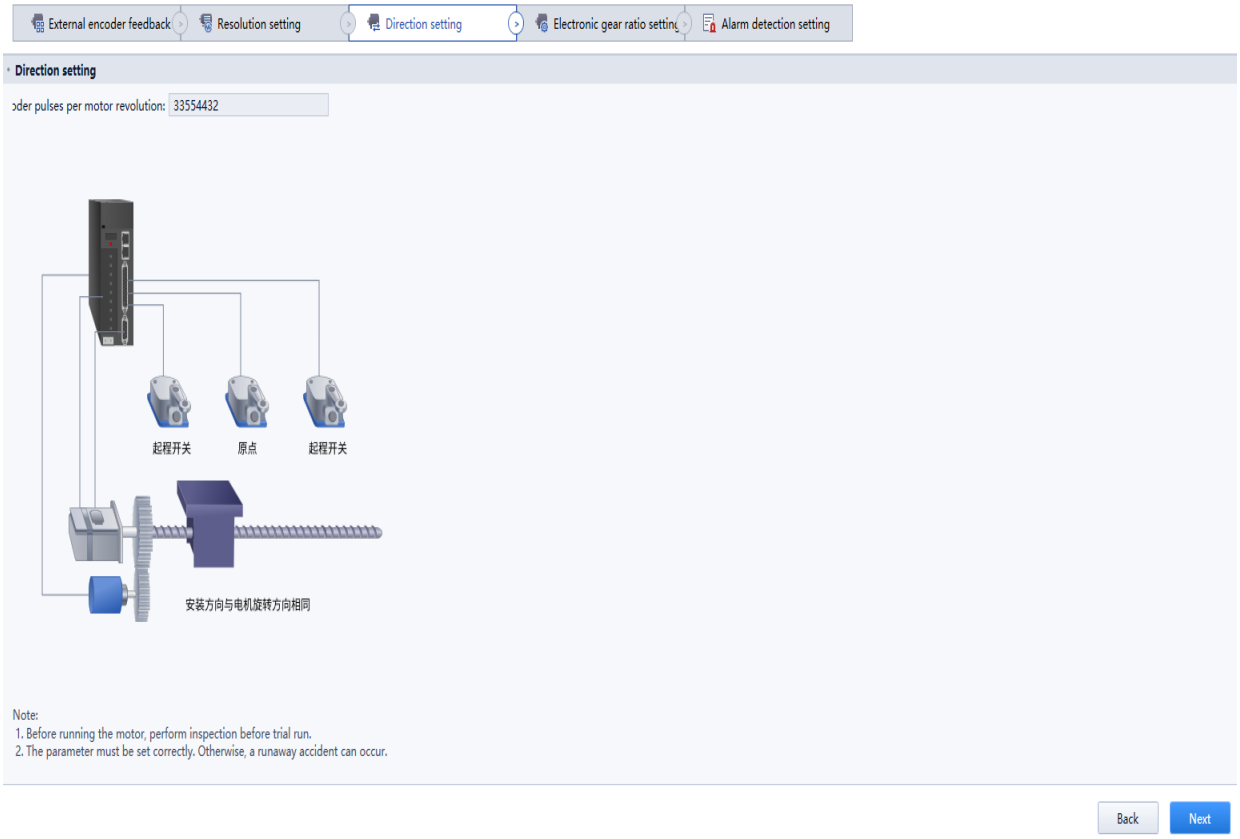
17.3.19.2 External Encoder Resolution Settings

This step mainly aims to calculate the number of pulses of the external encoder, which can be done in the following two ways:

1. Manually rotate the motor while observing the internal encoder pulse counter. After completing one full revolution, observe the value change in the pulse counter. The absolute value of this change indicates the number of pulses per revolution of the fully closed-loop encoder.
2. Before rotating the motor, the current value of the internal position pulse feedback is X1, and the current value of the fully closed-loop encoder position pulse feedback is Y1. After rotating the motor, X1 becomes X2, and Y1 becomes Y2. The number of pulses per revolution of the fully -closed-loop encoder is: Servo motor resolution × (Y2 - Y1) ÷ (X2 - X1).

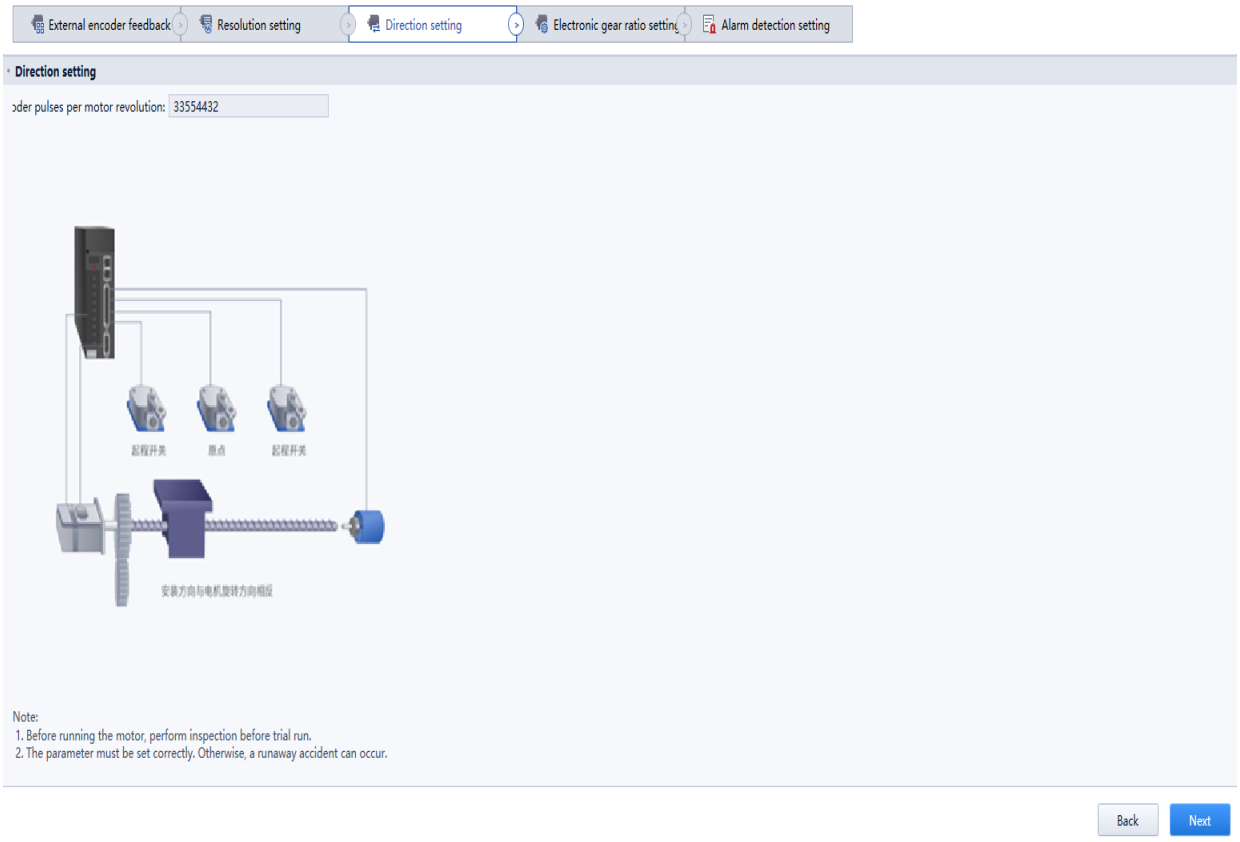
You can choose whether to use jog mode for motor revolution. The jog operation interface is hidden or displayed based on your selection, which is shown below:

Click "Next" to jump to the "Direction setting" tab. Click "Back" to jump to the "External encoder feedback type setting" tab



17.3.19.3 External Encoder Direction Settings

This step aims to determine the operation direction of the external encoder, and check whether this direction is consistent with that of the internal encoder. If not, positive feedback will be generated, leading to a runaway fault.



The operating direction can be determined based on the change in the number of pulses of the external encoder per motor revolution. If the change is negative, the direction is reverse; if the change is positive, the direction is forward. This interface does not involve parameter writing, but only determines whether the current condition matches the diagram. There are two main installation scenarios. Click "Next" to jump to the

"Electronic fear ratio setting" tab. Click "Back" to jump to the "Resolution setting" tab. The interface is as follows:

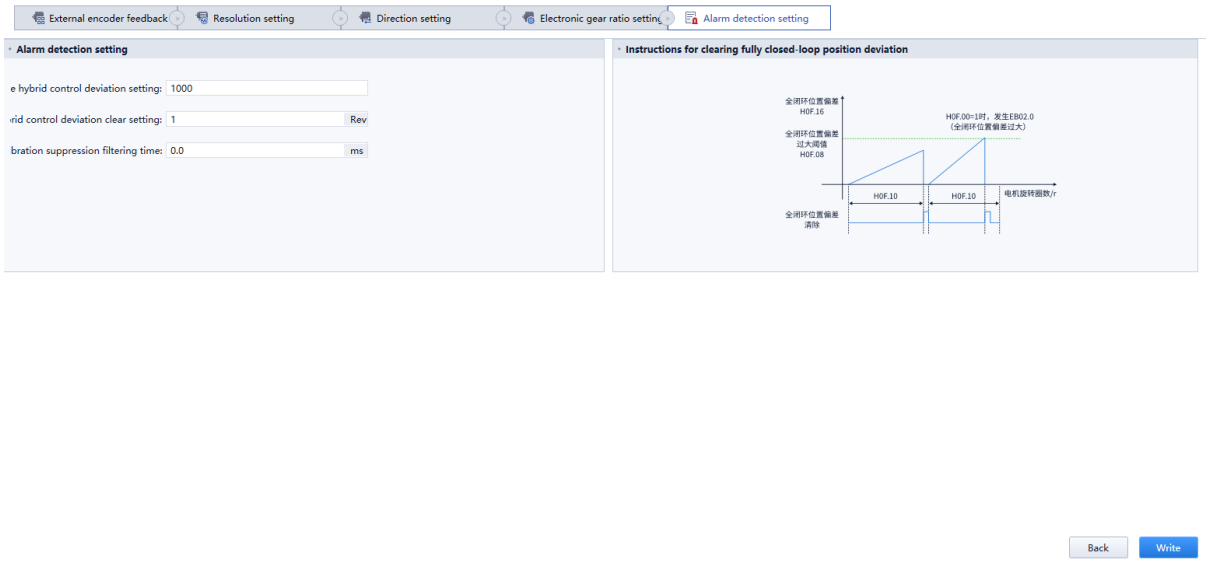
Installation direction same as motor revolution direction:

Installation direction opposite to motor revolution direction:

17.3.19.4 Electronic Gear Ratio Settings

This step sets the electronic gear ratio according to the encoder feedback mode. For the external encoder feedback mode, the first group of electronic gear ratios needs to be set on this tab. For the inter/outer loop switchover mode, both the first and second groups of electronic gear ratios need to be set. Click "Next" to jump to the "Alarm detection setting" tab. Click "Back" to jump to the "Direction setting" tab. The interface is as follows:

17.3.19.5 Alarm Detection Settings

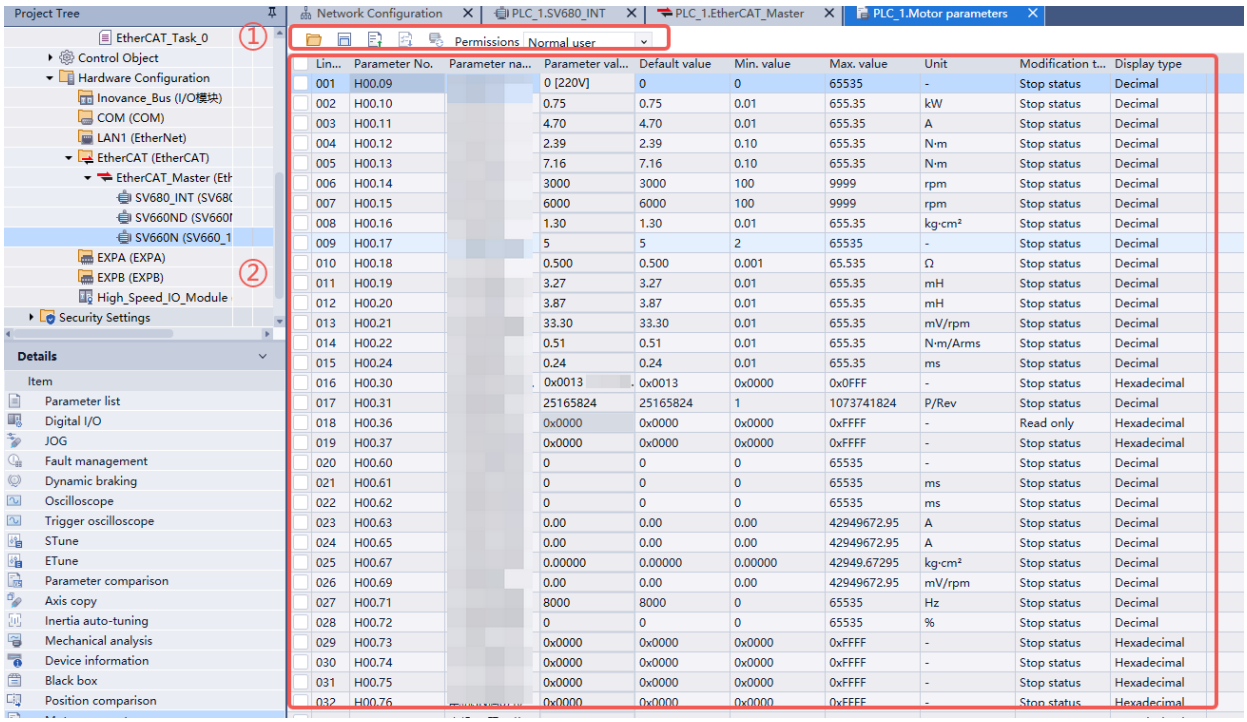


This step is the final step of this function. It is used to configure the deviation threshold, deviation clear setting, and first-order low-pass filter for deviation in compound control.

1. The deviation threshold sets the allowable positional tolerance between the motor and the external encoder. The unit is one reference unit (same as one external encoder unit). For example, if the deviation threshold is set to 1000, EB02.0 (Excessive position deviation in fully closed-loop mode) will be output when the deviation in compound control (displacement deviation between the motor-driven mechanism and the external encoder measurement) exceeds the displacement corresponding to 1000 external encoder pulses. The deviation threshold must be smaller than (fully closed-loop encoder pulse count per motor revolution) × (deviation reset value in compound control); otherwise, the fault code cannot be output.

2. The deviation clear value set the number of motor, upon the attainment of which the accumulated deviation in compound control will be cleared. For example, if the deviation clear value is set to 50, the system detects whether the accumulated deviation in compound control during 50 motor revolutions exceeds the deviation threshold. If so, a fault will be reported. If not, the accumulated deviation is cleared and the monitoring cycle is reinitialized after the motor completes 50 revolutions.

3. The first-order low-pass filter for deviation indicates the time constant of the first-order filter. It is used to filter vibrations in compound control deviation, enhancing the speed smoothness in the fully closed-loop mode.



Click "Next" to write the configured parameters in this interface to the servo drive to complete the fully closed-loop commissioning. Click "Back" to jump to the "Electronic gear ratio setting" tab. The interface is shown in the figure below:

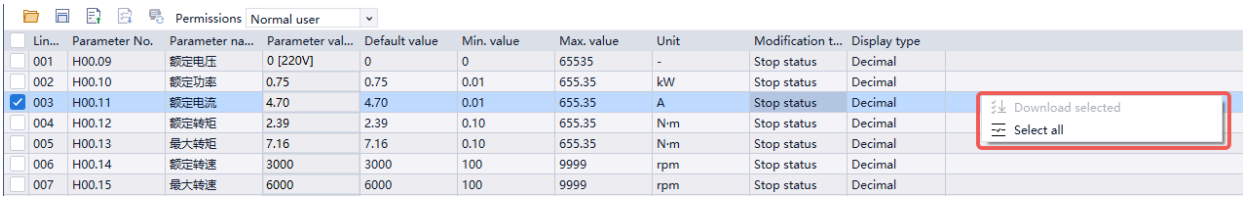
17.3.20 Bus Motor Parameters

- **Function interface**

Select a servo drive in the project tree, and double-click "Motor parameters" in the detailed view to open the interface, as shown in the figure below.

The function interface consists of two parts: the toolbar and the parameter editing area.

No.	Description	Description
①	Toolbar	Performs related operations on the motor bus parameter list.
②	Parameter editing area	Configures the various functions of the motor bus parameters, which can be used in conjunction with the toolbar.



- **Toolbar**

Icon	Description	Configuration	Restriction
		1. Select an axis for the current device from the drop-down list. 2. Click "Parameter value" to modify the parameter through drop-down box selection or direct input.	/
	Open file	Opens the motor parameter file.	/
	Save file	Saves the motor parameter file.	/
	Upload all parameters	Uploads all motor parameters.	/
	Write selected parameters	Writes the selected parameter values to the device.	It is disabled under normal user permission and enabled for super administrators.
	Motor angle initialization	Initializes the motor angle.	Disabled under normal user permission, enabled under super administrator permission.
Permissions switchover		Switches permission of the current motor parameter table between "Normal user" and "Super administrator".	/

- **Download setting**

Right-click in the parameter editing area to pop up the download menu.

Function	Description	Restriction
Download selected	Writes the selected parameter values to the device.	It is disabled under normal user permission and enabled for super administrators.
Select all	Selects all parameters in the current table.	/
Deselect all	Deselects all parameters in the current table.	/

17.3.21 Process Segment

17.3.21.1 Overview

Function description

This feature is supported only for the STD60N series products.

The process segment wizard is a backend module designed to help users configure parameters related to process segments. The interface includes configuration of general parameters, process segment parameters, homing, process segments, event trigger, and commissioning.

The process segment function mainly consists of six functions: general parameter configuration, process segment parameter configuration, homing configuration, process segment configuration, event trigger configuration, and commissioning.

Function entry

Select a servo drive in the project tree and double-click "Process segment" in the detailed view to open the interface.

17.3.21.2 General Parameter Configuration

This tab involves configuration of general parameters, including axis selection, control mode selection, process segment deceleration time, electronic gear ratio settings, and positive/negative limit settings. The interface is as follows:

Click "Read" to read the corresponding parameter values from the drive and refresh them on the current page. Click "Download" to download all parameters on the current page.

17.3.21.3 Process Segment Parameter Configuration

This tab involves configuration of parameters related to the process segment, including acceleration/deceleration time, target speed, and waiting time.

Click "Read" to read the corresponding parameter values from the drive and refresh them in all tables. Click "Download" to download all parameters on the current page.

17.3.21.4 Homing Configuration

This tab involves configuration of homing method and homing process segment. The parameters on this tab are consistent with those in the "Homing" interface of the device.

Click "Read" to read the corresponding parameter values from the drive and refresh them on the current page. Click "Download" to download all parameters on the current page.

17.3.21.5 Process Segment Configuration

This function is supported only by the STD60N, SV680N-INT, SV670N-INT, SV680LN, and SVD60N series products.

There are 15 process segments, and each segment has the same function. Each process segment consists of its definition and data. There are 6 process segment operation modes by default:

0 - Undefined, 1 - Constant speed mode, 2 - Positioning mode: Stop when this segment is done running, 3 - Positioning mode: Load the next segment after this segment is done running, 7 - Jump to, 8 - Write parameters.

Interface introduction

When the operation mode is set to "0 - Undefined", there are no corresponding parameter settings, and this process segment performs no operation.

- **Constant speed mode**

This mode involves the configuration of process segment definition and data.

The process segment definition mainly includes configuration of whether to update immediately, whether to automatically update after DelayTime, speed unit, acceleration/deceleration time, and delay time.

The process segment data is used to set the target speed.

Positioning mode

This mode involves the configuration of process segment definition and data.

The process segment definition mainly includes configuration of whether to update immediately, whether to allow segment intersection, position reference type, acceleration/deceleration time, target speed, and delay time.

The process segment data is used to set the position reference.

After the settings of a certain process segment are completed, the next process segment will be automatically performed (for example, after the settings of process segment 1, process segment 2 will be automatically performed).

Jump mode

This mode involves the configuration of process segment definition and data.

The process segment definition mainly includes configuration of whether to update immediately and delay time.

The process segment data is used to set the process segment numbers for jumping.

- **Parameter-write mode**

This mode involves the configuration of process segment definition and data.

The process segment definition mainly includes configuration of whether to update immediately, whether to automatically update after DelayTime, whether to save to EEPROM, parameter group number, parameter number, and delay time.

The process segment data is used to set the parameter value to be written.

For STD60N series stepper devices, if H0d.99 parameter exists and its value is 1, the corresponding process segment will include an additional homing mode compared to the default settings.

- **Homing mode**

This mode only involves the configuration of process segment definition.

The process segment definition includes configuration of process segment numbers for jumping and delay time.

17.3.21.6 Event Trigger Configuration

This tab configures the rising/falling edge events used to trigger a specific process segment. Through the device's I/O functions, corresponding rising and falling edge events can be triggered. Currently, STD60N devices only support the trigger configuration of rising edge events.

17.3.21.7 Commissioning

After enabling the device, enter the corresponding process segment number in the text box. Click "Start" and the specified process segment starts running; click "Stop" and the process segment stops running.

Check "Display monitored process segment" and the text box below will display the running process segment number of the current device in real time.

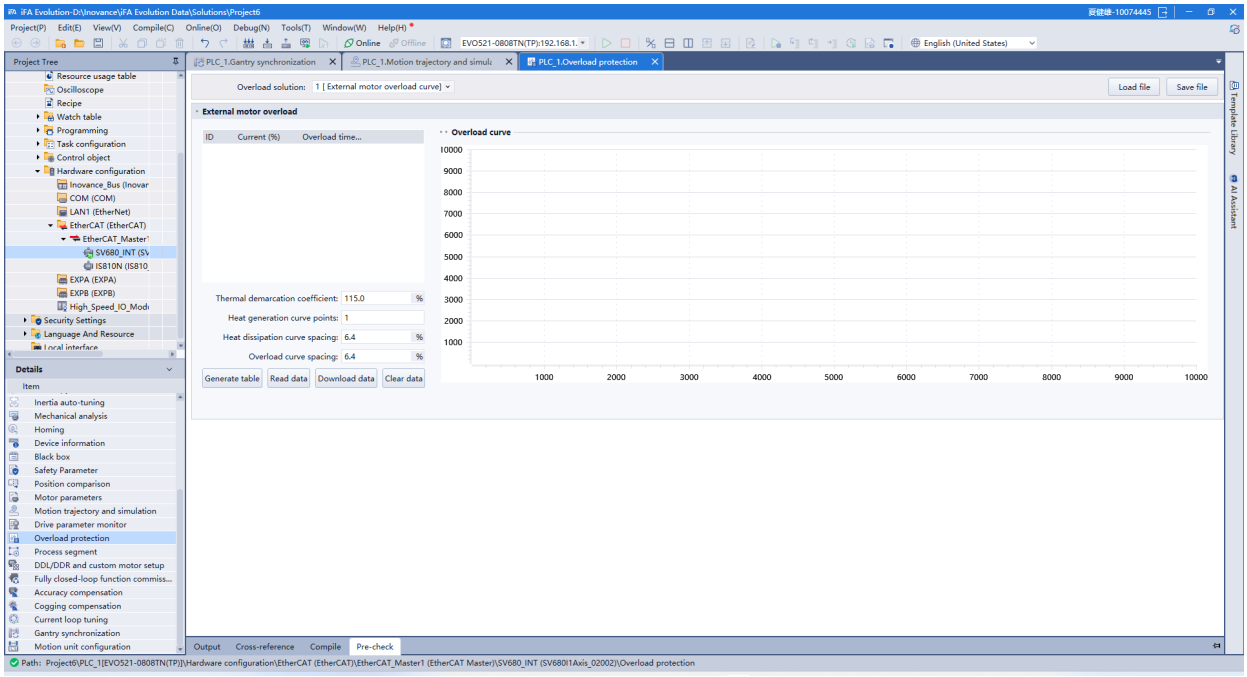
The "Commissioning" tab includes configuration of servo enable switch, process segment run/stop, and process segment monitoring. The interface is as follows:

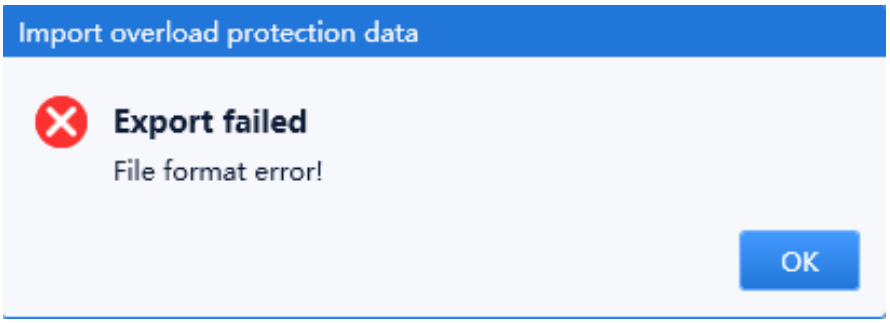
17.3.22 Overload Protection

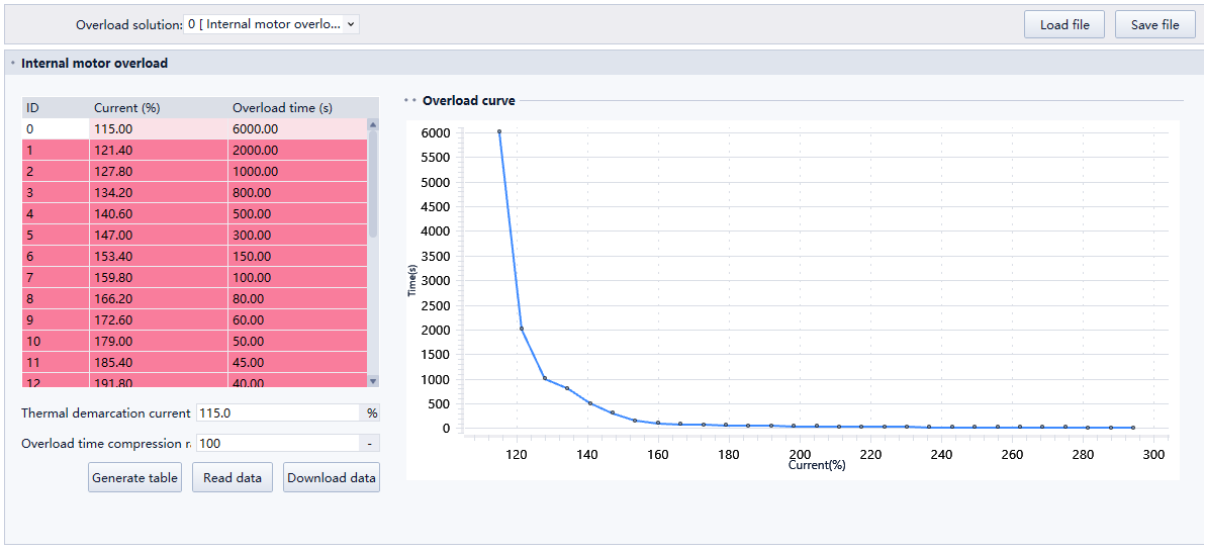
This function is available only for the SV680N-INT, SV670N-INT, and SV680LN series.

Select a servo drive in the project tree, and double-click "Overload protection" in the detailed view to open the interface.

The overload protection interface mainly consists of overload solution selection, sub-interfaces of each solution, file loading, and file saving. The interface is as follows.







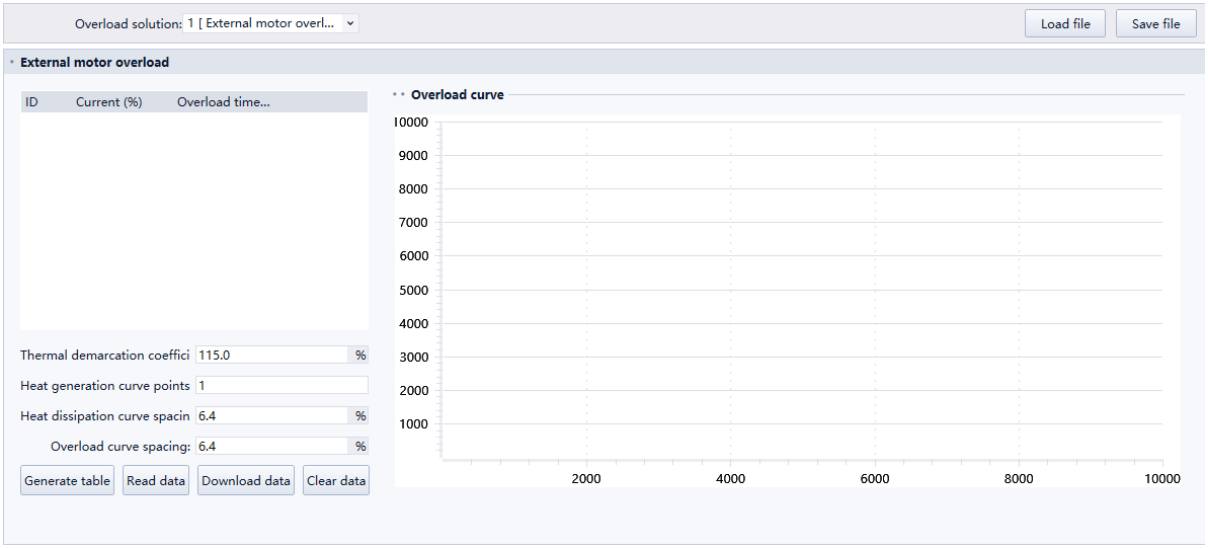


Table17-3-22-1

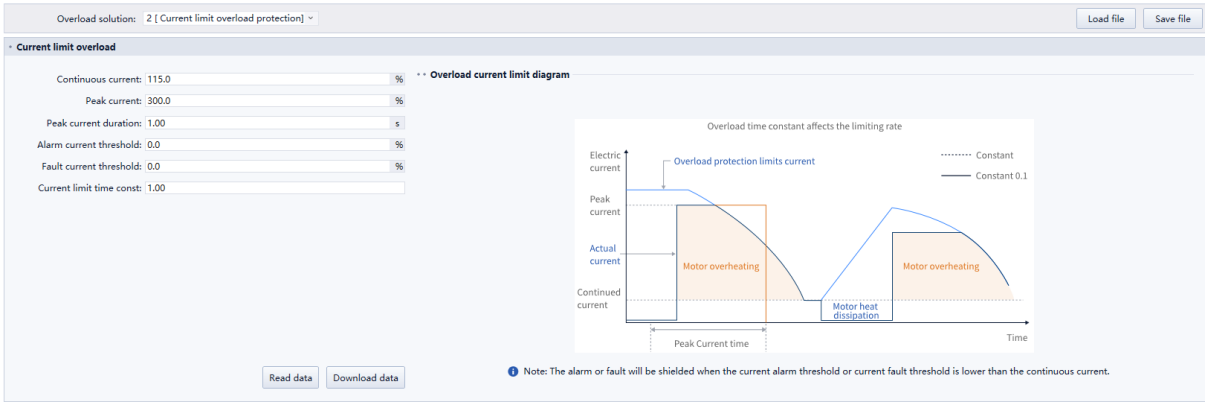
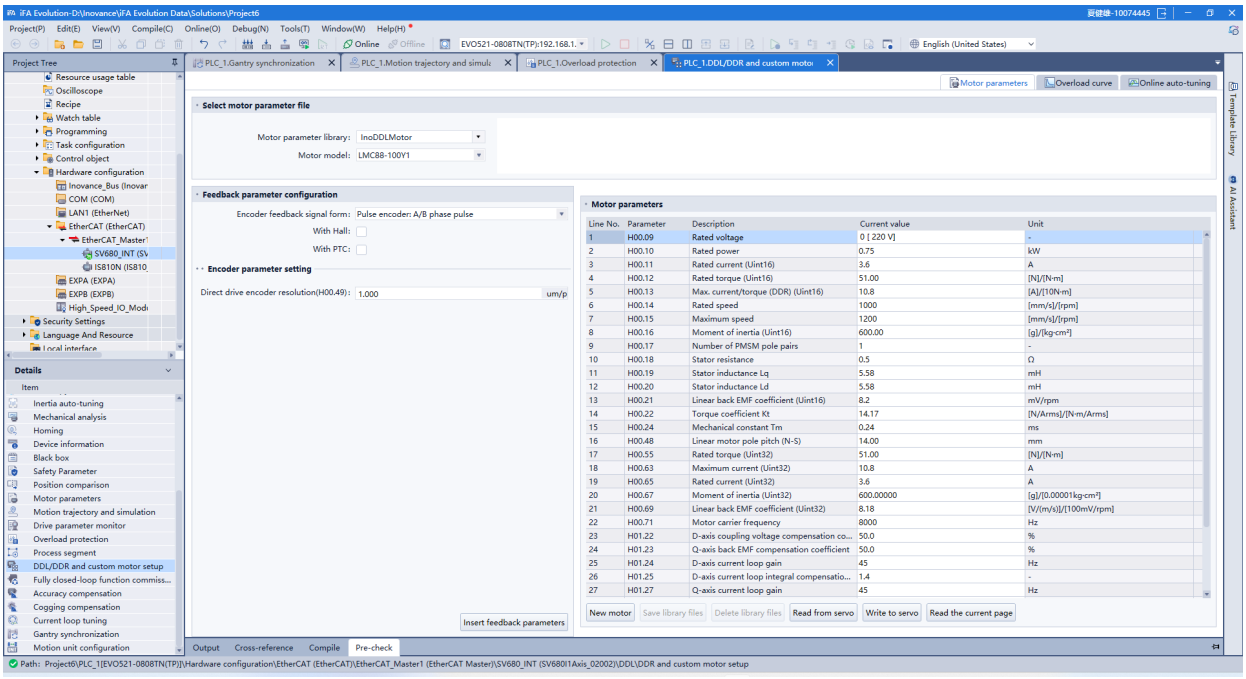
Description	Description
Overload solution	Downloads the solution type to the drive based on the selected solution. According to the selected solution, different solution views are switched.
Load file	Opens the solution saved on the local drive. Only files in the CSV format are supported. When importing overload protection data fails, the following dialog box is displayed. 
Save file	The saved content includes the overload solution type, overload protection data, and related parameters in turn. The file format is CSV.



- The interface for "0 [Internal motor overload curve]" is as follows.

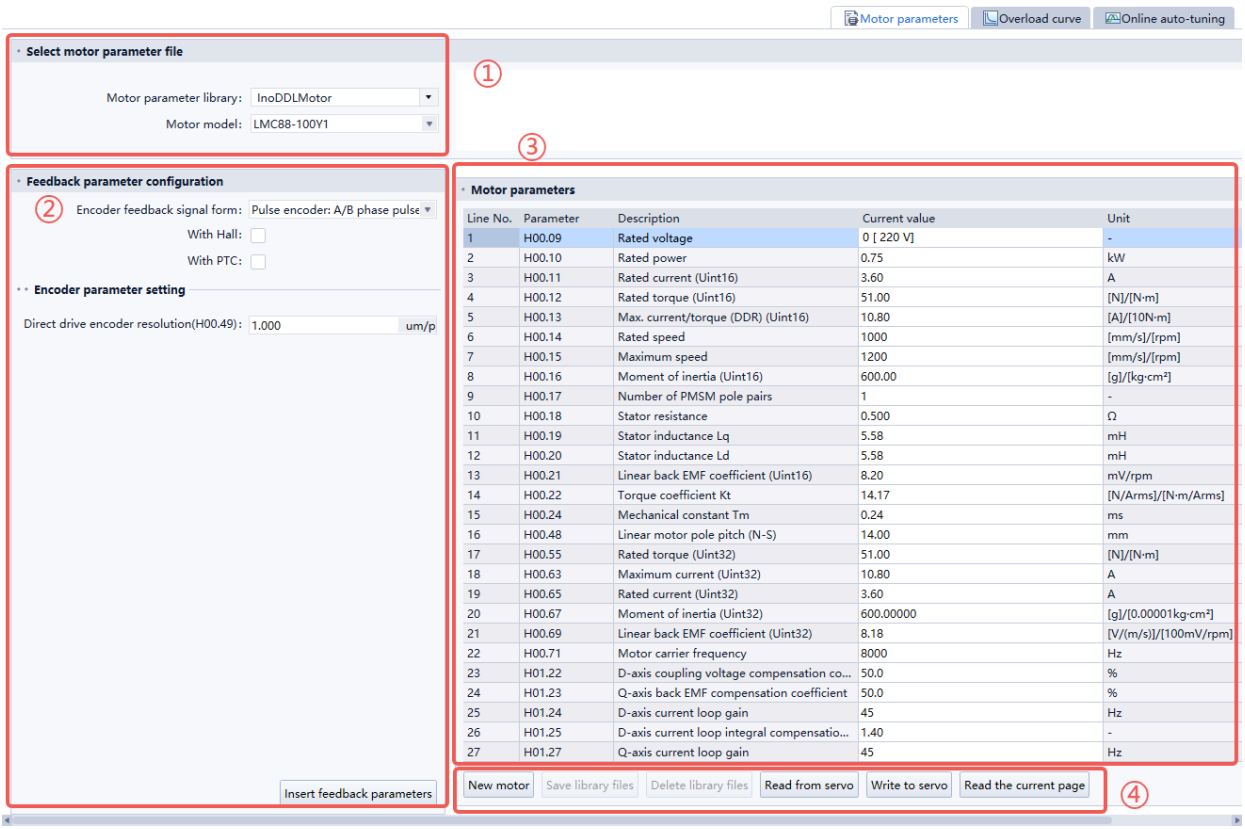
- The interface for "1 [External motor overload curve]" is as follows.

- The interface for "2 [Current limit overload protection]" is as follows.



17.3.23 Motor Management Library

This function is available only to the SV680N-INT, SV670N-INT, and SV680LN series.



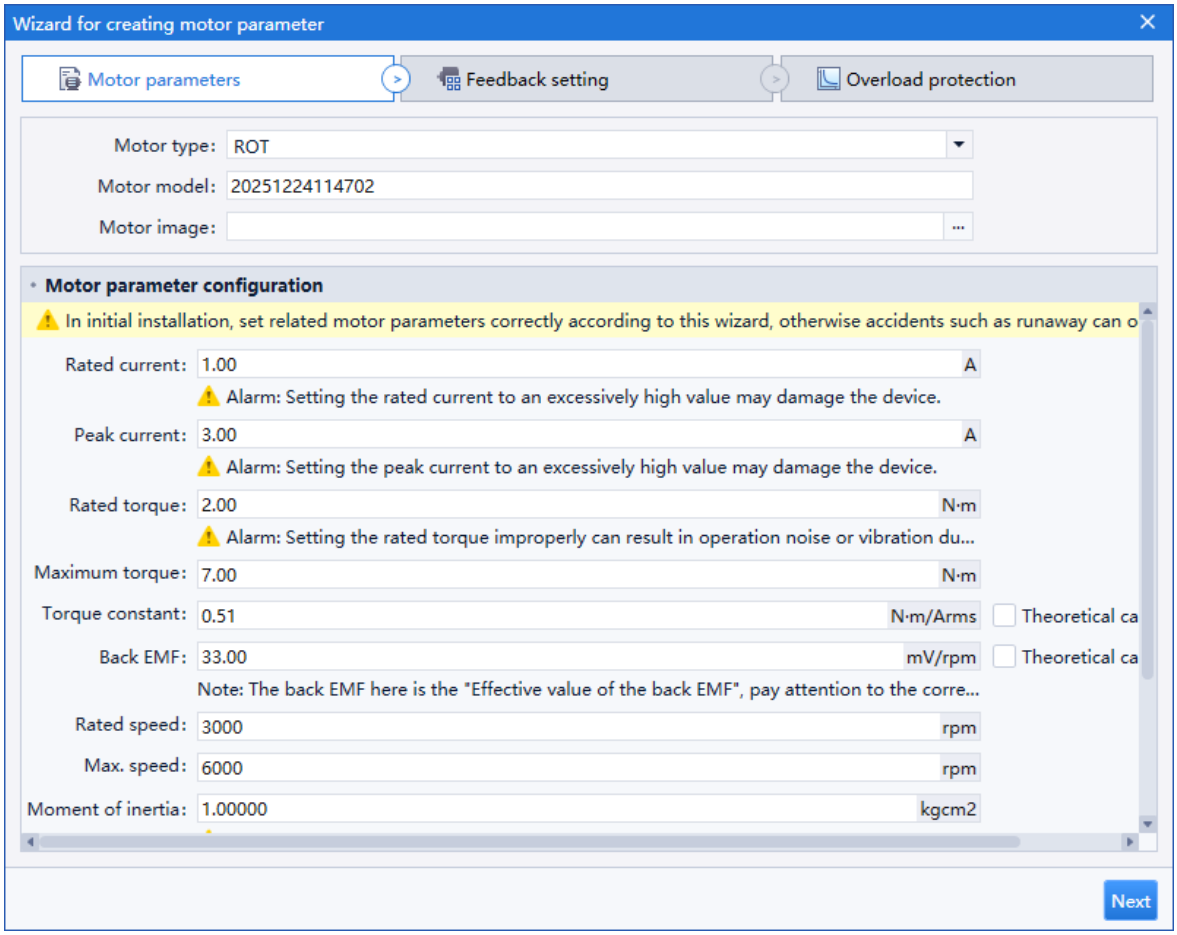
Select a servo drive in the project tree, and double-click "DDL/DDR and custom motor setup" in the detailed view to open the interface.

The interface is mainly composed of "Motor parameters", "Overload curve", and "Online auto-tuning". The interface is as follows.

- **Motor parameters**

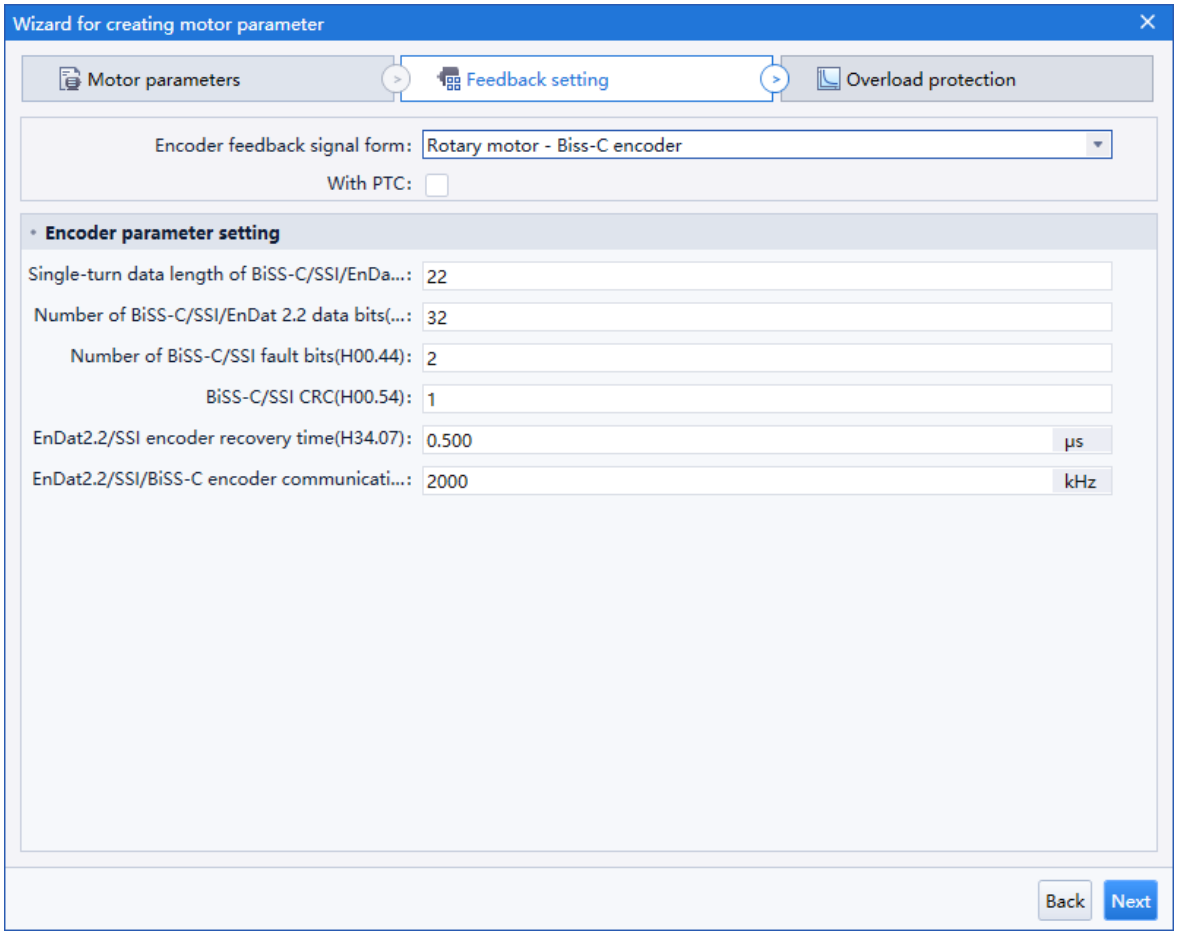
On this tab, select the motor type. You can configure parameters of the corresponding motor type according to the wizard. The supported motor types vary with different devices.

No.	Description	Description
①	Select motor parameter file	Selects the motor parameter library and motor model.



No.	Description		Description
②	Feedback parameter configuration		Include "Encoder feedback signal form" and "Encoder parameter setting". This feature is only available for certain motor models. Click the "Insert feedback parameters" button. The configuration parameters will be synchronized to the "Motor parameters" list on the right.
③	Motor parameters		Configure motor parameters.
④	Function area	New motor	See "New motor".
		Save library files	After selecting the motor parameter file in the main interface, you can adjust the parameters in the parameter list, and then click "Save library files" to add the adjusted motor parameter file to the corresponding motor parameter library. Restrictions: • The motor model name defaults to current motor model + copy and is modifiable. • If the current motor parameter library is UserDDLMotor, UserDDRMotor or UserROTMotor, and there are parameters in the motor parameter list, the button is enabled; otherwise the button is disabled. • Naming rules: ◦ It consists of Latin characters, Chinese characters (including spaces), and must not exceed 50 characters. ◦ It can be composed of letters, numbers, Chinese characters and ~, !, @, #, $, %, ^, &, ( ), _, -, {}. ◦ Single quotes, double quotes, consecutive underscores, ending with an underscore, and starting with double underscores are not allowed. ◦ It cannot start or end with a space. ◦ The following characters are not allowed: \, /, :, *, ?, <, >, |. ◦ Case-sensitive. Half-width and full-width characters are distinguished.
		Delete library files	Deletes the selected motor parameter file from the library. Restrictions: If the current motor parameter library is UserDDLMotor, UserDDRMotor or UserROTMotor, and the current motor model is not empty, the button is enabled; otherwise the button is disabled.

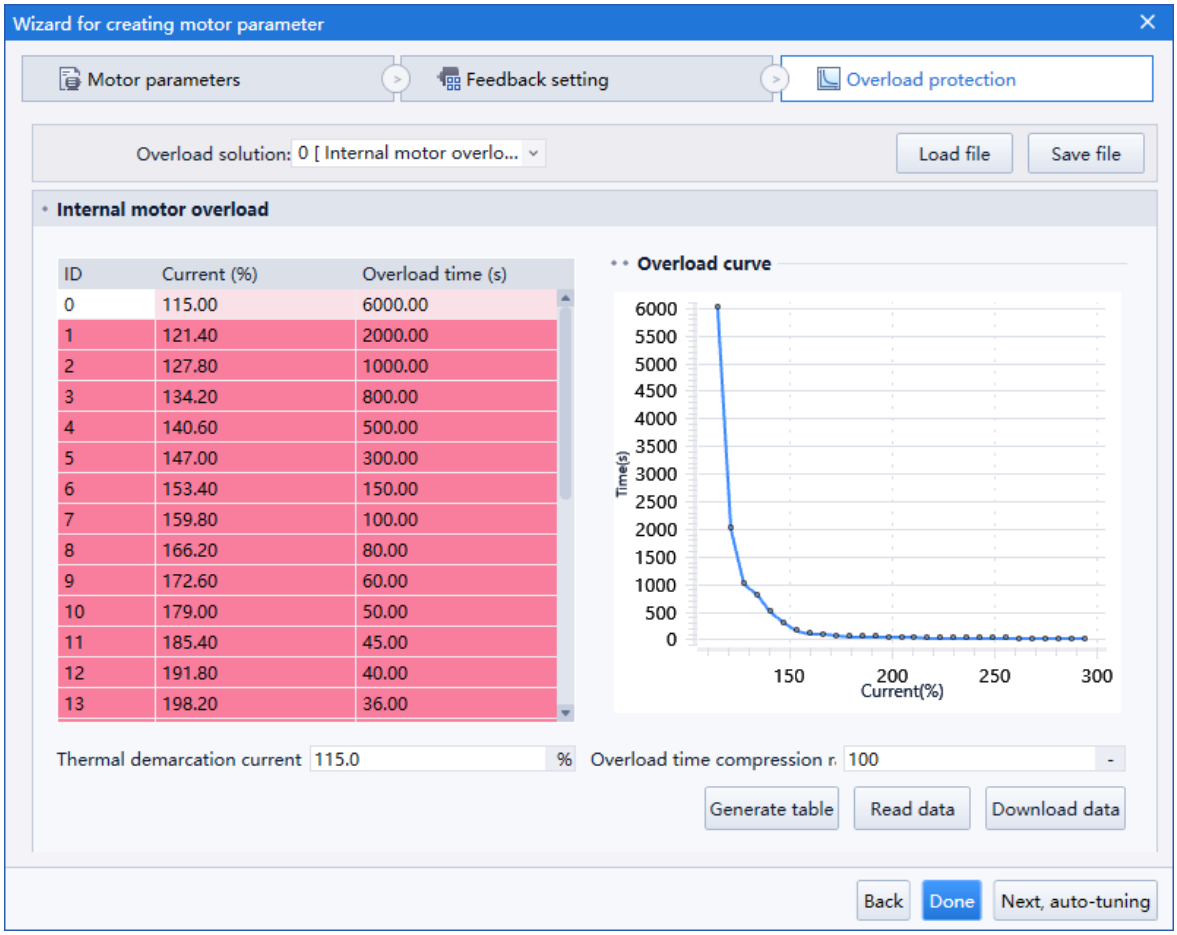
No.	Description		Description
		Read from servo	When the device is connected, click the "Read from servo" button to create a motor parameter file named "yyyyMMddHHmmss" (year, month, day, minute, second) according to the device type, and read the current values of relevant parameters in this motor parameter file from the device. Constraint: Motor parameters and feedback parameters are created based on the current motor type. Their values are read from the device.
		Write to servo	Writes the current parameter values in the current motor parameter file into the servo device. Restrictions: If there are parameters in the motor parameter list, the button is enabled; otherwise, the button is disabled.
		Read the current page	Reads parameter values of the current motor parameter file from the servo device. Restrictions: If there are parameters in the motor parameter list, the button is enabled; otherwise, the button is disabled.



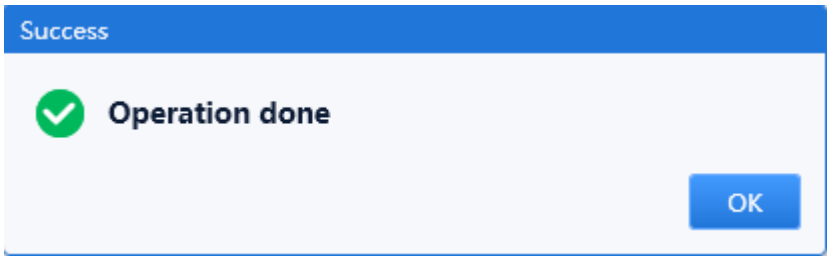
- **New motor**

  Click the "New motor" button in the function area. The "Wizard for creating motor parameter" dialog box pops up. Configure the relevant motor parameters according to the wizard, and save them to the motor parameter library.

1. Configure motor parameters. Set "Motor type", "Motor model", "Motor image", and configure parameters in the "Motor parameter configuration" area.
   In the motor parameter interface, when you select a motor type, the corresponding parameters of the motor type are displayed. Configure the parameters according to the wizard. The supported motor types may vary with different devices.



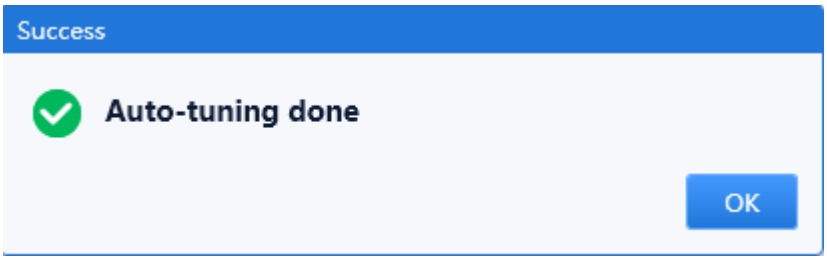
2. Click "Next" to enter the "Feedback setting" interface.
   In the "Feedback setting" interface, the parameter configuration of the encoder is displayed according to the selected encoder feedback signal form. You just need to configure the relevant parameters according to the wizard. The types of encoder feedback signal forms supported by different motor types may differ, and the types of parameters that need to be set among different encoder feedback signal forms also differ.



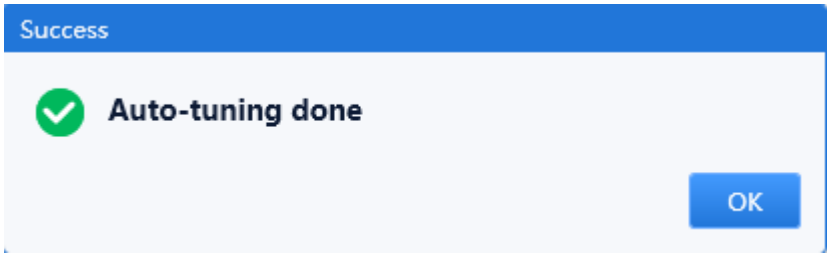
3. Click "Next" to enter the "Overload protection" interface.

   In the "Overload protection" interface, according to the selected overload protection scheme, the parameter configuration of the corresponding overload protection scheme is displayed. You just need to configure the relevant parameters according to the wizard. After the parameter configuration is completed, you can click the "OK" button to save the created parameters to the motor parameter file library.

4. The "Operation done" dialog box is displayed. You can also click "Next, auto-tuning".

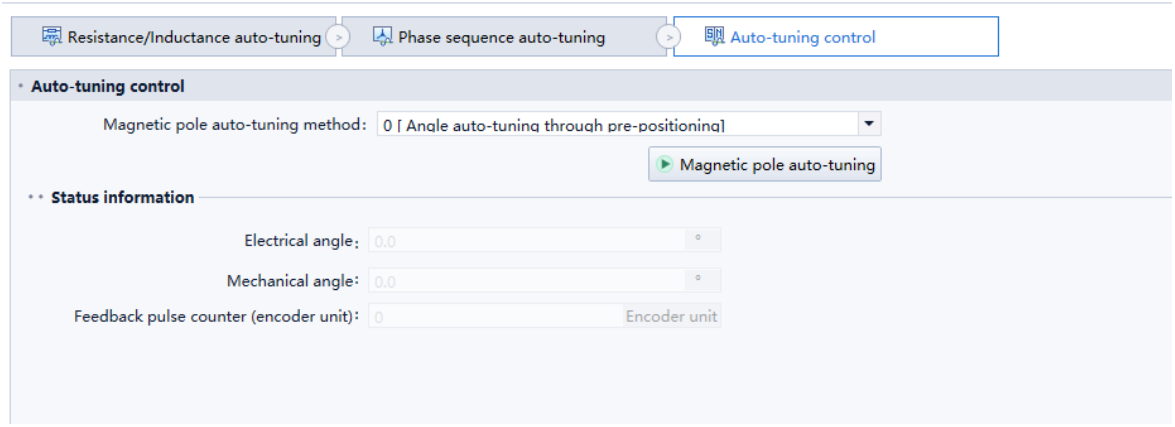


- **Overload curve**

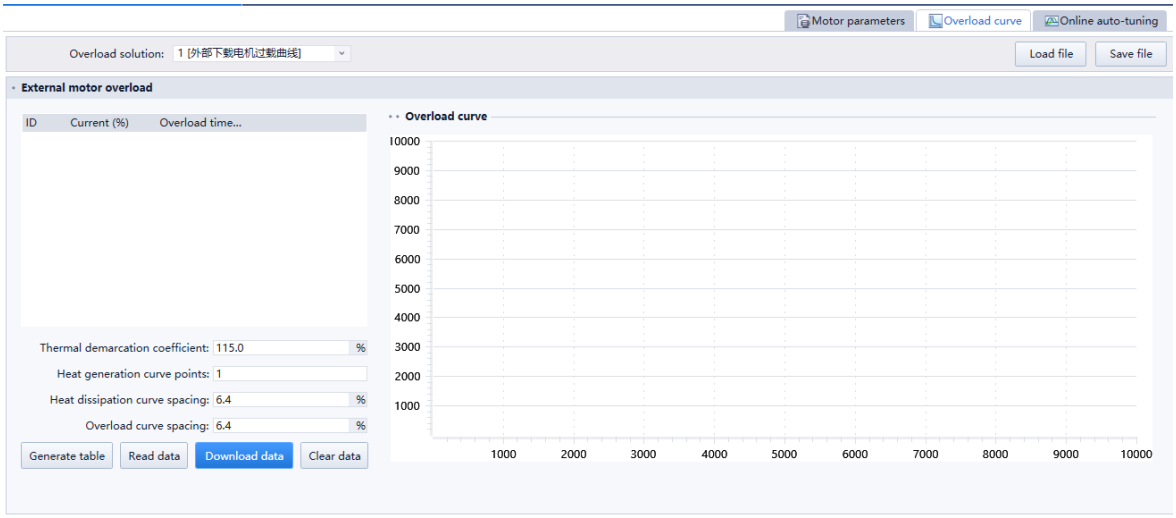


- **Online auto-tuning**

Note: Online auto-tuning is unavailable for the voice coil motor.



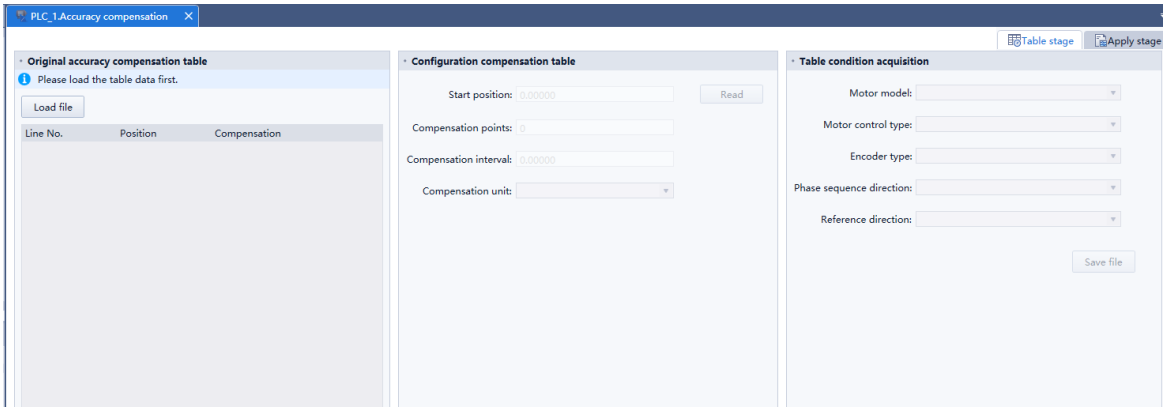
1. Click "Online auto-tuning" to enter the wizard interface. The "Resistance/Inductance auto-tuning" interface is displayed. Click the "Resistance/Inductance auto-tuning" button. After the motor auto-tuning is successful, a dialog box indicating successful auto-tuning appears.



2. Click "Next" to enter the "Phase sequence auto-tuning" interface. Click the "UVW phase sequence auto-tuning" button. After the auto-tuning is successful, a dialog box indicating successful auto-tuning and effective after power-off appears.

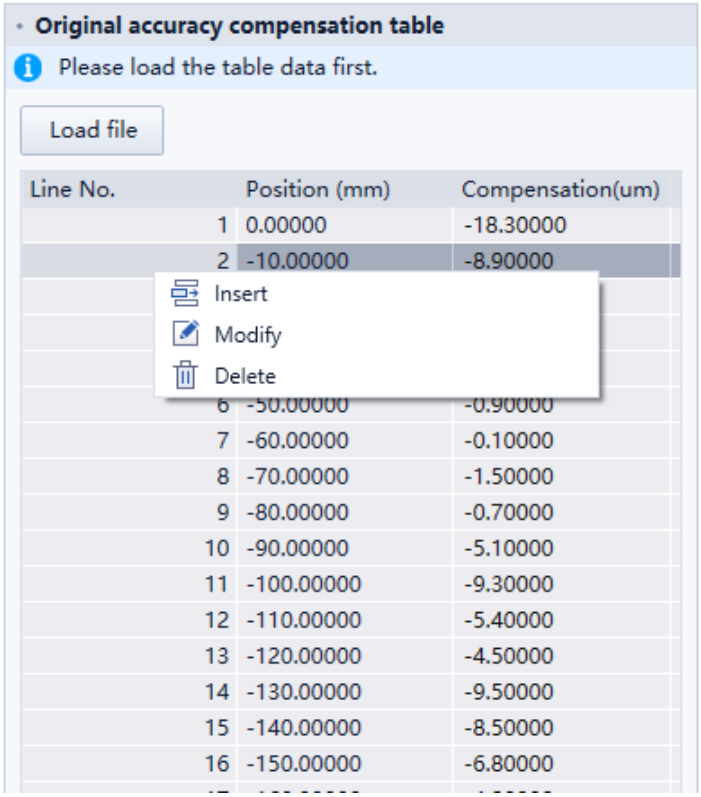
3. Click "Next" to enter the "Auto-tuning control" interface.
   Note: Hall auto-tuning is required at initial installation if the device is equipped with one. The interface is as follows.

4. Click "Hall auto-tuning" to enter the interface. During the auto-tuning process, you can view that the status information data changes. If a dialog box indicating auto-tuning failure appears, click "OK" and retry until the auto-tuning is successful.



17.3.24 Accuracy Compensation

This function is available only for the SV680N-INT, SV670N-INT, and SV680LN series.

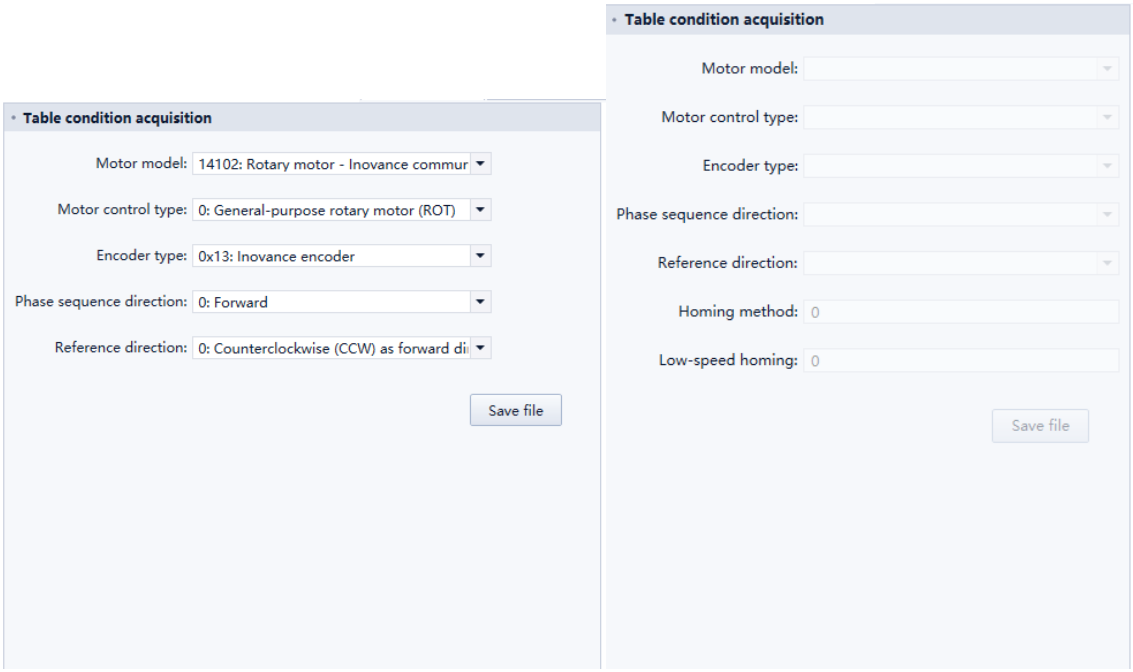


Select a servo device in the project tree, and double-click "Accuracy compensation" in the detailed view to open the interface. The interface contains the "Table stage" and "Apply stage" tabs.

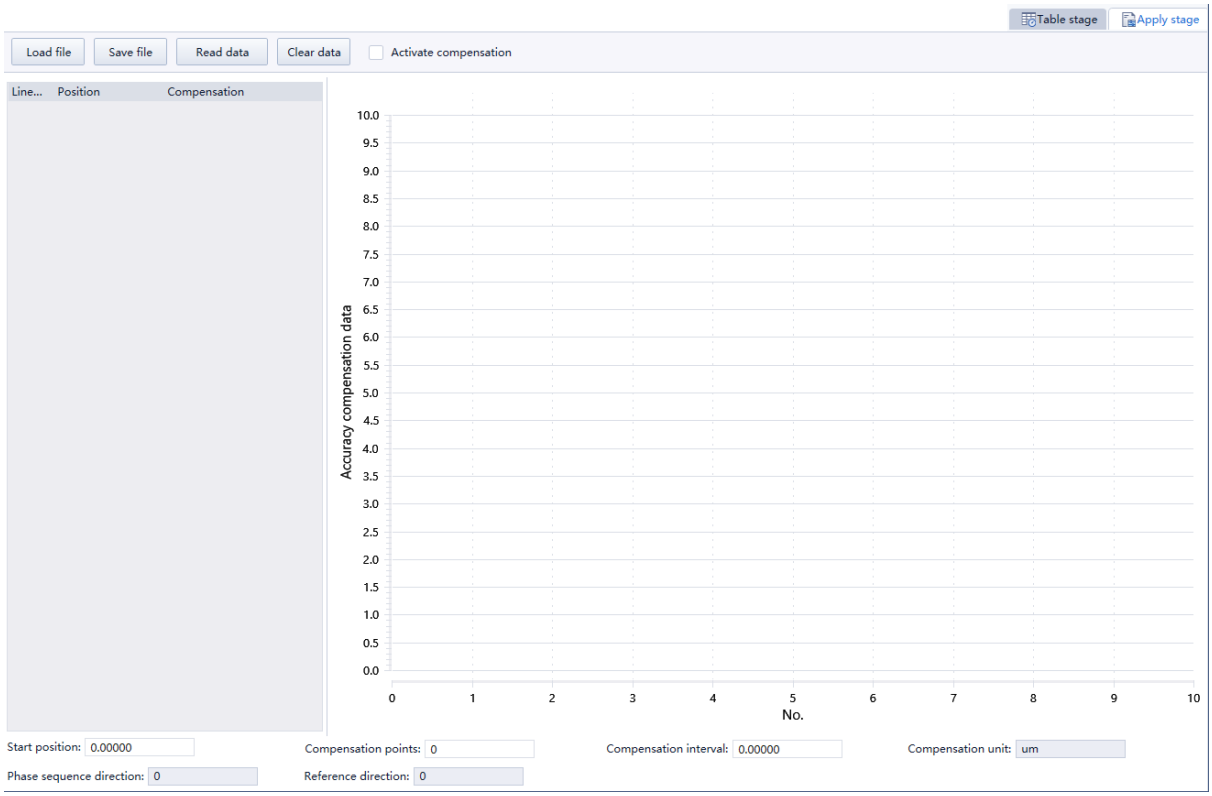
- **Table stage**

  The table stage of accuracy compensation mainly consists of three steps: loading the original accuracy compensation table, configuring the compensation table and obtaining the table conditions. The interface is as follows.

1. Load the original accuracy compensation table.
   Load the file. Only RTL and RTA files are currently supported. After selecting the corresponding file, all point information will be displayed in the table. You can right-click the data and select "Insert", "Modify", or "Delete" to edit the data.



2. Configure the compensation table.
   After the data is successfully imported, relevant configuration information will be automatically generated based on the table data. It mainly includes start position, number of compensation points, compensation interval and compensation unit. The compensation unit is determined by the current motor control type (H00.40). When the value of H00.40 is 0 or 1, the unit is arcsec/mrad; otherwise, the unit is um/mm. When the value of encoder selection (H00.30) is 0x10, 0x12, 0x13, or 0x17, a "Read" button will be displayed below "Start position". Clicking the "Read" button will display the single turn position feedback value of the absolute encoder (H0B.71) in the text box.



3. Obtain the table conditions. This step includes configurations of the following: motor model, motor control type, encoder type, phase sequence direction, and reference direction.
   After data is imported and the device is online, the relevant drive parameters are read and the parameter values in "Table condition acquisition" are updated. Default values are remains when the device is offline.

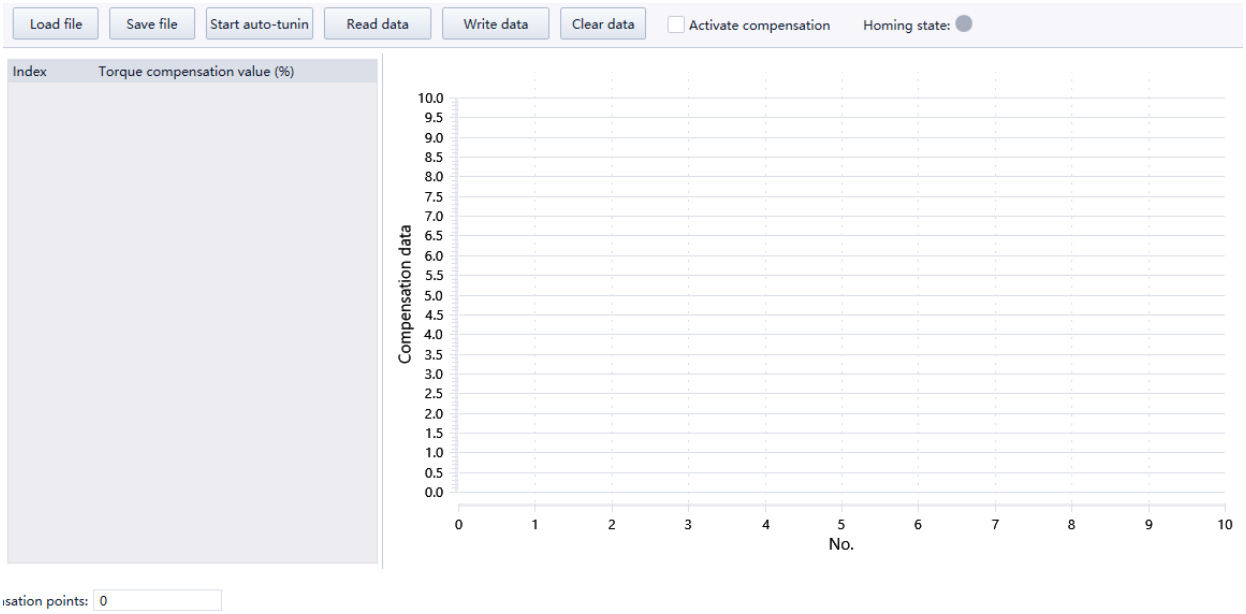
Read the value of the encoder selection (H00.30). If the value equals 0x10, 0x12, 0x13, or 9x17, "Homing method" and "Low-speed homing" are not displayed.
If the device is online, and the encoder type (H00.30) is a specific model, "Homing method" and "Low-speed homing" are displayed.

4. Click the "Save file" button. Save the preprocessed accuracy compensation data in a CSV file. The table stage is completed.

- **Apply stage**
  In this phase, the main functions include loading files, saving files, reading compensation data, clearing data, activating compensation, and forced homing. The function interface is as follows.

See the following table for function descriptions.

Description	Description
Load file	◦ Function: Imports the local accuracy compensation data file. After importing, the corresponding data will be displayed in the table, and the corresponding content will be displayed in the corresponding text box. ◦ Restrictions: The imported file must be of CSV format. If it is an absolute encoder, homing mode and homing low-speed text boxes will not be displayed.
Save file	◦ Function: Saves the data on the current interface locally. ◦ Restrictions: The data is saved to a CSV file.
Read data	◦ Function: Obtains the accuracy compensation data stored in the drive. The read data is updated into the table. ◦ Restrictions: The device must be online. When the device is of the absolute encoder type, the read start position is always 0.
Activate compensation	◦ Function: Downloads the current data to the drive and starts accuracy compensation. ◦ Restrictions: The device must be online. Data must be available on the current interface.
Clear data	◦ Function: Clears the accuracy compensation data saved in the drive. ◦ Restrictions: The device must be online.
Forced homing	◦ Function: Performs forced homing according to the homing configuration in the table stage. ◦ Restrictions: The device must be online.
Homing state	◦ Function: Displays the current homing status.
Table	◦ Function: Draws a line chart of the data in the table on the left.



During file loading, if the file is incorrect, you will be prompted with the following message: The loaded file and the used motor do not match. Check the file first.

The motor model and encoder model are displayed according to the loaded file. When the device is offline and the file is loaded, the motor model and encoder model are also displayed according to the loaded file.

17.3.25 Cogging Compensation

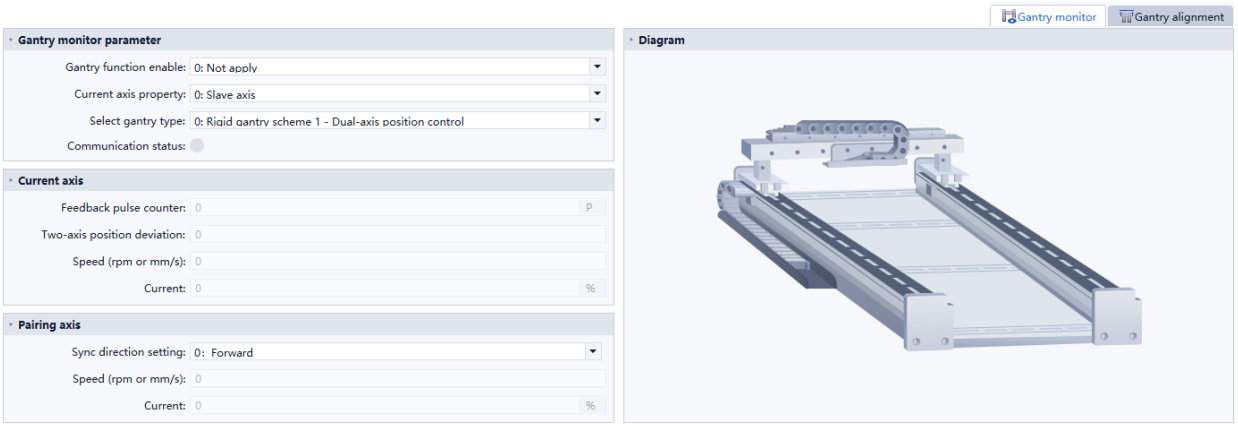
This function is available only for the SV680N-INT, SV670N-INT, and SV680LN series.

Select a servo device in the project tree, and double-click "Cogging compensation" in the detailed view to open the interface. The main functions include loading file, saving file, starting cogging auto-tuning, reading compensation data, writing compensation data, activating compensation, and clearing data. The interface is as follows.

See the following table for function descriptions.

Description	Description
Load file	• Function: Imports the local cogging fluctuation compensation data file. After import, the data will be displayed in the table, and the content will be displayed in the corresponding text box. • Restrictions: The import file format is CSV.
Save file	• Function: Saves the data on the current interface locally. • Restrictions: The file is saved to the CSV format. If it is an absolute encoder, homing mode and homing low-speed text boxes will not be displayed.
Read data	• Function: Obtains the accuracy compensation data stored in the drive. The read data is updated into the table. • Restrictions: The device must be online.
Write data	• Function: Writes the compensation data on the current interface into the drive. • Restrictions: The device must be online. Data must be available on the current interface.
Activate compensation	• Function: Enables cogging fluctuation compensation. • Restrictions: The device must be online.
Clear Data	• Function: Clears the accuracy compensation data saved in the drive. • Restrictions: The device must be online.

Description	Description
Homing state	• Function: Displays the current homing status. • Restrictions: This control is displayed only when the current device is not an absolute encoder type.
Table	• Function: Draws a line chart of the data in the table on the left. You can insert, modify and delete data from the table with the context menu. After the data is changed, the curve on the right side is refreshed synchronously.
Start auto-tuning	• Function: Enables cogging torque fluctuation auto-tuning. After auto-tuning, the current drive compensation data is read automatically. • Restrictions: After cogging auto-tuning is enabled, the device will enter the auto-tuning state and be enabled automatically. At this time, all buttons on the interface are unavailable. When auto-tuning is completed or fails, all button states will become available.
Compensation data count	• Restrictions: For 16-bit data types, the maximum data count is 1024. For 32-bit data types, the maximum data count is 2048.



17.3.26 Gantry Synchronization

This function is available only for SV680N-INT and SV680LN series.

Select a servo device in the project, and double-click "Gantry synchronization" in the detailed view to open the interface. Gantry synchronization mainly includes gantry monitoring and gantry alignment.

- **Gantry monitoring**

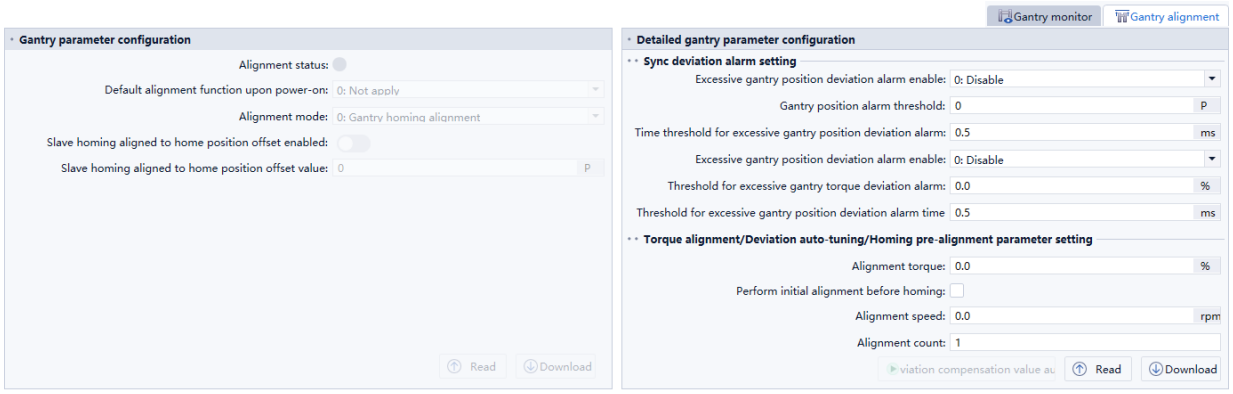
The interface is as follows.

Description	Description	Restriction
Gantry function enable	1. The corresponding address is 0x1402. 2. Initializes the drop-down box and displays the current value. 3. Switches the option to write the value.	You cannot write values in running state.

Description	Description	Restriction
Current axis property	1. The corresponding address is 0x1403. 2. Initializes the drop-down box and displays the current value. 3. Switches the option to write the value.	You cannot write values in running state.
Select gantry type	1. The corresponding address is 0x1404. 2. Initializes the drop-down box and displays the current value. 3. Switches the option to write the value. 4. If a rigid gantry is selected, the gantry alignment tab cannot be configured.	You cannot write values in running state.
Feedback pulse counter	Address: 0x0B11 + axis offset	read-only
Two-axis position deviation	Address: 0x1423 + axis offset	read-only
Speed (current axis)	Address: 0x1428 + axis offset	read-only
Current (current axis)	Address: 0x1426 + axis offset	read-only
Sync direction setting	1. Address: 0x1405 + axis offset 2. Initializes the drop-down box and displays the current value. 3. Switches the option to write the value.	You cannot write values in running state.
Speed (paired axis)	Address: 0x1429 + axis offset	read-only
Current (paired axis)	Address: 0x1427 + axis offset	read-only
Diagram	Displays the scene of gantry synchronization in a three-dimensional diagram.	-
Communication status	1. The status mark is gray by default. 2. Address: 0x1400 + axis offset 3. Cyclic transmit and read. The interval is 300 ms in the early software. 4. If the difference between the value and 1 is 1e-6 (0.000001), the status mark is green; otherwise, it is gray.	-

- **Gantry alignment**

The interface is as follows.



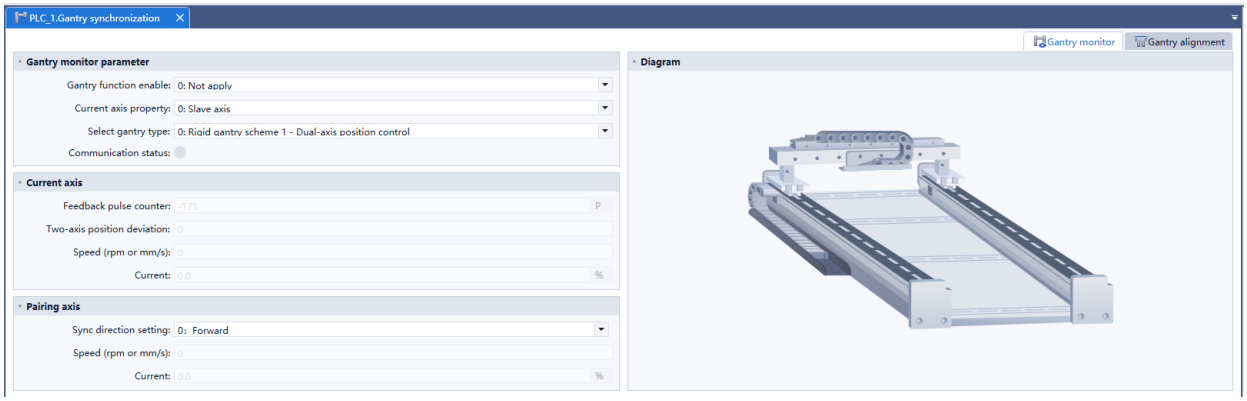


Table17-3-26-1

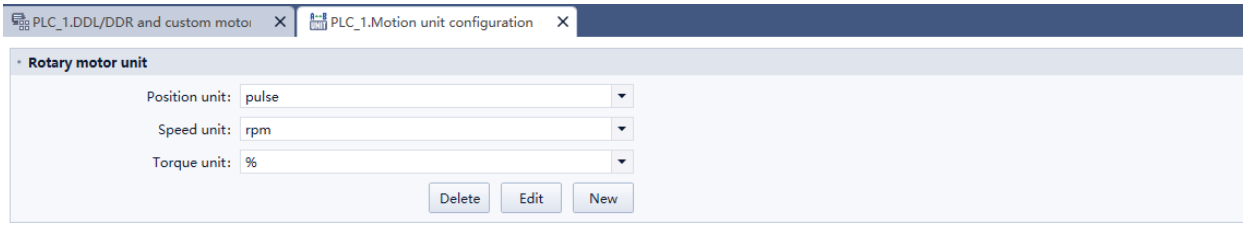
Description	Description	Restriction
Alignment status	Displays alignment status. Address: 0x1401 + axis offset; cyclic transmit and read; interval: 300 ms	-
Default alignment function upon power-on	You can select the alignment mode upon power-on from the drop-down list. The options include "0: No apply" and "1: Aligned by default upon initial power-on of two axes". The parameter address is 0x1414.	Restrictions: You cannot write values in running state.
Alignment mode	You can select the alignment mode from the drop-down list. Options include "0: Gantry homing alignment", "2: Gantry torque alignment", "3: Gantry enable alignment", and "4: Gantry DI alignment". The parameter address is 0x1415.	Restrictions: Value cannot be written while running
Slave homing aligned to home position offset enabled	Address: 0x1447 + axis offset	-
Slave homing aligned to home position offset value	Displays the value of address 0x1448 + axis offset.	-
Read	Click "Read" to read the parameter values corresponding to alignment status, power-on alignment, alignment mode, offset enable and offset value, and refresh the control display.	Restrictions: The function is unavailable when the device is offline.

Description	Description	Restriction
Download	Click "Download" to write parameter values corresponding to alignment state, power-on alignment, alignment mode, offset enable, and offset value.	Restrictions: The function is unavailable when the device is offline. You cannot write values in running state.

- **Pairing axis parameter configuration**

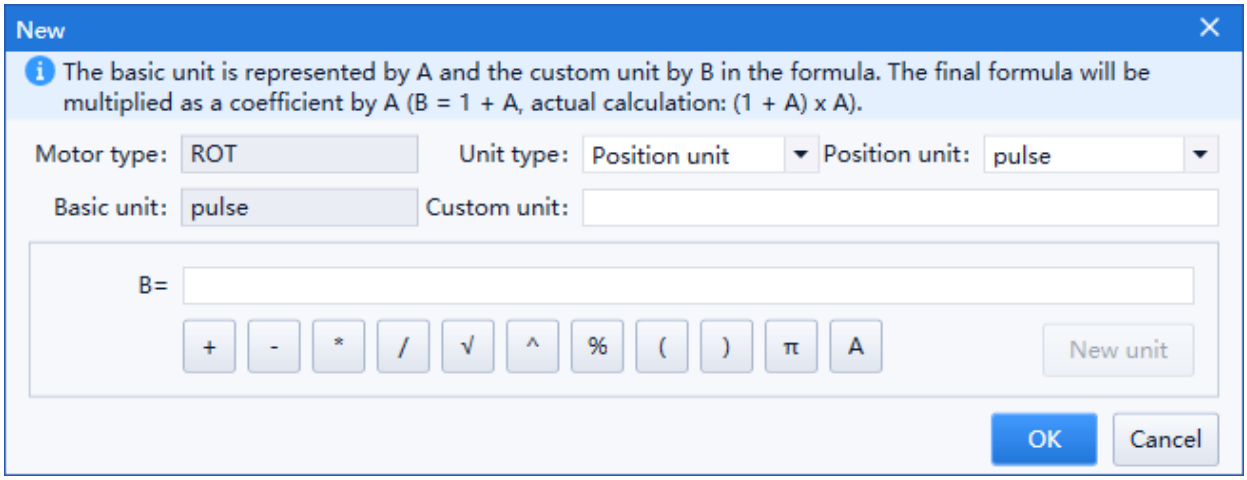
The axis pairing parameter configuration function is available only for SV680LN series.



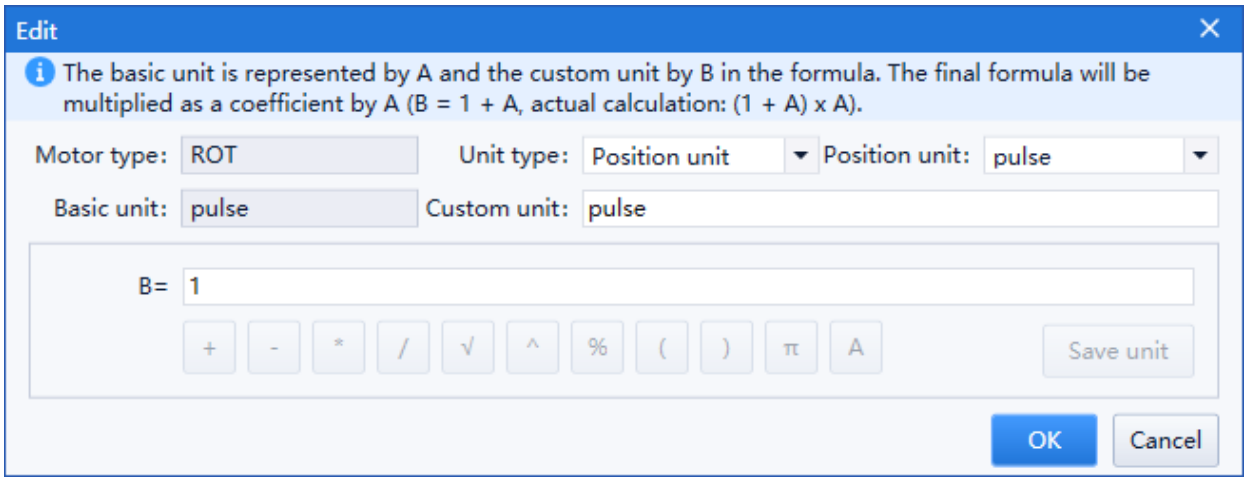
Function	Description
Pairing axis parameter address	• Address: 0x140F + axis offset • Initializes the drop-down box and displays the current value. • Switches the option to write the value.
Pairing axis parameter data	• Address: 0x1410 + axis offset • Reads the address value and initializes the control and range.
Used to enable pairing axis parameters.	• Address: 0x1411 + axis offset • Initializes the drop-down box and displays the current value.
Download	• Function: Writes the value of the axis pairing parameter address, the axis pairing parameter data, and the axis pairing parameter enable setting. • Restrictions: You cannot write values when the device is offline.

17.3.27 Motion Unit Configuration

This function is available only for the SV680N-INT, SV670N-INT, and SV680LN series.



Select a servo drive in the project tree, and double-click "Motion unit configuration" in the detailed view to open the interface. The interface is as follows.



Description	Description
Position unit	• Function: You can select the position unit from the drop-down box. Options for rotary motors include "r", "rad", and "pulse". Options for linear motors include "mm", "um", "pulse", and "pitch". • Restrictions: ◦ If a linear motor (H0040 = 2 or 3) is used, the unit configuration of the linear motor is displayed. If a rotary motor is used (H0040 = 0 or 1), the unit configuration of the rotary motor is displayed. ◦ Linear motor switching coefficient: pulse -> mm = 2 * H0048/H0031, pulse -> um = 2000 * H0048/H0031, pulse -> pitch = 1/H0031. Rotary motor switching coefficient: pulse -> rad = 2 * pi/H0031, pulse -> r = 1/H0031. ◦ After switching units, each module takes effect synchronously.
Speed unit	• Function: You can select the position unit from the drop-down box. Options for rotary motors include "rpm", "r/s", and "rad/s". Options for linear motors include "mm/s" and "rad/s". • Restrictions: ◦ If a linear motor (H0040 = 2 or 3) is used, the unit configuration of the linear motor is displayed. If a rotary motor is used (H0040 = 0 or 1), the unit configuration of the rotary motor is displayed. ◦ Linear motor conversion coefficient: mm/s -> um/s = original value * 1000; mm/s -> pulse/s = original value * H0031 / (2 * H0048); mm/s -> rad/s = original value * pi / H0048. Rotary motor conversion coefficient: rpm -> r/s = 1/60; rpm -> rad/s = 2 * pi / 60. ◦ After switching units, each module takes effect synchronously.
Torque unit	• Function: Configure position units via a drop-down list. For rotary motors, the drop-down options include %; for linear motors, the drop-down options include %. • Restrictions: If a linear motor (H0040 = 2 or 3) is used, the unit configuration of the linear motor is displayed. If a rotary motor is used (H0040 = 0 or 1), the unit configuration of the rotary motor is displayed.
Custom unit	• Function: Supports creating, modifying, and deleting custom units and their corresponding conversion formulas. • Restrictions: /

Click the "New" or "Edit" button to enter the following editing interface.

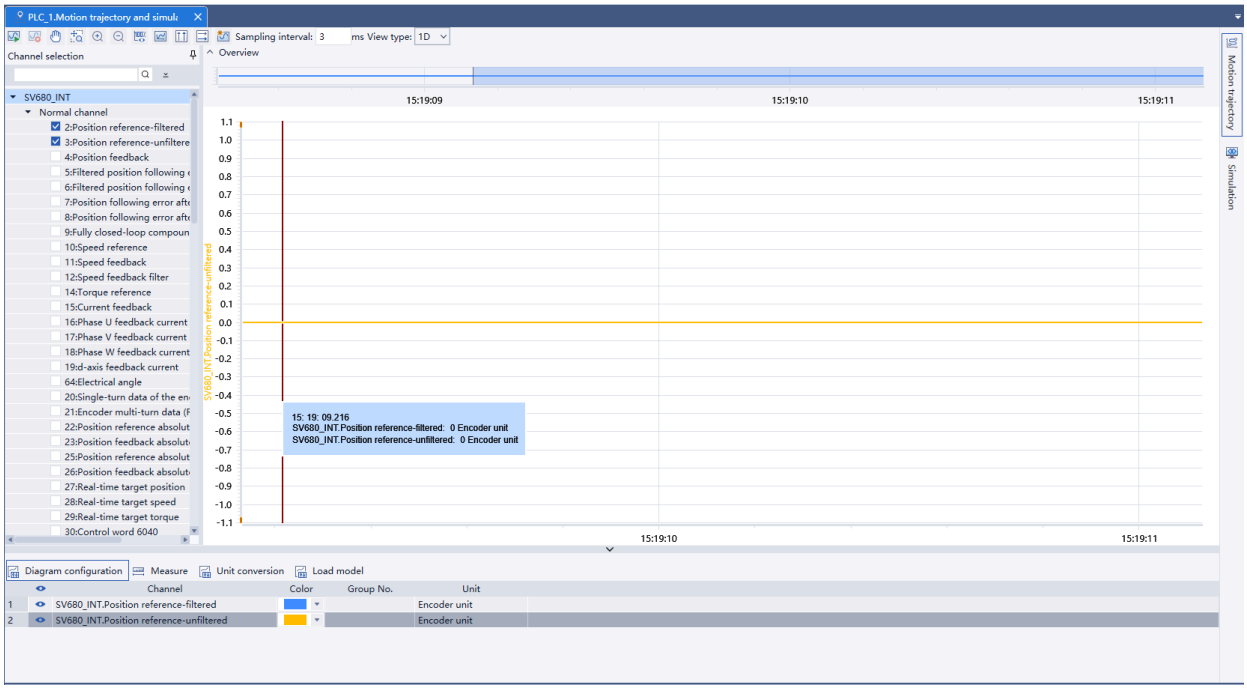
17.3.28 Motion Trajectory and Simulation

This function is currently not supported for the IS650N, SVD630ND, SV660ND, SV680LN, STD60N, and SV670LN series products.

Select a servo drive in the project tree, and double-click "Motion trajectory and simulation" in the detailed view to open the interface.

The motion trajectory and simulation function mainly consists of two parts: "Motion trajectory" and "Simulation".



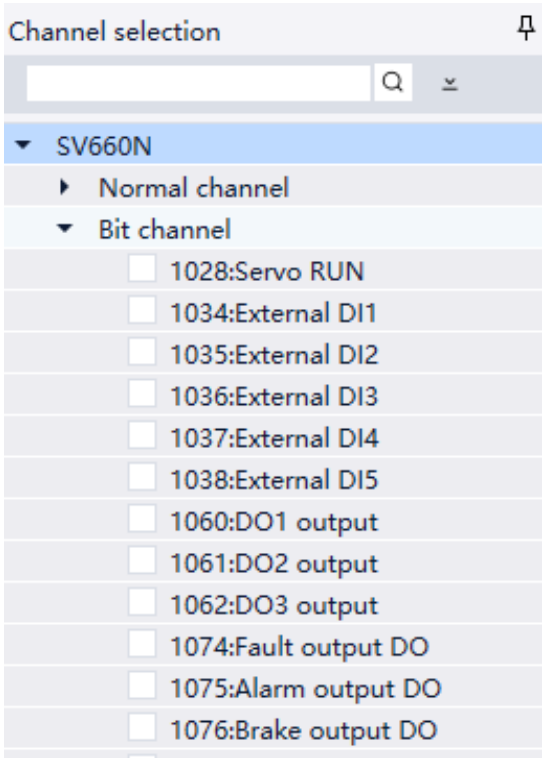
Motion trajectory: Obtains position references and position feedbacks from drive devices via EtherNet-PLC/EoE communication, and plots them as 1D, 2D, 3D, and circular curves. It also provides tools for curve analysis.

Simulation: Supports both file-based and reference-based data sources. It generates simulation curves by incorporating load parameters and drive parameters.

17.3.28.1 Motion Trajectory

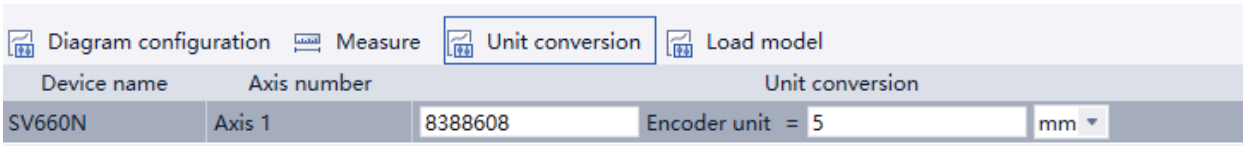
- **Function interface**

  Select a servo device in the project tree, and double-click "Motion trajectory and simulation" in the detailed view to open the interface. On the right side, click the "Motion trajectory" tab. The tab consists of three parts: the toolbar, the curve display area, and the tabs for diagram configuration, unit conversion, load model, and measurement, as shown in the figure below.

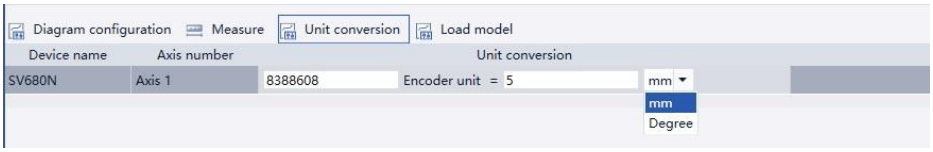


- **Basic operating process**

1. Select a channel from "Channel selection" and configure channel parameters.
2. Set "Sampling interval" and "View type" in the toolbar.
3. Click the "Start" icon in the toolbar to view the curve and perform analysis.

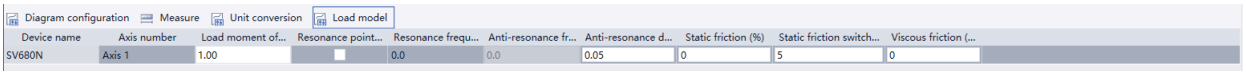


> NOTE
>
> The 1D curve is displayed by default. To view the 2D/3D curve, change the view type to 2D/3D.



- **Channel selection**

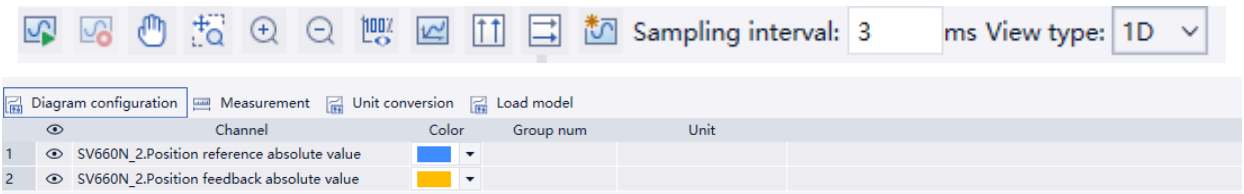
Refer to the following figure for channel selection.



- **Unit conversion**

Function	Description	Restriction
Device name	Displays all device names under the current project.	read-only
Axis number	Displays the axis number of the current device.	read-only
Unit conversion	Used to convert between the encoder unit and the user unit. Options include mm and degree. 	/

- **Load model**



Function	Description	Restriction
Device name	Displays all device names under the current project.	read-only

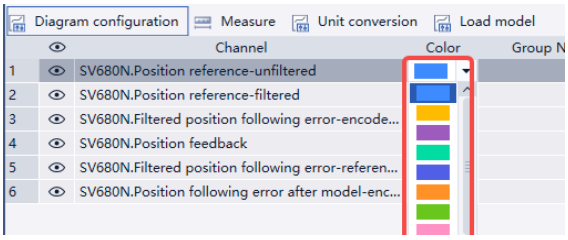
Function	Description	Restriction
Axis Number	Displays the axis number of the current device.	read-only
Load moment of inertia ratio	It sets the ratio of the load inertia against the rotor (of the motor) inertia.	Range: 0.00 to 120.00
Resonance point exists	Sets whether there is any resonance point.	/
Resonance frequency (Hz)	Defines the model resonance frequency.	read-only
Anti-resonance frequency (Hz)	Defines the model anti-resonance frequency.	• This cell is editable only when the corresponding "Resonance point exists" is checked. • Range: 0.0 to 300.0
Anti-resonance damping coefficient	Defines the model anti-resonance damping.	Range: 0.00 to 1.00
Static friction (%)	Defines the static friction of the model.	Range: 0 to 100
Static friction switchover speed (rpm)	Defines the static friction switchover speed of the model.	Range: 0 to 3000
Viscous friction (%/100)	Defines the viscous friction of the model.	Range: 0 to 100

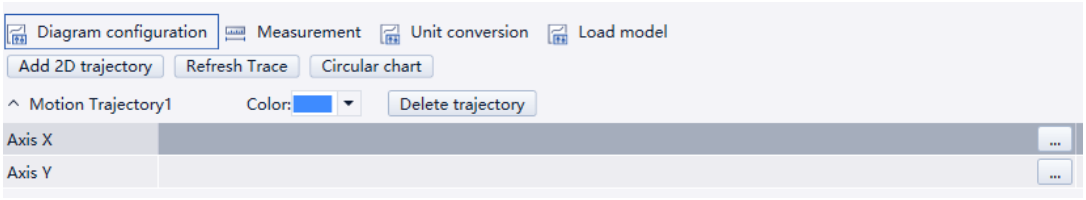
- **Diagram configuration**

  The view type of the "Diagram configuration" tab is set by the view type in the toolbar, with options 1D, 2D, and 3D. The 1D curve is automatically added after acquired by the channel.

Diagram configuration (1D)

Function	Description	Restriction
Display/hide	Displays the current curve.	/
	Hides the current curve.	/
Channel	Displays channel names.	read-only





Function	Description	Restriction
Color	Sets the color of the channel curve. 	/
Group	Used to view channels in groups in multi-channel mode.	Channels without a group number are all in a separate group.
Unit	Displays the unit of the current channel.	read-only

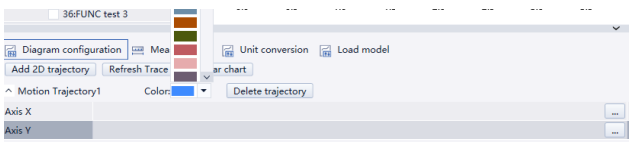


Diagram configuration (2D)

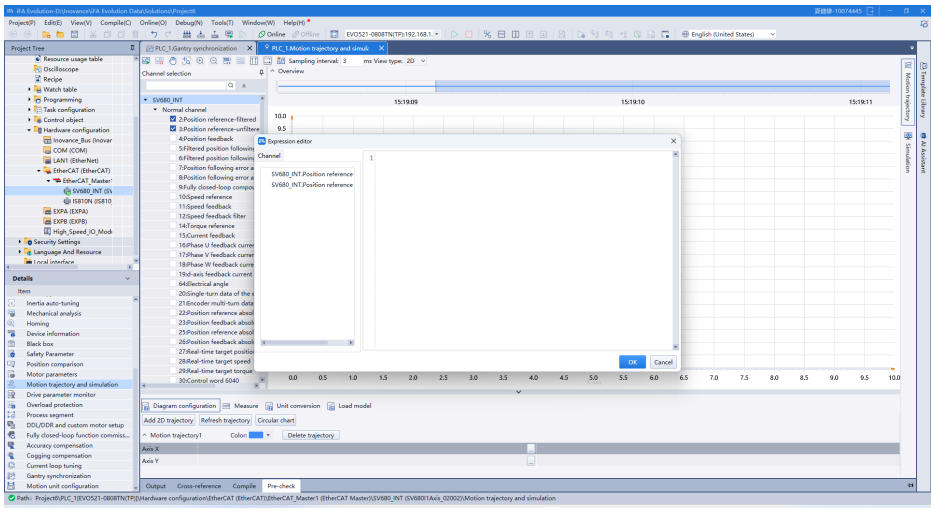
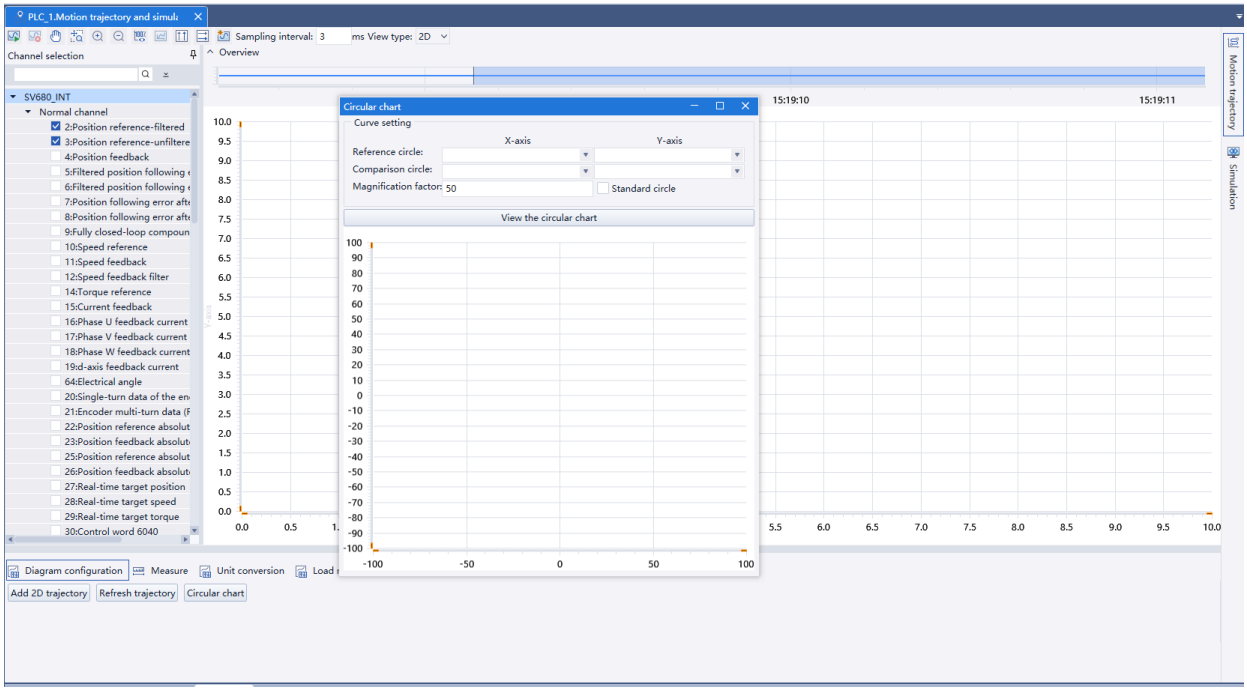


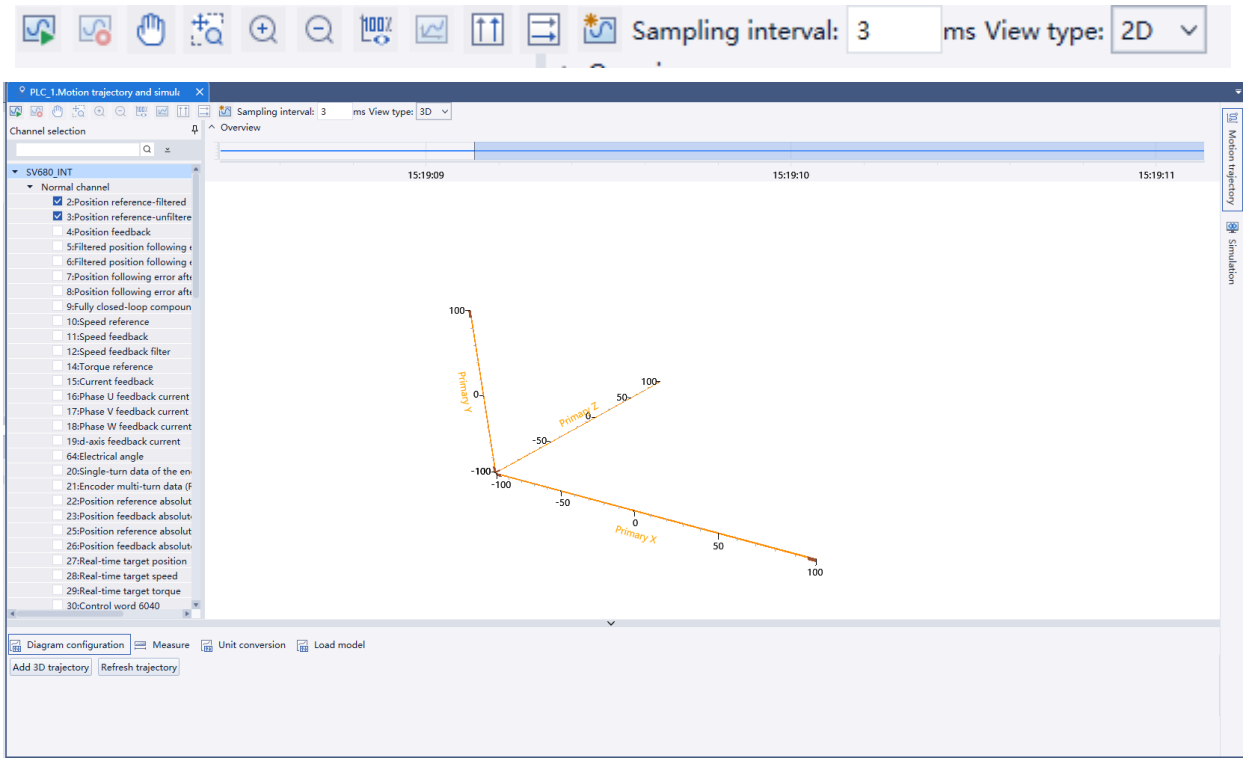
When the view type is 2D, you can view the 2D curve or circular curve on the diagram configuration tab.



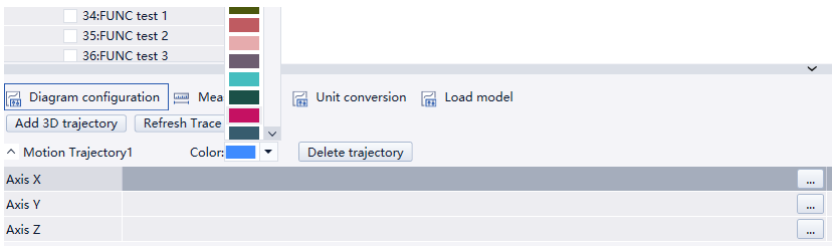
The setting of the 2D curve is as follows.

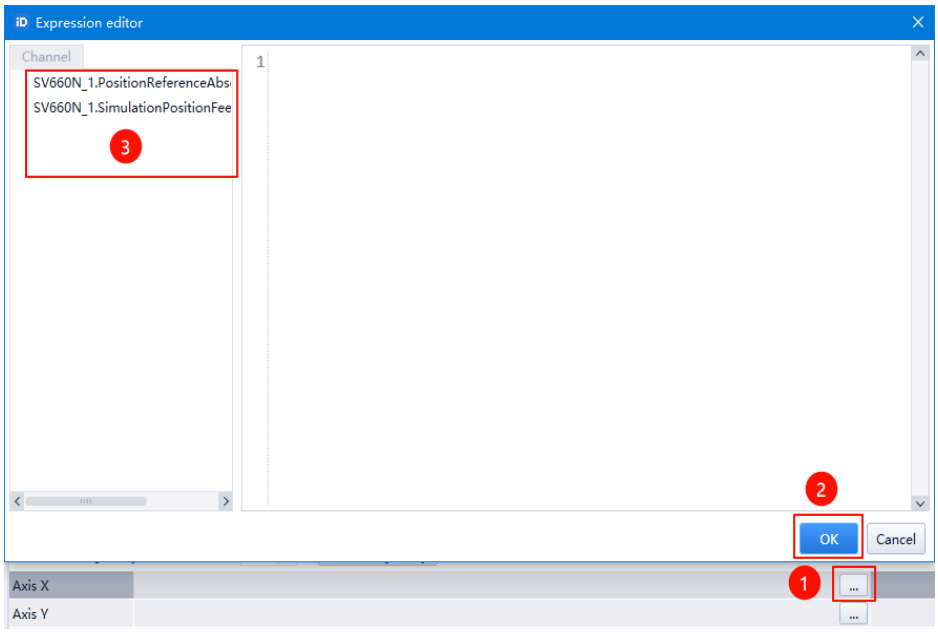
Function	Description	Restriction
Add 2D trajectory	Adds a new 2D trajectory.	/
Refresh trajectory	Refreshes the current trajectory.	/
Trajectory name	Name of the current trajectory. It is automatically generated and cannot be changed, such as motion trajectory 1.	read-only
Color	Sets the color of the channel curve. 	/
Delete trajectory	Deletes the current trajectory.	/

Function	Description	Restriction
Axis X	X-axis selection: Selects channels by dragging to edit the formula. 	/
Axis Y	Y-axis selection: Selects channels by dragging to edit the formula. For the schematic diagram, see the X-axis setting.	/



The setting of the circular chart is as follows.

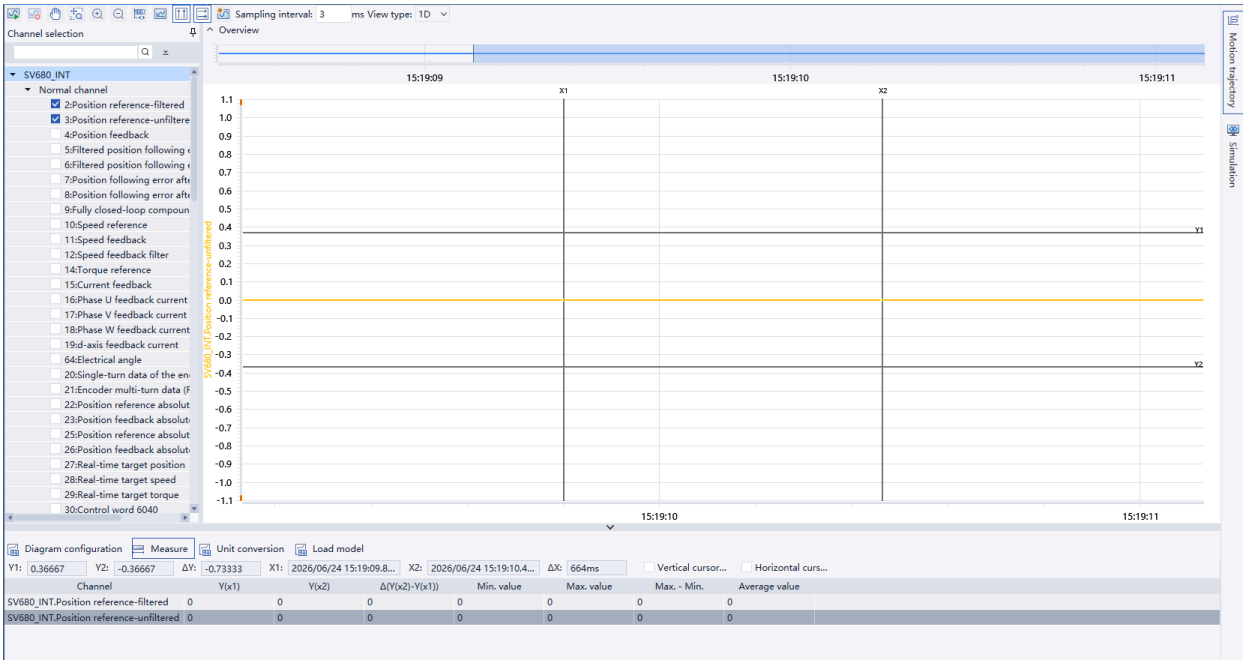




Function		Description	Restriction
Curve setting	Reference circle	Sets the reference circle.	/
	Comparison circle	Used to analyze the error relative to the reference circle.	/
	Magnification factor	Magnification of the error between the comparison circle and reference circle.	/

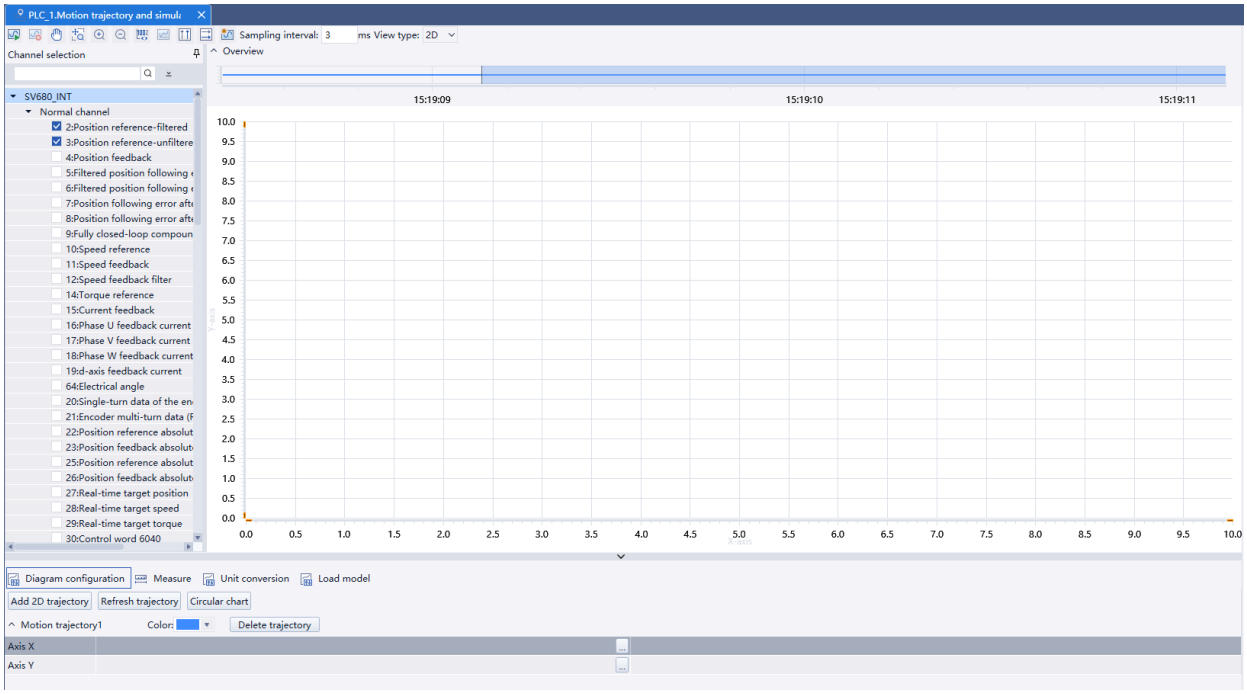
Function		Description	Restriction
	Standard circle	Sets whether the reference circle is used as the standard circle.	/
View the circular chart		Click to generate the circular chart.	/

Diagram configuration (3D)



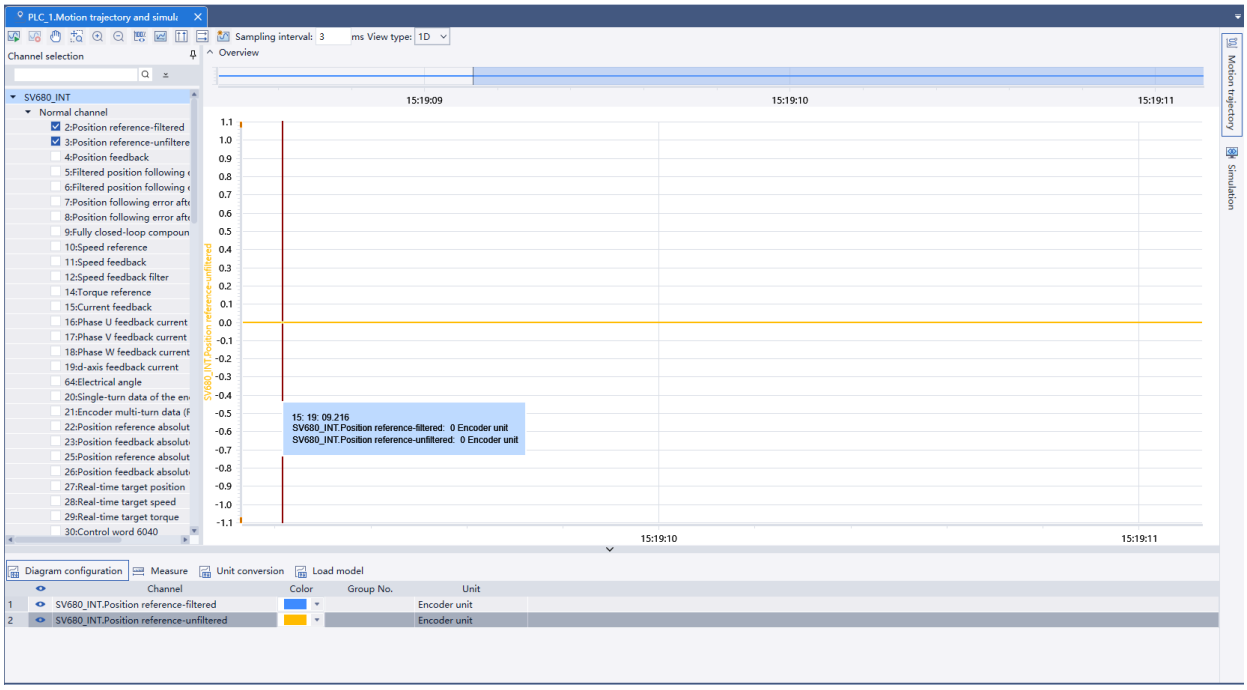
Function	Description	Restriction
Add 3D trajectory	Adds a new 3D trajectory.	/
Refresh trajectory	Refreshes the current trajectory.	/
Trajectory name	Name of the current trajectory. It is automatically generated and cannot be changed, such as motion trajectory 1.	read-only
Color	Sets the color of the channel curve. 	/
Delete trajectory	Deletes the current trajectory.	/

Function	Description	Restriction
Axis X	X-axis selection: Selects channels by dragging the mouse to edit the formula.  Figure 17-3-28-1-1 X-axis settings	/
Axis Y	Y-axis selection: Selects channels by dragging to edit the formula. For the schematic diagram, see the X-axis setting.	/
Axis Z	Z-axis selection: Selects channels by dragging to edit the formula. For the schematic diagram, see X-axis setting.	/



- Measurement

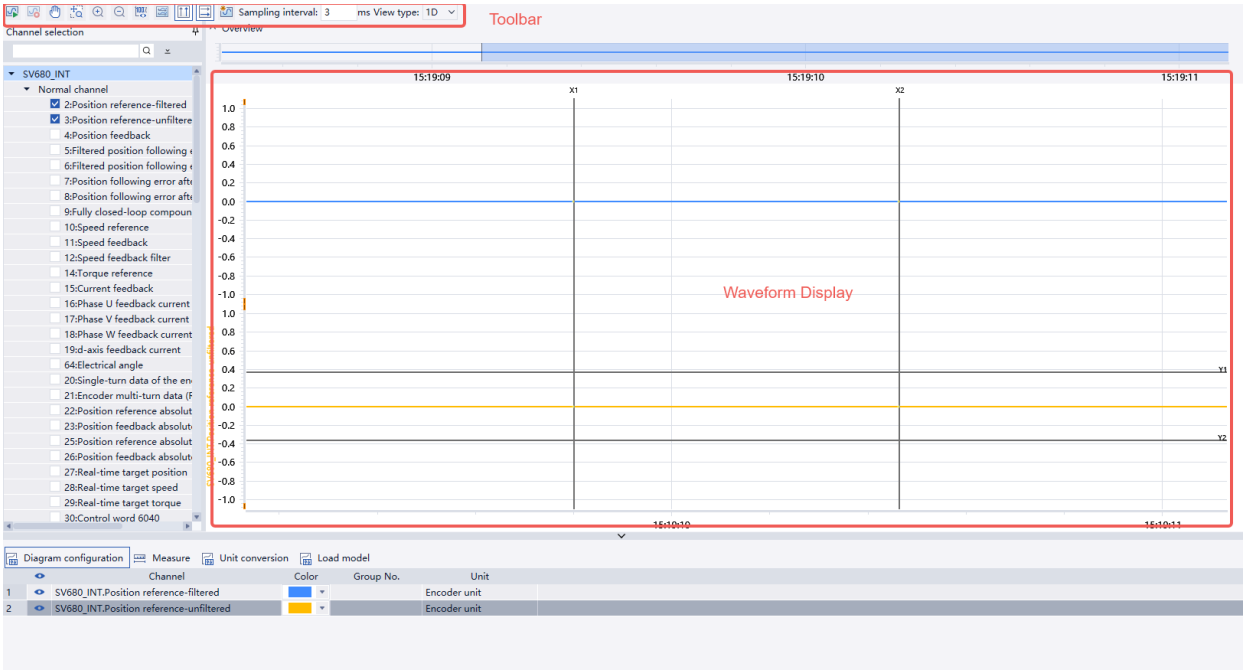
The view type of the "Measure" tab is set by "View type" in the toolbar, with options set to 1D, 2D, and 3D.



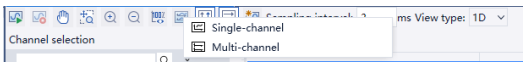
This tab includes X-axis cursor and Y-axis cursor measurement. For details, see the analysis auxiliary function in the oscilloscope section.

Measurement (1D)

Measurement (2D)



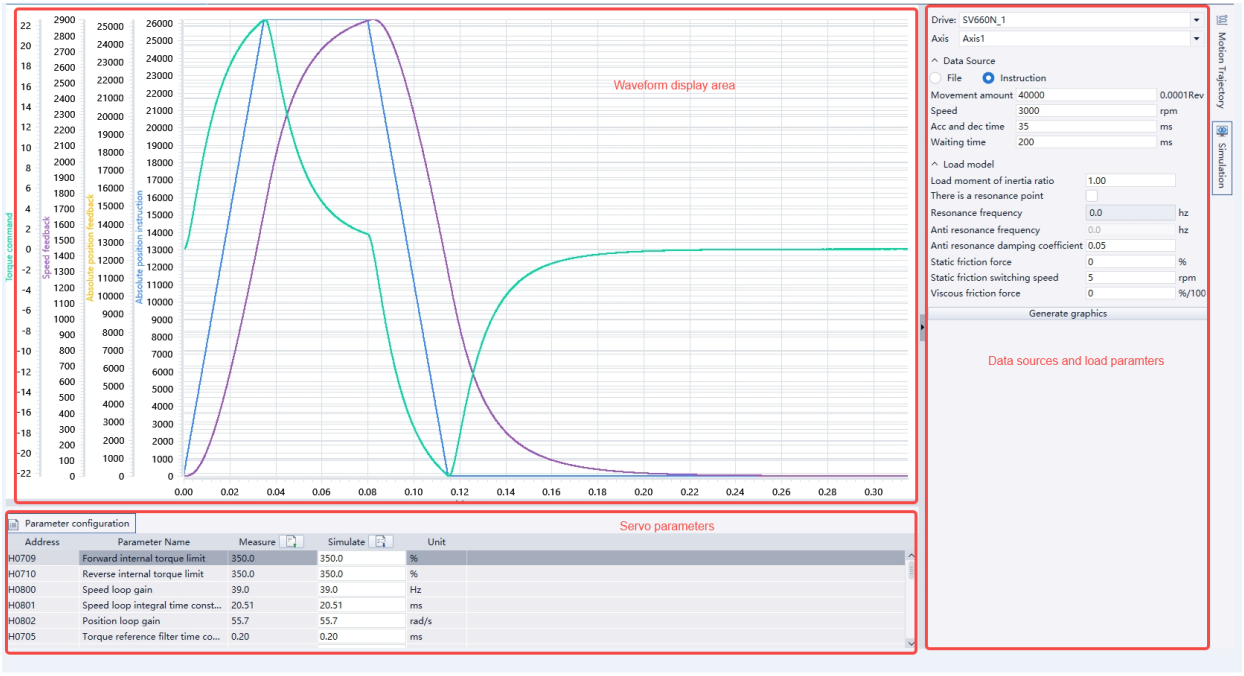
Measurement (3D)



Function	Description	Restriction
Start/Stop measuring	After clicking "Start measuring," the system enters the measurement mode. In the 3D graphic, select two points as "Select point 1" and "Select point 2". After clicking "Stop measuring," the selected points and measurement results are cleared, and the view mode is displayed.	/
Reset	Clears the selected points and measurement results, but the system remains in the measurement mode. You can re-select points 1 and 2 for measurement.	/

- **Curve display**

Plots the sampling results as a curve.



Function		Description	Restriction
	Start	Starts acquiring data and drawing the curve.	• The drive must be online. • When a fault occurs on the parameter configuration interface, this process fails.
	Immediate stop	Stops data acquisition.	/
	Pan	When enabled, you can drag the curve in the view, which is mutually exclusive with the zoom function.	It is disabled by default, selected and enabled at continuous acquisition, and disabled at triggered acquisition.
	Zoom	Zooms in or zooms out the curve. When the function is enabled, you can select a waveform segment from the X axis and Y axis for observation. It is mutually exclusive with the drag function. Drag the mouse from the left to right to zoom in the curve. Drag the mouse from right to left to zoom out.	• Disabled by default. • Unselected but enabled during continuous acquisition. • Unselected and disabled by default during trigger acquisition.
	Zoom +	Zooms in on the entire curve.	It is disabled by default, enabled at continuous acquisition, and disabled at triggered acquisition.
	Zoom -	Zooms out on the entire curve.	It is disabled by default, enabled at continuous acquisition, and disabled at triggered acquisition.

Function		Description	Restriction
	Show all	Displays 100% in the X and Y axis directions.	It is disabled by default, and enabled at continuous acquisition.
	Single-channel/ Multi-channel	Switches between single-channel and multi-channel. Single-channel display is the default type when motion profile is turned on. 	/
	Vertical cursor	Displays a group of cursors (t1, t2) in horizontal direction, and the statistical data of the sampled data between cursor (t1, t2) in the measurement table.	Restrictions: It is disabled upon acquisition and enabled after successful acquisition.
	Horizontal cursor	Displays a group of cursors (Y1, Y2) in vertical direction, and displays the cursor values in the measurement window.	• The Y axis cursor is displayed in the channel where the current viewing signal is located. Switching the current viewing signal also switches the Y axis cursor. • Restrictions: It is disabled upon acquisition and enabled after successful acquisition.
	Export data	Exports the oscilloscope data file (CSV format).	This function is disabled when acquisition starts.
Sampling interval		Sets the sampling interval.	/
View type		Sets the view type (1D/2D/3D).	/

17.3.28.2 Simulation

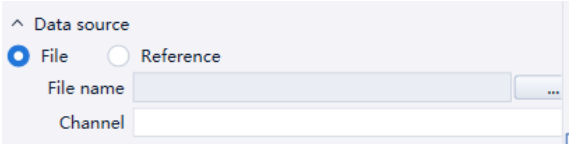
- **Function interface**

  Select a servo device in the project, and double-click "Motion trajectory and simulation" in the detailed view. Select the "Simulation" tab on the right side of the interface, which consists of the following parts: waveform display area, drive parameters, data source, and load model, as shown in the figure below.

- **Basic operating process**

  Configure servo drive parameters > data sources and load parameters > view waveform and analysis.

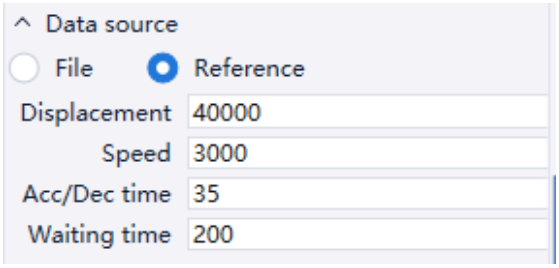
- **Parameter configuration**



Function	Description	Restriction
Address	Parameter code	read-only
Parameter name	Description of the parameter	read-only
Measure	Click  to upload the drive parameters.	read-only
Simulate	Customized parameters are used for simulation. After simulation, click  to download.	/
Unit	Displays the unit of the current parameter.	read-only

- **Data source and load parameter configuration**

1. Select the drive for simulation through the drop-down box.



2. Select the data source, which includes "File" and "Reference".

Data source (file)

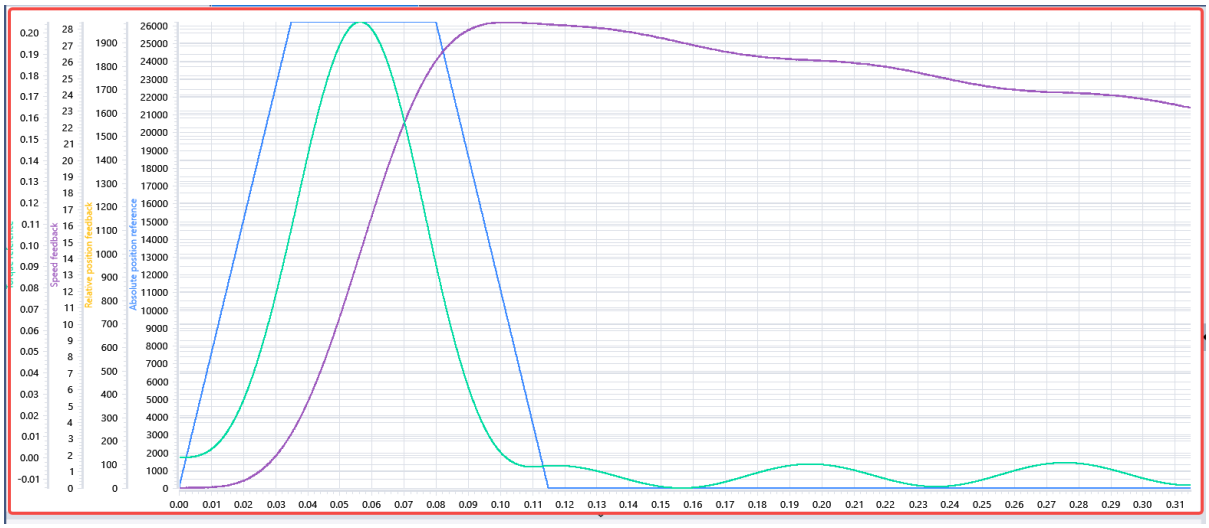
Function	Description	Restriction
File name	Click "..." to upload the data source file.	The file is exported by the "Motion trajectory and simulation" function.
Channel	Select the channel through the drop-down box.	/

Data source (reference)

Function	Description	Restriction
Displacement	Defines the displacement of the reference.	Range: 0 to 65535
Speed	Sets the reference speed.	Range: 1 to 3000
Acc/Dec time	Sets the acceleration/deceleration time of the reference.	Range: 1 to 65535
Waiting time	Defines the waiting time of the reference.	Range: 0 to 65535

3. Sets the load model parameters.

Function	Description	Restriction
Load moment of inertia ratio	It sets the ratio of the load inertia against the rotor (of the motor) inertia.	Range: 0.00 to 120.00
Resonance point exists	Sets whether there is any resonance point.	/
Resonance frequency	Defines the model resonance frequency.	read-only
Anti-resonance frequency	Defines the model anti-resonance frequency.	◦ This is editable only when "Resonance point exists" is checked. ◦ Range: 0.0 to 300.0
Anti-resonance damping coefficient	Defines the model anti-resonance damping.	Range: 0.00 to 1.00
Static friction	Defines the static friction of the model.	Range: 0 to 100

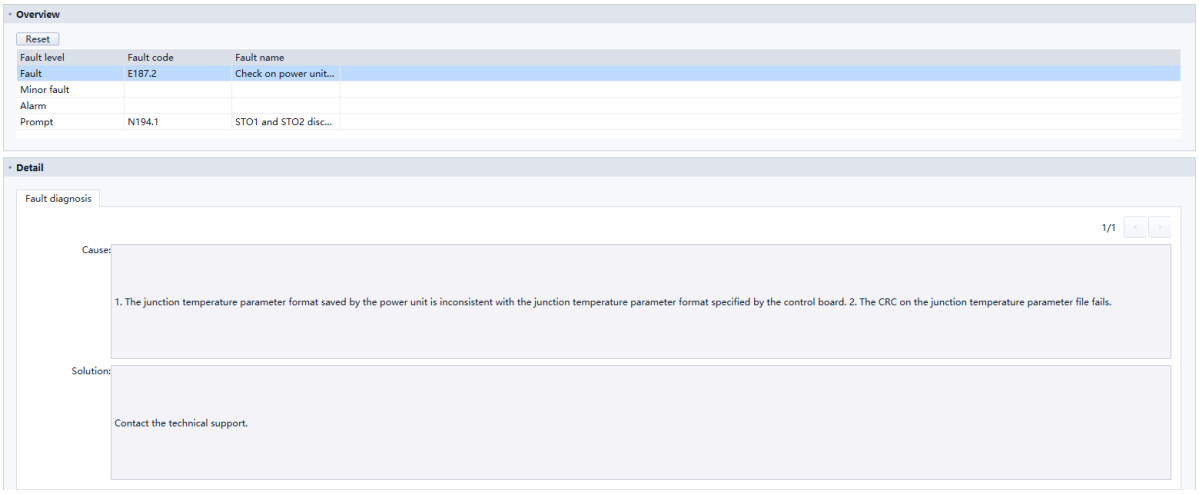


Function	Description	Restriction
Static friction switchover speed	Defines the static friction switchover speed of the model.	Range: 0 to 3000
Viscous friction	Defines the viscous friction of the model.	Range: 0 to 100

4. Click "Generate graphics" to generate the corresponding simulation curve.

- **Waveform display area**

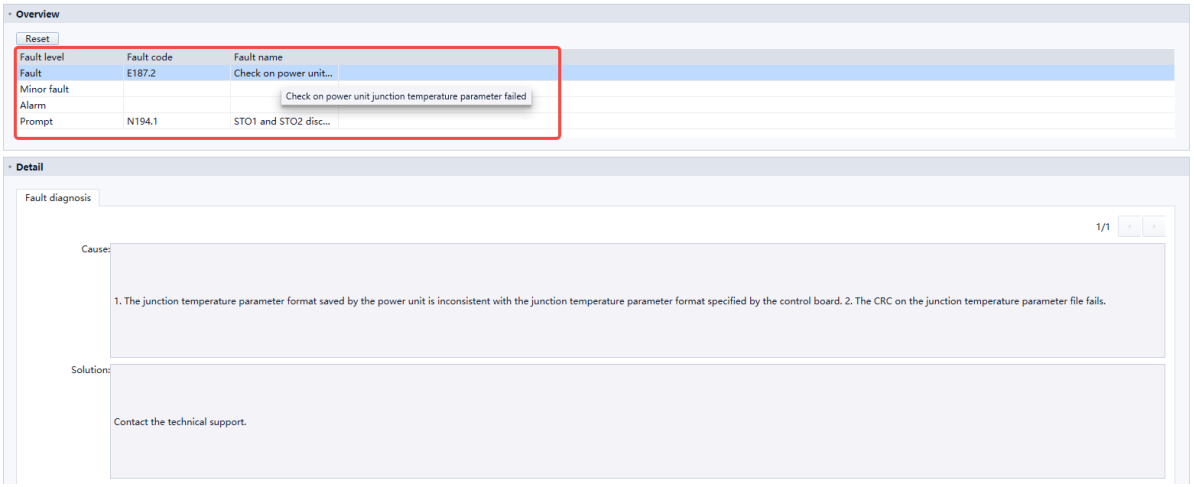
  The waveform area displays the simulated curve, including torque references, speed feedback, relative position feedback and absolute position references.



17.4 Common AC Drive Functions

17.4.1 Fault Management

17.4.1.1 AC Drive Fault Management

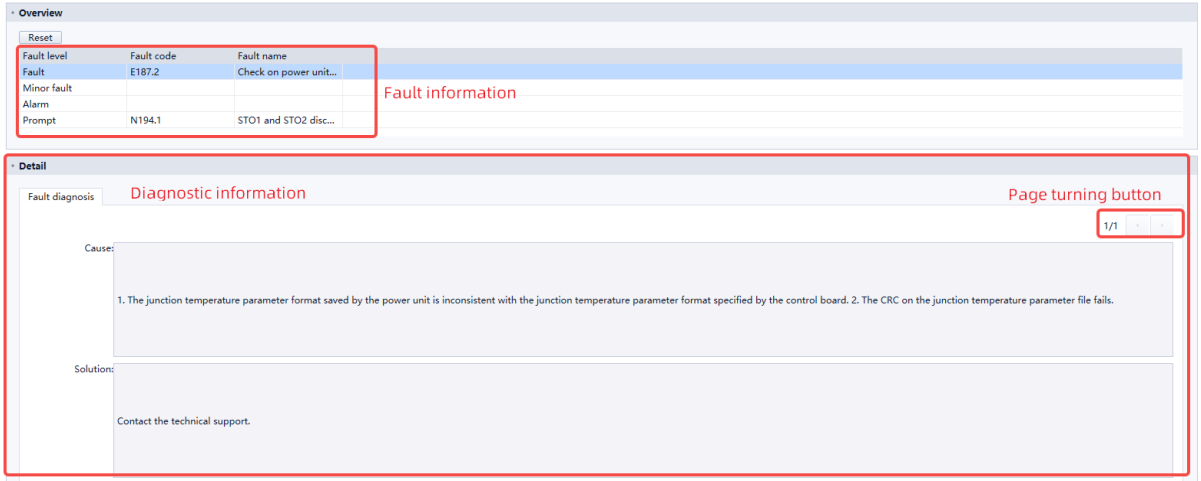


Select an AC drive in the project tree, double-click "Fault management" in the detailed view to open the interface. The interface displays detailed information about the current faults of the device and their solutions, helping users troubleshoot and resolve issues. The following figure shows the AC drive fault management interface, which mainly consists of the following parts:

- Fault overview area: Displays basic information of current faults and allows for a "Reset" operation.
- Fault diagnosis area: Displays information of the fault causes and solutions.

17.4.1.2 Fault Overview

After entering the fault management interface, the fault overview area is shown below.



17.4.1.3 Troubleshooting

The main solution to faults is "Reset". Click "Reset" to reset the faults.

Restrictions:

The function is effective only on resettable faults.

The resettable fault can be reset only after the fault has been cleared.

Function	Description
Fault information	Displays the selected fault code and fault name.
Fault diagnosis information	Displays the fault cause, confirmation method, and solution of the selected fault code.
Page turning buttons	If there are multiple causes for a fault, you can use these buttons to view different fault diagnosis information.

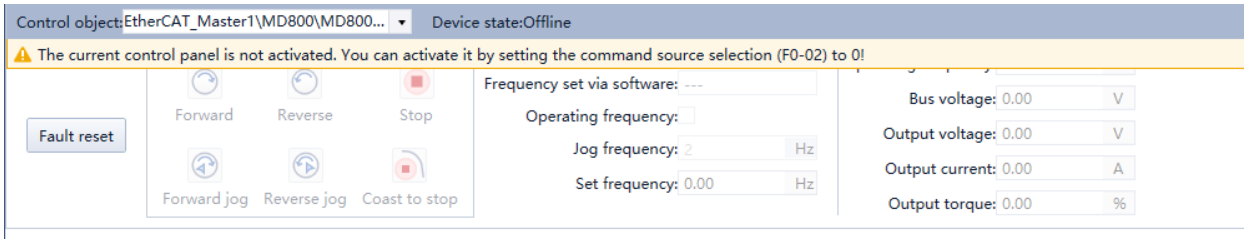
17.4.1.4 Fault Diagnostics

The fault diagnosis area displays the causes and solutions for the current fault, as shown below. For detailed function descriptions, see the following table.

Description	Description
Cause	Displays the cause of the fault.
Solution	Displays the solution of the fault.
Page turning buttons	If there are multiple causes for a fault, you can use these buttons to view different fault diagnosis information.

17.4.2 Control Panel

The control panel is used to perform trial run on the AC drive and monitor actual values of drive status and critical variables.



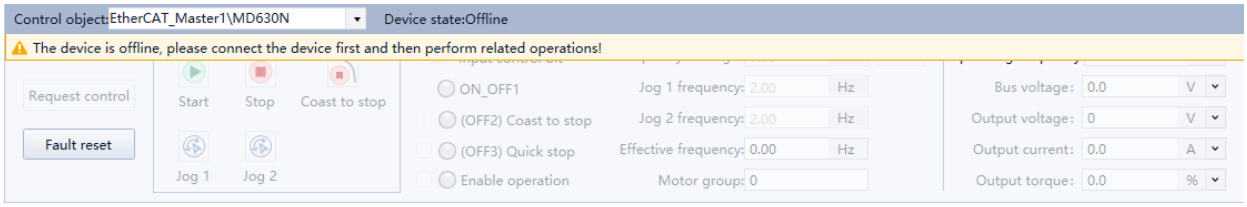
Function entry

After the device is added, double-click the "Control panel" node with the left mouse button to display the control panel interface in the workspace. All devices under the same project share a single control panel view. All devices on the same link are grouped into control objects for unified control. When entering the control panel from different links, the control object set changes to the device set of that link.

Path: Project tree > EtherCAT_Master > Device > Control panel.

Function interface

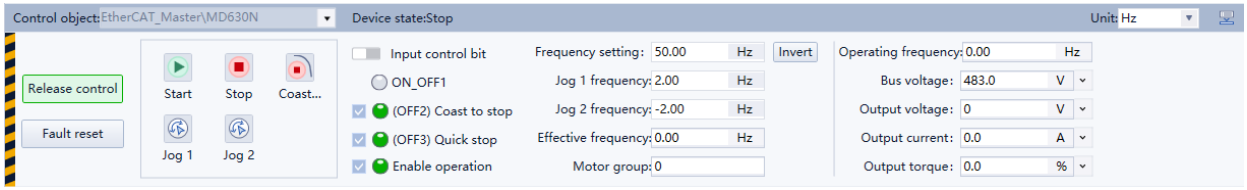
The control panel interface mainly consists of control objects, status monitoring, panel control, fault reset, motion control, frequency setting, and parameter monitoring.



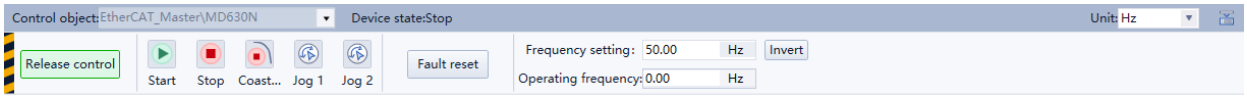
Control panel activation: When the interface is opened, it reads whether F0-02 (Command source selection) is 0. If so, the control panel is available; otherwise, it is disabled, and a prompt appears indicating that the parameter must be set to 0 for the control panel to be enabled.

Frequency setting validity: F0-03 (Selection of main frequency source X) is set to 0 or 1, and F0-07 (Frequency source superposition selection) is set to 2 or 3. When "Operating frequency" is checked, the main frequency source 0xF003 is set to 0, and the frequency superposition 0xF007 is set to 20. When "Operating frequency" is unchecked, the main frequency source 0xF003 is set to 5.

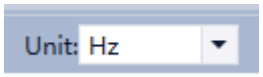
Note: The frequency input valid state cannot be switched during device operation.



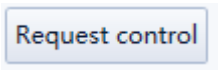
The control panel mainly consists of control objects, status monitoring, panel control, unit switching, control permission|fault reset, motion control, control bits, parameter setting, and parameter monitoring.

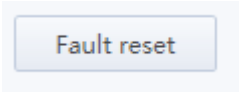


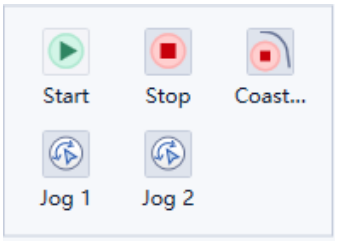
Note: The control panel can only be used after the disabled state is released.

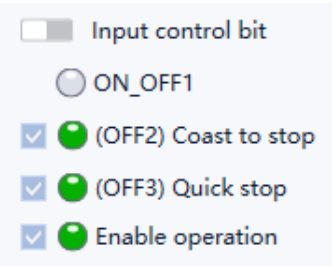


Taking the MD630/MD600 series AC drive as an example, the control panel interface is shown in the figure below:









Complete panel:

Simplified panel:

Description	Icon	Description
Control object		Function: You can select the device to be controlled from the drop-down box. All devices in the network link will be controlled. For the multi-axis device, the drop-down box displays "device name + parent device name". For example, the inverter of MD800 is shown as Inverter_1[MD800_1]. The rectifier device does not support this function. Note: • The name and ToolTips change with the name of the project node. • It is selectable, but not editable. • The control object is automatically switched when the panel is accessed from different entry points. • If the current control panel is in a controlled state, it cannot be switched to control other devices.
Device state		Displays the current device state.
Fault information		Displays the current highest-priority fault information of the device.
Unit switchover		Used to switch units. After switching units, the corresponding descriptions and units in the parameter setting and monitoring areas will change synchronously, and related values will be converted accordingly. Note: This function is currently supported only for MD630N and MD630S series products.
Complete panel/ Simplified panel switchover		Switches the panel view between full and simplified modes. Click the icon once to switch to the simplified panel, and click again to return to the complete panel.
Floating panel/Fixed panel switchover		Switches the panel state. Click the icon once to switch to the floating panel, and click again to return to the fixed panel.
Close		Closes the control panel.

<table>
<tr><th>Description</th><th>Icon</th><th>Description</th></tr>
<tr><td>Request control/ Release control</td><td>
</td><td>Click the button once to request control for the current control object, and click again to release control.

• Read upon focus loss.</td></tr>
</table>

Status monitoring

This function can be used to monitor drive status and actual value status:

Drive status:

- Operation status, fault code, and fault information.
- Operation status: Forward run, reverse run, stopped, tuning, and faulty.

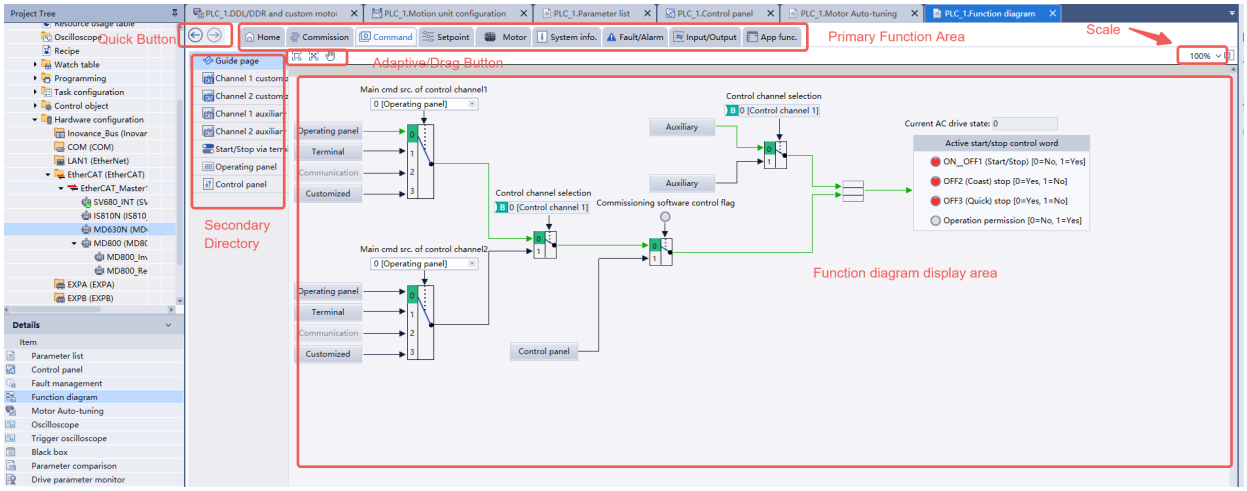
Parameter setting and parameter monitoring may vary across different device series. Refer to the actual device for details.

All status monitoring items are non-editable.

General settings

- When all devices in the current project are deleted or the current project is closed, the control panel view is closed.
- Among control objects, motion operations interfere with each other, but monitoring does not. That is, only one device can be controlled for motion at a time.

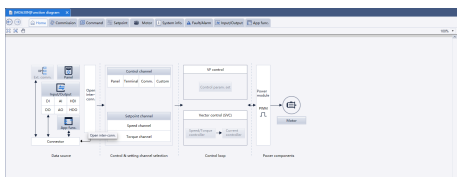
17.4.3 Function Diagram



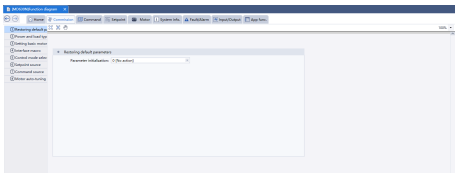
This function is currently supported only for MD630 series products.

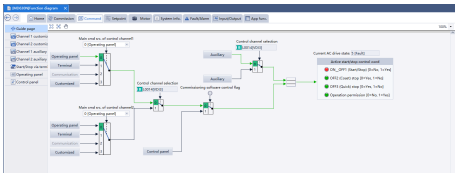
The function diagram presents the relationships between parameters in a data flow format, which significantly lowers the learning cost for users to operate the AC drive. This function is specific to certain devices and may not be supported on all models.

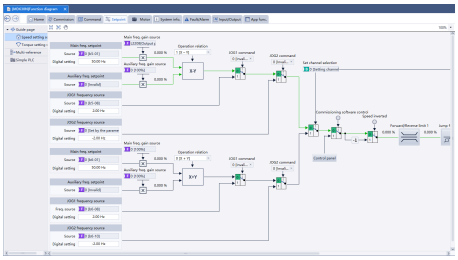
The following table lists the models that support the function diagram.

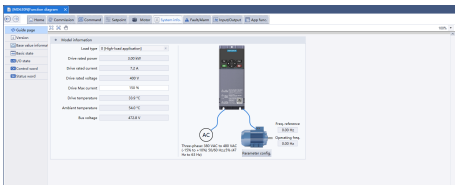


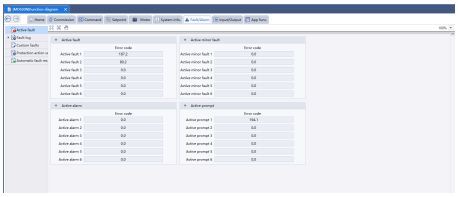
Series	Model
MD630	MD630N
	MD630S

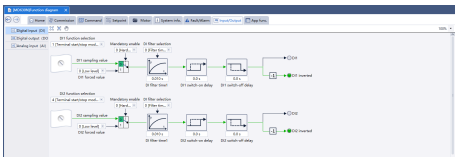


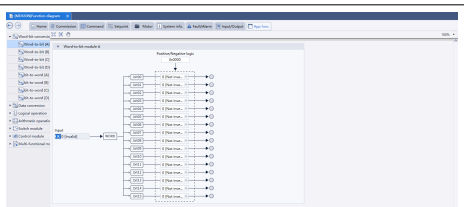










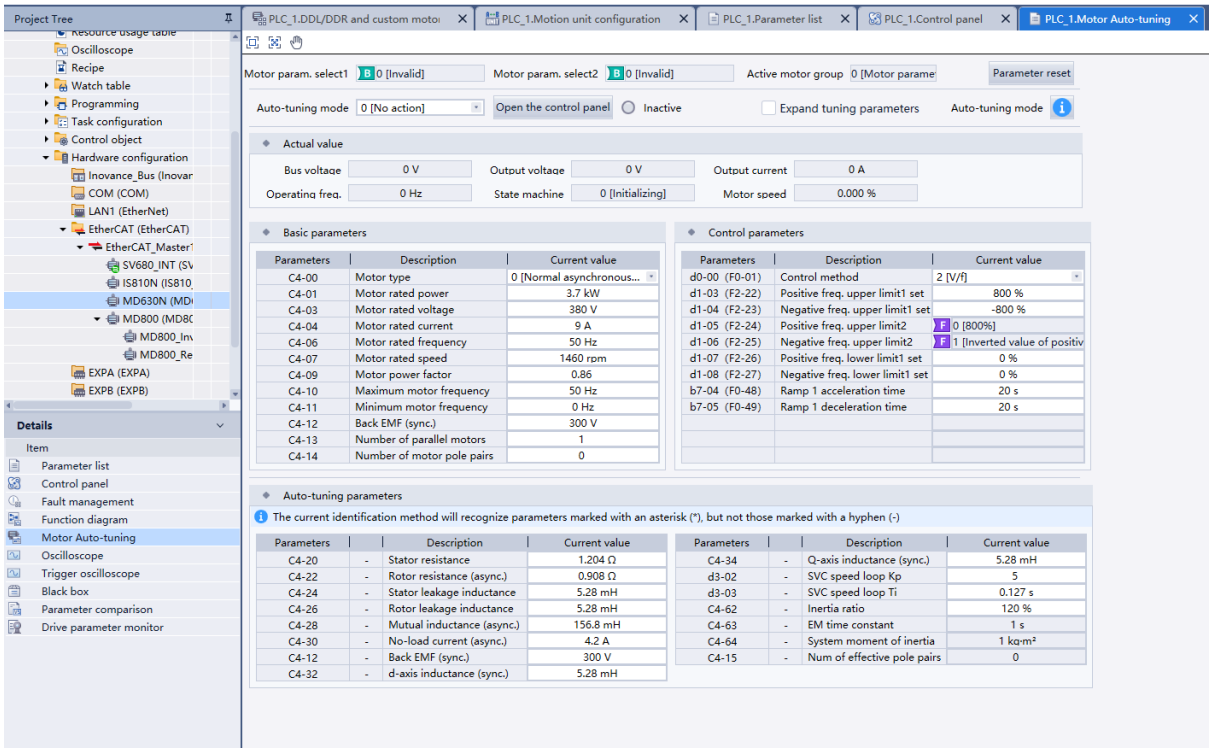


Taking the MD630 as an example, the structure tree of the function diagram is as follows; the home page provides an overview of the data flow in the function diagram. The function diagram includes 62 pages of mainstream functions, with each page containing different functions. The function diagram has 9 primary directories, each of which contains multiple secondary directories.

Description	Description
Shortcut icons	Back/Forward icons. Navigates to the previous/next page. If the current page is being accessed for the first time, the icon will be inactive.
Primary function area	Primary menu: Switches between primary directories.
Secondary directory	Secondary directory navigation tree: Switches between secondary directories.

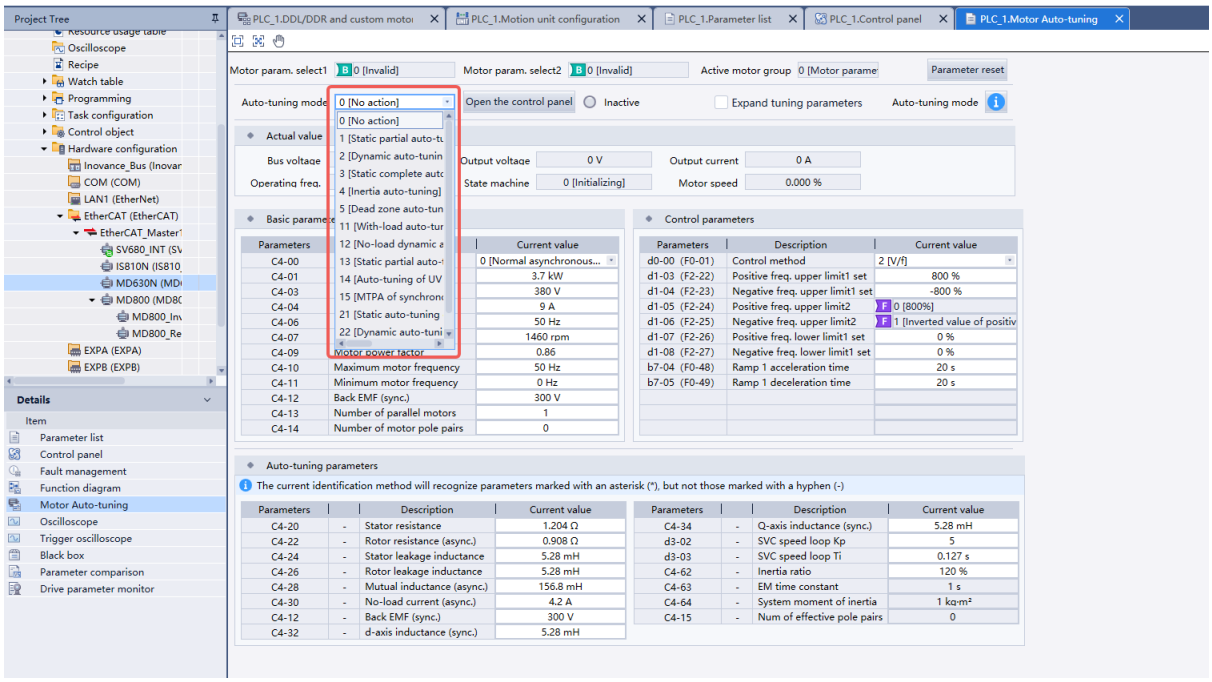
Primary function area

Description	Icon	Description
Home page		The home page offers a comprehensive overview of the function diagram's functions and the logical relationships between modules. It also provides direct access points to each module, enabling you to easily navigate to the desired module for queries and settings.



Description	Icon	Description
Quick commissioning		Used for basic parameter configuration and commissioning, helping you get started quickly.
Command source		Used to set system control commands from different sources to achieve motor start/stop, jog, forward/reverse operations.
Setpoint source		Used to set system frequency commands from different sources to achieve jog, normal operation, multi-reference, and simple PLC functions.
Motor parameters		Used to display motor-related parameters, making it easier for you to set the rated parameters for different motors and the current motor data group used by the AC drive.
System information		Used to query real-time system status information, software version information, base value information, etc.
Fault/ Alarm		Used to display fault-related parameters, fault protection, and auto-reset functions, helping you locate and analyze issues and providing early protection for the AC drive.
Input/ Output		Used to set terminal input/output functions and analog terminal input/output signals of the AC drive.
Application Function		Used to set parameters related to free function blocks, helping you freely select relevant modules to implement complex logic functions.

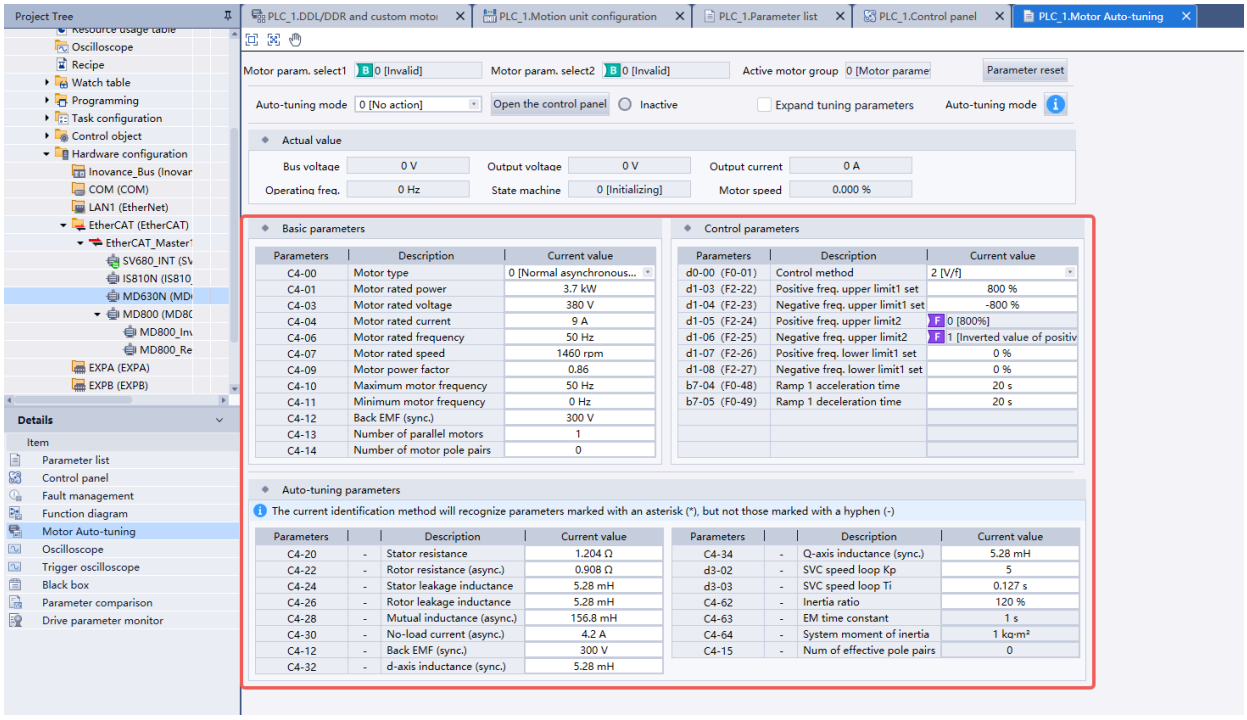
17.4.4 Motor Auto-Tuning



This function is currently supported only for MD630 series products.

Motor auto-tuning refers to the process where the AC drive autonomously learns the motor parameters.

1. Click "Motor auto-tuning" in the lower-left directory tree to enter the interface.



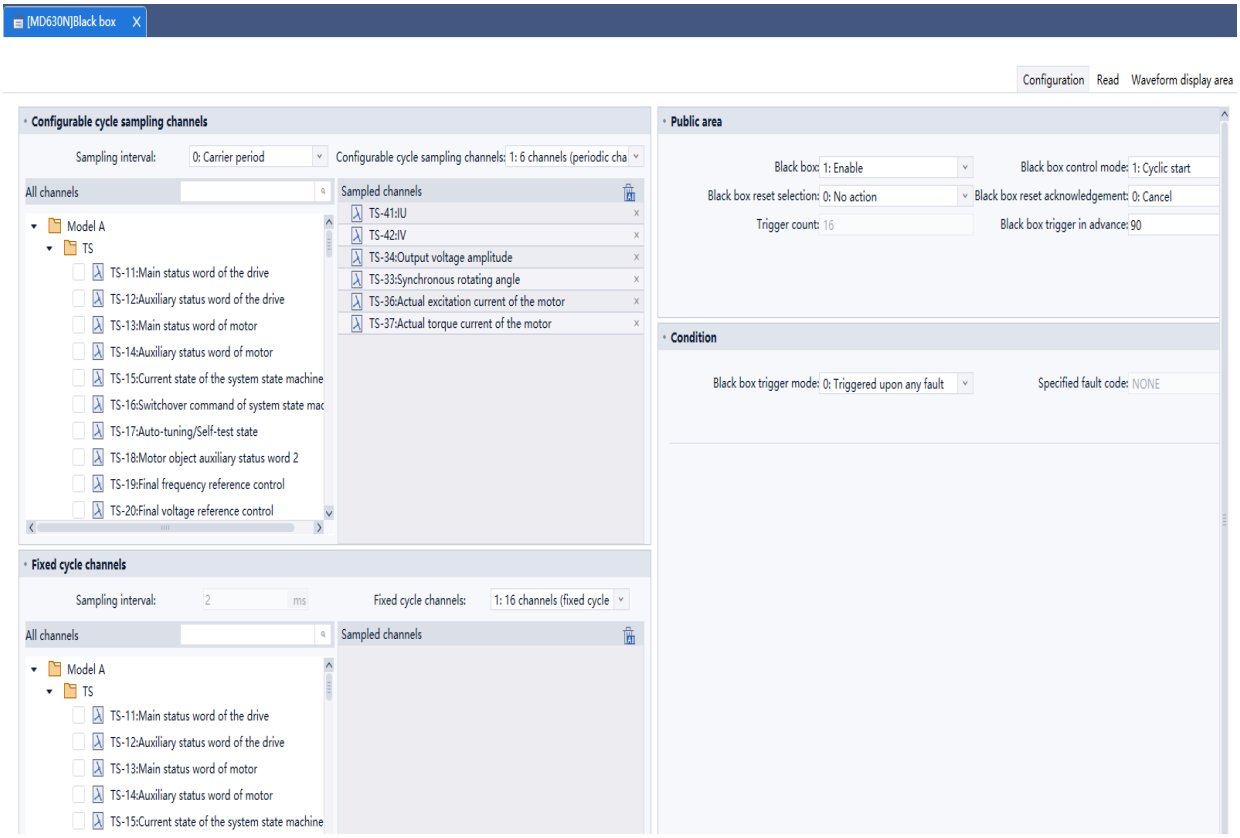
2. Set the auto-tuning mode.

3. Click "Open the control panel", "Request control", and then "Start" to start the motor.

4. Wait for the motor auto-tuning to complete, then check the related parameter changes.

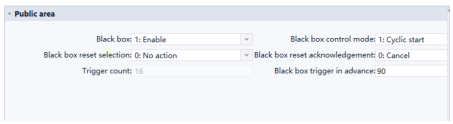
17.4.5 Black Box

17.4.5.1 Overview



This function analyzes the recorded data, operation statuses, and fault causes of the related devices to improve their maintainability.

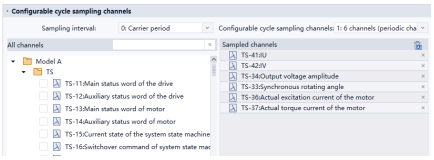
The following models currently support the black box feature:



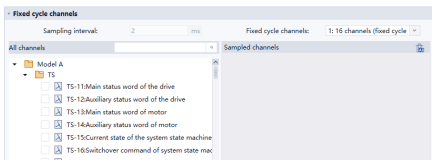
Series	Model
MD630	MD630N
	MD630S

Select an AC drive in the project tree, and double-click "Black box" in the detailed view to open the interface, which contains two tabs: "Configuration", "Read", and "Waveform display area".

17.4.5.2 Configuration

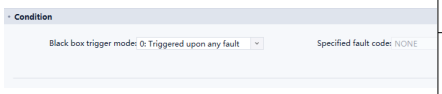


- **Public area:** Configuration area of black box common functions.



Description	Figure	Description
Enable black box		Enables or disables the black box function.
Black box control mode		Single start, stop after being triggered: Saves the record data after triggering, without repetitive startup. Cyclic start: After data is recorded after triggering, the black box enters the waiting status again.
Black box reset selection		No action: The original configuration is kept. Restore the black box configuration parameters: Restores the black box configuration parameters to default values.
Black box reset acknowledgement		Cancel: Cancels restoring black box parameters to default values. OK: Restores the black box configuration parameters to default values.
Trigger count		Number of triggering times of the black box.

Description	Figure	Description
Black box trigger in advance		Defines the pre-trigger setpoint of the black box (unit: %; range: 0 to 100).
RAM with history data		Checks whether there is historical data in the RAM.



- **Configurable cycle sampling channel:** Configures the variable of the record of the channel with configurable sampling cycle.

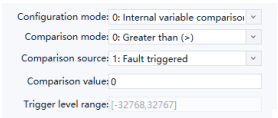
Description	Figure	Description
Channel search		Enter the keyword in the "All channels" text box and click to display the channels matching the keyword.
Configurable cycle sampling channels		Number of channels to be recorded
All channels		Displays available options in all channels with configurable sampling cycle. The data source is the configuration file.
Sampled channels		Displays the selected channels. The number of channels is adjusted according to the number of fixed cyclic sampling channels (3 or 6 channels supported).

- **Fixed cycle channels:** Configures the variables of the record of the archived cycle sampling channel.

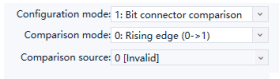
Description	Figure	Description
Channel search		Enter the keyword in the "All channels" text box and click to display the channels matching the keyword.
Fixed cycle channels		Number of channels to be recorded.
All channels		Displays available options in all channels with fixed sampling cycle. The data source is the configuration file.
Sampled channels		Displays the selected channels. The number of channels is adjusted according to the number of fixed cyclic sampling channels (8 or 16 channels supported).

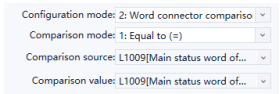
- **Condition:** Black box triggering condition

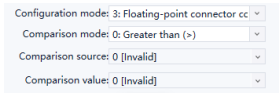
Function	Figure	Description
Black box trigger mode		Options include "Triggered upon any fault", "Triggered upon designated fault", "Custom", "Custom or triggered upon any fault", and "Custom or triggered upon designated fault".
Specified fault code		If the trigger mode is set to "Triggered upon designated fault" or "Custom or triggered upon designated fault", you must set this parameter to any device fault. If the trigger mode is set to other values, the parameter is unavailable.

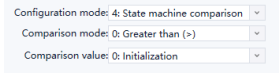


Trigger condition: Configures the black box trigger condition. When the trigger mode is set to a mode containing "Custom", you need to set the trigger condition. When the trigger mode is set to other values, the trigger condition parameters are unavailable.



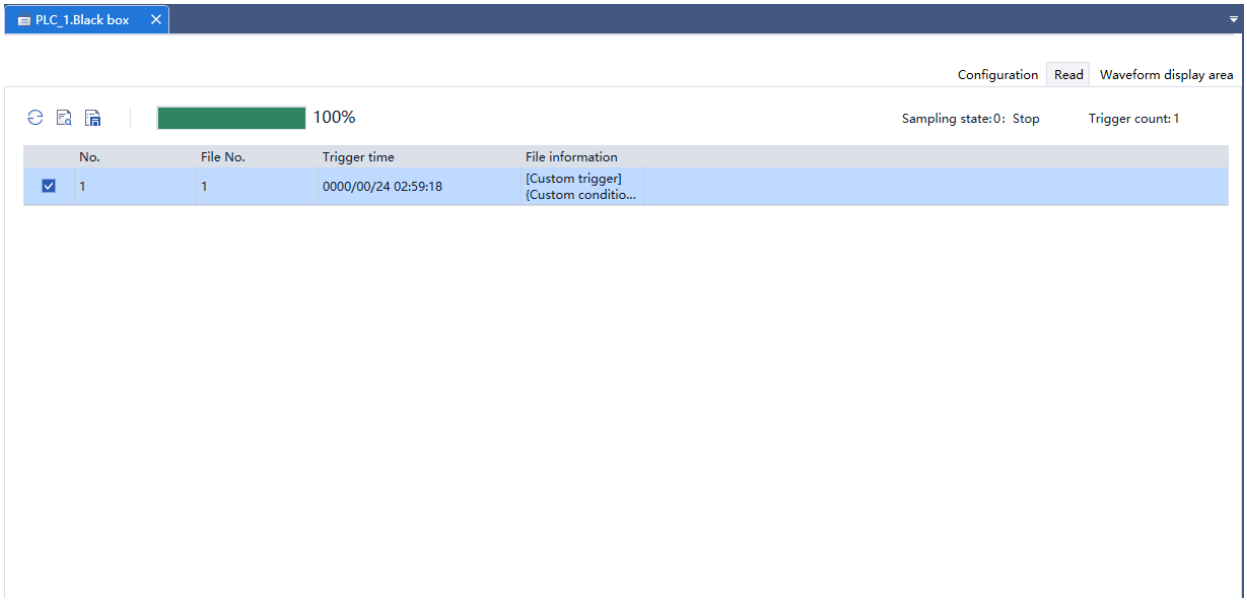






Trigger mode: user-defined condition A, user-defined condition B, user-defined condition A or B, and user-defined conditions A and B.

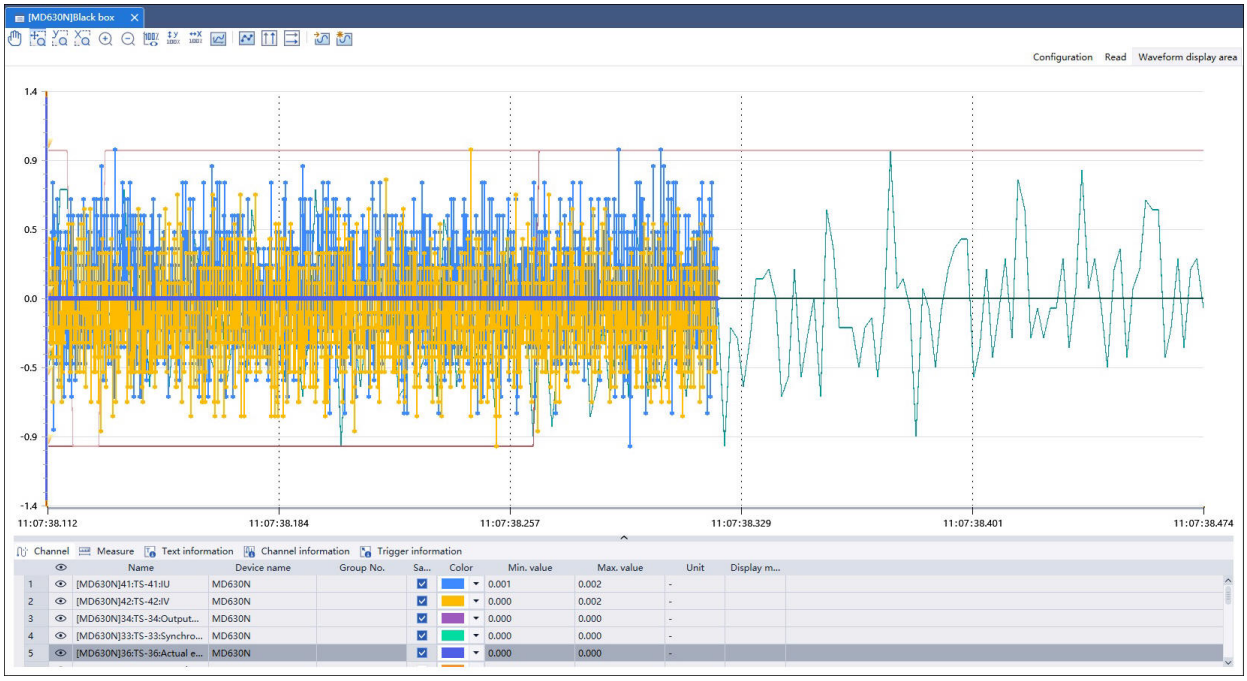
Configuration modes of conditions A and B include internal variable comparison, bit connector comparison, word connector comparison, float point connector comparison, and state machine comparison.



In different configuration modes, the comparison method, source, and value may differ. Refer to the table below for details.

Table17-4-5-2-1

Description	**Figure**	Comparison Mode	Comparison Source	Comparison Value	Trigger Range
Internal variable comparison		Greater than, equal to, less than, greater than or equal to, less than or equal to	Black box channel + unconditional save + fault trigger + save during operation	Number	Channel range



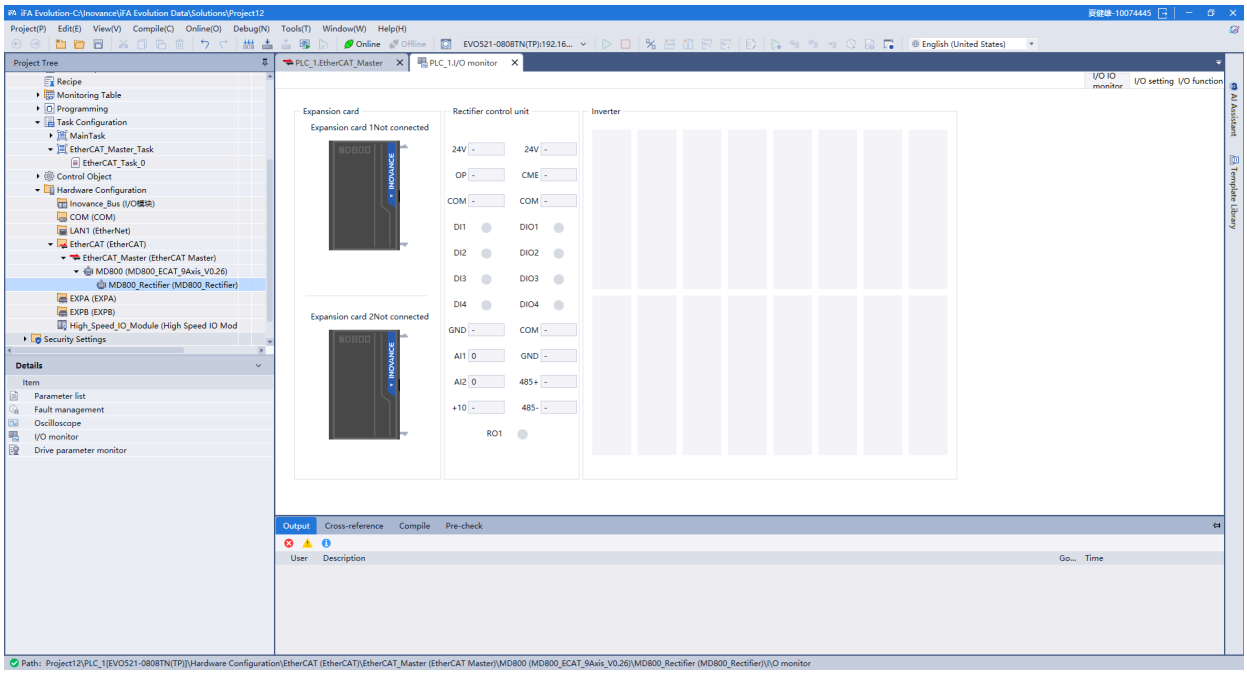
Description	Figure	Comparison Mode	Comparison Source	Comparison Value	Trigger Range
Bit connector comparison		Rising edge, falling edge, edge change, equal to logic 0, equal to logic 1	Invalid, connector B	/	/
Word connector comparison		Greater than, equal to, less than, greater than or equal to, less than or equal to	Invalid, K connector	Invalid, K connector	/
Float point connector comparison		Greater than, equal to, less than, greater than or equal to, less than or equal to	Invalid, connector F	Invalid, connector F	/
State machine comparison		Greater than, equal to, less than, greater than or equal to, less than or equal to	/	Initialization, switch-on disabled, switch-on enabled, operation permission, start, run, stop, self-test, auto-tuning	/

17.4.5.3 Read

Description	Icon	Description
Refresh directory		Refreshes the black box data directory recorded in the device.
Read file		Based on the selected file, obtains the configuration information and reads the data from the device. The displayed dialog box prompts you to save the read data. Select a proper directory and click "OK" to save the data to the specified directory. Then go to the waveform display area to view the waveform.
Save file		Saves the read file to local.
Progress bar	0%	Displays the operation progress bar.

17.4.5.4 Waveform Display

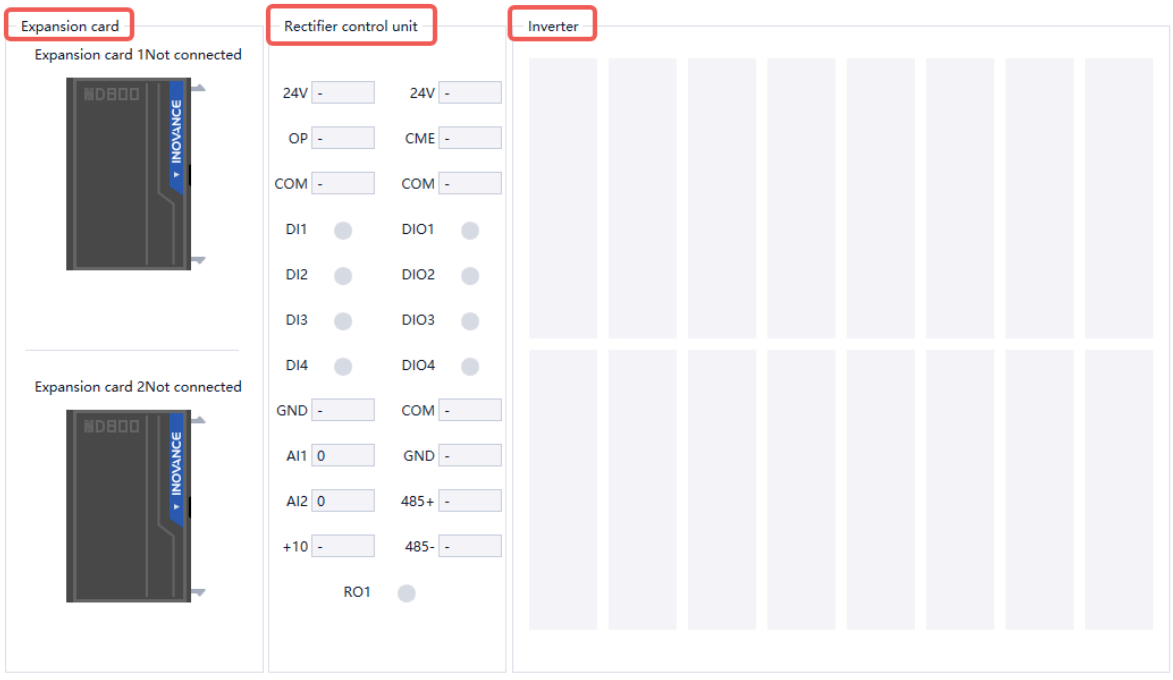
The toolbar on the "Waveform display area" is the same as that in the "Oscilloscope" interface. For details, see "Analysis Auxiliary Function". The waveform curve is displayed in the middle area and related information is displayed in the lower area. See the following table for details.



Function	Description
Channel	Displays channel information. You can also set the channel color and group number.
Measurement	Measures the waveform through the cursor, and displays the values of each curve in real time.
Channel information	Displays the sampling frequency, total sampling point count, and sampling point count before trigger of the speed and position references.
Trigger information	Displays the following two trigger messages: • Condition information: Displays the trigger condition based on the actual value. • Fault information: Displays the fault information generated upon triggering. Fault information is displayed dynamically; if there are no faults, nothing is displayed.
Text information	Displays relevant information about the device.

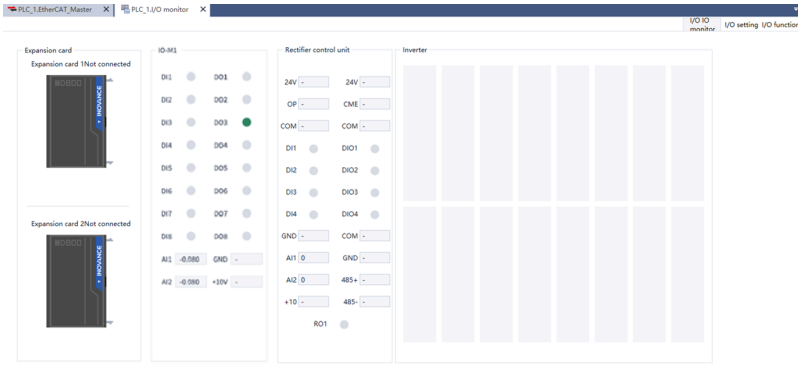
17.4.6 I/O monitoring

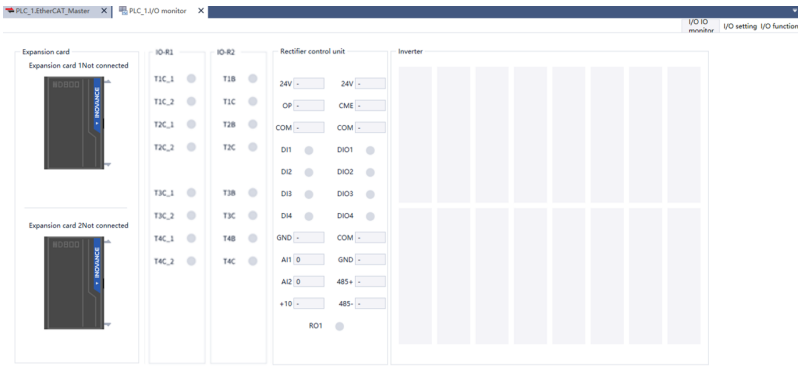
This feature is supported only for the MD800_Rectifier products.



Select an AC drive in the project tree, and double-click "I/O monitor" in the detailed view to open the interface.

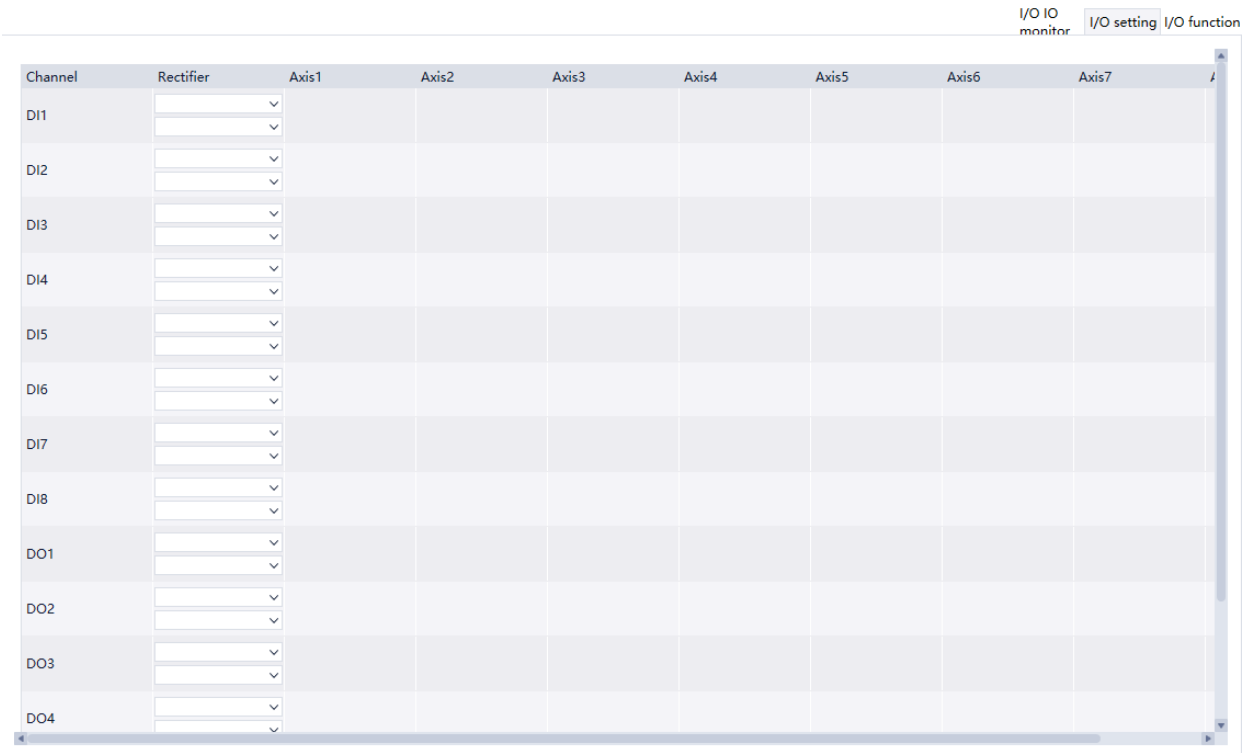
The interface mainly consists of three parts: I/O monitoring, I/O settings, and I/O functions, as shown below:





- ## I/O monitoring

This tab is used to monitor the status of expansion modules, rectifier control units, and inverter control units.



Function	Description
Expansion card	Supports insertion of IO-M1/IO-R1/IO-R2 type expansion cards.

Function	Description
	After an IO-M1 type expansion card is connected, the interface is as shown below. An "IO-M1" monitoring bar is generated between "Expansion card" and "Rectifier control unit".  After an IO-R1/IO-R2 type expansion card is connected, the interface is as shown below. "IO-R1"/"IO-R2" monitoring bars are generated between "Expansion card" and "Rectifier control unit". 
Rectifier control unit	Displays the DI/DO/AI status of the rectifier modules.
Inverter	Displays the status of each inverter expansion module under MD800. POW: Orange indicates the device is powered on. Gray indicates the device is powered off. RUN/STOP: Green with text "RUN" indicates the motor is running. Gray with text "STOP" indicates the motor is stopped. Fault code: If the device is faulty, the mark is displayed in red with the corresponding fault code text; otherwise, it is displayed in gray with no text.

- **I/O setting**

This tab is used to configure DI/DO/AI related functions for rectifier and inverter.

Function	Description
Read	Reads I/O configuration information from the device and updates it to the I/O settings page.
Write	Writes the user-configured I/O configuration information into the device.
Channel	I/O channel name (non-editable)
Rectifier	Physical channel selection and function configuration for the I/O channel corresponding to the rectifier
Axis 1 to Axis 8	Physical channel selection and function configuration for the I/O channel corresponding to the inverter
Restrictions	The hardware source for the same inverter cannot be the same. For example, if the hardware source selection for DI1 (F4-00) is set to 002, then the hardware source selection for DI2 (F4-02) cannot be set to 002.
	DIO function configuration: When a DIO hardware port is assigned to a DI function, this port cannot be assigned to a DO function. For example, when the hardware source selection for DI1 (F4-00) is set to 005 (rectifier DIO1), the rectifier DIO1 cannot be selected as the hardware source for the DO2/RO2 hardware source (F5-02) function, and the selection option for DO2/RO2 skips 001.
	When a DIO hardware port is assigned to a DO function, this port cannot be assigned to a DI function. For example, when the DO1/RO1 hardware source selection (F5-00) is set to 001, the rectifier DIO1 cannot be selected as the hardware source for the DI1 hardware source (F4-00) function, and the selection option for DI1 skips 005.

Function	Description
DO channel multiplexing	The DO hardware channels can be multiplexed across multiple axes, and the final DO status is determined by the logical OR of all associated axis statuses. For example, if DO1 is associated with the fault output function of axis 1 and axis 2, then DO1 becomes active whenever either axis 1 or axis 2 encounters a fault.

- **I/O functions**

This tab displays the device's I/O configuration information in a table. Unconfigured I/Os are displayed as blank, and modules without configured I/O functions are not displayed.

Function	Description
Read	Reads I/O configuration information from the device and updates it on the current page.
Card	I/O channel source (rectifier or I/O expansion card)
Channel	I/O channel name
Rectifier	I/O configuration function corresponding to the rectifier
Axis 1 to Axis 8	I/O function configured for the inverter module

17.5 Servo Parameter Description

See the guides in the table below for detailed parameter information of different servo drive series.

18 Common Instructions

Multiple libraries with different names may exist under the same functional category in the toolbox. To view instructions each library contains, you can obtain detailed information through the operations in the 12.3 library reference.

The following table lists the differences in software library supported by each product; general libraries are not mentioned as they are supported by all products.

Category		Library	EVO400	EVO500	EVO700/ EVO700C	EVO800 (Standalone)	EVO800 (Redundant)	APC520	APC760C
18.2 Extended Instructions	18.2.19 C Function Support	IOBlockHandle	√	√	√	×	×	√	√
	18.2.12 Special file processing	FileProc	√	√	√	×	×	√	√
18.3 Process Instructions	18.3.2 Advanced Process Control	PFC	×	×	×	×	×	√	×
	18.3.3 Motion Control	MotionControl	√	√	√	×	×	√	√
	18.3.4 Motor Control	ProcessControl	×	×	×	√	√	×	×

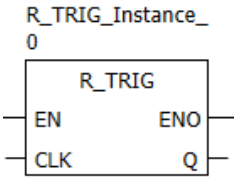
18.1 Basic Instructions

18.1.1 Bit Logic

18.1.1.1 Instruction List



Instruction	FB/FC	Function	Library	Applicable Library Version
18.1.1.2 R_TRIG	FB	Rising edge detection	Standard	Library version 1.0.0.0 and later
18.1.1.3 F_TRIG	FB	Falling edge detection		Library version 1.0.0.0 and later
18.1.1.4 Please	FB	Rising edge output	Util	Library version 1.0.0.0 and later
18.1.1.5 PLF	FB	Falling edge output		Library version 1.0.0.0 and later
18.1.1.6 SR	FB	Prioritize the set value	Standard	Library version 1.0.0.0 and later
18.1.1.7 RS	FB	Prioritize the reset value		Library version 1.0.0.0 and later
18.1.1.8 ALT	FB	Alternate output	Util	Library version 1.0.0.0 and later
18.1.1.9 BOUT	FC	Bit data output		Library version 1.0.0.0 and later
18.1.1.10 BSET	FC	Bit data setting		Library version 1.0.0.0 and later
18.1.1.11 BRST	FC	Bit data reset		Library version 1.0.0.0 and later

Instruction	FB/FC	Function	Library	Applicable Library Version
18.1.1.12 D_TRIG	FB	D flip-flop	Logic	Library version 1.0.0.0 and later

18.1.1.2 R_TRIG

The R_TRIG instruction is used to output a TRUE signal for only one task cycle when an input signal transitions from FALSE to TRUE (rising edge).

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
R_TRIG	Rising edge detection	FB		R_TRIG_Instance_0(CLK := , Q =>);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	CLK	Input signal	Follows data type	-	Valid when FALSE changes to TRUE.
Output	Q	Output signal	Follows data type	-	Rising edge detected.

  Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
CLK	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Q	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function description**

  When the input signal "CLK" transitions from FALSE to TRUE, the output signal "Q" is set to TRUE for only one task cycle; otherwise, "Q" is FALSE.

- **Sequence diagram**

- **Program example**

  The "bFlag" variable is initially FALSE; when the output signal "Q" is set to TRUE, the "bFlag" variable becomes TRUE.

  ST:

	Name	Data type	Address	Value
1	R_TRIG_Instance_0	R_TRIG		
2	bCLK	BOOL		TRUE
3	xResult	BOOL		FALSE
4	bFlag	BOOL		TRUE

```
R_TRIG_Instance_0(
CLK  TRUE  := bCLK  TRUE ,
Q  FALSE  => xResult  FALSE );
IF xResult  FALSE  THEN
    bFlag  TRUE  := TRUE;
END_IFRETURN
```

  LD:

	Name	Data type	Address	Value
1	R_TRIG_Instance_0	R_TRIG		
2	bCLK	BOOL		TRUE
3	xResult	BOOL		FALSE
4	bFlag	BOOL		TRUE

18.1.1.3 F_TRIG

The F_TRIG instruction is used to output a TRUE signal for only one task cycle when an input signal transitions from TRUE to FALSE (falling edge).

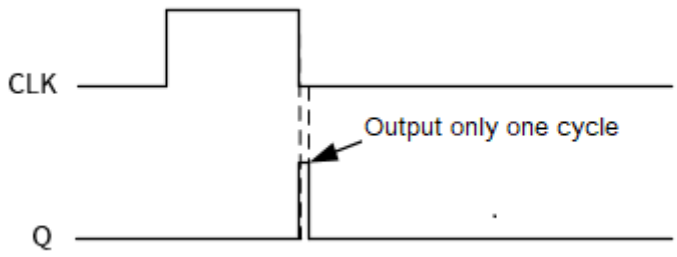
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
F_TRIG	Falling edge detection	FB	F_TRIG_Instance_0 F_TRIG EN ENO CLK Q	F_TRIG_Instance_0(CLK := , Q =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	CLK	Input signal	Follows data type	-	Valid when TRUE changes to FALSE.
Output	Q	Output signal	Follows data type	-	Falling edge detected.

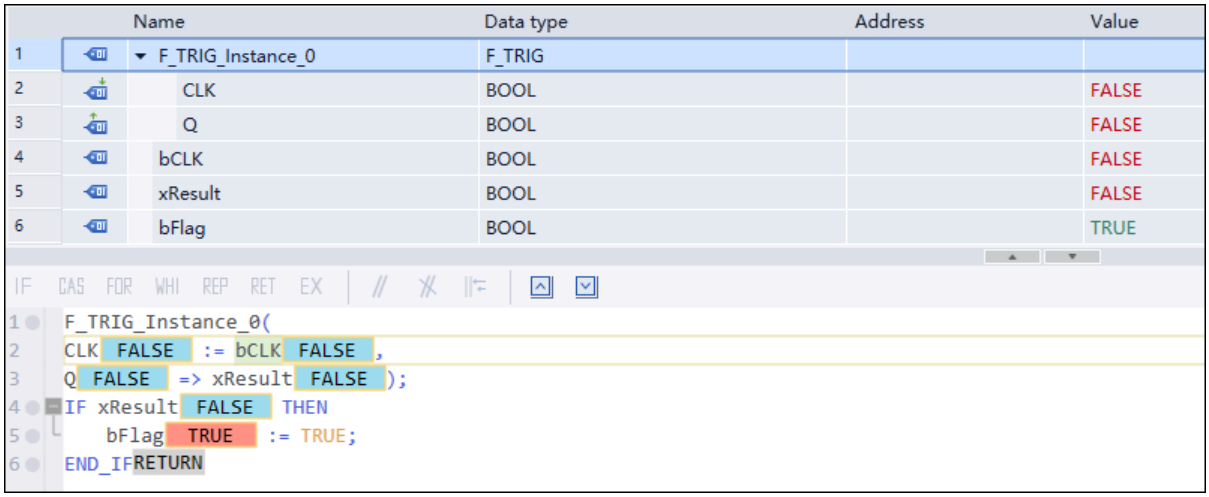


Variable type

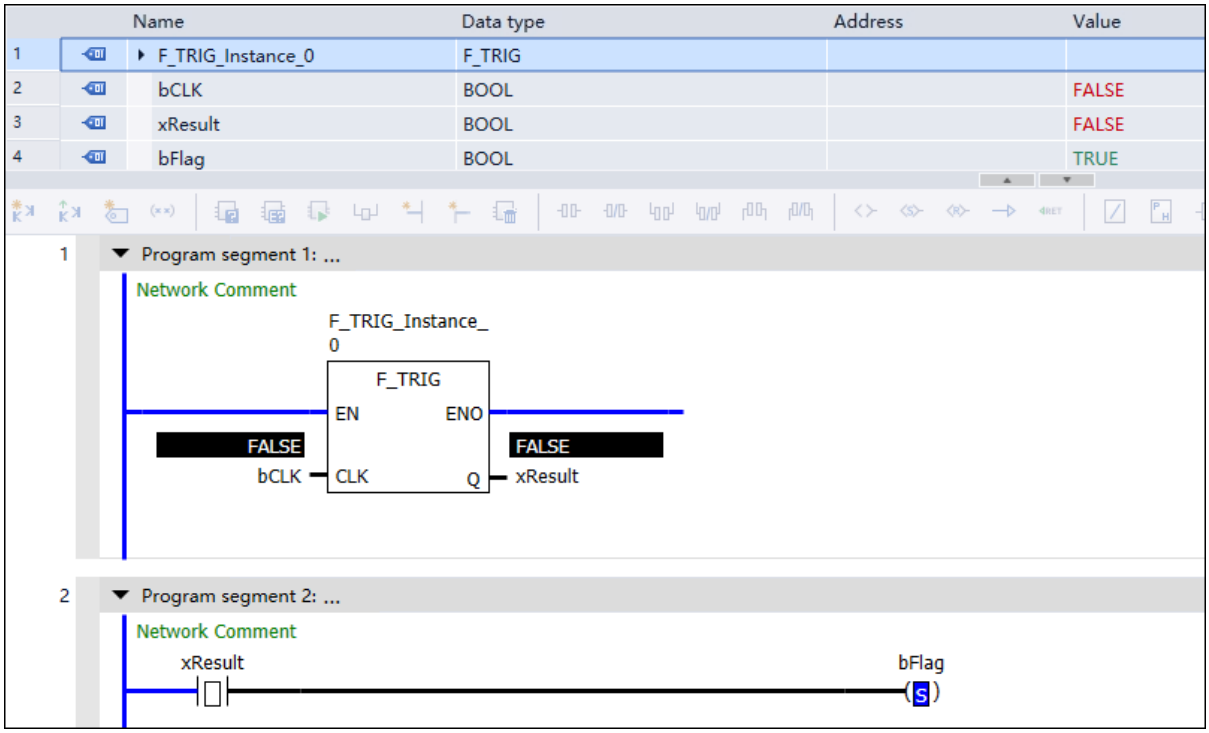
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
CLK	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Q	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function description**

When the input signal "CLK" transitions from TRUE to FALSE, the output signal "Q" is set to TRUE for only one task cycle; otherwise, "Q" is FALSE.



- **Sequence diagram**



- **Program example**

The "bFlag" variable is initially FALSE; when the output signal "Q" is set to TRUE, the "bFlag" variable becomes TRUE.

ST:

LD:

18.1.1.4 PLS

When the PLS instruction detects a rising edge on the input variable xExecute, xOut will be set to TRUE for one scan cycle and then be set to FALSE.

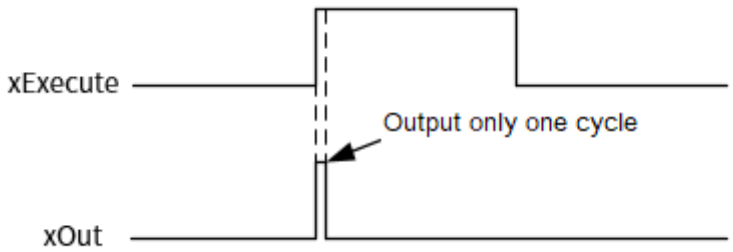
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
PLS	Rising edge output	FB	PLS_Instance_0 PLS EN ENO xExecute xOut	PLS_Instance_0(xExecute := , xOut =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	xExecute	Input signal	Follows data type.	FALSE	The BOOL value to be detected.
Output	xOut	Output signal	Follows data type.	FALSE	Set to ON if a rising edge on xExecute is detected.

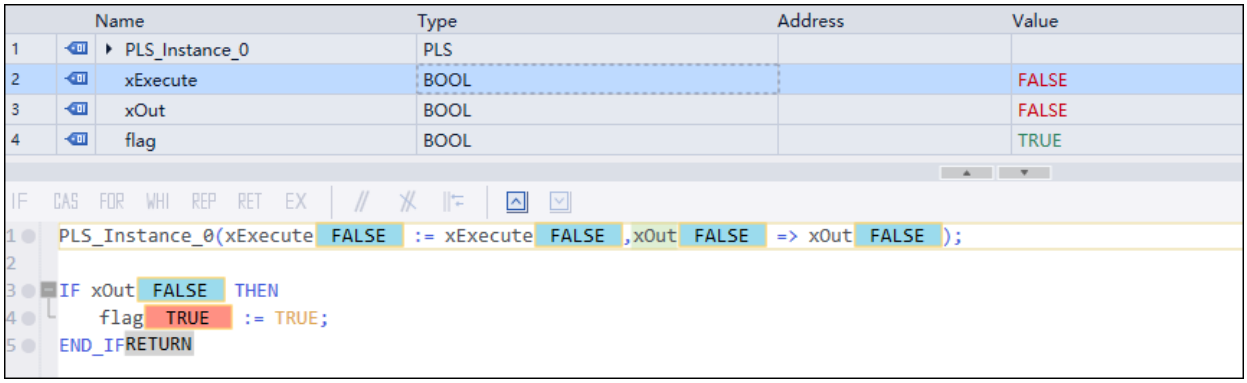


Variable type

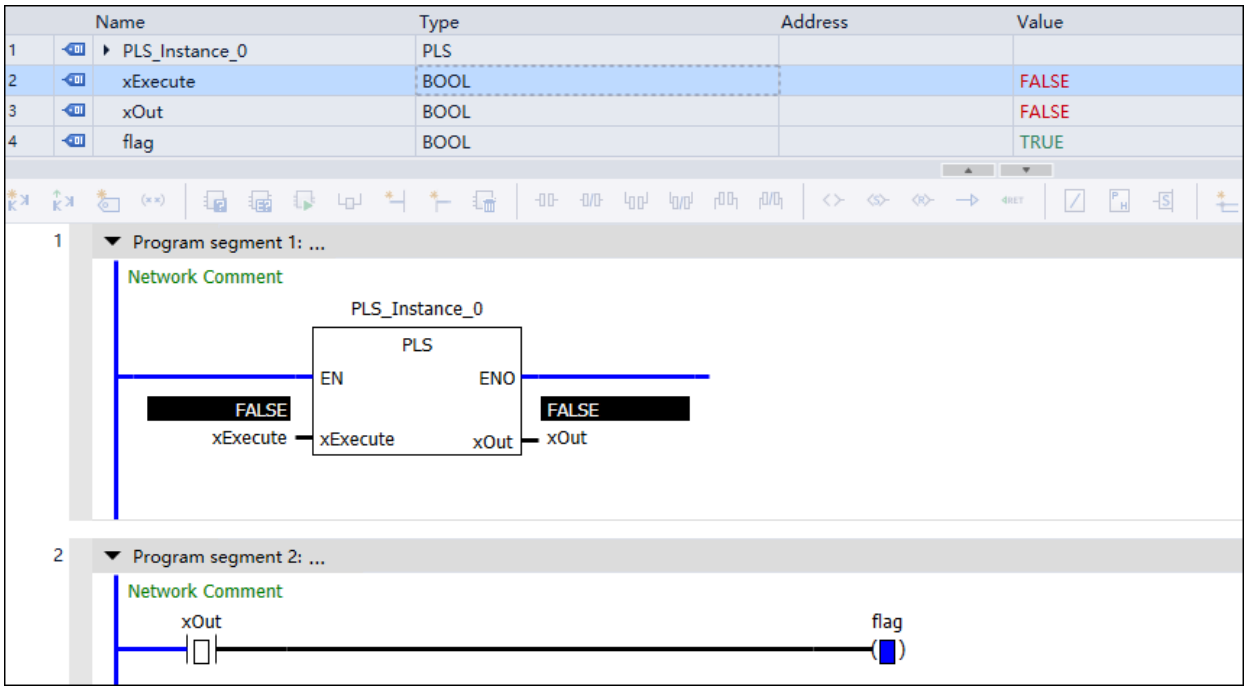
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
xExecute	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
xOut	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function description**

  When the PLS instruction detects a rising edge on the input variable xExecute, xOut will be set to TRUE for one scan cycle and then be set to FALSE.



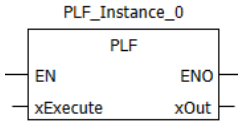
- **Sequence diagram**



- **Program example**

  The initial value of input variable xExecute is set to FALSE. Manually set the value of xExecute to TRUE to generate a rising edge signal. Since the TRUE status of output variable xOut lasts only for one scan cycle, the change in output value cannot be observed directly; therefore, add a flag variable to assist in observing the status of output variable xOut.

ST:



LD:

18.1.1.5 PLF

When the PLF instruction detects a falling edge on the input variable xExecute, xOut will be set to TRUE for one scan cycle and then be set to FALSE.

- **Instruction format**

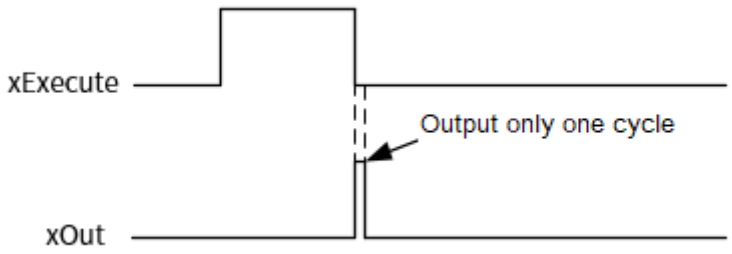
Instruction	Name	FB/FC	LD Representation	ST Representation
PLF	Falling edge output	FB		PLF_Instance_0(xExecute := , xOut =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	xExecute	Input signal	Follows data type.	FALSE	The BOOL value to be detected.

Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	xOut	Output signal	Follows data type.	FALSE	Set to ON if a falling edge on xExecute is detected.

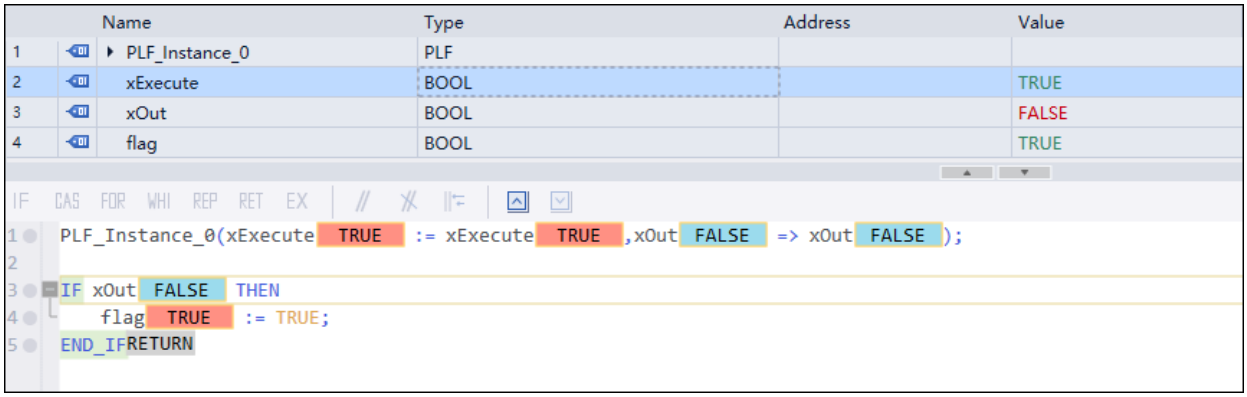


Variable type

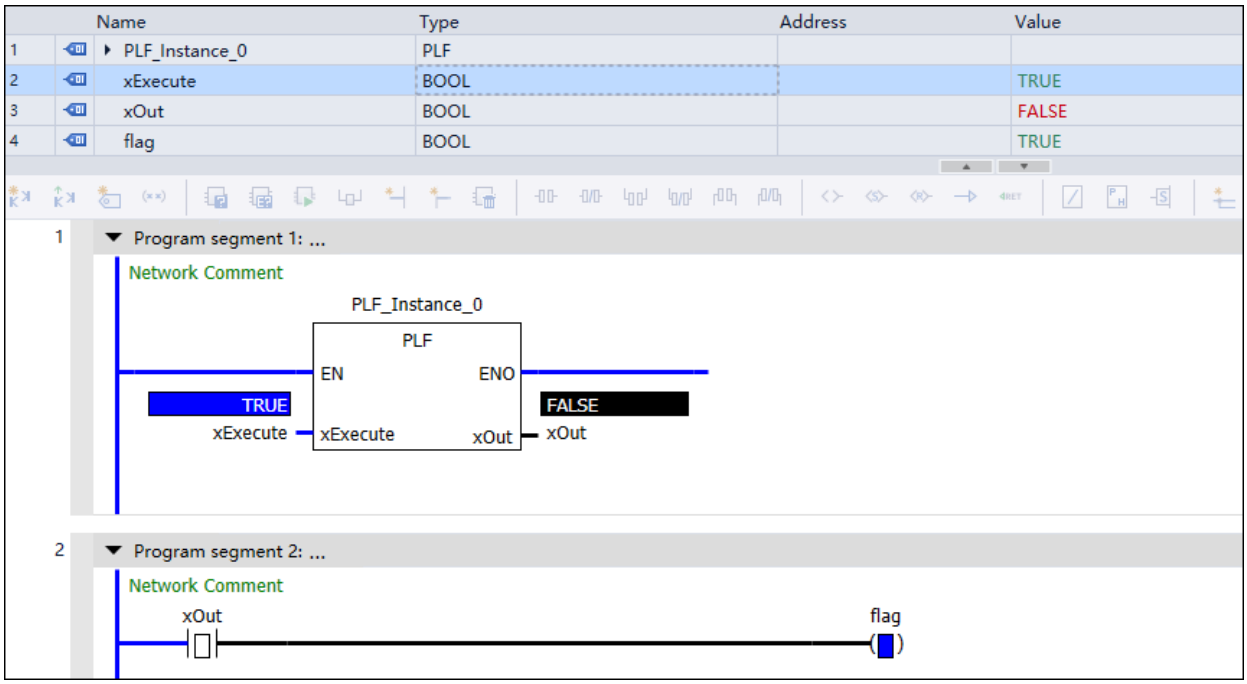
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
xExecute	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
xOut	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function description**

  When the PLF instruction detects a falling edge on the input variable xExecute, xOut will be set to TRUE for one scan cycle and then be set to FALSE.



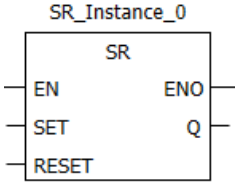
- **Sequence diagram**



- **Program example**

  The initial value of input variable xExecute is set to TRUE. Manually set the value of xExecute to FALSE to generate a falling edge signal. Since the TRUE status of output variable xOut lasts only for one scan cycle, the change in output value cannot be observed directly; therefore, add a flag variable to assist in observing the status of output variable xOut.

  ST:



LD:

18.1.1.6 SR

When both the set input signal and the reset input signal are valid, the set input signal has priority.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
SR	Prioritize the set value	FB		SR_Instance_0(SET := , RESET :=, Q =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	SET	Set signal	Follows data type	-	Set signal

Input/Output	Variable	Name	Valid Range	Default Value	Description
	RESET	Reset signal	Follows data type	-	Reset signal
Output	Q	Output signal	Follows data type	-	Set signal is prioritized to be output.

Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
SET	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
RESET	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Q	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function description**

  When both the set input signal SET and the reset input signal RESET are valid, the set input signal SET has priority and becomes the output Q.

SET	RESET	Q
TRUE	TRUE	TRUE
FALSE	TRUE	FALSE
TRUE	FALSE	TRUE
FALSE	FALSE	Remain

- **Sequence diagram**

- **Program example**

  ST:

		Name	Data type	Address	Value
1		SR_Instance_0	SR		
2		bSET	BOOL		TRUE
3		bRESET	BOOL		TRUE
4		bQ	BOOL		TRUE

```
SR_Instance_0(
SET TRUE := bSET TRUE,
RESET TRUE := bRESET TRUE,
Q TRUE => bQ TRUE);RETURN
```

  LD:

		Name	Data type	Address	Value
1		SR_Instance_0	SR		
2		bSET	BOOL		TRUE
3		bRESET	BOOL		TRUE
4		bQ	BOOL		TRUE

18.1.1.7 RS

When both the set input signal and the reset input signal are valid, the reset input signal has priority.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
RS	Prioritize the reset value	FB		RS_Instance_0(SET := , RESET := , Q =>);

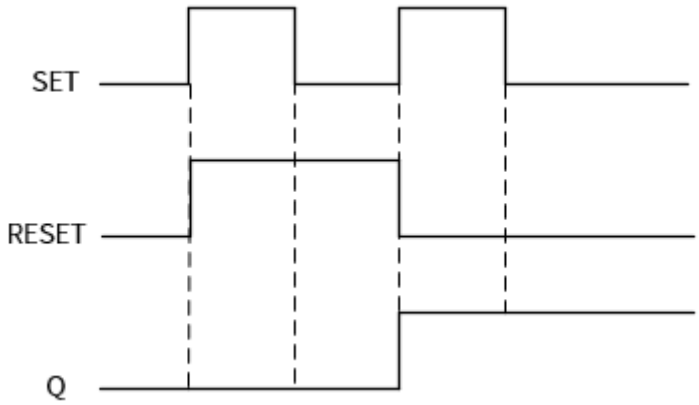
- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	SET	Set signal	Follows data type	-	Set signal
	RESET	Reset signal	Follows data type	-	Reset signal
Output	Q	Output signal	Follows data type	-	Reset signal is prioritized to be output.

  Variable type

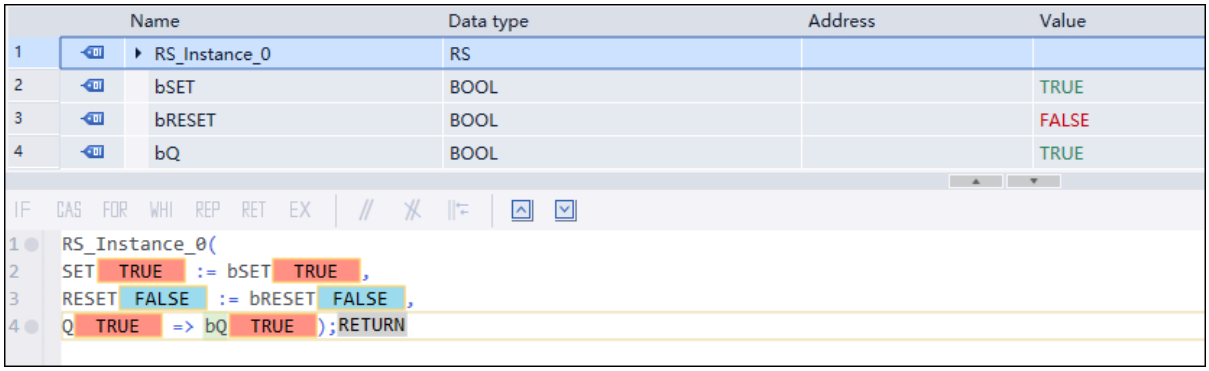
Variable Name	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
SET	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
RESET	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Q1	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–



- **Function description**

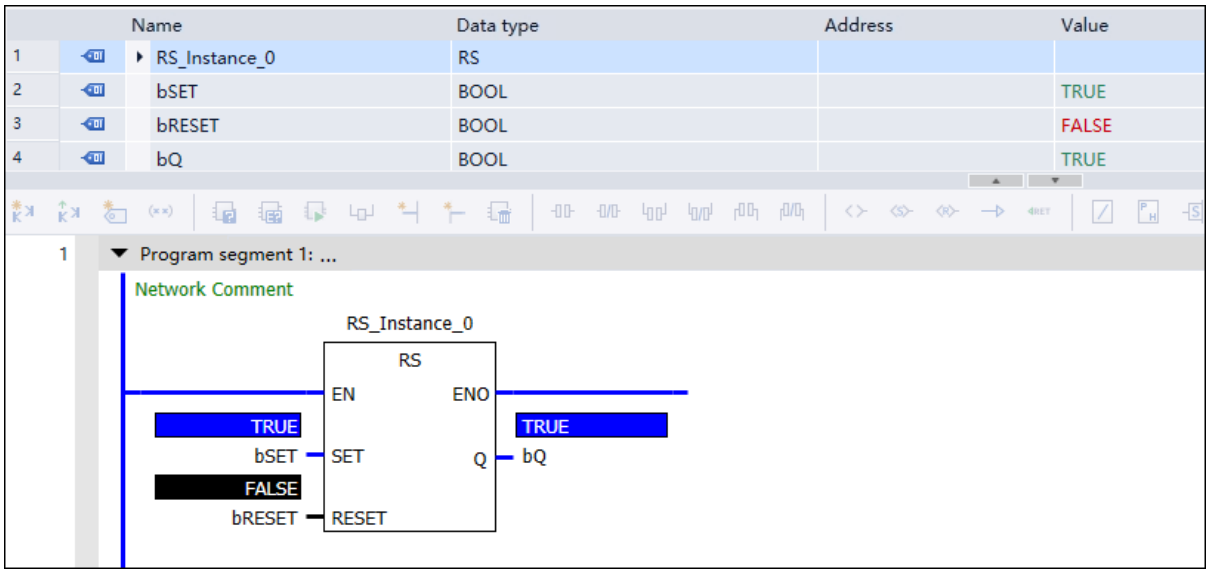
  When both the set input signal SET and the reset input signal RESET are valid, the reset input signal RESET has priority and becomes the output Q.

SET	RESET	Q
TRUE	TRUE	FALSE
FALSE	TRUE	FALSE



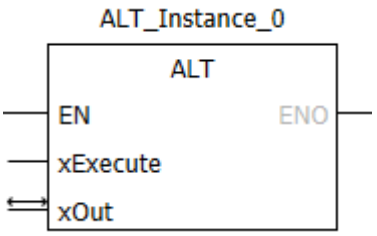
SET	RESET	Q
TRUE	FALSE	TRUE
FALSE	FALSE	Remain

- **Sequence diagram**



- **Program example**

ST:



LD:

18.1.1.8 ALT

When the ALT instruction detects a rising edge on xExecute, the status of xOut will be reversed.

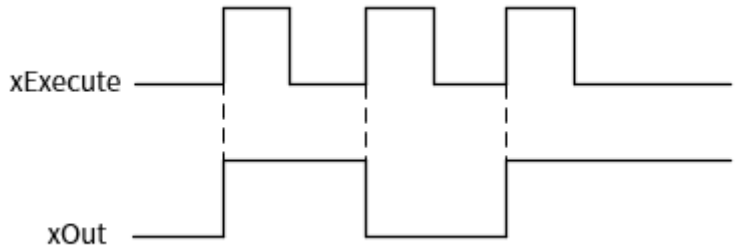
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ALT	Alternate output	FB		ALT_Instance_0(xExecute := , xOut :=);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	xExecute	Input signal	Follows data type.	FALSE	The BOOL value to be detected.
Input/Output	xOut	Input/Output signal	Follows data type	FALSE	Reverse the status of xOut if a rising edge on xExecute is detected.



Variable type

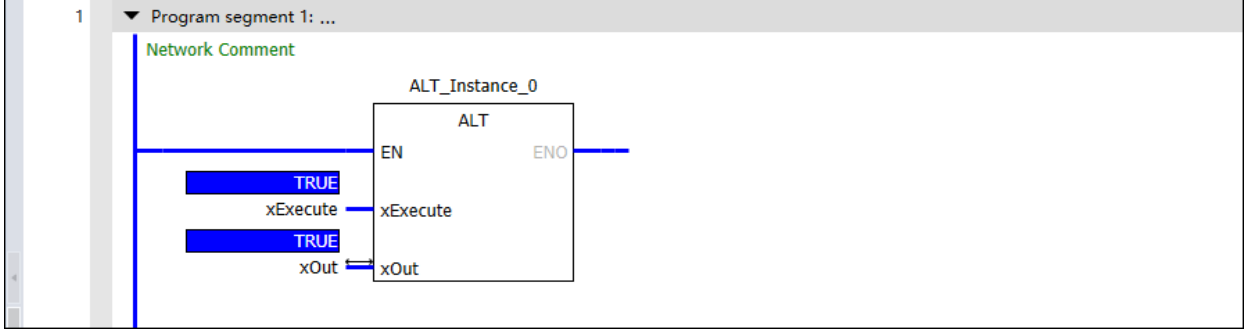
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
xExecute	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
xOut	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function description**

When the ALT instruction detects a rising edge on xExecute, the status of xOut will be reversed.

- **Sequence diagram**

- **Program example**



ST:

		Name	Type	Address	Value
1		ALT_Instance_0	ALT		
2		xExecute	BOOL		TRUE
3		xOut	BOOL		TRUE

```
1  ALT_Instance_0(xExecute := xExecute, xOut := xOut);
2  RETURN
```

LD:

		Name	Type	Address	Value
1		ALT_Instance_0	ALT		
2		xExecute	BOOL		TRUE
3		xOut	BOOL		TRUE

18.1.1.9 BOUT

The BOUT instruction is used to set the status of the specified data bit. If the input variable xEnable is TRUE, the status of uiBit is set to TRUE; if the input variable xEnable is FALSE, the status of uiBit is set to FALSE.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
BOUT	Bit data output	FC		:= BOUT(xEnable := , wData := , uiBit :=);

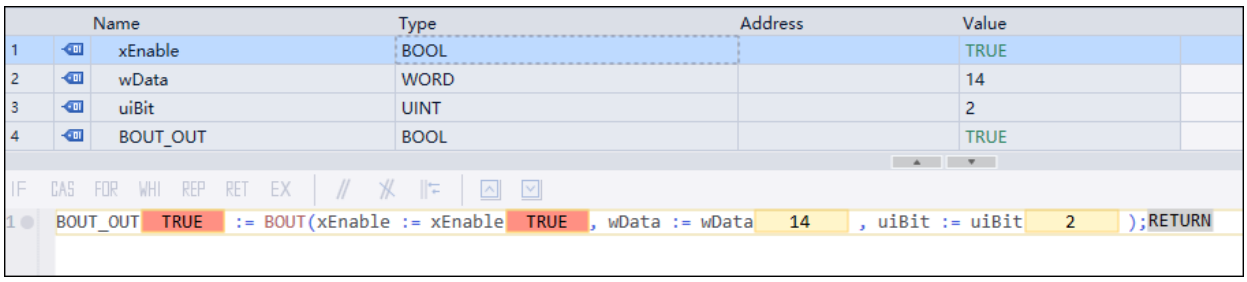
- **Related variables**

  Variable

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	xEnable	Input signal	Follows data type.	FALSE	Level-triggered switch
	uiBit	Input signal	Follows data type	0	The bit to be operated on.
Input/ Output	wData	Input/ Output signal	Follows data type	0	Data to operate
Output	OUT	Output signal	Follows data type.	FALSE	Return value of the function.

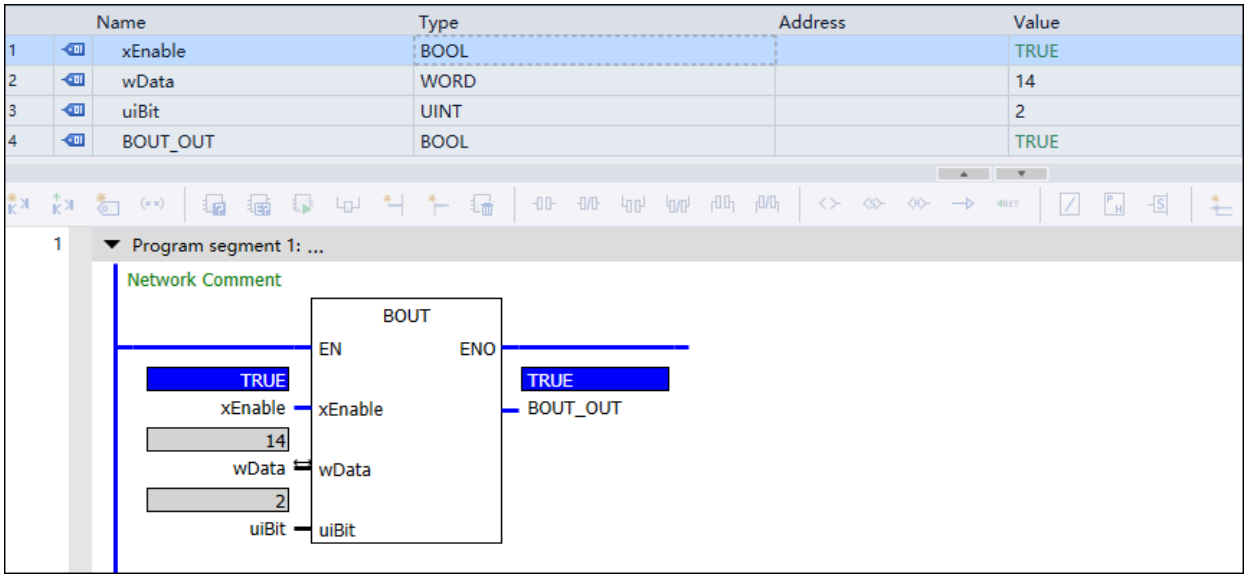
  Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
xEnable	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
wData	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
uiBit	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
OUT	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–



- **Function description**

  The BOUT instruction is used to set the status of the specified data bit. If the input variable xEnable is TRUE, the status of uiBit is set to TRUE; if the input variable xEnable is FALSE, the status of uiBit is set to FALSE.

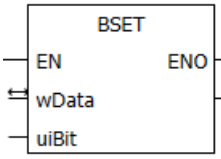


- **Program example**

Set the initial value of wData to 10 (#1010 in binary format). When uiBit = 2 and xEnable = TRUE, bit2 of wData is set, resulting in wData = 14 (2#1110 in binary format).

ST:

LD:



- **Precautions**
  - If uiBit is greater than 16, the instruction execution fails, and the return value is FALSE, with the output variable remaining at its initial value.
  - The instruction returns TRUE upon successful execution, otherwise returns FALSE.

18.1.1.10 BSET

Sets the status of the specified data bit to ON, and the set bit will remain ON. The ON status of the set bit will remain regardless of whether the BSET instruction is driven, and the bit can be reset to OFF using the BRST instruction.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
BSET	Bit data setting	FC		:= BSET(wData := , uiBit :=);

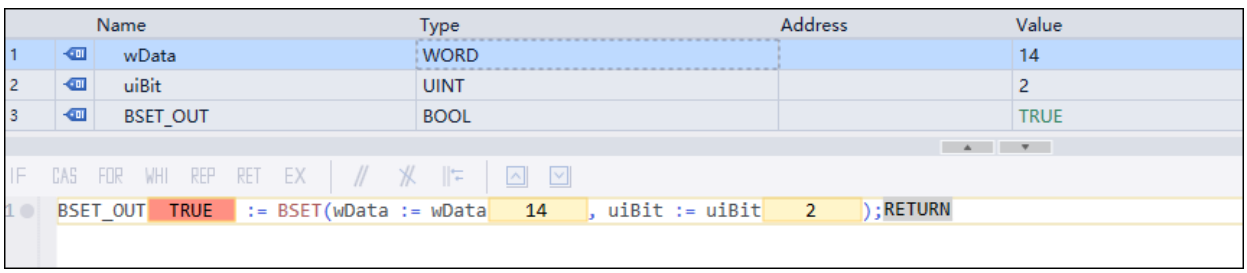
- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input/Output	wData	Input/Output signal	Follows data type	0	Data to operate
Input	uiBit	Input signal	Follows data type	0	The bit to be operated on.
Output	OUT	Output signal	Follows data type.	FALSE	Return value of the function.

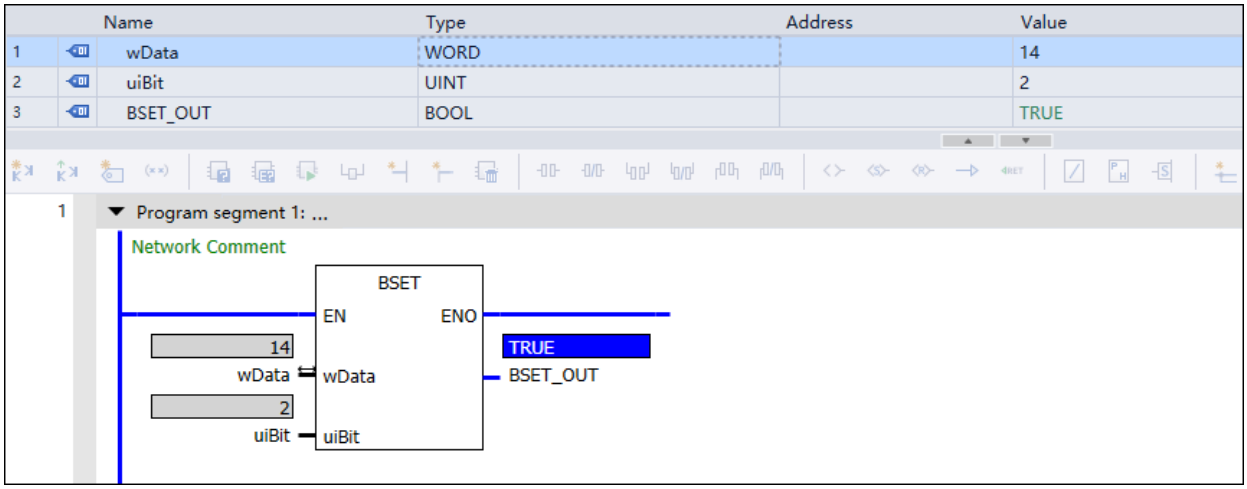
Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
wData	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
uiBit	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
OUT	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–



- **Function description**

  Sets the status of the specified data bit to ON, and the set bit will remain ON. The ON status of the set bit will remain regardless of whether the BSET instruction is driven, and the bit can be reset to OFF using the BRST instruction.

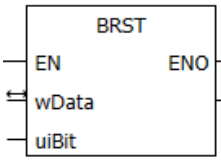


- **Program example**

  Set the initial value of wData to 10 (#1010 in binary format). When uiBit = 2, bit2 of wData is set, resulting in wData = 14 (2#1110 in binary format).

  ST:

  LD:



- **Precautions**
  - If uiBit is greater than 15, the instruction execution fails, and the return value is FALSE, with the output variable remaining at its initial value.
  - The instruction returns TRUE upon successful execution, otherwise returns FALSE.

18.1.1.11 BRST

The BRST instruction is used to reset the status of the specified data bit to OFF.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
BRST	Bit data reset	FC		:= BRST(wData := , uiBit :=);

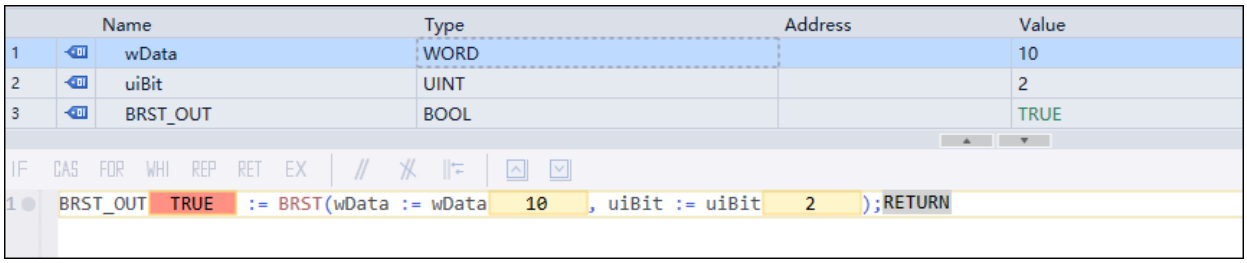
- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input/Output	wData	Input/Output signal	Follows data type	0	Data to operate
Input	uiBit	Input signal	Follows data type	0	The bit to be operated on.
Output	OUT	Output signal	Follows data type.	FALSE	Return value of the function.

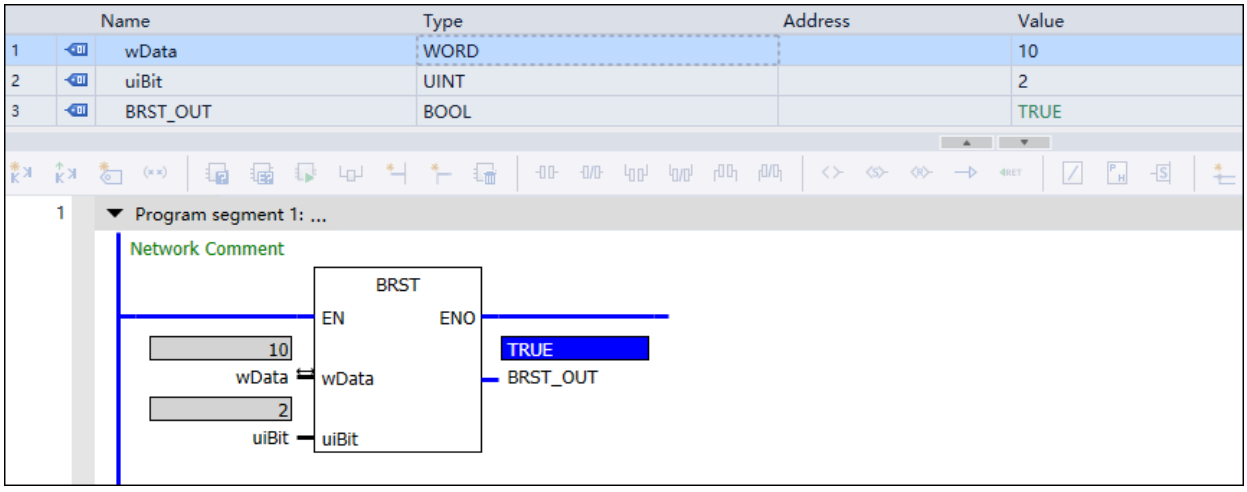
Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
wData	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
uiBit	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
OUT	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–



- **Function description**

  Resets the status of the specified data bit to OFF.

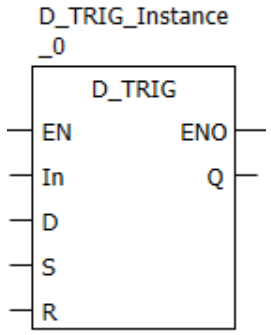


- **Program example**

  Set the initial value of wData to 14 (#1110 in binary format). When uiBit = 2, bit2 of wData is reset, resulting in wData = 10 (2#1010 in binary format).

  ST:

  LD:



- **Precautions**
  - If uiBit is greater than 15, the instruction execution fails, and the return value is FALSE, with the output variable remaining at its initial value.
  - The instruction returns TRUE upon successful execution, otherwise returns FALSE.

18.1.1.12 D_TRIG

The D_TRIG instruction is used as a D flip-flop.

- **Instruction format**

Instruction	Name	FB/FC	Ladder Diagram Representation	Structured Text Representation
D_TRIG	D flip-flop	FB		D_TRIG_Instance_0(In := , D := , S := , R := , Q =>);

- **Related variables**

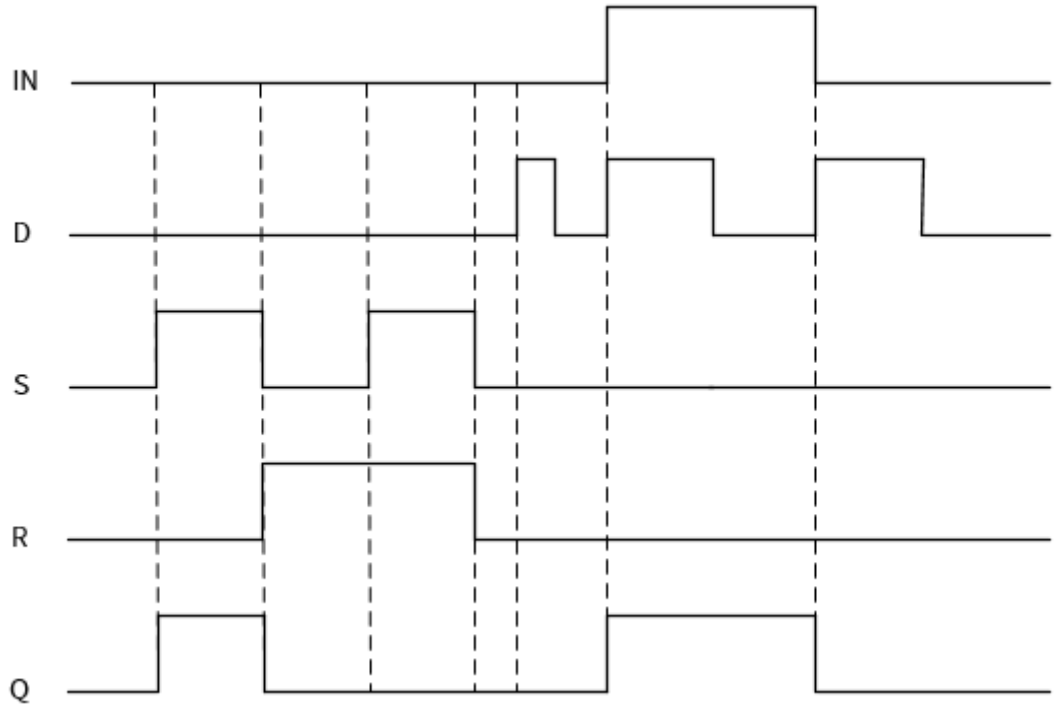
Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Input	Follows data type	-	Input
	D	Flip-flop	Follows data type	-	Flip-flop
	S	Set a bit	Follows data type	-	Sets the signal.
	R	Reset a bit	Follows data type	-	Reset
Output	Q	A flag indicating whether the input changes.	Follows data type	-	A flag indicating whether the input changes.

Data type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TOD	DT	STRING
In	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
D	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TOD	DT	STRING
S	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
R	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Q	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

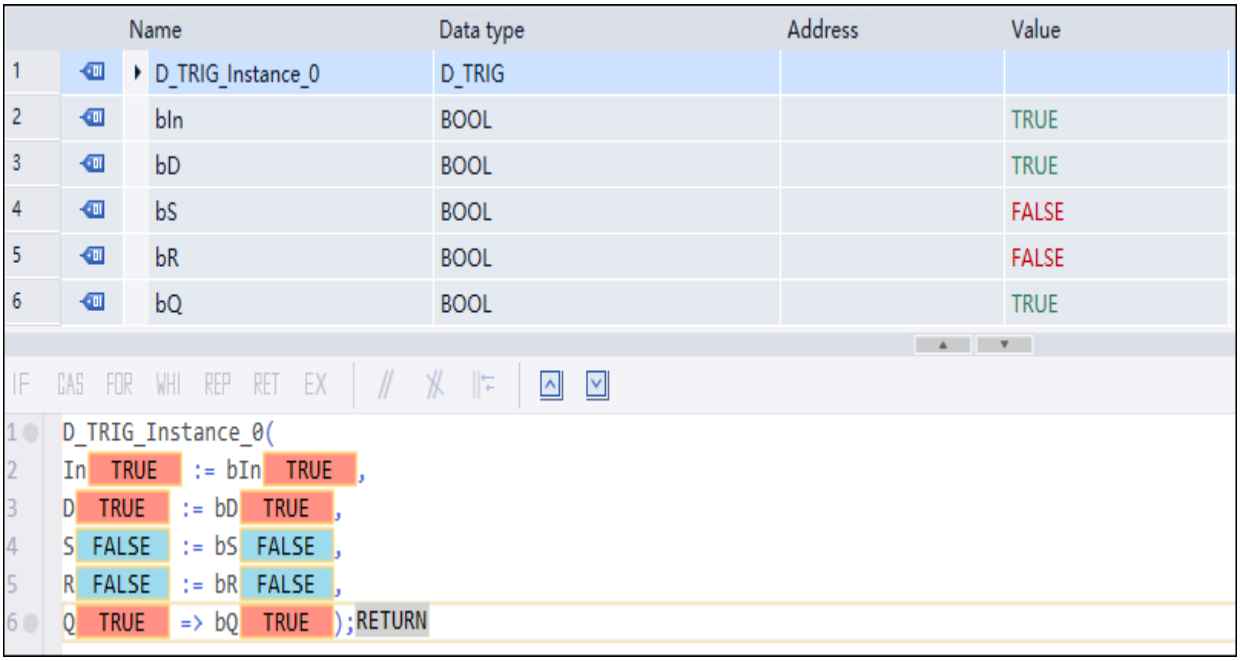


- **Function description**

  When input parameters are known, the output Q includes the following five cases as shown in the table:

S	R	D	In	Q
1	0	*	*	1
0	1	*	*	0
1	1	*	*	0
0	0	0 -> 1	In	In
0	0	Others	In	Q(n-1)

  Q(n-1) represents the output value Q from the previous cycle.



- **Sequence diagram**

- **Program example**

  When input variable In is TRUE, input variable S and R are FALSE, and input variable D changes from FALSE to TRUE, the output variable Q becomes TRUE.

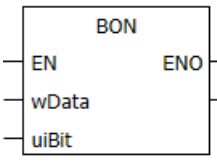
18.1.2.28 CopyNumToWord	FC	Bit pattern copy (integer to WORD-type bit string)		Library version 1.0.0.0 and later
18.1.2.29 CopyNumToDword	FC	Bit pattern copy (integer to DWORD-type bit string)		Library version 1.0.0.0 and later
18.1.2.30 CopyNumToLword	FC	Bit pattern copy (integer to LWORD-type bit string)		Library version 1.0.0.0 and later
18.1.2.31 CopyRealToDword	FC	Bit pattern copy (real number to DWORD-type bit string)		Library version 1.0.0.0 and later
18.1.2.32 CopyLrealToLword	FC	Bit pattern copy (long real number to LWORD-type bit string)		Library version 1.0.0.0 and later
18.1.2.33 Dispart8Bit	FC	Data separation by byte		Library version 1.0.0.0 and later



Instruction	FB/FC	Function	Library	Applicable Library Version
18.1.2.34 DispartDigit	FC	Data separation by digit		Library version 1.0.0.0 and later
18.1.2.35 DispartReal	FC	Separates mantissa and exponent		Library version 1.0.0.0 and later
18.1.2.36 Exchange	FC	Variable exchange		Library version 1.0.0.0 and later
18.1.2.37 FixNumToString	FC	Fixed-decimal number-to-string conversion		Library version 1.0.0.0 and later
18.1.2.38 GRAY	FC	Gray Code Conversion		Library version 1.0.0.0 and later
18.1.2.39 GrayToBin_BYTE	FC	Gray code-to-bit string conversion		Library version 1.0.0.0 and later
18.1.2.40 GrayToBin_WORD	FC	Gray code-to-bit string conversion		Library version 1.0.0.0 and later
18.1.2.41 GrayToBin_DWORD	FC	Gray code-to-bit string conversion		Library version 1.0.0.0 and later
18.1.2.42 GrayToBin_LWORD	FC	Gray code-to-bit string conversion		Library version 1.0.0.0 and later
18.1.2.43 LineToColm	FC	Line-to-column conversion		Library version 1.0.0.0 and later
18.1.2.44 MoveDigit	FC	Digit transfer		Library version 1.0.0.0 and later
18.1.2.45 ReadNbit_BYTE	FC	N-bit read group		Library version 1.0.0.0 and later
18.1.2.46 ReadNbit_WORD	FC	N-bit read group		Library version 1.0.0.0 and later
18.1.2.47 ReadNbit_DWORD	FC	N-bit read group		Library version 1.0.0.0 and later
18.1.2.48 ReadNbit_LWORD	FC	N-bit read group		Library version 1.0.0.0 and later
18.1.2.49 SetBlock	FC	Block setting		Library version 1.0.0.0 and later
18.1.2.50 StringToFixNum	FC	Conversion from a string to a fixed-decimal number		Library version 1.0.0.0 and later
18.1.2.51 TransBits	FC	Multiple bit transfer		Library version 1.0.0.0 and later
18.1.2.52 Unite8Bit_BYTE	FC	Byte data join group		Library version 1.0.0.0 and later
18.1.2.53 Unite8Bit_WORD	FC	Byte data join group		Library version 1.0.0.0 and later

Instruction	FB/FC	Function	Library	Applicable Library Version
18.1.2.54 Unite8Bit_DWORD	FC	Byte data join group		Library version 1.0.0.0 and later
18.1.2.55 Unite8Bit_LWORD	FC	Byte data join group		Library version 1.0.0.0 and later
18.1.2.56 UniteDigit_BYTE	FC	4-bit join group		Library version 1.0.0.0 and later
18.1.2.57 UniteDigit_WORD	FC	4-bit join group		Library version 1.0.0.0 and later
18.1.2.58 UniteDigit_DWORD	FC	4-bit join group		Library version 1.0.0.0 and later
18.1.2.59 UniteDigit_LWORD	FC	4-bit join group		Library version 1.0.0.0 and later
18.1.2.60 UniteReal	FC	Combine mantissa and exponent		Library version 1.0.0.0 and later
18.1.2.61 WriteNbit_BYTE	FC	N-bit write group		Library version 1.0.0.0 and later
18.1.2.62 WriteNbit_WORD	FC	N-bit write group		Library version 1.0.0.0 and later
18.1.2.63 WriteNbit_DWORD	FC	N-bit write group		Library version 1.0.0.0 and later
18.1.2.64 WriteNbit_LWORD	FC	N-bit write group		Library version 1.0.0.0 and later
18.1.2.65 StringSum	FC	String sum calculation		Library version 1.0.0.0 and later

18.1.2.2 BON

Checks the status of the uiBit-th bit in data wData, stores the result in BON and outputs from the right.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
BON	Gets the status of the specified bit in the data.	FC		:= BON(wData := , uiBit :=);

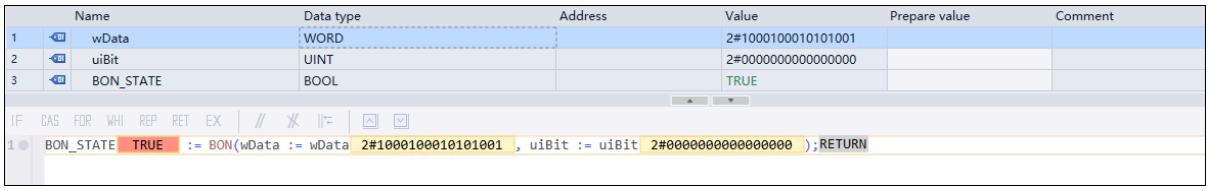
- **Related variables**

  Variable

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	wData	Data source	Follows data type	0	The data (in decimal format) to be checked.
	uiBit	Bit to check	Follows data type	0	The bit (in binary format) of the data to be checked.
Output	Out	Judgment result	Follows data type	FALSE	The status of the uiBit-th bit in wData.

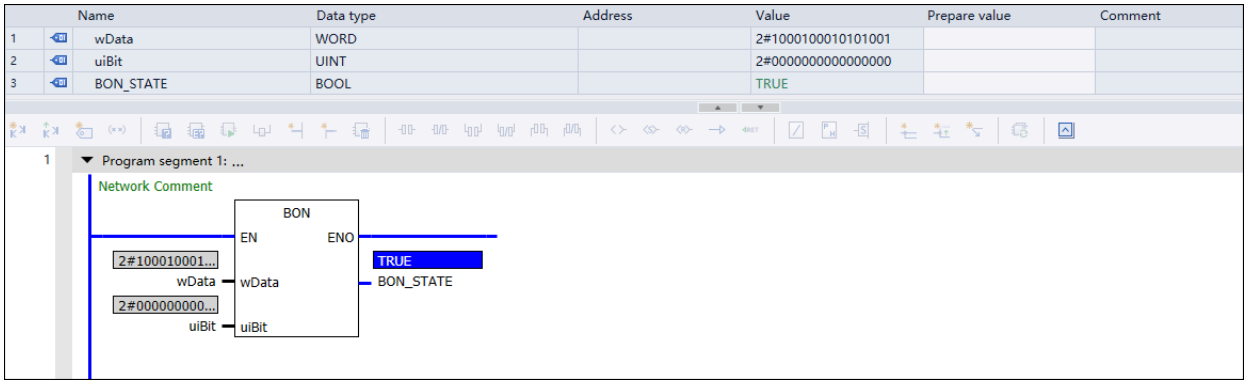
Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
wData	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
uiBit	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–



- **Function description**

  Checks the status of the uiBit-th bit in data wData, stores the result in BON and outputs from the right.



- **Program example**

  Input the data to be checked (wData), input the bit number to be checked (uiBit), and the corresponding bit status BON_STATE will be output. The initial value of wData is 2#1000100010101001.

  ST:

  LD:

- **Precautions**
  - If uiBit is greater than 16, the return value is FALSE, with the output variable remaining at its initial value.
  - The status of the uiBit-th bit in data wData is returned.

18.1.2.3 SUM

Counts the number of bits set to 1 in binary-format data stores the result in SUM and outputs it from the right.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
SUM	Total number of ON bits	FC	SUM EN ENO wData	:= SUM(wData :=);

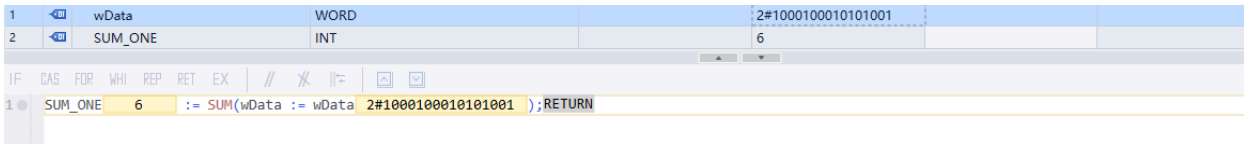
- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	wData	Data source	Follows data type	0	The data (in decimal format) to be checked.
Output	Out	Judgment result	Follows data type	0	Stores the number of bits set to 1 in wData (in binary format).

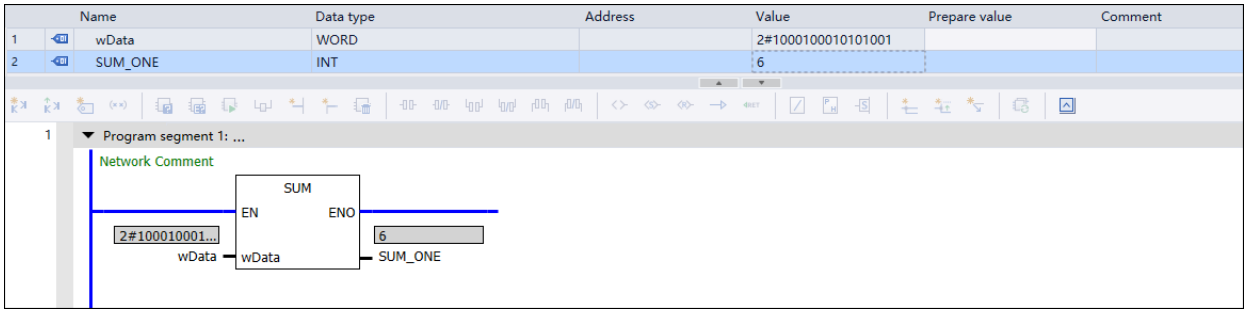
Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
wData	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–



- **Function description**

  Counts the number of bits set to 1 in binary-format data stores the result in SUM and outputs it from the right.

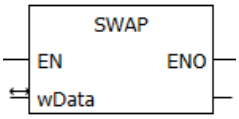


- **Program example**

  Input the data wData to be checked, count the number of bits set to 1 in binary-format data, and output the result as SUM_ONE. The initial value of wData is 2#1000100010101001.

  ST:

  LD:



- **Precautions**
  - Returns the number of bits set to 1 in binary-format data wData.

18.1.2.4 SWAP

Swaps the high 8 bits and low 8 bits of a 16-bit data type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
SWAP	High-low byte swap	FC		:= SWAP(wData :=);

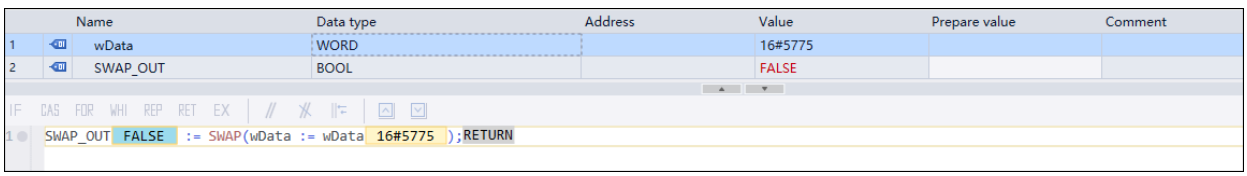
- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input/Output	wData	Input data	Follows data type	0	Data to operate
Output	Out	Execution result	Follows data type	FALSE	The result of the instruction.

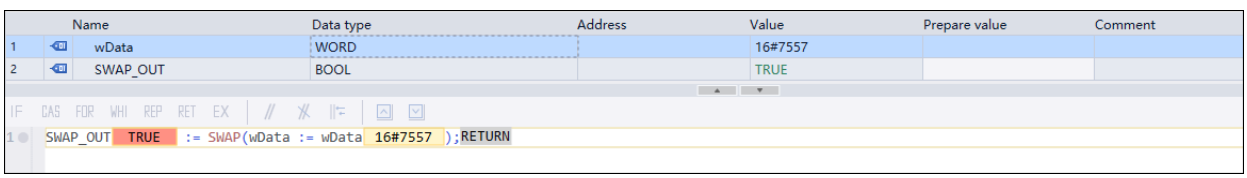
  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
wData	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–



- **Function description**

  Swaps the high 8 bits and low 8 bits of a 16-bit data type, and returns the result of the instruction.

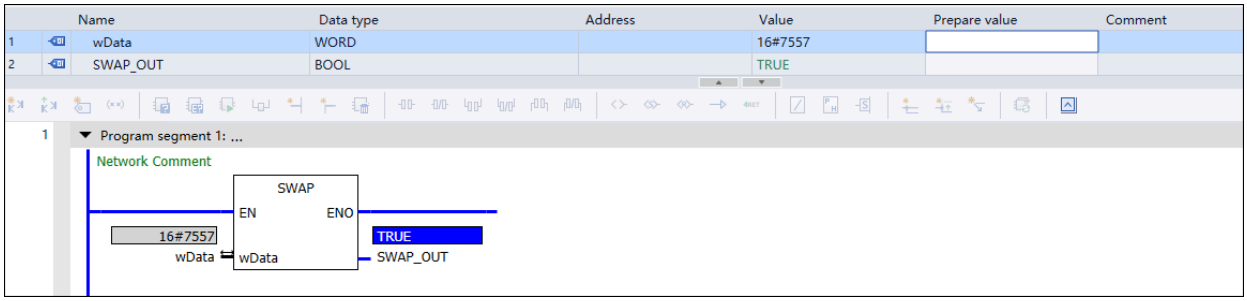


- **Program example**

  ST:

  Before execution:

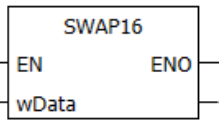
  After execution:



LD:

Before execution:

After execution:



- **Precautions**
  - Returns TRUE if the instruction executes successfully, otherwise returns FALSE.

18.1.2.5 SWAP16

Swaps the high 8 bits and low 8 bits of a 16-bit data type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
SWAP16	Byte swap	FC		:= SWAP16(wData :=);

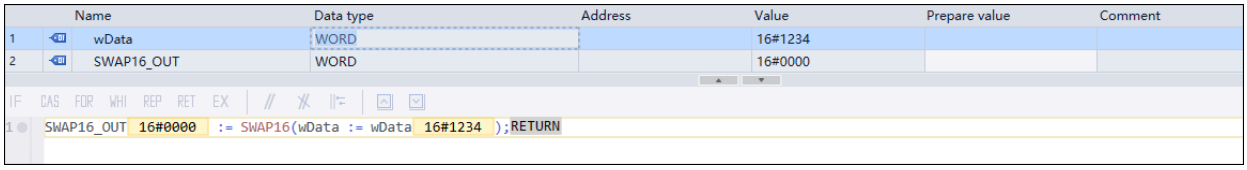
- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	wData	Input data	Follows data type	0	Data to operate
Output	Out	Swap result	Follows data type	0	The swap result after instruction execution.

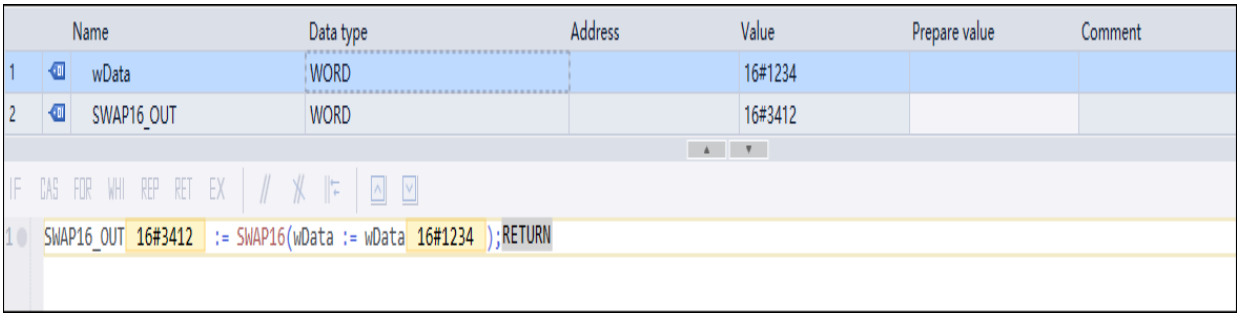
Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
wData	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–



- **Function description**

  Swaps the high 8 bits and low 8 bits of a 16-bit data type, and returns the swap result.



- **Program example**

  ST:

  Before execution:

  After execution:

  LD:

  Before execution:

  After execution:

- **Precautions**
  - Returns the 16-bit data whose high 8 bits and low 8 bits are swapped.

18.1.2.6 SWAP32

Swaps the high 16 bits and low 16 bits of a 32-bit data type, and also swaps the high 8 bits and low 8 bits within each 16-bit segment.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
SWAP32	Byte swap	FC	SWAP32 EN ENO wData	:= SWAP32(wData :=);

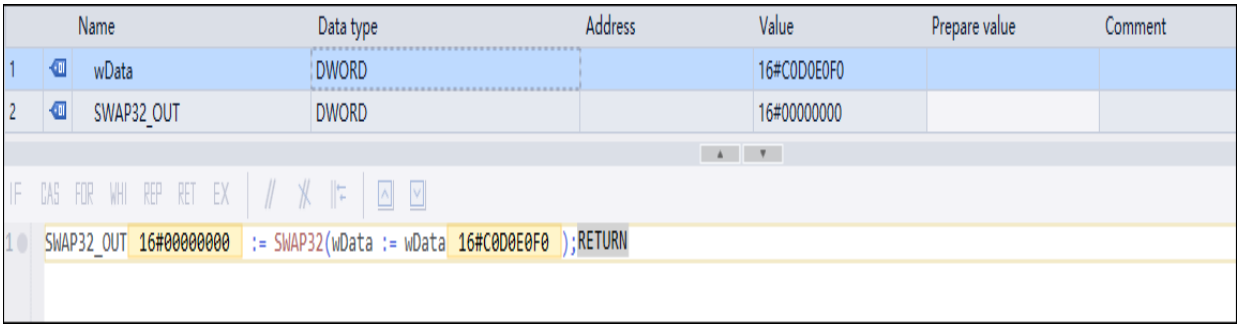
- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	wData	Input data	Follows data type	0	Data to operate
Output	Out	Swap result	Follows data type	0	The swap result after instruction execution.

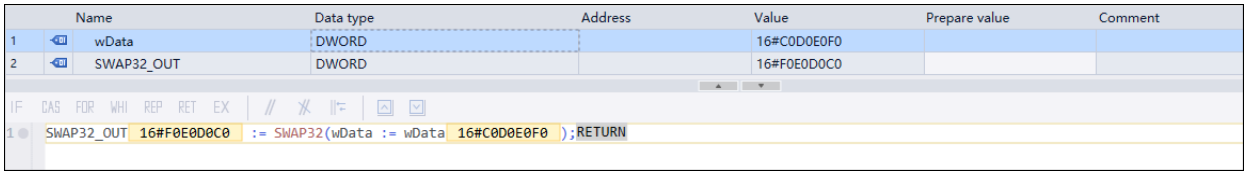
Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
wData	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–



- **Function description**

Swaps the high 16 bits and low 16 bits of a 32-bit data type, and also swaps the high 8 bits and low 8 bits within each 16-bit segment. The swap result is returned.



- **Program example**

  ST:

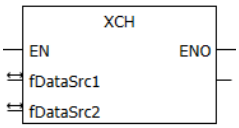
  Before execution:

  After execution:

  LD:

  Before execution:

  After execution:



- **Precautions**
  - Returns the swap result.

18.1.2.7 XCH

Swaps two floating-point values.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
XCH	Data exchange	FC		:= XCH(fDataSrc1 := , fDataSrc2 :=);

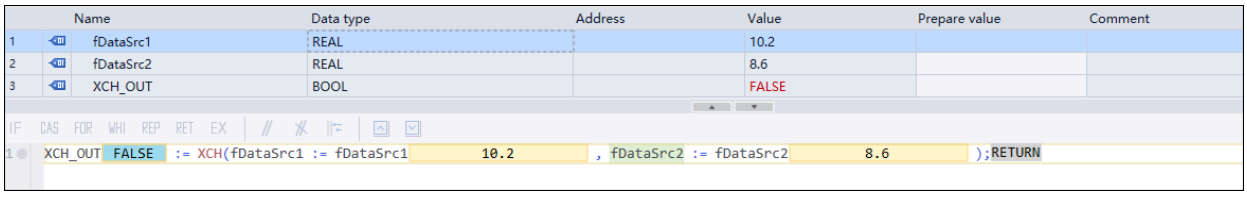
- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input/Output	fDataSrc1	Data 1 to swap	Follows data type	0	The data to be swapped.
	fDataSrc2	Data 2 to swap	Follows data type	0	The data to be swapped.
Output	Out	Execution result	Follows data type	0	The result of the instruction execution.

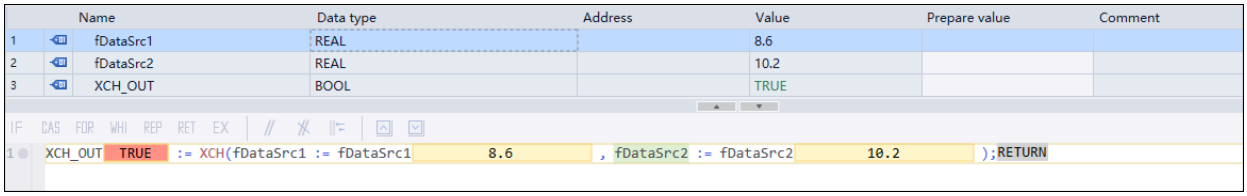
  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
fDataSrc1	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
fDataSrc2	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
Out	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–



- **Function description**

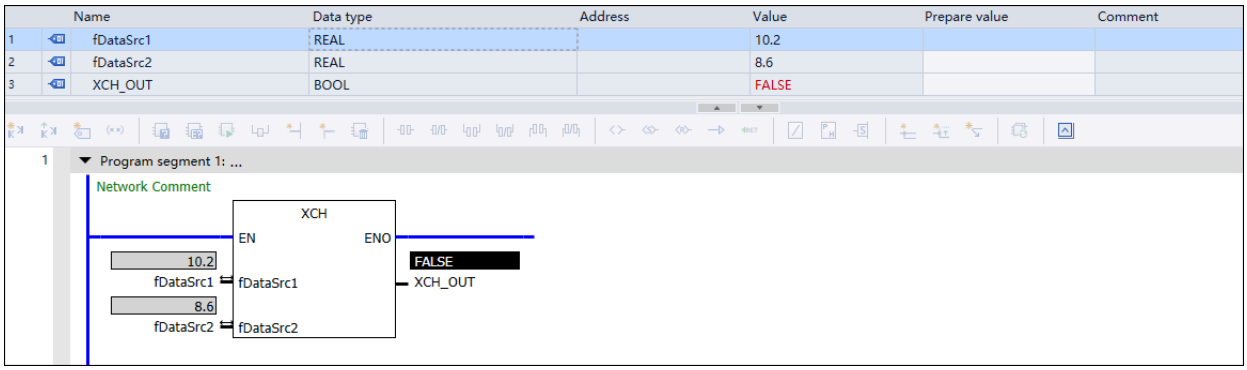
  Swaps two floating-point values and returns the instruction execution result.



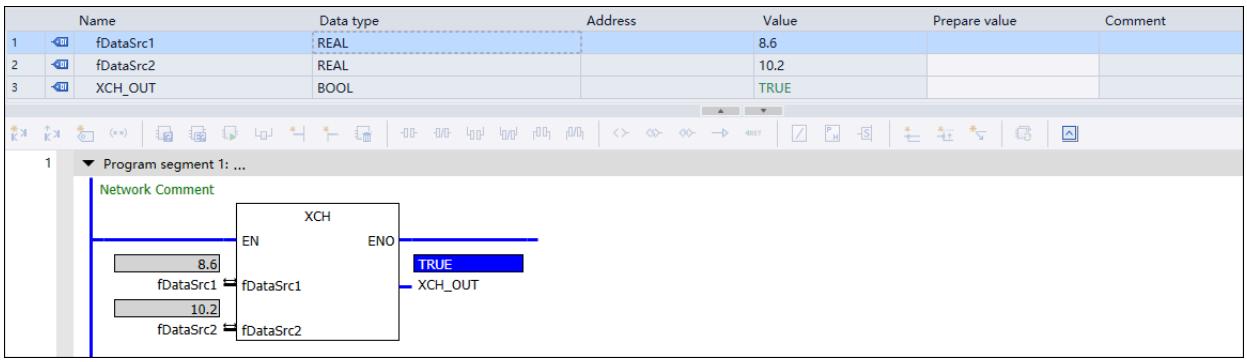
- **Program example**

  ST:

  Before execution:



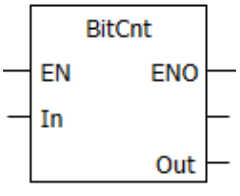
After execution:



LD:

Before execution:

After execution:



- **Precautions**
  - Returns TRUE if the instruction executes successfully, otherwise returns FALSE.

18.1.2.8 BitCnt

Counts the total number of bits with value TRUE in the bit string.

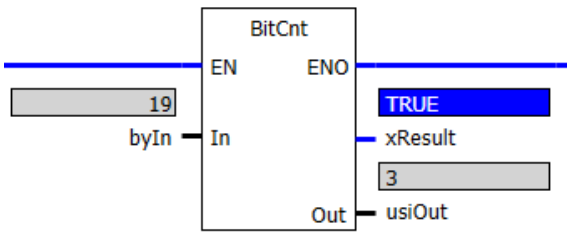
- **Instruction format**

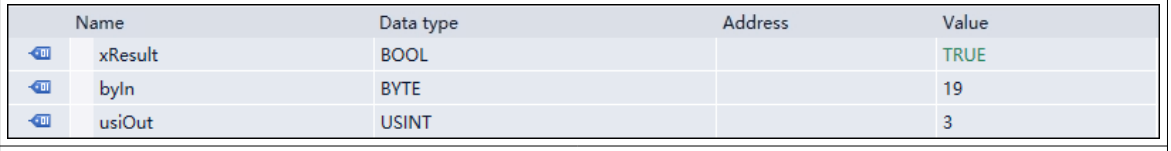
Instruction	Name	FB/FC	LD Representation	ST Representation
BitCnt	Bit counter	FC		:= BitCnt(In := , Out =>);

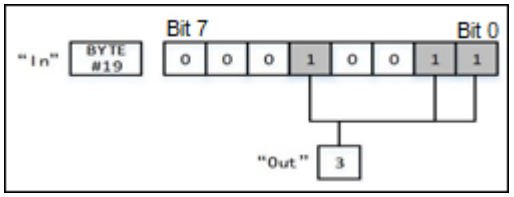
- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Counted object	Follows data type	-	The object to be counted.
Output	Out	Count result	Follows data type	0	The number of bits with value TRUE in the counted object.





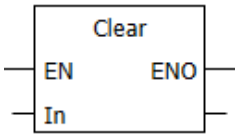


Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	√	√	√	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function description**

  Counts the total number of bits with value TRUE in the object In.



- **Program example**

	LD	ST
Define variables	VAR xResult: BOOL; byIn: BYTE := 19; usiOut: USINT; END_VAR	
Program		xResult TRUE := BitCnt(In := byIn 19, Out => usiOut 3);RETURN
Operation result		
Principle analysis		

18.1.2.9 Clear

Initializes the input variable.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
Clear	Initialization	FC		:= Clear(In :=);

- **Related variables**

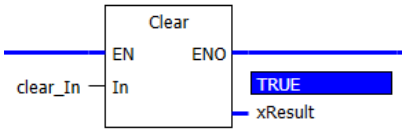
Variable

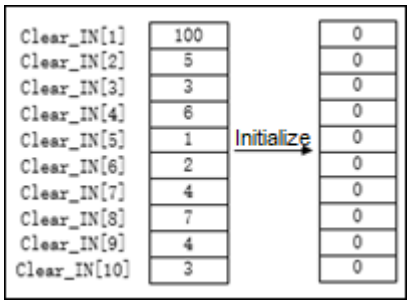
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Initialization object	Follows data type	-	The object to be initialized.

Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
	An enumeration value, a structure, an array, or a single element of an array.																			

- **Function description**
  - Initializes the value of the object "In" to the initial value for each data type.
  - The initial value for each data type is shown in the table below.



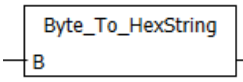


Data Type	Initial Value
BOOL	FALSE
BYTE, WORD, DWORD, LWORD	16#0
USINT, UINT, UDINT, ULINT, SINT, INT, DINT, LINT, REAL, LREAL	0
TIME	T#0ms
DATE	D#1970-1-1

Data Type	Initial Value
TOD	TOD#0:0:0
DT	DT#1970-1-1-0:0:0
STRING	''

When "In" is an array or a single element of an array, it is handled shown in the table below.

"In"	Processing Method
Array	Initializes all elements of the array
A single element of an array	Initializes only the element
Structure	Initializes all elements of the structure
A single element of a structure	Initializes only the element



- **Program example**

	LD	ST
Define variables	VAR xResult: BOOL; clear_In: ARRAY[1..10] OF UINT := [100,5,3,6,1,2,4,7,4,3]; END_VAR	
Program		
Operation result		
Principle analysis		

18.1.2.10 Byte_To_HexString

This instruction converts bytes to hexadecimal text strings.

- **Instruction format**

Instruction	Name	FB/FC	Ladder Diagram Representation	Structured Text Representation
Byte_To_HexString	Byte-to-hexadecimal text string conversion	FC		:= Byte_To_HexString(B :=);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	B	Byte to convert	0 to 255	0	Input data address
Output	Out	Return value	-	'00'	Hexadecimal string

  Variable types

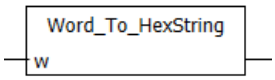
	Boolean	Bit String				Integer								Real Number		Time, duration, date, and text string				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
B	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√

- **Function description**

  This instruction converts bytes to hexadecimal text strings.

- **Program example**

	LD	ST
Define variables	VAR byB: BYTE; strOut: STRING; END_VAR	
Program		
Operation result		



Name	Type	Address	Value
byB	BYTE		12
strOut	STRING		'0C'

- **Precautions**
  - The value range of B is 0 to 255. If the value is not within the range, an error occurs.
  - The output range is '00' to 'FF', that is, 00000000 to 11111111.

18.1.2.11 Word_To_HexString

This instruction converts words to hexadecimal text strings.

- **Instruction format**

Instruction	Name	FB/FC	Ladder Diagram Representation	Structured Text Representation
Word_To_HexString	Word-to-hexadecimal text string conversion	FC		:= Word_To_HexString(w :=);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	w	Word to convert	0 to FFFF	0	Input data address
Output	Out	Return value	-	'0000'	Hexadecimal string

Variable types

	Boolean	Bit String				Integer								Real Number		Time, duration, date, and text string				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
w	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√

- **Function description**

  This instruction converts words to hexadecimal text strings.

- **Program example**

	LD	ST
Define variables	VAR wInput: WORD; strOut: STRING; END_VAR	
Program		

	LD	ST
Operation result		

- **Precautions**
  - The value range of B is 0 to 65535. If the value is not within the range, an error occurs.
  - The output range is '0000' to 'FFFF', that is, 0000 0000 0000 0000 to 1111 1111 1111 1111.

18.1.2.12 Dword_To_HexString

This instruction converts doublewords (DWORD) to hexadecimal text strings.

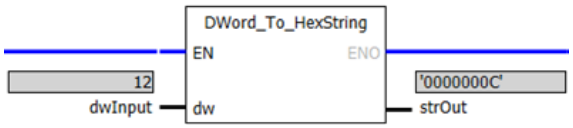
- **Instruction format**

Instruction	Name	FB/FC	Ladder Diagram Representation	Structured Text Representation
Dword_To_HexString	Doubleword-to-hexadecimal text string conversion	FC		:= Dword_To_HexString(dw :=);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	dw	Doubleword to convert	0 to FFFF FFFF	0	Input data address
Output	Out	Return value	-	'0000 0000'	Hexadecimal string



Variable types

	Boolean	Bit String				Integer								Real Number		Time, duration, date, and text string				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
dw	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√

- **Function description**

  This instruction converts doublewords (DWORD) to hexadecimal text strings.

- **Program example**

	LD	ST
Define variables	VAR dwInput: DWORD; strOut: STRING; END_VAR	
Program		
Operation result		

- **Precautions**
  - The value range of dw is 0 to 4294967295. If the value is not within the range, an error occurs.
  - The output range is '0000 0000' to 'FFFF_FFFF', that is, 0000 0000 0000 0000 0000 0000 0000 0000 to 1111 1111
    1111 1111 1111 1111 1111 1111.

18.1.2.13 ColmToLine_BYTE

Extracts the value at the specified position of each array element and outputs as a bit string.

- **Instruction format**

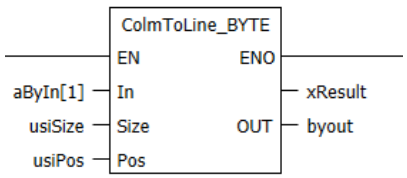
Instruction	Name	FB/FC	LD Representation	ST Representation
ColmToLine_BYTE	Specified position combination output of array elements	FC		:= ColmToLine_BYTE(In := , Size := , Pos := , OUT =>);

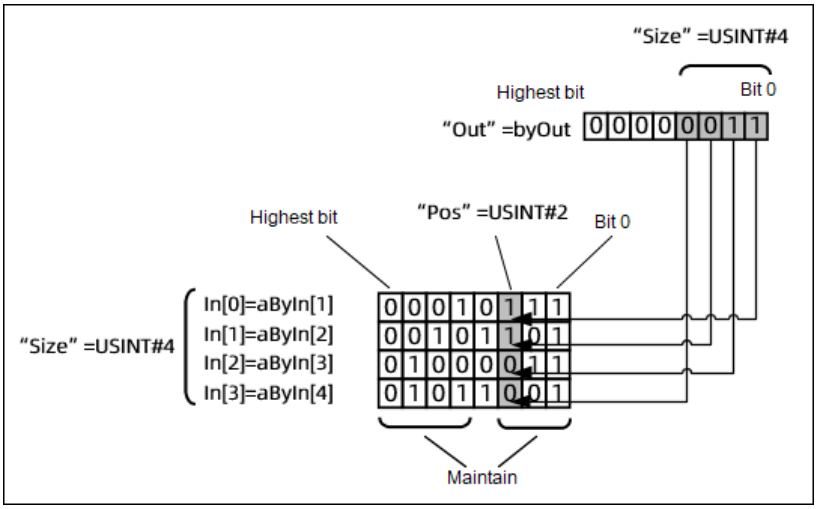
- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In[ ] array	Array where the conversion object is located	Follows data type	-	Array of objects to be converted
	Size	Number of elements in the conversion object	Follows data type	1	Number of elements in In[ ] to be converted
	Pos	Bit position to convert	Follows data type	0	Bit position to be converted

Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	Out	Conversion result	Follows data type	0	Conversion result





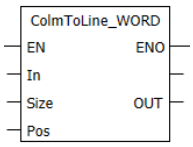
Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In[ ] array	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Size	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Pos	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function description**
  - Extracts the value at the specified position of each array element and outputs as a bit string in an arranged way.
  - Extracts "Size" array elements from the input array In[ ] starting at In[0], and extracts only the "Pos"-th bit value from these array elements. Arranges them into a "Size"-bit string, and stores it at the least significant bit position of the conversion result "Out". All remaining bits of "Out" are set to FALSE.
- **Program example**

	LD	ST

Define variables	VAR
	xResult: BOOL;
	aByIn:ARRAY[0..4] OF byte := [1,23,45,67,89];
	usiSize: USINT := 4;
	usiPos: USINT := 2;
	byout:BYTE;
	END_VAR	



<table>
<tr><th></th><th>LD</th><th>ST</th></tr>
<tr><td>Program</td><td>
</td><td><pre>xResult := ColmToLine_BYTE(In := aByIn[1],
  Size := usiSize,
  Pos := usiPos,
  OUT => byout);</pre></td></tr>
<tr><td>Operation result</td><td colspan="2">
<table>
<tr><th></th><th>Name</th><th>Data type</th><th>Address</th><th>Value</th></tr>
<tr><td></td><td>xResult</td><td>BOOL</td><td></td><td>TRUE</td></tr>
<tr><td></td><td>aByIn</td><td>ARRAY [0..4] OF BYTE</td><td></td><td></td></tr>
<tr><td></td><td>aByIn[0]</td><td>BYTE</td><td></td><td>2#00000001</td></tr>

Out	A signed integer with the same size as "In"																			

- **Function description**

  Copies a bit string directly to a signed integer. There are 4 instruction names, depending on the combination of data types for "In" and "Out".

"In"	"Out"	Instruction
BYTE	SINT	CopyByteToNum
WORD	INT	CopyWordToNum
DWORD	DINT	CopyDwordToNum
LWORD	LINT	CopyLwordToNum

- **Program example**

	LD	ST
Define variables	VAR xResult: BOOL; wIn: WORD := 10; iOut: INT; END_VAR	
Program		xResult := CopyWordToNum(In := wIn, Out => iOut);
Operation result		

18.1.2.21 CopyDwordToNum

Copies a bit string directly to a signed integer.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
CopyDwordToNum	Bit pattern copy (DWORD-type bit string to signed integer)	FC		:= CopyDwordToNum(In := , Out =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Copy source	Follows data type	0	Source to be copied
Output	Out	Paste target	Follows data type	0	Target to paste to

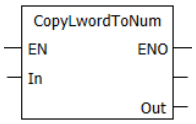
Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	-	-	-	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Out	A signed integer with the same size as "In"																			

- **Function description**

  Copies a bit string directly to a signed integer. There are 4 instruction names, depending on the combination of data types for "In" and "Out".

"In"	"Out"	Instruction
BYTE	SINT	CopyByteToNum
WORD	INT	CopyWordToNum
DWORD	DINT	CopyDwordToNum
LWORD	LINT	CopyLwordToNum



- **Program example**

	LD	ST
Define variables	VAR xResult: BOOL; dwIn: DWORD := 10; diOut: DINT; END_VAR	
Program	CopyDwordToNum EN ENO dwIn In xResult Out diOut	xResult := CopyDwordToNum(In := dwIn, Out => diOut);
Operation result	Name / Data type / Address / Value xResult / BOOL / / TRUE dwIn / DWORD / / 2#00000000000000000000000000001010 diOut / DINT / / 2#00000000000000000000000000001010	

18.1.2.22 CopyLwordToNum

Copies a bit string directly to a signed integer.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
CopyLwordToNum	Bit pattern copy (LWORD-type bit string to signed integer)	FC		:= CopyLwordToNum(In := , Out =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Copy source	Follows data type	0	Source to be copied
Output	Out	Paste target	Follows data type	0	Target to paste to

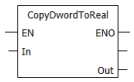
Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	-	-	-	-	-	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Out	A signed integer with the same size as "In"																			

- **Function description**

Copies a bit string directly to a signed integer. There are 4 instruction names, depending on the combination of data types for "In" and "Out".

"In"	"Out"	Instruction
BYTE	SINT	CopyByteToNum
WORD	INT	CopyWordToNum
DWORD	DINT	CopyDwordToNum
LWORD	LINT	CopyLwordToNum



- **Program example**

	LD	ST
Define variables	VAR xResult: BOOL; lwIn: LWORD := 10; liOut: LINT; END_VAR	
Program		xResult := CopyLwordToNum(In := lwIn, Out => liOut);
Operation result		

18.1.2.23 CopyDwordToReal

Copies a bit string directly into a real number.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
CopyDwordToReal	Bit pattern copy (DWORD-type bit string to real number)	FC		:= CopyDwordToReal(In := , Out =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Copy source	Follows data type	0	Source to be copied
Output	Out	Paste target	Follows data type	0	Target to paste to

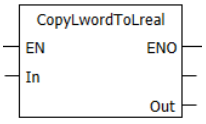
Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	-	-	-	-	-	-	-	-	-	-	-	-	-	√	-	-	-	-	-	-

- **Function description**

  Copies a bit string directly into a real number. There are 2 instruction names, depending on the combination of data types for "In" and "Out".

"In"	"Out"	Instruction
DWORD	REAL	CopyDwordToReal
LWORD	LREAL	CopyLwordToLreal



- **Program example**

	LD	ST
Define variables	VAR xResult: BOOL; dwIn: DWORD := 10; reOut: REAL; END_VAR	
Program	CopyDwordToReal EN ENO dwIn — In — xResult Out — reOut	xResult := CopyDwordToReal(In := dwIn, Out => reOut);
Operation result	Name / Data type / Address / Value xResult / BOOL / / TRUE dwIn / DWORD / / 2#00000000000000000000000000001010 reOut / REAL / / 2#00000000000000000000000000001010	

18.1.2.24 CopyLwordToLreal

Copies a bit string directly into a real number.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
CopyLwordToLreal	Bit pattern copy (LWORD-type bit string to long real number)	FC		:= CopyLwordToLreal(In := , Out =>);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Copy source	Follows data type	0	Source to be copied
Output	Out	Paste target	Follows data type	0	Target to paste to

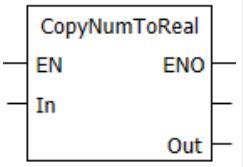
  Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	-	-	-	-	-	-	-	-	-	-	-	-	-	-	√	-	-	-	-	-

- **Function description**

  Copies a bit string directly into a real number. There are 2 instruction names, depending on the combination of data types for "In" and "Out".

"In"	"Out"	Instruction
DWORD	REAL	CopyDwordToReal
LWORD	LREAL	CopyLwordToLreal



- **Program example**

	LD	ST
Define variables	VAR xResult: BOOL; lwIn: LWORD := 10; lreOut: LREAL; END_VAR	
Program		xResult := CopyLwordToLreal(In := lwIn, Out => lreOut);
Operation result		

18.1.2.25 CopyNumToReal

Copies a signed integer directly into a real number.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
CopyNumToReal	Bit pattern copy (integer to real number)	FC		:= CopyNumToReal(In := , Out =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Copy source	Follows data type	0	Source to be copied
Output	Out	Paste target	Follows data type	0	Target to paste to

Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Out	-	-	-	-	-	-	-	-	-	-	-	-	-	√	-	-	-	-	-	-

- **Function**

  The source content is copied directly to the target "Out" without any processing. There are 2 instruction names, depending on the combination of data types for "In" and "Out".

"In"	"Out"	Instruction
DINT	REAL	CopyNumToReal
LINT	LREAL	CopyNumToLreal

- **Program example**

	LD	ST
Define variables	VAR xResult: BOOL; diIn: DINT:= 10; reOut: REAL; END_VAR	
Program		xResult := CopyNumToReal(In := diIn, Out => reOut);
Operation result		

Name	Data type	Address	Value
xResult	BOOL		TRUE
diIn	DINT		2#00000000000000000000000000001010
reOut	REAL		2#00000000000000000000000000001010

18.1.2.26 CopyNumToLreal

Copies a signed integer directly into a real number.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
CopyNumToLreal	Bit pattern copy (integer to long real number)	FC		:= CopyNumToLreal(In := , Out =>);

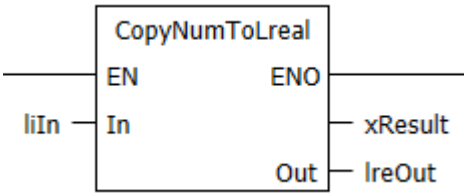
- **Related variables**

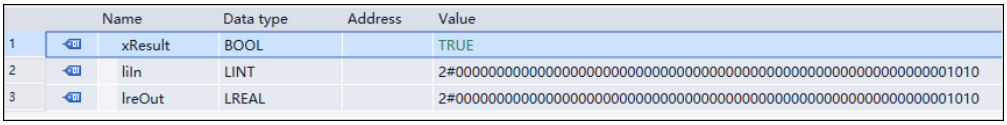
Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Copy source	Follows data type	0	Source to be copied
Output	Out	Paste target	Follows data type	0	Target to paste to

Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–
Out	-	-	-	-	-	-	-	-	-	-	-	-	-	-	√	-	-	-	-	-





- **Function**

The source content is copied directly to the target "Out" without any processing. There are 2 instruction names, depending on the combination of data types for "In" and "Out".

"In"	"Out"	Instruction
DINT	REAL	CopyNumToReal
LINT	LREAL	CopyNumToLreal

- **Program example**

	LD	ST
Define variables	VAR xResult: BOOL; liIn: LINT := 10; lreOut: LREAL; END_VAR	

	LD	ST
Program		`xResult := CopyNumToLreal(In := liIn, Out => lreOut);`
Operation result		

	Name	Data type	Address	Value
1	xResult	BOOL		TRUE
2	liIn	LINT		2#0000000000000000000000000000000000000000000000000000000000001010
3	lreOut	LREAL		2#0000000000000000000000000000000000000000000000000000000000001010

18.1.2.27 CopyNumToByte

Copies a signed integer directly into a bit string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
CopyNumToByte	Bit pattern copy (integer to BYTE-type bit string)	FC		:= CopyNumToByte(In := , Out =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Copy source	Follows data type	0	Source to be copied
Output	Out	Paste target	Follows data type	0	Target to paste to

Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Out	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  The source content is copied directly to the target "Out" without any processing. There are 4 instruction names, depending on the combination of data types for "In" and "Out".

"In"	"Out"	Instruction
SINT	BYTE	CopyNumToByte
INT	WORD	CopyNumToWord
DINT	DWORD	CopyNumToDword
LINT	LWORD	CopyNumToLword

- **Program example**

	LD	ST
Define variables	VAR xResult: BOOL; siIn: SINT := 10; byOut: BYTE; END_VAR	
Program		xResult:= CopyNumToByte(In := siIn, Out => byOut);
Operation result		

Name	Data type	Address	Value
xResult	BOOL		TRUE
siIn	SINT		2#00001010
byOut	BYTE		2#00001010

18.1.2.28 CopyNumToWord

Copies a signed integer directly into a bit string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
CopyNumToWord	Bit pattern copy (integer to WORD-type bit string)	FC		:= CopyNumToWord(In := , Out =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Copy source	Follows data type	0	Source to be copied
Output	Out	Paste target	Follows data type	0	Target to paste to

Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–
Out	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

The source content is copied directly to the target "Out" without any processing. There are 4 instruction names, depending on the combination of data types for "In" and "Out".

"In"	"Out"	Instruction
SINT	BYTE	CopyNumToByte
INT	WORD	CopyNumToWord
DINT	DWORD	CopyNumToDword
LINT	LWORD	CopyNumToLword

- **Program example**

	LD	ST
Define variables	VAR xResult: BOOL; iIn: INT := 10; wOut: WORD; END_VAR	
Program		xResult := CopyNumToWord(In := iIn, Out => wOut);
Operation result		

	Name	Data type	Address	Value
	xResult	BOOL		TRUE
	iIn	INT		2#0000000000001010
	wOut	WORD		2#0000000000001010

18.1.2.29 CopyNumToDword

Copies a signed integer directly into a bit string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
CopyNumToDword	Bit pattern copy (integer to DWORD-type bit string)	FC		:= CopyNumToDword(In := , Out =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Copy source	Follows data type	0	Source to be copied
Output	Out	Paste target	Follows data type	0	Target to paste to

Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–
Out	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  The source content is copied directly to the target "Out" without any processing. There are 4 instruction names, depending on the combination of data types for "In" and "Out".

"In"	"Out"	Instruction
SINT	BYTE	CopyNumToByte
INT	WORD	CopyNumToWord
DINT	DWORD	CopyNumToDword
LINT	LWORD	CopyNumToLword

- **Program example**

	LD	ST
Define variables	VAR xResult: BOOL; diIn: DINT := 10; dwOut: DWORD; END_VAR	
Program		xResult := CopyNumToDword(In := diIn, Out => dwOut);
Operation result		

Name	Data type	Address	Value
xResult	BOOL		TRUE
diIn	DINT		2#00000000000000000000000000001010
dwOut	DWORD		2#00000000000000000000000000001010

18.1.2.30 CopyNumToLword

Copies a signed integer directly into a bit string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
CopyNumToLword	Bit pattern copy (integer to LWORD-type bit string)	FC		:= CopyNumToLword(In := , Out =>);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Copy source	Follows data type	0	Source to be copied
Output	Out	Paste target	Follows data type	0	Target to paste to

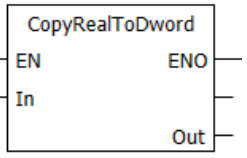
  Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–
Out	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  The source content is copied directly to the target "Out" without any processing. There are 4 instruction names, depending on the combination of data types for "In" and "Out".

"In"	"Out"	Instruction
SINT	BYTE	CopyNumToByte
INT	WORD	CopyNumToWord
DINT	DWORD	CopyNumToDword
LINT	LWORD	CopyNumToLword



- **Program example**

	LD	ST
Define variables	VAR xResult: BOOL; liIn: LINT := 10; lwOut: LWORD; END_VAR	
Program		xResult := CopyNumToLword(In := liIn, Out => lwOut);
Operation result		

18.1.2.31 CopyRealToDword

Copies a real number directly into a bit string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
CopyRealToDword	Bit pattern copy (real number to DWORD-type bit string)	FC		:= CopyRealToDword(In := , Out =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Copy source	Follows data type	0	Source to be copied
Output	Out	Paste target	Follows data type	0	Target to paste to

Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Out	-	-	-	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

- **Function**

  Copies a real number directly into a bit string. There are 2 instruction names, depending on the combination of data types for "In" and "Out".

"In"	"Out"	Instruction
REAL	DWORD	CopyRealToDword
LREAL	LWORD	CopyLrealToLword

- **Program example**

	LD	ST
Define variables	VAR xResult: BOOL; reIn: REAL := 3.5; dwOut: DWORD; END_VAR	
Program		xResult := CopyRealToDword(In := reIn, Out => dwOut);
Operation result		

Name	Data type	Address	Value
xResult	BOOL		TRUE
reIn	REAL		2#01000000011000000000000000000000
dwOut	DWORD		2#01000000011000000000000000000000

18.1.2.32 CopyLrealToLword

Copies a real number directly into a bit string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
CopyLrealToLword	Bit pattern copy (long real number to LWORD-type bit string)	FC		:= CopyLrealToLword(In := , Out =>);

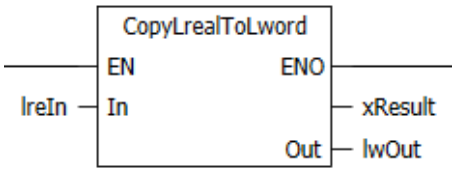
- **Related variables**

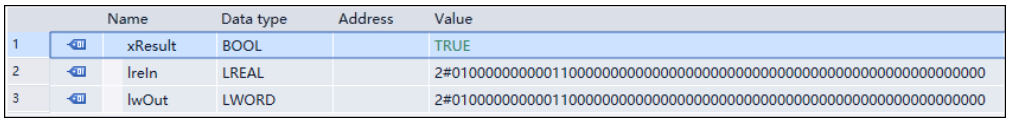
  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Copy source	Follows data type	0	Source to be copied
Output	Out	Paste target	Follows data type	0	Target to paste to

  Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–		√	–	–	–	–	–
Out	-	-	-	-	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-





- **Function**

  Copies a real number directly into a bit string. There are 2 instruction names, depending on the combination of data types for "In" and "Out".

"In"	"Out"	Instruction
REAL	DWORD	CopyRealToDword
LREAL	LWORD	CopyLrealToLword

- **Program example**

	LD	ST
Define variables	VAR xResult: BOOL; lreIn: LREAL := 3.5; lwOut: LWORD; END_VAR	

	LD	ST
Program		`xResult := CopyLrealToLword(In := lreIn, Out => lwOut);`
Operation result		

18.1.2.33 Dispart8Bit

Separates a bit string by 1 byte.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
Dispart8Bit	Data separation by byte	FC		:= Dispart8Bit(In := , Num := , AryOut :=);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Separation object	Follows data type	-	A bit string to be separated
	Num	Number of digits for separation	Follows data type	1	Number of bytes for separation
Input/Output	AryOut[ ] array	Separation result	Follows data type	-	An array indicating the separation result

Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	√	√	√	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Num	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
AryOut[ ] array	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  Separates "In" by 1 byte and saves the result in the array "AryOut[ ]".

  The least significant byte is stored in AryOut[0], and the next byte is stored in AryOut[1]. The number of byte for separation "Num" is processed in the same way.

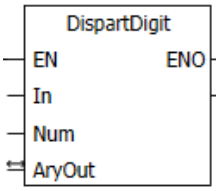
- **Program example**

	LD	ST

Define variables	VAR
	xResult: BOOL;
	dwIn: DWORD := 16#F35567C2;
	siNum: USINT := 4;
	aryByOut: ARRAY[1..5] OF byte;
	END_VAR	

Program		
Operation result		

Name	Data type	Address	Value
xResult	BOOL		TRUE
dwIn	DWORD		16#F35567C2
siNum	USINT		4
aryByOut	ARRAY [1..5] OF BYTE		
aryByOut[1]	BYTE		0
aryByOut[2]	BYTE		16#C2
aryByOut[3]	BYTE		16#67
aryByOut[4]	BYTE		16#55
aryByOut[5]	BYTE		16#F3



- **Precautions**
  - When the value of "Num" exceeds the valid range, the return value is FALSE, and "AryOut[ ]" remains unchanged.
  - If the value of "Num" is 0, the return value is TRUE, and "AryOut[ ]" remains unchanged.

- When the value of "Num" exceeds the valid range of "AryOut[ ]", the return value is FALSE, and "AryOut[ ]" remains unchanged.
- If the dimension of "AryOut[ ]" is greater than 3, the return value is FALSE, and "AryOut[ ]" remains unchanged.

18.1.2.34 DispartDigit

Separates a bit string by 1 digit (4 bits).

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
DispartDigit	Data separation by digit	FC		:= DispartDigit(In := , Num := , AryOut :=);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Separation object	Follows data type	-	A bit string to be separated
	Num	Number of bits to separate	Follows data type	1	Number of bits to separate
Input/Output	AryOut[ ] array	Separation result	16#00 to 16#0F	-	An array indicating the separation result

Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	√	√	√	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Num	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Ary Out[ ] array	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  Separates "In" by 1 digit (4 bits) and saves the result in the array "AryOut[ ]".

  The least significant digit is stored in "AryOut[0]". The 4th bit to 7th bit in the BYTE-type "AryOut[0]" are added with 16#0. The number of digits for separation "Num" is processed in the same way.

- **Program example**

	LD	ST
Define variables		

```
VAR
    xResult: BOOL;
    wIn: WORD := 16#a35c;
    usiNum : USINT := 4;
    abAryOut: ARRAY [1..5] OF BYTE;
END_VAR
```

Program		`xResult := DispartDigit(In := wIn, Num := usiNum, AryOut := abAryOut[1]);`
Operation result Operation result		

	Name	Data type	Address	Value
1	xResult	BOOL		TRUE
2	wIn	WORD		16#A35C
3	usiNum	USINT		4
4	abAryOut	ARRAY [1..5] OF BYTE		
5	abAryOut[1]	BYTE		12
6	abAryOut[2]	BYTE		5
7	abAryOut[3]	BYTE		3
8	abAryOut[4]	BYTE		10
9	abAryOut[5]	BYTE		0

- **Precautions**
  - If the value of "Num" is 0, the return value is TRUE, and "AryOut[ ]" remains unchanged.
  - When the value of "Num" exceeds the valid range, the return value is FALSE, and "AryOut[ ]" remains unchanged.
  - When the value of "Num" exceeds the valid range of "AryOut[ ]", the return value is FALSE, and "AryOut[ ]" remains unchanged.
  - If the dimension of "AryOut[ ]" is greater than 3, the return value is FALSE, and "AryOut[ ]" remains unchanged.

18.1.2.35 DispartReal

Separates a real number into the signed mantissa and the exponent.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
DispartReal	Separates mantissa and exponent	FC		:= DispartReal(In := , Fraction => , Exponent =>);

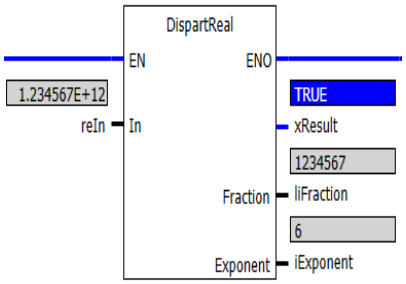
- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Real Number	Follows data type	-	A real number to be separated
Output	Fraction	Signed mantissa part	Follows data type	0	Signed mantissa part
	Exponent	Exponent part	Follows data type	0	Exponent part

Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–
Fraction	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–
Exponent	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–

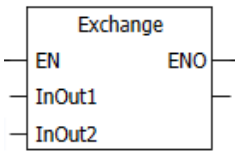


- **Function**

Separates the real number "In" into the signed mantissa part "Fraction" and the exponent part "Exponent".

When "In" is of REAL type, "Fraction" is a 7-digit integer; when "In" is of LREAL type, "Fraction" is a 15-digit integer. The valid range of "Fraction" differs depending on the data type of "In".

Data Type of "In"	Valid Range of "Fraction"
REAL	-9999999 to 9999999
LREAL	-999999999999999 to 999999999999999



- **Program example**

	LD	ST
Define variables	VAR xResult: BOOL; reIn: REAL := 123.4567e+10; liFraction: LINT; iExponent: INT; END_VAR	
Program		
Operation result		

18.1.2.36 Exchange

Exchanges the values of two variables.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
Exchange	Variable exchange	FC		:= Exchange(InOut1 := , InOut2 :=);

- **Related variables**

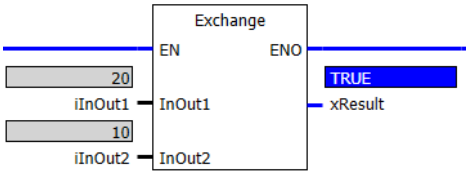
Variable

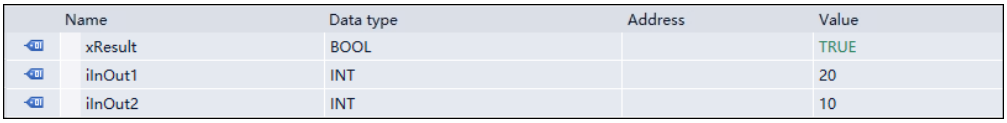
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	InOut1	Exchange object 1	Follows data type	-	Exchange object 1
	InOut2	Exchange object 2	Follows data type	-	Exchange object 2

Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	Out	Return value	Follows data type	-	Return value.

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
InOut1	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
	A specified member of an enumeration or a structure																			
InOut2	Same data type as "InOut1"																			





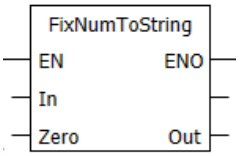
- **Function**

  Exchanges the values of "InOut1" and "InOut2".

- **Program example**

	LD	ST

Define variables	VAR
	xResult: BOOL;
	iInOut1: INT := 10;
	iInOut2: INT := 20;
	END_VAR	



Program		xResult TRUE := Exchange(InOut1 := iInOut1 20, InOut2 := iInOut2 10);RETURN
Operation result		

- **Precautions**
  - The data types of "InOut1" and "InOut2" must be consistent; otherwise, an exception will occur during compilation.
  - If "InOut1" and "InOut2" are both of STRING type, and the string length of one is greater than the other, the function returns FALSE, and "InOut1" and "InOut2" remain unchanged.

18.1.2.37 FixNumToString

Converts a signed fixed-decimal number to a decimal string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
FixNumToString	Fixed-decimal number-to-string conversion	FC		:= FixNumToString(In := , Zero := , Out =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Fixed-decimal number	Follows data type	0	A signed fixed-decimal number
	Zero	Zero supplement	Follows data type	0	Supplement of zeros if there are less than 3 decimal digits TRUE: Supplements with "0". FALSE: Do not supplement with "0".
Output	Out	Decimal string	Follows data type	''	A decimal string to be output

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Zero	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√

- **Function description**

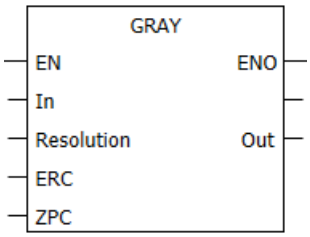
  Converts the signed fixed-decimal number "In" to a decimal string "Out". The conversion steps are as follows:

  1. Converts "In" from hexadecimal format to decimal format.
  2. Divides this value by 1000.
  3. When there is less than 3 decimal places in "In", "Zero" specifies whether to supplement decimal places of "Out" with "0" to make the value with three decimal digits. If the value of "Zero" is TRUE, supplement "Out" with "0".
  4. "Out" ends with a NULL character.

- **Program example**

	LD	ST
Define variables	VAR xResult: BOOL; dwIn: DWORD := 10000; xZero : BOOL; strOut : STRING[12]; END_VAR	
Program		xReturn TRUE := FixNumToString(In := dwIn 10000 , Zero := xZero TRUE , Out => strOut '10.000');RETURN
Operation result		

		Name	Data type	Address	Value
1		dwIn	DWORD		10000
2		xZero	BOOL		TRUE
3		strOut	STRING(12)		'10.000'
4		xReturn	BOOL		TRUE



- **Precautions**

  If the conversion result exceeds the valid range of "Out", the function returns FALSE and "Out" remains unchanged.

18.1.2.38 GRAY

Converts a Gray code to an angle.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
Gray	Gray Code Conversion	FC		:= GRAY(In := , Resolution := , ERC := , ZPC := , Out =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	Follows data type	0	Gray code of the conversion object
	Resolution	Resolution	Follows data type	0	Resolution
	ERC	Encoder remainder correction value	Follows data type	_R256	Encoder remainder correction value
	ZPC	Home correction value	Follows data type	0	Home correction value
Output	Out	Conversion result	Follows data type	0	Conversion result

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Resolution	See function description for detailed functions of the enumeration type_eGRY_RESOLUTION.																			

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
ERC	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
ZPC	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–

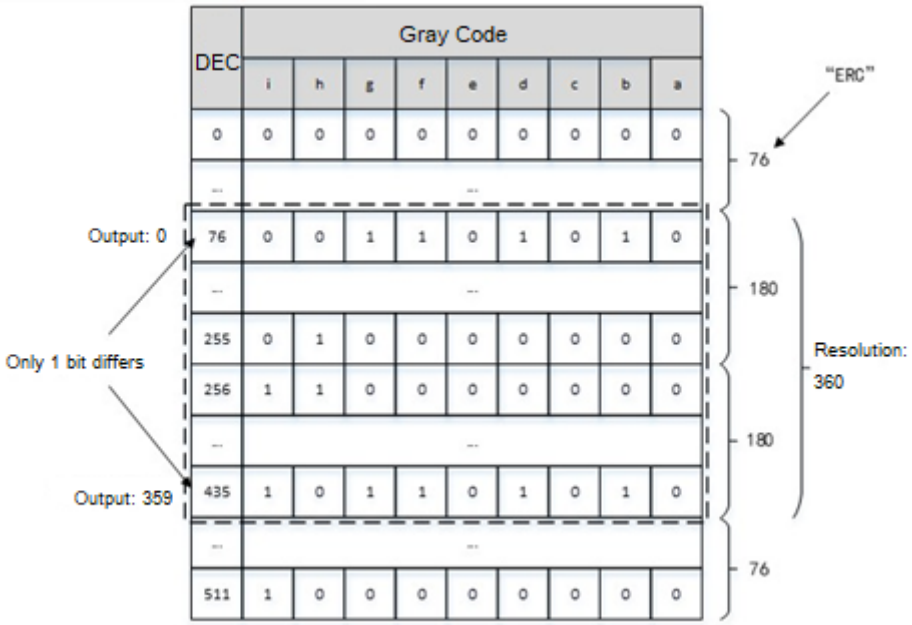
- **Function**

  Converts the output value f a rotary encoder ("In") represented in Gray code into an angle value. The conversion result "Out" is in degrees. The data type of "Resolution" is enumeration type_eGRY_RESOLUTION. The meanings of the enumeration values are as follows in the table below.

Enumeration Value	Definition
_R256	256
_R1B	1-bit (2)
_R2B	2-bit (4)
_R3B	3-bit (8)
_R4B	4-bit (16)
_R5B	5-bit (32)
_R6B	6-bit (64)
_R7B	7-bit (128)
_R8B	8-bit (256)
_R9B	9-bit (512)
_R10B	10-bit (1024)
_R11B	11-bit (2048)
_R12B	12-bit (4096)
_R13B	13-bit (8192)
_R14B	14-bit (16384)
_R15B	15-bit (32768)

Enumeration Value	Definition
_R360	360
_R720	720
_R1024	1024

Gray code is a type of alternate binary code. Two adjacent values in Gray code differ by only one binary bit, such as 0 and 1, and 1 and 2.



Gray code is commonly used in outputs of absolute encoders.

The following table shows the 4-bit binary code and Gray code.

Decimal Number	Binary Code				Gray Code			
	2^3	2^2	2^1	2^0	d	c	b	a
0	0	0	0	0	0	0	0	0
1	0	0	0	1	0	0	0	1
2	0	0	1	0	0	0	1	1
3	0	0	1	1	0	0	1	0
4	0	1	0	0	0	1	1	0
5	0	1	0	1	0	1	1	1
6	0	1	1	0	0	1	0	1
7	0	1	1	1	0	1	0	0
8	1	0	0	0	1	1	0	0
9	1	0	0	1	1	1	0	1
10	1	0	1	0	1	1	1	1
11	1	0	1	1	1	1	1	0
12	1	1	0	0	1	0	1	0
13	1	1	0	1	1	0	1	1
14	1	1	1	0	1	0	0	1
15	1	1	1	1	1	0	0	0

With the use of Gray code, when the encoder output value increases or decreases by 1, only one bit changes, thus preventing incorrect output values. The encoder remainder correction value "ERC" specifies the Gray code range when the encoder resolution is not a power of 2, ensuring that the maximum and minimum encoder output values in Gray code differ by only one bit.

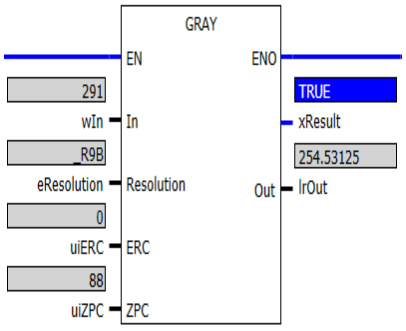
Take an absolute encoder with a resolution of 360 as an example. The Gray code requires 9 bits, and the range of values representable by 9 bits is 0 to 511. In this case, Gray code is used within a range of 180 from the center of 0 to 511, i.e., from 76 to 435. Thus, the Gray code representing output value 0 is 001101010 (76 decimal), and the Gray code representing output value 359 is 101101010 (435 decimal), differing by only one bit. At this point, the encoder remainder correction value "ERC" is 76.

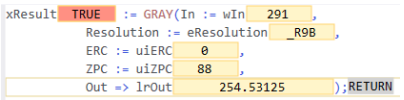
The home correction value "ZPC" is set to offset the initial angle of a rotary encoder. For example, to offset the initial angle of a rotary encoder with a resolution of 256 by 90 degrees, the value of "ZPC" is 256 × (90 / 360) = 64.

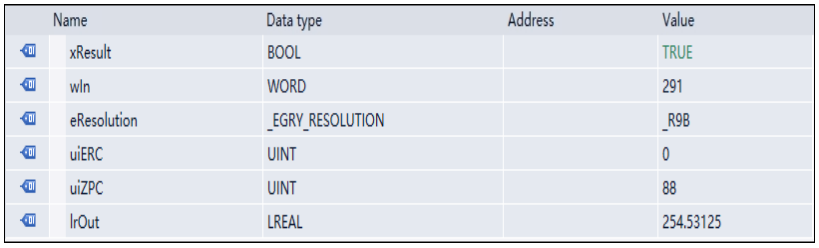
The following table shows an example when "In" = WORD#16#123, "Resolution" = _R9B, "ERC" = UINT#0, and "ZPC" = UINT#88.

Since the resolution is 9 bits, one unit of Gray code corresponds to 360° / 29 = 0.703125°.

The decimal value corresponding to Gray code 16#123 is 450. Therefore, the angle value before correction is 0.703125° × 450 = 316.40625°.







The value of "ERC" is 0, and the value of "ZPC" is 88. Therefore, the corrected angle value is 316.40625° - (0 + 88) × 0.703125° = 254.53125°.

The value of "Out" is LREAL#254.53125.

- **Program example**

	LD	ST

Define variables	VAR
	xResult: BOOL;
	wIn: WORD := 16#123;
	eResolution: _eGRY_RESOLUTION := _eGRY_RESOLUTION._R9B;
	uiERC:UINT := 0;
	uiZPC: UINT := 88;
	lrOut: LREAL;
	END_VAR	

	LD	ST
Program		
Operation result		

	Name	Data type	Address	Value
	xResult	BOOL		TRUE
	wIn	WORD		291
	eResolution	_EGRY_RESOLUTION		_R9B
	uiERC	UINT		0
	uiZPC	UINT		88
	lrOut	LREAL		254.53125

- **Precautions**

  An exception occurs under the following conditions. The function returns FALSE, and "Out" is initialized to 0.

  - The value of "ERC" is greater than "Resolution".
  - The value of "ZPC" is greater than "Resolution".
  - The value of "In" after converted to a bit string is less than "ERC".
  - The value of the bit string corrected with "ERC" is greater than "Resolution".

18.1.2.39 GrayToBin_BYTE

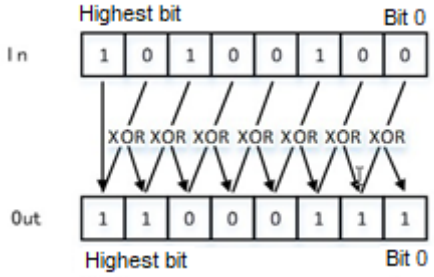
Converts a Gray code to a bit string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
GrayToBin_BYTE	Gray code-to-bit string conversion	FC		:= GrayToBin_BYTE(In := , OUT =>);

- **Related variables**

  Variable



Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	Follows data type	0	Conversion object
Output	Out	Conversion result	Follows data type	-	Conversion result

  Variable types

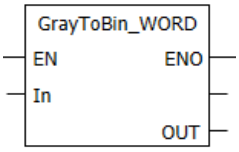
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - Converts the Gray code object "In" to a bit string.
  - The conversion steps are described below.

1. The most significant bit (bit 7) of In is directly used as the most significant bit (bit 7) of Out.
2. The XOR operation result on bit 6 of "In" and bit 7 of "Out" is assigned to bit 6 of "Out".
3. The same method is used to determine the values through the least significant bit (bit 0) of "Out".

- **Program example**

	LD	ST
Define variables	VAR xResult: BOOL; byIn: BYTE := 2#10100100; byOut: BYTE; END_VAR	
Program	GrayToBin_BYTE EN ENO byIn — In xResult OUT — byOut	xResult:= GrayToBin_BYTE(In := byIn, OUT => byOut);
Operation result	Name / Data type / Address / Value xResult / BOOL / / TRUE byIn / BYTE / / 2#10100100 byOut / BYTE / / 2#11000111	



- **Precautions**

The data types of "In" and "OUT" must be consistent; otherwise, an exception will occur during compilation.

18.1.2.40 GrayToBin_WORD

Converts a Gray code to a bit string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
GrayToBin_WORD	Gray code-to-bit string conversion	FC		:= GrayToBin_WORD(In := , OUT =>);

- **Related variables**

Variable

	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	√	√	√	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
InOut[ ] array	–	√	√	√	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Size	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
Pos	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  Takes the bits from a bit string and outputs them to the specified bit position in array elements.

  - Extracts "Size" bits from the least significant bit of "In" and decomposes them into individual bits.
  - Each extracted bit is stored in the "Pos"-bit of each element in the result array InOut[ ], starting from InOut[0]. A total of "Size" array elements are saved.
  - For bits in the result array InOut[ ] that are not saved, their values remain unchanged.

- **Program example**

<table>
<tr><th></th><th>LD</th><th>ST</th></tr>
<tr><td>Define variables</td><td colspan="2">

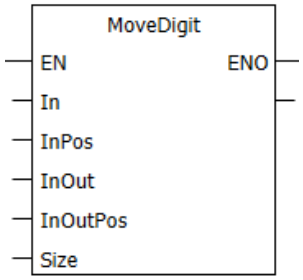
```
VAR
    xResult: BOOL;
    byIn: BYTE := 99;
    aryInOut: ARRAY[0..4] OF BYTE;
    uiSize: UINT := 4;
    uiPos: UINT := 2;
END_VAR
```

</td></tr>
<tr><td>Program</td><td>
</td><td>

```
xResult  TRUE  := LineToColm(In := byIn  99 ,
          InOut := aryInOut[1]  2#00000100 ,
          Size := uiSize  4 ,
          Pos := uiPos  2 );RETURN
```

</td></tr>
<tr><td>Operation result</td><td colspan="2">

Name	Data type	Address	Value
xResult	BOOL		TRUE
byIn	BYTE		99
aryInOut	ARRAY [0..4] OF BYTE		
aryInOut[0]	BYTE		2#00000000
aryInOut[1]	BYTE		2#00000100
aryInOut[2]	BYTE		2#00000100
aryInOut[3]	BYTE		2#00000000
aryInOut[4]	BYTE		2#00000000
uiSize	UINT		4
uiPos	UINT		2



</td></tr>
</table>

- **Precautions**
  - When the value of "Size" is 0, the value of InOut[ ] remains unchanged, and the function returns TRUE.
  - When the value of "Size" exceeds the valid range, the value of InOut[ ] remains unchanged, and the function returns FALSE.
  - When the value of "Pos" exceeds the valid range, the value of InOut[ ] remains unchanged, and the function returns FALSE.
  - When the value of "Size" exceeds the array area of InOut[ ], the value of InOut[ ] remains unchanged, and the function returns FALSE.
  - If the array exceeds 3 dimensions, the value of InOut[ ] remains unchanged, and the function returns FALSE.

18.1.2.44 MoveDigit

Moves multiple digits (4 bits per digit) in a bit string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
MoveDigit	Digit transfer	FC		:= MoveDigit(In := , InPos := , InOut := , InOutPos := , Size :=);

- **Related variables**

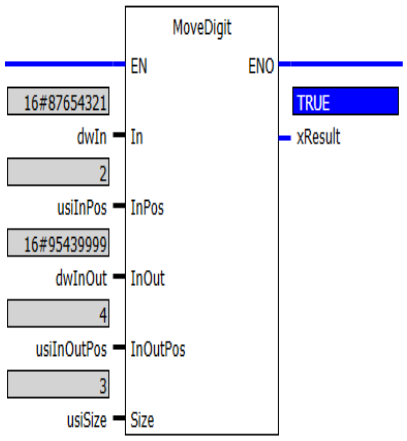
Variable

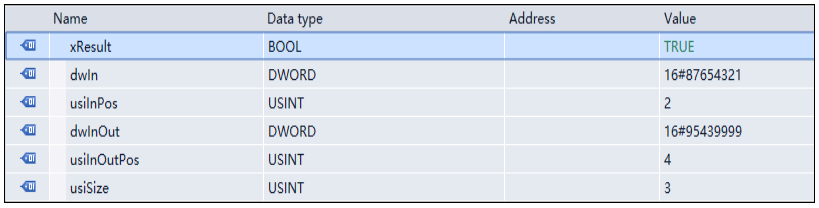
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Move source	Follows data type	-	Move source
	InPos	Digit position of the move source	Follows data type	0	Digit position of the move source
	InOut	Move destination	Follows data type	-	Move destination
	InOutPos	Digit position of the move destination	Follows data type	0	Digit position of the move destination
	Size	Number of digits to move	Follows data type	1	Number of digits to move
Output	Out	Return value	Follows data type	-	Return value.

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	√	√	√	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
InPos	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
InOut	–	√	√	√	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
InOutPos	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Size	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Out	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–





- **Function**

  Transfers "Size" number of digits starting from the digit position "InPos" in the source "In" to the digit position "InOutPos" in the destination "InOut".

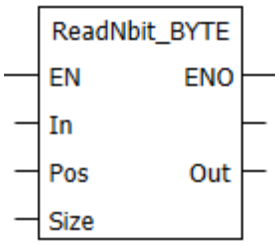
- **Program example**

	LD	ST

Define variables	VAR
	xResult: BOOL;
	dwIn: DWORD := 16#87654321;
	usiInPos: USINT := 2;
	dwInOut: DWORD := 16#99999999;
	usiInOutPos: USINT := 4;
	usiSize: USINT := 3;
	END_VAR	

Program		xResult TRUE := MoveDigit(In := dwIn 16#87654321, InPos := usiInPos 2, InOut := dwInOut 16#95439999, InOutPos := usiInOutPos 4, Size := usiSize 3);RETURN
Operation result		

Name	Data type	Address	Value
xResult	BOOL		TRUE
dwIn	DWORD		16#87654321
usiInPos	USINT		2
dwInOut	DWORD		16#95439999
usiInOutPos	USINT		4
usiSize	USINT		3



- **Precautions**
  - If the specified destination digit exceeds the most significant bit of "InOut", the remaining data will be stored in the least significant bit of "InOut".
  - If the specified source digit exceeds the most significant bit of "In", the remaining data will be moved to the least significant bit of "In".

- When the value of "Size" is 0, the function returns TRUE, and "InOut" remains unchanged.
- An exception occurs under the following conditions. The function returns FALSE, and "InOut" remains unchanged.
  - The value of "InPos" exceeds the valid range.
  - The value of "InOutPos" exceeds the valid range.
  - The value of "Size" exceeds the valid range.

18.1.2.45 ReadNbit_BYTE

Reads multiple bits from a bit string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ReadNbit_BYTE	N-bit read group	FC		:= ReadNbit_BYTE(In := , Pos := , Size := , Out =>);

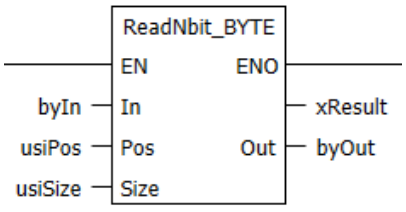
- **Related variables**

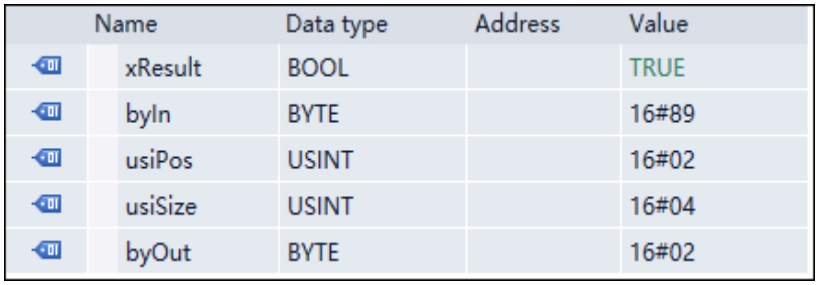
Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Read source	Follows data type	0	A bit string to be read and written to "Out"
	Pos	Read position	Follows data type	0	Bit position to be read
	Size	Read size	Follows data type	1	The number of bits to be read
Output	Out	Read result	Follows data type	-	Write result

Variable type

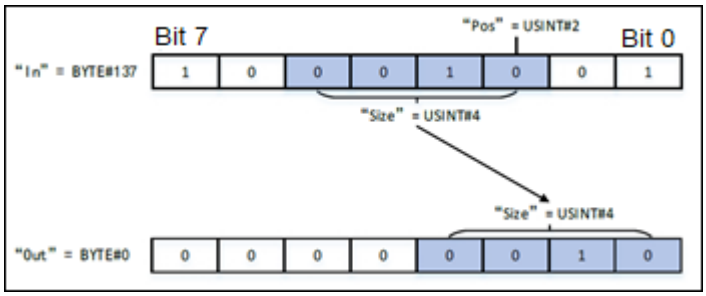
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Pos	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Size	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–





- **Function**

  Reads "Size" bits from the bit string "In" starting at read position "Pos", and stores the result in "Out".



- **Program example**

	LD	ST

Define variables	VAR
	xResult: BOOL;
	byIn: BYTE := 137;
	usiPos: USINT := 2;
	usiSize: USINT := 4;
	byOut: BYTE;
	END_VAR	

Program		xResult := ReadNbit_BYTE(In := byIn, Pos := usiPos, Size := usiSize, Out => byOut);
Operation result		

Name	Data type	Address	Value
xResult	BOOL		TRUE
byIn	BYTE		16#89
usiPos	USINT		16#02
usiSize	USINT		16#04
byOut	BYTE		16#02

	LD	ST
Principle		

- **Precautions**
  - The data types of "In" and "Out" must be the same; otherwise, the function returns FALSE.
  - When the value of "Size" is 0, the value of "Out" is 16#0.
  - An exception occurs and the function returns FALSE, with "Out" set to 16#0, under the following conditions:
    - The value of "Pos" exceeds the valid range.
    - The value of "Size" exceeds the valid range.
    - The bits to be read specified by "Pos" and "Size" exceed the number of bits in "In".

18.1.2.46 ReadNbit_WORD

Reads multiple bits from a bit string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ReadNbit_WORD	N-bit read group	FC		:= ReadNbit_WORD(In := , Pos := , Size := , Out =>);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Read source	Follows data type	0	A bit string to be read and written to "Out"
	Pos	Read position	Follows data type	0	Bit position to be read
	Size	Read size	Follows data type	1	The number of bits to be read
Output	Out	Read result	Follows data type	-	Write result

Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Pos	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Size	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

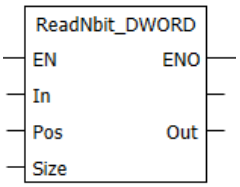
  Reads "Size" bits from the bit string "In" starting at read position "Pos", and stores the result in "Out".

- **Program example**

	LD	ST

Define variables	VAR
	xResult: BOOL;
	wIn: WORD := 137;
	usiPos: USINT := 2;
	usiSize: USINT := 4;
	wOut: WORD;
	var1: BOOL;
	END_VAR	

Program	ReadNbit_WORD EN ENO wIn — In — xResult usiPos — Pos — Out — wOut usiSize — Size	xResult := ReadNbit_WORD(In := wIn, Pos := usiPos, Size := usiSize, Out => wOut);
Operation result	Name / Data type / Address / Value xResult / BOOL / / TRUE wIn / WORD / / 16#0089 usiPos / USINT / / 16#02 usiSize / USINT / / 16#04 wOut / WORD / / 16#0002	



- **Precautions**
  - The data types of "In" and "Out" must be the same; otherwise, the function returns FALSE.

- When the value of "Size" is 0, the value of "Out" is 16#0.
- An exception occurs and the function returns FALSE, with "Out" set to 16#0, under the following conditions:
  - The value of "Pos" exceeds the valid range.
  - The value of "Size" exceeds the valid range.
  - The bits to be read specified by "Pos" and "Size" exceed the number of bits in "In".

18.1.2.47 ReadNbit_DWORD

Reads multiple bits from a bit string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ReadNbit_DWORD	N-bit read group	FC		:= ReadNbit_DWORD(In := , Pos := , Size := , Out =>);

- **Related variables**

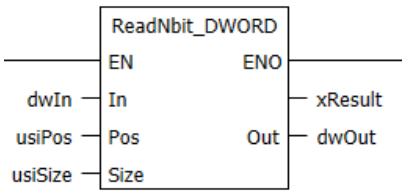
Variable

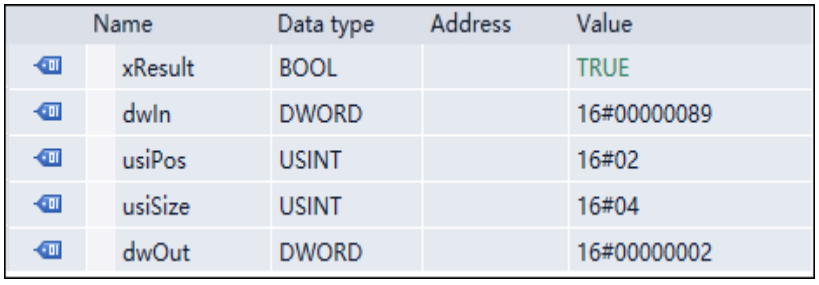
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Read source	Follows data type	0	A bit string to be read and written to "Out"
	Pos	Read position	Follows data type	0	Bit position to be read
	Size	Read size	Follows data type	1	The number of bits to be read
Output	Out	Read result	Follows data type	-	Write result

Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Pos	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Size	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–





- **Function**

  Reads "Size" bits from the bit string "In" starting at read position "Pos", and stores the result in "Out".

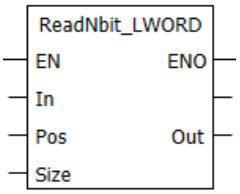
- **Program example**

	LD	ST

Define variables	VAR
	xResult: BOOL;
	dwIn: DWORD := 137;
	usiPos: USINT := 2;
	usiSize: USINT := 4;
	dwOut: DWORD;
	END_VAR	

Program		xResult := ReadNbit_DWORD(In := dwIn, Pos := usiPos, Size := usiSize, Out => dwOut);
Operation result		

	Name	Data type	Address	Value
	xResult	BOOL		TRUE
	dwIn	DWORD		16#00000089
	usiPos	USINT		16#02
	usiSize	USINT		16#04
	dwOut	DWORD		16#00000002



- **Precautions**
  - The data types of "In" and "Out" must be the same; otherwise, the function returns FALSE.
  - When the value of "Size" is 0, the value of "Out" is 16#0.

- An exception occurs and the function returns FALSE, with "Out" set to 16#0, under the following conditions:
  - The value of "Pos" exceeds the valid range.
  - The value of "Size" exceeds the valid range.
  - The bits to be read specified by "Pos" and "Size" exceed the number of bits in "In".

18.1.2.48 ReadNbit_LWORD

Reads multiple bits from a bit string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ReadNbit_LWORD	N-bit read group	FC		:= ReadNbit_LWORD(In := , Pos := , Size := , Out =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Read source	Follows data type	0	A bit string to be read and written to "Out"
	Pos	Read position	Follows data type	0	Bit position to be read
	Size	Read size	Follows data type	1	The number of bits to be read
Output	Out	Read result	Follows data type	-	Write result

Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Pos	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Size	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  Reads "Size" bits from the bit string "In" starting at read position "Pos", and stores the result in "Out".

- **Program example**

	LD	ST
Define variables		

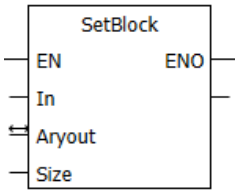
```
VAR
    xResult: BOOL;
    lwIn: LWORD := 137;
    usiPos: USINT := 2;
    usiSize: USINT := 4;
    lwOut: LWORD;
END_VAR
```

Program

```
xResult := ReadNbit_LWORD(In := lwIn,
    Pos := usiPos,
    Size := usiSize,
    Out => lwOut);
```

Operation result

	Name	Data type	Address	Value
	xResult	BOOL		TRUE
	lwIn	LWORD		16#0000000000000089
	usiPos	USINT		16#02
	usiSize	USINT		16#04
	lwOut	LWORD		16#0000000000000002



- **Precautions**
  - The data types of "In" and "Out" must be the same; otherwise, the function returns FALSE.
  - When the value of "Size" is 0, the value of "Out" is 16#0.

- An exception occurs and the function returns FALSE, with "Out" set to 16#0, under the following conditions:
  - The value of "Pos" exceeds the valid range.
  - The value of "Size" exceeds the valid range.
  - The bits to be read specified by "Pos" and "Size" exceed the number of bits in "In".

18.1.2.49 SetBlock

Moves the input value to multiple array elements.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
SetBlock	Block setting	FC		:= SetBlock(In := , Aryout := , Size :=);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Move source	Follows data type	-	Move source
	Size	Number of elements to move	Follows data type	1	Number of array elements to move
Input/Output	AryOut[ ] array	Move destination array	Follows data type	-	Move destination array

Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
	An enumeration, a structure, or a structure member can also be specified.																			
Size	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
AryOut[ ]	An array of elements with the same data type as "In"																			

- **Function**

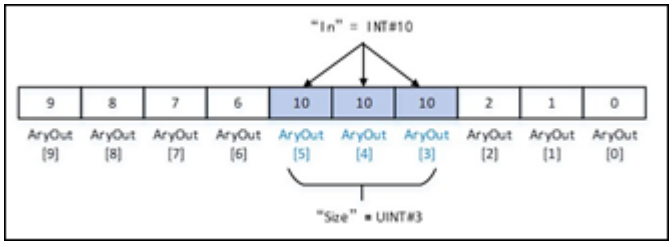
  Moves the value of "In" to "Size" elements in destination AryOut[ ] starting from AryOut[0].

- **Program example**

Define variables

```
VAR
    xResult: BOOL;
    iIn: INT := 10;
    iaryOut: ARRAY[0..9] OF INT := [0,1,2,3,4,5,6,7,8,9];
    uiSize: UINT := 3;
END_VAR
```

Program

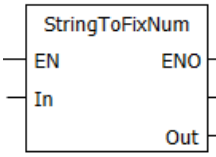


```
xResult TRUE := SetBlock(In := iIn 10,
          Aryout := iaryOut[3] 10,
          Size := uiSize 3 );RETURN
```

Operation result

	Name	Data type	Address	Value
	xResult	BOOL		TRUE
	iIn	INT		10
▾	iaryOut	ARRAY [0..9] OF INT		
	iaryOut[0]	INT		0
	iaryOut[1]	INT		1
	iaryOut[2]	INT		2
	iaryOut[3]	INT		10
	iaryOut[4]	INT		10
	iaryOut[5]	INT		10
	iaryOut[6]	INT		6
	iaryOut[7]	INT		7
	iaryOut[8]	INT		8
	iaryOut[9]	INT		9
	uiSize	UINT		3

Principle analysis



- **Precautions**
  - A compilation exception occurs when the data types of "In" and AryOut[ ] differ.

- When both "In" and AryOut[ ] are of STRING type, their sizes must be consistent. If the length of "In" exceeds the element length of AryOut[ ], the function returns FALSE, and AryOut[ ] remains unchanged.
- When the value of "Size" is 0, the function returns TRUE, and AryOut[ ] remains unchanged.
- When the value of "Size" exceeds the array area of AryOut[ ], the function returns FALSE, and AryOut[ ] remains unchanged.
- A compilation exception occurs when "In" and AryOut[ ] are of unsupported data types.
- If the array exceeds 3 dimensions, the function returns FALSE, and AryOut[ ] remains unchanged.

18.1.2.50 StringToFixNum

Converts a decimal string to a signed fixed-decimal number.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
StringToFixNum	Conversion from a string to a fixed-decimal number	FC		:= StringToFixNum(In := , Out =>);

- **Related variables**

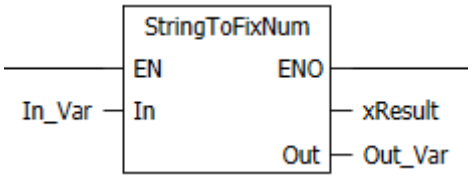
Variable

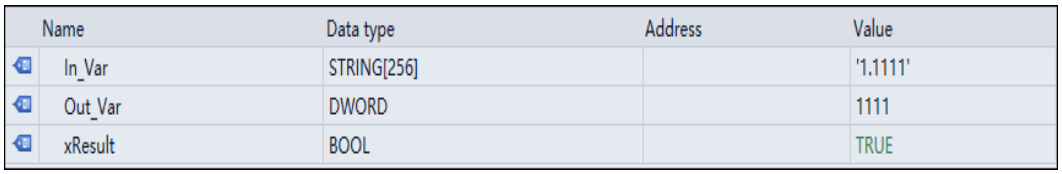
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Decimal string	Follows data type	''	Decimal string
Output	Out	Fixed-decimal number	Follows data type	0	Fixed-decimal number

Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
Out	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**





Converts the decimal string "In" to a fixed-decimal number. The conversion steps are as follows:

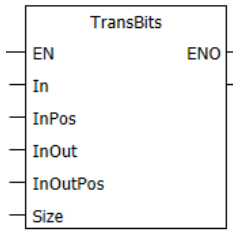
1. Multiplies the value represented by "In" by 1000.
2. Truncates the decimal places of this value.
3. Converts this value into a 32-bit hexadecimal number (DWORD type).

Name	Format
Operator	Consecutive spaces after the sign can be ignored.
Integer part	The integer part is the consecutive digits (0 to 9) after the sign and before the decimal point. The sign can be omitted. Consecutive spaces between the sign and the integer part can be ignored. When there is no decimal point or fractional part, the integer part is the characters up to the exponent. When there is no decimal point, fractional part, or exponent part, the integer part is the characters up to the end of the string. The integer part cannot be omitted. The maximum number of digits in the integer part is the maximum string length of 1985 minus the total number of bytes in the sign, decimal point, fractional part, exponent part, and spaces before and after the sign.
Decimal point	The decimal point is the single dot (".") following the integer part. When there is no fractional part, the decimal point must be omitted.
Fractional part	The fractional part is the consecutive digits (0 to 9) after the decimal point and before the exponent part. When there is no exponent part, the fractional part is the characters up to the end of the string. The fractional part can be omitted. When there is no decimal point, there is no fractional part. The maximum number of digits in the fractional part is 15.

Name	Format
Exponent part	The exponent part consists of a single "e" or "E" followed by a single "+" or "-" and then consecutive digits (0 to 9) to the end of the string. When there is no fractional part, the exponent part is the string after the decimal point. When there is no decimal point or fractional part, the exponent part is the string following the integer part. The exponent part can be omitted. The maximum number of digits in the exponent part is 3.

- **Program example**

	LD	ST
Define variables	VAR In_Var: STRING[256] := '1.1111'; Out_Var: DWORD; xResult: BOOL; END_VAR	
Program		xResult := StringToFixNum(In := In_Var, Out => Out_Var);
Operation result		



Name	Data type	Address	Value
In_Var	STRING[256]		'1.1111'
Out_Var	DWORD		1111
xResult	BOOL		TRUE

- **Precautions**
  - The digits after the fourth decimal in In digit are truncated.
  - The underscore (16#5F) in "In" is ignored.
  - If "In" is not NULL-terminated, the function returns FALSE.
  - If "In" contains characters that cannot be converted to numbers, the function returns FALSE.
  - If the conversion result exceeds the valid range of "Out", the function returns FALSE.

18.1.2.51 TransBits

Moves multiple bits in a bit string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
TransBits	Multiple bit transfer	FC		:= TransBits(In := , InPos := , InOut := , InOutPos := , Size :=);

- **Related variables**

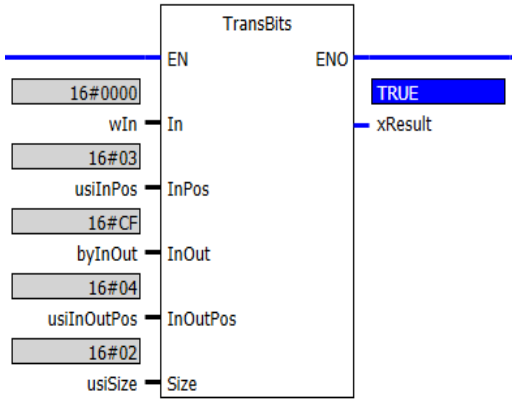
Variable

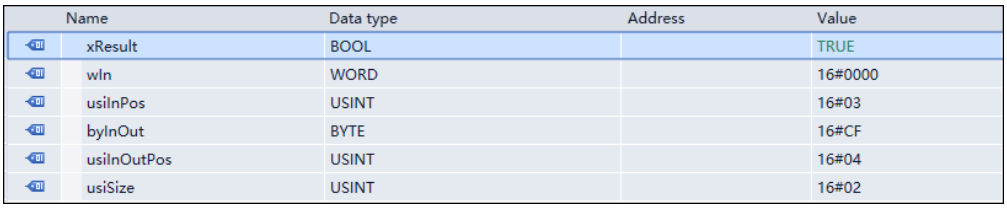
Input	Variable	Name	Valid Range	Default Value	Description
Input	In	Move source	Follows data type	-	Move source
	InPos	Bit position in the move source	0 to ("In" bit count - 1)	0	Bit position in "In" to transfer
	InOut	Move destination	Follows data type	-	Move destination
	InOutPos	Bit position in the move destination	0 to ("InOut" bit count - 1)	0	Bit position in "InOut" to receive
	Size	Number of bits to transfer	0 to the minimum bit count of "In" and "InOut"	1	Number of bits to transfer

Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	√	√	√	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
InPos	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
InOut	–	√	√	√	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
InOutPos	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Size	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–

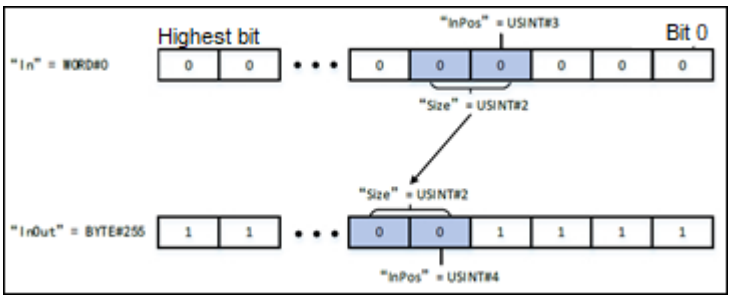
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Out	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–





- **Function**

  Moves "Size" bits starting from position "InPos" in the source "In" to bit position "InOutPos" in the destination "InOut".



- **Program example**

	LD	ST

Define variables	VAR
	xResult: BOOL;
	wIn: WORD := 0;
	usiInPos: USINT := 3;
	byInOut: BYTE := 255;
	usiInOutPos: USINT := 4;
	usiSize: USINT := 2;
	END_VAR	

Program		xResult TRUE := TransBits(In := wIn 16#0000 , InPos := usiInPos 16#03 , InOut := byInOut 16#CF , InOutPos := usiInOutPos 16#04 , Size := usiSize 16#02);RETURN
Operation result		

Name	Data type	Address	Value
xResult	BOOL		TRUE
wIn	WORD		16#0000
usiInPos	USINT		16#03
byInOut	BYTE		16#CF
usiInOutPos	USINT		16#04
usiSize	USINT		16#02

	LD	ST
Principle analysis		

- **Precautions**
  - When the value of "Size" is 0, no bit is moved.
  - The bits in "InOut" unrelated to the move operation remain unchanged.
  - An exception occurs under the following conditions. The function returns FALSE, and output variables remain unchanged.
    - The value of "InPos" exceeds the valid range.
    - The value of "InOutPos" exceeds the valid range.
    - The value of "Size" exceeds the valid range.
    - The value of "InPos" or "Size" exceeds the bit count of "In".
    - The value of "InOutPos" or "Size" exceeds the bit count of "InOut".

18.1.2.52 Unite8Bit_BYTE

Joins bytes of data into a bit string.

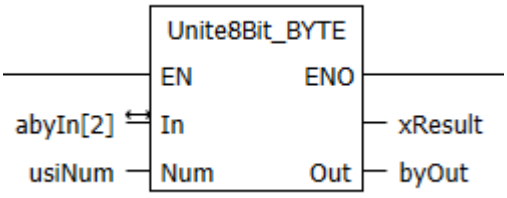
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
Unite8Bit_BYTE	Byte data join group	FC		:= Unite8Bit_BYTE(In := , Num := , Out =>);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input/Output	In[ ] array	Array of objects to join	Follows data type	-	Array to join
Input	Num	Number of bytes to join	Follows data type	1	Number of bytes to join
Output	Out	Join result	Follows data type	0	A bit string indicating the join result



Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In[ ] array	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Num	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

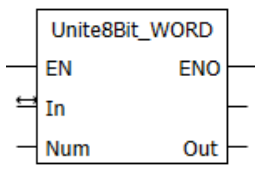
- **Function**
  - Joins the elements in the array In[ ] to generate the bit string "Out" as the join result. The number of array elements to be joined is specified by "Num".
  - Elements from In[0] to In["Num"-1] are joined to generate a bit string of "Num" bytes. If "Num" is less than the length of "Out", zeros are supplemented to the high bits of "Out".
- **Program example**

	LD	ST

Define variables	VAR
	xResult: BOOL;
	abyIn: ARRAY[1..10] OF BYTE := [10(1)];
	usiNum: USINT := 1;
	byOut: BYTE;
	END_VAR	

Program		xResult := Unite8Bit_BYTE(In := abyIn[2], Num := usiNum, Out => byOut);

	LD	ST
Operation result		



Name	Data type	Address	Value
xResult	BOOL		TRUE
abyIn	ARRAY [1..10] OF BYTE		
abyIn[1]	BYTE		1
abyIn[2]	BYTE		1
abyIn[3]	BYTE		1
abyIn[4]	BYTE		1
abyIn[5]	BYTE		1
abyIn[6]	BYTE		1
abyIn[7]	BYTE		1
abyIn[8]	BYTE		1
abyIn[9]	BYTE		1
abyIn[10]	BYTE		1
usiNum	USINT		1
byOut	BYTE		16#01

- **Precautions**
  - When the value of "Num" is 0, "Out" is initialized to 0, and the function returns TRUE.
  - When the value of "Num" exceeds the valid range, the function returns FALSE, and "Out" is initialized to 0.
  - When the value of "Num" exceeds the array area of In[ ], the function returns FALSE, and "Out" is initialized to 0.
  - If the array exceeds 3 dimensions, the function returns FALSE, and "Out" is initialized to 0.

18.1.2.53 Unite8Bit_WORD

Joins bytes of data into a bit string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
Unite8Bit_WORD	Byte data join group	FC		:= Unite8Bit_WORD(In := , Num := , Out =>);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description

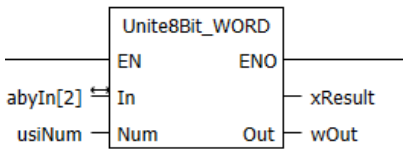
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Num	Number of bytes to join	Follows data type	1	Number of bytes to join
Output	Out	Join result	Follows data type	0	A bit string indicating the join result



Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In[ ] array	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Num	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

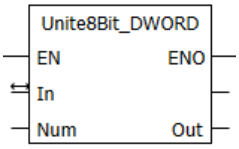
- **Function**
  - Joins the elements in the array In[ ] to generate the bit string "Out" as the join result. The number of array elements to be joined is specified by "Num".
  - Elements from In[0] to In["Num"-1] are joined to generate a bit string of "Num" bytes. If "Num" is less than the length of "Out", zeros are supplemented to the high bits of "Out".
- **Program example**

	LD	ST

Define variables	VAR
	xResult: BOOL;
	abyIn: ARRAY[1..10] OF BYTE := [10(1)];
	usiNum: USINT := 1;
	wOut: WORD;
	END_VAR	

Program		xResult := Unite8Bit_WORD(In := abyIn[2], Num := usiNum, Out => wOut);

	LD	ST
Operation result		



Name	Data type	Address	Value
xResult	BOOL		TRUE
abyIn	ARRAY [1..10] OF BYTE		
abyIn[1]	BYTE		1
abyIn[2]	BYTE		1
abyIn[3]	BYTE		1
abyIn[4]	BYTE		1
abyIn[5]	BYTE		1
abyIn[6]	BYTE		1
abyIn[7]	BYTE		1
abyIn[8]	BYTE		1
abyIn[9]	BYTE		1
abyIn[10]	BYTE		1
usiNum	USINT		1
wOut	WORD		16#0001

- **Precautions**
  - When the value of "Num" is 0, "Out" is initialized to 0, and the function returns TRUE.
  - When the value of "Num" exceeds the valid range, the function returns FALSE, and "Out" is initialized to 0.
  - When the value of "Num" exceeds the array area of In[ ], the function returns FALSE, and "Out" is initialized to 0.
  - If the array exceeds 3 dimensions, the function returns FALSE, and "Out" is initialized to 0.

18.1.2.54 Unite8Bit_DWORD

Joins bytes of data into a bit string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
Unite8Bit_DWORD	Byte data join group	FC		:= Unite8Bit_DWORD(In := , Num := , Out =>);

- **Related variables**

  Variable

Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In[ ] array	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Num	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

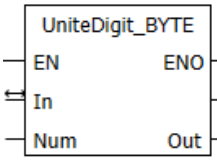
- **Function**
  - Joins the elements in the array In[ ] to generate the bit string "Out" as the join result. The number of array elements to be joined is specified by "Num".
  - Elements from In[0] to In["Num"-1] are joined to generate a bit string of "Num" bytes. If "Num" is less than the length of "Out", zeros are supplemented to the high bits of "Out".
- **Program example**

	LD	ST

Define variables	VAR
	xResult: BOOL;
	abyIn: ARRAY[1..10] OF BYTE := [10(1)];
	usiNum: USINT := 1;
	lwOut: LWORD;
	END_VAR	

Program		xResult := Unite8Bit_LWORD(In := abyIn[2], Num := usiNum, Out => lwOut);

	LD	ST
Operation result		



Name	Data type	Address	Value
xResult	BOOL		TRUE
abyIn	ARRAY [1..10] OF BYTE		
abyIn[1]	BYTE		1
abyIn[2]	BYTE		1
abyIn[3]	BYTE		1
abyIn[4]	BYTE		1
abyIn[5]	BYTE		1
abyIn[6]	BYTE		1
abyIn[7]	BYTE		1
abyIn[8]	BYTE		1
abyIn[9]	BYTE		1
abyIn[10]	BYTE		1
usiNum	USINT		1
lwOut	LWORD		16#0000000000000001

- **Precautions**
  - When the value of "Num" is 0, "Out" is initialized to 0, and the function returns TRUE.
  - When the value of "Num" exceeds the valid range, the function returns FALSE, and "Out" is initialized to 0.
  - When the value of "Num" exceeds the array area of In[ ], the function returns FALSE, and "Out" is initialized to 0.
  - If the array exceeds 3 dimensions, the function returns FALSE, and "Out" is initialized to 0.

18.1.2.56 UniteDigit_BYTE

Joins digits (4-bit unit) of data into a bit string.

- **Instruction format**

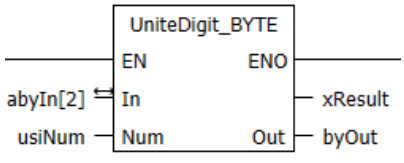
Instruction	Name	FB/FC	LD Representation	ST Representation
UniteDigit_BYTE	4-bit join group	FC		:= UniteDigit_BYTE(In := , Num := , Out =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input/Output	In[ ] array	Array of objects to join	Follows data type	-	Array to join

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Num	Number of digits to join	Follows data type	1	Number of digits to join
Output	Out	Join result	Follows data type	0	A bit string indicating the join result



Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In[ ] array	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Num	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

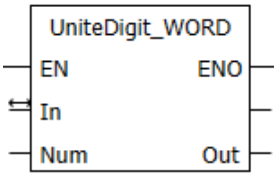
- **Function**
  - Joins the lower 4 bits (1 digit = 4 bits) of each element in the In[ ] array to generate the bit string "Out" as the join result. The number of array elements to be joined is specified by "Num".
  - The lower 4 bits of In[0] to In["Num" - 1] are joined to generate a bit string of "Num" digits. If "Num" is less than the length of "Out", 16#0 is supplemented to the high bits of "Out".
- **Program example**

	LD	ST

Define variables	VAR
	xResult: BOOL;
	abyIn: ARRAY[1..10] OF BYTE := [10(1)];
	usiNum: USINT := 2;
	byOut: BYTE;
	END_VAR	

Program		xResult := UniteDigit_BYTE(In := abyIn[2], Num := usiNum, Out => byOut);

	LD	ST
Operation result		



Name	Data type	Address	Value
xResult	BOOL		TRUE
abyIn	ARRAY [1..10] OF BYTE		
abyIn[1]	BYTE		16#01
abyIn[2]	BYTE		16#01
abyIn[3]	BYTE		16#01

	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In[] array	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Num	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

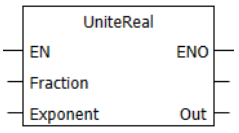
- **Function**
  - Joins the lower 4 bits (1 digit = 4 bits) of each element in the In[ ] array to generate the bit string "Out" as the join result. The number of array elements to be joined is specified by "Num".
  - The lower 4 bits of In[0] to In["Num" - 1] are joined to generate a bit string of "Num" digits. If "Num" is less than the length of "Out", 16#0 is supplemented to the high bits of "Out".
- **Program example**

	LD	ST

Define variables	VAR
	xResult: BOOL;
	abyIn: ARRAY[1..10] OF BYTE := [10(1)];
	usiNum: USINT := 2;
	lwOut: LWORD;
	END_VAR	

Program		xResult := UniteDigit_LWORD(In := abyIn[2], Num := usiNum, Out => lwOut);

	LD	ST
Operation result		



Name	Data type	Address	Value
xResult	BOOL		TRUE
abyIn	ARRAY [1..10] OF BYTE		
abyIn[1]	BYTE		16#01
abyIn[2]	BYTE		16#01
abyIn[3]	BYTE		16#01
abyIn[4]	BYTE		16#01
abyIn[5]	BYTE		16#01
abyIn[6]	BYTE		16#01
abyIn[7]	BYTE		16#01
abyIn[8]	BYTE		16#01
abyIn[9]	BYTE		16#01
abyIn[10]	BYTE		16#01
usiNum	USINT		16#02
lwOut	LWORD		16#0000000000000011

- **Precautions**
  - When the value of "Num" is 0, "Out" is 0, and the function returns TRUE.
  - When the value of "Num" exceeds the valid range, the function returns FALSE, and "Out" is 0.
  - When the value of "Num" exceeds the array area of In[ ], the function returns FALSE, and "Out" is 0.
  - If the array exceeds 3 dimensions, the function returns FALSE, and "Out" is initialized to 0.

18.1.2.60 UniteReal

Combines a signed mantissa and exponent to generate a real number.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
UniteReal	Combine mantissa and exponent	FC		:= UniteReal(Fraction := , Exponent := , Out =>);

- **Related variables**

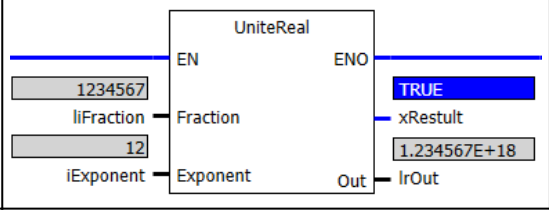
  Variable

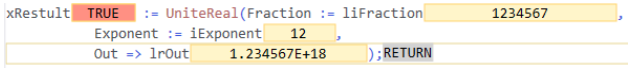
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Fraction	Signed mantissa part	Follows data type	-	Signed mantissa part
	Exponent	Exponent part	Follows data type	0	Exponent part

Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	Out	Real Number	Follows data type	0	A real number indicating the combination result

Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Fraction	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–	–	–
Exponent	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–





- **Function**

  Combines the signed mantissa "Fraction" and the exponent "Exponent" to obtain the real number "Out".

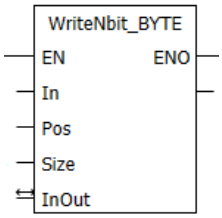
- **Program example**

	LD	ST

Define variables	VAR
	xRestult: BOOL;
	liFraction: LINT := 1234567;
	iExponent: INT := 12;
	lrOut: LREAL;
	END_VAR	

Program		

	LD	ST
Operation result		



Name	Data type	Address	Value
xRestult	BOOL		TRUE
liFraction	LINT		1234567
iExponent	INT		12
lrOut	LREAL		1.234567E+18

- **Precautions**
  - Depending on the values of "Fraction" and "Exponent", converting integers to real numbers may introduce errors.
  - When the combined result exceeds the valid range of "Out", if "Exponent" is positive, the value of "Out" becomes infinity with the same sign as "Fraction". If "Exponent" is negative, the value of "Out" becomes 0.

18.1.2.61 WriteNbit_BYTE

Writes multiple bits into a bit string.

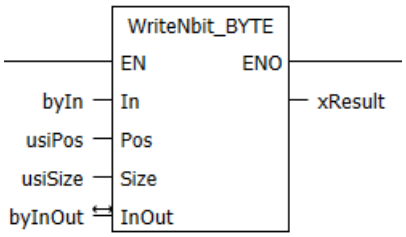
- **Instruction format**

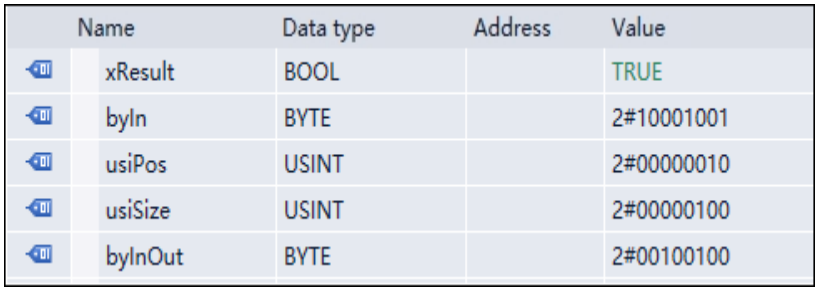
Instruction	Name	FB/FC	LD Representation	ST Representation
WriteNbit_BYTE	N-bit write group	FC		:= WriteNbit_BYTE(In := , Pos := , Size := , InOut :=);

- **Related variables**

Variable

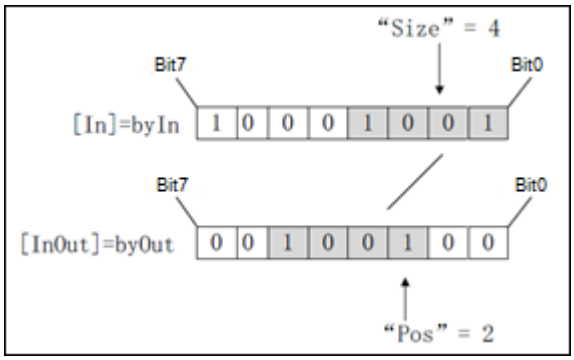
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Read source	Follows data type	0	A bit string to be read and written to "InOut"
	Pos	Write position	Follows data type	0	Bit position to write to
	Size	Write size	Follows data type	0	The number of bits to be written
Input/Output	InOut	Write target	Follows data type	-	Write result





Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Pos	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Size	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
In Out	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–



- **Function**
  - The function first reads the lower "Size" bits from the source "In".
  - Then, it writes the read value to the write position "Pos" of the target "InOut".
- **Program example**

	LD	ST

Define variables	VAR
	xResult: BOOL;
	byIn: BYTE := 16#89;
	usiPos: USINT := 2;
	usiSize: USINT := 4;
	byInOut: BYTE;
	END_VAR	

Program		xResult := WriteNbit_BYTE(In := byIn, Pos := usiPos, Size := usiSize, InOut := byInOut);
Operation result		

Name	Data type	Address	Value
xResult	BOOL		TRUE
byIn	BYTE		2#10001001
usiPos	USINT		2#00000010
usiSize	USINT		2#00000100
byInOut	BYTE		2#00100100

	LD	ST
Principle analysis		

- **Precautions**
  - A compilation exception occurs when the data types of "In" and "InOut" differ.
  - When the value of "Size" is 0, the value of "InOut" remains unchanged.
  - When "Size" or "Pos" exceeds the valid range, an exception occurs, the function returns FALSE, and the value of "InOut" remains unchanged.
  - When the bit string "InOut" does not contain enough bits for the number of bits specified by "Size" from the position specified by "Pos", an exception occurs, the function returns FALSE, and the value of "InOut" remains unchanged.

18.1.2.62 WriteNbit_WORD

Writes multiple bits into a bit string.

- **Instruction format**

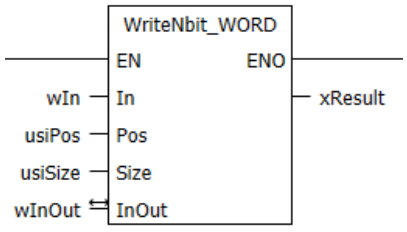
Instruction	Name	FB/FC	LD Representation	ST Representation
WriteNbit_WORD	N-bit write group	FC		:= WriteNbit_WORD(In := , Pos := , Size := , InOut :=);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Read source	Follows data type	0	A bit string to be read and written to "InOut"
	Pos	Write position	Follows data type	0	Bit position to write to
	Size	Write size	Follows data type	0	The number of bits to be written

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input/Output	InOut	Write target	Follows data type	-	Write result



Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Pos	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Size	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
InOut	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - The function first reads the lower "Size" bits from the source "In".
  - Then, it writes the read value to the write position "Pos" of the target "InOut".
- **Program example**

	LD	ST

Define variables	VAR
	xResult: BOOL;
	wIn: WORD := 16#89;
	usiPos: USINT := 2;
	usiSize: USINT := 4;
	wInOut: WORD;
	END_VAR	

Program		xResult := WriteNbit_WORD(In := wIn, Pos := usiPos, Size := usiSize, InOut := wInOut);

	LD	ST
Operation result		
Principle analysis		

- **Precautions**
  - A compilation exception occurs when the data types of "In" and "InOut" differ.
  - When the value of "Size" is 0, the value of "InOut" remains unchanged.
  - When "Size" or "Pos" exceeds the valid range, an exception occurs, the function returns FALSE, and the value of "InOut" remains unchanged.
  - When the bit string "InOut" does not contain enough bits for the number of bits specified by "Size" from the position specified by "Pos", an exception occurs, the function returns FALSE, and the value of "InOut" remains unchanged.

18.1.2.63 WriteNbit_DWORD

Writes multiple bits into a bit string.

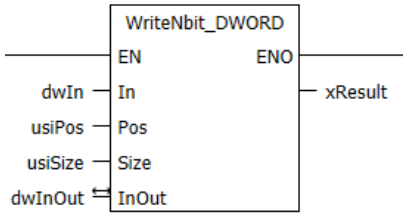
- **Instruction format**

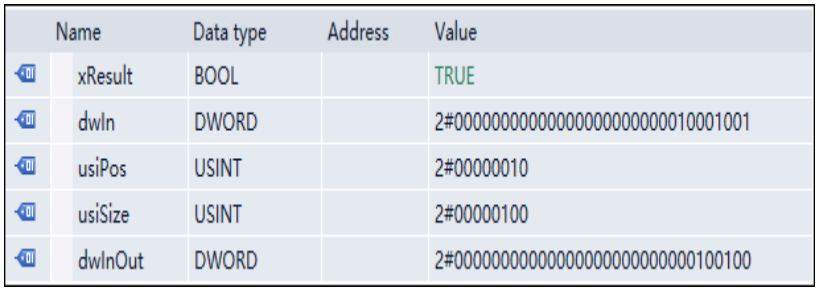
Instruction	Name	FB/FC	LD Representation	ST Representation
WriteNbit_DWORD	N-bit write group	FC		:= WriteNbit_DWORD(In := , Pos := , Size := , InOut :=);

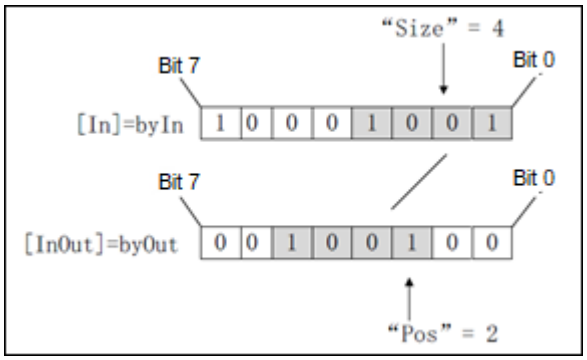
- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Read source	Follows data type	0	A bit string to be read and written to "InOut"
	Pos	Write position	Follows data type	0	Bit position to write to
	Size	Write size	Follows data type	0	The number of bits to be written
Input/Output	InOut	Write target	Follows data type	-	Write result







Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Pos	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Size	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
InOut	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - The function first reads the lower "Size" bits from the source "In".
  - Then, it writes the read value to the write position "Pos" of the target "InOut".
- **Program example**

	LD	ST

Define variables	VAR
	xResult: BOOL;
	dwIn: DWORD := 16#89;
	usiPos: USINT := 2;
	usiSize: USINT := 4;
	dwInOut: DWORD;
	END_VAR	

	LD	ST
Program		`xResult := WriteNbit_DWORD(In := dwIn, Pos := usiPos, Size := usiSize, InOut := dwInOut);`
Operation result		
Principle analysis		

- **Precautions**
  - A compilation exception occurs when the data types of "In" and "InOut" differ.
  - When the value of "Size" is 0, the value of "InOut" remains unchanged.
  - When "Size" or "Pos" exceeds the valid range, an exception occurs, the function returns FALSE, and the value of "InOut" remains unchanged.
  - When the bit string "InOut" does not contain enough bits for the number of bits specified by "Size" from the position specified by "Pos", an exception occurs, the function returns FALSE, and the value of "InOut" remains unchanged.

18.1.2.64 WriteNbit_LWORD

Writes multiple bits into a bit string.

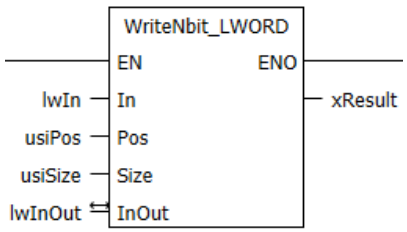
- **Instruction format**

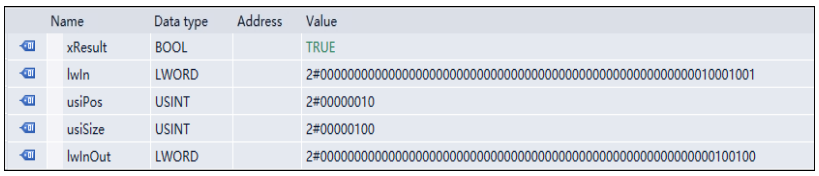
Instruction	Name	FB/FC	LD Representation	ST Representation
WriteNbit_LWORD	N-bit write group	FC		:= WriteNbit_LWORD(In := , Pos := , Size := , InOut :=);

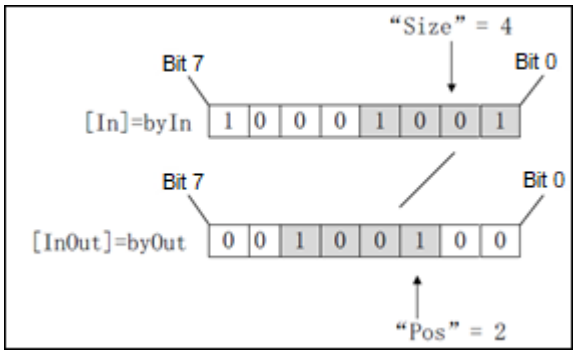
- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Read source	Follows data type	-	A bit string to be read and written to "InOut"
	Pos	Write position	Follows data type	0	Bit position to write to
	Size	Write size	Follows data type	0	The number of bits to be written
Input/Output	InOut	Write target	Follows data type	-	Write result







Variable type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Pos	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
Size	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
InOut	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - The function first reads the lower "Size" bits from the source "In".
  - Then, it writes the read value to the write position "Pos" of the target "InOut".
- **Program example**

	LD	ST

Define variables	VAR
	xResult: BOOL;
	lwIn: LWORD := 16#89;
	usiPos: USINT := 2;
	usiSize: USINT := 4;
	lwInOut: LWORD;
	END_VAR	

	LD	ST
Program		`xResult := WriteNbit_LWORD(In := lwIn, Pos := usiPos, Size := usiSize, InOut := lwInOut);`
Operation result		
Principle analysis		

- **Precautions**
  - A compilation exception occurs when the data types of "In" and "InOut" differ.
  - When the value of "Size" is 0, the value of "InOut" remains unchanged.
  - When "Size" or "Pos" exceeds the valid range, an exception occurs, the function returns FALSE, and the value of "InOut" remains unchanged.
  - When the bit string "InOut" does not contain enough bits for the number of bits specified by "Size" from the position specified by "Pos", an exception occurs, the function returns FALSE, and the value of "InOut" remains unchanged.

18.1.2.65 StringSum

Calculates the sum value (the sum of character codes of all characters) of a string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
StringSum	String sum calculation	FC		:= StringSum(In := , Size := , Out =>);

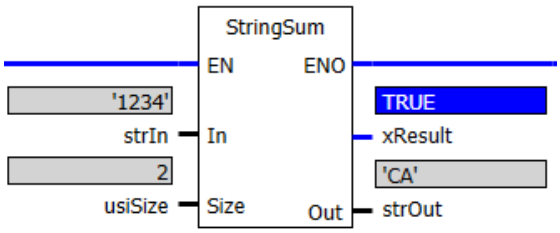
- **Related variables**

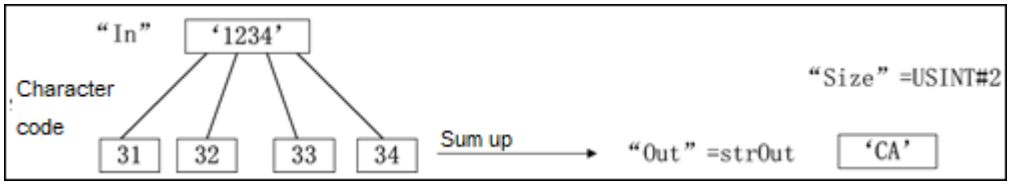
  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Input string	Follows data type	-	Input string
	Size	Byte size	1 or 2	1	Byte size of the sum value
Output	Out	Sum value	Number of bytes specified by "Size"	-	Sum value

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
Size	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√





- **Function description**

  Calculates the sum value (the sum of character codes of all characters) of the input string "In". The sum value "Out" indicates the number of bytes specified by "Size". "Out" is represented as a hexadecimal string, with a NULL character stored at the end.

- **Program example**

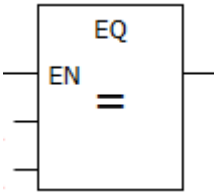
  In the following example, the input parameter "In" is "1234" and "Size" is 2.

Item	LD	ST
Define variables	VAR strIn: STRING[256] := '1234'; usiSize: USINT := 2; xResult: BOOL; strOut: STRING[2]; END_VAR	

<table>
<tr><th>Item</th><th>LD</th><th>ST</th></tr>
<tr><td>Program</td><td>
</td><td>xResult TRUE := StringSum(In := strIn '1234',
Size := usiSize 2 ,
Out => strOut 'CA');RETURN</td></tr>
<tr><td>Operation result</td><td colspan="2"><table>
<tr><th></th><th>Name</th><th>Data type</th><th>Address</th><th>Value</th></tr>
<tr><td></td><td>strIn</td><td>STRING[256]</td><td></td><td>'1234'</td></tr>
<tr><td></td><td>usiSize</td><td>USINT</td><td></td><td>2</td></tr>
<tr><td></td><td>xResult</td><td>BOOL</td><td></td><td>TRUE</td></tr>
<tr><td></td><td>strOut</td><td>STRING[2]</td><td></td><td>'CA'</td></tr>
</table></td></tr>
<tr><td>Principle analysis</td><td colspan="2">
</td></tr>
</table>

- **Precautions**
  - When the sum of the character codes in "In" exceeds the number of bits specified by "Size", the higher bits are discarded, and the function returns FALSE.
  - When the value of "Size" is out of the valid range, an exception occurs in the program, and the function returns FALSE.
  - When the byte count of "In" is 0 (NULL), an exception occurs in the program, and the function returns FALSE.
  - When "In" is not NULL-terminated, the result may become abnormal.

18.1.3 Comparison Operations



18.1.3.1 Instruction List

Instruction	FB/FC	Function	Library	Applicable Library Version
18.1.3.2 EQ	FC	Equal instruction	-	-
18.1.3.3 GE	FC	Greater than or equal instruction		
18.1.3.4 GT	FC	Greater than instruction		
18.1.3.5 LE	FC	Less than or equal instruction		
18.1.3.6 LT	FC	Less than instruction		
18.1.3.7 NE	FC	Not equal instruction		

18.1.3.2 EQ

EQ determines whether the two input values are equal. If the first input value equals the second, the output is TRUE; otherwise, the output is FALSE.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
EQ	Equal instruction	FC		=

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Input 1	Follows data type	-	Data 1
	In2	Input 2	Follows data type	-	Data 2
Output	Out	Return value	Follows data type	FALSE	Comparison result

Data type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING

  LD:

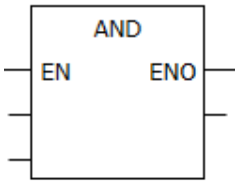
18.1.4 Logic Operations

18.1.4.1 Instruction List



Instruction	FB/FC	Function	Library	Applicable Library Version
18.1.4.2 AND	FC	AND instruction	-	-

Instruction	FB/FC	Function	Library	Applicable Library Version
18.1.4.3 NOT	FC	NOT instruction		
18.1.4.4 OR	FC	OR instruction		
18.1.4.5 XOR	FC	XOR instruction		
18.1.4.6 TestABit	FC	Outputs the value of the specified bit	OMUtils	Library version 1.3.0.0 and later
18.1.4.7 TestABitN	FC	Outputs the inverted value of the specified bit		Library version 1.3.0.0 and later
18.1.4.8 SetBits	FC	Sets multiple bits consecutively		Library version 1.3.0.0 and later
18.1.4.9 ResetBits	FC	Resets multiple bits consecutively		Library version 1.3.0.0 and later
18.1.4.10 RESET_BF	FC	Batch reset		Applicable to library version 1.5.0.0 and later
18.1.4.11 SET_BF	FC	Batch setting		Applicable to library version 1.5.0.0 and later

18.1.4.2 AND

Bitwise AND: When the same bit in all inputs is 1, the corresponding output bit is 1; if not, the output bit is 0.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AND	AND instruction	FC		AND ;

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Input 1	Follows data type	-	Data 1
	In2	Input 2	Follows data type	-	Data 2
Output	Out	Return value	Follows data type	-	Comparison result

Data type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING

Out	√	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–	–	–

- **Function**

  Bitwise XOR: When one input is 1 and the other is 0 for the same bit of the two inputs, the corresponding output bit is 1; otherwise, when the two input values are the same for the same bit, the output bit is 0.

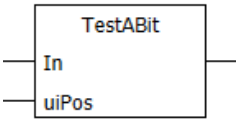
- **Program example**

  ST:



LD:

18.1.4.6 TestABit

TestABit outputs the value at the specified bit in the input.

- **Instruction format**

Instruction	Name	FB/FC	Ladder Diagram Representation	Structured Text Representation
TestABit	Outputs the value of the specified bit	FC		:= TestABit(In := , uiPos :=);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Bit string	Follows data type	-	Bit string
	uiPos	Bit position	0 to ("In" bit count - 1)	0	The position of the specified bit
Output	TestABit	Bit value	Follows data type	-	The value of the specified bit

Data type

	Boolean	Bit String				Integer								Real Number		Time, duration, date, and text string				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–	–	–

	Boolean	Bit String				Integer								Real Number		Time, duration, date, and text string				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
uiPos	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
TestABit	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

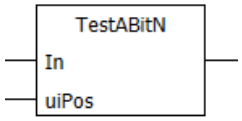
- **Function description**

  When EN is TRUE, the value of the bit at position "uiPos" in input "In" is output to the instruction return value "TestABit".

- **Program example**

	LD	ST
Define variables	VAR iIn: INT; uiPos: UINT; xOut: BOOL; END_VAR	
Program		xOut TRUE := TestABit(In := iIn 10 , uiPos := uiPos 1);
Operation result		

	Name	Type	Address	Value
1	iIn	INT		10
2	uiPos	UINT		1
3	xOut	BOOL		TRUE



- **Note**

  When uiPos < 0 or uiPos > (number of bits in "In" - 1), "TestABit" returns FALSE.

18.1.4.7 TestABitN

TestABitN outputs the inverted value at the specified bit in the input.

- **Instruction format**

Instruction	Name	FB/FC	Ladder Diagram Representation	Structured Text Representation
TestABitN	Outputs the inverted value of the specified bit	FC		:= TestABitN(In := , uiPos :=);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Bit string	Follows data type	-	Bit string
	uiPos	Bit position	0 to ("In" bit count - 1)	0	The position of the specified bit
Output	TestABitN	Bit value	Follows data type	-	The inverted value of the specified bit

Data type

	Boolean	Bit String				Integer								Real Number		Time, duration, date, and text string				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–	–	–
uiPos	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
TestABitN	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

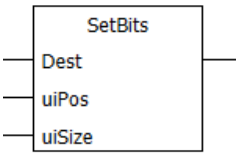
- **Function description**

  When EN is TRUE, the inverted value of the bit at position "uiPos" in input "In" is output to the instruction return value "TestABit".

- **Program example**

	LD	ST
Define variables	VAR iIn: INT; uiPos: UINT; xOut: BOOL; END_VAR	

	LD	ST
Program		xOut FALSE := TestABitN(In := iIn 10 , uiPos := uiPos 1);
Operation result		



- **Note**

  When uiPos < 0 or uiPos > (number of bits in "In" - 1), "TestABitN" returns FALSE.

18.1.4.8 SetBits

Sets consecutive bits in a bit string.

- **Instruction format**

Instruction	Name	FB/FC	Ladder Diagram Representation	Structured Text Representation
SetBits	Sets multiple bits consecutively	FC		:= SetBits(Dest := , uiPos := , uiSize :=);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Dest	Bit string	Follows data type	-	Bit string
	uiPos	Bit position	0 to ("Dest" bit count - 1)	0	The position of the specified bit
	uiSize	Number of bits	0 to "Dest" bit count	0	Number of bits
Output	SetBits	Result	Follows data type	-	TRUE: Operation succeeded. FALSE: Operation failed.

  Data type

	Boolean	Bit String				Integer								Real Number		Time, duration, date, and text string				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Dest	–	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–	–	–
uiPos	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
uiSize	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
SetBits	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function description**

  Sets consecutive bits in a bit string to TRUE.

- **Program example**

	LD	ST
Define variables	VAR iIn: INT; uiSize: UINT; xOut: BOOL; END_VAR	
Program		xOut TRUE := SetBits(Dest := iIn 10 , uiPos := uiPos 1 , uiSize := uiSize 0);
Operation result		

	Name	Type	Address	Value
1	iIn	INT		10
2	uiPos	UINT		1
3	uiSize	UINT		0
4	xOut	BOOL		TRUE

- **Precautions**
  - When (uiPos + uiSize) > bit count of "Dest", the instruction is not executed and returns FALSE.
  - When uiSize is 0, the instruction is executed normally and returns TRUE.

18.1.4.9 ResetBits

Resets consecutive bits in a bit string.

- **Instruction format**

Instruction	Name	FB/FC	Ladder Diagram Representation	Structured Text Representation
ResetBits	Resets multiple bits consecutively	FC		:= ResetBits(Dest := , uiPos := , uiSize :=);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Dest	Bit string	Follows data type	-	Bit string
	uiPos	Bit position	0 to ("Dest" bit count - 1)	0	The position of the specified bit
	uiSize	Number of bits	0 to "Dest" bit count	0	Number of bits
Output	ResetBits	Result	Follows data type	-	TRUE: Operation succeeded. FALSE: Operation failed.

Data type

	Boolean	Bit String				Integer								Real Number		Time, duration, date, and text string				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Dest	–	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–	–	–
uiPos	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
uiSize	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–

	Boolean	Bit String				Integer								Real Number		Time, duration, date, and text string				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
ResetBits	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function description**

  Sets consecutive bits in a bit string to FALSE.

- **Program example**

	LD	ST
Define variables	VAR iIn: INT; uiSize: UINT; xOut: BOOL; END_VAR	
Program		xOut TRUE := ResetBits(Dest := iIn 8 , uiPos := uiPos 1 , uiSize := uiSize 1);
Operation result		

Name	Type	Address	Value
iIn	INT		8
uiPos	UINT		1
uiSize	UINT		1
xOut	BOOL		TRUE

- **Precautions**
  - When (uiPos + uiSize) > bit count of "Dest", the instruction is not executed and returns FALSE.
  - When uiSize is 0, the instruction is executed normally and returns TRUE.

18.1.4.10 RESET_BF

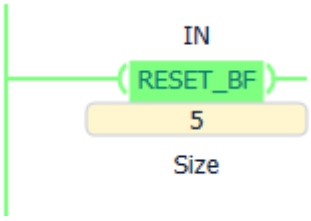
This instruction batch resets a BOOL array.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
RESET_BF	Batch reset	FC	??? RESET_BF ???	:= RESET_BF(Dest := , uiSize :=);

- **Related variables**

Variable



Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Dest	Variable to be reset	Follows data type	-	Variable to be reset.
	uiSize	Reset length	Follows data type	-	Reset length.

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Dest	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
uiSize	-	-	-	-	-	-	√	-	-	-	-	-	-	-	-	-	-	-	-	-

- **Function**
  - Sets the specified number of bits (uiSize) in the Dest variable to FALSE, starting from the specified bit.
  - The Dest input must be a BOOL array with a valid array index; otherwise, a compilation fault will be reported.
  - The input for uiSize must be a constant.
- **Program example**

	LD	ST
Define variables	VAR IN: ARRAY[0..10] OF BOOL; Size: UINT; END_VAR	

<table>
<tr><th></th><th>LD</th><th>ST</th></tr>
<tr><td>Program</td><td>
</td><td>
</td></tr>
<tr><td>Operation result</td><td>
<table>
<tr><th></th><th>Name</th><th>Type</th><th>Address</th><th>Value</th></tr>
<tr><td>1</td><td>VAR</td><td></td><td></td><td></td></tr>
<tr><td>2</td><td>IN</td><td>ARRAY [0..10] OF BOOL</td><td></td><td></td></tr>
<tr><td>3</td><td>IN[0]</td><td>BOOL</td><td></td><td>FALSE</td></tr>
<tr><td>4</td><td>IN[1]</td><td>BOOL</td><td></td><td>FALSE</td></tr>
<tr><td>5</td><td>IN[2]</td><td>BOOL</td><td></td><td>FALSE</td></tr>
<tr><td>6</td><td>IN[3]</td><td>BOOL</td><td></td><td>FALSE</td></tr>
<tr><td>7</td><td>IN[4]</td><td>BOOL</td><td></td><td>FALSE</td></tr>
<tr><td>8</td><td>IN[5]</td><td>BOOL</td><td></td><td>TRUE</td></tr>
<tr><td>9</td><td>IN[6]</td><td>BOOL</td><td></td><td>TRUE</td></tr>
<tr><td>10</td><td>IN[7]</td><td>BOOL</td><td></td><td>TRUE</td></tr>
<tr><td>11</td><td>IN[8]</td><td>BOOL</td><td></td><td>TRUE</td></tr>
<tr><td>12</td><td>IN[9]</td><td>BOOL</td><td></td><td>TRUE</td></tr>
<tr><td>13</td><td>IN[10]</td><td>BOOL</td><td></td><td>TRUE</td></tr>
<tr><td>14</td><td>Size</td><td>UINT</td><td></td><td>5</td></tr>
</table>
</td></tr>
</table>

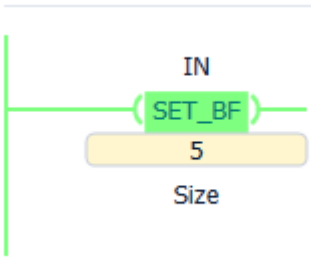
18.1.4.11 SET_BF

This instruction batch sets a BOOL array.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
SET_BF	Batch setting	FC		:= SET_BF(Dest := , uiSize :=);

- **Related variables**



Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Dest	Variable to be set	Follows data type	-	Variable to be set.
	uiSize	Set length	Follows data type	-	Set length

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Dest	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
uiSize	-	-	-	-	-	-	√	-	-	-	-	-	-	-	-	-	-	-	-	-

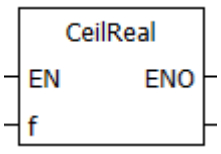
- **Function**
  - Sets the specified number of bits (uiSize) in the Dest variable to TRUE, starting from the specified bit.
  - The Dest input must be a BOOL array with a valid array index; otherwise, a compilation fault will be reported.
  - The input for uiSize must be a constant.
- **Program example**

	LD	ST
Define variables	VAR IN: ARRAY[0..10] OF BOOL; Size: UINT; END_VAR	
Program		SET_BF(Dest := IN, uiSize := Size 5);RETURN
Operation result		

	Name	Type	Address	Value
1	VAR			
2	IN	ARRAY [0..10] OF BOOL		
3	IN[0]	BOOL		TRUE
4	IN[1]	BOOL		TRUE
5	IN[2]	BOOL		TRUE
6	IN[3]	BOOL		TRUE
7	IN[4]	BOOL		TRUE
8	IN[5]	BOOL		FALSE
9	IN[6]	BOOL		FALSE
10	IN[7]	BOOL		FALSE
11	IN[8]	BOOL		FALSE
12	IN[9]	BOOL		FALSE
13	IN[10]	BOOL		FALSE
14	Size	UINT		5

18.1.5 Mathematical Operations

18.1.5.1 Instruction List



Instruction	FB/FC	Function	Library	Applicable Library Version

18.1.5.37 NORM_X	FC	Normalization instruction		Library version 1.3.0.0 and later

18.1.5.2 CeilReal

Rounds up to get the smallest integer greater than or equal to the input value.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
CeilReal	Round up	FC		:= CeilReal(f :=);

- **Related variables**

  Variable

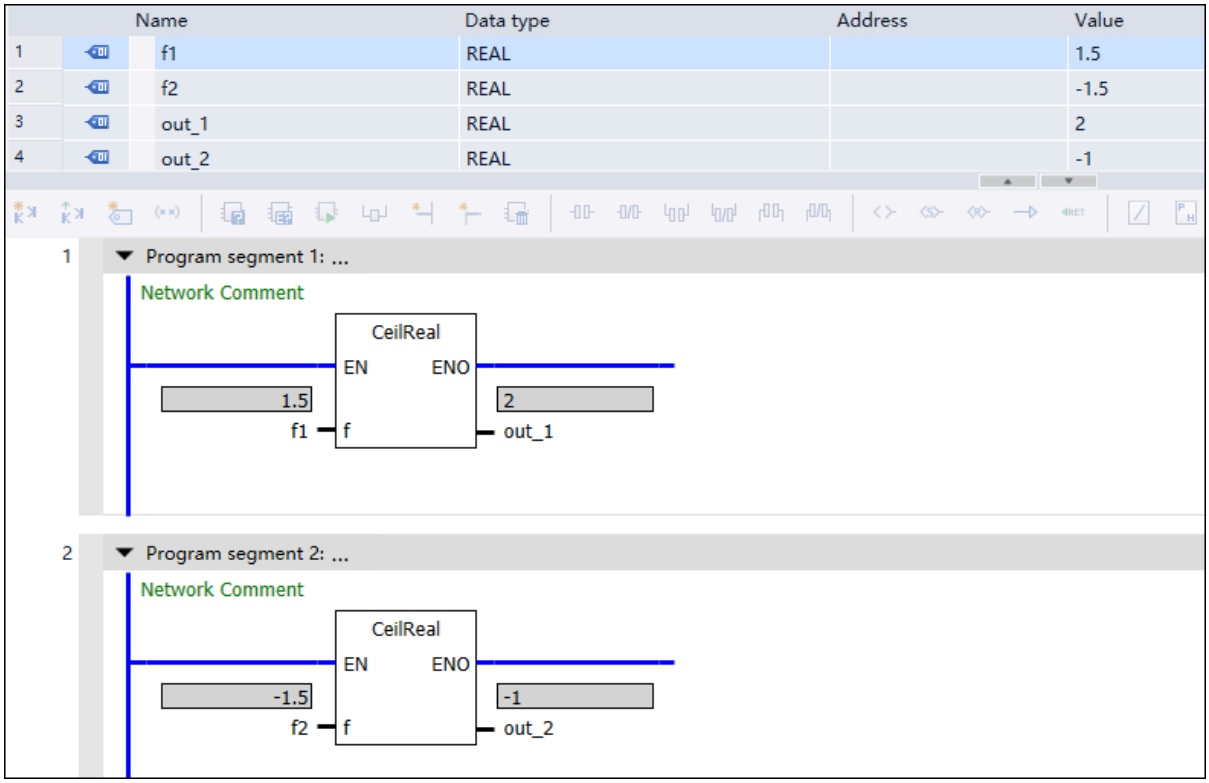
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	f	The input floating-point value	Follows data type	-	The input long floating-point value
Output	Out	Return value	Follows data type	-	The rounded-up value

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
f	–	–	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–

- **Function**

  Rounds up to get the smallest integer greater than or equal to the input value.



- **Program example**

  ST:

	Name	Data type	Address	Value
1	f1	REAL		1.5
2	f2	REAL		-1.5
3	out_1	REAL		2
4	out_2	REAL		-1

```
IF  CAS  FOR  WHI  REP  RET  EX
1  out_1  2  := CeilReal(f := f1  1.5  );
2  out_2  -1  := CeilReal(f := f2  -1.5  );RETURN
```

  LD:

18.1.5.3 CeilLReal

Rounds up to get the smallest integer greater than or equal to the input value.

- **Instruction format**

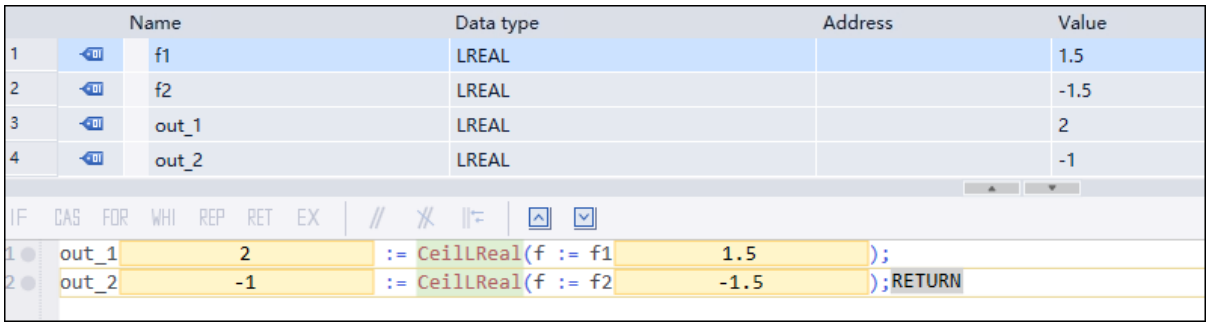
Instruction	Name	FB/FC	LD Representation	ST Representation
CeilLReal	Round up	FC		:= CeilLReal(f :=);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	f	The input long floating-point value	Follows data type	-	The input long floating-point value
Output	Out	Return value	Follows data type	-	The rounded-up value

Variable types



Variable Name	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
f	–	–	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–

- **Function**

  Rounds up to get the smallest integer greater than or equal to the input value.

- **Program example**

  ST:

  LD:

18.1.5.4 FloorReal

Rounds down to get the largest integer less than or equal to the input value.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
FloorReal	Round down	FC		:= FloorReal(f :=);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	f	The input floating-point value	Follows data type	-	The input long floating-point value
Output	Out	Return value	Follows data type	-	The rounded-down value

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
f	–	–	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–

- **Function**

  Rounds down to get the largest integer less than or equal to the input value.

- **Program example**

  ST:

	Name	Data type	Address	Value
1	f1	REAL		1.5
2	f2	REAL		-1.5
3	out_1	REAL		1
4	out_2	REAL		-2

```
1  out_1  1   := FloorReal(f := f1  1.5  );
2  out_2  -2  := FloorReal(f := f2  -1.5 );RETURN
```

LD:

	Name	Data type	地址	值
1	f1	REAL		1.5
2	f2	REAL		-1.5
3	out_1	REAL		1
4	out_2	REAL		-2

18.1.5.5 FloorLReal

Rounds down to get the largest integer less than or equal to the input value.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
FloorLReal	Round down	FC		:= FloorLReal(f :=);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	f	The input long floating-point value	Follows data type	-	The input long floating-point value
Output	Out	Return value	Follows data type	-	The rounded-down value

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
f	–	–	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–

- **Function**

  Rounds down to get the largest integer less than or equal to the input value.

- **Program example**

  ST:

  LD:

18.1.5.6 TruncateF

Truncates a floating-point number to get its integer part.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
TruncateF	Truncation	FC		:= TruncateF(f :=);

- **Related variables**

  Variable

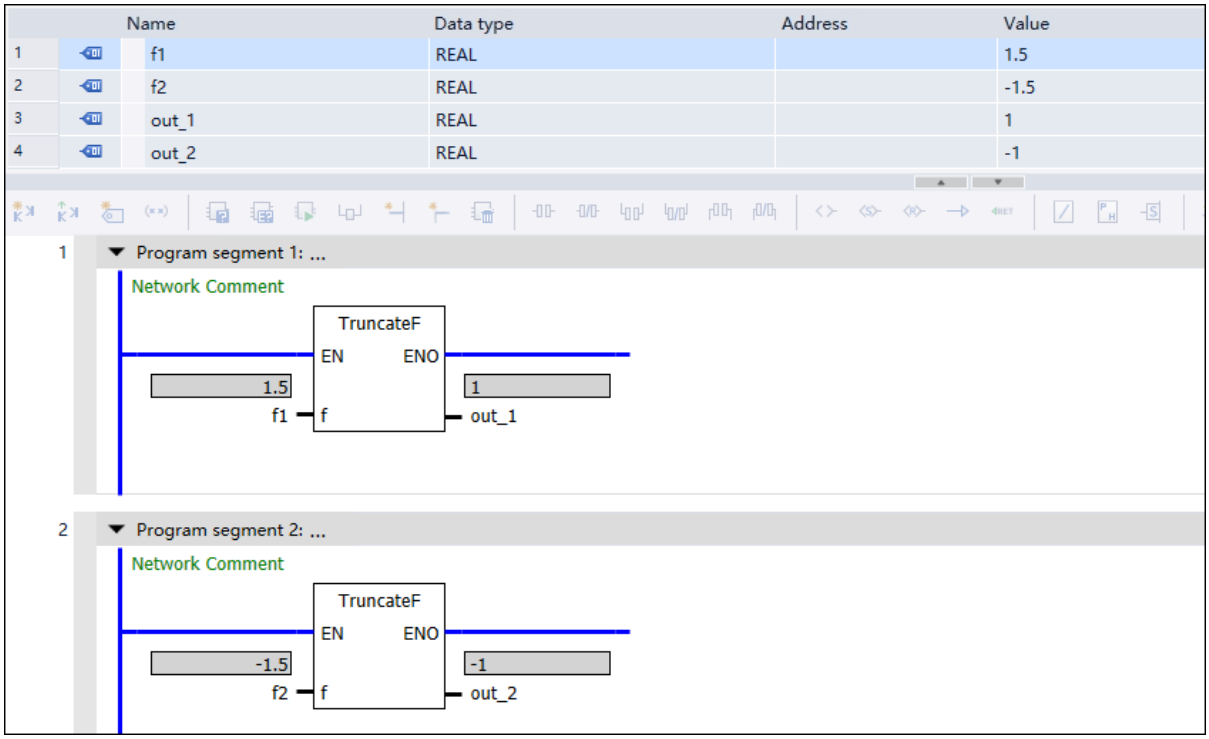
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	f	The input floating-point value	Follows data type	-	The input long floating-point value
Output	Out	Return value	Follows data type	-	The truncated value

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TOD	DT	STRING
f	–	–	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–

- **Function**

  Truncates a floating-point number to get its integer part.

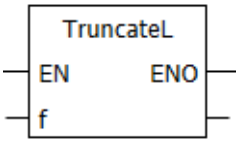


- **Program example**

  ST:

	Name	Data type	Address	Value
1	f1	REAL		1.5
2	f2	REAL		-1.5
3	out_1	REAL		1
4	out_2	REAL		-1

```
1  out_1  1    := TruncateF(f := f1  1.5  );
2  out_2  -1   := TruncateF(f := f2  -1.5 );RETURN
```



LD:

18.1.5.7 TruncateL

Truncates a long floating-point number to get its integer part.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
TruncateL	Truncation	FC		:= TruncateL(f :=);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	f	The input long floating-point value	Follows data type	-	The input long floating-point value
Output	Out	Return value	Follows data type	-	The truncated value

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TOD	DT	STRING
f	–	–	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–

- **Function**

  Truncates a long floating-point number to get its integer part.

- **Program example**

  ST:

  LD:

18.1.5.8 fmodLR

Calculates the remainder of floating-point number division.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
fmodLR	Floating-point modulo-division	FC		:= fmodLR(X := , Y :=);

- **Related variables**

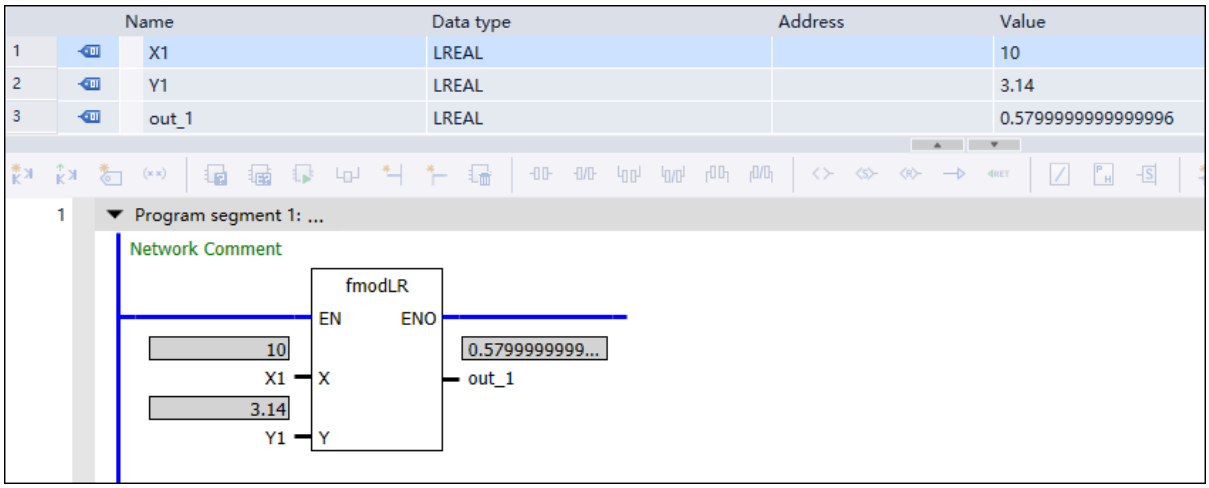
Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	X	Dividend	Follows data type	-	Dividend
	Y	Divider	Follows data type	-	Divider
Output	Out	Remainder	Follows data type	-	Remainder

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
X	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–
Y	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–

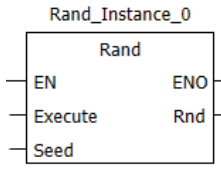
- **Function**



Calculates the remainder of floating-point number division.

- **Program example**

ST:



LD:

18.1.5.9 Rand

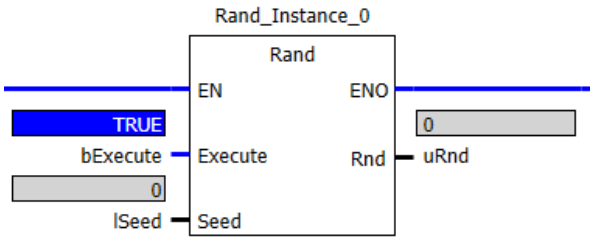
Generates pseudorandom numbers.

- **Instruction format**

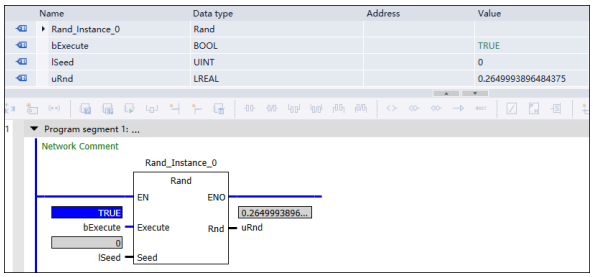
Instruction	Name	FB/FC	LD Representation	ST Representation
Rand	Pseudorandom number generation	FB		Rand_Instance_0(Execute := , Seed := , Rnd =>);

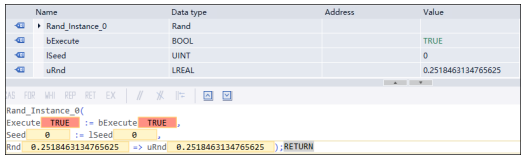
- **Related variables**

Variable



Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Execute	Triggering	Follows data type	-	A trigger for random number generation
	Seed	Random number mode	Follows data type	0	Random number sequence (0 means not specified).





Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	Rnd	Random number	0.000000000000000e+0 to 1.000000000000000e+0	-	Random number

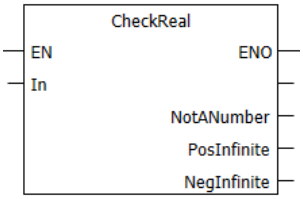
Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Execute	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Seed	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
Rnd	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–

- **Function**
  - Generates a random number "Rnd", whose value changes each time the instruction is executed.
  - The random number mode "Seed" is used to specify the random number sequence. If the value of "Seed" is the same, the same random number sequence is generated each time the program runs. Therefore, reproducible random numbers can be generated.
  - When the value of "Seed" is 0, irreproducible random numbers are generated. To avoid generating the same random number sequence each time the program runs, set the value of "Seed" to 0.
- **Program example**

	LD	ST
Define variables	VAR Rand_Instance_0: Rand; bExecute: BOOL := TRUE; lSeed: UINT; uRnd: LREAL; END_VAR	
Program		Rand_Instance_0(Execute FALSE := bExecute TRUE, Seed 0 := lSeed 0, Rnd 0 => uRnd 0);RETURN

	LD	ST
Operation result		



- **Precautions**

  The value of "Rand" is a real number between 0 and 1.

18.1.5.10 CheckReal

Checks whether a real number is infinite or non-numeric data.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
CheckReal	Real number check	FC		:= CheckReal(In := , NotANumber => , PosInfinite => , NegInfinite =>);

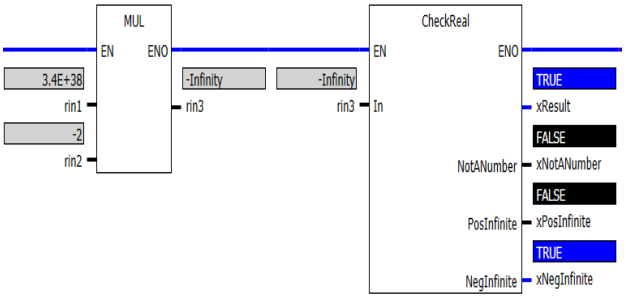
- **Related variables**

  Input variables

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Real Number	Follows data type	-	Real number
Output	NotANumber	Non-numeric data check result	FALSE, TRUE	FALSE	TRUE: Non-numeric data FALSE: Not non-numeric data
	PosInfinite	Positive infinity check result	FALSE, TRUE	FALSE	TRUE: Positive infinity FALSE: Not positive infinity
	NegInfinite	Negative infinity check result	FALSE, TRUE	FALSE	TRUE: Negative infinity FALSE: Not negative infinity

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–
NotANumber	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
PosInfinite	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
NegInfinite	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–



- **Function**

  Checks whether the real number "In" is non-numeric data, positive infinity, or negative infinity. The corresponding results are output to "NotANumber", "PosInfinite", and "NegInfinite", respectively.

- **Program example**

	LD	ST
Define variables		
Program		

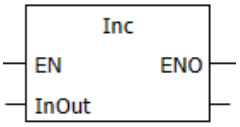
```
VAR
    xResult: BOOL;
    rin1: REAL:=3.4E+38;
    rin2: REAL:=-2;
    rin3: REAL;
    xNotANumber: BOOL;
    xPosInfinite: BOOL;
    xNegInfinite: BOOL;
END_VAR
```

```
rin3 -Infinity :=rin1 3.4E+38 *rin2 -2 ;
xResult TRUE := CheckReal(In := rin3 -Infinity ,
    NotANumber => xNotANumber FALSE ,
    PosInfinite =>xPosInfinite FALSE ,
    NegInfinite =>xNegInfinite TRUE );RETURN
```

	LD	ST

Operation result

Name	Data type	Address	Value
xResult	BOOL		TRUE
rin1	REAL		3.4E+38
rin2	REAL		-2
rin3	REAL		-Infinity
xNotANumber	BOOL		FALSE
xPosInfinite	BOOL		FALSE
xNegInfinite	BOOL		TRUE



- **Precautions**

  In OMUtils library versions 1.2.0.1 and earlier, a compilation fault occurs if the parameter passed to "In" is not a real number.
  In OMUtils library versions 1.3.0.0 and later, no compilation fault occurs if the parameter passed to "In" is an integer.

18.1.5.11 Inc

Increments an integer value.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
Inc	Increment operation	FC		:= Inc(InOut :=);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	InOut	Input data	Follows data type	-	Input data

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
InOut	–	–	–	–	–	√	√	√	√	√	√	√	√	–	–	–	–	–	–	–

- **Function**

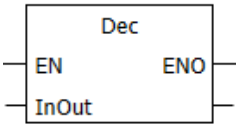
Increments the input data "InOut". When the calculation result exceeds the maximum value of "InOut", it resets to the minimum value.

- **Program example**

  The following table shows examples of the Inc instruction. When the input value is INT#4, the value of "InOut" after instruction execution is INT#5.

	LD	ST
Define variables	VAR iVal: INT := 4; xResult: BOOL; END_VAR	
Program		
Operation result		

Name	Data type	Address	Value
iVal	INT		5
xResult	BOOL		TRUE



- **Precautions**

  The function returns TRUE.

18.1.5.12 Dec

Decrements an integer value.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
Dec	Decrement operation	FC		:= Dec(InOut :=);

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	InOut	Input data	Follows data type	-	Input data

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In Out	–	–	–	–	–	√	√	√	√	√	√	√	√	–	–	–	–	–	–	–

- **Function**

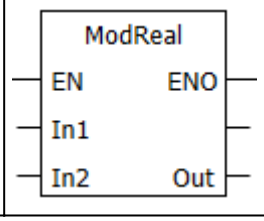
  Decrements the input data "InOut". When the calculation result is less than the minimum value of "InOut", it resets to the maximum value.

- **Program example**

  - The following table shows examples of the Dec instruction. When the input value is INT#4, the value of "InOut" after executing the instruction is INT#3.

	LD	ST
Define variables	VAR iVal :INT := 4; xResult:BOOL; END_VAR	
Program		xResult TRUE := Dec(InOut := iVal 3);RETURN
Operation result		

	Name	Data type	Address	Value
	iVal	INT		3
	xResult	BOOL		TRUE



- **Precautions**

  The function returns TRUE.

18.1.5.13 ModReal

Calculates the remainder of real number division.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ModReal	Real number modulo-division	FC		:= ModReal(In1 := , In2 := , Out =>);

- **Related variable**

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Dividend	Follows data type	-	Dividend
	In2	Divider	Follows data type	-	Divider
Output	Out	Remainder	Follows data type	-	Remainder

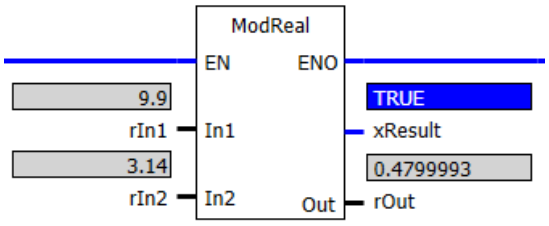
Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
In2	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–

- **Function**

  Calculates the remainder obtained by dividing the dividend "In1" by the divisor "In2". The instruction is performed according to the following expression.

  Out = In1 - (In1 / In2) In2, where the division within parentheses truncates the decimal part. The following table shows example values for "In1", "In2", and "Out":



Value of In1	Value of In2	Value of Out
9.9	3.14	0.48
9.9	-3.14	0.48
-9.9	3.14	-0.48
-9.9	-3.14	-0.48

- **Program example**

<table>
<tr><th></th><th>LD</th><th>ST</th></tr>
<tr><td>Define variables</td><td colspan="2">

```
VAR
    rIn1: REAL := 9.9;
    rIn2: REAL := 3.14;
    rOut: REAL;
    xResult: BOOL;
END_VAR
```

</td></tr>
<tr><td>Program</td><td>

</td><td>

```
xResult TRUE := ModReal(In1 := rIn1 9.9 ,
        In2 := rIn2 3.14 ,
        Out => rOut 0.4799993 );RETURN
```

</td></tr>
<tr><td>Operation result</td><td colspan="2">

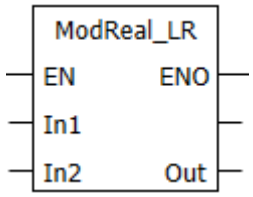
Name	Data type	Address	Value
rIn1	REAL		9.9
rIn2	REAL		3.14
rOut	REAL		0.4799993
xResult	BOOL		TRUE

</td></tr>
</table>

- **Precautions**

  When passing an integer parameter to "In1" or "In2", the data type is converted as follows before inputting.

Data Type of Parameter Passed to In1 or In2	Data Type of In1 or In2
USIN, UINT, SINT, INT	REAL
UDINT, DINT, ULINT, LINT	Data may be lost



Depending on the values in "In1" and "In2", the value of "Out" is as shown in the table below.

0		In1				
		0	Number	+∞	-∞	Non-numeric
In2	0	Non-numeric	Non-numeric	Non-numeric	Non-numeric	Non-numeric
	Number	0	Remainder of "In1" divided by "In2"	Non-numeric	Non-numeric	Non-numeric
	+∞	0	Value of "In1"	Non-numeric	Non-numeric	Non-numeric
	-∞	0	Value of "In1"	Non-numeric	Non-numeric	Non-numeric
	Non-numeric	Non-numeric	Non-numeric	Non-numeric	Non-numeric	Non-numeric

18.1.5.14 ModReal_LR

Calculates the remainder of long real number division.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ModReal_LR	Long real number modulo-division	FC		:= ModReal_LR(In1 := , In2 := , Out =>);

- **Related variable**

Variable

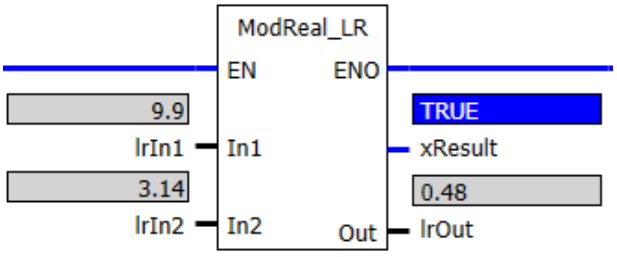
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Dividend	Follows data type	-	Dividend
	In2	Divider	Follows data type	-	Divider
Output	Out	Remainder	Follows data type	-	Remainder

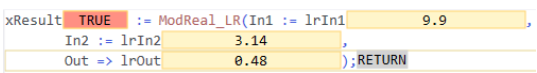
Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–
In2	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–

- **Function**

Calculates the remainder obtained by dividing the dividend "In1" by the divisor "In2". The instruction is performed according to the following expression.





Out = In1 - (In1 / In2) In2, where the division within parentheses truncates the decimal part. The following table shows example values for "In1", "In2", and "Out":

Value of In1	Value of In2	Value of Out
9.9	3.14	0.48
9.9	-3.14	0.48
-9.9	3.14	-0.48
-9.9	-3.14	-0.48

- **Program example**

	LD	ST

Define variables	VAR
	lrIn1: LREAL := 9.9;
	lrIn2: LREAL := 3.14;
	lrOut: LREAL;
	xResult: BOOL;
	END_VAR	

Program		
Operation result		

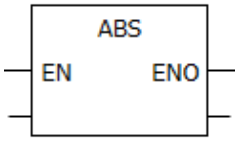
	Name	Data type	Address	Value
	lrIn1	LREAL		9.9
	lrIn2	LREAL		3.14
	lrOut	LREAL		0.48
	xResult	BOOL		TRUE

- **Precautions**

When passing an integer parameter to "In1" or "In2", the data type is converted as follows before inputting.

Data Type of Parameter Passed to In1 or In2	Data Type of In1 or In2
USINT, UINT, SINT, INT, UDINT, DINT	LREAL
ULINT, LINT	Data may be lost

Depending on the values in "In1" and "In2", the value of "Out" is as shown in the table below.



0		In1				
		0	Number	+∞	-∞	Non-numeric
In2	0	Non-numeric	Non-numeric	Non-numeric	Non-numeric	Non-numeric

0		In1				
		0	Number	+∞	-∞	Non-numeric
	Number	0	Remainder of "In1" divided by "In2"	Non-numeric	Non-numeric	Non-numeric
	+∞	0	Value of "In1"	Non-numeric	Non-numeric	Non-numeric
	-∞	0	Value of "In1"	Non-numeric	Non-numeric	Non-numeric
	Non-numeric	Non-numeric	Non-numeric	Non-numeric	Non-numeric	Non-numeric

18.1.5.15 ABS

Assigns the absolute value of the input data to the output variable.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ABS	Absolute value	FC		ABS()

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Input Variable	Follows data type	-	Variable to be calculated
Output	Out	Return value	Follows data type	-	Calculation result

Data type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	–

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Out	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	–

- **Function**

  Assigns the absolute value of the input data to the output variable.

- **Program example**

  ST:

  LD:

18.1.5.16 ACOS

Calculates the arc cosine of the input value and outputs the result in radians.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ACOS	Arc cosine calculation	FC		ACOS()

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Input Variable	Follows data type	-	Variable to be calculated
Output	Out	Return value	Follows data type	-	Calculation result

Data type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–

- **Function**

  Calculates the arc cosine of the input value and outputs the result in radians.

- **Program example**

  ST:

  LD:

18.1.5.17 ADD

Adds the two inputs on the left and outputs the addition result on the right.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ADD	Addition instruction	FC		+ ;

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Value to be added	Follows data type	-	Value 1 to be added
	In2	Value to be added	Follows data type	-	Value 2 to be added
Output	Out	Return value	Follows data type	-	Calculation result

  Data type

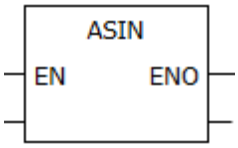
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	–
In2	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–
Out	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–

- **Function**

  Adds the two inputs on the left and outputs the addition result on the right.

- **Program example**

  ST:



LD:

18.1.5.18 ASIN

Calculates the arc sine of the input value and outputs the result in radians.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ASIN	Arc sine calculation	FC		ASIN()

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Input Variable	Follows data type	-	Variable to be calculated
Output	Out	Return value	Follows data type	-	Calculation result

Data type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–

- **Function**

  Calculates the arc sine of the input value and outputs the result in radians.

- **Program example**

  ST:

  LD:

18.1.5.19 ATAN

Calculates the arc tangent of the input value and outputs the result in radians.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ATAN	Arc tangent calculation	FC		ATAN()

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Input Variable	Follows data type	-	Variable to be calculated
Output	Out	Return value	Follows data type	-	Calculation result

Data type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–

- **Function**

  Calculates the arc tangent of the input value and outputs the result in radians.

- **Program example**

  ST:

  LD:

18.1.5.20 COS

Calculates the cosine value of the input, and outputs the result.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
COS	Cosine calculation	FC		COS()

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Input Variable	Follows data type	-	Variable to be calculated
Output	Out	Return value	Follows data type	-	Calculation result

  Data type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–

- **Function**

  Calculates the cosine value of the input, and outputs the result.

- **Program example**

  ST:

  LD:

18.1.5.21 DIV

Divides the two inputs on the left and outputs the division result on the right.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
DIV	Division instruction	FC		/ ;

- **Related variable**

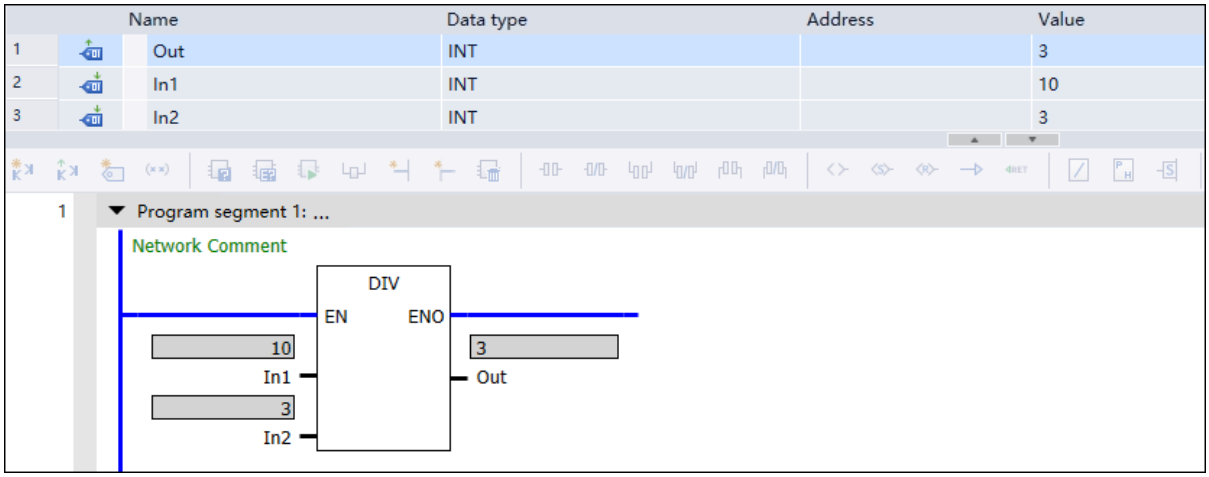
Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Dividend	Follows data type	-	Dividend
	In2	Divisor	Follows data type	-	Divisor
Output	Out	Return value	Follows data type	-	Calculation result

Data type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–
In2	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–
Out	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–

- **Function**

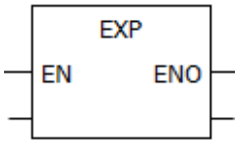


Divides the two inputs on the left and outputs the division result on the right.

- **Program example**

ST:

LD:



- **Precautions**

Dividing by zero produces different results depending on the target system.

18.1.5.22 EXP

Performs exponential function operation on the input value and outputs the function result.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
EXP	Exponential calculation	FC		EXP()

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Input Variable	Follows data type	-	Variable to be calculated
Output	Out	Return value	Follows data type	-	Calculation result

Data type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–

- **Function**

  Performs exponential function operation on the input value and outputs the function result.

- **Program example**

  ST:

  LD:

18.1.5.23 EXPT

Outputs the power operation result, with the input variable 2 as the exponent and the input variable 1 as the base number.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
EXPT	Exponentiation	FC		EXPT(,)

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Base number	Follows data type	-	Base number
	In2	Exponent	Follows data type	-	Exponent
Output	Out	Return value	Follows data type	-	Calculation result

Data type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–
In2	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–

- **Function**

  Outputs the power operation result, with the input variable 2 as the exponent and the input variable 1 as the base number.

- **Program example**

  ST:

  LD:

- **Precautions**

  The function result is undefined if any of the following conditions occur:

  1. The base number is negative.
  2. The base number is 0 and the exponent is less than or equal to 0.

18.1.5.24 LN

Calculates the natural logarithm of the input value, and outputs the result.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
LN	Natural logarithm	FC		LN()

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Input Variable	Follows data type	-	Variable to be calculated
Output	Out	Return value	Follows data type	-	Calculation result

  Data type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–

- **Function**

  Calculates the natural logarithm of the input value, and outputs the result.

- **Program example**

  ST:

  LD:

18.1.5.25 LOG

Calculates the base-10 logarithm of the input value, and outputs the result.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
LOG	Base-10 logarithm	FC		LOG()

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Input Variable	Follows data type	-	Variable to be calculated
Output	Out	Return value	Follows data type	-	Calculation result

Data type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–

- **Function**

  Calculates the base-10 logarithm of the input value, and outputs the result.

- **Program example**

  ST:

  LD:

18.1.5.26 MOD

Divides the two inputs on the left and outputs the non-negative integer remainder after division on the right.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
MOD	Modulo-division	FC		MOD ;

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Dividend	Follows data type	-	Dividend
	In2	Divisor	Follows data type	-	Divisor
Output	Out	Return value	Follows data type	-	Calculation result

  Data type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1	–	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–	–	–
In2	–	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–	–	–
Out	–	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–	–	–

- **Function**

  Divides the two inputs on the left and outputs the integer remainder after division on the right.

- **Program example**

  ST:

  LD:

- **Precautions**

  Dividing by zero produces different results depending on the target system.

18.1.5.27 MOVE

Assigns the value of a variable to another variable of the same type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
MOVE	Value assignment	FC	MOVE EN ENO	:=

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Move source	Follows data type	-	Input data
Output	Out	Move destination	Follows data type	-	Output data.

  Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Out	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√

- **Function description**

  Assigns the value of a variable to another variable of the same type.

- **Program example**

  ST:

```
Out := MOVE(In);
RETURN
```

  LD:

18.1.5.28 MUL

Multiplies the two inputs on the left and outputs the multiplication result on the right.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
MUL	Multiplication instruction	FC		*

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Value to multiply	Follows data type	-	Input
	In2	Value to multiply	Follows data type	-	Input
Output	Out	Return value	Follows data type	-	Calculation result

Data type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–
In2	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–
Out	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–

- **Function**

  Multiplies the two inputs on the left and outputs the multiplication result on the right.

- **Program example**

  ST:

  LD:

18.1.5.29 SIN

Calculates the sine value of the input, and outputs the result.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
SIN	Sine calculation	FC		SIN()

- **Related variable**

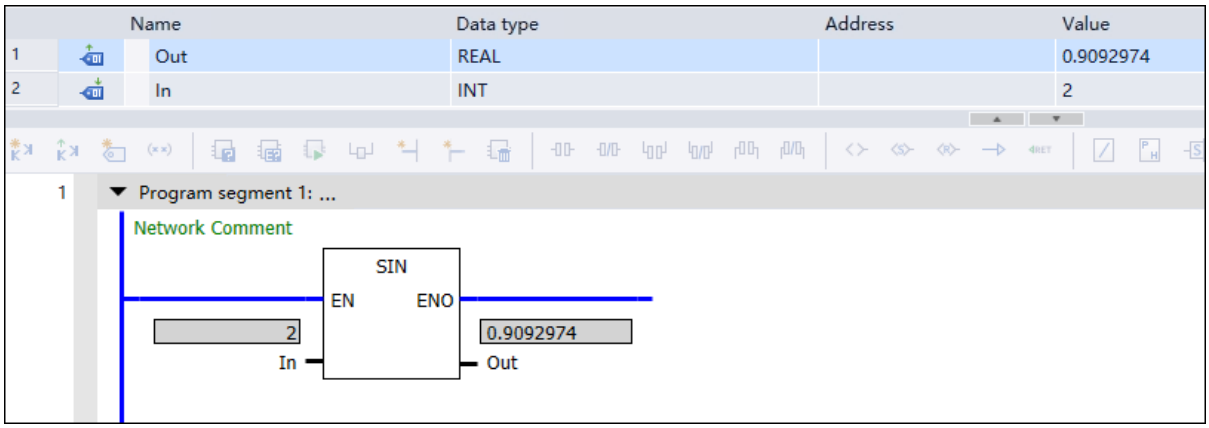
Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Input Variable	Follows data type	-	Variable to be calculated
Output	Out	Return value	Follows data type	-	Calculation result

Data type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–

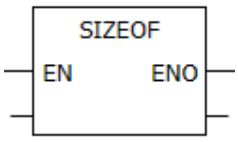
- **Function**



Calculates the sine value of the input, and outputs the result.

- **Program example**

ST:



LD:

18.1.5.30 SIZEOF

Calculate the number of bytes for the input variable.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
SIZEOF	Size calculation	FC		:= SIZEOF( );

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Source data	Follows data type	-	Target data
Output	Out	Data length	Follows data type	0	Data length

Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
Out	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  Calculate the number of bytes for the input variable. The SIZEOF operator always produces an unsigned value. The type of the returned variable is adapted to the length detection of the input variable.

- **Program example**

  Example 1 defines an INT array with 11 elements, resulting in a size of 22.

  Example 2 defines a DINT array with 6 elements, resulting in a size of 24.

  ST:

  LD:

18.1.5.31 SQRT

Calculates the square root of the input value, and outputs the result.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
SQRT	Square root calculation	FC		SQRT()

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Input Variable	Follows data type	-	Input variable
Output	Out	Return value	Follows data type	-	Calculation result

Data type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–

- **Function**

  Calculates the square root of the input value, and outputs the result.

- **Program example**

  ST:

  LD:

18.1.5.32 SUB

Subtracts the two inputs on the left and outputs the subtraction result on the right.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
SUB	Subtraction instruction	FC		- ;

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Minuend	Follows data type	-	Minuend
	In2	Subtrahend	Follows data type	-	Subtrahend
Output	Out	Return value	Follows data type	-	Calculation result

Data type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	–
In2	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Out	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–

- **Function**

  Subtracts subtrahend "In2" from minuend "In1", and outputs the subtraction result on the right.

- **Program example**

  ST:

  LD:

18.1.5.33 TAN

Calculates the tangent value of the input, and outputs the result.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
TAN	Tangent calculation	FC		TAN()

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Input Variable	Follows data type	-	Variable to be calculated
Output	Out	Return value	Follows data type	-	Calculation result

Data type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–

- **Function**

  Calculates the tangent value of the input, and outputs the result.

- **Program example**

  ST:

  LD:

18.1.5.34 RAD

Converts floating-point degrees to radians.

- **Instruction format**

Instruction	Name	FB/FC	Ladder Diagram Representation	Structured Text Representation
RAD	Degrees to radians	FC		:= RAD(fAngle :=);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Angle	Input degree	Follows data type	0	Input degree
Output	Out	Output radian	Follows data type	0	Output radians

Variable types

	Boolean	Bit String				Integer								Real Number		Time, duration, date, and text string				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Angle	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–

- **Function description**

The calculation formula for converting floating-point degrees to radians is: radians = degrees × π/180.

- **Program example**

	LD	ST
Define variables	VAR fAngle: LREAL; fRadian: LREAL; END_VAR	

	LD	ST
Program		
Operation result		

Name	Type	Address	Value
fAngle	LREAL		180
fRadian	LREAL		3.141592653589793

18.1.5.35 DEG

Converts floating-point radians to degrees.

- **Instruction format**

Instruction	Name	FB/FC	Ladder Diagram Representation	Structured Text Representation
DEG	Radians to degrees	FC		:= DEG(fRadian :=);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	fRadian	Input radian	Follows data type	0	Input radian
Output	Out	Output degree	Follows data type	0	Output degree

Variable types

	Boolean	Bit String				Integer								Real Number		Time, duration, date, and text string				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
fRadian	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–

- **Function description**

The calculation formula for converting floating-point radians to degrees is: degrees = radians × π/180.

- **Program example**

	LD	ST
Define variables	VAR fRadian: LREAL; fAngle: LREAL; END_VAR	
Program		
Operation result		

Name	Type	Address	Value
fRadian	LREAL		3.141592653589793
fAngle	LREAL		180

18.1.5.36 SCALE_X

SCALE_X is a linear scaling instruction.

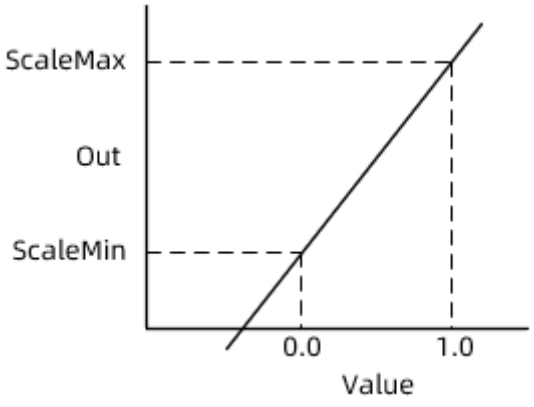
- **Instruction format**

Instruction	Name	FB/FC	Ladder Diagram Representation	Structured Text Representation
SCALE_X	Scaling instruction	FC		:= SCALE_X(ScaleMin := , Value := , ScaleMax := , Out :=);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	ScaleMin	Lower limit of standard value	Follows data type	-	Lower limit of standard value
	Value	Input value to scale	Follows data type	-	Input value to scale
	ScaleMax	Upper limit of standard value	Follows data type	-	Upper limit of standard value
	Out	Scaled output value	Follows data type	-	Scaled output value



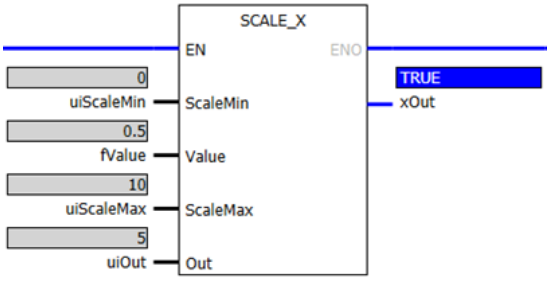
Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	SCALE_X	Result	Follows data type	-	TRUE: Operation succeeded. FALSE: Operation failed.

Variable types

	Boolean	Bit String				Integer								Real Number		Time, duration, date, and text string				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
ScaleMin	–	–	–	–	–	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–
Value	–	–	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–
ScaleMax	–	–	–	–	–	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–
Out	–	–	–	–	–	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–
SCALE_X	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function description**

  The standardized real input "Value" (0.0 <= "Value" <= 1.0) is scaled according to the data type and range specified by parameters "ScaleMin" and "ScaleMax": Out := Value × (ScaleMax - ScaleMin) + ScaleMin.



- **Program example**

<table>
<tr><th></th><th>LD</th><th>ST</th></tr>
<tr><td>Define variables</td><td colspan="2">

```
VAR
    uiScaleMin: UINT;
    fValue: LREAL;
    uiScaleMax: UINT;
    uiOut: UINT;
    xOut: BOOL;
END_VAR
```

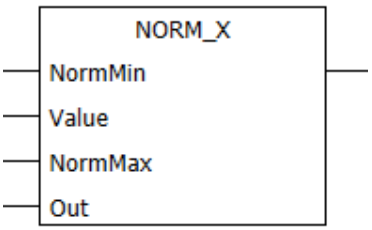
</td></tr>
<tr><td>Program</td><td>

</td><td>

```
xOut TRUE := SCALE_X( ScaleMin := uiScaleMin 0 ,
                      Value := fValue 0.5 ,
                      ScaleMax := uiScaleMax 10 ,
                      Out := uiOut 5 );
```

</td></tr>
<tr><td>Operation result</td><td colspan="2">

Name	Type	Address	Value
uiScaleMin	UINT		0
fValue	LREAL		0.5
uiScaleMax	UINT		10
uiOut	UINT		5
xOut	BOOL		TRUE



</td></tr>
</table>

- **Precautions**
  - "ScaleMin", "ScaleMax", and "Out" must have the same data type.
  - The range of "Value" is [0.0, 1.0]. If "Value" is less than 0.0 or greater than 1.0, the linear scaling instruction will generate "Out" values less than "ScaleMin" or greater than "ScaleMax". If these values are within the range of the "Out" data type, "SCALE_X" returns TRUE. If these values are beyond the allowable range, the "Out" parameter is set to an intermediate value equal to the least significant part of the scaled real number before its conversion to the "Out" data type. In such cases, "SCALE_X" returns FALSE.
  - Parameter "ScaleMin" must be less than "ScaleMax"; otherwise, "Out" is filled with the least significant part of the real number "Value", and "SCALE_X" returns FALSE.
  - If the parameter "Value" is +/-INF or +/-NaN, the input "Value" is written to "Out", and "SCALE_X" returns FALSE.

18.1.5.37 NORM_X

NORM_X is a normalization instruction.

- **Instruction format**

Instruction	Name	FB/FC	Ladder Diagram Representation	Structured Text Representation
NORM_X	Normalization instruction	FC		:= NORM_X(NormMin := , Value := , NormMax := , Out :=);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	NormMin	Lower limit of standard value	Follows data type	-	Lower limit of standard value
	Value	Value to be normalized	Follows data type	-	Value to be normalized
	NormMax	Upper limit of standard value	Follows data type	-	Upper limit of standard value
	Out	Normalized value	Follows data type	-	Normalized value
Output	NORM_X	Result	Follows data type	-	TRUE: Operation succeeded. FALSE: Operation failed.

Variable types

	Boolean	Bit String				Integer								Real Number		Time, duration, date, and text string				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
NormMin	–	–	–	–	–	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–
Value	–	–	–	–	–	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–

	Boolean	Bit String				Integer								Real Number		Time, duration, date, and text string				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
NormMax	–	–	–	–	–	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–
NORM_X	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function description**

  The real input "Value" is normalized based on the data type and range specified by "NormMin" and "NormMax". "Out" equals (Value - NormMin) / (NormMax - NormMin), where (0.0 <= "Out" <= 1.0).

  The following figure shows how to normalize a value.

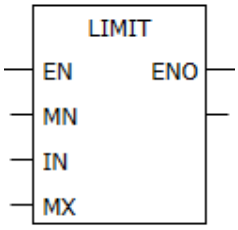
- **Program example**

	LD	ST
Define variables	VAR uiNormMin: UINT; uiValue: UINT; uiNormMax: UINT; fOut: LREAL; xOut: BOOL; END_VAR	

<table>
<tr><th></th><th>LD</th><th>ST</th></tr>
<tr><td>Program</td><td>
</td><td>
</td></tr>
<tr><td>Operation result</td><td colspan="2">
</td></tr>
</table>

- **Precautions**
  - "NormMin", "NormMax", and "Value" must have the same data type.
  - The range of "Value" is ["NormMin", "NormMax"]. If "Value" is less than "NormMin" or greater than "NormMax", the linear scaling instruction will generate "Out" values less than 0.0 or greater than 1.0. If these values are beyond the allowable range of the "Out" data type, "Out" is set to an intermediate value equal to the least significant part of the normalized real number before its conversion to the "Out" data type. In such cases, "NORM_X" returns TRUE.
  - "NormMin" should be less than "NormMax", otherwise, "Value" is extended to fill double-word size, and "NORM_X" returns FALSE.
  - If the parameter "Value" is +/-INF or +/-NaN, the input "Value" is written to "Out", and "NORM_X" returns FALSE.

18.1.6 Selection Operations



18.1.6.1 Instruction List

Instruction	FB/FC	Function	Library	Applicable Library Version
18.1.6.2 LIMIT	FC	Limit value instruction	-	-
18.1.6.3 MAX	FC	Maximum value instruction		
18.1.6.4 MIN	FC	Minimum value instruction		
18.1.6.5 MUX	FC	Select one from multiple		
18.1.6.6 SEL	FC	Binary selection		

18.1.6.2 LIMIT

Limits the input value between the specified maximum and minimum values, and outputs the limited value.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
LIMIT	Limit value instruction	FC		LIMIT(, ,)

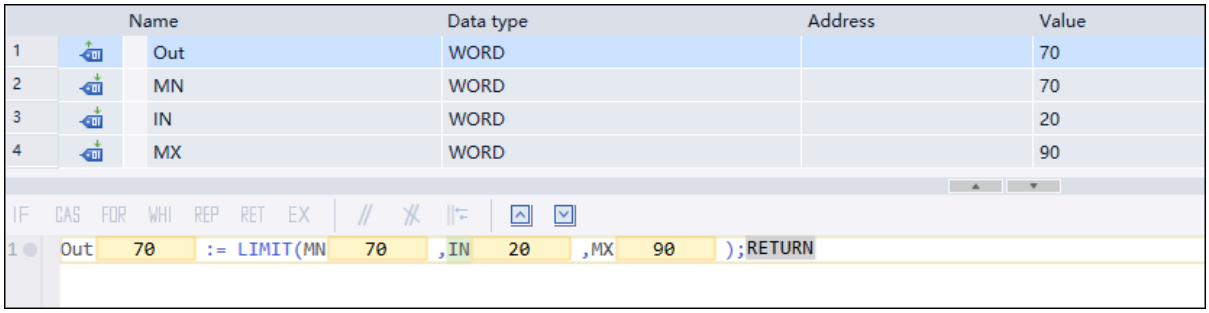
- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	MN	Input signal	Follows data type	-	Minimum value
	IN	Input signal	Follows data type	-	The value to be limited
	MX	Input signal	Follows data type	-	Maximum value
Output	Out	Return value	Follows data type	-	Calculation result

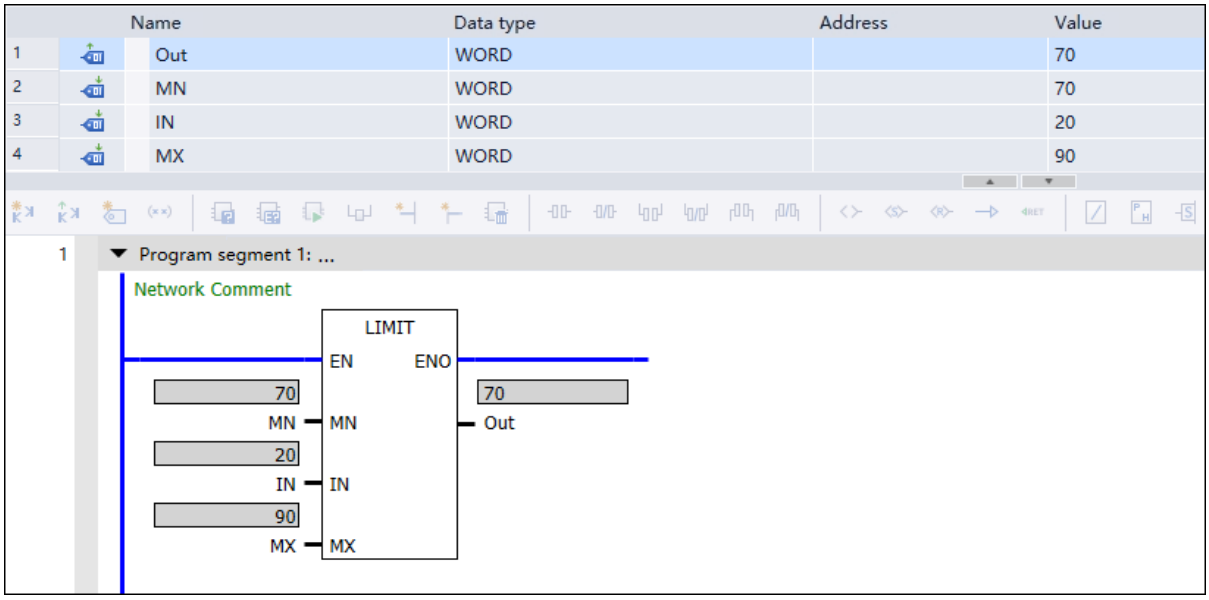
Data type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
MN	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
IN	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
MX	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
Out	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√



- **Function description**

"MX" is the upper limit of the result, and "MN" is the lower limit. If "IN" exceeds the upper limit "MX", the output result is "MX". If "IN" is less than the lower limit "MN", the output result is "MN". If "IN" is within the range of "MN" and "MX", the output value is "IN".

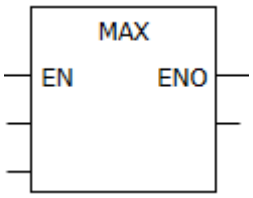


- **Program example**

  In the following example, "MN" is set to 70, "MX" to 90, and "IN" to 20; then the result "Out" is 70.

  ST:

  LD:



- **Precautions**

  The data types of "Out", "MX", "IN", and "MN" must be the same.

18.1.6.3 MAX

Outputs the maximum of the two input values on the right.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
MAX	Maximum value instruction	FC		MAX(,)

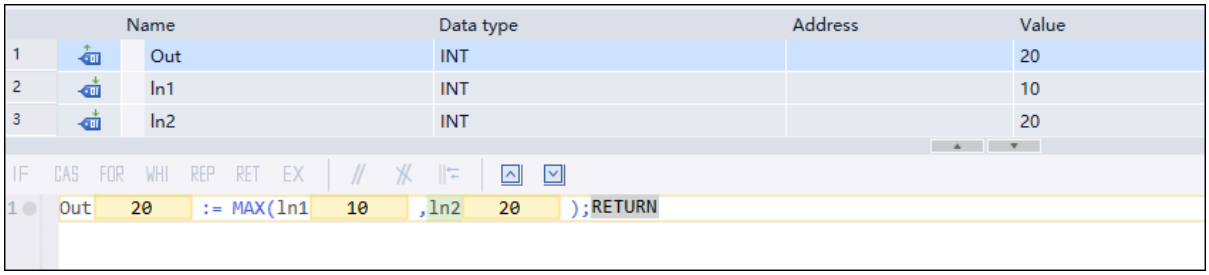
- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Comparand	Follows data type	-	Comparand 1
	In2	Comparand	Follows data type	-	Comparand 2
Output	Out	Return value	Follows data type	-	The larger number of the two comparands

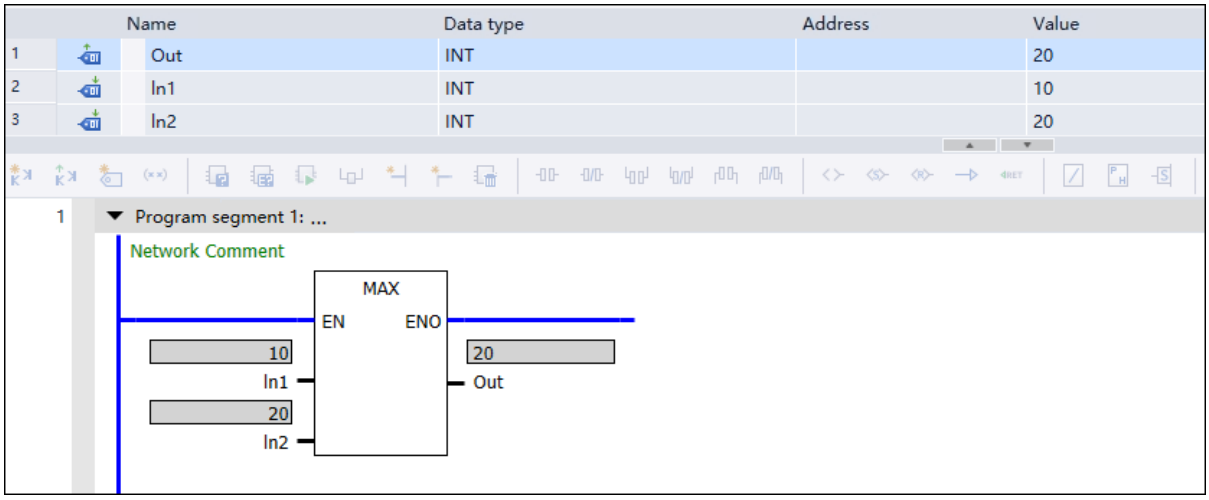
Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
In2	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
Out	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√



- **Function description**

  Outputs the maximum of the two input values on the right.



- **Program example**

  The following example outputs the maximum of the two input values.

  ST:

  LD:

18.1.6.4 MIN

Outputs the minimum of the two input values on the right.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
MIN	Minimum value instruction	FC		MIN(,)

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Comparand	Follows data type	-	Comparand 1
	In2	Comparand	Follows data type	-	Comparand 2
Output	Out	Return value	Follows data type	-	The smaller number of the two comparands

Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
In2	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
Out	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√

- **Function description**

  Outputs the minimum of the two input values on the right.

- **Program example**

  ST:

  LD:

18.1.6.5 MUX

Selects the K-th value from the input values, where K = 0 corresponds to the first value. If K is greater than the number of compared values or if K is negative, the last value (InN) is output.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
MUX	Select one from multiple	FC		MUX(, ,)

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	K	Selector bit	Follows data type	-	Selector bit
	In0 to InN	Comparand	Follows data type	-	Data source for selection
Output	Out	Return value	Follows data type	-	Selection result

  Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
K	–	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–	–	–
In0 to InN	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
OUT	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√

- **Function description**

  Selects the K-th value from the input values, where K = 0 corresponds to the first value. If K is greater than the number of compared values or if K is negative, the last value (InN) is output.

  The default number of compared values for the MUX instruction is 2; additional inputs are required if there are more than 2 compared values.

  The following figure shows how to add an input in LD programming.

- **Program example**

  Input a set of data: 30, 70, 20, and 90. When K is set to 0, the output is 30.

  ST:

	Name	Data type	Address	Value
1	Out	INT		30
2	K	INT		0
3	In1	INT		30
4	In2	INT		70
5	In3	INT		20
6	In4	INT		90

```
1  Out := MUX(K := 0, In1 := 30, In2 := 70, In3 := 20, In4 := 90);RETURN
```

  LD:

18.1.6.6 SEL

Selects one of two input values based on "G".

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
SEL	Binary selection	FC		SEL(, ,);

- **Related variable**

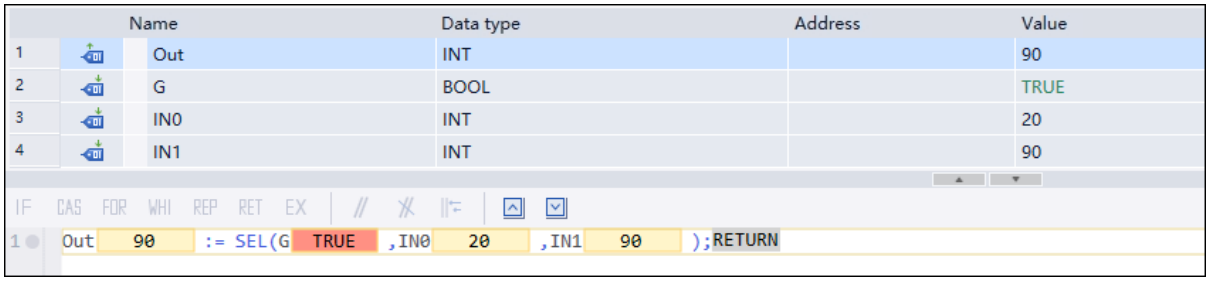
Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	G	Input signal	Follows data type	-	Outputs IN0 when G = FALSE; outputs IN1 when G = TRUE.
	IN0	Input signal	Follows data type	-	Output when G = FALSE
	IN1	Input signal	Follows data type	-	Output when G = TRUE

Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	Out	Return value	Follows data type	-	Output result

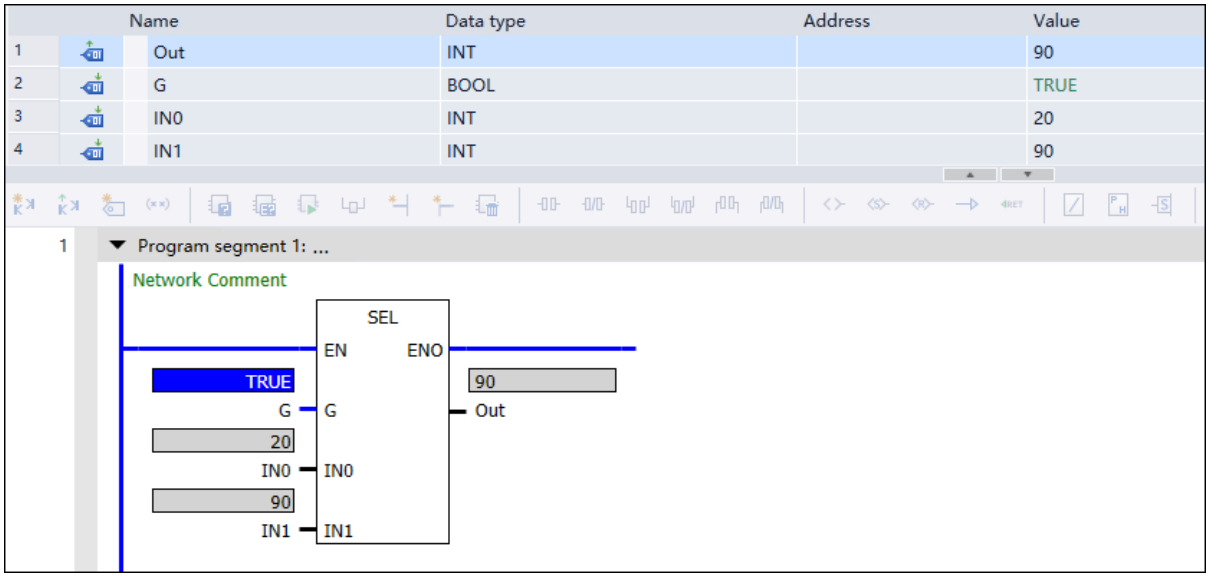
Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
G	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
IN0	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
IN1	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
Out	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√



- **Function description**

  Outputs IN0 when G = FALSE; outputs IN1 when G = TRUE.



- **Program example**

  Set the input values IN0 and IN1 to 20 and 90, and set G = TRUE. Then, 90 (value of IN1) is output.

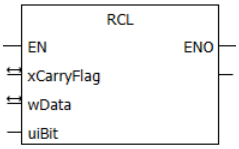
  ST:

  LD:

- **Precautions**

  When G = TRUE, the expression before IN0 will not be calculated. When G = FALSE, the expression before IN1 will not be calculated.

18.1.7 Shift Operations



18.1.7.1 Instruction List

Instruction	FB/FC	Function	Library	Applicable Library Version
18.1.7.2 RCL	FC	Rotation left with carry	Util	Library version 1.0.0.0 and later
18.1.7.3 RCR	FC	Rotation right with carry		Library version 1.0.0.0 and later
18.1.7.4 ROLE	FC	Rotate left shift instruction	-	-
18.1.7.5 ROR	FC	Rotate right shift instruction		
18.1.7.6 SHL	FC	Left shift instruction		
18.1.7.7 SHR	FC	Right shift instruction		

18.1.7.2 RCL

Rotates the operand to the left. Bits that are shifted out from the left are directly appended to the rightmost bit. When a carry occurs, the carry flag is set to ON.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
RCL	Rotation left with carry	FC		:= RCL(xCarryFlag := , wData := , uiBit :=);

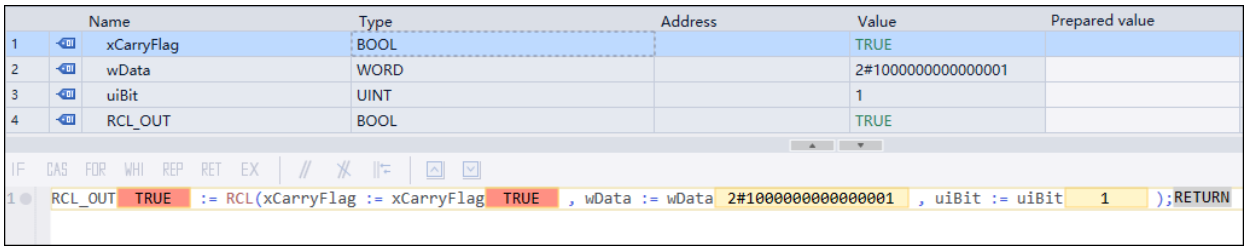
- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input/Output	xCarryFlag	Carry flag	Follows data type	-	Carry flag
	wData	Data Source	Follows data type	-	Data source
Input	uiBit	Number of bits to rotate	Follows data type	-	Number of bits to rotate
Output	OUT	Return value	Follows data type	-	Execution result

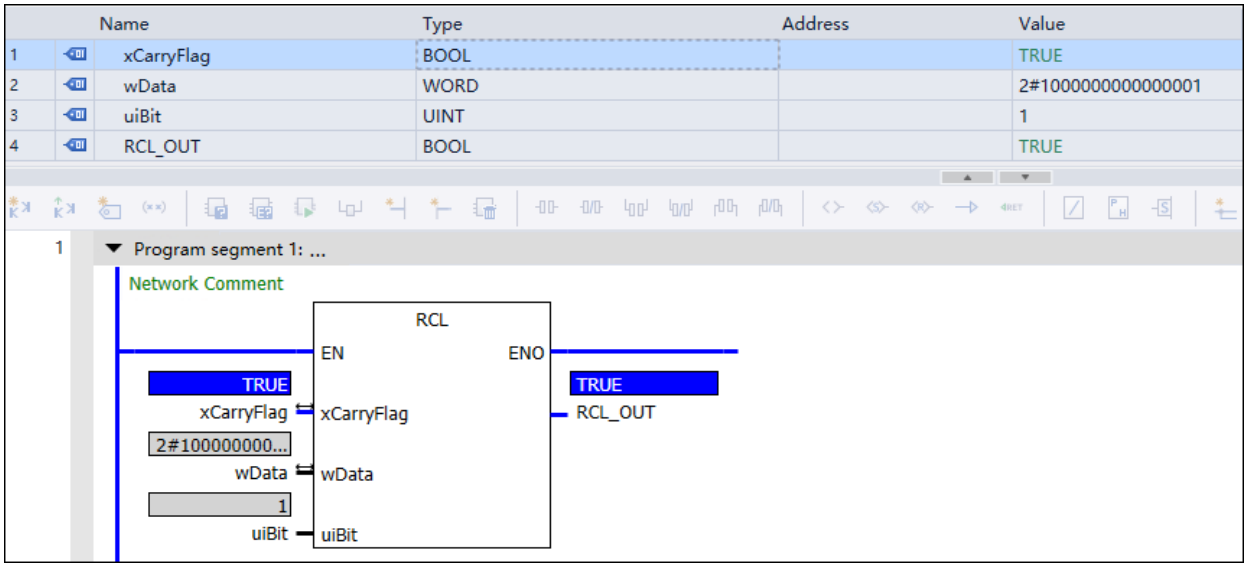
Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
xCarryFlag	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
wData	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
uiBit	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
OUT	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–



- **Function**

Rotates the operand to the left. Bits that are shifted out from the left are directly appended to the rightmost bit. When a carry occurs, the carry flag is set to ON.



- **Program example**

  When the input source "wData" is set to 2#1100000000000000 and "uiBit" to 1, upon triggering the first time, the output signal "OUT" becomes 2#1000000000000001. The valid data shifts left by 1 bit, and the carry flag is set to TRUE.

  ST:

  LD:

- **Precautions**
  - If "uiBit" is less than 1 or greater than 16, the instruction execution fails, and the return value is FALSE, with the output variable remaining at its initial value.
  - The instruction returns TRUE upon successful execution, otherwise returns FALSE.

18.1.7.3 RCR

Rotates the operand to the right. Bits that are shifted out from the right are directly appended to the leftmost bit. When a carry occurs, the carry flag is set to ON.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
RCR	Rotation right with carry	FC	RCR EN ENO xCarryFlag wData uiBit	:= RCR(xCarryFlag := , wData := , uiBit :=);

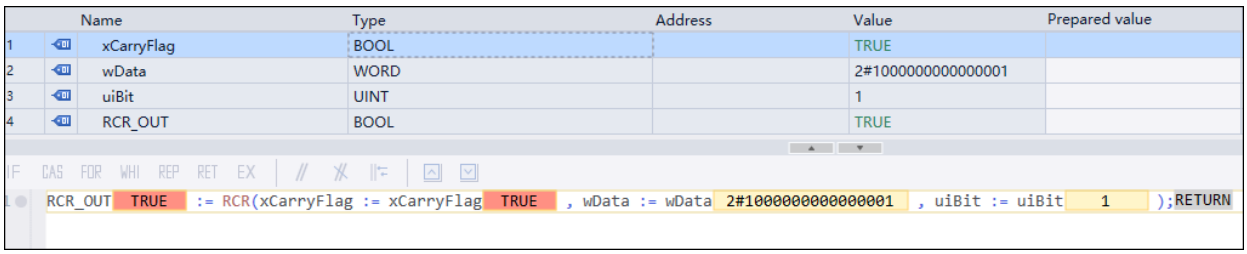
- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input/Output	xCarryFlag	Carry flag	Follows data type	-	Carry flag
	wData	Data Source	Follows data type	-	Data source
Input	uiBit	Number of bits to rotate	Follows data type	-	Number of bits to rotate
Output	OUT	Return value	Follows data type	-	Execution result

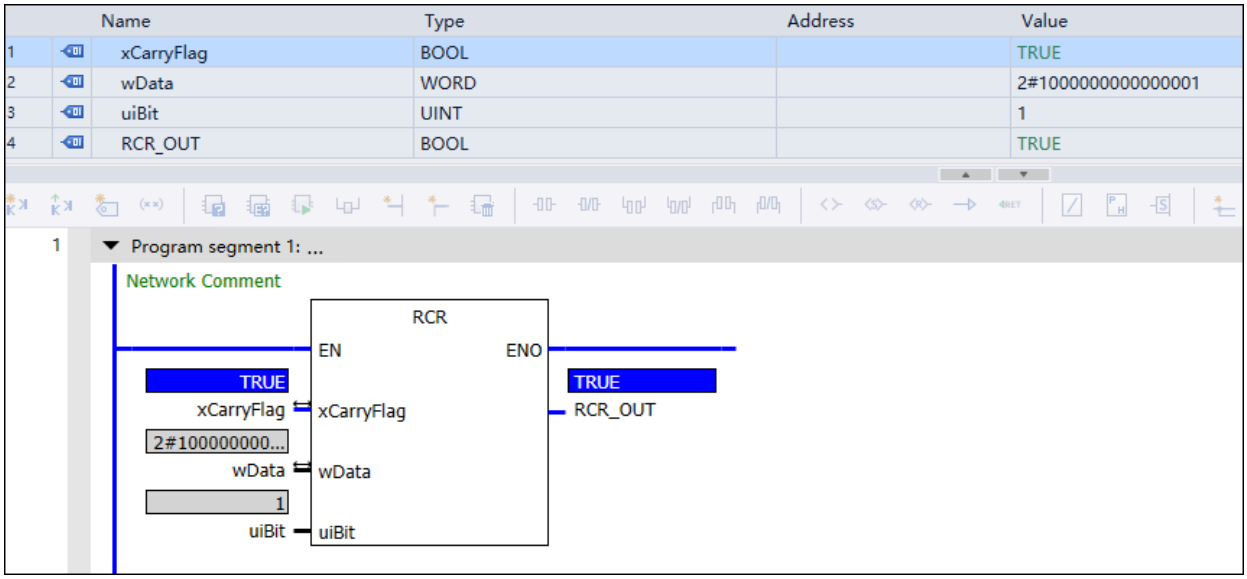
Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
xCarryFlag	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
wData	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
uiBit	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
OUT	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–



- **Function**

  Rotates the operand to the right. Bits that are shifted out from the right are directly appended to the leftmost bit. When a carry occurs, the carry flag is set to ON.

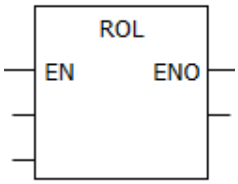


- **Program example**

  When the input source "wData" is set to 2#0000000000000011 and "uiBit" to 1, upon triggering the first time, the output signal "OUT" becomes 2#1000000000000001. The valid data shifts right by 1 bit, and the carry flag is set to TRUE.

  ST:

  LD:



- **Precautions**
  - If "uiBit" is less than 1 or greater than 16, the instruction execution fails, and the return value is FALSE, with the output variable remaining at its initial value.
  - The instruction returns TRUE upon successful execution, otherwise returns FALSE.

18.1.7.4 ROL

Rotates the input value to the left, with the bits shifted out from the left directly appended to the rightmost bit.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ROL	Rotate left shift instruction	FC		ROL(,)

- **Related variable**

Variable

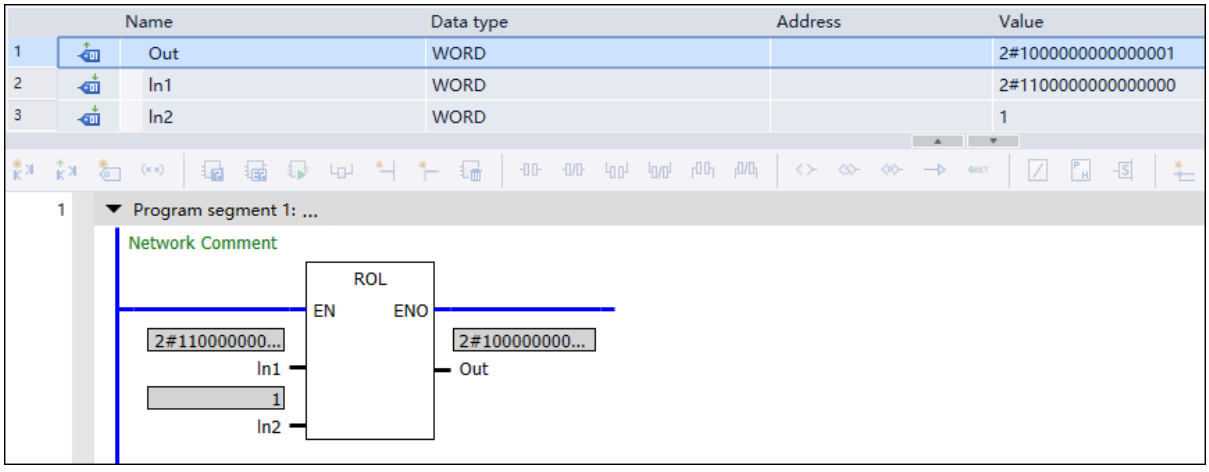
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Data Source	Follows data type	-	Data source
	In2	Number of shifted bits	Follows data type	-	Number of shifted bits
Output	Out	Return value	Follows data type	-	Shifted result

Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1	–	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–	–	–
In2	–	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–	–	–
Out	–	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–	–	–

- **Function**

  Rotates the input value to the left, with the bits shifted out from the left directly appended to the rightmost bit.

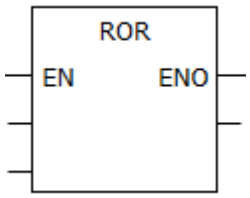


- **Program example**

  When the input source "In1" is set to 2#1100000000000000 and "In2" to 1, the output signal "Out" becomes 2#1000000000000001. The valid data shifts left by 1 bit.

  ST:

  LD:



- **Precautions**

  The instruction supports integer data types.

18.1.7.5 ROR

Rotates the input value to the right, with the bits shifted out from the right directly appended to the leftmost bit.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ROR	Rotate right shift instruction	FC		ROR(,)

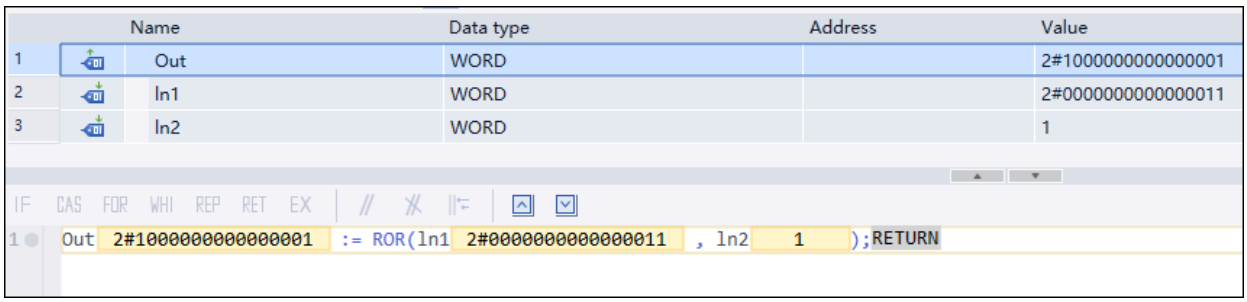
- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Data Source	Follows data type	-	Data source
	In2	Number of shifted bits	Follows data type	-	Number of shifted bits
Output	Out	Return value	Follows data type	-	Shifted result

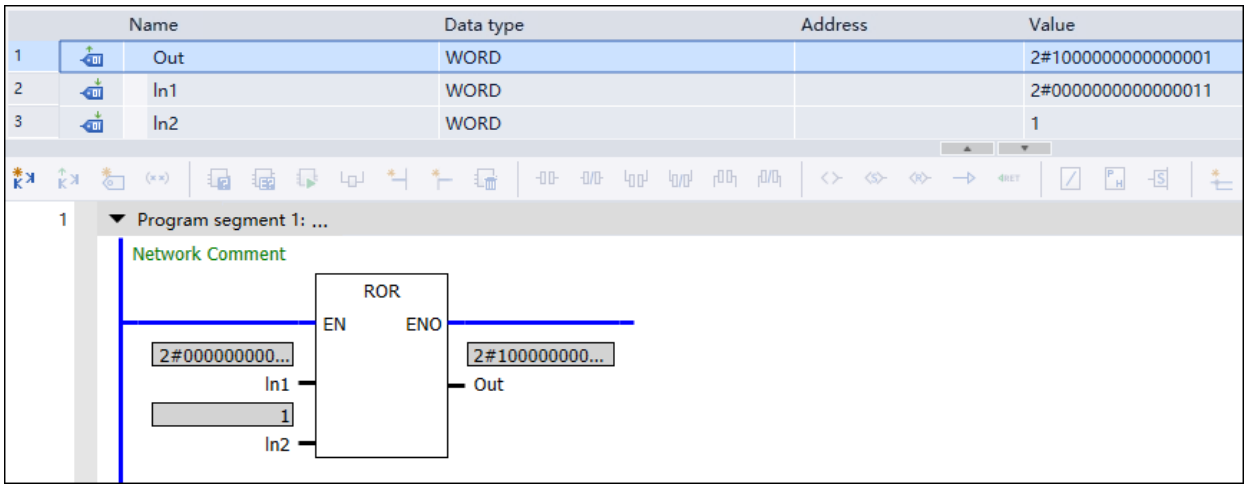
Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1	–	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–	–	–
In2	–	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–	–	–
Out	–	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–	–	–



- **Function**

Rotates the input value to the right, with the bits shifted out from the right directly appended to the leftmost bit.

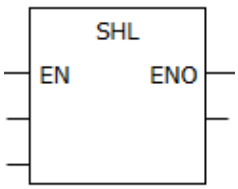


- **Program example**

When the input source "In1" is set to 2#0000000000000011 and "In2" to 1, the output signal "Out" becomes 2#1000000000000001. The valid data shifts right by 1 bit.

ST:

LD:



- **Precautions**

  The instruction supports integer data types.

18.1.7.6 SHL

Shifts the input value to the left. The bits shifted out from the left are ignored and zeros are automatically filled in on the right.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
SHL	Left shift instruction	FC		SHL(,)

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Data Source	Follows data type	-	Data source

Input/Output	Variable	Name	Valid Range	Default Value	Description
	In2	Number of shifted bits	Follows data type	-	Number of shifted bits
Output	Out	Return value	Follows data type	-	Shifted result

Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1	–	√	√	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–	–	–

18.1.8.2 CTU

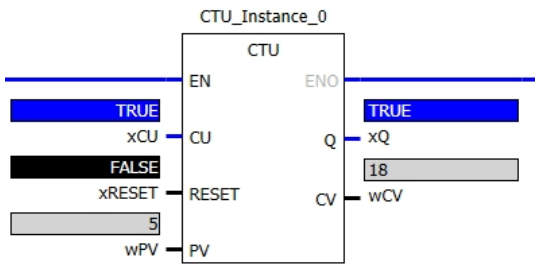
CTU is an addition counter.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
CTU	Addition counter	FB		CTU_Instance_0(CU := , Reset := , PV := , Q => , CV =>);

- **Related variable**

Variable



Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	CU	Counter input	Follows data type	-	Counter input
	RESET	Reset signal	Follows data type	-	TRUE: Resets "CV" to 0.
	PV	Preset value	Follows data type	-	Preset value of the counter
Output	Q	Counter output	Follows data type	-	TRUE: Counter output is ON. FALSE: Counter output is OFF.
	CV	Count value	Follows data type	-	The current value of the counter

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
CU	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
RESET	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
PV	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Q	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
CV	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - If the reset signal "RESET" is set to TRUE, the counter value "CV" is reset to 0, the counter output "Q" becomes FALSE. The status of the counter input "CU" will not affect this instruction.
  - When "CU" changes from FALSE to TRUE (rising edge of the signal), this instruction is executed, and "CV" is incremented by "1". Upon each rising-edge signal of "CU", "CV" is incremented, until it reaches the maximum value of the specified data type (Max. 65535 for WORD type).
  - The counter output "Q" can be used to query the counting status. The status of "Q" is determined by "CV". If "CV" is greater than or equal to the preset value "PV", the status of "Q" is set to TRUE. In all other cases, the status of "Q" is FALSE.
- **Program example**
  - When "RESET" is set to TRUE, "CV" is reset to 0, and "Q" becomes FALSE. After "RESET" becomes FALSE, "CV" starts to be incremented. "Q" becomes TRUE when "CV" reaches the value of "PV".
  - The following example sets the preset value "PV" to 5.

	LD	ST
Define variables	VAR CTU_Instance_0: CTU; xCU: BOOL; xRESET: BOOL; wPV: WORD := 5; xQ: BOOL; wCV: WORD; END_VAR	
Program		CTU_Instance_0(CU TRUE := xCU TRUE , RESET FALSE := xRESET FALSE , PV 5 := wPV 5 , Q TRUE => xQ TRUE , CV 18 => wCV 18);RETURN

  - When the preset value "PV" is set to 5, the timing diagram is shown in the figure below.

18.1.8.3 CTD

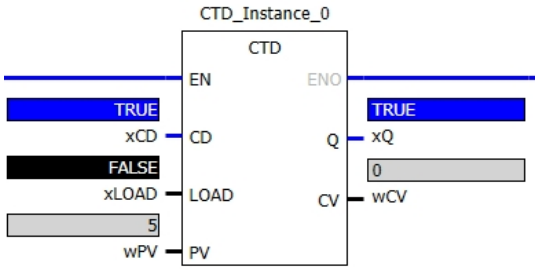
CTD is a subtraction counter.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
CTD	Subtraction counter	FB	CTD_Instance_0 CTD EN ENO CD Q LOAD CV PV	CTD_Instance_0(CD := , LOAD := , PV := , Q => , CV =>);

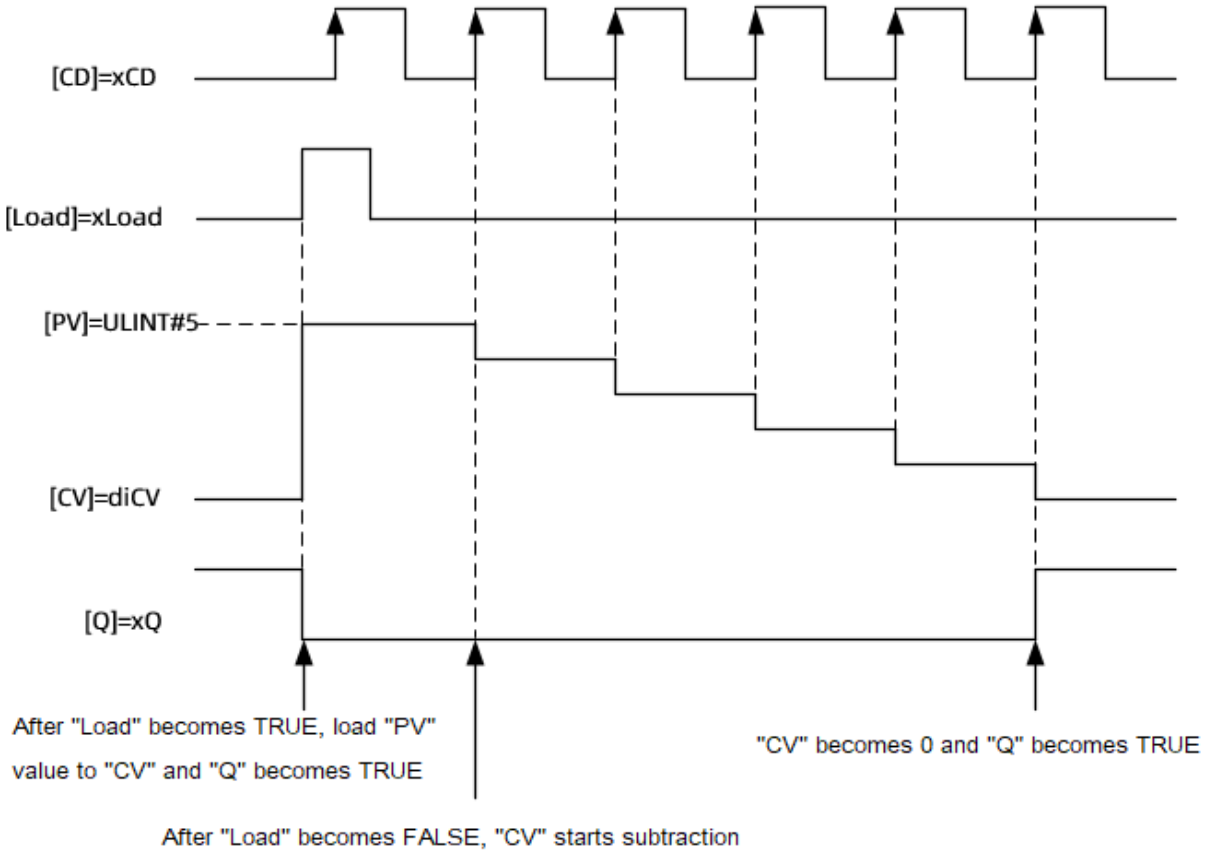
- **Related variable**

Variable



Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	CD	Counter input	Follows data type	-	Counter input
	LOAD	Load signal	Follows data type	-	TRUE: Loads "PV" into "CV".

Input/Output	Variable	Name	Valid Range	Default Value	Description
	PV	Preset value	Follows data type	-	Preset value of the counter
Output	Q	Counter output	Follows data type	-	TRUE: Counter output is ON. FALSE: Counter output is OFF.
	CV	Count value	Follows data type	-	The current value of the counter

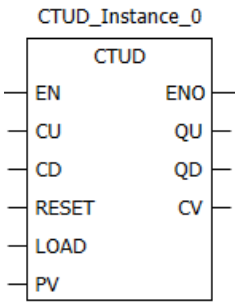


Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
CD	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
LOAD	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
PV	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Q	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
CV	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - If the load signal "LOAD" is set to TRUE, the preset value "PV" is loaded into the count value "CV", and the counter output "Q" becomes FALSE.
  - When the counter input signal "CD" changes from FALSE to TRUE (rising edge), "CV" is decremented. When "CV" becomes less than 0, "Q" becomes TRUE, and even if "CD" is at a rising edge, no subtraction is performed on "CV".
- **Program example**
  - When "LOAD" is set to TRUE, "PV" is loaded into "CV", and "Q" becomes FALSE. After "LOAD" becomes FALSE, "CV" starts to be decremented, "CV" becomes 0, and "Q" becomes TRUE.
  - The following example sets the preset value "PV" to 5.

	LD	ST
Define variables	VAR CTD_Instance_0: CTD; xCD: BOOL; xLOAD: BOOL; wPV: WORD := 5; xQ: BOOL; wCV: WORD; END_VAR	
Program		CTD_Instance_0(CD TRUE := xCD TRUE, LOAD FALSE := xLOAD FALSE, PV 5 := wPV 5, Q TRUE => xQ TRUE, CV 0 => wCV 0);RETURN



◦ When the preset value "PV" is set to 5, the timing diagram is shown in the figure below.

18.1.8.4 CTUD

CTUD is an addition/subtraction counter.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
CTUD	Addition/ subtraction counter	FB		CTUD_Instance_0(CU := , CD := , RESET := , LOAD := , PV := , QU => , QD => , CV =>);

- **Related variable**

  Variable

QU	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
QD	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
CV	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

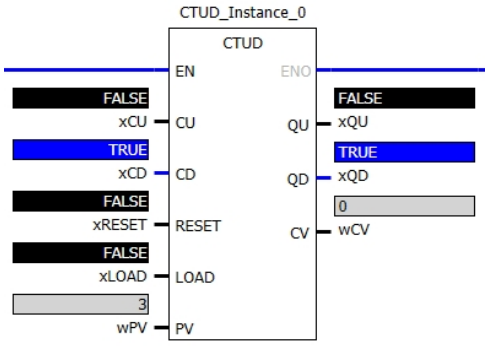
  CTUD is a counter that performs addition and subtraction operations based on the input signals. It combines the functions of both the addition counter and the subtraction counter. Data type of preset value "PV" and counter value "CV" is WORD.

  ◦ Addition counter function

  When the reset signal "RESET" is set to TRUE, the counter value "CV" becomes 0, and the addition counter output "QU" becomes FALSE. When addition counter input signal "CU" changes from FALSE to

TRUE (rising edge), this instruction is executed, and "CV" is incremented by "1". Upon each rising-edge signal of "CU", "CV" is incremented, until it reaches the maximum value of the specified data type (Max. 65535 for WORD type).

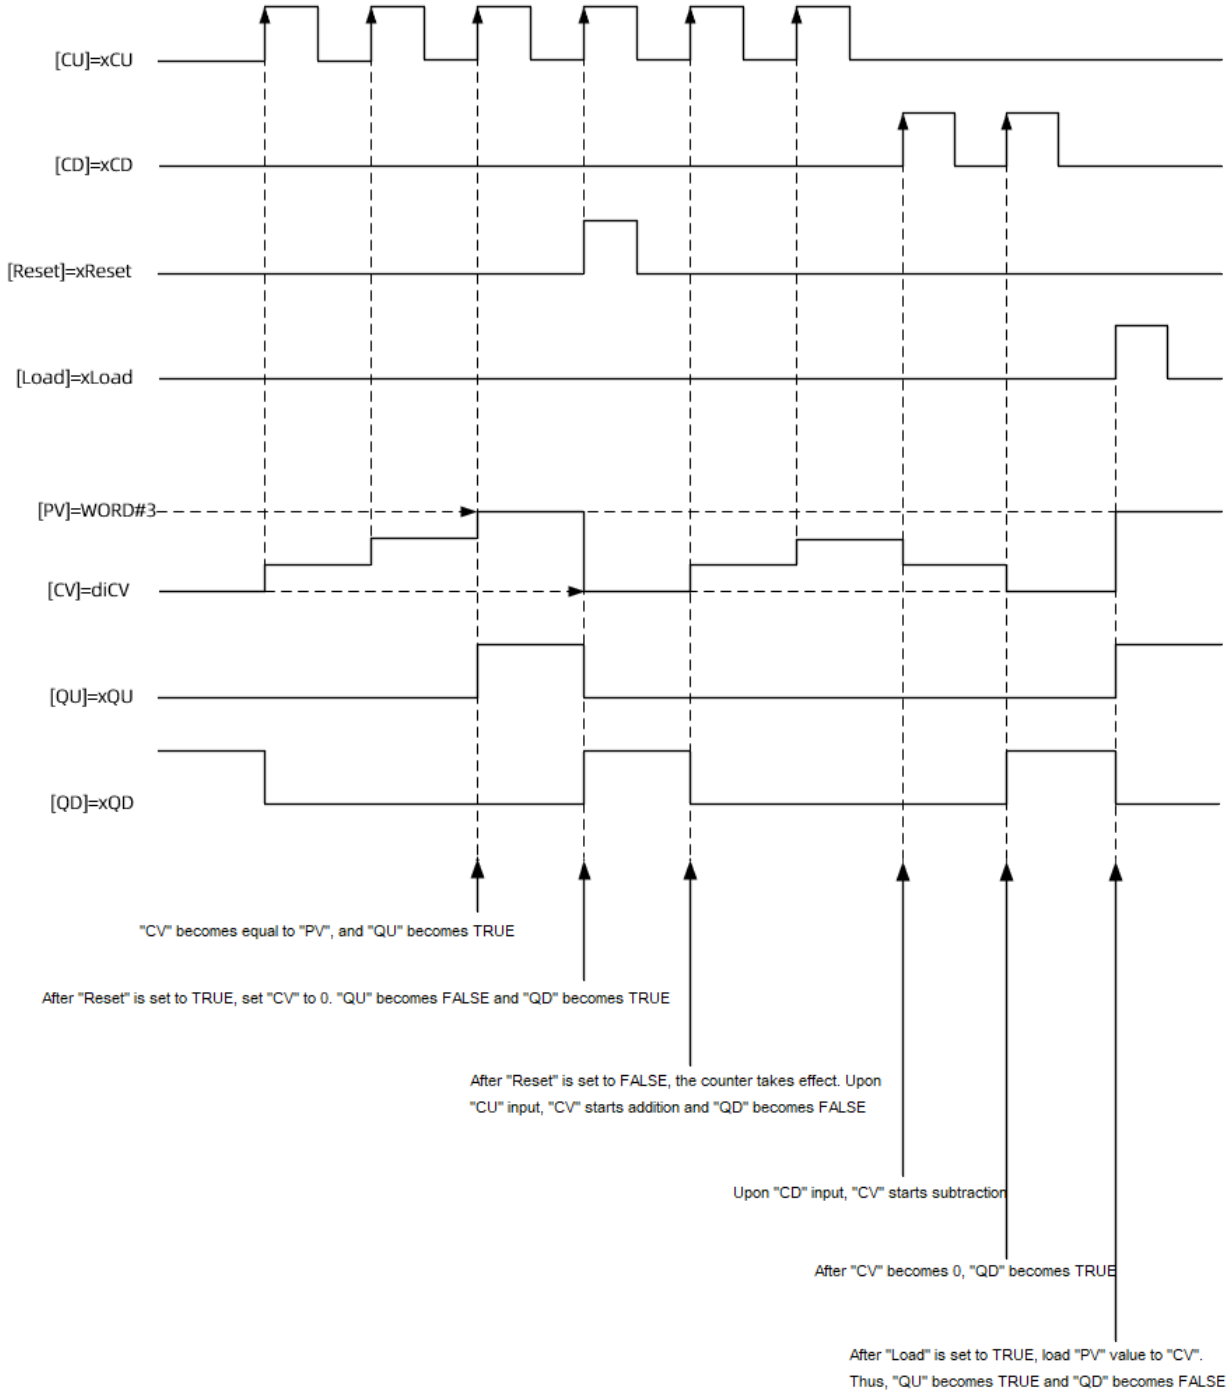
◦ Subtraction counter function



When the load signal "LOAD" is set to TRUE, the preset value "PV" is loaded into the count value "CV", and the subtraction counter output "QD" becomes FALSE. When the subtraction counter input signal "CD" changes from FALSE to TRUE (rising edge), "CV" is decremented. When the value of "CV" is less than 0, the value of "QD" becomes TRUE. When the value of "CV" is less than 0, even if a larger value of "CD" is input, "CV" remains unchanged.

◦ Common functions of the addition/subtraction counter

When "LOAD" or "RESET" is TRUE, the rising edges of "CU" and "CD" are ignored, and "CV" does not perform addition or subtraction operations. When "CU" and "CD" are both at the rising edge, "CV" does not change. When both "RESET" and "LOAD" are TRUE, "RESET" takes priority, and the value of "CV" becomes 0. When "RESET" is set to TRUE, the value of "CV" becomes 0, and the value of "QD" becomes TRUE. When "LOAD" is set to TRUE, the value of "CV" becomes equal to "PV", and the value of "QU" becomes TRUE.

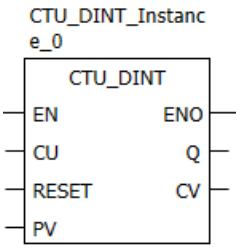


RESET	LOAD	CV	QU	QD	Action
FALSE	FALSE	Lower than 0	FALSE	TRUE	Acts only as an addition counter. When "CU" is at a rising edge, "CV" performs addition. When "CD" is at a rising edge, no subtraction is performed.
		Between 0 and "PV"	FALSE	FALSE	Acts as both addition/subtraction counter. When "CU" is at a rising edge, "CV" performs addition. When "CD" is at a rising edge, "CV" performs subtraction.
		Greater than "PV"	TRUE	FALSE	Acts only as a subtraction counter. When "CD" is at a rising edge, "CV" performs subtraction. When "CU" is at the rising edge, no addition operation is performed.
TRUE	FALSE	0	FALSE	TRUE	Reset status of the addition counter. The value of "CV" is set to 0.
FALSE	TRUE	"PV"	TRUE	FALSE	Reset status of the subtraction counter. The value of "CV" is set to "PV".
TRUE	TRUE	0	FALSE	TRUE	Reset status of the addition counter. "Reset" takes priority over "LOAD", and the value of "CV" is set to 0.

- **Program example**
  - The following example sets the preset value "PV" to 3.

	LD	ST
Define variables	VAR CTUD_Instance_0: CTUD; xCU: BOOL; xCD: BOOL; xREST: BOOL; xLOAD: BOOL; wPV: WORD := 3; xQU: BOOL; xQD: BOOL; wCV: WORD; END_VAR	
Program		CTUD_Instance_0(CU FALSE := xCU FALSE , CD TRUE := xCD TRUE , RESET FALSE := xRESET FALSE , LOAD FALSE := bLOAD FALSE , PV 3 := wPV 3 , QU FALSE => bQU FALSE , QD TRUE => bQD TRUE , CV 0 => wCV 0);RETURN

◦ When the preset value "PV" is set to 3, the timing diagram is shown in the figure below.



- When the input signal "CU" changes from FALSE to TRUE (rising edge), "CV" is incremented. When "CV" becomes equal to the preset value "PV", "QU" becomes TRUE.
- When "RESET" is set to TRUE, "CV" is reset to 0, "QU" becomes FALSE, and "QD" becomes TRUE.
- After "RESET" becomes FALSE, "CV" starts to be incremented and "QD" becomes TRUE. "QU" becomes TRUE when "CV" reaches the value of "PV".
- When the input signal "CD" changes from FALSE to TRUE (rising edge), "CV" is decremented. When the value of "CV" becomes 0, the value of "QD" becomes TRUE.
- When "LOAD" is set to TRUE, "PV" is loaded into "CV", "QD" becomes FALSE, and "QU" becomes TRUE.
- After "LOAD" becomes FALSE, "CV" starts to be decremented and "QU" becomes FALSE. When "CV" becomes 0, "QD" becomes TRUE.

18.1.8.5 CTU_DINT

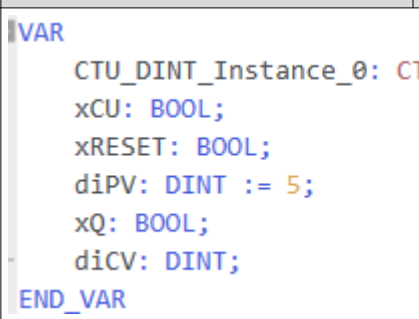
A counter that performs addition on the count value each time the counter input signal is received. The data type of the preset value and count value is DINT.

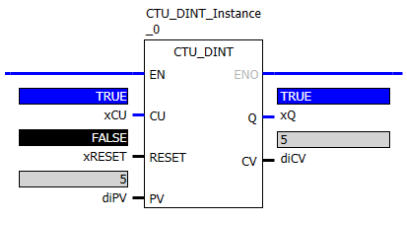
- **Instruction format**

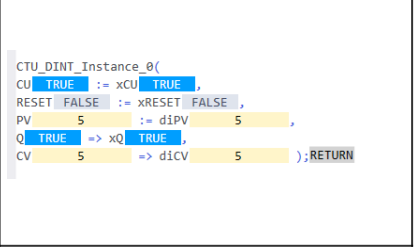
Instruction	Name	FB/FC	Ladder Diagram Representation	Structured Text Representation
CTU_DINT	Addition counter	FB		CTU_DINT_Instance_0(CU := , RESET := , PV := , Q => , CV =>);

- **Related variable**

Variable







Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	CU	Counter input	Follows data type	-	Counter input
	RESET	Reset signal	Follows data type	-	TRUE: Resets "CV" to 0.

CV	Same data type as "PV"																			

- **Function description**
  - If the load signal "LOAD" is set to TRUE, the preset value "PV" is loaded into the count value "CV", and the counter output "Q" becomes FALSE. At this time, the rising edge of "CD" is ignored, and no subtraction operation is performed on "CV".
  - If the load signal "LOAD" is set to FALSE and the counter input signal "CD" changes from FALSE to TRUE (rising edge), a subtraction operation is performed on "CV". When the value of "CV" is less than 0, even if "CD" is at a rising edge, no subtraction operation is performed on "CV", and the value of "Q" becomes TRUE.
- **Program example**
  - When "LOAD" is set to TRUE, "PV" is loaded into "CV", and "Q" becomes FALSE. After "LOAD" becomes FALSE, "CV" starts to be decremented, "CV" becomes 0, and "Q" becomes TRUE.
  - The following example sets the preset value "PV" to 5.

	LD	ST
Define variables		
Program		

```
VAR
    CTD_DINT_Instance_0: CTD_DINT;
    xCD: BOOL;
    xLOAD: BOOL;
    xPV: DINT := 5;
    xQ: BOOL;
    xCV: WORD;
END_VAR
```

```
CTD_DINT_Instance_0(
CD FALSE := xCD FALSE,
LOAD FALSE := xLOAD FALSE,
PV 5 := xPV 5,
Q TRUE => xQ TRUE,
CV 0 => xCV 0);RETURN
```

  - When the preset value "PV" is set to 5, the timing diagram is shown in the figure below.

18.1.8.10 CTD_UDINT

A counter that performs subtraction on the count value each time the counter input signal is received. The data type of the preset value and count value is UDINT.

- **Instruction format**

CV	Same data type as "PV"																			

- **Function description**

  A counter that performs addition and subtraction operations based on the addition/subtraction input signals. It combines the functions of both the addition counter and the subtraction counter. The data type of the preset value and the counter value is DINT.

  ◦ Addition counter function

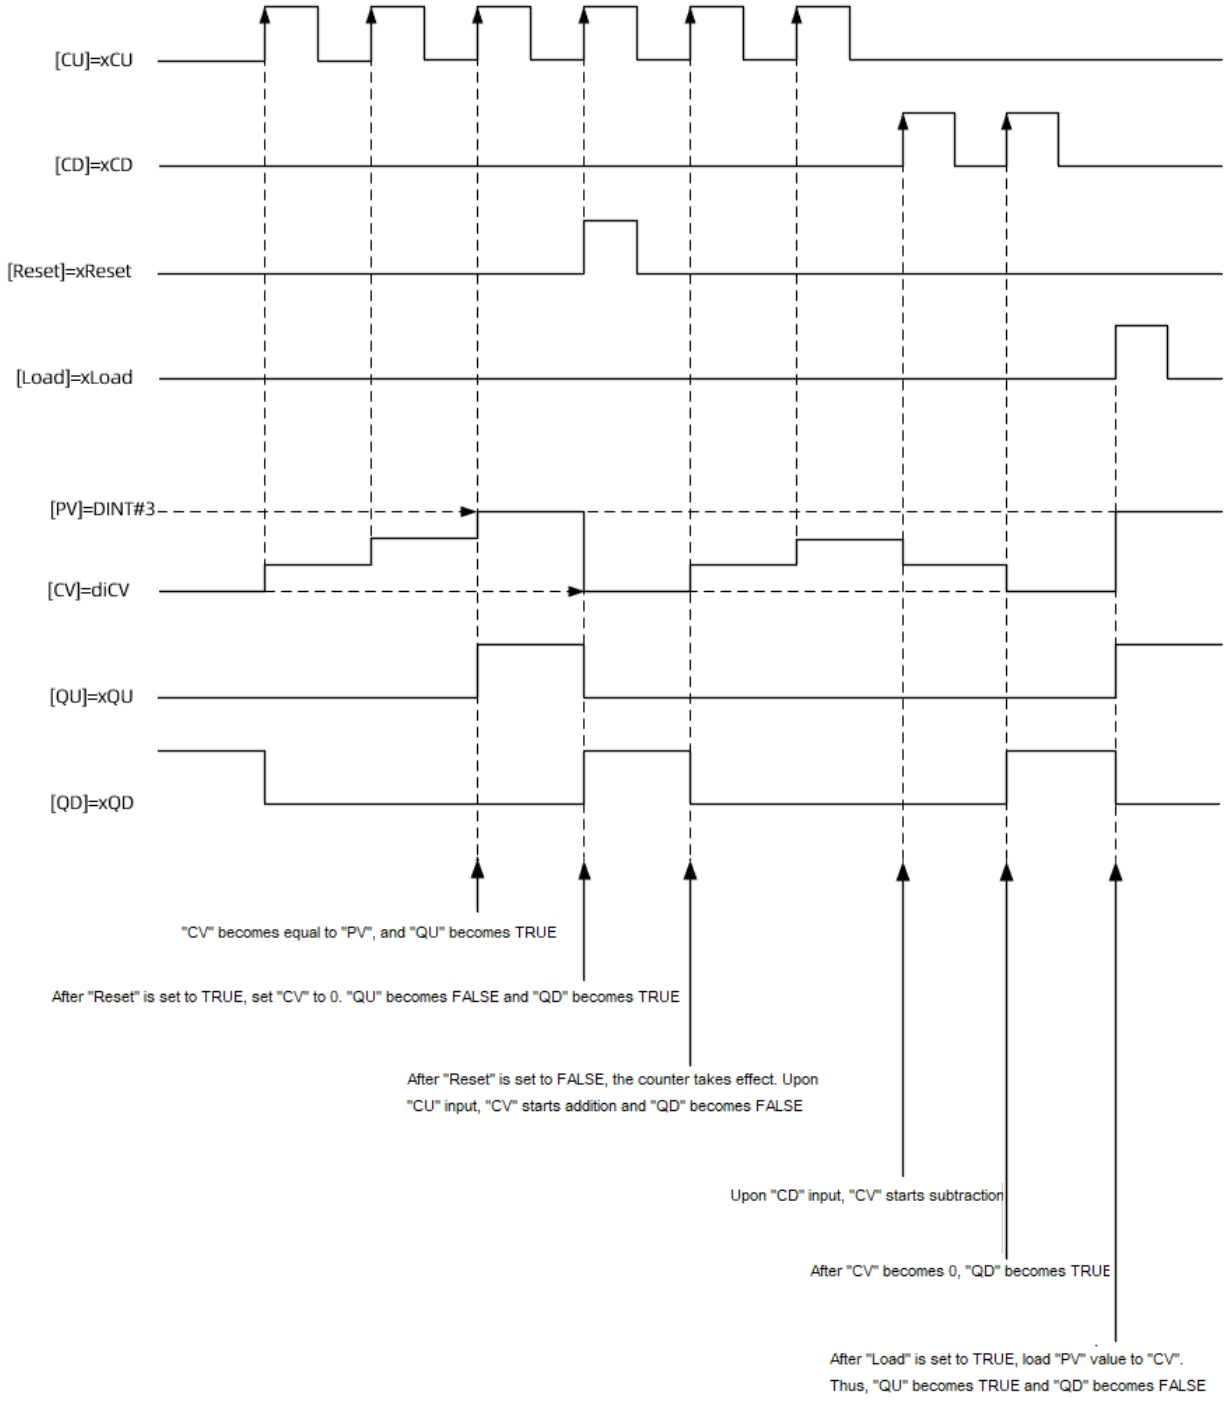
  When the reset signal "RESET" is set to TRUE, the counter value "CV" becomes 0, and the addition counter output "QU" becomes FALSE. When addition counter input signal "CU" changes from FALSE to TRUE (rising edge), this instruction is executed, and "CV" is incremented by "1". Upon each rising-edge signal of "CU", "CV" is incremented, until it reaches the maximum value of the specified data type.

  ◦ Subtraction counter function

  When the load signal "LOAD" is set to TRUE, the preset value "PV" is loaded into the count value "CV", and the subtraction counter output "QD" becomes FALSE. When the subtraction counter input signal "CD" changes from FALSE to TRUE (rising edge), "CV" is decremented. When the value of "CV" is less than 0, the value of "QD" becomes TRUE. When the value of "CV" is less than 0, even if a larger value of "CD" is input, "CV" remains unchanged.

  ◦ Common functions of the addition/subtraction counter

  When "LOAD" or "RESET" is TRUE, "CU" and "CD" are ignored. No addition or subtraction operation is performed on "CV". When "CU" and "CD" are both at the rising edge, "CV" does not change. When both "RESET" and "LOAD" are TRUE, "RESET" takes priority, and the value of "CV" becomes 0. When "RESET" is set to TRUE, the value of "CV" becomes 0, and the value of "QD" becomes TRUE. When "LOAD" is set to TRUE, the value of "CV" becomes equal to "PV", and the value of "QU" becomes TRUE.

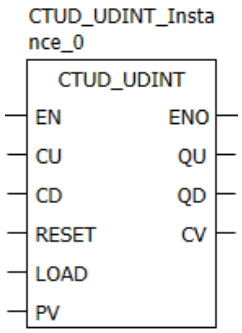


Reset	Load	CV	QU	QD	Action
FALSE	FALSE	Lower than 0	FALSE	TRUE	Acts only as an addition counter. When "CU" is at a rising edge, "CV" performs addition. When "CD" is at a rising edge, no subtraction is performed.
		Between 0 and "PV"	FALSE	FALSE	Acts as both addition/subtraction counter. When "CU" is at a rising edge, an addition operation is performed on "CV"; when "CD" is at a rising edge, a subtraction operation is performed on "CV".
		Greater than "PV"	TRUE	FALSE	Acts only as a subtraction counter. When "CD" is at a rising edge, "CV" performs subtraction. When "CU" is at the rising edge, no addition operation is performed.
TRUE	FALSE	0	FALSE	TRUE	Reset status of the addition counter. The value of "CV" is set to 0.
FALSE	TRUE	"PV"	TRUE	FALSE	Reset status of the subtraction counter. The value of "CV" is set to "PV".
TRUE	TRUE	0	FALSE	TRUE	Reset status of the addition counter. "RESET" takes priority over "LOAD", and the value of "CV" is set to 0.

- **Program example**
  - The following example sets the preset value "PV" to 3.

	LD	ST
Define variables	VAR CTUD_DINT_Instance_0: CTUD_DINT; xCU: BOOL; xCD: BOOL; xRESET: BOOL; xLOAD: BOOL; diPV: DINT := 3; xQU: BOOL; xQD: BOOL; diCV : DINT; END_VAR	

	LD	ST
Program		CTUD_DINT_Instance_0(CU FALSE := xCU FALSE , CD TRUE := xCD TRUE , RESET FALSE := xRESET FALSE , LOAD FALSE := xLOAD FALSE , PV 3 := diPV 3 , QU FALSE => xQU FALSE , QD TRUE => xQD TRUE , CV 0 => diCV 0);RETURN



- When the preset value "PV" is set to 3, the timing diagram is shown in the figure below.
  - When the input signal "CU" changes from FALSE to TRUE (rising edge), "CV" is incremented. When "CV" becomes equal to the preset value "PV", "QU" becomes TRUE.
  - When "RESET" is set to TRUE, "CV" is reset to 0, "QU" becomes FALSE, and "QD" becomes TRUE.
  - After "RESET" becomes FALSE, "CV" starts to be incremented and "QD" becomes TRUE. "QU" becomes TRUE when "CV" reaches the value of "PV".
  - When the input signal "CD" changes from FALSE to TRUE (rising edge), "CV" is decremented. When the value of "CV" becomes 0, the value of "QD" becomes TRUE.
  - When "LOAD" is set to TRUE, "PV" is loaded into "CV", "QD" becomes FALSE, and "QU" becomes TRUE.
  - After "LOAD" becomes FALSE, "CV" starts to be decremented and "QU" becomes FALSE. When "CV" becomes 0, "QD" becomes TRUE.

18.1.8.14 CTUD_UDINT

A counter that performs addition and subtraction operations based on the addition/subtraction input signals. The data type of the preset value and count value is UDINT.

- **Instruction format**

Instruction	Name	FB/FC	Ladder Diagram Representation	Structured Text Representation

CV	Same data type as "PV"																			

- **Function description**

  A counter that performs addition and subtraction operations based on the addition/subtraction input signals. It combines the functions of both the addition counter and the subtraction counter. The data type of the preset value and counter value is LINT.

  ◦ Addition counter function

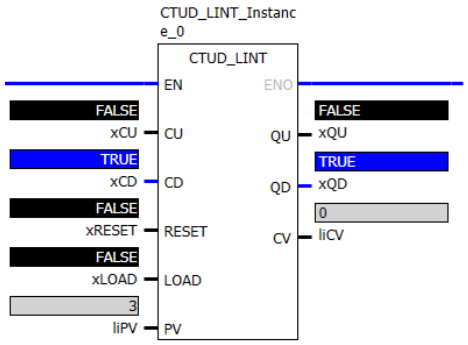
  When the reset signal "RESET" is set to TRUE, the counter value "CV" becomes 0, and the addition counter output "QU" becomes FALSE. When addition counter input signal "CU" changes from FALSE to TRUE (rising edge), this instruction is executed, and "CV" is incremented by "1". Upon each rising-edge signal of "CU", "CV" is incremented, until it reaches the maximum value of the specified data type.

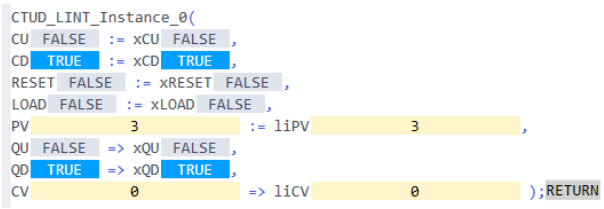
  ◦ Subtraction counter function

  When the load signal "LOAD" is set to TRUE, the preset value "PV" is loaded into the count value "CV", and the subtraction counter output "QD" becomes FALSE. When the subtraction counter input signal "CD" changes from FALSE to TRUE (rising edge), "CV" is decremented. When the value of "CV" is less than 0, the value of "QD" becomes TRUE. When the value of "CV" is less than 0, even if a larger value of "CD" is input, "CV" remains unchanged.

  ◦ Common functions of the addition/subtraction counter

  When "LOAD" or "RESET" is TRUE, "CU" and "CD" are ignored. No addition or subtraction operation is performed on "CV". When "CU" and "CD" are both at the rising edge, "CV" does not change. When both

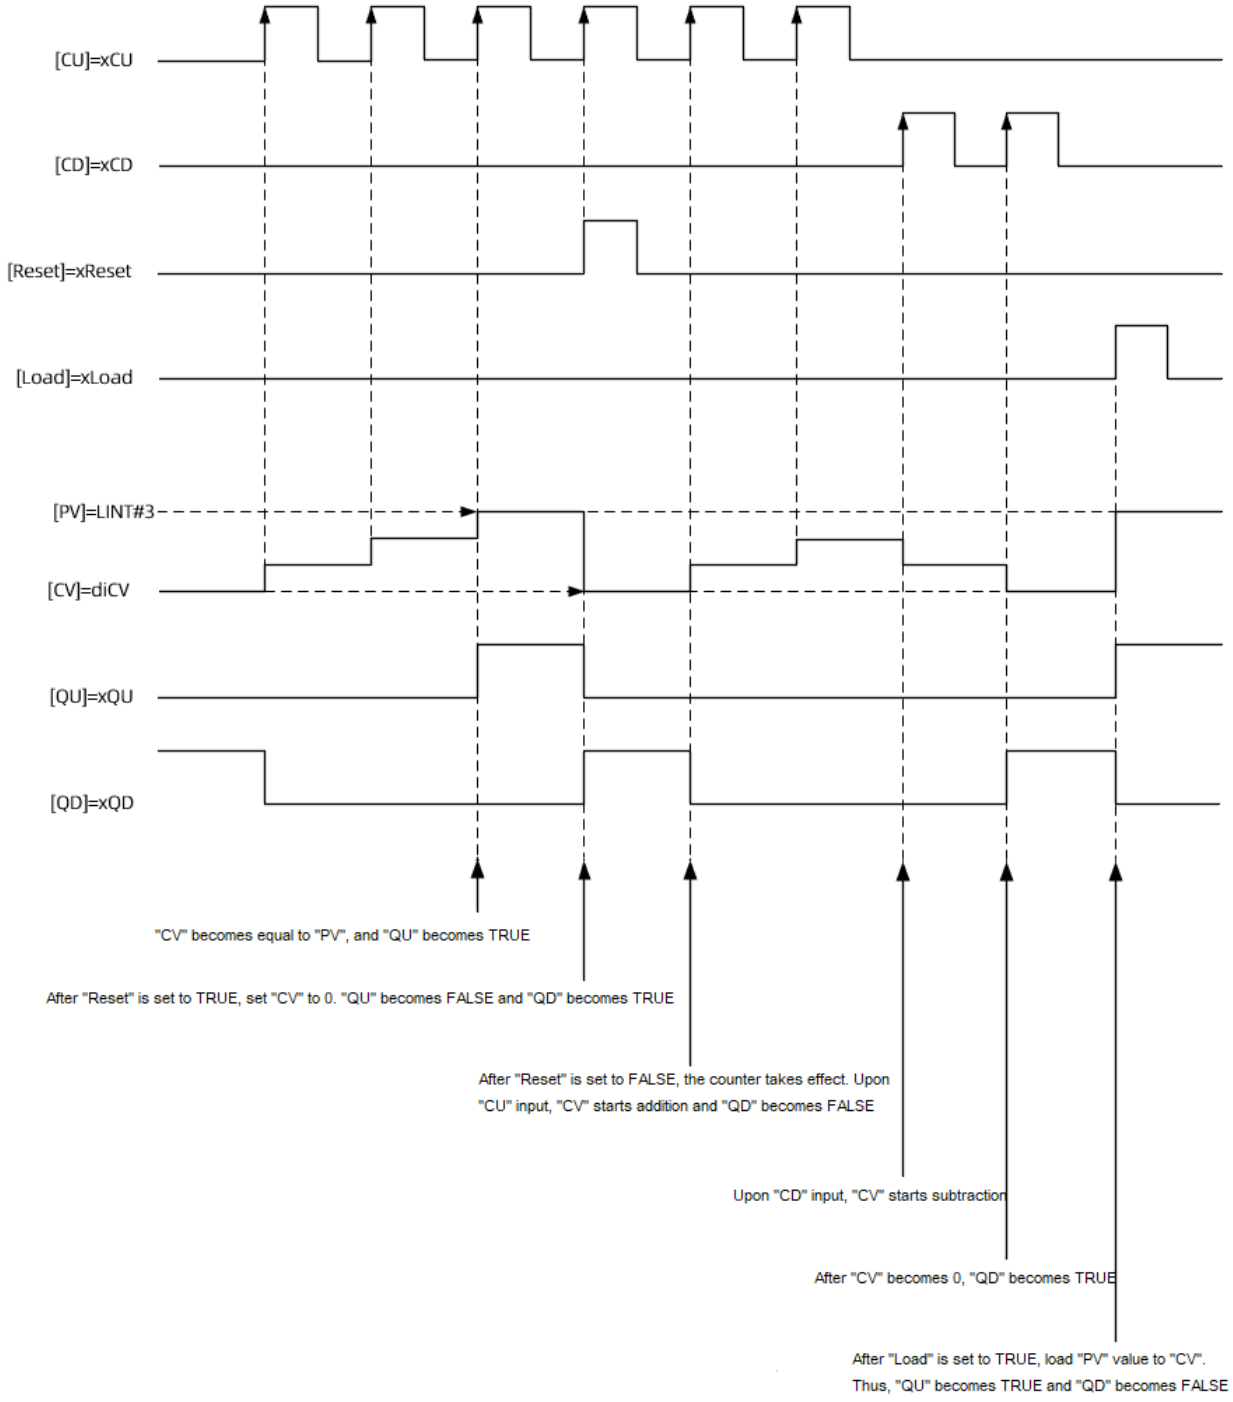




"RESET" and "LOAD" are TRUE, "RESET" takes priority, and the value of "CV" becomes 0. When "RESET" is set to TRUE, the value of "CV" becomes 0, and the value of "QD" becomes TRUE. When "LOAD" is set to TRUE, the value of "CV" becomes equal to "PV", and the value of "QU" becomes TRUE.

Reset	Load	CV	QU	QD	Action
FALSE	FALSE	Lower than 0	FALSE	TRUE	Acts only as an addition counter. When "CU" is at a rising edge, "CV" performs addition. When "CD" is at a rising edge, no subtraction is performed.
		Between 0 and "PV"	FALSE	FALSE	Acts as both addition/ subtraction counter. When "CU" is at a rising edge, an addition operation is performed on "CV"; when "CD" is at a rising edge, a subtraction operation is performed on "CV".
		Greater than "PV"	TRUE	FALSE	Acts only as a subtraction counter. When "CD" is at a rising edge, "CV" performs subtraction. When "CU" is at the rising edge, no addition operation is performed.

Reset	Load	CV	QU	QD	Action
TRUE	FALSE	0	FALSE	TRUE	Reset status of the addition counter. The value of "CV" is set to 0.
FALSE	TRUE	"PV"	TRUE	FALSE	Reset status of the subtraction counter. The value of "CV" is set to "PV".
TRUE	TRUE	0	FALSE	TRUE	Reset status of the addition counter. "RESET" takes priority over "LOAD", and the value of "CV" is set to 0.

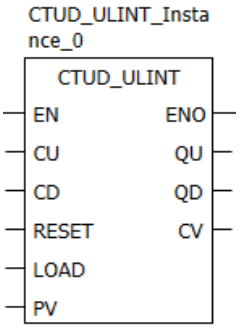


- **Program example**
  - The following example sets the preset value "PV" to 3.

	LD	ST
Define variables	VAR CTUD_LINT_Instance_0: CTUD_LINT; xCU: BOOL; xCD: BOOL; xRESET: BOOL; xLOAD: BOOL; liPV: LINT := 3; xQU: BOOL; xQD: BOOL; liCV : LINT; END_VAR	

	LD	ST
Program		

◦ When the preset value "PV" is set to 3, the timing diagram is shown in the figure below.



- When the input signal "CU" changes from FALSE to TRUE (rising edge), "CV" is incremented. When "CV" becomes equal to the preset value "PV", "QU" becomes TRUE.
- When "RESET" is set to TRUE, "CV" is reset to 0, "QU" becomes FALSE, and "QD" becomes TRUE.
- After "RESET" becomes FALSE, "CV" starts to be incremented and "QD" becomes TRUE. "QU" becomes TRUE when "CV" reaches the value of "PV".
- When the input signal "CD" changes from FALSE to TRUE (rising edge), "CV" is decremented. When the value of "CV" becomes 0, the value of "QD" becomes TRUE.
- When "LOAD" is set to TRUE, "PV" is loaded into "CV", "QD" becomes FALSE, and "QU" becomes TRUE.
- After "LOAD" becomes FALSE, "CV" starts to be decremented and "QU" becomes FALSE. When "CV" becomes 0, "QD" becomes TRUE.

18.1.8.16 CTUD_ULINT

A counter that performs addition and subtraction operations based on the addition/subtraction input signals. The data type of the preset value and count value is ULINT.

- **Instruction format**

Instruction	Name	FB/FC	Ladder Diagram Representation	Structured Text Representation
CTUD_ULINT	Reversible counter	FB		CTUD_ULINT_Instance_0(CU := , CD := , RESET := , LOAD := , PV := , QU => , QD => , CV =>);

(2) When input signal "IN" changes from FALSE to TRUE, "Q" is set to TRUE after "ET" completes timing

18.1.9.5 TON2

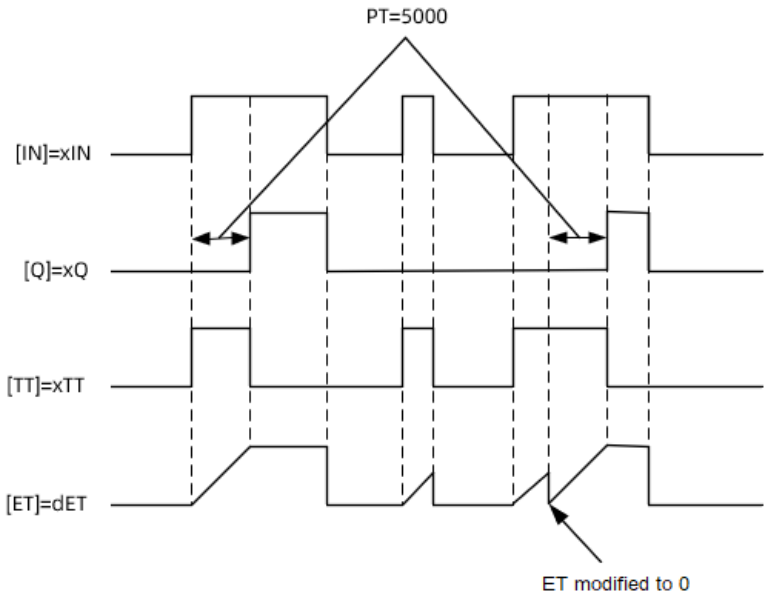
On-delay timer. The timer output can be modified during timing.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
TON2	Power-on delay timer	FB	TON2_Instance_0 TON2 IN Q PT TT ET	TON2_Instance_0(IN := , PT := , Q => , TT => , ET =>);

- **Related variables**

Variable



Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Input signal	Follows data type.	FALSE	Input signal. Timing starts when FALSE transitions to TRUE.
	PT	Delay time	Follows data type	0	Delay time.
Output	Q	Timing completion signal	Follows data type	FALSE	Timing completion signal TRUE when "ET" is equal to or greater than PT.
	TT	Timing in progress	Follows data type	FALSE	TRUE during timing; FALSE when not timing or when timing is complete.
	ET	Current timing time	Follows data type	0	Timing output. Modifying "ET" during timing takes effect immediately.

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
IN	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
PT	-	-	-	-	-	-	-	-	-	-	-	√	-	-	-	-	-	-	-	-
Q	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
TT	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
ET	-	-	-	-	-	-	-	-	-	-	-	√	-	-	-	-	-	-	-	-

- **Function**
  - The input signal "PT" sets the delay time. Timing starts when the input signal "IN" transitions from FALSE to TRUE. During timing, "TT" is set to TRUE, and the accumulated time "ET" increases over time. When "ET" reaches the set time "PT", timing is complete, and "Q" is set to TRUE.
  - The timer resets when "IN" transitions from TRUE to FALSE. "ET" becomes 0, and "TT" and "Q" become FALSE.
  - If the timer is active and the input signal "IN" transitions to FALSE before "ET" reaches "PT", the timer is reset.
  - When modifying the "ET" parameter, the internal "ET" timing value must be forcibly written via the Set accessor of the ModifyET property.
- **Timing diagram**

  Set "PT" to 5000. When the cumulative time for variable "IN" being TRUE reaches 5000 ms, "Q" becomes TRUE. If "IN" is set to FALSE before the cumulative time reaches "PT", "ET" and "TT" are reset. If "ET" is modified to 0 during timing, the elapsed time increases from the newly set value.

- **Program example**

  ST:

  - When input signal "IN" is FALSE.

	Name	Type	Address	Value
1	TON2_Instance_0	TON2		
2	xIN	BOOL		FALSE
3	dPT	DINT		5000
4	xQ	BOOL		FALSE
5	xTT	BOOL		FALSE
6	dET	DINT		0
7	Mod_ET	BOOL		FALSE
8	dET_Mod	DINT		0
9	R_TRIG_Instance_0	R_TRIG		

```
TON2_Instance_0(
IN  FALSE  := xIN  FALSE ,
PT     5000      := dPT     5000     ,
Q  FALSE  => xQ  FALSE ,
TT  FALSE  => xTT  FALSE ,
ET     0         => dET     0        );

R_TRIG_Instance_0(
CLK  FALSE  := Mod_ET  FALSE ,
Q => );

IF R_TRIG_Instance_0.Q  FALSE  THEN
    TON2_Instance_0.ModifyET := dET_Mod     0       ;
END_IFRETURN
```

  - When input signal "IN" transitions from FALSE to TRUE, during "ET" timing.

	Name	Type	Address	Value
1	TON2_Instance_0	TON2		
2	xIN	BOOL		TRUE
3	dPT	DINT		5000
4	xQ	BOOL		FALSE
5	xTT	BOOL		TRUE
6	dET	DINT		3710
7	Mod_ET	BOOL		FALSE
8	dET_Mod	DINT		0
9	R_TRIG_Instance_0	R_TRIG		

```
TON2_Instance_0(
IN  TRUE  := xIN  TRUE ,
PT     5000      := dPT     5000     ,
Q  FALSE  => xQ  FALSE ,
TT  TRUE  => xTT  TRUE ,
ET     3710      => dET     3710     );

R_TRIG_Instance_0(
CLK  FALSE  := Mod_ET  FALSE ,
Q => );

IF R_TRIG_Instance_0.Q  FALSE  THEN
    TON2_Instance_0.ModifyET := dET_Mod     0       ;
END_IFRETURN
```

  - During "ET" timing, the rising edge of Mod_ET serves as the modification trigger signal. The set value dET_Mod (dET_Mod = 0) is force-written into the internal "ET" timing value of the timer through the Set accessor of the ModifyET property.

	Name	Type	Address	Value
1	TON2_Instance_0	TON2		
2	xIN	BOOL		TRUE
3	dPT	DINT		5000
4	xQ	BOOL		FALSE
5	xTT	BOOL		TRUE
6	dET	DINT		60
7	Mod_ET	BOOL		TRUE
8	dET_Mod	DINT		0
9	R_TRIG_Instance_0	R_TRIG		

```
TON2_Instance_0(
IN TRUE := xIN TRUE,
PT 5000 := dPT 5000,
Q FALSE => xQ FALSE,
TT TRUE => xTT TRUE,
ET 60 => dET 60);

R_TRIG_Instance_0(
CLK TRUE := Mod_ET TRUE,
Q => );

IF R_TRIG_Instance_0.Q FALSE THEN
    TON2_Instance_0.ModifyET := dET_Mod 0;
END_IFRETURN
```

◦ "ET" timing is complete.

	Name	Type	Address	Value
1	TON2_Instance_0	TON2		
2	xIN	BOOL		TRUE
3	dPT	DINT		5000
4	xQ	BOOL		TRUE
5	xTT	BOOL		FALSE

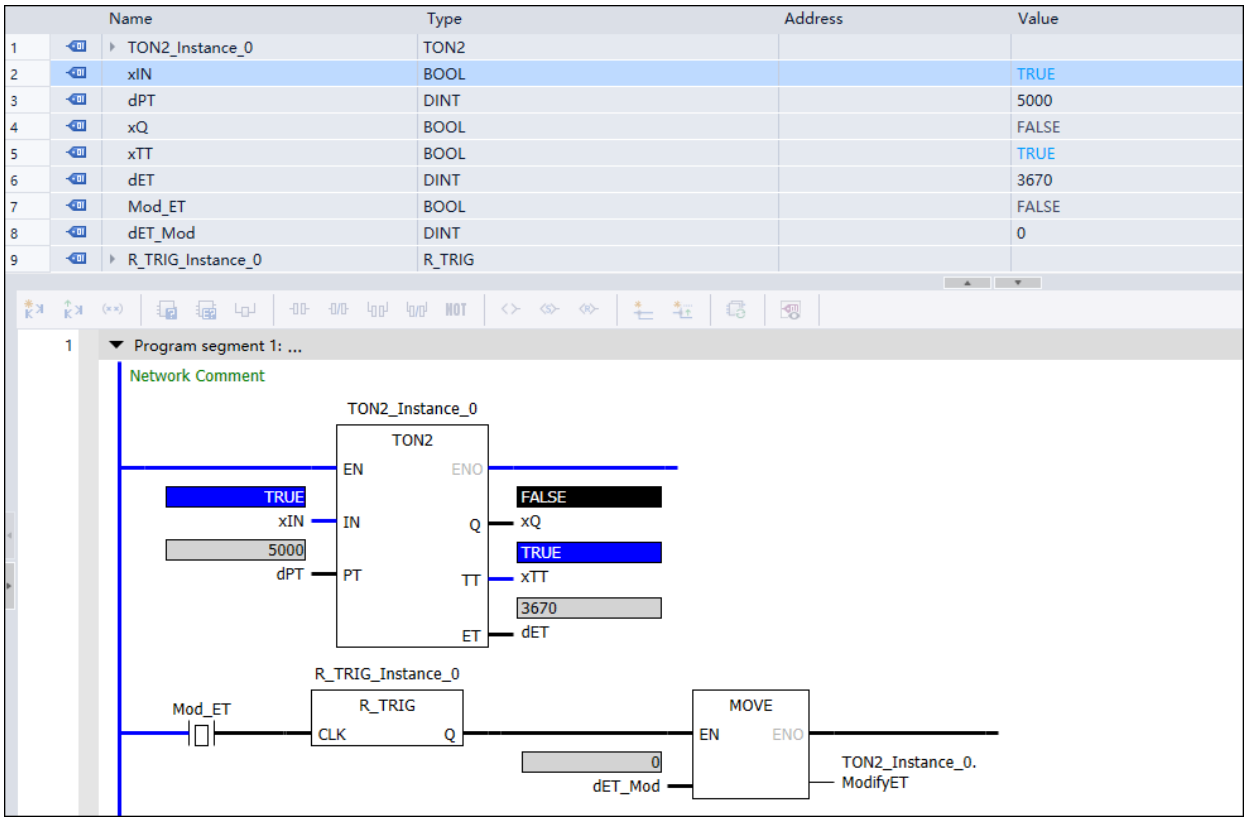
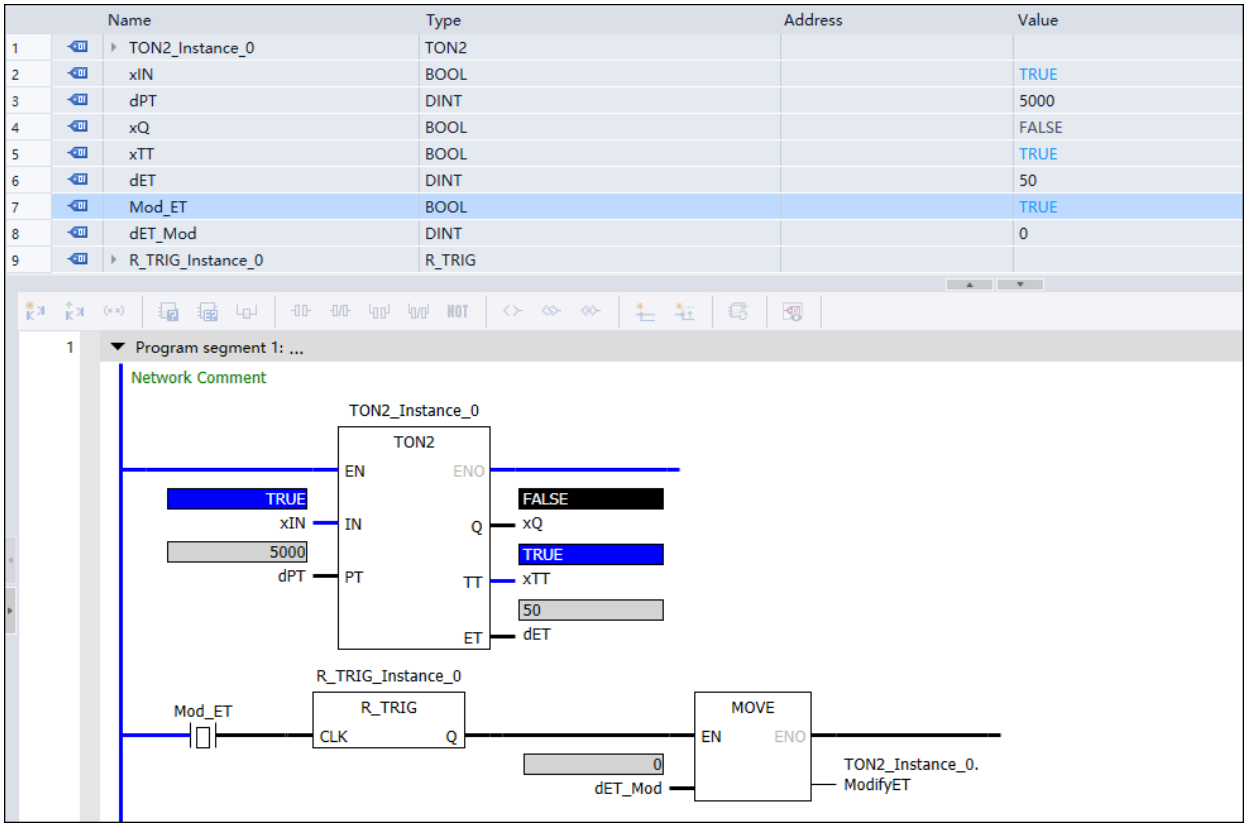
R_TRIG_Instance_0(
CLK TRUE := Mod_ET TRUE,
Q => );

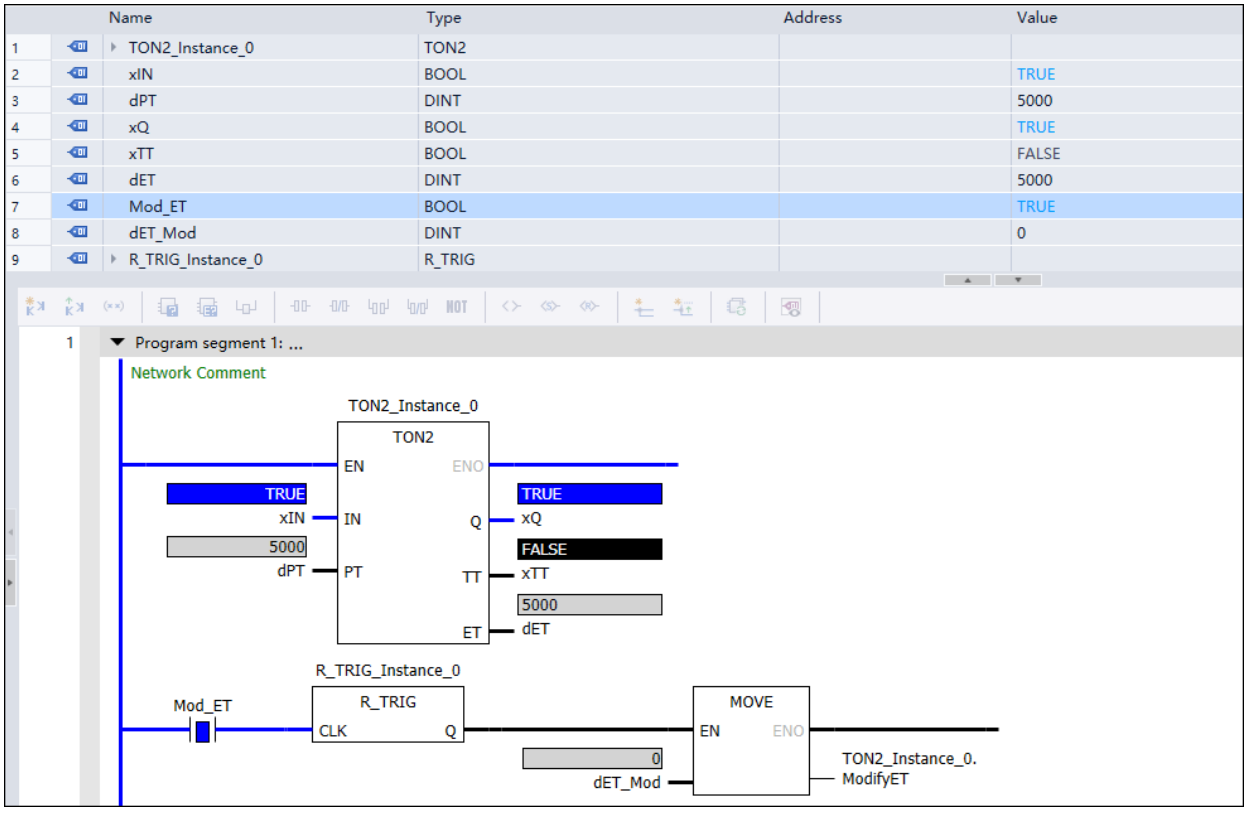


IF R_TRIG_Instance_0.Q FALSE THEN
    TON2_Instance_0.ModifyET := dET_Mod 0;
END_IFRETURN
```

LD:



◦ When input signal "IN" is FALSE.



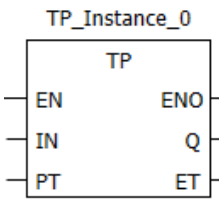
◦ When input signal "IN" transitions from FALSE to TRUE, during "ET" timing.

◦ During "ET" timing, the rising edge of Mod_ET serves as the modification trigger signal. The set value dET_Mod (dET_Mod = 0) is force-written into the internal "ET" timing value of the timer through the Set accessor of the ModifyET property.

◦ "ET" timing is complete.

- **Precautions**
  - PT and "ET" are set in ms, with a timing accuracy of 1 ms.
  - If "PT" or "ET" is input with a value less than 0, it is automatically corrected to 0 for operation.
  - Before "ET" reaches "PT", the value of "ET" can be changed. The following actions will occur.

Timer status	Value of Q	New Value of ET	Action
Before timing	FALSE	-	When the value of "IN" becomes TRUE, "ET" starts increasing from 0, and the modified value does not take effect.
After timing	TRUE	-	The value of "Q" remains TRUE. The value of "ET" changes (timer is not running).
During timing	FALSE	PT ≥ ET	Timing restarts based on the modified value of ET. When "ET" reaches the value of "PT", "Q" becomes TRUE, and "ET" stops increasing.
		PT < ET	The value of "Q" immediately becomes TRUE, and "ET" immediately stops increasing.



- Before the value of "ET" reaches the value of "PT", "PT" can be modified, and the following actions will occur.

Timer status	Value of Q	New Value of PT	Action
After timing	TRUE	-	The value of "Q" remains TRUE. The value of "ET" does not change and remains at the value of "PT" before it is modified.
During timing	FALSE	"PT" ≥ "ET"	When the value of "IN" becomes TRUE, timing continues. When the value of "ET" reaches the new value of "PT", the value of "Q" becomes TRUE, and "ET" stops increasing.
		"PT" < "ET"	When the value of "IN" becomes TRUE, the value of "Q" immediately becomes TRUE. "ET" also immediately stops increasing.

18.1.9.6 TP

Outputs the current timing time and timing status based on the input timing time.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
TP	Standard timer	FB		TP_Instance_0(IN := , PT := , Q => , ET =>);

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Input signal	Follows data type	-	Starts timing when "IN" changes from FALSE to TRUE.
	PT	Set timing time	Follows data type	-	Set time
Output	Q	Timing completion signal	Follows data type	-	Timing completes when "Q" changes from TRUE to FALSE.
	ET	Current timing time	Follows data type	-	Current timing time

1  TP_Instance_0(
2  IN TRUE := xIN TRUE,
3  PT T#5s := xPT T#5s,
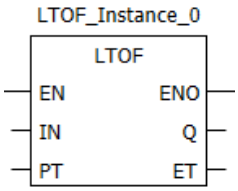
4  Q FALSE => xQ FALSE,
5  ET T#5s => xResult T#5s );RETURN
```

  LD:

  (1) Input signal "IN" is TRUE



(2) Current timing time (ET) equals set timing time (PT)

18.1.9.7 LTOF

Outputs a timing completion signal after a delay following power-off.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
LTOF	Power-off delay timer	FB		LTOF_Instance_0(IN := , PT := , Q => , ET =>);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Input signal	Follows data type	-	Starts timing when "IN" changes from TRUE to FALSE.
	PT	Set timing time	Follows data type	-	Set time
Output	Q	Output	Follows data type	-	Timing completes when "Q" changes from TRUE to FALSE.
	ET	Current timing time	Follows data type	-	Elapsed time since the falling edge of "IN".

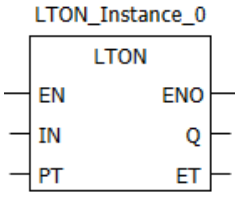
Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String					
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	LTIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
IN	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
PT	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–
Q	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String					
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	LTIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
ET	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–

- **Function**

  The input signal "PT" sets the timing duration. When the input signal "IN" changes from TRUE to FALSE, timing starts. After timing completes, "Q" is set to FALSE.



- **Program example**

  The program example is similar to 18.1.9.3 TOF in the standard library, except that the data types of "PT" and "ET" are changed from TIME to LTIME, thus providing higher precision.

18.1.9.8 LTON

Outputs a timing completion signal after a delay following power-on.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
LTON	Power-on delay timer	FB		LTON_Instance_0(IN := , PT := , Q => , ET =>);

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Input signal	Follows data type	-	Starts timing when "IN" changes from FALSE to TRUE.
	PT	Set timing time	Follows data type	-	Set time

Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	Q	Output	Follows data type	-	Timing completes when "Q" changes from FALSE to TRUE.
	ET	Current timing time	Follows data type	-	Current timing time

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String					
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	LTIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
IN	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

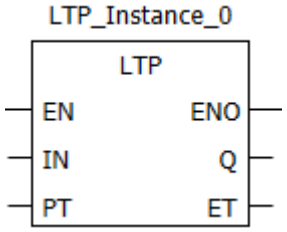
Q	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
ET	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–

- **Function**

  Input signal "PT" sets the timing duration. When input signal "IN" changes from FALSE to TRUE, timing starts. After timing completes, "Q" is set to TRUE.



- **Program example**

  The program example is similar to 18.1.9.4 TON in the standard library, except that the data types of "PT" and "ET" are changed from TIME to LTIME, thus providing higher precision.

18.1.9.9 LTP

Outputs the current timing time and timing status based on the input timing time.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
LTP	Standard timer	FB		LTP_Instance_0(IN := , PT := , Q => , ET =>);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Input signal	Follows data type	-	Starts timing when "IN" changes from FALSE to TRUE.
	PT	Set timing time	Follows data type	-	Set time
Output	Q	Timer output	Follows data type	-	Timing completes when "Q" changes from TRUE to FALSE.
	ET	Timing time output	Follows data type	-	Elapsed time since the rising edge of "IN".

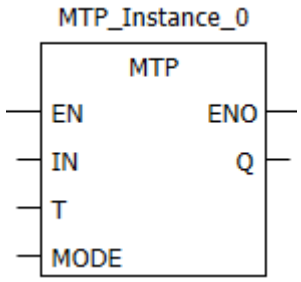
Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String					
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	LTIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
IN	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
PT	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	-	√	–	–	–	–
Q	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String					
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	LTIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
ET	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–

- **Function**

  When "IN" is TRUE, "Q" outputs a high-level signal for the duration "PT". "ET" displays the current timing time; when "ET" = "PT", "Q" becomes FALSE.



- **Program example**

  The program example is similar to 18.1.9.6 TP in the standard library, except that the data types of "PT" and "ET" are changed from TIME to LTIME, thus providing higher precision.

18.1.9.10 MTP

A pulse timing output block.

- **Instruction format**

Instruction	Name	FB/FC	Ladder Diagram Representation	Structured Text Representation
MTP	Pulse timing output block	FB		MTP_Instance_0(IN := , T := , MODE := , Q =>);

- **Related variables**

  Variable

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Input	Follows data type	-	Input
	T	Set timing time	Follows data type	TIME#0ms	Timing time.
	MODE	Input mode	Follows data type	-	FALSE for maximum pulse timing. TRUE for minimum pulse timing.

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Output	Q	Pulse output	Follows data type	-	Pulse output

Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TOD	DT	STRING
IN	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
T	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–
MODE	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Q	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  Includes both maximum and minimum pulse timing functions.

  ◦ Maximum pulse timing

  When the pulse input "IN" is on a rising edge, the output "Q" is 1. When the timing time reaches "T" or when "IN" is on a falling edge, the output "Q" is reset to 0.

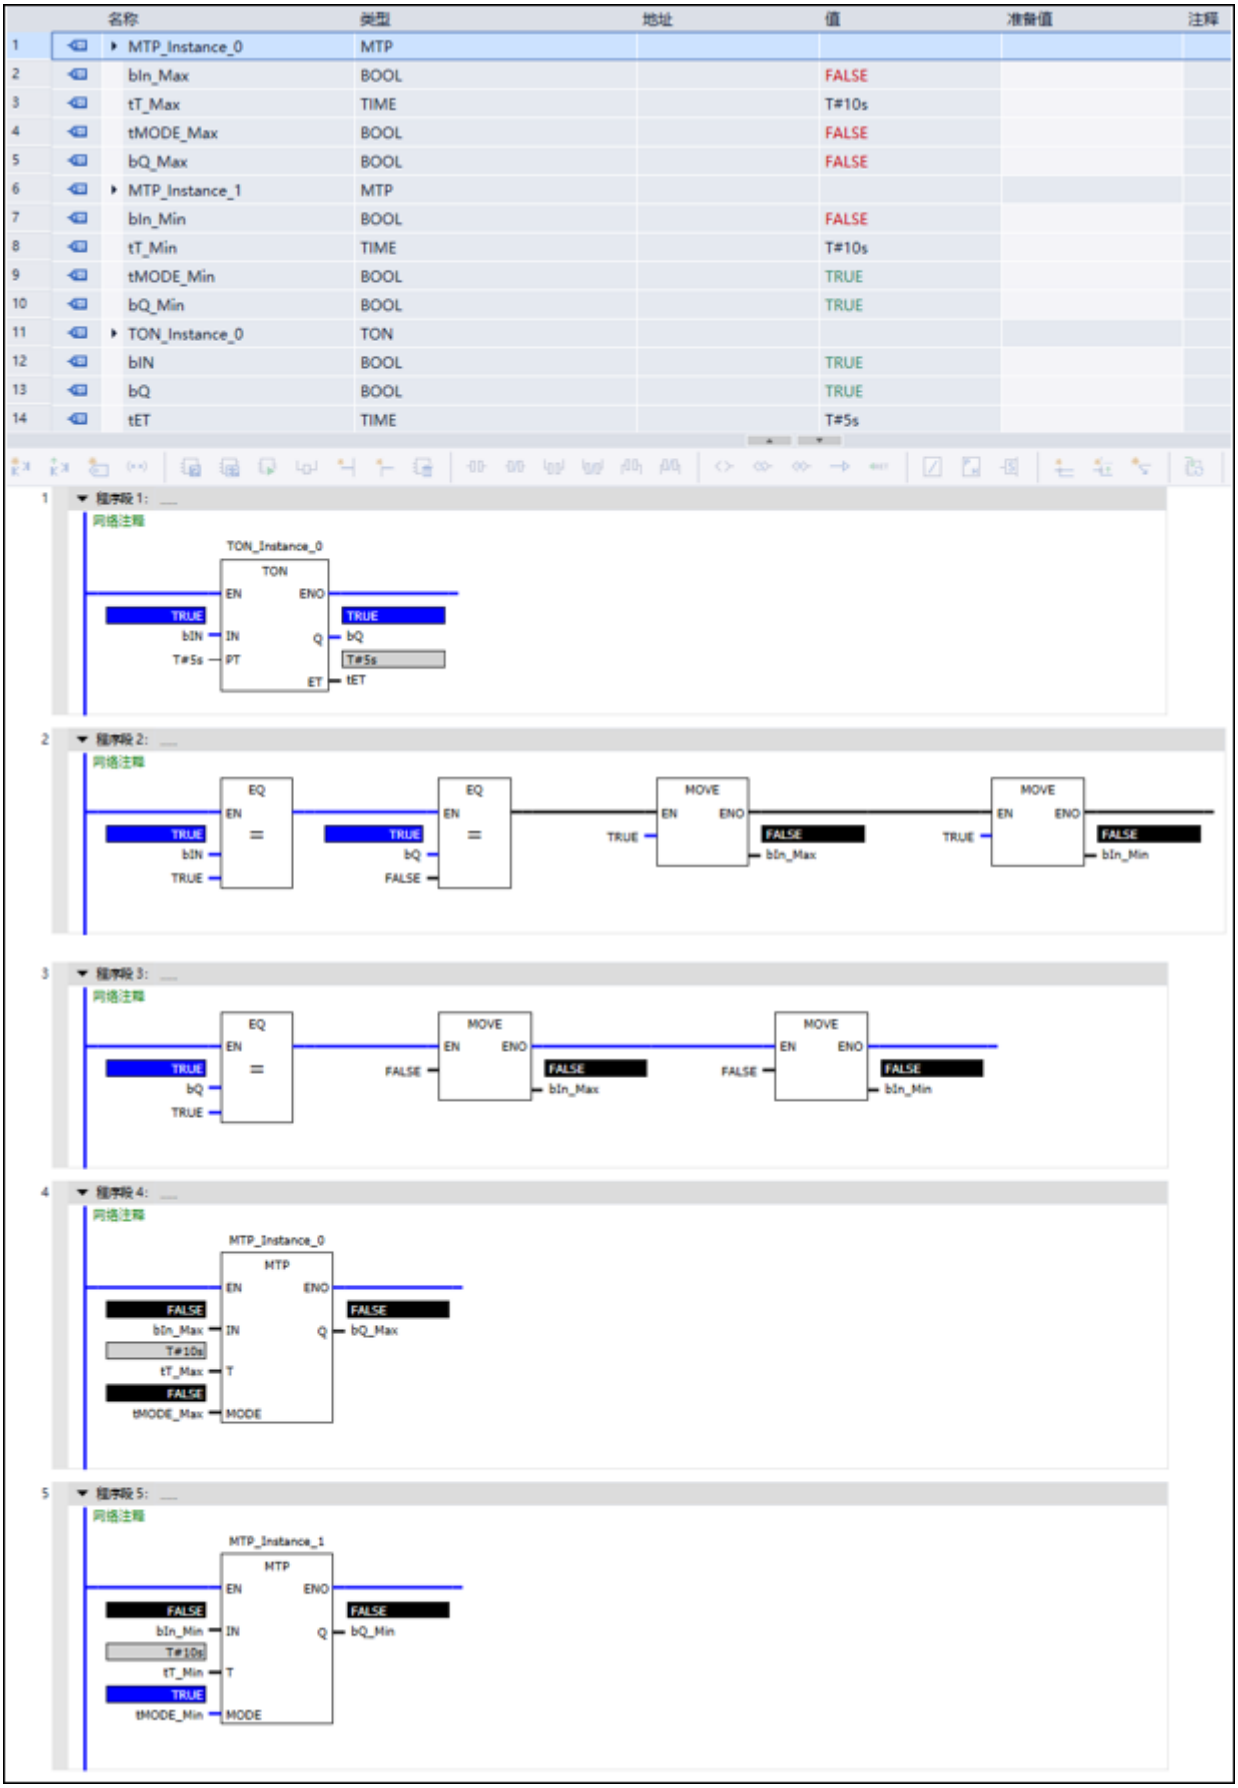
  ◦ Minimum pulse timing output

  When the pulse input "IN" is on a rising edge, the output "Q" is 1. When the timing time reaches "T" or when "IN" is on a falling edge, the output "Q" is reset to 0.

- **Program example**

  ◦ If T is set to T#10s, MTP_Instance_0 will set MODE to FALSE for maximum pulse timing, and MTP_Instance_1 will set MODE to TRUE for minimum pulse timing.

  ▪ When TON_Instance_0 sets "PT" to T#5s, the high-level input time of "IN" is 5s. Under maximum pulse timing, the high-level output time of "Q" is 5s. Under minimum pulse timing, the high-level output time of "Q" is 10s.



- When TON_Instance_0 sets "PT" to T#15s, the high-level input time of "IN" is 15s. Under maximum pulse timing, the high-level output time of "Q" is 10s. Under minimum pulse timing, the high-level output time of "Q" is 15s.

ST:

	Name	Data type	Address	Value
1	MTP_Instance_0	MTP		
2	bIn_Max	BOOL		FALSE
3	tT_Max	TIME		T#10s
4	tMODE_Max	BOOL		FALSE
5	bQ_Max	BOOL		FALSE

- **Function**

  In industrial production, a common requirement is for equipment to start and stop periodically according to user-defined time setting to fulfill process needs. For example, equipment may need to perform scheduled cleaning and maintenance during weekdays, operating for certain durations every morning and evening from Monday to Friday. Another example is that equipment may need to operate periodically during specific or multiple time slots based on temporary work arrangements. In both cases, a flexibly configurable function block tailored to on-site processes is indispensable to ensure the smooth execution of production processes.

  This block functions similarly to a clock timer. The system time is compared with the set time, and an event output is generated when the condition is met. The following two timing modes are supported:

  - **Time-based setting**

    - Set times support year, month, day, hour, minute, second, and millisecond, and each can be individually enabled or disabled via a switch for timing function. When the set time is reached, the output "OUT" becomes TRUE.

TimeSwitch_Instance_0	TimeSwitch					不公开	
SWOPT	BOOL		FALSE			不公开	时间判定方式选择：0-按时间判断 1-按星期判断
YEAR_Set	WORD		1970			不公开	设定判断时间：年
MONT_Set	BYTE		1			不公开	设定判断时间：月
DAY_Set	BYTE		0			不公开	设定判断时间：日

MIN_SWON	BOOL		TRUE			不公开	分判定开启开关
SEC_SWON	BOOL		FALSE			不公开	秒判定开启开关

- The following parameter configuration faults will trigger "ERR" to become TRUE and output "OUT" to become FALSE.

1. The year check switch is enabled, and the set year is less than 1970.
2. The month check switch is enabled, and the set month is outside the range [1,12].
3. The day check switch is enabled, and the set day exceeds the number of days in the specified month of the year, such as setting 30 for February.
4. The hour check switch is enabled, and the set hour is outside the range [0, 23].
5. The minute check switch is enabled, and the set minute is outside the range [0, 59].
6. The second check switch is enabled, and the set second is outside the range [0, 59].

◦ **Weekday-based setting**

- Set times support weekdays.

SWOPT	BOOL		TRUE			

	Mon_Start	TIME_OF_DAY					不公开	星期一的起始设定时间
	Mon_End	TIME_OF_DAY					不公开	星期一的停止设定时间
	Tue_Start	TIME_OF_DAY					不公开	星期二的起始设定时间
	Tue_End	TIME_OF_DAY					不公开	星期二的停止设定时间
	Wed_Start	TIME_OF_DAY					不公开	星期三的起始设定时间
	Wed_End	TIME_OF_DAY					不公开	星期三的停止设定时间
	Thur_Start	TIME_OF_DAY					不公开	星期三的起始设定时间

	Fri_End	TIME_OF_DAY		TOD#0:0:0			不公开	星期五的停止设定时间
	Sat_Start	TIME_OF_DAY		TOD#0:0:0			不公开	星期六的起始设定时间
	Sat_End	TIME_OF_DAY		TOD#0:0:0			不公开	星期六的停止设定时间
	Sun_Start	TIME_OF_DAY		TOD#0:0:0			不公开	星期日的起始设定时间
	Sun_End	TIME_OF_DAY		TOD#0:0:0			不公开	星期日的停止设定时间

- For example, in a sequential control process, the equipment may need to start at different times during the week and stop at other times. Additionally, two other equipment may need to operate simultaneously with the main motor at fixed times each week. All of these can be achieved through this function block.

- When the start time is set later than the end time, "ERR" becomes TRUE and "OUT" becomes FALSE.

- **Program example**

  Turn on the device at the fixed time 2024-9-24-3:13, and after reaching the set time, "OUT" becomes TRUE.

ET	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–

- **Function**

  Accumulates the period of time during which the timer input "IN" is TRUE.

  When "RESET" is FALSE, the timer starts when "IN" changes from FALSE to TRUE, and the accumulated time "ET" increases simultaneously as time elapses.

  When "IN" changes from TRUE to FALSE, the timer stops. The value of "ET" at that moment is retained. When "IN" becomes TRUE again, the timer starts again.

  "ET" starts increasing from the retained value. When "ET" reaches the set time "PT", the timer output "Q" becomes TRUE. At this point, "ET" stops increasing.

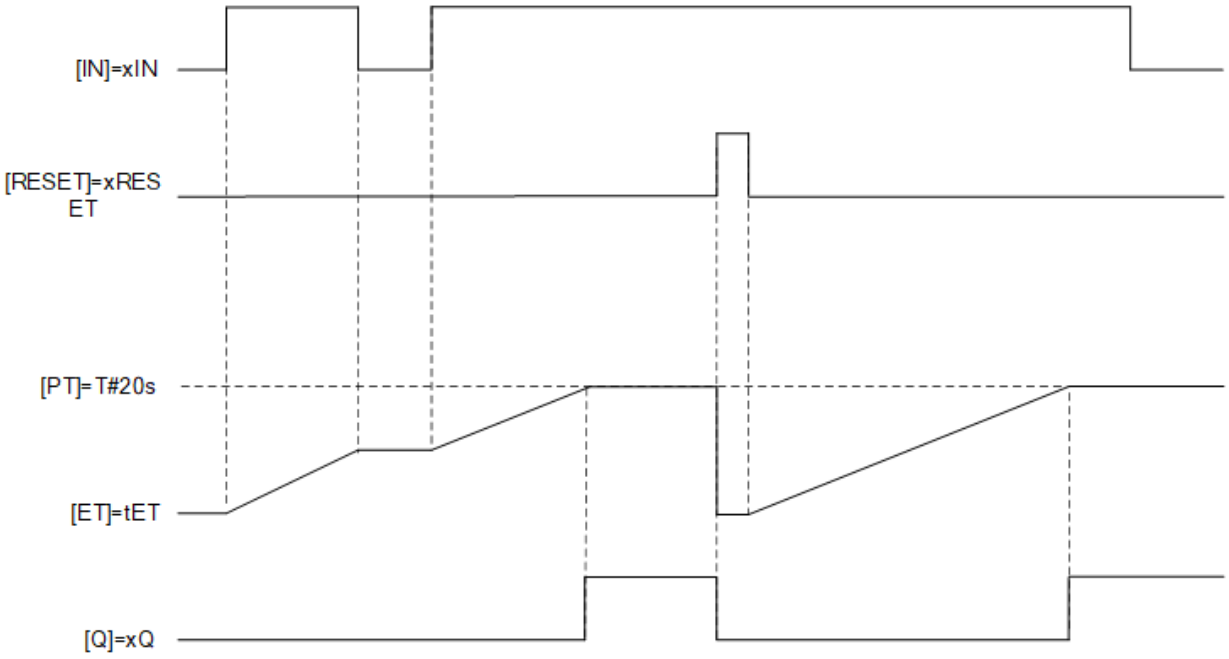
  When "RESET" becomes TRUE, the timer resets. The value of "ET" becomes 0, and "Q" becomes FALSE.

- **Program example**

  - The following example sets "PT" to T#20s.

	LD	ST
Variable definition		
Program		

```
VAR
    AccumulationTimer_Instance_0: AccumulationTimer;
    xIN: BOOL := FALSE;
    tPT: TIME := TIME#15ms;
    xRESET: BOOL := FALSE;
    xQ: BOOL;
    tET: TIME;
END_VAR
```



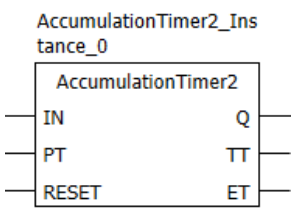
```
AccumulationTimer_Instance_0(
IN := xIN,
PT := tPT,
RESET := xRESET,
Q => xQ,
ET => tET);RETURN
```

	LD	ST
Operation result		

Name	Data type	Address	Value
AccumulationTimer_Instance_0	AccumulationTimer		
xIN	BOOL		TRUE
tPT	TIME		T#20s
xRESET	BOOL		FALSE
xQ	BOOL		TRUE
tET	TIME		T#20s

- The timing diagram when "PT" = T#20s is shown in the figure below. When "RESET" is FALSE and the accumulated time reaches 20s, the value of "Q" becomes TRUE. When "RESET" is set to TRUE, "ET" and "Q" are reset.

- **Precautions**
  - "ET" and "Q" are updated when this instruction is executed. Strictly speaking, the condition for "Q" to become TRUE is not the moment when the accumulated timer operation time reaches "PT". Instead, it is the moment when the accumulated timer operation time reaches "PT", and this instruction is executed for the first time after that. Therefore, a maximum delay of one task cycle may occur.
  - "PT" and "ET" are set in milliseconds, with a timing accuracy of 1 ms.
  - When both "IN" and "RESET" become TRUE, "RESET" takes priority. That is, the value of "ET" becomes 0, and "Q" becomes FALSE.
  - If the value of "IN" is already TRUE when execution starts, timing begins from that moment.
  - When "PT" is set to T#0ms, "Q" becomes TRUE immediately after the value of "IN" becomes TRUE.
  - If the MainTask cycle time of the system is greater than "PT", the value of "ET" equals the task cycle time. After one task cycle completes, the value of "Q" becomes TRUE.
  - Before the value of "ET" reaches the value of "PT", "PT" can be modified, and the following actions will occur.



Timer Status	Value of "Q"	New Value of PT	Action
After timing	TRUE	-	The value of "Q" remains TRUE. The value of "ET" does not change and remains at the value of "PT" before it is modified.
During timing	FALSE	"PT" ≥ "ET"	When the value of "IN" becomes TRUE, timing continues. When the value of "ET" reaches the new value of "PT", the value of "Q" becomes TRUE, and "ET" stops increasing.
		"PT" < "ET"	When the value of "IN" becomes TRUE, the value of "Q" immediately becomes TRUE. "ET" also immediately stops increasing.

- After the operation is stopped via the user interface, "ET" and "Q" will continue their calculations.
- For "PT", the timing error which "Q" is TRUE ranges from -100 ns to (100 ns + 1 task cycle). Details of the above range are shown below.
  - ±100 ns is the timing error for "ET".
  - For each task cycle, "ET" is judged to check if it reaches "PT". If "ET" reaches "PT", there is a delay of one task cycle.

18.1.9.13 AccumulationTimer2

Accumulation timer. The timer output can be modified during timing.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AccumulationTimer2	Accumulating timer	FB		AccumulationTimer2_Instance_0(IN := , PT := , RESET := , Q => , TT => , ET =>);

- **Related variables**

  Variable

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Input signal	Follows data type.	FALSE	TRUE: Timer is active. FALSE: Timer is stopped.
	PT	Set time	Follows data type	0	Set time
	RESET	Reset a bit	Follows data type	FALSE	TRUE: Timer is reset. FALSE: Timer is not reset.
Output	Q	Timing completion signal	Follows data type	FALSE	Timing completion signal TRUE when "ET" is equal to or greater than PT.
	TT	Timing in progress	Follows data type	FALSE	TRUE during timing; FALSE when not timing or when timing is complete.
	ET	Accumulated time	Follows data type	0	Accumulated time. Modifying "ET" during timing takes effect immediately.

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
IN	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
PT	-	-	-	-	-	-	-	-	-	-	-	√	-	-	-	-	-	-	-	-
RESET	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Q	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
TT	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
ET	-	-	-	-	-	-	-	-	-	-	-	√	-	-	-	-	-	-	-	-

- **Function**
  - The accumulating timer calculates the total duration for which the timer input signal "IN" is TRUE. "PT" and "ET" are set in ms.
  - When "RESET" is FALSE, the timer starts when "IN" changes from FALSE to TRUE. During timing, "TT" is set to TRUE, and the accumulated time "ET" increases over time.
  - When "IN" transitions from TRUE to FALSE, the timer stops but retains the "ET" value at that moment. When "IN" becomes TRUE again, the timer starts again.

- "ET" starts increasing from the retained value. When "ET" reaches the set time "PT", the timer output "Q" becomes TRUE. At this point, "ET" stops increasing.
- When "RESET" becomes TRUE, the timer resets. "ET" becomes 0, and "TT" and "Q" become FALSE.
- When modifying the "ET" parameter, the internal "ET" timing value must be forcibly written via the Set accessor of the ModifyET property.

- **Timing diagram**

  Set "PT" to 5000. When "RESET" is FALSE and the accumulated time for variable "IN" being TRUE reaches 5000 ms, variable "Q" becomes TRUE. When "RESET" is set to TRUE, "ET" and "Q" are reset. During timer operation, if "ET" is modified to 0, "ET" starts increasing from the set value.

- **Program example**

  ST:

  - When input signal "IN" is FALSE.

	Name	Type	Address	Value
1	AccumulationTimer2_Instance_0	AccumulationTimer2		
2	xIN	BOOL		FALSE
3	dPT	DINT		5000
4	xRESET	BOOL		FALSE
5	xQ	BOOL		FALSE
6	xTT	BOOL		FALSE
7	dET	DINT		0
8	Mod_ET	BOOL		FALSE
9	dET_Mod	DINT		0
10	R_TRIG_Instance_0	R_TRIG		

```
AccumulationTimer2_Instance_0(
IN FALSE := xIN FALSE ,
PT 5000 := dPT 5000 ,
RESET FALSE := xRESET FALSE ,
Q FALSE => xQ FALSE ,
TT FALSE => xTT FALSE ,
ET 0 => dET 0 );

R_TRIG_Instance_0(
CLK FALSE := Mod_ET FALSE ,
Q => );

IF R_TRIG_Instance_0.Q FALSE THEN
    AccumulationTimer2_Instance_0.ModifyET := dET_Mod 0 ;
END_IFRETURN
```

  - When input signal "IN" transitions from FALSE to TRUE, during "ET" timing.

	Name	Type	Address	Value
1	AccumulationTimer2_Instance_0	AccumulationTimer2		
2	xIN	BOOL		TRUE
3	dPT	DINT		5000
4	xRESET	BOOL		FALSE
5	xQ	BOOL		FALSE
6	xTT	BOOL		TRUE
7	dET	DINT		2210
8	Mod_ET	BOOL		FALSE
9	dET_Mod	DINT		0
10	R_TRIG_Instance_0	R_TRIG		

```
AccumulationTimer2_Instance_0(
IN TRUE := xIN TRUE ,
PT 5000 := dPT 5000 ,
RESET FALSE := xRESET FALSE ,
Q FALSE => xQ FALSE ,
TT TRUE => xTT TRUE ,
ET 2210 => dET 2210 );

R_TRIG_Instance_0(
CLK FALSE := Mod_ET FALSE ,
Q => );

IF R_TRIG_Instance_0.Q FALSE THEN
    AccumulationTimer2_Instance_0.ModifyET := dET_Mod 0 ;
END_IFRETURN
```

- During "ET" timing, the rising edge of Mod_ET serves as the modification trigger signal. The set value dET_Mod is forcibly written to the timer's internal "ET" timing value via the Set accessor of the ModifyET property.

	Name	Type	Address	Value
1	AccumulationTimer2_Instance_0	AccumulationTimer2		
2	xIN	BOOL		TRUE
3	dPT	DINT		5000
4	xRESET	BOOL		FALSE
5	xQ	BOOL		FALSE
6	xTT	BOOL		TRUE
7	dET	DINT		1170
8	Mod_ET	BOOL		TRUE
9	dET_Mod	DINT		0
10	R_TRIG_Instance_0	R_TRIG		

```
AccumulationTimer2_Instance_0(
IN TRUE := xIN TRUE ,
PT 5000 := dPT 5000 ,
RESET FALSE := xRESET FALSE ,
Q FALSE => xQ FALSE ,
TT TRUE => xTT TRUE ,
ET 1170 => dET 1170 );

R_TRIG_Instance_0(
CLK TRUE := Mod_ET TRUE ,
Q => );

IF R_TRIG_Instance_0.Q FALSE THEN
    AccumulationTimer2_Instance_0.ModifyET := dET_Mod 0 ;
END_IFRETURN
```

- "ET" timing is complete.

	Name	Type	Address	Value
1	AccumulationTimer2_Instance_0	AccumulationTimer2		
2	xIN	BOOL		TRUE
3	dPT	DINT		5000
4	xRESET	BOOL		FALSE
5	xQ	BOOL		TRUE
6	xTT	BOOL		FALSE
7	dET	DINT		5000

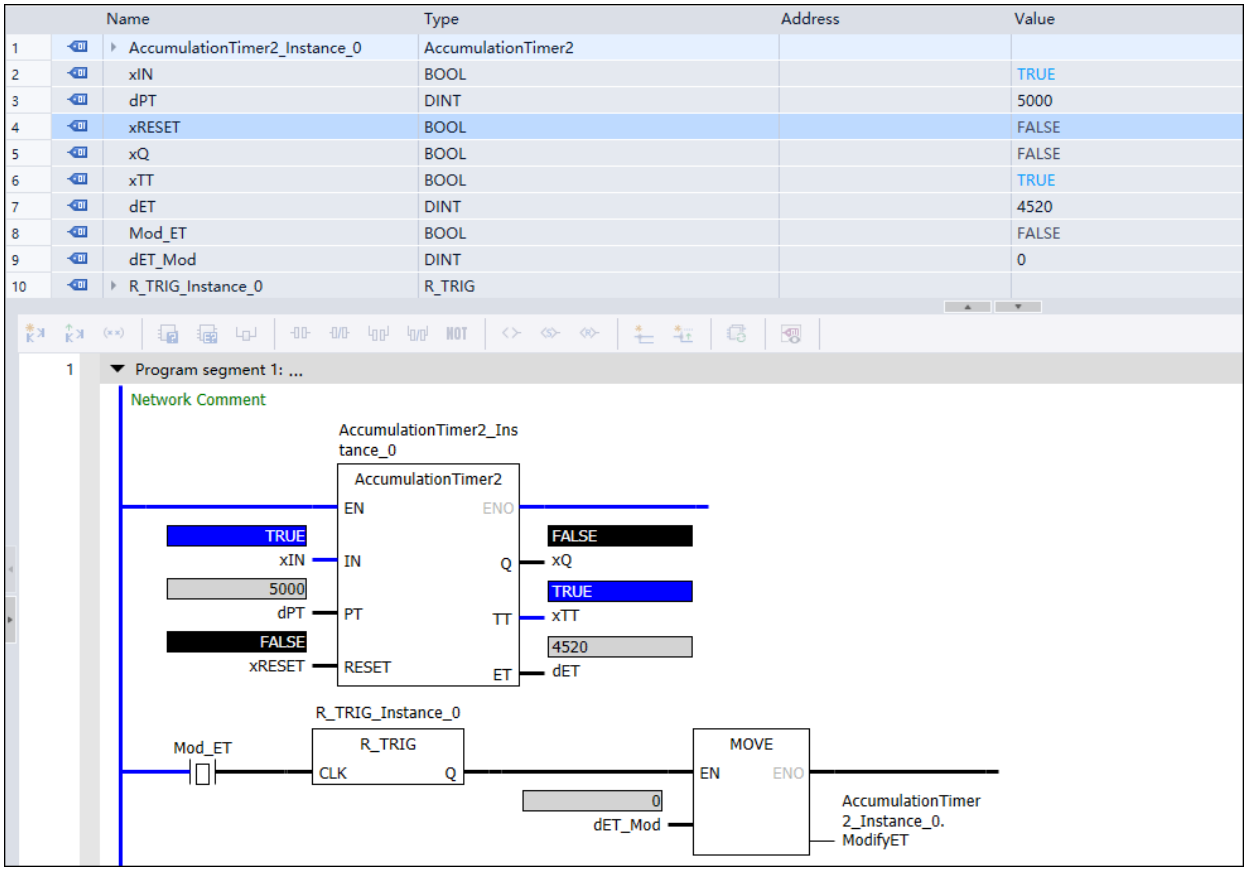
CLK  TRUE   := Mod_ET  TRUE  ,
Q => );

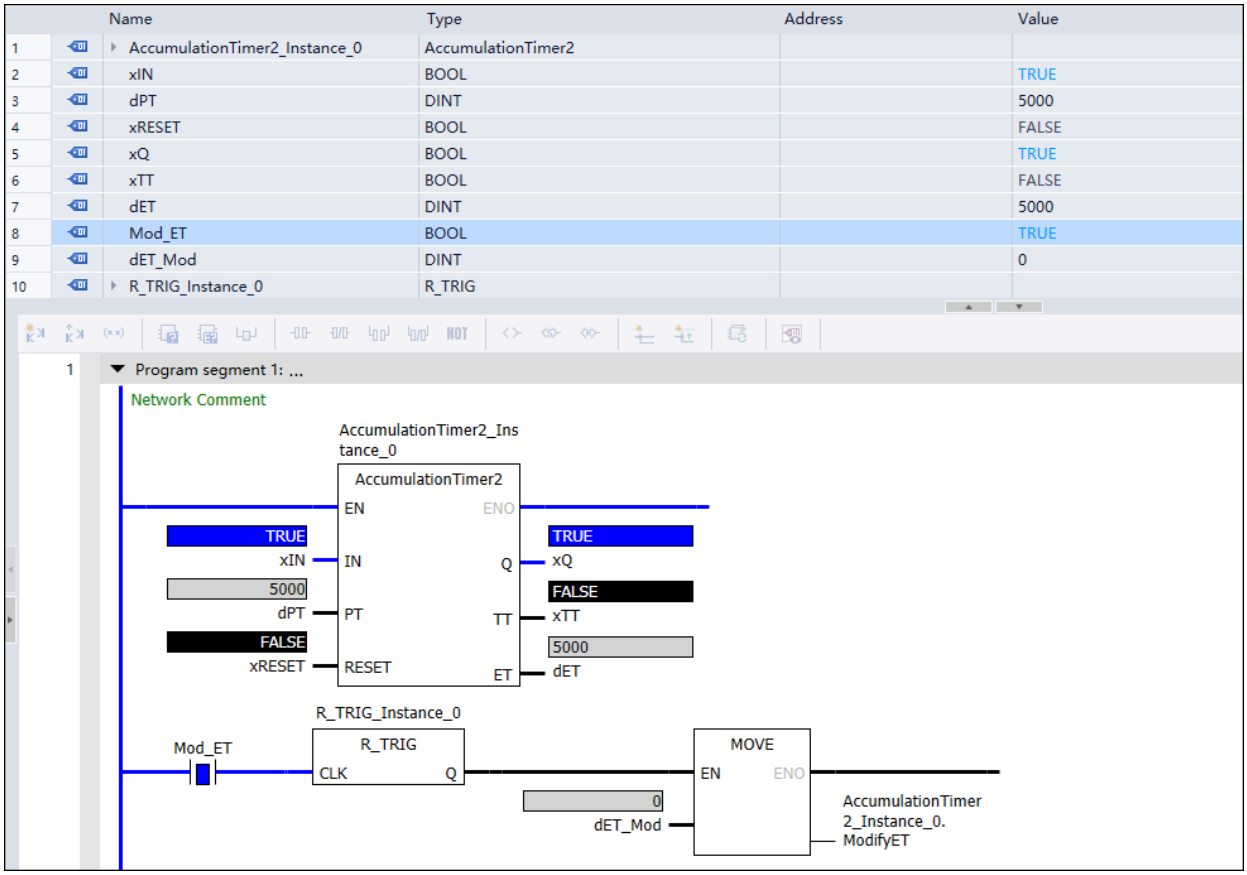
IF R_TRIG_Instance_0.Q  FALSE  THEN
    AccumulationTimer2_Instance_0.ModifyET := dET_Mod      0      ;
END_IFRETURN
```



LD:

◦ When input signal "IN" is FALSE.

	Name	Type	Address	Value
1	AccumulationTimer2_Instance_0	AccumulationTimer2		
2	xIN	BOOL		FALSE
3	dPT	DINT		5000
4	xRESET	BOOL		FALSE
5	xQ	BOOL		FALSE
6	xTT	BOOL		FALSE
7	dET	DINT		0
8	Mod_ET	BOOL		FALSE
9	dET_Mod	DINT		0
10	R_TRIG_Instance_0	R_TRIG		



◦ When input signal "IN" transitions from FALSE to TRUE, during "ET" timing.

◦ During "ET" timing, the rising edge of Mod_ET serves as the modification trigger signal. The set value dET_Mod is forcibly written to the timer's internal "ET" timing value via the Set accessor of the ModifyET property.

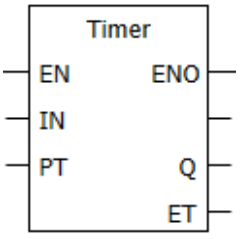
◦ "ET" timing is complete.

- **Precautions**
  - When both "IN" and "RESET" become TRUE, "RESET" takes priority, meaning the value of "ET" becomes 0 and "Q" becomes FALSE.
  - If the value of "IN" is already TRUE when execution starts, timing begins from that moment.
  - When "PT" is set to 0, "Q" becomes TRUE immediately after the value of "IN" becomes TRUE.
  - If the system cycle time of the system is greater than "PT", the value of "ET" equals the task cycle time. After one task cycle completes, the value of "Q" becomes TRUE.
  - When the input for the delay time "PT" or the current timing time "ET" is less than 0, it is automatically corrected to 0 for operation.
  - Before "ET" reaches "PT", the value of "ET" can be changed. The following actions will occur.

Timer Status	Value of "Q"	New Value of PT	Action
Before timing	FALSE	-	When the value of "IN" becomes TRUE, "ET" starts increasing from 0, and the modified value does not take effect.
After timing	TRUE	-	The value of "Q" remains TRUE, and the value of "ET" changes (the timer does not run).
Timing in progress/ stopped	FALSE	"PT" ≥ "ET"	When the value of "IN" becomes TRUE, timing restarts based on the modified value of "ET". When the value of "ET" reaches the value of "PT", the value of "Q" becomes TRUE, and "ET" stops increasing.

Timer Status	Value of "Q"	New Value of PT	Action
		PT < ET	When the value of "IN" becomes TRUE, the value of "Q" immediately becomes TRUE, and "ET" immediately stops increasing.

- Before the value of "ET" reaches the value of "PT", "PT" can be modified, and the following actions will occur.



Timer Status	Value of "Q"	New Value of PT	Action
After timing	TRUE	-	The value of "Q" remains TRUE, and the value of "ET" also remains unchanged (retaining the "PT" value before the change).
Timing in progress/ stopped	FALSE	"PT" ≥ "ET"	When the value of "IN" becomes TRUE, timing continues. When the value of "ET" reaches the new value of "PT", the value of "Q" becomes TRUE, and "ET" stops increasing.
		"PT" < "ET"	When the value of "IN" becomes TRUE, the value of "Q" immediately becomes TRUE. "ET" also immediately stops increasing.

- When "Q" becomes TRUE, the timing error range for "PT" is -100 ns to (100 ns + one task cycle). This error range includes the following cases:
  - ±100 ns is the timing error for "ET".
  - For each task cycle, "ET" is judged to check if it reaches "PT". If "ET" reaches "PT", there is a delay of one task cycle.
- "ET" and "Q" are updated when this instruction is executed. Strictly speaking, the condition for "Q" becoming TRUE is not when the cumulative time of the timer equals "PT", but rather when the cumulative time reaches "PT" and the current instruction is executed for the first time. Therefore, a maximum delay of one task cycle may occur.

18.1.9.14 Timer

100-ms timer.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
Timer	100-ms timer	FC		:= Timer(IN := , PT := , Q => , ET =>);

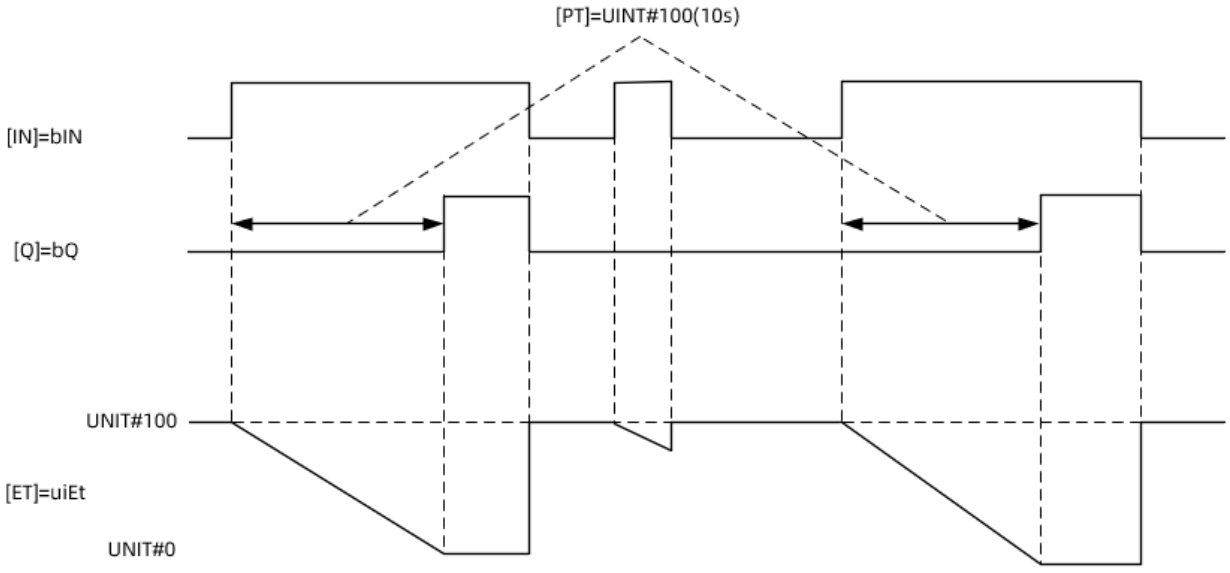
- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Timer input	Follows data type	-	TRUE: Timer is active. FALSE: Timer is stopped.
	PT	Set time	Follows data type	-	Maximum value for timing, in increments of 100 ms
Output	Q	Timer output	Follows data type	-	TRUE: "ET" reaches "PT". FALSE: "ET" has not reached "PT".
	ET	Remaining time	Follows data type	-	Remaining time

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
IN	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
PT	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
Q	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
ET	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–



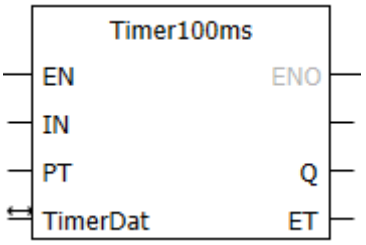
- **Function**
  - This instruction outputs TRUE when the set time elapses after the timer starts. The time is set in increments of 100 ms.
  - The timer is reset when timer input value of "IN" changes to FALSE. Remaining time "ET" is set to set time "PT", and timer output "Q" changes to FALSE. The timer starts when "IN" changes to TRUE. The value of "ET" is constantly decremented as time elapses. When "ET" reaches 0, timer output "Q" changes to TRUE. ET is not decremented after that. The timer is reset if "IN" changes to FALSE after the timer starts but before "ET" reaches 0.
- **Sequence diagram**
  - The following table shows an example when "PT" = UINT#100.

<table>
<tr><th></th><th>LD</th><th>ST</th></tr>
<tr><td>Define variables</td><td colspan="2">
<pre>
VAR
    bResult: BOOL;
    bIN: BOOL := TRUE;
    uiPT: UINT := 100;
    bQ: BOOL;
    uiET: UINT;
END_VAR
</pre>
</td></tr>
<tr><td>Program</td><td>

</td><td>
<pre>
bResult TRUE := Timer(IN := bIN TRUE,
        PT := uiPT 100,
        Q => bQ TRUE,
        ET => uiET 0);RETURN
</pre>
</td></tr>
<tr><td>Simulation results</td><td colspan="2">

</td></tr>
</table>

- The timing diagram when "PT" = UINT#100 is shown in the figure below. The value of "Q" becomes TRUE 10s after "IN" becomes TRUE, and the value of "ET" decreases to 0.



- **Precautions**
  - If multiple timers are called within the same POU program block, program faults may occur.
  - There is a one-task-cycle delay for "Q" to become TRUE after the timer reaches "PT". The timer checks at each task cycle whether "ET" has reached "PT". If so, "Q" is set to TRUE after a delay of one task cycle.
  - The timer starts as soon as operation starts if the value of "IN" has been TRUE.
  - If the value of "PT" changes, the new value needs to be used from the next time when the timer is reset. It does not take effect while timing is in progress.

18.1.9.15 Timer100ms

100-ms timer.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
Timer100ms	100-ms timer	FC		:= Timer100ms(IN := , PT := , TimerDat := , Q => , ET =>);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input/Output	TimerDat	Timer status	-	-	Current status of the timer
Input	IN	Timer input	TRUE, FALSE	-	TRUE: Timer is active. FALSE: Timer is stopped.
	PT	Set time	Follows data type	-	Elapsed time from timer start to "Q" being TRUE, measured in 100-ms units.
Output	Q	Timer output	TRUE, FALSE	-	TRUE: Timer execution completed. FALSE: Timer execution not completed.
	ET	Remaining time	Follows data type	-	"ET" = "PT" - elapsed time. "ET" is not less than 0, measured in 100-ms units.

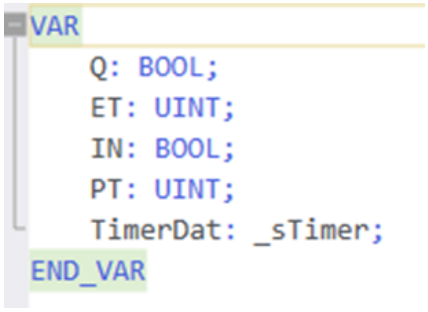
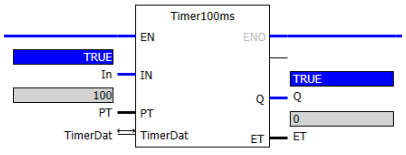
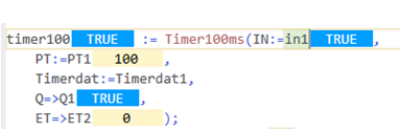
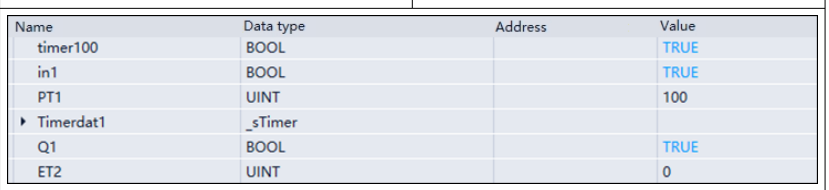
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
PT	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
Q	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
ET	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–









- **Function description**

  This instruction implements a timer function that outputs TRUE after a preset time from timer start. The specific principle is as follows:

  - When "IN" is set to TRUE, the timer starts, and the remaining time (ET) begins to decrease continuously from the preset time (PT) until "ET" reaches 0, at which point the timer output (Q) becomes TRUE.
  - If "IN" is set to FALSE during timer operation, the timer resets, the output remaining time becomes "PT", and the output becomes FALSE; when "IN" is set to TRUE again, the timer restarts.

- **Sequence diagram**

  - The following table shows an example when "PT" = UINT#100.

	LD	ST
Define variables		
Program		
Operation result		

  - The timing diagram when "PT" = UINT#100 is shown in the figure below. The value of "Q" becomes TRUE 10s after "IN" becomes TRUE, and the value of "ET" decreases to 0.

- **Notes**
  - Multiple instances of this instruction can be called simultaneously.
  - The TimerDat parameter must be passed a variable that has not been initialized; it is prohibited to share the same TimerDat variable among multiple instructions.
  - When "IN" is set to TRUE, timing starts immediately. If the instruction is not executed due to program reasons, "ET" is not updated, but timing continues. When the instruction is executed, "ET" becomes the time elapsed since the start.
    For example: When the instruction (PT = 10s) is executed 5s after "IN" is set to TRUE, "ET" remains at 10s during this period and becomes 5s upon execution.
  - During the execution of this instruction, changes to "PT" are not effective; the modified "PT" will take effect the next time this instruction is executed.

OUT	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√

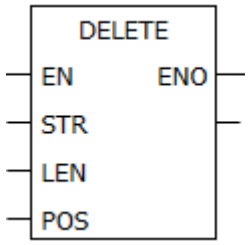
- **Function description**

  Concatenates input strings STR1 and STR2, and outputs the result.

- **Program example**

  ST:

  LD:



- **Precautions**

  If the length of the concatenated string exceeds 1985, the string will be truncated.

18.1.10.3 DELETE

Deletes a specified-length string at a specified position from the input string, and outputs the processed string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
DELETE	String deletion	FC		:= DELETE(STR := , LEN := , POS :=);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	STR	Source data	Follows data type	-	Source data
	LEN	Data length	Follows data type	-	Data length
	POS	Data position	Follows data type	-	Data position
Output	OUT	Return value	Follows data type	-	Target string

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
STR	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√

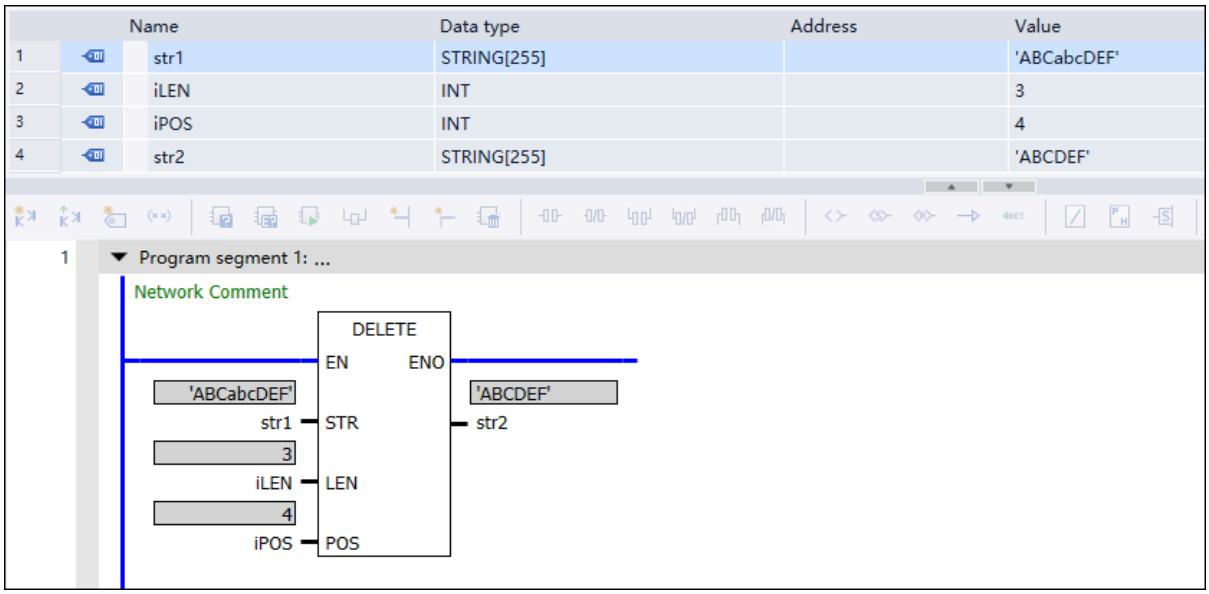
POS	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–
OUT	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√

- **Function description**

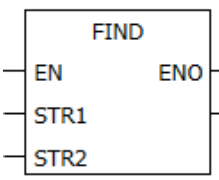


Deletes a string of length LEN from position POS in the input string STR, and generates a new string as the return value.

- **Program example**

ST:

LD:



- **Precautions**

If POS = 0, deletion starts from the first character.

18.1.10.4 FIND

Searchs for the position of the target string within the input source string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
FIND	Get index of string in searched string	FC		:= FIND(STR1 := , STR2 :=);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	STR1	Source data 1	Follows data type	-	Source data

Input/Output	Variable	Name	Valid Range	Default Value	Description
	STR2	Source data 2	Follows data type	-	Target string
Output	OUT	Return value	Follows data type	-	Position of the target string within the source data

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
STR1	_	_	_	_	_	_	_	_	_	_	_	_	_	_	_	_	_	_	_	√
STR2	_	_	_	_	_	_	_	_	_	_	_	_	_	_	_	_	_	_	_	√
OUT	_	_	_	_	_	_	_	_	_	_	√	_	_	_	_	_	_	_	_	_

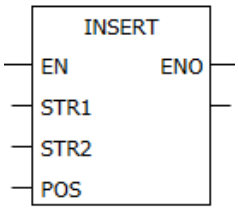
- **Function**

  Searchs for string STR2 within the input string STR1 and returns the position of the first character of STR2 in STR1.

- **Program example**

  ST:

  LD:



- **Precautions**
  - If the target string does not exist, the return value is 0.
  - The maximum supported string length is 1985.

18.1.10.5 INSERT

Inserts a string at the specified position in the input source string, and outputs the result string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
INSERT	String insertion	FC		:= INSERT(STR1 := , STR2 := , POS :=);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	STR1	Source data	Follows data type	-	Source data 1
	STR2	Source data	Follows data type	-	Source data 2
	POS	Insertion position	Follows data type	-	Data position
Output	OUT	Return value	Follows data type	-	Result string

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
STR1	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
STR2	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
POS	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–
OUT	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√

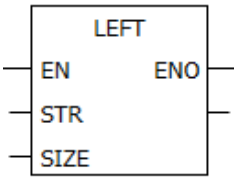
- **Function description**

  Inserts STR2 after the POS-th character of input string STR1, and generates a new string as the output.

- **Program example**

  ST:

  LD:



- **Precautions**
  - If POS equals 0, STR2 is inserted before STR1.

- The maximum supported string length is 1985.
- If POS is greater than the string length, the output result is the data corresponding to STR1.

18.1.10.6 LEFT

Returns the string of the specified length from the left of the source string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
LEFT	Return string from left	FC		:= LEFT(STR := , SIZE :=);

- **Related variable**

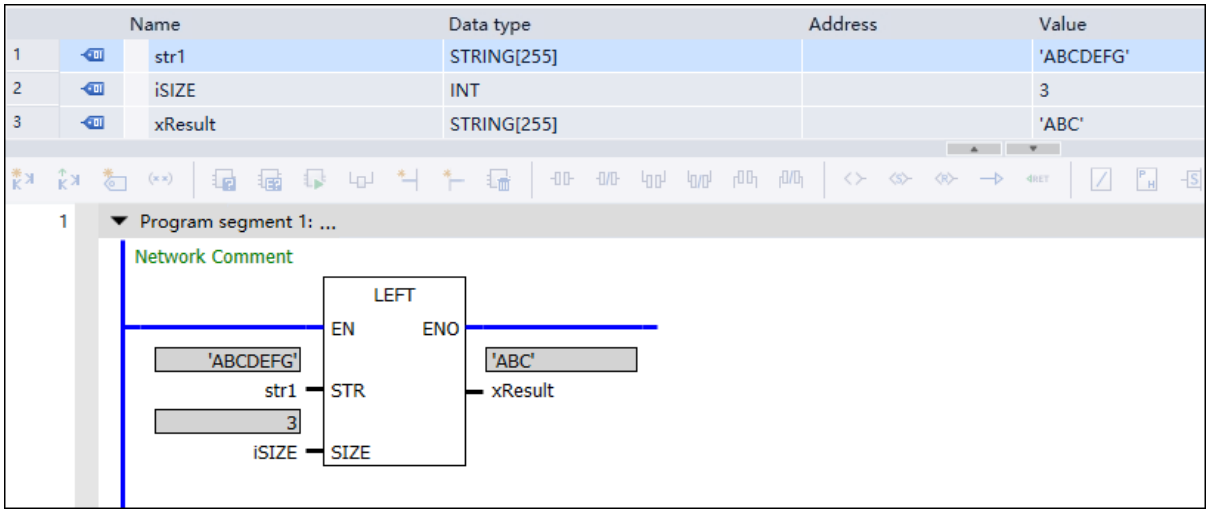
Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	STR	Source data	Follows data type	-	Source data
	SIZE	Data length	Follows data type	-	Data length
Output	OUT	Return value	Follows data type	-	Target string

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
STR	_	_	_	_	_	_	_	_	_	_	_	_	_	_	_	_	_	_	_	√
SIZE	_	_	_	_	_	_	_	_	_	_	√	_	_	_	_	_	_	_	_	_
OUT	_	_	_	_	_	_	_	_	_	_	_	_	_	_	_	_	_	_	_	√

- **Function description**

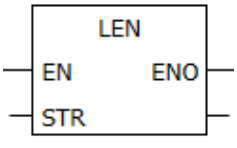


Takes a string from the left of STR and returns the string of the specified SIZE length.

- **Program example**

  ST:

  LD:



- **Precautions**
  - If the input SIZE is 0, the output string is empty.
  - The maximum supported string length is 1985.
  - If the input SIZE is greater than the length of the input string, the output string is the original input string.

18.1.10.7 LEN

Gets the number of characters in the target string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
LEN	Get string length	FC		:= LEN(STR :=);

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	STR	Source data	Follows data type	-	Target string

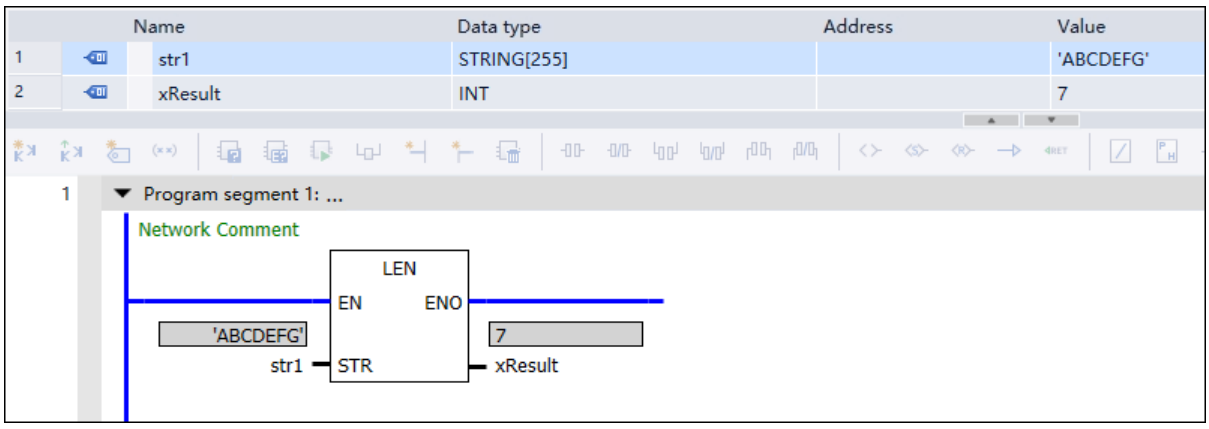
Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	OUT	Return value	Follows data type	-	Number of characters in the target string

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
STR	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
OUT	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–

- **Function**

  Gets the number of characters in the target string.



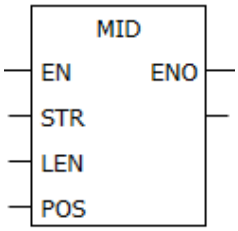
- **Program example**

  ST:

```
xResult := LEN(STR := str1);
RETURN
```

	Name	Data type	Address	Value
1	str1	STRING[255]		'ABCDEFG'
2	xResult	INT		7

  LD:



- **Precautions**
  - The maximum supported string length is 1985.
  - If the string size is not defined, the maximum string length is 80.

◦ Spaces within the string also occupy one character length.

18.1.10.8 MID

Gets a string of specified length from a specified position in the source string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
MID	Return string from middle	FC		:= MID(STR := , LEN := , POS :=);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	STR	Source data	Follows data type	-	Source data
	LEN	Data length	Follows data type	-	Data length
	POS	Target position	Follows data type	-	Position to extract string
Output	OUT	Return value	Follows data type	-	Target string

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
STR	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
LEN	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–
POS	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
OUT	_	_	_	_	_	_	_	_	_	_	_	_	_	_	_	_	_	_	-	√

- **Function description**

  Extracts a string of specified length LEN from the specified position POS in the input string STR as the output string.

- **Program example**

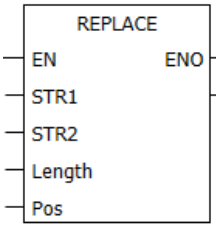
  ST:

	Name	Data type	Address	Value	Prepare va
1	str1	STRING[255]		'ABCDEFG'	
2	iLEN	INT		3	
3	iPOS	INT		2	
4	xResult	STRING[255]		'BCD'	

```
1  xResult := MID(STR := str1, LEN := iLEN, POS := iPOS);RETURN
```

  LD:

	Name	Data type	Address	Value
1	str1	STRING[255]		'ABCDEFG'
2	iLEN	INT		3
3	iPOS	INT		2
4	xResult	STRING[255]		'BCD'



- **Precautions**
  - The maximum supported string length is 1985.
  - If the specified position POS exceeds the string length, no output will be produced.
  - If the specified length LEN exceeds the remaining length of the input string from the specified position POS, the function behaves the same as RIGHT.

18.1.10.9 REPLACE

Replaces a portion of the original string with the target string, and returns the new string generated after the replacement.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
REPLACE	String replacement	FC		:= REPLACE(STR1 := , STR2 := , Length := , Pos :=);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	STR1	Source data 1	Max length: 255	-	Source data 1
	STR2	Source data 2	Max length: 255	-	Source data 2
	Length	Data length	Follows data type	-	Data length
	Pos	Data position	Follows data type	-	Data position
Output	OUT	Return value	Max length: 255	-	Target string

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
STR1	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
STR2	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
Length	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Pos	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–
OUT	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√

- **Function description**

  Replaces Length characters in STR1 starting at position Pos with STR2, and returns the new string after replacement.

- **Program example**

  ST:

  LD:

18.1.10.10 RIGHT

Returns the string of the specified length from the right of the source string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
RIGHT	Return string from right	FC		:= RIGHT(STR := , SIZE :=);

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	STR	Source data	Follows data type	-	Source data
	SIZE	Data length	0 to 255	-	Data length
Output	OUT	Return value	Follows data type	-	Target string

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
STR	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
SIZE	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–
OUT	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√

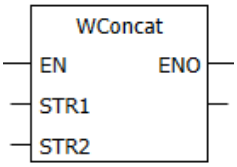
- **Function description**

  Takes a string from the right of STR and returns the string of the specified SIZE length.

- **Program example**

  ST:

LD:



- **Precautions**
  - If the input SIZE is 0, the output string is empty.
  - The maximum supported string length is 1985.
  - If the input SIZE is greater than the length of the input string, the output string is the original input string.

18.1.10.11 WConcat

Concatenates two wide strings and outputs from the right.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
WConcat	Wide string concatenation	FC		:= WConcat(STR1 := , STR2 :=);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	STR1	Source data 1	Max length: 1985	-	Source data 1
	STR2	Source data 2	Max length: 1985	-	Source data 2
Output	OUT	Return value	Max length: 1985	-	Concatenated string

Variable types

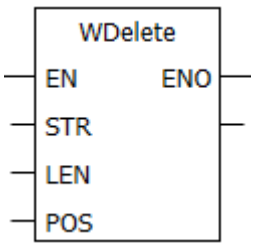
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String					
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
STR1	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
STR2	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
OUT	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√

- **Function description**

  Concatenates input wide strings STR1 and STR2, and outputs the result.

- **Program example**

  WConcat is similar to 18.1.10.2 CONCAT in the standard library, except that STR1, STR2, and UT change from STRING type to WSTRING type, thus providing a larger representation range.



- **Precautions**

  If the length of the concatenated wide string exceeds 1985, the string will be truncated.

18.1.10.12 WDelete

Deletes a specified-length string at a specified position from the input wide string, and outputs the processed wide string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
WDelete	Wide string deletion	FC		:= WDelete(STR := , LEN := , POS :=);

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	STR	Source data	Max length: 1985	-	Source data

Input/Output	Variable	Name	Valid Range	Default Value	Description
	LEN	Data length	Follows data type	-	Data length
	POS	Data position	Follows data type	-	Data position
Output	OUT	Return value	Max length: 1985	-	Target string

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String					
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
STR	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
LEN	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–
POS	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–
OUT	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√

- **Function description**

  Deletes a string of length LEN from position POS in the input wide string STR, and generates a new wide string as the return value.

- **Program example**

  WDelete is similar to 18.1.10.3 DELETE in the standard library, except that "STR" and "OUT" change from STRING type to WSTRING type, thus providing a larger representation range.

- **Precautions**
  - If POS = 0, deletion starts from the first character.
  - The maximum supported string length is 1985.

18.1.10.13 WFind

Searchs for the position of the target wide string within the input source wide string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
WFind	Wide string search	FC		:= WFind(STR1 := , STR2 :=);

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	STR1	Source data 1	Max length: 1985	-	Source data
	STR2	Source data 2	Max length: 1985	-	Target string
Output	OUT	Return value	Follows data type	-	Position of the target string within the source data

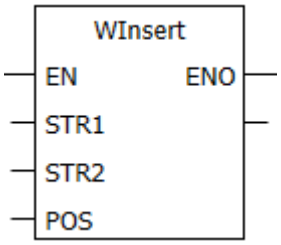
  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String					
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
STR1	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
STR2	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
OUT	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–

- **Function**

  Searchs for wide string STR2 within the input wide string STR1 and returns the position of the first character of STR2 in STR1.

- **Program example**



WFind is similar to 18.1.10.4 FIND in the standard library, except that STR1 and STR2 change from STRING type to WSTRING type, thus providing a larger representation range.

- **Precautions**
  - If the target string does not exist, the return value is 0.
  - The maximum supported string length is 1985.

18.1.10.14 WInsert

Inserts a string at the specified position in the input source wide string, and outputs the result string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
WInsert	Wide string insertion	FC		:= WInsert(STR1 := , STR2 := , POS :=);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	STR1	Source data 1	Max length: 1985	-	Source data 1
	STR2	Source data 2	Max length: 1985	-	Source data 2
	POS	Insertion position	Follows data type	-	Insertion position
Output	OUT	Return value	Max length: 1985	-	Result string

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String					
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
STR1	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√

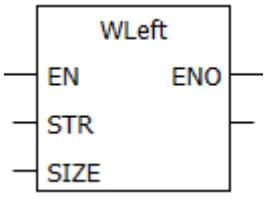
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String					
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
STR2	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
POS	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–
OUT	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√

- **Function description**

  Inserts STR2 after the POS-th character of the input wide string STR1, and generates a new wide string as the output.

- **Program example**

  WInsert is similar to 18.1.10.5 INSERT in the standard library, except that "STR1", "STR2", and "OUT" change from STRING type to WSTRING type, thus providing a larger representation range.



- **Precautions**

  - If POS = 0, then STR2 is inserted before STR1.
  - The maximum supported string length is 1985.
  - If POS is not less than the string length, the output result is the data corresponding to STR1.

18.1.10.15 WLeft

Returns the wide string of the specified length from the left of the source wide string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
WLeft	Return wide string from left	FC		:= WLeft(STR := , SIZE :=);

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	STR	Source data	Max length: 1985	-	Source data
	SIZE	Data length	Follows data type	-	Target string
Output	OUT	Return value	Max length: 1985	-	Target string

Variable types

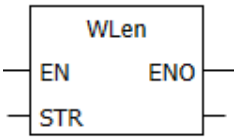
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String					
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
STR	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
SIZE	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–
OUT	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√

- **Function description**

  Takes a wide string from the left of STR and returns the string of the specified SIZE length.

- **Program example**

  WLeft is similar to 18.1.10.6 LEFT in the standard library, except that "STR" and "OUT" change from STRING type to WSTRING type, thus providing a larger representation range.



- **Precautions**

  - If the input SIZE is 0, the output string is empty.
  - The maximum supported string length is 1985.
  - If the input SIZE is greater than the length of the input string, the output string is the original input string.

18.1.10.16 WLen

Gets the number of characters in the target wide string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
WLen	Get the length of the input wide string.	FC		:= WLen(STR :=);

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	STR	Source data	Max length: 1985	-	Target string
Output	OUT	Return value	Follows data type	-	Number of characters in the target string

  Variable types

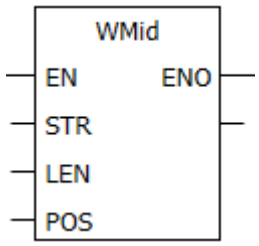
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String					
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
STR	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
OUT	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–

- **Function**

  Gets the number of characters in the target wide string.

- **Program example**

  WLen is similar to 18.1.10.7 LEN in the standard library, except that STR changes from STRING type to WSTRING type, thus providing a larger representation range.



- **Precautions**

  - If the string size is not defined, the maximum string length is 80.
  - Spaces within the string also occupy one character length.

18.1.10.17 WMid

Returns a wide string of specified length from a specified position in the source wide string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
WMid	Return wide string from middle	FC		:= WMid(STR := , LEN := , POS :=);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	STR	Source data	Max length: 1985	-	Source data
	LEN	Data length	Follows data type	-	Data length
	POS	Target position	Follows data type	-	Position to extract string
Output	OUT	Return value	Max length: 1985	-	Target string

Variable types

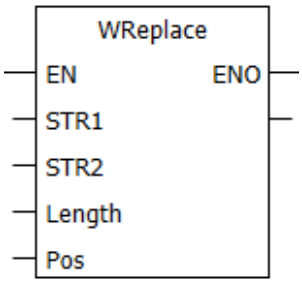
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String					
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
STR	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
LEN	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–
POS	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–
OUT	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√

- **Function description**

Extracts a wide string of specified length LEN from the specified position POS in the input wide string STR as the output string.

- **Program example**

  WMid is similar to 18.1.10.8 MID in the standard library, except that "STR" and "OUT" change from STRING type to WSTRING type, thus providing a larger representation range.



- **Precautions**

  - If the specified position POS exceeds the string length, no output will be produced.
  - If the specified length LEN exceeds the remaining length of the input string from the specified position POS, the function behaves the same as WRight.

18.1.10.18 WReplace

Replaces a portion of the original wide string with the target wide string, and returns the new wide string generated after the replacement.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
WReplace	Wide string replacement	FC		:= WReplace(STR1 := , STR2 := , Length := , Pos :=);

- **Related variable**

  Variable

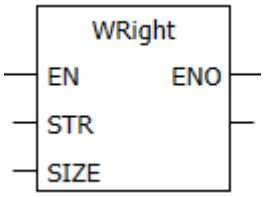
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	STR1	Source data 1	Max length: 1985	-	Source data 1
	STR2	Source data 2	Max length: 1985	-	Source data 2
	Length	Data length	0 to 1985	-	Data length
	Pos	Data position	0 to 1985	-	Data position
Output	OUT	Return value	Max length: 1985	-	Target string

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String					
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
STR1	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
STR2	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
Length	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–
Pos	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–
OUT	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√

- **Function description**

  Replaces Length characters in STR1 starting at position Pos with STR2, and returns the new wide string after replacement.



- **Program example**

  WReplace is similar to 18.1.10.9 REPLACE in the standard library, except that "STR1", "STR2", and "OUT" change from STRING type to WSTRING type, thus providing a larger representation range.

18.1.10.19 WRight

Returns the wide string of the specified length from the right of the source wide string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
WRight	Return wide string from right	FC		:= WRight(STR := , SIZE :=);

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	STR	Source data	Max length: 1985	-	Source data
	SIZE	Data length	Follows data type	-	Data length
Output	OUT	Return value	Max length: 1985	-	Target string

Variable types

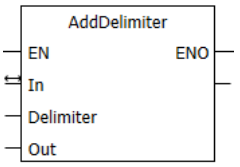
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String					
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
STR	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
SIZE	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–
OUT	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√

- **Function description**

  Takes a wide string from the right of STR and returns the string of the specified SIZE length.

- **Program example**

  WRight is similar to 18.1.10.10 RIGHT in the standard library, except that "STR" and "OUT" change from STRING type to WSTRING type, thus providing a larger representation range.



- **Precautions**

  - If the input SIZE is 0, the output string is empty.
  - If the input SIZE is greater than the length of the input string, the output string is the original input string.

18.1.10.20 AddDelimiter

Converts REAL-type array elements into a delimited string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AddDelimiter	Write REAL-type array elements into a delimited string	FC		:= AddDelimiter(In := , Delimiter := , Out :=);

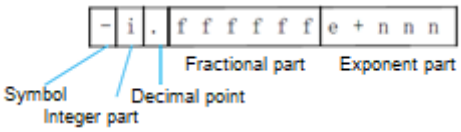
- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Delimiter	Delimiter	Follows data type	_COMMA	Delimiter
	Out	Delimited string	Max length: 1985	-	Delimited string
Input/Output	In[ ] array	Input array	Follows data type	-	Array for conversion

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In[ ] array	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
Delimiter	Enumeration type _eDELIMITER. For details, see function description for enumeration values.																			
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√



- **Function description**

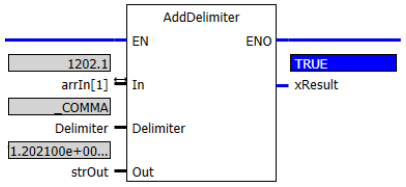
  - Converts "Size" elements of the input array "In" starting from In[0] into strings sequentially, then concatenates them with the delimiter "Delimiter". Outputs the concatenated string to the return value "Out", with a NULL character at the end.
  - The data type of "Delimiter" is the enumeration type _eDELIMITER, whose meanings are as shown in the following table.

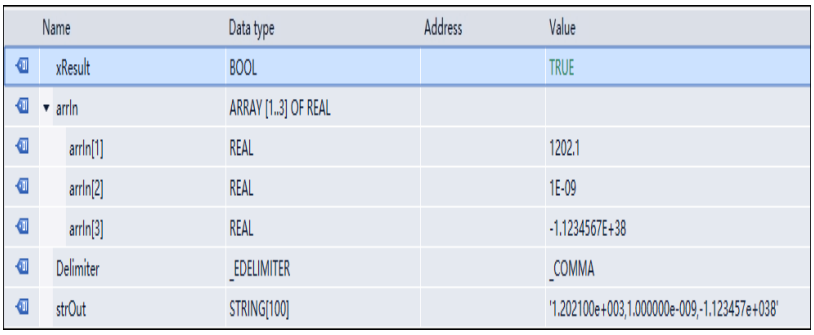
Enumerator	Definition
1 (_COMMA)	','
2 (_TAB)	'$T'
3 (_SEMICOLON)	';'

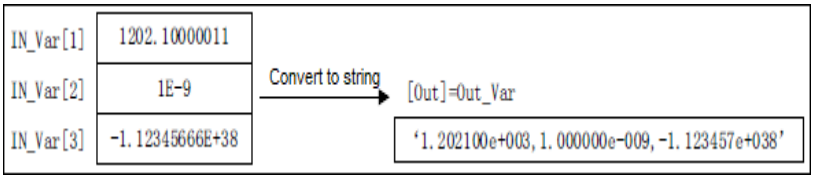
Enumerator	Definition
4 (_SPACE)	' '

◦ The return string after conversion is structured as shown below.

Item	Content
Symbol column	When the value of an array element is negative, "-" (minus sign) is added. When the value of an array element is positive, "+" (plus sign) is not added.
Integer part	Always represents with one digit.
Decimal point	Always represents the value of structural elements, even if not a decimal.
Fractional part	Represents with 6 digits.
Exponent	"e" represents the base "10" in scientific notation. The number of digits in nn is 3. When the absolute value of the array element value is greater than 1.0, the sign of nn is "+"; when the absolute value of the array element value is less than 1.0, the sign of nn is "-"; when the array element value is 0, the sign of nn is "+".







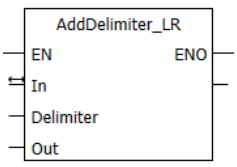
◦ When the array element value is infinity or non-numeric, the string is as shown in the table below.

Array Element Value	String
+∞	'infinity'
-∞	'-infinity'
Non-numeric	'nan'

◦ Examples are shown in the table below.

Array Element Value	Converted String
REAL#3.14e1	'3.140000e+001'
REAL#-123.4567	'-1.234567e+002'
REAL#0	'0.000000e+000'

- **Program example**



Item	LD	ST
Define variables	VAR xResult: BOOL; arrIn: ARRAY[1..3] OF REAL := [1202.100000000111,1E-9,-1.1234567E+38]; Delimiter: _eDELIMITER := _EDELIMITER._COMMA; strOut: STRING[100]; END_VAR	
Program		
Operation result		
Principle analysis		

- **Precautions**
  - When the byte length required for the conversion of the input "In" exceeds the defined byte length of output "Out", the actual output string consists of the maximum number of complete bytes that can be output within the defined byte length.
  - When the byte length required for the conversion of the input "In" exceeds 1985 (the maximum byte length defined for the output "Out"), the actual output string consists of the maximum number of complete bytes that can be output within a 1985-byte length.
  - The byte count of "Out" must not be less than 14; otherwise, the function returns FALSE, and the value of "Out" remains unchanged.

18.1.10.21 AddDelimiter_LR

Converts LREAL-type array elements into a delimited string.

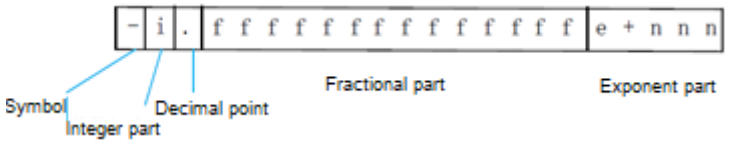
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AddDelimiter_LR	Write LREAL-type array elements into a delimited string	FC		:= AddDelimiter_LR(In := , Delimiter := , Out :=);

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Delimiter	Delimiter	Follows data type	_COMMA	Delimiter
	Out	Delimited string	Max length: 1985	-	Delimited string
Input/Output	In[ ] array	Input array	Follows data type	-	Array for conversion



Variable types

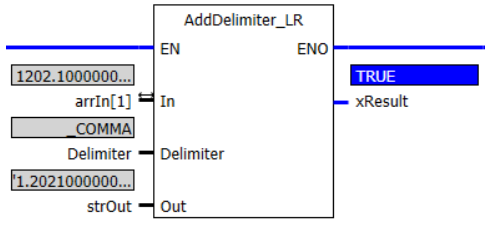
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In[ ] array	_	_	_	_	_	_	_	_	_	_	_	_	_	_	√	_	_	_	_	_
Delimiter	Enumeration type _eDELIMITER. For details, see function description for enumeration values.																			
Out	_	_	_	_	_	_	_	_	_	_	_	_	_	_	_	_	_	_	_	√

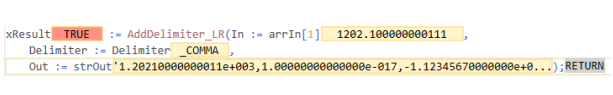
- **Function description**
  - Converts "Size" elements of the input array "In" starting from In[0] into strings sequentially, then concatenates them with the delimiter "Delimiter". Outputs the concatenated string to the return value "Out", with a NULL character at the end.
  - The data type of "Delimiter" is the enumeration type _eDELIMITER. The meaning of the enumeration is as shown in the following table.

Enumerator	Definition
1 (_COMMA)	','
2 (_TAB)	'$T'
3 (_SEMICOLON)	';'
4 (_SPACE)	' '

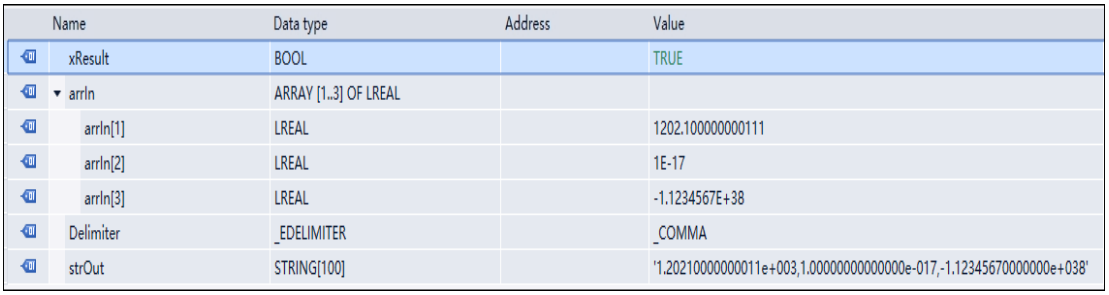
  - The return string after conversion is structured as shown below.

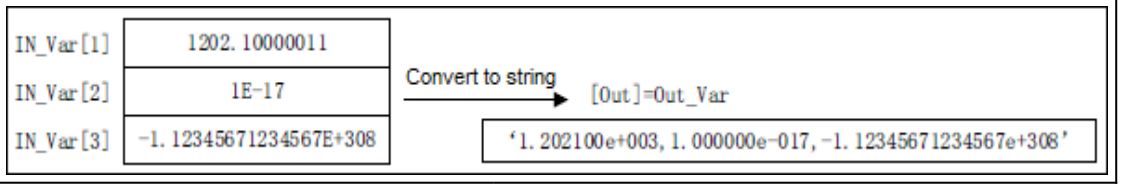
Item	Content
Symbol column	When the value of an array element is negative, "-" (minus sign) is added. When the value of an array element is positive, "+" (plus sign) is not added.
Integer part	Always represents with one digit.
Decimal point	Always represents the value of structural elements, even if not a decimal.
Fractional part	Represents with 14 digits.
Exponent	"e" represents the base "10" in scientific notation. The number of digits in nn is 3. When the absolute value of the array element value is greater than 1.0, the sign of nn is "+"; when the absolute value of the array element value is less than 1.0, the sign of nn is "-"; when the array element value is 0, the sign of nn is "+".





- When the array element value is infinity or non-numeric, the string is as shown in the table below.





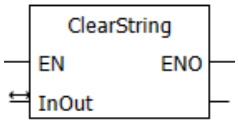
Array Element Value	String
+∞	'infinity'
-∞	'-infinity'
Non-numeric	'nan'

- Examples are shown in the table below.

Array Element Value	Converted String
LREAL#3.14e1	'3.14000000000000e+001'
LREAL#-123.4567	'-1.23456700000000e+002'
LREAL#0	'0.00000000000000e+000'

- **Program example**

Item	LD	ST
Define variables	VAR xResult: BOOL; arrIn: ARRAY[1..3] OF LREAL := [1202.100000000111,1E-17,-1.1234567E+38]; Delimiter: _eDELIMITER := _EDELIMITER._COMMA; strOut: STRING[100]; END_VAR	
Program		



Item	LD	ST
Operation result		
Principle analysis		

- **Precautions**
  - When the byte length required for the conversion of the input "In" exceeds the defined byte length of output "Out", the actual output string consists of the maximum number of complete bytes that can be output within the defined byte length.
  - When the byte length required for the conversion of the input "In" exceeds 1985 (the maximum byte length defined for the output "Out"), the actual output string consists of the maximum number of complete bytes that can be output within a 1985-byte length.
  - The byte count of "Out" must not be less than 22; otherwise, the function returns FALSE, and the value of "Out" remains unchanged.

18.1.10.22 ClearString

Clears the input string.

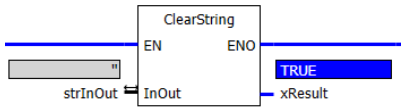
- **Instruction format**

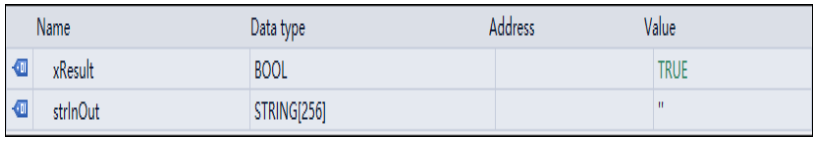
Instruction	Name	FB/FC	LD Representation	ST Representation
ClearString	Clear string	FC		:= ClearString(InOut :=);

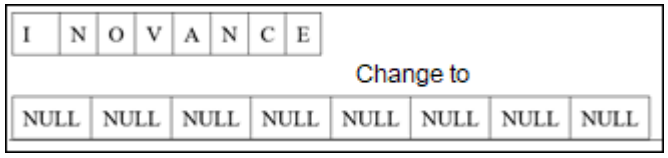
- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input/Output	InOut	Clear string	Follows data type	-	The string to clear and output







Variable types

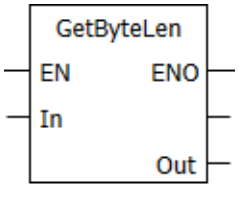
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√

- **Function description**

  Clears the content of the string "InOut", and stores NULL characters in it.

- **Program example**

Item	LD	ST
Define variables	VAR xResult: BOOL; strInOut: STRING[256] := 'INOVANCE'; END_VAR	
Program		
Operation result		
Principle analysis		



- **Precautions**

  The return value is always TRUE.

18.1.10.23 GetByteLen

Calculates the number of bytes in a string.

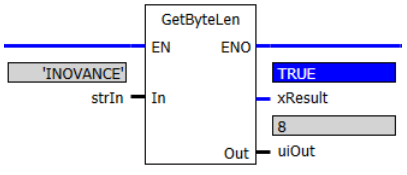
- **Instruction format**

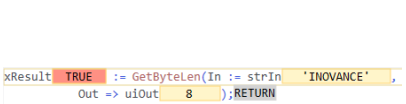
Instruction	Name	FB/FC	LD Representation	ST Representation
GetByteLen	String byte length calculation	FC		:= GetByteLen(In := , Out =>);

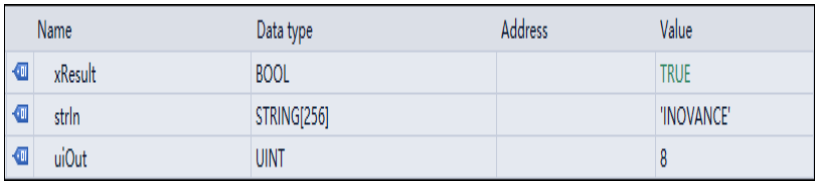
- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Counted object	Follows data type	-	The object string whose byte length is to be calculated
Output	Out	Number of bytes	0 to 1985	-	Number of bytes







Variable types

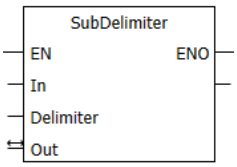
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
Out	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  Calculates the number of bytes in the object string "In" from beginning to end; the NULL character at the end of the string is not included.

- **Program example**

Item	LD	ST
Define variables	VAR xResult: BOOL; strIn: STRING[256] := 'INOVANCE'; uiOut: UINT; END_VAR	
Program		
Operation result		
Principle analysis		



- **Precautions**

The length of the input string is limited by the data type STRING.

18.1.10.24 SubDelimiter

Reads data from a delimited string and outputs it as a real number array.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
SubDelimiter	Reads data from a delimited real number string	FC		:= SubDelimiter(In := , Delimiter := , Out :=);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Input string	Maximum 1985 bytes	''	The delimited string to be read
	Delimiter	Delimiter	Follows data type	_COMMA	Delimiter
Input/Output	Out[ ] array	A real number array to store the return array	Follows data type	-	A real number array to store the results of data conversion

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	√
Delimiter	Enumeration type _eDELIMITER. For details, see function description for enumeration values.																			
Out[ ] array	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
	Array of enumerations can also be specified.																			

- **Function**
  - Converts the strings separated by the delimiter "Delimiter" in the input string "In" into the elements of the real number array "Out", and saves them sequentially as values of each array element.
  - The data type of "Delimiter" is the enumeration type _eDELIMITER, and the meanings of the enumeration values are as follows.

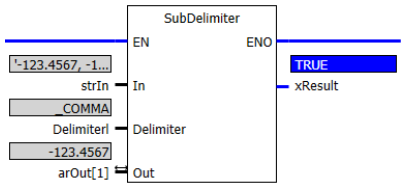
Enumeration Value	Definition
_COMMA	','
_TAB	'$T'
_SEMICOLON	';'
_SPACE	' '

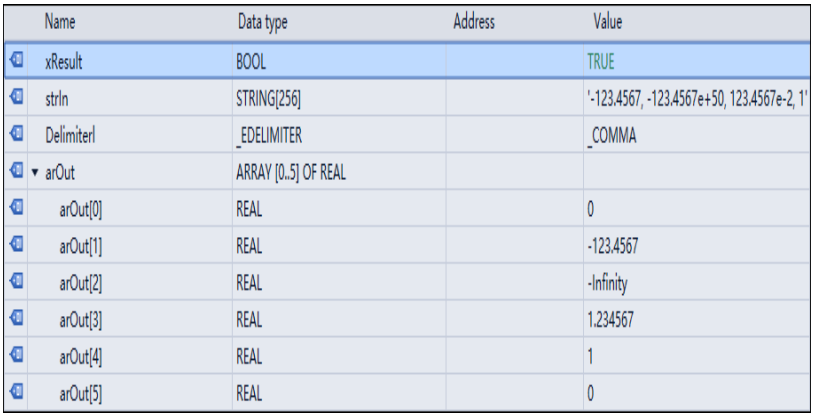
  - When the number of data items separated by delimiters in "In" exceeds the number of elements in "Out", the remaining data will be ignored.
  - When the number of data items separated by delimiters in "In" is less than the number of elements in "Out", the values of the missing elements remain unchanged.
  - The data in "In" separated by delimiters is of STRING type. The REAL-type string format is as follows.

Name	Format
Operator	With leading consecutive ' ' (spaces) ignored, a standalone '+' or '-' is treated as a sign. The '+' sign can be omitted, and consecutive spaces following the sign are ignored.
Integer part	The part from after the sign to before the decimal point is the integer part. Consecutive spaces after the sign are not included in the integer part, and the sign may be omitted. The integer part consists of numbers "0" to "9" and cannot be omitted. The maximum number of digits in the integer part is the maximum text string length of 1985 minus the total number of bytes in the following: the sign, decimal point, fractional part, exponent, and blank characters before and after the sign.

Name	Format
Decimal point	The decimal point is the single dot (".") following the integer part. When there is no fractional part, the decimal point must be omitted.
Fractional part	The part from after the decimal point to before the exponent part is the fractional part. When there is no exponent part, the entire string after the decimal point is the fractional part. The fractional part consists of numbers "0" to "9". The fractional part may be omitted. The maximum number of digits in the fractional part is 15. When there is no decimal point, the fractional part does not exist.
Exponent part	The exponent part is the part from the standalone 'e' following the fractional part and the standalone '+' or '-' after it, to the end of the string. When there is no fractional part, the string after the decimal point is considered the exponent part. When there is no decimal point or fractional part, the exponent part is the string following the integer part. The numeric part of the exponent consists of numbers "0" to "9". The exponent part may be omitted. The maximum number of digits in the exponent's numeric part is 3.

◦ The following table shows examples of conversion rules.





Format	STRING	REAL
Signed, with decimal point, with fractional part, no exponent part	'-123.4567'	-123.4567
Signed, with decimal point, with fractional part, with exponent part	'+123.4567e+02'	12345.67
Unsigned, with decimal point, with fractional part, with exponent part	'123.4567e-02'	1.234567
Unsigned, no decimal point, no fractional part, no exponent part	'1'	1

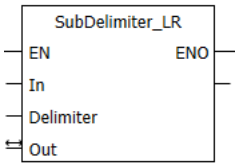
◦ Notes for conversion:

- When the value represented by the input string exceeds the valid range of the REAL data type, the conversion result is positive/negative infinity.
- When the input string does not represent a real number value, an exception occurs during conversion, and the function returns FALSE.
- When there are two or more consecutive '_' (underscore) characters at any intermediate position in the input string, conversion is successfully performed.
- When there is an '_' (underscore) between the '-' (minus sign) or '+' (plus sign) at the beginning of the input string, conversion is successfully performed.

- When an '_' (underscore) is at the beginning or end of the input string, conversion is successfully performed.
- When an '_' (underscore) is at any intermediate position in the input string, it is ignored.
- When the content of the input string exceeds the precision representable by the REAL data type, rounding is applied.
- When the content of the input string is closer to 0 than the minimum value representable by the REAL data type, the conversion result is 0.

- **Program example**

Item	LD	ST
Define variables	VAR xResult: BOOL; strIn: STRING[256] := '-123.4567, -123.4567e+50, 123.4567e-2, 1'; Delimiterl: _eDELIMITER := _eDELIMITER._COMMA; arOut: ARRAY[0..5] OF REAL; END_VAR	
Program		
Operation result		



Name	Data type	Address	Value
xResult	BOOL		TRUE
strIn	STRING[256]		'-123.4567, -123.4567e+50, 123.4567e-2, 1'
Delimiterl	_EDELIMITER		_COMMA
▾ arOut	ARRAY [0..5] OF REAL		
arOut[0]	REAL		0
arOut[1]	REAL		-123.4567
arOut[2]	REAL		-Infinity
arOut[3]	REAL		1.234567
arOut[4]	REAL		1
arOut[5]	REAL		0

- **Precautions**
  - When the number of conversion results for "In" is large, set a larger task cycle; otherwise, it may lead to high CPU utilization and even PLC crash.
  - When there is more than one consecutive delimiter in "In", the delimited data does not exist. If nonexistent data is output as REAL#0 in the corresponding element of the Out[ ] array.
  - When "In" contains data that does not conform to the real number data format, no conversion is performed for the invalid data and subsequent data, the function returns FALSE, and the successfully converted values remain unchanged.
  - Do not use the delimiter in "In" for purposes other than separation. Even if used for other purposes, the instruction will still treat it as a delimiter.
  - When the conversion result exceeds the Out[ ] array area, the function returns FALSE, and the data within the range will be saved.

18.1.10.25 SubDelimiter_LR

Reads data from a delimited string and outputs it as a long real number array.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
SubDelimiter_LR	Reads data from a delimited long real number string	FC		:= SubDelimiter_LR(In := , Delimiter := , Out :=);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Input string	Maximum 1985 bytes	''	The delimited string to be read
	Delimiter	Delimiter	Follows data type	_COMMA	Delimiter
Input/Output	Out[ ] array	A real number array to store the return array	Follows data type	-	A real number array to store the results of data conversion

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	√
Delimiter	Enumeration type _eDELIMITER. For details, see function description for enumeration values.																			
Out[ ] array	-	-	-	-	-	-	-	-	-	-	-	-	-	-	√	-	-	-	-	-

- **Function**
  - Converts the strings separated by the delimiter "Delimiter" in the input string "In" into the elements of the long real number array "Out", and saves them sequentially as values of each array element.

- The data type of "Delimiter" is the enumeration type _eDELIMITER, and the meanings of the enumeration values are as follows.

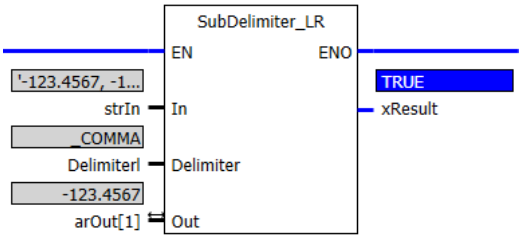
Enumeration Value	Definition
_COMMA	','
_TAB	'$T'
_SEMICOLON	';'
_SPACE	' '

- When the number of data items separated by delimiters in "In" exceeds the number of elements in "Out", the remaining data will be ignored.
- When the number of data items separated by delimiters in "In" is less than the number of elements in "Out", the values of the missing elements remain unchanged.
- The data in "In" separated by delimiters is of STRING type. The conversion rules for STRING-type data are as follows. The LREAL-type string format is as follows.

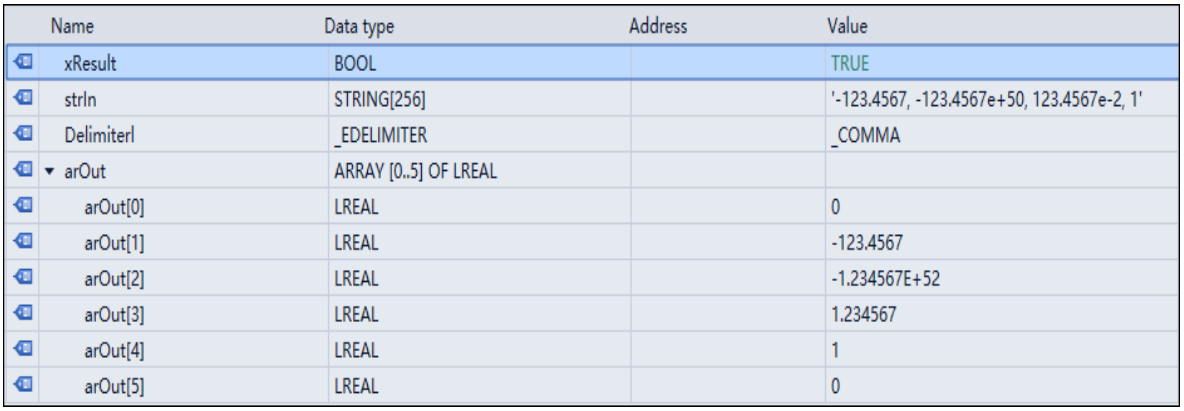
Name	Format
Operator	With leading consecutive ' ' (spaces) ignored, a standalone '+' or '-' is treated as a sign. The '+' sign can be omitted, and consecutive spaces following the sign are ignored.
Integer part	The part from after the sign to before the decimal point is the integer part. Consecutive spaces after the sign are not included in the integer part, and the sign may be omitted. When there is no decimal point or fractional part, the integer part is the characters up to the exponent. When there is no decimal point, fractional part, or exponent part, the integer part is whole string. The integer part consists of numbers "0" to "9" and cannot be omitted. The maximum number of digits in the integer part is the maximum text string length of 1985 minus the total number of bytes in the following: the sign, decimal point, fractional part, exponent, and blank characters before and after the sign.

Name	Format
Decimal point	The decimal point is the single dot (".") following the integer part. When there is no fractional part, the decimal point must be omitted.
Fractional part	The part from after the decimal point to before the exponent part is the fractional part. When there is no exponent part, the entire string after the decimal point is the fractional part. The fractional part consists of numbers "0" to "9". The fractional part may be omitted. The maximum number of digits in the fractional part is 15. When there is no decimal point, the fractional part does not exist.
Exponent part	The exponent part is the part from the standalone 'e' following the fractional part and the standalone '+' or '-' after it, to the end of the string. When there is no fractional part, the string after the decimal point is considered the exponent part. When there is no decimal point or fractional part, the exponent part is the string following the integer part. The numeric part of the exponent consists of numbers "0" to "9". The exponent part may be omitted. The maximum number of digits in the exponent's numeric part is 3.

◦ The following table shows examples of conversion rules.



Format	STRING	LREAL
Signed, with decimal point, with fractional part, no exponent part	'-123.4567'	-123.45670318603516
Signed, with decimal point, with fractional part, with exponent part	'+123.4567e+02'	12345.669921875
Unsigned, with decimal point, with fractional part, with exponent part	'123.4567e-02'	1.2345670461654663



Format	STRING	LREAL
Unsigned, no decimal point, no fractional part, no exponent part	'1'	1

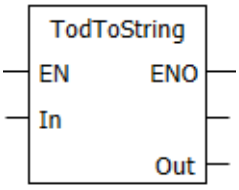
◦ Notes for conversion:

- When the value represented by the input string exceeds the valid range of the LREAL data type, the conversion result is positive/negative infinity.
- When the input string does not represent a long real number value, the conversion result is 0 and the function returns FALSE.
- When there are two or more consecutive '_' (underscore) characters at any intermediate position in the input string, conversion is successfully performed.
- When there is an '_' (underscore) between the '-' (minus sign) or '+' (plus sign) at the beginning of the input string, conversion is successfully performed.
- When an '_' (underscore) is at the beginning or end of the input string, a fault occurs.
- When an '_' (underscore) is at any intermediate position in the input string, it is ignored.
- When the content of the input string exceeds the precision representable by the LREAL data type, rounding is applied.
- When the content of the input string is closer to 0 than the minimum value representable by the LREAL data type, the conversion result is 0.

- **Program example**

Item	LD	ST
Define variables	VAR xResult: BOOL; strIn: STRING[256] := '-123.4567, -123.4567e+50, 123.4567e-2, 1'; Delimiterl: _eDELIMITER := _eDELIMITER._COMMA; arOut: ARRAY[0..5] OF LREAL; END_VAR	
Program		xResult TRUE := SubDelimiter_LR(In := strIn'-123.4567, -123.4567e+50, 123.4567e-2,..., Delimiter := Delimiterl _COMMA , Out := arOut[1] -123.4567);RETURN

Item	LD	ST
Operation result		



Name	Data type	Address	Value
xResult	BOOL		TRUE
strIn	STRING[256]		'-123.4567, -123.4567e+50, 123.4567e-2, 1'
DelimiterI	_EDELIMITER		_COMMA
arOut	ARRAY [0..5] OF LREAL		
arOut[0]	LREAL		0
arOut[1]	LREAL		-123.4567
arOut[2]	LREAL		-1.234567E+52
arOut[3]	LREAL		1.234567
arOut[4]	LREAL		1
arOut[5]	LREAL		0

- **Precautions**
  - When the number of conversion results for "In" is large, set a larger task cycle; otherwise, it may lead to high CPU utilization and even PLC crash.
  - When there is more than one consecutive delimiter in "In", the delimited data does not exist. If nonexistent data is output as LREAL#0 in the corresponding element of the Out[ ] array.
  - When "In" contains data that does not conform to the real number data format, no conversion is performed for the invalid data and subsequent data, the function returns FALSE, and the successfully converted values remain unchanged.
  - Do not use the delimiter in "In" for purposes other than separation. Even if used for other purposes, the instruction will still treat it as a delimiter.
  - When the conversion result exceeds the Out[ ] array area, the function returns FALSE, and the data within the range will be saved.

18.1.10.26 TodToString

Converts a time to a string.

- **Instruction format**

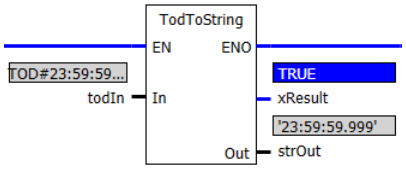
Instruction	Name	FB/FC	LD Representation	ST Representation
TodToString	Time-to-string conversion	FC		:= TodToString(In := , Out =>);

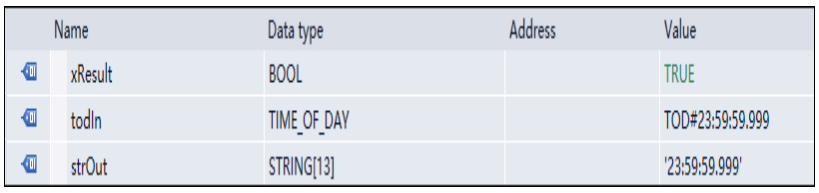
- **Related variable**

  Variable

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Time of day	Follows data type	TIME_OF_DAY#: 0:0:0	Hour, minute, second

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Output	Out	String	13 bytes (12 half-width alphaumeric characters + final NULL character)	-	String





Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√

- **Function description**

  Converts the time "In" to the string "Out", with a NULL character appended to the end.

- **Program example**

	LD	ST
Define variables	VAR xResult: BOOL; todIn: TIME_OF_DAY := TOD#23:59:59.999; strOut: STRING[13]; END_VAR	
Program		
Operation result		

- **Precautions**
  - "Out" is represented in hours, minutes, seconds, and milliseconds.
  - The return value is always TRUE.

18.1.10.27 ToLCase

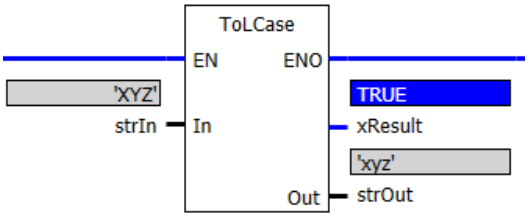
Converts all half-width letters in a string to lowercase.

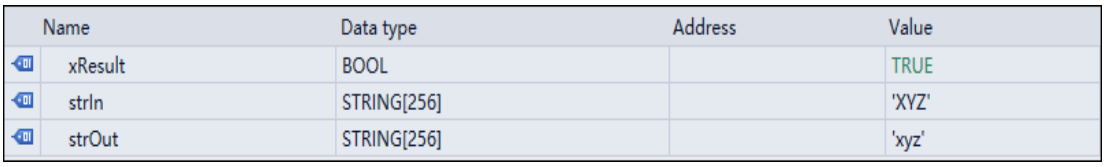
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ToLCase	Convert to lowercase	FC		:= ToLCase(In := , Out =>);

- **Related variable**

Variable





Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	Follows data type	-	The target string to be converted
Output	Out	Conversion result	Follows data type	-	Sum value

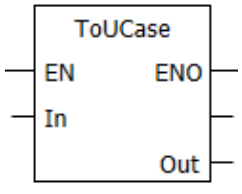
Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√

- **Function description**
  - ToLCase converts all half-width letters in the input string "In" to lowercase letters.
  - This instruction outputs a NULL character at the end of the string. Characters that are not half-width letters are not affected.
- **Program example**

The following table shows an example when "In" = 'XYZ'. The output value is 'xyz'.

Item	LD	ST
Define variables	VAR xResult: BOOL; strIn: STRING[256] := 'XYZ'; strOut: STRING[256]; END_VAR	
Program		xResult TRUE := ToLCase(In := strIn 'XYZ', Out => strOut 'xyz');RETURN
Operation result		



Name	Data type	Address	Value
xResult	BOOL		TRUE
strIn	STRING[256]		'XYZ'
strOut	STRING[256]		'xyz'

- **Precautions**
  - Full-width alphabetic and non-alphabetic characters are not subject to conversion.
  - An exception may occur if the character code of "In" is invalid, resulting in inaccurate "Out" values.
  - When "In" is not NULL-terminated, the result may become abnormal.
  - When the conversion result exceeds the size of "Out", only the portion up to the length of "Out" is displayed.
  - The return value is always TRUE.

18.1.10.28 ToUCase

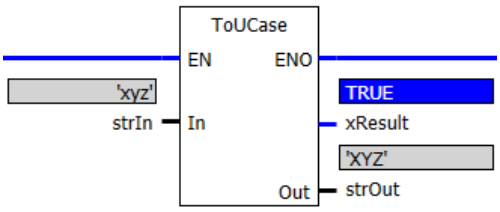
Converts all half-width letters in a string to uppercase.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ToUCase	Convert to uppercase	FC		:= ToUCase(In := , Out =>);

- **Related variable**

Variable



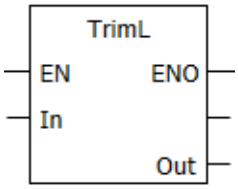
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	Follows data type	-	The target string to be converted
Output	Out	Conversion result	Follows data type	-	Sum value

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√

- **Function description**
  - ToLCase converts all half-width letters in the input string "In" to uppercase letters.
  - This instruction outputs a NULL character at the end of the string. Characters that are not half-width letters are not affected.
- **Program example**

  The following shows an example when "In" = 'xyz'. The output value is 'XYZ'.



Item	LD	ST
Define variables	VAR xResult: BOOL; strIn: STRING[256] := 'xyz'; strOut: STRING[256]; END_VAR	
Program		xResult TRUE := ToUCase(In := strIn 'xyz', Out => strOut 'XYZ');RETURN
Operation result	Name / Data type / Address / Value xResult / BOOL / / TRUE strIn / STRING[256] / / 'xyz' strOut / STRING[256] / / 'XYZ'	

- **Precautions**
  - Full-width alphabetic and non-alphabetic characters are not subject to conversion.
  - An exception may occur if the character code of "In" is invalid, resulting in inaccurate "Out" values.
  - When "In" is not NULL-terminated, the result may become abnormal.
  - When the conversion result exceeds the size of "Out", only the portion up to the length of "Out" is displayed.
  - In OMUtils library versions 1.2.0.1 and earlier, the return value is always TRUE.
    In OMUtils library versions 1.3.0.0 and later, the return value is FALSE for empty strings.

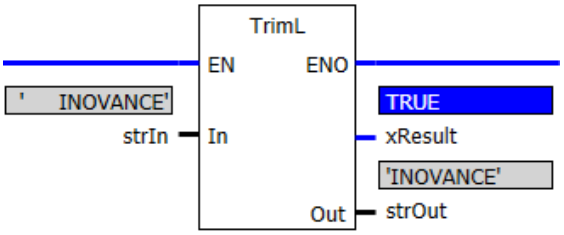
18.1.10.29 TrimL

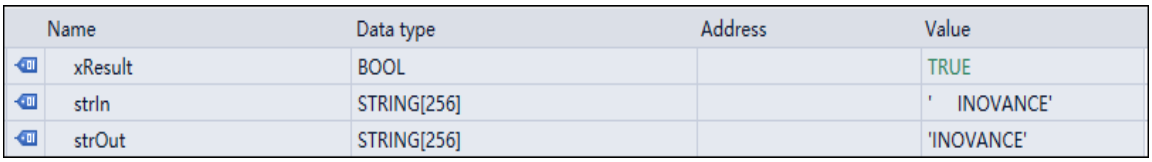
Trims leading spaces from a string.

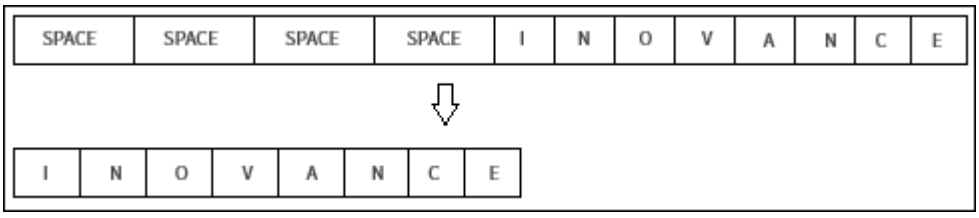
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
TrimL	Trim string from the left	FC		:= TrimL(In := , Out =>);

- **Related variable**







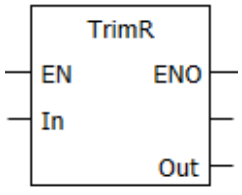
Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	String to trim	Follows data type	-	String to trim
Output	Out	Trimming result	Follows data type	-	The string after trimming

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√

- **Function description**
  - Trims spaces from the beginning of the object string "In" up to the first occurrence of a character. When there are no spaces at the beginning, no processing is performed.
  - The instruction outputs the result including the NULL character at the end of the string.
- **Program example**



<table>
<tr><th>Item</th><th>LD</th><th>ST</th></tr>
<tr><td>Define variables</td><td colspan="2"><pre>VAR
    xResult: BOOL;
    strIn: STRING[256] := '   INOVANCE';
    strOut: STRING[256];
END_VAR</pre></td></tr>
<tr><td>Program</td><td>
</td><td>
</td></tr>
<tr><td>Operation result</td><td colspan="2">
</td></tr>
<tr><td>Principle analysis</td><td colspan="2">
</td></tr>
</table>

- **Precautions**
  - Half-width and full-width spaces are both treated as spaces.
  - The instruction outputs the result including the NULL character at the end of the string.
  - The return value is always TRUE.

18.1.10.30 TrimR

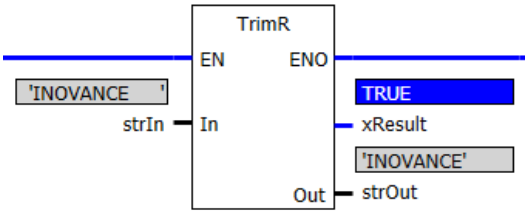
Trims trailing spaces from a string.

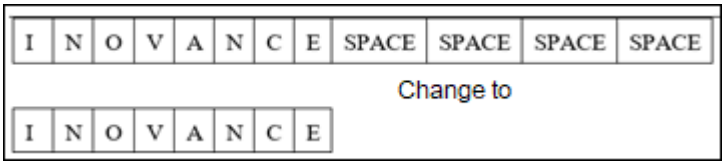
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
TrimR	Trim string from the right	FC		:= TrimR(In := , Out =>);

- **Related variable**

Variable





Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	String to trim	Follows data type	-	String to trim

Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	Out	Trimming result	Follows data type	-	The string after trimming

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√

- **Function description**
  - Trims spaces between the last character of the object string "In" and the end of the string. When there are no trailing spaces, no processing is performed.
  - The instruction outputs results including the NULL character at the beginning of the string.
- **Program example**

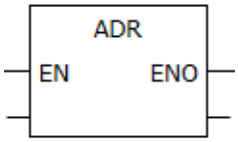
Item	LD	ST
Define variables	VAR xResult: BOOL; strIn: STRING[256] := 'INOVANCE '; strOut: STRING[256]; END_VAR	
Program		xResult TRUE := TrimR(In := strIn 'INOVANCE ', Out => strOut 'INOVANCE');RETURN
Operation result		
Principle analysis		

- **Precautions**
  - Half-width and full-width spaces are both treated as spaces.
  - The instruction outputs results including the NULL character at the beginning of the string.

◦ The return value is always TRUE.

18.1.11 Pointer

18.1.11.1 Instruction List



Instruction	FB/FC	Function	Library	Applicable Library Version
18.1.11.2 ADR	FC	Address retrieval instruction	-	-

18.1.11.2 ADR

ADR: Retrieves the memory address of the input variable.

^: Retrieves the content at the address of the input variable and assigns the result to the output variable.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ADR	Address retrieval instruction	FC		:= ADR( );
^	Address content retrieval instruction	FC		^

- **Related variable**

Variable

ADR

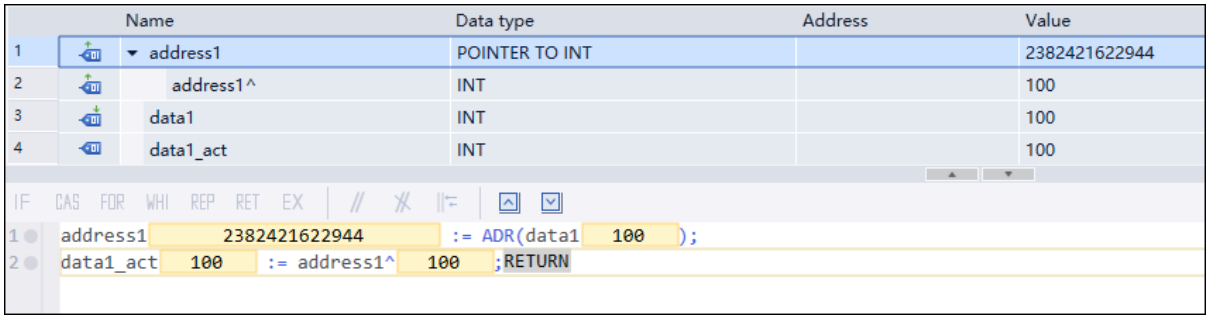
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Source data	Follows data type	-	Target data
Output	Out	Address of target data	Follows data type	-	Target data address

^

Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	Out	Points to address content	Follows data type	-	Points to address content

Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
Out	POINTER_TO_<TYPE>																			
Out	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-



- **Program example**

  ADR/^

  ADR returns the address of a reference in DWORD format. This address can be used to modify the operation pointer of a function or for pointer operations within the project.

  After program execution, the pointer automatically generates a parameter address. Adding ^ after the pointer indicates the content at the address pointed to, for example, the value at the addressed location is 100.

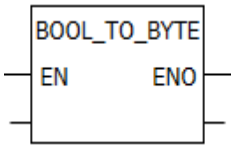
  ST:

  LD:

- **Precautions**
  - For online modification, the address content will change, causing the POINTER_TO_<TYPE> variable to point to an unavailable memory area. To avoid this issue, ensure the pointer value is updated in each cycle.
  - Do not return the function's POINTER_TO_<TYPE> variable to the calling function or assign it to a global variable.

18.1.12 Conversion Operators

18.1.12.1 Instruction List



Instruction	FB/FC	Function	Library	Applicable Library Version
18.1.12.2 BOOL_TO_	FC	Boolean type conversion instruction	-	-
18.1.12.3 BYTE_TO_	FC	Byte type conversion instruction		
18.1.12.4 DATE_TO_	FC	Date type conversion instruction		
18.1.12.5 DINT_TO_	FC	Long integer conversion instruction		
18.1.12.6 DT_TO_	FC	Datetime type conversion instruction		
18.1.12.7 DWORD_TO_	FC	Double-word type conversion instruction		
18.1.12.8 INT_TO_	FC	Integer type conversion instruction		

Instruction	FB/FC	Function	Library	Applicable Library Version
18.1.12.9 LINT_TO_	FC	Long integer conversion instruction		
18.1.12.10 LREAL_TO_	FC	LREAL type conversion instruction		
18.1.12.11 LTIME_TO_	FC	Time type conversion instruction		
18.1.12.12 LWORD_TO_	FC	Byte type conversion instruction		
18.1.12.13 REAL_TO_	FC	Real type conversion instruction		
18.1.12.14 SINT_TO_	FC	Short integer conversion instruction		
18.1.12.15 STRING_TO_	FC	Character type conversion instruction		
18.1.12.16 TIME_TO_	FC	Time type conversion instruction		
18.1.12.17 TOD_TO_	FC	Time-of-day conversion instruction		
18.1.12.18 UDINT_TO_	FC	Unsigned long integer conversion instruction		
18.1.12.19 UINT_TO_	FC	Unsigned integer type conversion instruction		
18.1.12.20 ULINT_TO_	FC	Unsigned long integer type conversion instruction		
18.1.12.21 USINT_TO_	FC	Unsigned short integer type conversion instruction		
18.1.12.22 WORD_TO_	FC	Byte type conversion instruction		
18.1.12.23 WSTRING_TO_	FC	Character type conversion instruction		
18.1.12.24 UNICODE_TO_UTF8	FC	UNICODE-to-UTF8 conversion	OMUtils	Library version 1.2.0.0 and later

18.1.12.2 BOOL_TO_<TYPE>

Converts a Boolean variable to another type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
BOOL_TO_<TYPE>	Boolean type conversion instruction	FC		BOOL_TO_BYTE

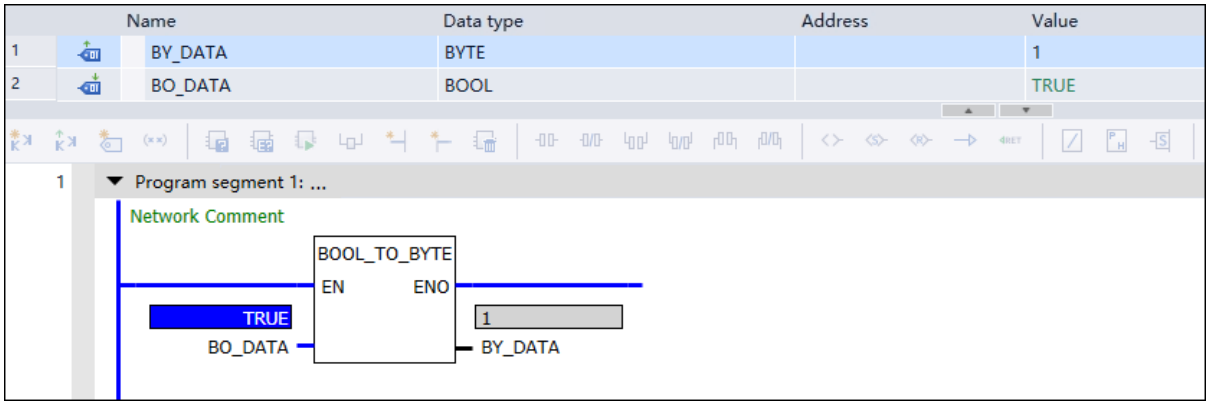
- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Data Source	Follows data type	-	Data source
Output	OUT	Result data	Follows data type	-	Converted data

  Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String						
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	LTIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
IN	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
OUT	-	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√



- **Program example**

  Take BOOL_TO_BYTE as an example.

  ST:

  LD:

18.1.12.3 BYTE_TO_<TYPE>

Converts a byte-type variable to another type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
BYTE_TO_<TYPE>	Byte type conversion instruction	FC		BYTE_TO_DINT

- **Related variables**

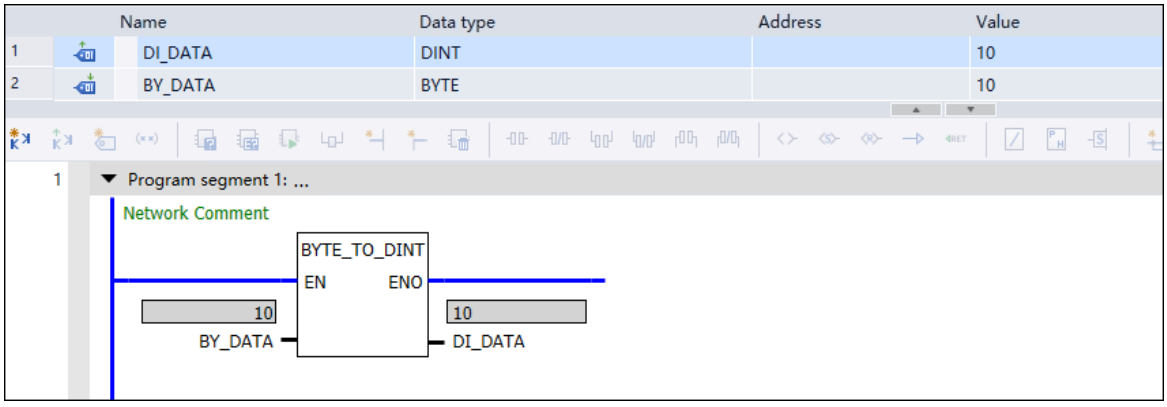
Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Data Source	Follows data type	-	Data source
Output	OUT	Result data	Follows data type	-	Converted data

Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String						
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	LTIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
IN	-	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String						
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	LTIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
OUT	√	-	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√



- **Program example**

  Take BYTE_TO_DINT as an example.

  ST:

  LD:

18.1.12.4 DATE_TO_<TYPE>

Converts a date type variable to another type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
DATE_TO_<TYPE>	Date type conversion instruction	FC		DATE_TO_DWORD

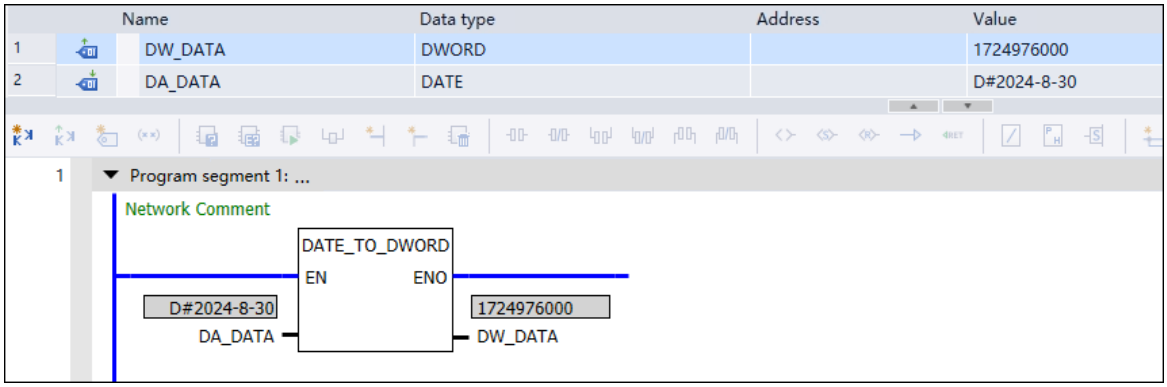
- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Data Source	Follows data type	-	Data source
Output	OUT	Result data	Follows data type	-	Converted data

  Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String						
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	LTIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
IN	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	√	-	-	-	-
OUT	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	-	√	√	√	√



- **Program example**

  Take DATE_TO_DWORD as an example.

  ST:

  LD:

18.1.12.5 DINT_TO_<TYPE>

Converts a long integer type variable to another type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
DINT_TO_<TYPE>	Long integer conversion instruction	FC		DINT_TO_BOOL

- **Related variables**

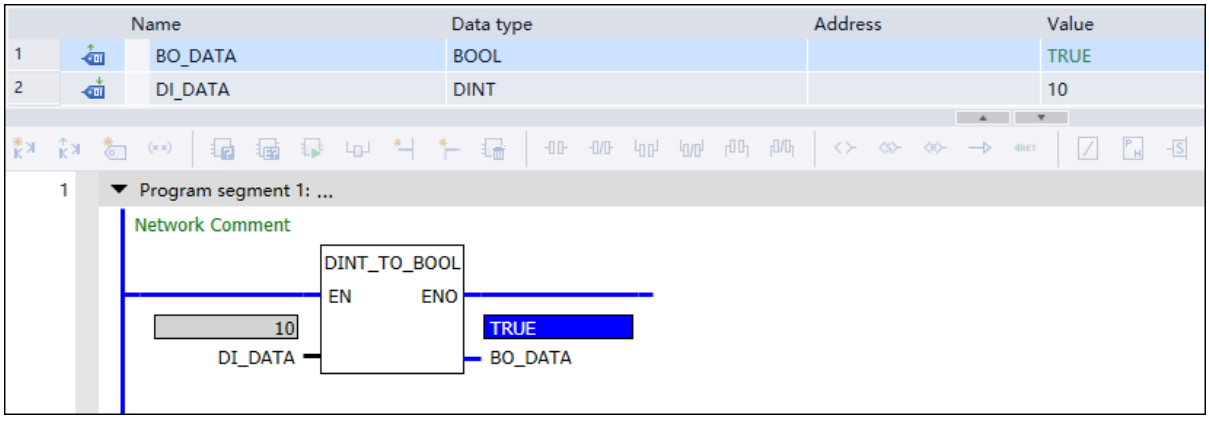
Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Data Source	Follows data type	-	Data source
Output	OUT	Result data	Follows data type	-	Converted data

Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String						
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	LTIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
IN	-	-	-	-	-	-	-	-	-	-	-	√	-	-	-	-	-	-	-	-	-	-

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String							
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	LTIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
OUT	√	√	√	√	√	√	√	√	√	√	√	-	√	√	√	√	√	√	√	√	√	√



- **Program example**

  Take DINT_TO_BOOL as an example.

  ST:

  LD:

18.1.12.6 DT_TO_<TYPE>

Converts a datetime-type variable into another type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
DT_TO_<TYPE>	Datetime type conversion instruction	FC		DT_TO_DWORD

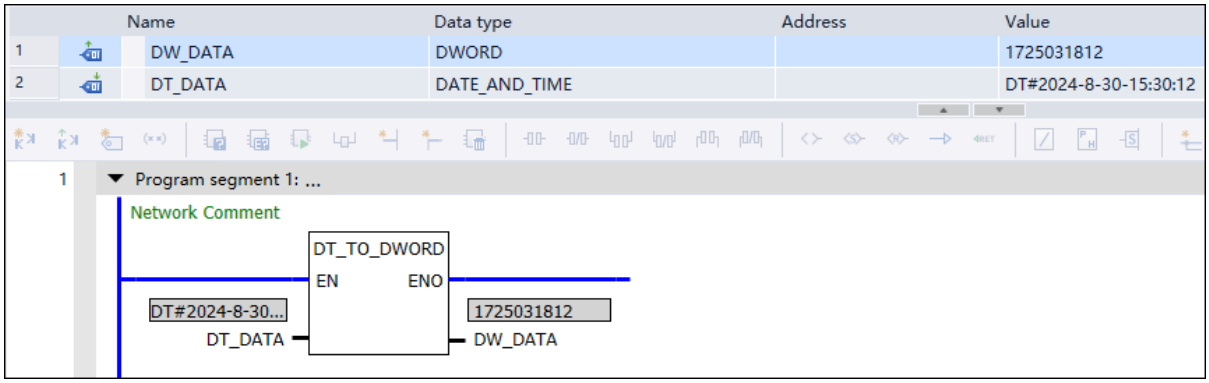
- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Data Source	Follows data type	-	Data source
Output	OUT	Result data	Follows data type	-	Converted data

  Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String						
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	LTIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
IN	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	√	-	-
OUT	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	-	√	√

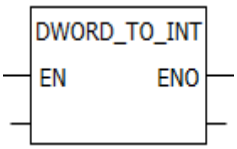


- **Program example**

  Take DT_TO_DWORD as an example. When the input is DT#2024-8-30-15:30:12, the output result is 1725031812, representing the number of seconds elapsed from 1970-1-1 00:00:00 to 2024-8-30 15:30:12.

  ST:

  LD:



- **Precautions**
  - Take DT_TO_BOOL as an example, when the input is DT#1970-1-1-0:0:0, the output is FALSE; otherwise, the output is TRUE.
  - When the output result exceeds the value range of the target data type, the result will be taken modulo the maximum value representable by that data type.

18.1.12.7 DWORD_TO_<TYPE>

Converts a double-word type variable to another type.

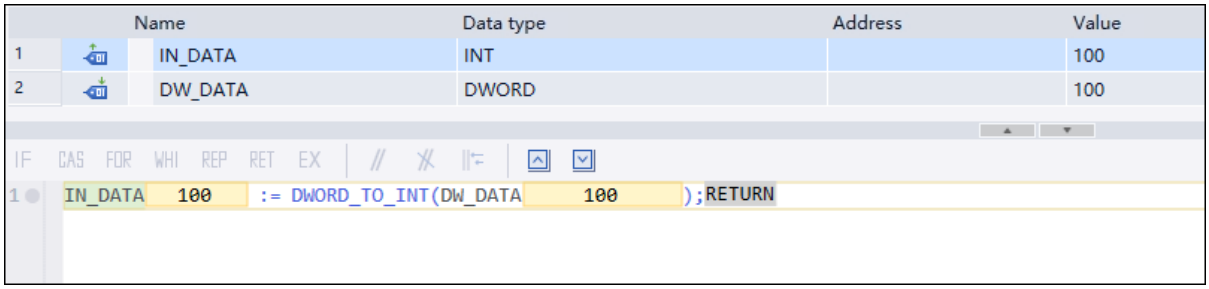
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
DWORD_TO_<TYPE>	Double-word type conversion instruction	FC		DWORD_TO_INT

- **Related variables**

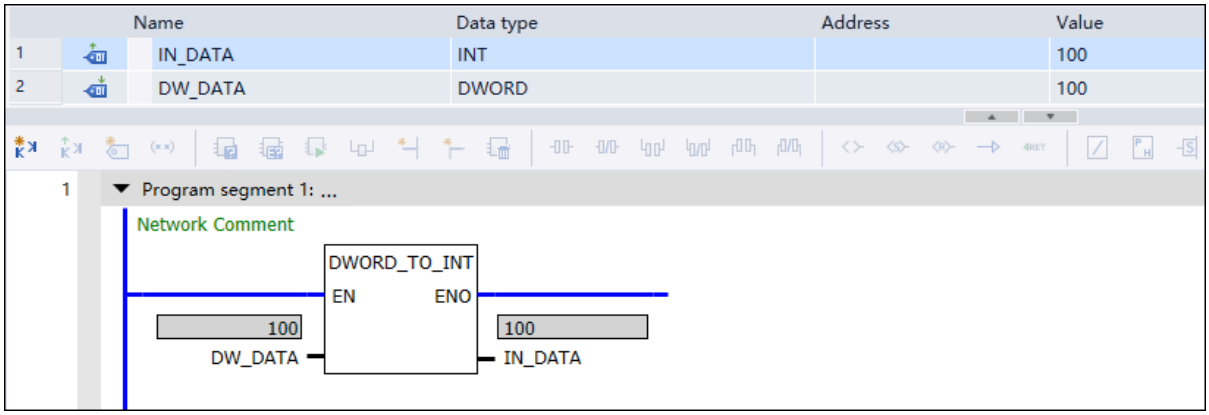
Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Data Source	Follows data type	-	Data source
Output	OUT	Result data	Follows data type	-	Converted data



Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String						
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	LTIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
IN	-	-	-	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
OUT	√	√	√	-	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√



- **Program example**

  Take DWORD_TO_INT as an example.

  ST:

  LD:

18.1.12.8 INT_TO_<TYPE>

Converts an integer type variable to another type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
INT_TO_<TYPE>	Integer type conversion instruction	FC		INT_TO_BYTE

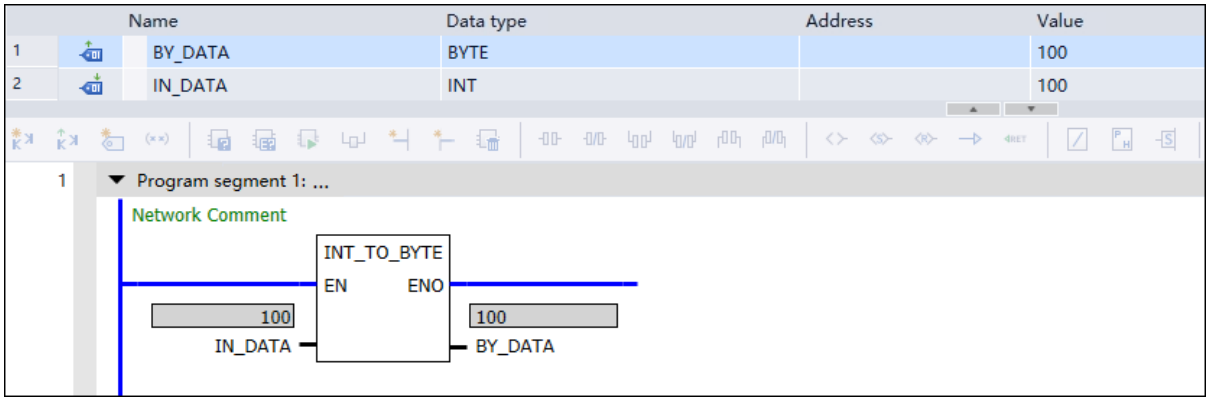
- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Data Source	Follows data type	-	Data source
Output	OUT	Result data	Follows data type	-	Converted data

  Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String						
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	LTIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
IN	-	-	-	-	-	-	-	-	-	-	√	-	-	-	-	-	-	-	-	-	-	-
OUT	√	√	√	√	√	√	√	√	√	√	-	√	√	√	√	√	√	√	√	√	√	√



- **Program example**

  Take INT_TO_BYTE as an example.

  ST:

  LD:

18.1.12.9 LINT_TO_<TYPE>

Converts a long integer type variable to another type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
LINT_TO_<TYPE>	Long integer conversion instruction	FC		LINT_TO_BYTE

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description

	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	LTIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
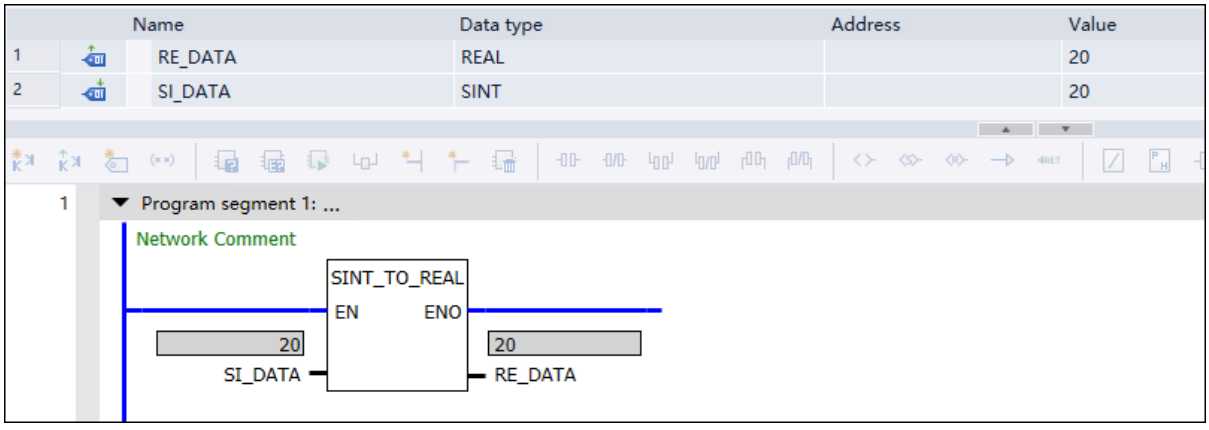
OUT	√	√	√	√	√	√	√	√	√	-	√	√	√	√	√	√	√	√	√	√	√	√



- **Program example**

  Take SINT_TO_REAL as an example.

  ST:

  LD:

18.1.12.15 STRING_TO_<TYPE>

Converts a character type variable to another type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
STRING_TO_<TYPE>	Character type conversion instruction	FC		STRING_TO_DWORD

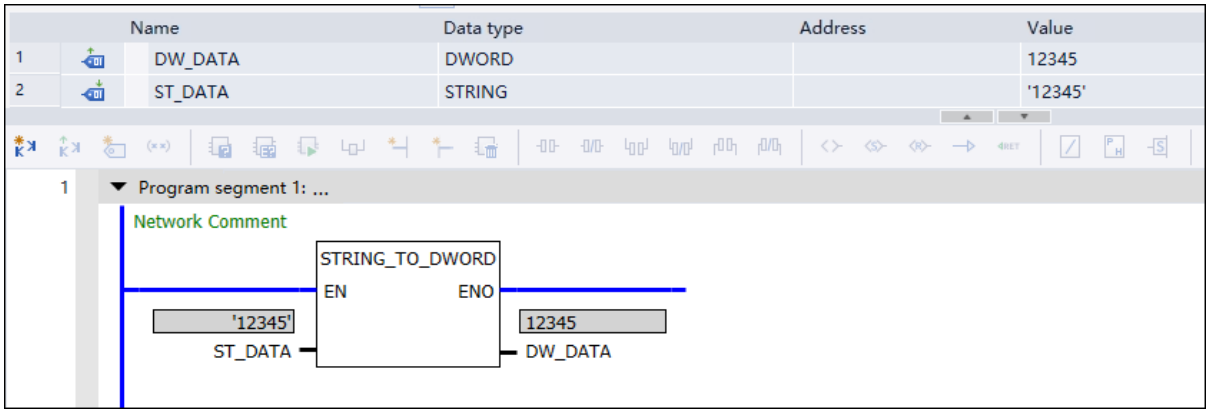
- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Data Source	Follows data type	-	Data source
Output	OUT	Result data	Follows data type	-	Converted data

  Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String						
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	LTIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
IN	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	√	-
OUT	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	-	√

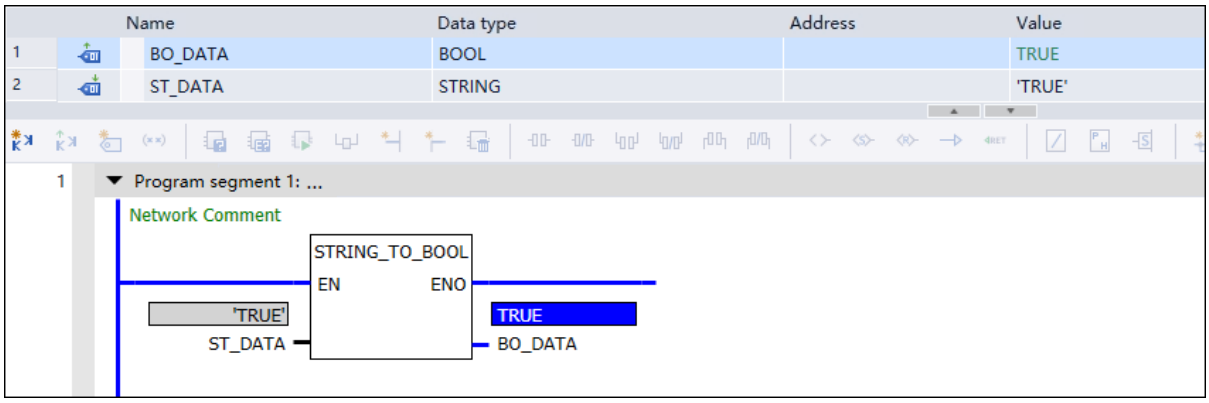


- **Program example**

  Take STRING_TO_DWORD as an example.

  ST:

  LD:



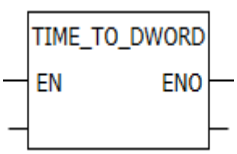
- **Special example**

  Take STRING_TO_BOOL as an example.

  ST:

  LD:

  The corresponding BOOL type variable will be set to TRUE only when the input STRING type data is "TRUE".



- **Note**

  : Take STRING_TO_WSTRING as an example, Chinese characters are not supported for conversion.

18.1.12.16 TIME_TO_<TYPE>

Converts a time type variable to another type.

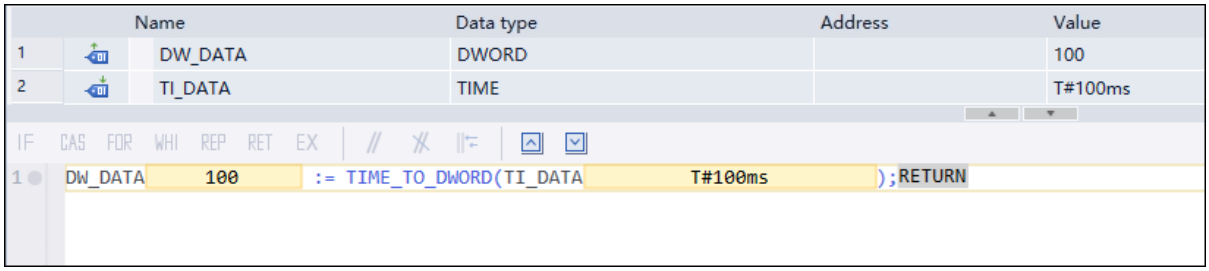
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
TIME_TO_<TYPE>	Time type conversion instruction	FC		TIME_TO_DWORD

- **Related variables**

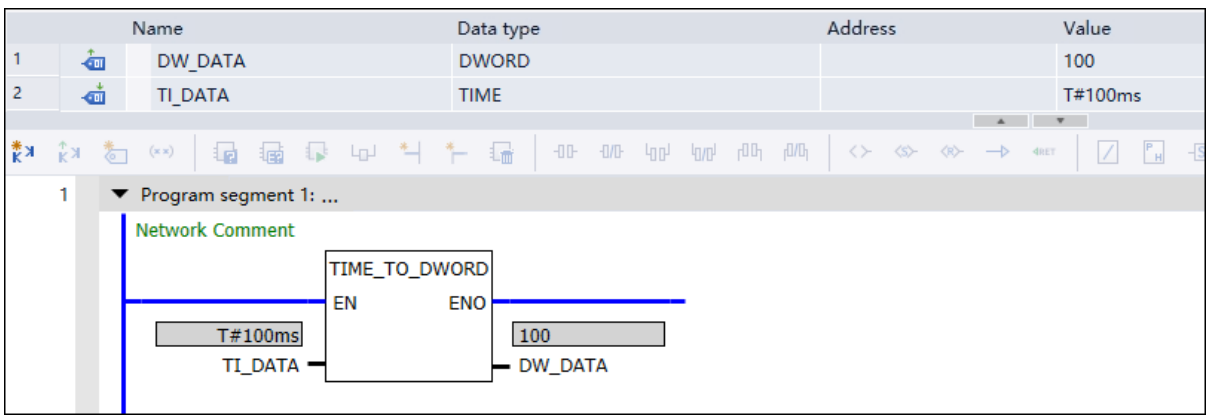
Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Data Source	Follows data type	-	Data source
Output	OUT	Result data	Follows data type	-	Converted data



Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String						
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	LTIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
IN	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	√	-	-	-	-	-	-
OUT	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	-	√	√	√	√	√	√



- **Program example**

  Take TIME_TO_DWORD as an example.

  ST:

  LD:

18.1.12.17 TOD_TO_<TYPE>

Converts the time-of-day variable to another type.

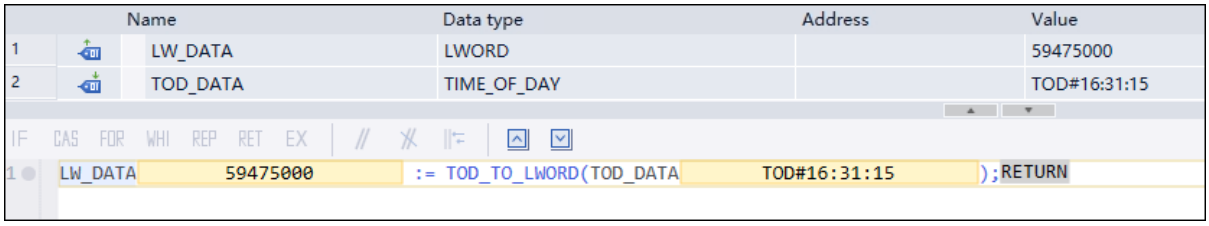
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
TOD_TO_<TYPE>	Time-of-day conversion instruction	FC		TOD_TO_LWORD

- **Related variables**

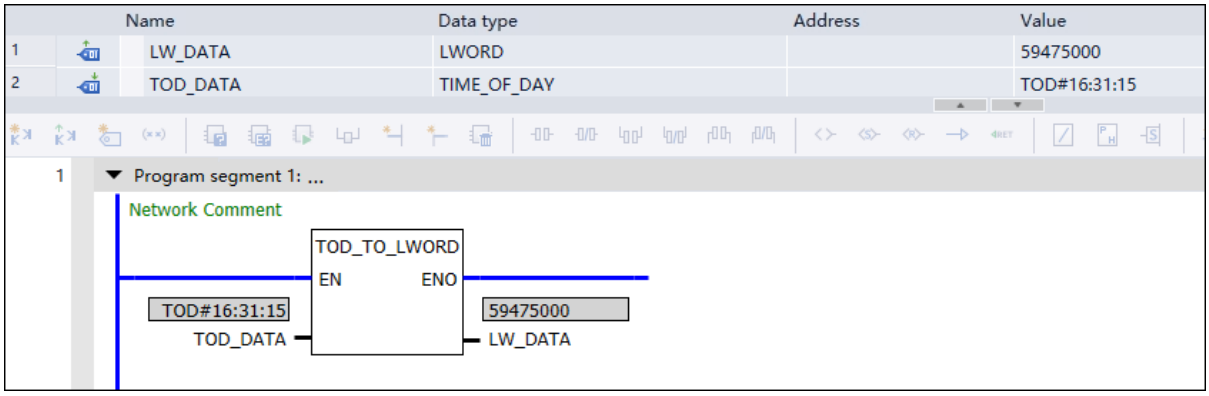
Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Data Source	Follows data type	-	Data source
Output	OUT	Result data	Follows data type	-	Converted data



Data Type

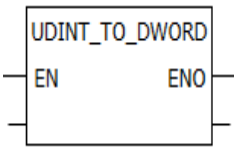
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String						
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	LTIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
IN	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	√	-	-	-
OUT	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	-	√	√	√



- **Program example**

Take TOD_TO_LWORD as an example.

ST:



LD:

18.1.12.18 UDINT_TO_<TYPE>

Converts an unsigned long integer type variable to another type.

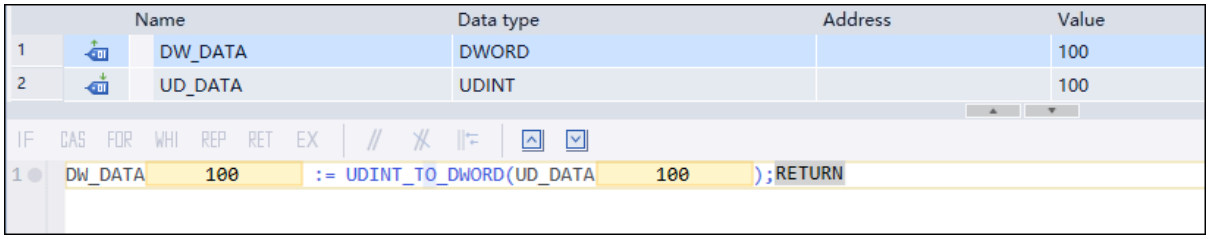
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
UDINT_TO_<TYPE>	Unsigned long integer conversion instruction	FC		UDINT_TO_DWORD

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Data Source	Follows data type	-	Data source
Output	OUT	Result data	Follows data type	-	Converted data



Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String						
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	LTIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING

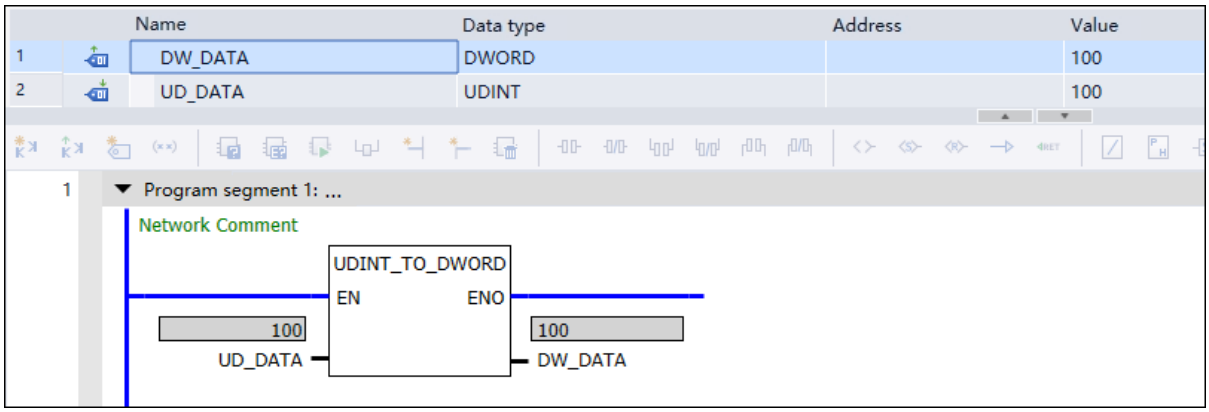
OUT	√	√	√	√	√	√	√	-	√	√	√	√	√	√	√	√	√	√	√	√	√	√



- **Program example**

  Take UDINT_TO_DWORD as an example.

  ST:

  LD:

18.1.12.19 UINT_TO_<TYPE>

Converts an unsigned integer type variable to another type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
UINT_TO_<TYPE>	Unsigned integer type conversion instruction	FC		UINT_TO_BYTE

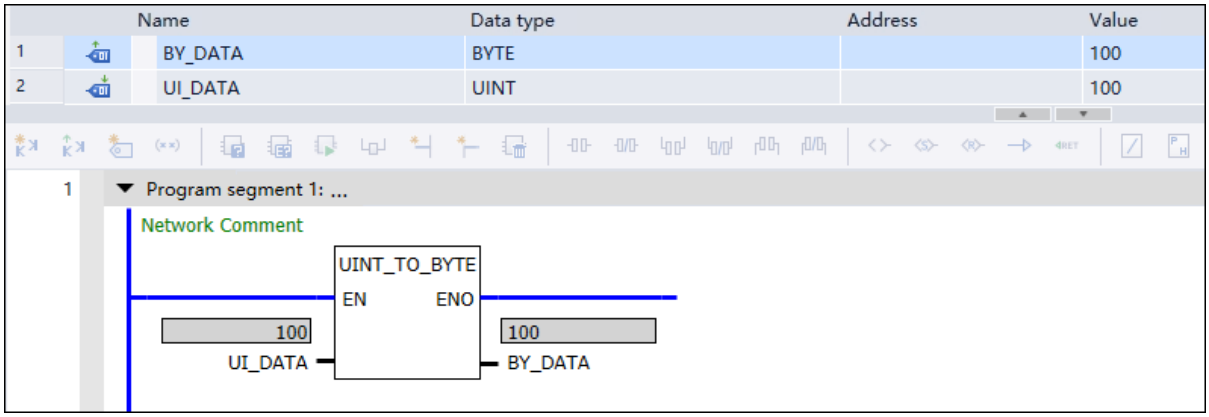
- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Data Source	Follows data type	-	Data source
Output	OUT	Result data	Follows data type	-	Converted data

  Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String						
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	LTIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
IN	-	-	-	-	-	-	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
OUT	√	√	√	√	√	√	-	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√



- **Program example**

  Take UINT_TO_BYTE as an example.

  ST:

  LD:

18.1.12.20 ULINT_TO_<TYPE>

Converts an unsigned long integer type variable to another type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ULINT_TO_<TYPE>	Unsigned long integer type conversion instruction	FC	ULINT_TO_BYTE EN ENO	ULINT_TO_BYTE

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Data Source	Follows data type	-	Data source
Output	OUT	Result data	Follows data type	-	Converted data

Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String						
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	LTIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING

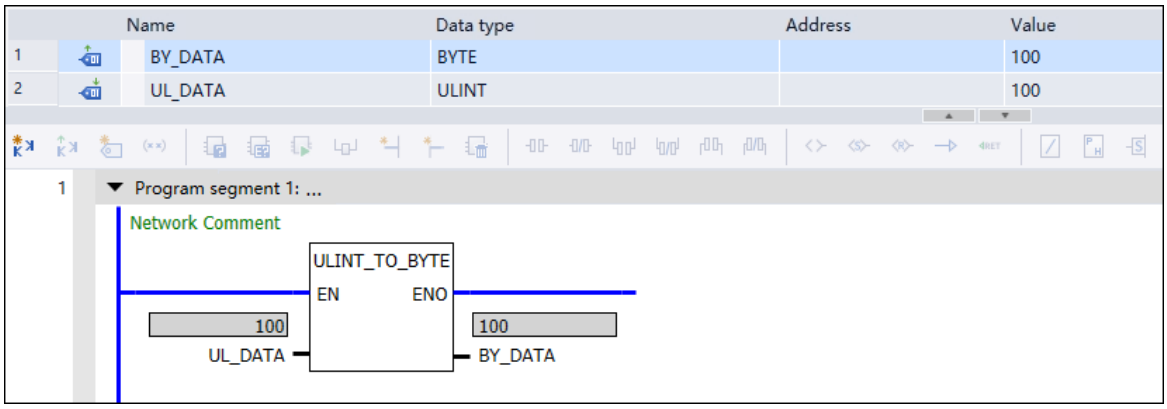
OUT	√	√	√	√	√	√	√	√	-	√	√	√	√	√	√	√	√	√	√	√	√	√



- **Program example**

  Take ULINT_TO_BYTE as an example.

  ST:

  LD:

18.1.12.21 USINT_TO_<TYPE>

Converts an unsigned short integer type variable to another type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
USINT_TO_<TYPE>	Unsigned short integer type conversion instruction	FC		USINT_TO_BYTE

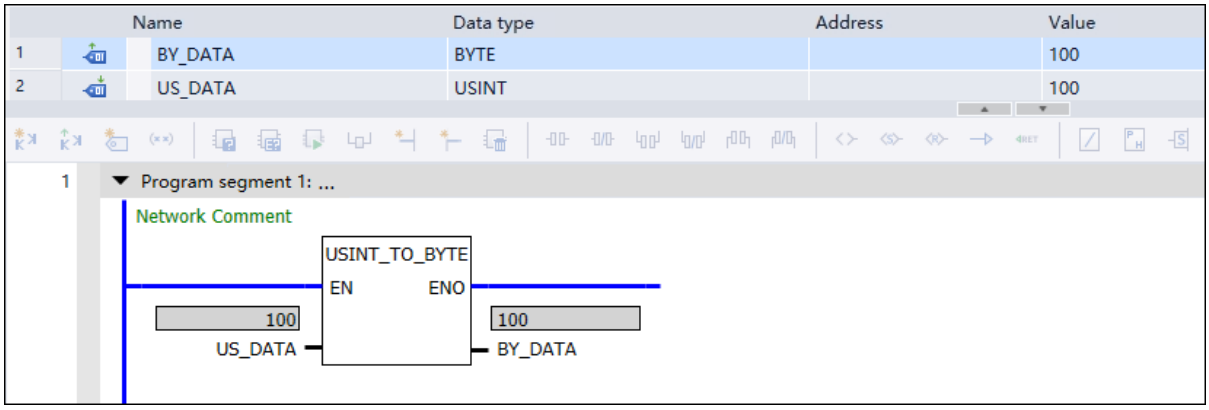
- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Data Source	Follows data type	-	Data source
Output	OUT	Result data	Follows data type	-	Converted data

  Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String						
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	LTIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
IN	-	-	-	-	-	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
OUT	√	√	√	√	√	-	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√



- **Program example**

  Take USINT_TO_BYTE as an example.

  ST:

  LD:

18.1.12.22 WORD_TO_<TYPE>

Converts a byte-type variable to another type.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
WORD_TO_<TYPE>	Byte type conversion instruction	FC		WORD_TO_DT

- **Related variables**

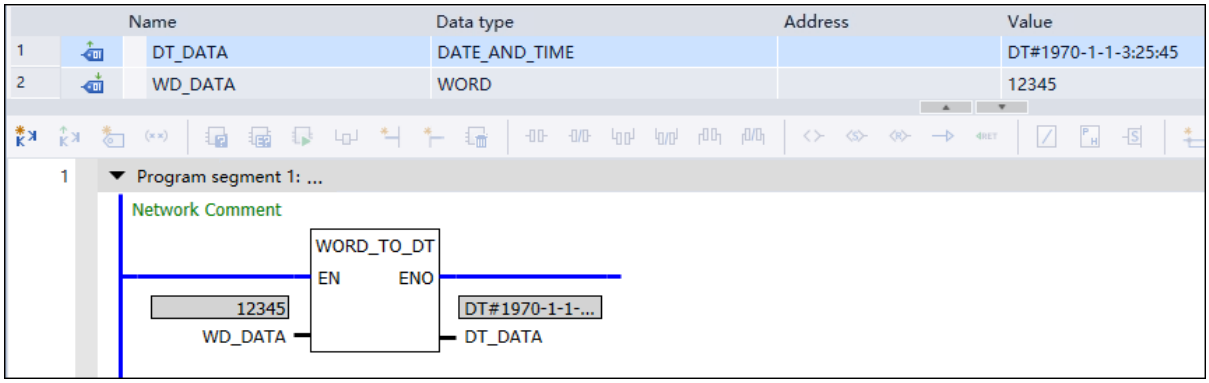
Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Data Source	Follows data type	-	Data source
Output	OUT	Result data	Follows data type	-	Converted data

Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String						
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	LTIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
IN	-	-	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String						
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	LTIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
OUT	√	√	-	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√



- **Program example**

  Take WORD_TO_DT as an example.

  ST:

  LD:

18.1.12.23 WSTRING_TO_<TYPE>

Converts a variable-length double-byte character type variable to another type.

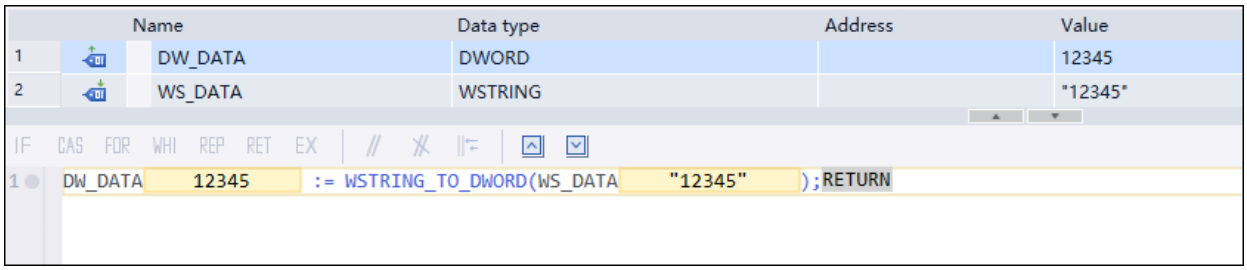
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
WSTRING_TO_<TYPE>	Character type conversion instruction	FC	WSTRING_TO_DWORD EN ENO	WSTRING_TO_DWORD

- **Related variables**

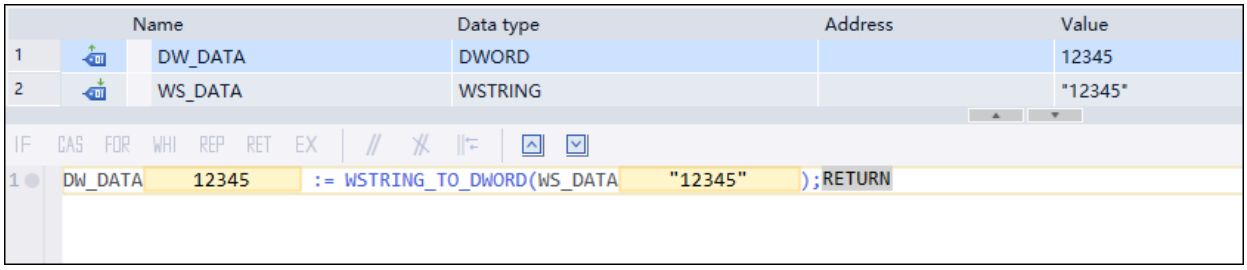
Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Data Source	Follows data type	-	Data source
Output	OUT	Result data	Follows data type	-	Converted data



Data Type

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String						
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	LTIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
IN	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	√
OUT	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√	-



- **Program example**

  Take WSTRING_TO_DWORD as an example.

  ST:

  LD:

- **Note**

  : Take WSTRING_TO_STRING as an example, Chinese characters are not supported for conversion.

18.1.12.24 UNICODE_TO_UTF8

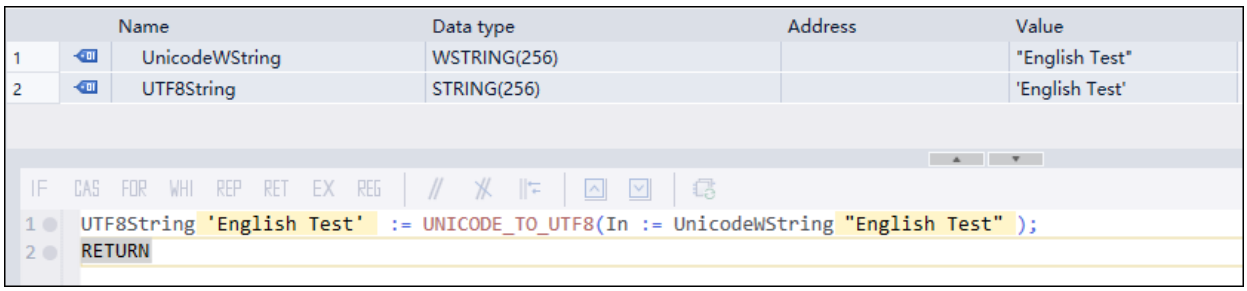
Converts the UNICODE encoding format to UTF8 encoding.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
UNICODE_TO_UTF8	UNICODE-to-UTF8 conversion	FC		:= UNICODE_TO_UTF8(In :=);

- **Related variable**

  Variable



Input/ Output	Variable	Name	Data Type	Valid Range	Default Value	Description
Input	IN	UNICODE encoded character	WSTRING	Follows data type	-	The UNICODE encoded character to be converted
Output	UNICODE_TO_UTF8	Conversion result	STRING	Follows data type	-	The UTF8 encoded character resulting from the conversion

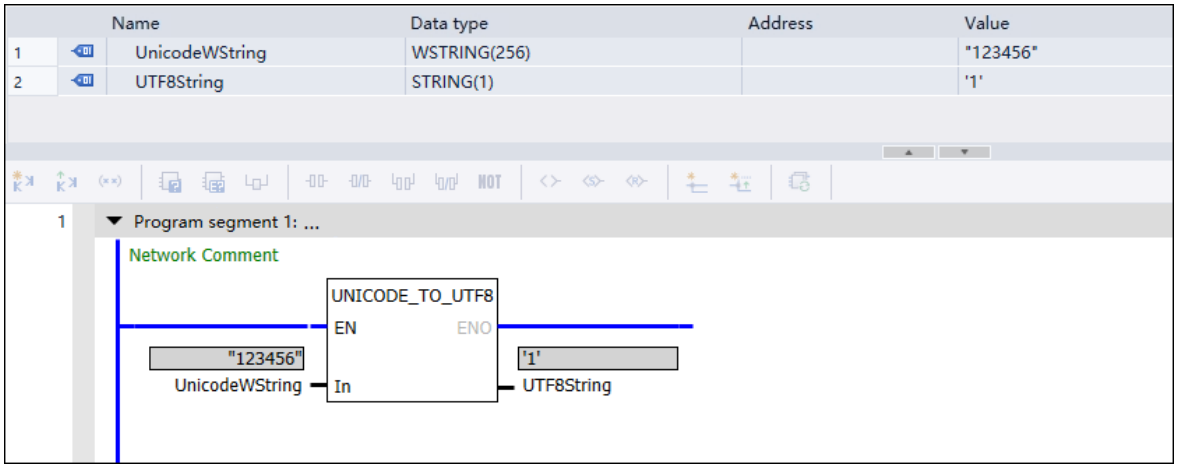
- **Function**

  Converts a wide string to a UTF-8 string. For data that cannot be converted to UTF8 encoding, the conversion proceeds, so abnormal data may result when illegal characters are present.

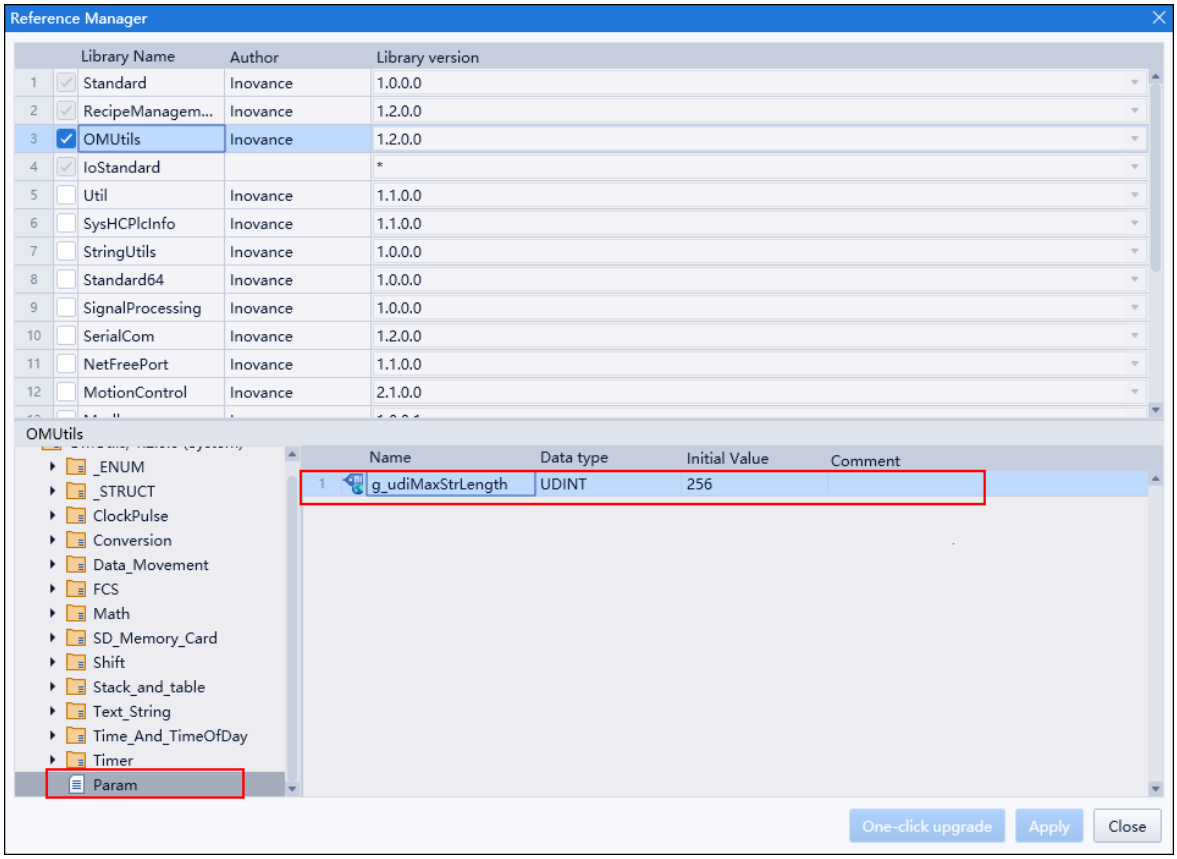
- **Program example**

  ST:

  LD:



- **Precautions**
  - When the input UNICODE encoding is invalid, the encoding conversion proceeds, and illegal characters will be directly copied into the output string.



If the input UNICODE contains invalid encoding, the conversion proceeds, and valid encoding after the invalid encoding can be converted normally.

  - When the output string length is less than the length after conversion, the remaining part of the string will be truncated.

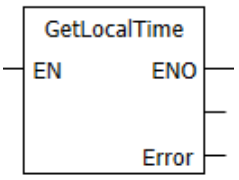
- The instruction defaults to supporting a character length of 256. The maximum supported length of the instruction can be modified by updating the global variable g_udiMaxStrLength in the OMUtil library's parameter list and then downloading the program. Parts exceeding the maximum length will be truncated.

18.2 Extended Instructions

18.2.1 System Time

18.2.1.1 Instruction List

Instruction	FB/FC	Function	Library	Applicable Library Version
18.2.1.2 GetLocalTime	FC	Gets the current time of the PLC system	Standard	Library version 1.0.0.0 and later



Instruction	FB/FC	Function	Library	Applicable Library Version
18.2.1.3 GetSysTimeMs	FC	Gets the time elapsed since system startup to the current time		Library version 1.0.0.0 and later
18.2.1.4 GetSysTimeUs	FC	Gets the time elapsed since system startup to the current time		Library version 1.0.0.0 and later
18.2.1.5 GetSysTimeNs	FC	Gets the time elapsed since system startup to the current time		Library version 1.0.0.0 and later
18.2.1.6 GetSysTimeRTC	FC	Gets the real-time clock time of the current control system		Library version 1.0.0.0 and later
18.2.1.7 SetSysTimeRTC	FB	Sets the real-time clock time of the current control system		Library version 1.0.0.0 and later
18.2.1.8 GetSystemTime	FC	Gets the time elapsed since the system startup (in ms/us /ns)		Library version 1.2.0.0 and later
18.2.1.9 ADD_DT_TIME	FC	Adds time to date and time	OMUtils	Library version 1.0.0.0 and later
18.2.1.10 ADD_TOD_TIME	FC	Adds time to time of day		Library version 1.0.0.0 and later
18.2.1.11 CheckLeapYear	FC	Checks for leap year		Library version 1.0.0.0 and later
18.2.1.12 DateStructToDt	FC	Joins date and time		Library version 1.0.0.0 and later
18.2.1.13 DateToSec	FC	Converts date to seconds		Library version 1.0.0.0 and later
18.2.1.14 DaysToMonth	FC	Converts days to month		Library version 1.0.0.0 and later
18.2.1.15 DIVTIME	FC	Divides time		Library version 1.0.0.0 and later
18.2.1.16 DtToDateStruct	FC	Breaks down date and time		Library version 1.0.0.0 and later
18.2.1.17 Days to Seconds	FC	Converts date and time to seconds		Library version 1.0.0.0 and later
18.2.1.18 GetDayOfWeek	FC	Gets day of week		Library version 1.0.0.0 and later
18.2.1.19 Get Days of Month	FC	Gets the number of days in month		Library version 1.0.0.0 and later
18.2.1.20 GetSystemDate_sDt	FC	Gets the current system time		Library version 1.0.0.0 and later

Instruction	FB/FC	Function	Library	Applicable Library Version
18.2.1.21 GetWeekOfYear	FC	Gets week number		Library version 1.0.0.0 and later
18.2.1.22 MULTIME	FC	Multiplies time		Library version 1.0.0.0 and later
18.2.1.23 NanoSecToTime	FC	Converts nanoseconds to time.		Library version 1.0.0.0 and later
18.2.1.24 SecToTime	FC	Converts seconds to time		Library version 1.0.0.0 and later
18.2.1.25 SecToDate	FC	Converts seconds to date		Library version 1.0.0.0 and later
18.2.1.26 SecToTod	FC	Converts seconds to time of day		Library version 1.0.0.0 and later
18.2.1.27 Second to Date	FC	Converts seconds to date and time		Library version 1.0.0.0 and later
18.2.1.28 SUB_DATE_DATE	FC	Subtracts date		Library version 1.0.0.0 and later
18.2.1.29 SUB_DT_DT	FC	Subtracts date and time		Library version 1.0.0.0 and later
18.2.1.30 SUB_DT_TIME	FC	Subtracts time from date and time		Library version 1.0.0.0 and later
18.2.1.31 SUB_TOD_TIME	FC	Subtracts time from time of day		Library version 1.0.0.0 and later
18.2.1.32 SUB_TOD_TOD	FC	Subtracts time of day		Library version 1.0.0.0 and later
18.2.1.33 TimeToNanoSec	FC	Converts time to nanoseconds		Library version 1.0.0.0 and later
18.2.1.34 TimeToSec	FC	Converts time to seconds		Library version 1.0.0.0 and later
18.2.1.35 TodToSec	FC	Converts time to seconds		Library version 1.0.0.0 and later
18.2.1.36 TruncDt	FC	Truncates date and time		Library version 1.0.0.0 and later
18.2.1.37 TruncTime	FC	Truncates time		Library version 1.0.0.0 and later
18.2.1.38 TruncTod	FC	Truncates time of day		Library version 1.0.0.0 and later

18.2.1.2 GetLocalTime

Gets the current time of the PLC system (including time zone information).

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
GetLocalTime	Gets the current time of the PLC system	FC		:= GetLocalTime(Error =>);

- **Related variable**

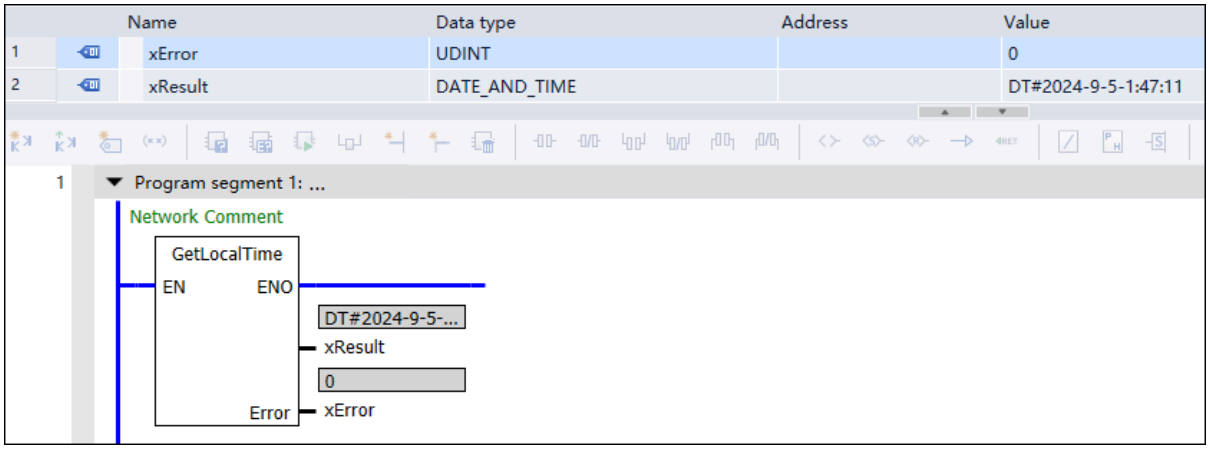
Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	Out	Return value	Follows data type	-	Returns the current time of the PLC.
	Error	Error flag	Follows data type	-	0: No fault. 1: Failed to get system time. 2: Failed to get hardware RTC time. 3: Failed to get both system time and hardware RTC time.

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–
Error	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–

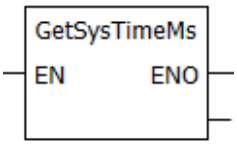
- **Function**



Gets the current time of the PLC system (including time zone information).

- **Program example**

ST:



LD:

18.2.1.3 GetSysTimeMs

Gets the time elapsed since system startup in ms.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
GetSysTimeMs	Gets the time elapsed since system startup to the current time	FC		:= GetSysTimeMs();

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	Out	Return value	Follows data type	-	Returns the time elapsed since system startup to the current time in ms.

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Out	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  Gets the time elapsed since system startup in ms.

- **Program example**

  ST:

  LD:

18.2.1.4 GetSysTimeUs

Gets the time elapsed since system startup in us.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
GetSysTimeUs	Gets the time elapsed since system startup to the current time	FC		:= GetSysTimeUs();

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	Out	Return value	Follows data type	-	Returns the time elapsed since system startup to the current time in us.

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Out	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  Gets the time elapsed since system startup in us.

- **Program example**

  ST:

  LD:

18.2.1.5 GetSysTimeNs

Gets the time elapsed since system startup in ns.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
GetSysTimeNs	Gets the time elapsed since system startup to the current time	FC		:= GetSysTimeNs();

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	Out	Return value	Follows data type	-	Returns the time elapsed since system startup to the current time in ns.

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Out	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  Gets the time elapsed since system startup in ns.

- **Program example**

  ST:

  LD:

18.2.1.6 GetSysTimeRTC

Gets the current real-time clock time of the control system, without timezone information (accurate to second).

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
GetSysTimeRTC	Gets the real-time clock time of the current control system	FC		:= GetSysTimeRTC(Error =>);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	Out	Return value	Follows data type	-	Gets the current real-time system time, displayed in DT format.
	Error	Success indicator	Follows data type	-	Indicates whether the time retrieval succeeds: 0: Retrieval successful. 1: System time retrieval failed. 2: Hardware RTC time retrieval failed.

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–
Error	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  Gets the current real-time clock time of the control system, without timezone information (accurate to second).

- **Program example**

  ST:

  LD:

18.2.1.7 SetSysTimeRTC

Sets the current real-time clock time of the control system, without timezone information (accurate to second).

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
SetSysTimeRTC	Sets the real-time clock time of the current control system	FB		SetSysTimeRTC_Instance_0(Execute := , SetTime := Error=>);

- **Related variable**

Variable

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	Execute	Enable	Follows data type	FALSE	A rising edge-triggered switch for executing the function block
	SetTime	Set time	Follows data type	-	Sets the real-time clock time of the current system, accurate to second.
Output	Error	Success indicator	Follows data type	-	Indicates whether the time setting succeeds: 0: Setting successful. 1: System time setting failed. 2: Hardware RTC time setting failed. 3: System time can only be set up to January 19, 2038, 11:14:07 A.M. 24: This instruction is not supported in simulation mode.

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Execute	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
SetTime	–	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	√	–

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Error	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  Sets the current time of the control system, without timezone information (accurate to second).

- **Program example**

  ST:

	Name	Data type	Address	Value
1	SetSysTimeRTC_Instance_0	SetSysTimeRTC		
2	Execute	BOOL		TRUE
3	SetTime	DATE_AND_TIME		DT#2024-12-3-12:27:34
4	Error	UDINT		0
5	xExecute	BOOL		TRUE
6	DT_Set	DATE_AND_TIME		DT#2024-12-3-12:27:34
7	udiError	UDINT		0

```
1  SetSysTimeRTC_Instance_0(
2  Execute  TRUE  := xExecute  TRUE ,
3  SetTime  DT#2024-12-3-12:27:34  := DT_Set  DT#2024-12-3-12:27:34 ,
4  Error  0  => udiError  0 );
5  RETURN
```

  LD:

	Name	Data type	Address	Value
1	SetSysTimeRTC_Instance_0	SetSysTimeRTC		
2	Execute	BOOL		TRUE
3	SetTime	DATE_AND_TIME		DT#2024-12-3-12:27:34
4	Error	UDINT		0
5	xExecute	BOOL		TRUE
6	DT_Set	DATE_AND_TIME		DT#2024-12-3-12:27:34
7	udiError	UDINT		0

18.2.1.8 GetSystemTime

Gets the time elapsed since the system startup.

- **Instruction format**

Instruction	Name	FB/FC	Ladder Diagram Representation	Structured Text Representation
GetSystemTime	Gets the time elapsed since the system startup (in ms/us/ns)	FC		:= GetSystemTime(uliTimeMs => , uliTimeUs => , uliTimeNs =>);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	uliTimeMs	Running time (ms)	Follows data type	-	Running time (ms)
	uliTimeUs	Running time (us)	Follows data type	-	Running time (us)
	uliTimeNs	Running time (ns)	Follows data type	-	Running time (ns)

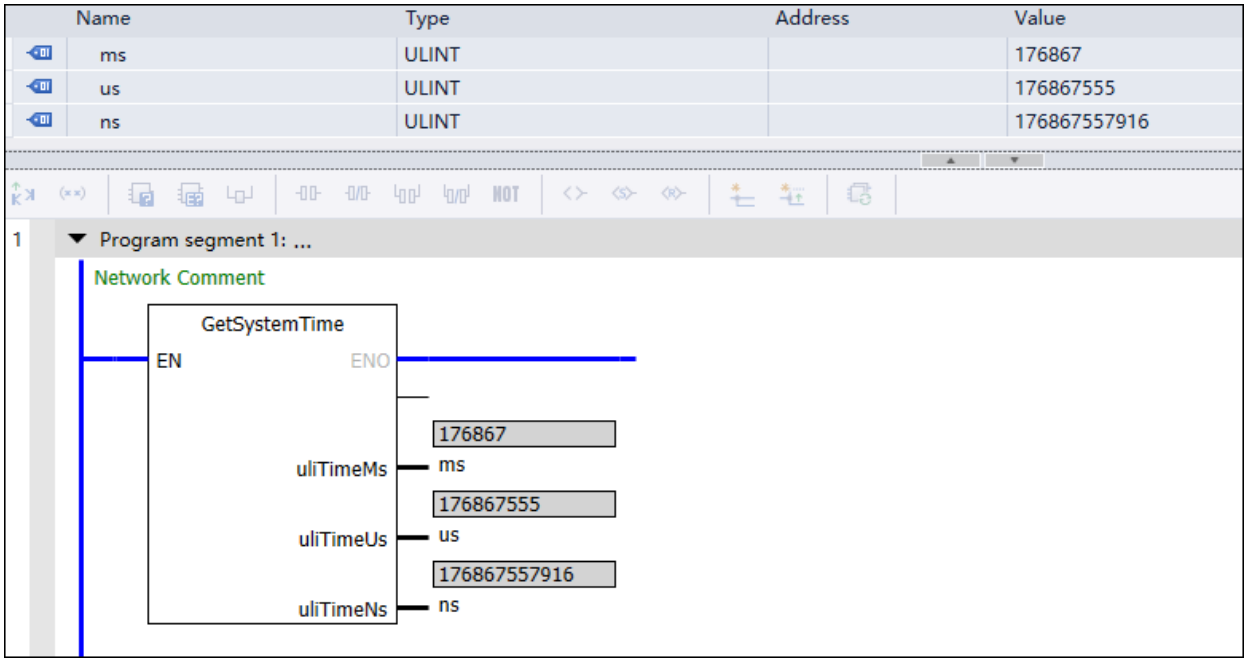
Variable types

	Boolean	Bit String				Integer								Real Number		Time, duration, date, and text string				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
uliTimeMs	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–
uliTimeUs	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–

	Boolean	Bit String				Integer								Real Number		Time, duration, date, and text string				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
uliTimeNs	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–

- **Function description**

  Gets the time elapsed since the system startup.



- **Program example**

  ST:

Name	Type	Address	Value	Prepared value	Comment
ms	ULINT		158127		
us	ULINT		158127556		
ns	ULINT		158127557782		

```
GetSystemTime(uliTimeMs => ms , uliTimeUs => us , uliTimeNs => ns );
```

  LD:

18.2.1.9 ADD_DT_TIME

Adds "In2" (time) to "In1" (date and time), and returns "Out" (date and time).

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ADD_DT_TIME	Adds time to date and time	FC		:= ADD_DT_TIME(In1 := , In2 := , Out =>);

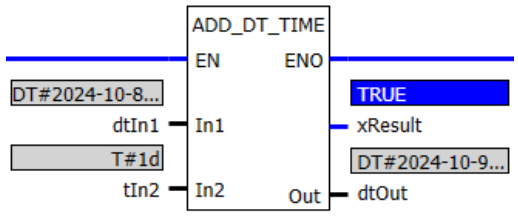
- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Date and time to be added	Follows data type	DATE_AND_TIME#1970-1-1-0:0:0	Date and time to be added
	In2	Time to add	Follows data type	TIME#0ms	Time to add
Output	Out	Addition result (date and time)	Follows data type	-	Addition result (date and time)

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–
In2	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–



- **Function**

Adds "In2" (time) to "In1" (date and time), and returns "Out" (date and time).

- **Program example**

xResult TRUE := ADD_DT_TIME(In1 := dtIn1 DT#2024-10-8-14:39:17,
    In2 := tIn2 T#1d,
    Out => dtOut DT#2024-10-9-14:39:17 );RETURN
```

</td></tr>
<tr><td>Operation result</td><td colspan="2">

Name	Data type	Address	Value
xResult	BOOL		TRUE
dtIn1	DATE_AND_TIME		DT#2024-10-8-14:39:17
tIn2	TIME		T#1d
dtOut	DATE_AND_TIME		DT#2024-10-9-14:39:17

</td></tr>
</table>

- **Precautions**

  When the result of addition exceeds the valid range of Out, no program fault occurs and the following operation is executed.

  DT#2106-2-7-6:28:15 + T#1s → DT#1970-1-1-0:0:0

18.2.1.10 ADD_TOD_TIME

Adds "In2" (time) to "In1" (time of day), and returns "Out" (time of day).

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ADD_TOD_TIME	Adds time to time of day	FC		:= ADD_TOD_TIME(In1 := , In2 := , Out =>);

- **Related variable**

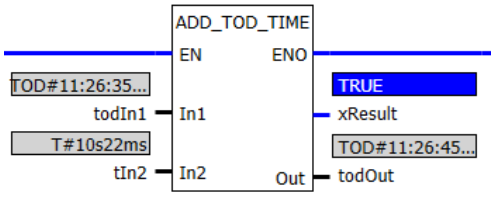
  Variable

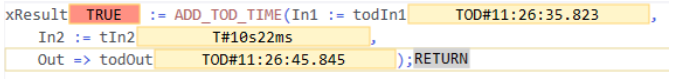
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Time of day to be added	Follows data type	TIME_OF_DAY#0:0:0	Time of day to be added
	In2	Time to add	Follows data type	TIME#0ms	Time to add

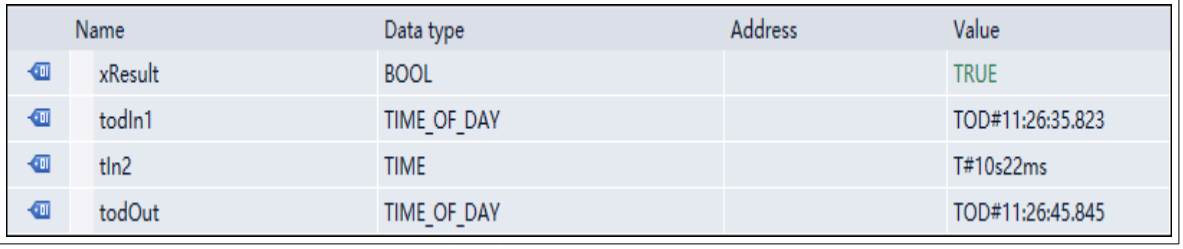
Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	Out	Addition result (time of day)	Follows data type	-	Addition result (time of day)

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–
In2	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–







- **Function**

  Adds "In2" (time) to "In1" (time of day), and returns "Out" (time of day).

- **Program example**

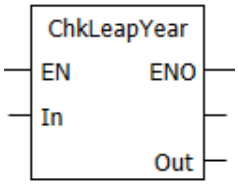
Item	LD	ST

Define variables	VAR
	xResult: BOOL;
	todIn1: TIME_OF_DAY := TOD#11:26:35.823;
	tIn2: TIME := T#10s22ms;
	todOut: TIME_OF_DAY;
	END_VAR	

Program		
Operation result		

Name	Data type	Address	Value
xResult	BOOL		TRUE
todIn1	TIME_OF_DAY		TOD#11:26:35.823
tIn2	TIME		T#10s22ms
todOut	TIME_OF_DAY		TOD#11:26:45.845

- **Precautions**



When the result of addition exceeds the valid range of Out, no program fault occurs and the following operation is executed.

TOD#23:59:59.999 + T#1s1ms → TOD#0:0:1

18.2.1.11 ChkLeapYear

Checks whether the input year is a leap year.

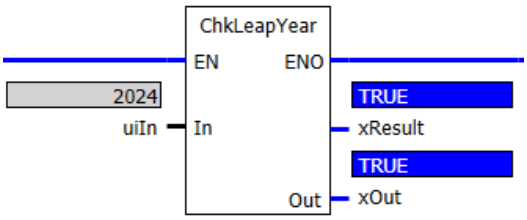
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
ChkLeapYear	Checks for leap year	FC		:= ChkLeapYear(In := , Out =>);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Year	1970 to 2106	1970	Year
Output	Out	Check result	Follows data type	-	TRUE: "In" is a leap year. FALSE: "In" is not a leap year.



Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

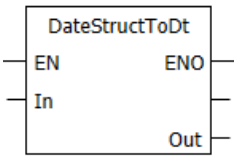
- **Function**

This instruction checks whether the year In is a leap year. If so, the result Out is TRUE; if not, Out is FALSE.

- **Program example**

Item	LD	ST
Define variables	VAR xResult: BOOL; uiIn: UINT := 2024; xOut: BOOL; END_VAR	
Program		xResult TRUE := ChkLeapYear(In := uiIn 2024 , Out => xOut TRUE);RETURN
Operation result		

Name	Data type	Address	Value
xResult	BOOL		TRUE
uiIn	UINT		2024
xOut	BOOL		TRUE



- **Precautions**

  When the value of In exceeds the valid range, a program fault occurs, the value of Out is FALSE, and the return value is FALSE.

18.2.1.12 DateStructToDt

Joins year, month, day, hour, minute, and second into date and time.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
DateStructToDt	Joins date and time	FC		:= DateStructToDt(In := , Out =>);

- **Related variable**

  Variable

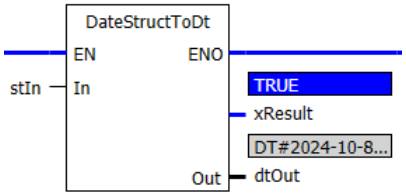
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Date and time	Follows the data type (_sDT)	-	Year, month, day, hour, minute, and second to be joined
Output	Out	Date and time	DT#1970-1-1-0:0:0 to DT#2106-2-7-6:28:15	-	Date and time after joining

  _sDT structure

Variable	Name	Content	Data Type	Valid Range	Initial Value	Unit
uiYear	Year	Year	UINT	1970 to 2106	1970	Year
uiMonth	Month	Month	UINT	1 to 12	1	Month
uiDay	Day	Day	UINT	1 to 31	1	Day
uiHour	Hour	Hour	UINT	0 to 23	0	Hour
uiMinute	Minute	Minute	UINT	0 to 59	0	Minute
uiSecond	Second	Second	UINT	0 to 59	0	Second
uiMillisecond	Millisecond	Millisecond	UINT	0 to 999	0	Millisecond
uiDayOfWeek	Day of the week	Day of the week	UINT	1 to 7	1	-

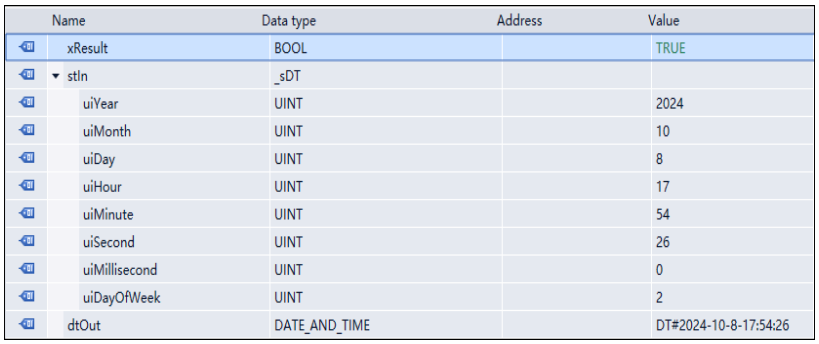
Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	_sDT																			
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–



- **Function**

  Joins year, month, day, hour, minute, and second into date and time.

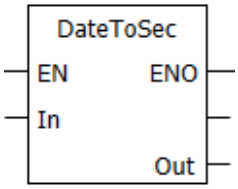


- **Program example**

Item	LD	ST
Define variables		
Program		

```
VAR
    xResult: BOOL;
    stIn: _sDT := (uiYear := 2024, uiMonth := 10, uiDay := 8, uiHour := 17, uiMinute := 54, uiSecond := 26, uiDayOfWeek := 2);
    dtOut: DATE_AND_TIME;
END_VAR
```

```
xResult := DateStructToDt(In := stIn,
Out => dtOut );RETURN
```



Item	LD	ST
Operation result		

- **Precautions**
  - The valid range of the output DT Out is DT#1970-1-1-0:0:0 to DT#2106-2-7-6:28:15.
  - If the value of Out exceeds the valid range, the return value is FALSE and the operation result is DT#1970-1-1-0:0:0.
  - If the value of In exceeds the valid range of each element in the _sDT structure, the return value is FALSE and the operation result is DT#1970-1-1-0:0:0.
  - The initial value of each element in the _sDT structure is the breakdown value of DT#1970-1-1-0:0:0.

18.2.1.13 DateToSec

Converts a date to the number of seconds from 00:00:00 on January 1, 1970.

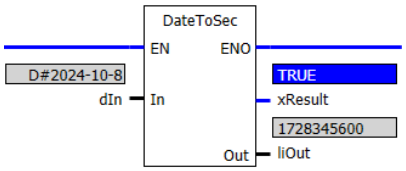
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
DateToSec	Converts date to seconds	FC		:= DateToSec(In := , Out =>);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Date	Follows data type.	DATE#1970-1-1	Date
Output	Out	Conversion result	0 to 4294967295	0	Number of seconds since 00:00:00 on January 1, 1970



Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–

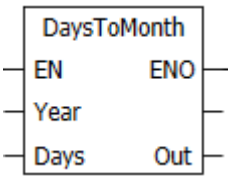
- **Function**

  Returns the number of seconds from 00:00:00 on January 1, 1970 to 00:00:00 on the date specified by In. The unit is Out is second.

- **Program example**

Item	LD	ST
Define variables	VAR xResult: BOOL; dIn: DATE := D#2024-10-08; liOut: LINT; END_VAR	
Program		
Operation result		

Name	Data type	Address	Value
xResult	BOOL		TRUE
dIn	DATE		D#2024-10-8
liOut	LINT		1728345600



- **Precautions**

  To convert the number of seconds from 00:00:00 on January 1, 1970 to a date, use the 18.2.1.25 SecToDate instruction.

18.2.1.14 DaysToMonth

Calculates the month based on the number of days from January 1.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
DaysToMonth	Converts days to month	FC		:= DaysToMonth(Year := , Days := , Out =>);

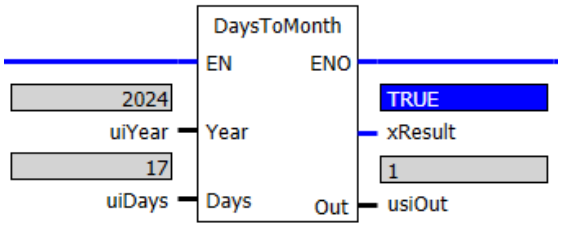
- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Year	Year	1970 to 2106	1970	Year
	Days	Number of days	Year ranges from 1 to 365 when it is a common year. Year ranges from 1 to 366 when it is a leap year.	1	Number of days from January 1
Output	Out	Month	1 to 12	0	Month

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Year	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
Days	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–



- **Function**

  Calculates the month based on Days (number of days from January 1 in Year).

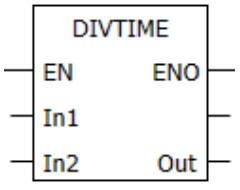
- **Program example**

<table>
<tr><th>Item</th><th>LD</th><th>ST</th></tr>
<tr><td>Define variables</td><td colspan="2">

```
VAR
    xResult: BOOL;
    uiYear: UINT := 2024;
    uiDays: UINT := 17;
    usiOut: USINT;
END_VAR
```

</td></tr>
<tr><td>Program</td><td>
</td><td>

```
xResult := DaysToMonth(Year := uiYear ,
           Days := uiDays ,
           Out => usiOut );RETURN
```



</td></tr>
<tr><td>Operation result</td><td colspan="2">
<table>
<tr><th></th><th>Name</th><th>Data type</th><th>Address</th><th>Value</th></tr>
<tr><td></td><td>xResult</td><td>BOOL</td><td></td><td>TRUE</td></tr>
<tr><td></td><td>uiYear</td><td>UINT</td><td></td><td>2024</td></tr>
<tr><td></td><td>uiDays</td><td>UINT</td><td></td><td>17</td></tr>
<tr><td></td><td>usiOut</td><td>USINT</td><td></td><td>1</td></tr>
</table>
</td></tr>
</table>

- **Precautions**
  - When the value of Year exceeds the valid range, no fault occurs, the value of Out is 0, and the return value is FALSE.
  - When the value of Days exceeds the valid range, no fault occurs, the value of Out is 0, and the return value is FALSE.

18.2.1.15 DIVTIME

Divides a time by a specified number.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
DIVTIME	Divides time	FC		:= DIVTIME(In1 := , In2 := , Out =>);

- **Related variable**

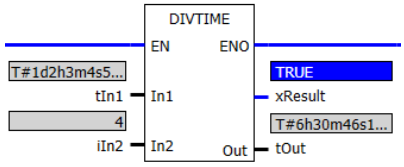
Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Dividend time	Follows data type	TIME#0ms	Dividend time
	In2	Divider	Follows data type	-	Divider

Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	Out	Result time of division	Follows data type	-	Result time of division

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–
In2	–	–	–	–	–	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–



- **Function**

  This instruction divides a time In1 by a number In2. The result of division Out is a time.

- **Program example**

Item	LD	ST

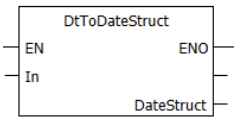
Define variables	VAR
	xResult: BOOL;
	tIn1: TIME := T#1d2h3m4s5ms;
	iIn2: INT := 4;
	tOut: TIME;
	END_VAR	

Program		
Operation result		

Name	Data type	Address	Value
xResult	BOOL		TRUE
tIn1	TIME		T#1d2h3m4s5ms
iIn2	INT		4
tOut	TIME		T#6h30m46s1ms

- **Precautions**
  - When the division result exceeds the valid range of Out, the value of Out is T#0ms and the return value is FALSE.
  - When In2 is negative, the value of Out is T#0ms, and the return value is FALSE.

- When In2 is an integer with a value of 0, the value of Out is T#0ms, and the return value is FALSE.
- When In2 is a real number:
  - When the input value of In2 makes the value of Out exceed the upper limit of the TIME type, the value of Out is T#0ms and the return value is FALSE.
  - Division result less than 1 ms is rounded. When In2 is a real number, the division result may have an error of several milliseconds due to a higher number of significant digits.
  - When In2 is a valid value and is greater than 4294967295, the value of Out is T#0ms, and the function returns FALSE.
- When the value of In2 is 0, positive infinity, negative infinity, or non-numeric data, the corresponding value of Out is listed in the following table.



Value of In2	Value of Out
0	T#0ms
+∞	T#0ms
-∞	T#0ms
Non-numeric	T#0ms

Note: If In2 is a REAL value less than 1e-6, or an LREAL value less than 1e-15, it is treated as zero, resulting in a division-by-zero operation.

18.2.1.16 DtToDateStruct

Converts date and time to year, month, day, hour, minute, and second.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
DtToDateStruct	Breaks down date and time	FC		:= DtToDateStruct(In := , DateStruct =>);

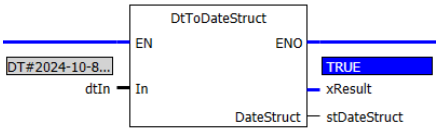
- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Date and time	Follows data type	DT#1970-1-1-0:0:0	Date and time to break down
Output	DateStruct	Date and time	Follows the data type (_sDT)	-	Date and time after breakdown

  _sDT structure

Variable	Name	Content	Data Type	Valid Range	Initial Value	Unit
uiYear	Year	Year	UINT	1970 to 2106	1970	Year
uiMonth	Month	Month	UINT	1 to 12	1	Month
uiDay	Day	Day	UINT	1 to 31	1	Day
uiHour	Hour	Hour	UINT	0 to 23	0	Hour
uiMinute	Minute	Minute	UINT	0~9	0	Minute
uiSecond	Second	Second	UINT	0 to 59	0	Second
uiMillisecond	Millisecond	Millisecond	UINT	0~999	0	Millisecond
uiDayOfWeek	Day of the week	Day of the week	UINT	1 to 7	1	-



- **Variable types**

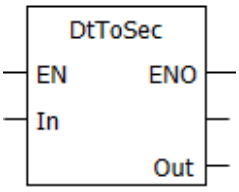
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–
DateStruct	_sDT																			

- **Function**

  Converts In (date and time) to year, month, day, hour, minute, and second in the _sDT structure format.

- **Program example**

Item	LD	ST
Define variables	VAR xResult: BOOL; dtIn: DATE_AND_TIME := DT#2024-10-08-15:14:43; stDateStruct: _SDT; END_VAR	
Program		xResult TRUE := DtToDateStruct(In := dtIn DT#2024-10-8-15:14:43 , DateStruct => stDateStruct);RETURN



Item	LD	ST
Operation result		

- **Precautions**
  - The valid range of the input date and time In is DT#1970-1-1-0:0:0 to DT#2106-2-7-6:28:15.
  - If the value of In exceeds the valid range, the return value is FALSE and the operation result is the breakdown result of DT#1970-1-1-0:0:0.
  - The initial value of each element in the _sDT structure is the breakdown value of DT#1970-1-1-0:0:0.

18.2.1.17 DtToSec

Converts a date and time to the number of seconds from 00:00:00 on January 1, 1970.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
DtToSec	Converts date and time to seconds	FC		:= DtToSec(In := , Out =>);

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Date and time	Follows data type	DATE_AND_TIME#1970-1-1-0:0:0	Date and time
Output	Out	Conversion result	0 to 4294967295	0	Number of seconds since 00:00:00 on January 1, 1970

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
IN	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–

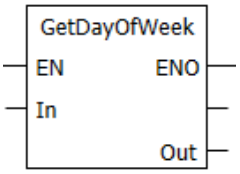
- **Function**

  Converts In (date and time) to the number of seconds from 00:00:00 on January 1, 1970. The converted value is in seconds, and values less than one second are truncated.

- **Program example**

Item	LD	ST
Define variables	VAR xResult: BOOL; dtIn: DATE_AND_TIME := DT#2023-5-22-23:59:59; liOut: LINT; END_VAR	
Program		xResult TRUE := DtToSec(In := dtIn DT#2023-5-22-23:59:59 , Out => liOut 1684799999);RETURN
Operation result		

	Name	Data type	Address	Value
	xResult	BOOL		TRUE
	dtIn	DATE_AND_TIME		DT#2023-5-22-23:59:59
	liOut	LINT		1684799999



- **Precautions**

  To convert the number of seconds from 00:00:00 on January 1, 1970 to a date, use the 18.2.1.25 SecToDate instruction.

18.2.1.18 GetDayOfWeek

Gets the day of the week for the specified date or date and time.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
GetDayOfWeek	Gets day of week	FC		:= GetDayOfWeek(In := , Out =>);

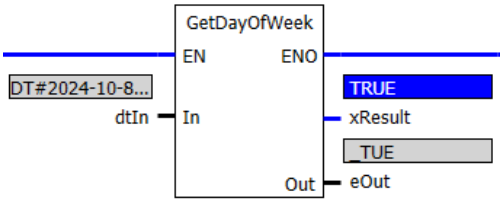
- **Related variables**

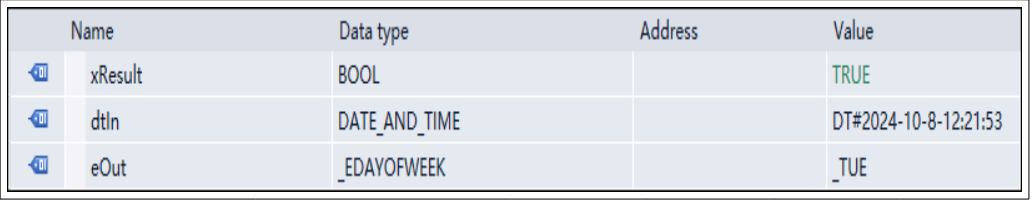
  Input variables

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Date or date and time	Range for data type DATE: DATE#1970-1-1 to DATE#2106-2-7 Range for data type DT: DT#1970-1-1-0:0:0 to DT#2106-2-7-6:28:15	-	Data type DATE: Year-month-day Data type DT: Year-month-day-hour-minute-second
Output	Out	Week	Follows data type (_eDAYOFWEEK)	-	Day of week

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	√	–
Out	See "Function description" for the enumerators of enumeration type _eDAYOFWEEK.																			





- **Function**

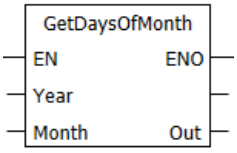
  Gets the day of the week for the specified date or date and time. The data type of Out is enumerated type _eDAYOFWEEK. The meanings of the enumerators are as follows.

Enumeration Value	Definition
_MON	Monday

Enumeration Value	Definition
_TUE	Tuesday
_WED	Wednesday
_THU	Thursday
_FRI	Friday
_SAT	Saturday
_SUN	Sunday

- **Program example**

Item	LD	ST
Define variables	VAR xResult: BOOL; dtIn: DATE_AND_TIME := DT#2024-10-08-12:21:53; eOut: _EDAYOFWEEK; END_VAR	
Program		
Operation result		



Name	Data type	Address	Value
xResult	BOOL		TRUE
dtIn	DATE_AND_TIME		DT#2024-10-8-12:21:53
eOut	_EDAYOFWEEK		_TUE

- **Precautions**
  - When the value of In exceeds the valid range, a program fault occurs, the value of Out is _MON, and the return value is FALSE.
  - The input parameter passed to In must be a variable; if a constant is passed, a compilation fault occurs.

18.2.1.19 GetDaysOfMonth

Gets the number of days in the specified month.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
GetDaysOfMonth	Gets the number of days in month	FC		:= GetDaysOfMonth(Year := , Month := , Out =>);

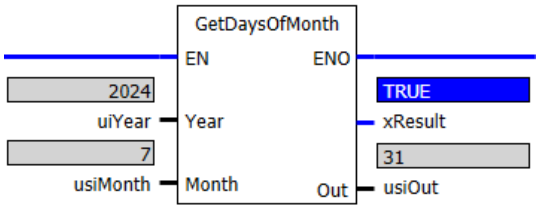
- **Related variable**

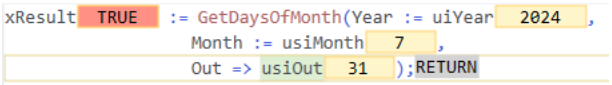
  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Year	Year	1970 to 2106	1970	Year
	Month	Month	1 to 12	1	Month
Output	Out	Number of days	28 to 31	-	Number of days

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Year	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
Month	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–





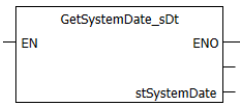
- **Function**

  Gets the number of days in the month specified by "Month" and "Year".

- **Program example**

Item	LD	ST

Define variables		VAR
		xResult: BOOL;
		uiYear: UINT := 2024;
		usiMonth: USINT := 7;
		usiOut: USINT;
		END_VAR



<table>
<tr><th>Item</th><th>LD</th><th>ST</th></tr>
<tr><td>Program</td><td>
</td><td>
</td></tr>
<tr><td>Operation result</td><td colspan="2">
<table>
<tr><th></th><th>Name</th><th>Data type</th><th>Address</th><th>Value</th></tr>
<tr><td></td><td>xResult</td><td>BOOL</td><td></td><td>TRUE</td></tr>
<tr><td></td><td>uiYear</td><td>UINT</td><td></td><td>2024</td></tr>
<tr><td></td><td>usiMonth</td><td>USINT</td><td></td><td>7</td></tr>
<tr><td></td><td>usiOut</td><td>USINT</td><td></td><td>31</td></tr>
</table>
</td></tr>
</table>

- **Precautions**
  - When the value of Year exceeds the valid range, the value of Out is 0, and the return value is FALSE.
  - When the value of Month exceeds the valid range, the value of Out is 0, and the return value is FALSE.

18.2.1.20 GetSystemDate_sDt

Outputs the current system time in _sDT structure format.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
GetSystemDate_sDt	Gets the current system time	FC		:= GetSystemDate_sDt(stSystemDate =>);

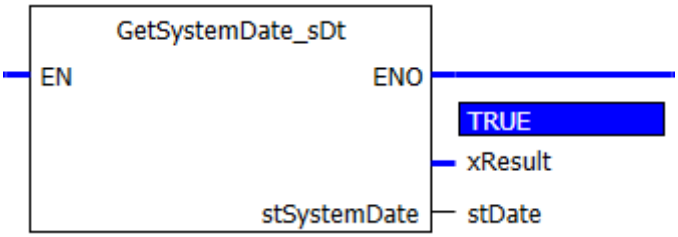
- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	stSystemDate	System time	Follows data type	-	Structure of system time

Variable types

	Boolean	Bit String					Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
stSystemDate	_sDT																			

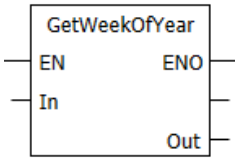


_sDT structure

Variable	Name	Content	Data Type	Valid Range	Initial Value	Unit
uiYear	Year	Year	UINT	1970 to 2106	0	Year
uiMonth	Month	Month	UINT	1 to 12	0	Month
uiDay	Day	Day	UINT	1 to 31	0	Day
uiHour	Hour	Hour	UINT	0 to 23	0	Hour
uiMinute	Minute	Minute	UINT	0 to 59	0	Minute
uiSecond	Second	Second	UINT	0 to 59	0	Second
uiMillisecond	Millisecond	Millisecond	UINT	0 to 999	0	Millisecond
uiDayOfWeek	Day of the week	Day of the week	UINT	1 to 7	0	-

- **Function**

  Outputs the current system time in _sDT structure format.



- **Program example**

Item	LD	ST
Define variables	VAR stDate: _SDT; xResult: BOOL; END_VAR	
Program		
Operation result		

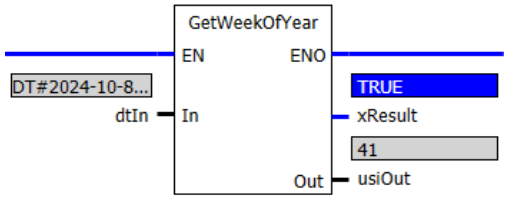
18.2.1.21 GetWeekOfYear

Gets the week number for the specified date or date and time.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
GetWeekOfYear	Gets week number	FC		:= GetWeekOfYear(In := , Out =>);

- **Related variables**



Input variables

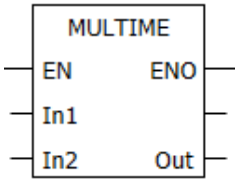
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Date or date and time	Range for data type DATE: DATE#1970-1-1 to DATE#2106-2-7 Range for data type DATE_AND_TIME: DATE_AND_TIME#1970-1-1-0:0:0 to DT#2106-2-7-6:28:15	-	Data type DATE: Year-month-day Data type DATE_AND_TIME: Year-month-day-hour-minute-second
Output	Out	Week number	1 to 54	-	Week number

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	√	–
Out	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - Gets the week number for the date or date and time specified by In.
  - A week is considered from Monday to Sunday. The week count increments upon the transition from Sunday to Monday.
  - January 1 is always in week 1.
- **Program example**

Item	LD	ST
Define variables	VAR xResult: BOOL; dtIn: DATE_AND_TIME := DT#2024-10-08-15:34:22; usiOut: USINT; END_VAR	
Program		
Operation result		



Name	Data type	Address	Value
xResult	BOOL		TRUE
dtIn	DATE_AND_TIME		DT#2024-10-8-15:34:22
usiOut	USINT		41

- **Precautions**
  - When the value of In exceeds the valid range, a program fault occurs, the value of Out is 0, and the return value is FALSE.
  - The input parameter transmitted to In must be a variable. If a constant is transmitted to In, a compilation error occurs.

18.2.1.22 MULTIME

Multiplies a time by a specified number.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
MULTIME	Multiplies time	FC		:= MULTIME(In1 := , In2 := , Out =>);

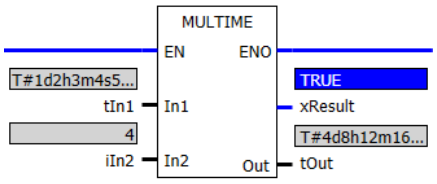
- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Multiplicand time	Follows data type	TIME#0ms	Multiplicand time
	In2	Multiplier	Follows data type	-	Multiplier
Output	Out	Product result time	Follows data type	-	Product result time

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–
In2	–	–	–	–	–	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–



- **Function**

  This instruction multiplies a time In1 by multiplier In2. The result of multiplication in Out is a time.

- **Program example**

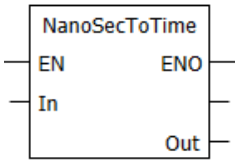
Item	LD	ST

Define variables	VAR
	xResult: BOOL;
	tIn1: TIME := T#1d2h3m4s5ms;
	iIn2: INT := 4;
	tOut: TIME;
	END_VAR	

Program		xResult TRUE := MULTIME(In1 := tIn1 T#1d2h3m4s5ms , In2 := iIn2 4 , Out => tOut T#4d8h12m16s20ms);RETURN
Operation result		

	Name	Data type	Address	Value
	xResult	BOOL		TRUE
	tIn1	TIME		T#1d2h3m4s5ms
	iIn2	INT		4
	tOut	TIME		T#4d8h12m16s20ms

- **Precautions**
  - When the multiplication result exceeds the valid range of Out, the value of Out is T#0ms and the return value is FALSE.
  - When In2 is negative, a program fault occurs, the value of Out is T#0ms, and the return value is FALSE.
  - When the input value of In2 makes the value of Out exceed the upper limit of the TIME type, the value of Out is T#0ms and the return value is FALSE.
  - When In2 is a real number, any fractional part of the product result that is less than 1 ms is truncated.



- When In2 is a real number, the product result containing more valid digits may cause an error of several milliseconds.
- When the value of In2 is positive infinity, negative infinity, or non-numeric data, the corresponding value of Out is listed in the following table.

"In2" Value	Value of Out
+∞	T#0ms
-∞	T#0ms
Non-numeric	T#0ms

18.2.1.23 NanoSecToTime

This instruction converts the number of nanoseconds to a time.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
NanoSecToTime	Converts nanoseconds to time.	FC		:= NanoSecToTime(In := , Out =>);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Number of nanoseconds	0 to 4294967295000000	0	Number of nanoseconds
Output	Out	Conversion result	Follows data type	TIME#0ms	Time

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–

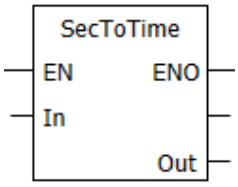
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–

- **Function**

  Converts nanoseconds "In" to time.

- **Program example**

Item	LD	ST
Define variables	VAR xResult: BOOL; liIn: LINT := 888888888888; tOut: TIME; END_VAR	
Program		xResult TRUE := NanoSecToTime(In := liIn 888888888888 , Out => tOut T#14m48s888ms);RETURN
Operation result		



Name	Data type	Address	Value
xResult	BOOL		TRUE
liIn	LINT		888888888888
tOut	TIME		T#14m48s888ms

- **Precautions**
  - If In is beyond the input range, the function returns FALSE and outputs T#0ms.
  - To convert a time to the number of nanosecond, use the 18.2.1.33 TimeToNanoSec instruction.

18.2.1.24 SecToTime

Converts the number of seconds to a time.

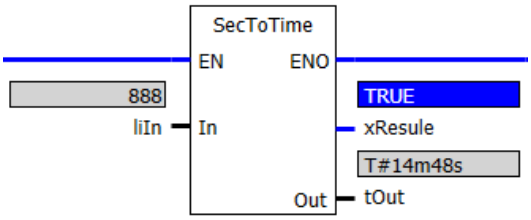
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
SecToTime	Converts seconds to time	FC		:= SecToTime(In := , Out =>);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Number of seconds	0 to 4294967	0	Number of seconds
Output	Out	Conversion result	Follows data type	TIME#0ms	Time



Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–

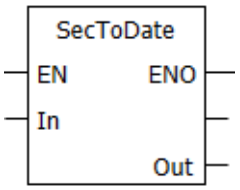
- **Function**

Converts seconds "In" to time.

- **Program example**

Item	LD	ST
Define variables	VAR xResule: BOOL; liIn: LINT := 888; tOut: TIME; END_VAR	
Program		xResule TRUE := SecToTime(In := liIn 888, Out => tOut T#14m48s);RETURN

Item	LD	ST
Operation result		



Name	Data type	Address	Value
xResule	BOOL		TRUE
liIn	LINT		888
tOut	TIME		T#14m48s

- **Precautions**
  - To convert a time to the number of seconds, use the 18.2.1.34 TimeToSec instruction.
  - The unit of In is seconds.
  - When the value of In exceeds the valid range, the return value is FALSE and Out is T#0s.

18.2.1.25 SecToDate

Converts the number of seconds since January 1, 1970, 00:00:00 to a date.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
SecToDate	Converts seconds to date	FC		:= SecToDate(In := , Out =>);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Number of seconds	0 to 4294967295	0	Number of seconds since 00:00:00 on January 1, 1970
Output	Out	Conversion result	Follows data type	DATE#1970-1-1	Date

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–

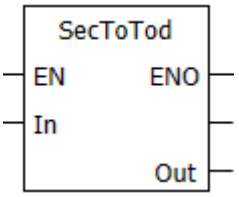
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–

- **Function**

  Converts the number of seconds "In" since January 1, 1970, 00:00:00 to a date. Values less than one day are truncated.

- **Program example**

Item	LD	ST
Define variables	VAR xResult: BOOL; liIn: LINT := 888888888; dOut: DATE; END_VAR	
Program		xResult TRUE := SecToDate(In := liIn 888888888, Out => dOut D#1998-3-3);RETURN
Operation result		



Name	Data type	Address	Value
xResult	BOOL		TRUE
liIn	LINT		888888888
dOut	DATE		D#1998-3-3

- **Precautions**
  - To convert a date to the number of seconds from 00:00:00 on January 1, 1970, use the 18.2.1.13 DateToSec instruction.
  - If the value of In exceeds the valid range, the return value changes to FALSE and the value of Out changes to D#1970-1-1.

18.2.1.26 SecToTod

Converts the number of seconds from 00:00:00 to time of day.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
SecToTod	Converts seconds to time of day	FC		:= SecToTod(In := , Out =>);

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Number of seconds	0 to 9223372036854775807	0	Number of seconds since 00:00:00 on January 1, 1970
Output	Out	Conversion result	Follows data type	TIME_OF_DAY#0:0:0	Time of day

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–

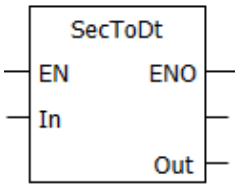
- **Function**

  Converts the number of seconds from 00:00:00 (In) to time of day. When the value of In is greater than 24 hours (86400 seconds), divide the value of In by 24 hours and then convert the remainder into a TOD.

- **Program example**

Item	LD	ST
Define variables	VAR xResult: BOOL; liIn: LINT := 888888888; tdOut: TIME_OF_DAY; END_VAR	

Item	LD	ST
Program		
Operation result		



Name	Data type	Address	Value
xResult	BOOL		TRUE
liIn	LINT		888888888
tdOut	TIME_OF_DAY		TOD#1:34:48

- **Precautions**
  - To convert a TOD to the number of seconds from 00:00:00, use the 18.2.1.35 TodToSec instruction.
  - If the value of In exceeds the valid range, the return value changes to FALSE and the value of Out changes to TOD#0:0:0.

18.2.1.27 SecToDt

Converts the number of seconds since January 1, 1970, 00:00:00 to a date and time.

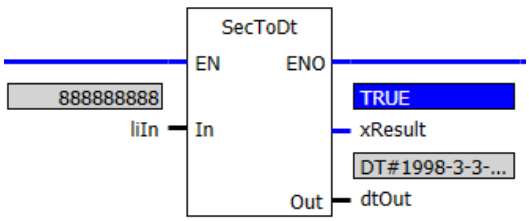
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
SecToDt	Converts seconds to date and time	FC		:= SecToDt(In := , Out =>);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Number of seconds	0 to 4294967295	0	Number of seconds since 00:00:00 on January 1, 1970
Output	Out	Conversion result	Follows data type	DATE_AND_TIME#1970-1-1-0:0:0	Date and time



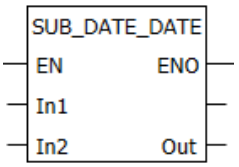
Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–

- **Function**

  Converts the number of seconds since January 1, 1970, 00:00:00 (In) to a date and time.

- **Program example**



Item	LD	ST
Define variables	VAR xResult: BOOL; liIn: LINT := 888888888; dtOut: DATE_AND_TIME; END_VAR	
Program		
Operation result		

- **Precautions**
  - To convert a DT to the number of seconds from 00:00:00 on January 1, 1970, use the 18.2.1.17 DtToSec instruction.
  - If the value of In exceeds the valid range, the return value changes to FALSE and the value of Out changes to DT#1970-1-1-0:0:0.

18.2.1.28 SUB_DATE_DATE

Subtracts a date from another date.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
SUB_DATE_DATE	Subtracts date	FC		:= SUB_DATE_DATE(In1 := , In2 := , Out =>);

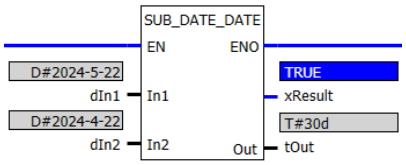
- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Subtrahend date	DATE#1970-1-1 to DATE#2106-2-7	DATE#1970-1-1	Subtrahend date
	In2	Minuend date	DATE#1970-1-1 to DATE#2106-2-7	DATE#1970-1-1	Minuend date
Output	Out	Subtraction result	Follows data type	-	Subtraction result

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–
In2	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–



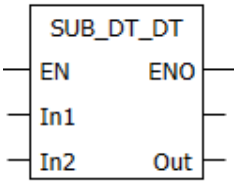
- **Function**

  Subtracts date In2 from date In1. The subtraction result Out is a time.

- **Program example**

Item	LD	ST

Define variables	VAR
	xResult: BOOL;
	dIn1: DATE := D#2024-5-22;
	dIn2: DATE := D#2024-4-22;
	tOut: TIME;
	END_VAR	



Program		
Operation result		

- **Precautions**
  - When the result of subtraction exceeds the valid range of Out, a program fault occurs, the value of Out is T#0ms, and the return value is FALSE.
  - Since the minimum unit for input DATE is s and for TIME is ms, the result must be less than 4294967 to remain within the valid range of Out.
  - When the value of In1 is less than In2, no program fault occurs and the following operation is executed.
    - In1 is incremented by T#4295030400s, which corresponds to the maximum value of DATE (DATE#2106-2-7) plus one additional day.
    - For example: DATE#1970-1-1 - DATE#2106-2-7 = (DATE#1970-1-1 + T#4295030400s) - DATE#2106-2-7 = T#1d

18.2.1.29 SUB_DT_DT

Subtracts date and time from date and time.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
SUB_DT_DT	Subtracts date and time	FC		:= SUB_DT_DT(In1 := , In2 := , Out =>);

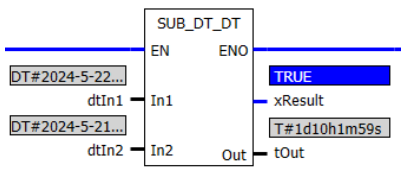
- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Subtrahend date and time	Follows data type	DATE_AND_TIME#1970-1-1-0:0:0	Subtrahend date and time
	In2	Minuend date and time	Follows data type	DATE_AND_TIME#1970-1-1-0:0:0	Minuend date and time
Output	Out	Subtraction result	Follows data type	-	Subtraction result

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–
In2	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–



- **Function**

  Subtracts date and time In2 from date and time In1. The subtraction result is a time.

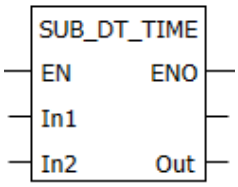
- **Program example**

Item	LD	ST

Define variables	VAR
	xResult: BOOL;
	dtIn1: DATE_AND_TIME := DT#2024-5-22-21:24:32;
	dtIn2: DATE_AND_TIME := DT#2024-5-21-11:22:33;
	tOut: TIME;
	END_VAR	

Program		

Item	LD	ST
Operation result		



Name	Data type	Address	Value
xResult	BOOL		TRUE
dtIn1	DATE_AND_TIME		DT#2024-5-22-21:24:32
dtIn2	DATE_AND_TIME		DT#2024-5-21-11:22:33
tOut	TIME		T#1d10h1m59s

- **Precautions**
  - When the result of subtraction exceeds the valid range of Out, a program fault occurs, the value of Out is T#0ms, and the return value is FALSE.
  - Since the minimum unit for input DATE is s and for TIME is ms, the result must be less than 4294967 to remain within the valid range of Out.
  - When the value of In1 is less than In2, no program fault occurs and the following operation is executed.
    - In1 is incremented by T#4294967296s, which corresponds to the maximum value of DT.
    - For example: DT#1970-1-1-0:0:0 - DT#2106-2-6-6:28:15 = (DT#1970-1-1-0:0:0 + T#4294967296s) - DT#2106-2-6-6:28:15 = T#1d1s

18.2.1.30 SUB_DT_TIME

Subtracts a time from date and time.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
SUB_DT_TIME	Subtracts time from date and time	FC		:= SUB_DT_TIME(In1 := , In2 := , Out =>);

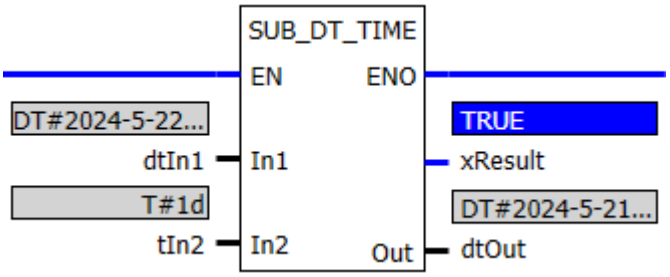
- **Related variable**

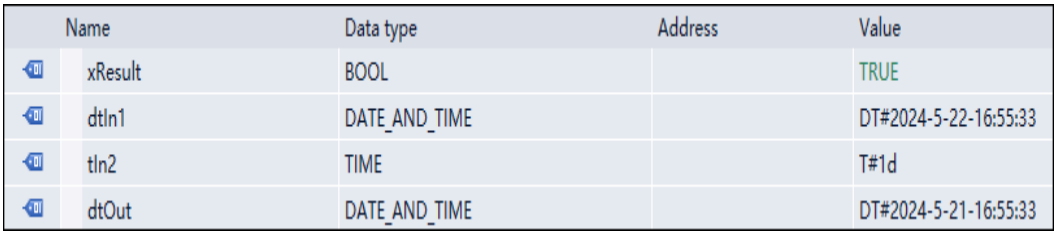
Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Subtrahend date and time	Follows data type	DATE_AND_TIME#1970-1-1-0:0:0	Subtrahend date and time
	In2	Minuend time	Follows data type	TIME#0ms	Minuend time
Output	Out	Subtraction result	Follows data type	-	Subtraction result

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–
In2	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–





- **Function**

  Subtracts time In2 from date and time In1. The subtraction result Out is a date and time.

- **Program example**

Item	LD	ST

Define variables	VAR
	xResult: BOOL;
	dtIn1: DATE_AND_TIME := DT#2024-5-22-16:55:33;
	tIn2: TIME := T#1d;
	dtOut: DATE_AND_TIME;
	END_VAR	

Program		
Operation result		

Name	Data type	Address	Value
xResult	BOOL		TRUE
dtIn1	DATE_AND_TIME		DT#2024-5-22-16:55:33
tIn2	TIME		T#1d
dtOut	DATE_AND_TIME		DT#2024-5-21-16:55:33

- **Precautions**

  When the result of subtraction exceeds the valid range of Out, no program fault occurs and the following operation is executed.

  - In1 is incremented by T#4294967296s, which corresponds to the maximum value of DT.
  - For example: DT#1970-1-1-0:0:0 - T#1d = (DT#1970-1-1-0:0:0 + T#4294967296s) - T#1d = DT#2106-2-6-6:28:15

18.2.1.31 SUB_TOD_TIME

Subtracts a time from time of day.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
SUB_TOD_TIME	Subtracts time from time of day	FC		:= SUB_TOD_TIME(In1 := , In2 := , Out =>);

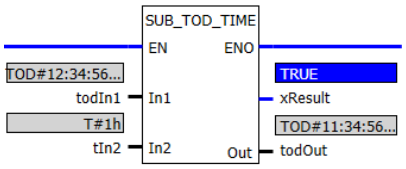
- **Related variable**

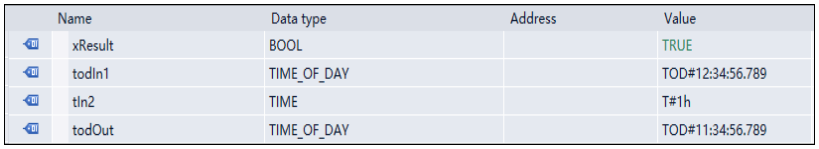
Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Subtrahend TOD	Follows data type	TIME_OF_DAY#0:0:0	Subtrahend TOD
	In2	Minuend time	Follows data type	TIME#0ms	Minuend time
Output	Out	Subtraction result	Follows data type	-	Subtraction result

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–
In2	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–





- **Function**

Subtracts time In2 from time of day In1. The subtraction result Out is a TOD.

- **Program example**

Item	LD	ST

Define variables	VAR
	xResult: BOOL;
	todIn1: TIME_OF_DAY := TOD#12:34:56.789;
	tIn2: TIME := T#1h;
	todOut: TIME_OF_DAY;
	END_VAR	

Program		
Operation result		

- **Precautions**

  When the result of subtraction exceeds the valid range of Out, no program fault occurs and the following operation is executed.

  - In1 is incremented by T#86400000S(24h).
  - For example: TOD#0:0:0 - T#1ms = (TOD#0:0:0 + T#86400000S) - T#1ms = TOD#23:59:59:999

18.2.1.32 SUB_TOD_TOD

Subtracts time of day from time of day.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
SUB_TOD_TOD	Subtracts time of day	FC		:= SUB_TOD_TOD(In1 := , In2 := , Out =>);

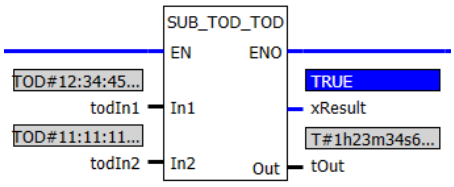
- **Related variable**

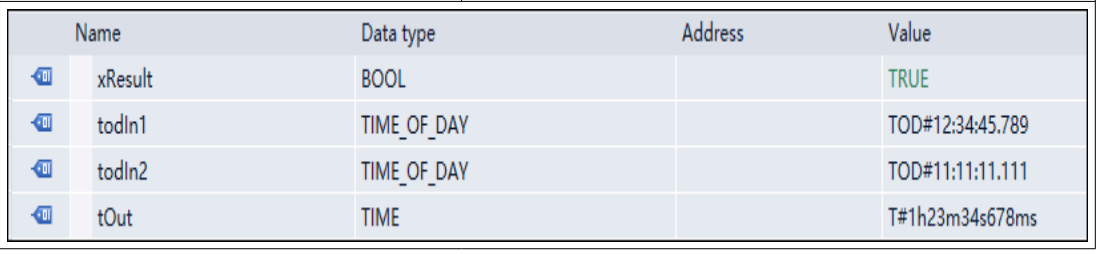
  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In1	Subtrahend TOD	Follows data type	TIME_OF_DAY#0:0:0	Subtrahend TOD
	In2	Minuend TOD	Follows data type	TIME_OF_DAY#0:0:0	Minuend TOD
Output	Out	Subtraction result	Follows data type	-	Subtraction result

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In1	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–
In2	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–





- **Function**

  Subtracts TOD In2 from TOD In1. The subtraction result Out is a time.

- **Program example**

Item	LD	ST

Define variables	VAR
	xResult: BOOL;
	todIn1: TIME_OF_DAY := TOD#12:34:45.789;
	todIn2: TIME_OF_DAY := TOD#11:11:11.111;
	tOut: TIME;
	END_VAR	

Program		xResult TRUE := SUB_TOD_TOD(In1 := todIn1 TOD#12:34:45.789 , In2 := todIn2 TOD#11:11:11.111 , Out => tOut T#1h23m34s678ms);RETURN
Operation result		

Name	Data type	Address	Value
xResult	BOOL		TRUE
todIn1	TIME_OF_DAY		TOD#12:34:45.789
todIn2	TIME_OF_DAY		TOD#11:11:11.111
tOut	TIME		T#1h23m34s678ms

- **Precautions**

  When the value of In1 is less than In2, no program fault occurs and the following operation is executed.

  - In1 is incremented by T# 86400000S(24h).
  - For example: TOD#13:34:56.789 - TOD#13:35:56.789 = (TOD#13:34:56.789 + T# 86400000S) - TOD#13:35:56.789 = T#23h59m

18.2.1.33 TimeToNanoSec

Converts time to the number of nanoseconds.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
TimeToNanoSec	Converts time to nanoseconds	FC		:= TimeToNanoSec(In := , Out =>);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Time	Follows data type	TIME#0ms	Time
Output	Out	Conversion result	Follows data type	0	Number of nanoseconds

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–

- **Function**

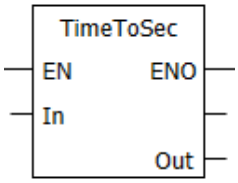
Converts time In to number of nanoseconds.

- **Program example**

Item	LD	ST
Define variables	VAR xResult: BOOL; tIn: TIME := T#1m40s; liOut: LINT; END_VAR	

Item	LD	ST
Program		
Operation result		

	Name	Data type	Address	Value
	xResult	BOOL		TRUE
	tIn	TIME		T#1m40s
	liOut	LINT		100000000000



- **Precautions**

  To convert the number of nanoseconds to a time, use the 18.2.1.23 NanoSecToTime instruction.

18.2.1.34 TimeToSec

Converts a time to the number of seconds.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
TimeToSec	Converts time to seconds	FC		:= TimeToSec(In := , Out =>);

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Time	Follows data type	TIME#0ms	Time
Output	Out	Conversion result	Follows data type	0	Number of seconds

  Variable types

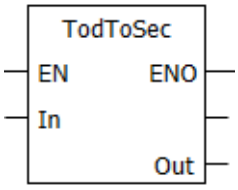
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–

- **Function**

  Converts time In to number of seconds. Values less than one second will be truncated.

- **Program example**

Item	LD	ST
Define variables	VAR xResult: BOOL; tIn: TIME := T#1m40s; liOut: LINT; END_VAR	
Program		
Operation result		



Name	Data type	Address	Value
xResult	BOOL		TRUE
tIn	TIME		T#1m40s
liOut	LINT		100

- **Precautions**
  - To convert the number of seconds to a time, use the 18.2.1.24 SecToTime instruction.
  - The unit of Out is seconds.

18.2.1.35 TodToSec

Converts time of day to the number of seconds from 00:00:00.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
TodToSec	Converts time to seconds	FC		:= TodToSec(In := , Out =>);

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Time of day	Follows data type	TIME_OF_DAY#0:0:0	Time of day
Output	Out	Conversion result	0 to 86399	0	Number of seconds since 00:00:00

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–

- **Function**

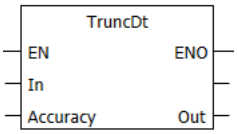
  Converts time of day In to the number of seconds from 00:00:00. The converted value is in seconds. Values less than one second will be truncated.

- **Program example**

Item	LD	ST
Define variables	VAR xResult: BOOL; todIn: TIME_OF_DAY := TOD#12:00:00.001; liOut: LINT; END_VAR	

Item	LD	ST
Program		
Operation result		

	Name	Data type	Address	Value
	xResult	BOOL		TRUE
	todIn	TIME_OF_DAY		TOD#12:0:0.001
	liOut	LINT		43200



- **Precautions**

  To convert the number of seconds from 00:00:00 to a TOD, use the 18.2.1.26 SecToTod instruction.

18.2.1.36 TruncDt

Truncates all digits below the specified unit in a DT variable.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
TruncDt	Truncates date and time	FC		:= TruncDt(In := , Accuracy := , Out =>);

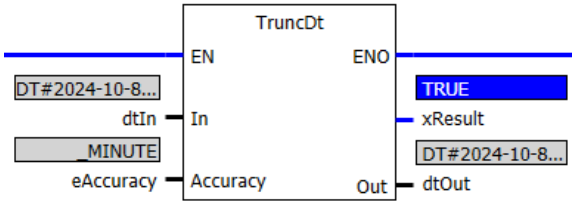
- **Related variable**

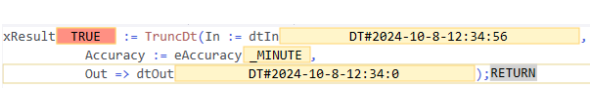
  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	DT to truncate	Follows data type	DATE_AND_TIME#1970-1-1-0:0:0	DT to truncate
	Accuracy	Smallest time unit to leave after truncation	Follows data type (_eSUBSEC)	_SEC	Smallest time unit to leave after truncation
Output	Out	DT after truncation	Follows data type	-	DT after truncation

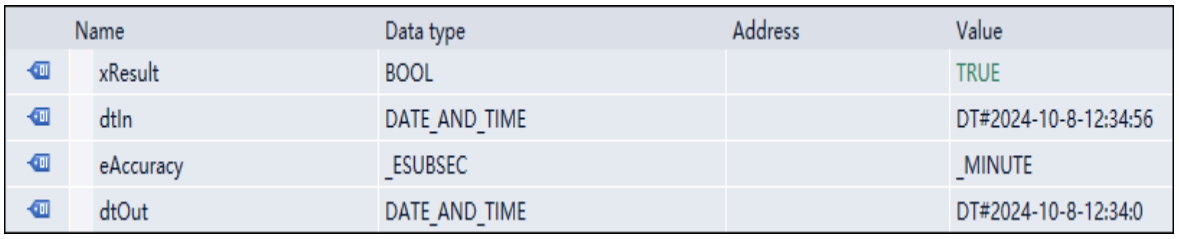
  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–
Accuracy	See "Function description" for the enumerators of enumeration type _eSUBSEC.																			
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–





- **Function**
  - This instruction truncates all digits below the smallest unit specified by Accuracy from the date and time In. The result after truncation is stored in Out.
  - Accuracy is of enumeration type _eSUBSEC, and the meanings of enumeration values are as follows in the table.
  - _MILLISEC cannot be used for enumerators; otherwise, a program fault occurs and the return value is FALSE.



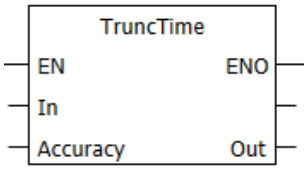
Enumeration Value	Definition
_MILLISEC	Millisecond
_SEC	Second
_MINUTE	Minute
_HOUR	Hour

- **Program example**

Item	LD	ST

Define variables	VAR
	xResult: BOOL;
	dtIn: DATE_AND_TIME := DT#2024-10-08-12:34:56;
	eAccuracy:_ESUBSEC := _ESUBSEC._MINUTE;
	dtOut: DATE_AND_TIME;
	END_VAR	

Program		



Item	LD	ST
Operation result		

Name	Data type	Address	Value
xResult	BOOL		TRUE
dtIn	DATE_AND_TIME		DT#2024-10-8-12:34:56
eAccuracy	_ESUBSEC		_MINUTE
dtOut	DATE_AND_TIME		DT#2024-10-8-12:34:0

18.2.1.37 TruncTime

Truncates all digits below the specified unit in a TIME variable.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
TruncTime	Truncates time	FC		:= TruncTime(In := , Accuracy := , Out =>);

- **Related variable**

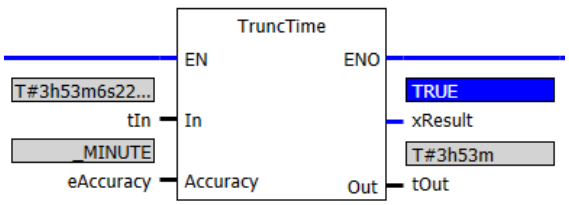
Variable

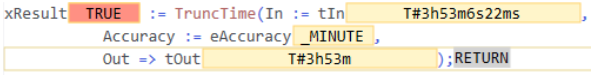
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Time to truncate	Follows data type	TIME#0ms	Time to truncate
	Accuracy	Smallest time unit to leave after truncation	Follows data type (_eSUBSEC)	_SEC	Smallest time unit to leave after truncation
Output	Out	Time after truncation	Follows data type	-	Time after truncation

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–
Accuracy	See "Function description" for the enumerators of enumeration type _eSUBSEC.																			

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–



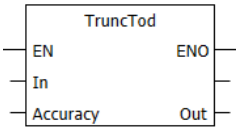


- **Function**
  - This instruction truncates all digits below the smallest unit specified by Accuracy from the time In. The result after truncation is stored in Out.
  - Accuracy is of enumeration type _eSUBSEC, and the meanings of enumeration values are as follows in the table.

Enumeration Value	Definition
_MILLISEC	Millisecond
_SEC	Second
_MINUTE	Minute
_HOUR	Hour

- **Program example**

Item	LD	ST



Define variables	VAR
	xResult: BOOL;
	tIn: TIME := T#3h53m6s22ms;
	eAccuracy: _ESUBSEC := _ESUBSEC._MINUTE;
	tOut: TIME;
	END_VAR	

Program		
Operation result		

18.2.1.38 TruncTod

Truncates all digits below the specified unit in a TOD variable.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
TruncTod	Truncates time of day	FC		:= TruncTod(In := , Accuracy := , Out =>);

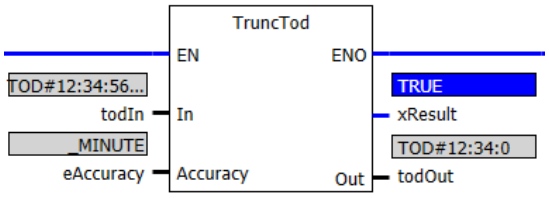
- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	TOD to truncate	Follows data type	TIME_OF_DAY#0:0:0	TOD to truncate
	Accuracy	Smallest time unit to leave after truncation	Follows data type (_eSUBSEC)	_SEC	Smallest time unit to leave after truncation
Output	Out	TOD after truncation	Follows data type	-	TOD after truncation

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–
Accuracy	See "Function description" for the enumerators of enumeration type _eSUBSEC.																			
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–



- **Function**
  - This instruction truncates all digits below the smallest unit specified by Accuracy from the time of day In. The result after truncation is stored in Out.
  - Accuracy is of enumeration type _eSUBSEC, and the meanings of enumeration values are as follows in the table.

Enumeration Value	Definition
_MILLISEC	Millisecond
_SEC	Second
_MINUTE	Minute
_HOUR	Hour

18.2.2.8 STATISTICS_REAL	FB	Data statistics and analysis		Library version 1.0.0.0 and later
18.2.2.9 VARIANCE	FB	Variance calculation		Library version 1.0.0.0 and later

18.2.2.2 HYSTERESIS

HYSTERESIS is used for limit determination.

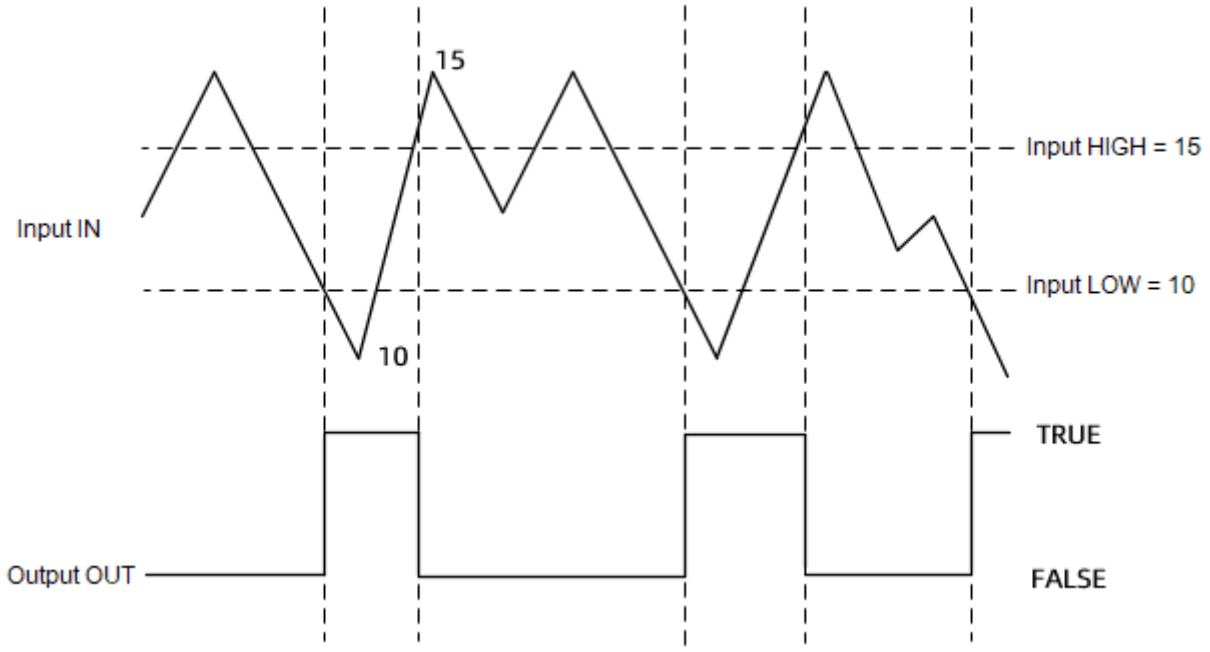
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
HYSTERESIS	Limit determination	FB		HYSTERESIS_Instance_0(IN := , HIGH := , LOW := , OUT =>);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Input data	Follows data type	0	Input data
	HIGH	Upper limit	Follows data type	0	Upper limit
	LOW	Lower limit	Follows data type	0	Lower limit
Output	OUT	Output data	Follows data type	FALSE	Output data.



Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
IN	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–
HIGH	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–
LOW	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–
OUT	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  If input "IN" is less than the lower limit "LOW", "OUT" is TRUE, and remains TRUE until "IN" is greater than the upper limit "HIGH". At this time, "OUT" changes to FALSE, and remains FALSE until "IN" is less than "LOW". OUT changes from FALSE to TRUE and remains until "IN" exceeds the upper limit HIGH, at which point "OUT" changes to FALSE, repeating this cycle.

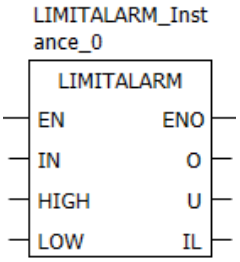
- **Timing diagram**

- **Program example**

  ST:

	Name	Data type	Address	Value
1	INTEGRAL_Instance_0	INTEGRAL		
2	IN	REAL		1
3	TM	DWORD		1000
4	RESET	BOOL		FALSE
5	OUT	REAL		7
6	OVERFLOW	BOOL		FALSE

```
INTEGRAL_Instance_0(
IN := IN1,
TM := TM1,
RESET := RESET1,
OUT => OUT1,
OVERFLOW => OVERFLOW1);RETURN
```



LD:

18.2.2.3 LIMITALARM

Monitors whether the input value is within the upper and lower limits.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
LIMITALARM	Upper and lower limit monitoring	FB		LIMITALARM_Instance_0(IN := , HIGH := , LOW := , O => , U => , IL =>);

- **Related variable**

Variable

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Input data	Follows data type	0	Input data
	HIGH	Upper limit	Follows data type	0	Upper limit
	LOW	Lower limit	Follows data type	0	Lower limit
Output	O	Output data 1	Follows data type	-	Output data 1
	U	Output data 2	Follows data type	-	Output data 2
	IL	Output data 3	Follows data type	-	Output data 3

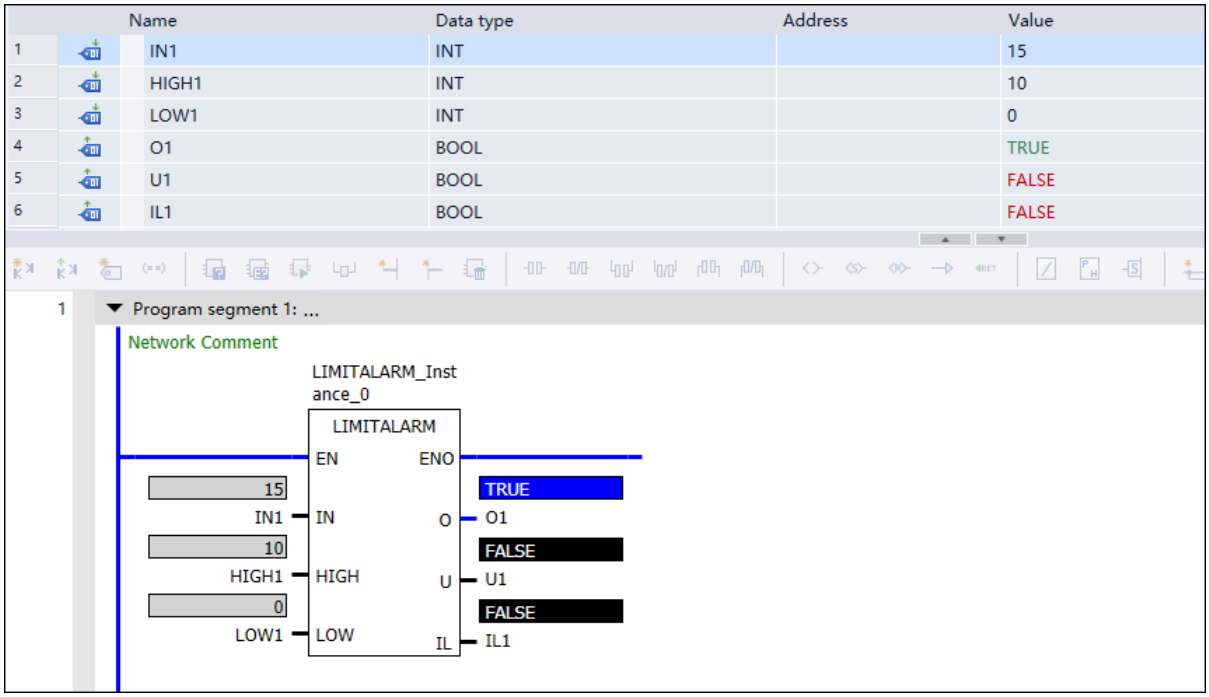
Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
IN	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–
HIGH	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–
LOW	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–
O	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
U	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
IL	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  When input "IN" is below the lower limit "LOW", output "U" is TRUE; when "IN" is above the upper limit "HIGH", output "O" is TRUE. When input is within the upper and lower limits, output IL is TRUE.



- **Program example**

  ST:

		Name	Data type	Address	Value
1		IN1	INT		15
2		HIGH1	INT		10
3		LOW1	INT		0
4		O1	BOOL		TRUE
5		U1	BOOL		FALSE
6		IL1	BOOL		FALSE

```
LIMITALARM_Instance_0(
IN 15 := IN1 15,
HIGH 10 := HIGH1 10,
LOW 0 := LOW1 0,
O TRUE => O1 TRUE,
U FALSE => U1 FALSE,
IL FALSE => IL1 FALSE );RETURN
```

  LD:

18.2.2.4 DERIVATIVE

DERIVATIVE is used for derivative calculation.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
DERIVATIVE	Derivative value calculation	FB	DERIVATIVE_Instance_0 DERIVATIVE EN ENO IN OUT TM RESET	DERIVATIVE_Instance_0(IN := , TM := , RESET := , OUT =>);

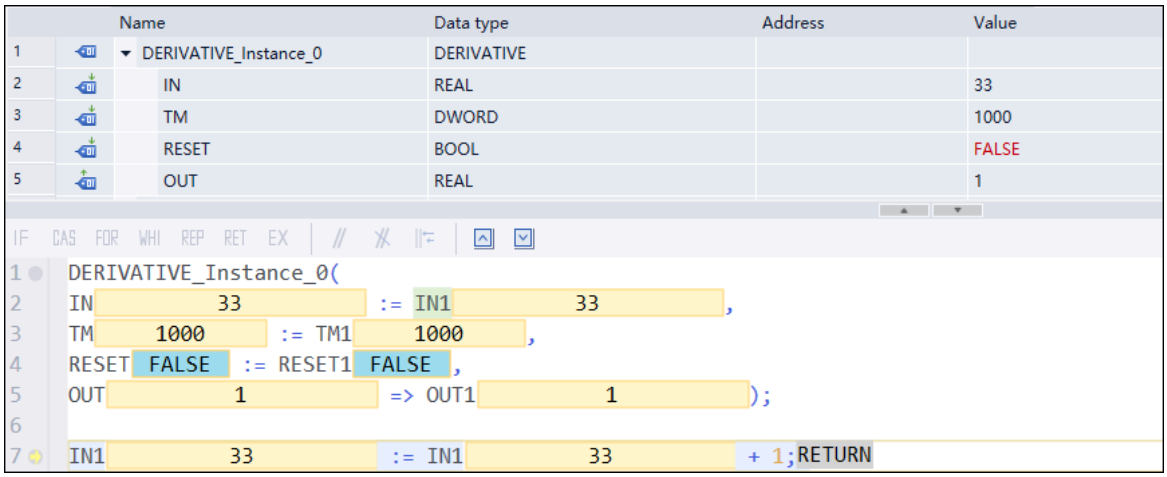
- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Input data	Follows data type	-	Input data
	TM	Derivative time	Follows data type	-	Derivative time (unit: ms)
	RESET	Reset	Follows data type	-	Reset
Output	OUT	Derivative value	Follows data type	-	Derivative value

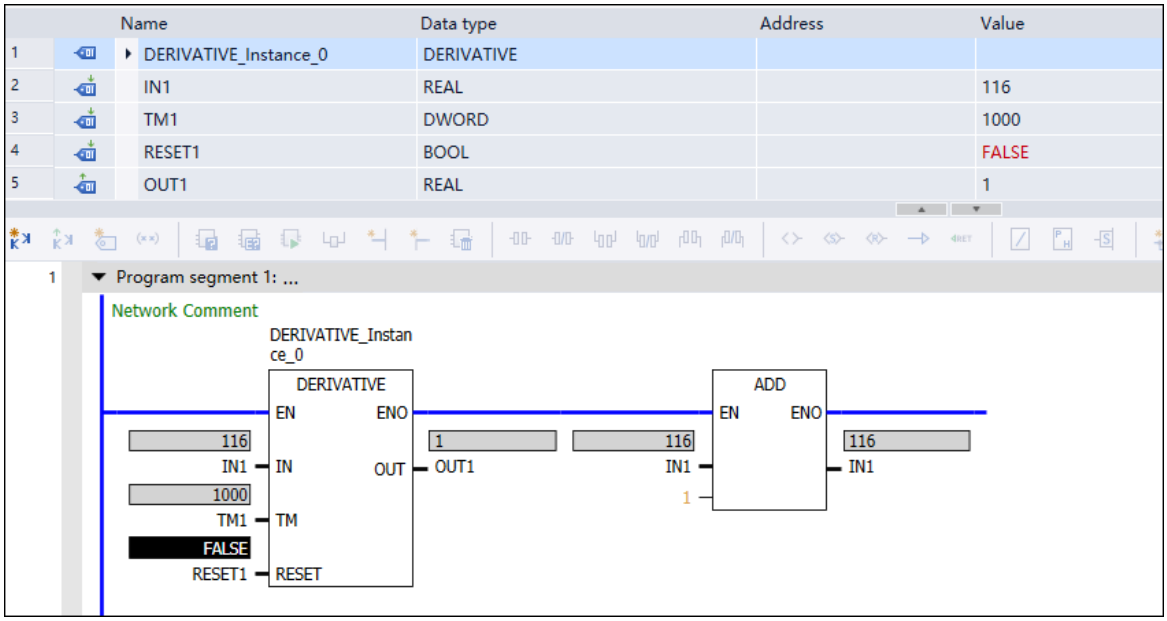
Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
IN	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
TM	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
RESET	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
OUT	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–



- **Function**

  Calculates the derivative of input "IN" within TM time and outputs "OUT". When "RESET" is TRUE, historical data is cleared and "OUT" is 0. It is recommended to set TM to the task scheduling cycle.



- **Program example**

  The following example sets the task scheduling cycle to 1000 ms. Each time the task executes, the input "IN" increments by 1. As a result, the derivative (rate of change) of "IN" is 1.

  ST:

  LD:

18.2.2.5 INTEGRAL

INTEGRAL is used for integral calculation.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
INTEGRAL	Integral value calculation	FB		INTEGRAL_Instance_0(IN := , TM := , RESET := , OUT => , OVERFLOW => ;

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Input data	Follows data type	-	Input data
	TM	Integral time	Follows data type	-	Integral time (unit: ms)
	RESET	Reset	Follows data type	-	Reset
Output	OUT	Integral value	Follows data type	-	Integral value
	OVERFLOW	Overflow flag	Follows data type	FALSE	Checks whether the output data exceeds the upper limit of the REAL type.

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
IN	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
TM	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
RESET	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
OUT	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
OVERFLOW	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  Calculates the integral value of input "IN" within TM time and outputs "OUT". When "RESET" is TRUE, the historical data is cleared and "OUT" is 0.

  It is recommended to set "TM" to the task scheduling cycle. When the value of "OUT" exceeds the upper limit of the REAL type, "OVERFLOW" is set to TRUE.

- **Program example**

  The following example sets the task scheduling cycle to 1000 ms. Each time the task executes, the input "IN" increments by 1 and the integral value of "IN" increases over time. After 7 cycles, the output is 7. After 38 cycles, the output is 38.

  ST:

	Name	Type	Address	Value
1	INTEGRAL_Instance_0	INTEGRAL		
2	IN	REAL		1
3	TM	DWORD		1000
4	RESET	BOOL		FALSE
5	OUT	REAL		7
6	OVERFLOW	BOOL		FALSE

```
INTEGRAL_Instance_0(
IN := 1 := IN1 1,
TM 1000 := TM1 1000,
RESET FALSE := RESET1 FALSE,
OUT 7 => OUT1 7,
OVERFLOW FALSE => OVERFLOW1 FALSE );RETURN
```

  LD:

18.2.2.6 LIN_TRAFO

LIN_TRAFO is used for linear scaling.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
LIN_TRAFO	Linear scaling	FB		LIN_TRAFO_Instance_0(IN := , IN_MIN := , IN_MAX := , OUT_MIN := , OUT_MAX := , OUT => , ERROR =>);

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Input data	Follows data type	-	Input data
	IN_MIN	Input lower limit	Follows data type	-	Reset
	IN_MAX	Input upper limit	Follows data type	-	Input upper limit
	OUT_MIN	Output lower limit	Follows data type	-	Output lower limit
	OUT_MAX	Output upper limit	Follows data type	-	Output upper limit
Output	OUT	Output value	Follows data type	-	Output value
	ERROR	Fault flag	Follows data type	-	Fault flag

Variable types

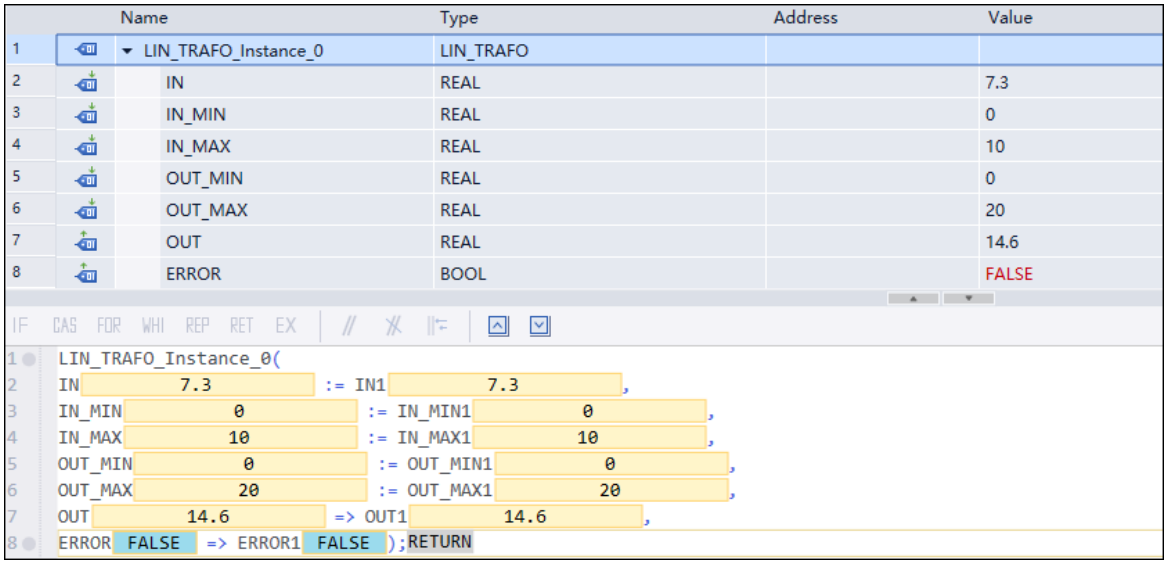
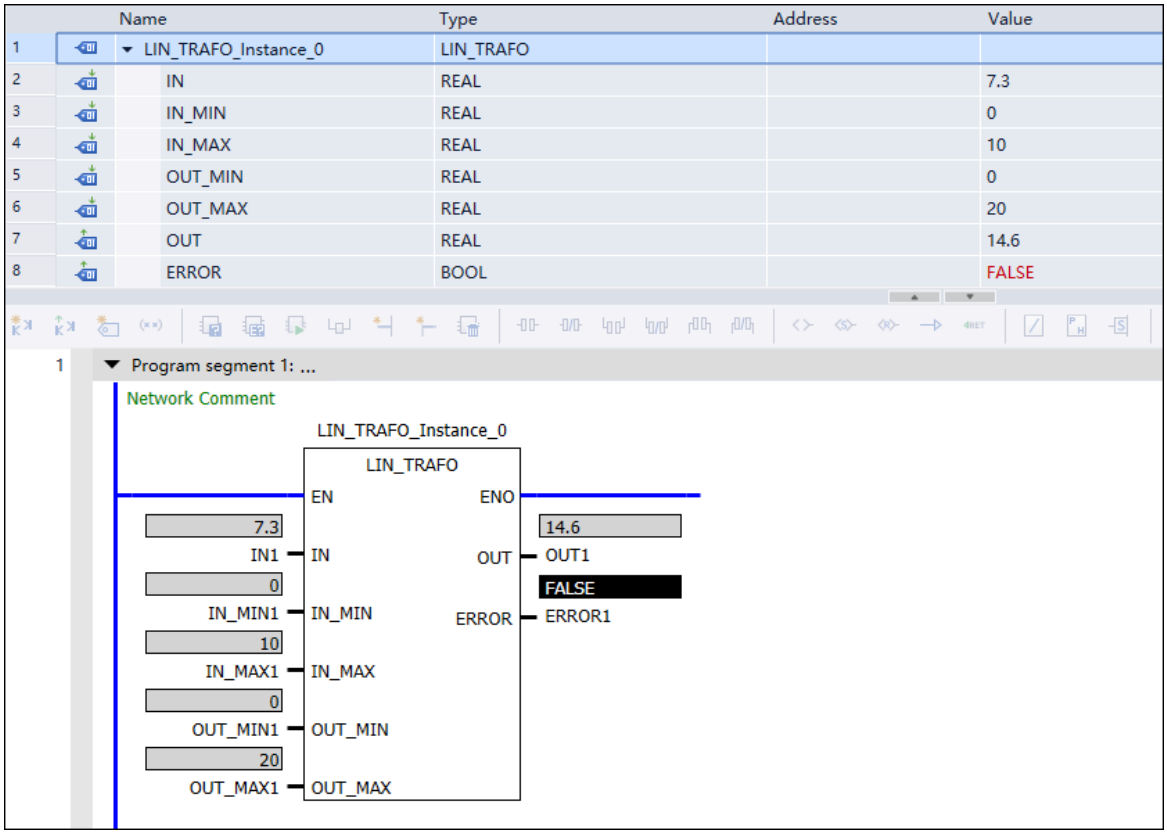
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
IN	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
IN_MIN	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
IN_MAX	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
OUT_MIN	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
OUT_MAX	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
OUT	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
ERROR	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–



- **Function**

Performs linear scaling on input data based on the following rule:

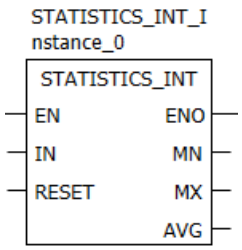


$$OUT = \frac{IN - IN_MIN}{IN_MAX - IN_MIN} * (OUT_MAX - OUT_MIN) + OUT_MIN$$

- **Program example**

  ST:

  LD:



- **Precautions**

  When the input upper limit and input lower limit are equal, or when the input exceeds the limit range, ERROR is set to TRUE.

18.2.2.7 STATISTICS_INT

STATISTICS_INT is used for integer data statistics and analysis.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
STATISTICS_INT	Data statistics and analysis	FB		STATISTICS_INT_Instance_0(IN := , RESET := , MN => , MX => , AVG =>);

- **Related variable**

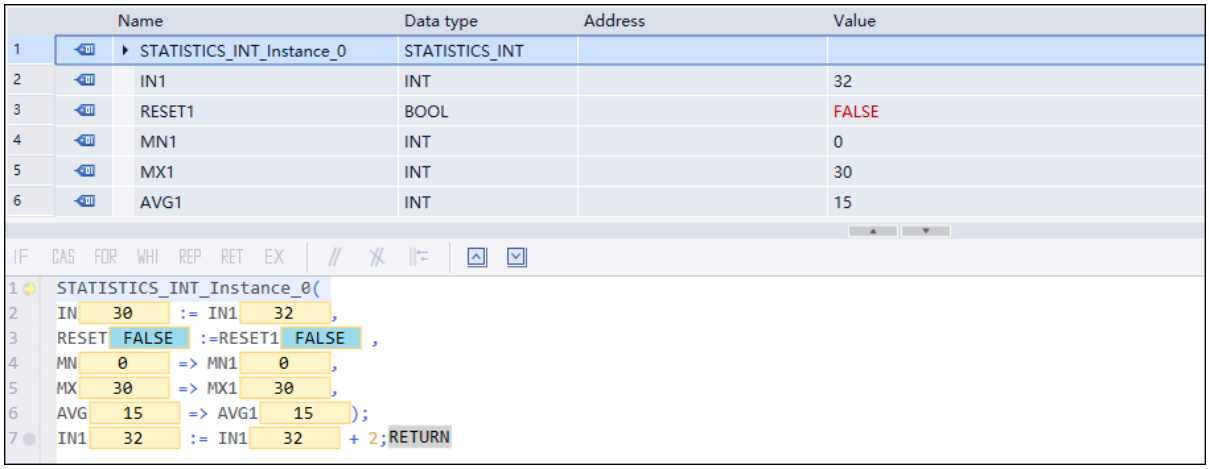
Variable

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Input data	Follows data type	-	Input data
	RESET	Reset a bit	Follows data type	-	When set to TRUE, AVG is set to 0, and "MN" and "MX" are set to the minimum and maximum values for that data type, respectively.
Output	MN	Minimum input value	Follows data type	-32768	Minimum input value
	MX	Maximum input value	Follows data type	32767	Maximum input value
	AVG	Average input value	Follows data type	-	Average input value

Variable types

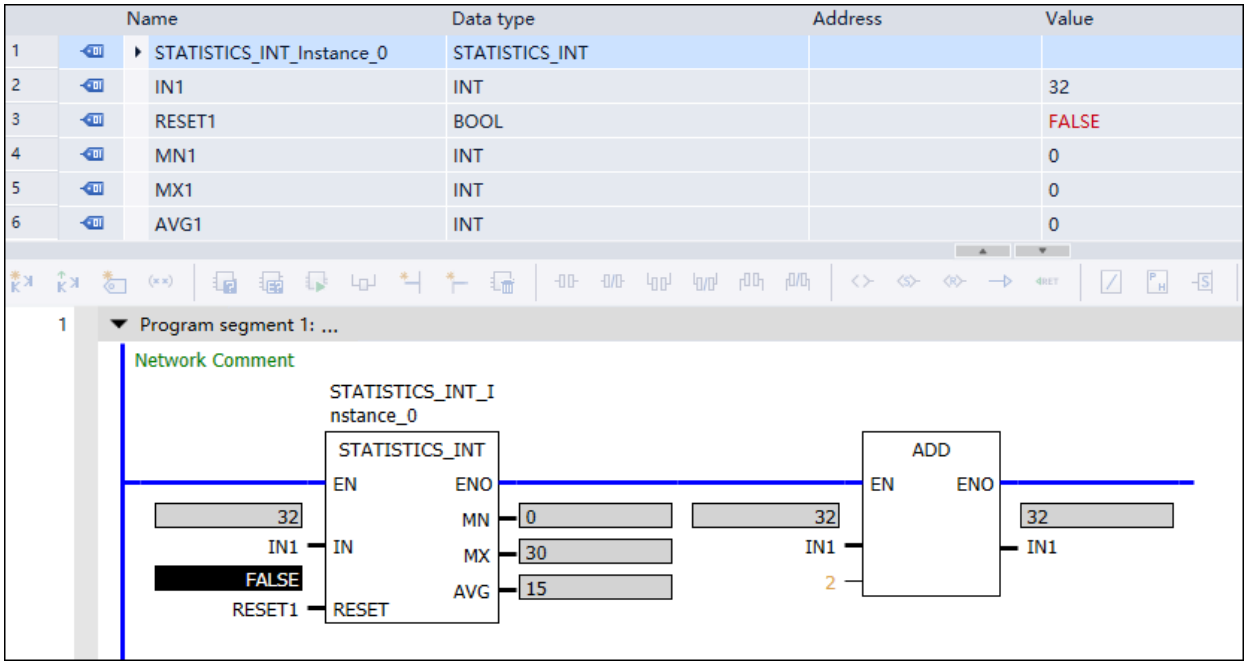
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
IN	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
RESET	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
MN	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–
MX	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–
AVG	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–



- **Function**

  Statically calculates the maximum, minimum, and average values of input data "IN". When "RESET" is set to 1, "AVG" is initialized to input "IN".



- **Program example**

  The following example sets "RESET" to 0, and "IN" to 0. "IN" increments by 2 per task scheduling cycle. The simulation results after 15 cycles are shown in the following figure.

  ST:

  LD:

18.2.2.8 STATISTICS_REAL

STATISTICS_INT is used for floating-point data statistics and analysis.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
STATISTICS_REAL	Data statistics and analysis	FB		STATISTICS_REAL_Instance_0(IN := , RESET := , MN => , MX => , AVG =>);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Input data	Follows data type	-	Input data
	RESET	Reset a bit	Follows data type	-	When set to TRUE, AVG is set to 0, and "MN" and "MX" are set to the minimum and maximum values for that data type, respectively.
Output	MN	Minimum input value	Follows data type	-3.402823466E+38	Minimum input value

Input/Output	Variable	Name	Valid Range	Default Value	Description
	MX	Maximum input value	Follows data type	3.402823466E+38	Maximum input value
	AVG	Average input value	Follows data type	-	Average input value

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
IN	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
RESET	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
MN	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
MX	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
AVG	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–

- **Function**

  Statically calculates the maximum, minimum, and average values of input data "IN". When "RESET" is set to 1, "AVG" is initialized to 0.

- **Program example**

  The following example sets "RESET" to 0, and "IN" to 0. "IN" increments by 1.5 per task scheduling cycle. The simulation results after 10 cycles are shown in the following figure.

  ST:

	Name	Data type	Address	Value
1	STATISTICS_REAL_Instance_0	STATISTICS_REAL		
2	IN1	REAL		16.5
3	RESET1	BOOL		FALSE
4	MN1	REAL		0
5	MX1	REAL		15
6	AVG	REAL		7.5000005

```
STATISTICS_REAL_Instance_0(
IN := 15 := IN1 16.5,
RESET FALSE := RESET1 FALSE,
MN => MN1 0,
MX => MX1 15,
AVG 7.5000005 => AVG 7.5000005);
IN1 := IN1 + 1.5;RETURN
```

  LD:

18.2.2.9 VARIANCE

VARIANCE is used for variance calculation.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
VARIANCE	Variance calculation	FB		VARIANCE_Instance_0(IN := , RESET := , OUT =>);

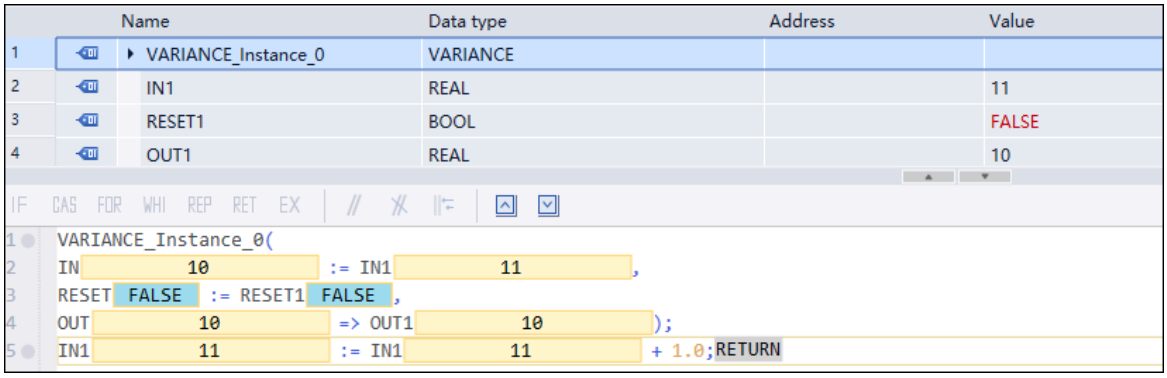
- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Input data	Follows data type	-	Input data
	RESET	Reset a bit	Follows data type	-	When set to TRUE, "OUT" is set to 0.
Output	OUT	Variance output	Follows data type	-	Minimum input value

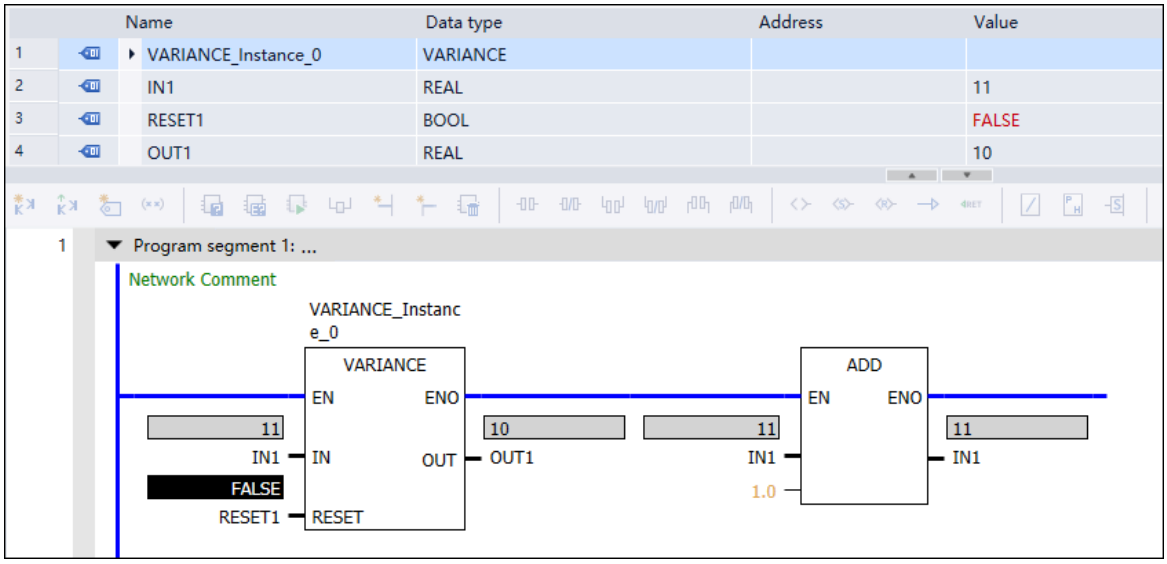
Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
IN	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–
RESET	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
OUT	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–



- **Function**

  Calculates the variance of input data "IN". When "RESET" is set to 1, output "OUT" is initialized to 0.



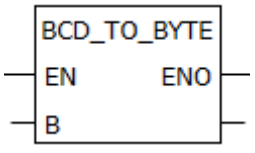
- **Program example**

  The following example sets "RESET" to 0, and "IN" to 0. "IN" increments by 1.0 per task scheduling cycle. The simulation results after 10 cycles are shown in the following figure.

  ST:

  LD:

18.2.3 BCD Code Conversion



18.2.3.1 Instruction List

Instruction	FB/FC	Function	Library	Applicable Library Version
18.2.3.2 BCD_TO_BYTE	FC	BCD to byte	Util	Library version 1.0.0.0 and later
18.2.3.3 BCD_TO_DWORD	FC	BCD to double word		Library version 1.0.0.0 and later
18.2.3.4 BCD_TO_INT	FC	BCD to integer		Library version 1.0.0.0 and later
18.2.3.5 BCD_TO_WORD	FC	BCD to word		Library version 1.0.0.0 and later
18.2.3.6 BYTE_TO_BCD	FC	Byte to BCD		Library version 1.0.0.0 and later
18.2.3.7 DWORD_TO_BCD	FC	Double word to BCD		Library version 1.0.0.0 and later
18.2.3.8 INT_TO_BCD	FC	Integer to BCD		Library version 1.0.0.0 and later
18.2.3.9 WORD_TO_BCD	FC	Word to BCD		Library version 1.0.0.0 and later

18.2.3.2 BCD_TO_BYTE

Converts the BCD code of the source data into BYTE type data.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
BCD_TO_BYTE	BCD to byte	FC		:= BCD_TO_BYTE(B :=);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	B	Input data	Follows data type	-	Input data
Output	OUT	Output data	Follows data type	-	Output data.

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
B	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
OUT	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  This instruction converts BCD of the source data to bytes.

- **Program example**

  ST:

  LD:

- **Precautions**

  There are no restrictions on the input of BCD_TO_BYTE. If the input is not in BCD format, it is processed with carry.

  For example: If BCDTest is 2#11110101, where the high 4 bits are 2#1111 (exceeding the BCD code format), 0110 (carry offset) will be added, resulting in 2#10101. This value is parsed as 15 in BCD format. The low-order four bits 2#0101 are parsed as 5 in BCD format. The final conversion result is 155.

18.2.3.3 BCD_TO_DWORD

Converts the BCD code of the source data into a DWORD type data.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
BCD_TO_DWORD	BCD to double word	FC		:= BCD_TO_DWORD(X :=);

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	X	Input data	Follows data type	-	Input data
Output	OUT	Output data	Follows data type	-	Output data.

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
X	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
OUT	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

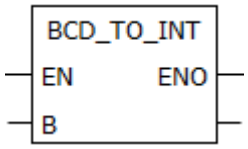
- **Function**

  This instruction converts BCD of the source data to doublewords.

- **Program example**

  ST:

  LD:



- **Precautions**

  The BCD_TO_DWORD instruction supports carry processing. For example, if BCDTest is set to 2#11111111111111111111111111111111, where the high-order 16 bits (2#1111111111111111) are parsed as decimal 16665 and the low-order 16 bits (2#1111111111111111) are parsed as decimal 16665. The final conversion result is166666665.

18.2.3.4 BCD_TO_INT

Converts the BCD code of the source data into an INT type data.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
BCD_TO_INT	BCD to integer	FC		:= BCD_TO_INT(B :=);

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	B	Input data	Follows data type	-	Input data
Output	OUT	Output data	Follows data type	-	Output data.

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
B	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
OUT	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–

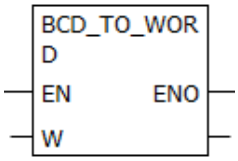
- **Function**

  This instruction converts BCD of the source data to integers.

- **Program example**

  ST:

  LD:



- **Precautions**

  This instruction can only convert data within the range of 0 to 99. The input must meet the BCD code format; otherwise, the output will be -1.

18.2.3.5 BCD_TO_WORD

Converts the BCD code of the source data into a WORD type data.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
BCD_TO_WORD	BCD to word	FC		:= BCD_TO_WORD(W :=);

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	W	Input data	Follows data type	-	Input data
Output	OUT	Output data	Follows data type	-	Output data.

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
W	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
OUT	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  This instruction converts BCD of the source data to words.

- **Program example**

  ST:

  LD:

- **Precautions**

  The BCD_TO_WORD instruction supports carry processing. For example, if BCDTest is set to 2#1111111111111111, where the high-order 8 bits (2#11111111) are parsed as decimal 165 and the low-order 8 bits (2#1111111) are parsed as decimal 165. The final conversion result is 16665.

18.2.3.6 BYTE_TO_BCD

Converts the source data of BYTE type into BCD code.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
BYTE_TO_BCD	Byte to BCD	FC	BYTE_TO_BCD EN ENO B	:= BYTE_TO_BCD(B :=) ;

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	B	Input data	Follows data type	-	Input data
Output	OUT	Output data	Follows data type	-	Output data.

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
B	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
OUT	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

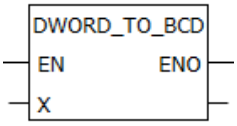
- **Function**

  This instruction converts bytes of the source data to BCD.

- **Program example**

  ST:

  LD:



- **Precautions**

  The BYTE_TO_BCD instruction only converts the tens and ones digits.

18.2.3.7 DWORD_TO_BCD

Converts the source data of DWORD type into BCD code.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
DWORD_TO_BCD	Double word to BCD	FC		:= DWORD_TO_BCD(X :=);

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	X	Input data	Follows data type	-	Input data
Output	OUT	Output data	Follows data type	-	Output data.

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
X	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
OUT	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

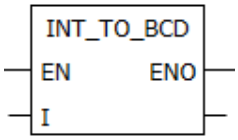
- **Function**

  This instruction converts doublewords of the source data to BCD.

- **Program example**

  ST:

  LD:



- **Precautions**

  The DWORD_TO_BCD instruction only converts to the thousands digit.

18.2.3.8 INT_TO_BCD

Converts the source data of INT type into BCD code.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
INT_TO_BCD	Integer to BCD	FC		:= INT_TO_BCD(I :=);

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	I	Input data of INT type	Follows data type	-	If the integer is 39, 39 is input.
Output	OUT	BCD after conversion	Follows data type	-	If the integer 39 is converted to BCD 2#00101001, the output is 2#00101001 (10#57 or 16#39).

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
I	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–
OUT	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

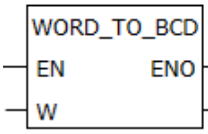
- **Function**

  This instruction converts integers of the source data to BCD.

- **Program example**

  ST:

  LD:



- **Precautions**

  This instruction can only convert data between 0 and 99. When the data to convert is not in the range, the conversion result is 255.

18.2.3.9 WORD_TO_BCD

Convert source data of WORD type into BCD code.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
WORD_TO_BCD	Word to BCD	FC		:= WORD_TO_BCD(W :=);

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	W	Input data	Follows data type	-	Input data
Output	OUT	Output data	Follows data type	-	Output data.

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
W	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
OUT	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  This instruction converts words of the source data to BCD.

- **Program example**

  ST:

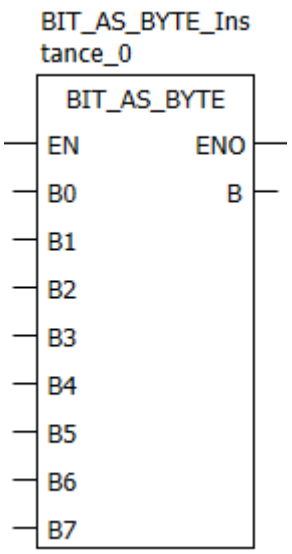
  LD:

- **Precautions**

  The WORD_TO_BCD instruction only converts the thousands, hundreds, tens, and ones digits.

18.2.4 Byte/Bit Operations

18.2.4.1 Instruction List



Instruction	FB/FC	Function	Library	Applicable Library Version
18.2.4.2 BIT_AS_BYTE	FB	8 bits to byte	Util	Library version 1.0.0.0 and later
18.2.4.3 BIT_AS_WORD	FB	16 bits to word		Library version 1.0.0.0 and later
18.2.4.4 BIT_AS_DWORD	FB	32 bits to doubleword		Library version 1.0.0.0 and later
18.2.4.5 BYTE_AS_BIT	FB	Byte split		Library version 1.0.0.0 and later
18.2.4.6 WORD_AS_BIT	FB	Word split		Library version 1.0.0.0 and later
18.2.4.7 DWORD_AS_BIT	FB	Doubleword split		Library version 1.0.0.0 and later
18.2.4.8 EXTRACT	FC	Bit extract		Library version 1.0.0.0 and later
18.2.4.9 PACK	FC	Bit packing		Library version 1.0.0.0 and later
18.2.4.10 PUTBIT	FC	Bit assignment		Library version 1.0.0.0 and later
18.2.4.11 SWITCHBIT	FC	Toggle specific bit value		Library version 1.0.0.0 and later
18.2.4.12 UNPACK	FB	Bit split		Library version 1.0.0.0 and later
18.2.4.13 UnpackWord	FB	Word split		Library version 1.3.0.0 and later

Instruction	FB/FC	Function	Library	Applicable Library Version
18.2.4.14 NSHLC	FC	Shift N-bits left with carry	OMUtils	Library version 1.0.0.0 and later
18.2.4.15 NSHRC	FC	Shift N-bits right with carry		Library version 1.0.0.0 and later

18.2.4.2 BIT_AS_BYTE

Converts eight input values of BOOL type into values of BYTE type, and outputs them from the right side.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
BIT_AS_BYTE	8 bits to byte	FB		BIT_AS_BYTE_Instance_0(B0 := , B1 := , B2 := , B3 := , B4 := , B5 := , B6 := , B7 := , B =>);

- **Related variable**

Variable

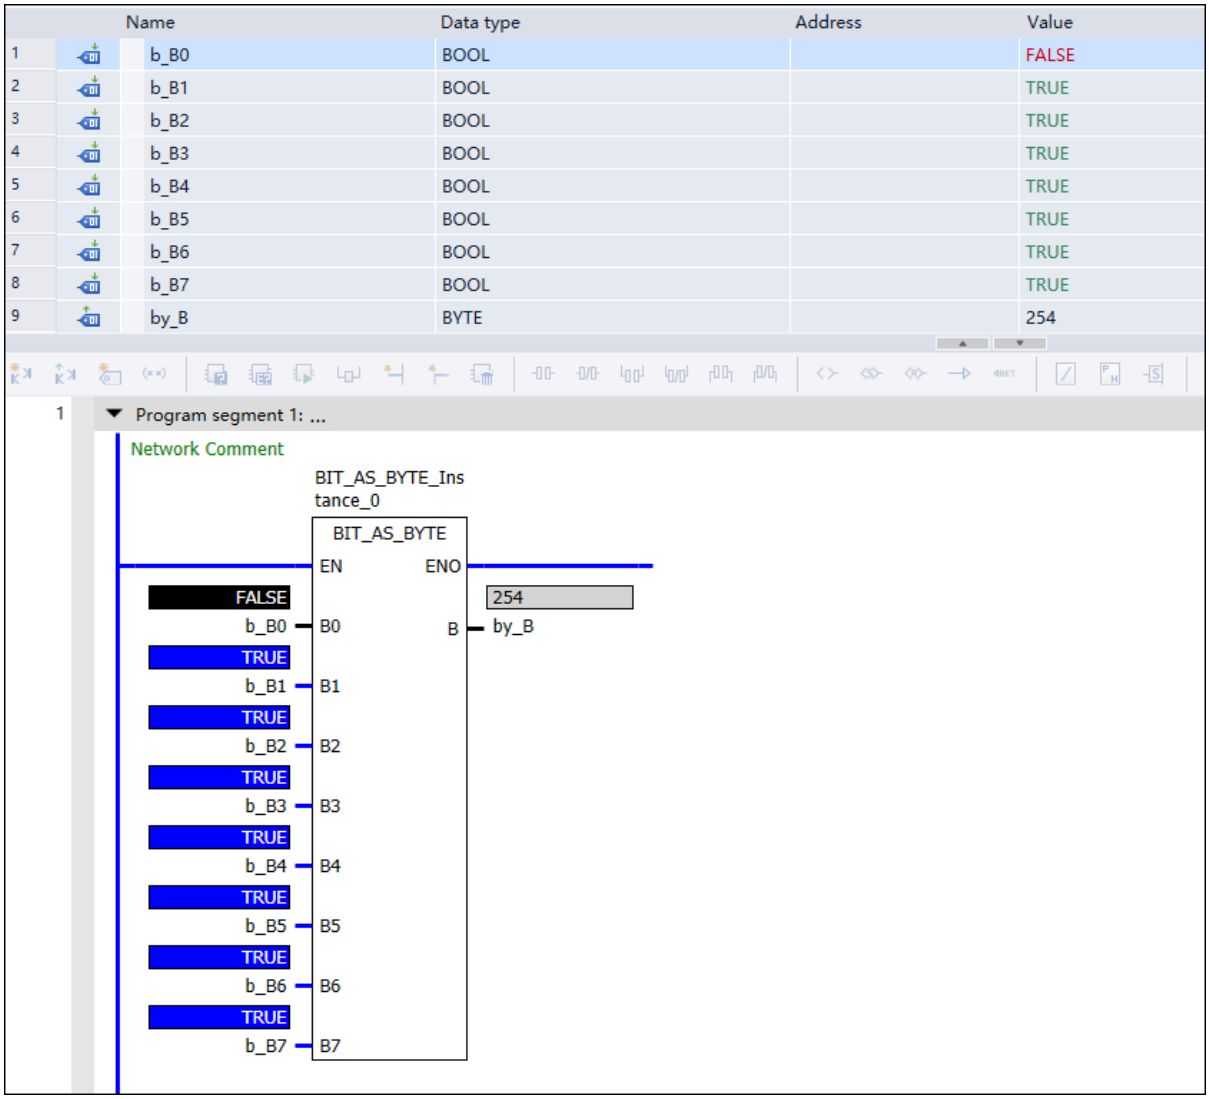
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	B0 to B7	BOOL values to be converted	Follows data type	-	BOOL values to be converted, corresponding to each bit
Output	OUT	Return value	Follows data type	-	Conversion result

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
B0 to B7	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
B	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  Converts eight input values of BOOL data type to BYTE type and outputs from the right side, with B0 to B7 corresponding to bit 1 to bit 8 in the output byte.



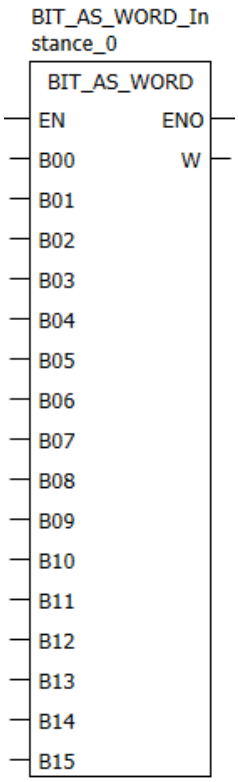
- **Program example**

  ST:

	Name	Data type	Address	Value
1	b_B0	BOOL		FALSE
2	b_B1	BOOL		TRUE
3	b_B2	BOOL		TRUE
4	b_B3	BOOL		TRUE
5	b_B4	BOOL		TRUE
6	b_B5	BOOL		TRUE
7	b_B6	BOOL		TRUE
8	b_B7	BOOL		TRUE
9	by_B	BYTE		254
10	BIT_AS_BYTE_Instance_0	BIT_AS_BYTE		

```
1  BIT_AS_BYTE_Instance_0(
2  B0 FALSE := b_B0 FALSE,
3  B1 TRUE  := b_B1 TRUE ,
4  B2 TRUE  := b_B2 TRUE ,
5  B3 TRUE  := b_B3 TRUE ,
6  B4 TRUE  := b_B4 TRUE ,
7  B5 TRUE  := b_B5 TRUE ,
8  B6 TRUE  := b_B6 TRUE ,
9  B7 TRUE  := b_B7 TRUE ,
10 B  254   => by_B  254  );RETURN
```

  LD:



- **Precautions**
  - A fault occurs when the input is not of BOOL type.
  - The output range is 0 and 255.

18.2.4.3 BIT_AS_WORD

Packs 16 bits of the input data into a word.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
BIT_AS_WORD	16 bits to word	FB		BIT_AS_WORD_Instance_0(B00 := , B01 := , B02 := , B03 := , B04 := , B05 := , B06 := , B07 := , B08 := , B09 := , B10 := , B11 := , B12 := , B13 := , B14 := , B15 := , W =>);

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	B00 to B15	BOOL values to be converted	Follows data type	-	BOOL values to be converted, corresponding to each bit
Output	W	Return value	Follows data type	-	Conversion result

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING

  LD:

18.2.4.8 EXTRACT

Reads the status of bit N in data source X and outputs from the right side.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
EXTRACT	Bit extract	FC		:= EXTRACT(X := , N :=);

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	X	Data source	Follows data type	-	Data to operate
	N	Read bit	Follows data type	-	Bit to read
Output	OUT	Read bit status	Follows data type	-	Status of the read bit

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
X	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
N	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
OUT	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

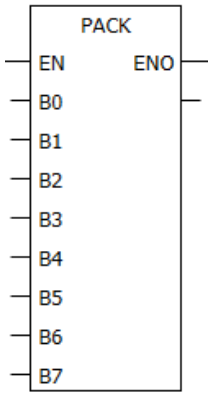
- **Function**

  This instruction reads the status of bit N in data source X and provides output from the right side.

- **Program example**

  ST:

LD:



- **Precautions**

  If the bit to read exceeds the data boundary or falls outside the normal numerical operation range, the returned result may be abnormal.

18.2.4.9 PACK

Packs eight bits of the input data into a byte and outputs it from the right side.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
PACK	Bit packing	FC		:= PACK(B0 := , B1 := , B2 := , B3 := , B4 := , B5 := , B6 := , B7 :=);

- **Related variable**

  Variable

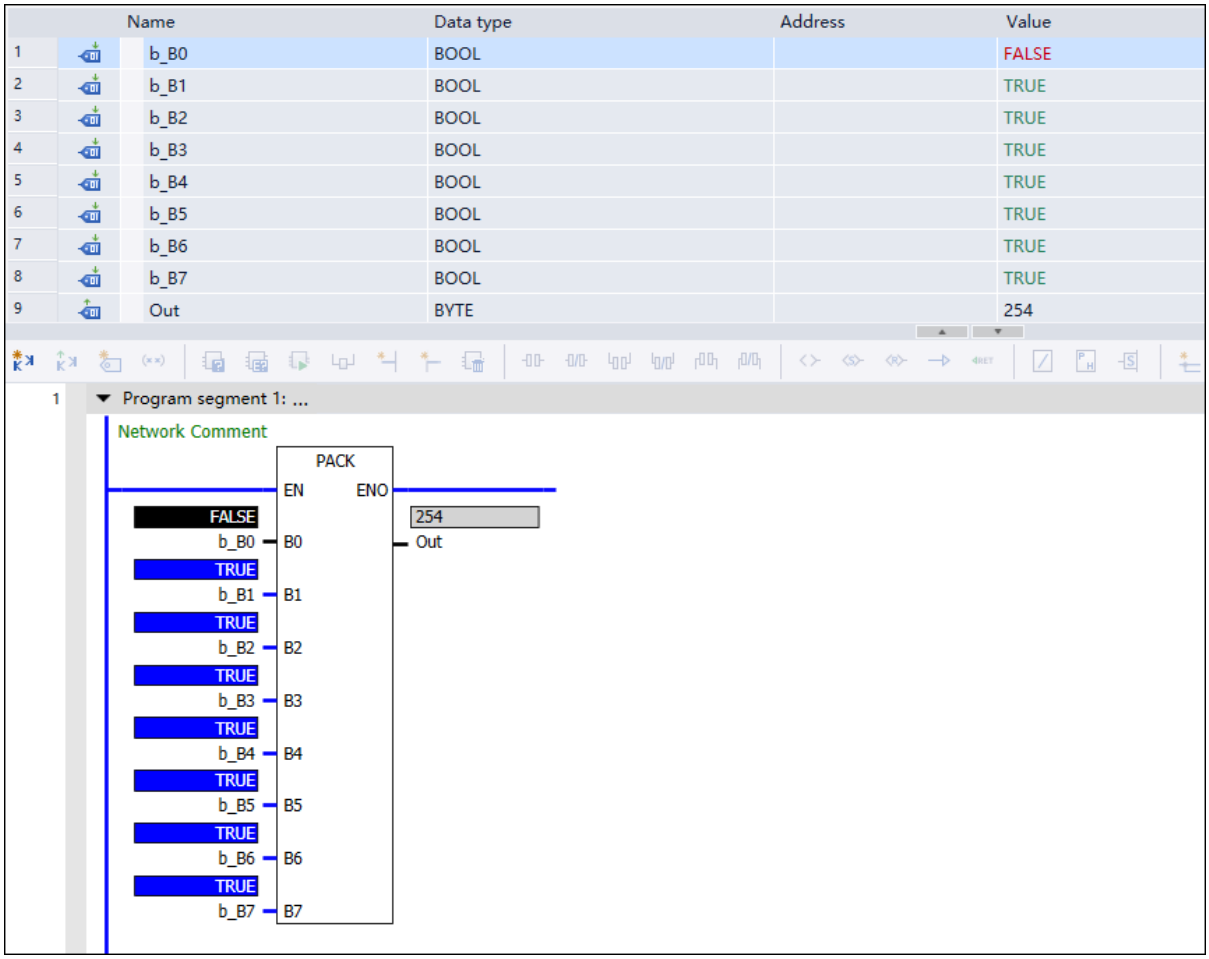
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	B0 to B7	Data source	Follows data type	-	Bits to pack
Output	OUT	Output target	Follows data type	-	Conversion result

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
B0 to B7	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
OUT	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  Packs eight bits of the input data into a byte and outputs it from the right side.



- **Program example**

  ST:

	Name	Data type	Address	Value
1	b_B0	BOOL		FALSE
2	b_B1	BOOL		TRUE
3	b_B2	BOOL		TRUE
4	b_B3	BOOL		TRUE
5	b_B4	BOOL		TRUE
6	b_B5	BOOL		TRUE
7	b_B6	BOOL		TRUE
8	b_B7	BOOL		TRUE
9	Out	BYTE		254

```
IF  CAS  FOR  WHI  REP  RET  EX
1  Out 254 := PACK(
2  B0 := b_B0 FALSE , B1 := b_B1 TRUE , B2 := b_B2 TRUE , B3 := b_B3 TRUE ,
3  B4 := b_B4 TRUE , B5 := b_B5 TRUE , B6 := b_B6 TRUE , B7 := b_B7 TRUE );RETURN
```

  LD:

18.2.4.10 PUTBIT

PUTBIT is used for bit assignment.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
PUTBIT	Bit assignment	FC		:= PUTBIT(X := , N := , B :=);

- **Related variable**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	X	Data source	Follows data type	-	Data to operate
	N	Operation bit	Follows data type	-	Bit to operate

Input/Output	Variable	Name	Valid Range	Default Value	Description
	B	Operating switch	Follows data type	-	Operating switch of bit
Output	OUT	Target position	Follows data type	-	Data after operation

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
X	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

B	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
OUT	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

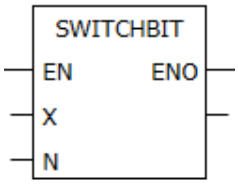
- **Function**

  Modifies the bit N of input X to the switch value B.

- **Program example**

  ST:

  LD:



- **Precautions**

  If the bit to operate exceeds the data boundary or falls outside the normal numerical operation range, the returned result may be abnormal.

18.2.4.11 SWITCHBIT

Toggles specific bit value.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
SWITCHBIT	Toggle specific bit value	FC		:= SWITCHBIT(X := , N :=);

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	X	Data source	Follows data type	-	Data to operate
	N	Read bit	Follows data type	-	Bit to read
Output	OUT	Return value	Follows data type	-	Return value.

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
X	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
N	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
OUT	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

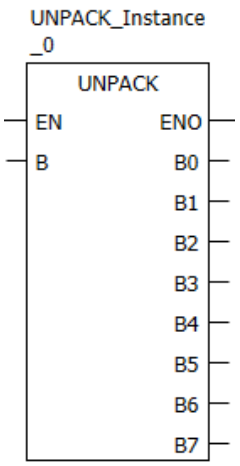
- **Function**

  Toggles the status of bit N in data source X, and outputs the result as X.

- **Program example**

  ST:

  LD:



- **Precautions**

  If the bit to read exceeds the data boundary or falls outside the normal numerical operation range, the returned result may be abnormal.

18.2.4.12 UNPACK

Converts the byte in B into bits and outputs them from the right side.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
UNPACK	Bit split	FB		UNPACK_Instance_0(B := , B0 => , B1 => , B2 =>, B3 => , B4 => , B5 => , B6 => , B7 =>);

- **Related variable**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	B	Data source	Follows data type	-	Data to operate
Output	B0 to B7	Output target	Follows data type	-	Conversion result

8	b_B6	BOOL		TRUE
9	b_B7	BOOL		FALSE

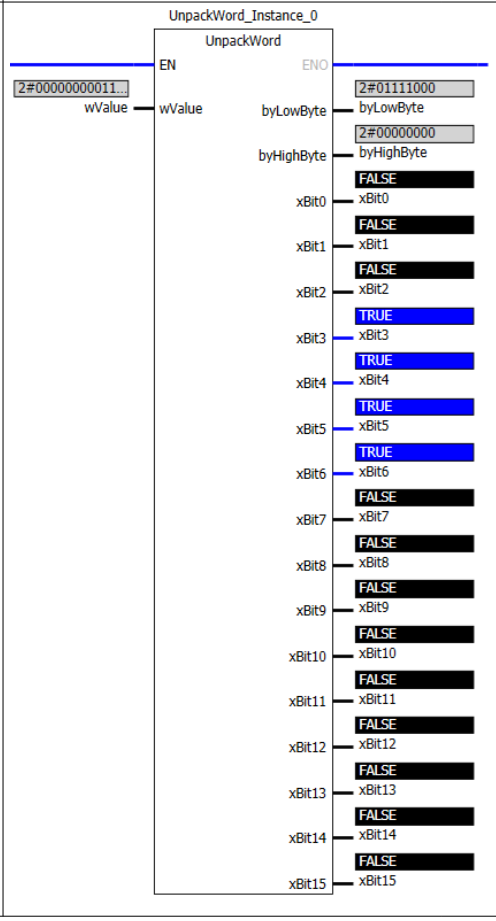
18.2.4.13 UnpackWord

Outputs the values of the lower eight bits, upper eight bits, and each bit of the WORD type input.

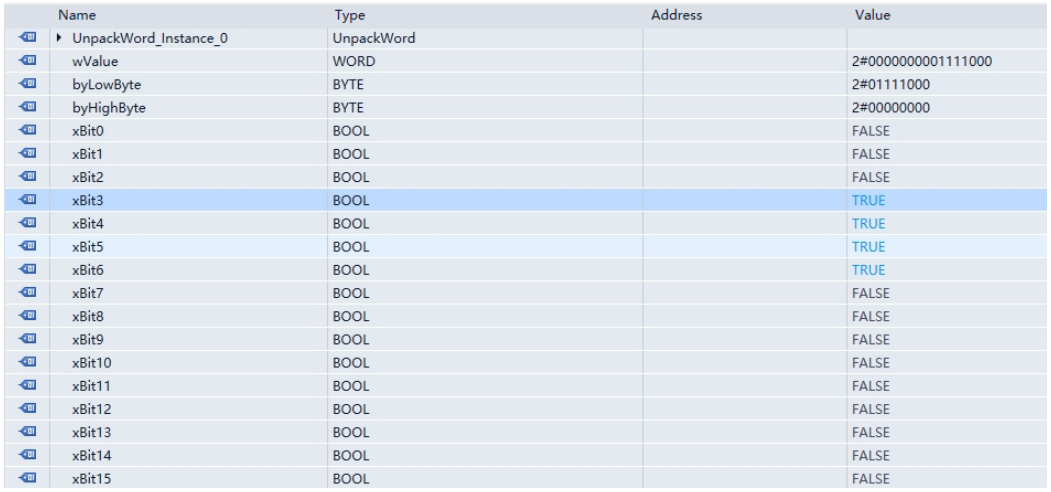
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
UnpackWord	Word split	FB		UnpackWord_Instance_0(wValue := , byLowByte => , wValue xBit0 => , xBit1 => , xBit2 => , xBit3 => , xBit4 => , xBit5 => , xBit6 => , xBit7 => , xBit8 => , xBit9 => , xBit10 => , xBit11 => , xBit12 => , xBit13 => , xBit14 => , xBit15 =>);

- **Related variables**



Variable



Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	wValue	WORD value to be converted	Follows data type	-	WORD value to be converted
Output	byLowByte	Lower eight bit values of the input	Follows data type	-	Lower eight bit values of the input.
	byHighByte	Upper eight bit values of the input	Follows data type	-	Upper eight bit values of the input.
	xBit0 to xBit15	Individual bit value of the input	Follows data type	-	Individual bit value of the input.

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
wValue	-	-	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
byLowByte	-	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
byHighByte	-	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
xBit0 to xBit15	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

- **Function**
  - Outputs the value of each bit of wValue, as well as the values of the upper and lower eight bits.
  - Only WORD type is supported for input; other types will be forcibly converted.
- **Program example**

	LD	ST
Define variables	VAR UnpackWord_Instance_0: UnpackWord; wValue: WORD; byLowByte: BYTE; byHighByte: BYTE; xBit0: BOOL; xBit1: BOOL; xBit2: BOOL; xBit3: BOOL; xBit4: BOOL; xBit5: BOOL; xBit6: BOOL; xBit7: BOOL; xBit8: BOOL; xBit9: BOOL; xBit10: BOOL; xBit11: BOOL; xBit12: BOOL; xBit13: BOOL; xBit14: BOOL; xBit15: BOOL; END VAR

18.2.4.14 NSHLC

Shifts the input array along with the carry flag (CY) to the left (toward higher bits) by a specified number of bits.

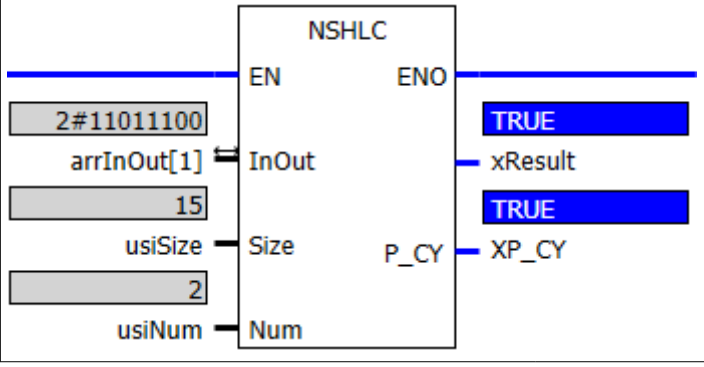
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
NSHLC	Shift N-bits left with carry	FC		:= NSHLC(InOut := , Size := , Num := , P_CY =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Size	Number of bits in the shift object	Follows data type	1	Number of bits in the shift object
	Num	Number of bits to shift	Follows data type	1	Number of bits to shift
Input/Output	InOut[ ] array	Array where the shift object is located	Follows data type	-	Array where the shift object is located
Output	P_CY	Carry flag	Follows data type	-	Carry flag



Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
InOut[] array	√	√	√	√	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Size	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Num	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
P_CY	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - Shifts Size bits in InOut[0] starting from InOut[0] left by Num bits. The last overflow bit is output to the carry flag (CY) and the vacated bits on the opposite side are filled with 0.
  - The shift direction is left, from the least-significant bits to the most-significant bits.
- **Program example**

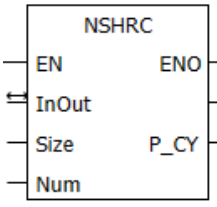
	LD	ST

Define variables	VAR
	xResult: BOOL;
	arrInOut: ARRAY[0..4] OF BYTE := [5(2#10110111)];
	usiSize: USINT := 15;
	usiNum: USINT := 2;
	XP_CY: BOOL;
	END_VAR	

Program		

	LD	ST

Operation result



Name	Data type	Address	Value
xResult	BOOL		TRUE
arrInOut	ARRAY [0..4] OF BYTE		
arrInOut[0]	BYTE		2#10110111
arrInOut[1]	BYTE		2#11011100
arrInOut[2]	BYTE		2#11011110
arrInOut[3]	BYTE		2#10110111
arrInOut[4]	BYTE		2#10110111
usiSize	USINT		15
usiNum	USINT		2
XP_CY	BOOL		TRUE

- **Precautions**
  - When the value of Num or Size is 0, the shift operation is not performed. The function returns TRUE, InOut[] does not change, and the value of P_CY is FALSE.
  - When the value of Num is greater than or equal to Size, all Size bits (starting from bit 0 of InOut[0]) are set to FALSE. Additionally, the value of P_CY changes to FALSE, and the function returns TRUE.
  - When the value of Size exceeds the total number of bits in the InOut[] array, the function returns FALSE, InOut[] does not change, and the value of P_CY is FALSE.
  - When the input array has more than three dimensions, the function returns FALSE, InOut[ ] remains unchanged, and the value of P_CY is FALSE.

18.2.4.15 NSHRC

Shifts the input array along with the carry flag (CY) to the right (toward lower bits) by a specified number of bits.

- **Instruction format**

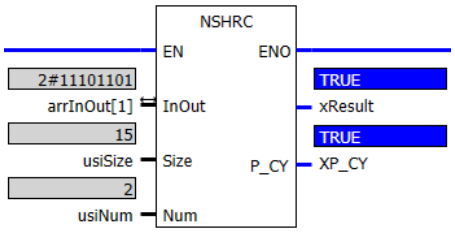
Instruction	Name	FB/FC	LD Representation	ST Representation
NSHRC	Shift N-bits right with carry	FC		:= NSHRC(InOut := , Size := , Num := , P_CY =>);

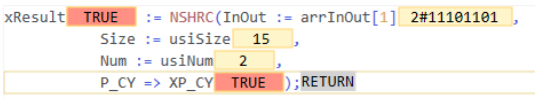
- **Related variables**

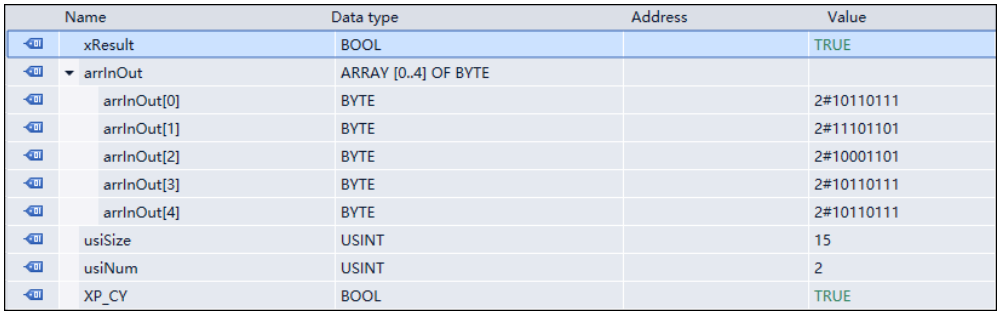
  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	Size	Number of bits in the shift object	Follows data type	1	Number of bits in the shift object
	Num	Number of bits to shift	Follows data type	1	Number of bits to shift

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input/Output	InOut[ ] array	Array where the shift object is located	Follows data type	-	Array where the shift object is located
Output	P_CY	Carry flag	Follows data type	-	Carry flag







Variable types

	Bool ean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
InOut[ ] array	√	√	√	√	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Size	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Num	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
P_CY	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - Shifts Size bits in InOut[0] starting from InOut[0] left by Num bits. The last overflow bit is output to the carry flag (CY) and the vacated bits on the opposite side are filled with 0.
  - The shift direction is right, from the most-significant bits to the least-significant bits.
- **Program example**

	LD	ST

Define variables	VAR
	xResult: BOOL;
	arrInOut: ARRAY[0..4] OF BYTE := [5(2#10110111)];
	usiSize: USINT := 15;
	usiNum: USINT := 2;
	XP_CY: BOOL;
	END_VAR	

	LD	ST
Program		
Operation result		

Name	Data type	Address	Value
xResult	BOOL		TRUE
arrInOut	ARRAY [0..4] OF BYTE		
arrInOut[0]	BYTE		2#10110111
arrInOut[1]	BYTE		2#11101101
arrInOut[2]	BYTE		2#10001101

18.2.5.21 AnyNumFmt	FC	Numeric format conversion	OMUtils	Applicable to library version 1.5.0.0 and later

18.2.5.2 DateToString

Converts a date to a string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
DateToString	Conversion from date to string	FC		:= DateToString(In := , Out =>);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Date	Follows data type	DATE#1970-1-1	Date
Output	Out	Conversion result	10 bytes	-	Conversion result

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√

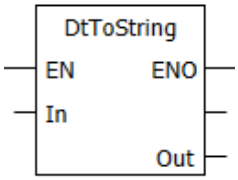
- **Function description**

  Converts the date In to the string Out, appending NULL characters at the end of Out.

- **Program example**

	LD	ST
Define variables		
Program		

	LD	ST
Operation result		



- **Precautions**

  The default type of the output variable Out is STRING[10], a string of length 10. If the defined length of the output string is less than 10, the output follows implicit conversion rules and may be truncated.

18.2.5.3 DtToString

Converts a date and time to a string.

- **Instruction format**

Instruction	Name	FB/FC	Ladder Diagram Representation	Structured Text Representation
DtToString	Conversion from date and time to string	FC		:= DtToString(In := , Out =>);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Date and Time	Follows data type	DATE_AND_TIME#1970-1-1-0:0:0	Conversion object
Output	Out	Conversion result	19 bytes	-	Conversion result

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√

- **Function description**

Converts the date and time In to the string Out. NULL characters are appended to the end of Out.

- **Program example**

	LD	ST
Define variables	VAR xResult: BOOL; dtIn: DATE_AND_TIME:= DT#2024-10-08-16:20:50; strOut: STRING[19]; END_VAR	
Program		
Operation result		

Name	Data type	Address	Value
xResult	BOOL		TRUE
dtIn	DATE_AND_TIME		DT#2024-10-8-16:20:50
strOut	STRING[19]		'2024-10-08-16:20:50'

18.2.5.4 Decoder

Sets the specified bit to TRUE and the other bits to FALSE in an array element that consists of a maximum of 256 bits.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
Decoder	Bit decoder	FC		:= Decoder(In := , Size := , InOut :=);

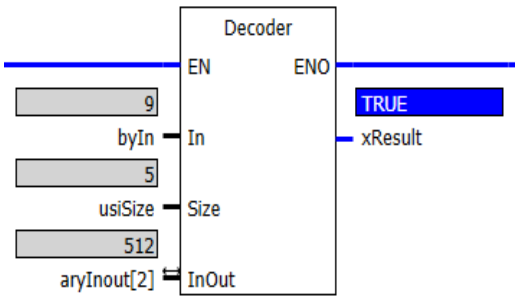
- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Bit position to convert	Follows data type	0	Bit position to convert
	Size	Number of bits to convert	0 to 8	1	Number of bits to convert
Input/Output	InOut[ ] array	Array where the conversion object is located	Follows data type	-	Array where the conversion object is located

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Size	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
InOut[ ] array	√	√	√	√	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–



- **Function**

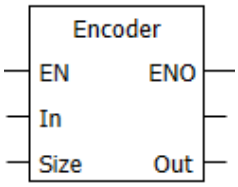
  This instruction converts array elements with 2^{Size} bits that start from InOut[0] in array InOut[]. It sets the specified bit to TRUE and other bits to FALSE. The position to be set to TRUE is specified by the conversion bit position In. Input parameters passed to InOut[ ] shall be specified along with the element index, such as Array[3].

- **Program example**

	LD	ST

Define variables	VAR
	byIn: BYTE := 9;
	usiSize: USINT := 5;
	aryInout: ARRAY [1..10] OF WORD := [10(65535)];
	xResult: BOOL;
	END_VAR	

Program		xResult TRUE := Decoder(In := byIn 9 , Size := usiSize 5 , InOut := aryInout[2] 512);RETURN



<table>
<tr><th></th><th>LD</th><th>ST</th></tr>
<tr><td>Operation result</td><td colspan="2">
<table>
<tr><th>Name</th><th>Data type</th><th>Address</th><th>Value</th></tr>
<tr><td>byIn</td><td>BYTE</td><td></td><td>9</td></tr>
<tr><td>usiSize</td><td>USINT</td><td></td><td>5</td></tr>
<tr><td>arylnout</td><td>ARRAY [1..10] OF WORD</td><td></td><td></td></tr>
<tr><td>arylnout[1]</td><td>WORD</td><td></td><td>65535</td></tr>
<tr><td>arylnout[2]</td><td>WORD</td><td></td><td>512</td></tr>
<tr><td>arylnout[3]</td><td>WORD</td><td></td><td>0</td></tr>
<tr><td>arylnout[4]</td><td>WORD</td><td></td><td>65535</td></tr>
<tr><td>arylnout[5]</td><td>WORD</td><td></td><td>65535</td></tr>
<tr><td>arylnout[6]</td><td>WORD</td><td></td><td>65535</td></tr>
<tr><td>arylnout[7]</td><td>WORD</td><td></td><td>65535</td></tr>
<tr><td>arylnout[8]</td><td>WORD</td><td></td><td>65535</td></tr>
<tr><td>arylnout[9]</td><td>WORD</td><td></td><td>65535</td></tr>
<tr><td>arylnout[10]</td><td>WORD</td><td></td><td>65535</td></tr>
<tr><td>xResult</td><td>BOOL</td><td></td><td>TRUE</td></tr>
</table>
</td></tr>
<tr><td>Principle analysis</td><td colspan="2">
</td></tr>
</table>

- **Precautions**
  - When the value of Size exceeds the number of bits in the array elements of InOut[ ], the return value is FALSE and InOut[ ] does not change.
  - When the value of Size exceeds the valid range, the return value is FALSE and InOut[ ] does not change.
  - When the value of Size is 0, all bits in InOut[0] change to FALSE.
  - When the number of bits in the InOut[ ] elements exceeds the number of bits represented by Size, the values of the remaining bits remain unchanged. For example, if Size = 2 and the InOut[ ] elements are of WORD type, the lower four bits of InOut[0] are processed, and the values of the remaining bits (bit 4 to bit 15) remain unchanged.
  - When the value of "IN" exceeds the number of bits represented by "Size", the actual bit position is determined by the remainder of "IN" divided by 2^{Size}. For example, if "IN" = 9 and Size = 2, the valid bit range is 4 bits and InOut[0] (9 mod 4 = 1) is set to 1.

18.2.5.5 Encoder

Calculates the position of the TRUE bit in array elements that consist of a maximum of 256 bits.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
Encoder	Bit encoder	FC		:= Encoder(In := , Size := , Out =>);

- **Related variables**

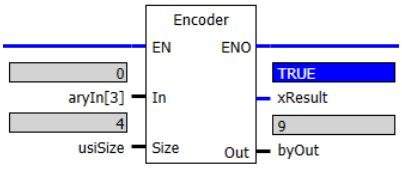
Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In[ ] array	Array where the conversion object is located	Follows data type	-	Array where the conversion object is located
	Size	Number of bits to convert	0 to 8	1	Number of bits to convert
Output	Out	Return position	Follows data type	-	Return position

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In[ ] array	√	√	√	√	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Size	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - Calculates the position of a TRUE bit in a range of bits in the array In[ ].
  - The range consists of 2^{Size} bits starting from In[0]. The position of the TRUE bit is stored in binary form in the lower Size bits of the output Out. The remaining higher bits of Out are set to FALSE.
  - If there are multiple TRUE bits in the specified range, the position of the highest TRUE bit is found.
  - Input parameters passed to In[ ] shall be specified along with the element index, such as Array[3].
- **Program example**



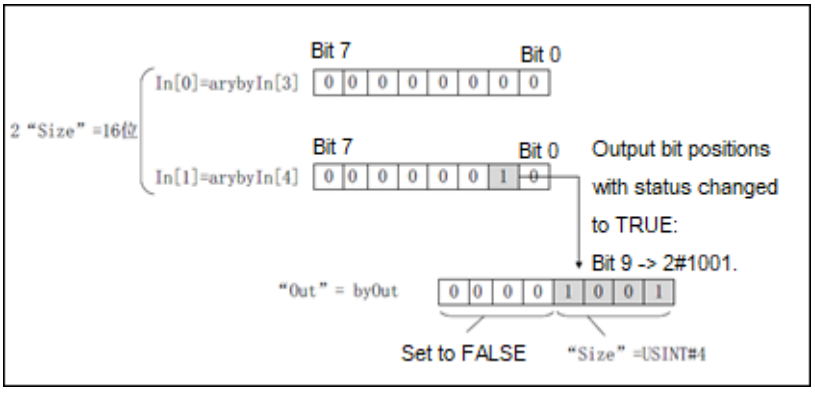
In the following example, Size is set to USINT#4 and the array In[ ] is of BYTE type. Since Size = USINT#4, the bit range for calculation consists of 16(2^4) bits starting from In[0].

In the figure below, the 9th bit in this range is TRUE. Therefore, the binary form of 9 (2#1001) is stored in the lower four bits of Out, while the upper four bits are set to FALSE.

<table>
<tr><th></th><th>LD</th><th>ST</th></tr>
<tr><td>Define variables</td><td colspan="2">

```
VAR
    aryIn: ARRAY [1..4] OF BYTE := [7,9,0,2];
    usiSize: USINT := 4;
    byOut: BYTE;
    xResult: BOOL;
END_VAR
```

</td></tr>
<tr><td>Program</td><td>



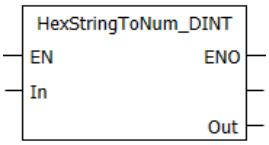
</td><td>

```
xResult TRUE := Encoder(In := aryIn[3] 0 ,
        Size := usiSize 4 ,
        Out => byOut 9 );RETURN
```

</td></tr>
<tr><td>Operation result</td><td colspan="2">

Name	Data type	Address	Value
aryIn	ARRAY [1..4] OF BYTE		
aryIn[1]	BYTE		7
aryIn[2]	BYTE		9
aryIn[3]	BYTE		0
aryIn[4]	BYTE		2
usiSize	USINT		4
byOut	BYTE		9
xResult	BOOL		TRUE

</td></tr>
<tr><td>Principle analysis</td><td colspan="2">



</td></tr>
</table>

- **Precautions**
  - When the value of Size is 0, the return value is TRUE, and all bits of Out are FALSE.
  - When the value of Size exceeds the valid range, a fault occurs, the return value is FALSE, and the value of Out is set to default.
  - When the value of 2^{Size} exceeds the number of bits in the In[ ] array elements, the return value is FALSE, and the value of Out is set to default.
  - When all bits in In[ ] that are specified by Size are FALSE, a fault occurs, the return value is FALSE, and the value of Out is set to default.

18.2.5.6 HexStringToNum_DINT

Converts a hexadecimal string to a double integer.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
HexStringToNum_DINT	Conversion from hexadecimal string to integer	FC		:= HexStringToNum_DINT(In := , Out =>);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Hexadecimal string	Follows data type	-	Hexadecimal string
Output	Out	Double integer	Follows data type	-	Double integer

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
Out	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–

- **Function**

  Converts the hexadecimal string In to the double integer Out.

  Half-width spaces (16#20) and '0' (16#30) in the upper digits, and underscores (16#5F) in the string are ignored.

- **Program example**

	LD	ST
Define variables		
Program		

	LD	ST
Operation result		

- **Precautions**
  - If the conversion result exceeds the valid range of Out, no fault occurs, but the value of Out may not match expectations.
  - If In does not end with a NULL character, the conversion may fail.
  - If In includes characters that cannot be converted to numbers, a fault occurs, the return value is FALSE, and the value of Out remains unchanged.
  - If In contains only half-width spaces and underscores, the function returns FALSE, and Out remains unchanged.

18.2.5.7 HexStringToNum_INT

Converts a hexadecimal string to an integer.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
HexStringToNum_INT	Conversion from hexadecimal string to integer	FC		:= HexStringToNum_INT(In := , Out =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Hexadecimal string	Follows data type	-	Hexadecimal string
Output	Out	Integer	Follows data type	-	Integer

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
Out	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–

- **Function**

  Converts the hexadecimal string In to the integer Out.

  Half-width spaces (16#20) and '0' (16#30) in the upper digits, and underscores (16#5F) in the string are ignored.

- **Program example**

	LD	ST
Define variables	VAR xResult: BOOL; strIn: STRING[256] := ' 80'; iOut: INT; END_VAR	
Program		
Operation result		

	Name	Data type	Address	Value
	xResult	BOOL		TRUE
	strIn	STRING[256]		' 80'
	iOut	INT		16#0080

- **Precautions**
  - If the conversion result exceeds the valid range of Out, no fault occurs, but the value of Out may not match expectations.
  - If In does not end with a NULL character, the conversion may fail.
  - If In includes characters that cannot be converted to numbers, a fault occurs, the return value is FALSE, and the value of Out remains unchanged.
  - If In contains only half-width spaces and underscores, the function returns FALSE, and Out remains unchanged.

18.2.5.8 HexStringToNum_LINT

Converts a hexadecimal string to a long integer.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
HexStringToNum_LINT	Conversion from hexadecimal string to long integer	FC		:= HexStringToNum_LINT(In := , Out =>);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Hexadecimal string	Follows data type	-	Hexadecimal string
Output	Out	Long integer	Follows data type	-	Long integer

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
Out	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–

- **Function**

  Converts the hexadecimal format string In to the long integer Out.

  Half-width spaces (16#20) and '0' (16#30) in the upper digits, and underscores (16#5F) in the string are ignored.

- **Program example**

	LD	ST
Define variables	VAR xResult: BOOL; strIn: STRING[256] := ' 80'; liOut: LINT; END_VAR	
Program		
Operation result		

- **Precautions**
  - If the conversion result exceeds the valid range of Out, no fault occurs, but the value of Out may not match expectations.
  - If In does not end with a NULL character, the conversion may fail.
  - If In includes characters that cannot be converted to numbers, a fault occurs, the return value is FALSE, and the value of Out remains unchanged.
  - If In contains only half-width spaces and underscores, the function returns FALSE, and Out remains unchanged.

18.2.5.9 HexStringToNum_SINT

Converts a hexadecimal string to a short integer.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
HexStringToNum_SINT	Conversion from hexadecimal string to shorter integer	FC		:= HexStringToNum_SINT(In := , Out =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Hexadecimal string	Follows data type	-	Hexadecimal string
Output	Out	Short integer	Follows data type	-	Short integer

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
Out	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–

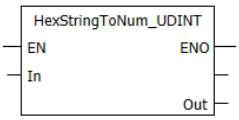
- **Function**

  Converts the hexadecimal format string In to the short integer Out.

  Half-width spaces (16#20) and '0' (16#30) in the upper digits, and underscores (16#5F) in the string are ignored.

- **Program example**

	LD	ST
Define variables	VAR xResult: BOOL; strIn: STRING[256] := ' 80'; siOut: SINT; END_VAR	
Program	HexStringToNum_SINT EN / ENO ' 80' → strIn In TRUE → xResult 16#80 → siOut Out	xResult TRUE := HexStringToNum_SINT(In := strIn ' 80', Out => siOut 16#80);RETURN
Operation result		



Name	Data type	Address	Value
xResult	BOOL		TRUE
strIn	STRING[256]		' 80'
siOut	SINT		16#80

- **Precautions**
  - If the conversion result exceeds the valid range of Out, no fault occurs, but the value of Out may not match expectations.
  - If In does not end with a NULL character, the conversion may fail.
  - If In includes characters that cannot be converted to numbers, a fault occurs, the return value is FALSE, and the value of Out remains unchanged.
  - If In contains only half-width spaces and underscores, the function returns FALSE, and Out remains unchanged.

18.2.5.10 HexStringToNum_UDINT

Converts a hexadecimal string into an unsigned double integer.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
HexStringToNum_UDINT	Conversion from hexadecimal string to unsigned double integer	FC		:= HexStringToNum_UDINT(In := , Out =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Hexadecimal string	Follows data type	-	Hexadecimal string
Output	Out	Unsigned double integer	Follows data type	-	Unsigned double integer

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
Out	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–

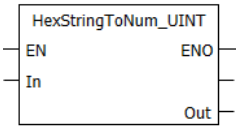
- **Function**

Converts the hexadecimal string In to the unsigned double integer Out.

Half-width spaces (16#20) and '0' (16#30) in the upper digits, and underscores (16#5F) in the string are ignored.

- **Program example**

<table>
<tr><th></th><th>LD</th><th>ST</th></tr>
<tr><td>Define variables</td><td colspan="2">
<pre>
VAR
    xResult: BOOL;
    strIn: STRING[256] := '   80';
    udiOut: UDINT;
END_VAR
</pre>
</td></tr>
<tr><td>Program</td><td>



</td><td>
<pre>
xResult TRUE := HexStringToNum_UDINT(In := strIn ' 80',
    Out => udiOut 16#00000080);RETURN
</pre>
</td></tr>
<tr><td>Operation result</td><td colspan="2">
<table>
<tr><th></th><th>Name</th><th>Data type</th><th>Address</th><th>Value</th></tr>
<tr><td></td><td>xResult</td><td>BOOL</td><td></td><td>TRUE</td></tr>
<tr><td></td><td>strIn</td><td>STRING[256]</td><td></td><td>' 80'</td></tr>
<tr><td></td><td>udiOut</td><td>UDINT</td><td></td><td>16#00000080</td></tr>
</table>
</td></tr>
</table>

- **Precautions**
  - If the conversion result exceeds the valid range of Out, no fault occurs, but the value of Out may not match expectations.
  - If In does not end with a NULL character, the conversion may fail.
  - If In includes characters that cannot be converted to numbers, a fault occurs, the return value is FALSE, and the value of Out remains unchanged.
  - If In contains only half-width spaces and underscores, the function returns FALSE, and Out remains unchanged.

18.2.5.11 HexStringToNum_UINT

Converts a hexadecimal string into an unsigned integer.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
HexStringToNum_UINT	Conversion from hexadecimal string to unsigned integer	FC		:= HexStringToNum_UINT(In := , Out =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Hexadecimal string	Follows data type	-	Hexadecimal string
Output	Out	Unsigned integer	Follows data type	-	Unsigned integer

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
Out	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  Converts the hexadecimal string In to the unsigned integer Out.

  Half-width spaces (16#20) and '0' (16#30) in the upper digits, and underscores (16#5F) in the string are ignored.

- **Program example**

	LD	ST
Define variables	VAR xResult: BOOL; strIn: STRING[256] := ' 80'; uiOut: UINT; END_VAR	
Program	HexStringToNum_UINT EN / ENO ' 80' → strIn In TRUE → xResult 16#0080 → uiOut Out	xResult TRUE := HexStringToNum_UINT(In := strIn ' 80', Out => uiOut 16#0080);RETURN
Operation result		

	Name	Data type	Address	Value
	xResult	BOOL		TRUE
	strIn	STRING[256]		' 80'
	uiOut	UINT		16#0080

- **Precautions**
  - If the conversion result exceeds the valid range of Out, no fault occurs, but the value of Out may not match expectations.
  - If In does not end with a NULL character, the conversion may fail.
  - If In includes characters that cannot be converted to numbers, a fault occurs, the return value is FALSE, and the value of Out remains unchanged.
  - If In contains only half-width spaces and underscores, the function returns FALSE, and Out remains unchanged.

18.2.5.12 HexStringToNum_ULINT

Converts a hexadecimal string into an unsigned long integer.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
HexStringToNum_ULINT	Conversion from hexadecimal string to unsigned long integer	FC		:= HexStringToNum_ULINT(In := , Out =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Hexadecimal string	Follows data type	-	Hexadecimal string
Output	Out	Unsigned long integer	Follows data type	-	Unsigned long integer

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
Out	–	–	–	–	–	–	–	–	√	_	–	–	–	–	–	–	–	–	–	–

- **Function**

Converts the hexadecimal string In to the unsigned long integer Out.

Half-width spaces (16#20) and '0' (16#30) in the upper digits, and underscores (16#5F) in the string are ignored.

- **Program example**

	LD	ST
Define variables	VAR xResult: BOOL; strIn: STRING[256] := ' 80'; uliOut: ULINT; END_VAR	
Program		
Operation result		

- **Precautions**
  - If the conversion result exceeds the valid range of Out, no fault occurs, but the value of Out may not match expectations.
  - If In does not end with a NULL character, the conversion may fail.
  - If In includes characters that cannot be converted to numbers, a fault occurs, the return value is FALSE, and the value of Out remains unchanged.
  - If In contains only half-width spaces and underscores, the function returns FALSE, and Out remains unchanged.

18.2.5.13 HexStringToNum_USINT

Converts a hexadecimal string into an unsigned short integer.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
HexStringToNum_USINT	Conversion from hexadecimal string to unsigned shorter integer	FC		:= HexStringToNum_USINT(In := , Out =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Hexadecimal string	Follows data type	-	Hexadecimal string
Output	Out	Unsigned short integer	Follows data type	-	Unsigned short integer

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√
Out	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  Converts the hexadecimal string In to the unsigned short integer Out.

  Half-width spaces (16#20) and '0' (16#30) in the upper digits, and underscores (16#5F) in the string are ignored.

- **Program example**

	LD	ST
Define variables	VAR xResult: BOOL; strIn: STRING[256] := ' 80'; usiOut: USINT; END_VAR	
Program	HexStringToNum_USINT EN / ENO ' 80' / strIn – In TRUE / xResult 16#80 / usiOut – Out	xResult TRUE := HexStringToNum_USINT(In := strIn ' 80', Out => usiOut 16#80);RETURN
Operation result	Name / Data type / Address / Value xResult / BOOL / / TRUE strIn / STRING[256] / / ' 80' usiOut / USINT / / 16#80	

- **Precautions**
  - If the conversion result exceeds the valid range of Out, no fault occurs, but the value of Out may not match expectations.
  - If In does not end with a NULL character, the conversion may fail.
  - If In includes characters that cannot be converted to numbers, a fault occurs, the return value is FALSE, and the value of Out remains unchanged.
  - If In contains only half-width spaces and underscores, the function returns FALSE, and Out remains unchanged.

18.2.5.14 MovingAverage

Calculates the moving average of the input.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
MovingAverage	Moving average calculation	FC		:= MovingAverage(In := , CurIndex := , Buf := , BufSize := , Q := , Out :=);

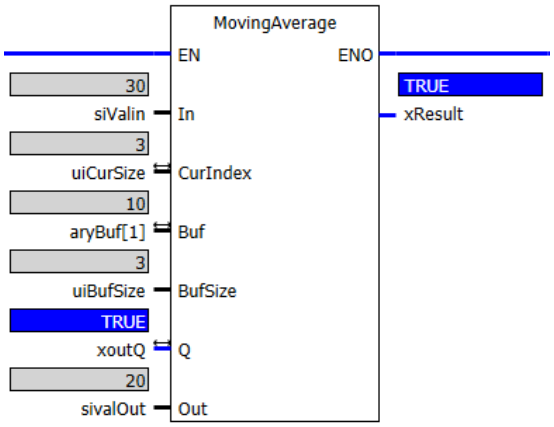
- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Input Value	Follow data type	-	Input value for average calculation
	BufSize	Maximum number of elements	Follows data type	1	Maximum number of elements for average calculation
	Out	Operation result	Follows data type	-	Operation result
Input/Output	CurInDex	Input value storage position	Follows data type	-	Position in Buf[ ] where In is stored
	Buf[ ] array	Input value storage array	Follows data type	-	Array where In is stored
	Q	Calculation completion flag	Follows data type	-	TRUE: The number of values stored in Buf[ ] ≥ BufSize FALSE: The number of values stored in Buf[ ] < BufSize

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–
BufSize	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
CurInDex	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
Buf[ ] array	Array with the same data type as elements of In																			
Q	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	–	–	–	–	√	√	√	√	√	√	√	√	√	√	–	–	–	–	–



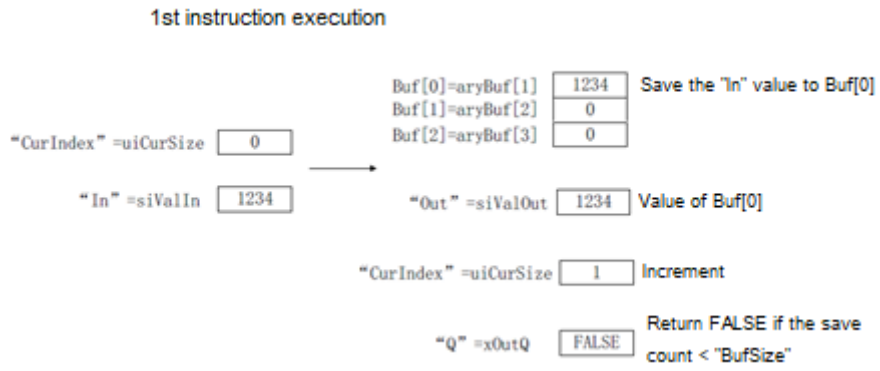
- **Function**

  Each time this instruction is executed, the input value In is stored in the array Buf[ ]. The average of the stored values is calculated and output to Out. The maximum number of elements used for the average calculation is specified by BufSize.

- **Program example**

  The following example sets BufSize to UINT#3. The instruction is executed three times, with input values In set to 10, 20, and 30 respectively.

	LD	ST
Define variables	VAR siValin: SINT; uiCurSize: UINT; aryBuf:ARRAY[1..4] OF SINT; uiBufSize: UINT := 3; xoutQ: BOOL; sivalOut: SINT; xResult: BOOL; END_VAR	



<table>
<tr><th></th><th>LD</th><th>ST</th></tr>
<tr><td>Program</td><td>
</td><td>xResult TRUE := MovingAverage(In := siValin 30 ,
CurIndex := uiCurSize 3 ,
Buf := aryBuf[1] 10 ,
BufSize := uiBufSize 3 ,
Q := xoutQ TRUE ,
Out := sivalOut 20);RETURN</td></tr>
<tr><td>Operation result</td><td colspan="2"><table>
<tr><th></th><th>Name</th><th>Data type</th><th>Address</th><th>Value</th></tr>
<tr><td></td><td>siValin</td><td>SINT</td><td></td><td>30</td></tr>
<tr><td></td><td>uiCurSize</td><td>UINT</td><td></td><td>3</td></tr>
<tr><td></td><td>aryBuf</td><td>ARRAY [1..4] OF SINT</td><td></td><td></td></tr>
<tr><td></td><td>aryBuf[1]</td><td>SINT</td><td></td><td>10</td></tr>
<tr><td></td><td>aryBuf[2]</td><td>SINT</td><td></td><td>20</td></tr>
<tr><td></td><td>aryBuf[3]</td><td>SINT</td><td></td><td>30</td></tr>
<tr><td></td><td>aryBuf[4]</td><td>SINT</td><td></td><td>0</td></tr>
<tr><td></td><td>uiBufSize</td><td>UINT</td><td></td><td>3</td></tr>
<tr><td></td><td>xoutQ</td><td>BOOL</td><td></td><td>TRUE</td></tr>
<tr><td></td><td>sivalOut</td><td>SINT</td><td></td><td>20</td></tr>
<tr><td></td><td>xResult</td><td>BOOL</td><td></td><td>TRUE</td></tr>
</table></td></tr>
</table>

- Initial input value

  Set the input value storage position CurIndex to 0 and execute the instruction. After Buf[BufSize-1] is cleared, the input value In is stored in Buf[0].

  When the calculation completion flag "Q" is FALSE, the average is calculated based on the values from Buf[0] to Buf[CurIndex+1]. The result is stored in "Out", and "CurIndex" is incremented.

  If the number of values stored in the array Buf[ ] has not reached "BufSize", the value of "Q" remains FALSE.

- Value input up to the BufSize-th time

  Each time the instruction is executed, the input value In is stored in Buf[CurIndex]. The average is calculated based on the values from Buf[0] to Buf[CurIndex+1]. The result is stored in Out, and CurIndex is incremented.

  If the number of values stored in the array Buf[ ] reaches "BufSize", "Q" becomes TRUE.

- Value input after the BufSize-th time

  Each time the instruction is executed, Buf[0] to Buf[BufSize–1] are overwritten with the value of In cyclically. The average of Buf[0] to Buf[BufSize–1] is calculated and stored in Out.

  If "CurIndex" reaches "BufSize", it resets to 1. It will increment again when new data is input, and "Q" remains TRUE.

- Initialization of stored values

  If the value of CurSize is set to 0 before the instruction is executed, values of Buf[0] to Buf[BufSize–1] change to 0. The current input value In is then stored in Buf[0]. "CurIndex" becomes 1, and "Q" becomes FALSE.

- Change of the BufSize value

  If the value of BufSize changes before the instruction is executed, the operation is performed with the new value of BufSize and the current value of CurIndex.

- **Precautions**
  - The data types of In, Out, and the elements of Buf[ ] must be consistent; otherwise, a compilation fault will occur.
  - The size of the array Buf[ ] shall be set to a value greater than BufSize. When the value of BufSize exceeds the size of Buf[ ], the return value is FALSE and Out outputs the default value.
  - When the calculation result exceeds the valid range of Out, the instruction does not trigger an exception, and an invalid value is stored in Out.
  - When the value of "BufSize" is 0, "Out" and "CurIndex" change to 0, and "Q" changes to TRUE.
  - When changing the value of BufSize, CurIndex must be set to 0 to initialize the stored values.

18.2.5.15 NumToDecString

Converts an integer to a decimal string with a fixed length.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
NumToDecString	Conversion from integer to fixed-length decimal string	FC	NumToDecString EN ENO In L Out Fill	:= NumToDecString(In := , L := , Fill := , Out =>);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Integer	Follows data type	-	Integer
	L	Number of characters	0 to 1985	1	String
	Fill	Character to fill	1 (_EFill_CHR._BLANK) 2 (_EFill_CHR._ZERO)	1 (_EFill_CHR._BLANK)	Character to fill
Input/Output	Out	String	Follows data type	-	String

Variable types

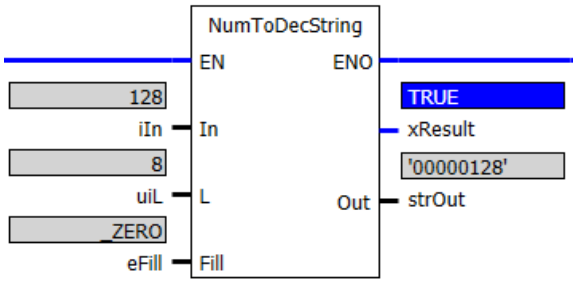
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	√	√	√	√	√	√	√	√	–	–	–	–	–	–	–
L	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
Fill	See "Function description" for the enumerators for _EFill_CHR.																			
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√

- **Function description**

  This instruction converts integer In to a decimal text string of UTF-8 alphanumeric characters. If In contains a negative value, a minus sign (–) is added at the beginning of the string.

  The instruction sets the number of characters in the output string Out to L. If the string length is insufficient, the high-order digits are filled with characters specified by Fill. If the number of characters in the conversion result exceeds L, L characters from the low-order digits of the conversion result are assigned to Out. The data type of Fill is the enumerated type _EFill_CHR.

  The meanings of the enumerators are as follows.



Enumerator	Definition
1 (_EFill_CHR._BLANK)	' ' (Half-width blank character)

Enumerator	Definition
2 (_EFill_CHR._ZERO)	'0'

- **Program example**

	LD	ST

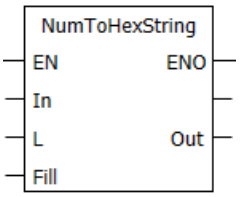
Define variables	VAR
	iIn: INT := 128;
	uiL:UINT :=8;
	eFill:_eFILL_CHR := _EFILL_CHR._ZERO;
	strOut:STRING[256];
	xResult: BOOL;
	END_VAR	

Program		xResult TRUE := NumToDecString(In := iIn 128 , L := uiL 8 , Fill := eFill _ZERO , Out => strOut '00000128');RETURN
Operation result		

Name	Data type	Address	Value
iIn	INT		128
uiL	UINT		8
eFill	_EFILL_CHR		_ZERO
strOut	STRING[256]		'00000128'
xResult	BOOL		TRUE

- **Precautions**

  When the value of L is 0, the value of Out does not change. When the number of characters in the conversion result exceeds L, L characters from the low-order digits of the conversion result are stored in Out. The following is an example.



Value of In	Value of L	Value of Out
128	2	28

  - When the value of L exceeds the valid range, a fault occurs, the return value is FALSE, and the value of Out remains unchanged.
  - When the value of Fill exceeds the valid range, a compilation fault will occur.
  - When the conversion result exceeds the range of Out, the output value is incorrect.

18.2.5.16 NumToHexString

Converts an integer to a hexadecimal string with a fixed length.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
NumToHexString	Conversion from integer to fixed-length hexadecimal string	FC		:= NumToHexString(In := , L := , Fill := , Out =>);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Integer	Follows data type	-	Integer
	L	Number of characters	0 to 1985	1	String
	Fill	Character to fill	1 (_EFill_CHR._BLANK) 2 (_EFill_CHR._ZERO)	1 (_EFill_CHR._BLANK)	Character to fill
Input/Output	Out	String	Follows data type	-	String

  Variable types

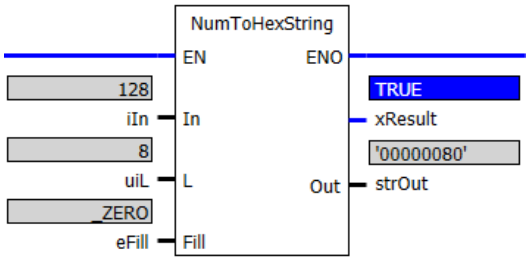
	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	√	√	√	√	√	√	√	√	–	–	–	–	–	–	–
L	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
Fill	See "Function description" for the enumerators for _EFill_CHR.																			
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√

- **Function description**

  This instruction converts the integer In to a hexadecimal string of UTF-8 alphanumeric characters. If In is negative, it is expressed in its two's complement (bits inverted and then 1 added).

  The instruction sets the number of characters in the output string Out to L. If the string length is insufficient, the high-order digits are filled with characters specified by Fill. If the number of

characters in the conversion result exceeds L, L characters from the low-order digits of the conversion result are assigned to Out. The data type of Fill is the enumerated type _EFill_CHR.



The meanings of the enumerators are as follows.

Enumerator	Definition
1 (_EFill_CHR._BLANK)	' ' (Half-width blank character)
2 (_EFill_CHR._ZERO)	'0'

- **Program example**

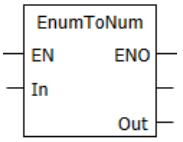
	LD	ST

Define variables	VAR
	iIn: INT := 128;
	uiL:UINT := 8;
	eFill:_eFILL_CHR := _EFILL_CHR._ZERO;
	strOut:STRING[256];
	xResult: BOOL;
	END_VAR	

Program		xResult TRUE := NumToHexString(In := iIn 128 , L := uiL 8 , Fill := eFill _ZERO , Out => strOut '00000080');RETURN
Operation result	Name / Data type / Address / Value iIn / INT / / 128 uiL / UINT / / 8 eFill / _EFILL_CHR / / _ZERO strOut / STRING[256] / / '00000080' xResult / BOOL / / TRUE	

- **Precautions**

When the value of L is 0, the value of Out does not change. When the number of characters in the conversion result exceeds the value of L, L characters from the lower characters of the conversion result are stored in Out. The following is an example.



Value of In	Value of L	Value of Out
128	2	80

  - When the value of L exceeds the valid range, a fault occurs, the return value is FALSE, and the value of Out remains unchanged.
  - When the value of Fill exceeds the valid range, a compilation fault will occur.
  - When the conversion result exceeds the range of Out, the output value is incorrect.

18.2.5.17 EnumToNum

Converts the value of an enumeration type element to a double integer.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
EnumToNum	Conversion from enumeration to integer	FC		:= EnumToNum(In := , Out =>);

- **Related variables**

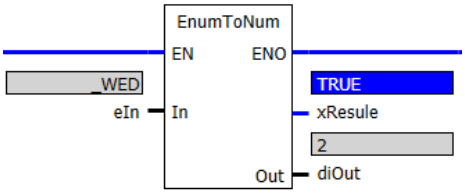
Variable

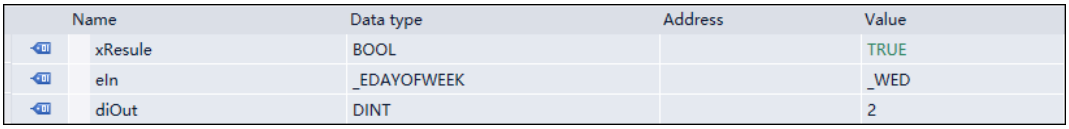
Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	Follows data type	-	Conversion object
Output	Out	Conversion result	Follows data type	-	Conversion result

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	Supports user-defined enumeration types. Take the enumeration elements of _eDAYOFWEEK as an example. Refer to the function description below for details.																			
Out	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–

- **Function**





Converts the value of the enumeration type element In to a DINT type value and outputs the result to Out.

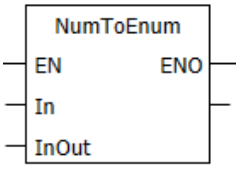
Enumeration type example: _EDAYOFWEEK

Enumerator	Definition
0 (_EDAYOFWEEK._MON)	Monday

Enumerator	Definition
1 (_EDAYOFWEEK._TUE)	Tuesday
2 (_EDAYOFWEEK._WED)	Wednesday
3 (_EDAYOFWEEK._THU)	Thursday
4 (_EDAYOFWEEK._FRI)	Friday
5 (_EDAYOFWEEK._SAT)	Saturday
6 (_EDAYOFWEEK._SUN)	Sunday

- **Program example**

	LD	ST
Define variables	VAR xResule: BOOL; eIn: _eDAYOFWEEK := _EDAYOFWEEK._WED; diOut: DINT; END_VAR	
Program		xResule TRUE := EnumToNum(In := eIn _WED , Out => diOut 2);RETURN
Operation result		



Name	Data type	Address	Value
xResule	BOOL		TRUE
eIn	_EDAYOFWEEK		_WED
diOut	DINT		2

- **Precautions**
  - When the value of In after conversion exceeds the DINT data range, a fault occurs. The return value is FALSE, and Out is initialized to 0.
  - Set the basic data type for In to BYTE, WORD, DWORD, LWORD, USINT, UINT, UDINT, ULINT, SINT, INT, DINT, or LINT. Otherwise, the return value is FALSE and Out is initialized to 0.

18.2.5.18 NumToEnum

Converts a double integer to an enumerated type element.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
NumToEnum	Conversion from integer to enumeration	FC		:= NumToEnum(In := , InOut :=);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	Follows data type	-	Conversion object
Output	InOut	Conversion result	Follows data type	-	Conversion result

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–
In Out	Supports user-defined enumeration types. Take the enumeration elements of _eDAYOFWEEK as an example. Refer to the function description below for details.																			

- **Function**

  Converts the double integer In to an enumeration value, and outputs the result to InOut.

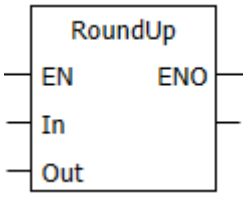
  Enumeration type example: _EDAYOFWEEK

Enumerator	Definition
0 (_EDAYOFWEEK._MON)	Monday
1 (_EDAYOFWEEK._TUE)	Tuesday
2 (_EDAYOFWEEK._WED)	Wednesday
3 (_EDAYOFWEEK._THU)	Thursday
4 (_EDAYOFWEEK._FRI)	Friday
5 (_EDAYOFWEEK._SAT)	Saturday
6 (_EDAYOFWEEK._SUN)	Sunday

- **Program example**

	LD	ST
Define variables	VAR xResule: BOOL; diIn: DINT := 2; eInOut: _eDAYOFWEEK; END_VAR	

	LD	ST
Program		
Operation result		



Name	Data type	Address	Value
xResule	BOOL		TRUE
diIn	DINT		2
eInOut	_EDAYOFWEEK		_WED

- **Precautions**
  - When the converted value of In exceeds the range of the enumeration InOut, a fault occurs. The return value is FALSE, and Out does not change.
  - Ensure that the converted value of In corresponds to one of the defined enumeration values of InOut; otherwise, unexpected results may occur. In such cases, the return value is TRUE, and Out is the numeric value converted from In.
  - Set the basic data type for the enumeration value of InOut to BYTE, WORD, DWORD, LWORD, USINT, UINT, UDINT, ULINT, SINT, INT, DINT, or LINT. Otherwise, the return value is FALSE and Out does not change.

18.2.5.19 RoundUp

Converts a real number to an integer by rounding it up, away from zero.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
RoundUp	Round up real number	FC		:= RoundUp(In := , Out :=);

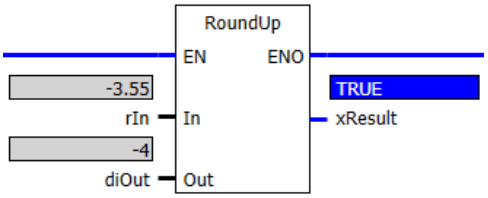
- **Related variables**

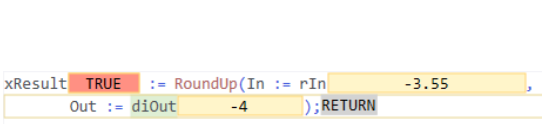
Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	Follows data type	-	Conversion object
	Out	Conversion result	Follows data type	-	Conversion result

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	√	√	–	–	–	–	–	–	–





- **Function**

  Rounds the input real number In up to zero decimal places, and outputs the result to Out.

Input Value	Output Value
REAL#1.6	DINT#2
REAL#1.5	DINT#2
REAL#1.4	DINT#2
REAL#2.5	DINT#3
REAL#-1.6	DINT#-2
REAL#-1.5	DINT#-2
REAL#-1.4	DINT#-2
REAL#-2.5	DINT#-3

- **Program example**

  The following example sets In to REAL#-3.55, the output Out is DINT#-4, as shown below:

	LD	ST
Define variables	VAR xResult: BOOL; rIn: REAL := -3.55; diOut: DINT; END_VAR	
Program		

	LD	ST
Operation result		
Principle analysis		

- **Precautions**
  - When the conversion result exceeds the valid range of Out, the value of Out is incorrect and the function returns TRUE. When the value of In exceeds the floating-point precision range (6 valid digits for REAL and 15 valid digits for LREAL), precision loss will occur.
  - The data types of In and Out must match, otherwise, a program fault occurs and the function returns FALSE.
  - If the input or output is an element of an array with three or more dimensions, the function returns FALSE without performing the conversion.

18.2.5.20 AnyBASE64

AnyBASE64 is an encoding method for transmitting 8-bit byte code, which represents binary data based on 64 printable characters.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AnyBASE64	BASE64 encoding	FC		AnyBASE64(TextToEncode := , uiSize := , isLastBlock := , EncodedText := , udiError => , uiEncodedSize =>);

- **Related variables**

Variable

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	TextToEncode	Data to be converted	Follows data type	-	Data to be processed. Supports arrays, array elements, and STRING types.
	uiSize	Conversion length	>= 0	0	Conversion length (number of elements).
	isLastBlock	Whether the current text is complete	TRUE, FALSE	FALSE	TRUE: The current text is complete. FALSE: The current text is only a part.

Input/ Output	Variable	Name	Valid Range	Default Value	Description
	EncodedText	Data after conversion	Follows data type	-	Data after conversion. Supports arrays, array elements, and STRING types.
Output	udiError	Fault Code	>=0	0	0: No fault 1: The text is too long. 2: The text character length is not an integer multiple of 3. 3: The output array length is less than 4/3 times the length of the input array to be converted. 4: The text pointer is null or the length uiSize = 0. 5: The conversion length exceeds the data length. 6: The input type for "TextToEncode" or "EncodedText" is an array with more than three dimensions.
	uiEncodedSize	Length of the converted text	>=0	0	Number of bytes in the converted text.

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String					
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
TextToEncode	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	√	-
	You can also specify the entire array or a single element of the array.																				
uiSize	-	-	-	-	-	-	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-
isLastBlock	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
EncodedText	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	√	-
	You can also specify the entire array or a single element of the array.																				
udiError	-	-	-	-	-	-	-	√	-	-	-	-	-	-	-	-	-	-	-	-	-
uiEncodedSize	-	-	-	-	-	-	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-

- **Function description**

  Specific encoding method:

Base64 requires converting every three 8-bit bytes into four 6-bit bytes (since 3 × 8 = 4 × 6 = 24). Then, two high-order zeros are padded to each 6-bit bytes to form four 8-bit bytes. Each byte corresponds to a number less than 64, which is the character index. The converted string will theoretically be one-third longer than the original.

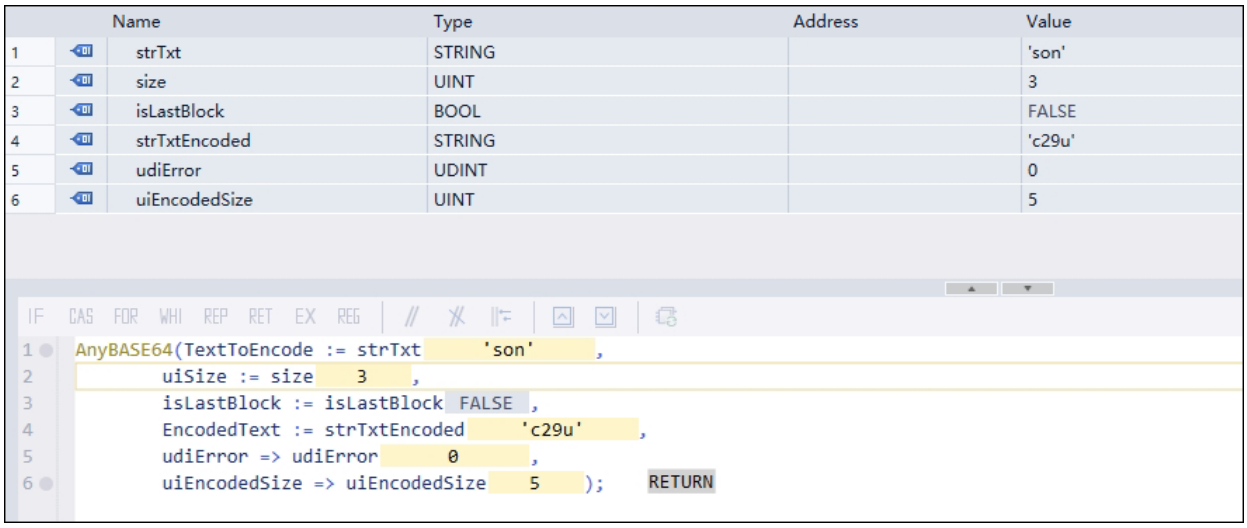
Three English characters can be exactly converted into four Base64 characters. If the condition is not to meet, the remaining bytes of the source text are individually converted according to the encoding rules (1 byte → 2 Base64 chars, 2 bytes → 3 Base64 chars, missing bits are padded with zeros). The result is then filled to 4 bytes using equal signs (=), with at most two equal signs. If the remainder is 0, the original byte count is exactly a multiple of 3 (ideal case). If the remainder is 1, it is converted into two Base64 characters. To make the Base64 output length a multiple of 4, two equal signs are appended; similarly, if the remainder is 2, one equal sign is appended. If the length of uiSize is greater than the length of the original string, append the difference with character "A" to the converted result.

- When isLastBlock is TRUE and uiSize is 3, the encoding principle and results are shown in the table below:

Character	y	o	-
ASCII code	121	111	-
Binary bits	0 1 1 1 1 0 0 1	0 1 1 0 1 1 1 1	0 0 0 0 0 0 0 0
Encoding byte	00 011110	00 010110	00 111100	00 000000
Index number	30	22	60	0
Base64 encoding	e	W	8	=

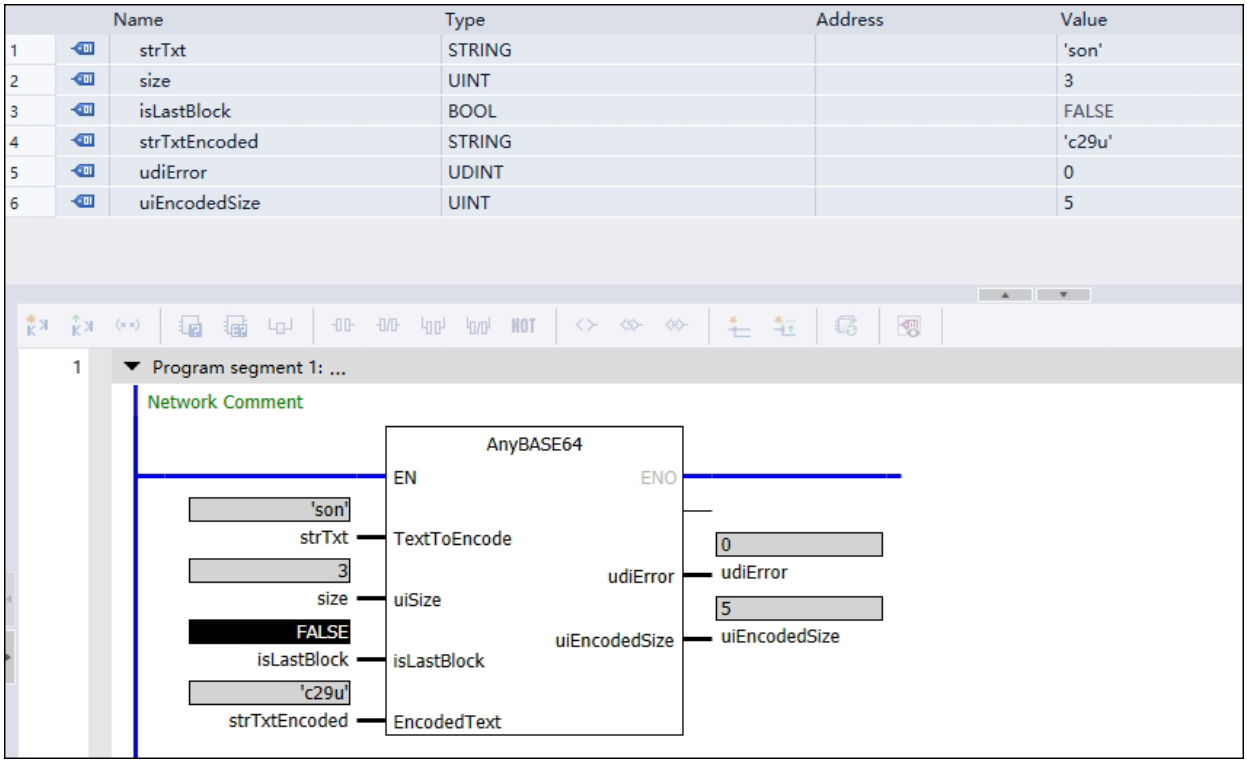
- When isLastBlock is TRUE and uiSize is 1, the encoding principle and results are shown in the table below:

Character	y	-	-
ASCII code	121	-	-
Binary bits	0 1 1 1 1 0 0 1	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0
Encoding byte	00 011001	00 010000	00 000000	00 000000
Index number	25	16	0	0
Base64 encoding	Z	Q	=	=



- When isLastBlock is TRUE and uiSize is 3, the encoding principle and results are shown in the table below:

Character	y	o	u
ASCII code	121	111	117
Binary bits	0 1 1 1 1 0 0 1	0 1 1 0 1 1 1 1	0 1 1 1 0 1 0 1
Encoding byte	00 011110	00 010110	00 111101	00 110101
Index number	30	22	61	53
Base64 encoding	e	W	9	1



- **Program example**

  Set TextToEncode to 'son', and the encoded output data is 'c29u'.

  ST:

  LD:

◦ Encoding example 1: Input 'Son', uiSize = 3, isLastBlock = 1 → AnyBASE64 encoded result: 'U29u'.

ASCII character	S	o	n
Decimal	83	111	110
Binary	01010011	01101111	01101110

Each group consists of 6 bits	010100	110110	111101	101110
High-order padding with zeros	00010100	00110110	00111101	00101110
Corresponding Base64 index	20	54	61	46
Corresponding Base64 character	U	2	9	u

◦ Encoding example 2: Input 'Son', uiSize = 2, isLastBlock = 1 → AnyBASE64 encoded result: 'U28u'.

ASCII character	S	o	-
Decimal	83	111	-
Binary	01010011	01101111	-

Each group consists of 6 bits	010100	110110	111100	-
High-order padding with zeros	00010100	00110110	00111100	-

ASCII character	S	o	-
Corresponding Base64 index	20	54	60	-
Corresponding Base64 character	U	2	8	=

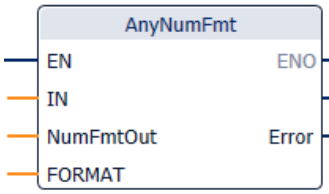
◦ Encoding example 3: Input 'Son', uiSize = 1, isLastBlock = 1 → AnyBASE64 encoded result: 'Uw==='.

ASCII character	S	-	-
Decimal	83	-	-
Binary	01010011	-	-
Each group consists of 6 bits	010100	110000	-	-
High-order padding with zeros	00010100	00110000	-	-
Corresponding Base64 index	20	48	-	-
Corresponding Base64 character	U	w	=	=

◦ Encoding example 4 (Chinese): For Base64 encoding of Chinese characters, use the String type under the UTF-8 format.
For example, input "你", uiSize = 3 → AnyBASE64 encoded result: '5L2g'.

ASCII character	你		
Decimal	228	189	160
Binary	11100100	10111101	10100000
Each group consists of 6 bits	111001	001011	110110	000000
High-order padding with zeros	00111001	00001011	00110110	00100000
Corresponding Base64 index	57	11	54	32
Corresponding Base64 character	5	L	2	g

◦ Fault description:
If any of the following errors occur, udiEncoded outputs 0 and the text result is incorrect. Normal usage should proceed when no ERROR is detected.



Condition	ERROR
TextToEncode is a null pointer.	4
uiSize = 0	4
uiSize > 32767 The length of input string is greater than 32767	1
isLastBlock = FALSE (only part of the text) and the length is not a multiple of 3.	2
The output array length is less than 4/3 times the length of the input array to be converted.	3
The conversion length exceeds the data length.	5
The input type for "TextToEncode" or "EncodedText" is an array with more than three dimensions.	6

- **Precautions**
  - The data length of EncodedText must be greater than 4/3 times the length of TextToEncode; otherwise, an error occurs with error code 3. If the conversion length uiSize exceeds the length of TextToEncode, an error occurs with error code 5.
  - When inputting array elements, conversion begins from the specified input array elements.

18.2.5.21 AnyNumFmt

Convert scientific notation to decimal or decimal to scientific notation.

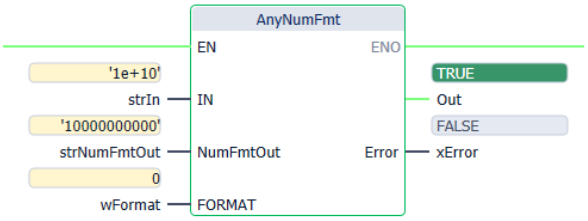
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
AnyNumFmt	Numeric format conversion	FC		:= AnyNumFmt(IN := , NumFmtOut := , FORMAT := , Error =>);

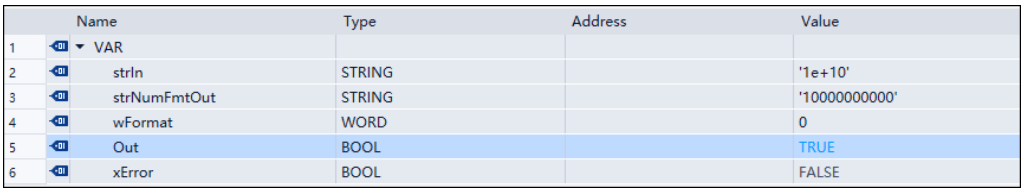
- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Numeric string to be converted	Follows data type	-	Numeric string to be converted.
	NumFmtOut	Numeric string after conversion	Follows data type	-	Numeric string after conversion.



Input/Output	Variable	Name	Valid Range	Default Value	Description
	FORMAT	Conversion format	Follows data type	-	0: Converts scientific notation to decimal format. 1: Converts decimal format to scientific notation format.
Output	Error	Faulty status	Follows data type	-	Function execution status.



Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String					
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING	WSTRING
IN	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	√	√
NumFmtOut	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	√	√
FORMAT	-	-	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Error	√	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

- **Function**
  - When FORMAT is 0, if "IN" is in decimal format, "NumFmtOut" remains consistent with "IN"; when "FORMAT" is 1, if "IN" is in scientific notation format, "NumFmtOut" remains consistent with "IN"; when "FORMAT" is any other value, the instruction does not execute.
  - If "IN" contains leading or trailing zeros, they will be removed in the converted string.
- **Program example**

Here is an example of converting scientific notation to decimal, as shown in the figure below:

<table>
<tr><th></th><th>LD</th><th>ST</th></tr>
<tr><td>Define variables</td><td colspan="2">
<pre>
VAR
    strIn: STRING := '1e+10';
    strNumFmtOut: STRING;
    wFormat: WORD;
    Out: BOOL;
    xError: BOOL;
END_VAR
</pre>
</td></tr>
<tr><td>Program</td><td>

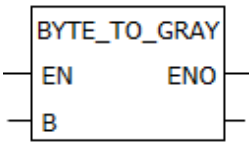
</td><td>
<pre>
AnyNumFmt(IN := strIn   '1e+10'   ,
      NumFmtOut := strNumFmtOut '10000000000' ,
      FORMAT := wFormat   0   ,
      Error => xError FALSE);RETURN
</pre>
</td></tr>
<tr><td>Operation result</td><td colspan="2">

</td></tr>
</table>

- Precautions
  - Ensure that the data types of "IN" and NumFmtOut are consistent, otherwise a compilation error will occur.
  - The following situations will cause an error:
    - Output or output string length exceeds 255.
    - Input contains characters other than numbers, decimal points, and scientific notation indicators.
    - There are more than one decimal point, e|E, minus sign, or plus sign.
    - A decimal point, e|E, or plus sign appears at the beginning.
    - A minus sign appears not at the first position or immediately after e/E.
    - A plus sign appears not immediately after e/E.
    - The length of the converted string exceeds the size of NumFmtOut. (When converting scientific notation to a floating-point number, if the converted string size exceeds NumFmtOut due to leading zero padding, the system will not report an error, and NumFmtOut will output 0.)

18.2.6 Gray Code Conversion

18.2.6.1 Instruction List



Instruction	FB/FC	Function	Library	Applicable Library Version
18.2.6.2 BYTE_TO_GRAY	FC	Conversion from bit string to Gray code	Util	Library version 1.0.0.0 and later

Instruction	FB/FC	Function	Library	Applicable Library Version
18.2.6.4 DWORD_TO_GRAY	FC	Conversion from bit string to Gray code		Library version 1.0.0.0 and later
18.2.6.5 GRAY_TO_BYTE	FC	Conversion from Gray code to bit string		Library version 1.0.0.0 and later
18.2.6.6 GRAY_TO_WORD	FC	Conversion from Gray code to bit string		Library version 1.0.0.0 and later
18.2.6.7 GRAY_TO_DWORD	FC	Conversion from Gray code to bit string		Library version 1.0.0.0 and later
18.2.6.8 BinToGray_BYTE	FC	Conversion from bit string to Gray code	OMUtils	Library version 1.0.0.0 and later
18.2.6.9 BinToGray_WORD	FC	Conversion from bit string to Gray code		Library version 1.0.0.0 and later
18.2.6.10 BinToGray_DWORD	FC	Conversion from bit string to Gray code		Library version 1.0.0.0 and later
18.2.6.11 BinToGray_LWORD	FC	Conversion from bit string to Gray code		Library version 1.0.0.0 and later

18.2.6.2 BYTE_TO_GRAY

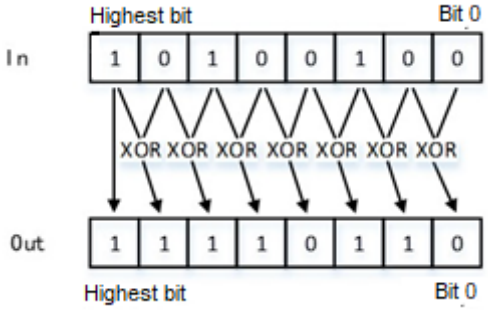
Converts a bit string to a Gray code.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
BYTE_TO_GRAY	Conversion from bit string to Gray code	FC		:= BYTE_TO_GRAY(B :=);

- **Related variables**

Variable



Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	Follows data type	-	Conversion object
Output	Out	Conversion result	Follows data type	-	Conversion result

Variable types

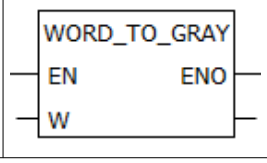
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - Converts the bit string In to the Gray code Out.
  - The conversion steps are described below.

    1. The most significant bit (bit 7) of In is directly used as the most significant bit (bit 7) of Out.
    2. The XOR of the bit 7 and bit 6 of In is used as the bit 6 of Out.
    3. The same method is used to determine the values through the least significant bit (bit 0) of Out.

- **Program example**

	LD	ST
Define variables	VAR byIn: BYTE := 2#10100100; xResult: BYTE; END_VAR	
Program	BYTE_TO_GRAY EN ENO byIn — B — xResult	xResult := BYTE_TO_GRAY(B := byIn);
Operation result	Name / Data type / Address / Value byIn / BYTE / / 2#10100100 xResult / BYTE / / 2#11110110	



- **Precautions**

  The data types of "In" and "OUT" must be consistent; otherwise, an exception will occur during compilation.

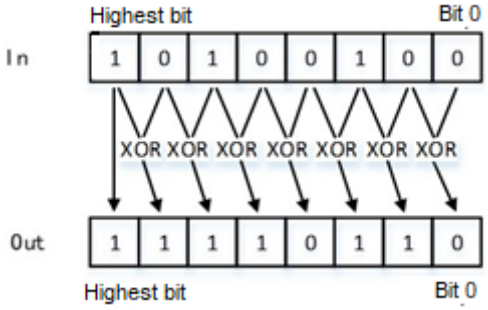
18.2.6.3 WORD_TO_GRAY

Converts a bit string to a Gray code.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
WORD_TO_GRAY	Conversion from bit string to Gray code	FC		:= WORD_TO_GRAY(W :=);

- **Related variables**



Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	Follows data type	-	Conversion object
Output	Out	Conversion result	Follows data type	-	Conversion result

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - Converts the bit string In to the Gray code Out.
  - The conversion steps are described below.
    1. The most significant bit (bit 7) of In is directly used as the most significant bit (bit 7) of Out.
    2. The XOR of the bit 7 and bit 6 of In is used as the bit 6 of Out.
    3. The same method is used to determine the values through the least significant bit (bit 0) of Out.

- **Program example**

	LD	ST
Define variables	VAR xResult: WORD; wIn: WORD := 2#0000000011110110; END_VAR	
Program	WORD_TO_GRAY EN ENO wIn — W — xResult	xResult := WORD_TO_GRAY(W := wIn);
Operation result	Name / Data type / Address / Value xResult / WORD / / 2#0000000010001101 wIn / WORD / / 2#0000000011110110	

- **Precautions**

  The data types of "In" and "OUT" must be consistent; otherwise, an exception will occur during compilation.

18.2.6.4 DWORD_TO_GRAY

Converts a bit string to a Gray code.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
DWORD_TO_GRAY	Conversion from bit string to Gray code	FC	DWORD_TO_GRAY EN ENO X	:= DWORD_TO_GRAY(X :=);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	Follows data type	-	Conversion object

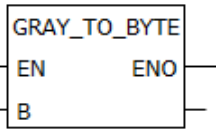
Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - Converts the bit string In to the Gray code Out.
  - The conversion steps are described below.
    1. The most significant bit (bit 7) of In is directly used as the most significant bit (bit 7) of Out.
    2. The XOR of the bit 7 and bit 6 of In is used as the bit 6 of Out.
    3. The same method is used to determine the values through the least significant bit (bit 0) of Out.

- **Program example**

	LD	ST
Define variables	VAR dwIn: DWORD := 2#00000000000000000000000010100100; xResult: DWORD; END_VAR	
Program	DWORD_TO_GRAY EN ENO dwIn – X – xResult	xResult := DWORD_TO_GRAY(X := dwIn);
Operation result	Name / Data type / Address / Value dwIn / DWORD / / 2#00000000000000000000000010100100 xResult / DWORD / / 2#00000000000000000000000011110110	



- **Precautions**

The data types of "In" and "OUT" must be consistent; otherwise, an exception will occur during compilation.

18.2.6.5 GRAY_TO_BYTE

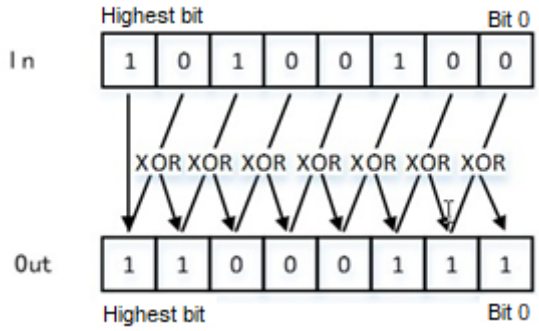
Converts a Gray code to a bit string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
GRAY_TO_BYTE	Conversion from Gray code to bit string	FC		:= GRAY_TO_BYTE(B :=);

- **Related variables**

  Variable



Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	Follows data type	-	Conversion object
Output	Out	Conversion result	Follows data type	-	Conversion result

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - Converts a Gray code to a bit string.
  - The conversion steps are described below.

    1. The most significant bit (bit 7) of In is directly used as the most significant bit (bit 7) of Out.
    2. The XOR of bit 6 of In and bit 7 of Out is used as the bit 6 of Out.
    3. The same method is used to determine the values through the least significant bit (bit 0) of Out.

- **Program example**

	LD	ST
Define variables	VAR xResult: BYTE; byIn: BYTE := 2#10100100; END_VAR	
Program	GRAY_TO_BYTE EN ENO byIn — B — xResult	xResult:= GRAY_TO_BYTE(B := byIn);
Operation result	Name / Data type / Address / Value xResult / BYTE / / 2#11000111 byIn / BYTE / / 2#10100100	

- **Precautions**

  The data types of "In" and "OUT" must be consistent; otherwise, an exception will occur during compilation.

18.2.6.6 GRAY_TO_WORD

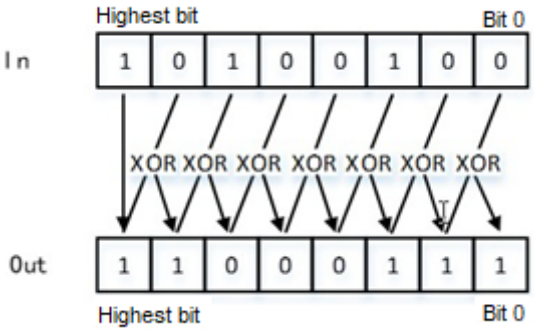
Converts a Gray code to a bit string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
GRAY_TO_WORD	Conversion from Gray code to bit string	FC	GRAY_TO_WORD EN ENO W	:= GRAY_TO_WORD(W :=);

- **Related variables**

  Variable



Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	Follows data type	-	Conversion object

Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	Out	Conversion result	Follows data type	-	Conversion result

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

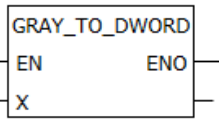
- **Function**
  - Converts a Gray code to a bit string.
  - The conversion steps are described below.
    1. The most significant bit (bit 7) of In is directly used as the most significant bit (bit 7) of Out.
    2. The XOR of bit 6 of In and bit 7 of Out is used as the bit 6 of Out.
    3. The same method is used to determine the values through the least significant bit (bit 0) of Out.

- **Program example**

	LD	ST
Define variables	VAR xResult: WORD; wIn: WORD := 2#0000000010100100; END_VAR	
Program	GRAY_TO_WORD EN ENO wIn W xResult	xResult := GRAY_TO_WORD(W := wIn);

	LD	ST
Operation result		

	Name	Data type	Address	Value
	xResult	WORD		2#0000000011000111
	wIn	WORD		2#0000000010100100



- **Precautions**

  The data types of "In" and "OUT" must be consistent; otherwise, an exception will occur during compilation.

18.2.6.7 GRAY_TO_DWORD

Converts a Gray code to a bit string.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
GRAY_TO_DWORD	Conversion from Gray code to bit string	FC		:= GRAY_TO_DWORD(X :=);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	Follows data type	-	Conversion object
Output	Out	Conversion result	Follows data type	-	Conversion result

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - Converts a Gray code to a bit string.

◦ The conversion steps are described below.

1. The most significant bit (bit 7) of In is directly used as the most significant bit (bit 7) of Out.
2. The XOR of bit 6 of In and bit 7 of Out is used as the bit 6 of Out.
3. The same method is used to determine the values through the least significant bit (bit 0) of Out.

- **Program example**

	LD	ST
Define variables	VAR xResult: DWORD; dwIn: DWORD := 2#00000000000000000000000010100100; END_VAR	
Program	GRAY_TO_DWORD EN ENO dwIn — X — xResult	xResult := GRAY_TO_DWORD(X := dwIn);
Operation result	Name / Data type / Address / Value xResult / DWORD / / 2#00000000000000000000000011000111 dwIn / DWORD / / 2#00000000000000000000000010100100	

- **Precautions**

  The data types of "In" and "OUT" must be consistent; otherwise, an exception will occur during compilation.

18.2.6.8 BinToGray_BYTE

Converts a bit string to a Gray code.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
BinToGray_BYTE	Conversion from bit string to Gray code	FC	BinToGray_BYTE EN ENO In OUT	:= BinToGray_BYTE(In := , OUT =>);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	Follows data type	-	Conversion object
Output	OUT	Conversion result	Follows data type	-	Conversion result

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
OUT	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - This instruction converts the bit string in the data to convert In to a gray code.
  - The instruction name is determined by the data types of "In" and "OUT".
  - The conversion steps are described below.
    1. The most significant bit (bit 7) of "In" is directly used as the most significant bit (bit 7) of "OUT".
    2. The XOR of the bit 7 and bit 6 of "In" is used as the bit 6 of "OUT".
    3. The same method is used to determine the values through the least significant bit (bit 0) of "OUT".

- **Program example**

	LD	ST
Define variables	VAR xResult: BOOL; byIn: BYTE:=2#10100100; byOut: BYTE; END_VAR	

<table>
<tr><th></th><th>LD</th><th>ST</th></tr>
<tr><td>Program</td><td>
</td><td><pre>xResult := BinToGray_BYTE(In := byIn,

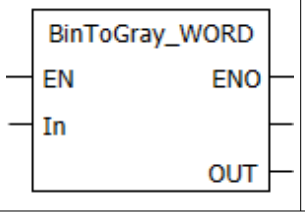
<tr><td></td><td>byOut</td><td>BYTE</td><td></td><td>2#11110110</td></tr>
</table>
</td></tr>
</table>



- **Precautions**

  The data types of "In" and "OUT" must be consistent; otherwise, an exception will occur during compilation.

18.2.6.9 BinToGray_WORD

Converts a bit string to a Gray code.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
BinToGray_WORD	Conversion from bit string to Gray code	FC		:= BinToGray_WORD(In := , OUT =>);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	Follows data type	-	Conversion object
Output	OUT	Conversion result	Follows data type	-	Conversion result

  Variable types

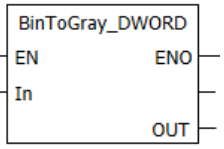
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	√	–		–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
OUT	–	–	√	–		–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - This instruction converts the bit string in the data to convert In to a gray code.
  - The instruction name is determined by the data types of "In" and "OUT".
  - The conversion steps are described below.
    1. The most significant bit (bit 7) of "In" is directly used as the most significant bit (bit 7) of "OUT".
    2. The XOR of the bit 7 and bit 6 of "In" is used as the bit 6 of "OUT".
    3. The same method is used to determine the values through the least significant bit (bit 0) of "OUT".

- **Program example**

	LD	ST
Define variables	VAR xResult: BOOL; wIn: WORD := 2#0000000010100100; wOut: WORD; END_VAR	
Program	BinToGray_WORD EN ENO wIn – In xResult OUT – wOut	xResult := BinToGray_WORD(In := wIn, OUT => wOut);

	LD	ST
Operation result		



- **Precautions**

  The data types of "In" and "OUT" must be consistent; otherwise, an exception will occur during compilation.

18.2.6.10 BinToGray_DWORD

Converts a bit string to a Gray code.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
BinToGray_DWORD	Conversion from bit string to Gray code	FC		:= BinToGray_DWORD(In := , OUT =>);

- **Related variables**

  Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	Follows data type	-	Conversion object
Output	Out	Conversion result	Follows data type	-	Conversion result

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - This instruction converts the bit string in the data to convert In to a gray code.

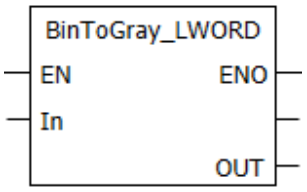
◦ The instruction name is determined by the data types of In and Out.

◦ The conversion steps are described below.

1. The most significant bit (bit 7) of In is directly used as the most significant bit (bit 7) of Out.
2. The XOR of the bit 7 and bit 6 of In is used as the bit 6 of Out.
3. The same method is used to determine the values through the least significant bit (bit 0) of Out.

- **Program example**

	LD	ST
Define variables	VAR xResult: BOOL; dwIn: DWORD := 2#00000000000000000000000010100100; dwOut: DWORD; END_VAR	
Program	BinToGray_DWORD EN ENO dwIn — In — xResult OUT — dwOut	xResult := BinToGray_DWORD(In := dwIn, OUT => dwOut);
Operation result	Name / Data type / Address / Value xResult / BOOL / / TRUE dwIn / DWORD / / 2#00000000000000000000000010100100 dwOut / DWORD / / 2#00000000000000000000000011110110	



- **Precautions**

The data types of "In" and "OUT" must be consistent; otherwise, an exception will occur during compilation.

18.2.6.11 BinToGray_LWORD

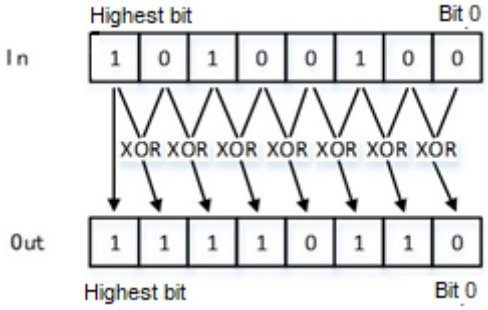
Converts a bit string to a Gray code.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
BinToGray_LWORD	Conversion from bit string to Gray code	FC		:= BinToGray_LWORD(In := , OUT =>);

- **Related variables**

  Variable



Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In	Conversion object	Follows data type	-	Conversion object
Output	Out	Conversion result	Follows data type	-	Conversion result

  Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
Out	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - This instruction converts the bit string in the data to convert In to a gray code.
  - The instruction name is determined by the data types of In and Out.
  - The conversion steps are described below.

    1. The most significant bit (bit 7) of In is directly used as the most significant bit (bit 7) of Out.
    2. The XOR of the bit 7 and bit 6 of In is used as the bit 6 of Out.
    3. The same method is used to determine the values through the least significant bit (bit 0) of Out.

- **Program example**

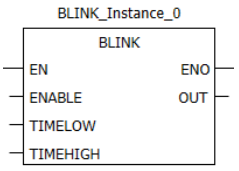
	LD	ST
Define variables	VAR xResult: BOOL; lwIn: LWORD := 2#0000000000000000000000000000000000000000000000000000000010100100; lwOut: LWORD; END_VAR	
Program	BinToGray_LWORD EN ENO lwIn — In — xResult OUT — lwOut	xResult := BinToGray_LWORD(In := lwIn, OUT => lwOut);
Operation result	Name / Data type / Address / Value xResult / BOOL / / TRUE lwIn / LWORD / / 2#0000000000000000000000000000000000000000000000000000000010100100 lwOut / LWORD / / 2#0000000000000000000000000000000000000000000000000000000011110110	

- **Precautions**

  The data types of "In" and "OUT" must be consistent; otherwise, an exception will occur during compilation.

18.2.7 Signal Processing

18.2.7.1 Instruction List



Instruction	FB/FC	Function	Library	Applicable Library Version
18.2.7.2 BLINK	FB	Pulse signal generator	Util	Library version 1.0.0.0 and later
18.2.7.3 GEN	FB	Cyclic signal generator		Library version 1.0.0.0 and later
18.2.7.4 FREQ_MEASURE	FB	Frequency measurement		Library version 1.0.0.0 and later
18.2.7.5 GetClk_1ms	FC	1-ms timing pulse	OMUtils	Library version 1.2.0.0 and later
18.2.7.6 GetClk_10ms	FC	10-ms timing pulse		Library version 1.2.0.0 and later
18.2.7.7 GetClk_20ms	FC	20-ms timing pulse		Library version 1.2.0.0 and later

Instruction	FB/FC	Function	Library	Applicable Library Version
18.2.7.8 GetClk_100ms	FC	100-ms timing pulse		Library version 1.2.0.0 and later
18.2.7.9 GetClk_1s	FC	1-s timing pulse		Library version 1.2.0.0 and later
18.2.7.10 GetClk_1min	FC	1-min timing pulse		Library version 1.2.0.0 and later

18.2.7.2 BLINK

BLINK is used as a pulse signal generator.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
BLINK	Pulse signal generator	FB		BLINK_Instance_0(ENABLE := , TIMELOW := , TIMEHIGH := , OUT =>);

- **Related variable**

Variable

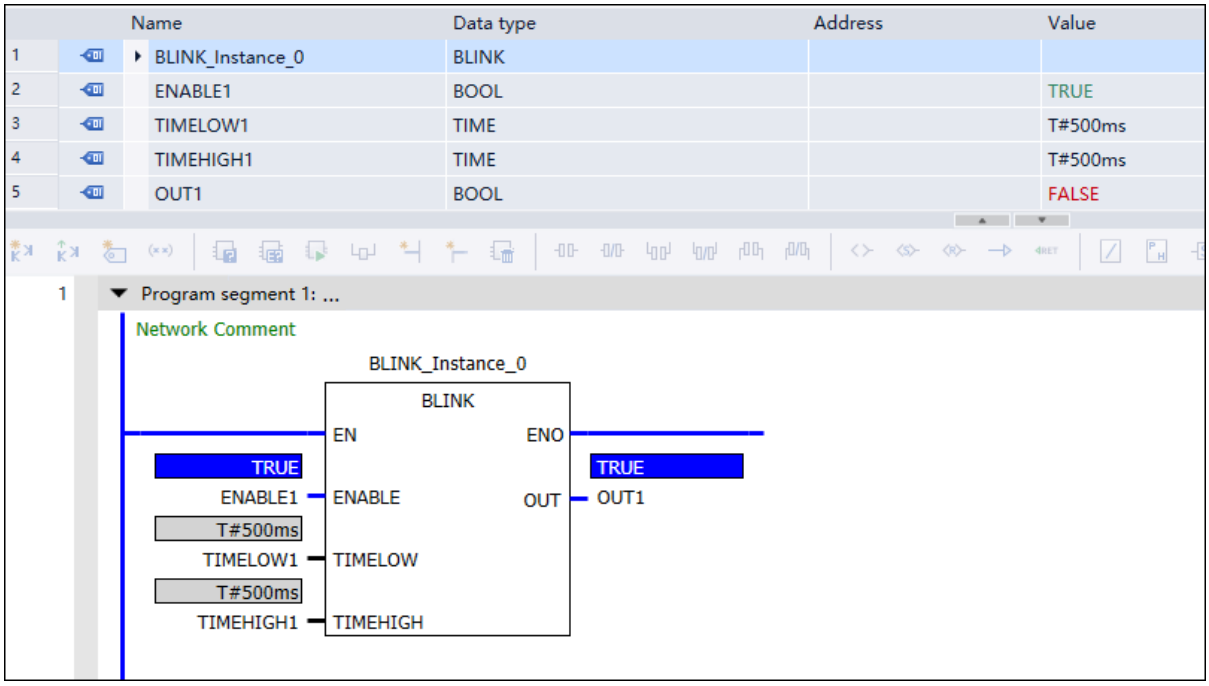
Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	ENABLE	Instruction enable	Follows data type	-	TRUE: The instruction starts working.
	TIMELOW	Low-level duration	Follows data type	-	Duration for remaining the low level for pulse signals
	TIMEHIGH	High-level duration	Follows data type	-	Duration for remaining the high level for pulse signals
Output	OUT	Pulse signal output	Follows data type	-	Output value of a pulse signal

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
ENABLE	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
TIMELOW	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–
TIMEHIGH	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–
OUT	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**

  If ENABLE is set to TRUE, this instruction sets the output to TRUE within the period specified by TIMEHIGH and then sets the output to FALSE in the period specified by TIMELOW.



- **Program example**

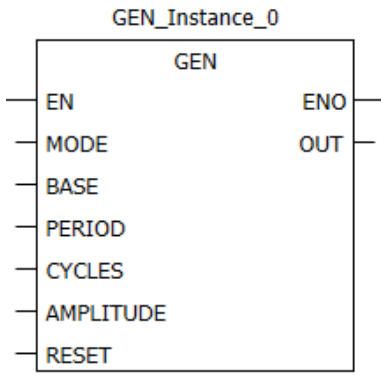
  ST:

	Name	Data type	Address	Value
1	BLINK_Instance_0	BLINK		
2	ENABLE1	BOOL		TRUE
3	TIMELOW1	TIME		T#500ms
4	TIMEHIGH1	TIME		T#500ms
5	OUT1	BOOL		TRUE

```
BLINK_Instance_0(
ENABLE  TRUE  := ENABLE1  TRUE ,
TIMELOW  T#500ms  := TIMELOW1  T#500ms ,
TIMEHIGH  T#500ms  :=TIMEHIGH1  T#500ms ,
OUT  TRUE  => OUT1  TRUE );RETURN
```

  LD:

TRACE:



- **Precautions**

  When "ENABLE" is set to FALSE, the output "OUT" retains its last value.

18.2.7.3 GEN

Generates specified function waveforms based on the input parameters.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
GEN	Cyclic signal generator	FB		GEN_Instance_0(MODE := , BASE := , PERIOD := , CYCLES := , AMPLITUDE := , RESET := , OUT =>);

- **Related variable**

  Variable

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	MODE	Signal type	GEN_MODE	TRIANGLE	MODE is an enumerator of the GEN_MODE type, with the following enumeration values: 0: TRIANGLE, indicating triangular waves with the output range from -AMPLITUDE to +AMPLITUDE 1: TRIANGLE_POS, indicating triangular waves with the output range from 0 to +AMPLITUDE 2: SAWTOOTH_RISE, indicating rising sawtooth waves with the output range from -AMPLITUDE to +AMPLITUDE 3: SAWTOOTH_FALL, indicating falling sawtooth waves with the output range from +AMPLITUDE to -AMPLITUDE 4: RECTABGLE, indicating square waves with the output range from -AMPLITUDE to +AMPLITUDE 7: SINE, indicating sine waves 8: COSINE, indicating cosine waves
	BASE	Circulating mode	Follows data type	FALSE	TRUE: Outputs signals by the cycle period specified by PERIOD FALSE: Outputs signals by the cycle times specified by CYCLES

Input/ Output	Variable	Name	Valid Range	Default Value	Description
	PERIOD	Cycle period	Follows data type	TIME#1s 0ms	This variable is valid when BASE is TRUE, specifying the cycle period for output signals.
	CYCLES	Loop count	Follows data type	1000	This variable is valid when BASE is FALSE, specifying the cycle times for output signals.
	AMPLITUDE	Signal vibration amplitude	Follows data type	0	Amplitude of the function, determining the oscillation range of the curve
	RESET	Reset a bit	Follows data type	FALSE	TRUE: Resets the output signal to 0. FALSE: Outputs the signal normally.
Output	OUT	Signal output value	Follows data type	0	Output value of a periodic signal

Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING

18.2.7.4 FREQ_MEASURE

Measures the (average) frequency (Hz) of the input Boolean signal.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
FREQ_MEASURE	Frequency measurement	FB	FREQ_MEASURE_Instance_0 FREQ_MEASURE EN ENO IN OUT PERIODS VALID RESET	FREQ_MEASURE_Instance_0(IN := , PERIODS := , RESET := , OUT => , VALID =>);

- **Related variables**

  Variable

Input/ Output	Variable	Name	Valid Range	Default Value	Description
Input	IN	Input signal	Follows data type	-	TRUE: The instruction starts working.
	PERIODS	Measurement period	Follows data type	1	Ranges from 1 (default) to 10. The time interval between two rising edges of the input signal is one period. By averaging the frequency values over N periods, we can obtain the frequency of the input signal. This variable specifies the number of periods used for the averaging operation.
	RESET	Reset a bit	Follows data type	-	When the value is TRUE, the frequency is re-measured. During normal execution, the value should be FALSE.
Output	OUT	Frequency output	Follows data type	-	Frequency of the input signal, in the unit of Hz
	VALID	Operation flag	Follows data type	-	The value is TRUE when the first operation is completed or the operation fails. The value is FALSE for other time.

Variable types

18.2.7.5 GetClk_1ms

Outputs a timing pulse of 1 ms.

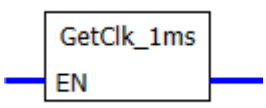
- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
GetClk_1ms	1-ms timing pulse	FC		:= GetClk_1ms();

- **Related variables**

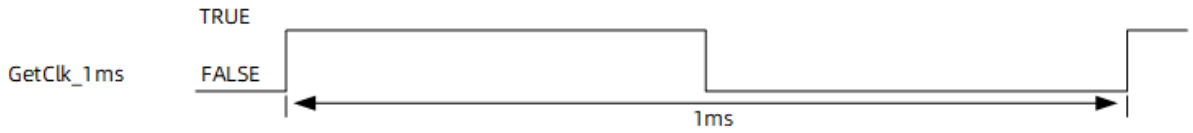
Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Output	Out	Return value	Follows data type	-	Pulse output



Variable types

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
Out	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–



- **Function**

Outputs a timing pulse of 1 ms.

- **Program example**

Name	LD	ST
Define variables	VAR x1ms: BOOL; END_VAR	
Program		x1ms FALSE :=GetClk_1ms();
Operation result		

- **Timing diagram**

- **Precautions**

  When using this instruction in a ladder diagram program, if the EN input is FALSE, the output becomes FALSE. The period of the timing pulse is not affected by instruction calls, task type, or task cycle. It is an absolute pulse generated by the system:

  - The pulse waveform is independent of calling location, task cycle, and task type.
  - The value obtained through the instruction is the instantaneous value of the pulse at the current moment. Therefore, multiple calls within the same cycle may yield different results.
  - After the PLC switches to RUN mode, the result of the first cycle is indeterminate and may be TRUE or FALSE.

18.2.7.6 GetClk_10ms

Outputs a timing pulse of 10 ms.

- **Instruction format**

xError	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
eErrorID	UTIL_ERROR. For details, see 18.2.8.11 Fault Code.																			
fValue	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–

- **Function**

  When xEnable is set to TRUE, the sampling variable fValue is input based on the given scan period count uiSampleCycle and sampling count uiSampleNum. Sample data for consecutively uiSampleNum times and average the sampled data.

  The larger uiSampleNum is, the higher the signal smoothness, but the lower the sensitivity.

  The smaller uiSampleNum is, the lower the signal smoothness, but the higher the sensitivity.

  For general flow calculation, set uiSampleNum to 12. For pressure calculation, set uiSampleNum to 4.

  Advantages: Suitable for filtering signals with random interference that fluctuate around a certain average value.

  Disadvantages: Not suitable for real-time control with a slow measurement speed or requiring a fast data calculation speed, and it consumes a significant amount of RAM.

- **Sequence diagram**

- **Program example**

  The sampling type is consecutive sampling. The raw data for sampling is sourced from the consecutively updated program variables.

  The number of samples for the sampling calculation is 3 (unsigned integer ranging from 1 to 3000).

  The sampling period is 1 (data sampling is executed once every given number of running periods, with the default value of 1).

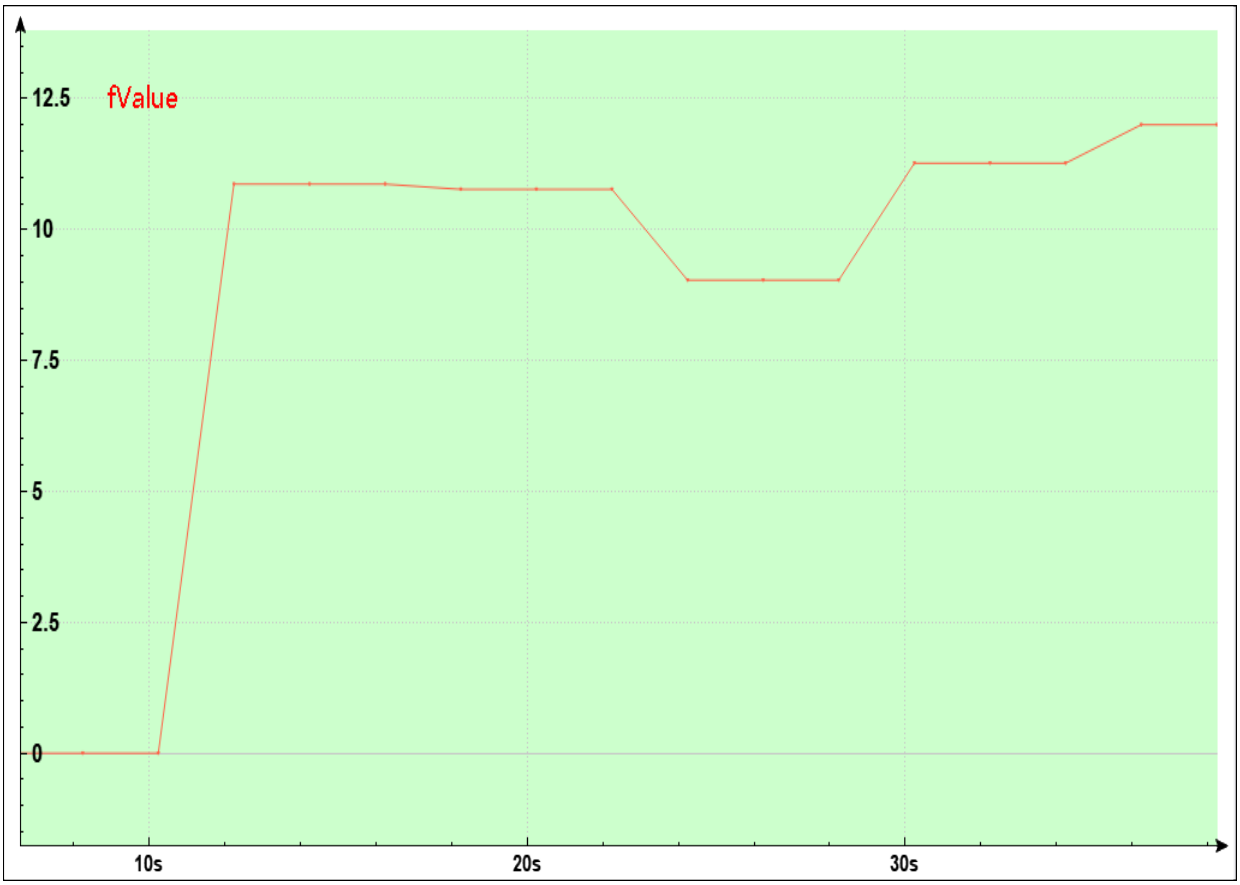
  When the input xFilter is TRUE, the function block is enabled and begins sampling and filtering. With the number of samples set to 3, filter calculation is performed once for every three samples collected. The arithmetic average of the 3 sample values is calculated as the filter output value, and the filter execution flag xValid is set to TRUE.

  ST:

Name	Data type	Address	Value
ArithmeticAverageFilter_Instanc...	ArithmeticAverageFilter		
xEnable	BOOL		TRUE
fSample	REAL		9.5
uiSampleNum	UINT		3
uiSampleCycle	UINT		1
xBusy	BOOL		TRUE
xValid	BOOL		TRUE
xError	BOOL		FALSE
eErrorID	UTIL_ERROR		NO_ERROR
fValue	REAL		9.033333

```
ArithmeticAverageFilter_Instance_0(
xEnable TRUE := xEnable TRUE,
fSample 9.5 := fSample 9.5,
uiSampleNum 3 := uiSampleNum 3,
uiSampleCycle 1 := uiSampleCycle 1,
xBusy TRUE => xBusy TRUE,
xValid TRUE => xValid TRUE,
xError FALSE => xError FALSE,
eErrorID NO_ERROR => eErrorID NO_ERROR,
fValue 9.033333 => fValue 9.033333 );RETURN
```

  LD:



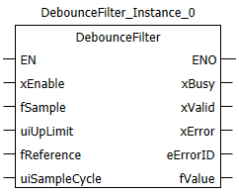
The sampling values of 12 consecutive periods are respectively 9.8, 9.8, 13.0, 12.5, 11.4, 8.4, 8.7, 8.9, 9.5, 11.1, 10.7, and 12.0.

After filtering, the values are respectively 0, 0, 10.87, 10.87, 10.87, 10.77, 10.77, 10.77, 9.03, 9.03, 9.03, and 11.27.

The following figure shows the curve before filtering.

The following figure shows the curve after filtering.

- **Precautions**
  - In the filter function block, the input parameter uiSampleCycle indicates the sampling period. When the value of uiSampleCycle is 1, sampling is performed every period. When the value of uiSampleCycle is 3, sampling is performed once every three periods. The function block execution flag xValid outputs



TRUE, indicating that the filtering is valid. The filter output value of fValue is updated when the filter output is valid.

- If the sampled data is stored in an array, the data needs to be put in the filter function block one by one and handled by the user.
- If the value of the input parameter uiSampleNum is not within the valid range, the xError flag is set to TRUE, and the function block generates a fault code eErrorID, indicating the message: "SAMPLENUM_PARAMETER_SET_ERROR". To handle the fault, you need to reset the uiSampleNum parameter within the valid range and re-trigger a flow to reset the fault and the xError signal.
- For details about faults, see UTIL_ERROR.

18.2.8.3 DebounceFilter

Calculates the debounce filter.

- Instruction format

Instruction	Name	FB/FC	LD Representation	ST Representation
DebounceFilter	Debounce filter	FB		DebounceFilter_Instance_0(xEnable := , fSample := , uiUpLimit := , fReference := , uiSampleCycle := , xBusy => , xValid => , xError => , eErrorID => , fValue =>);

- **Related variables**

xError	√	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–
eErrorID	UTIL_ERROR. For details, see 18.2.8.11 Fault Code.																			

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
fValue	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–

- **Function**

  When xEnable is set to TRUE, the sampling variable fSample is input based on the given scan period count uiSampleCycle, sampling reference value fReference, and filter upper limit uiUpLimit.

  Compare each sampled value with the current effective value:

  If the sampling value is equal to the current effective value, set the current count value to zero.

  If the sampling value is not equal to the current effective value, increment the count value by 1 and check whether the count value exceeds the upper limit uiUpLimit.

  If the count value exceeds the upper limit, replace the current filter value with the current sampling value, output the value, and reset the count value to zero.

  Advantages: Suitable for slowly changing parameters; it prevents repeated on/off switchovers on the controller or numerical jitters on the display near critical values.

  Disadvantages: Not suitable for rapidly changing parameters; if the value sampled at the time of counter overflow happens to be an interference value, it may be mistakenly introduced into the system as an effective value.

- **Sequence diagram**

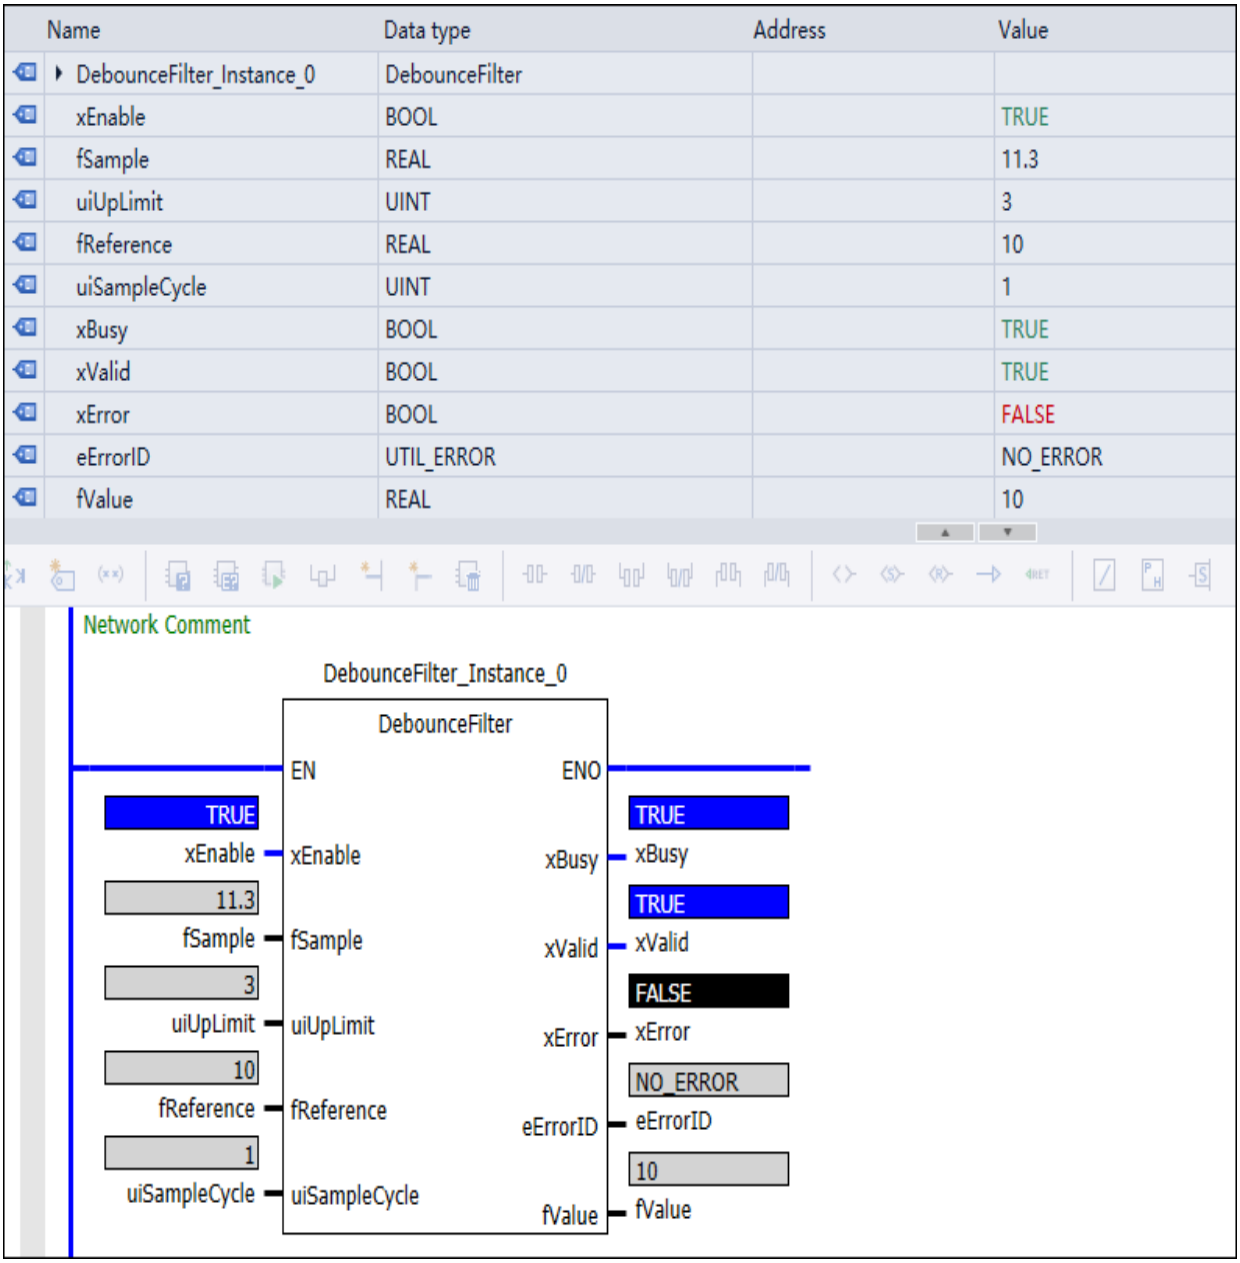
- **Program example**

The sampling type is consecutive sampling. The raw data for sampling is sourced from the consecutively updated program variables.

The reference effective value of the sample is 10.0 (user-defined reference value of the floating-point type).

The maximum number of jitters for the sample value on the counter is 3 (unsigned integer).

The sampling period is 1 (data sampling is executed once every given number of running periods, with the default value of 1).



When the input xEnable is set to TRUE, the function block starts sampling and filtering with energy flow effective. Set the reference value to 10.0 as the effective value. Compare the sampling value with the current effective value. If they are the same, reset the jitter counter value to zero. If they are different, increase the counter value by 1. When the counter value exceeds the counter value upper limit, replace the current effective value with the current sampling value as the filter effective value, output the effective value, and set the filter execution valid flag xValid to TRUE.

ST:

Name	Data type	Address	Value
DebounceFilter_Instance_0	DebounceFilter		
xEnable	BOOL		TRUE
fSample	REAL		11.3
uiUpLimit	UINT		3
fReference	REAL		10
uiSampleCycle	UINT		1

fValue	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–

- **Function**

  When xEnable is set to TRUE, the sampling variable fSample is input based on the given scan period count uiSampleCycle, sampling reference value fReference, and input first-order low-pass filter coefficient fCoefficient (0 to 1).

  Each time a new value is sampled: Current filter result = fCoefficient x Current sampling value + (1 - fCoefficient) x Previous filter result

  Advantages: It suppresses periodic interference well, and is suitable for systems with high-frequency oscillations.

  Disadvantages: It has phase lag and low sensitivity. The lagging program depends on the value of the fCoefficient. It cannot eliminate interference signals with the filter frequency higher than half of the sampling frequency.

- **Sequence diagram**

- **Program example**

  The sampling type is consecutive sampling. The raw data for sampling is sourced from the consecutively updated program variables.

  The first-order low-pass filter coefficient is 0.01 (floating-point type).

  The filter reference value is 10.0 and the sampling period is 1 (i.e., sample once per cycle).

  When the input xEnable is set to TRUE, the function block starts sampling and filtering with energy flow effective. Set the initial reference value to 10.0 as the effective value and the first-order low-pass filter coefficient to 0.01. Calculate the filter value as follows: Current filter result = fCoefficient x Current sampling value + (1 - fCoefficient) x Previous filter result. Output the filter value, and set the filter execution valid flag xValid to TRUE.

  ST:

Name	Data type	Address	Value
FirstOrderLagFilter_Instance_0	FirstOrderLagFilter		
xEnable	BOOL		TRUE
fSample	REAL		12.8
fCoefficient	REAL		0.01
fReference	REAL		10
uiSampleCycle	UINT		1
xBusy	BOOL		TRUE
xValid	BOOL		TRUE
xError	BOOL		FALSE
eErrorID	UTIL_ERROR		NO_ERROR
fValue	REAL		10.026019

```
FirstOrderLagFilter_Instance_0(
xEnable  TRUE  := xEnable  TRUE ,
fSample  12.8  := fSample  12.8 ,
fCoefficient  0.01  := fCoefficient  0.01 ,
fReference  10  := fReference  10 ,

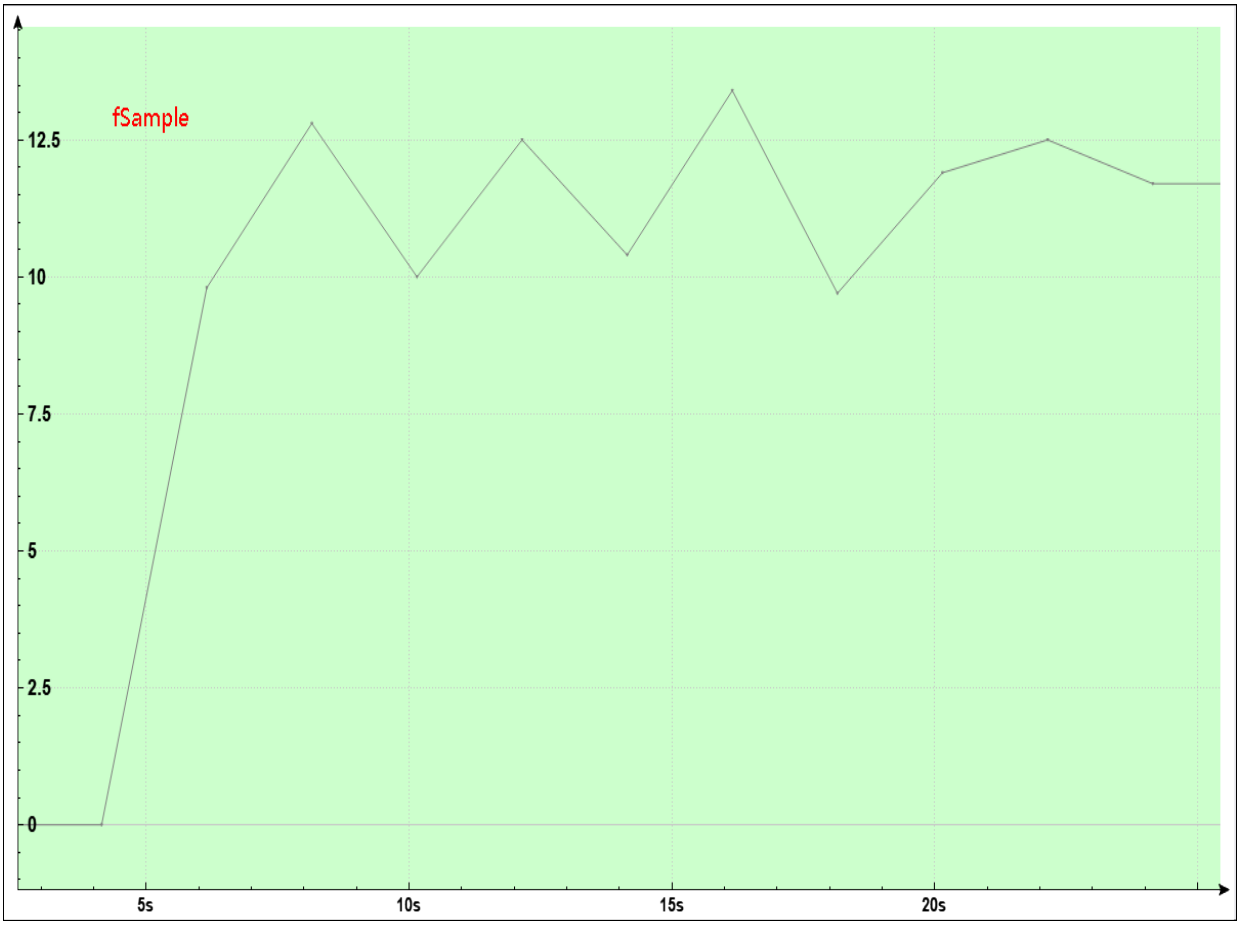
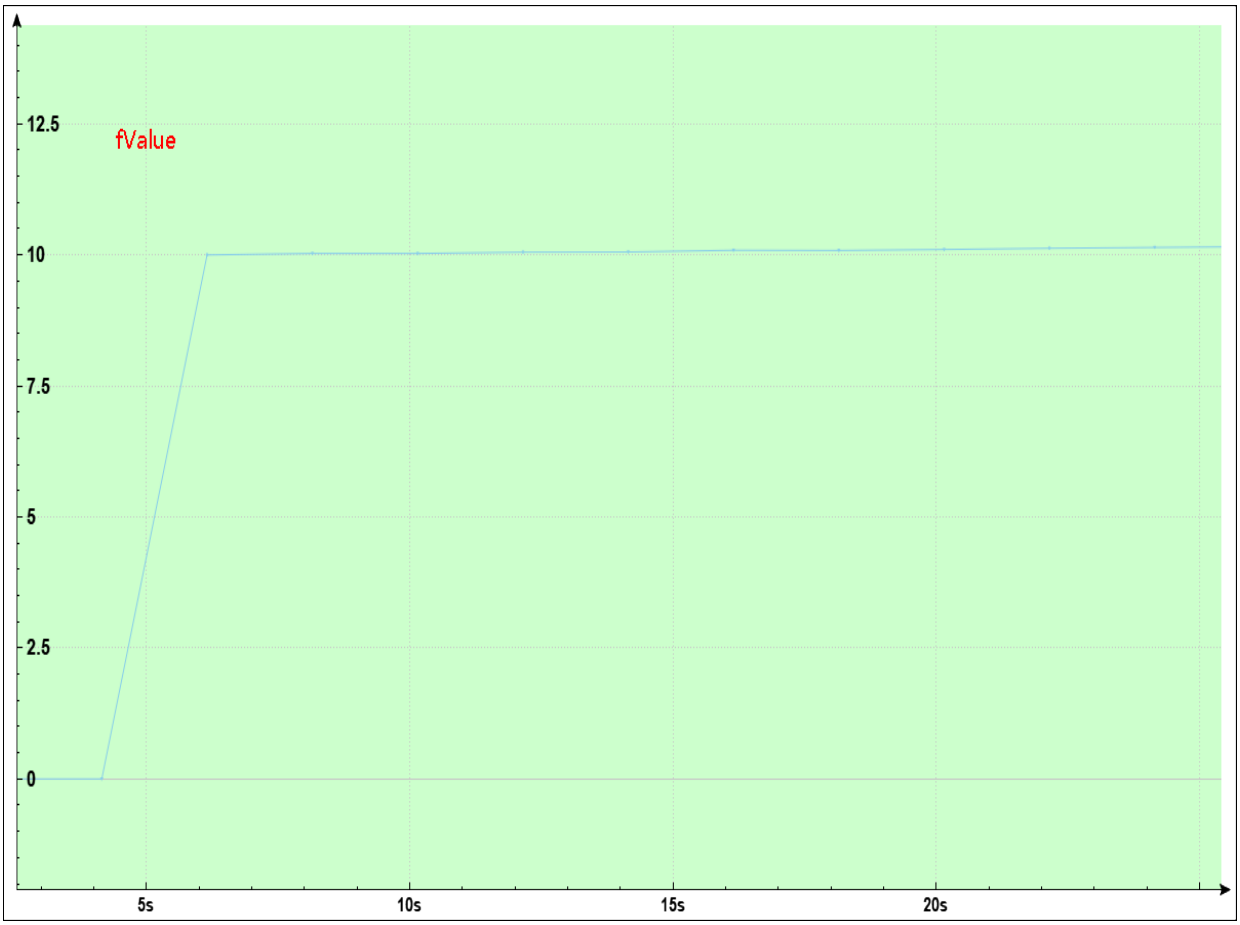
fValue  10.026019  => fValue  10.026019 );
```



LD:



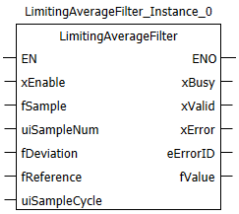
The sampling values of 10 consecutive periods are respectively 9.8, 12.8, 10.0, 12.5, 10.4, 13.4, 9.7, 11.9, 12.5, and 11.7.

After filtering, the values are respectively 9.998, 10.03, 10.03, 10.05, 10.05, 10.09, 10.08, 10.10, 10.13, and 10.14.

The following figure shows the curve before filtering.

The following figure shows the curve after filtering.

- **Precautions**
  - In the filter function block, the input parameter uiSampleCycle indicates the sampling period. When the value of uiSampleCycle is 1, sampling is performed every period. When the value of uiSampleCycle



is 3, sampling is performed once every three periods. If the output of the function block flag FirstOrderLagFilter.xValid is TRUE, the filter is valid. The filter output value of fValue is updated when the filter output is valid.

- If the sampled data is stored in an array, the data needs to be put in the filter function block one by one and handled by the user.
- For details about errors, see UTIL_ERROR.

18.2.8.5 LimitingAverageFilter

Calculates limiting average filter.

fValue	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–

- **Function**

  When xEnable is set to TRUE, the sampling variable fSample is input based on the given scan period count uiSampleCycle, sampling count uiSampleNum, sampling reference effective value fReference, and maximum allowable deviation fDeviation for two consecutive samples.

  Both limiting filter and recursive average filter are used. Limit each new sampled data and then add it to the queue for recursive average filter processing.

  Advantages: Combines the advantages of both limiting filter and recursive average filter. It can eliminate sampling deviations caused by occasional pulse interference.

  Disadvantages: Consumes a significant amount of RAM.

- **Sequence diagram**

- **Program example**

  The sampling type is consecutive sampling. The raw data for sampling is sourced from the consecutively updated program variables.

  The maximum allowable deviation in amplitude is 1.5 (deviation range of the floating-point type).

  The amplitude reference value is 10.0 (user-defined reference value of the floating-point type).

  The number of samples for the sampling calculation is 3 (unsigned integer ranging from 1 to 3000).

  The sampling period is 1 (data sampling is executed once every given number of running periods, with the default value of 1).

  When the input xEnable is set to TRUE, the function block starts sampling and filtering with energy flow effective. Set the initial reference value to 10.0 as the effective value. Compare the sampling value with the previous effective value. If the absolute difference between them is greater than the set maximum deviation value of 1.5, use the previous effective value as the current effective value. If it is less than or equal to the maximum deviation value, use the current value as the effective value. Then output the effective value as the filter value, and set the filter execution valid flag xValid to TRUE.

  ST:

fValue	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–

- **Function**

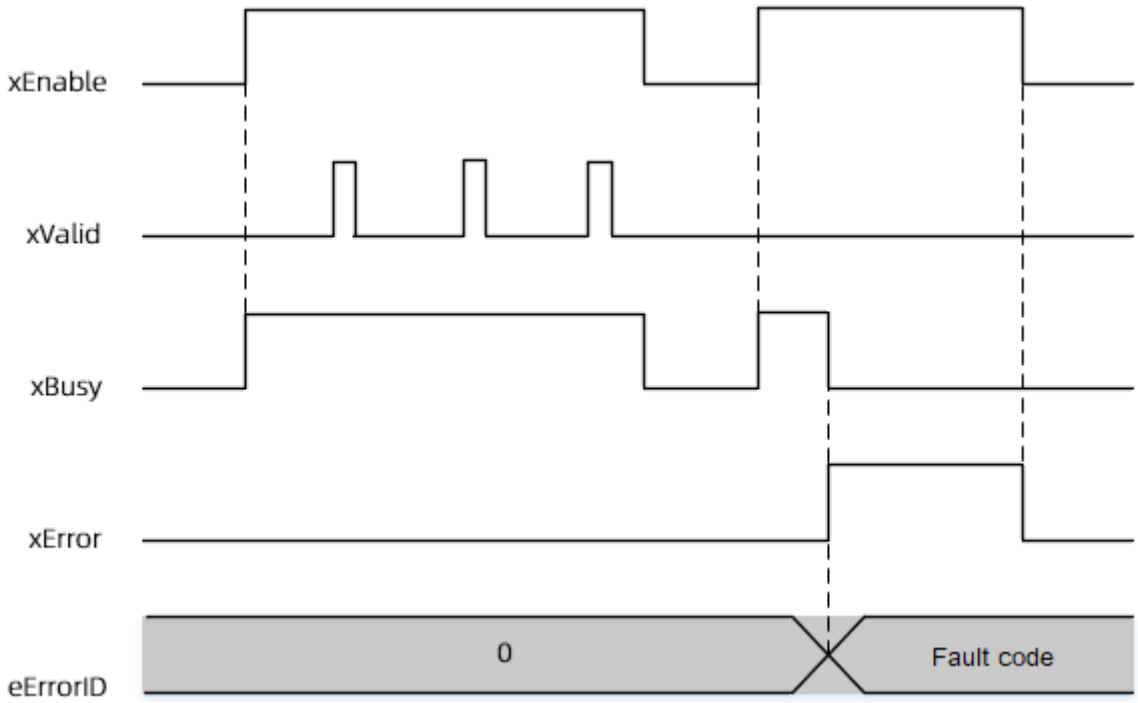
  When xEnable is set to TRUE, the sampling variable fSample is input based on the given scan period count uiSampleCycle, filter counter upper limit uiUpLimit, reference value fReference, and maximum allowable deviation fDeviation for two consecutive samples.

  Both limiting filter and debounce filter are used. Limiting filter is used before debounce filter.

  If the difference between the current value and the previous value is less than or equal to the value of fDeviation, the current value is valid and is used as the sampling value for debounce filter.

If the difference between the current value and the previous value is greater than the value of fDeviation, the current value is invalid. In this case, the current value is discarded, and the previous value is used as the sampling value for debounce filter.

Use the output of limiting filter as the sampling value for debounce filter, and compare it with the current effective value:



If the sampling value is equal to the current effective value, set the current count value to zero.

If the sampling value is not equal to the current effective value, increment the count value by 1 and check whether the count value exceeds the upper limit uiUpLimit; if so, replace the current filter value with the current sampling value, output the value, and reset the count value to zero.

Advantages: Combines the advantages of both limiting filter and debounce filter. It overcomes certain defects of debounce filter, preventing introduction of interference values into the system.

Disadvantages: Not suitable for rapidly changing parameters.

- **Sequence diagram**

- **Program example**

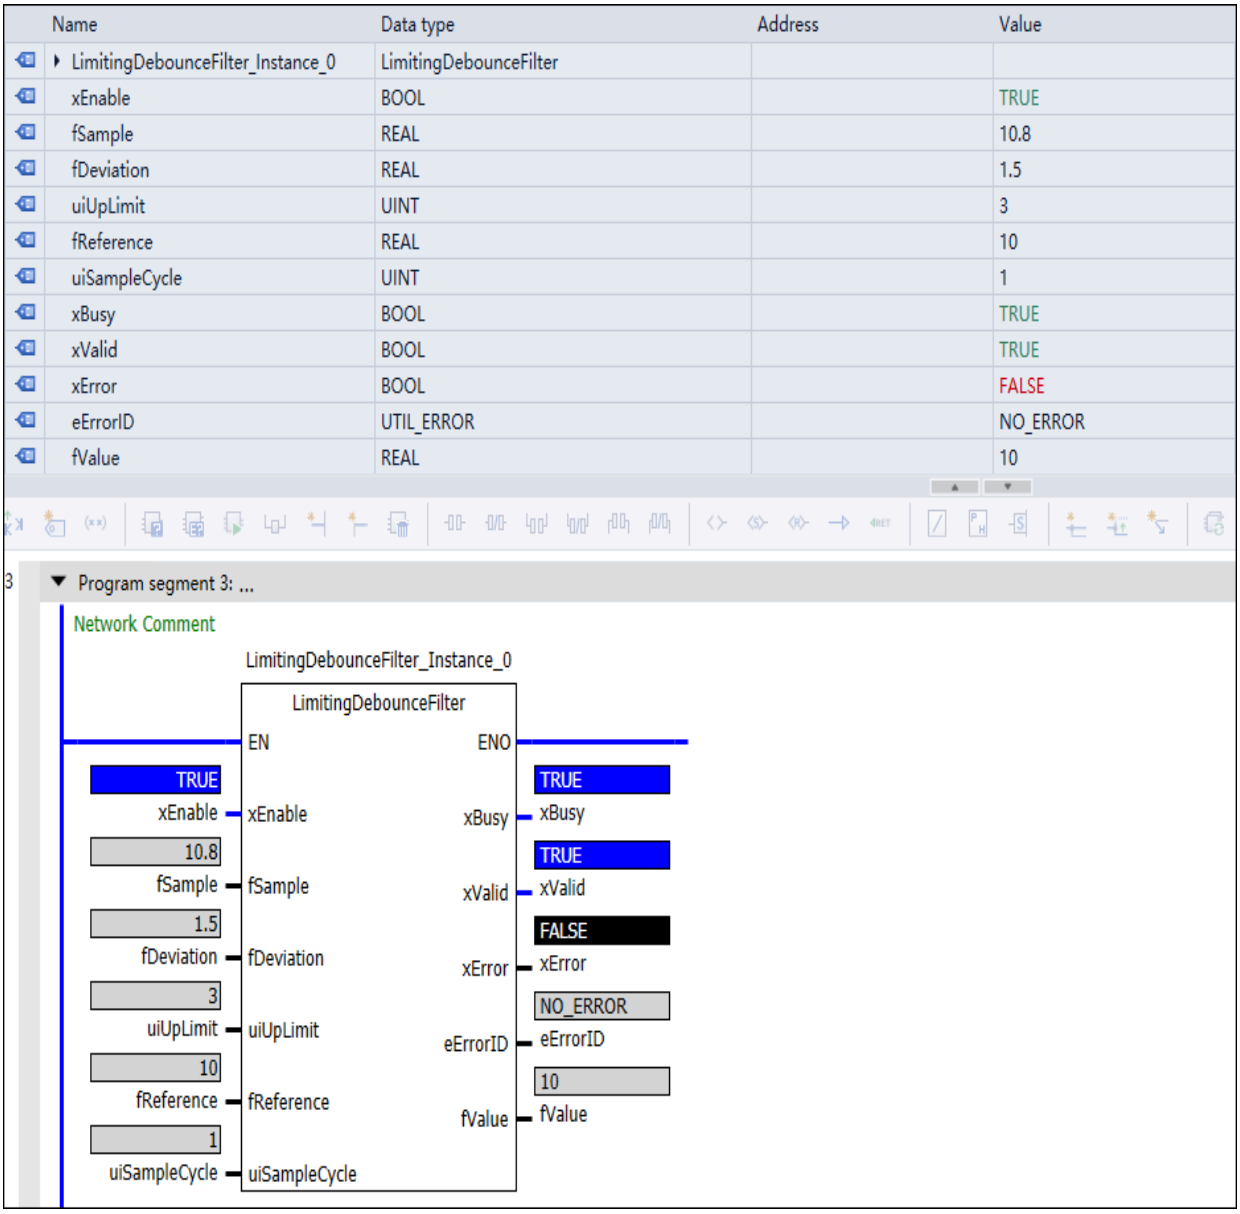
The sampling type is consecutive sampling. The raw data for sampling is sourced from the consecutively updated program variables.

The reference effective value of the sample is 10.0 (user-defined reference value of the floating-point type).

The maximum number of jitters for the sample value on the counter is 3 (unsigned integer).

The sampling period is 1 (data sampling is executed once every given number of running periods, with the default value of 1).

When the input xEnable is set to TRUE, the function block starts sampling and filtering with energy flow effective. Set the reference value to 10.0 as the effective value. Compare the sampling value with the current effective value. If they are the same, reset the jitter counter value to zero. If they are different, increase the counter value by 1. When the counter value exceeds the counter value upper



limit, replace the current effective value with the current sampling value as the filter effective value, output the effective value, and set the filter execution valid flag xValid to TRUE.

- **Function**

  When xEnable is set to TRUE, the sampling variable fSample is input based on the given scan period count uiSampleCycle, reference value fReference, and maximum allowable deviation fDeviation for two consecutive samples.

  Each time a new sample is obtained, if the difference between the current value and the previous value is less than or equal to the value of fDeviation, the current value is valid and is output as the filter value.

  If the difference between the current value and the previous value is greater than the value of fDeviation, the current value is invalid. In this case, the current value is discarded, and the previous value is output as the filter value.

  Advantage: It effectively suppresses pulse interference caused by occasional factors.

  Disadvantage: It cannot suppress periodic interference, causing poor smoothness.

- **Sequence diagram**

- **Program example**

  The sampling type is consecutive sampling. The raw data for sampling is sourced from the consecutively updated program variables.

  The amplitude reference value is 10.0 (user-defined reference value of the floating-point type). The maximum allowable deviation in amplitude is 1.5 (deviation range of the floating-point type).

  The filter calculation period is 1 (the sampling filter is executed once every given number of running period, with the default value of 1).

  When the input xEnable is set as energy flow effective, the limiting filter function block starts the sampling filter. Set the initial reference value to 10.0 as the effective value. Compare the sampling value with the previous effective value. If the absolute difference between them is greater than the set maximum deviation value of 1.5, use the previous effective value as the current effective value. If the absolute difference is less than or equal to the maximum deviation value, use the current value as the effective value. Then output the effective value as the filter value, and set the filter execution valid flag xValid to TRUE.

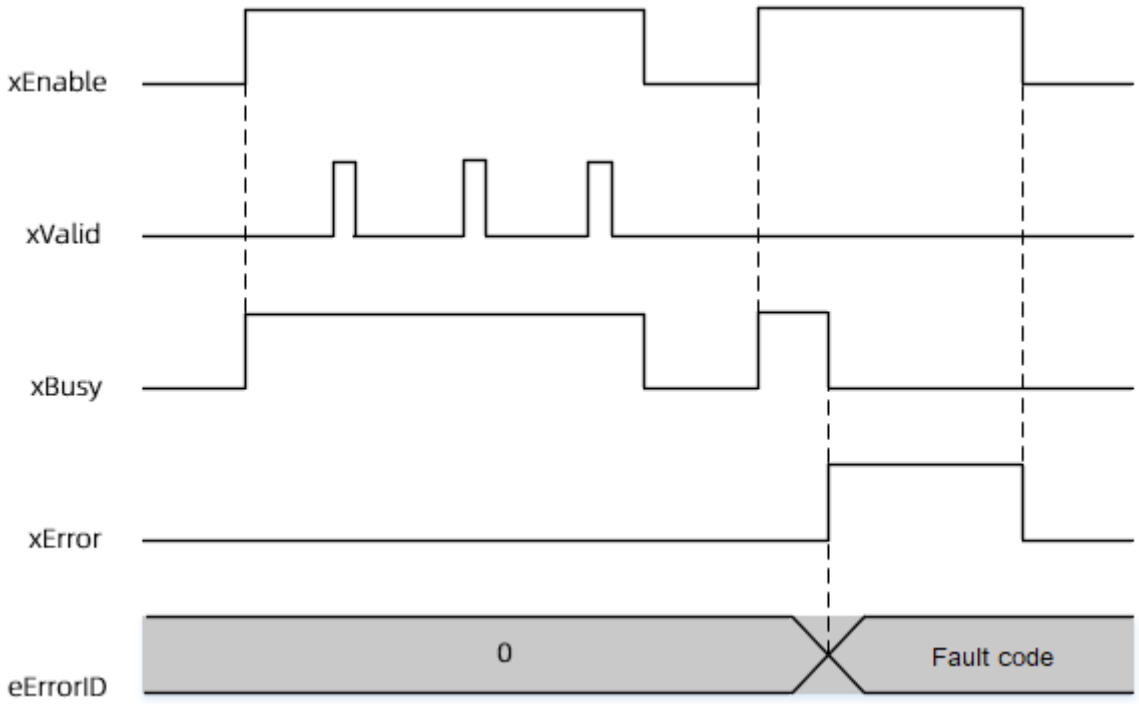
fValue	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–



- **Function**

  When xEnable is set to TRUE, the sampling variable fSample is input based on the given scan period count uiSampleCycle and sampling count uiSampleNum. Sample data for consecutively uiSampleNum times, sort the sampled data, exclude the maximum value and minimum value, and average the rest values. This means using both median value filtering and one-dimensional arithmetic mean filtering. In general, uiSampleNum is set to 3 to 14.

  Advantages: Combines the advantages of both median value filtering and arithmetic average filtering. It can eliminate sampling deviations caused by occasional pulse interference, suppress periodic interferences, and provide high smoothness. It is suitable for systems with high-frequency oscillations.

  Disadvantages: It provides a slower calculation speed, similar to arithmetic average filtering, and it consumes a significant amount of RAM.

- **Sequence diagram**

- **Program example**

  The sampling type is consecutive sampling. The raw data for sampling is sourced from the consecutively updated program variables.

  The number of samples for the sampling calculation is 4 (unsigned integer ranging from 3 to 3000).

  The sampling period is 1 (data sampling is executed once every given number of running periods, with the default value of 1).

  When the input value of xEnable is TRUE, the function block starts sampling and filtering with energy flow effective. Set the number of samples for the sampling calculation to 4, indicating that filter calculation is performed once for every four sampling values. Sort the four sampling values by numerical value, exclude the maximum value and minimum value, and average the rest two values. Output the average value as the filter value, and set the filter execution valid flag xValid to TRUE.

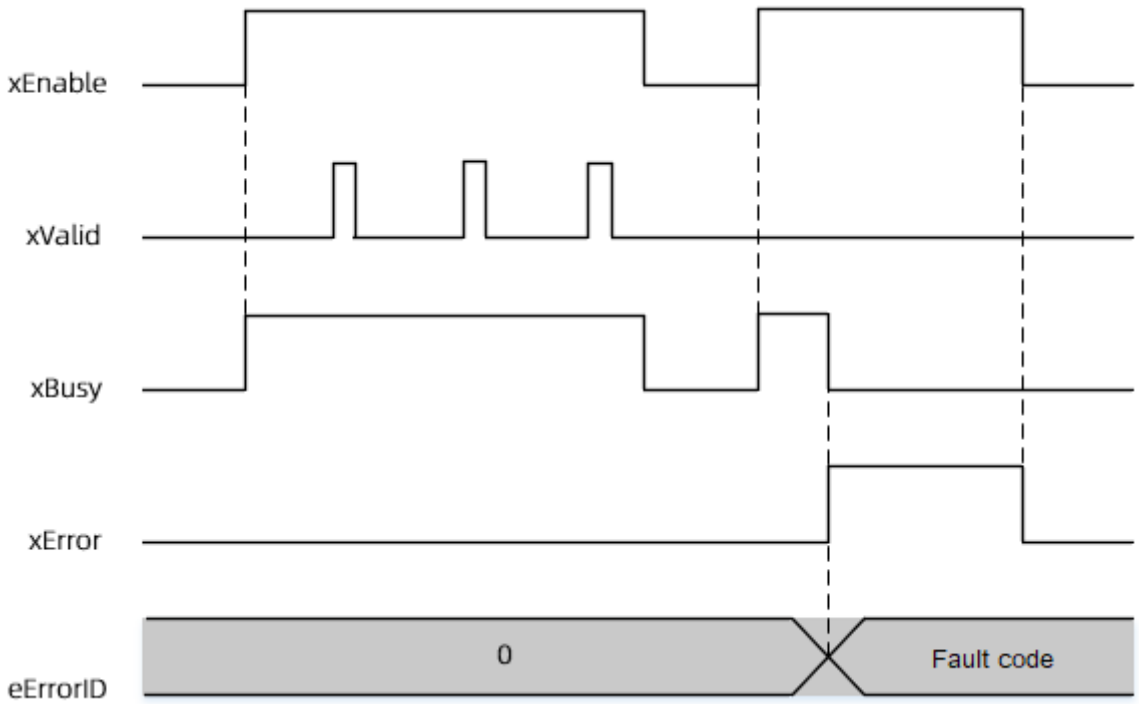
fValue	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–



- **Function**

  When xEnable is set to TRUE, the sampling variable fValue is input based on the given scan period count uiSampleCycle and sampling count uiSampleNum. Sample data for consecutively uiSampleNum times, sort the sampled data by size, and take the middle value as the filter value for this period.

  Advantages: It effectively suppresses pulse interference caused by occasional factors, and provides good filtering effect for slowly changing parameters such as the temperature and liquid level.

  Disadvantages: Not suitable for rapidly changing parameters such as flow rate and speed.

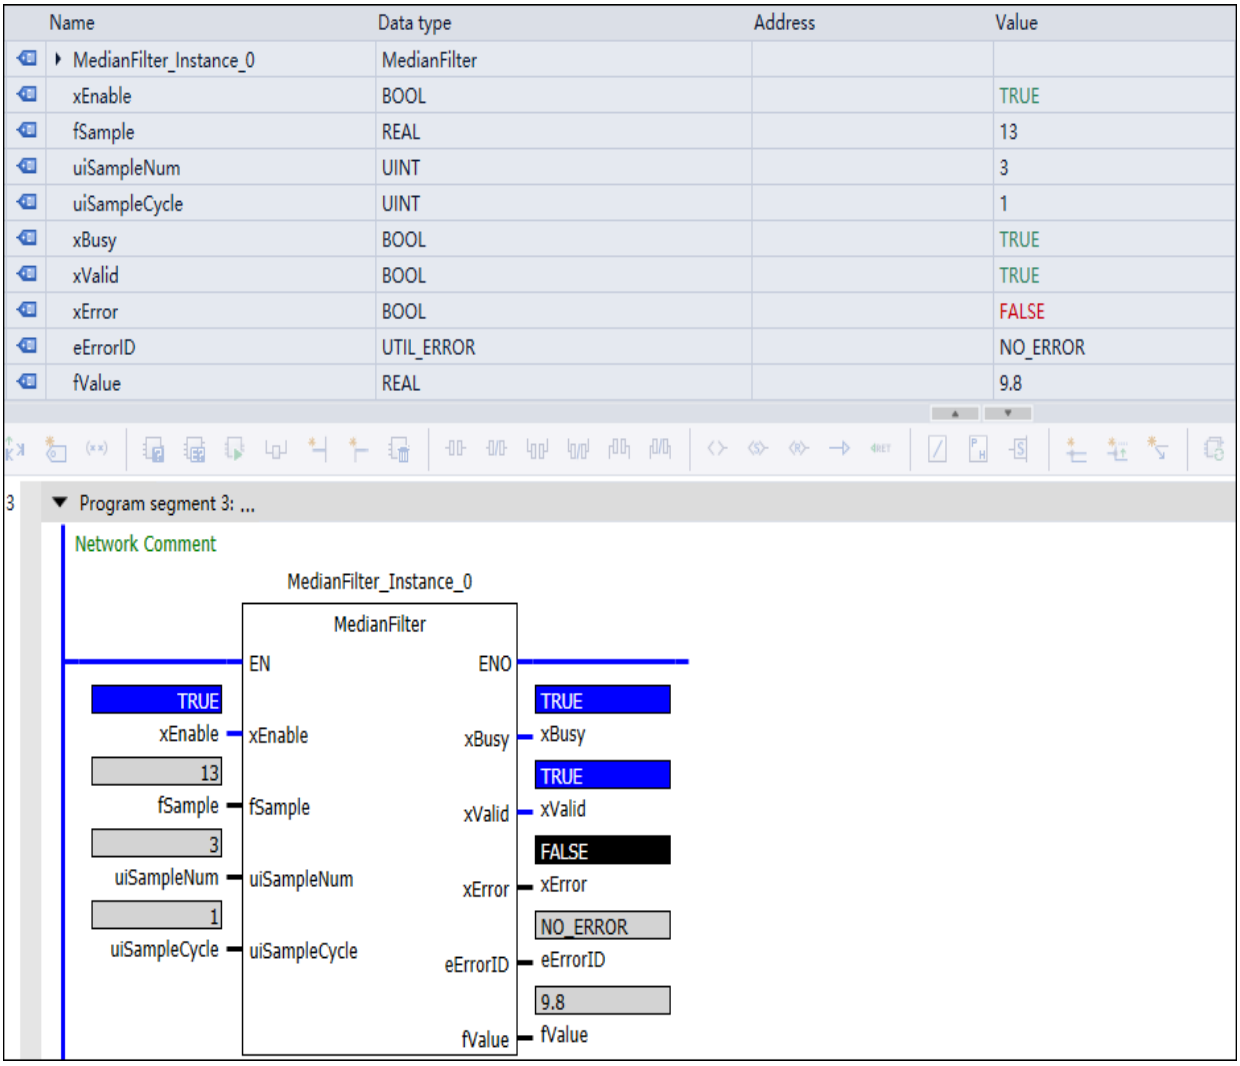
- **Timing diagram**

- **Program example**

  The sampling type is consecutive sampling. The raw data for sampling is sourced from the consecutively updated program variables.

  The number of samples for the sampling calculation is 3 (unsigned integer ranging from 1 to 3000).

The sampling period is 1 (data sampling is executed once every given number of running periods, with the default value of 1).



When the input xFilter is TRUE, the function block is enabled and begins sampling and filtering. With the number of samples set to 3, filter calculation is performed once for every three samples collected. Sort the three sampling values by numerical value, output the middle value as the filter value, and set the filter execution valid flag xValid to TRUE.

ST:

	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
fValue	–	–	–	–	–	–	–	–	–	–	–	–	–	√	–	–	–	–	–	–

- **Function**

  When xEnable is set to TRUE, the sampling variable fSample is input based on the given scan period count uiSampleCycle and queue length uiQueueCount. Consider consecutively uiQueueCount samples as a queue with the fixed length of uiQueueCount. Place each newly sampled piece of data to the end of the queue, and discard the first piece of data in the queue, following the FIFO principle. Afterward, average N data samples in the queue for a new filter result.

  The larger uiQueueCount is, the higher the signal smoothness, but the lower the sensitivity.

  The smaller uiQueueCount is, the lower the signal smoothness, but the higher the sensitivity.

  For general flow calculation, set uiQueueCount to 12. For pressure calculation, set uiQueueCount to 4. For liquid level calculation, set uiQueueCount to 4 to 12. For temperature calculation, set uiQueueCount to 4.

  Advantages: Suppresses periodic interference well and provides high smoothness. It is suitable for systems with high-frequency oscillations.

  Disadvantages: It has low sensitivity and provides poor suppression for occasional pulse interference. It is not effective in eliminating sampling deviations caused by pulse interference. It is not suitable for situations with significant pulse interference, and may consume a significant amount of RAM

- **Sequence diagram**

- **Program example**

  The sampling type is consecutive sampling. The raw data for sampling is sourced from the consecutively updated program variables.

  The number of samples for the sampling calculation is 3 (unsigned integer ranging from 1 to 3000).

  The sampling period is 1 (data sampling is executed once every given number of running periods, with the default value of 1).

  When the input value of xEnable is TRUE, the function block starts sampling and filtering with the energy flow effective. Set the number of sample queues for the sampling calculation to 3. Place each newly sampled piece of data to the end of the queue, and discard the first piece of data in the queue, following the FIFO principle. Average the three sampling values in the queue, output the result as the filter value, and set the filter execution valid flag xValid to TRUE.

18.2.10.11 StackLIFO	FC	Retrieve the top value from a stack		Library version 1.0.0.0 and later

Instruction	FB/FC	Function	Library	Applicable Library Version
18.2.10.12 StackPush	FC	Push a value into a stack		Library version 1.0.0.0 and later
18.2.10.13 TableCmp	FC	Table comparison		Library version 1.0.0.0 and later
18.2.10.14 ZoneCmp	FC	Zone comparison		Library version 1.0.0.0 and later
18.2.10.15 RAMP_INT	FB	Ramp function (integer type)	Util	Library version 1.0.0.0 and later
18.2.10.16 RAMP_REAL	FB	Ramp function (real number type)		Library version 1.0.0.0 and later
18.2.10.17 CHARCURVE	FB	Characteristic curve function		Library version 1.0.0.0 and later
18.2.10.18 BZAND_TAB	FC	Dead zone control		Library version 1.0.0.0 and later
18.2.10.19 RAMP_TAB	FB	Ramp instruction		Library version 1.0.0.0 and later
18.2.10.20 ZONE_TAB	FC	Zone control		Library version 1.0.0.0 and later

18.2.10.2 RecMax

Gets the maximum value of a specified member from a structure array.

- **Instruction format**

Instruction	Name	FB/FC	LD Representation	ST Representation
RecMax	Get the maximum record	FC		:= RecMax(In := , Size := , Member := , Out := , InOutPos := , Num =>);

- **Related variables**

Variable

Input/Output	Variable	Name	Valid Range	Default Value	Description
Input	In[ ] array	Structure array to search	Follows data type	-	Array of structures to search

Input/Output	Variable	Name	Valid Range	Default Value	Description
	Size	Number of elements to search	Follows data type	1	Number of array elements to search
	Member	Member to search	Follows data type	-	Member of In[ ] structure array to search
	Out	Search result	Follows data type	-	Search result
Input/Output	InOutPos[ ] array	Index array of search results	Follows data type	-	Array storing the indices of the searched elements
Output	Num	Number of searched elements	Follows data type	-	Number of searched elements

Variable types

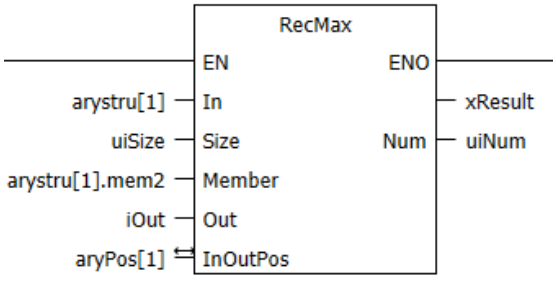
	Boolean	Bit String				Integer								Real Number		Time/Duration/ Date/String				
	BOOL	BYTE	WORD	DWORD	LWORD	USINT	UINT	UDINT	ULINT	SINT	INT	DINT	LINT	REAL	LREAL	TIME	DATE	TIME_OF_DAY	DATE_AND_TIME	STRING
In[ ] array	Specify an array of structures.																			
Size	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
Member	–	–	–	–	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
	Data with the same data type as the search member of In[ ]																			
Out	–	–	–	–	–	√	√	√	√	√	√	√	√	√	√	√	√	√	√	√
InOutPos[ ] array	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–
Num	–	–	–	–	–	–	√	–	–	–	–	–	–	–	–	–	–	–	–	–

- **Function**
  - This instruction searches the Size elements of the structure array In[ ] (from In[0] to In[Size-1]) to get the value of the specified structure member Member. The member to search from any element of In[ ] is

passed to the Member parameter. The indices of the searched elements are assigned to InOutPos[0] and the number of searched elements is assigned to Num. If there are more than two searched elements, the index of the lowest-order searched element is stored in InOutPos[0].

- Input parameters passed to In[ ] shall be specified along with the element index, such as array[3]. The relationships between values with data types that are not integers or real numbers are determined as follows.

Data Type	Relationship
TIME	The numerically larger value is considered to be larger.
DATA, TOD, DT	Later date or TOD are considered to be larger.
STRING	Character encoding is used for size comparison. The comparison steps are as follows: 1. Compare the character encodings of the first character of each string. If the encodings are different, the size of string is determined by the corresponding encoding values. 2. If the encodings are the same, compare the encodings of the second, third, and subsequent characters until a difference is found. 3. If the lengths of the strings are different, NULL characters (16#00) are added to the shorter string to complete the comparison.



RecMax retrieves the maximum value. The maximum value of the member to search is assigned to search result Out.

- **Program example**

  The following example sets Size to UINT#5.

Item	LD	ST
Define variables		
Program		

```
VAR
    xResult: BOOL;
    arystru: ARRAY [1..5] OF STRUCT_TEST := [(mem2 := 1234), (mem2 := 2345), (mem2 := 3456), (mem2 := 1234), (mem2 := 3456)];
    uiSize: UINT := 5;
    iOut: INT;
    aryPos: ARRAY [1..5] OF UINT;
    uiNum: UINT;
END_VAR
```

```
xResult := RecMax(In := arystru[1],
Size := uiSize,
Member := arystru[1].mem2,
Out := iOut,
InOutPos := aryPos[1],
Num => uiNum);
```
